
Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Input**.
5. Drag an HDFS component to the pipeline canvas on the left.
6. Right-click the HDFS component and select **Configure Attributes**.
7. In the **HDFS Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the HDFS type. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create an HDFS data source.
File Path	The path of the source file.
File Type	The type of the source file. Valid values: **TexT**, **CSV**, **ORC**, **RC**, and **Sequence**.
File Encoding	The encoding format of the source file. Valid values: **UTF-8** and **GBK**.
Field Delimiter	The delimiter that is used to separate fields in the source file. If you do not specify this parameter, a comma (,) is used as the field delimiter.
Compression Format	The compression format of the source file. Valid values: ○ **zip** ○ **gzip** ○ **bzip2**

Parameter	Description
Output Fields	The output fields to be generated. You can create output fields by using one of the following methods: ○ Click **Batch Create**. In the Batch Create in JSON Format dialog box, configure multiple output fields in the JSON format. Example: `[{ "index": 0, "name": "user_id", "type": "String" }, { "index": 1, "name": "user_name", "type": "String" }]` In the example, index, name, and type specify the sequence number, name, and data type of the output field, respectively. ○ Click **Create Output Field**. Set the **Source Serial Number**, **Field**, and **Type** parameters as required. You can also perform the following operations on existing fields: ○ Click the icon in the **Actions** column to edit a field. ○ Click the icon in the **Actions** column to delete a field.

8. Click **OK**.

Copy an HDFS input component

1. Right-click an HDFS input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an HDFS input component

1. Right-click an HDFS input component and select **Delete**.

2. In the message that appears, click **OK**.

Select a data sending mode for an HDFS input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to the downstream nodes.

1. Right-click an HDFS input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.6.10. Manage Hive input components

This topic describes how to configure, copy, and delete a Hive input component, and how to select a data sending mode for a Hive input component.

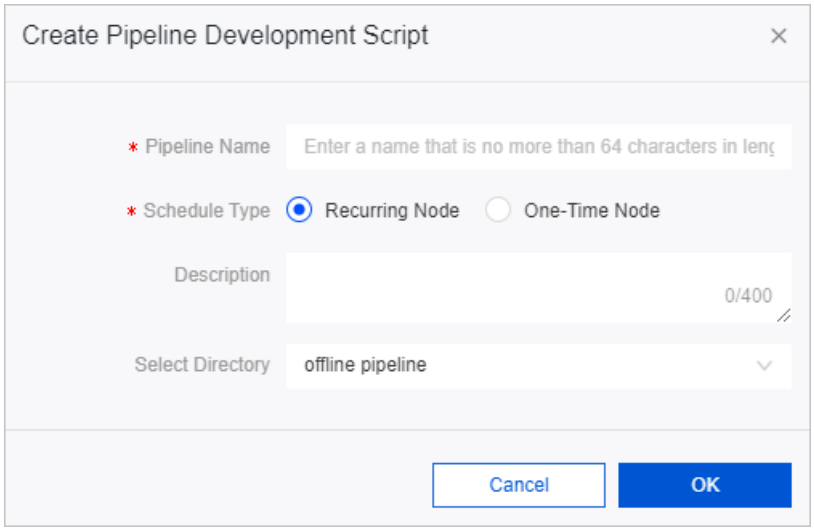
Context

A Hive input component is used to import data from a Hive database to Dataphin for integration and reprocessing.

Configure a Hive input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Input**.
5. Drag a Hive component to the pipeline canvas on the left.
6. Right-click the Hive component and select **Configure Attributes**.
7. In the **Hive Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the Hive type. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Table	The source table.
File Encoding	The encoding format of the source table. Valid values: **UTF-8** and **GBK**.
Compression Format	The format that is used to compress the source file. Valid values: ○ **zip** ○ **gzip** ○ **bzip2**
Field Delimiter	The delimiter that is used to separate fields in the source table. If you do not specify this parameter, a comma (,) is used as the field delimiter.
Output Fields	The output fields to be generated based on the input configuration. You can click **Manage Fields** and perform the following operations in the **Manage Fields** dialog box: ○ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section. ○ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section. You can also click the icon in the **Actions** column to delete a field.

8. Click **OK**.

Copy a Hive input component

1. Right-click a Hive input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a Hive input component

1. Right-click a Hive input component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for a Hive input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to the downstream nodes.

1. Right-click a Hive input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.6.11. Manage Hbase input components

This topic describes how to configure, copy, and delete an Hbase input component, and how to select a data sending mode for an Hbase input component.

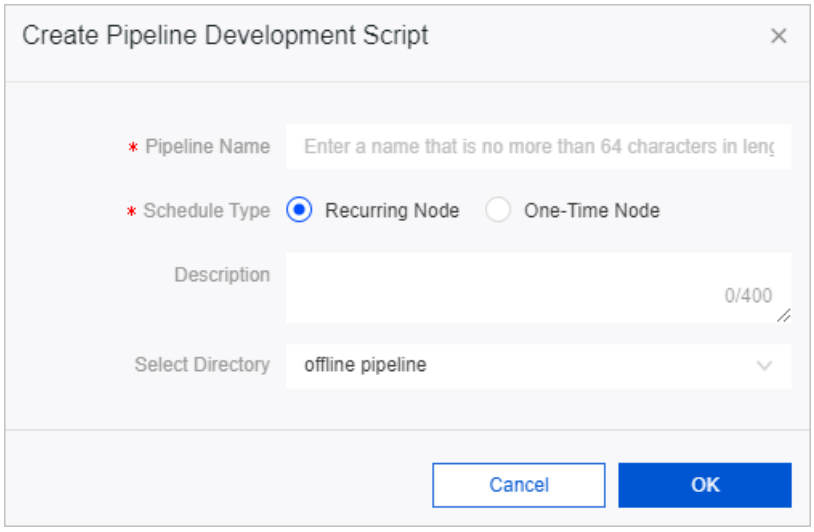
Context

An Hbase input component is used to import data from an HBase database to Dataphin for integration and reprocessing.

Configure an Hbase input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Input**.
5. Drag an Hbase component to the pipeline canvas on the left.
6. Right-click the Hbase component and select **Configure Attributes**.
7. In the **HBase Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the HBase type. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create an HBase data source.
Table	The source table.
Mode	The mode of the source table. Valid values: **Normal Mode** and **Multiple Versions**. If you select **Multiple Versions**, you must set the Version parameter to specify the versions of data to read. If you set the Version parameter to -1, all versions of data will be read.
File Encoding	The encoding format of the source table. Valid values: **UTF-8** and **GBK**.
Input Filtering	The filter condition for input fields. For example, you can enter `"startRowkey":"20190101000000"`.

Parameter	Description
Output Fields	The output fields to be generated based on the input configuration. You can create output fields by using one of the following methods: ○ Click **Create Output Field**. Set the **Column Family**, **Field**, and **Type** parameters as required. ○ Click **Batch Create**. In the Batch Create in JSON Format dialog box, configure multiple output fields in the JSON format and click **OK**. Example: `[{ "index": 0, "name": "user_id", "type": "String" }, { "index": 1, "name": "user_name", "type": "String" }]` In the example, index, name, and type specify the sequence number, name, and data type of the output field, respectively. You can also perform the following operations on existing fields: ○ Click the icon in the **Actions** column to delete a field. ○ Click the icon in the **Actions** column to edit a field.

8. Click **OK**.

Copy an Hbase input component

1. Right-click an Hbase input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an Hbase input component

1. Right-click an Hbase input component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for an Hbase input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to the downstream nodes.

1. Right-click an Hbase input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.

- **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.6.12. Manage MongoDB input components

This topic describes how to configure, copy, and delete a MongoDB input component, and how to select a data sending mode for a MongoDB input component.

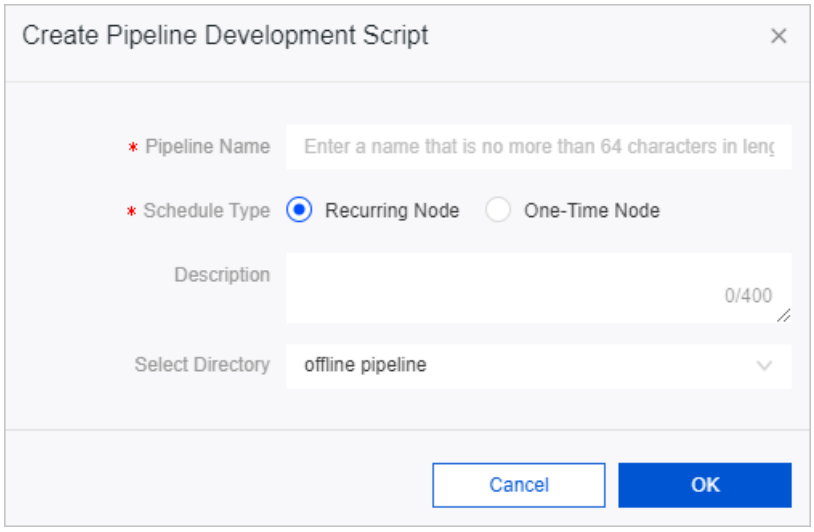
Context

A MongoDB input component is used to import data from a MongoDB database to Dataphin for integration and reprocessing.

Configure a MongoDB input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Input**.
5. Drag a MongoDB component to the pipeline canvas on the left.
6. Right-click the MongoDB component and select **Configure Attributes**.
7. In the **MongoDB Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the MongoDB type. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Table	The source table.
Input Filtering	The filter condition for input fields. For example, you can enter *ds=${biz date}*. The **Input Filtering** parameter is applicable to the following scenarios: ○ Specify a fixed portion of data. ○ Use parameters to filter data.
Output Fields	The output fields to be generated. You can create output fields by using one of the following methods: ○ Click **Batch Create**. In the Batch Create in JSON Format dialog box, configure multiple output fields in the JSON format and click **OK**. Example: `[{ "name":"cf1:a", "type":"String" },` `{ "name":"cf1:b", "type":"String" }]` ○ Click **Create Output Field**. Set the **Field** and **Type** parameters as required. You can also perform the following operations on existing fields: ○ Click the icon in the **Actions** column to edit a field. ○ Click the icon in the **Actions** column to delete a field.

8. Click **OK**.

Copy a MongoDB input component

1. Right-click a MongoDB input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a MongoDB input component

1. Right-click a MongoDB input component and select **Delete**.

2. In the message that appears, click **OK**.

Select a data sending mode for a MongoDB input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to the downstream nodes.

1. Right-click a MongoDB input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.6.13. Manage LogicalTable input components

This topic describes how to configure, copy, and delete a LogicalTable input component, and how to select a data sending mode for a LogicalTable input component.

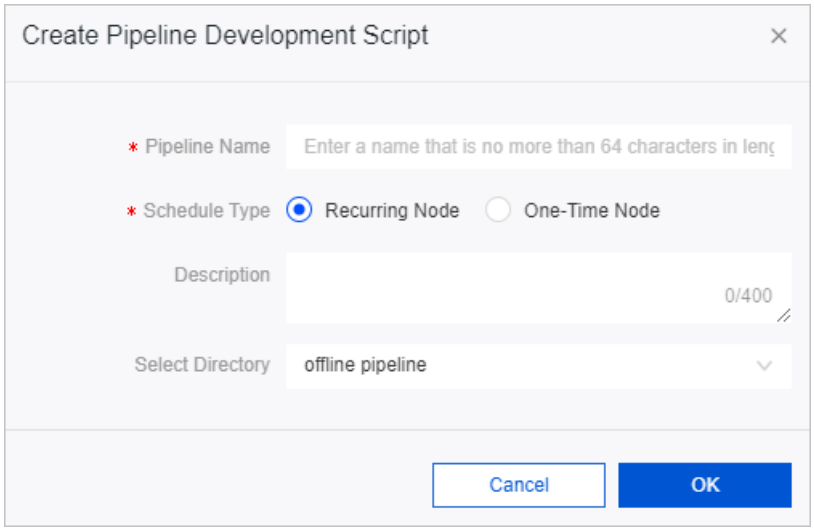
Context

A LogicalTable input component is used to import data from a logical table created in Dataphin to a database for integration and reprocessing.

Configure a LogicalTable input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Input**.
5. Drag a LogicalTable component to the pipeline canvas on the left.
6. Right-click the LogicalTable component and select **Configure Attributes**.
7. In the **Logical Table Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Business Units	The business unit where the logical table resides.

Parameter	Description
Logical Table Type	The type of the logical table. Valid values: ○ **Logical Aggregate Table** ○ **Logical Dimension Table** ○ **Logical Fact Table**
Logical Tables	The logical table. The system displays the logical tables on which your account has the read-through permission. You can also click the icon to go to the Develop page and create a logical table.
Logical Table Output Mode	The output mode of the logical table. Valid values: ○ **Without Association**: The output fields to be generated are the fields of the selected logical table. ○ **With Association**: The output fields to be generated are the fields of the selected logical table and associated table.
Output Fields	The output fields to be generated. You can perform the following steps to preview the output fields: i. Click **Manage Fields**. ii. Select one or more fields in the **All Fields** section. The output fields to be generated appear in the Output Field Preview section. You can also click the icon in the **Actions** column to delete a field.

8. Click **OK**.

Copy a LogicalTable input component

1. Right-click a LogicalTable input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a LogicalTable input component

1. Right-click a LogicalTable input component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for a LogicalTable input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to the downstream nodes.

1. Right-click a LogicalTable input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream

node.

9.8.2.6.14. Manage ADB for MySQL3.0 input components

This topic describes how to configure, copy, and delete an ADB for MySQL3.0 input component, and how to select a data sending mode for an ADB for MySQL3.0 input component.

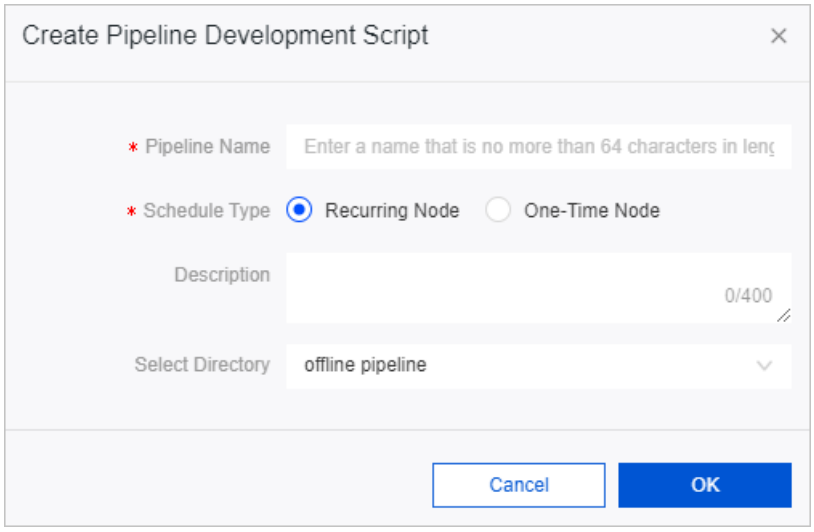
Context

An ADB for MySQL3.0 input component is used to import data from an AnalyticDB for MySQL 3.0 database to Dataphin for integration and reprocessing.

Configure an ADB for MySQL3.0 input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Input**.
5. Drag an **ADB for MySQL3.0** component to the pipeline canvas on the left.
6. Right-click the **ADB for MySQL3.0** component and select **Configure Attributes**.
7. In the **ADB for MySQL 3.0 Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the input component. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create an AnalyticDB for MySQL V3.0 data source.
Source Table	The quantity of source tables. Valid values: **Single Table** and **Multiple Tables**. **Note** If you select **Multiple Tables**, you must specify multiple source tables that have the same schema.
Table	The one or more source tables. Specify one or more source tables based on the **Source Table** parameter. ○ If you set **Source Table** to **Single Table**, click the icon and select a source table from the **Table** drop-down list. ○ If you set **Source Table** to **Multiple Tables**, perform the following steps to specify the source tables: a. Enter an expression in the Table field. Dataphin allows you to enter an enumeration expression, a regular-like expression, or a combination of both, for example, `table_[001-100];table_102`. b. Click the icon. c. In the **Confirm Match Details** dialog box, select the tables that match the expression you entered. d. Click **OK**.
Split Key	The shard key of the source table. You can specify a column in the source table as the shard key. We recommend that you use the primary key or an indexed column as the shard key. If you specify multiple source tables, you need to specify only one shard key because the source tables have the same schema.

Parameter	Description
Input Filtering	The filter condition for input fields. For example, you can enter *ds=${biz date}*. The **Input Filtering** parameter is applicable to the following scenarios: ○ Specify a fixed portion of data. ○ Use parameters to filter data.
Output Fields	The output fields to be generated based on the input configuration. You can also perform the following operations to manage fields: ○ Click the icon in the **Actions** column to delete a field. ○ Click **Manage Fields**. In the **Manage Fields** dialog box, perform the following operations: ■ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section. ■ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section.

8. Click **OK**.

Copy an ADB for MySQL3.0 input component

1. Right-click an ADB for MySQL3.0 input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an ADB for MySQL3.0 input component

1. Right-click an ADB for MySQL3.0 input component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for an ADB for MySQL3.0 input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to the downstream nodes.

1. Right-click an ADB for MySQL3.0 input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.6.15. Manage ADB for PostgreSQL input components

This topic describes how to configure, copy, and delete an ADB for PostgreSQL input component, and how to select a data sending mode for an ADB for PostgreSQL input component.

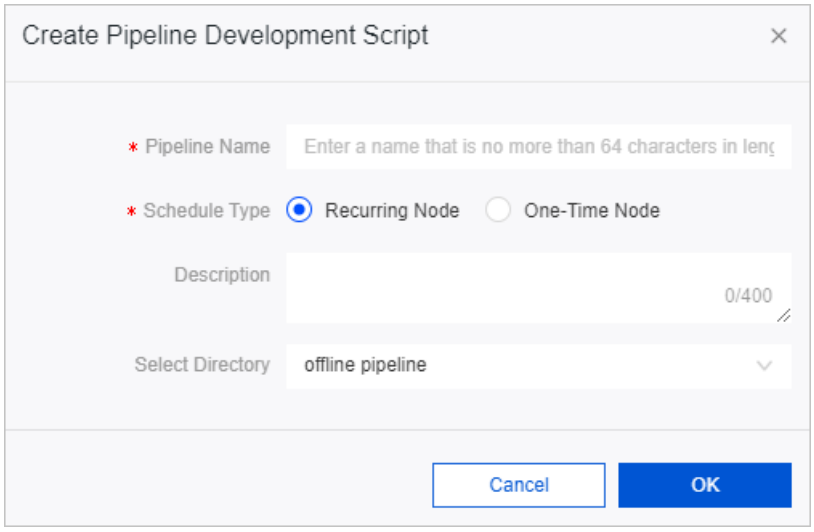
Context

An ADB for PostgreSQL input component is used to import data from an AnalyticDB for PostgreSQL database to Dataphin for integration and reprocessing.

Configure an ADB for PostgreSQL input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Input**.
5. Drag an **ADB for PostgreSQL** component to the pipeline canvas on the left.
6. Right-click the **ADB for PostgreSQL** component and select **Configure Attributes**.
7. In the **ADB for PostgreSQL Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the input component. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create an AnalyticDB for PostgreSQL data source.
Source Table	The quantity of source tables. Valid values: **Single Table** and **Multiple Tables**. **Note** If you select **Multiple Tables**, you must specify multiple source tables that have the same schema.
Table	The one or more source tables. Specify one or more source tables based on the **Source Table** parameter. ○ If you set the **Source Table** parameter to **Single Table**, click the icon and select a source table from the **Table** drop-down list. ○ If you set **Source Table** to **Multiple Tables**, perform the following steps to specify the source tables: a. Enter an expression in the Table field. Dataphin allows you to enter an enumeration expression, a regular-like expression, or a combination of both, for example, `table_[001-100];table_102`. b. Click the icon. c. In the **Confirm Match Details** dialog box, select the tables that match the expression you entered. d. Click **OK**.
Split Key	The shard key of the source table. You can specify a column in the source table as the shard key. We recommend that you use the primary key or an indexed column as the shard key. If you specify multiple source tables, you need to specify only one shard key because the source tables have the same schema.

Parameter	Description
Input Filtering	The filter condition for input fields. For example, you can enter `ds=${bizdate}`. The **Input Filtering** parameter is applicable to the following scenarios: ○ Specify a fixed portion of data. ○ Use parameters to filter data.
Output Fields	The output fields to be generated based on the input configuration. You can also perform the following operations to manage fields: ○ Click the icon in the **Actions** column to delete a field. ○ Click **Manage Fields**. In the **Manage Fields** dialog box, perform the following operations: ■ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section. ■ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section.

8. Click **OK**.

Copy an ADB for PostgreSQL input component

1. Right-click an ADB for PostgreSQL input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an ADB for PostgreSQL input component

1. Right-click an ADB for PostgreSQL input component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for an ADB for PostgreSQL input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to the downstream nodes.

1. Right-click an ADB for PostgreSQL input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.6.16. Manage LogHub input components

This topic describes how to configure, copy, and delete a LogHub input component, and how to select a data sending mode for a LogHub input component.

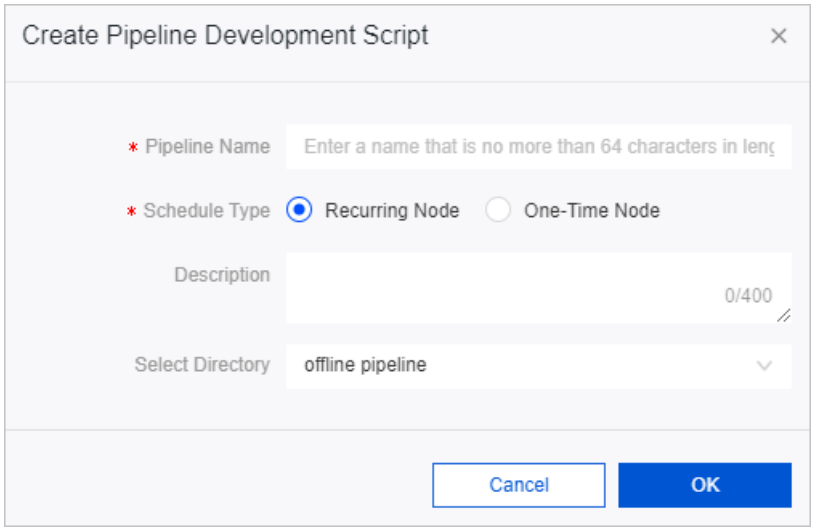
Context

A LogHub input component is used to import data from a LogHub data source to Dataphin for integration and reprocessing.

Configure a LogHub input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Input**.
5. Drag a LogHub component to the pipeline canvas on the left.
6. Right-click the LogHub component and select **Configure Attributes**.
7. In the **Loghub Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the LogHub type. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Logstore	The Logstore where the source data resides. All data in the Logstore is from the same data source.
Log StartTime	The start time of the period in which the required logs were generated. The value is in the format `yyyyMMddHHmmss`.
Log EndTime	The end time of the period in which the required logs were generated. The value is in the format `yyyyMMddHHmmss`.
Batch Number	The number of data records to read at a time. You can enter a number in the **Batch Number** field. Alternatively, you can click the upwards or downwards arrow in the field to adjust the value. Default value: 256. The system can read up to 1,000 data records at a time.

Parameter	Description
Output Fields	The output fields to be generated. You can create output fields by using one of the following methods: ○ Click **Batch Create**. In the Batch Create in JSON Format dialog box, configure multiple output fields in the JSON format and click **OK**. Example: `[{ "index": 0, "name": "user_id", "type": "String" }, { "index": 1, "name": "user_name", "type": "String" }]` In the example, index, name, and type specify the sequence number, name, and data type of the output field, respectively. ○ Click **Create Output Field**. Set the **Field**, **Source Serial Number**, and **Type** parameters as required. You can also perform the following operations on existing fields: ○ Click the icon in the **Actions** column to edit a field. ○ Click the icon in the **Actions** column to delete a field.

8. Click **OK**.

Copy a LogHub input component

1. Right-click a LogHub input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a LogHub input component

1. Right-click a LogHub input component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for a LogHub input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to the downstream nodes.

1. Right-click a LogHub input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.

- **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.7. Component library: Conversion components

Conversion components are used to convert the input data from an upstream component and transmit the converted data to downstream components. This topic describes how to configure the properties of the Field Selection, Field Computing, and Filtering components.

Go to the script development tab of a single offline pipeline. Click **Component Library** in the upper-right corner and then the icon before **Conversion** to open the **Conversion** list.

Field selection

A **Field Selection** component is used to filter the input fields from an upstream component, rename the fields, and change the order of output fields.

1. Drag and drop a **Field Selection** component to the pipeline canvas on the left.
2. Right-click the component box and select **Configure Attributes**.
3. In the **Field Selection Configuration** dialog box that appears, set relevant parameters as prompted and click **OK**.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can click **Manage Fields** to perform the following operations in the dialog box that appears: ○ Select one or more fields and click the icon to move the selected fields from the **Selected Input Fields** list to the **Unselected Input Fields** list. ○ Select one or more fields and click the icon to move the selected fields from the **Unselected Input Fields** list to the **Selected Input Fields** list. You can also perform the following operations on existing fields: ○ Click the icon in the Actions column to edit an existing field. ○ Click the icon in the Actions column to delete an existing field.

Field computing

The applicable scenarios of a **Field Computing** component include but are not limited to:

- Split an input field from an upstream component into multiple fields.

- Generate derived fields based on the input fields from an upstream component.
- Map or de-identify the values of input fields from an upstream component.

To configure the properties of a Field Computing component, follow these steps:

1. Drag and drop a **Field Computing** component to the pipeline canvas on the left.
2. Right-click the component box and select **Configure Attributes**.
3. In the **Field Computing Configuration** dialog box that appears, set relevant parameters as prompted and click **OK**.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can create an output field by following these steps: i. Click **+ Create Field**. ii. In the **Create Field** dialog box that appears, set **Name** and **Expression** as prompted, and select a data type from the **Data Type** drop-down list. iii. Click **OK**. You can also click the icon in the Actions column to delete an existing field.

Filtering

A **Filtering** component is used to filter the input data from an upstream component and transmit the data that meets the specified filter conditions to output components.

1. Drag and drop a **Filtering** component to the pipeline canvas on the left.
2. Right-click the component box and select **Configure Attributes**.
3. In the **Conversion-Filtering Configuration** dialog box that appears, set relevant parameters as prompted and click **OK**.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Input Fields	The input fields based on the upstream input.
Filter Conditions	The filter conditions for input fields. The following operators are supported: **=, !=, >, >=, <, <=, like, in, is null**, and **is not null**. For example, you can enter `user_id is not null and user_name like '%a%'` .
Output Fields	The output fields to be generated.

9.8.2.7.1. Manage Field Selection components

This topic describes how to configure, copy, and delete a Field Selection component, and how to select a data sending mode for a Field Selection component.

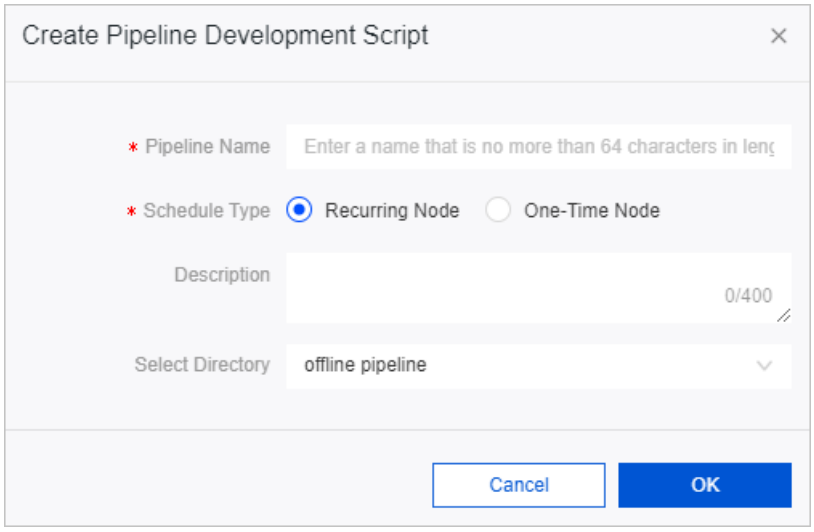
Context

A Field Selection component is used to filter the input fields from an upstream component, rename the fields, and change the order of output fields.

Configure a Field Selection component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Conversion**.
5. Drag a Field Selection component to the pipeline canvas on the left.
6. Right-click the Field Selection component and select **Configure Attributes**.
7. In the **Field Selection Configuration** dialog box, set the parameter as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Input Fields	The input fields based on the upstream input.

Parameter	Description
Output Fields	The output fields to be generated. You can click **Manage Fields** and perform the following operations in the dialog box that appears: ○ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section. ○ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section. You can also perform the following operations on existing fields: ○ Click the icon in the **Actions** column to edit a field. ○ Click the icon in the **Actions** column to delete a field.

8. Click **OK**.

Copy a Field Selection component

1. Right-click a Field Selection component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a Field Selection component

1. Right-click a Field Selection component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for a Field Selection component

If a conversion component is connected to multiple components in the downstream, you must select a mode in which the data of the conversion component is sent to the downstream nodes.

1. Right-click a Field Selection component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.7.2. Manage Field Computing components

This topic describes how to configure, copy, and delete a Field Computing component, and how to select a data sending mode for a Field Computing component.

Context

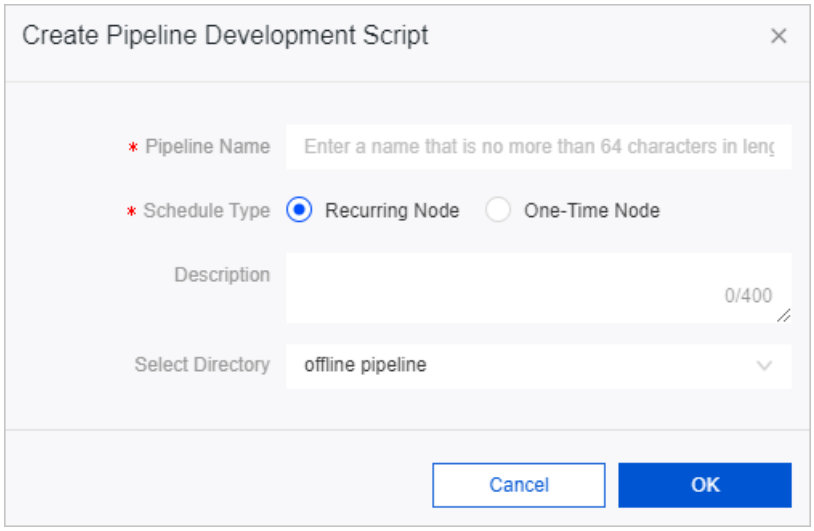
The applicable scenarios of a Field Computing component include but are not limited to:

- Split an input field from an upstream component into multiple fields.

- Generate derived fields based on the input fields from an upstream component.
- Map or de-identify the values of the input fields from an upstream component.

Configure a Field Computing component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.
   v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

   vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Conversion**.
5. Drag a Field Computing component to the pipeline canvas on the left.
6. Right-click the Field Computing component and select **Configure Attributes**.
7. In the **Field Computing Configuration** dialog box, set the parameter as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. To create an output field, perform the following steps: i. Click **Create Field**. ii. In the **Create Field** dialog box, set the **Name**, **Expression**, and **Data Type** parameters. When you set the **Expression** parameter, you can view the functions in the system and their usage in the **Function** section on the right. iii. Click **OK**. To delete an output field, click the icon in the **Actions** column.

8. Click **OK**.

Copy a Field Computing component

1. Right-click a Field Computing component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a Field Computing component

1. Right-click a Field Computing component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for a Field Computing component

If a conversion component is connected to multiple components in the downstream, you must select a mode in which the data of the conversion component is sent to the downstream nodes.

1. Right-click a Field Computing component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.7.3. Manage Filtering components

This topic describes how to configure, copy, and delete a Filtering component, and how to select a data sending mode for a Filtering component.

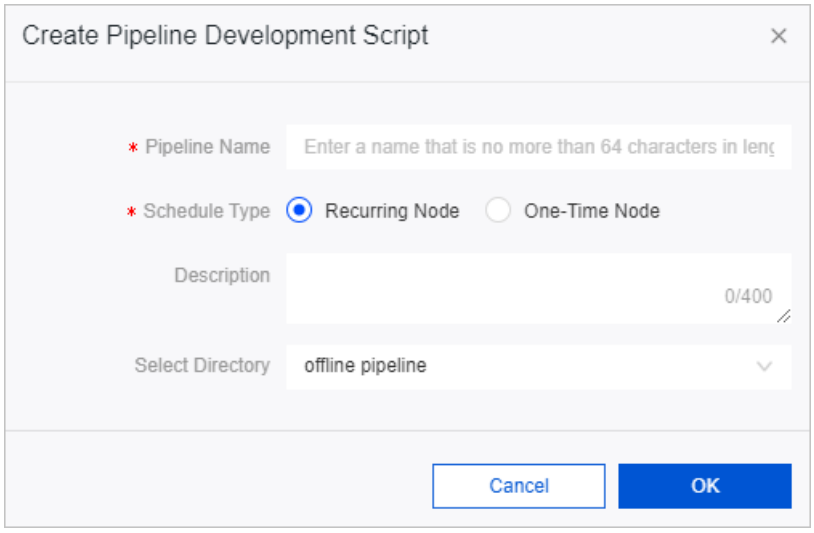
Context

A Filtering component is used to filter the input data from an upstream component and send the data that meets the specified filter conditions to output components.

Configure a Filtering component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Conversion**.
5. Drag a **Filtering** component to the pipeline canvas on the left.
6. Right-click the **Filtering** component and select **Configure Attributes**.
7. In the **Conversion-Filtering Configuration** dialog box, set the parameter as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Input Fields	The input fields based on the upstream input.

Parameter	Description
Filter Conditions	The filter conditions for the input data. You can specify the filter conditions by using one of the following methods: ○ Perform the following steps: a. Click the icon in the **Field** column and select a field from the drop-down list. b. Click the icon in the **Operator** column and select an operator from the drop-down list. The following operators are supported: =, != , >, >=, <, <=, **LINKE**, **IS NULL**, and **IS NOT NULL**. c. Click the icon in the **Content** column and select **Table Field** or **Custom Recipients** from the drop-down list. ■ If you select **Table Field**, another drop-down list appears in the Content column. Select a field from the drop-down list. ■ If you select **Custom Recipients**, a field appears in the Content column. Enter a recipient in the field. Click the icon and then the icon. Select a data type from the drop-down list. d. Click the icon in the **Actions** column. The icon appears in a new line. Click this icon and select **AND** or **OR** from the drop-down list. ○ Click **Switch to Script Mode** and enter filter conditions in the code editor that appears. For example, you can enter `user_id is not null and user_name like '%a%'` . The following operators are supported: =, != , >, >=, <, <=, **LIKE**, **IS NULL**, and **IS NOT NULL**.
Output Fields	The output fields to be generated.

8. Click **OK**.

Copy a Filtering component

1. Right-click a Filtering component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a Filtering component

1. Right-click a Filtering component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for a Filtering component

If a conversion component is connected to multiple components in the downstream, you must select a mode in which the data of the conversion component is sent to the downstream nodes.

1. Right-click a Filtering component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.8. Component library: Process components

Process components are used in the data transmission process for throttling and conditional distribution. This topic describes how to configure the properties for throttling and conditional distribution.

Go to the script development tab of a single offline pipeline and open the component library.

Click the > icon before **Process** to open the **Process** list.

Throttling

An **Access Limit** component is used to control read/write operations on downstream service databases. To configure the properties for throttling, follow these steps:

1. Drag and drop an **Access Limit** component to the pipeline canvas on the left.
2. Right-click the component box and select **Configure Attributes**.
3. In the **Access Limit Configuration** dialog box that appears, set relevant parameters as prompted and click **OK**.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Speed Limit	The upper limit of the data transmission speed. ○ If you select **Data Volume-based Limit**, you can select a maximum data transmission rate. Valid values: **1M/s**, **2M/s**, **5M/s**, and **10M/s**. ○ If you select **Data Record-based Limit**, you must enter the maximum number of data records, for example, 30 records per second.

Conditional distribution

A **Conditional Distribution** component is used to split the input data from an upstream component and distribute the data to different downstream components.

1. Drag and drop a **Conditional Distribution** component to the pipeline canvas on the left.
2. Right-click the component box and select **Configure Attributes**.
3. In the **Conditional Distribution Configuration** dialog box that appears, set relevant parameters as prompted and click **OK**.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Input Fields	The input fields based on the upstream input.
Merge Logic Configuration	The conditions for distribution. The following operators are supported: =, !=, >, >=, <, <=, like, in, is null, and is not null. For example, you can enter `user_id is not null and user_name like '%a%'`. Currently, distribution is only based on the results of true and false. If you do not specify the conditions for distribution, the result defaults to true.
Output Fields	The output fields to be generated. You can click **Manage Fields** to perform the following operations in the dialog box that appears: ○ Select one or more fields and click the icon to move the selected fields from the **Selected Input Fields** list to the **Unselected Input Fields** list. ○ Select one or more fields and click the icon to move the selected fields from the **Unselected Input Fields** list to the **Selected Input Fields** list. You can also perform the following operations on existing fields: ○ Click the icon in the Actions column to edit an existing field. ○ Click the icon in the Actions column to delete an existing field.

9.8.2.8.1. Manage Access Limit components

This topic describes how to configure, copy, and delete an Access Limit component.

Context

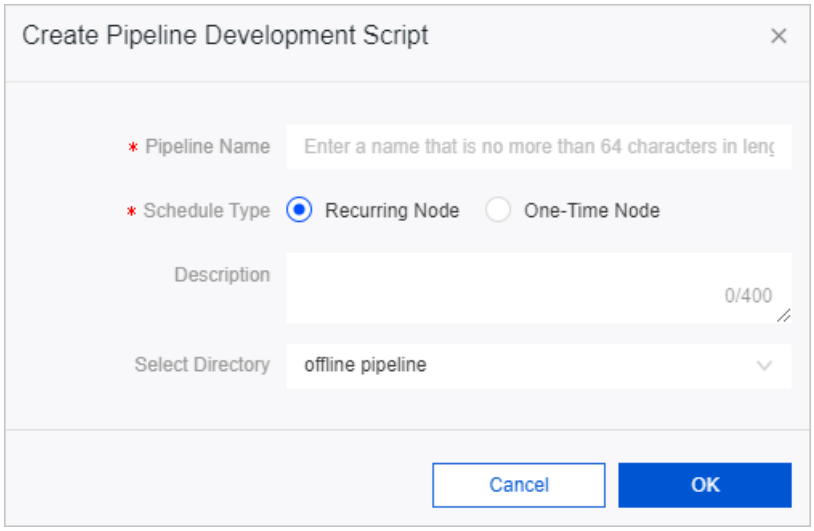
An Access Limit component is used to control read/write operations on downstream databases.

Configure an Access Limit component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.

iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the icon before **Process**.
5. Drag an Access Limit component to the pipeline canvas on the left.
6. Right-click the Access Limit component and select **Configure Attributes**.
7. In the **Access Limit Configuration** dialog box, set the parameter as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Speed Limit	The upper limit of the data transmission speed. ○ If you select **Data Volume-based Limit**, you can select a maximum data transmission rate. Valid values: **1M/s**, **2M/s**, **5M/s**, and **10M/s**. ○ If you select **Data Record-based Limit**, you must enter the maximum number of data records that can be sent per second, for example, 30 records per second.

8. Click **OK**.

Copy an Access Limit component

1. Right-click an Access Limit component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an Access Limit component

1. Right-click an Access Limit component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.8.2. Manage Conditional Distribution components

This topic describes how to configure, copy, and delete a Conditional Distribution component.

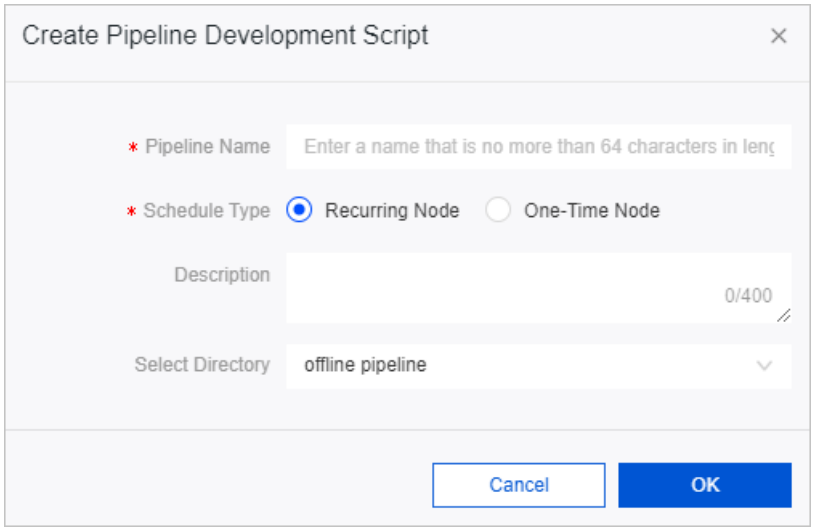
Context

A Conditional Distribution component is used to split the input data from an upstream component and distribute the data to different downstream components.

Configure a Conditional Distribution component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Process**.
5. Drag a Conditional Distribution component to the pipeline canvas on the left.
6. Right-click the Conditional Distribution component and select **Configure Attributes**.
7. In the **Conditional Distribution Configuration** dialog box, set the parameter as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Input Fields	The input fields based on the upstream input.

Parameter	Description
Merge Logic Configuration	The conditions for distribution. The following operators are supported: =, != , >, >=, <, <=, LIKE, IN, IS NULL, and IS NOT NULL. For example, you can enter `user_id is not null and user_name like '%a%'` . Distribution is only based on the results of true and false. If you do not specify the conditions for distribution, the result defaults to true.
Output Fields	The output fields to be generated. You can click **Manage Fields** and perform the following operations in the dialog box that appears: ○ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section. ○ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section. You can also perform the following operations on existing fields: ○ Click the icon in the **Actions** column to edit a field. ○ Click the icon in the **Actions** column to delete a field.

8. Click **OK**.

Copy a Conditional Distribution component

1. Right-click a Conditional Distribution component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a Conditional Distribution component

1. Right-click a Conditional Distribution component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9. Output components

9.8.2.9.1. Manage MySQL output components

This topic describes how to configure, copy, and delete a MySQL output component.

Context

A MySQL output component is used to write data processed by Dataphin to a MySQL database for data consumption.

Configure a MySQL output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.

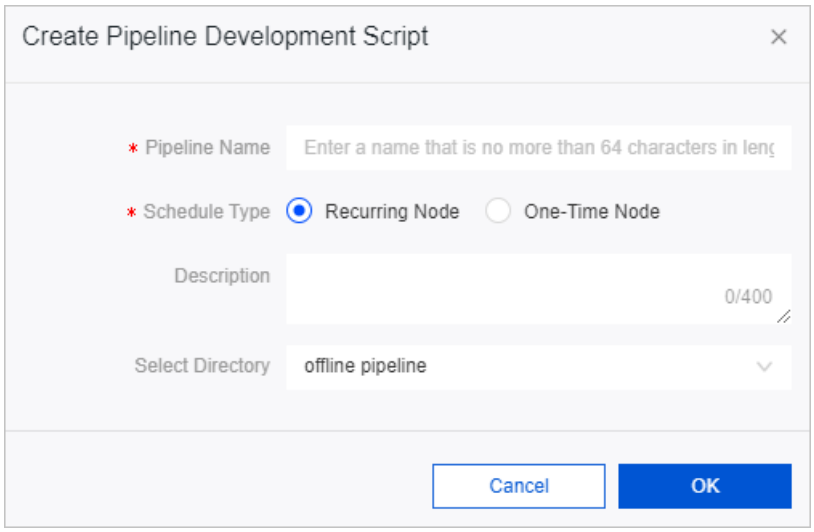
i. On the Dataphin homepage, click **R&D** in the top navigation bar.

ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.

iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.

iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the icon before **Output**.
5. Drag a MySQL component to the pipeline canvas on the left.
6. Right-click the MySQL component and select **Configure Attributes**.
7. In the **MySQL Output Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source.
Table	The destination table.
Loading Policy	The policy for writing data to the destination table. Valid values: ○ **Overwrite Data**: uses the source data to overwrite the existing data in the destination table. ○ **Append Data**: appends the source data to the destination table, without modifying the existing data in the destination table.
Parse Solution	Optional. The operations before and after data output. For more information, move the pointer over **Component Description** in the upper-right corner of the dialog box.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can click **Manage Fields** and perform the following operations in the dialog box that appears: ○ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section. ○ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section.
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select **Position-based Mapping** or **Name-based Mapping**.

8. Click **OK**.

Copy a MySQL output component

1. Right-click a MySQL output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a MySQL output component

1. Right-click a MySQL output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.2. Manage DRDS output components

This topic describes how to configure, copy, and delete a DRDS output component.

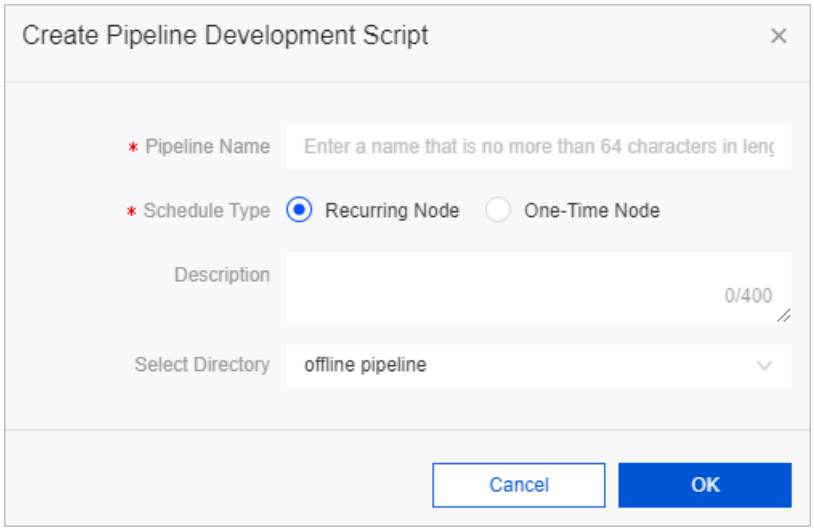
Context

A DRDS output component is used to write data processed by Dataphin to a PolarDB-X database for data consumption.

Configure a DRDS output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Output**.
5. Drag a DRDS component to the pipeline canvas on the left.
6. Right-click the DRDS component and select **Configure Attributes**.
7. In the **DRDS Output Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to Data Source to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Table	The destination table.
Loading Policy	The policy for writing data to the destination table. Valid values: ○ **Overwrite Data**: uses the source data to overwrite the existing data in the destination table. ○ **Append Data**: appends the source data to the destination table, without modifying the existing data in the destination table.
Parse Solution	Optional. The operations before and after data output. To specify operations before or after data output, click **Enter Preparation Statement** or **Enter Completion Statement** next to **Parse Solution** and enter SQL statements.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can click **Manage Fields** and perform the following operations in the dialog box that appears: ○ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section. ○ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section.
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select **Position-based Mapping** or **Name-based Mapping**.

8. Click **OK**.

Copy a DRDS output component

1. Right-click a DRDS output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a DRDS output component

1. Right-click a DRDS output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.3. Manage Maxcompute output components

This topic describes how to configure, copy, and delete a Maxcompute output component.

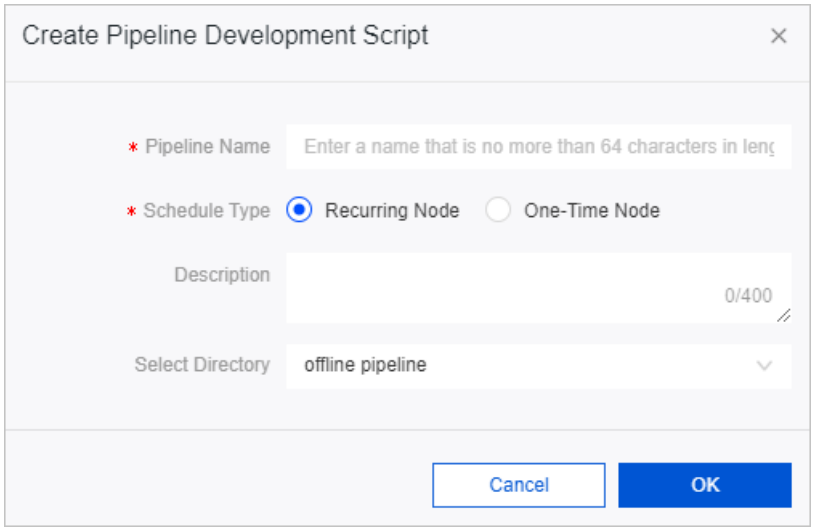
Context

A Maxcompute output component is used to write data processed by Dataphin to a MaxCompute project for data consumption.

Configure a Maxcompute output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the icon before **Output**.
5. Drag a Maxcompute component to the pipeline canvas on the left.
6. Right-click the Maxcompute component and select **Configure Attributes**.
7. In the **Maxcompute Output Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Table	The destination table. You can also perform the following steps to create a destination table: i. Click **Generate Target Table by One Click**. ii. In the dialog box that appears, write an SQL script as required and click **Create**. By default, the table created is the destination table for the output data.
Loading Policy	The policy for writing data to the destination table. Valid values: ○ **Overwrite Data**: uses the source data to overwrite the existing data in the destination table. ○ **Append Data**: appends the source data to the destination table, without modifying the existing data in the destination table.
Partitioning	The partition information required if the destination table is a partitioned table. ○ If the table you selected is a partitioned table, you must enter partition information, for example, ds=${bizdate}. ○ If the table you selected is not a partitioned table, you do not need to set this parameter.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can click **Manage Fields** and perform the following operations in the dialog box that appears: ○ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section. ○ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section.

Parameter	Description
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select **Position-based Mapping** or **Name-based Mapping**.

8. Click **OK**.

Copy a Maxcompute output component

1. Right-click a Maxcompute output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a Maxcompute output component

1. Right-click a Maxcompute output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.4. Manage SQL Server output components

This topic describes how to configure, copy, and delete an SQL Server output component.

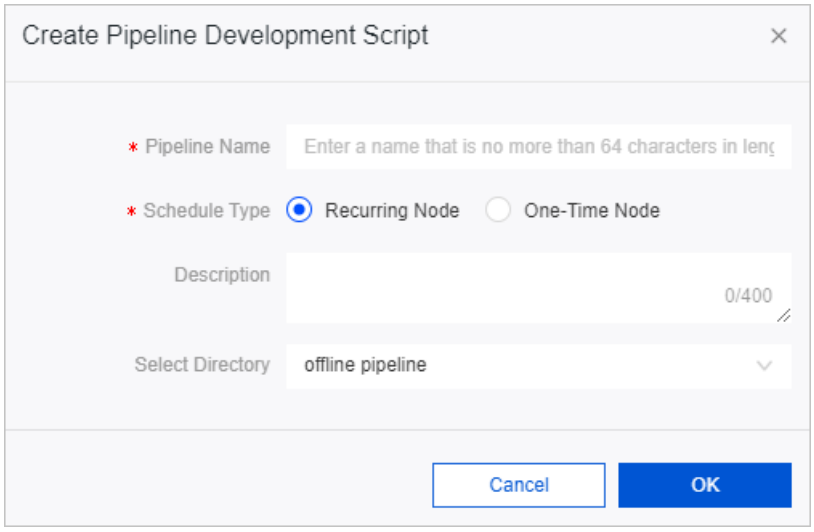
Context

An SQL Server output component is used to write data processed by Dataphin to an SQL Server database for data consumption.

Configure an SQL Server output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Output**.
5. Drag an SQL Server component to the pipeline canvas on the left.
6. Right-click the SQL Server component and select **Configure Attributes**.
7. In the **SQL Server Output Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Table	The destination table.
Parse Solution	Optional. The operations before and after data output. To specify operations before or after data output, click **Enter Preparation Statement** or **Enter Completion Statement** next to **Parse Solution** and enter SQL statements. ○ **Enter Preparation Statement**: the SQL statements to execute before data output. ○ **Enter Completion Statement**: the SQL statements to execute after data output.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can click **Manage Fields** and perform the following operations in the dialog box that appears: ○ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section. ○ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section.
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select **Position-based Mapping** or **Name-based Mapping**. ○ **Position-based Mapping**: The fields in the **Input Fields** section and those in the **Output Fields** section are mapped based on their positions. ○ **Name-based Mapping**: The fields in the **Input Fields** section and those in the **Output Fields** section are mapped based on their names.

8. Click **OK**.

Copy an SQL Server output component

1. Right-click an SQL Server output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an SQL Server output component

1. Right-click an SQL Server output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.5. Manage ORACLE output components

This topic describes how to configure, copy, and delete an ORACLE output component.

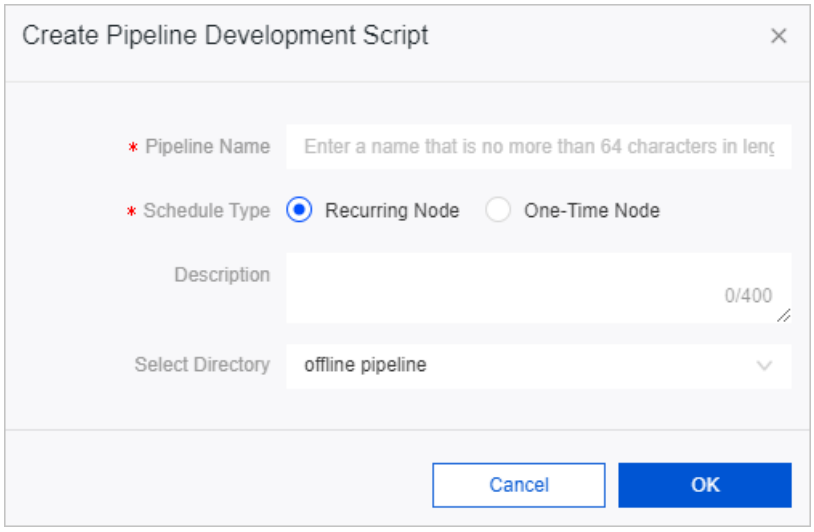
Context

An ORACLE output component is used to write data processed by Dataphin to an Oracle database for data consumption.

Configure an ORACLE output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Output**.
5. Drag an ORACLE component to the pipeline canvas on the left.
6. Right-click the ORACLE component and select **Configure Attributes**.
7. In the **Oracle Output Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the properties has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Table	The destination table.
Parse Solution	Optional. The operations before and after data output. To specify operations before or after data output, click **Enter Preparation Statement** or **Enter Completion Statement** next to **Parse Solution** and enter SQL statements. ○ **Enter Preparation Statement**: the SQL statements to execute before data output. ○ **Enter Completion Statement**: the SQL statements to execute after data output.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can click **Manage Fields** and perform the following operations in the dialog box that appears: ○ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section. ○ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section.
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select **Position-based Mapping** or **Name-based Mapping**.

8. Click **OK**.

Copy an ORACLE output component

1. Right-click an ORACLE output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an ORACLE output component

1. Right-click an ORACLE output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.6. Manage PostgreSQL output components

This topic describes how to configure, copy, and delete a PostgreSQL output component.

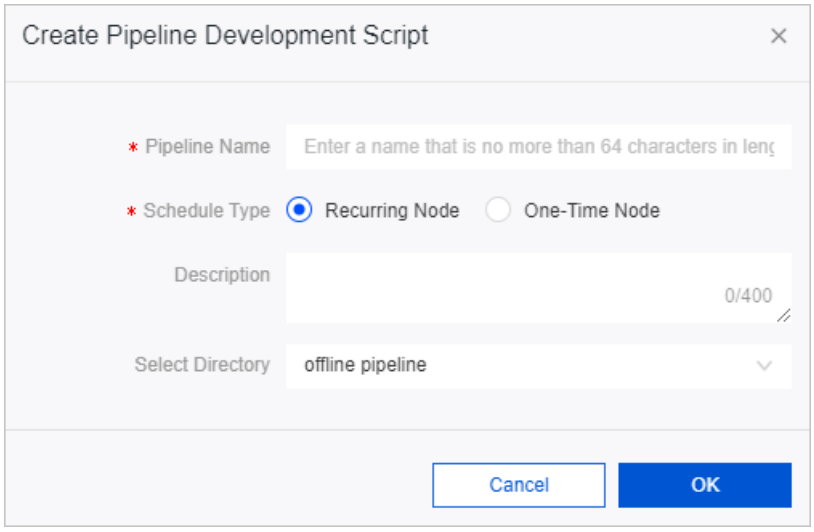
Context

A PostgreSQL output component is used to write data processed by Dataphin to a PostgreSQL database for data consumption.

Configure a PostgreSQL output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Output**.
5. Drag a PostgreSQL component to the pipeline canvas on the left.
6. Right-click the PostgreSQL component and select **Configure Attributes**.
7. In the **PostgreSQL Output Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to Data Source to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Table	The destination table.
Parse Solution	Optional. The operations before and after data output. To specify operations before or after data output, click Enter Preparation Statement or Enter Completion Statement next to Parse Solution and enter SQL statements. ○ Enter Preparation Statement: the SQL statements to execute before data output. ○ Enter Completion Statement: the SQL statements to execute after data output.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can click Manage Fields and perform the following operations in the dialog box that appears: ○ Select one or more fields in the Selected Input Fields section and click the icon to move the fields to the Unselected Input Fields section. ○ Select one or more fields in the Unselected Input Fields section and click the icon to move the fields to the Selected Input Fields section.
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click Quick Mapping and select Position-based Mapping or Name-based Mapping.

8. Click **OK**.

Copy a PostgreSQL output component

1. Right-click a PostgreSQL output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a PostgreSQL output component

1. Right-click a PostgreSQL output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.7. Manage Vertica output components

This topic describes how to configure, copy, and delete a Vertica output component.

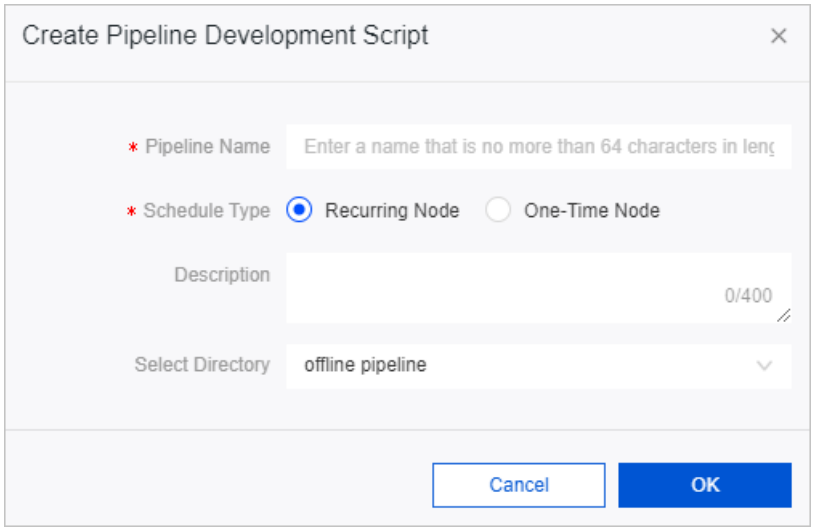
Context

A Vertica output component is used to write data processed by Dataphin to a Vertica database for data consumption.

Configure a Vertica output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the icon before **Output**.
5. Drag a Vertica component to the pipeline canvas on the left.
6. Right-click the Vertica component and select **Configure Attributes**.
7. In the **Vertica Output Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Table	The destination table.
Parse Solution	Optional. The operations before and after data output. To specify operations before or after data output, click **Enter Preparation Statement** or **Enter Completion Statement** next to **Parse Solution** and enter SQL statements. ○ **Enter Preparation Statement**: the SQL statements to execute before data output. ○ **Enter Completion Statement**: the SQL statements to execute after data output.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can click **Manage Fields** and perform the following operations in the dialog box that appears: ○ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section. ○ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section.
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select **Position-based Mapping** or **Name-based Mapping**.

8. Click **OK**.

Copy a Vertica output component

1. Right-click a Vertica output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a Vertica output component

1. Right-click a Vertica output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.8. Manage FTP output components

This topic describes how to configure, copy, and delete an FTP output component.

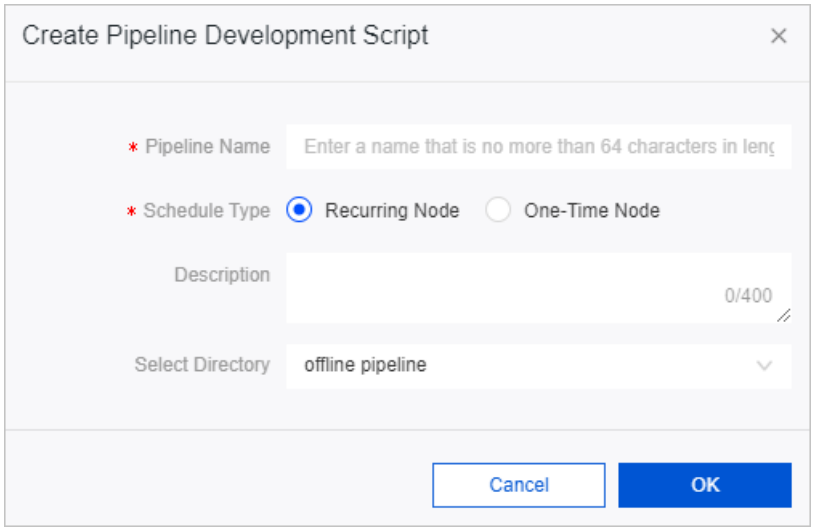
Context

An FTP output component is used to write data processed by Dataphin to an FTP server for data consumption.

Configure an FTP output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Output**.
5. Drag an FTP component to the pipeline canvas on the left.
6. Right-click the FTP component and select **Configure Attributes**.
7. In the **FTP Output Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the  icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
File Path	The path of the destination file.
File Type	The type of the destination file. Valid values: **TexT** and **CSV**.
File Encoding	The encoding format of the destination file. Valid values: **UTF-8** and **GBK**.
Field Delimiter	Optional. The delimiter that is used to separate fields in the destination file. If you do not specify this parameter, a comma (,) is used as the field delimiter.
Loading Policy	The policy for writing data to the destination file. Valid values: ○ **Overwrite Data**: uses the source data to overwrite the existing data in the destination file. ○ **Append Data**: appends the source data to the destination file, without modifying the existing data in the destination file.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can create output fields by using one of the following methods: ○ Click **Batch Create**. In the Batch Create in JSON Format dialog box, configure multiple output fields in the JSON format. Example: `[{ "name":"cf1:a", "type":"String" },` `{ "name":"cf1:b", "type":"String" }]` ○ Click **Create Output Field**. Set the **Field** and **Type** parameters as required. You can also perform the following operations on existing fields: ○ Click the  icon in the **Actions** column to edit a field. ○ Click the  icon in the **Actions** column to delete a field.

Parameter	Description
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select **Position-based Mapping** or **Name-based Mapping**.

8. Click **OK**.

Copy an FTP output component

1. Right-click an FTP output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an FTP output component

1. Right-click an FTP output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.9. Manage HDFS output components

This topic describes how to configure, copy, and delete an HDFS output component.

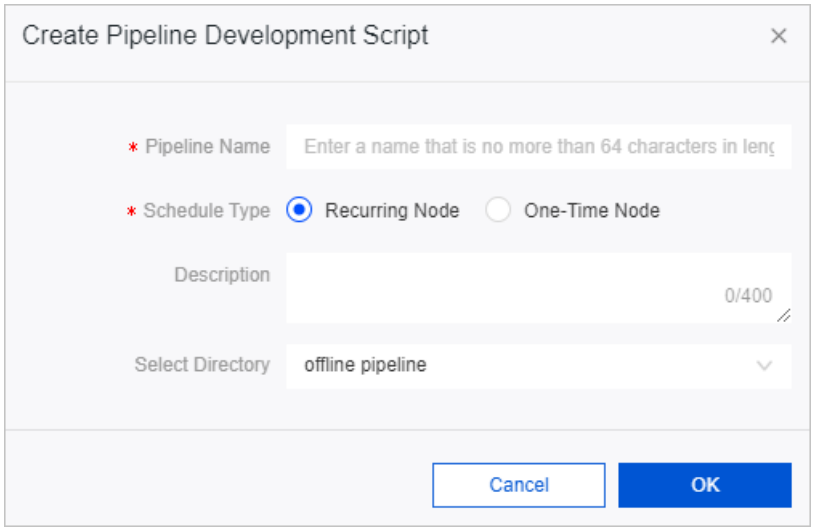
Context

An HDFS output component is used to write data processed by Dataphin to an HDFS for data consumption.

Configure an HDFS output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Output**.
5. Drag an HDFS component to the pipeline canvas on the left.
6. Right-click the HDFS component and select **Configure Attributes**.
7. In the **HDFS Output Configuration** dialog box, set the parameters as prompted.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
File Path	The path of the destination file.
File Type	The type of the destination file. Valid values: **TexT** and **ORC**.
File Encoding	The encoding format of the destination file. Valid values: **UTF-8** and **GBK**.
Field Delimiter	Optional. The delimiter that is used to separate fields in the destination file. If you do not specify this parameter, a comma (,) is used as the field delimiter.
Loading Policy	The policy for writing data to the destination file. Valid values: ○ **Overwrite Data**: uses the source data to overwrite the existing data in the destination file. ○ **Append Data**: appends the source data to the destination file, without modifying the existing data in the destination file.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can create output fields by using one of the following methods: ○ Click **Batch Create**. In the Batch Create in JSON Format dialog box, configure multiple output fields in the JSON format. Example: `[{ "name":"cf1:a", "type":"String" },` `{ "name":"cf1:b", "type":"String" }]` ○ Click **Create Output Field**. Set the **Field** and **Type** parameters as prompted. You can also perform the following operations on existing fields: ○ Click the icon in the **Actions** column to edit a field. ○ Click the icon in the **Actions** column to delete a field.

Parameter	Description
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select **Position-based Mapping** or **Name-based Mapping**.

8. Click **OK**.

Copy an HDFS output component

1. Right-click an HDFS output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an HDFS output component

1. Right-click an HDFS output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.10. Manage MongoDB output components

This topic describes how to configure, copy, and delete a MongoDB output component.

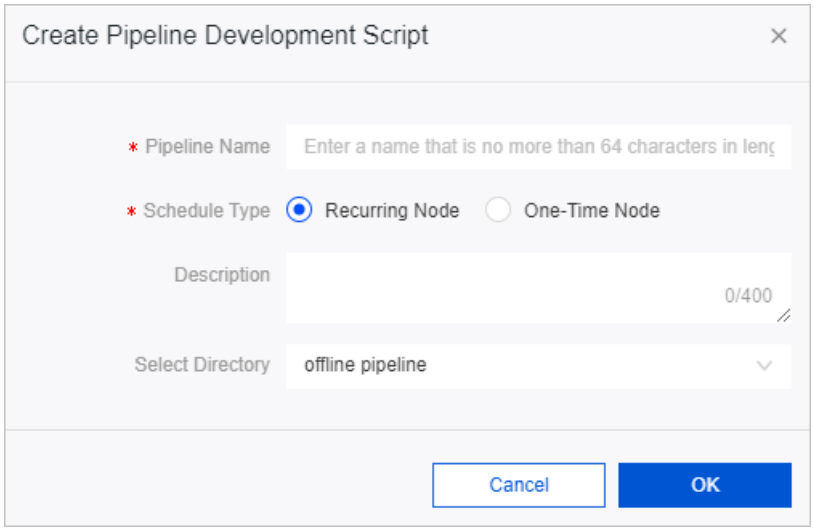
Context

A MongoDB output component is used to write data processed by Dataphin to a MongoDB database for data consumption.

Configure a MongoDB output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Output**.
5. Drag a MongoDB component to the pipeline canvas on the left.
6. Right-click the MongoDB component and select **Configure Attributes**.
7. In the **MongoDB Output Configuration** dialog box, set the parameters as prompted.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MongoDB data source.
Table	The destination table.
Update Information	The update information of fields. For example, you can enter `{"isUpsert":"true","upsertkey""unique_id"}` .
Field Delimiter	The delimiter that is used to separate fields in the destination table. If you do not specify this parameter, a comma (,) is used as the field delimiter.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can create output fields by using one of the following methods: ○ Click **Batch Create**. In the Batch Create in JSON Format dialog box, configure multiple output fields in the JSON format. Example: `[{ "name":"cf1:a", "type":"String" },` `{ "name":"cf1:b", "type":"String" }]` ○ Click **Create Output Field**. Set the **Field** and **Type** parameters as prompted. You can also perform the following operations on existing fields: ○ Click the icon in the **Actions** column to edit a field. ○ Click the icon in the **Actions** column to delete a field.
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select **Position-based Mapping** or **Name-based Mapping**.

8. Click **OK**.

Copy a MongoDB output component

1. Right-click a MongoDB output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a MongoDB output component

1. Right-click a MongoDB output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.11. Manage Hbase output components

This topic describes how to configure, copy, and delete an Hbase output component.

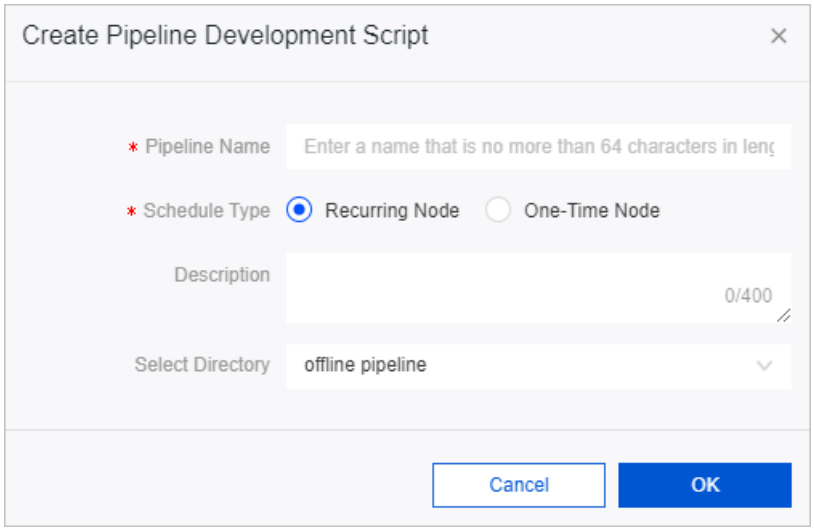
Context

An Hbase output component is used to write data processed by Dataphin to an HBase database for data consumption.

Configure an Hbase output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Output**.
5. Drag an Hbase component to the pipeline canvas on the left.
6. Right-click the Hbase component and select **Configure Attributes**.
7. In the **HBase Output Configuration** dialog box, set the parameters as prompted.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the  icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
File Encoding	The encoding format of the destination table. Valid values: **UTF-8** and **GBK**.
Version Column	The timestamp of data written to the destination table in HBase. For example, you can enter {"index":-1,"value":123456789}.
Rowkey	The rowkey rule of the destination table. The rowkey is composed of several output fields that are connected by an underscore (_). Example: `[{"index":0,"type":"string"},{"index":2,"type":"string"},{"index":-1,"string","value":"_"}]` In this example, the rowkey is composed of the first and third output fields that are connected by an underscore (_).
Input Fields	The input fields based on the upstream input.

Parameter	Description
Output Fields	The output fields to be generated. You can create output fields by using one of the following methods: ○ Click **Batch Create**. In the Batch Create in JSON Format dialog box, configure multiple output fields in the JSON format. Example: `[{ "name": "col_integer", "type": "integer" }, { "name": "col_long", "type": "long" }, { "name": "col_double", "type": "double" }]` In the example, name and type specify the name and data type of the output field, respectively. ○ Click **Create Output Field**. Set the **Column Family**, **Field**, and **Type** parameters as prompted. You can also perform the following operations on existing fields: ○ Click the icon in the **Actions** column to edit a field. ○ Click the icon in the **Actions** column to delete a field.
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select Position-based Mapping or **Name-based Mapping**.

8. Click **OK**.

Copy an Hbase output component

1. Right-click an Hbase output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an Hbase output component

1. Right-click an Hbase output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.12. Manage Hive output components

This topic describes how to configure, copy, and delete a Hive output component.

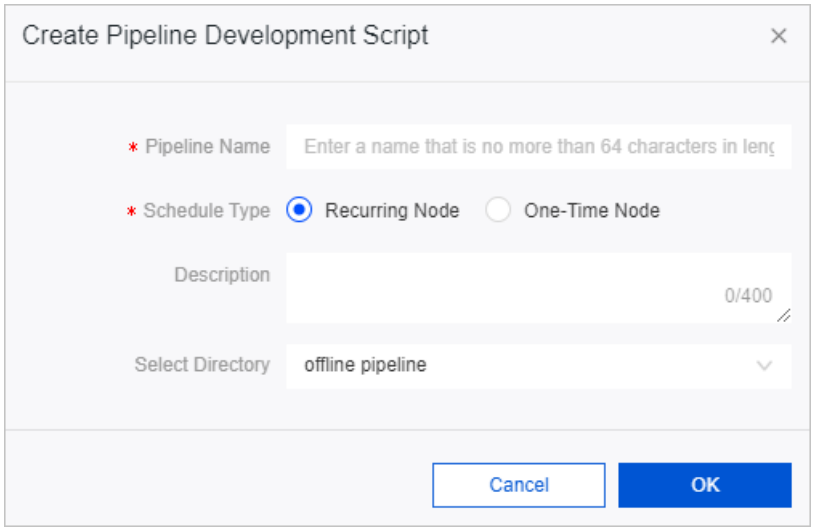
Context

A Hive output component is used to write data processed by Dataphin to a Hive database for data consumption.

Configure a Hive component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Output**.
5. Drag a Hive component to the pipeline canvas on the left.
6. Right-click the Hive component and select **Configure Attributes**.
7. In the **Hive Output Configuration** dialog box, set the parameters as prompted.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the  icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a Hive data source.
Table	The destination table.
File Encoding	The encoding format of the destination table. Valid values: **UTF-8** and **GBK**.
Field Delimiter	Optional. The delimiter that is used to separate fields in the destination table. If you do not specify this parameter, a comma (,) is used as the field delimiter.
Loading Policy	The policy for writing data to the destination table. Valid values: ○ **Overwrite Data**: uses the source data to overwrite the existing data in the destination table. ○ **Append Data**: appends the source data to the destination table, without modifying the existing data in the destination table.
Compression Format	The compression format of the destination table. Valid values: ○ **zip** ○ **gzip** ○ **bzip2**
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can click **Manage Fields** and perform the following operations in the dialog box that appears: ○ Select one or more fields in the **Selected Input Fields** section and click the  icon to move the fields to the **Unselected Input Fields** section. ○ Select one or more fields in the **Unselected Input Fields** section and click the  icon to move the fields to the **Selected Input Fields** section.

Parameter	Description
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select **Position-based Mapping** or **Name-based Mapping**.

8. Click **OK**.

Copy a Hive component

1. Right-click a Hive component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a Hive component

1. Right-click a Hive component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.13. Manage ElasticSearch output components

This topic describes how to configure, copy, and delete an ElasticSearch output component.

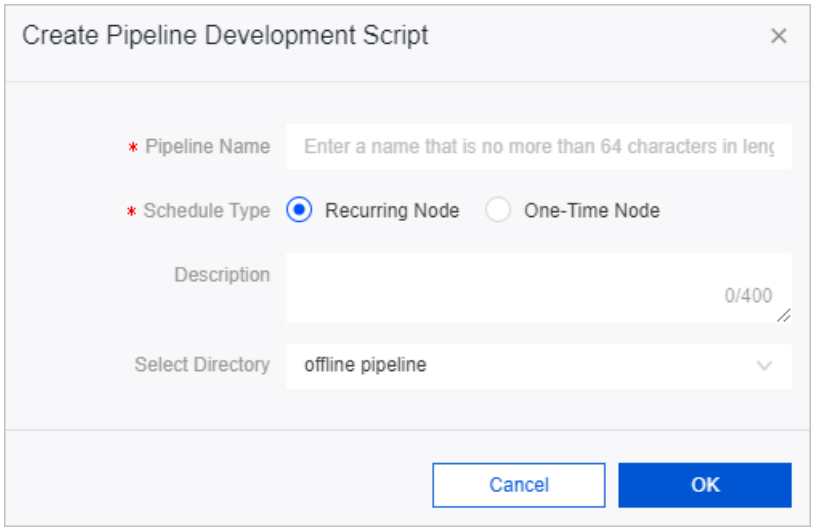
Context

An ElasticSearch output component is used to write data processed by Dataphin to an Elasticsearch database for data consumption.

Configure an ElasticSearch output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Output**.
5. Drag an ElasticSearch component to the pipeline canvas on the left.
6. Right-click the ElasticSearch component and select **Configure Attributes**.
7. In the **ElasticSearch Output Configuration** dialog box, set the parameters as prompted.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Index	The index of the destination table.
Index Type	The index type of the destination table.
Loading Policy	The policy for writing data to the destination table. Valid values: ○ **Overwrite Data**: uses the source data to overwrite the existing data in the destination table. ○ **Append Data**: appends the source data to the destination table, without modifying the existing data in the destination table.
Field Delimiter	Optional. The delimiter that is used to separate fields in the destination table. If you do not specify this parameter, a comma (,) is used as the field delimiter.
Input Fields	The input fields based on the upstream input.

Parameter	Description
Output Fields	The output fields to be generated. You can create output fields by using one of the following methods: ○ Click **Batch Create**. In the Batch Create in JSON Format dialog box, configure multiple output fields in the JSON format. Example: `[{ "name": "col_integer", "type": "integer" }, { "name": "col_long", "type": "long" }, { "name": "col_double", "type": "double" }]` In the example, name and type specify the name and data type of the output field, respectively. ○ Click **Create Output Field**. Set the **Field** and **Type** parameters as required. You can also perform the following operations on existing fields: ○ Click the icon in the **Actions** column to edit a field. ○ Click the icon in the **Actions** column to delete a field.
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select **Position-based Mapping** or **Name-based Mapping**.

8. Click **OK**.

Copy an ElasticSearch output component

1. Right-click an ElasticSearch output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an ElasticSearch output component

1. Right-click an ElasticSearch output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.14. Manage ADB for MySQL2.0 output components

This topic describes how to configure, copy, and delete an ADB for MySQL2.0 output component.

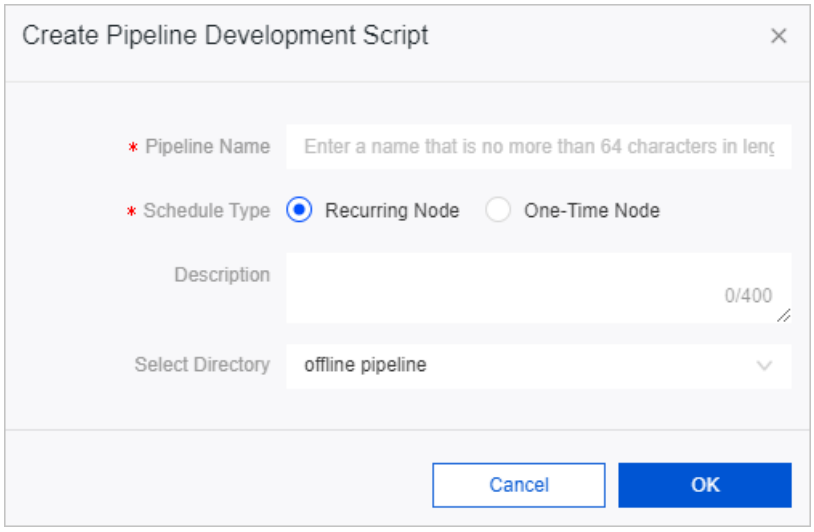
Context

An ADB for MySQL2.0 output component is used to write data processed by Dataphin to an AnalyticDB for MySQL 2.0 database for data consumption.

Configure an ADB for MySQL2.0 output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Output**.
5. Drag an **ADB for MySQL2.0** component to the pipeline canvas on the left.
6. Right-click the **ADB for MySQL2.0** component and select **Configure Attributes**.
7. In the **AnalyticDB for MySQL 2.0 Output Configuration** dialog box, set the parameters as prompted.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the  icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create an AnalyticDB for MySQL V3.0 data source.
Table	The destination table.
Mode	The mode for writing data to the destination table. Valid values: ○ **Insert Mode**: applicable when fewer than 10 million data records are to be written. If you select this mode, perform the following operations to set the **Parse Solution** parameter: ■ Click **Enter Preparation Statement** and enter the SQL statements to execute before data output. ■ Click **Enter Completion Statement** and enter the SQL statements to execute after data output. ○ **Load Mode**: applicable when more than 10 million data records are to be written. If you select this mode, you must set the following parameters: ■ **Load policy**: the policy for writing data to the destination table. Valid values: **Append Data** and **Overwrite Data**. ■ **Load Parameters**: the parameters for connecting to MaxCompute. Example: `{"accessid":"<yourAccessKeyId>","accessKey":"*<yourAccessKeySecret>","odpsServer":"****", "tunnelServer":"****","accountType":"aliyun","project":"transfer_project"}` ■ **Alibaba Cloud Account**: the Alibaba Cloud account that is authorized to write data, for example, ALIYUN$garuda_data@aliyun.com.
Input Fields	The input fields based on the upstream input.

Parameter	Description
Output Fields	The output fields to be generated. You can click **Manage Fields** and perform the following operations in the dialog box that appears: ○ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section. ○ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section.
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select **Position-based Mapping** or **Name-based Mapping**.

8. Click **OK**.

Copy an ADB for MySQL2.0 output component

1. Right-click an ADB for MySQL2.0 output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an ADB for MySQL2.0 output component

1. Right-click an ADB for MySQL2.0 output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.15. Manage ADB for MySQL3.0 output components

This topic describes how to configure, copy, and delete an ADB for MySQL3.0 output component.

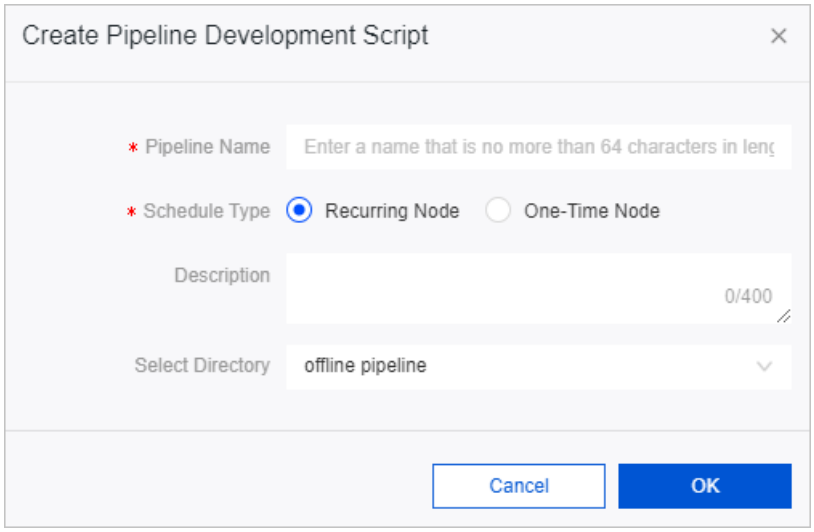
Context

An ADB for MySQL3.0 output component is used to write data processed by Dataphin to an AnalyticDB for MySQL 3.0 database for data consumption.

Configure an ADB for MySQL3.0 output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Output**.
5. Drag an ADB for MySQL3.0 component to the pipeline canvas on the left.
6. Right-click the ADB for MySQL3.0 component and select **Configure Attributes**.
7. In the **AnalyticDB for MySQL 3.0 Output Configuration** dialog box, set the parameters as prompted.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source.
Table	The destination table.
Loading Policy	The policy for writing data to the destination table. Valid values: ○ **Overwrite Data**: uses the source data to overwrite the existing data in the destination table. ○ **Append Data**: appends the source data to the destination table, without modifying the existing data in the destination table.
Parse Solution	Optional. The operations before and after data output. To specify operations before or after data output, click **Enter Preparation Statement** or **Enter Completion Statement** next to **Parse Solution** and enter SQL statements. ○ **Enter Preparation Statement**: the SQL statements to execute before data output. ○ **Enter Completion Statement**: the SQL statements to execute after data output.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can click **Manage Fields** to perform the following operations in the dialog box that appears: ○ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section. ○ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section.
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select **Position-based Mapping** or **Name-based Mapping**.

8. Click **OK**.

Copy an ADB for MySQL3.0 output component

1. Right-click an ADB for MySQL3.0 output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an ADB for MySQL3.0 output component

1. Right-click an ADB for MySQL3.0 output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.2.9.16. Manage ADB for PostgreSQL output components

This topic describes how to configure, copy, and delete an ADB for PostgreSQL output component.

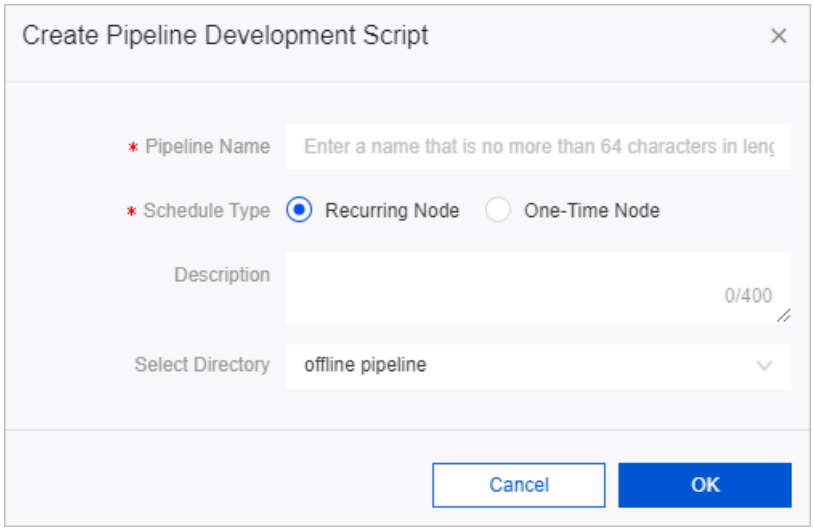
Context

An ADB for PostgreSQL output component is used to write data processed by Dataphin to an AnalyticDB for PostgreSQL database for data consumption.

Configure an ADB for PostgreSQL output component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Output**.
5. Drag an **ADB for PostgreSQL** component to the pipeline canvas on the left.
6. Right-click the **ADB for PostgreSQL** component and select **Configure Attributes**.
7. In the **AnalyticDB for PostgreSQL Output Configuration** dialog box, set the parameters as prompted.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the same type as the output component. ○ The account that you use to configure the component has the write-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Table	The destination table.
Parse Solution	Optional. The operations before and after data output. To specify operations before or after data output, click **Enter Preparation Statement** or **Enter Completion Statement** next to **Parse Solution** and enter SQL statements. ○ **Enter Preparation Statement**: the SQL statements to execute before data output. ○ **Enter Completion Statement**: the SQL statements to execute after data output.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated. You can click **Manage Fields** to perform the following operations in the dialog box that appears: ○ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section. ○ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section.
Mapping	The mapping between the input and output fields. To specify mappings one by one, click a field in the input field list and a field in the output field list. To specify multiple mappings at a time, click **Quick Mapping** and select **Position-based Mapping** or **Name-based Mapping**.

8. Click **OK**.

Copy an ADB for PostgreSQL output component

1. Right-click an ADB for PostgreSQL output component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an ADB for PostgreSQL output component

1. Right-click an ADB for PostgreSQL output component and select **Delete**.
2. In the message that appears, click **OK**.

9.8.3. Data ingestion

9.8.3.1. Create a folder for storing sync tasks

You can use different folders to manage different types of sync tasks. This topic describes how to create a folder for storing sync tasks and the operations that you can perform on created folders.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the **Data Processing** tab, move the pointer over the left-side navigation submenu and click the icon. The Sync Tasks section appears.
6. In the **Sync Tasks** section, click the icon next to **Sync Tasks**.
7. In the **Create Folder** dialog box, set the **Name** and **Select Directory** parameters.
8. Click **OK**.The following table describes the operations that you can perform on created folders.

Operation	Description
Rename a folder	To rename a folder, perform the following steps: i. In the Sync Tasks section, move the pointer over the icon next to the folder that you want to rename and select **Rename**. ii. In the field that appears, enter a new name. iii. Press the Enter key.
Move a folder	To move a folder, perform the following steps: i. In the Sync Tasks section, move the pointer over the icon next to the folder that you want to move and select **Move**. ii. In the **Move Folder** dialog box, set the **Select Directory** parameter to the destination directory. iii. Click **OK**.

Operation	Description
Delete a folder	To delete a folder, perform the following steps: i. In the Sync Tasks section, move the pointer over the icon next to the folder that you want to delete. ii. Select **Delete**. **Note** You can delete only the folders that do not contain subfolders or items.

9.8.3.2. Create a destination table for data synchronization

A destination table for data synchronization is a table that Dataphin uses to process business data. It is in the computing engine bound to the project to which the business belongs. This topic describes how to create a destination table for data synchronization.

Context

Dataphin allows you to create a destination table for data synchronization by creating an ad hoc query task or a batch processing task.

Create a destination table by creating an ad hoc query task

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Ad Hoc Query** tab in the left-side navigation pane.
5. Create a folder for storing ad hoc query tasks.
   i. In the **Ad Hoc Query** section, click the icon next to **Ad Hoc Query**.
   ii. In the **Create Folder** dialog box, set the **Name** and Select Directory parameters.
   iii. Click **OK**.
6. Create an ad hoc query task.
   i. In the **Ad Hoc Query** section, click the icon next to **Ad Hoc Query**.
   ii. In the **Create Item** dialog box, set the **Name**, **Description**, and **Select Directory** parameters.
   iii. Click **OK**. The Code Editor tab appears.
7. Write the code of the ad hoc query task on the Code Editor tab.

i. Write SQL statements to create a destination table. In this example, write the following SQL statements:

```
-- Table<store_sales (23 cols)  partition=ss_sold_date_sk>
drop table if exists store_sales;
create table if not exists store_sales(
    ss_sold_date_sk bigint
,   ss_sold_time_sk bigint
,   ss_item_sk bigint
,   ss_customer_sk bigint
,   ss_cdemo_sk bigint
,   ss_hdemo_sk bigint
,   ss_addr_sk bigint
,   ss_store_sk bigint
,   ss_promo_sk bigint
,   ss_ticket_number bigint
,   ss_quantity int
,   ss_wholesale_cost double
,   ss_list_price double
,   ss_sales_price double
,   ss_ext_discount_amt double
,   ss_ext_sales_price double
,   ss_ext_wholesale_cost double
,   ss_ext_list_price double
,   ss_ext_tax double
,   ss_coupon_amt double
,   ss_net_paid double
,   ss_net_paid_inc_tax double
,   ss_net_profit double
)
partitioned by (ds string)
```

ii. Click **Precompile** in the upper-right corner of the Code Editor tab to check whether the SQL statement complies with the standard.If the SQL statements do not comply with the standard, click **Beautify** in the upper-right corner. Then, Dataphin automatically adjusts the SQL statements so that they comply with the standard.

iii. Click **Run** in the upper-right corner of the Code Editor tab to execute the SQL statements. Then, check whether the SQL statements are executed based on the information on the Console tab in the lower part of the page.

8. If the SQL statements are executed, click the icon in the upper-right corner of the Code Editor tab.

Create a destination table by creating a batch processing task

1. On the Dataphin homepage, click **R&D** in the top navigation bar.
2. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
3. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
4. On the **Data Processing** tab, move the pointer over the left-side navigation submenu and click the icon. The Batch Processing Tasks section appears.
5. Create a folder for storing batch processing tasks.
   i. In the **Batch Processing Tasks** section, click the icon next to **Batch Processing Tasks**.
   ii. In the **Create Folder** dialog box, set the **Name** and Select Directory parameters.
   iii. Click **OK**.
6. Create a batch processing task of the MAX_COMPUTE_SQL type.
   i. In the **Batch Processing Tasks** section, click the icon next to **Batch Processing Tasks** and select **MAX_COMPUTE_SQL**.
   ii. In the **Create Item** dialog box, set the parameters as required.

Parameter	Description
Name	The name of the batch processing task, for example, SQL.
Schedule Type	The scheduling type of the task. Valid values: **Recurring Node** and **One-Time Node**.
Description	The description of the task.
Select Directory	The folder for storing the task.

   iii. Click **OK**. The Code Editor tab appears.
7. Write the code of the batch processing task on the Code Editor tab.

i. Write SQL statements to create a destination table. In this example, write the following SQL statements:

```
-- Table<customer (18 cols)>

drop table if exists customer;
create table if not exists customer(
    c_customer_sk bigint
,   c_customer_id string
,   c_current_cdemo_sk bigint
,   c_current_hdemo_sk bigint
,   c_current_addr_sk bigint
,   c_first_shipto_date_sk bigint
,   c_first_sales_date_sk bigint
,   c_salutation string
,   c_first_name string
,   c_last_name string
,   c_preferred_cust_flag string
,   c_birth_day int
,   c_birth_month int
,   c_birth_year int
,   c_birth_country string
,   c_login string
,   c_email_address string
,   c_last_review_date_sk bigint
)
;
```

ii. Click **Precompile** in the upper-right corner of the Code Editor tab to check whether the SQL statement complies with the standard.If the SQL statements do not comply with the standard, click **Beautify** in the upper-right corner. Then, Dataphin automatically adjusts the SQL statements so that they comply with the standard.

iii. Click **Run** in the upper-right corner of the Code Editor tab to execute the SQL statements. Then, check whether the SQL statements are executed based on the information on the Console tab in the lower part of the page.

8. (Optional)Configure the scheduling policy.
   - If you set the Schedule Type parameter to **Recurring Node**, you must configure the scheduling policy. For more information, see Configure a scheduling policy.
     - If you set the Schedule Type parameter to **One-Time Node**, you do not need to configure the scheduling policy.
9. Save, submit, and publish the batch processing task.

i. Click the icon in the upper-right corner of the Code Editor tab to save the task.

ii. Click the icon in the upper-right corner of the Code Editor tab to submit the task.

iii. (Optional)Publish the batch processing task.

- If the current project is in Dev mode, publish the task to the corresponding project in Prod mode. For more information, see Publishing management.
- If the current project is in Basic mode, you do not need to publish the task. The task can be scheduled in the production environment after you submit it.

9.8.3.3. Create a sync task

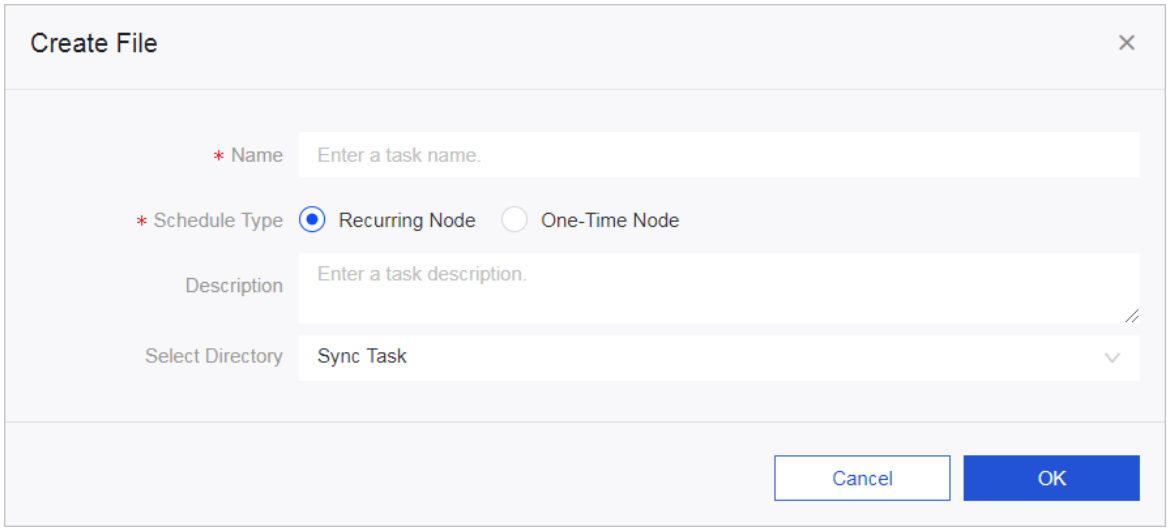
This topic describes how to create a sync task for synchronizing data from a business data source to a destination table in Dataphin.

Prerequisites

Destination tables for data synchronization are created. For more information, see Create a destination table for data synchronization.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the **Data Processing** tab, move the pointer over the left-side navigation submenu and click the icon. The Sync Tasks section appears.
6. Create a folder for storing sync tasks.
   i. In the **Sync Tasks** section, click the icon next to **Sync Tasks**.
   ii. In the **Create Folder** dialog box, set the **Name** and Select Directory parameters.
   iii. Click **OK**.
7. In the **Sync Tasks** section, click the icon next to **Sync Tasks**.
8. In the **Create Item** dialog box, set the parameters as required.



Parameter	Description
Name	The name of the sync task.
Schedule Type	The scheduling type of the task. Valid values: ○ **Recurring Node**: If you select this option, you must configure the scheduling policy. ○ **One-Time Node**: If you select this option, you do not need to configure the scheduling policy.
Description	The description of the task.
Select Directory	The directory for storing the task.

9. Click **OK**. The sync task is created and is in the **Draft** state.

   The following table describes the operations that you can perform on sync tasks in the **Draft** state.

Operation	Description
Modify a sync task	To modify a sync task, perform the following steps: i. In the **Sync Tasks** section, move the pointer over the icon next to the sync task that you want to modify and select **Change**. ii. On the configuration tab of the sync task, modify the task settings. For more information, see Configure a sync task.
Rename a sync task	To rename a sync task, perform the following steps: i. In the **Sync Tasks** section, move the pointer over the icon next to the sync task that you want to rename and select **Rename**. ii. In the field that appears, enter a new name. iii. Press the Enter key.

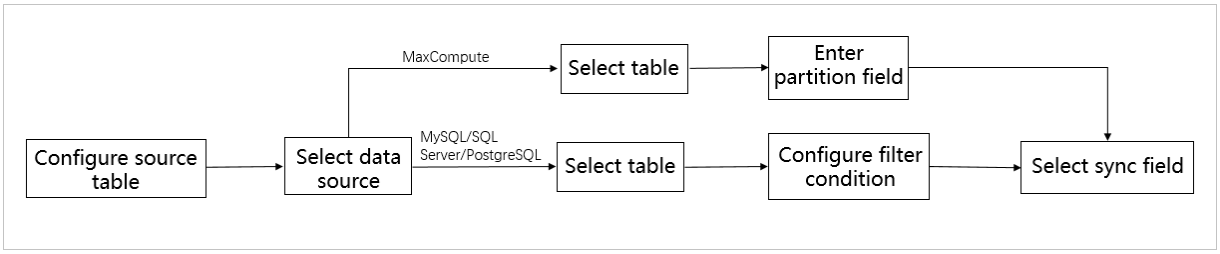
Operation	Description
Move a sync task	To move a sync task, perform the following steps: i. In the **Sync Tasks** section, move the pointer over the icon next to the sync task that you want to move and select **Move**. ii. In the **Move Folder** dialog box, set the **Select Directory** parameter to the destination directory. iii. Click **OK**.
Delete a sync task	To delete a sync task, perform the following steps: i. In the **Sync Tasks** section, move the pointer over the icon next to the sync task that you want to delete and select **Delete**. ii. In the **Tip** dialog box, enter your comments. iii. Click **OK**.

9.8.3.4. Configure a sync task

You can configure a sync task to synchronize data from a source table to a destination table. This topic describes how to configure a sync task.

Configuration process

The following figure shows how to configure a sync task.



The following table describes the data sources that Dataphin supports for both the source and destination tables.

Data storage type	Data source
Relational database	MySQL, Vertica, Oracle, SQL Server, PostgreSQL, and PolarDB-X
Analytical database	AnalyticDB, AnalyticDB for MySQL V3.0, and AnalyticDB for PostgreSQL
Alibaba Cloud big data warehouse	MaxCompute
Application database	LogHub
Open-source big data warehouse	Hive and HBase

Data storage type	Data source
Unstructured data storage	FTP, HDFS, and Elasticsearch
NoSQL database	MongoDB

Note If you select HBase, HBase 0.94.x and HBase 1.1.x are supported.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Sync Tasks** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.

   You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the **Data Processing** tab, move the pointer over the left-side navigation submenu and click the icon. The Sync Tasks section appears.
3. In the **Sync Tasks** section, click a created sync task. On the tab that appears, set the parameters as required.
   i. Set the parameters in the **Source** section. This section displays parameters based on the data source of the source table that you select. For more information about the parameters in this section, see Data sources.
   ii. Set the parameters in the **Target** section. This section displays parameters based on the data source of the destination table that you select. For more information about the parameters in this section, see Data sources.
   iii. Set the parameters in the **Source Fields** section. After you select a source table in the Source section, the fields of the source table appear in the **Source Fields** section.You can click the icon in the **Actions** column to remove a field.

   If you need to add a field that you have removed, click **Create Field**. In the dialog box that appears, check the **Field and Description** and **Data Type** parameters of the field, select the field, and then click **Add**.
   iv. Set the parameters in the **Target Fields** section. After you select a destination table in the Target section, the fields of the destination table appear in the **Target Fields** section.You can click the icon in the **Actions** column to remove a field.

   If you need to add a field that you have removed, click **Create Field**. In the dialog box that appears, check the **Field and Description** and **Data Type** parameters of the field, select the field, and then click **Add**.

v. Match the source and destination fields.

- If each source field has the same name as a destination field and the number of source fields equals that of destination fields, the system automatically matches the source and destination fields.
- If the source and destination fields have different names, you must manually match the source and destination fields. Remove the destination fields whose names are different from the source fields. Move the pointer over an empty row in the destination field list and select a field from the list that appears.

4. Set required limits for the sync task in the **Sync Limits** section. The parameters in this section are used to control the concurrency and fault tolerance. In most cases, you can use the default settings.

Parameter	Description
Speed Limit	The maximum data transmission rate during synchronization. Default value: 1MB/s. Dataphin will try to reach but will not exceed this rate. This parameter determines the size of scheduled resources when the sync task is running. The higher the speed limit is, the more resources are scheduled.
Concurrent Tasks	The maximum number of concurrent sync tasks.
Error Threshold	The maximum number of errors that are allowed during synchronization before the sync task is terminated. The default value is 0, which indicates that no errors are allowed.

5. Configure the scheduling policy for the sync task. For more information, see Configure a scheduling policy.
6. Save, submit, and then publish the sync task.

i. Click the icon in the upper-right corner to save the sync task.

ii. Click the icon in the upper-right corner to submit the sync task.

iii. (Optional)Publish the sync task.

- If the current project is in Dev mode, publish the sync task to the corresponding project in Prod mode. For more information, see Publishing management.
- If the current project is in Basic mode, you do not need to publish the sync task.

The following table describes the operations that you can perform on a sync task in the **Submitted** state.

Operation	Description

Operation	Description
Modify a sync task	To modify a sync task, perform the following steps: a. In the Sync Tasks section, move the pointer over the icon next to the sync task that you want to modify and select **Change**. b. On the tab that appears, modify the configuration of the sync task. For more information, see Configure a sync task. You can modify a sync task only when it is locked by you or unlocked. If the task is locked by another user, the icon appears in the upper-right corner. You can click the icon to steal the lock. After the lock is stolen, the icon appears, and you can modify the sync task. **Note** After you modify a sync task in the **Submitted** state and save the modification, the status of the sync task changes to **Developing**.
Rename a sync task	To rename a sync task, perform the following steps: a. In the Sync Tasks section, move the pointer over the icon next to the sync task that you want to rename and select **Rename**. b. In the field that appears, enter a new name and press Enter.
Move a sync task	To move a sync task, perform the following steps: a. In the Sync Tasks section, move the pointer over the icon next to the sync task that you want to move and select **Move**. b. In the **Move File** dialog box, set the **Select Directory** parameter to the destination directory and click **OK**.
Unpublish a sync task	To unpublish a sync task, perform the following steps: ■ In the Sync Tasks section, move the pointer over the icon next to the sync task that you want to unpublish and select **Unpublish**. ■ In the **Tip** dialog box, enter your comments and click **OK**.
Unpublish and delete a sync task	To unpublish and delete a sync task, perform the following steps: ■ In the Sync Tasks section, move the pointer over the icon next to the sync task that you want to unpublish and delete and select **Unpublish and Delete**. ■ In the **Tip** dialog box, enter your comments and click **OK**.

9.8.3.5. Configure a scheduling policy

Dataphin allows you to configure the scheduling rules and dependencies of nodes to make sure that tasks can be properly scheduled. This topic describes how to configure a scheduling policy for a sync task.

Prerequisites

Sync tasks are configured. For more information, see Configure a sync task.

Context

- Dataphin allows you to configure scheduling policies only for recurring tasks.
- A dependency is a semantic connection between two or more nodes. The status of an upstream node affects the running of its downstream nodes.
- After you configure dependencies for an upstream node and its downstream nodes, the downstream nodes can be run only after the upstream node is run. Before the system runs a node, the system checks the scheduling time that is configured for the node and determines whether to run the node.
- If a scheduling configuration is submitted before the specified scheduling time, the configuration takes effect after the specified scheduling time. If a dependency is configured after the specified scheduling time, the dependency takes effect for the instances that are generated the next day.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. Go to the **Sync Tasks** section.
   i. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   ii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iii. On the **Data Processing** tab, move the pointer over the left-side navigation submenu and click the icon. The Sync Tasks section appears.
4. In the **Sync Tasks** section, click a configured sync task.
5. On the tab that appears, click **Scheduling Configuration**.
6. In the **Scheduling Configuration** pane, set the parameters as required.

i. Set the parameters in the **Basic Information** section.Dataphin automatically generates the node name, node ID, node type, and owner. You cannot modify these parameters.

Parameter	Description
Description	The description of the scheduling policy.
Priority	The priority based on which the sync task is scheduled. Valid values: ■ **Lowest Priority** ■ **Low Priority** ■ **Medium Priority** ■ **High Priority** ■ **Highest Priority**
Parameters	The specified values for the parameters that are used in the code of the task. Dataphin allows you to specify the parameters that are used in the code of a task. The specified values are used when the task is run. You can click **Parameters and Descriptions** to know how to configure the parameters.

ii. Set the parameters in the **Scheduling Configuration** section.

Parameter	Description
Schedule Mode	The scheduling mode of the task. Valid values: ■ **Normal**: runs the task based on the specified recurrence. By default, this option is selected. ■ **Dry-run**: runs the task based on the specified recurrence. However, the scheduling system does not run the task but returns a success response. ■ **Pause Scheduling**: runs the task based on the specified recurrence. However, the scheduling system does not run the task but returns a failure response. You can select this check box if you need to suspend a task and run it later.

Parameter	Description
Recurrence	The recurrence of the task. Valid values: ■ **Day**: automatically runs the task once per day. When you create a recurring task, the task is set to run at 00:00 every day by default. You can also click the  icon to specify a time for the task to be run as needed. ■ **Week**: automatically runs the task at a specified time point on specified days of each week. On the other days, the scheduling system still generates an instance every day to ensure the proper running of downstream instances. However, the system does not actually run the instance or consume resources but directly returns a success response. Assume that you set Recurrence to Week and specify that the task is run every Monday and Tuesday. The scheduling system generates and runs instances every Monday and Tuesday. Every Wednesday, Thursday, Friday, Saturday, and Sunday, the scheduling system generates instances and returns success responses without running the instances. ■ **Month**: automatically runs the task at a specified time point on specified days of each month. On the other days, the scheduling system still generates an instance every day to ensure the proper running of downstream instances. However, the system does not actually run the instance or consume resources but directly returns a success response. Assume that you set Recurrence to Month and specify that the task is run on the seventh day of each month. The scheduling system generates and runs an instance on the seventh day of each month. On the other days, the scheduling system generates instances and returns success responses without running the instances. ■ **Hour**: automatically runs the task at a specified interval during a specified time period or at specified time points every day. The scheduling system automatically generates instances for the task and runs the instances at the specified interval or time points. Assume that you set Recurrence to Hour, select Time Period, and set the Start, End, and Interval parameters to 00:00, 23:59, and 1, respectively. The scheduling system automatically generates instances for the task and runs an instance every hour. ■ **Minute**: automatically runs the task at a specified interval during a specified time period every day. Assume that you set Recurrence to Minute and set the Start, End, and Interval parameters to 00:00, 23:59, and 05, respectively. The scheduling system automatically generates instances for the task and runs an instance every 5 minutes.

Parameter	Description
Depend on Previous Instance	Specifies whether the current task is run after the previous instance of another task or of the current task is run. If you select Depend on Previous Instance, you must further select Current Task or Select Task. ■ If you select **Current Task**, the current task is run after the previous instance of the current task is run. ■ If you select **Select Task**, enter a keyword in the search box that appears to search for and select one or more tasks to depend on.

iii. Set the parameters in the **Dependency** section.

Parameter	Description
Upstream Dependency	The upstream nodes on which the current node depends. To specify an upstream node, perform the following steps: a. Click **Create Upstream Dependency**. b. In the **Create Upstream Dependency** dialog box, search for a node based on the output name. **Note** Each node output name is globally unique in Dataphin. c. Click **OK**. To remove a node from the upstream node list, click the icon in the **Actions** column.
Current Node	The output name for the current node. You can set multiple output names for a node, which can be used to configure dependencies for other nodes. To set an output name, perform the following steps: a. Click **Add**. b. In the **Add Output Task Nodes for Current Task Node** dialog box, enter an output name. Observe uniform rules when you set each output name for the current node. Set an output name in the format of `Project name. Table name`. This helps other users find this node when they configure the upstream dependency for their nodes. c. Click **OK**. You can also perform the following operations on an existing output name: ■ To delete an output name, click the icon in the **Actions** column. ■ To view the downstream nodes after the current node is submitted or published, click the icon in the **Actions** column.

7. Click **OK**.
8. Save, submit, and then publish the sync task.

i. On the configuration tab of the sync task, click the icon in the upper-right corner to save the sync task.

ii. On the configuration tab of the sync task, click the icon in the upper-right corner to submit the sync task.

iii. (Optional)Publish the sync task.

- If the current project is in Dev mode, publish the sync task to the corresponding project in Prod mode. For more information, see Publishing management.
- If the current project is in Basic mode, you do not need to publish the sync task. The task can be scheduled in the production environment after you submit it.

9.8.3.6. Run a one-time sync task

This topic describes how to run a one-time task.

Prerequisites

- One-time tasks are created. For more information, see Create a sync task.
- One-time tasks are configured. For more information, see Configure a sync task.

Context

Description on running of sync tasks:

- You do not need to run recurring tasks. Dataphin automatically runs recurring tasks based on their scheduling settings.
- One-time tasks run only after you trigger them manually.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Prod** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click **Scheduling** in the top navigation bar.
5. On the **Scheduling** page, move the pointer over the left-side navigation submenu and click the icon. The One-time Tasks section appears.
6. Run a one-time task.
   i. In the **One-Time Tasks** section, click the one-time task that you want to run.
   ii. On the page that appears, click **Run** in the upper-right corner.
   iii. In the **Run** dialog box, set the **Instance Name** and **Data Timestamp** parameters based on your business needs. The default value of **Data Timestamp** is the date of the day before.
   iv. Click **OK**.

9.8.3.7. Verify a sync task

This topic describes how to verify a sync task.

Prerequisites

Sync tasks are created and run. For more information about how to run a one-time task, see Run a one-time sync task.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Ad Hoc Query** tab in the left-side navigation pane.
5. Create a folder for storing ad hoc query tasks.
   i. In the **Ad Hoc Query** section, click the icon next to **Ad Hoc Query**.
   ii. In the **Create Folder** dialog box, enter a folder name and select a directory.
   iii. Click **OK**.
6. Create an ad hoc query task.
   i. In the **Ad Hoc Query** section, click the icon next to **Ad Hoc Query**.
   ii. In the **Create Item** dialog box, set the **Name**, **Description**, and **Select Directory** parameters.
   iii. Click **OK**. The Code Editor tab appears.
7. Write the code of the ad hoc query task on the Code Editor tab.
   i. Enter the following SQL statement on the Code Editor tab:

```
select * from Destination table name where ds='Data timestamp';
```

   ii. Click **Precompile** in the upper-right corner of the Code Editor tab to check whether the SQL statement complies with the standard.If the SQL statement does not comply with the standard, click **Beautify** in the upper-right corner. Then, Dataphin automatically adjusts the SQL statement so that it complies with the standard.
   iii. Click **Run** in the upper-right corner of the Code Editor tab to execute the SQL statement. Then, check whether the sync task is running properly based on the result returned by the ad hoc query task.

9.9. Data modeling and development

9.9.1. Data modeling and development

9.9.1.1. Overview

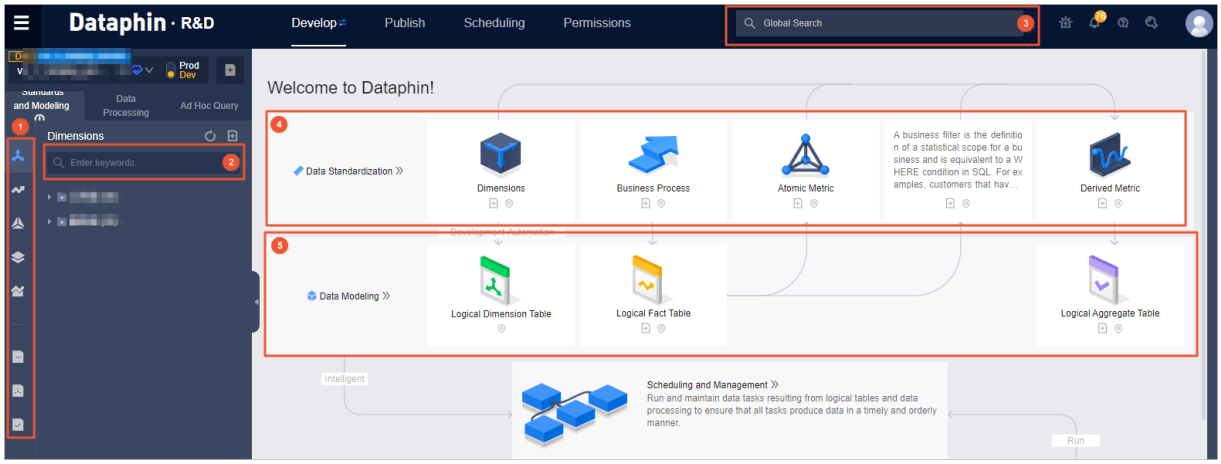
Dataphin provides the data standardization and data modeling features for building data warehouses. These features allow you to build data models in a systematic manner.

Go to the Standards and Modeling tab

To go to the **Standards and Modeling** tab, perform the following steps:

1. Log on to the Dataphin console.
2. Go to the **Standards and Modeling** tab.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.

On the **Standards and Modeling** tab, you can create data standardization objects and logical tables.



No.	Description
1	The left-side navigation submenu. Move the pointer over this submenu and click an item as needed. In the section that appears, you can create a corresponding data standardization object or logical table.
2	The local search box. Enter a keyword in the search box to search for data standardization objects or logical tables.
3	The global search box. Enter a keyword in the search box to search for objects in Dataphin. To search for a data distilling object, you must have activated the data distilling feature.
4	The **Data Standardization** section. This section displays the types of data standardization objects. Click the icon below each type to create a corresponding data standardization object.
5	The **Data Modeling** section. This section displays the types of logical tables that are supported for data modeling. Click the icon below each type to create a corresponding logical table.

Prerequisites

- External data is imported to the data sources that are configured for the current project. For more information, see Data ingestion.
- The current project is in Basic or Dev mode. After you go to the Develop page, select a project in the upper-left corner first. Dataphin allows you to use the data standardization and data modeling features for projects in Basic or Dev-Prod mode. For more information, see Create projects and Create business units.
- The current project is bound to a business unit. Otherwise, the data standardization and data modeling features are unavailable. For more information about how to bind a project to a business unit, see Create projects.
- If the current project is in Basic mode, the project is bound to a business unit in Basic mode. If the project in Basic mode is bound to a business unit in Prod mode, you cannot perform data standardization and data modeling. You can only use the data processing and ad hoc query features.
- If the current project is in Dev-Prod mode, the project mode switch is switched to Dev, so that you can create, modify, or delete objects. After you submit a created or modified object, publish the object. After the object is published, it can be automatically scheduled in the corresponding project in Prod mode.

9.9.1.2. Data standardization: Dimensions

9.9.1.2.1. Create a dimension

A dimension reflects a perspective from which you view an object. You may need to view an object from multiple aspects or at multiple levels. To this end, Dataphin allows you to define dimensions for data standardization. This topic describes how to create a dimension.

Prerequisites

Data domains are created. For more information, see Create a data domain.

Context

A dimension is a statistical object. It is an entity that exists, for example, the time, region, and product dimensions. By creating dimensions, you can standardize your business entities or master data during architectural design to guarantee that they are unique.

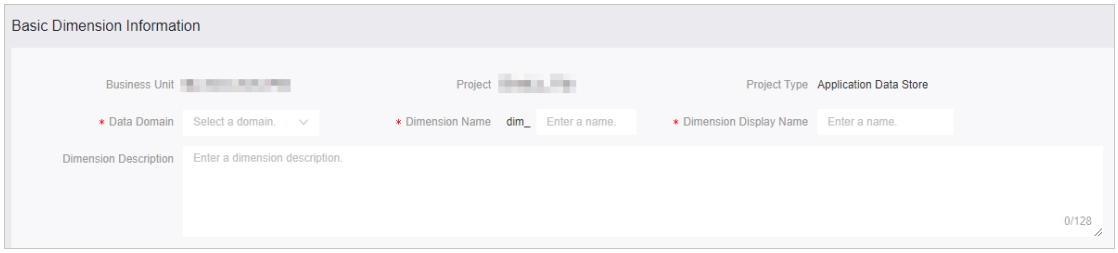
Procedure

1. Log on to the Dataphin console.
2. Go to the **Dimensions** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the Standards and Modeling tab, move the pointer over the left-side navigation submenu and click the icon. The Dimensions section appears.
3. Go to the **Create Dimension** tab by using one of the following methods:

- In the left-side navigation pane, click the icon next to the project name and choose **Data Standardization > Dimensions**.
- In the **Dimensions** section, click the icon next to **Dimensions**.
- In the right-side workspace of the Develop page, click the icon below **Dimensions**.
- In the **Dimensions** section, click **Dimensions Object List** in the lower part. The **Dimensions** tab of the **Object Explorer** tab appears. Click **Create Dimension**.

4. On the **Create Dimension** tab, set the parameters as required.

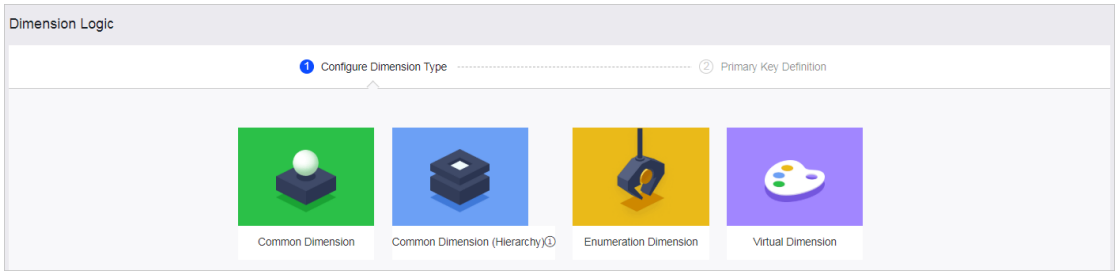
   i. Set the parameters in the **Basic Dimension Information** section.



Parameter	Description
Dimension Name	The name of the dimension. The name can contain letters, digits, and underscores (_). By default, the name starts with the dim_ prefix.
Dimension Display Name	The display name of the dimension. The display name can contain letters, digits, underscores (_), and hyphens (-).
Dimension Description	The description of the dimension to be created.
Data Domain	The data domain to which the dimension belongs. If no data domain is available, create one first.

   ii. Set the parameters in the **Dimension Logic** section.

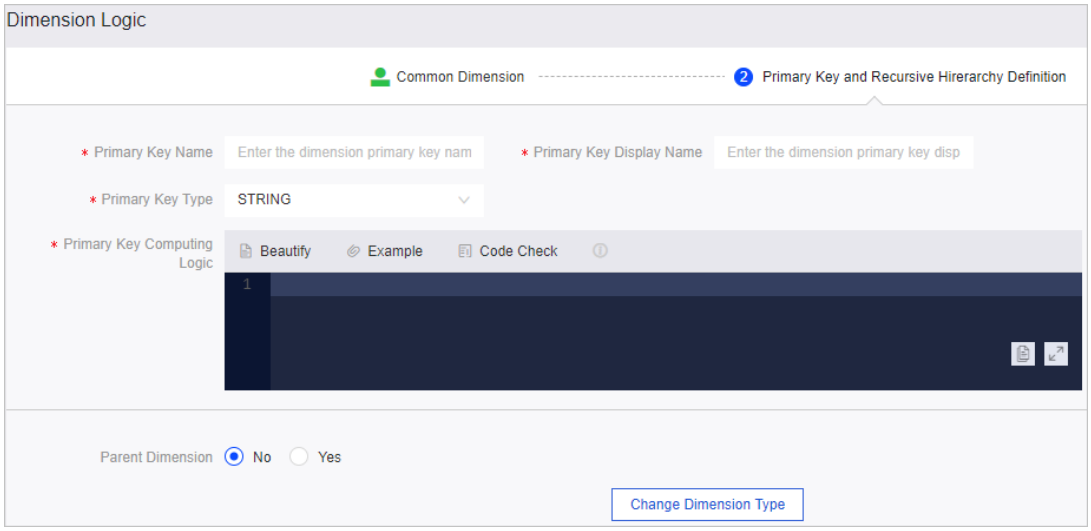
   The dimension logic defines the scope of the dimension and determines the logical characteristics of the dimension. The dimension logic ensures that the dimension is true and unique. The following table describes the four dimension types provided by Dataphin to meet different needs.



Dimension type	Description

Dimension type	Description
Common Dimension	To create a common dimension, enter the primary key information. Set the parent dimension as needed. After you create and publish a common dimension, Dataphin automatically generates a logical dimension table.
Common Dimension (Hierarchy)	To create a common dimension by hierarchy, enter the primary key information and define the dimension hierarchy and logic. You can analyze data from multiple dimensions in a stable hierarchy. After you create and publish a common dimension by hierarchy, Dataphin automatically generates a set of logical dimension tables by hierarchy.
Enumeration Dimension	To define an enumeration dimension, enter enumeration codes and values.
Virtual Dimension	To create a virtual dimension, enter the primary key information. Dataphin allows you to define virtual dimensions that have no business entities and cannot be specified by a fixed data scope in a source table. A virtual dimension can also be used in data standardization and data modeling.

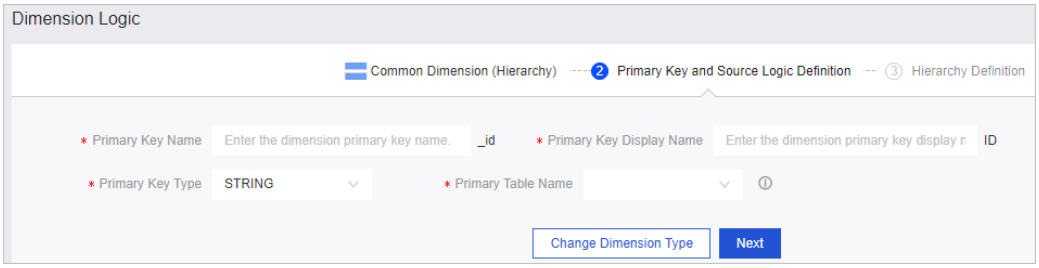
- If you select **Common Dimension**, set the parameters as described in the following table.



Parameter	Description
Primary Key Name	The name of the primary key for the dimension. The name can contain letters, digits, and underscores (_).
Primary Key Display Name	The display name of the primary key for the dimension. The display name can contain letters, digits, underscores (_), and hyphens (-).
Primary Key Type	The data type of the primary key for the dimension. Valid values: **STRING**, **BIGINT**, **DOUBLE**, **DATETIME**, and **DECIMAL**.
Primary Key Computing Logic	The computing logic of the primary key for the dimension. To prevent maintenance exceptions or data errors, configure the time-based partitioning conditions in the code. a. Click **Example** to view the description about the computing logic of the primary key for the dimension and the sample SQL statement. `select province from dataphin_test where ds='${bizdate}';` b. After you enter an SQL statement, click **Code Check** to verify whether the SQL statement you entered is valid.
Parent Dimension	The parent dimension of the dimension. Valid values: **Yes** and **No**. If you select **Yes**, select a parent dimension from the drop-down list.

- If you select **Common Dimension (Hierarchy)**, perform the following steps to set the parameters:

a. Set the parameters in the **Primary Key and Source Logic Definition** step and click **Next**.

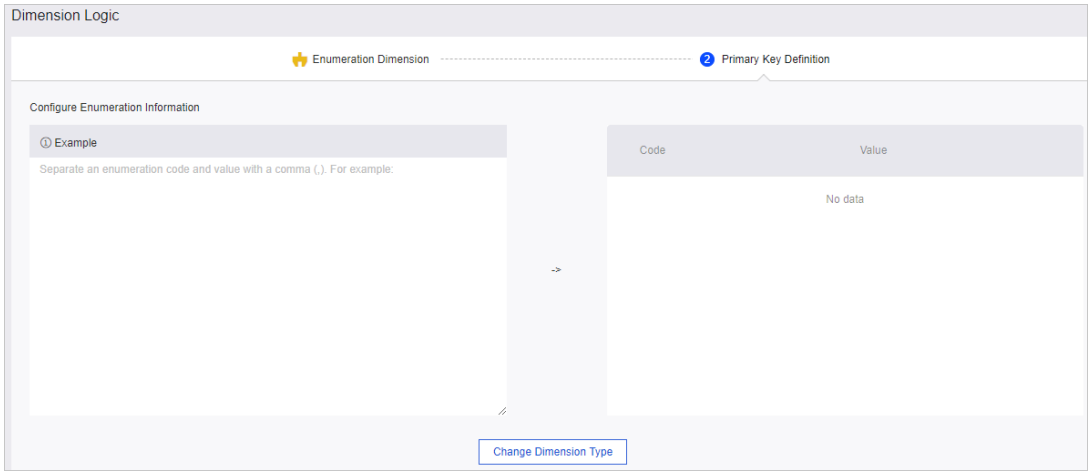


Parameter	Description
Primary Key Name	The name of the primary key for the dimension. The name can contain letters, digits, and underscores (_).
Primary Key Display Name	The display name of the primary key for the dimension. The display name can contain letters, digits, underscores (_), and hyphens (-).
Primary Key Type	The data type of the primary key for the dimension. Valid values: **STRING**, **BIGINT**, **DOUBLE**, **DATETIME**, and **DECIMAL**.
Primary Table Name	The name of the main source table for the dimension. This table is also the destination table for a sync task. **Note** We recommend that you select a table from the production environment.

b. Set the parameters in the **Hierarchy Definition** step.

Parameter	Description
Child Field	The child field in the hierarchy.
Parent Field	The parent field in the hierarchy.
Name Field	The field of the dimension name in the hierarchy.
Number of Levels	The number of levels in the hierarchy. A maximum of nine levels are supported.
Generate Leaf Dimension	Specifies whether to generate a leaf dimension. Valid values: ■ **Yes**: Dataphin automatically generates a leaf dimension. ■ **No**: Dataphin generates a leaf dimension only if you have defined the computing logic for the leaf dimension.
Root-level Dimension Definition	The judgment condition for the root-level dimension based on the field in the main source table. For example, you can enter is_parent='ture', where parent indicates the field in the main source table.
Time-based Partitioning	The judgment condition for the data timestamp and statistical period based on the field in the main source table. For example, you can enter ds=${bizdate}.

■ If you select **Enumeration Dimension**, set the parameters as instructed.



In the left-side field of the **Configure Enumeration Information** section, enter enumeration codes and values. Separate each enumeration code and its value with a comma (,).

```
F,female
M,male
```

In the right-side field, Dataphin automatically parses the enumeration codes and values that you entered in the **Code** and **Value** columns, respectively.

- If you select **Virtual Dimension**, set the parameters as described in the following table.

Parameter	Description
Primary Key Name	The name of the primary key for the dimension. The name can contain letters, digits, and underscores (_).
Primary Key Display Name	The display name of the primary key for the dimension. The display name can contain letters, digits, underscores (_), and hyphens (-).
Primary Key Type	The data type of the primary key for the dimension. Valid values: **STRING**, **BIGINT**, **DOUBLE**, **DATETIME**, and **DECIMAL**.

> **Note** If a virtual dimension is associated with a logical dimension table or a logical fact table, you can create derived metrics based on this virtual dimension. The value of the virtual dimension used to compose the statistic granularity is extracted from the associated field.

5. After you set the parameters on the **Create Dimension** tab, click the icon in the upper-right corner to save the dimension.
6. Submit the dimension.
   i. On the **Create Dimension** tab, click the icon in the upper-right corner to submit the dimension.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
   - After you submit a common dimension, Dataphin automatically generates the corresponding logical dimension table for the dimension.
   - After you submit a common dimension by hierarchy, Dataphin generates a set of logical dimension tables by hierarchy for the dimension.
7. (Optional)Publish the dimension.
   - If the current project is in Dev mode, publish the dimension to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the dimension after you submit it.

9.9.1.2.2. View the logical dimension table of a dimension

This topic describes how to view the logical dimension table that is generated for a dimension.

Prerequisites

Dimensions are created. For more information, see Create a dimension.

Procedure

1. Log on to the Dataphin console.

2. Go to the **Dimensions** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the Standards and Modeling tab, move the pointer over the left-side navigation submenu and click the icon. The Dimensions section appears.
3. View the logical dimension table of a dimension by using one of the following methods:
   - In the **Dimensions** section, click the data domain to which the dimension for which you want to view the logical dimension table belongs and the type of the dimension. Click the dimension. On the View Attributes tab, move the pointer over the icon and select **Logical Dimension Table**.
   - In the **Dimensions** section, click **Dimensions Object List** in the lower part. The **Dimensions** tab of the **Object Explorer** tab appears. Find the dimension for which you want to view the logical dimension table and click the icon in the **Actions** column.
4. On the tab that appears, view the information about the logical dimension table of the dimension.

9.9.1.2.3. Modify a dimension

A dimension reflects a perspective from which you view an object. You may need to view an object from multiple aspects or at multiple levels. To this end, Dataphin allows you to define dimensions for data standardization. This topic describes how to modify a dimension.

Prerequisites

Dimensions are created. For more information, see Create a dimension.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Dimensions** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the Standards and Modeling tab, move the pointer over the left-side navigation submenu and click the icon. The Dimensions section appears.
3. Go to the **Change Dimension** tab by using one of the following methods:
   - In the **Dimensions** section, click the data domain to which the dimension that you want to modify belongs and the type of the dimension. Click the dimension. On the View Attributes

tab, click **Change**.

- In the **Dimensions** section, click the data domain to which the dimension that you want to modify belongs and the type of the dimension. Move the pointer over the icon next to the dimension and select **Change**.
- In the **Dimensions** section, click **Dimensions Object List** in the lower part. The **Dimensions** tab of the **Object Explorer** tab appears. Find the dimension that you want to modify and click the icon in the **Actions** column.

4. (Optional)Steal the lock of the dimension.
   - If the dimension is locked by yourself, you do not need to steal the lock.
   - If the dimension is locked by another user, click the icon in the upper-right corner of the **Change Dimension** tab to steal the lock.
5. On the **Change Dimension** tab, modify the parameters as needed. For more information, see Create a dimension.
6. After you modify the parameters on the **Change Dimension** tab, click the icon in the upper-right corner to save the dimension.
7. Submit the dimension.
   i. On the **Change Dimension** tab, click the icon in the upper-right corner to submit the dimension.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
8. (Optional)Publish the dimension.
   - If the current project is in Dev mode, publish the dimension to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the dimension after you submit it.

9.9.1.2.4. Unpublish and delete a dimension

This topic describes how to unpublish, unpublish and delete, and delete dimensions in different states.

Prerequisites

Dimensions are created. For more information, see Create a dimension.

Context

- A dimension may be in the following states:
  - After you create and save a dimension, it enters the **Draft** state.
  - After you submit a dimension, it enters the **Submitted** state.
  - After you modify and save a dimension in the **Submitted** state, it enters the **Developing** state.
  - After you unpublish a dimension in the **Submitted** state, it enters the **Draft** state.

- You can unpublish only the dimensions in the **Developing** or **Submitted** state.
- You can delete only the dimensions in the **Draft** state.
- You can unpublish and delete only the dimensions in the **Developing** or **Submitted** state.

Unpublish a dimension

> **Note** You can unpublish only a dimension for which no dependency is configured.

1. Log on to the Dataphin console.
2. Go to the **Dimensions** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the Standards and Modeling tab, move the pointer over the left-side navigation submenu and click the icon. The Dimensions section appears.
3. (Optional)Steal the lock of the dimension to be unpublished.
   - If the dimension is locked by yourself, you do not need to steal the lock.
   - If the dimension is locked by another user, click the icon in the upper-right corner of the **Change Dimension** tab to steal the lock. For more information about how to go to the **Change Dimension** tab, see Modify a dimension.
4. Open the **Tip** dialog box for unpublishing a dimension by using one of the following methods:
   - In the **Dimensions** section, click the data domain to which the dimension that you want to unpublish belongs and the type of the dimension. Click the dimension. On the View Attributes tab, move the pointer over the icon and select **Unpublish**.
   - In the **Dimensions** section, click the data domain to which the dimension that you want to unpublish belongs and the type of the dimension. Move the pointer over the icon next to the dimension and select **Unpublish**.
   - In the **Dimensions** section, click **Dimensions Object List** in the lower part. The **Dimensions** tab of the **Object Explorer** tab appears. Find the dimension that you want to unpublish and choose > **Unpublish** in the **Actions** column.
5. In the **Tip** dialog box, enter your comments.
6. Click **OK**.

Delete a dimension

1. (Optional)Steal the lock of the dimension to be deleted.
   - If the dimension is locked by yourself, you do not need to steal the lock.
   - If the dimension is locked by another user, click the icon in the upper-right corner of the

Change Dimension tab to steal the lock. For more information about how to go to the **Change Dimension** tab, see Modify a dimension.

2. Open the **Tip** dialog box for deleting a dimension by using one of the following methods:
   - In the **Dimensions** section, click the data domain to which the dimension that you want to delete belongs and the type of the dimension. Move the pointer over the icon next to the dimension and select **Delete**.
   - In the **Dimensions** section, click **Dimensions Object List** in the lower part. The **Dimensions** tab of the **Object Explorer** tab appears. Find the dimension that you want to delete and choose > **Delete** in the **Actions** column.
3. In the **Tip** dialog box, enter your comments.
4. Click **OK**.

Unpublish and delete a dimension

> **Note** You can unpublish and delete only a dimension for which no dependency is configured.

1. (Optional)Steal the lock of the dimension to be unpublished and deleted.
   - If the dimension is locked by yourself, you do not need to steal the lock.
   - If the dimension is locked by another user, click the icon in the upper-right corner of the **Change Dimension** tab to steal the lock. For more information about how to go to the **Change Dimension** tab, see Modify a dimension.
2. Open the **Tip** dialog box for unpublishing and deleting a dimension by using one of the following methods:
   - In the **Dimensions** section, click the data domain to which the dimension that you want to unpublish and delete belongs and the type of the dimension. Move the pointer over the icon next to the dimension and select **Unpublish and Delete**.
   - In the **Dimensions** section, click **Dimensions Object List** in the lower part. The **Dimensions** tab of the **Object Explorer** tab appears. Find the dimension that you want to unpublish and delete and choose > **Unpublish and Delete** in the **Actions** column.
   - In the **Dimensions** section, click the data domain to which the dimension that you want to unpublish and delete belongs and the type of the dimension. Click the dimension. On the View Attributes tab, move the pointer over the icon and select **Unpublish and Delete**.
3. In the **Tip** dialog box, enter your comments.
4. Click **OK**.

9.9.1.3. Data standardization: Business processes

9.9.1.3.1. Create a business process

A business process describes the events that are necessary for specific business. For example, a business process in commerce involves placing orders, paying, and refunding. By creating a business process, you can standardize the events in specific business during architectural design and make sure that they are unique. This topic describes how to create a business process.

Prerequisites

Data domains are created. For more information, see Create a data domain.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Business Processes** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Business Processes section appears.
3. Open the **Create Business Process** dialog box by using one of the following methods:
   - In the left-side navigation pane, click the icon next to the project name and choose **Data Standardization** > **Business Processes**.
   - In the Business Processes section, click the icon next to **Business Processes**.
   - In the right-side workspace of the Develop page, click the icon below **Business Process**.
   - In the Business Processes section, click **Business Processes Object List** in the lower part. The **Business Processes** tab of the **Object Explorer** tab appears. Click **Create Business Process**.
4. In the **Create Business Process** dialog box, set the parameters as required.

Parameter	Description
Data Domain	The data domain to which the business process to be created belongs.
Name	The name of the business process. The name can contain letters, digits, and underscores (_).
Display Name	The display name of the business process. The display name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the business process.

5. Submit the business process.
   i. After you set the parameters, click **Submit**.
   ii. In the dialog box that appears, enter your comments.

iii. Click **OK**.

6. (Optional)Publish the business process.
   - If the current project is in Dev mode, publish the business process to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the business process after you submit it.

9.9.1.3.2. Modify a business process

A business process describes the events that are necessary for specific business. For example, a business process in commerce involves placing orders, paying, and refunding. This topic describes how to modify a business process.

Prerequisites

Business processes are created. For more information, see Create a business process.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Business Processes** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the  icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the  icon. The Business Processes section appears.
3. Open the **Change Business Process** dialog box by using one of the following methods:
   - In the **Business Processes** section, click the data domain to which the business process that you want to modify belongs. Click the business process. On the View Attributes tab, click **Change**.
   - In the **Business Processes** section, click the data domain to which the business process that you want to modify belongs. Move the pointer over the  icon next to the business process and select **Change**.
   - In the **Business Processes** section, click **Business Processes Object List** in the lower part. The **Business Processes** tab of the **Object Explorer** tab appears. Find the business process that you want to modify and click the  icon in the **Actions** column.
4. In the **Change Business Process** dialog box, modify the parameters as needed. For more information, see Create a business process.
5. Submit the business process.
   i. After you modify the parameters, click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.

6. (Optional)Publish the business process.
   - If the current project is in Dev mode, publish the business process to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the business process after you submit it.

9.9.1.3.3. Clone a business process

This topic describes how to clone a business process.

Prerequisites

Business processes are created. For more information, see Create a business process.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Business Processes** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Business Processes section appears.
3. Open the **Create Business Process** dialog box by using one of the following methods:
   - In the **Business Processes** section, click the data domain to which the business process that you want to clone belongs. Click the business process. On the View Attributes tab, move the pointer over the icon and select **Clone**.
   - In the **Business Processes** section, click **Business Processes Object List** in the lower part. The **Business Processes** tab of the **Object Explorer** tab appears. Find the business process that you want to clone and choose > **Clone** in the **Actions** column.
4. In the **Create Business Process** dialog box, set the parameters as required. For more information, see Create a business process.
5. Submit the business process.
   i. After you set the parameters, click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
6. (Optional)Publish the business process.
   - If the current project is in Dev mode, publish the business process to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the business process after you submit it.

9.9.1.3.4. Create a logical table

This topic describes how to create a logical fact table based on a business process.

Prerequisites

Business processes are created. For more information, see Create a business process.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Business Processes** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Business Processes section appears.
3. Open the **Create Logical Fact Table** dialog box by using one of the following methods:
   - In the **Business Processes** section, click the data domain to which the business process for which you want to create a logical fact table belongs. Click the business process. On the View Attributes tab, move the pointer over the icon and select **Create Logical Table**.
   - In the **Business Processes** section, click **Business Processes Object List** in the lower part. The **Business Processes** tab of the **Object Explorer** tab appears. Find the business process for which you want to create a logical fact table and click the icon in the **Actions** column.
4. In the **Create Logical Fact Table** dialog box, set the parameters as required. For more information, see Create a logical fact table.
5. Submit and publish the logical fact table that you create. For more information, see Create a logical fact table.

9.9.1.3.5. View logical fact tables related to a business process

This topic describes how to view logical fact tables that are related to a business process.

Prerequisites

Business processes are created. For more information, see Create a business process.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Business Processes** section.

i. On the Dataphin homepage, click **R&D** in the top navigation bar.

ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.

iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.

iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Business Processes section appears.

3. In the **Business Processes** section, click **Business Processes Object List** in the lower part.
4. On the **Business Processes** tab of the **Object Explorer** tab, find the business process for which you want to view related logical fact tables and click the icon in the **Actions** column.
5. In the **Related Logical Fact Tables** list, view the logical fact tables that are related to the business process.

9.9.1.3.6. Delete a business process

A business process describes the events that are necessary for specific business. For example, a business process in commerce involves placing orders, paying, and refunding. This topic describes how to delete a business process.

Prerequisites

Business processes are created. For more information, see Create a business process.

Context

You can delete only the business processes that have no related logical fact tables.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Business Processes** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Business Processes section appears.
3. Open the **Tip** dialog box for deleting a business process by using one of the following methods:
   - In the **Business Processes** section, click the data domain to which the business process that you want to delete belongs. Click the business process. On the View Attributes tab, move the pointer over the icon and select **Delete**.

- In the **Business Processes** section, click the data domain to which the business process that you want to delete belongs. Move the pointer over the icon next to the business process and select **Delete**.
- In the **Business Processes** section, click **Business Processes Object List** in the lower part. The **Business Processes** tab of the **Object Explorer** tab appears. Find the business process that you want to delete and choose > **Delete** in the **Actions** column.

4. In the **Tip** dialog box, enter your comments.
5. Click **OK**.

9.9.1.4. Logical tables: Logical dimension tables

9.9.1.4.1. Edit model information

One logical dimension table corresponds to one dimension. A logical dimension table stores dimension attributes that describe facts. After you submit or publish a dimension, Dataphin automatically generates a logical dimension table. For the logical dimension table, Dataphin allows you to add attributes, create a dimension association, add child dimensions, and configure a logical table conversion task.

Usage notes

You can edit a logical dimension table by creating a dimension association, adding attributes, and adding child dimensions. Note the following points when you edit model information:

- You only need to store persistent attributes of a dimension in its corresponding logical dimension table.
- You do not need to define fields for child dimensions if these fields are defined in the published parent dimension. Dataphin can automatically reference such fields.

Create a dimension association

1. Log on to the Dataphin console.
2. Go to the **Logical Dimension Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the Standards and Modeling tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Dimension Tables section appears.
3. In the **Logical Dimension Tables** section, click the logical dimension table for which you want to create a dimension association. The configuration tab of the logical dimension table appears.
4. On the configuration tab of the logical dimension table, click **Create Dimension Association** in the Central Table section.
5. In the **Create Dimension Association** dialog box, set the parameters as required.

Section	Description
Associated Dimension	The dimension to be associated with the current logical dimension table.
Edit Association Logic	The logic for associating a field in the current logical dimension table with the specified dimension. Select a field from the drop-down list under Dimension Table Field to Be Associated.
Edit Dimension Role	The role of the specified dimension. In this section, you must specify the **Role Name** and **Role Display Name** parameters.
Default Value Settings	The value of the specified field when the field cannot be associated with the specified dimension. By default, the Default Value parameter is set to -110.

6. Click **OK**.

Add attributes

1. In the **Logical Dimension Tables** section, click the logical dimension table for which you want to add attributes. The configuration tab of the logical dimension table appears.
2. On the configuration tab of the logical dimension table, click **Add Attributes** in the Central Table section.
3. In the **Create Attribute** dialog box, set the parameters as required.
   - If you set the **Source Table** parameter to **Import Fields**, perform the following steps to add fields: Click the icon next to each desired field in the **Select New Fields** section to add the field to the **Create Field** section. Then, enter a display name for the field in the **Field Display Name** column. Click **Save and Verify**.
   - If you set the **Source Table** parameter to **Customize Fields**, enter SQL statements in the code editor to define fields. You can click **Example** in the upper part of the code editor to view the sample SQL statement. Click **Code Check** to verify the syntax of the SQL statements you entered. After the SQL statements pass the verification, click **Save and Verify**.

Create a child dimension

1. In the **Logical Dimension Tables** section, click the logical dimension table for which you want to create a child dimension. The configuration tab of the logical dimension table appears.
2. On the configuration tab of the logical dimension table, click **Add Child Dimension** in the Central Table section.
3. On the **Inherit from Dimension** tab, set the parameters as required.

Section	Parameter	Description
Basic Dimension Information	**Dimension Name**	The name of the child dimension.
	Dimension Display Name	The display name of the child dimension.

Section	Parameter	Description
	Dimension Description	The description of the child dimension.
Dimension Logic	Primary Key Name	The name of the primary key of the child dimension.
	Primary Key Display Name	The display name of the primary key of the child dimension.
	Primary Key Type	The data type of the primary key of the child dimension. Click the icon and select a data type from the drop-down list.
	Primary Key Computing Logic	The primary key computing logic that you want to define for the child dimension. Perform the following steps: i. Click **Example** to view the description about the primary key computing logic and the sample SQL statement. ii. In the code editor, enter SQL statements for defining the primary key computing logic. iii. Click **Code Check** to verify the syntax of the SQL statements you entered.
	Parent Dimension	The parent dimension of the child dimension to be created. By default, the dimension that corresponds to the current logical dimension table is selected as the parent dimension. You can also click the icon and select a parent dimension from the drop-down list.

4. On the **Inherit from Dimension** tab, click the icon in the upper-right corner to save the inherited dimension.
5. Submit the inherited dimension.
   i. On the **Inherit from Dimension** tab, click the icon in the upper-right corner to submit the inherited dimension.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
6. Publish the inherited dimension.
   - If the current project is in Dev mode, publish the inherited dimension to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the inherited dimension after you submit it.

9.9.1.4.2. Edit a central table

This topic describes how to edit a central table for a logical dimension table, such as adding attributes, creating dimension associations, and defining computing logic.

Prerequisites

Dimensions are created. For more information, see Create a dimension.

Add attributes

1. Log on to the Dataphin console.
2. Go to the **Logical Dimension Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the Standards and Modeling tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Dimension Tables section appears.
3. In the **Logical Dimension Tables** section, click the logical dimension table to which you want to add attributes. The configuration tab of the logical dimension table appears.
4. (Optional)Steal the lock of the logical dimension table.
   - If the logical dimension table is locked by yourself, you do not need to steal the lock.
   - If the logical dimension table is locked by another user, click the icon in the upper-right corner to steal the lock.
5. On the configuration tab of the logical dimension table, click **Central Table Settings** in the top navigation bar.
6. On the **Central Table Settings** tab, move the pointer over **Create Field** and select **Attribute**.
7. In the **Create Attribute** dialog box, set the parameters as required. For more information, see Add attributes.
8. Save, submit, and then publish the logical dimension table.
   i. After you add attributes, click the icon in the upper-right corner of the configuration tab to save the attributes.
   ii. On the configuration tab of the logical dimension table, click the icon in the upper-right corner to submit the logical dimension table.
   iii. In the dialog box that appears, enter your comments.
   iv. Click **OK**.

v. (Optional)Publish the logical dimension table.

- If the current project is in Dev mode, publish the logical dimension table to the corresponding project in Prod mode. For more information, see Publishing management.
- If the current project is in Basic mode, you do not need to publish the logical dimension table after you submit it.

Create a dimension association

1. On the configuration tab of the logical dimension table, click **Central Table Settings** in the top navigation bar.
2. On the **Central Table Settings** tab, move the pointer over **Create Field** and select **Dimension Association**.
3. In the **Create Dimension Association** dialog box, set the parameters as required. For more information, see Create a dimension association.
4. Save, submit, and then publish the logical dimension table.
   i. After you create a dimension association, click the icon in the upper-right corner of the configuration tab to save the dimension association.
   ii. On the configuration tab of the logical dimension table, click the icon in the upper-right corner to submit the logical dimension table.
   iii. In the dialog box that appears, enter your comments.
   iv. Click **OK**.
   v. (Optional)Publish the logical dimension table.
   - If the current project is in Dev mode, publish the logical dimension table to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the logical dimension table after you submit it.

Define public computing logic

1. On the configuration tab of the logical dimension table, click **Central Table Settings** in the top navigation bar.
2. On the **Central Table Settings** tab, click **Define Public Computing Logic** next to **Create Field**.
3. In the **Define Public Computing Logic** dialog box, read the description on the right and click **Create Public Computing Logic** on the left.
4. In the dialog box that appears, enter a name for the public computing logic in the field and click **OK**. A code editor appears.
5. Perform the following steps to define the public computing logic:
   i. Click **Example** to view the description about the public computing logic and the sample SQL statement.
   ii. Enter SQL statements.

iii. Click **Code Check** to verify the SQL statements you entered.

If the SQL statements do not comply with the standard, click **Beautify** in the upper-right corner. Then, Dataphin automatically adjusts the SQL statements so that they comply with the standard.

iv. After the SQL statements pass the verification, click **Save**.

You can also perform the following steps to delete existing computing logic:

- Select the computing logic to be deleted or click **Select All** in the lower part of the Define Public Computing Logic dialog box.
- Click **Delete**.
- In the **Delete Public Computing Logic** message, click **OK**.
- Another **Delete Public Computing Logic** message appears. Click **OK**.

6. Click **Finish** in the lower-right corner of the Define Public Computing Logic dialog box.
7. Save, submit, and then publish the logical dimension table.

i. After you define the computing logic, click the icon in the upper-right corner of the configuration tab to save the computing logic.

ii. On the configuration tab of the logical dimension table, click the icon in the upper-right corner to submit the logical dimension table.

iii. In the dialog box that appears, enter your comments.

iv. Click **OK**.

v. (Optional)Publish the logical dimension table.

- If the current project is in Dev mode, publish the logical dimension table to the corresponding project in Prod mode. For more information, see Publishing management.
- If the current project is in Basic mode, you do not need to publish the logical dimension table after you submit it.

View computing logic

1. On the configuration tab of the logical dimension table, click **Central Table Settings** in the top navigation bar.
2. On the **Central Table Settings** tab, click **Group by Type** to view the primary key, attributes, associated dimensions, and system field of the logical dimension table. Click **Group by Source** to view the primary key, system field, and source logical tables of the logical dimension table.
3. On the **Group by Type** or **Group by Source** tab, find the field for which you want to view the computing logic and click the icon in the **Computing Logic (All)** column.

You can use one of the following methods to filter fields:

- Click the icon next to **Computing Logic (All)** to filter fields by computing logic status.
- Enter a keyword in the search box to search for fields.

Modify a field

> **Note** On the configuration tab of a logical dimension table, you can only modify fields that are associated with dimensions.

If you need to modify the primary key, move the pointer over the icon in the **Actions** column and click **Details**. On the tab that appears, modify the parameters as needed. For more information, see Modify a dimension.

To modify fields that are associated with dimensions, perform the following steps:

1. On the configuration tab of the logical dimension table, click **Central Table Settings** in the top navigation bar.
2. On the **Central Table Settings** tab, click **Group by Type** or **Group by Source** to view fields as needed.
3. On the **Group by Type** or **Group by Source** tab, find the field that you want to modify and click the icon in the **Actions** column.
4. In the **Change Field** dialog box, modify the **Field Name**, **Field Display Name**, **Description**, and **Data Type** parameters as needed.
5. Click **OK**.
6. In the **Confirm Close** message, click **OK**.
7. Save, submit, and then publish the logical dimension table.
   i. After you modify the field, click the icon in the upper-right corner of the configuration tab to save the modified field.
   ii. On the configuration tab of the logical dimension table, click the icon in the upper-right corner to submit the logical dimension table.
   iii. In the dialog box that appears, enter your comments.
   iv. Click **OK**.
   v. (Optional)Publish the logical dimension table.
      - If the current project is in Dev mode, publish the logical dimension table to the corresponding project in Prod mode. For more information, see Publishing management.
      - If the current project is in Basic mode, you do not need to publish the logical dimension table after you submit it.

Delete a field

> **Note** You can delete only the fields that are associated with dimensions.

1. On the configuration tab of the logical dimension table, click **Central Table Settings** in the top navigation bar.
2. On the **Central Table Settings** tab, click **Group by Type** or **Group by Source** to view fields as needed.
3. On the **Group by Type** or **Group by Source** tab, find the field that you want to delete and click the icon in the **Actions** column.

4. In the message that appears, click **OK**.

9.9.1.4.3. Configure a logical table conversion task

To specify the retention period, partition fields, and custom parameters for a logical dimension table, you can configure a logical table conversion task for the table. This topic describes how to configure a logical table conversion task for a logical dimension table.

Prerequisites

Dimensions are created. For more information, see Create a dimension.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Logical Dimension Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Dimension Tables section appears.
3. In the **Logical Dimension Tables** section, click the logical dimension table for which you want to configure a logical table conversion task. The configuration tab of the logical dimension table appears.
4. (Optional)Steal the lock of the logical dimension table.
   - If the logical dimension table is locked by yourself, you do not need to steal the lock.
   - If the logical dimension table is locked by another user, click the icon in the upper-right corner to steal the lock.
5. On the configuration tab of the logical dimension table, click **Logical Table Conversion Task Settings** in the top navigation bar.
6. In the **Logical Table Conversion Task Settings** pane, set the parameters as required.

Parameter	Description
Retention (Days)	The retention period of the logical dimension table. You can enter a value in the field or select one of the following options: 7, 14, 30, and 365.
Select Partitioning Fields	The partition fields of the logical dimension table.

Parameter	Description
Custom Parameter Settings	The custom parameters to be specified for the logical dimension table.

7. Click **OK**.
8. Save, submit, and then publish the logical dimension table.
   i. On the configuration tab of the logical dimension table, click the icon in the upper-right corner to save the logical table conversion task.
   ii. On the configuration tab of the logical dimension table, click the icon in the upper-right corner to submit the logical dimension table.
   iii. In the dialog box that appears, enter your comments.
   iv. Click **OK**.
   v. (Optional)Publish the logical dimension table.
      - If the current project is in Dev mode, publish the logical dimension table to the corresponding project in Prod mode. For more information, see Publishing management.
      - If the current project is in Basic mode, you do not need to publish the logical dimension table after you submit it.

9.9.1.4.4. Configure a scheduling policy

Dataphin allows you to configure the scheduling rules and dependencies of nodes to make sure that tasks can be properly scheduled. This topic describes how to configure a scheduling policy for a logical dimension table.

Prerequisites

Dimensions are created. For more information, see Create a dimension.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Logical Dimension Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Dimension Tables section appears.
3. In the **Logical Dimension Tables** section, click the logical dimension table for which you want

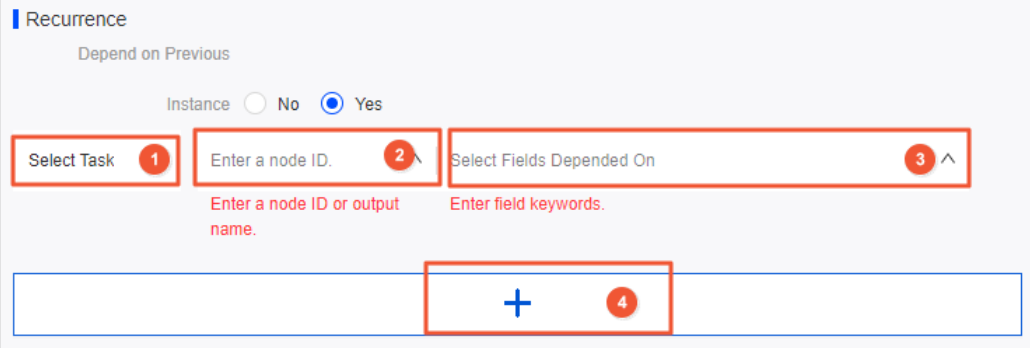
to configure a scheduling policy. The configuration tab of the logical dimension table appears.

4. (Optional)Steal the lock of the logical dimension table.
   - If the logical dimension table is locked by yourself, you do not need to steal the lock.
   - If the logical dimension table is locked by another user, click the icon in the upper-right corner to steal the lock.
5. On the configuration tab of the logical dimension table, click **Scheduling Configuration** in the top navigation bar.
6. In the **Scheduling Configuration** pane, set the parameters as required.
   i. Set the parameters in the **Basic Information** section.Dataphin automatically generates values for the **Logical Table Name**, **Task Type**, and **Description** parameters. You cannot change these values.

Parameter	Description
Description	The description of the scheduling policy.
Priority	The priority based on which the logical table task is scheduled. Valid values: ■ **Lowest Priority** ■ **Low Priority** ■ **Medium Priority** ■ **High Priority** ■ **Highest Priority**
Parameters	The specified values for the parameters that are used in the code of the task. You can click **Parameters and Descriptions** to view the rules for setting task parameters and the time parameters that are supported in the scheduling system of Dataphin.

   ii. Set the Depend on Previous Instance parameter in the **Recurrence** section.
   - If you set the **Depend on Previous Instance** parameter to **No**, the task of the logical dimension table does not depend on previous instances.
   - If you set the **Depend on Previous Instance** parameter to **Yes**, perform the following steps to configure dependencies:
     a. Click the + icon.

b. Set the parameters as required.



No.	Description
1	Select the node type. You can select **Select Task** or **Nodes of This Logical Table** from the drop-down list.
2	■ If you select **Select Task**, specify a node ID by using one of the following methods: ■ Click the icon, enter a keyword to search for the desired node ID, and then select the node ID. ■ Click Enter a node ID and select a node ID from the drop-down list. ■ If you select **Nodes of This Logical Table**, click the icon, select the fields to depend on, and then click **OK**.
3	Select the fields to depend on by using one of the following methods: ■ Click the icon, enter a keyword to search for fields, select the desired fields, and then click OK. ■ Click Select Fields Depended On, select the desired fields, and then click **OK**.
4	To add more dependencies, click the icon.

iii. Set the parameters in the **Dependency** section.

Parameter or section	Description
Automatic Parse	Specifies whether to automatically parse the dependencies of the logical table task. If you click **Parse Input and Output**, Dataphin automatically parses the task dependencies on instances of upstream nodes and the current node, and displays the dependency information in the **Upstream Dependency** and **Logical Table Node (This Node)** sections, respectively. If you click **Parse Input and Output** repeatedly, the system updates the information in the **Upstream Dependency** and **Logical Table Node (This Node)** sections.
Upstream Dependency	The upstream nodes on which the physical node of the logical dimension table depends. You can add a dependent upstream node for the logical table task by using one of the following methods: ■ Add a parsed node as a dependent upstream node. a. Click **Parse Error Information**. Source physical tables and other nodes related to the logical dimension table appear. b. Select a node and click **Confirm Association**. ■ Add a system node, for example, a zero-load node, as a dependent upstream node. a. Click **Add Upstream Dependency**. b. Select an upstream node and a source physical table. You can click the + icon to add more dependent upstream nodes. c. Click **OK**.
Logical Table Node (This Node)	The output name of the logical table task. Dataphin automatically generates the output information about the task.

7. Click **OK**.
8. Save, submit, and then publish the logical dimension table.
   i. On the configuration tab of the logical dimension table, click the icon in the upper-right corner to save the configured scheduling policy.
   ii. On the configuration tab of the logical dimension table, click the icon in the upper-right corner to submit the logical dimension table.
   iii. In the dialog box that appears, enter your comments.
   iv. Click **OK**.

v. (Optional)Publish the logical dimension table.

- If the current project is in Dev mode, publish the logical dimension table to the corresponding project in Prod mode. For more information, see Publishing management.
- If the current project is in Basic mode, you do not need to publish the logical dimension table after you submit it.

9.9.1.4.5. Unpublish and delete a logical dimension table

This topic describes how to unpublish and delete logical dimension tables in different states.

Prerequisites

Dimensions are created. For more information, see Create a dimension.

Context

A logical dimension table may be in the following states:

- After you create and save a logical dimension table, it enters the **Draft** state.
- After you submit a logical dimension table, it enters the **Submitted** state.
- After you modify and save a logical dimension table in the **Submitted** state, it enters the **Developing** state.
- After you unpublish a logical dimension table in the **Submitted** state, it enters the **Draft** state.

Limits on unpublishing and deleting logical dimension tables:

- You can unpublish only the logical dimension tables in the **Developing** or **Submitted** state.
- You can delete only the logical dimension tables in the **Draft** state.

Unpublish a logical dimension table

1. Log on to the Dataphin console.
2. Go to the **Logical Dimension Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project. You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Dimension Tables section appears.
3. In the **Logical Dimension Tables** section, move the pointer over the icon next to the logical dimension table that you want to unpublish and select **Unpublish**.
4. In the **Tip** dialog box, enter your comments.
5. Click **OK**.

Delete a logical dimension table

1. In the **Logical Dimension Tables** section, move the pointer over the icon next to the logical dimension table that you want to delete and select **Delete**.
2. In the **Tip** dialog box, enter your comments.
3. Click **OK**.

9.9.1.5. Logical tables: Logical fact tables

9.9.1.5.1. Create a logical fact table

A logical fact table describes a business process in detail. This topic describes how to create a logical fact table.

Prerequisites

Data domains are created.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Logical Fact Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Fact Tables section appears.
3. Open the **Create Logical Fact Table** dialog box by using one of the following methods:
   - In the left-side navigation pane, click the icon next to the project name and choose **Logical Tables > Logical Fact Tables**.
   - In the **Logical Fact Tables** section, click the icon next to **Logical Fact Tables**.
   - In the right-side workspace of the Develop page, click the icon below **Logical Fact Table**.
4. In the **Create Logical Fact Table** dialog box, perform the following steps:

i. Set the parameters in the **Basic Information** step.

Parameter	Description
Data Domain	The data domain to which the business process to be described by the logical fact table belongs.
Business Process	The business process to be described by the logical fact table.
Fact Table Type	The type of the logical fact table. Valid values: **Transaction Fact Table** and **Periodic Snapshot Fact Table**. ■ Transaction fact tables track and measure events that occur in business activities. For example, you can design a transaction fact table to track and measure the order payment event in order transactions. ■ Periodic snapshot fact tables measure the status of entities at regular intervals. For example, you can use a periodic snapshot fact table to track the account balance or commodity inventory.
Name	The name of the logical fact table. The value of the Name parameter is in the `fct_Business process name_Custom name_di` or `fct_Business process name_Custom name_df` format. The suffix of the name varies with the value of the Fact Table Type parameter. ■ If you set the Fact Table Type parameter to **Transaction Fact Table**, Dataphin automatically suffixes the name of the logical fact table with di. ■ If you set the Fact Table Type parameter to **Periodic Snapshot Fact Table**, Dataphin automatically suffixes the name of the logical fact table with df.
Display Name	The display name of the logical fact table. The display name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the logical fact table.
Main Source Table	The main source table of the logical fact table. You can select a physical table or a logical table as the main source table.

ii. Click **Next**.

iii. Set the parameters in the **Primary Key Definition** step.

- If you set the **Set Primary Key** parameter to **No**, you can determine whether to set the Filter Conditions parameter based on your needs.
- If you set the **Set Primary Key** parameter to **Yes**, set the required parameters as described in the following table.

Parameter	Description
Field Name	The name of the primary key field. Example: item_id
Field Display Name	The display name of the primary key field. Example: commodity_id
Field Data Type	The data type of the primary key field.
Field Computing Logic	The computing logic of the primary key field.

> **Note** If you specify a unique primary key field, for example, order_id, for a logical fact table, you must associate other fields that are added to the logical fact table with the primary key field.

iv. Click **Submit**.

5. Add measures.

i. On the configuration tab of the logical fact table, open the **Create Measure** dialog box by using one of the following methods:

- Click **Add Measure** in the **Central Table** section.
- Click **Central Table Settings** in the top navigation bar. On the Central Table Settings tab, move the pointer over **Create Field** and select **Measure**.

ii. In the **Create Measure** dialog box, set the parameters as required.

- If you set the **Source Table** parameter to **Import Fields**, perform the following steps to add fields: Click the icon next to each desired field in the **Select New Fields** section to add the field to the **Create Field** section. Then, enter a display name for the field in the **Field Display Name** column. Click **Save and Verify**.
- If you set the **Source Table** parameter to **Customize Fields**, enter SQL statements in the code editor to define fields. You can click **Example** in the upper part of the code editor to view the sample SQL statement. Click **Code Check** to verify the syntax of the SQL statements you entered. After the SQL statements pass the verification, click **Save and Verify**.

6. Add dimension associations.

i. On the configuration tab of the logical fact table, open the **Create Dimension Association** dialog box by using one of the following methods:

- Click **Create Dimension Association** in the **Central Table** section.
- Click **Central Table Settings** in the top navigation bar. On the Central Table Settings tab, move the pointer over **Create Field** and select **Dimension Association**.

ii. In the **Create Dimension Association** dialog box, set the parameters as required.

Parameter	Description
Associated Dimension	The dimension to be associated with the current logical fact table.
Edit Association Logic	The logic for associating a field in the current logical fact table with the specified dimension. Select a measure from the drop-down list under Fact Table Field to Be Associated.
Edit Dimension Role	The role of the specified dimension. ■ **Role Name**: the role name of the dimension. By default, Dataphin sets this parameter to the name of the specified dimension. ■ **Role Display Name**: the role display name of the dimension. By default, Dataphin sets this parameter to the display name of the specified dimension. You can change the values of the **Role Name** and **Role Display Name** parameters based on your business needs.
Default Value Settings	The default value that is used when the foreign key of the logical fact table cannot be associated with the specified dimension. By default, the **Default Value** parameter is set to -110.

7. Add fact attributes.
   i. On the configuration tab of the logical fact table, open the **Create Fact Attribute** dialog box by using one of the following methods:
      - Click **Add Fact Attribute** in the **Central Table** section.
      - Click **Central Table Settings** in the top navigation bar. On the Central Table Settings tab, move the pointer over **Create Field** and select **Fact Attribute**.
   ii. In the **Create Fact Attribute** dialog box, set the parameters as required.
      - If you set the **Source Table** parameter to **Import Fields**, perform the following steps to add fields: Click the icon next to each desired field in the **Select New Fields** section to add the field to the **Create Field** section. Then, enter a display name for the field in the **Field Display Name** column. Click **Save and Verify**.
      - If you set the **Source Table** parameter to **Customize Fields**, enter SQL statements in the code editor to define fields. You can click **Example** in the upper part of the code editor to view the sample SQL statement. Click **Code Check** to verify the syntax of the SQL statements you entered. After the SQL statements pass the verification, click **Save and Verify**.
8. Submit and publish the logical fact table.
   i. On the configuration tab of the logical fact table, click the **Submit** icon in the upper-right corner to submit the logical fact table.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.

iv. (Optional)Publish the logical fact table.

- If the current project is in Dev mode, publish the logical fact table to the corresponding project in Prod mode. For more information, see Publishing management.
- If the current project is in Basic mode, you do not need to publish the logical fact table after you submit it.

9.9.1.5.2. Configure a logical table conversion task

To specify the retention period, partition fields, and custom parameters for a logical fact table, you can configure a logical table conversion task for the table. This topic describes how to configure a logical table conversion task for a logical fact table.

Prerequisites

Logical fact tables are created. For more information, see Create a logical fact table.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Logical Fact Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Fact Tables section appears.
3. In the **Logical Fact Tables** section, move the pointer over the icon next to the logical fact table for which you want to configure a logical table conversion task and select **Change**.
4. (Optional)Steal the lock of the logical fact table.
   - If the logical fact table is locked by yourself, you do not need to steal the lock.
   - If the logical fact table is locked by another user, click the icon in the upper-right corner to steal the lock.
5. On the configuration tab of the logical fact table, click **Logical Table Conversion Task Settings** in the top navigation bar.
6. In the **Logical Table Conversion Task Settings** pane, set the parameters as required.

Parameter	Description
Retention (Days)	The retention period of the logical fact table. You can enter a value in the field or select one of the following options: 7, 14, 30, and 365.

Parameter	Description
Select Partitioning Fields	The partition fields of the logical fact table.
Custom Parameter Settings	The custom parameters to be specified for the logical fact table.

7. Click **OK**.
8. Save, submit, and then publish the logical fact table.
   i. On the configuration tab of the logical fact table, click the icon in the upper-right corner to save the logical table conversion task.
   ii. On the configuration tab of the logical fact table, click the icon in the upper-right corner to submit the logical fact table.
   iii. In the dialog box that appears, enter your comments.
   iv. Click **OK**.
   v. (Optional)Publish the logical fact table.
      - If the current project is in Dev mode, publish the logical fact table to the corresponding project in Prod mode. For more information, see Publishing management.
      - If the current project is in Basic mode, you do not need to publish the logical fact table after you submit it.

9.9.1.5.3. Modify a logical fact table

A logical fact table describes a business process in detail. This topic describes how to modify a logical fact table.

Prerequisites

Logical fact tables are created. For more information, see Create a logical fact table.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Logical Fact Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Fact Tables section appears.

3. In the **Logical Fact Tables** section, move the pointer over the icon next to the logical fact table that you want to modify and select **Change**.
4. (Optional)Steal the lock of the logical fact table.
   - If the logical fact table is locked by yourself, you do not need to steal the lock.
   - If the logical fact table is locked by another user, click the icon in the upper-right corner to steal the lock.
5. On the configuration tab of the logical fact table, modify settings about the central table, logical table conversion task, and scheduling policy. For more information, see Create a logical fact table, Configure a scheduling policy, and Configure a logical table conversion task.
6. Save, submit, and then publish the logical fact table.
   i. On the configuration tab of the logical fact table, click the icon in the upper-right corner to save the logical fact table.
   ii. On the configuration tab of the logical fact table, click the icon in the upper-right corner to submit the logical fact table.
   iii. In the dialog box that appears, enter your comments.
   iv. Click **OK**.
   v. (Optional)Publish the logical fact table.
      - If the current project is in Dev mode, publish the logical fact table to the corresponding project in Prod mode. For more information, see Publishing management.
      - If the current project is in Basic mode, you do not need to publish the logical fact table after you submit it.

9.9.1.5.4. Configure a scheduling policy

Dataphin allows you to configure the scheduling rules and dependencies of nodes to make sure that tasks can be properly scheduled. This topic describes how to configure a scheduling policy for a logical fact table.

Prerequisites

Logical fact tables are created. For more information, see Create a logical fact table.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Logical Fact Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.

iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.

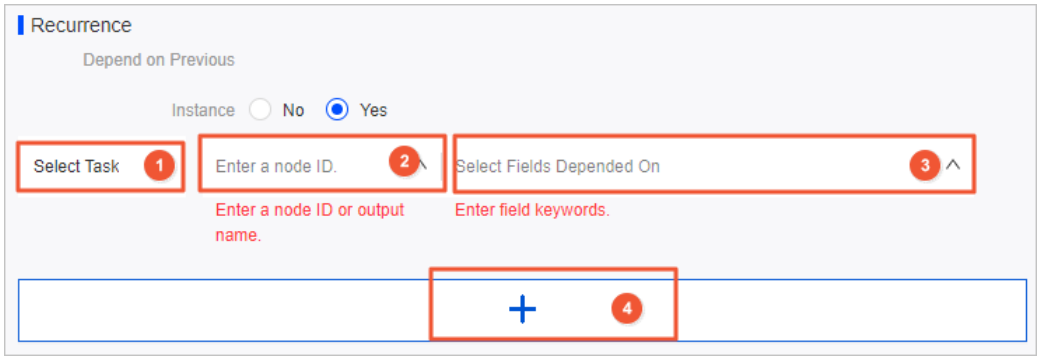
iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Fact Tables section appears.

3. In the **Logical Fact Tables** section, click the logical fact table for which you want to configure a scheduling policy. The configuration tab of the logical fact table appears.
4. (Optional)Steal the lock of the logical fact table.
   - If the logical fact table is locked by yourself, you do not need to steal the lock.
   - If the logical fact table is locked by another user, click the icon in the upper-right corner to steal the lock.
5. On the configuration tab of the logical fact table, click **Scheduling Configuration** in the top navigation bar.
6. In the **Scheduling Configuration** pane, set the parameters as required.
   i. Set the parameters in the **Basic Information** section.Dataphin automatically generates values for the **Logical Table Name**, **Task Type**, and **Description** parameters. You cannot change these values.

Parameter	Description
Description	The description of the scheduling policy.
Priority	The priority based on which the logical table task is scheduled. Valid values: ■ **Lowest Priority** ■ **Low Priority** ■ **Medium Priority** ■ **High Priority** ■ **Highest Priority**
Parameters	The specified values for the parameters that are used in the code of the task. You can click **Parameters and Descriptions** to view the rules for setting task parameters and the time parameters that are supported in the scheduling system of Dataphin.

   ii. Set the Depend on Previous Instance parameter in the **Recurrence** section.
   - If you set the **Depend on Previous Instance** parameter to **No**, the task of the logical fact table does not depend on previous instances.

- If you set the **Depend on Previous Instance** parameter to **Yes**, perform the following steps to configure dependencies:
  a. Click the + icon.
  b. Set the parameters as required.



No.	Description
1	Select the node type. You can select **Select Task** or **Nodes of This Logical Table** from the drop-down list.
2	■ If you select **Select Task**, specify a node ID by using one of the following methods: ■ Click the icon, enter a keyword to search for the desired node ID, and then select the node ID. ■ Click Enter a node ID and select a node ID from the drop-down list. ■ If you select **Nodes of This Logical Table**, click the icon, select the fields to depend on, and then click **OK**.
3	Select the fields to depend on by using one of the following methods: ■ Click the icon, enter a keyword to search for fields, select the desired fields, and then click **OK**. ■ Click Select Fields Depended On, select the desired fields, and then click **OK**.
4	To add more dependencies, click the + icon.

iii. Set the parameters in the **Dependency** section.

Parameter or section	Description
Automatic Parse	Specifies whether to automatically parse the dependencies of the logical table task. If you click **Parse Input and Output**, Dataphin automatically parses the task dependencies on instances of upstream nodes and the current node, and displays the dependency information in the **Upstream Dependency** and **Logical Table Node (This Node)** sections, respectively. If you click **Parse Input and Output** repeatedly, the system updates the information in the **Upstream Dependency** and **Logical Table Node (This Node)** sections.
Upstream Dependency	The upstream nodes on which the physical node of the logical fact table depends. You can add a dependent upstream node for the logical table task by using one of the following methods: ■ Add a parsed node as a dependent upstream node. a. Click **Parse Error Information**. Source physical tables and other nodes related to the logical fact table appear. b. Select a node and click **Confirm Association**. ■ Add a system node, for example, a zero-load node, as a dependent upstream node. a. Click **Add Upstream Dependency**. b. Select an upstream node and a source physical table. You can click the + icon to add more dependent upstream nodes. c. Click **OK**.
Logical Table Node (This Node)	The output name of the logical table task. Dataphin automatically generates the output information about the task.

7. Click **OK**.
8. Save, submit, and then publish the logical fact table.
   i. On the configuration tab of the logical fact table, click the icon in the upper-right corner to save the configured scheduling policy.
   ii. On the configuration tab of the logical fact table, click the icon in the upper-right corner to submit the logical fact table.
   iii. In the dialog box that appears, enter your comments.
   iv. Click **OK**.

v. (Optional)Publish the logical fact table.
   - If the current project is in Dev mode, publish the logical fact table to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the logical fact table after you submit it.

9.9.1.5.5. View historical version information

This topic describes how to view historical version information about a logical fact table.

Prerequisites

Logical fact tables are created. For more information, see Create a logical fact table.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Logical Fact Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Fact Tables section appears.
3. In the **Logical Fact Tables** section, move the pointer over the icon next to the logical fact table for which you want to view historical version information and select **Change**.
4. On the configuration tab of the logical fact table, click **Versions** in the top navigation bar.
5. In the **Versions** pane, view the historical version information about the logical fact table.
6. Find a version and click **Details** in the **Actions** column.
7. On the page that appears, you can view the basic information, scheduling information, and code details about the version. You can also view the settings of the logical table conversion task in this version.

9.9.1.5.6. Unpublish and delete a logical fact table

This topic describes how to unpublish and delete logical fact tables in different states.

Prerequisites

Logical fact tables are created. For more information, see Create a logical fact table.

Context

A logical fact table may be in the following states:

- After you create and save a logical fact table, it enters the **Draft** state.
- After you submit a logical fact table, it enters the **Submitted** state.
- After you modify and save a logical fact table in the **Submitted** state, it enters the **Developing** state.
- After you unpublish a logical fact table in the **Submitted** state, it enters the **Draft** state.

Limits on unpublishing and deleting logical fact tables:

- You can unpublish only the logical fact tables in the **Developing** or **Submitted** state.
- You can delete only the logical fact tables in the **Draft** state.

Unpublish a logical fact table

1. Log on to the Dataphin console.
2. Go to the **Logical Fact Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project. You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Fact Tables section appears.
3. In the **Logical Fact Tables** section, move the pointer over the icon next to the logical fact table that you want to unpublish and select **Unpublish**.
4. In the **Tip** dialog box, enter your comments.
5. Click **OK**.

Delete a logical fact table

1. In the **Logical Fact Tables** section, move the pointer over the icon next to the logical fact table that you want to delete and select **Delete**.
2. In the **Tip** dialog box, enter your comments.
3. Click **OK**.

9.9.1.6. Data standardization: Atomic metrics

9.9.1.6.1. Create an atomic metric

An atomic metric is an abstraction of statistical criteria and specific algorithms. Dataphin introduces the concept of development automation. To define a metric, you must specify its statistical criteria, which is the computing logic. This increases development efficiency and ensures the consistency of statistical results.

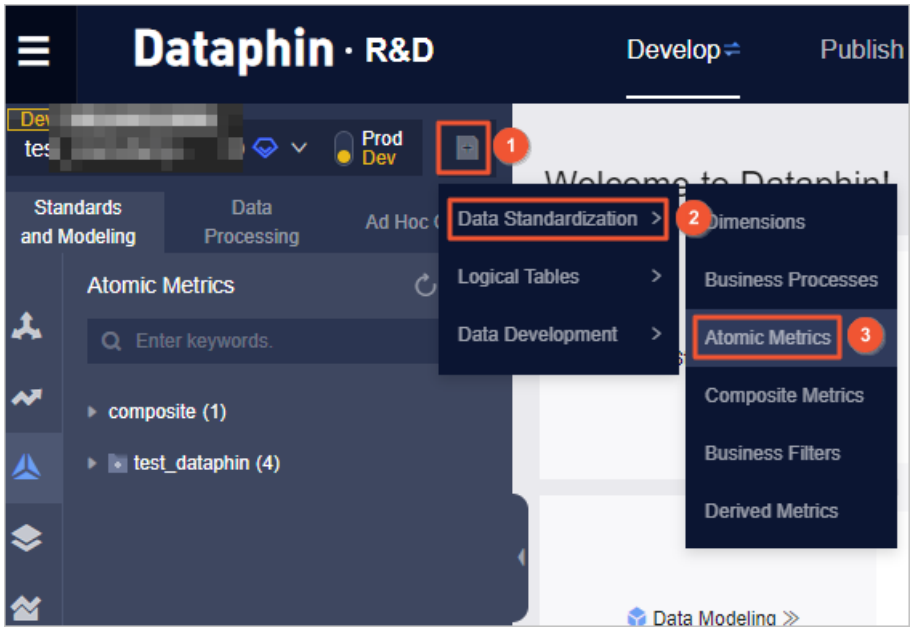
Context

Dataphin allows you to create atomic metrics and composite metrics based on different computing logic. Before you create an atomic metric or a composite metric, take note of the following descriptions:

- An atomic metric is a metric whose value is directly obtained, for example, a payment amount.
- A composite metric is a metric whose value is calculated based on submitted atomic metrics and specified computing logic. For example, you have submitted two atomic metrics. One atomic metric measures the total payment amount and the other measures the number of customers who made the payments. Then, you can create a composite metric that uses the two atomic metrics to calculate the average payment amount per customer.

Create an atomic metric

1. Log on to the Dataphin console.
2. Go to the **Atomic Metrics** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the Standards and Modeling tab, move the pointer over the left-side navigation submenu and click the icon. The Atomic Metrics section appears.
3. Go to the **Create Atomic Metric** tab by using one of the following methods:
   - In the left-side navigation pane, click the icon next to the project name and choose **Data Standardization > Atomic Metrics**.

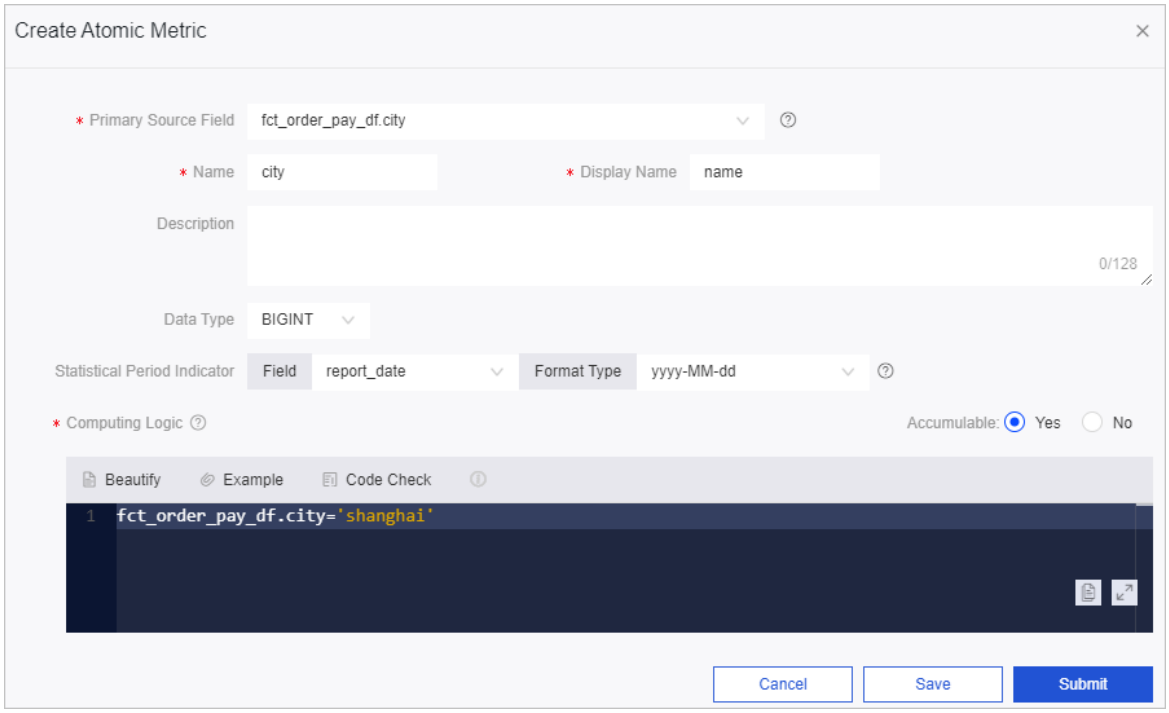


- In the Atomic Metrics section, click the icon next to **Atomic Metrics** and select **Create Atomic Metric.**
- In the right-side workspace of the Develop page, click the icon below **Atomic Metric** and select **Create Atomic Metric.**
- In the Atomic Metrics section, click **Atomic Metrics Object List** in the lower part. The **Atomic Metrics** tab of the **Object Explorer** tab appears. Click **Create Atomic Metric** in the upper-right corner and select **Atomic Metrics.**

4. On the **Create Atomic Metric** tab, select a data domain and a source table in the **Select Source Information** section.

Parameter	Description
Data Domain	The data domain of the business process to which the source table that you want to select belongs.
Source Table	The source table that contains the fields that you want to reference in the computing logic of the atomic metric. To ensure that all atomic metric models are standard, Dataphin supports only logical dimension tables and logical fact tables as the source table. **Note** After you select the source table, a list of existing atomic metrics that are defined based on the source table appears in the Atomic Metrics section.

5. In the **Atomic Metrics** section, click **Create Atomic Metric.**
6. In the **Create Atomic Metric** dialog box, set the parameters as required.



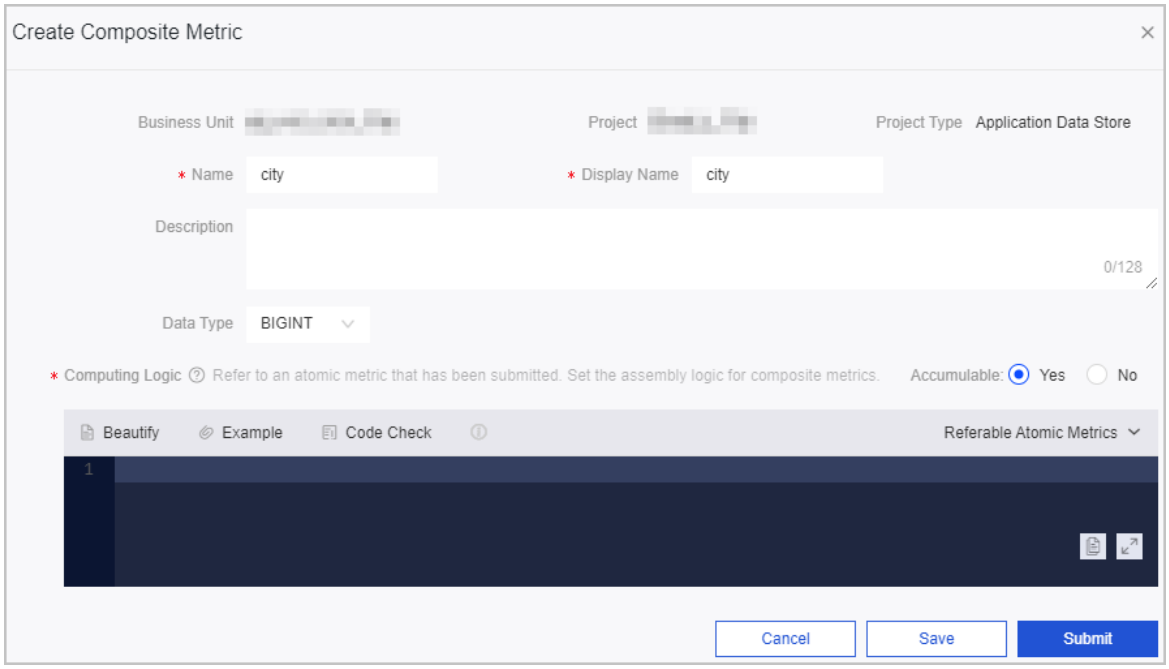
Parameter	Description
Primary Source Field	The primary source field of the atomic metric. You can select Entire Table or a field in the source table from the drop-down list.
Name	The name of the atomic metric. The name of the selected primary source field is automatically entered in the Name field. You can modify the name as needed.
Display Name	The display name of the atomic metric. The display name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the atomic metric.
Data Type	The data type of the atomic metric. Valid values: **STRING**, **BIGINT**, **DOUBLE**, **DATETIME**, and **DECIMAL**.
Field	The field to be associated with the statistical period. By default, the time-based partition field in the business unit to which the atomic metric belongs is selected.
Format Type	The format of the value of the field associated with the statistical period when the value is used in computation.

Parameter	Description
Computing Logic	The computing logic of the atomic metric. Enter an SQL statement, for example, count(distinct order_id), to define the atomic metric based on the source logical table. In the SQL statement, order_id is a field in the source table. Perform the following steps to define the computing logic: i. Click **Example** to view the description about the computing logic of atomic metrics and the sample SQL statement. ii. After you enter an SQL statement, click **Code Check** to verify the SQL statement you entered.

7. Submit and publish the atomic metric.
   i. After you set the parameters, click **Submit**.
   ii. (Optional)Publish the atomic metric.
   - If the current project is in Dev mode, publish the atomic metric to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the atomic metric. The atomic metric can be used for scheduling after you submit it.

Create a composite metric

1. Open the **Create Composite Metric** dialog box by using one of the following methods:
   - In the left-side navigation pane, click the icon next to the project name and choose **Data Standardization > Composite Metrics**.
   - In the **Atomic Metrics** section, click the icon next to Atomic Metrics and select **Create Composite Metric**.
   - In the right-side workspace of the Develop page, click the icon below **Atomic Metric** and select **Create Composite Metric**.
   - In the Atomic Metrics section, click **Atomic Metrics Object List** in the lower part. The **Atomic Metrics** tab of the **Object Explorer** tab appears. Click **Create Atomic Metric** in the upper-right corner and select **Composite**.
2. In the **Create Composite Metric** dialog box, set the parameters as required.



Parameter	Description
Name	The name of the composite metric. The name can contain letters, digits, and underscores (_).
Display Name	The display name of the composite metric. The display name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the composite metric.
Data Type	The data type of the composite metric. Valid values: **STRING**, **BIGINT**, **DOUBLE**, **DATETIME**, and **DECIMAL**.

Parameter	Description
Computing Logic	The computing logic of the composite metric. When you define the computing logic, you can use submitted atomic metrics as needed. ○ In the code editor, enter an SQL statement in the form of a formula that uses submitted atomic metrics to define the computing logic of the composite metric. ○ a. Click the icon next to **Referable Atomic Metrics** and select a data domain and a source table. b. In the atomic metric list that appears, click **Add** next to an atomic metric to reference the atomic metric in the SQL statement you entered. You can also enter a keyword in the search box next to the icon to search for atomic metrics. In the atomic metric list that appears, click **Add** next to an atomic metric to reference the atomic metric in the SQL statement you entered. For example, crt_amt and usr_cnt are two submitted atomic metrics that measure the total payment amount and the number of customers who made the payments, respectively. You can enter `crt_amt/usr_cnt` in the code editor to define a composite metric that calculates the average payment amount per customer.

3. After you set the parameters, click **Submit**.
4. (Optional)Publish the composite metric.
   - If the current project is in Dev mode, publish the composite metric to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the composite metric. The composite metric can be used for scheduling after you submit it.

9.9.1.6.2. Modify an atomic metric

An atomic metric is an abstraction of statistical criteria and specific algorithms. To define an atomic metric, you must specify its statistical criteria, which is the computing logic. This topic describes how to modify an atomic metric.

Prerequisites

Atomic metrics are created. For more information, see Create an atomic metric.

Context

After you modify the computing logic of an atomic metric, the modification applies to all the derived metrics that are created based on the atomic metric. Before you modify an atomic metric, you must consider the impact on the related derived metrics.

Procedure

1. Log on to the Dataphin console.

2. Go to the **Atomic Metrics** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the Standards and Modeling tab, move the pointer over the left-side navigation submenu and click the icon. The Atomic Metrics section appears.
3. Open the **Change Atomic Metric** dialog box by using one of the following methods:
   - In the Atomic Metrics section, move the pointer over the icon next to the atomic metric that you want to modify and select **Change**.
   - In the Atomic Metrics section, click the atomic metric that you want to modify. On the View Attributes tab, click **Change**.
   - a. In the Atomic Metrics section, click **Atomic Metrics Object List** in the lower part. The **Atomic Metrics** tab of the **Object Explorer** tab appears.
     b. Find the atomic metric that you want to modify and click the icon in the **Actions** column.
4. In the **Change Atomic Metric** dialog box, modify the parameters as needed. For more information, see Create an atomic metric.
5. After you modify the parameters, click **Submit**.
6. (Optional)Publish the atomic metric.
   - If the current project is in Dev mode, publish the atomic metric to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the atomic metric. The atomic metric can be used for scheduling after you submit it.

9.9.1.6.3. View atomic metrics that share the same source table

Dataphin allows you to create multiple atomic metrics based on the same source logical table. This topic describes how to view atomic metrics that share the same source table.

Prerequisites

Atomic metrics are created. For more information, see Create an atomic metric.

Context

Dataphin allows you to view the atomic metrics that share the same source table with a specific atomic metric.

> **Note** Composite metrics do not share the same source table with each other.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Atomic Metrics** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the Standards and Modeling tab, move the pointer over the left-side navigation submenu and click the icon. The Atomic Metrics section appears.
3. In the **Atomic Metrics** section, click the atomic metric that want to view. On the View Attributes tab, click **View Same Source**.
4. On the Same-Source Atomic Metrics tab, view the atomic metrics that share the same source table with the atomic metric.

9.9.1.6.4. Clone an atomic metric

Dataphin allows you to clone an atomic metric. This operation creates an atomic metric that shares the same source table with an existing atomic metric. This topic describes how to clone an atomic metric.

Prerequisites

Atomic metrics are created. For more information, see Create an atomic metric.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Atomic Metrics** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the Standards and Modeling tab, move the pointer over the left-side navigation submenu and click the icon. The Atomic Metrics section appears.
3. In the **Atomic Metrics** section, click the atomic metric that you want to clone. On the View Attributes tab, move the pointer over the icon and select **Clone**.
4. In the **Clone Atomic Metric** dialog box, set the parameters as required. For more information,

see Create an atomic metric.

5. Click **Submit**.
6. In the dialog box that appears, enter your comments.
7. Click **OK**.
8. (Optional)Publish the atomic metric.
   - If the current project is in Dev mode, publish the atomic metric to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the atomic metric. The atomic metric can be used for scheduling after you submit it.

9.9.1.6.5. View derived metrics created based on an atomic metric

Dataphin allows you to view derived metrics that are created based on an atomic metric. This topic describes how to view derived metrics of an atomic metric.

Prerequisites

Atomic metrics are created. For more information, see Create an atomic metric.

Context

Dataphin allows you to create derived metrics based on atomic metrics in the **Submitted** and Developing states. You can view derived metrics of only the atomic metrics in the **Submitted** and Developing states.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Atomic Metrics** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the Standards and Modeling tab, move the pointer over the left-side navigation submenu and click the icon. The Atomic Metrics section appears.
3. In the **Atomic Metrics** section, click the atomic metric for which you want to view derived metrics. On the View Attributes tab, move the pointer over the icon and select **Related Derived Metrics**.
4. On the Derived Metrics tab of the **Object Explorer** tab, view all the derived metrics that are created based on the atomic metric.

9.9.1.6.6. Create a derived metric

Dataphin allows you to create a derived metric based on an atomic metric. This topic describes how to create a derived metric based on an atomic metric.

Prerequisites

Atomic metrics are created. For more information, see Create an atomic metric.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Atomic Metrics** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the Standards and Modeling tab, move the pointer over the left-side navigation submenu and click the icon. The Atomic Metrics section appears.
3. In the **Atomic Metrics** section, click the atomic metric based on which you want to create a derived metric. On the View Attributes tab, move the pointer over the icon and select **Create Derived Metric**.
4. On the **Create Derived Metric** tab, set the parameters as required. For more information, see Create a derived metric.
5. Submit the derived metric.
   i. After you set the parameters, click **Preview Derived Metric**.
   ii. Click **Submit**.
   iii. In the dialog box that appears, enter your comments.
   iv. Click **OK**.
6. (Optional)Publish the derived metric.
   - If the current project is in Dev mode, publish the derived metric to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the derived metric. The derived metric can be used for scheduling after you submit it.

9.9.1.6.7. Unpublish and delete an atomic metric

This topic describes how to unpublish, unpublish and delete, and delete atomic metrics in different states.

Prerequisites

Atomic metrics are created. For more information, see Create an atomic metric.

Context

- An atomic metric may be in the following states:
  - After you create and save an atomic metric, it enters the **Draft** state.
  - After you submit an atomic metric, it enters the **Submitted** state.
  - After you modify and save an atomic metric in the **Submitted** state, it enters the **Developing** state.
  - After you unpublish an atomic metric in the **Submitted** state, it enters the **Draft** state.
- Limits on unpublishing atomic metrics:
  - You can unpublish only the atomic metrics in the **Developing** or **Submitted** state.
  - Only the super administrator, project administrator, and developer can unpublish atomic metrics.
  - Before you unpublish an atomic metric, make sure that the atomic metric is not used by any derived metrics or other atomic metrics.
- Limits on deleting atomic metrics:
  - You can delete only the atomic metrics in the **Draft** state.
  - Only the super administrator, project administrator, and developer can delete atomic metrics.
- Limits on unpublishing and deleting atomic metrics:
  - You can unpublish and delete only the atomic metrics in the **Developing** or **Submitted** state.
  - Only the super administrator, project administrator, and developer can unpublish and delete atomic metrics.
  - Before you unpublish and delete an atomic metric, make sure that the atomic metric is not used by any derived metrics or other atomic metrics.

Delete an atomic metric

1. Log on to the Dataphin console.
2. Go to the **Atomic Metrics** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the Standards and Modeling tab, move the pointer over the left-side navigation submenu and click the icon. The Atomic Metrics section appears.
3. Open the **Tip** dialog box for deleting an atomic metric by using one of the following methods:
   - In the Atomic Metrics section, move the pointer over the icon next to the atomic metric

that you want to delete and select **Delete**.

- In the Atomic Metrics section, click the atomic metric that you want to delete. On the View Attributes tab, move the pointer over the icon and select **Delete**.
- a. In the Atomic Metrics section, click **Atomic Metrics Object List** in the lower part. The **Atomic Metrics** tab of the **Object Explorer** tab appears.
  b. Find the atomic metric that you want to delete and choose > **Delete** in the **Actions** column.

4. In the **Tip** dialog box, enter your comments.
5. Click **OK**.

Unpublish an atomic metric

1. Open the **Tip** dialog box for unpublishing an atomic metric by using one of the following methods:
   - In the Atomic Metrics section, move the pointer over the icon next to the atomic metric that you want to unpublish and select **Unpublish**.
   - In the Atomic Metrics section, click the atomic metric that you want to unpublish. On the View Attributes tab, move the pointer over the icon and select **Unpublish**.
   - a. In the Atomic Metrics section, click **Atomic Metrics Object List** in the lower part. The **Atomic Metrics** tab of the **Object Explorer** tab appears.
     b. Find the atomic metric that you want to unpublish and choose > **Unpublish** in the **Actions** column.
2. In the **Tip** dialog box, enter your comments.
3. Click **OK**.

Unpublish and delete an atomic metric

1. Open the **Tip** dialog box for unpublishing and deleting an atomic metric by using one of the following methods:
   - In the Atomic Metrics section, move the pointer over the icon next to the atomic metric that you want to unpublish and delete and select **Unpublish and Delete**.
   - In the Atomic Metrics section, click the atomic metric that you want to unpublish and delete. On the View Attributes tab, move the pointer over the icon and select **Unpublish and Delete**.
   - a. In the Atomic Metrics section, click **Atomic Metrics Object List** in the lower part. The **Atomic Metrics** tab of the **Object Explorer** tab appears.
     b. Find the atomic metric that you want to unpublish and delete and choose > **Unpublish and Delete** in the **Actions** column.
2. In the **Tip** dialog box, enter your comments.
3. Click **OK**.

9.9.1.7. Data standardization: Business filters

9.9.1.7.1. Create a business filter

A business filter is used to define the scope of business to be measured. This topic describes how to create a business filter.

Prerequisites

Data domains are created. For more information, see Create a data domain.

Context

- Dataphin allows you to create business filters based on logical dimension tables or logical fact tables.
- Business filters are used to define the conditions for derived metrics in a standardized manner, whereas atomic metrics are used to define the computing logic of derived metrics in a standardized manner.
- To make sure that derived metrics can be created in a uniform and standard manner, you must create business filters for a business unit based on the same logical table.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Business Filters** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Business Filters section appears.
3. Go to the **Create Business Filter** tab by using one of the following methods:
   - In the left-side navigation pane, click the icon next to the project name and choose **Data Standardization** > **Business Filters**.
   - In the **Business Filters** section, click the icon next to **Business Filters**.
   - In the right-side workspace of the Develop page, click the icon below **Business Filter**.
   - In the **Business Filters** section, click **Business Filters Object List** in the lower part. The **Business Filters** tab of the **Object Explorer** tab appears. Click **Create Business Filter**.
4. On the **Create Business Filter** tab, set the **Data Domain** and **Source Table** parameters in the Select Source Information section.
5. In the **Business Filter Source** section, click **Create Business Filter**.

6. In the **Create Business Filter** dialog box, set the parameters as required.

Parameter	Description
Primary Source Field	The primary source field of the business filter.
Name	The name of the business filter. The name can contain letters, digits, and underscores (_).
Display Name	The display name of the business filter. The display name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the business filter.
Computing Logic	The computing logic of the business filter. i. Click **Example** to view the description about the computing logic of business filters and the sample SQL statement. `select province from dataphin_test where ds='${bizdate}';` ii. Click **Code Check** to verify the SQL statements you entered.

7. Submit the business filter.
   i. After you set the parameters, click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
8. (Optional)Publish the business filter.
   - If the current project is in Dev mode, publish the business filter to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the business filter after you submit it.

9.9.1.7.2. Clone a business filter

This topic describes how to clone a business filter.

Prerequisites

Business filters are created. For more information, see Create a business filter.

Context

Procedure

1. Log on to the Dataphin console.
2. Go to the **Business Filters** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.

ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.

iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.

iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Business Filters section appears.

3. Open the **Clone Business Filter** dialog box by using one of the following methods:
   - In the **Business Filters** section, click the data domain to which the business filter that you want to clone belongs. Click the business filter. On the View Attributes tab, move the pointer over the icon and select **Clone**.
   - In the **Business Filters** section, click **Business Filters Object List** in the lower part. The **Business Filters** tab of the **Object Explorer** tab appears. Find the business filter that you want to clone and choose > **Clone** in the **Actions** column.
4. In the **Clone Business Filter** dialog box, set the parameters as required.
5. Submit the business filter.
   i. After you set the parameters, click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
6. (Optional)Publish the business filter.
   - If the current project is in Dev mode, publish the business filter to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the business filter after you submit it.

9.9.1.7.3. View business filters that share the same source table

Dataphin allows you to create multiple business filters based on the same source logical table. This topic describes how to view business filters that share the same source table.

view business filters that share the same source table

Prerequisites

Business filters are created. For more information, see Create a business filter.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Business Filters** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.

ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project. You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.

iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.

iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Business Filters section appears.

3. Go to the **Same-Source Business Filters** tab by using one of the following methods:
   - In the **Business Filters** section, click the data domain to which the business filter for which you want to view business filters that share the same source table belongs. Click the business filter. On the View Attributes tab, click **View Same Source**.
   - In the **Business Filters** section, click **Business Filters Object List** in the lower part. The **Business Filters** tab of the **Object Explorer** tab appears. Find the business filter for which you want to view business filters that share the same source table and click the icon in the **Actions** column.
4. On the **Same-Source Business Filters** tab, view the business filters that share the same source table with the business filter.

9.9.1.7.4. View derived metrics created based on a business filter

Dataphin allows you to view derived metrics that are created based on a business filter. This topic describes how to view derived metrics of a business filter.

Prerequisites

Business filters are created. For more information, see Create a business filter.

Context

Dataphin allows you to create derived metrics based on business filters in the **Submitted** and Developing states. You can view derived metrics of only the business filters in the **Submitted** and Developing states.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Business Filters** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.

iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.

iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Business Filters section appears.

3. Go to the **Derived Metrics** tab by using one of the following methods:
   - In the **Business Filters** section, click **Business Filters Object List** in the lower part. The **Business Filters** tab of the **Object Explorer** tab appears. Find the business filter for which you want to view derived metrics and click the icon in the **Actions** column.
   - In the **Business Filters** section, click the data domain to which the business filter for which you want to view derived metrics belongs. Click the business filter. On the View Attributes tab, move the pointer over the icon and select **Related Derived Metrics**.
4. On the **Derived Metrics** tab of the Object Explorer tab, view all the derived metrics that are created based on the business filter.

9.9.1.7.5. Modify a business filter

A business filter is used to define the scope of business to be measured. This topic describes how to modify a business filter.

Prerequisites

Business filters are created. For more information, see Create a business filter.

Context

After the computing logic of a business filter is modified, the statistical analysis logic for all the derived metrics that are created based on the business filter is also updated.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Business Filters** section.

   i. On the Dataphin homepage, click **R&D** in the top navigation bar.

   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.

   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.

   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Business Filters section appears.
3. Open the **Change Business Filter** dialog box by using one of the following methods:
   - In the **Business Filters** section, click the data domain to which the business filter that you want to modify belongs. Click the business filter. On the View Attributes tab, click **Change**.
   - In the **Business Filters** section, click the data domain to which the business filter that you

want to modify belongs. Move the pointer over the icon next to the business filter and select **Change**.

- In the **Business Filters** section, click **Business Filters Object List** in the lower part. The **Business Filters** tab of the **Object Explorer** tab appears. Find the business filter that you want to modify and click the icon in the **Actions** column.

4. In the **Change Business Filter** dialog box, modify the parameters as needed. For more information, see Create a business filter.
5. Submit the business filter.
   i. After you modify the parameters, click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
6. (Optional)Publish the business filter.
   - If the current project is in Dev mode, publish the business filter to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the business filter after you submit it.

9.9.1.7.6. Unpublish and delete a business filter

This topic describes how to unpublish, unpublish and delete, and delete business filters in different states.

Prerequisites

Business filters are created. For more information, see Create a business filter.

Context

- A business filter may be in the following states:
  - After you create and save a business filter, it enters the **Draft** state.
  - After you submit a business filter, it enters the **Submitted** state.
  - After you modify and save a business filter in the **Submitted** state, it enters the **Developing** state.
  - After you unpublish a business filter in the **Submitted** state, it enters the **Draft** state.
- Limits on unpublishing business filters:
  - You can unpublish only the business filters in the **Developing** or **Submitted** state.
  - You can unpublish only the business filters without derived metrics.
- Limits on deleting business filters: You can delete only the business filters in the **Draft** state.
- Limits on unpublishing and deleting business filters:
  - You can unpublish and delete only the business filters in the **Developing** or **Submitted** state.
  - You can unpublish and delete only the business filters without derived metrics.

Delete a business filter

1. Log on to the Dataphin console.

2. Go to the **Business Filters** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Business Filters section appears.
3. Open the **Tip** dialog box for deleting a business filter by using one of the following methods:
   - In the **Business Filters** section, click the data domain to which the business filter that you want to delete belongs. Move the pointer over the icon next to the business filter and select **Delete**.
   - In the **Business Filters** section, click the data domain to which the business filter that you want to delete belongs. Click the business filter. On the View Attributes tab, move the pointer over the icon and select **Delete**.
   - In the **Business Filters** section, click **Business Filters Object List** in the lower part. The **Business Filters** tab of the **Object Explorer** tab appears. Find the business filter that you want to delete and choose > **Delete** in the **Actions** column.
4. In the **Tip** dialog box, enter your comments.
5. Click **OK**.

Unpublish a business filter

1. Open the **Tip** dialog box for unpublishing a business filter by using one of the following methods:
   - In the **Business Filters** section, click the data domain to which the business filter that you want to unpublish belongs. Move the pointer over the icon next to the business filter and select **Unpublish**.
   - In the **Business Filters** section, click the data domain to which the business filter that you want to unpublish belongs. Click the business filter. On the View Attributes tab, move the pointer over the icon and select **Unpublish**.
   - In the **Business Filters** section, click **Business Filters Object List** in the lower part. The **Business Filters** tab of the **Object Explorer** tab appears. Find the business filter that you want to unpublish and choose > **Unpublish** in the **Actions** column.
2. In the **Tip** dialog box, enter your comments.
3. Click **OK**.

Unpublish and delete a business filter

1. Open the **Tip** dialog box for unpublishing and deleting a business filter by using one of the

following methods:

- In the **Business Filters** section, click the data domain to which the business filter that you want to unpublish and delete belongs. Move the pointer over the icon next to the business filter and select **Unpublish and Delete**.
- In the **Business Filters** section, click **Business Filters Object List** in the lower part. The **Business Filters** tab of the **Object Explorer** tab appears. Find the business filter that you want to unpublish and delete and choose > **Unpublish and Delete** in the **Actions** column.
- In the **Business Filters** section, click the data domain to which the business filter that you want to unpublish and delete belongs. Click the business filter. On the View Attributes tab, move the pointer over the icon and select **Unpublish and Delete**.

2. In the **Tip** dialog box, enter your comments.
3. Click **OK**.

9.9.1.8. Data standardization: Derived metrics

9.9.1.8.1. Create a derived metric

Derived metrics are used to define the scope of business for atomic metrics. This topic describes how to create a derived metric.

Prerequisites

Data domains are created. For more information, see Create a data domain.

Context

Dataphin allows you to create derived metrics in a standard and unambiguous manner. Note the following information about derived metrics:

- A derived metric consists of the following elements: atomic metric, business filter, statistical period, and statistic granularity.
- Dataphin allows you to create derived metrics based on logical dimension tables or logical fact tables.
- A derived metric belongs to only one source logical table in a business unit.
- An atomic metric and a derived metric may belong to logical tables in different data domains. Therefore, a derived metric may belong to multiple data domains.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Derived Metrics** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.

iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Derived Metrics section appears.

3. Go to the **Create Derived Metric** tab by using one of the following methods:
   - In the left-side navigation pane, click the icon next to the project name and choose **Data Standardization > Derived Metrics**.
   - In the **Derived Metrics** section, click the icon next to **Derived Metrics**.
   - In the right-side workspace of the Develop page, click the icon below **Derived Metric**.
   - In the **Derived Metrics** section, click **Derived Metrics Object List** in the lower part. The **Derived Metrics** tab of the **Object Explorer** tab appears. Click **Create Derived Metric**.
4. Create a derived metric.
   i. On the **Create Derived Metric** tab, select an atomic metric.
   ii. Click **Next**.
   iii. In the **Define Derived Metric** step, set the parameters as required.

Parameter	Description
Granularity	The statistic granularity of the derived metric. You can click **Add Statistic Granularity** to add statistic granularities for the derived metric. A derived metric supports at most three statistic granularities.
Statistical Period	The statistical period of the derived metric. You can click **Add Statistical Period** to add statistical periods for the derived metric. A derived metric supports at most three statistical periods.
Business Filter	The business filter of the derived metric. You can click **Add Business Filter** to add business filters for the derived metric. A derived metric supports at most three business filters.

   iv. After you set the parameters, click **Preview Derived Metric**.
5. (Optional)In the **Change Derived Metric** section, set the **Derived Metric Name** and **Derived Metric Display Name** parameters.
6. Save and submit the derived metric.
   i. Click **Save** to save the derived metric.
   ii. Click **Submit** to submit the derived metric.
   iii. In the dialog box that appears, enter your comments.
   iv. Click **OK**.
7. (Optional)Publish the derived metric.
   - If the current project is in Dev mode, publish the derived metric to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the derived metric after you submit it.

9.9.1.8.2. Modify a derived metric

Derived metrics are used to define the scope of business for atomic metrics. This topic describes how to modify a derived metric.

Prerequisites

Derived metrics are created. For more information, see Create a derived metric.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Derived Metrics** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Derived Metrics section appears.
3. Open the **Change Derived Metric** dialog box by using one of the following methods:
   - In the **Derived Metrics** section, click the data domain to which the derived metric that you want to modify belongs. Click the derived metric. On the View Attributes tab, click **Change**.
   - In the **Derived Metrics** section, click the data domain to which the derived metric that you want to modify belongs. Move the pointer over the icon next to the derived metric that you want to modify and select **Change**.
   - In the **Derived Metrics** section, click **Derived Metrics Object List** in the lower part. The **Derived Metrics** tab of the **Object Explorer** tab appears. Find the derived metric that you want to modify and click the icon in the **Actions** column.
4. In the **Change Derived Metric** dialog box, modify the parameters as needed. For more information, see Create a business filter.
5. (Optional)Save the derived metric.If you do not want to submit the modified derived metric, click **Save**.
6. Submit the derived metric.
   i. Click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
7. (Optional)Publish the derived metric.
   - If the current project is in Dev mode, publish the derived metric to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the derived metric after you submit it.

9.9.1.8.3. Unpublish and delete a derived metric

This topic describes how to unpublish, unpublish and delete, and delete derived metrics in different states.

Prerequisites

Derived metrics are created. For more information, see Create a derived metric.

Context

- A derived metric may be in the following states:
  - After you create and save a derived metric, it enters the **Draft** state.
  - After you submit a derived metric, it enters the **Submitted** state.
  - After you modify and save a derived metric in the **Submitted** state, it enters the **Developing** state.
  - After you unpublish a derived metric in the **Submitted** state, it enters the **Draft** state.
- Limits on unpublishing, deleting, and unpublishing and deleting derived metrics:
  - You can unpublish only the derived metrics in the **Developing** or **Submitted** state.
  - You can delete only the derived metrics in the **Draft** state.
  - You can unpublish and delete only the derived metrics in the **Developing** or **Submitted** state.

Delete a derived metric

1. Log on to the Dataphin console.
2. Go to the **Derived Metrics** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Derived Metrics section appears.
3. Open the **Tip** dialog box for deleting a derived metric by using one of the following methods:
   - In the **Derived Metrics** section, click the data domain to which the derived metric that you want to delete belongs. Move the pointer over the icon next to the derived metric that you want to delete and select **Delete**.
   - In the **Derived Metrics** section, click **Derived Metrics Object List** in the lower part. The **Derived Metrics** tab of the **Object Explorer** tab appears. Find the derived metric that you want to delete and click the icon in the **Actions** column.
4. In the **Tip** dialog box, enter your comments.
5. Click **OK**.

Unpublish a derived metric

1. Open the **Tip** dialog box for unpublishing a derived metric by using one of the following methods:
   - In the **Derived Metrics** section, click the data domain to which the derived metric that you want to unpublish belongs. Move the pointer over the icon next to the derived metric that you want to unpublish and select **Unpublish**.
   - In the **Derived Metrics** section, click the data domain to which the derived metric that you want to unpublish belongs. Click the derived metric. On the View Attributes tab, move the pointer over the icon and select **Unpublish**.
   - In the **Derived Metrics** section, click **Derived Metrics Object List** in the lower part. The **Derived Metrics** tab of the **Object Explorer** tab appears. Find the derived metric that you want to unpublish and click the icon in the **Actions** column.
2. In the **Tip** dialog box, enter your comments.
3. Click **OK**.

Unpublish and delete a derived metric

1. Open the **Tip** dialog box for unpublishing and deleting a derived metric by using one of the following methods:
   - In the **Derived Metrics** section, click the data domain to which the derived metric that you want to unpublish and delete belongs. Move the pointer over the icon next to the derived metric that you want to unpublish and delete and select Unpublish and Delete.
   - In the **Derived Metrics** section, click **Derived Metrics Object List** in the lower part. The **Derived Metrics** tab of the **Object Explorer** tab appears. Find the derived metric that you want to unpublish and delete and click the icon in the **Actions** column.
   - In the **Derived Metrics** section, click the data domain to which the derived metric that you want to unpublish and delete belongs. Click the derived metric. On the View Attributes tab, move the pointer over the icon and select **Unpublish and Delete**.
2. In the **Tip** dialog box, enter your comments.
3. Click **OK**.

9.9.1.8.4. View the logical aggregate table associated with a derived metric

Dataphin allows you to view the logical aggregate table that is associated with a derived metric. This topic describes how to view the logical aggregate table that is associated with a derived metric.

Prerequisites

Derived metrics are created. For more information, see Create a derived metric.

Context

Dataphin can aggregate only the derived metrics in the **Submitted** state to logical aggregate

tables. Therefore, you can view only the logical aggregate table that is associated with a derived metric in the **Submitted** state.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Derived Metrics** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Derived Metrics section appears.
3. Go to the details page of the logical aggregate table that is associated with a derived metric by using one of the following methods:
   - In the **Derived Metrics** section, click **Derived Metrics Object List** in the lower part. The **Derived Metrics** tab of the **Object Explorer** tab appears. Find the derived metric for which you want to view the associated logical aggregate table and choose > **View Aggregate Table** in the **Actions** column.
   - In the **Derived Metrics** section, click the data domain to which the derived metric for which you want to view the associated logical aggregate table belongs. Click the derived metric. On the View Attributes tab, click **View Relative Aggregate Tables**.
4. On the tab that appears, view information about the logical aggregate table that is associated with the derived metric.

9.9.1.9. Logical tables: Logical aggregate tables

9.9.1.9.1. Create a logical aggregate table

A logical aggregate table stores statistics about a statistic granularity. This topic describes how to create a logical aggregate table.

Prerequisites

- Dimensions are created. For more information, see Create a dimension.
- Derived metrics are created. For more information, see Create a derived metric.

Context

Note the following information about logical aggregate tables:

- A logical aggregate table consists of statistical metrics at a specific statistic granularity.
- All statistical metrics in a logical aggregate table have the same statistic granularity.
- If the statistic granularity of a derived metric is the same as that of a logical aggregate table, Dataphin automatically associates the derived metric with this logical aggregate table.

The statistical metrics of a logical aggregate table are categorized into the following types:

- Derived metrics that are automatically aggregated by Dataphin
- Custom metrics

Procedure

1. Log on to the Dataphin console.
2. Go to the **Logical Aggregate Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Aggregate Tables section appears.
3. Open the **Create Logical Aggregate Table** dialog box by using one of the following methods:
   - In the left-side navigation pane, click the icon next to the project name and choose **Logical Tables > Logical Aggregate Tables**.
   - In the **Logical Aggregate Tables** section, click the icon next to **Logical Aggregate Tables**.
   - In the right-side workspace of the Develop page, click the icon below **Logical Aggregate Table**.
4. In the **Create Logical Aggregate Table** dialog box, perform the following steps:
   i. In the **Primary Key Information** step, set the **Granularity** parameter.You can select one or more submitted or published dimensions as the statistic granularity.
   ii. Click **Next**.
   iii. In the **Logical Aggregate Table Description** step, enter the description of the logical aggregate table.
5. Submit the logical aggregate table.
   i. After you set the parameters in the **Create Logical Aggregate Table** dialog box, click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
6. (Optional)Publish the logical aggregate table.
   - If the current project is in Dev mode, publish the logical aggregate table to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the logical aggregate table after you submit it.

9.9.1.9.2. Modify a logical aggregate table

A logical aggregate table stores statistics about a statistic granularity. This topic describes how to modify a logical aggregate table.

Prerequisites

Logical aggregate tables are created. For more information, see Create a logical aggregate table.

Context

You can perform the following operations on a logical aggregate table:

- Add derived metrics.
- Add custom metrics.
- Modify derived metrics.
- View details of derived metrics and custom metrics.
- Move derived metrics or custom metrics to a specified category.
- Delete custom metrics.

Add a derived metric

1. Log on to the Dataphin console.
2. Go to the **Logical Aggregate Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Aggregate Tables section appears.
3. In the **Logical Aggregate Tables** section, move the pointer over the icon next to the logical aggregate table that you want to modify and select **Change**.
4. Steal the lock of the logical aggregate table.
   - If the logical aggregate table is locked by yourself, you do not need to steal the lock.
   - If the logical aggregate table is locked by another user, click the icon in the upper-right corner to steal the lock.
5. On the configuration tab of the logical aggregate table, click the **Derived Metrics** tab.
6. On the **Derived Metrics** tab, click **Create Derived Metric**.
7. Create, submit, and publish a derived metric. For more information, see Create a logical aggregate table.
8. Submit and publish the logical aggregate table.
   i. On the configuration tab of the logical aggregate table, click the icon in the upper-right corner to submit the logical aggregate table.
   ii. In the dialog box that appears, enter your comments.

iii. Click **OK**.

iv. Publish the logical aggregate table.

- If the current project is in Dev mode, publish the logical aggregate table to the corresponding project in Prod mode. For more information, see Publishing management.
- If the current project is in Basic mode, you do not need to publish the logical aggregate table after you submit it.

Modify a derived metric

1. On the **Derived Metrics** tab of the configuration tab of the logical aggregate table, find the derived metric that you want to modify and click Details in the **Actions** column. On the View Attributes tab, click **Change**.
2. In the **Change Derived Metric** dialog box, set the parameters and then submit and publish the derived metric. For more information, see Modify a derived metric.
3. Submit the logical aggregate table.
   i. On the configuration tab of the logical aggregate table, click the icon in the upper-right corner to submit the logical aggregate table.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
4. (Optional)Publish the logical aggregate table.
   - If the current project is in Dev mode, publish the logical aggregate table to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the logical aggregate table after you submit it.

View details of a derived metric

1. On the **Derived Metrics** tab of the configuration tab of the logical aggregate table, find the derived metric for which you want to view details and click **Details** in the **Actions** column.
2. On the View Attributes tab, view information about the derived metric, including the business unit and project to which it belongs and its associated atomic metrics.

Move a derived metric to a specified category

1. On the **Derived Metrics** tab of the configuration tab of the logical aggregate table, find the derived metric that you want to move and click **Category** in the **Actions** column.
2. In the **Categorize Metric** dialog box, enter a group name.
3. Click **Create** to create a group.
4. Set the Categorize To parameter to the created group and click **OK**.
5. Submit the logical aggregate table.
   i. On the configuration tab of the logical aggregate table, click the icon in the upper-right corner to submit the logical aggregate table.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.

6. (Optional)Publish the logical aggregate table.
   - If the current project is in Dev mode, publish the logical aggregate table to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the logical aggregate table after you submit it.

Add a custom metric

1. On the configuration tab of the logical aggregate table, click the **Custom Metrics** tab.
2. On the **Custom Metrics** tab, click **Create Custom Metric**.
3. In the **Create Custom Metric** dialog box, perform the following steps:
   i. In the **Primary Key Information** step, select the source physical table and set the primary key and association logic.
   ii. Click **Associate and Go to Next Step**.
   iii. In the **Logical Aggregate Table Description** step, select a field from the section on the left and click the > sign.
   iv. Click **OK**.
4. Submit the logical aggregate table.
   i. On the configuration tab of the logical aggregate table, click the icon in the upper-right corner to submit the logical aggregate table.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
5. (Optional)Publish the logical aggregate table.
   - If the current project is in Dev mode, publish the logical aggregate table to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the logical aggregate table after you submit it.

View details of a custom metric

1. On the **Custom Metrics** tab of the configuration tab of the logical aggregate table, find the custom metric for which you want to view details and click **Details** in the **Actions** column.
2. On the View Attributes tab, view information on the **Table Structure** and **Table Information** tabs.

Delete a custom metric

1. On the **Custom Metrics** tab of the configuration tab of the logical aggregate table, find the custom metric that you want to delete and click **Delete** in the **Actions** column.
2. In the message that appears, click **OK**.
3. Submit the logical aggregate table.
   i. On the configuration tab of the logical aggregate table, click the icon in the upper-right corner to submit the logical aggregate table.
   ii. In the dialog box that appears, enter your comments.

iii. Click **OK**.

4. (Optional)Publish the logical aggregate table.
   - If the current project is in Dev mode, publish the logical aggregate table to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the logical aggregate table after you submit it.

Move a custom metric to a specified category

1. On the **Custom Metrics** tab of the configuration tab of the logical aggregate table, find the custom metric that you want to move and click **Category** in the **Actions** column.
2. In the **Categorize Metric** dialog box, enter a group name.
3. Click **Create** to create a group.
4. Set the Categorize To parameter to the created group and click **OK**.
5. Submit the logical aggregate table.
   i. On the configuration tab of the logical aggregate table, click the icon in the upper-right corner to submit the logical aggregate table.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
6. (Optional)Publish the logical aggregate table.
   - If the current project is in Dev mode, publish the logical aggregate table to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the logical aggregate table after you submit it.

9.9.1.9.3. Configure a logical table conversion task

To configure the custom parameters for a logical aggregate table, you can configure a logical table conversion task for the table. This topic describes how to configure a logical table conversion task for a logical aggregate table.

Prerequisites

Logical aggregate tables are created. For more information, see Create a logical aggregate table.

Context

The default retention period of a logical aggregate table is 36,000 days. You cannot modify the retention period.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Logical Aggregate Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.

ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.

iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.

iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Aggregate Tables section appears.

3. In the **Logical Aggregate Tables** section, move the pointer over the icon next to the logical aggregate table for which you want to configure a logical table conversion task and select **Change**.
4. On the configuration tab of the logical aggregate table, click **Logical Table Conversion Task Settings** in the top navigation bar.
5. On the **Logical Table Conversion Task Settings** tab, configure the custom parameters. For more information, see Create a logical aggregate table.
6. Submit the logical aggregate table.

   i. On the configuration tab of the logical aggregate table, click the icon in the upper-right corner to save the logical aggregate table.

   ii. In the dialog box that appears, enter your comments.

   iii. Click **OK**.
7. (Optional)Publish the logical aggregate table.
   - If the current project is in Dev mode, publish the logical aggregate table to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the logical aggregate table after you submit it.

9.9.1.9.4. View details of a logical aggregate table

A logical aggregate table stores statistics about a statistic granularity. This topic describes how to view details of a logical aggregate table.

Prerequisites

Logical aggregate tables are created. For more information, see Create a logical aggregate table.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Logical Aggregate Tables** section.

   i. On the Dataphin homepage, click **R&D** in the top navigation bar.

   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.

   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.

iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Aggregate Tables section appears.

3. In the **Logical Aggregate Tables** section, move the pointer over the icon next to the logical aggregate table for which you want to view details and select **Change**.
4. On the configuration tab of the logical aggregate table, click **Table Information** in the top navigation bar.In the **Logical Aggregate Table Details** pane, you can perform the following operations:
   - View the primary key in the **Primary Key Information** section.
   - View the name, display name, and description in the **Logical Aggregate Table Description** section.
   - Click the dimension name next to **Granularity** to view the dimension information.

   Click **OK**. You can modify the description of the logical aggregate table in the **Logical Aggregate Table Description** section.
5. (Optional)Submit and publish the logical aggregate table.If you modify the description of the logical aggregate table in the **Logical Aggregate Table Description** section, submit and publish the logical aggregate table. To submit and publish a logical aggregate table, perform the following steps:
   i. On the configuration tab of the logical aggregate table, click the icon in the upper-right corner to save the logical aggregate table.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
   iv. Publish the logical aggregate table.
      - If the current project is in Dev mode, publish the logical aggregate table to the corresponding project in Prod mode. For more information, see Publishing management.
      - If the current project is in Basic mode, you do not need to publish the logical aggregate table after you submit it.

9.9.1.9.5. Delete a logical aggregate table

A logical aggregate table stores statistics about a statistic granularity. This topic describes how to delete a logical aggregate table.

Prerequisites

Logical aggregate tables are created. For more information, see Create a logical aggregate table.

Context

You can delete only the logical aggregate tables that have no derived metrics or custom metrics.

Procedure

1. Log on to the Dataphin console.

2. Go to the **Logical Aggregate Tables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.
   iii. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.
   iv. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon. The Logical Aggregate Tables section appears.
3. In the Logical Aggregate Tables section, move the pointer over the icon next to the logical aggregate table that you want to delete and click **Delete**.
4. In the **Tip** dialog box, enter your comments.
5. Click **OK**.

9.9.1.10. Standards and modeling: Modeling engine

Based on the built-in rules of the modeling engine, Dataphin verifies the logical tables during logical table creation, submission, and logical tables task scheduling, and then converts these logical tables into physical tables. Therefore, you can query these physical tables. Modeling engine is used to ensure the model quality and control of the R&D process. Standard, reliable, stable, and efficient models rely on the intelligent modeling engine service.

Query logical tables using SQL statements

Dataphin supports the query of a logical table based on the snowflake schema. The snowflake schema can query data based on [logical model. dimension-associated field. dimension-associated field.....attribute] (such as order.buyer.membership type.type). This can improve the coding efficiency of the SQL queries.

```
SELECT a.bob_cw_bob_ooo,
  a.ds_1d__t_dts,
  a.ds_cw_234444444556,
  a.dim_cc.code
FROM
  LD_retail.dws_cc a
where a.dim_cc.value is NOT NULL
```

- **Query logical fact tables or logical dimension tables**

- SQL syntax:

```
SELECT Column,
    LTable.Column,  // Logical table name.field name
    LTable.Role(relation - dimension).....Dimension_Column,  //Logical table name.role name (dim
ension-associated field name).dimension attribute name
FROM  LD.LTable  //Business unit name.logical table name
WHERE  ...
```

```
SELECT Column,
    LTable_Alias.Column,
    LTable_Alias.Role(relation - dimension).....Dimension_Column
FROM  LD.LTable  Alias
WHERE  ...
```

- SQL format:

```
SELECT a. dim_industry.in_name,
    a.dim_industry.IN_ID,
    name,
    ceo_name,
    company_id
FROM  LD_demo.dim_company.dim_industry.in_name  a
WHERE  ds = '${bizdate}'
LIMIT  100;
```

- **Query logical aggregate tables**
  - SQL syntax:

```
SELECT Column,
    LTable.Column,
    LTable.Dimension(granularity).....Dimension_Column,
FROM  LD.LTable
WHERE  ...
```

```
SELECT Column,
    Alias.Column,
    Alias.Dimension (granularity).....Dimension_Column
FROM  LD.LTable Alias
WHERE  ...
```

- SQL format:

```
SELECT customer_id,
      c.dim_customer.address_line1,
      c.dim_customer.dim_tax_rate.tx_name,
      crt_trd_comm_amt_30d_trd_valid,
      acct_cnt_td_actv_account,
      watch_sec_cnt_td_actv_watches,
      avg_crt_trd_comm_7d,
      crt_trd_acct_cnt_7d,
      crt_trd_cnt_1d,
      avg_crt_trd_comm_1d,
      crt_trd_comm_amt_1d_trd_valid,
      crt_trd_acct_cnt_1d,
      watch_sec_cnt_td_inac_watches,
      watch_sec_cnt_td,
      acct_cnt_td,
      crt_trd_cnt_7d
FROM  LD_DEMO.DWS_CUSTOMER c
WHERE ds='${bizdate}'
LIMIT 100;
```

Note

- If two dimension-associated fields referenced by dimension roles in a logical dimension table have the same name, you need to set different display names. This is to prevent conflicts with field names in an SQL statement.
- Only logical dimension tables of parent dimensions can be queried. If a dimension is a child dimension, you can only use the child dimension based on the logical dimension tables of the parent dimension, or dimension-associated fields.
- Fields contained in the logical dimension table of a child dimension are displayed in the list of logical dimension table fields of the parent dimension.
- A dimension that composes the statistic granularity of a logical aggregate table can be referenced in a similar way to associate a dimension to a logical aggregate table. You can obtain the [dimension _ primary key] data by running the *SELECT* *command. To prevent slow query of a full table, we recommend that you obtain the primary key by using the *SELECT logical table name.dimension table name.primary key* statement and obtain the attribute information by using the *SELECT logical table name.dimension table name.attribute* statement.

Verify the repetition of the computing logic

One of the core benefits of Dataphin is the unique definition, which requires that the name and computing logic are unique. When you submit a standard definition or logical tables, Dataphin will verify the name, display name, and computing logic of the object. You can only submit them when the definition or objects are unique. If duplicate computing logic exists, the system displays a message to help you avoid creating objects with the same name but different meanings or vice versa.

When you submit and publish objects, the system parses the requests based on the abstract syntax tree (AST) and verifies the repetition of computing logic (or expressions). The objects include time periods, dimensions, logical dimension table fields, logical fact tables, logical fact table fields, atomic metrics, business filters, and custom metrics of logical aggregate tables. If duplicate computing logic exists, the system displays a message to indicate that the object computing logic is repeated.

Refresh model versions in a dynamic way

Dynamic refresh can improve the efficiency of submitting and converting logical tables. It can help increase the flexibility of modifying logical tables, and reduce the computing engine resource consumption for physical table changes, historical data changes, and migration. During SQL task scheduling, the system automatically identifies and routes to the corresponding physical tables based on the latest logical table conversion to obtain the required data.

To view the version information of a logical table, you can select **Versions** on the top of the logical table tab.

9.9.2. Batch processing

9.9.2.1. Overview

Batch processing overview

Dataphin allows you to create and run batch processing tasks during the data development process and manage the functions and files that are used in these tasks.

Dataphin allows you to create batch processing tasks of the **MAX_COMPUTRE_SQL**, **MAX_COMPUTE_MR**, **SPARK_JAR_ON_MAX_COMPUTE**, **SHELL**, **PYTHON**, and **VIRTUAL** types. You can synchronize data, create destination tables, create complex data models, and process logical tables by using batch processing tasks.

The development process of a batch processing task consists of the following steps:

1. Create resources. For more information, see Create a resource.
2. Create batch processing functions. For more information, see Create a UDF.
3. Create batch processing tasks. For more information, see Create a batch processing task.

9.9.2.2. Resource management

9.9.2.2.1. Create a folder

This topic describes how to create a folder for storing resources.

Context

Folders help you categorize and manage resources.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Resource Management** section appears.
6. In the **Resource Management** section, click the icon next to **Resource Management**.
7. In the **Create Folder** dialog box, enter a folder name and select a directory.
8. Click **OK**.The following table describes the operations that you can perform on created folders.

Operation	Description
Rename a folder	To rename a folder, perform the following steps: i. In the Resource Management section, move the pointer over the icon next to the folder that you want to rename and select **Rename**. ii. In the field that appears, enter a new name. iii. Press the Enter key.
Move a folder	To move a folder, perform the following steps: i. In the Resource Management section, move the pointer over the icon next to the folder that you want to move and select **Move**. ii. In the **Move Folder** dialog box, set the **Select Directory** parameter to the destination directory. iii. Click **OK**.
Delete a folder	To delete a folder, perform the following steps: i. In the Resource Management section, move the pointer over the icon next to the folder that you want to delete. ii. Select **Delete**. **Note** You can delete only the folders that do not contain subfolders or items.

9.9.2.2.2. Create a resource

Dataphin provides the Resource Management section on the Develop page for you to store and manage files that are required during coding, such as JAR, JSON, and Python files. This topic describes how to create a resource.

Context

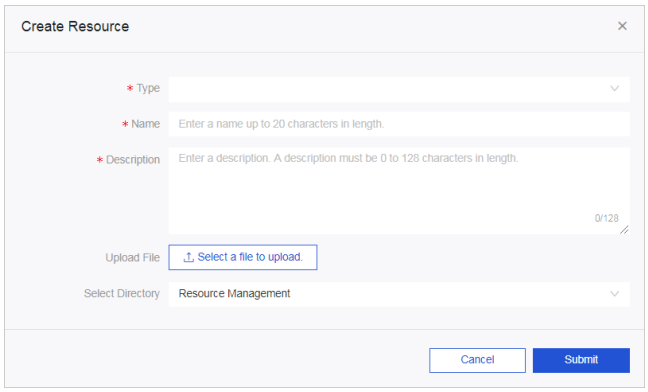
To reference files based on your business needs when you develop batch processing tasks, you can upload these files to Dataphin.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.

   > **Note** If the current project is in Dev mode, publish the resource to the corresponding project in Prod mode. Then, you can view published resources in the production environment.

4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the **Data Processing** tab, move the pointer over the left-side navigation submenu and click the icon. The **Resource Management** section appears.
6. Open the **Create Resource** dialog box by using one of the following methods:
   - In the Resource Management section, click the icon next to **Resource Management**.
   - In the left-side navigation pane, click the icon next to the project name and choose **Data Processing** > **Resources**.
   - In the right-side workspace of the **Develop** page, click the icon next to **Resources**.
7. In the **Create Resource** dialog box, set the parameters as required.



Parameter	Description

Parameter	Description
Type	The type of the file to upload. Valid values: file, jar, Python, and others. The maximum size of each file is 50 MB. You can upload up to 1,000 files. Note If the network connection is unstable, we recommend that you upload files that are not larger than 100 MB.
Name	The name of the resource to create. The name of the resource must be unique in the project.
Description	The description of the resource.
Upload File	The file to upload. Select the file to upload based on the value of the Type parameter.
Resource Usage	The usage of the resource. Valid values: Non-UDF, Batch Processing UDF, and Stream Processing UDF.
Select Directory	The directory for storing the resource. Select an existing directory.

8. Submit the resource.
   i. Click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
9. (Optional)Publish the resource.
   - If the current project is in **Dev** mode, publish the resource to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in **Basic** mode, you do not need to publish the resource after you submit it.

9.9.2.2.3. Modify a resource

To modify an uploaded file, you can modify the corresponding resource and upload the modified file to replace the original file. This topic describes how to modify a resource.

Prerequisites

Resources are created. For more information, see Create a resource.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.

5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Resource Management** section appears.
6. In the **Resource Management** section, move the pointer over the icon next to the resource that you want to modify and select **Change**.
7. In the **Change Resource** dialog box, modify the parameters as needed. You can change the value of the **Description** parameter and re-upload a file.
8. Submit the resource.
   i. Click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
9. (Optional)Publish the resource.
   - If the current project is in **Dev** mode, publish the resource to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in **Basic** mode, you do not need to publish the resource after you submit it.

9.9.2.2.4. Move a resource

This topic describes how to move a resource to another directory.

Prerequisites

Resources are created. For more information, see Create a resource.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Resource Management** section appears.
6. In the **Resource Management** section, move the pointer over the icon next to the resource that you want to move and select **Move**.
7. In the **Move File** dialog box, set the **Select Directory** parameter to the destination directory.
8. Click **OK**.

9.9.2.2.5. Delete a resource

You can delete a resource that is no longer used. This topic describes how to delete a resource.

Prerequisites

Resources are created. For more information, see Create a resource.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Resource Management** section appears.
6. In the **Resource Management** section, move the pointer over the icon next to the resource that you want to delete and select **Delete**.

   Note You cannot delete the resource if it is referenced by a task.
7. In the **Tip** dialog box, enter your comments.
8. Click **OK**.

9.9.2.3. Manage batch processing functions

9.9.2.3.1. Create a folder

This topic describes how to create a folder for storing functions.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Batch Processing Functions** section appears.
6. In the **Batch Processing Functions** section, click the icon next to **Batch Processing Functions**.
7. In the **Create Folder** dialog box, enter a folder name and select a directory.
8. Click **OK**.The following table describes the operations that you can perform on created folders.

Operation	Description
Rename a folder	To rename a folder, perform the following steps: i. In the Batch Processing Functions section, move the pointer over the icon next to the folder that you want to rename and select **Rename**. ii. In the field that appears, enter a new name. iii. Press the Enter key.
Move a folder	To move a folder, perform the following steps: i. In the Batch Processing Functions section, move the pointer over the icon next to the folder that you want to move and select **Move**. ii. In the **Move Folder** dialog box, set the **Select Directory** parameter to the destination directory. iii. Click **OK**.
Delete a folder	To delete a folder, perform the following steps: i. In the Batch Processing Functions section, move the pointer over the icon next to the folder that you want to delete. ii. Select **Delete**. **Note** You can delete only the folders that do not contain subfolders or items.

9.9.2.3.2. Create a UDF

Dataphin provides the Batch Processing Functions section on the Develop page. In this section, you can manage SQL functions to be used in batch processing tasks, including system built-in functions that are commonly used by computing engines and user-defined functions (UDFs). System built-in functions cannot be modified. This topic describes how to create a UDF.

Prerequisites

Resources are created. For more information, see Create a resource.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.

4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing Tab, move the pointer over the left-side navigation submenu and click the icon. The **Batch Processing Functions** section appears.
6. Open the **Create Function** dialog box by using one of the following methods:
   - In the Batch Processing Functions section, click the icon next to **Batch Processing Functions**.
   - In the left-side navigation pane, click the icon next to the project name and choose **Data Processing > Batch Processing Functions**.
   - In the right-side workspace of the **Develop** page, click the icon below **Batch Processing Function**.
7. In the **Create Function** dialog box, set the parameters as required.

Parameter	Description
Name	The name of the function to create. The name can contain letters, digits, and underscores (_), and must start with a letter.
Resource	The resource to be referenced by the function. You can view the resources that are available for the current project in the drop-down list. Note - You can create only functions that reference Python or JAR files. - If you select multiple resources, they must be of the same type. - If you do not have any resources, you must create one. For more information, see Create a resource.
Class	The class of the function to create. You can extract the class from the resources in the MaxCompute computing engine. Example: `test_udf.UDFGETSrcId`.
Type	The type of the function to create. Valid values: **Window**, **Statistic**, **Numeric**, **String**, **DateTime**, **ip address-related function**, **URL**, **Codec**, **Business**, and **Other**.
Function Syntax	The syntax of the function to create. The syntax of a function is the format for referencing the function. Example: `bigintweekday (datetime date)`.

Parameter	Description
Description	The description of the function to create. select get_week_date("20170810",0,2), -- Query the date of the Tuesday in t he week of August 10, 2017. from cndata.dual
Select Directory	The directory of the function to create. By default, the User-Defined Function directory is selected. You can also select another directory from the drop-down list.

8. Submit the UDF.
   i. After you set the parameters, click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**. The UDF is created and registered with MaxCompute.

   Note If the resources referenced by UDFs are updated, submit the UDFs again so that the UDFs registered with MaxCompute are updated.

   You can reference the UDF in an SQL statement and execute the statement in a task on the **Ad Hoc Query** tab to check whether the function meets your expectation. For more information, see Create an ad hoc query task. The following SQL statement is used as an example:

```
select
get_week_date("20170810",0,2), -- Query the date of the Tuesday in the week of August 10, 2017.
from cndata.dual
```

9. (Optional)Publish the UDF.
   - If the current project is in **Dev** mode, publish the UDF to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in **Basic** mode, you do not need to publish the UDF after you submit it.

9.9.2.3.3. Modify a UDF

Dataphin provides the Batch Processing Functions section on the Develop page. In this section, you can manage SQL functions to be used in batch processing tasks, including system built-in functions that are commonly used by computing engines and UDFs. System built-in functions cannot be modified. This topic describes how to modify a UDF.

Prerequisites

UDFs are created. For more information, see Create a UDF.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing Tab, move the pointer over the left-side navigation submenu and click the icon. The **Batch Processing Functions** section appears.
6. In the **Batch Processing Functions** section, move the pointer over the icon next to the UDF that you want to modify and select **Change**.
7. In the **Change Function** dialog box, modify the parameters as needed. You can change the values of the **Resource**, **Class**, **Type**, **Function Syntax**, and **Description** parameters. For more information, see Create a UDF.
8. Submit the UDF.
   i. After you modify the parameters, click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
9. (Optional)Publish the UDF.
   - If the current project is in Dev mode, publish the UDF to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the UDF. After you submit a UDF, it can be referenced in batch processing tasks that are scheduled.

9.9.2.3.4. Move a UDF

This topic describes how to move a UDF to another directory.

Prerequisites

UDFs are created. For more information, see Create a UDF.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing Tab, move the pointer over the left-side navigation submenu and click the icon. The **Batch Processing Functions** section appears.

6. In the **Batch Processing Functions** section, move the pointer over the icon next to the UDF that you want to move and select **Move**.
7. In the **Move File** dialog box, set the **Select Directory** parameter to the destination directory.
8. Click **OK**.

9.9.2.3.5. Delete a UDF

Dataphin provides the Batch Processing Functions section on the Develop page. In this section, you can manage SQL functions to be used in batch processing tasks, including system built-in functions that are commonly used by computing engines and UDFs. System built-in functions cannot be modified. This topic describes how to delete a UDF.

Prerequisites

UDFs are created. For more information, see Create a UDF.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing Tab, move the pointer over the left-side navigation submenu and click the icon. The **Batch Processing Functions** section appears.
6. In the **Batch Processing Functions** section, move the pointer over the icon next to the UDF that you want to delete and select **Delete**.

   > **Note** You cannot delete a UDF that is referenced in a task.

7. In the **Tip** dialog box, enter your comments.
8. Click **OK**.

9.9.2.4. Create a folder for storing batch processing tasks

This topic describes how to create a folder for storing batch processing tasks.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
4. On the Data Processing Tab, move the pointer over the left-side navigation submenu and click the icon. The **Batch Processing Tasks** section appears.

5. In the Batch Processing Tasks section, click the icon next to **Batch Processing Tasks**.
6. In the **Create Folder** dialog box, enter a folder name and select a directory.
7. Click **OK**.The following table describes the operations that you can perform on created folders.

Operation	Description
Rename a folder	To rename a folder, perform the following steps: i. In the Batch Processing Tasks section, move the pointer over the icon next to the folder that you want to rename and select **Rename**. ii. In the field that appears, enter a new name. iii. Press the Enter key.
Move a folder	To move a folder, perform the following steps: i. In the Batch Processing Tasks section, move the pointer over the icon next to the folder that you want to move and select **Move**. ii. In the **Move Folder** dialog box, set the **Select Directory** parameter to the destination directory. iii. Click **OK**.
Delete a folder	To delete a folder, perform the following steps: i. In the Batch Processing Tasks section, move the pointer over the icon next to the folder that you want to delete. ii. Select **Delete**. **Note** You can delete only the folders that do not contain subfolders or items.

9.9.2.5. Create batch processing tasks

9.9.2.5.1. Create a batch processing task of the MAX_COMPUTE_SQL type

This topic describes how to create a batch processing task of the MAX_COMPUTE_SQL type in Dataphin.

Context

You can create a batch processing task of the MAX_COMPUTE_SQL type based on your needs to process existing data and obtain required data.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Batch Processing Tasks** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the Data Processing Tab, move the pointer over the left-side navigation submenu and click the icon. The **Batch Processing Tasks** section appears.
3. In the Batch Processing Tasks section, click the icon next to **Batch Processing Tasks** and select **MAX_COMPUTE_SQL**. The Create Item dialog box appears.
4. Set the task parameters, write the code of the task, and then run the code.
   i. In the **Create Item** dialog box, set the parameters as required.

Parameter	Description
Name	The name of the batch processing task, for example, SQL.
Schedule Type	The scheduling type of the task. Valid values: **Recurring Node** and **One-Time Node**.
Description	The description of the task.
Select Directory	The folder for storing the task.

   ii. Click **OK**.
   iii. On the **Code Editor** tab, write the SQL code of the task.
   iv. Click **Run** in the upper-right corner to run the code.
5. (Optional)Configure the scheduling policy.
   - If you set the Schedule Type parameter to **Recurring Node**, you must configure the scheduling policy. For more information, see Configure a scheduling policy.
     - If you set the Schedule Type parameter to **One-Time Node**, you do not need to configure the scheduling policy.
6. Save and submit the task.
   i. Click the icon in the upper-right corner of the Code Editor tab to save the task.
   ii. Click the icon in the upper-right corner of the Code Editor tab to submit the task.
7. (Optional)Publish the task.
   - If the current project is in Dev mode, publish the task to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the task. The task can be

scheduled in the production environment after you submit it.

9.9.2.5.2. Create a batch processing task of the MAX_COMPUTE_MR type

This topic describes how to create a batch processing task of the MAX_COMPUTE_MR type in Dataphin.

Prerequisites

JAR packages are uploaded. For more information, see Create a resource.

Context

A batch processing task of the MAX_COMPUTE_MR type must reference JAR packages. Before you create a batch processing task of the MAX_COMPUTE_MR type, you must upload the JAR packages to be referenced by the task.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Batch Processing Tasks** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the Data Processing Tab, move the pointer over the left-side navigation submenu and click the icon. The **Batch Processing Tasks** section appears.
3. In the Batch Processing Tasks section, click the icon next to **Batch Processing Tasks** and select **MAX_COMPUTE_MR**. The Create Item dialog box appears.
4. Set the task parameters, write the code of the task, and then run the code.
   i. In the **Create Item** dialog box, set the parameters as required.

Parameter	Description
Name	The name of the batch processing task, for example, MR.
Schedule Type	The scheduling type of the task.**Valid values: Recurring Node** and **One-Time Node**.
Description	The description of the task.
Select Directory	The folder for storing the task.

   ii. Click **OK**.

iii. On the **Code Editor** tab, write the code of the task.In this example, write the following code:

```
@resource_reference{"mr_odps.jar"}
add jarmr_odps.jar as momo.jar -f;
jar -resources  momo.jar -classpath mr_odps.jar hive.WordCountOdps wc_in wc_out;
```

iv. Click **Run** in the upper-right corner to run the code.

5. (Optional)Configure the scheduling policy.
   - If you set the Schedule Type parameter to **Recurring Node**, you must configure the scheduling policy. For more information, see Configure a scheduling policy.
     - If you set the Schedule Type parameter to **One-Time Node**, you do not need to configure the scheduling policy.
6. Save and submit the task.
   i. Click the icon in the upper-right corner of the Code Editor tab to save the task.
   ii. Click the icon in the upper-right corner of the Code Editor tab to submit the task.
7. (Optional)Publish the task.
   - If the current project is in Dev mode, publish the task to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the task. The task can be scheduled in the production environment after you submit it.

9.9.2.5.3. Create a batch processing task of the SPARK_JAR_ON_MAX_COMPUTE type

This topic describes how to create a batch processing task of the SPARK_JAR_ON_MAX_COMPUTE type in Dataphin.

Prerequisites

JAR or Python packages are uploaded. For more information, see Create a resource.

Context

A batch processing task of the SPARK_JAR_ON_MAX_COMPUTE type must reference JAR or Python packages. Before you create a batch processing task of the SPARK_JAR_ON_MAX_COMPUTE type, you must upload the JAR or Python packages to be referenced by the task.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Batch Processing Tasks** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.

ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.

iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.

iv. On the left-side navigation submenu, click the icon.

3. In the **Batch Processing Tasks** section, click the icon next to Batch Processing Tasks and select **SPARK_JAR_ON_MAX_COMPUTE**.
4. Set the task parameters, write the code of the task, and then run the code.
   i. In the **Create Item** dialog box, set the task parameters.

Parameter	Description
Name	The name of the batch processing task, for example, Spark_python.
Schedule Type	The scheduling type of the task. Valid values: **Recurring Node** and **One-Time Node**.
Description	The description of the task.
Select Directory	The folder for storing the task.

   ii. Click **OK**.

   iii. On the **Code Editor** tab, write the code of the task.In this example, write the following code:

```
@resource_reference{"spark.py"}
spark-submit
--deploy-mode cluster
--conf spark.hadoop.odps.task.major.version=cupid_v2
--conf spark.hadoop.odps.end.point=http://service.cn.maxcompute.aliyun.com/api
--conf spark.hadoop.odps.runtime.end.point=http://service.cn.maxcompute.aliyun-inc.com/api
--master yarn
spark.py
```

   In the sample code, `required_resource{}` specifies the JAR or Python package to be referenced, and all the other statements are fixed.

   iv. Click **Run** in the upper-right corner to run the code.

5. (Optional)Configure the scheduling policy.
   - If you set the Schedule Type parameter to **Recurring Node**, you must configure the scheduling policy. For more information, see Configure a scheduling policy.
     - If you set the Schedule Type parameter to **One-Time Node**, you do not need to configure the scheduling policy.
6. Save and submit the task.

i. Click the icon in the upper-right corner of the Code Editor tab to save the task.

ii. Click the icon in the upper-right corner of the Code Editor tab to submit the task.

7. (Optional)Publish the task.
   - If the current project is in Dev mode, publish the task to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the task. The task can be scheduled in the production environment after you submit it.

9.9.2.5.4. Create a batch processing task of the SHELL type

This topic describes how to create a batch processing task of the SHELL type in Dataphin.

Prerequisites

JSON packages are uploaded. For more information, see Create a resource.

Context

A batch processing task of the SHELL type must reference JSON packages. Before you create a batch processing task of the SHELL type, you must upload the JSON packages to be referenced by the task.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Batch Processing Tasks** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the left-side navigation submenu, click the icon.
3. In the **Batch Processing Tasks** section, click the icon next to Batch Processing Tasks and select **SHELL**.
4. Set the task parameters, write the code of the task, and then run the code.

i. In the **Create Item** dialog box, set the task parameters.

Parameter	Description
Name	The name of the batch processing task, for example, DataX.
Schedule Type	The scheduling type of the task. In this example, select **Recurring Node**.
Description	The description of the task.
Select Directory	The folder for storing the task.

ii. Click **OK**.

iii. On the **Code Editor** tab, write the code of the task.

In this example, write the following code:

```
@required_resource{required_memory=2Gb;required_cpus=1.0}
@resource_reference{"Datax.json"}
python $DATA_HOME/bin/datax.py --jvm '-Xms2g -Xmx2g' Datax.json
```

In the sample code:

- required_resource{} specifies the computing resources to be allocated to the task.
- $DATAX_HOME is a system built-in parameter that specifies the installation directory of the sync task. The entry class of the sync task is in the bin subdirectory of the installation directory.
- `--jvm '-Xms2g -Xmx2g'` specifies the memory size of the Java virtual machine (JVM) when a sync task is running. We recommend that you set the memory size the same as the value of required_memory in required_resource.

Enter the following code for a sync task that requires a small amount of computing resources:

```
@resource_reference{"Datax.json"}
python $DATA_HOME/bin/datax.py Datax.json
```

iv. Click **Run** in the upper-right corner to run the code.

5. (Optional)Configure the scheduling policy.
   - If you set the Schedule Type parameter to **Recurring Node**, you must configure the scheduling policy. For more information, see Configure a scheduling policy.
     - If you set the Schedule Type parameter to **One-Time Node**, you do not need to configure the scheduling policy.
6. Save and submit the task.
   i. Click the icon in the upper-right corner of the Code Editor tab to save the task.
   ii. Click the icon in the upper-right corner of the Code Editor tab to submit the task.
7. (Optional)Publish the task.

- If the current project is in Dev mode, publish the task to the corresponding project in Prod mode. For more information, see Publishing management.
- If the current project is in Basic mode, you do not need to publish the task. The task can be scheduled in the production environment after you submit it.

9.9.2.5.5. Create a batch processing task of the PYTHON type

This topic describes how to create a batch processing task of the PYTHON type in Dataphin.

Prerequisites

Python packages are uploaded. For more information, see Create a resource.

Context

A batch processing task of the PYTHON type must reference Python packages. Before you create a batch processing task of the PYTHON type, you must upload the Python packages to be referenced by the task.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Batch Processing Tasks** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the left-side navigation submenu, click the icon.
3. In the **Batch Processing Tasks** section, click the icon next to Batch Processing Tasks and select **PYTHON**.
4. Set the task parameters, write the code of the task, and then run the code.
   i. In the **Create Item** dialog box, set the task parameters.

Parameter	Description
Name	The name of the batch processing task, for example, Python.
Schedule Type	The scheduling type of the task. Valid values: **Recurring Node** and **One-Time Node**.
Description	The description of the task.
Select Directory	The folder for storing the task.

   ii. Click **OK**.

iii. On the Code Editor tab, write the code of the task.

In this example, write the following code:

```
#! /usr/bin/python
# -*- coding: latin-1 -*-
import time
import datetime
import base64
import hashlib
import json
import sys
import csv
from odps import ODPS
def main():
    print "Hello World"
```

We recommend that you comment out the first two lines of the Python code. This helps avoid code execution errors when the system encoding format is used.

iv. Click **Run** in the upper-right corner to run the code.

5. (Optional)Configure the scheduling policy.
   - If you set the Schedule Type parameter to **Recurring Node**, you must configure the scheduling policy. For more information, see Configure a scheduling policy.
     - If you set the Schedule Type parameter to **One-Time Node**, you do not need to configure the scheduling policy.
6. Save and submit the task.
   i. Click the icon in the upper-right corner of the Code Editor tab to save the task.
   ii. Click the icon in the upper-right corner of the Code Editor tab to submit the task.
7. (Optional)Publish the task.
   - If the current project is in Dev mode, publish the task to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the task. The task can be scheduled in the production environment after you submit it.

9.9.2.5.6. Create a zero load node of the VIRTUAL type

When you configure the scheduling policy for a node, you can configure the node to depend on the zero load node as required. This topic describes how to create a zero load node of the VIRTUAL type in Dataphin.

Context

Before you build a data model, you can create a zero load node for the data model. After that, when you configure the scheduling policy for a node in the data model, you can configure the node to depend on the zero load node.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Batch Processing Tasks** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the left-side navigation submenu, click the icon.
3. In the **Batch Processing Tasks** section, click the icon next to Batch Processing Tasks and select **VIRTUAL**.
4. Set the task parameters, write the code of the task, and then run the code.
   i. In the **Create Item** dialog box, set the task parameters.

Parameter	Description
Name	The name of the batch processing task, for example, Virtual.
Schedule Type	The scheduling type of the task. Valid values: **Recurring Node** and **One-Time Node**.
Description	The description of the task.
Select Directory	The folder for storing the task.

   ii. Click **OK**.
   iii. On the **Code Editor** tab, write the SQL code of the task.
   iv. Click **Run** in the upper-right corner to run the code.

> **Note** Dataphin does not run the code of a zero load node. Instead, Dataphin directly sets the code execution result to successful.

5. (Optional)Configure the scheduling policy.
   - If you set the Schedule Type parameter to **Recurring Node**, you must configure the scheduling policy. For more information, see Configure a scheduling policy.
     - If you set the Schedule Type parameter to **One-Time Node**, you do not need to configure the scheduling policy.
6. Save and submit the zero load node.
   i. Click the icon in the upper-right corner of the Code Editor tab to save the task.

ii. Click the icon in the upper-right corner of the Code Editor tab to submit the task.

7. (Optional)Publish the zero load node.
   - If the current project is in Dev mode, publish the node to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the node. The node can be scheduled in the production environment after you submit it.

9.9.2.6. Configure a scheduling policy

Dataphin allows you to configure the scheduling rules and dependencies of nodes to make sure that tasks can be properly scheduled. This topic describes how to configure a scheduling policy for a batch processing task.

Prerequisites

Batch processing tasks are created. For more information, see Create a batch processing task.

Context

- Dataphin allows you to configure scheduling policies only for recurring tasks.
- A dependency is a semantic connection between two or more nodes. The status of an upstream node affects the running of its downstream nodes.
- After you configure dependencies for an upstream node and its downstream nodes, the downstream nodes can be run only after the upstream node is run. Before the system runs a node, the system checks the scheduling time that is configured for the node and determines whether to run the node.
- If a scheduling configuration is submitted before the specified scheduling time, the configuration takes effect after the specified scheduling time. If a dependency is configured after the specified scheduling time, the dependency takes effect for the instances that are generated the next day.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. Go to the **Scheduling Configuration** tab of the batch processing task for which you want to configure a scheduling policy.
   i. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   ii. On the left-side navigation submenu, click .
   iii. In the **Batch Processing Tasks** section, click the batch processing task for which you want to configure a scheduling policy. The Code Editor tab of the batch processing task appears.

iv. (Optional)Steal the lock of the batch processing task.

- If the batch processing task is locked by yourself, you do not need to steal the lock.
- If the batch processing task is locked by another user, click the icon in the upper-right corner to steal the lock.

v. Click the **Scheduling Configuration** tab.

5. In the **Scheduling Configuration** pane, set the parameters as required.

i. Set the parameters in the **Basic Information** section.Dataphin automatically generates the node name, node ID, node type, and owner. You cannot modify these parameters.

Parameter	Description
Description	The description of the scheduling policy.
Priority	The priority based on which the batch processing task is scheduled. Valid values: ■ **Lowest Priority** ■ **Low Priority** ■ **Medium Priority** ■ **High Priority** ■ **Highest Priority**
Parameters	The specified values for the parameters that are used in the code of the task. Dataphin allows you to specify the parameters that are used in the code of a task. The specified values are used when the task is run. You can click **Parameters and Descriptions** to know how to configure the parameters.

ii. Set the parameters in the **Scheduling Configuration** section.

Parameter	Description
Schedule Mode	The scheduling mode of the task. Valid values: ■ **Normal**: runs the task based on the specified recurrence. By default, this option is selected. ■ **Dry-run**: runs the task based on the specified recurrence. However, the scheduling system does not actually run the task but directly returns a success response. ■ **Pause Scheduling**: runs the task based on the specified recurrence. However, the scheduling system does not actually run the task but directly returns a failure response. You can select this check box if you need to suspend a task and run it later.

Parameter	Description
Recurrence	The recurrence of the task. Valid values: ■ **Day**: automatically runs the task once per day. When you create a recurring task, the task is set to run at 00:00 every day by default. You can also click the icon to specify a time for the task to be run as needed. ■ **Week**: automatically runs the task at a specified time point on specified days of each week. On the other days, the scheduling system still generates an instance every day to ensure the proper running of downstream instances. However, the system does not actually run the instance or consume resources but directly returns a success response. Assume that you set Recurrence to Week and specify that the task is run every Monday and Tuesday. The scheduling system generates and runs instances every Monday and Tuesday. Every Wednesday, Thursday, Friday, Saturday, and Sunday, the scheduling system generates instances and returns success responses without running the instances. ■ **Month**: automatically runs the task at a specified time point on specified days of each month. On the other days, the scheduling system still generates an instance every day to ensure the proper running of downstream instances. However, the system does not actually run the instance or consume resources but directly returns a success response. Assume that you set Recurrence to Month and specify that the task is run on the seventh day of each month. The scheduling system generates and runs an instance on the seventh day of each month. On the other days, the scheduling system generates instances and returns success responses without running the instances. ■ **Hour**: automatically runs the task at a specified interval during a specified time period or at specified time points every day. The scheduling system automatically generates instances for the task and runs the instances at the specified interval or time points. Assume that you set Recurrence to Hour, select Time Period, and set the Start, End, and Interval parameters to 00:00, 23:59, and 1, respectively. The scheduling system automatically generates instances for the task and runs an instance every hour. ■ **Minute**: automatically runs the task at a specified interval during a specified time period every day. Assume that you set Recurrence to Minute and set the Start, End, and Interval parameters to 00:00, 23:59, and 05, respectively. The scheduling system automatically generates instances for the task and runs an instance every 5 minutes.

Parameter	Description
Depend on Previous Instance	Specifies whether the current task is run after the previous instance of another task or of the current task is run. If you select Depend on Previous Instance, you must further select Current Task or Select Task. ■ If you select **Current Task**, the current task is run after the previous instance of the current task is run. ■ If you select **Select Task**, enter a keyword in the search box that appears to search for and select one or more tasks to depend on.

iii. Set the parameters in the **Dependency** section.

Parameter	Description
Start Parsing	**Start Parsing** is available for SQL tasks. After you click Start Parsing, Dataphin parses the table referenced in the code and finds the output name that is the same as the table name. Dataphin automatically configures the node corresponding to this output name as the upstream node on which the current node depends. If the project referenced in the code is a variable or no project is specified in the code, Dataphin parses the name of the production project by default to ensure stable scheduling. Assume that the name of the production project is `onedata_dev`. ■ If the code contains `select * from s_order`, the `onedata.s_order` node is parsed as the upstream node. ■ If the code contains `select * from ${onedata}.s_order`, the `onedata.s_order` node is parsed as the upstream node. ■ If the code contains `select * from onedata.s_order`, the `onedata.s_order` node is parsed as the upstream node. ■ If the code contains `select * from onedata_dev.s_order`, the `onedata_dev.s_order` node is parsed as the upstream node.

Parameter	Description
Upstream Dependency	The upstream nodes on which the current node depends. To specify an upstream node, perform the following steps: a. Click **Create Upstream Dependency**. b. In the **Create Upstream Dependency** dialog box, search for an upstream node in one of the following ways: ■ Enter a keyword to search for an upstream node whose output name contains the keyword. ■ Enter **virtual** to search for the zero load node. A root node is generated for each tenant or enterprise during initialization. The root node is a zero load node and its name starts with virtual. **Note** The output name of a node is globally unique and is not case-sensitive. c. Click **OK**. To remove a node from the upstream node list, click the icon in the **Actions** column.
Current Node	The output name for the current node. You can set multiple output names for a node, which can be used to configure dependencies for other nodes. To set an output name, perform the following steps: a. Click **Add**. b. In the **Add Output Task Nodes for Current Task Node** dialog box, enter an output name. Observe uniform rules when you set each output name for the current node. In general, set an output name in the format of `Project name.Table name`, which is not case-sensitive. This helps other users find this node when they configure the upstream dependency for their nodes. For example, if the name of the development project is `onedata_dev`, we recommend that you set the output name to `onedata.s_order`. If you set the output name to `onedata_dev.s_order`, the current node can be parsed as an upstream node for other nodes only when the code contains `select * from onedata_dev.s_order`. c. Click **OK**. You can also perform the following operations on an existing output name: ■ To delete an output name, click the icon in the **Actions** column. ■ To view the downstream nodes of the current node, click the icon in the **Actions** column.

6. Click **OK**.

9.9.2.7. Modify a batch processing task

Batch processing tasks are used to process data offline during data development. This topic describes how to modify a batch processing task.

Prerequisites

Batch processing tasks are created. For more information, see Create a batch processing task.

Context

If the batch processing task that you want to modify is locked by another user, click the icon in the upper-right corner to steal the lock.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the left-side navigation submenu, click .
6. In the **Batch Processing Tasks** section, move the pointer over the icon next to the batch processing task that you want to modify and select **Change**.
7. Modify the batch processing task.
   i. (Optional)Steal the lock of the batch processing task.
      - If the batch processing task is locked by yourself, you do not need to steal the lock.
      - If the batch processing task is locked by another user, click the icon in the upper-right corner to steal the lock.
   ii. Modify the code or scheduling policy of the batch processing task.
8. Save and submit the batch processing task.
   i. Click the icon in the upper-right corner to save the batch processing task.
   ii. Click the icon in the upper-right corner to submit the batch processing task.
   iii. Publish the batch processing task.
      - If the current project is in Dev mode, publish the task to the corresponding project in Prod mode. For more information, see Publishing management.
      - If the current project is in Basic mode, you do not need to publish the task. The task can be scheduled in the production environment after you submit it.

9.9.2.8. Unpublish and delete a batch processing task

Batch processing tasks are used to process data offline during data development. This topic describes how to unpublish, unpublish and delete, and delete batch processing tasks in different states.

Prerequisites

Batch processing tasks are created. For more information, see Create a batch processing task.

Context

- A batch processing task may be in the following states:
  - After you create and save a batch processing task, it enters the **Draft** state.
  - After you submit a batch processing task, it enters the **Submitted** state.
  - After you modify and save a batch processing task in the **Submitted** state, it enters the **Developing** state.
  - After you unpublish a batch processing task in the **Submitted** state, it enters the **Draft** state.
- Limits on unpublishing, deleting, and unpublishing and deleting batch processing tasks:
  - You can unpublish batch processing tasks only when they are in the **Developing** or **Submitted** state.
  - You can delete batch processing tasks only when they are in the **Draft** state.
  - You can unpublish and delete batch processing tasks only when they are in the **Developing** or **Submitted** state.

Unpublish a batch processing task

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the left-side navigation submenu, click the icon.
6. In the **Batch Processing Tasks** section, move the pointer over the icon next to the batch processing task that you want to unpublish and select **Unpublish**.
7. In the **Tip** dialog box, enter your comments.
8. Click **OK**.

Unpublish and delete a batch processing task

1. In the **Batch Processing Tasks** section, move the pointer over the icon next to the batch processing task that you want to unpublish and delete and select **Unpublish and Delete**.
2. In the **Tip** dialog box, enter your comments.

3. Click **OK**.

Delete a batch processing task

1. In the **Batch Processing Tasks** section, move the pointer over the icon next to the batch processing task that you want to delete and select **Delete**.
2. In the **Tip** dialog box, enter your comments.
3. Click **OK**.

9.9.2.9. View the version information about a batch processing task

This topic describes how to view the version information about a batch processing task, including the details and code of each version.

Prerequisites

Batch processing tasks are created. For more information, see Create a batch processing task.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the left-side navigation submenu, click the icon.
6. In the **Batch Processing Tasks** section, click the batch processing task whose version information you want to view.
7. On the configuration tab of the task, click **Versions** in the top navigation bar.
8. In the **Versions** pane, view the historical versions of the batch processing task.
   - Click **Details** in the **Actions** column of a version to view the details about the version.
   - Click **Compare Code Version** in the **Actions** column of a version to compare the code of the version with that of other versions.
   - Click **View Code** in the **Actions** column of a version to view the code of the version.

9.9.2.10. Move a batch processing task

Dataphin allows you to move a batch processing task to a specified folder. This topic describes how to move a batch processing task.

Prerequisites

Batch processing tasks are created. For more information, see Create a batch processing task.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the left-side navigation submenu, click the icon.
6. In the **Batch Processing Tasks** section, move the pointer over the icon next to the batch processing task that you want to move and select **Move**.
7. In the **Move File** dialog box, set the **Select Directory** parameter to the destination folder.
8. Click **OK**.

9.9.2.11. Rename a batch processing task

Dataphin allows you to rename a batch processing task. This topic describes how to rename a batch processing task.

Prerequisites

Batch processing tasks are created. For more information, see Create a batch processing task.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the left-side navigation submenu, click the icon.
6. In the **Batch Processing Tasks** section, move the pointer over the icon next to the batch processing task that you want to rename and select **Rename**.
7. In the field that appears, enter a new name.
8. Press the Enter key.

9.9.3. Stream processing

9.9.3.1. Overview

Data Processing allows you to run and manage stream processing tasks that are created during the data development process. You can also manage the files, metatables, and templates that are used in these tasks.

Dataphin allows you to create stream processing tasks of the **FLINK_SQL** and **FLINK_TEMPLATE_SQL** types. For more information, see Create a stream processing task of the FLINK_SQL type and Create a stream processing task of the FLINK_TEMPLATE_SQL type.

To develop a stream processing task, perform the following steps:

1. Create a resource. For more information, see Create a resource.
2. Create a stream processing function. For more information, see Create a UDF.
3. Create a stream metatable. For more information, see Create a stream metatable.
4. Optional. Create a stream processing template. For more information, see Create a stream processing template.
5. Create a stream processing task. For more information, see Create a stream processing task of the FLINK_SQL type or Create a stream processing task of the FLINK_TEMPLATE_SQL type.

> **Note** Stream processing templates can be used only by stream processing tasks of the FLINK_TEMPLATE_SQL type.

9.9.3.2. Resource management

9.9.3.2.1. Create a folder

This topic describes how to create a folder for storing resources.

Context

Folders help you categorize and manage resources.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Resource Management** section appears.
6. In the **Resource Management** section, click the icon next to **Resource Management**.
7. In the **Create Folder** dialog box, enter a folder name and select a directory.
8. Click **OK**.The following table describes the operations that you can perform on created folders.

Operation	Description
Rename a folder	To rename a folder, perform the following steps: i. In the Resource Management section, move the pointer over the icon next to the folder that you want to rename and select **Rename**. ii. In the field that appears, enter a new name. iii. Press the Enter key.
Move a folder	To move a folder, perform the following steps: i. In the Resource Management section, move the pointer over the icon next to the folder that you want to move and select **Move**. ii. In the **Move Folder** dialog box, set the **Select Directory** parameter to the destination directory. iii. Click **OK**.
Delete a folder	To delete a folder, perform the following steps: i. In the Resource Management section, move the pointer over the icon next to the folder that you want to delete. ii. Select **Delete**. **Note** You can delete only the folders that do not contain subfolders or items.

9.9.3.2.2. Create a resource

Dataphin provides the Resource Management section on the Develop page for you to store and manage files that are required during coding, such as JAR, JSON, and Python files. This topic describes how to create a resource.

Context

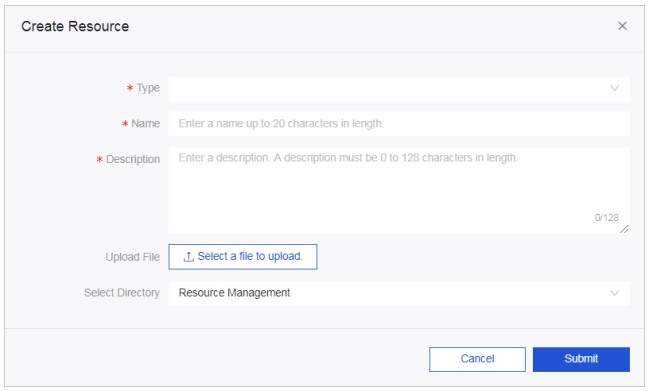
To reference files based on your business needs when you develop batch processing tasks, you can upload these files to Dataphin.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.

> **Note** If the current project is in Dev mode, publish the resource to the corresponding project in Prod mode. Then, you can view published resources in the production environment.

4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the **Data Processing** tab, move the pointer over the left-side navigation submenu and click the icon. The **Resource Management** section appears.
6. Open the **Create Resource** dialog box by using one of the following methods:
   - In the Resource Management section, click the icon next to **Resource Management**.
   - In the left-side navigation pane, click the icon next to the project name and choose **Data Processing > Resources**.
   - In the right-side workspace of the **Develop** page, click the icon next to **Resources**.
7. In the **Create Resource** dialog box, set the parameters as required.



Parameter	Description
Type	The type of the file to upload. Valid values: **file**, **jar**, **Python**, and **others**. The maximum size of each file is 50 MB. You can upload up to 1,000 files. **Note** If the network connection is unstable, we recommend that you upload files that are not larger than 100 MB.
Name	The name of the resource to create. The name of the resource must be unique in the project.
Description	The description of the resource.
Upload File	The file to upload. Select the file to upload based on the value of the **Type** parameter.
Resource Usage	The usage of the resource. Valid values: **Non-UDF**, **Batch Processing UDF**, and **Stream Processing UDF**.
Select Directory	The directory for storing the resource. Select an existing directory.

8. Submit the resource.
   i. Click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
9. (Optional)Publish the resource.
   - If the current project is in **Dev** mode, publish the resource to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in **Basic** mode, you do not need to publish the resource after you submit it.

9.9.3.2.3. Modify a resource

To modify an uploaded file, you can modify the corresponding resource and upload the modified file to replace the original file. This topic describes how to modify a resource.

Prerequisites

Resources are created. For more information, see Create a resource.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Resource Management** section appears.
6. In the **Resource Management** section, move the pointer over the icon next to the resource that you want to modify and select **Change**.
7. In the **Change Resource** dialog box, modify the parameters as needed. You can change the value of the **Description** parameter and re-upload a file.
8. Submit the resource.
   i. Click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.
9. (Optional)Publish the resource.
   - If the current project is in **Dev** mode, publish the resource to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in **Basic** mode, you do not need to publish the resource after you submit it.

9.9.3.2.4. Move a resource

This topic describes how to move a resource to another directory.

Prerequisites

Resources are created. For more information, see Create a resource.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Resource Management** section appears.
6. In the **Resource Management** section, move the pointer over the icon next to the resource that you want to move and select **Move**.
7. In the **Move File** dialog box, set the **Select Directory** parameter to the destination directory.
8. Click **OK**.

9.9.3.2.5. Delete a resource

You can delete a resource that is no longer used. This topic describes how to delete a resource.

Prerequisites

Resources are created. For more information, see Create a resource.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Resource Management** section appears.
6. In the **Resource Management** section, move the pointer over the icon next to the resource that you want to delete and select **Delete**.

> **Note** You cannot delete the resource if it is referenced by a task.

7. In the **Tip** dialog box, enter your comments.
8. Click **OK**.

9.9.3.3. Manage stream processing functions

9.9.3.3.1. Create a folder for storing stream processing functions

This topic describes how to create a folder for storing stream processing functions.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the left-side navigation submenu, click the icon.
6. In the **Stream Processing Functions** section, click the icon next to Stream Processing Functions.
7. In the **Create Folder** dialog box, enter a folder name and select a folder.
8. Click **OK**.The following table describes the operations that you can perform on created folders.

Operation	Description
Rename a folder	To rename a folder, perform the following steps: i. In the Stream Processing Templates section, move the pointer over the icon next to the folder that you want to rename and select **Rename**. ii. In the field that appears, enter a new name. iii. Press the Enter key.

Operation	Description
Move a folder	To move a folder, perform the following steps: i. In the Stream Processing Templates section, move the pointer over the icon next to the folder that you want to move and select **Move**. ii. In the **Move Folder** dialog box, set the **Select Directory** parameter to the destination folder. iii. Click **OK**.
Delete a folder	To delete a folder, perform the following steps: i. In the Stream Processing Templates section, move the pointer over the icon next to the folder that you want to delete. ii. Select **Delete**. **Note** You can delete only the folders that do not contain subfolders or items.

9.9.3.3.2. Create a UDF

Dataphin provides the Stream Processing Functions section on the Develop page. In this section, you can manage functions to be used in stream processing tasks, including system built-in functions and UDFs. System built-in functions cannot be modified. This topic describes how to create a UDF.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the left-side navigation submenu, click .
6. Open the **Create Function** dialog box in one of the following ways:
   - In the Stream Processing Functions section, click the icon next to **Stream Processing Functions**.
   - In the left-side navigation pane, click the icon next to the project name and choose **Data Processing** > **Stream Processing Functions**.
   - In the right-side workspace of the **Develop** page, click the icon next to **Stream**

Processing Functions.

7. In the **Create Function** dialog box, set the parameters as required.

Parameter	Description
Name	The name of the function to create. The name can contain letters, digits, and underscores (_), and must start with a letter.
Resource	The resource to be referenced by the function. You can view the resources that are available for the current project in the drop-down list. **Note** ○ If you select multiple resources, they must be of the same type. ○ If you do not have any resources, you must create one. For more information, see Create a resource.
Class	The class of the function to create. You can extract the class from the resources in the MaxCompute computing engine. Example: `test_udf.UDFGETSrcId`.
Type	The type of the function to create. Valid values: **Window**, **Statistic**, **Numeric**, **String**, **DateTime**, **ip address-related function**, **URL**, **Codec**, **Business**, and **Other**.
Function Syntax	The syntax of the function to create. The syntax of a function is the format for referencing the function. Example: `bigintweekday (datetime date)`.
Description	The description of the function to create. Example: `select get_week_date("20170810",0,2), -- Query the date of the Tuesday in the week of August 10, 2017. from cndata.dual`
Select Directory	The folder of the function to create.

8. Submit the UDF.
   i. After you set the parameters, click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**. The UDF is created and registered with MaxCompute.

Note If the resources referenced by UDFs are updated, submit the UDFs again so that the UDFs registered with MaxCompute are updated.

You can reference the UDF in an SQL statement and execute the statement in a task on the Ad Hoc Query tab to check whether the function meets your expectation. The following SQL statement is used as an example:

```
select
get_week_date("20170810",0,2), -- Query the date of the Tuesday in the week of August 10, 2017.
from  cndata.dual
```

9. (Optional)Publish the UDF.
   - If the current project is in Dev mode, publish the UDF to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the UDF after you submit it.

9.9.3.3.3. Modify a UDF

Dataphin provides the Stream Processing Functions section on the Develop page. In this section, you can manage functions to be used in stream processing tasks, including system built-in functions and UDFs. System built-in functions cannot be modified. This topic describes how to modify a UDF.

Prerequisites

UDFs are created. For more information, see Create a UDF.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the left-side navigation submenu, click the icon.
6. In the **Stream Processing Functions** section, move the pointer over the icon next to the UDF that you want to modify and select **Change**.
7. In the **Change Function** dialog box, set the **Resource**, **Class**, **Type**, **Function Syntax**, and **Description** parameters. For more information about the parameter description, see Create a UDF.
8. Submit the UDF.
   i. After you modify the parameters, click **Submit**.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.

iv. (Optional)Publish the UDF.

- If the current project is in Dev mode, publish the UDF to the corresponding project in Prod mode. For more information, see Publishing management.
- If the current project is in Basic mode, you do not need to publish the UDF. After you submit a UDF, it can be referenced in stream processing tasks for scheduling.

9.9.3.3.4. Move a UDF

Dataphin provides the Stream Processing Functions section on the Develop page. In this section, you can manage functions to be used in stream processing tasks, including system built-in functions and UDFs. System built-in functions cannot be modified. This topic describes how to move a UDF.

Prerequisites

UDFs are created. For more information, see Create a UDF.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the left-side navigation submenu, click the icon.
6. In the **Stream Processing Functions** section, move the pointer over the icon next to the UDF that you want to move and select **Move**.
7. In the **Move File** dialog box, set the **Select Directory** parameter to the destination folder.
8. Click **OK**.

9.9.3.3.5. Delete a UDF

Dataphin provides the Stream Processing Functions section on the Develop page. In this section, you can manage functions to be used in stream processing tasks, including system built-in functions and UDFs. System built-in functions cannot be modified. This topic describes how to delete a UDF.

Prerequisites

UDFs are created. For more information, see Create a UDF.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left

corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.

4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the left-side navigation submenu, click the icon.
6. In the **Stream Processing Functions** section, move the pointer over the icon next to the UDF that you want to delete and select **Delete**.

   > **Note** You cannot delete a UDF that is referenced in a task.

7. In the **Tip** dialog box, enter your comments.
8. Click **OK**.

9.9.3.4. Manage stream processing metatables

9.9.3.4.1. Create a folder for storing stream metatables

This topic describes how to create a folder for storing stream metatables.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Metatables** section appears.
6. In the **Stream Metatables** section, click the icon next to Stream Metatables.
7. In the **Create Folder** dialog box, enter a folder name and select a folder.
8. Click **OK**.The following table describes the operations that you can perform on created folders.

Operation	Description
Rename a folder	To rename a folder, perform the following steps: i. In the Stream Metatables section, move the pointer over the icon next to the folder that you want to rename and select **Rename**. ii. In the field that appears, enter a new name. iii. Press the Enter key.

Operation	Description
Move a folder	To move a folder, perform the following steps: i. In the Stream Metatables section, move the pointer over the icon next to the folder that you want to move and select **Move**. ii. In the **Move Folder** dialog box, set the **Select Directory** parameter to the destination folder. iii. Click **OK**.
Delete a folder	To delete a folder, perform the following steps: i. In the Stream Metatables section, move the pointer over the icon next to the folder that you want to delete. ii. Select **Delete**. **Note** You can delete only the folders that do not contain subfolders or items.

9.9.3.4.2. Create a stream metatable

Dataphin provides the Stream Metatables section on the Develop page. In this section, you can manage stream metatables to be used in stream processing tasks, including input tables, output tables, and dimension tables. This topic describes how to create a stream metatable.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Stream Metatables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Metatables** section appears.
3. Open the **Create Stream Metatable** dialog box by using one of the following methods:
   - In the **Stream Metatables** section, click the icon next to Stream Metatables.
   - In the left-side navigation pane, click the icon next to the project name and choose **Data Processing > Stream Metatables**.
   - In the right-side workspace of the **Develop** page, click the icon next to **Stream Metatables**.

4. In the **Create Stream Metatable** dialog box, set the parameters as required.

Parameter	Description
Metatable Name	The name of the stream metatable. **Note** The name must be unique in the project. Otherwise, the stream metatable cannot be published to the production environment.
Data Source	The data source of the stream metatable. The data sources that are connected to Dataphin are displayed in the drop-down list.
Source Table	The source table. If you select a data source of the **ALIYUN_HBASE**, **KAFKA_9_11**, **TABLE_STORE**, or **DRDS** type, enter the name of a source table from the corresponding data source as needed.
Topic	The source topic. If you select a data source of the **DATAHUB** or **LOG_SERVICE** type, select a topic from the drop-down list or enter the name of a topic from the corresponding data source.
Topic	The source topic. If you select a data source of the **ROCKET_MQ** type, enter the name of a topic from the corresponding data source.
Select Directory	The folder for storing the stream metatable.
Description	The description of the stream metatable.

5. Click **OK**.
6. (Optional)Add one or more fields to the stream metatable by using one of the following methods.
   - a. On the configuration tab of the stream metatable, move the pointer over **Add Field** and select **Use SQL Code**.

b. Enter code in the code editor of the **Use SQL Code** dialog box. Sample code:

```
create table dwi_pub_hbd_cate_mtr (
   rowkey  VARCHAR  comment 'rowkey',
   stat_date  VARCHAR  comment 'stat_date',
   keymin  VARCHAR  comment 'keymin',
   PRIMARY KEY(rowkey)
 )
  with (
    type='alihbase',
    diamondGroup='null',
    zkQuorum='hbasemaster74000.sg94.tbsite.net,hbasemaster74001.sg94.tbsite.net,hbase
master74002.sg94.tbsite.net,hbase74000.sg94.tbsite.net,hbase74001.sg94.tbsite.net',
    diamondKey='null',
    zkNodeParent='/group-sg94-lzd-mix',
    columnFamily='info',
    tableName='dwi_pub_hbd_cate_mtr_001',
    stringWriteMod='true'
 );
```

c. Click **OK**.

- a. On the configuration tab of the stream metatable, move the pointer over **Add Field** and select **Add Multiple Fields**.
  b. Enter code in the code editor of the **Add Multiple Fields** dialog box. Sample code:

```
ID, INT, description, false, true
name, INT, description, false, true
```

- a. On the configuration tab of the stream metatable, move the pointer over **Add Field** and select **Add Single Field**.
  b. In the **Add Single Field** dialog box, set the parameters as required.
  c.

Parameter	Description
Name	The name of the field.
Data Type	The data type of the field.
Primary Key	Specifies whether the field is a primary key.
Header	Specifies whether the field is an attribute field of the data source.
Description	The description of the field.

d. Click **OK**.

The following table describes the operations that you can perform on added fields.

Operation	Description
Edit a field	To edit a field, perform the following steps: i. In the field list of the stream metatable configuration page, find the field that you want to edit and click the icon in the **Actions** column. ii. In the Edit dialog box, modify the parameters as required. iii. Click **Finish**.
Delete a field	To delete a field, perform the following steps: i. In the field list of the stream metatable configuration page, find the field that you want to delete and click the icon in the **Actions** column. ii. In the **Information** message, click **OK**.
Sort fields	To sort fields, perform the following steps: i. On the stream metatable configuration page, click **Sort By**. ii. Sort the fields and click **Finish**.
Search for fields	On the stream metatable configuration page, enter a name or a keyword in the search box to search for fields.
Refresh	On the stream metatable configuration page, click the icon to reparse the fields from the stream metatable and refresh the field list.

7. Save and submit the stream metatable.
   i. Click the icon in the upper-right corner of the configuration tab to save the stream metatable.
   ii. Click the icon in the upper-right corner of the configuration tab to submit the stream metatable.
8. (Optional)Publish the stream metatable.
   - If the current project is in Dev mode, publish the stream metatable to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the stream metatable after you submit it.

9.9.3.4.3. Modify a stream metatable

Dataphin provides the Stream Metatables section on the Develop page. In this section, you can manage stream metatables to be used in stream processing tasks, including input tables, output tables, and dimension tables. This topic describes how to modify a stream metatable.

Prerequisites

Stream metatables are created. For more information, see Create a stream metatable.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Stream Metatables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Metatables** section appears.
3. In the **Stream Metatables** section, move the pointer over the icon next to the stream metatable that you want to modify and select **Change**.
4. (Optional)Steal the lock of the stream metatable.
   i. Steal the lock.
      - If the stream metatable is locked by yourself, you do not need to steal the lock.
      - If the stream metatable is locked by another user, click the icon in the upper-right corner to steal the lock.
   ii. After the lock is stolen, go to the next step to modify the metatable information and the fields in the stream metatable.
5. Modify the metatable information.
   i. In the top navigation bar of the configuration tab, click **Metatable Information**.
   ii. In the **Metatable Information** pane, modify the **Datasource**, **Source topic** or **Source table**, **Description**, and **Parameter k-v configuration** parameters.
   iii. Click **OK**.
6. Modify the fields in the stream metatable. For more information, see Create a stream metatable.
7. Save and submit the stream metatable.
   i. Click the icon in the upper-right corner of the configuration tab to save the stream metatable.
   ii. Click the icon in the upper-right corner of the configuration tab to submit the stream metatable.
8. (Optional)Publish the stream metatable.
   - If the current project is in Dev mode, publish the stream metatable to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the stream metatable

after you submit it.

9.9.3.4.4. View the version information about a stream metatable

Dataphin provides the Stream Metatables section on the Develop page. In this section, you can manage stream metatables to be used in stream processing tasks, including input tables, output tables, and dimension tables. This topic describes how to view the version information about a stream metatable.

Prerequisites

Stream metatables are created. For more information, see Create a stream metatable.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Stream Metatables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Metatables** section appears.
3. In the Stream Metatables section, click the stream metatable for which you want to view the version information.
4. In the top navigation bar of the configuration tab that appears, click **Version Details**. The Version Details pane appears.
5. Click the icon in the **Actions** column of a version to view the comparison between the current version and the reference version.
6. Click the icon in the **Actions** column of a version to view the code of the version.

9.9.3.4.5. Move a stream metatable

Dataphin provides the Stream Metatables section on the Develop page. In this section, you can manage stream metatables to be used in stream processing tasks, including input tables, output tables, and dimension tables. This topic describes how to move a stream metatable.

Prerequisites

Stream metatables are created. For more information, see Create a stream metatable.

Procedure

1. Log on to the Dataphin console.

2. Go to the **Stream Metatables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Metatables** section appears.
3. In the **Stream Metatables** section, move the pointer over the icon next to the stream metatable that you want to move and select **Move**.
4. In the **Move File** dialog box, set the **Select Directory** parameter to the destination folder.
5. Click **OK**.

9.9.3.4.6. Delete a stream metatable

Dataphin provides the Stream Metatables section on the Develop page. In this section, you can manage stream metatables to be used in stream processing tasks, including input tables, output tables, and dimension tables. This topic describes how to delete a stream metatable.

Prerequisites

Stream metatables are created. For more information, see Create a stream metatable.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Stream Metatables** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Metatables** section appears.
3. In the **Stream Metatables** section, move the pointer over the icon next to the stream metatable that you want to delete and select **Delete**.

   > **Note** You cannot delete a stream metatable if it is referenced by a stream processing task.

4. In the **Tip** dialog box, enter your comments.
5. Click **OK**.

9.9.3.5. Manage stream processing templates

9.9.3.5.1. Create a folder for storing stream processing templates

This topic describes how to create a folder for storing stream processing templates.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Processing Templates** section appears.
6. In the **Stream Processing Templates** section, click the icon next to Stream Processing Templates.
7. In the **Create Folder** dialog box, enter a folder name and select a folder.
8. Click **OK**.The following table describes the operations that you can perform on created folders.

Operation	Description
Rename a folder	To rename a folder, perform the following steps: i. In the Stream Processing Templates section, move the pointer over the icon next to the folder that you want to rename and select **Rename**. ii. In the field that appears, enter a new name. iii. Press the Enter key.
Move a folder	To move a folder, perform the following steps: i. In the Stream Processing Templates section, move the pointer over the icon next to the folder that you want to move and select **Move**. ii. In the **Move Folder** dialog box, set the **Select Directory** parameter to the destination folder. iii. Click **OK**.

Operation	Description
Delete a folder	To delete a folder, perform the following steps: i. In the Stream Processing Templates section, move the pointer over the icon next to the folder that you want to delete. ii. Select **Delete**. **Note** You can delete only the folders that do not contain subfolders or items.

9.9.3.5.2. Create a stream processing template

Dataphin provides the Stream Processing Templates section on the Develop page. In this section, you can manage templates that can be used in stream processing tasks to improve the coding efficiency. This topic describes how to create a stream processing template.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Stream Processing Templates** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Processing Templates** section appears.
3. Open the **Create Stream Processing Template** dialog box by using one of the following methods:
   - In the **Stream Processing Functions** section, click the icon next to Stream Processing Templates.
   - In the left-side navigation pane, click the icon next to the project name and choose **Data Processing > Stream Processing Templates**.
   - In the right-side workspace of the **Develop** page, click the icon next to **Stream Processing Template**.
4. In the **Create Stream Processing Template** dialog box, set the **Template Name**, **Select Directory**, and **Description** parameters.
5. Click **OK**.
6. Configure the stream processing template.
   i. Write the code of the stream processing template.

ii. In the top navigation bar of the configuration tab, click **Template Details**.

iii. In the **Template Details** pane, click **Parse** in the Parameter Configuration section.

iv. Set **Parameter Description** and **Default Value** for the parameters that are used in the stream processing template as required. In the Basic Information section, you can also modify or add a description for the template.

v. Click **OK**.If you reference this template when you create a stream processing task of the FLINK_TEMPLATE_SQL type, you can modify the parameters in the template on the configuration tab of the stream processing task.

7. Save and submit the stream processing template.

   i. Click the icon in the upper-right corner of the configuration tab to save the stream processing template.

   ii. Click the icon in the upper-right corner of the configuration tab to submit the stream processing template.

8. (Optional)Publish the stream processing template.
   - If the current project is in Dev mode, publish the stream processing template to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the stream processing template after you submit it.

9.9.3.5.3. Modify a stream processing template

Dataphin provides the Stream Processing Templates section on the Develop page. In this section, you can manage templates that can be used in stream processing tasks to improve the coding efficiency. This topic describes how to modify a stream processing template.

Prerequisites

Stream processing templates are created. For more information, see Create a stream processing template.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Stream Processing Templates** section.

   i. On the Dataphin homepage, click **R&D** in the top navigation bar.

   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. You can skip this step if the current project is in **Dev** or **Basic** mode.

   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.

   iv. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Processing Templates** section appears.

3. In the **Stream Processing Templates** section, move the pointer over the icon next to the stream processing template that you want to modify and select **Change**.

4. (Optional)Steal the lock of the stream processing template.
   i. Steal the lock.
      - If the stream processing template is locked by yourself, you do not need to steal the lock.
      - If the stream processing template is locked by another user, click the icon in the upper-right corner to steal the lock.
   ii. After the lock is stolen, go to the next step to modify the code and parameters in the stream processing template
5. Modify the code and parameters in the stream processing template. For more information, see Create a stream processing template.
6. Save and submit the stream processing template.
   i. Click the icon in the upper-right corner of the configuration tab to save the stream processing template.
   ii. Click the icon in the upper-right corner of the configuration tab to submit the stream processing template.
7. (Optional)Publish the stream processing template.
   - If the current project is in Dev mode, publish the stream processing template to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the stream processing template after you submit it.

9.9.3.5.4. View the version information about a stream processing template

Dataphin provides the Stream Processing Templates section on the Develop page. In this section, you can manage templates that can be used in stream processing tasks to improve the coding efficiency. This topic describes how to view the version information about a stream processing template.

Prerequisites

Stream processing templates are created. For more information, see Create a stream processing template.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Stream Processing Templates** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.

iv. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Processing Templates** section appears.

3. In the Stream Processing Templates section, click the stream processing template for which you want to view the version information.
4. In the top navigation bar of the configuration tab that appears, click **Version Details**. The Version Details pane appears.
5. Click the icon in the **Actions** column of a version to view the comparison between the current version and the reference version.
   - a. In the **Version Comparison** dialog box, click the **Code Comparison** tab to view the comparison between the code in the **Current Version** and **Reference Version** sections.
     b. To roll back to the reference version, click **Roll Back to Reference Version**.
     c. In the **Tip** message, click **OK**.
   - a. In the **Version Comparison** dialog box, click the **Template Parameter Comparison** tab to view the comparison between the parameter information in the **Current Version** and **Reference Version** sections.
     b. To roll back to the reference version, click **Roll Back to Reference Version**.
     c. In the **Tip** message, click **OK**.
6. Click the icon in the **Actions** column of a version to view the code of the version.

9.9.3.5.5. Move a stream processing template

Dataphin provides the Stream Processing Templates section on the Develop page. In this section, you can manage templates that can be used in stream processing tasks to improve the coding efficiency. This topic describes how to move a stream processing template.

Prerequisites

Stream processing templates are created. For more information, see Create a stream processing template.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Stream Processing Templates** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Processing Templates** section appears.
3. In the **Stream Processing Templates** section, move the pointer over the icon next to the stream processing template that you want to move and select **Move**.

4. In the **Move File** dialog box, set the **Select Directory** parameter to the destination folder.
5. Click **OK**.

9.9.3.5.6. Delete a stream processing template

Dataphin provides the Stream Processing Templates section on the Develop page. In this section, you can manage templates that can be used in stream processing tasks to improve the coding efficiency. This topic describes how to delete a stream processing template.

Prerequisites

Stream processing templates are created. For more information, see Create a stream processing template.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Stream Processing Templates** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Processing Templates** section appears.
3. Move the pointer over the icon next to the stream processing template that you want to delete and select **Delete**.

   > **Note** You can delete only the folders that do not contain subfolders or items.

4. In the **Tip** dialog box, enter your comments.
5. Click **OK**.

9.9.3.6. Manage stream processing tasks

9.9.3.6.1. Create a folder for storing stream processing tasks

This topic describes how to create a folder for storing stream processing tasks.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left

corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.

4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Processing Tasks** section appears.
6. In the **Stream Processing Tasks** section, click the icon next to Stream Processing Tasks.
7. In the **Create Folder** dialog box, enter a folder name and select a folder.
8. Click **OK**.The following table describes the operations that you can perform on created folders.

Operation	Description
Rename a folder	To rename a folder, perform the following steps: i. In the Stream Processing Tasks section, move the pointer over the icon next to the folder that you want to rename and select **Rename**. ii. In the field that appears, enter a new name. iii. Press the Enter key.
Move a folder	To move a folder, perform the following steps: i. In the Stream Processing Tasks section, move the pointer over the icon next to the folder that you want to move and select **Move**. ii. In the **Move Folder** dialog box, set the **Select Directory** parameter to the destination folder. iii. Click **OK**.
Delete a folder	To delete a folder, perform the following steps: i. In the Stream Processing Tasks section, move the pointer over the icon next to the folder that you want to delete. ii. Select **Delete**. **Note** You can delete only the folders that do not contain subfolders or items.

9.9.3.6.2. Create a stream processing task of the FLINK_SQL type

Dataphin allows you to manage stream processing tasks of the FLINK_SQL and FLINK_TEMPLATE_SQL types. This topic describes how to create a stream processing task of the FLINK_SQL type.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Stream Processing Tasks** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Processing Tasks** section appears.
3. Create a stream processing task of the FLINK_SQL type.
   i. Open the **Create Flink_SQL** dialog box by using one of the following methods:
      - In the Stream Processing Tasks section, click the icon next to **Stream Processing Tasks** and select **FLINK_SQL**.
      - In the left-side navigation pane, click the icon next to the project name and choose **Data Processing** > **Stream Processing Tasks** > **FLINK_SQL**.
      - In the right-side workspace of the **Develop** page, click the icon next to **FLINK_SQL**.
   ii. In the **Create Flink_SQL** dialog box, set the parameters as required.

Parameter	Description
Name	The name of the stream processing task. **Note** The name must be unique in the project. Otherwise, the stream processing task cannot be published to the production environment.
Select Directory	The folder for storing the stream processing task.
Resource Queue	The resource queue of the computing engine for stream processing that is bound to the current project.
Engine Version	The version of the computing engine supported by the selected resource queue.

   iii. Click **OK**.
4. Write the code of the stream processing task.

i. On the configuration tab, write the code to configure the stream processing task.

> **Note** If you do not have permissions to access the tables referenced in the stream processing task, enter related SET statements at the beginning of the code to specify the AccessKey ID and AccessKey secret required for accessing the tables.

ii. Click **Precompile** to check the syntax and related permissions of the stream processing task.

iii. Click **Debugging**. Then, you can configure the sample data for debugging and locally debug the stream processing task to make sure that the code to be submitted is correct.

iv. In the **Configure Debugging Data** dialog box, select a table in the left-side table list and click **Auto Sampling**.

v. In the pop-up dialog box, set the **Data Records** parameter and click **OK**.

vi. After the sampling is complete for all tables, click **OK** in the lower-right corner of the **Configure Debugging Data** dialog box.

vii. View the debugging data, intermediate result, and debugging result on the **Result** tab.

5. Set the parameters of the stream processing task.
   i. In the top navigation bar of the configuration tab, click **Task Parameters**.
   ii. In the Task Parameters pane, set parameters, including the checkpoint mode and interval, based on the sample code of the stream processing task.
   iii. Click **OK**.
6. Configure the stream processing task.
   i. In the top navigation bar of the configuration tab, click **Task Configuration**. The **Task Configuration** pane appears.

ii. Set the **Resource Configuration** parameter.

- If you select **System Recommended**, you do not need to configure resources.
- If you select **Custom**, you must click **Configure** to configure resources. You can configure resources in one of the following modes: **Visualization Mode** and **Code Editor**.

Mode	Description
Visualization Mode	To configure resources in visualization mode, perform the following steps: a. On the resource configuration page, click **Visualization Mode**. b. Click the icon in the upper-right corner of a compute node. c. In the dialog box that appears, set the parameters as required. d. Click **OK**. e. After you set the execution parameters for all compute nodes, click **Save** in the upper-right corner of the page.
Code Editor	To configure resources in the code editor, perform the following steps: a. On the resource configuration page, click **Code Editor**. b. In the code editor, set the execution parameters for compute nodes as required. Then, click **Save** in the upper-right corner of the page.

iii. In the **Task Configuration** pane, click the icon to turn on **Auto Optimization** and set the **Maximum CUs** and **Expected Maximum Memory** parameters as required. Then, click **OK**.

7. Save and submit the stream processing task.

i. Click the icon in the upper-right corner of the configuration tab to save the stream processing task.

ii. Click the icon in the upper-right corner of the configuration tab to submit the stream processing task.

8. (Optional)Publish the stream processing task.

- If the current project is in Dev mode, publish the stream processing task to the corresponding project in Prod mode. For more information, see Publishing management.
- If the current project is in Basic mode, you do not need to publish the stream processing task after you submit it.

9.9.3.6.3. Create a stream processing task of the FLINK_TEMPLATE_SQL type

Dataphin allows you to manage stream processing tasks of the FLINK_SQL and FLINK_TEMPLATE_SQL types. This topic describes how to create a stream processing task of the FLINK_TEMPLATE_SQL type.

Prerequisites

Stream processing templates are created. For more information, see Create a stream processing template.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Stream Processing Tasks** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
   iv. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Processing Tasks** section appears.
3. Create a stream processing task of the FLINK_TEMPLATE_SQL type.
   i. Open the **Create Flink_Template_SQL** dialog box by using one of the following methods:
      - In the Stream Processing Tasks section, click the icon next to **Stream Processing Tasks** and select **FLINK_TEMPLATE_SQL**.
      - In the left-side navigation pane, click the icon next to the project name and choose **Data Processing** > **Stream Processing Tasks** > **FLINK_TEMPLATE_SQL**.
      - In the right-side workspace of the **Develop** page, click the icon next to **FLINK_TEMPLATE_SQL**.

ii. In the **Create Flink_Template_SQL** dialog box, set the parameters as required.

Parameter	Description
Name	The name of the stream processing task. **Note** The name must be unique in the project. Otherwise, the stream processing task cannot be published to the production environment.
Select Directory	The folder for storing the stream processing task.
Resource Queue	The resource queue of the computing engine for stream processing that is bound to the current project.
Engine Version	The version of the computing engine supported by the selected resource queue.
Referenced Template	The template referenced by the stream processing task.

iii. Click **OK**.

4. Write the code of the stream processing task.
   i. On the configuration tab, write the code to configure the stream processing task.
   ii. Click **Precompile** to check the syntax and related permissions of the stream processing task.
   iii. Click **Debugging**. Then, you can configure the sample data for debugging and locally debug the stream processing task to make sure that the code to be submitted is correct.
   iv. In the **Configure Debugging Data** dialog box, select a table in the left-side table list and click **Auto Sampling**.
   v. In the pop-up dialog box, set the **Data Records** parameter and click **OK**.
   vi. After the sampling is complete for all tables, click **OK** in the lower-right corner of the **Configure Debugging Data** dialog box.
   vii. View the debugging data, intermediate result, and debugging result on the **Result** tab.
5. Set the parameters of the stream processing task.
   i. In the top navigation bar of the configuration tab, click **Task Parameters**.
   ii. In the Task Parameters pane, set parameters, including the checkpoint mode and interval, based on the sample code of the stream processing task.
   iii. Click **OK**.
6. Configure the stream processing task.
   i. In the top navigation bar of the configuration tab, click **Task Configuration**. The **Task Configuration** pane appears.

ii. Set the **Resource Configuration** parameter.

- If you select **System Recommended**, you do not need to configure resources.
- If you select **Custom**, you must click **Configure** to configure resources. You can configure resources in one of the following modes: **Visualization Mode** and **Code Editor**.

Mode	Description
Visualization Mode	To configure resources in visualization mode, perform the following steps: a. On the resource configuration page, click **Visualization Mode**. b. Click the icon in the upper-right corner of a compute node. c. In the dialog box that appears, set the parameters as required. d. Click **OK**. e. After you set the execution parameters for all compute nodes, click **Save** in the upper-right corner of the page.
Code Editor	To configure resources in the code editor, perform the following steps: a. On the resource configuration page, click **Code Editor**. b. In the code editor, set the execution parameters for compute nodes as required. Then, click **Save** in the upper-right corner of the page.

iii. In the **Task Configuration** pane, click the icon to turn on **Auto Optimization** and set the **Maximum CUs** and **Expected Maximum Memory** parameters as required. Then, click **OK**.

7. Set the parameters in the stream processing template referenced by the stream processing task.
   i. In the top navigation bar of the configuration tab, click **Template Parameters**.
   ii. In the **Template Parameters** pane, set the **Parameter Value** parameter.
   iii. Click **OK**.
8. Save and submit the stream processing task.
   i. Click the icon in the upper-right corner of the configuration tab to save the stream processing task.
   ii. Click the icon in the upper-right corner of the configuration tab to submit the stream processing task.

iii. (Optional)Publish the stream processing task.

- If the current project is in Dev mode, publish the stream processing task to the corresponding project in Prod mode. For more information, see Publishing management.
- If the current project is in Basic mode, you do not need to publish the stream processing task after you submit it.

9.9.3.6.4. Modify a stream processing task

Stream processing tasks are used to process data in real time during data development. This topic describes how to modify a stream processing task.

Prerequisites

Stream processing tasks are created. For more information, see Create a stream processing task of the FLINK_SQL type or Create a stream processing task of the FLINK_TEMPLATE_SQL type.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Processing Tasks** section appears.
6. In the **Stream Processing Tasks** section, move the pointer over the icon next to the stream processing task that you want to modify and select **Change**.
7. (Optional)Steal the lock of the stream processing task.
   i. Steal the lock.
      - If the stream processing task is locked by yourself, you do not need to steal the lock.
      - If the stream processing task is locked by another user, click the icon in the upper-right corner to steal the lock.
   ii. After the lock is stolen, go to the next step to modify the code, parameters, and configuration of the stream processing task.
8. Modify the code, parameters, and configuration of the stream processing task. For more information, see Create a stream processing task of the FLINK_SQL type or Create a stream processing task of the FLINK_TEMPLATE_SQL type.
9. Save and submit the stream processing task.
   i. Click the icon in the upper-right corner of the configuration tab to save the stream processing task.

ii. Click the icon in the upper-right corner of the configuration tab to submit the stream processing task.

iii. (Optional)Publish the stream processing task.

- If the current project is in Dev mode, publish the stream processing task to the corresponding project in Prod mode. For more information, see Publishing management.
- If the current project is in Basic mode, you do not need to publish the stream processing task after you submit it.

9.9.3.6.5. View the version information about a stream processing task

This topic describes how to view the version information about a stream processing task.

Prerequisites

Stream processing tasks are created. For more information, see Create a stream processing task of the FLINK_TEMPLATE_SQL type or Create a stream processing task of the FLINK_TEMPLATE_SQL type.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Processing Tasks** section appears.
6. In the **Stream Processing Tasks** section, click the stream processing task for which you want to view the version information.
7. In the top navigation bar of the configuration tab that appears, click **Version Details**. The Version Details pane appears.
8. Click the icon in the **Actions** column of a version to view the comparison between the current version and the reference version.
   - a. In the **Version Comparison** dialog box, click the **Code Comparison** tab to view the comparison between the code in the **Current Version** and **Reference Version** sections.
     b. To roll back to the reference version, click **Roll Back to Reference Version**.
     c. In the **Tip** message, click **OK**.
   - a. In the **Version Comparison** dialog box, click the **Task Parameter Comparison** tab to view the comparison between the parameter information in the **Current Version** and **Reference Version** sections.

b. To roll back to the reference version, click **Roll Back to Reference Version**.

c. In the **Tip** message, click **OK**.

9. Click the icon in the **Actions** column of a version to view the code of the version.

9.9.3.6.6. Move a stream processing task

Stream processing tasks are used to process data in real time during data development. This topic describes how to move a stream processing task.

Prerequisites

Stream processing tasks are created. For more information, see Create a stream processing task of the FLINK_TEMPLATE_SQL type or Create a stream processing task of the FLINK_TEMPLATE_SQL type.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Processing Tasks** section appears.
6. In the **Stream Processing Tasks** section, move the pointer over the icon next to the stream processing task that you want to move and select **Move**.
7. In the **Move File** dialog box, set the **Select Directory** parameter to the destination folder.
8. Click **OK**.

9.9.3.6.7. Unpublish or delete a stream processing task

This topic describes how to unpublish, unpublish and delete, and delete stream processing tasks in different states.

Prerequisites

Stream processing tasks are created. For more information, see Create a stream processing task of the FLINK_TEMPLATE_SQL type or Create a stream processing task of the FLINK_TEMPLATE_SQL type.

Context

- A stream processing task may be in the following states:
  - After you create and save a stream processing task, it enters the **Draft** state.
  - After you submit a stream processing task, it enters the **Submitted** state.

  - After you modify and save a stream processing task in the **Submitted** state, it enters the **Developing** state.
  - After you unpublish a stream processing task in the **Submitted** state, it enters the **Draft** state.

- You can unpublish stream processing tasks only when they are in the **Developing** or **Submitted** state.
- You can delete stream processing tasks only when they are in the **Draft**, **Developing** or **Submitted** state.

Unpublish a stream processing task

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Data Processing** tab in the left-side navigation pane.
5. On the Data Processing tab, move the pointer over the left-side navigation submenu and click the icon. The **Steam Processing Tasks** section appears.
6. In the **Stream Processing Tasks** section, move the pointer over the icon next to the stream processing task that you want to unpublish and select **Unpublish**.
7. In the **Tip** dialog box, enter your comments.
8. Click **OK**.

Delete a stream processing task

1. In the **Stream Processing Tasks** section, move the pointer over the icon next to the stream processing task that you want to delete and select **Delete**.
2. In the **Tip** dialog box, enter your comments.
3. Click **OK**.

9.9.4. Ad hoc query

9.9.4.1. Overview

Dataphin provides the ad hoc query feature for you to query data. Dataphin can automatically identify and change the SQL syntax based on your computing engine type.

Dataphin uses a business unit as the namespace for its unique logical table models. Therefore, Dataphin uses the following SQL syntax for logical tables:

- Logical tables are referenced in SQL statements in the format of Business unit.Logical table.
- The query logic can be in the format of [Business unit.Logical table.Dimension-associated role. ···. Dimension-associated role.Logical dimension table field]. If the query logic is used as a condition of a SELECT statement or a WHERE clause, you only need to enter the logic in the format of [Logical table.Dimension-associated role. ···.Dimension-associated role.Logical

dimension table field] to search for fields associated with dimensions.

Note The primary key field of a virtual dimension cannot be used in SQL statements. A virtual dimension can be used only to construct a statistic granularity.

9.9.4.2. Create an ad hoc query task

This topic describes how to create an ad hoc query task.

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.

   You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Ad Hoc Query** tab in the left-side navigation pane.
5. Create a folder for storing ad hoc query tasks.
   i. On the **Ad Hoc Query** tab, click the icon next to **Ad Hoc Query**.
   ii. In the **Create Folder** dialog box, enter a folder name and select a folder.
   iii. Click **OK**.
6. Create an ad hoc query task.
   i. Open the **Create Item** dialog box by using one of the following methods:
      - In the left-side navigation pane, click the icon next to the project name and select **Ad Hoc Query**.
      - On the **Ad Hoc Query** tab, click the icon next to Ad Hoc Query.
      - In the right-side workspace of the **Develop** page, click the icon next to **SQL Query** in the **Ad Hoc Query** section.
   ii. In the **Create Item** dialog box, set the **Name** and **Description** parameters and select the created folder.
   iii. Click **OK**. The Code Editor tab appears.
7. Write the code of the ad hoc query task on the Code Editor tab.
   i. Write SQL statements to create an ad hoc query task.
   ii. Click **Precompile** in the upper-right corner of the Code Editor tab to check whether the SQL statements comply with the standard.

   If the SQL statements do not comply with the standard, click **Beautify** in the upper-right corner. Then, Dataphin automatically adjusts the SQL statements so that they comply with the standard.
   iii. Click **Run** in the upper-right corner of the Code Editor tab to execute the SQL statements. Then, check whether the SQL statements are executed based on the information on the Console tab in the lower part of the page.
8. If the SQL statements are executed, click the icon in the upper-right corner of the Code

Editor tab.

9.9.4.3. Manage ad hoc query tasks

This topic describes how to edit, run, delete, move, and rename an ad hoc query task.

Edit an ad hoc query task

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.

   You can skip this step if the current project is in **Dev** or **Basic** mode.
4. On the **Develop** page, click the **Ad Hoc Query** tab in the left-side navigation pane.
5. On the **Ad Hoc Query** tab, move the pointer over the icon next to the ad hoc query task that you want to edit and select **Change**.
6. (Optional)In the upper-right corner of the configuration tab that appears, click the icon to steal the lock for the ad hoc query task.

   If you need to edit an ad hoc query task that is created by another user or an ad hoc query task that is created by yourself but has been locked by another user, you must steal the lock before you can edit the ad hoc query task.
   - If the ad hoc query task is created by another user or the ad hoc query task is created by yourself but has been locked by another user, you must steal the lock before you can edit the ad hoc query task.
   - If the ad hoc query task is locked by yourself, you do not need to steal the lock.

7. i. In the code editor on the configuration tab, edit the SQL statements of the ad hoc query task.

   In the SQL statements, reference tables based on the following rules:

   - When you query data in a physical table in another project, prefix the table name with the corresponding project name in SQL statements. For example, in the `select * from cloudtest_dev.table4` statement, cloudtest_dev indicates the project name and table4 indicates the name of the physical table.
   - When you query data in a logical table, prefix the table name with the corresponding business unit name in SQL statements. For example, in the `select province from ld_practice.dim_province` statement, ld_practice indicates the business unit name and dim_province indicates the name of the logical table.
   - When you query data in the development environment, suffix the name of the business unit or project in Prod mode with **_dev**. Dataphin automatically generates the corresponding variable for the business unit or project in Prod mode. For example, if you reference a business unit named LD_Trade, Dataphin automatically generates the business unit variable ${LD_Trade}. By default, this variable is replaced with LD_Trade_dev when the SQL statements are executed in the development environment, and replaced with LD_Trade when the SQL statements are executed in the production environment. You can assign a specific value for the variable when you write the SQL statements. This variable helps improve the flexibility of the SQL statements when they are executed in different environments.

   ii. Click **Precompile** in the upper-right corner of the configuration tab to check whether the SQL statements comply with the standard.

   If the SQL statements do not comply with the standard, click **Beautify** in the upper-right corner. Then, Dataphin automatically adjusts the SQL statements so that they comply with the standard.

   iii. Click **Run** in the upper-right corner of the configuration tab to execute the SQL statements. Then, check whether the SQL statements are executed based on the information on the Console tab in the lower part of the page.

8. If the SQL statements are executed, click the icon in the upper-right corner of the configuration tab.

Delete an ad hoc query task

> **Note** You can delete only ad hoc query tasks that have been locked by yourself.

1. On the **Ad Hoc Query** tab, move the pointer over the icon next to the ad hoc query task that you want to delete and select **Delete**.
2. In the **Tip** dialog box, enter your comments.
3. Click **OK**.

Move an ad hoc query task

> **Note** You can move only ad hoc query tasks that have been locked by yourself.

1. On the **Ad Hoc Query** tab, move the pointer over the icon next to the ad hoc query task that you want to move and select **Move**.
2. In the **Move File** dialog box, set the **Select Directory** parameter to the destination folder.
3. Click **OK**.

Rename an ad hoc query task

> **Note** You can rename only ad hoc query tasks that have been locked by yourself.

1. On the **Ad Hoc Query** tab, move the pointer over the icon next to the ad hoc query task that you want to rename and select **Rename**.
2. In the field that appears, enter a new name.
3. Press the Enter key.

9.10. Data distilling

9.10.1. Overview

Based on the data accumulated in data modeling of a Data Mid-End, the data distilling module of Dataphin provides data correlation and in-depth data mining for you to extract value from the data of target objects. This module generates code and scheduling tasks, identifies and connects target entities, and then generates tags for the target entities. It can quickly be applied to various businesses.

Before you use the data distilling module, follow these steps to initialize the module:

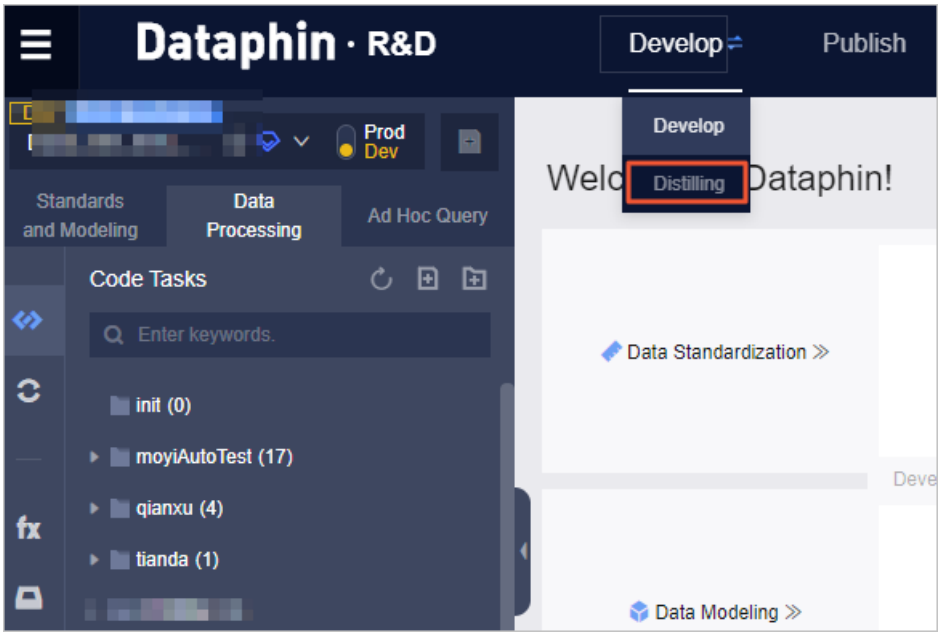
1. Log on to the Dataphin console.
2. Go to the R&D page. In the top navigation bar, move the pointer over **Develop** and select **Distilling**. The **Initialization Configuration** page appears.
3. Select a computing engine from the **Computing Engine** drop-down list and click **Test Connectivity**.

   If no computing engine is available, create one as described in Computing engines.
4. After the computing engine passes the connectivity test, click **Confirm and Initialize**. After the initialization is completed, go to the Distilling tab to develop data.

The data distilling module identifies and associates the master data in the Data Mid-End, that is, the core objects throughout all isolated business domains. Then, this module can interconnect data silos and further extract value from the data of target objects such as high-value tags that can be directly used. In this way, this module accumulates data assets to build a data distilling center.

The data distilling module consists of the Behavior Engine and Tag Engine: The Behavior Engine allows you to configure detailed behaviors and displays behavior statistics. The Tag Engine provides a graphical configuration workbench. It allows you to configure and automatically generate tags and manage tag tasks in different development states.

On the Dataphin homepage, click **R&D** in the top navigation bar. On the R&D page that appears, move the pointer over **Develop** in the top navigation bar and select **Distilling**. The Distilling tab appears.



9.10.2. Behavior Engine

9.10.2.1. Overview

This topic describes the features of the Behavior Engine.

The Behavior Engine consists of the Behavioral Elements, Behavior Rule, and Dashboard submodules.

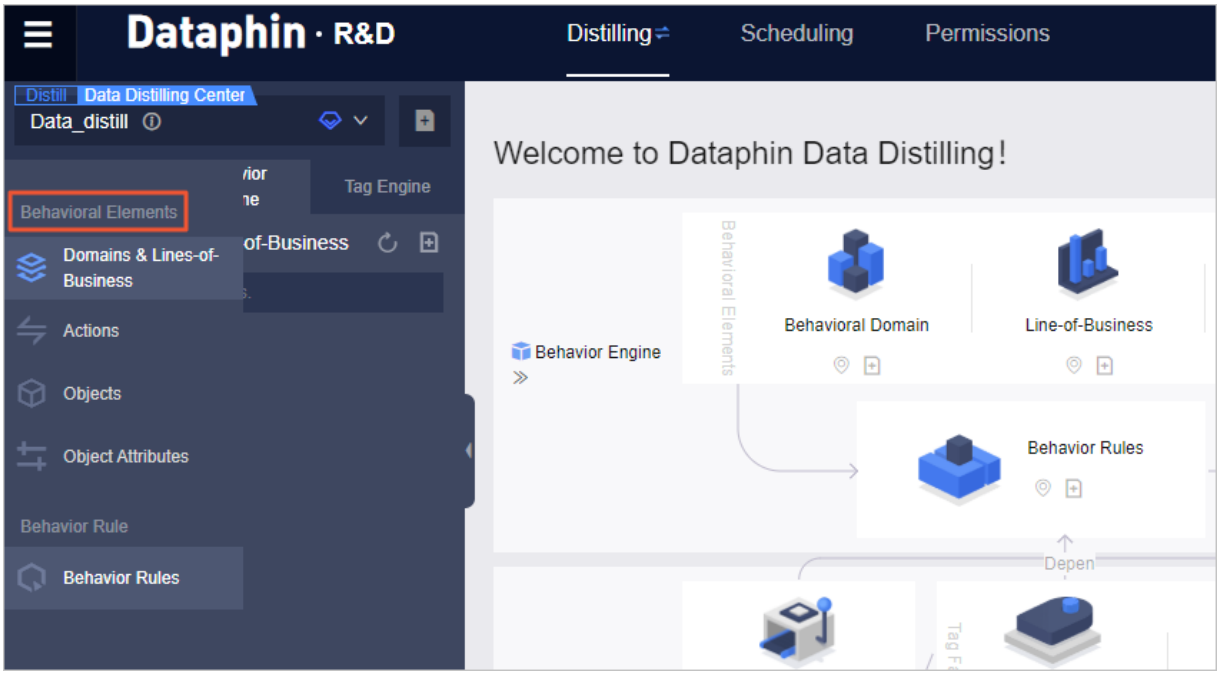
Behavioral Elements submodule

The Behavioral Elements submodule defines standard behavioral elements and their categories. Behavioral elements are categorized into behavioral domains, lines-of-business, actions, objects, and object attributes. You can manage behavioral elements by category.

- Behavioral domain: aggregates behavioral data that has consistent business meanings, such as the e-commerce domain and the entertainment domain.
- Line-of-business: segments behavioral data based on the behavioral domain, such as the Taobao line-of-business and the Tmall line-of-business. Lines-of-business are independent of each other.
- Action: the operation that the behavior subject performs, such as purchasing and browsing.
- Object: the thing on which the behavior subject performs the action, such as a commodity or a movie.
- Object attribute: the description of the object, such as the name, brand, and year.

For example, you can abstract the e-commerce industry as a behavioral domain, and divide the behavioral data in the e-commerce domain into the line-of-business in Mainland China and the line-of-business outside Mainland China by region. The action is payment and the object is commodity. Object attributes include the category, brand, price, size, and color that describe the commodity.

On the Distilling tab, click **Behavior Engine** in the left-side navigation pane. Then, move the pointer over the left-side navigation submenu. You can click a type of behavioral element to manage them on the management page.

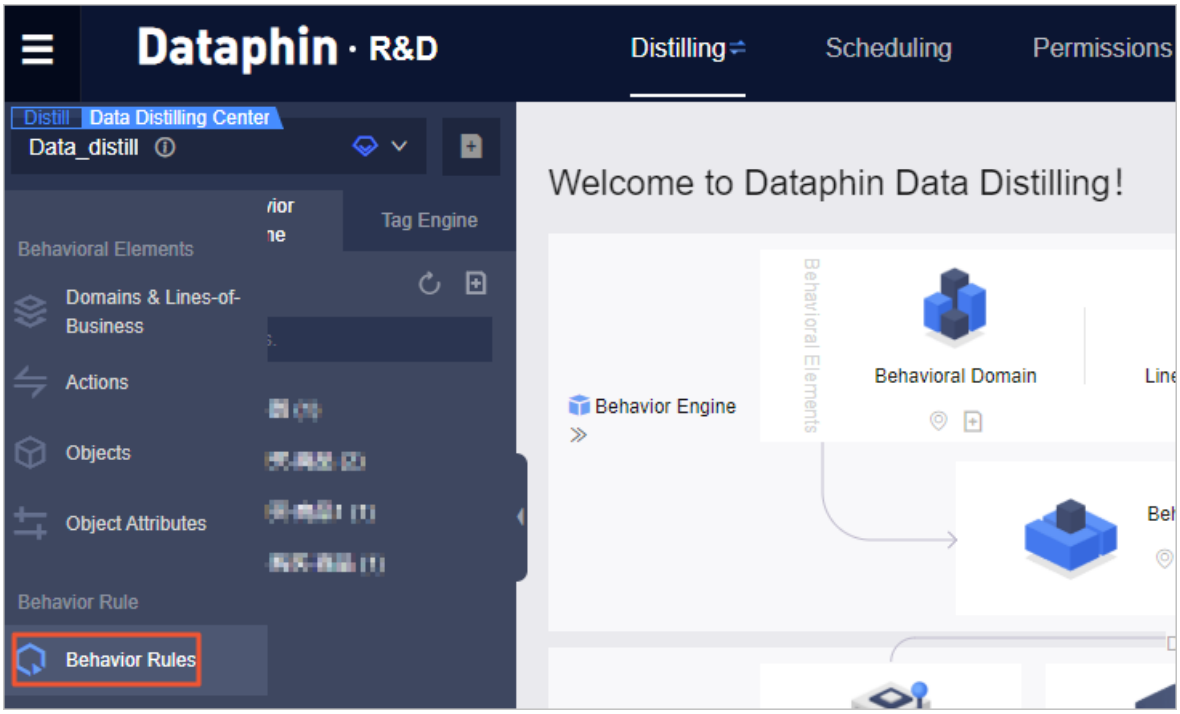


Behavior Rule submodule

Based on the defined behavioral elements, you can configure the corresponding data source and data processing and cleansing rules. Dataphin provides a data source rule for each behavior that is based on a behavioral domain, a line-of-business, an action, and an object to match standardized and structured behaviors with the actual data.

A behavior rule is determined based on the unique behavior and source table. When you preview, save, or submit a behavior rule, Dataphin checks whether the specific behavior and source table are unique.

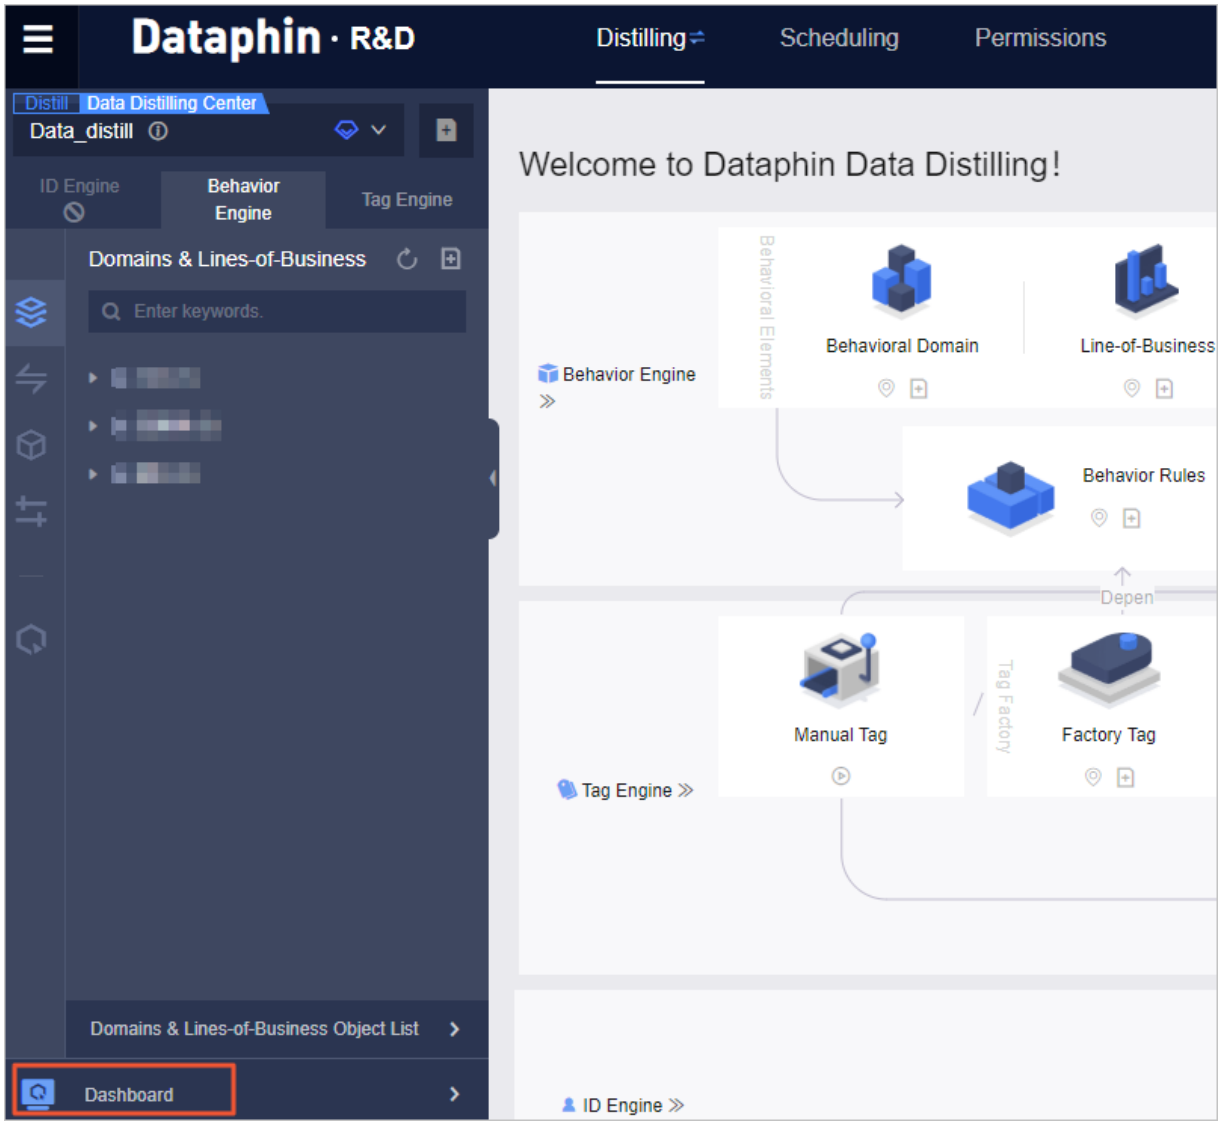
On the Distilling tab, click **Behavior Engine** in the left-side navigation pane. Then, move the pointer over the left-side navigation submenu. You can click **Behavior Rules** to go to the management page.



Dashboard submodule

The Dashboard submodule displays the distribution of behavioral data and the sampling data. It helps you dynamically obtain standardized and structured aggregation results of all behaviors centered on target objects.

On the Distilling tab, click **Behavior Engine** in the left-side navigation pane. Then, click **Dashboard** at the bottom. The Dashboard tab appears.

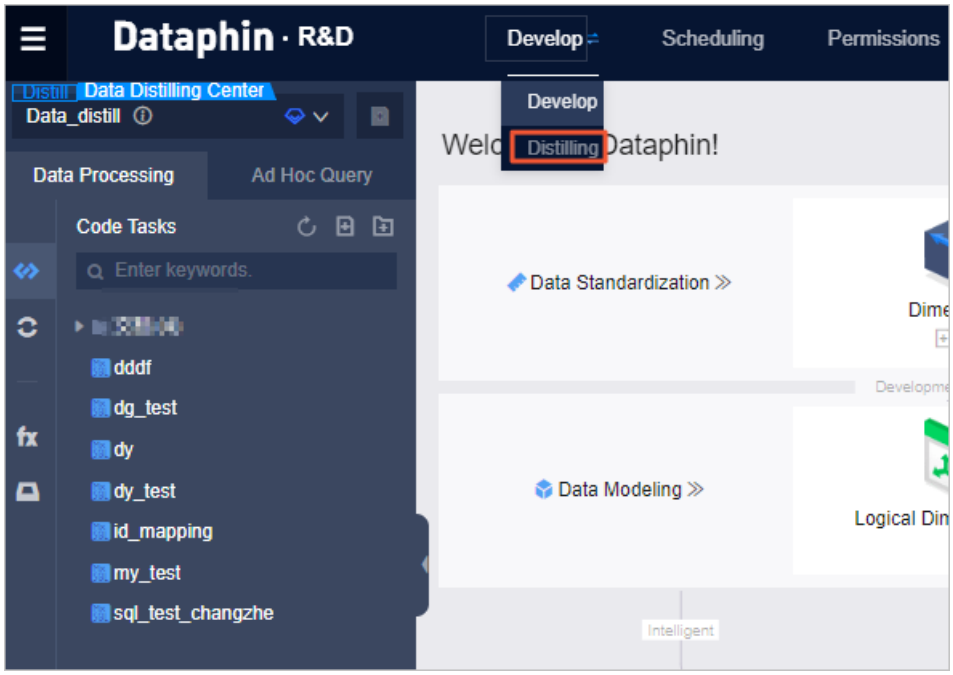


9.10.2.2. Manage behavioral domains

This topic describes how to create, edit, and delete a behavioral domain.

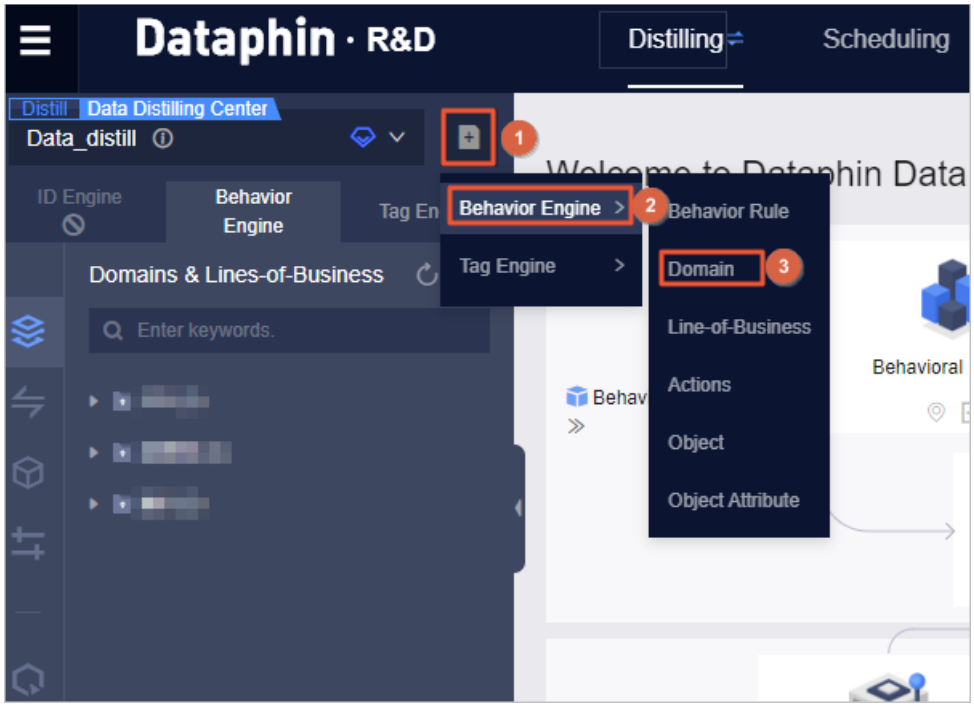
Create a behavioral domain

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the R&D page that appears, move the pointer over Develop in the top navigation bar and select **Distilling**.

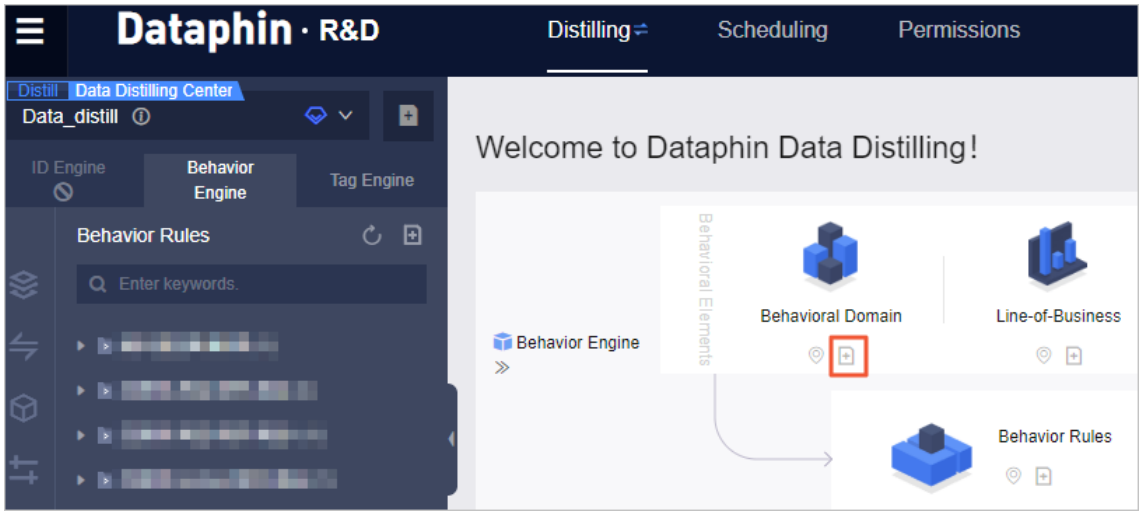


4. Open the **Create Domain** dialog box in one of the following ways:
   - On the Distilling tab, click **Behavior Engine** in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side navigation pane, click the icon and select **Behavioral Domain**.

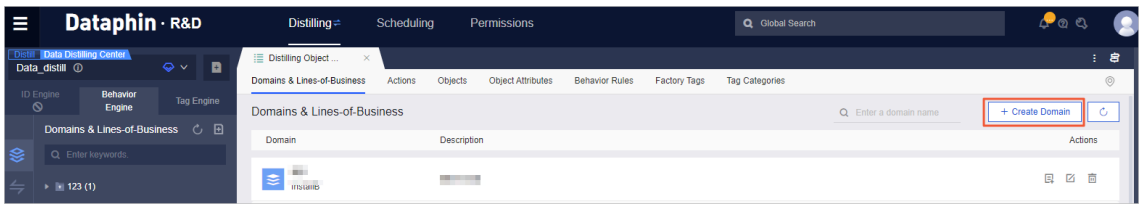
   - On the Distilling tab, click the icon next to the project name and choose **Behavior Engine > Domain**.



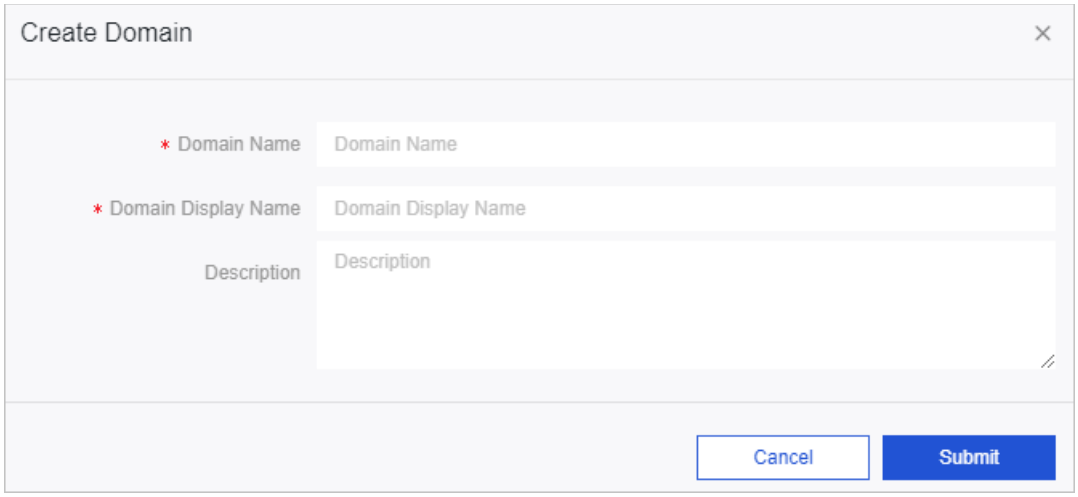
- On the Distilling tab, click the icon below **Behavioral Domain** in the workspace.



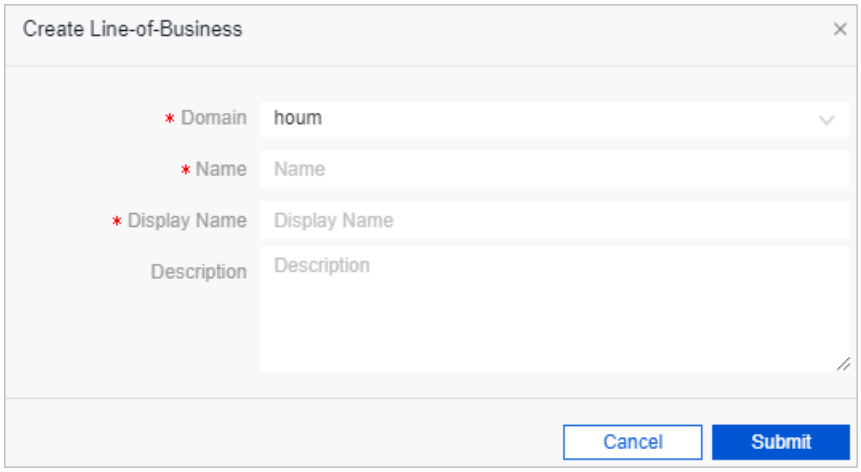
- On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Domains & Lines-of-Business on the left-side navigation submenu. Then, click **Domains & Lines-of-Business Object List** at the bottom of the left-side navigation pane. On the **Domains & Lines-of-Business** page that appears in the workspace, click **+ Create Domain** in the upper-right corner.



5. In the Create Domain dialog box that appears, set the **Domain Name**, **Domain Display Name**, and **Description** parameters. Then, click **Submit**.



6. In the **Description** dialog box that appears, enter the comments on the behavioral domain to be created. Then, click **OK**.



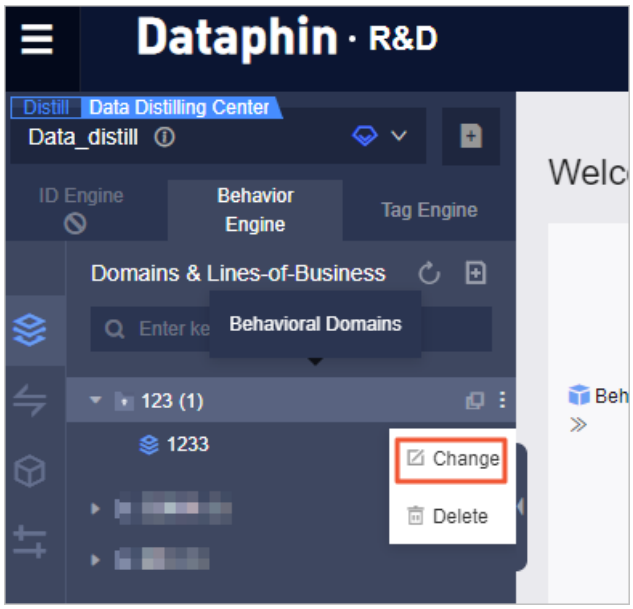
> **Note** Behavioral elements have no states. A behavioral element is published to the production environment after it is created. Therefore, you must enter and submit comments when creating a behavioral element.

Edit a behavioral domain

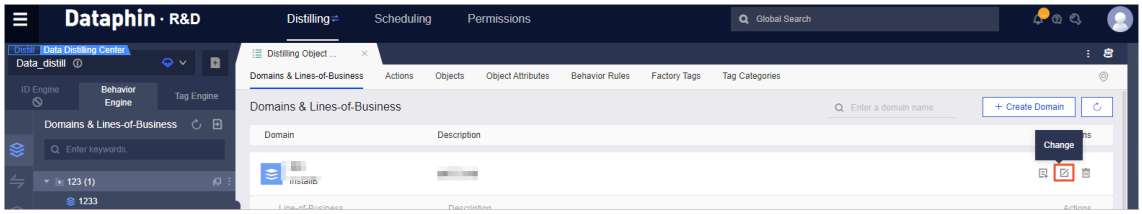
1. Open the **Change Domain** dialog box in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side list, click the target behavioral domain. On the View Attributes tab that appears, click **Change**.

   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the

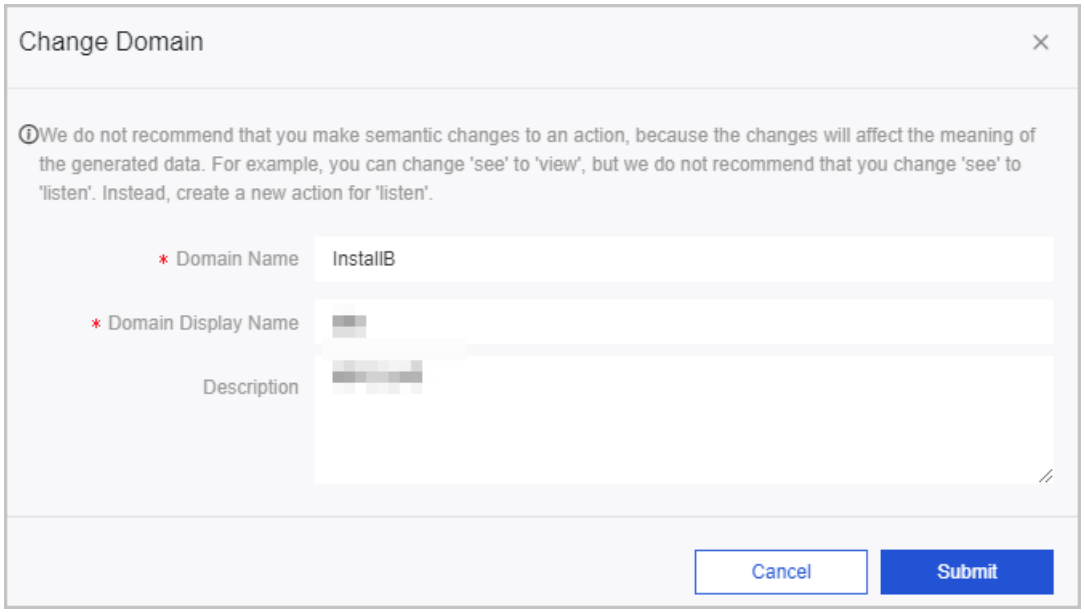
icon on the left-side navigation submenu. In the left-side list, move the pointer over the icon next to the target behavioral domain and select **Change**.



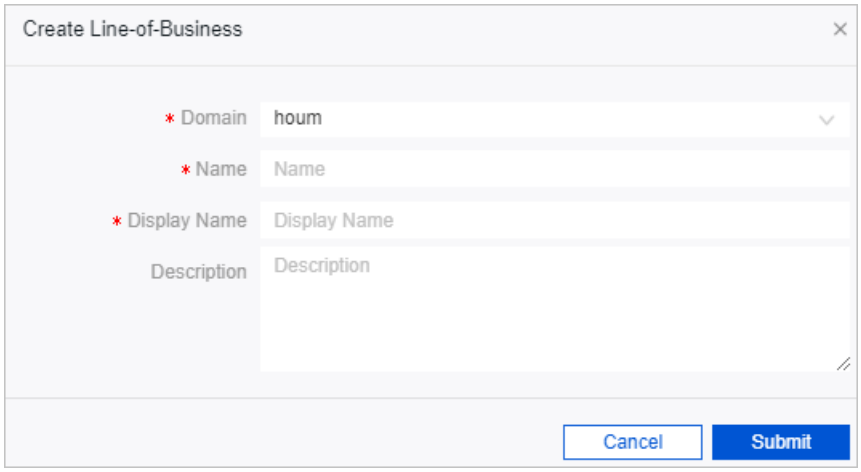
- On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Domains & Lines-of-Business on the left-side navigation submenu. Then, click **Domains & Lines-of-Business Object List** at the bottom of the left-side navigation pane. On the **Domains & Lines-of-Business** page that appears in the workspace, click the icon in the **Actions** column of the target behavioral domain.



2. In the Change Domain dialog box that appears, set the **Domain Name**, **Domain Display Name**, and **Description** parameters. Then, click **Submit**.



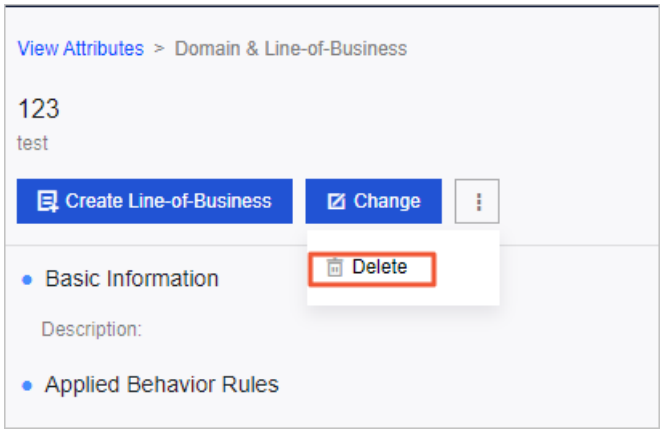
3. In the **Description** dialog box that appears, enter the comments on the behavioral domain to be modified. Then, click **OK**.



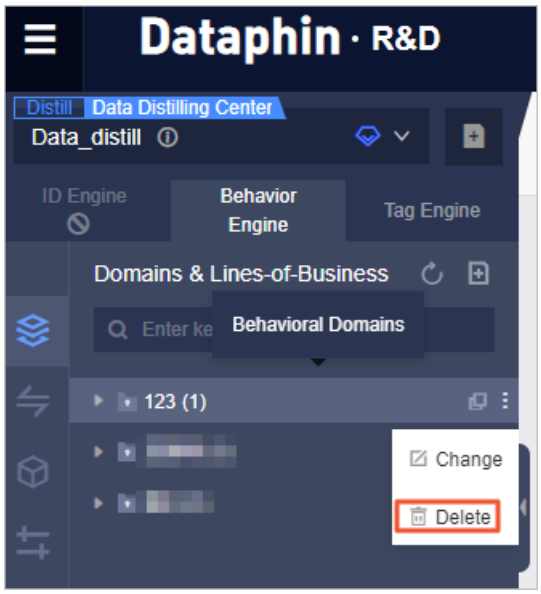
> **Note** Behavioral elements have no states. A behavioral element is published to the production environment after it is edited. Therefore, you must enter and submit comments when editing a behavioral element.

Delete a behavioral domain

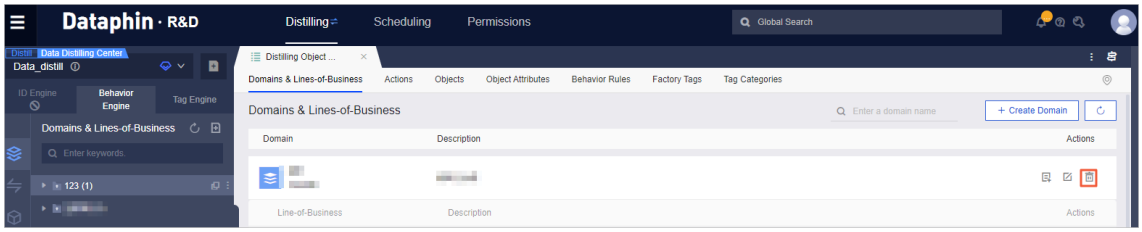
1. Open the **Delete Domain** dialog box in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side list, click the target behavioral domain. On the View Attributes tab that appears, click the icon and select **Delete**.



- On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side list, move the pointer over the icon next to the target behavioral domain and select **Delete**.



- On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Domains & Lines-of-Business on the left-side navigation submenu. Then, click **Domains & Lines-of-Business Object List** at the bottom of the left-side navigation pane. On the **Domains & Lines-of-Business** page that appears in the workspace, click the icon in the **Actions** column of the target behavioral domain.



2. In the **Delete Domain** dialog box that appears, enter the comments on the behavioral domain to be deleted. Then, click **OK**.

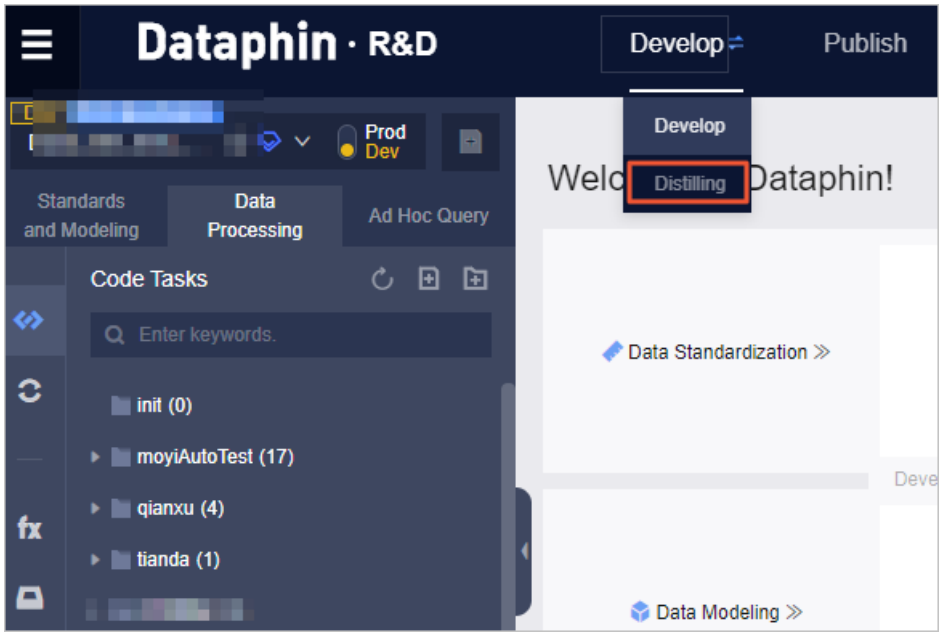
> **Note** A behavioral element is published to the production environment after it is created and is deleted from the production environment after the deletion operation. Therefore, you must enter and submit comments when deleting a behavioral element.

9.10.2.3. Manage lines-of-business

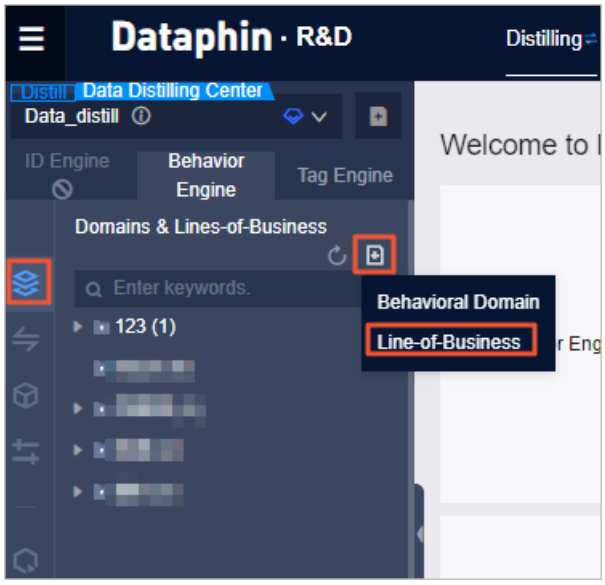
This topic describes how to create, edit, and delete a line-of-business.

Create a line-of-business

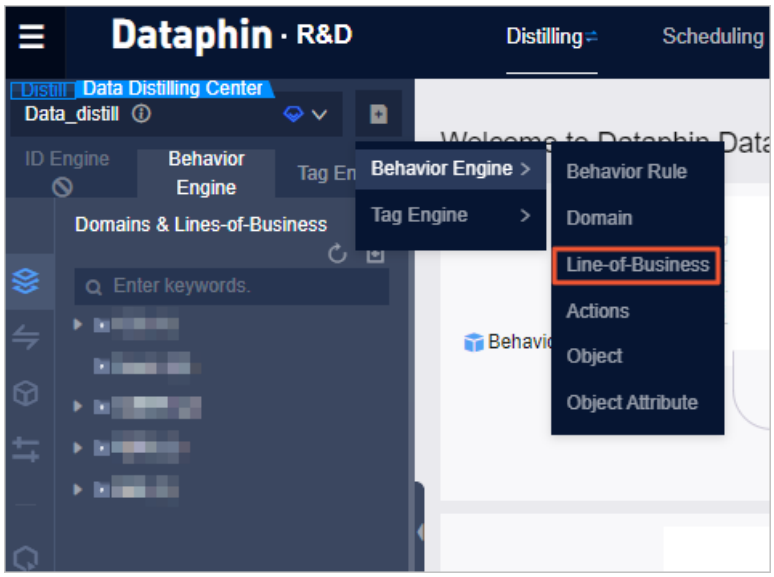
1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the R&D page that appears, move the pointer over Develop in the top navigation bar and select **Distilling**.



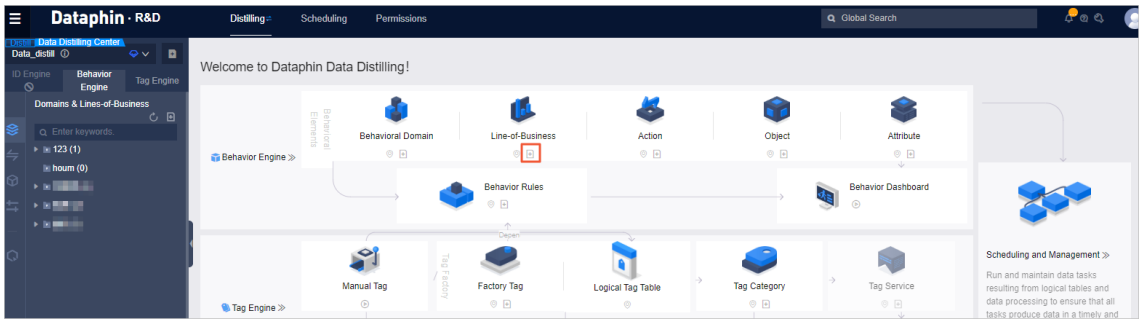
4. Open the **Create Line-of-Business** dialog box in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side navigation pane, click the icon and select **Line-of-Business**.



- On the Distilling tab, click the icon next to the project name and choose **Behavior Engine > Line-of-Business.**

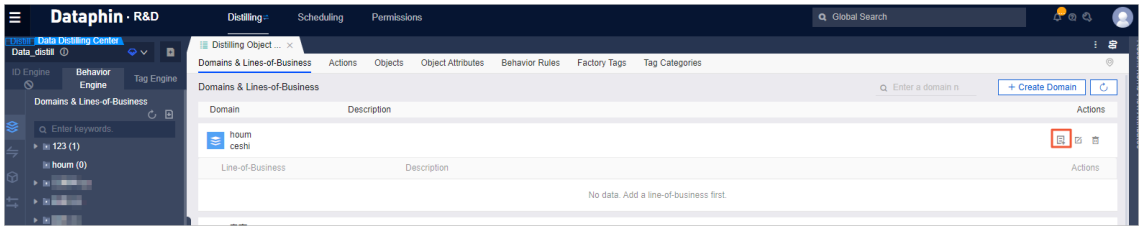


- On the Distilling tab, click the icon below **Line-of-Business** in the workspace.

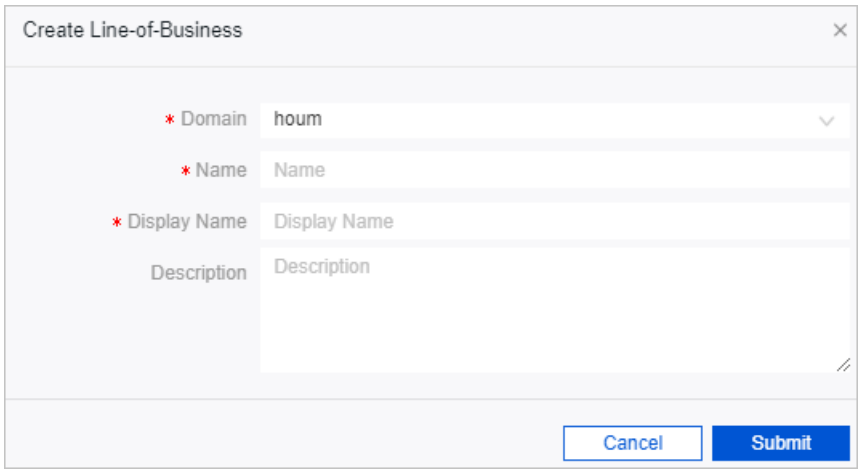


- On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Domains & Lines-of-Business on the left-side navigation submenu. Then, click **Domains & Lines-of-Business Object List** at the bottom of the left-side navigation pane. On the

Domains & Lines-of-Business page that appears in the workspace, click the icon in the **Actions** column of the target behavioral domain.

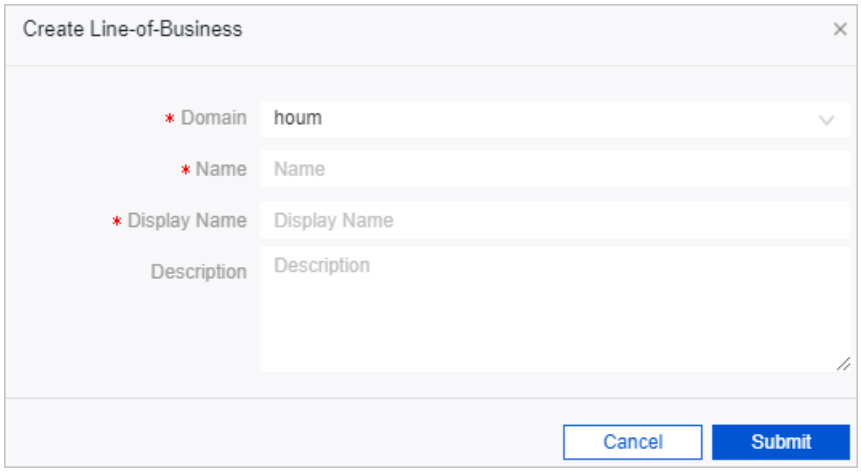


5. In the Create Line-of-Business dialog box that appears, set the **Domain**, **Name**, **Display Name**, and **Description** parameters. Then, click **Submit**.



> **Note**
>
> - The name and display name of the line-of-business cannot be the same as those of the existing lines-of-business.
> - A line-of-business depends on a behavioral domain. When you create a line-of-business, select the behavioral domain where the line-of-business resides from the drop-down list.

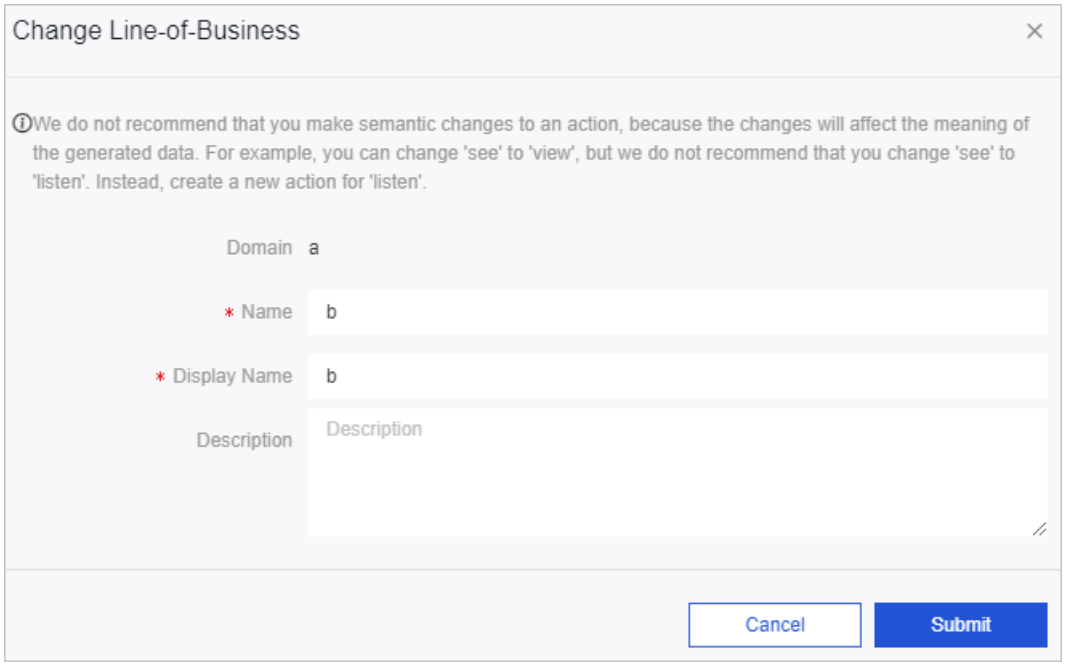
6. In the **Description** dialog box that appears, enter the comments on the line-of-business to be created. Then, click **OK**.



> **Note** A behavioral element is published to the production environment after it is created. Therefore, you must enter and submit comments when creating a behavioral element.

Edit a line-of-business

1. Open the **Change Line-of-Business** dialog box in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side line-of-business list, click the target line-of-business. On the View Attributes tab that appears, click **Change**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side line-of-business list, move the pointer over the icon next to the target line-of-business and select **Change**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Domains & Lines-of-Business on the left-side navigation submenu. Then, click **Domains & Lines-of-Business Object List** at the bottom of the left-side navigation pane. On the **Domains & Lines-of-Business** page that appears in the workspace, click the icon in the **Actions** column of the target line-of-business.
2. In the Change Line-of-Business dialog box that appears, set the **Name**, **Display Name**, and **Description** parameters. Then, click **Submit**.



> **Note** The name and display name of the line-of-business cannot be the same as those of the existing lines-of-business.

3. In the **Description** dialog box that appears, enter the comments on the line-of-business to be modified. Then, click **OK**.

> Note A behavioral element is published to the production environment after it is edited. Therefore, you must enter and submit comments when editing a behavioral element.

Delete a line-of-business

1. Open the **Delete Line-of-Business** dialog box in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side line-of-business list, click the target line-of-business. On the View Attributes tab that appears, click the icon and select **Delete**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side line-of-business list, move the pointer over the icon next to the target line-of-business and select **Delete**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Domains & Lines-of-Business on the left-side navigation submenu. Then, click **Domains & Lines-of-Business Object List** at the bottom of the left-side navigation pane. On the **Domains & Lines-of-Business** page that appears in the workspace, click the icon in the **Actions** column of the target line-of-business.
2. In the **Delete Line-of-Business** dialog box that appears, enter the comments on the line-of-business to be deleted. Then, click **OK**.

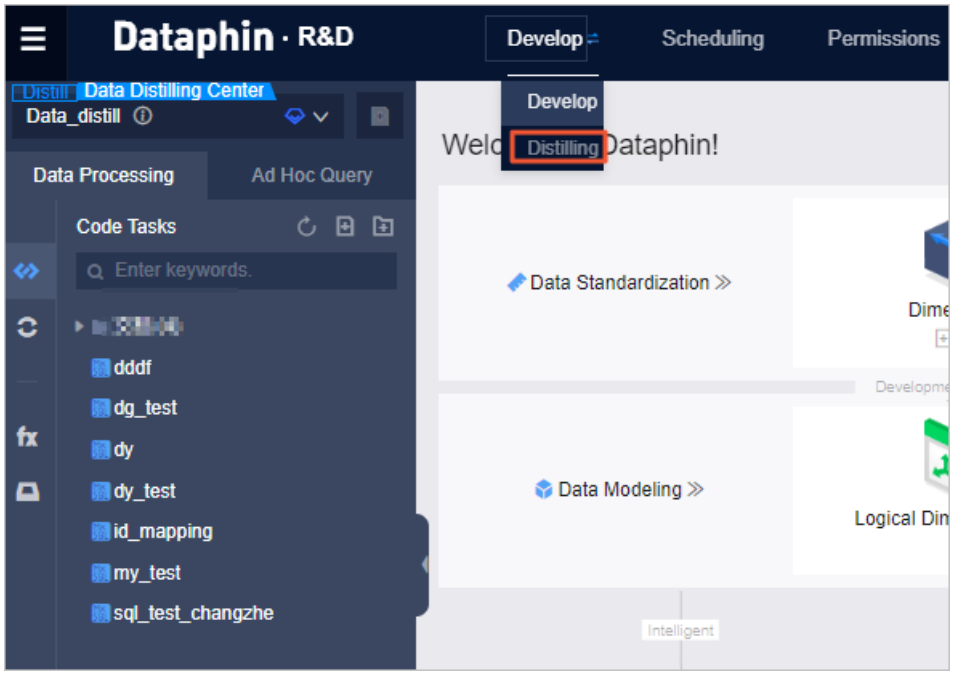
> Note
> - After a behavioral element is deleted, the relevant data is cleared from the production environment. Therefore, you must enter and submit comments when deleting a behavioral element.
> - You cannot delete a behavioral element on which a behavior rule depends.

9.10.2.4. Manage actions

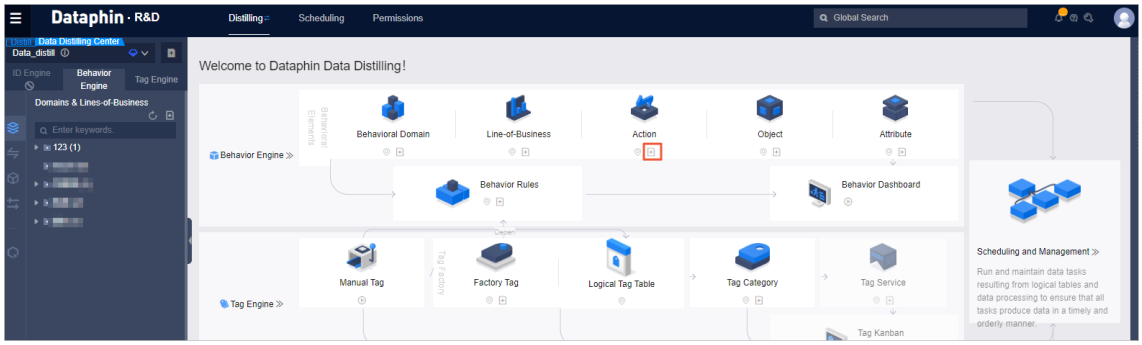
This topic describes how to create, edit, and delete an action.

Create an action

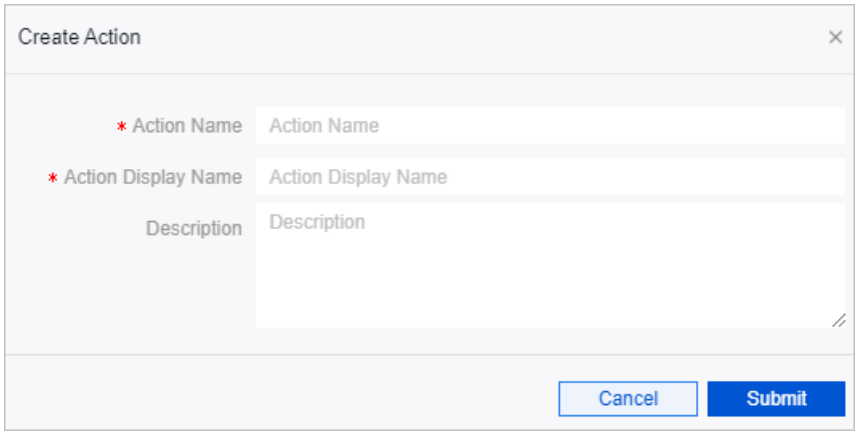
1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the R&D page that appears, move the pointer over Develop in the top navigation bar and select **Distilling**.



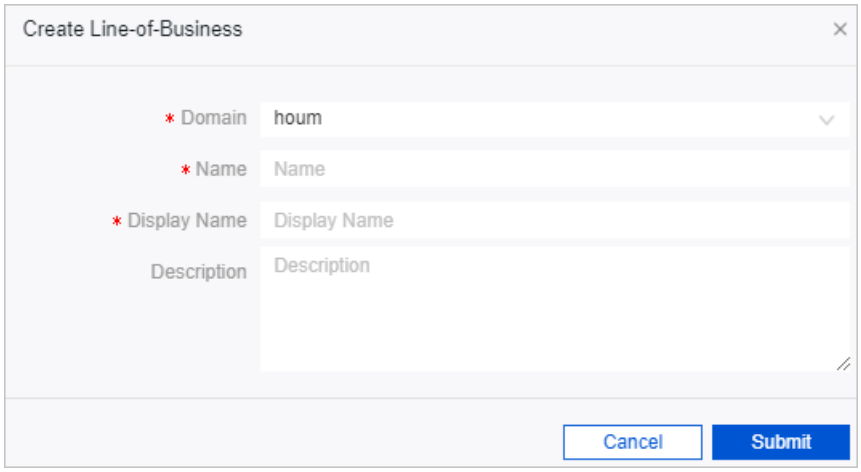
4. Open the **Create Action** dialog box in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side navigation pane, click the icon.
   - On the Distilling tab, click the icon next to the project name and choose **Behavior Engine > Actions**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Actions on the left-side navigation submenu. Then, click **Actions Object List** at the bottom of the left-side navigation pane. On the **Actions** page that appears in the workspace, click **+ Create Action** in the upper-right corner.
   - On the Distilling tab, click the icon below **Action** in the workspace.



5. In the Create Action dialog box that appears, set the **Action Name**, **Action Display Name**, and **Description** parameters. Then, click **Submit**.



6. In the **Description** dialog box that appears, enter the comments on the action to be created. Then, click **OK**.

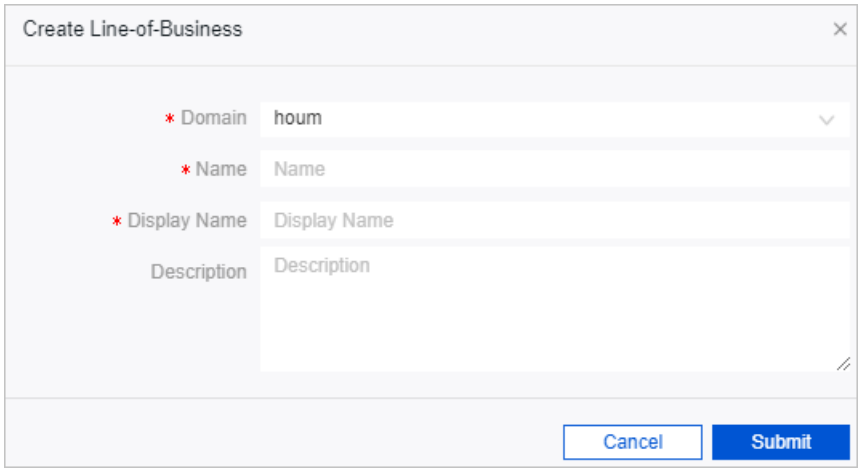


> **Note** Behavioral elements have no states. A behavioral element is published to the production environment after it is created. Therefore, you must enter and submit comments when creating a behavioral element.

Edit an action

1. Open the **Change Action** dialog box in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side action list, click the target action. On the View Attributes tab that appears, click **Change**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side action list, move the pointer over the icon next to the target action and select **Change**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Actions on the left-side navigation submenu. Then, click **Actions Object List** at the bottom of the left-side navigation pane. On the **Actions** page that appears in the workspace, click the icon in the **Actions** column of the target action.
2. In the Change Action dialog box that appears, set the **Action Name**, **Action Display Name**,

and **Description** parameters. Then, click **Submit**.



> **Note**
>
> - **Action Name**: the name of the action. The name can contain letters, digits, and underscores (_).
> - **Action Display Name**: the display name of the action. The display name can contain Chinese characters, digits, letters, underscores (_), and hyphens (-).
> - **Description**: the description of the action. The description can be up to 128 characters in length.

3. In the **Description** dialog box that appears, enter the comments on the action to be modified. Then, click **OK**.

> **Note** Behavioral elements have no states. A behavioral element is published to the production environment after it is edited. Therefore, you must enter and submit comments when editing a behavioral element.

Delete an action

1. Open the **Delete Action** dialog box in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side action list, click the target action. On the View Attributes tab that appears, click **Delete**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side action list, move the pointer over the icon next to the target action and select **Delete**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Actions on the left-side navigation submenu. Then, click **Actions Object List** at the bottom of the left-side navigation pane. On the **Actions** page that appears in the workspace, click the icon in the **Actions** column of the target action.
2. In the **Delete Action** dialog box that appears, enter the comments on the action to be deleted. Then, click **OK**.

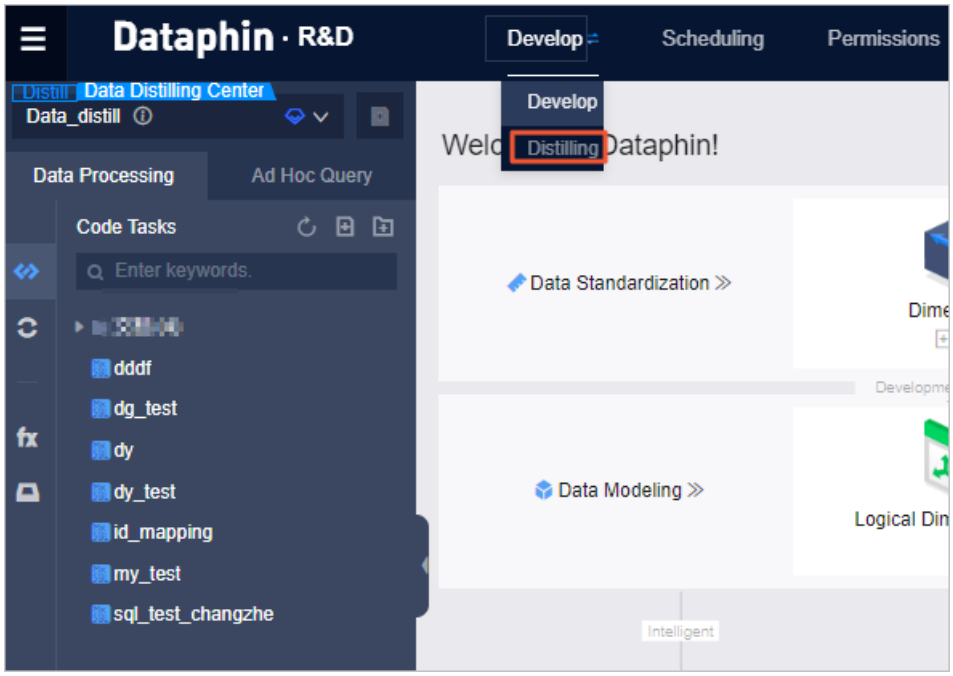
> **Note** A behavioral element is published to the production environment after it is created and is deleted from the production environment after the deletion operation. Therefore, you must enter and submit comments when deleting a behavioral element.

9.10.2.5. Manage objects

This topic describes how to create, edit, and delete an object.

Create an object

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the R&D page that appears, move the pointer over Develop in the top navigation bar and select **Distilling**.



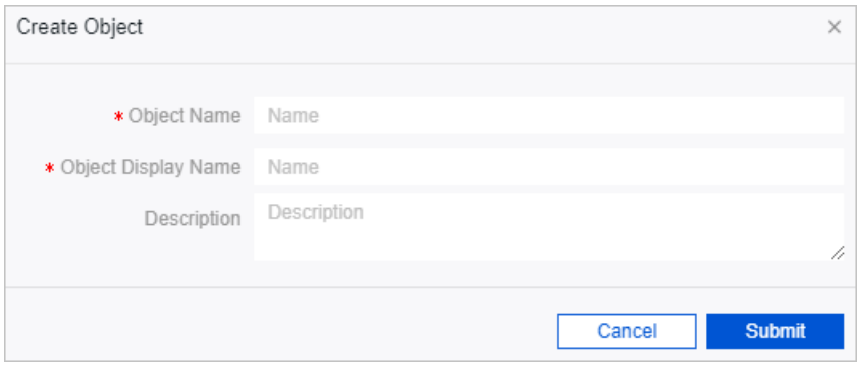
4. Open the Create Object dialog box in one of the following ways: On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side navigation pane, click the icon.

   On the Distilling tab, click the icon next to the project name and choose Behavior Engine > **Object**.

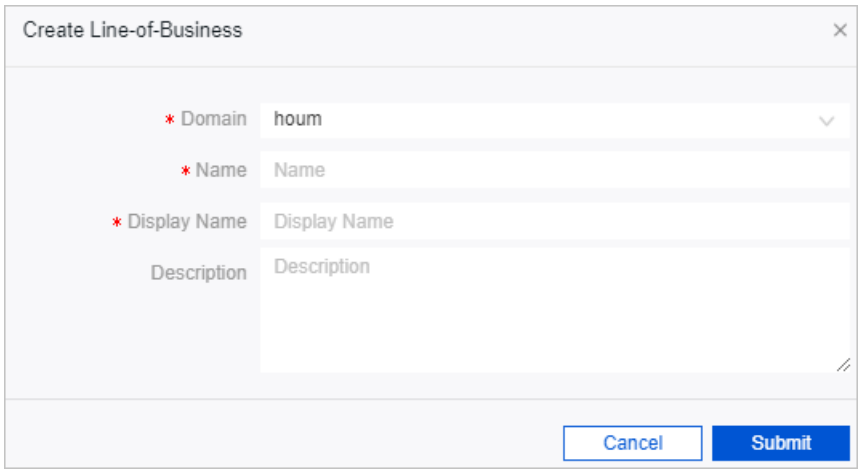
   On the Distilling tab, click the icon below **Object** in the workspace.

   On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Objects on the left-side navigation submenu. Then, click **Objects Object List** at the bottom of the left-side navigation pane. On the Objects page that appears in the workspace, click **+ Create Object** in the upper-right corner.
5. In the Create Object dialog box that appears, set the **Object Name**, **Object Display Name**,

and **Description** parameters. Then, click **Submit**.



6. In the **Description** dialog box that appears, enter the comments on the object to be created. Then, click **OK**.



> **Note** Behavioral elements have no states. A behavioral element is published to the production environment after it is created. Therefore, you must enter and submit comments when creating a behavioral element.

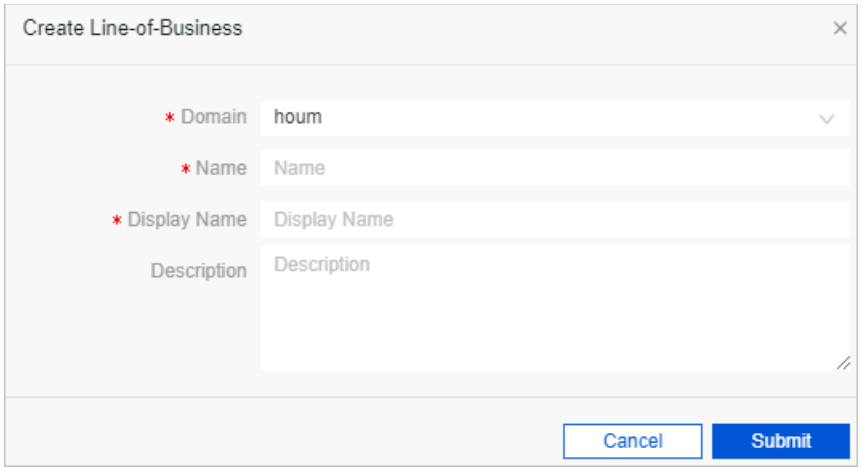
Edit an object

1. On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side object list, click the target object. On the View Attributes tab that appears, click Change.

   To edit an object, you can move the pointer over the icon next to the target object in the left-side object list and select **Change**.

   You can also click Objects Object List at the bottom of the left-side navigation pane. On the Objects page that appears in the workspace, click the icon in the **Actions** column of the target object.

2. In the **Change Object** dialog box that appears, set the **Object Name**, **Object Display Name**, and **Description** parameters. Then, click **Submit**.



3. In the **Description** dialog box that appears, enter the comments on the object to be modified. Then, click **OK**.

> **Note** Behavioral elements have no states. A behavioral element is published to the production environment after it is edited. Therefore, you must enter and submit comments when editing a behavioral element.

Delete an object

1. On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side object list, click the target object. On the View Attributes tab that appears, click **Delete**.

   To delete an object, you can move the pointer over the icon next to the target object in the left-side object list and select **Delete**.

   You can also click Objects Object List at the bottom of the left-side navigation pane. On the Objects page that appears in the workspace, click the icon in the **Actions** column of the target object.

2. In the **Delete Object** dialog box that appears, enter the comments on the object to be deleted. Then, click **OK**.

> **Note** A behavioral element is published to the production environment after it is created and is deleted from the production environment after the deletion operation. Therefore, you must enter and submit comments when deleting a behavioral element.

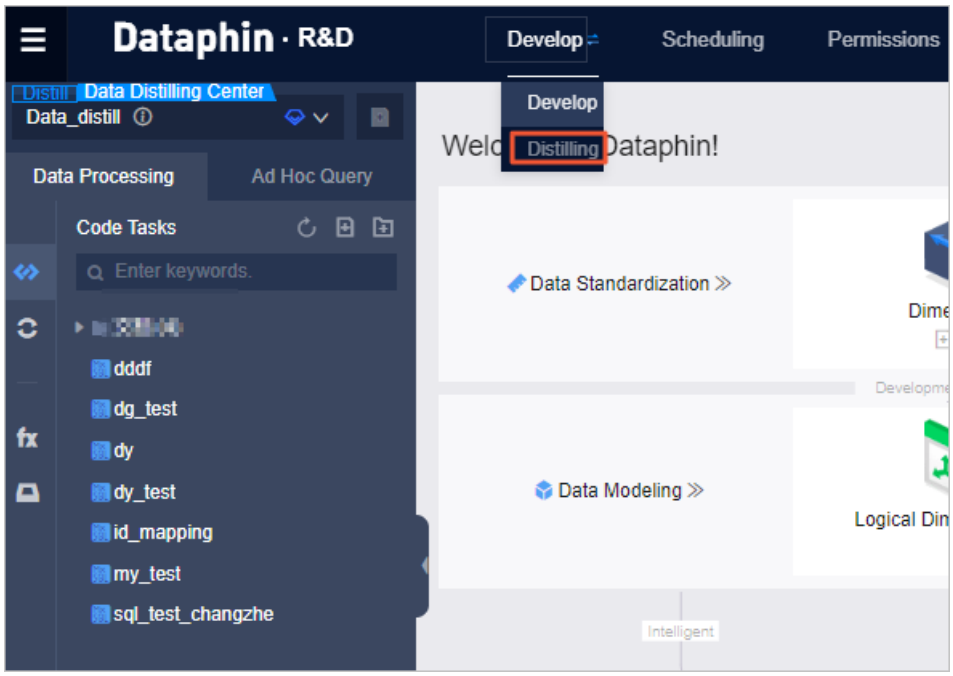
9.10.2.6. Manage object attributes

This topic describes how to create, edit, and delete an object attribute.

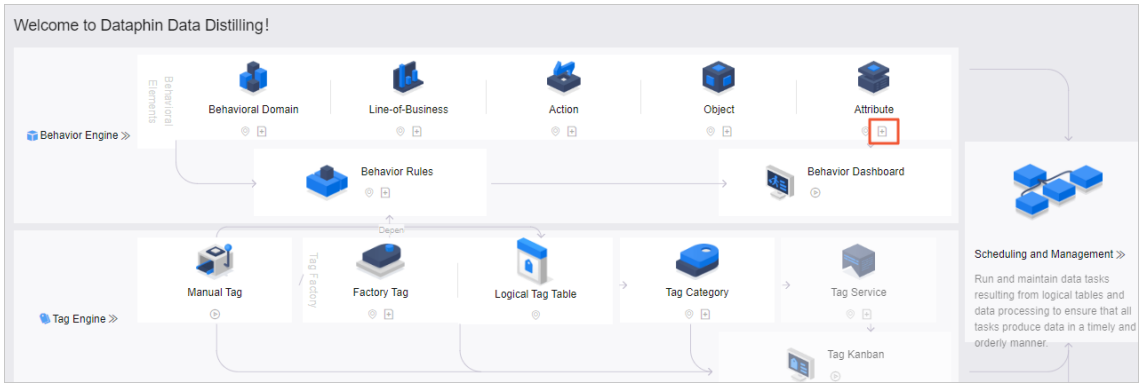
Create an object attribute

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the R&D page that appears, move the pointer over Develop in the top navigation bar and

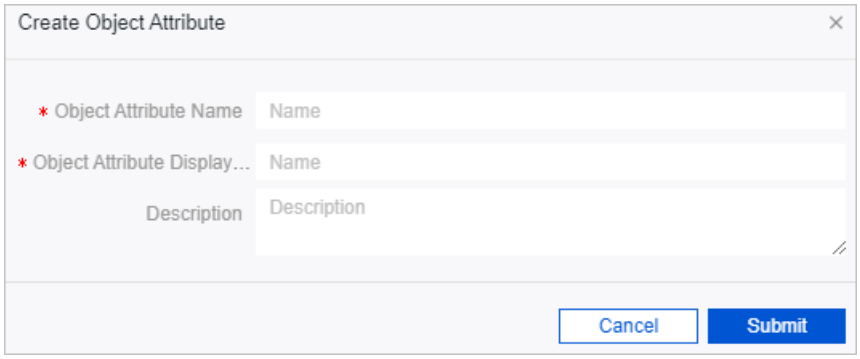
select **Distilling**.



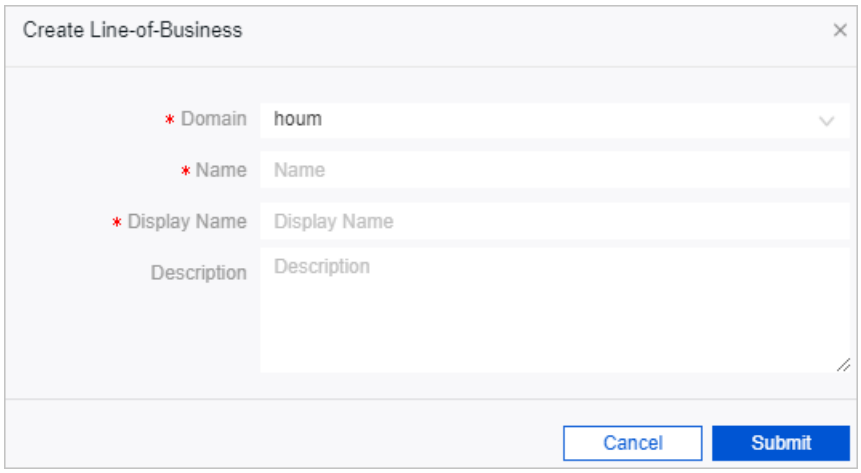
4. Open the **Create Object Attribute** dialog box in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side navigation pane, click the icon.
   - On the Distilling tab, click the icon next to the project name and choose **Behavior Engine > Object Attribute**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Object Attributes on the left-side navigation submenu. Then, click **Object Attributes Object List** at the bottom of the left-side navigation pane. On the **Object Attributes** page that appears in the workspace, click **+ Create Object Attribute** in the upper-right corner.
   - On the Distilling tab, click the icon below **Attribute** in the workspace.



5. In the Create Object Attribute dialog box that appears, set the **Object Attribute Name**, **Object Attribute Display Name**, and **Description** parameters. Then, click **Submit**.



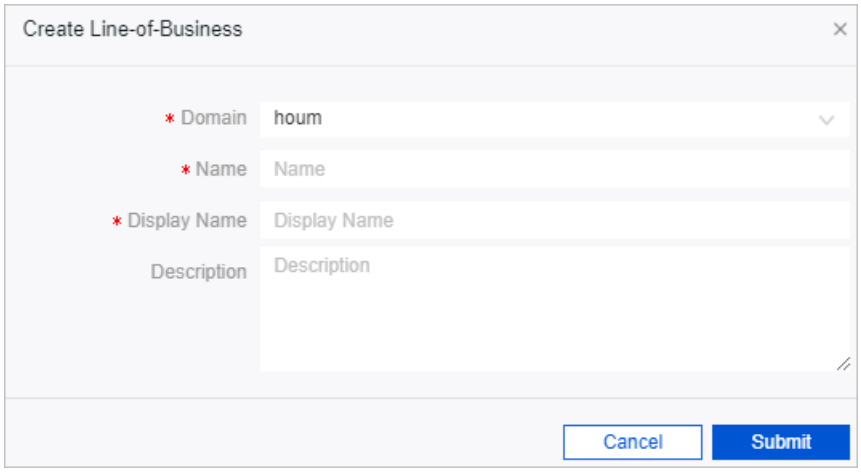
6. In the **Description** dialog box that appears, enter the comments on the object attribute to be created. Then, click **OK**.



> **Note** Behavioral elements have no states. A behavioral element is published to the production environment after it is created. Therefore, you must enter and submit comments when creating a behavioral element.

Edit an object attribute

1. Open the **Change Object Attribute** dialog box in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side object attribute list, click the target object attribute. On the View Attributes tab that appears, click **Change**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side object attribute list, move the pointer over the icon next to the target object attribute and select **Change**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Object Attributes on the left-side navigation submenu. Then, click **Object Attributes Object List** at the bottom of the left-side navigation pane. On the **Object Attributes** page that appears in the workspace, click the icon in the **Actions** column of the target object attribute.
2. In the Change Object Attribute dialog box that appears, set the **Object Attribute Name**, **Object Attribute Display Name**, and **Description** parameters. Then, click **Submit**.



3. In the **Description** dialog box that appears, enter the comments on the object attribute to be modified. Then, click **OK**.

> **Note** Behavioral elements have no states. A behavioral element is published to the production environment after it is edited. Therefore, you must enter and submit comments when editing a behavioral element.

Delete an object attribute

1. Open the **Delete Object Attributes** dialog box in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side object attribute list, click the target object attribute. On the View Attributes tab that appears, click **Delete**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side object attribute list, move the pointer over the icon next to the target object attribute and select **Delete**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Object Attributes on the left-side navigation submenu. Then, click **Object Attributes Object List** at the bottom of the left-side navigation pane. On the **Object Attributes** tab that appears in the workspace, click the icon in the **Actions** column of the target object attribute.
2. In the **Delete Object Attributes** dialog box that appears, enter the comments on the object attribute to be deleted. Then, click **OK**.

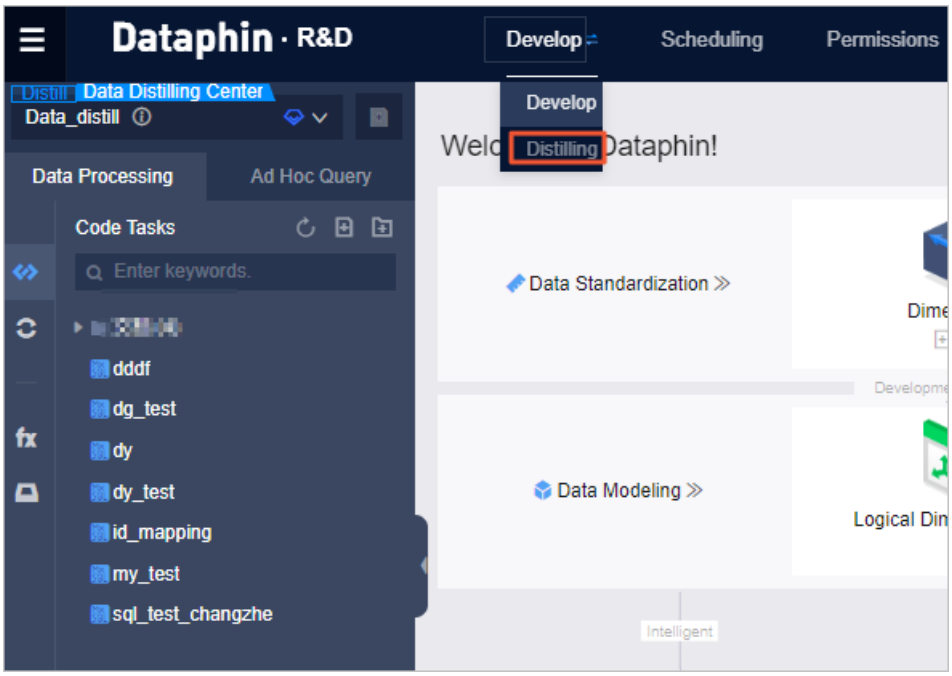
> **Note** A behavioral element is published to the production environment after it is created and is deleted from the production environment after the deletion operation. Therefore, you must enter and submit comments when deleting a behavioral element.

9.10.2.7. Create a behavior rule

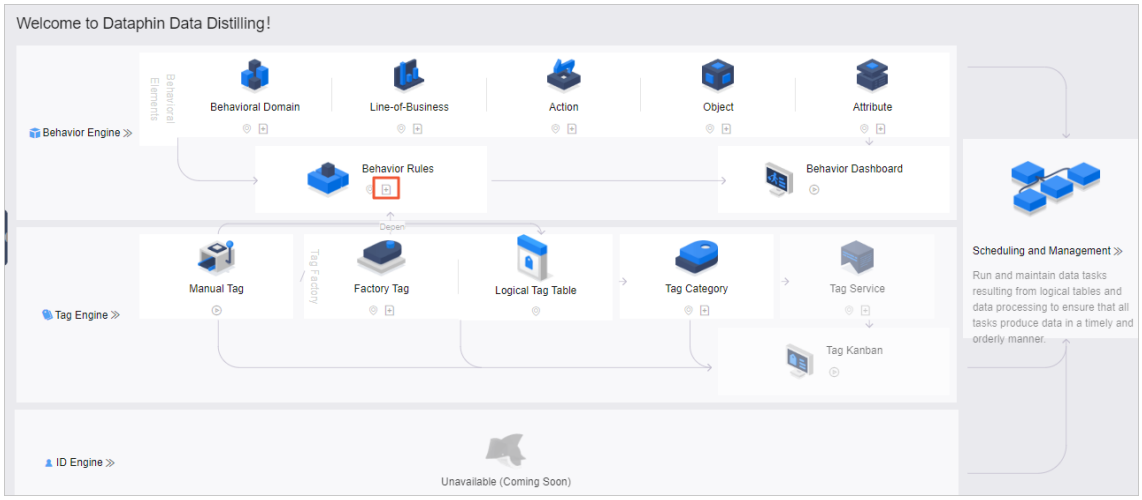
This topic describes how to create a behavior rule and configure the scheduling policy and conversion task settings for the rule.

1. Log on to the Dataphin console.

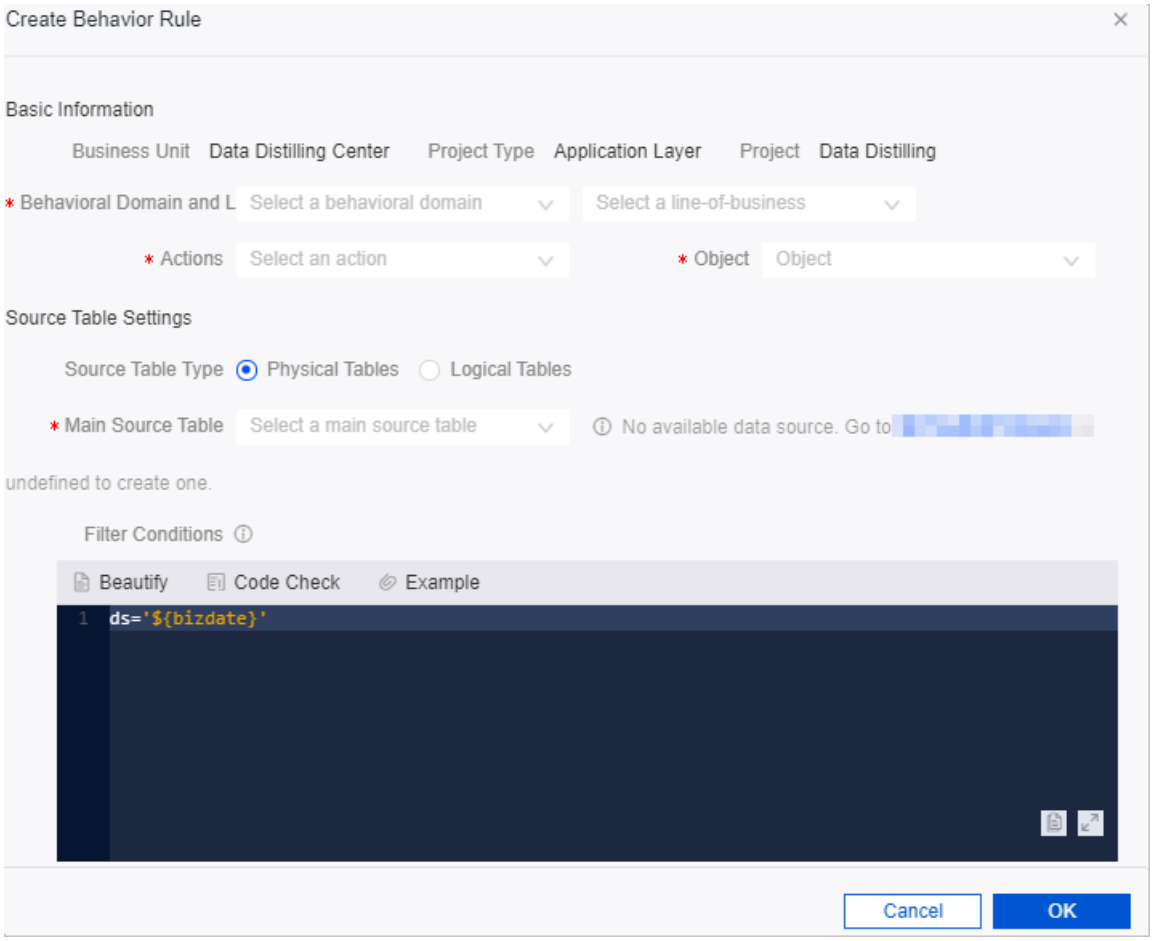
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the R&D page that appears, move the pointer over Develop in the top navigation bar and select **Distilling**.



4. Open the **Create Behavior Rule** dialog box in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side navigation pane, click the icon.
   - On the Distilling tab, click the icon next to the project name and choose **Behavior Engine > Behavior Rule**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Behavior Rules on the left-side navigation submenu. Then, click **Behavior Rules Object List** at the bottom of the left-side navigation pane. On the **Behavior Rules** page that appears in the workspace, click **+ Create Behavior Rule** in the upper-right corner.
   - On the Distilling tab, click the icon below **Behavior Rules** in the workspace.



5. In the **Create Behavior Rule** dialog box that appears, set the parameters as prompted.



Section	Parameter	Description
Basic Information	Behavioral Domain and Line-of-Business	Select a behavioral domain and a line-of-business.
	Actions	Select an action.
	Object	Select an object.

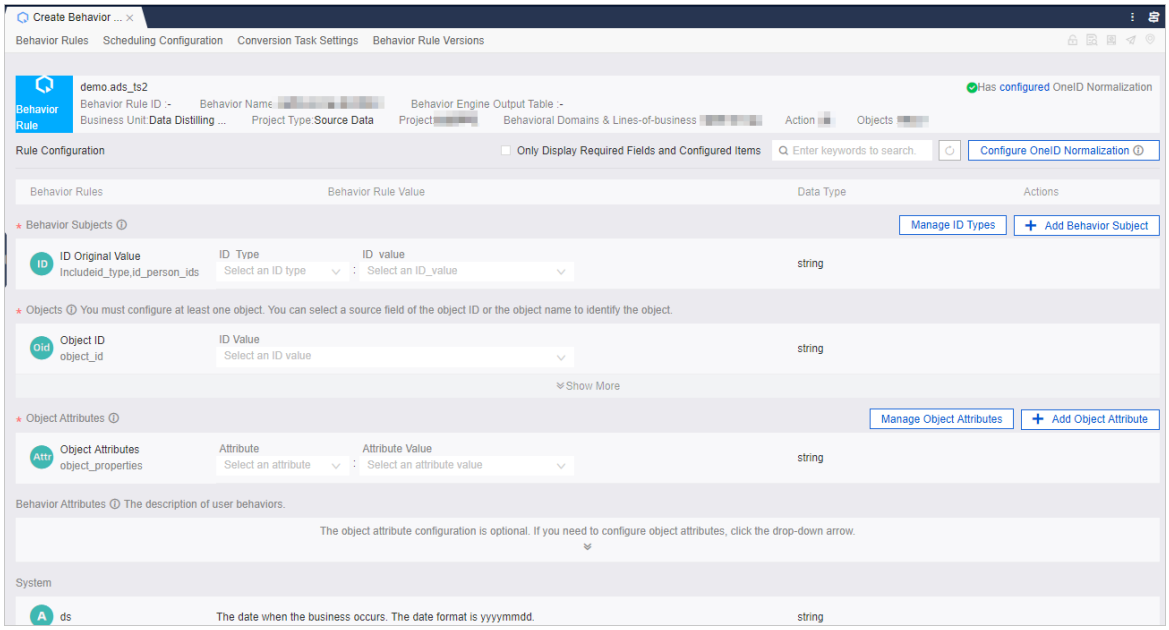
Section	Parameter	Description
Source Table Settings	Source Table Type	Select Physical Tables or Logical Tables.
	Main Source Table	○ If you set Source Table Type to Physical Tables, you can only select the main source table. ○ If you set Source Table Type to Logical Tables, select a business unit and then select the main source table.
	Filter Conditions	Enter filter conditions, such as `ds=${bizdate}`, used to cleanse data records in the source table.

> **Note**
> - If you select a main source table in the development environment, the system cannot automatically parse the task dependencies during scheduling configuration.
> - You must focus on the source table of the behavioral data and the filter conditions to make sure that the source table meets the behavioral data requirements. Otherwise, you cannot create a behavior rule.

6. Click **OK** to go to the **Rule Configuration** page.

   On the **Rule Configuration** page that appears, you can view the basic information and source table settings that have been configured for the behavior rule. To modify the basic information or source table settings of the behavior rule, click **Behavior Rules** at the top of the page. In the **Behavior Rules** dialog box that appears, set the parameters.

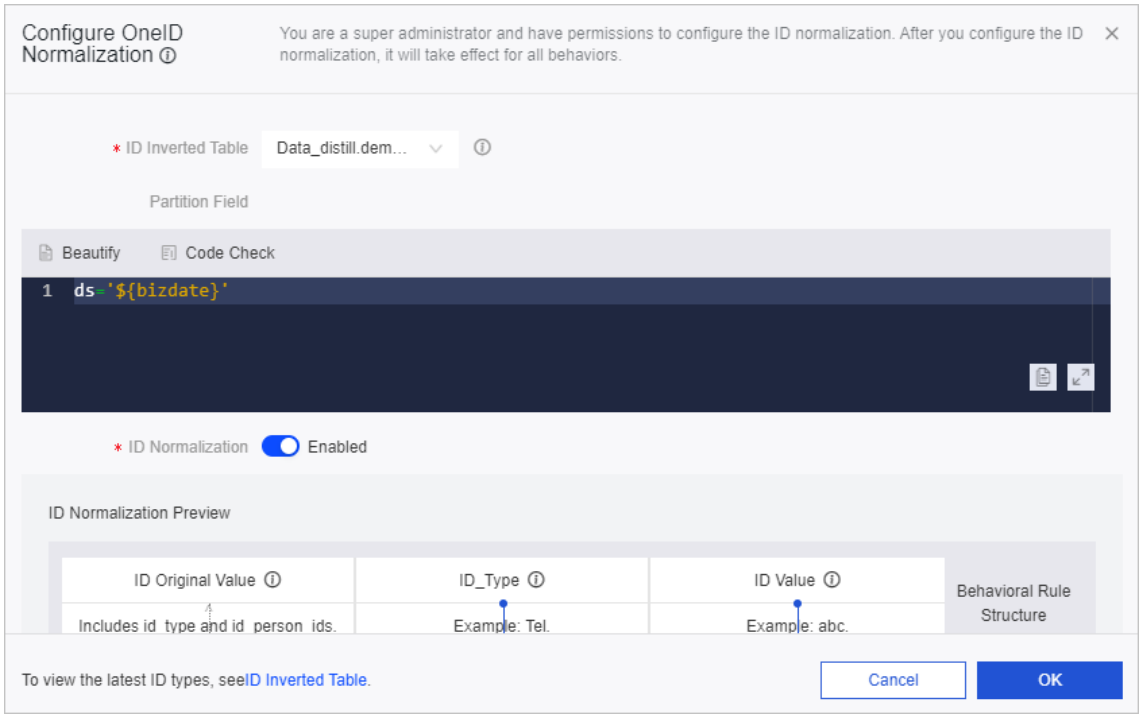
7. On the Rule Configuration page, set the parameters as prompted.



Section	Parameter	Description
Behavior Subjects	**ID Original Value**	Select an ID type from the **ID_Type** drop-down list and select an ID value from the **ID_value** drop-down list. ○ You can click **Manage ID Types**. In the Manage ID Types dialog box that appears, click **+ Add ID Type** to add a custom ID type. The built-in ID types include **OneID**, **Mobile**, **UserID**, **Email**, and **IPAddress**. ○ To add one or more behavior subjects, click **+ Add Behavior Subject**. You can delete an existing behavior subject only when more than one behavior subject exists. **Note** You can delete a custom ID type, but cannot delete or modify the built-in ID types.
Objects	**Object ID**	Select an ID value from the **ID Value** drop-down list.
	Object Display Name	Select a display name for the object from the **Object Display Name** drop-down list. **Note** In the Objects section, the object ID and display name are only used to identify objects and cannot be used as object attributes. If you want to use the object ID or display name as an object attribute, add the object ID or display name to the **Object Attributes** section.

Section	Parameter	Description
Object Attributes	Object Attributes	An object attribute is the factual description of an object, such as the name, year, or director of a video object. Select an object attribute from the **Attribute** drop-down list and select an attribute value from the **Attribute Value** drop-down list. ◦ If no object attribute is available, you can click **Manage Object Attributes** to go to the **Object Attributes** page. On the Object Attributes page that appears, you can create object attributes and manage existing object attributes. For more information, see Manage object attributes. ◦ You can click **+ Add Object Attribute** to add one or more object attributes. You can also delete existing object attributes. However, you must retain at least one object attribute. **Note** Make sure that the source fields of the attribute values are stable to prevent the subsequent tag calculation results from being affected by the attribute value changes. Generally, each attribute value of an object is stable and unique. You can select an object attribute that has been defined as a behavioral element from the Attribute drop-down list.
Behavior Attributes	Times Occurred	Optional. If the source table you select contains a field that indicates the number of occurrences of the behavior, you can click the icon and select an attribute value from the **Attribute Value** drop-down list to add the field as a behavior attribute.
System	ds	The partition field that is automatically created based on the system data timestamp for the Behavior Engine output table, in the format of yyyymmdd.

◦ If you have a standard ID inverted table, click **Configure OneID Normalization** to import the ID inverted table. The enabled ID normalization feature takes effect for all rules.

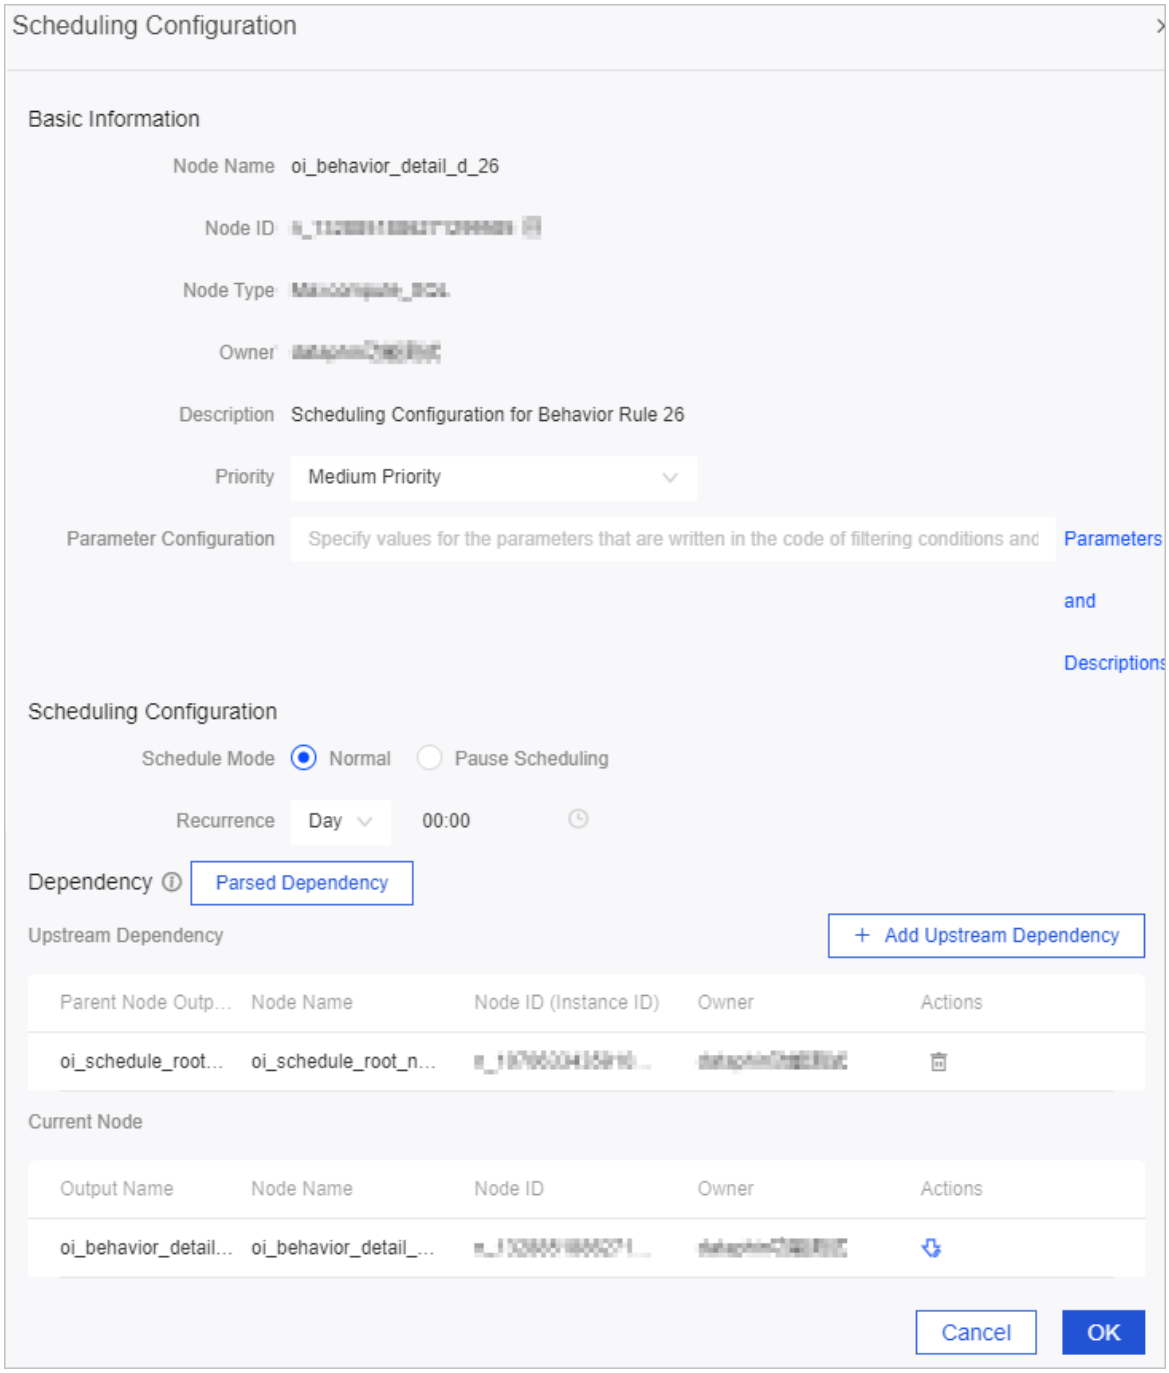


You can click ID Inverted Table at the bottom of the dialog box to view the table schema. If you have selected the ID type, you can click ID Type to view the details of the inverted table.

> **Note**
>
> - Only the super administrator can enable or disable ID normalization.
> - Based on the OneID methodology, the ID inverted table uses algorithms to connect different IDs of the same user through OneID.
> - After ID normalization is enabled, if the selected ID type of a behavior subject is normalized and contained in the ID inverted table, the result table generates records based on OneID and the ID type. If the ID type of the behavior subject is not normalized or is not contained in the ID inverted table, the result table generates records based on the ID type.

- **If you do not have a standard ID inverted table, you can also choose Develop > Data Processing in the Data_distill project to create a task and import the ID inverted table. Make sure that the output name of the task node for the ID inverted table is in the format of Project name.Table name, for example,** `Data_distill.Inverted table name` **.**

8. **On the Rule Configuration page, click Scheduling Configuration at the top. In the Scheduling Configuration dialog box that appears, set the parameters as prompted. Then, click OK.**

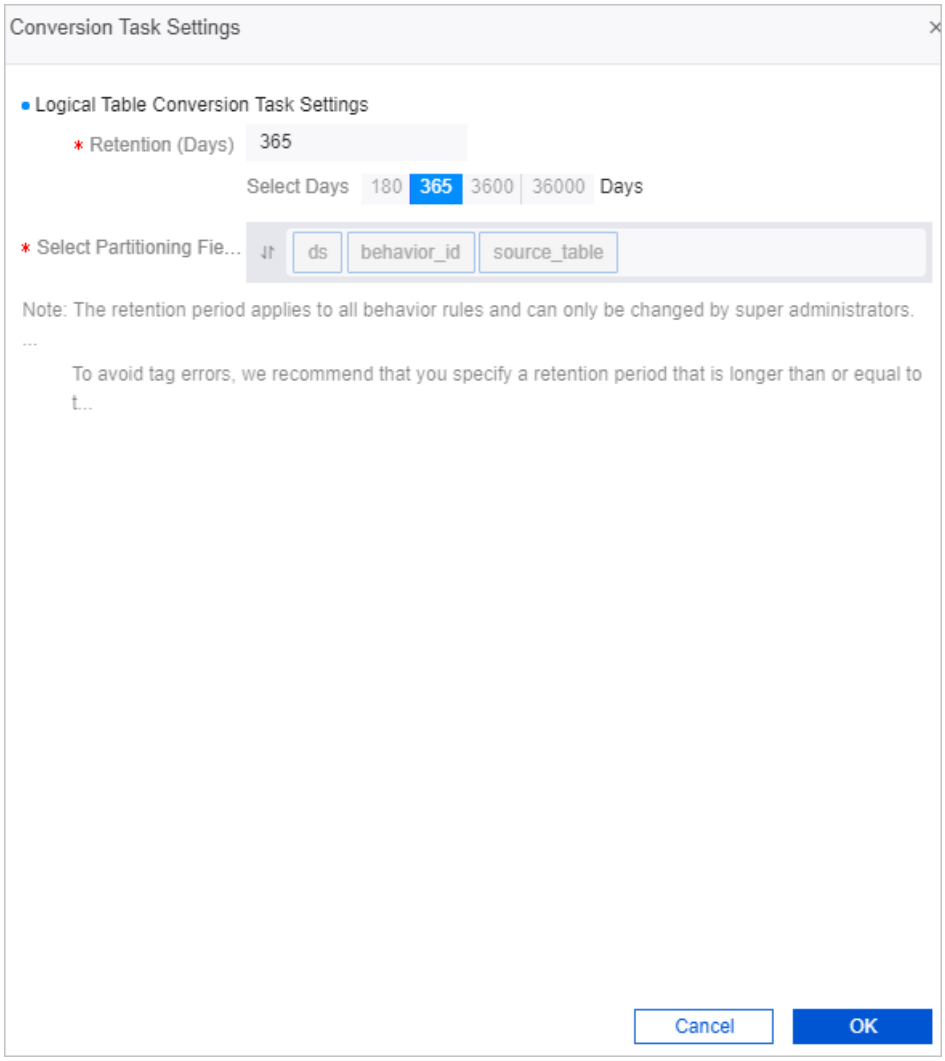


Section	Parameter	Description

Section	Parameter	Description
Basic Information	Priority	Dataphin automatically generates the node name, node ID, node type, owner, and description. You cannot modify these parameters. You can select the priority of the task corresponding to the behavior rule. Valid values: ○ Lowest Priority ○ Low Priority ○ Medium Priority ○ High Priority ○ Highest Priority
	Parameter Configuration	You can set variables for the filter conditions of the source table. For more information, see the page that appears after you click Parameters and Descriptions.
Scheduling Configuration	Schedule Mode	You can set Schedule Mode to Normal or Pause Scheduling.
	Recurrence	You can set Recurrence to Day, Week, or Month. ○ If you select Day, click the icon to specify the time of a day. ○ If you select Month, select a date from the drop-down list and then click the icon to specify the time of a day. ○ If you select Week, select a day in a week from the drop-down list and then click the icon to specify the time of a day.

Section	Parameter	Description
Dependency	Upstream Dependency	◦ You can click **Parsed Dependency**. Dataphin automatically parses the upstream dependency based on the selected source table. ◦ You can click **+ Add Upstream Dependency** to add nodes in the production environment that are from projects in Basic mode or Prod mode as the upstream dependency. **Note** ◦ If the source table is a logical table, the parent node parsed by the system cannot be deleted. ◦ If the source table is a physical table, the parent node parsed by the system can be deleted. ◦ If you change the source table, the parsed upstream nodes are cleared. You may need to manually parse the upstream dependency or modify the upstream nodes. ◦ If the automatic parsing fails, you can click **Parsed Dependency** to parse the dependency again. The parent node that you manually added will not be overwritten by the parsed parent node.
	Current Node	You can click the icon to view downstream nodes.

9. On the Rule Configuration page, click **Conversion Task Settings** at the top. In the Conversion Task Settings dialog box that appears, set the parameters as prompted. Then, click **OK**.



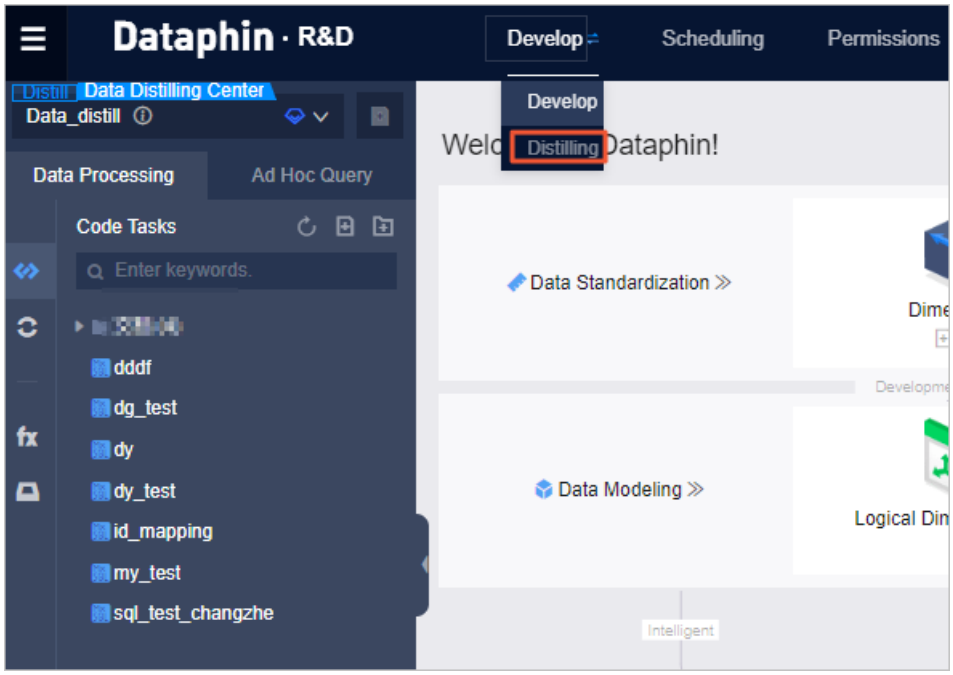
10. In the upper-right corner of the page, click the icon to preview the behavior rule, click the icon to save the configuration, or click the icon to submit the behavior rule.

9.10.2.8. Manage behavior rules

This topic describes how to manage behavior rules, for example, how to view and edit a behavior rule.

Edit a behavior rule

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the R&D page that appears, move the pointer over Develop in the top navigation bar and select **Distilling**.



4. Go to the **Rule Configuration** page in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side behavior rule list, click the target behavior rule. On the View Attributes tab that appears, click **Change**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Behavior Rules on the left-side navigation submenu. Then, click **Behavior Rules Object List** at the bottom of the left-side navigation pane. On the **Behavior Rules** page that appears in the workspace, click the icon in the **Actions** column of the target behavior rule.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side behavior rule list, move the pointer over the icon next to the target behavior rule and select **Change**.
5. On the **Rule Configuration** page that appears, click **Behavior Rules** at the top. In the Behavior Rules dialog box that appears, you can modify the basic information and source table settings of the behavior rule. You can also modify the rule configuration information on the Rule Configuration page. For more information, see Create a behavior rule.
6. In the upper-right corner of the page, click the icon to preview the behavior rule, click the icon to save the configuration, or click the icon to submit the edited behavior rule.
7. On the **Rule Configuration** page, click **Behavior Rule Versions** at the top. In the Node Version dialog box that appears, you can view the earlier versions of the submitted behavior rule.

View a behavior rule

1. View the information about a behavior rule in different dimensions in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side behavior rule list, click the

target behavior rule. On the View Attributes tab that appears, you can view the information about the behavior rule in the **Basic Information**, **Consumption Information**, **Behavior Subjects**, **Objects**, **Object Attributes**, and **Behavior Attributes** sections.

- On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Behavior Rules on the left-side navigation submenu. Then, click**Behavior Rules Object List** at the bottom of the left-side navigation pane. On the Behavior Rules page that appears in the workspace, set the filter conditions to view multiple behavior rules. You can click the ID in the**Rule ID** column of a behavior rule to view the information about the behavior rule on the View Attributes tab that appears.

  - **Behavior Name**: the name of the behavior.
  - **Rule ID**: the ID of the behavior rule corresponding to the behavior.
  - **Rule Source Table**: the source table of the behavior rule.
  - **Status**: the development status of the behavior rule. The valid values are Draft, Submitted, and Developing. **Developing** indicates that the submitted behavior rule is edited and saved but not submitted again, and the behavior rule is involved in task scheduling in the production environment based on the previous configuration. **Submitted** indicates that the behavior rule is involved in task scheduling in the production environment. **Draft** indicates that the new behavior rule is not submitted.
  - **Recent Refresh Status**: the status of retroactive data generation for the behavior rule. The valid values include No Retroactive Data, Running, Succeeded, and Failed. You can click the Refresh Log icon next to the status of retroactive data generation for a behavior rule to view all the retroactive data generation records of the behavior rule. In the **Refresh Records** window that appears, click the icon in the **Refresh Status** column of a retroactive data generation record. On the **Scheduling** tab that appears, you can view the directed acyclic graph (DAG) of the retroactive data generation instance.

Generate retroactive data

1. Open the**Generate Retroactive Data for Behavior Rules** dialog box in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side behavior rule list, move the pointer over the icon next to the behavior to which the target behavior rule belongs and select**Refresh**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side behavior rule list, move the

pointer over the icon next to the target behavior rule and select**Refresh**.

- On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Behavior Rules on the left-side navigation submenu. In the left-side behavior rule list, click the target behavior rule. On the View Attributes tab that appears, click**Generate Retroactive Data**.
- On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Behavior Rules on the left-side navigation submenu. Then, click**Behavior Rules Object List** at the bottom of the left-side navigation pane. On the**Behavior Rules** page that appears in the workspace, click the icon in the Actions column of the target behavior rule to open the**Generate Retroactive Data for Behavior Rules** dialog box.

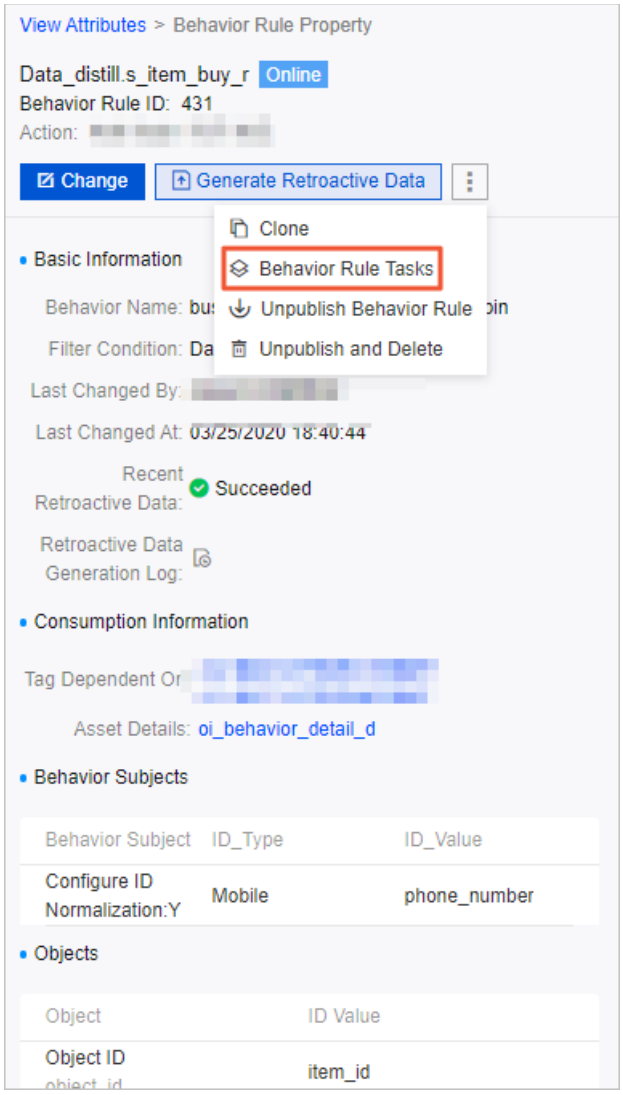
2. In the**Generate Retroactive Data for Behavior Rules** dialog box that appears, set**Effective Period** and**Instance Name** as prompted. Then, click**OK**.

> **Note** You can only generate retroactive data for behavior rules in the Submitted or Developing state.

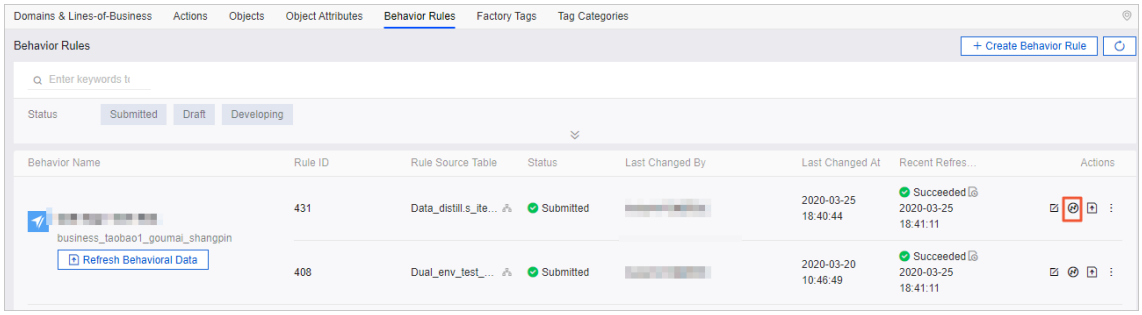
View a behavior rule task

1. Go to the**Behavior Rule Tasks** page of the Scheduling module in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side behavior rule list, move the pointer over the icon next to the target behavior rule and select**Behavior Rule Tasks**.

   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Behavior Rules on the left-side navigation submenu. In the left-side behavior rule list, click the target behavior rule. On the View Attributes tab that appears, click the icon and select**Behavior Rule Tasks**.



- On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Behavior Rules on the left-side navigation submenu. Then, click**Behavior Rules Object List** at the bottom of the left-side navigation pane. On the**Behavior Rules** page that appears in the workspace, click the icon in the Actions column of the target behavior rule.



2. On the**Behavior Rule Tasks** page of the Scheduling module that appears, view and maintain the production data.

> **Note** You can only view the behavior rule task for behavior rules in the Submitted or Developing state.

Clone a behavior rule

1. Go to the **Rule Configuration** page in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side behavior rule list, move the pointer over the icon next to the target behavior rule and select **Clone**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Behavior Rules on the left-side navigation submenu. In the left-side behavior rule list, click the target behavior rule. On the View Attributes tab that appears, click the icon and select **Clone**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Behavior Rules on the left-side navigation submenu. Then, click **Behavior Rules Object List** at the bottom of the left-side navigation pane. On the **Behavior Rules** page that appears in the workspace, click the icon in the Actions column of the target behavior rule and select **Clone**.
2. On the **Rule Configuration** page that appears, view the detailed configuration information about the cloned behavior rule. You can also modify the configuration based on your business requirements. For more information about how to modify the configuration, see Edit a behavior rule.

Unpublish a behavior rule

1. Open the **Tip** dialog box to unpublish a behavior rule in one of the following ways:
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side behavior rule list, move the pointer over the icon next to the target behavior rule and select **Unpublish**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Behavior Rules on the left-side navigation submenu. In the left-side behavior rule list, click the target behavior rule. On the View Attributes tab that appears, click the icon and select **Unpublish Behavior Rule**.
   - On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Behavior Rules on the left-side navigation submenu. Then, click **Behavior Rules Object List** at the bottom of the left-side navigation pane. On the **Behavior Rules** page that appears in the workspace, click the icon in the Actions column of the target behavior rule and select **Unpublish**.
2. In the **Tip** dialog box that appears, click **OK**. After a behavior rule is unpublished, it enters the Draft state.

> **Note** You cannot unpublish a behavior rule on which a tag in the Submitted or Developing state depends.

Unpublish and delete a behavior rule

1. Open the Tip dialog box to unpublish and delete a behavior rule in one of the following

ways:

- On the Distilling tab, click Behavior Engine in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side behavior rule list, move the pointer over the icon next to the target behavior rule and select **Unpublish and Delete**.
- On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Behavior Rules on the left-side navigation submenu. In the left-side behavior rule list, click the target behavior rule. On the View Attributes tab that appears, click the icon and select **Unpublish and Delete**.
- On the Distilling tab, click Behavior Engine in the left-side navigation pane and click Behavior Rules on the left-side navigation submenu. Then, click **Behavior Rules Object List** at the bottom of the left-side navigation pane. On the **Behavior Rules** page that appears in the workspace, click the icon in the Actions column of the target behavior rule and select **Unpublish and Delete**.

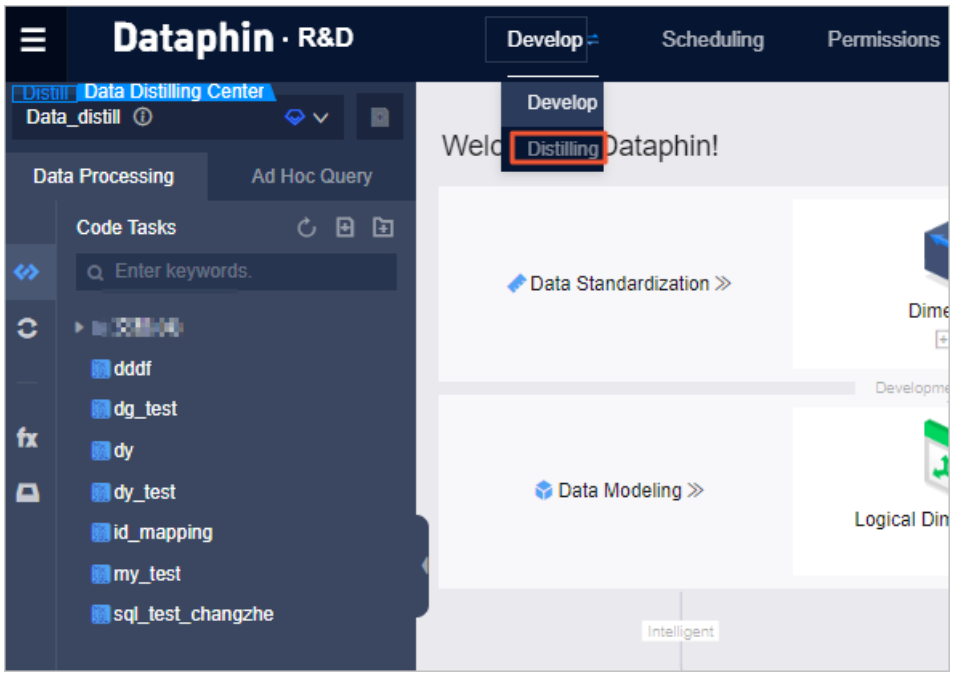
2. In the Tip dialog box that appears, enter the comments and click **OK**.

> **Note** You cannot unpublish and delete a behavior rule on which a tag in the Submitted or Developing state depends.

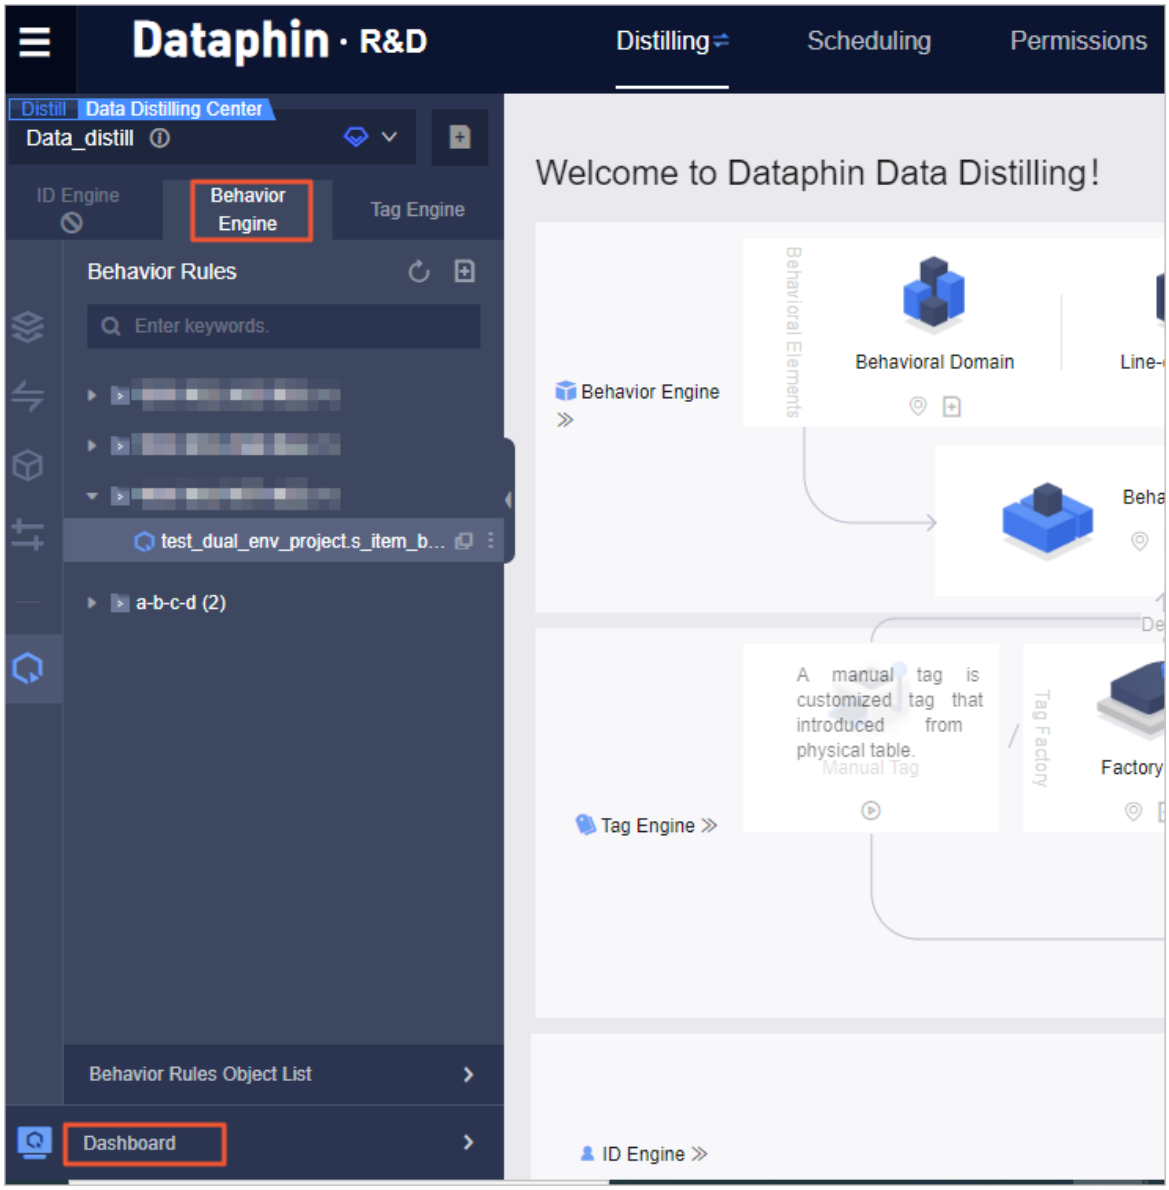
9.10.2.9. Dashboard

This topic describes how to view the distribution of behavioral data and the sampling data on the dashboard.

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the R&D page that appears, move the pointer over Develop in the top navigation bar and select **Distilling**.



4. On the Distilling tab that appears, click **Behavior Engine** in the left-side navigation pane. Then, click **Dashboard** at the bottom of the left-side navigation pane.



- In the left-side pane of the **Behavior Dashboard** page, the behavioral domain, line-of-business, and object appear at three levels.
  - You can click the name of a behavioral domain or a bar under **Domain** to view the distribution of behavioral data in the behavioral domain.
  - You can click a bar under **Line-of-Business** to view the distribution of behavioral data in a line-of-business.
  - You can also click a bar under **Objects** to view the distribution of behavioral data for an action.
- In the right-side pane of the **Behavior Dashboard** page, the sampling result of the behavioral data appears. By default, the sampling result of the global behavioral data appears. If you select a behavioral domain, the sampling result of the behavioral domain appears. The sampling data is sourced from the recurring tasks corresponding to behavior rules, and the sampling data timestamp is yesterday.

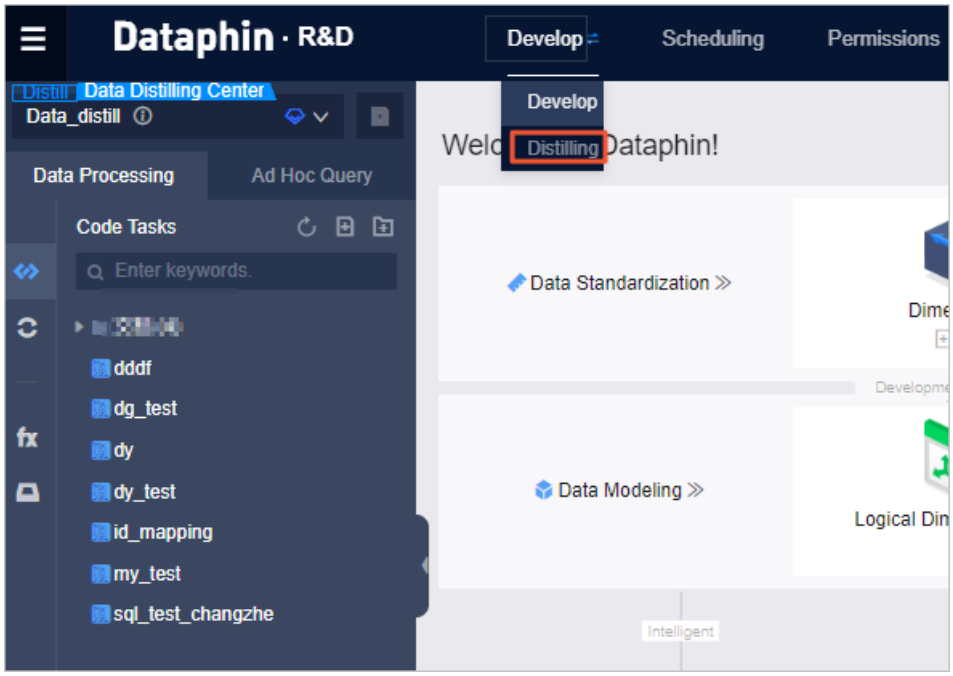
9.10.3. Tag Engine

9.10.3.1. Create a factory tag

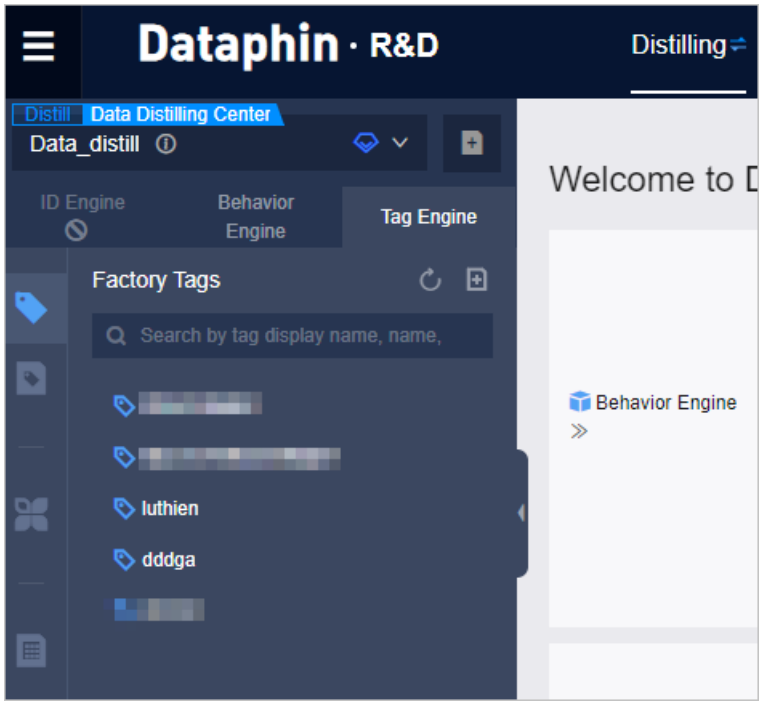
This topic describes how to create and configure a factory tag.

Create a factory tag

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the **R&D** page that appears, move the pointer over **Develop** in the top navigation bar and select **Distilling**.

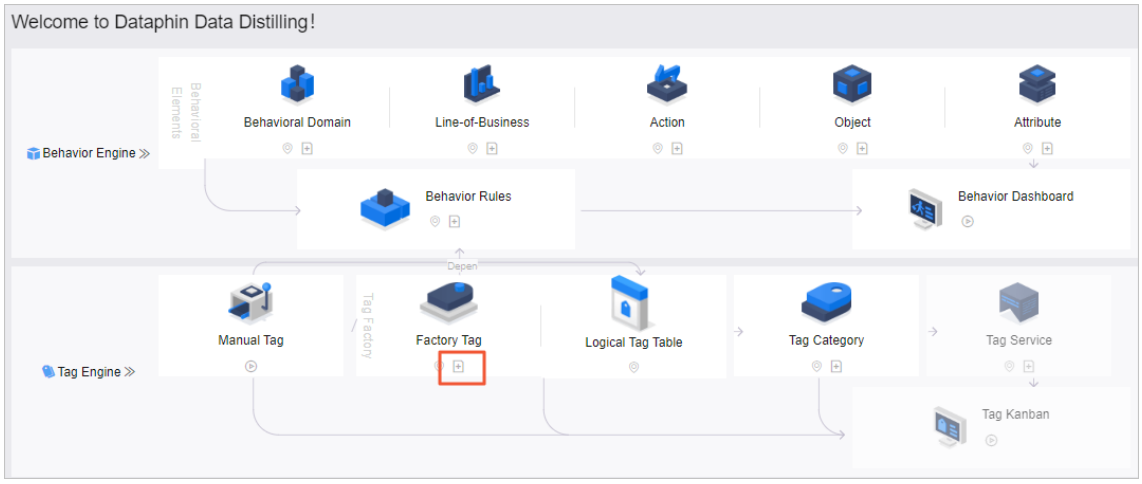


4. On the **Distilling** tab that appears, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu.



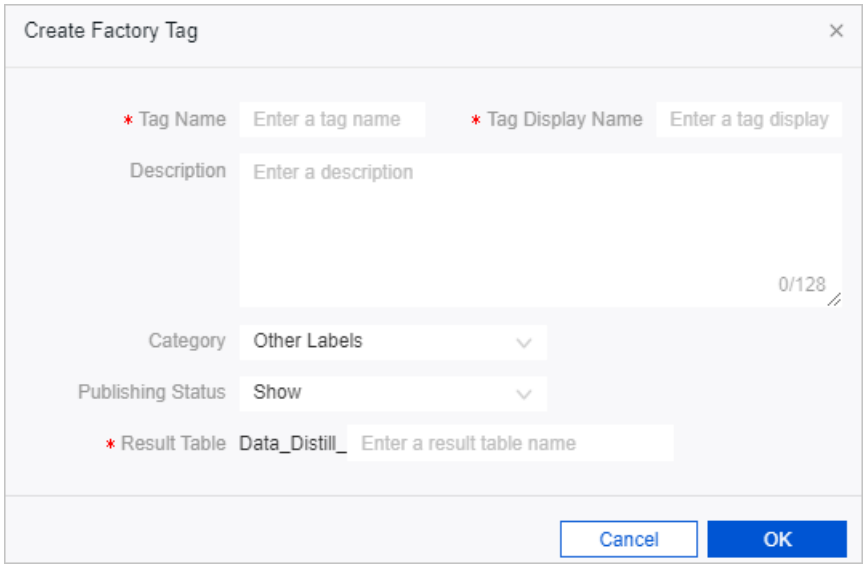
5. Open the **Create Factory Tag** dialog box in one of the following ways:
   - On the **Distilling** tab, click the icon in the upper-right corner of the left-side navigation pane.

   - On the **Distilling** tab, click the icon next to the project name and choose **Tag Engine** > **Factory Tags**.
   - On the **Distilling** tab, click the icon under **Factory Tag** in the workspace.



- On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. Then, click **Factory Tags Object List** at the bottom of the left-side navigation pane. On the **Factory Tags** page that appears in the workspace, click **+ Create Tag** in the upper-right corner.

6. In the **Create Factory Tag** dialog box that appears, set the parameters as prompted and click **OK**.



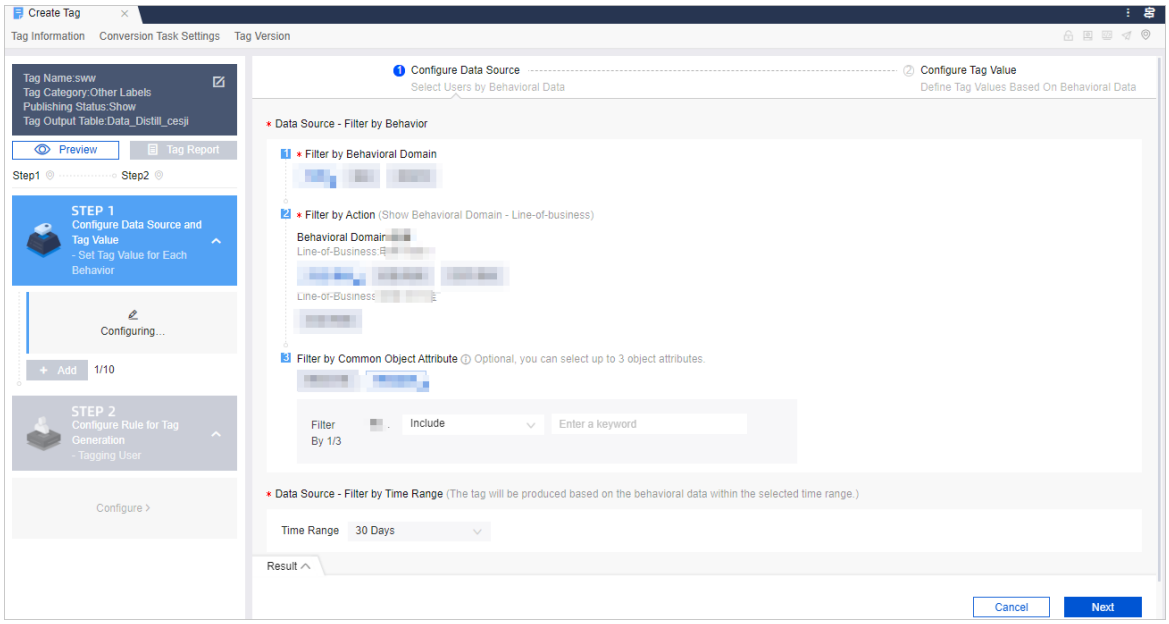
> **Note**
>
> - The value of **Tag Display Name** can contain Chinese characters, letters, digits, underscores (_), and hyphens (-). It cannot only contain digits.
> - The value of **Tag Name** can contain letters, digits, and underscores (_). It cannot only contain digits.

Configure the data source and tag values

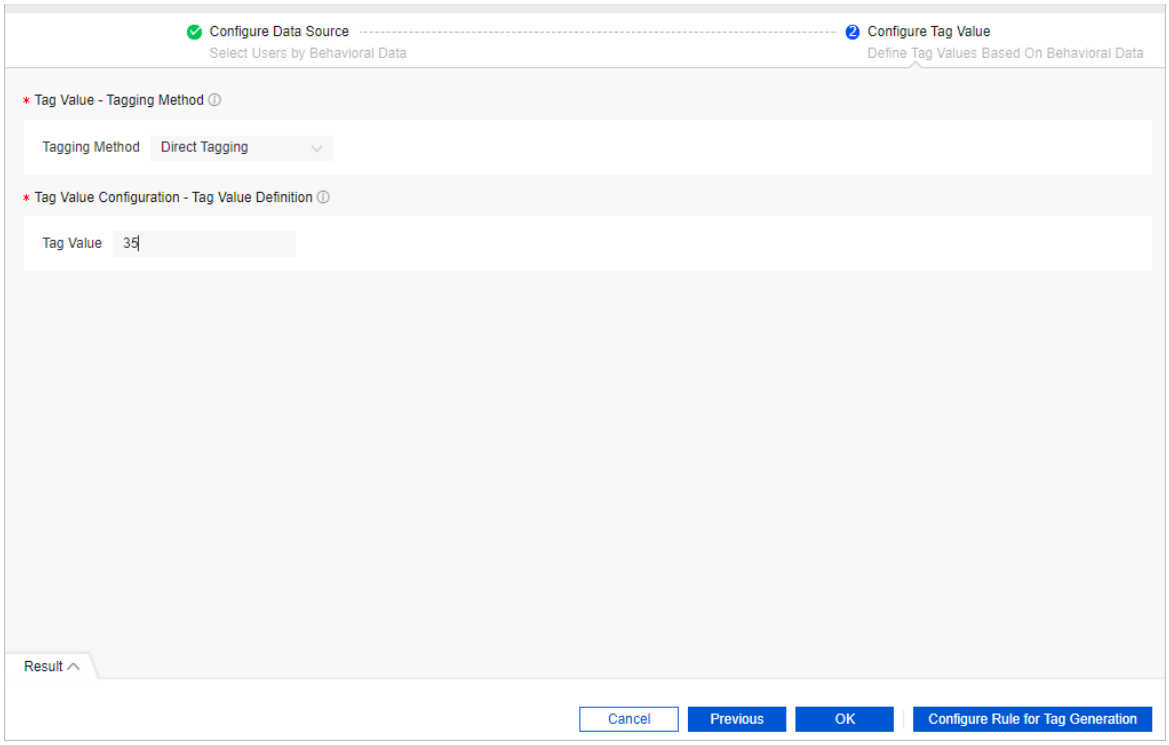
1. On the **Create Tag** tab that appears, click **Configure Data Source and Tag Value** under **Create Tag** and then click **Configure**.
2. In the **Configure Data Source** step, set the following parameters as prompted and click **Next**:
   - **Filter by Behavioral Domain**: Select the behavioral domain to which the source data

belongs. You can select multiple behavioral domains.

- **Filter by Action**: Select the actions and objects based on the line-of-business in the behavioral domain. You can select a maximum of 10 objects for all datasets. The number of actions is not limited.
- **Filter by Common Object Attribute**: If the selected behavioral data has common object attributes, you can filter the required source data based on the common object attributes. You can select a maximum of three common object attributes.
- **Data Source - Filter by Time Range**: Select the time range. Dataphin performs subsequent calculation based on the behavioral data in the selected time range to generate the final tag. The valid values are **30 Days**, **60 Days**, **90 Days**, **180 Days**, and **365 Days**.

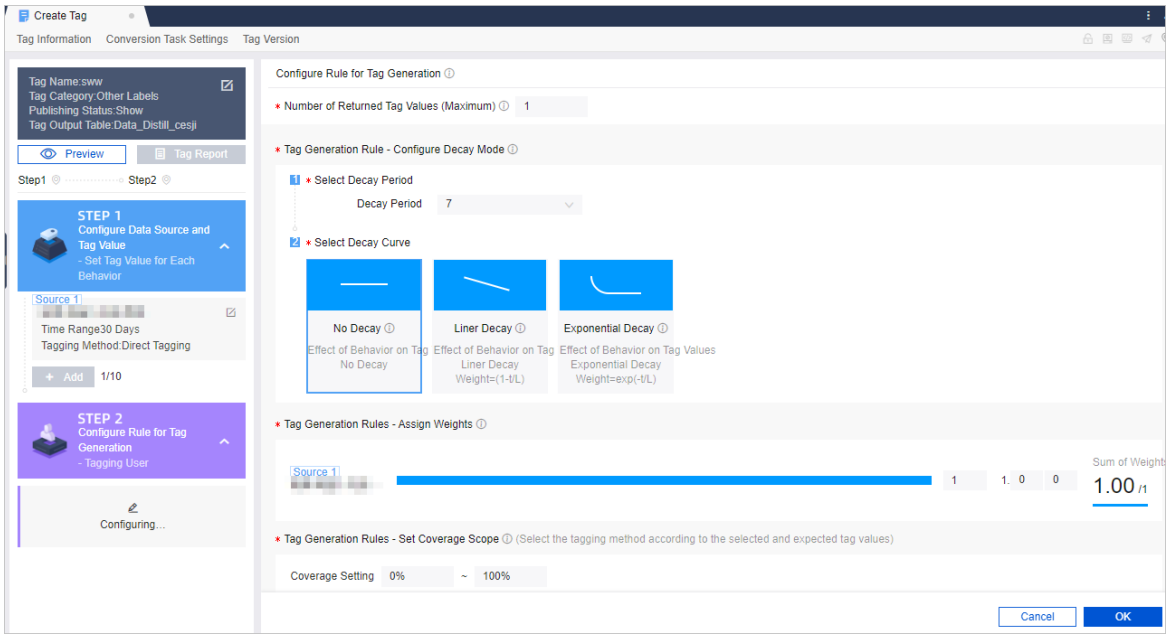


3. In the **Configure Tag Value** step, set the following parameters as prompted and click **OK**:
   - **Tag Value - Tagging Method**: the tagging method. Valid values: **Direct Tagging** and **Object Attribute Mapping**.
   - **Tag Value Configuration - Tag Value Definition**: the definition of the tag value. Set this parameter based on the value of the **Tag Value - Tagging Method** parameter.



4. Click **Configure Rule for Tag Generation** under **Configure Data Source and Tag Value** and then click **Configure**. In the **Configure Rule for Tag Generation** step, set the following parameters as prompted and click **OK**:
   - **Number of Returned Tag Values**: the maximum number of tag values that can be returned for each behavior subject ID. Each ID may generate multiple behavioral data records and therefore can have multiple tag values. Dataphin preferentially returns the tag value with the higher preference based on the number of tag values you set. You can view the tag value preference in the tag result table.
   - **Select Decay Period**: the period of the decay. The behaviors occurred in different periods have different impacts on tag values. Generally, behaviors in more recent periods have greater impacts. The behaviors occurred in the same period have the same impact on tag values. The impact of behaviors in different periods decreases with the time based on the specified decay period and curve. If the tag values change rapidly with the behavior, such as the diaper model preference, we recommend that you select a shorter period. If the tag values are stable and change slowly with the behavior, such as individual skin type prediction, we recommend that you select a longer period.
   - **Select Decay Curve**: the curve of the decay. You can set the decay mode for the behavioral data within the selected time range based on the number of segments in different decay periods. For example, if the time range is 90 days and the decay period is seven days, the number of segments is 13 (90/7 = 13). The impact of behavioral data in different periods on final tag values is related to the decay mode you select. For example, the behaviors of adding skincare products to favorites in the previous seven days and last seven days do not affect the definition of the efficacy preference for skincare products. In this case, you can select **No Decay**.
   - **Tag Generation Rules - Assign Weights**: the weights of behaviors based on the business judgment. Each weight can have a maximum of two decimal places, and the sum of weights is 1. A larger weight indicates a greater impact of this behavior on the final tag value.

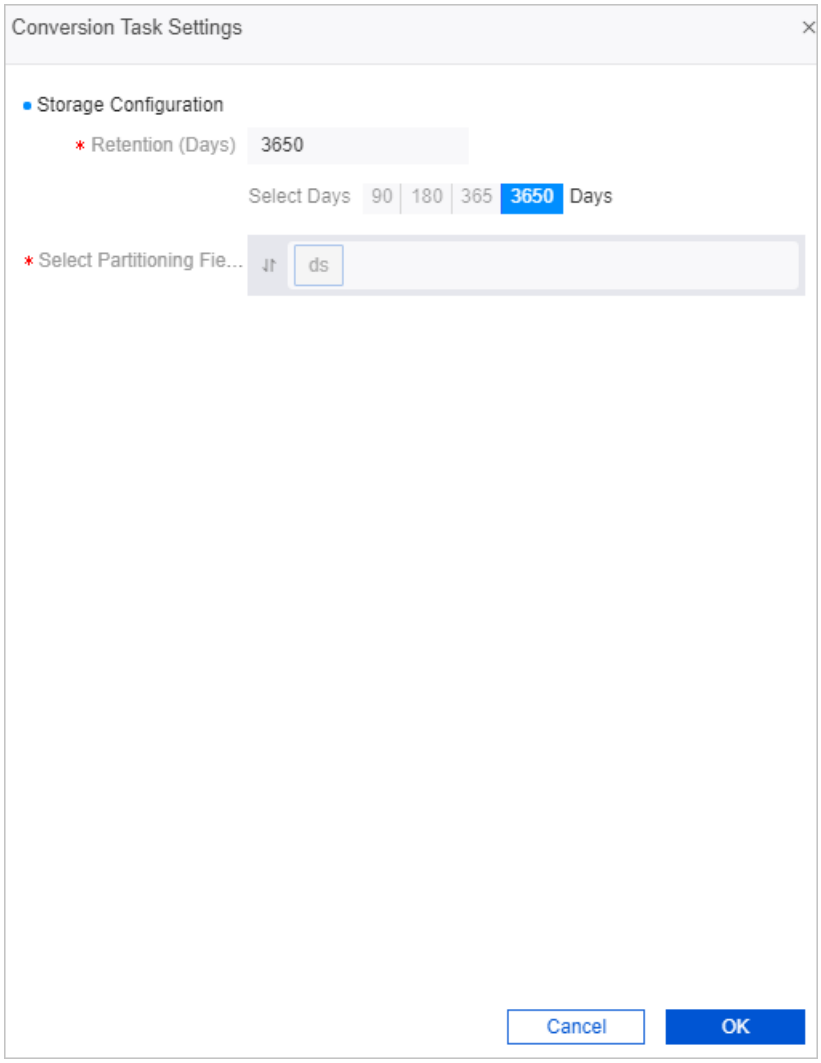
- **Tag Generation Rules - Set Coverage Scope**: the scope of the covered users.



After the preceding steps are completed, a factory tag in the **Draft** state is generated.

Configure conversion task settings

1. On the **Create Tag** tab, click **Conversion Task Settings** at the top. The **Conversion Task Settings** dialog box appears.
2. Set the parameters as prompted and click **OK**.



3. Click the icon in the upper-right corner of the page to save the configuration.
4. Click the icon in the upper-right corner of the page to test the factory tag. After the required information is specified, we recommend that you test the tag before submitting it to preview the distribution of tag values and the sampling data in the tag result table. A factory tag can be in the **Test Not Running**, **Test Running**, **Test Run Succeeded**, or **Test Run Failed** state.

   > **Note** You cannot modify the tag configuration during the test. To modify the tag configuration, stop the test first. After the test is stopped, the tag enters the **Test Run Failed** state. If you do not need to test the tag, you can directly submit the tag.

5. Click the icon in the upper-right corner of the page to submit the factory tag.

Note

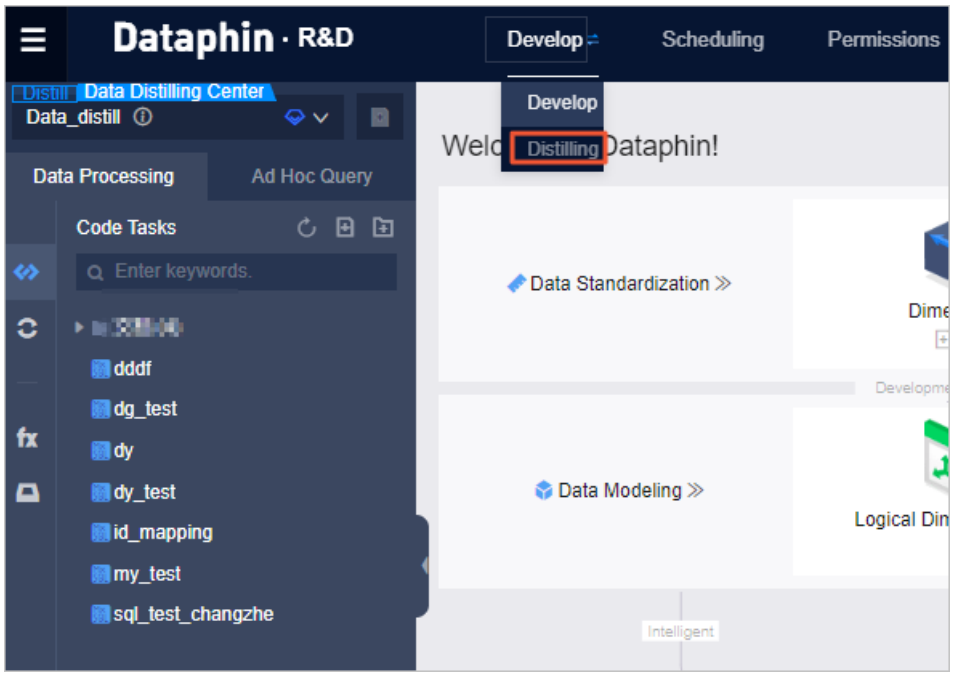
- After submitting the tag, you must generate retroactive data for the tag to obtain the historical behavioral data within the selected time range as the source data. If you do not generate retroactive data, the tag result table may be empty.
- After you submit the tag, it is published to the production environment. A recurring task is generated for scheduling.

9.10.3.2. Manage factory tags

This topic describes how to manage factory tags, for example, how to view, edit, unpublish, and unpublish and delete a factory tag, as well as how to generate retroactive data for a factory tag.

View a factory tag

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the **R&D** page that appears, move the pointer over **Develop** in the top navigation bar and select **Distilling**.



4. On the **Distilling** tab that appears, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu.
5. View the information about a factory tag in different dimensions in one of the following ways:
   - In the left-side factory tag list, click the target tag. On the **View Attributes** tab that appears, you can view the basic information about the tag.

On the **View Attributes** tab, click **Change** to go to the **Change Tag** tab. On the **Change Tag** tab, click **Tag Version** at the top. In the **Tag Version** dialog box that appears, you can view the versions of the tag.

On the **View Attributes** tab, click the result table name in the **Result Table** section to view the details of the result table.

On the **View Attributes** tab, click a behavior rule ID in the **Dependency** section to view the details of the behavior rule on which the tag depends.

On the **View Attributes** tab, click a behavior ID in the **Dependency** section to go to the **Distilling Object List** tab. On the **Behavior Rules** page that appears, you can view the basic information about the behavior.

- In the left-side navigation pane, click **Factory Tags Object List** at the bottom. On the **Factory Tags** page that appears in the workspace, set the filter conditions to view the information about multiple factory tags. You can also click the name of a factory tag to view the information about the tag.
  - **Development Status**: the status of the tag. The valid values are **Draft**, **Submitted**, and **Developing. Developing** indicates that the submitted tag is edited and saved but not submitted again, and the tag is involved in task scheduling in the production environment based on the previous configuration. **Submitted** indicates that the tag is involved in task scheduling in the production environment. **Draft** indicates that the new tag is not submitted.
  - **Category**: the category of the tag.
  - **Test Run Status**: the status of test run for the tag. The valid values are **Test Not Running**, **Test Running**, **Test Run Succeeded**, and **Test Run Failed**.
  - **Recent Retroactive Data**: the status of retroactive data generation for the tag. The valid values are **No Retroactive Data**, **Running**, **Succeeded**, and **Failed**. You can click the **Refresh Log** icon next to the status of retroactive data generation for a factory tag to view all the retroactive data generation records of the tag. In the **Refresh Records** window that appears, click the icon in the **Refresh Status** column of a retroactive data generation record. On the **Scheduling** tab that appears, you can view the directed acyclic graph (DAG) of the retroactive data generation instance.

Edit a factory tag

1. Go to the **Change Tag** tab in one of the following ways:
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side factory tag list, move the pointer over the icon next to the target tag and select**Change**.
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. In the left-side factory tag list, click the target tag. On the **View Attributes** tab that appears, click **Change**.
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. Then, click **Factory Tags Object List** at the bottom of the left-side navigation pane. On the **Factory Tags** page that appears in the workspace, click the icon in the **Actions** column of the target tag.
2. On the **Change Tag** tab that appears, set the parameters. For more information, see Create

a factory tag.

> Note You cannot modify the name of the result table if the tag is in the Submitted or Developing state.

Generate retroactive data

1. Open the **Generate Retroactive Data for Tags** dialog box in one of the following ways:
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. Then, click **Factory Tags Object List** at the bottom of the left-side navigation pane. On the **Factory Tags** page that appears in the workspace, click the icon in the **Actions** column of the target tag to open the**Generate Retroactive Data for Tags** dialog box.
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. In the left-side factory tag list, click the target tag. On the **View Attributes** tab that appears, click **Refresh**.
2. Set **Effective Period** and **Instance Name** as prompted. Then, click **OK**.

> Note You can only generate retroactive data for factory tags in the Submitted or Developing state.

View a tag task

1. Go to the **Tag Tasks** page of the **Scheduling** module in one of the following ways:
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side factory tag list, move the pointer over the icon next to the target tag and select**Tag Tasks**.
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. In the left-side factory tag list, click the target tag. On the **View Attributes** tab that appears, move the pointer over the icon and select **Tag Task**.
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. Then, click **Factory Tags Object List** at the bottom of the left-side navigation pane. On the **Factory Tags** page that appears in the workspace, click the icon in the **Actions** column of the target tag.

> Note You can only view the tag task for factory tags in the Submitted or Developing state.

2. On the **Tag Tasks** page of the **Scheduling** module that appears, view and maintain the production data.

View a tag report

1. View the report of a factory tag in one of the following ways:

- On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side factory tag list, move the pointer over the icon next to the target tag and select**Tag Report**.
- On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. In the left-side factory tag list, click the target tag. On the **View Attributes** tab that appears, click **View Tag Report**.
- On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. Then, click **Factory Tags Object List** at the bottom of the left-side navigation pane.

  On the **Factory Tags** page that appears in the workspace, if the development status of the target tag is **Submitted** or **Developing**, move the pointer over the icon in the **Actions** column and select **Tag Report**.

  If the development status of the target tag is **Draft**, click the icon in the **Actions** column.

2. On the tag report details tab that appears, view the information about the tag report.

Clone a factory tag

1. Go to the **Clone Tag** tab in one of the following ways:
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side factory tag list, move the pointer over the icon next to the target tag and select**Clone**.
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. In the left-side factory tag list, click the target tag. On the **View Attributes** tab that appears, move the pointer over the icon and select **Clone**.
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. Then, click **Factory Tags Object List** at the bottom of the left-side navigation pane. On the **Factory Tags** page that appears in the workspace, if the development status of the target tag is **Submitted** or **Developing**, move the pointer over the icon in the **Actions** column and select**Clone**.

     If the development status of the target tag is **Draft**, click the icon in the **Actions** column.

2. On the **Clone Tag** tab that appears, view the detailed configuration information about the cloned tag. You can also modify the configuration based on your business requirements. For more information about how to modify the configuration, see Edit a factory tag.

Unpublish a factory tag

1. Open the **Tip** dialog box to unpublish a factory tag in one of the following ways:
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side factory tag list, move the pointer over the icon next to the target tag and select**Unpublish**.

- On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. In the left-side factory tag list, click the target tag. On the **View Attributes** tab that appears, move the pointer over the icon and select **Unpublish**.
- On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. Then, click **Factory Tags Object List** at the bottom of the left-side navigation pane. On the **Factory Tags** page that appears in the workspace, move the pointer over the icon in the **Actions** column of the target tag and select**Unpublish**.

2. In the **Tip** dialog box that appears, click **OK**. After a factory tag is unpublished, it enters the **Draft** state.

> **Note** You can only unpublish factory tags in the **Submitted** or **Developing** state.

Unpublish and delete a factory tag

1. Open the **Tip** dialog box to unpublish and delete a factory tag in one of the following ways:
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side factory tag list, move the pointer over the icon next to the target tag and select **Unpublish and Delete**.
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. In the left-side factory tag list, click the target tag. On the **View Attributes** tab that appears, move the pointer over the icon and select **Unpublish and Delete**.
   - On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click **Factory Tags** on the left-side navigation submenu. Then, click **Factory Tags Object List** at the bottom of the left-side navigation pane. On the **Factory Tags** page that appears in the workspace, move the pointer over the icon in the **Actions** column of the target tag and select **Unpublish and Delete**.
2. In the **Tip** dialog box that appears, enter the comments and click **OK**.

9.10.3.3. Manage the logical tag table

This topic describes how to manage the logical tag table, for example, how to view the logical tag table and modify the factory tags and manual tags in the logical tag table.

Dataphin automatically creates a logical tag table when a distilling project is initialized. The logical tag table collects all the factory tags that are in the Submitted state and manual tags in physical tables by id_type and id_value. Note that manual tags in physical tables are not developed in the tag factory. The name of the logical tag table is fixed to Ads_distill_labels and cannot be changed.

View the logical tag table

1. Log on to the Dataphin console.
2. Go to the **Logical Tag Tables** section.

i. On the Dataphin homepage, click **R&D** in the top navigation bar.

ii. On the Develop page, move the pointer over **Develop** in the top navigation bar and select **Distilling**.

iii. On the **Distilling** page, click the **Tag Engine** tab in the left-side navigation pane.

iv. On the **Tag Engine** tab, click the icon on the left-side navigation submenu. The **Logical Tag Tables** section appears.

3. In the **Logical Tag Tables** section, click **Ads_distill_labels**. The **Logical Tag Table** tab appears.

   The **Logical Tag Table** tab consists of the **Factory Tags** and **Manual Tags** tabs. All the factory tags in the **Submitted** or **Developing** state are automatically attached to the logical tag table. You can also import manual tags that are developed by coding from physical tables to the logical tag table.

Modify a factory tag

1. On the **Logical Tag Table** tab, click **Factory Tags**.
2. On the **Factory Tags** tab, find the factory tag that you want to modify by using one of the following methods:
   - Click the icon. Then, filter factory tags by setting the **Category**, **Development Status**, **Test Run Status**, and **Last Refresh Status** parameters.
   - Enter a tag display name, tag name, or tag ID in the search box to search for your desired factory tag.
   - Find your desired factory tag in the tag list.
3. Click the icon in the **Actions** column.
4. On the **Change Tag** tab, modify the parameters as required. For more information, see Edit a factory tag.

Generate retroactive data for a factory tag

1. On the **Logical Tag Table** tab, click **Factory Tags**.
2. On the **Factory Tags** tab, find the factory tag for which you want to generate retroactive data by using one of the following methods:
   - Click the icon. Then, filter factory tags by setting the **Category**, **Development Status**, **Test Run Status**, and **Last Refresh Status** parameters.
   - Enter a tag display name, tag name, or tag ID in the search box to search for your desired factory tag.
   - Find your desired factory tag in the tag list.
3. Click the icon in the **Actions** column.
4. In the **Generate Retroactive Data for Tags** dialog box, set the parameters as required. For more information, see Generate retroactive data.

View the tag task under a factory tag

1. On the **Logical Tag Table** tab, click **Factory Tags**.

2. On the **Factory Tags** tab, find the factory tag whose tag task you want to view by using one of the following methods:
   - Click the icon. Then, filter factory tags by setting the **Category**, **Development Status**, **Test Run Status**, and **Last Refresh Status** parameters.
   - Enter a tag display name, tag name, or tag ID in the search box to search for your desired factory tag.
   - Find your desired factory tag in the tag list.
3. Click the icon in the **Actions** column.
4. In the **Tag Tasks** section on the Distilling Management tab, view the details about the tag task under the factory tag.

Clone a factory tag

1. On the **Logical Tag Table** tab, click **Factory Tags**.
2. On the **Factory Tags** tab, find the factory tag that you want to clone by using one of the following methods:
   - Click the icon. Then, filter factory tags by setting the **Category**, **Development Status**, **Test Run Status**, and **Last Refresh Status** parameters.
   - Enter a tag display name, tag name, or tag ID in the search box to search for your desired factory tag.
   - Find your desired factory tag in the tag list.
3. Move the pointer over the icon in the **Actions** column and select **Clone**.
4. On the **Clone Tag** tab, modify the parameters as required. For more information, see Edit a factory tag.

Unpublish a factory tag

1. On the **Logical Tag Table** tab, click **Factory Tags**.
2. On the **Factory Tags** tab, find the factory tag that you want to unpublish by using one of the following methods:
   - Click the icon. Then, filter factory tags by setting the **Category**, **Development Status**, **Test Run Status**, and **Last Refresh Status** parameters.
   - Enter a tag display name, tag name, or tag ID in the search box to search for your desired factory tag.
   - Find your desired factory tag in the tag list.
3. Move the pointer over the icon in the **Actions** column and select **Unpublish**.
4. In the **Tip** dialog box, enter your comments.
5. Click **OK**.

Unpublish and delete a factory tag

1. On the **Logical Tag Table** tab, click **Factory Tags**.

2. On the **Factory Tags** tab, find the factory tag that you want to unpublish and delete by using one of the following methods:
   - Click the icon. Then, filter factory tags by setting the **Category**, **Development Status**, **Test Run Status**, and **Last Refresh Status** parameters.
   - Enter a tag display name, tag name, or tag ID in the search box to search for your desired factory tag.
   - Find your desired factory tag in the tag list.
3. Move the pointer over the icon in the **Actions** column and select **Unpublish and Delete**.
4. In the **Tip** dialog box, enter your comments.
5. Click **OK**.

Create a manual tag

1. On the **Logical Tag Table** tab, click **Manual Tags**.
2. On the **Manual Tags** tab, click **Create Manual Tags** in the upper-right corner.
3. In the **Create Manual Tag** dialog box, perform the following steps:
   i. In the **Association Logic** step, set the **Source Physical Table** parameter and parameters in the **Association Logic** section.
   ii. Click **OK**.
   iii. In the **Add Fields** step, select the fields that are used to associate the source physical table with the logical tag table and click **Add >>**.
   iv. On the **New List** tab, set the **Tag Display Name** parameter.

   You can also modify the **Tag Name**, **Category**, and **Publishing Status** parameters. To delete a field from the New List tab, click the icon in the Actions column. In the message that appears, click **OK**.
   v. Click **OK**.
4. In the **Description** dialog box, enter your comments and click **OK**.

Modify a manual tag

1. On the **Logical Tag Table** tab, click **Manual Tags**.
2. On the **Manual Tags** tab, find the manual tag that you want to modify by using one of the following methods:
   - Filter manual tags by setting the **Category** parameter.
   - Enter a keyword in the search box to search for manual tags whose names contain the keyword.
   - Find your desired manual tag in the tag list.
3. Click the icon in the **Actions** column.
4. In the **Modify Manual Tag** dialog box, set the parameters as required.

Parameter	Description
Tag Name	The name of the manual tag. You cannot change the name.
Tag Display Name	The display name of the manual tag. You cannot change the display name.
Description	The description of the manual tag.
Category	The category of the manual tag.
Publishing Status	Specifies whether to show the manual tag.

5. Click **Submit**.
6. In the **Description** dialog box, enter your comments.
7. Click **OK**.

Delete a manual tag

1. On the **Logical Tag Table** tab, click **Manual Tags**.
2. On the **Manual Tags** tab, find the manual tag that you want to delete by using one of the following methods:
   - Filter manual tags by setting the **Category** parameter.
   - Enter a keyword in the search box to search for manual tags whose names contain the keyword.
   - Find your desired manual tag in the tag list.
3. Click the icon in the **Actions** column.
4. In the **Tip** dialog box, enter your comments.
5. Click **OK**.

9.10.3.4. Manage tag categories

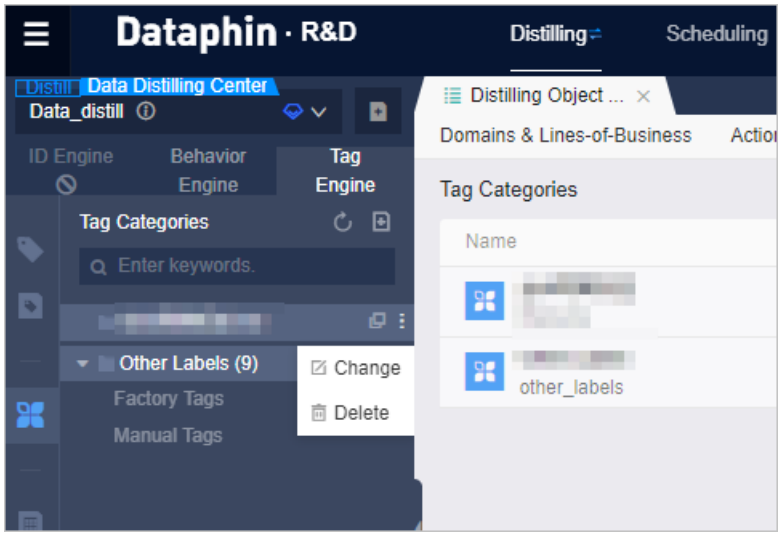
This topic describes how to create, edit, and delete a tag category.

Create a tag category

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the **R&D** page that appears, move the pointer over **Develop** in the top navigation bar and select **Distilling**. On the **Distilling** tab, click **Tag Engine** in the left-side navigation pane and click the icon on the left-side navigation submenu. In the left-side navigation pane, click the icon. In the **Create Category** dialog box that appears, set the parameters as prompted and click **OK**.

Edit a tag category

1. In the left-side tag category list, move the pointer over the icon next to the target category and select **Change**.



2. In the **Modify Category** dialog box that appears, set the parameters as prompted and click **OK**.

Delete a tag category

In the left-side tag category list, move the pointer over the icon next to the target category and select **Delete**. In the **Tip** dialog box that appears, enter the comments and click **OK**. Then, the tag category is deleted.

9.11. Task publishing

9.11.1. Publishing management

In Dev-Prod mode, to schedule data modeling, data processing, and data integration tasks that are generated in the development environment, you must publish them to the production environment. This topic describes how to publish tasks and view the publishing records.

- In Dev-Prod mode, tasks rest on the Objects to Publish page after you submit them. You must publish them before you can schedule and manage them in the production development.
- In Basic mode, tasks are directly submitted to the production environment.

> **Note** The publishing feature is available only in the development environment.

Objects to Publish page

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar. The Develop page appears.
3. Click **Publish** in the top navigation bar. The **Objects to Publish** page appears.

The **Objects to Publish** page displays tasks and files on four tabs: **Pipeline Script**, **Standards and Modeling**, **Batch Processing**, and **Stream Processing**. Tasks include stream processing tasks, batch processing tasks, and sync tasks. Files include resources, batch processing functions, stream processing functions, stream metatables, and stream processing templates.

On the **Objects to Publish** page, you can click the **Pipeline Script**, **Standards and Modeling**, **Batch Processing**, or **Stream Processing** tab to view objects to be published as required. The four tabs provide similar features. This section uses the **Standards and Modeling** tab as an example.You can filter objects by last submitter, last submission time, object type, and operation. You can also enter a keyword in the search box to search for objects whose names contain the keyword.

Parameter	Description
Object Name	The name of the object.
Object ID	The ID of the object.
Object Type	The type of the object.
Version	The version of the object.
Operation	The operation that was performed on the object. Valid values: ○ **Add** ○ **Update** ○ **Delete**
Last Submitted By	The user who submitted the object last time and the submission time.
Actions	○ a. Click the icon in the **Actions** column to publish the object. You can also select multiple objects and click **Publish** in the lower part of the page to publish them at a time. b. In the **Publish** dialog box, click **OK** to publish one or more objects. ○ Click the icon in the **Actions** column to view the publishing records of the object. ○ Click the icon in the **Actions** column to edit the object on the page that appears.

Publishing History page

In the left-side navigation pane, click **Publishing History**. On the **Publishing History** page, you can search for published objects and view the publishing status and details of a specific object. You can also click the Edit icon in the Actions column of an object to edit the object on the page that appears.You can filter objects by last publisher, last publishing time, object type, operation, and publishing status. You can also enter a keyword in the search box to search for objects whose names contain the keyword.

Parameter	Description
Publish Name	The publishing name of the object.
Publish ID	The publishing ID of the object.
Object Name	The name of the object.
Object ID	The ID of the object.
Object Type	The type of the object.
Node ID	The task ID of the object.
Version	The version of the object.
Operation	The operation that was performed on the object. Valid values: • **Add** • **Update** • **Delete**
Published By/Start Publishing At	The user who published the object and the publishing time.
Publishing Status/Finish Publishing At	The publishing status of the object and the time when the publishing was completed. Publishing states include: • **Publish Failed** • **Published Successfully** • **Publishing**
Actions	• Click **Details**. In the **Publishing Details** dialog box, view the publishing details. • Click the icon in the **Actions** column to edit the object on the page that appears. • Click the icon in the **Actions** column. On the **Objects to Publish** page, view the objects that failed to be published. Note that objects that failed to be published will rest on the **Objects to Publish** page. You can publish them again.

9.12. Scheduling center

9.12.1. Overview

Dataphin supports policy-based scheduling and management of code tasks that are generated by data modeling, coding, and data distilling. The scheduling and management feature includes global management, logical table management, and distilling management.

Scheduling page

The Scheduling page contains the Global Management tab. You can go to the Global Management tab by performing the following steps:

1. Log on to the Dataphin console.
2. Go to the **Global Management** tab by using one of the following methods:
   - If the project that you accessed last time is in **Basic** or **Prod** mode, use one of the following methods to go to the **Global Management** tab:
     - a. On the Dataphin homepage, click **Scheduling and Management** in the middle section, or click **Enter** next to **Scheduling** in the upper-right corner.
       b. On the Scheduling page, click the icon next to the project name in the upper-left corner, click the **Dev** tab, and then select a project. The **Global Management** tab appears by default.
     - a. On the Dataphin homepage, click **R&D** in the top navigation bar.
       b. On the Develop page, click the icon next to the project name in the upper-left corner, click the **Dev** tab, and then select a project.
       c. Click **Scheduling** in the top navigation bar. The **Global Management** tab appears by default.
   - If the project that you accessed last time is in **Dev** mode, use one of the following methods to go to the **Global Management** tab:
     - On the Dataphin homepage, click **Scheduling and Management** in the middle section, or click **Enter** next to **Scheduling** in the upper-right corner. The **Global Management** tab appears by default.
     - a. On the Dataphin homepage, click **R&D** in the top navigation bar.
       b. On the **Develop** page, click **Scheduling** in the top navigation bar. The **Global Management** tab appears by default.

In Dev-Prod mode, the scheduling tasks in projects in Dev mode are independent of those in the corresponding projects in Prod mode.

- In projects in Dev mode, the Scheduling page contains the **Global Management** and **Logical Table Management** tabs.
- The scheduling tasks in projects in Dev mode cannot automatically run. You must manually run the scheduling tasks to generate instances.
- In projects in Prod mode, the Scheduling page contains the **Global Management**, **Logical Table Management**, and **Monitoring** tabs. You can configure alert rules to monitor tasks only in projects in Prod mode.
- Dataphin generates and runs scheduling tasks in projects in Prod mode based on scheduling policies.
- You can click the Prod Dev icon next to the project name in the upper-left corner to switch between the Scheduling page of a project in Dev mode and that of the corresponding project in Prod mode.

  For example, if you click the Prod Dev icon on the Scheduling page of the test_dev project, the Scheduling page of the test project appears.

In projects in Basic mode:

- The Scheduling page contains the **Global Management**, **Logical Table Management**, and **Monitoring** tabs.
- Dataphin generates and runs scheduling tasks in projects in Basic mode based on scheduling policies. You can configure alert rules to monitor tasks in projects in Basic mode.

Tasks

A task is an object that can be scheduled in the production environment after you submit and publish its code and configuration in the development environment. A task can be scheduled at specified intervals or manually triggered. Tasks are classified into the following types based on the way they are run:

- **Recurring tasks**: the tasks for which a recurrence is configured. The scheduling system of Dataphin schedules recurring tasks at specified intervals and generates corresponding recurring instances.
- **One-time tasks**: the tasks that are not automatically triggered by the scheduling system. You can manually run a one-time task as needed. Each time you run a one-time task, a one-time instance is generated.
- **Stream processing tasks**: the tasks for processing streaming data. You must manually run production or test instances for stream processing tasks.

The scheduling sequence of a task is determined based on the recurrence, dependency, and priority that are configured for the task.

- To apply the code or configuration update of a task to the instance generated the next day, you must update the code or configuration before 23:00 on the current day.
- When an instance runs, Dataphin reads the latest code and scheduling configuration of the corresponding task.
- You can specify a data timestamp within the range from 1970 to 2099 for Dataphin to generate retroactive data. Each scheduling instance is retained for up to two weeks.

Instances

An instance is generated each time a task is run. Instances can be generated in one of the following ways:

- Recurring instances are automatically and periodically generated when recurring tasks are scheduled by the scheduling system.
- Retroactive data generation instances are generated when you generate retroactive data for tasks.
- One-time instances are generated when you run one-time tasks.
- Stream processing instances are generated when you run production or test instances for stream processing tasks.

Logical tables

Logical table management involves logical table tasks and logical table task instances.

- The **Logical Table Tasks** section displays the tasks of logical tables.
- The **Logical Table Task Instances** section displays the instances of logical table tasks that are run and the states of these instances.

Distilling management

Distilling management involves tasks and instances. Distilling management allows you to manage tasks and instances related to behavior rules and tags from a business standpoint.

9.12.2. Global management

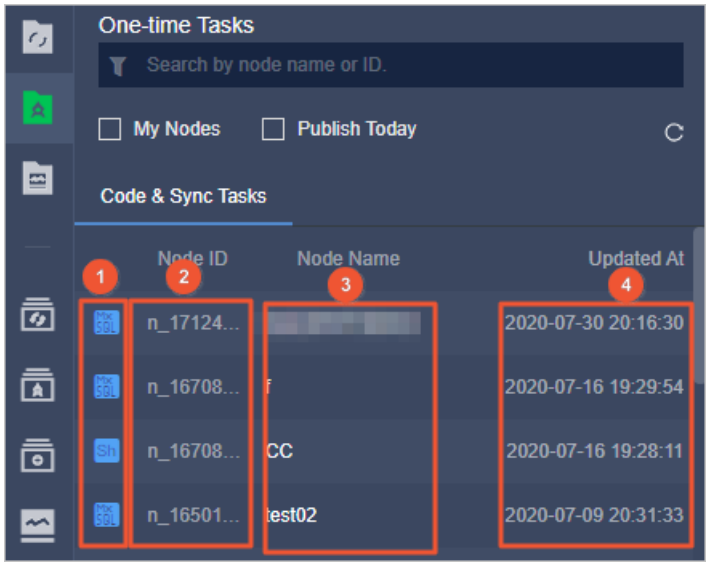
9.12.2.1. One-time tasks

The One-time Tasks section on the Global Management tab displays the one-time tasks that have been submitted and published. This topic describes the operations that you can perform on one-time tasks. For example, you can view, run, and modify one-time tasks.

Go to the One-time Tasks section

To go to the One-time Tasks section, perform the following steps:

1. Log on to the Dataphin console.
2. Go to the **Global Management** tab.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner, click the **Dev**, **Basic**, or **Prod** tab, and then select a project.
   iii. Click **Scheduling** in the top navigation bar. The **Global Management** tab appears by default.
3. Click the icon on the left-side navigation submenu. The **One-time Tasks** section appears.



No.	Description
1	The type of the task.
2	The node ID of the task.
3	The node name of the task.

No.	Description
4	The time when the task was last modified.

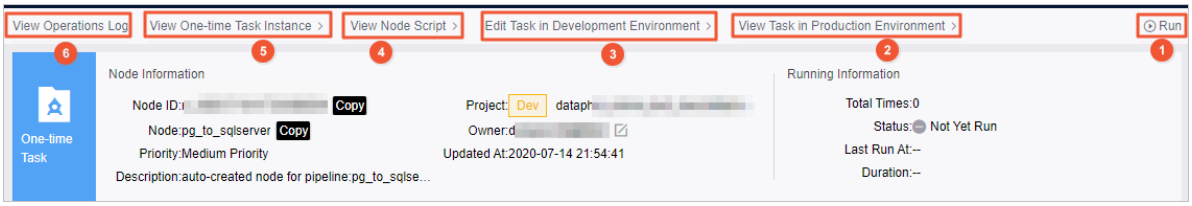
Search for one-time tasks

- Click the icon in the search box, click the icon next to **Owner** or **Task Type**, and then select an owner or a task type. You can also select both an owner and a task type to search for your desired one-time tasks.
- Enter a keyword in the search box to search for one-time tasks whose names contain the keyword.

Manage a one-time task in the right-side workspace

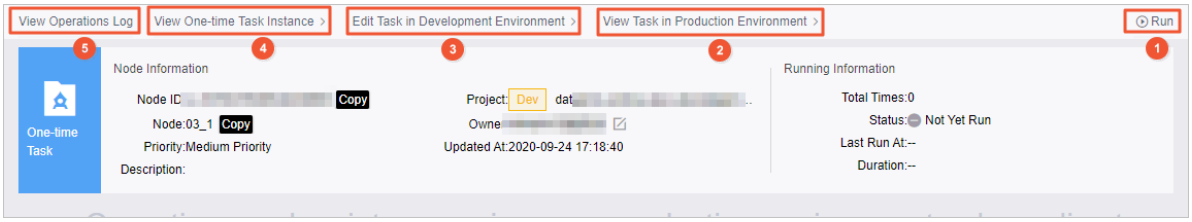
Click a one-time task in the **One-time Tasks** section. The task details appear in the right-side workspace.

- The following figure shows the workspace of a one-time task that is submitted or published from the **Integrated** module.



No.	Description
1	To run a one-time task, perform the following steps: i. Click **Run** in the upper-right corner. ii. In the **Run** dialog box, modify the **Instance Name** and **Data Timestamp** parameters or use their default values. iii. Click **OK**.
2	Click **View Task in Production Environment** to view the code of the task in the production environment.
3	Click **Edit Task in Development Environment** to edit the task in the development environment.
4	Click **View Node Script** to view the code of the task in the development environment.
5	Click **View One-time Task Instance**. In the One-time Task Instances section, view the instances that have been generated for the task.
6	Click **View Operations Log**. In the **Operations Log** pane, view the operation logs of the task.

- The following figure shows the workspace of a one-time task that is submitted or published from the **Develop** module.



No.	Description
1	To run a one-time task, perform the following steps: i. Click **Run** in the upper-right corner. ii. In the **Run** dialog box, modify the **Instance Name** and **Data Timestamp** parameters or use their default values. iii. Click **OK**.
2	Click **View Task in Production Environment** to view the code of the task in the production environment.
3	Click **Edit Task in Development Environment** to edit the task in the development environment.
4	Click **View One-time Task Instance**. In the One-time Task Instances section, view the instances that have been generated for the task.
5	Click **View Operations Log**. In the **Operations Log** pane, view the operation logs of the task.

9.12.2.2. Recurring tasks

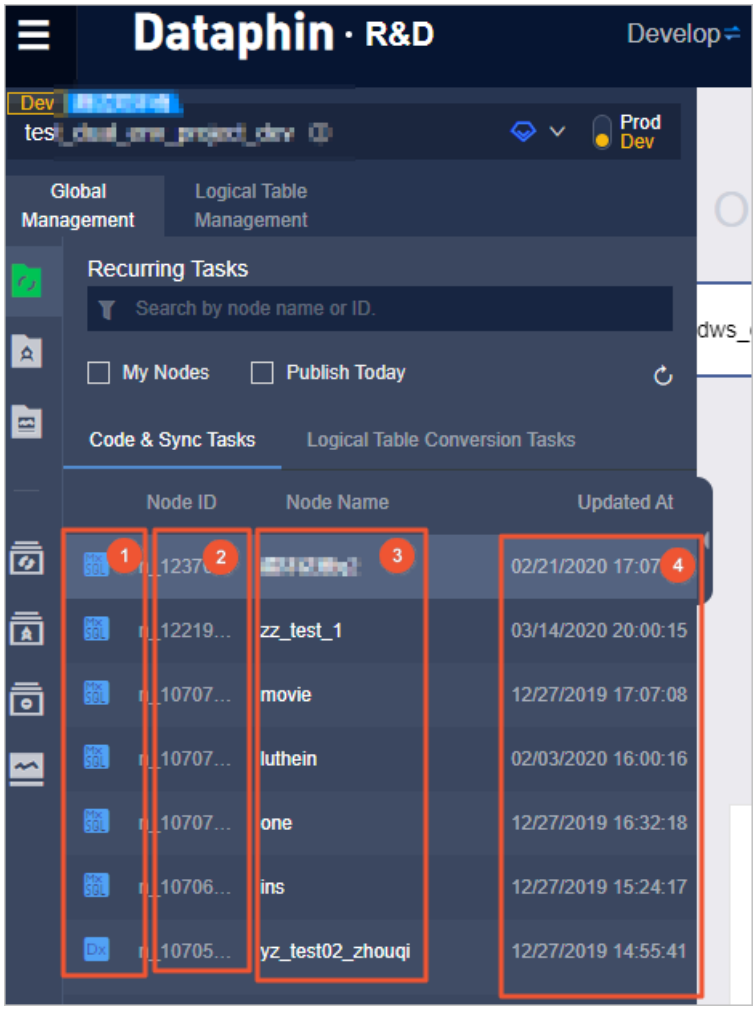
The Recurring Tasks section displays the recurring tasks that have been submitted and published. This topic describes the operations that you can perform on recurring tasks. For example, you can view recurring tasks and use DAGs to manage these tasks.

Go to the Recurring Tasks section

To go to the Recurring Tasks section, perform the following steps:

1. Log on to the Dataphin console.
2. Go to the **Global Management** tab.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner, click the **Dev**, **Basic**, or **Prod** tab, and then select a project.
   iii. Click **Scheduling** in the top navigation bar. The **Global Management** tab appears by default.

Click the icon on the left-side navigation submenu. The **Recurring Tasks** section appears.



No.	Description
1	The type of the task.
2	The node ID of the task.
3	The node name of the task.
4	The time when the task was last modified.

Search for recurring tasks

- Click the icon in the search box, click the icon next to **Owner** or **Task Type**, and then select an owner or a task type. You can also select both an owner and a task type to search for your desired recurring tasks.
- Enter a keyword in the search box to search for recurring tasks whose names contain the keyword.

Manage a recurring task in the right-side workspace

Click a recurring task in the **Recurring Tasks** section. The DAG of the task appears in the right-side workspace. Right-click the task node in the DAG. On the shortcut menu that appears, you can select menu items to perform supported operations.

- The following figure shows the shortcut menu for a recurring task that is submitted or published from the **Integrated** module.

Menu item	Description
Show Parent Nodes	Select **Show Parent Nodes** and select the layer that you want to view.
Show Child Nodes	Select **Show Child Nodes** and select the layer that you want to view.
View Node Script	Select **View Node Script**. On the Node Script page, view the code of the task.
View Script	Select **View Script**. On the **Pipeline Details** page, view the pipeline script of the task.
View Operations Log	Select **View Operations Log**. In the **Operations Log** pane, view the operation details of the task.
Change Owner	Select **Change Owner**. In the Change Owner dialog box, select a member to whom you want to transfer the ownership of the task. Note You can transfer a task only to a business unit administrator, the super administrator, or a project administrator.
View Instances	Choose **View Instances** > **View Recurring Instances**. In the **Recurring Task Instances** section, view the recurring instances that have been generated for the task.
	Choose **View Instances** > **View Retroactive Data Generation Instances**. In the **Retroactive Data Generation Instances** section, view the retroactive data generation instances that have been generated for the task.
Generate Retroactive Data	To generate retroactive data for the task, perform the following steps: i. Select **Generate Retroactive Data**. ii. In the **Generate Retroactive Data** dialog box, set the **Instance Name**, **Data Timestamp**, and Select Downstream Nodes parameters. iii. Click **OK**.

- The following figure shows the shortcut menu for a recurring task that is submitted or published from the **Develop** module.

Menu item	Description
Edit Node in Development Environment	Select **Edit Node in Development Environment** to edit the task in the development environment.

Menu item	Description
View Node in Production Environment	Select **View Node in Production Environment** to view the task in the production environment.
Show Parent Nodes	For more information, see the preceding table.
Show Child Nodes	
View Node Script	
View Operations Log	
Change Owner	
View Instances	Choose **View Instances** > **View Recurring Instances**. In the **Recurring Task Instances** section, view the recurring instances that have been generated for the task.
	Choose **View Instances** > **View Retroactive Data Generation Instances**. In the **Retroactive Data Generation Instances** section, view the retroactive data generation instances that have been generated for the task.
Generate Retroactive Data	To generate retroactive data for the task, perform the following steps: i. Select **Generate Retroactive Data**. ii. In the **Generate Retroactive Data** dialog box, set the **Instance Name**, **Data Timestamp**, and Select Downstream Nodes parameters. iii. Click **OK**.

9.12.2.3. Stream processing tasks

The Stream Processing Tasks section displays the stream processing tasks that have been submitted and published. These tasks must be run manually. This topic describes the operations that you can perform on stream processing tasks.

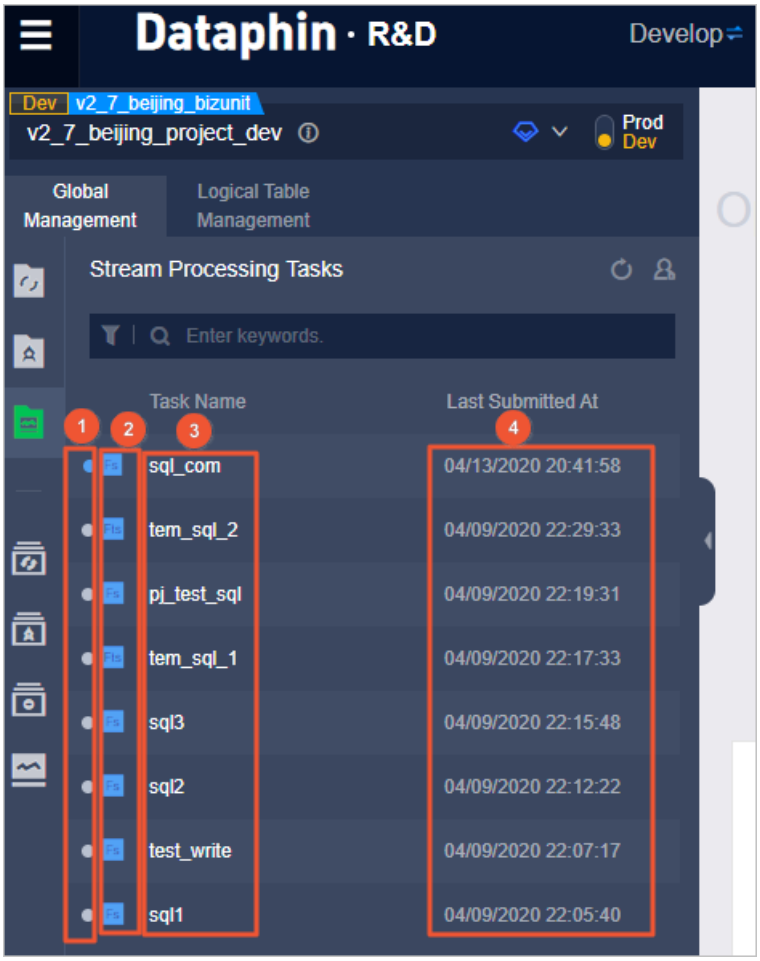
Go to the Stream Processing Tasks section

To go to the Stream Processing Tasks section, perform the following steps:

1. Log on to the Dataphin console.
2. Go to the **Global Management** tab.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner, click the **Dev**, **Basic**, or **Prod** tab, and then select a project.

iii. Click **Scheduling** in the top navigation bar. The **Global Management** tab appears by default.

Click the icon on the left-side navigation submenu. The **Stream Processing Tasks** section appears.



No.	Description
1	The status of the task. When you run a stream processing task in a project in Prod or Basic mode, a production instance is run. • : A production instance is running. • : No production instance is running. When you run a stream processing task in a project in Dev mode, a test instance is run. • : A test instance is running. • : No test instance is running.

No.	Description
2	The type of the task. Each task type is indicated by a unique icon. • : FLINK_SQL • : FLINK_TEMPLATE_SQL
3	The name of the task. The task name is the name of the stream processing task that you submitted.
4	The time when the task was last modified. By default, stream processing tasks are sorted in descending order of running time.

Search for stream processing tasks

- In the Stream Processing Tasks section, click the icon and then the icon. In the drop-down list that appears, select **FLINK_SQL** or **FLINK_TEMPLATE_SQL** to filter tasks of the specified type.
- Enter a task name in the search box to search for the specific task. Alternatively, enter a keyword in the search box to search for tasks whose names contain the keyword.

View stream processing tasks

Click the icon next to Stream Processing Tasks to view the stream processing tasks that you own.

Manage a stream processing task in the right-side workspace

Click a stream processing task in the **Stream Processing Tasks** section. The task details appear in the right-side workspace.

If a stream processing task in a project in Dev mode has no running test instance, click **Start Test Instance** in the upper-right corner of the workspace.

1. In the **Test Instance Parameter Configuration** dialog box, set the parameters as required.
2. ○ If you select **Print Log** for **Test Method**, set **Start Time for Reading Data**. Then, click **Start** to run a test instance.
   ○ If you select **Generate Table** for **Test Method**, set **Start Time for Reading Data** and specify the output table. Then, click **Start** to run a test instance.

The DAG displays information about the nodes of a stream processing task and relationships between the nodes. After you click a node in the DAG, the node details appear in the lower-left corner of the workspace.

You can perform the following operations on the task in the workspace:

- Click **Task Script** in the top navigation bar of the workspace. In the Task Scripts pane, view the code of the task. You can also click **Go to R&D Workbench and Edit Task Code** to edit the code.
- Click **Task Parameters** in the top navigation bar of the workspace. In the Task Parameters pane, view the parameters of the task. You can also click **Go to R&D Workbench and Edit Task Parameters** to modify the parameters.
- Click **Operations Log** in the top navigation bar of the workspace. In the Operations Log pane,

view the operation logs of the task.

- If the task belongs to a project in Dev mode, click **View Test Instance** in the top navigation bar of the workspace to view the test instance in the **Stream Processing Instances** section.
- If the task belongs to a project in Prod or Basic mode, click **View Production Instances** in the top navigation bar of the workspace to view the production instance in the **Stream Processing Instances** section.

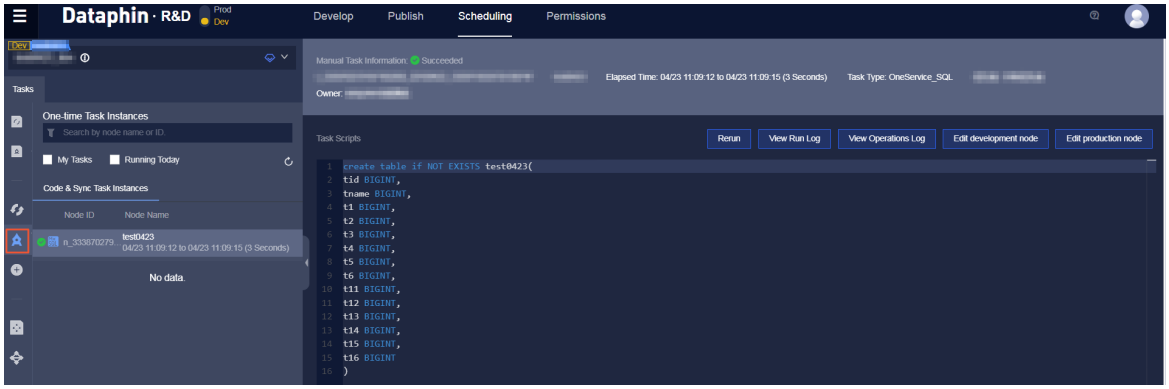
- If the task type is **FLINK_TEMPLATE_SQL**, click **Template Details** in the top navigation bar of the workspace. In the Template Details pane, view the template information. You can also click **Go to R&D Workbench to Edit Template** to edit the template information.

9.12.2.4. One-time instances

This topic describes the operations that you can perform on one-time instances.

One-time Task Instances page

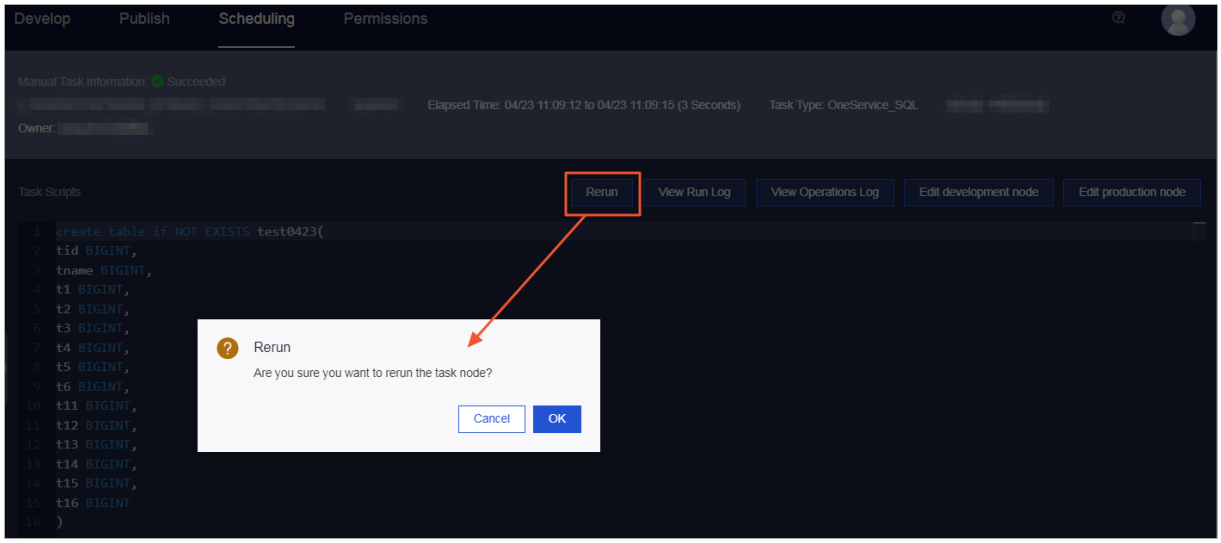
1. Go to the scheduling center. In the left-side navigation pane, click Global Management. On the left-side navigation submenu, click **One-time Task Instances**. The One-time Task Instances page appears.



2. In the left-side navigation pane of the One-time Task Instances page, view the one-time instance nodes that are sorted in descending order by running time.
   - In the left-side navigation pane, you can view the instance nodes and search for a specific instance node. In the search box at the top of the left-side navigation pane, you can enter a node name or ID to search for an instance node. You can also select the **My Task Instances** and **Running Today** check boxes to filter the instance nodes that you own and the instance nodes created on the current day, respectively. In the Code & Sync Task Instances section, all instance nodes that meet the search conditions are sorted in descending order by running time. By default, the task type (displayed as an icon), ID, name, start time, end time, and duration of an instance node are displayed in each row.
   - In the right-side workspace, you can view the code and details of the current one-time instance node, as well as the operations that can be performed on the current one-time instance node. The instance details are available at the top of the workspace, including the status, ID, name, running time, task type, and owner of the current instance node. You can rerun the instance, terminate the instance, view the operational logs, view the operations logs, and edit the node.

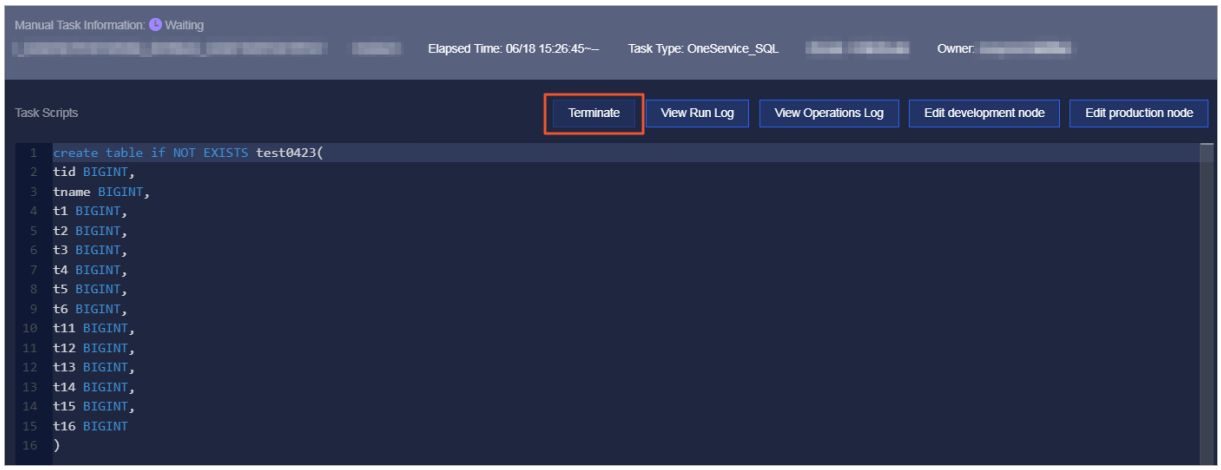
Rerun a one-time instance

As shown in the following figure, click **Rerun** in the upper-right corner of the workspace. In the dialog box that appears, click **OK**. Then, the current one-time instance is rerun.

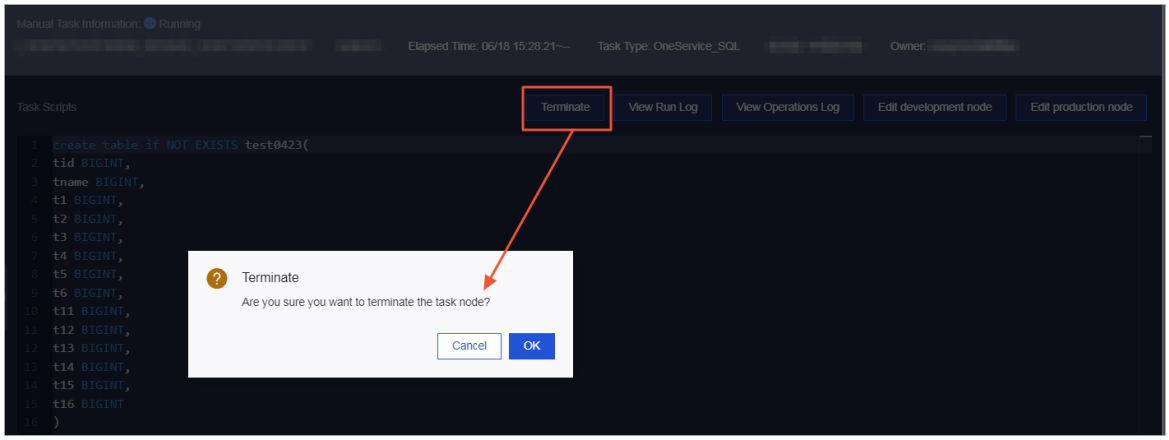


Note You can rerun a one-time instance only when the instance is completed, that is, the instance is in the Succeeded, Failed, or Not Yet Run state. Otherwise, the **Rerun** button is invisible.

Terminate a running one-time instance

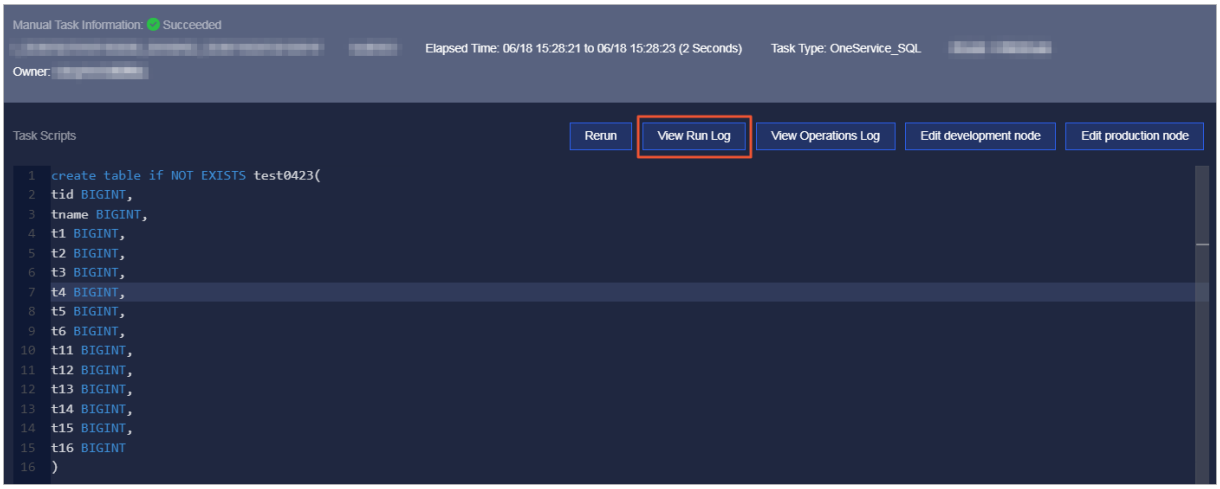


1. As shown in the preceding figure, if the current one-time instance is not completed, that is, the instance is in the Initial, Waiting, or Running state, the **Terminate** button is visible in the upper-right corner of the workspace.
2. Click **Terminate**. The Terminate dialog box appears, as shown in the following figure.

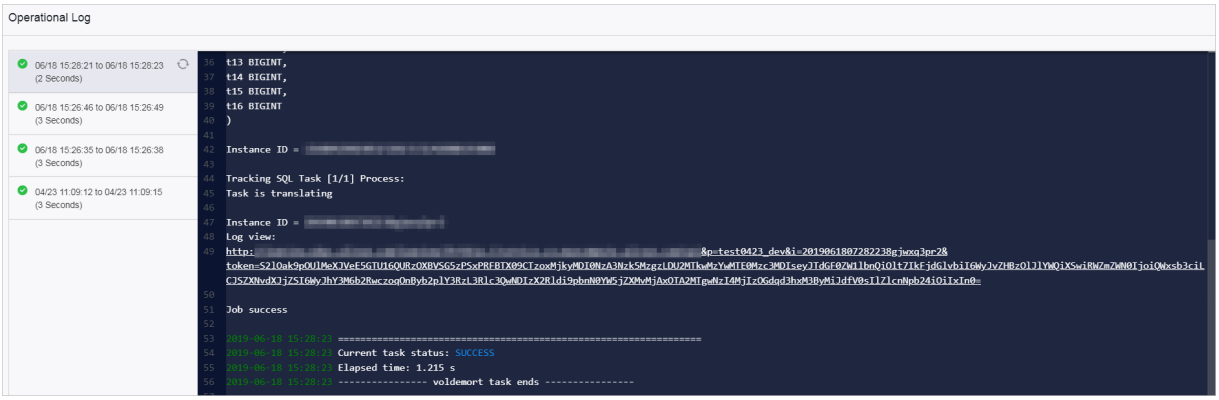


3. Click **OK**. Then, the current running instance is terminated. After a one-time instance is terminated, its final status is Failed.

View the operational logs of an instance

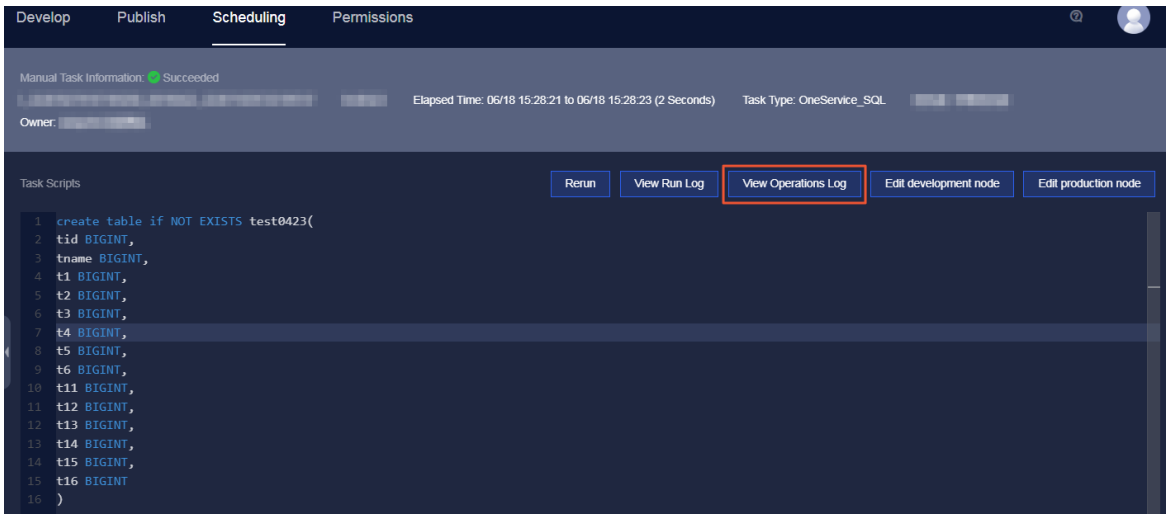


As shown in the preceding figure, click **View Operational Logs** at the top of the workspace. On the Operational Log page that appears, you can view the detailed running process of the current one-time instance, as shown in the following figure.

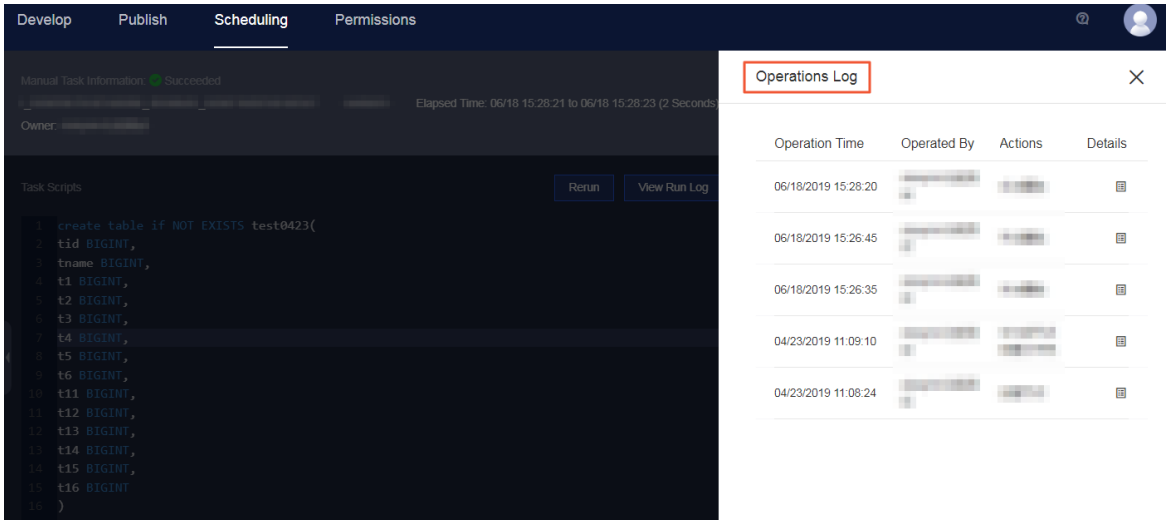


View the operations logs of a task

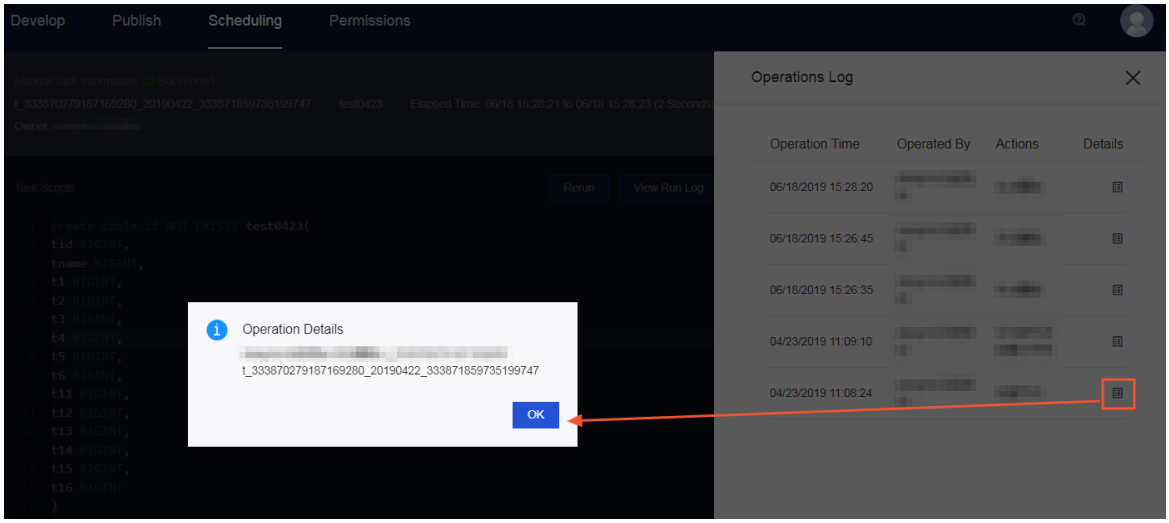
1. Click **View Operations Logs** at the top of the workspace, as shown in the following figure.



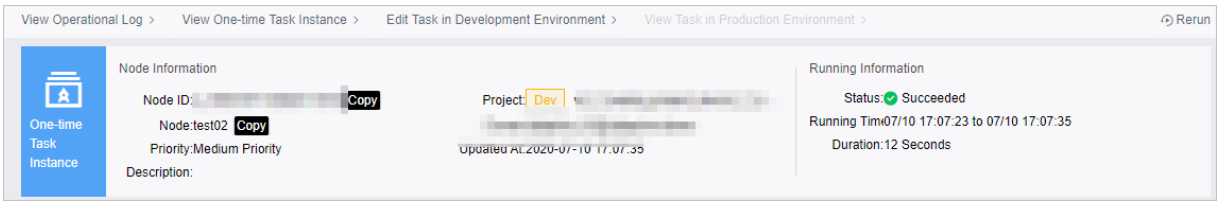
2. In the Operations Log dialog box that appears, you can view the operation history of the current task, as shown in the following figure.



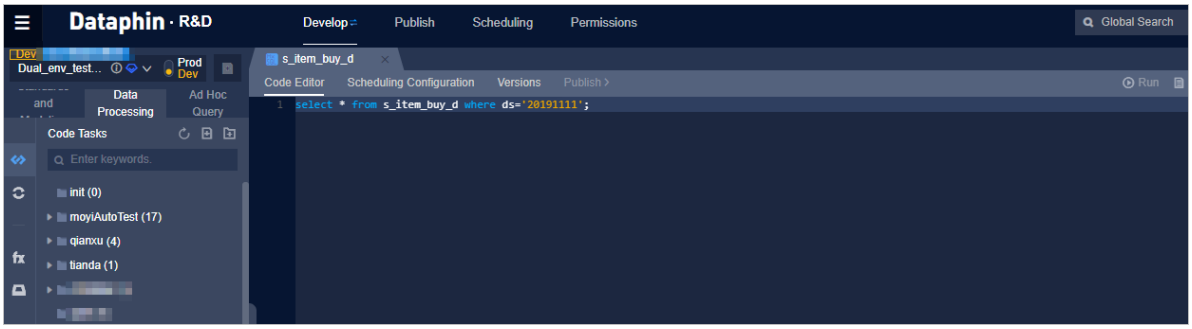
3. Click the icon in the **Details** column of an operation, as shown in the following figure. In the dialog box that appears, you can view the details of the operation.



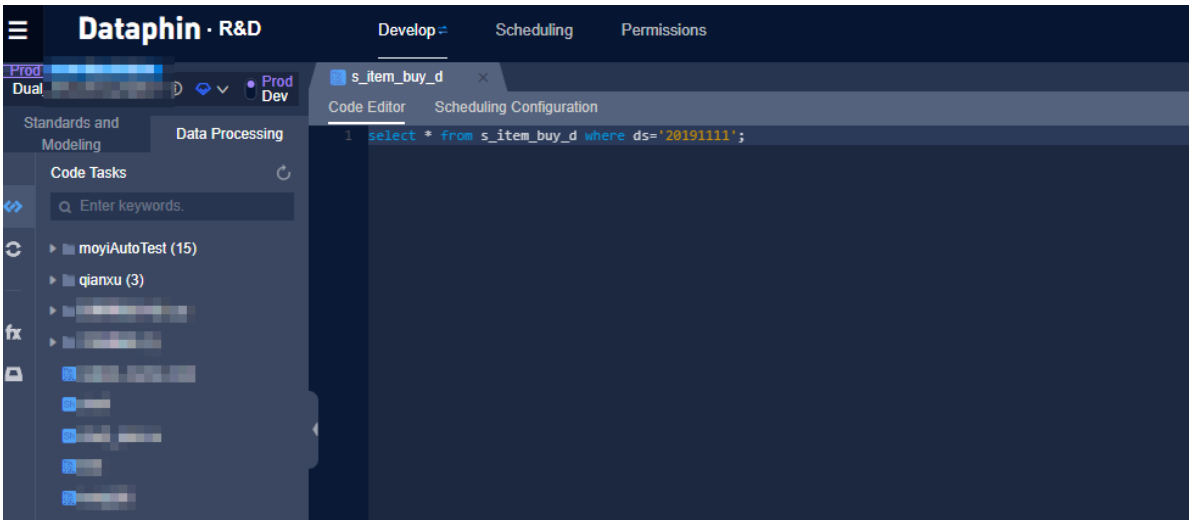
Edit a node



- Click **Edit Task in Development Environment** at the top of the workspace to go to the editing page of the node in the development environment, as shown in the following figure.



- Click **View Task in Production Environment** at the top of the workspace to go to the editing page of the node in the production environment, as shown in the following figure.



9.12.2.5. Recurring instances

Recurring instances are generated when recurring tasks are periodically scheduled in the production environment. This topic describes the operations that you can perform on recurring instances. For example, you can view recurring instances and use DAGs to manage these instances.

Go to the Recurring Task Instances section

To go to the Recurring Task Instances section, perform the following steps:

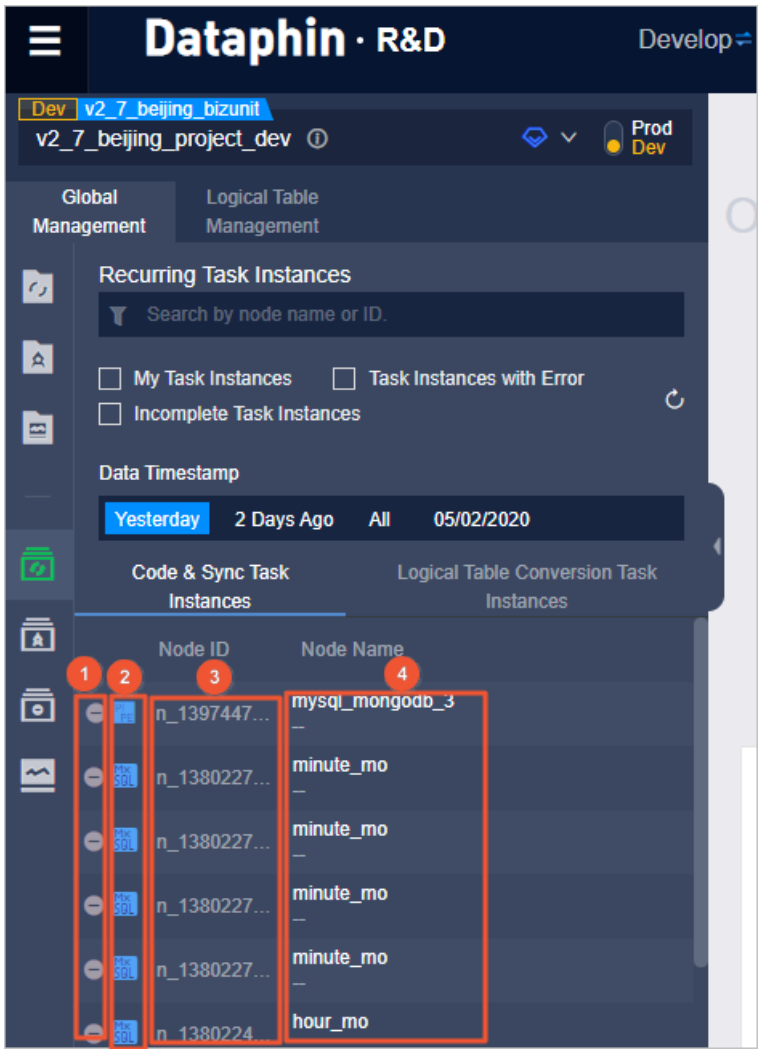
1. Log on to the Dataphin console.
2. Go to the **Global Management** tab.
    i. On the Dataphin homepage, click **R&D** in the top navigation bar.

ii. On the Develop page, click the icon next to the project name in the upper-left corner, click the **Dev**, **Basic**, or **Prod** tab, and then select a project.

iii. Click **Scheduling** in the top navigation bar. The **Global Management** tab appears by default.

- If the project that you accessed last time is in **Basic** or **Prod** mode, use one of the following methods to go to the **Global Management** tab:
  - a. On the Dataphin homepage, click **Scheduling and Management** in the middle section, or click **Enter** next to **Scheduling** in the upper-right corner.
    b. On the Scheduling page, click the icon next to the project name in the upper-left corner, click the **Dev** tab, and then select a project.
    c. The **Global Management** tab appears by default.
  - a. On the Dataphin homepage, click **R&D** in the top navigation bar.
    b. On the Develop page, click the icon next to the project name in the upper-left corner, click the **Dev** tab, and then select a project.
    c. Click **Scheduling** in the top navigation bar. The **Global Management** tab appears by default.
- If the project that you accessed last time is in **Dev** mode, use one of the following methods to go to the **Global Management** tab:
  - On the Dataphin homepage, click **Scheduling and Management** in the middle section, or click **Enter** next to **Scheduling** in the upper-right corner. The **Global Management** tab appears by default.
  - a. On the Dataphin homepage, click **R&D** in the top navigation bar.
    b. Click **Scheduling** in the top navigation bar. The **Global Management** tab appears by default.

Click the icon on the left-side navigation submenu. The **Recurring Task Instances** section appears.



No.	Description
1	The running status of the instance.
2	The task type of the instance. Each task type is indicated by a unique icon. • : MAX_COMPUTE_SQL • : MAX_COMPUTE_MR • : SPARK_JAR_ON_MAX_COMPUTE • : SHELL • : PYTHON • : VIRTUAL

No.	Description
3	The node ID of the instance.
4	The node name of the instance.

Search for recurring instances

You can use one of the following methods to search for recurring instances:

- Click the icon in the search box, click the icon next to **Owner**, **Task Type**, or **Status**, and then select an owner, a task type, or a status. You can also specify a flexible combination of **Owner**, **Task Type**, and **Status** to search for your desired recurring instances.
- Enter an instance name in the search box to search for the specific instance. Alternatively, enter a keyword in the search box to search for instances whose names contain the keyword.

Manage a recurring instance in the right-side workspace

Right-click an instance node in the DAG. On the shortcut menu that appears, you can select menu items to perform supported operations.

- The following figure shows the shortcut menu for a recurring instance that is generated for a recurring task submitted or published from the **Integrated** module.

Menu item	Description
Show Parent Nodes	Select **Show Parent Nodes** and select the layer that you want to view.
Show Child Nodes	Select **Show Child Nodes** and select the layer that you want to view.
View Operational Log	Select **View Operational Log**. On the Operational Log page, view the operational logs of the instance.
View Node Script	Select **View Node Script**. On the Node Script page, view the code of the instance.
View Script	Select **View Script**. On the **Pipeline Details** page, view the pipeline script of the instance.
View Operations Log	Select **View Operations Log**. In the **Operations Log** pane, view the operation details of the instance.
Terminate	Select **Terminate** to terminate the instance if it is in the **Wait Submission** or **Running** state.
Rerun and Resume Scheduling	Select **Rerun and Resume Scheduling** to rerun the instance if it is in the **Success**, **Not Running**, or **Failed** state.
Rerun Downstream Nodes	Select **Rerun Downstream Nodes** to rerun the downstream nodes of the instance.
Set to Succeeded and Resume Scheduling	Select **Set to Succeeded and Resume Scheduling** to set the running status of the instance to Success and schedule the instance.

Menu item	Description
Remove Upstream Dependency	Select **Remove Upstream Dependency** to remove the upstream dependencies of the instance.
Force Rerun	Select **Force Rerun** to forcibly rerun the instance.
Pause	Select **Pause** to pause the instance.

- The following figure shows the shortcut menu for a recurring instance that is generated for a recurring task submitted or published from the **Develop** module.
  - Click **Edit Node in Development Environment** to edit the task corresponding to the instance in the development environment.
  - Click **View Node in Production Environment** to view the task corresponding to the instance in the production environment.

  For more information about other supported operations, see the preceding table.

9.12.2.6. Stream processing instances

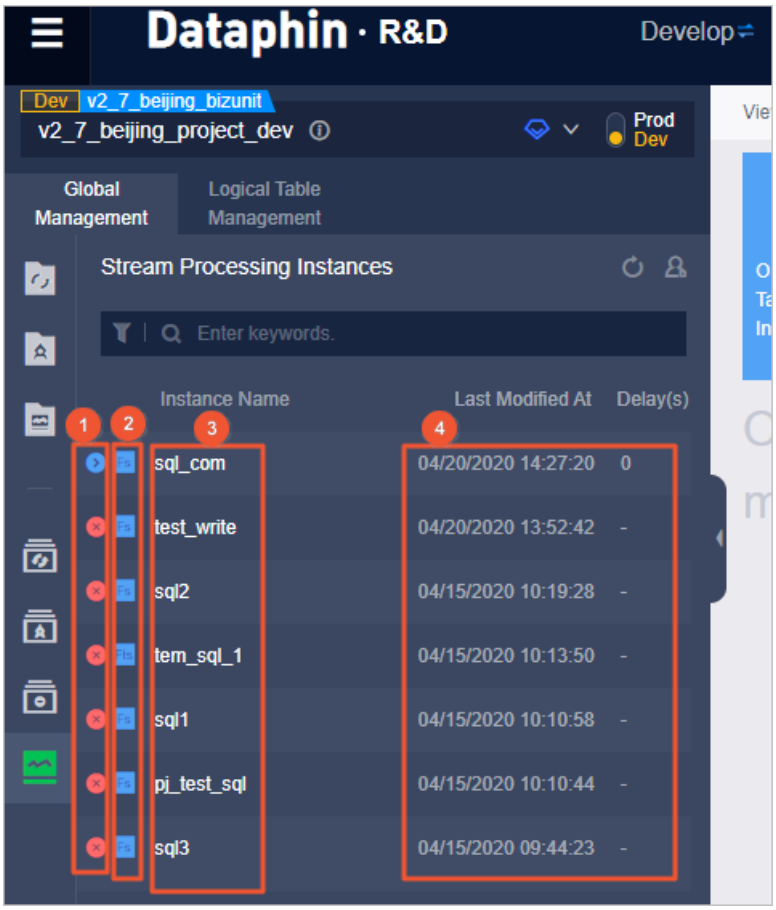
When you run a stream processing task in Dataphin, an instance is generated. A stream processing task has only one instance in an environment. This topic describes the operations that you can perform on stream processing instances.

Go to the Stream Processing Instances section

To go to the Stream Processing Instances section, perform the following steps:

1. Log on to the Dataphin console
2. Go to the **Global Management** tab.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner, click the **Dev**, **Basic**, or **Prod** tab, and then select a project.
   iii. Click **Scheduling** in the top navigation bar. The **Global Management** tab appears by default.

Click the icon on the left-side navigation submenu. The **Stream Processing Instances** section appears.



No.	Description
1	The running status of the instance. Each running status is indicated by a unique icon. • : Running • : Terminate • : Terminating • : Suspend • : Suspending • : Starting • : Failed to Run • After you resume a paused instance, the instance status changes from **Suspend** to **Resuming** and the icon changes to .

No.	Description
2	The task type of the instance. Each task type is indicated by a unique icon. • : FLINK_SQL • : FLINK_TEMPLATE_SQL
3	The name of the instance. The instance name is the name of the submitted stream processing task.
4	The time when the instance was last modified. By default, stream processing instances are sorted in descending order of running time.

Search for stream processing instances

- In the Stream Processing Instances section, click the icon and then the icon. In the drop-down list that appears, select **FLINK_SQL** or **FLINK_TEMPLATE_SQL** to filter instances of the specified type.
- Enter an instance name in the search box to search for the specific instance. Alternatively, enter a keyword in the search box to search for instances whose names contain the keyword.

View stream processing instances

Click the icon next to Stream Processing Instances to view the stream processing instances that you own.

Manage a stream processing instance in the right-side workspace

Click a stream processing instance in the **Stream Processing Instances** section. The DAG of the instance appears in the right-side workspace. The DAG shows the relationships between the nodes of the stream processing instance and the resource consumption of the nodes. After you click a node in the DAG, the node details appear in the lower-left corner of the workspace.

You can perform the following operations on the instance in the workspace:

- Click **Instance Code** in the top navigation bar of the workspace. In the Instance Code pane, view the code of the instance. You can also click **Go to R&D Workbench and Edit Task Code** to edit the code.
- Click **Instance Parameters** in the top navigation bar of the workspace. In the Instance Parameters pane, view the parameters of the instance. You can also click **Go to R&D Workbench and Edit Task Parameters** to modify the parameters.
- Click **Operations Log** in the top navigation bar of the workspace. In the Operations Log pane, view the operation logs of the instance.
- Click **View Stream Processing Task** in the top navigation bar of the workspace. In the Stream Processing Tasks section, view the stream processing task for which the instance was generated.
- If the task type is **FLINK_TEMPLATE_SQL**, click **Template Details** in the top navigation bar of the workspace. In the Template Details pane, view the template information. You can also click **Go to R&D Workbench to Edit Template** to edit the template information.
- Click **Runtime Analysis** in the top navigation bar of the workspace. On the page that appears,

view the running details of the instance, such as the failover information and logs.

In projects in Basic or Prod modes, you can pause, terminate, resume, rerun, and unpublish production instances. In projects in Dev mode, you can pause, rerun, and unpublish test instances. For more information, see the following description:

- For an instance in the **Running** state, you can click **Suspend** or **Terminate** in the upper-right corner of the workspace to pause or terminate the instance.
- For an instance in the **Suspend** state, you can click **Resume** or **Terminate** in the upper-right corner of the workspace to resume or terminate the instance.
- For an instance in the **Failed to Run** state, you can click **Rerun** or **Unpublish** in the upper-right corner of the workspace to rerun or delete the instance.

9.12.2.7. Retroactive data generation instances

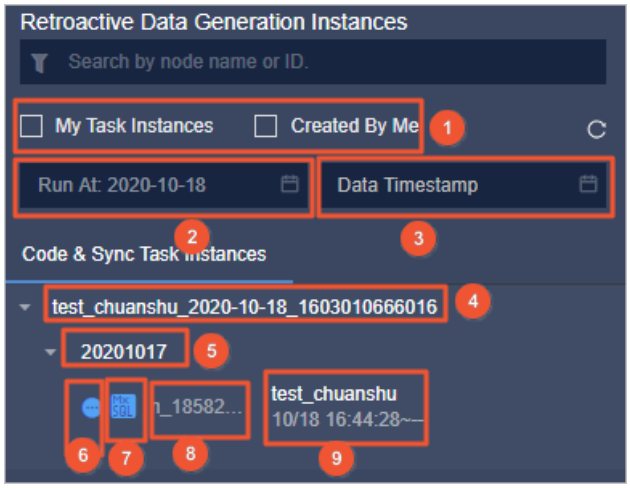
Retroactive data generation instances are generated when you generate retroactive data for recurring tasks. This topic describes the operations that you can perform on retroactive data generation instances.

Go to the Retroactive Data Generation Instances section

To go to the Retroactive Data Generation Instances section, perform the following steps:

1. Log on to the Dataphin console.
2. Go to the **Global Management** tab.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner, click the **Dev**, **Basic**, or **Prod** tab, and then select a project.
   iii. Click **Scheduling** in the top navigation bar. The **Global Management** tab appears by default.

Click the icon in the left-side navigation submenu. The **Retroactive Data Generation Instances** section appears. By default, this section displays the retroactive data generation instances that were run on the current day in descending order of running time.



No.	Description
1	The conditions for filtering the retroactive data generation instances that you own and those you created. You can select **My Task Instances** to filter the instances that you own or **Created By Me** to filter the instances that you created.
2	The date on which the retroactive data generation instance was run. You can click **Run At** and select a date to filter the instances that were run on that day.
3	The data timestamp of the retroactive data generation instance. You can click **Data Timestamp** and select a date to filter the instances that generate data for that date.
4	The display name of the retroactive data generation instance. The display name is in the format `Name of the task corresponding to the instance_Date on which the instance was run_Name of the instance`.
5	The data timestamp of the retroactive data generation instance. The data timestamp is the date for which the retroactive data generation instance generates data required by the corresponding recurring task.
6	The running status of the retroactive data generation instance.
7	The type of the recurring task for which the retroactive data generation instance was generated.
8	The node ID of the retroactive data generation instance.
9	The node name of the retroactive data generation instance.

Search for retroactive data generation instances

You can use one of the following methods to search for retroactive data generation instances:

- Click the icon in the search box, click the icon next to **Owner** or **Status**, and then select an owner or a status. You can also select both an owner and a status to search for your desired retroactive data generation instances.
- Enter the name of a retroactive data generation instance in the search box to search for the specific instance. Alternatively, enter a keyword in the search box to search for retroactive data generation instances whose names contain the keyword.

Manage a retroactive data generation instance in the right-side workspace

Click a retroactive data generation instance in the **Retroactive Data Generation Instances** section. The DAG of the instance appears in the right-side workspace. In the DAG, you can perform the following operations:

- Right-click the root node. On the shortcut menu that appears, select menu items to perform supported operations.

Menu item	Description
Show Parent Nodes	Select Show Parent Nodes and select the layer that you want to view.
Show Child Nodes	Select Show Child Nodes and select the layer that you want to view.
View Operational Log	Select **View Operational Log**. On the Operational Log page, view the operational logs of the root node.

- Right-click the instance node. On the shortcut menu that appears, select menu items to perform supported operations.

Menu item	Description
Show Parent Nodes	Select **Show Parent Nodes** and select the layer that you want to view.
Show Child Nodes	Select **Show Child Nodes** and select the layer that you want to view.
View Operational Log	Select **View Operational Log**. On the Operational Log page, view the operational logs of the instance.
View Node Script	Select **View Node Script**. On the Node Script page, view the code of the task corresponding to the instance in the development environment.
Edit Node in Development Environment	Select **Edit Task in Development Environment** to edit the task corresponding to the instance in the development environment.
View Node in Production Environment	Select **View Task in Production Environment** to view the code of the task corresponding to the instance in the production environment.
View Operations Log	Select **View Operations Log**. In the **Operations Log** pane, view the operation details of the instance.
Terminate	Select **Terminate** to terminate the instance if it is in the **Wait Submission** or **Running** state.
Rerun and Resume Scheduling	Select **Rerun and Resume Scheduling** to rerun the instance if it is in the **Success**, **Not Running**, or **Failed** state.
Rerun Downstream Nodes	Select **Rerun Downstream Nodes** to rerun the downstream nodes of the instance.
Set to Succeeded and Resume Scheduling	Select **Set to Succeeded and Resume Scheduling** to set the running status of the instance to Success and schedule the instance.
Remove Upstream Dependency	Select **Remove Upstream Dependency** to remove the upstream dependencies of the instance.
Force Rerun	Click **Force Rerun** to forcibly rerun the instance.
Pause	Click **Pause** to pause the instance.

9.12.3. Logical tables

9.12.3.1. Logical table tasks

This topic describes the operations that you can perform on logical table tasks.

Go to the Logical Table Tasks section

1. Log on to the Dataphin console.
2. Go to the **Logical Table Tasks** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner, click the **Dev**, **Basic**, or **Prod** tab, and then select a project.
   iii. Click **Scheduling** in the top navigation bar. The **Scheduling** page appears.
   iv. In the left-side navigation pane, click the **Logical Table Management** tab. The **Logical Table Tasks** section appears by default.
3. In the **Logical Table Tasks** section, you can view and search for logical tables and their conversion tasks. If you click a logical table in the Logical Table Tasks section, the DAG of the logical table appears in the right-side workspace. The DAG shows all the task nodes of the logical table and their relationships. The thumbnail of the DAG appears in the lower-right corner of the workspace.

No.	Description
1	The logical table.
2	The logical table tasks.

View the fields that are contained in a logical table task

1. In the **Logical Table Tasks** section, click the target logical table.
2. Move the pointer over the target logical table task and click the icon.
3. In the Logical Table Conversion Task Node pane, view the fields that are contained in the logical table task.

View the code of a logical table task

1. In the **Logical Table Tasks** section, click the target logical table. In the DAG in the right-side workspace, right-click the node of the target logical table task and select **View Node Script**.
2. On the **Node Script** page, view the code of the logical table task.

View the global DAG of a logical table task

1. In the **Logical Table Tasks** section, click the target logical table. In the DAG in the right-side workspace, right-click the node of the target logical table task and select **View Recurring Task**.
2. On the **Global Management** tab, view the logical table task in the **Recurring Tasks** section and the global DAG of the task in the right-side workspace.

View the global instance DAG of a logical table task

1. In the **Logical Table Tasks** section, click the target logical table. In the DAG in the right-side workspace, right-click the node of the target logical table task and choose **View Instances** > **View Recurring Instances**.
2. On the **Global Management** tab, view the instance of the logical table task in the **Recurring Task Instances** section and the global DAG of the instance in the right-side workspace.

View the retroactive data generation instances that have been generated for a logical table task

1. In the **Logical Table Tasks** section, click the target logical table. In the DAG in the right-side workspace, right-click the node of the target logical table task and choose **View Instances** > **View Retroactive Data Generation Instances**.
2. On the **Global Management** tab, view the retroactive data generation instances that have been generated for the logical table task in the **Retroactive Data Generation Instances** section.

Generate retroactive data for a logical table task

1. In the **Logical Table Tasks** section, click the target logical table. In the DAG in the right-side workspace, right-click the node of the target logical table task and select **Generate Retroactive Data**.
2. In the **Generate Retroactive Data** dialog box, set the **Instance Name**, **Data Timestamp**, and **Select Downstream Nodes** parameters.

   If you set **Select Downstream Nodes** to **Yes**, you must select downstream nodes for which you want to generate retroactive data.
3. Click **OK**.

9.12.3.2. Logical table task instances

Logical table task instances are generated when logical table tasks are run. This topic describes the operations that you can perform on logical table task instances.

Go to the Logical Table Task Instances section

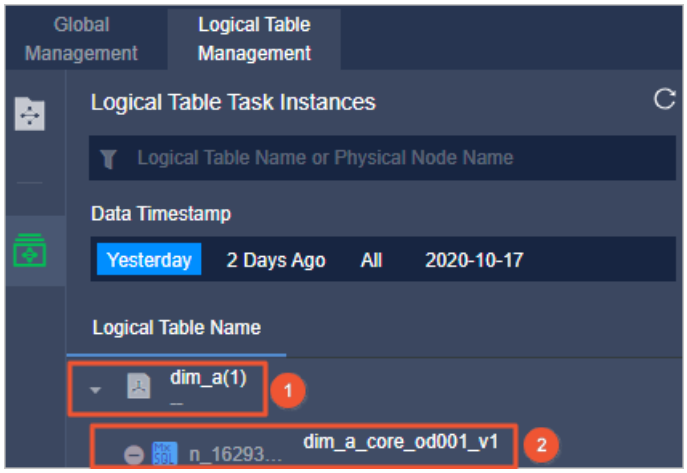
1. Log on to the Dataphin console.
2. Go to the **Logical Table Task Instances** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner, click the **Dev**, **Basic**, or **Prod** tab, and then select a project.

iii. Click **Scheduling** in the top navigation bar. The **Scheduling** page appears.

iv. In the left-side navigation pane, click the **Logical Table Management** tab. The **Logical Table Tasks** section appears by default.

v. On the left-side navigation submenu, click the icon. The **Logical Table Task Instances** section appears.

3. In the **Logical Table Task Instances** section, you can view and search for logical tables and their conversion task instances. If you click a logical table in the Logical Table Task Instances section, the DAG of the logical table appears in the right-side workspace. The DAG shows all the task instance nodes of the logical table and their running status, for example, Running, Success, or Failed. The thumbnail of the DAG appears in the lower-right corner of the workspace.Logical table task instances are displayed in a two-level hierarchy.



No.	Description
1	The logical table.
2	The logical table task instances.

View the fields that are contained in a logical table task instance

1. In the **Logical Table Task Instances** section, click the target logical table.
2. Move the pointer over the target logical table task instance and click the icon.
3. In the Logical Table Conversion Task Node pane, view the fields that are contained in the logical table task instance.

View the operational logs of a logical table task instance

1. In the **Logical Table Task Instances** section, click the target logical table. In the DAG in the right-side workspace, right-click the node of the target logical table task instance and select **View Operational Log**.
2. On the **Operational Log** page, view the operational logs of the logical table task instance.

View the code of a logical table task instance

1. In the **Logical Table Task Instances** section, click the target logical table. In the DAG in the right-side workspace, right-click the node of the target logical table task instance and

select **View Node Script**.

2. On the **Node Script** page, view the code of the logical table task instance.

Rerun a logical table task instance

> **Note** You can rerun a logical table task instance only when the instance is in the **Success**, **Not Running**, or **Failed** state.

1. In the **Logical Table Task Instances** section, click the target logical table. In the DAG in the right-side workspace, right-click the node of the target logical table task instance and select **Rerun and Resume Scheduling**.
2. In the **Rerun and Resume Scheduling** message, click **OK**.

View the global DAG of the logical table task for which a logical table task instance was generated

1. In the **Logical Table Task Instances** section, click the target logical table. In the DAG in the right-side workspace, right-click the node of the target logical table task instance and select **View Recurring Task**.
2. On the **Global Management** tab, view the task for which the logical table task instance was generated in the **Recurring Tasks** section and the global DAG of the task in the right-side workspace.

View the global DAG of a logical table task instance

1. In the **Logical Table Task Instances** section, click the target logical table. In the DAG in the right-side workspace, right-click the node of the target logical table task instance and choose **View Instances** > **View Recurring Instances**.
2. On the **Global Management** tab, view the logical table task instance in the Recurring Task Instances section and the global DAG of the instance in the right-side workspace.

View the retroactive data generation instances that have been generated for the task corresponding to a logical table task instance

1. In the **Logical Table Task Instances** section, click the target logical table. In the DAG in the right-side workspace, right-click the node of the target logical table task instance and choose **View Instances** > **View Retroactive Data Generation Instances**.
2. On the **Global Management** tab, view the retroactive data generation instances that have been generated for the task corresponding to the logical table task instance in the **Retroactive Data Generation Instances** section.

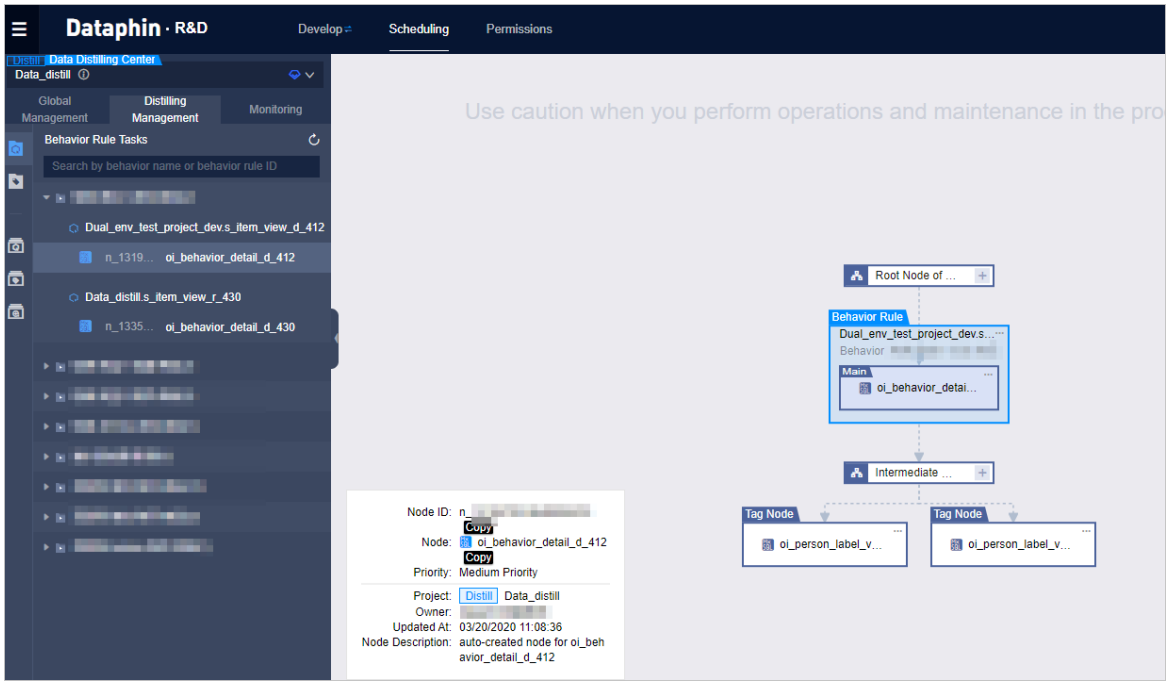
9.12.4. Distilling management

9.12.4.1. Behavior rule tasks

This topic describes the operations that you can perform on behavior rule tasks.

Behavior Rule Tasks page

1. Go to the scheduling center. Click the icon at the top of the left-side navigation pane and select the Data_distill project on the **Basic** tab. The **Distilling Management** tab appears.

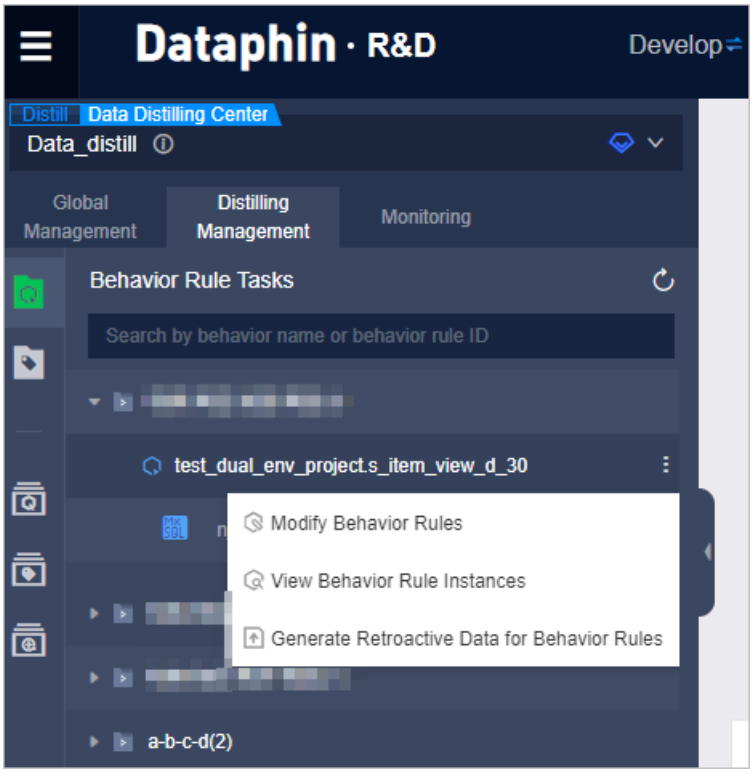


2. On the left-side navigation submenu, click **Behavior Rule Tasks**. The **Behavior Rule Tasks** page appears. In the left-side navigation pane, the behavior rule tasks are sorted in descending order by update time, and the first behavior rule task is selected by default.
   - In the left-side navigation pane, you can view and search for behavior rules and their nodes. You can enter a behavior name or behavior rule ID in the search box in the upper-left corner to search for a behavior rule task. When you search for a behavior rule task, the behavior rule ID must be exactly matched, whereas the behavior name supports fuzzy match.

     In the left-side navigation pane, the behavior rule tasks are displayed in three layers. The first layer displays the behavior. The second layer displays the behavior rules under the behavior. The third layer displays the task node of the behavior rule, including the type (displayed as an icon), ID, and name of the node. Move the pointer over a node. The ID, name, owner, and update time of the node appear.
   - The directed acyclic graph (DAG) in the workspace shows the node of the current behavior rule, the common nodes of the upstream data distilling center related to the current behavior rule, and the nodes of the downstream tags. The **Behavior Rule** box is added outside the node of the current behavior rule to display the behavior rule information. By default, all nodes except the node of the current behavior rule and the nodes of the downstream tags are hidden in node groups. You can click the **Expand** icon of a node group to view the nodes in the node group and their relationships in the DAG. In addition, the thumbnail of the DAG is available in the lower-right corner of the workspace.

Manage behavior rule tasks

- In the left-side navigation pane, move the pointer over the icon of a behavior. You can generate retroactive data for the behavior rules under the behavior.



Select **Generate Retroactive Data**. In the **Generate Retroactive Data for Behavior Rules** dialog box that appears, set the parameters as prompted and click **OK**.

- In the left-side navigation pane, move the pointer over the icon of a behavior rule. You can edit the behavior rule, view the task instances of the behavior rule, or generate retroactive data for the behavior rule.
  - Select **Modify Behavior Rules**. The **Change Behavior Rules** tab appears. For more information about how to edit the behavior rule, see Edit a behavior rule.
  - Select **View Behavior Rule Instances**. On the **Behavior Rule Task Instances** page that appears, you can view the task instances of the behavior rule. The default data timestamp is yesterday.
  - Select **Generate Retroactive Data for Behavior Rules**. In the **Generate Retroactive Data for Behavior Rules** dialog box that appears, set the parameters as prompted and click **OK**.

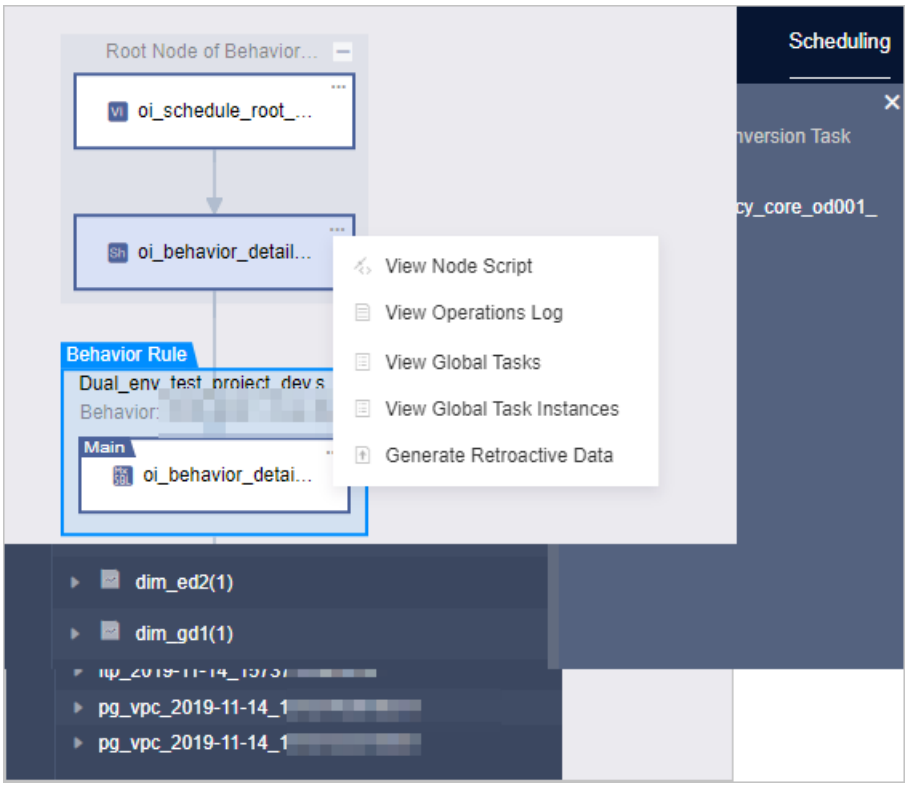
Shortcut operation items

In the upper-right corner of the workspace, the **Show All Node Groups**, **Hide All Node Groups**, and **Fit to Canvas** icons are available. In the upper-right corner of the workspace, you can click the **Refresh** button to view the latest node relationships. You can also search for a node in the DAG by node ID or output field name. A toolbar is available at the bottom of the workspace. You can zoom in or zoom out the DAG and view the DAG in full screen. You can drag the DAG or click a node to view the detailed information about the node in the lower-left corner of the workspace.

- Click the icon of the **Behavior Rule** box or right-click the **Behavior Rule** box. You can generate retroactive data for the behavior rule, edit the behavior rule, view behavior rule task instances, or view retroactive data generation instances.
  - Select **Generate Retroactive Data for Behavior Rules**. In the **Generate Retroactive Data for Behavior Rules** dialog box that appears, set the parameters as prompted and click **OK**.

- Select **Modify Behavior Rules**. On the **Change Behavior Rules** tab that appears, set the parameters as prompted. For more information, see Edit a behavior rule.
- Choose **View Instance** > **View Behavior Rule Instances**. On the **Behavior Rule Task Instances** page that appears, you can view the task instances of the behavior rule. The default data timestamp is yesterday.
- Choose **View Instance** > **View Retroactive Data Generation Instance of Behavior Rule**. On the **Retroactive Data Generation Instances** page that appears, you can view the retroactive data generation instances of the behavior rule. The default data timestamp is today.

- Click the **More** icon of a node (including the node of the current behavior rule) or right-click the node. You can view the node script, view operations logs, view global tasks, view global task instances, or generate retroactive data.



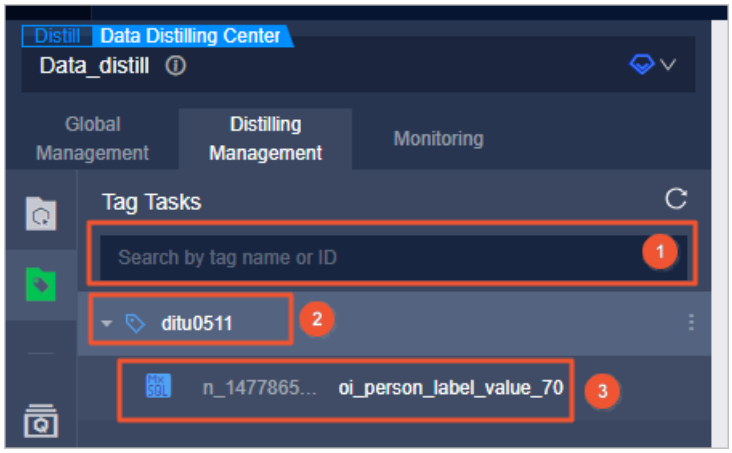
- Select **View Node Script**. On the **Node Script** page that appears, you can view the script of the node, but you cannot edit it.
- Select **View Operations Log**. In the **Operations Log** dialog box that appears, you can view the operation history of the node.
- Select **View Global Tasks**. On the **Recurring Tasks** page that appears, you can view the global DAG of the node.
- Select **View Global Task Instances**. On the **Recurring Task Instances** page that appears, you can view the global DAG of the node.
- Select **Generate Retroactive Data**. In the **Generate Retroactive Data** dialog box that appears, set the parameters as prompted and click **OK**.

9.12.4.2. Tag tasks

This topic describes the operations that you can perform on tags and tag tasks. For example, you can edit a tag, generate retroactive data for a tag, and view the task instances of a tag.

Go to the Tag Tasks section

1. Log on to the Dataphin console.
2. Go to the **Distilling Management** tab.
   - If the project that you accessed last time is the **Data_distill** project, click **Scheduling and Management** in the middle section, or click **Enter** next to **Scheduling** in the upper-right corner of the Dataphin homepage.
   - If the project that you accessed last time is not the **Data_distill** project, use one of the following methods to go to the **Distilling Management** tab:
     - a. On the Dataphin homepage, click **R&D** in the top navigation bar.
       b. On the **Develop** page, move the pointer over **Develop** in the top navigation bar and select **Distilling**.
       c. On the **Distilling** page, click **Scheduling** in the top navigation bar.
     - a. On the Dataphin homepage, click **Scheduling and Management** in the middle section, or click **Enter** next to **Scheduling** in the upper-right corner. The **Scheduling** page appears.
       b. Click the icon next to the project name in the upper-left corner, click the **Basic** tab, and then select the **Data_distill** project.
3. On the left-side navigation submenu, click the icon.
4. In the **Tag Tasks** section, view tag tasks.



No.	Description
1	The search box for you to search for tag tasks by tag name or ID.
2	The tag.
3	The tag task. The display name of a tag task is in the format of Tag task type_Tag task ID_Tag task name.

Generate retroactive data for a tag

1. Open the **Generate Retroactive Data for Tags** dialog box by using one of the following methods:

- In the **Tag Tasks** section, move the pointer over the icon next to the target tag and select **Generate Retroactive Data for Tags**.
- In the **Tag Tasks** section, click the target tag and then the target tag task. In the DAG in the right-side workspace, right-click the Tag box and select **Generate Retroactive Data for Tags**.

2. In the **Generate Retroactive Data for Tags** dialog box, set the parameters for the retroactive data generation instance.

Section	Operation
Effective Period	Specify the end date of the period for which you want to generate retroactive data.
Instance Name	Set the name of the retroactive data generation instance to be generated for the tag.

3. Click **OK**.

Edit a tag

1. Go to the Change Tag tab by using one of the following methods:
   - In the **Tag Tasks** section, move the pointer over the icon next to the target tag and select **Edit Tag**.
   - In the **Tag Tasks** section, click the target tag and then the target tag task. In the DAG in the right-side workspace, right-click the Tag box and select **Edit Tag**.
2. On the Change Tag tab, modify the tag parameters as required. For more information, see Edit a factory tag.

View the task instances of a tag

1. Go to the **Tag Task Instances** section by using one of the following methods:
   - In the **Tag Tasks** section, move the pointer over the icon next to the target tag and select **View Tag Instances**.
   - In the **Tag Tasks** section, click the target tag and then the target tag task. In the DAG in the right-side workspace, right-click the Tag box and choose **View Instance** > **Tag Instance**.
2. In the **Tag Task Instances** section, view the task instances that have been generated for the tag.

View the retroactive data generation instances for a tag

1. In the **Tag Tasks** section, click the target tag and then the target tag task. In the DAG in the right-side workspace, right-click the Tag box and choose **View Instance** > **Retroactive Data Generation Instance for Tags**.
2. In the **Retroactive Data Generation Instances** section, view the retroactive data generation instances that have been generated for the tag. You can view the details of each retroactive data generation instance.

View the code of a tag task

1. In the **Tag Tasks** section, click the target tag and then the target tag task. In the DAG in the right-side workspace, right-click the task node and select **View Node Script**.
2. On the **Node Script** page, view the code of the task.

View the operation logs of a tag task

1. In the **Tag Tasks** section, click the target tag and then the target tag task. In the DAG in the right-side workspace, right-click the task node and select **View Operations Log**.
2. In the **Operations Log** pane, view the operation logs of the task. You can click the icon in the **Details** column to view the operation details.

View the global DAG of a tag task

1. In the **Tag Tasks** section, click the target tag and then the target tag task. In the DAG in the right-side workspace, right-click the task node and select **View Global Tasks**.
2. On the **Global Management** tab, view the tag task in the **Recurring Tasks** section and the global DAG of the task in the right-side workspace.

View the global instance DAG of a tag task

1. In the **Tag Tasks** section, click the target tag and then the target tag task. In the DAG in the right-side workspace, right-click the task node and select **View Global Task Instances**.
2. On the **Global Management** tab, view the instance of the tag task in the **Recurring Task Instances** section and the global DAG of the instance in the right-side workspace.

Generate retroactive data for a tag task

1. In the **Tag Tasks** section, click the target tag and then the target tag task. In the DAG in the right-side workspace, right-click the task node and select **Generate Retroactive Data**.
2. In the **Generate Retroactive Data** dialog box, set the **Instance Name**, **Data Timestamp**, and **Select Downstream Nodes** parameters.

   If you set **Select Downstream Nodes** to **Yes**, you must select downstream nodes for which you want to generate retroactive data.
3. Click **OK**.

9.12.4.3. Behavior rule task instances

Behavior rule task instances are generated when behavior rule tasks are run. This topic describes the operations that you can perform on behavior rule task instances.

Go to the Behavior Rule Task Instances section

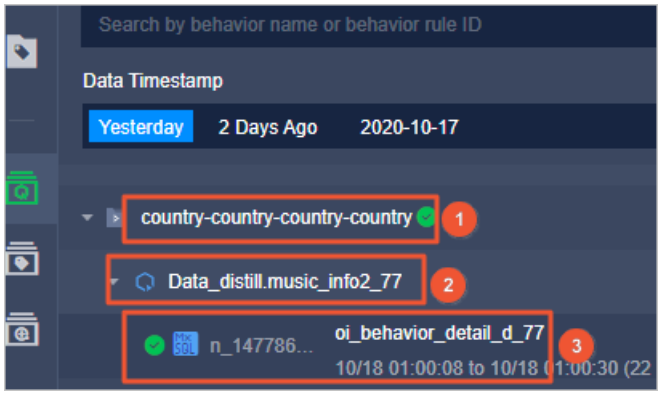
1. Log on to the Dataphin console.
2. Go to the **Distilling Management** tab.
   - If the project that you accessed last time is the **Data_distill** project, click **Scheduling and Management** in the middle section, or click **Enter** next to **Scheduling** in the upper-right corner of the Dataphin homepage.
   - If the project that you accessed last time is not the **Data_distill** project, use one of the

following methods to go to the **Distilling Management** tab:

- a. On the Dataphin homepage, click **R&D** in the top navigation bar.
  b. On the **Develop** page, move the pointer over **Develop** in the top navigation bar and select **Distilling**.
  c. On the **Distilling** page, click **Scheduling** in the top navigation bar.
- a. On the Dataphin homepage, click **Scheduling and Management** in the middle section, or click **Enter** next to **Scheduling** in the upper-right corner. The **Scheduling** page appears.
  b. Click the icon next to the project name in the upper-left corner, click the **Basic** tab, and then select the **Data_distill** project.

3. On the left-side navigation submenu, click the icon.
4. In the **Behavior Rule Task Instances** section, view behavior rule task instances.

   You can view and search for behaviors, behavior rules, and behavior rule task instances in the Behavior Rule Task Instances section. If you click a behavior rule task instance in the Behavior Rule Task Instances section, the DAG of the instance appears in the right-side workspace. The DAG shows the node of the current behavior rule task instance and its upstream and downstream nodes. The thumbnail of the DAG appears in the lower-right corner of the workspace.Behavior rule task instances are displayed in a three-level hierarchy.



No.	Description
1	The behavior and the overall running status of all task instances under the behavior. ○ The overall running status is Success only if all task instances under the behavior are properly run. ○ The overall running status is Failed if any task instance under the behavior failed. ○ The overall running status is Running if some task instances under the behavior are properly run and the others are running.
2	The behavior rule.

No.	Description
3	The behavior rule task instances. You can move the pointer over an instance to view the instance information, including the instance ID, name, owner, and running time.

Search for behavior rule task instances

In the **Behavior Rule Task Instances** section, you can search for behavior rule task instances by using one of the following methods:

- Click **Yesterday** or **2 Days Ago** below **Data Timestamp** to filter behavior rule task instances.
- Enter a behavior name or behavior rule ID in the search box to search for specific behavior rule task instances.
- Click the date below Data Timestamp and select a date to filter behavior rule task instances.

Modify a behavior rule

1. Go to the Change Behavior Rules tab by using one of the following methods:
   - In the **Behavior Rule Task Instances** section, click the target behavior. Move the pointer over the icon next to the target behavior rule and select **Modify Behavior Rules**.
   - In the **Behavior Rule Task Instances** section, click the target behavior, behavior rule, and behavior rule task instance in sequence. In the DAG in the right-side workspace, right-click the Behavior Rule box and select **Modify Behavior Rules**.
2. On the **Change Behavior Rules** tab, modify the behavior rule. For more information, see Edit a behavior rule.

View the behavior rule task under a behavior rule

1. Go to the **Behavior Rule Tasks** section by using one of the following methods:
   - In the **Behavior Rule Task Instances** section, click the target behavior. Move the pointer over the icon next to the target behavior rule and select **View Behavior Rule Tasks**.
   - In the **Behavior Rule Task Instances** section, click the target behavior, behavior rule, and behavior rule task instance in sequence. In the DAG in the right-side workspace, right-click the Behavior Rule box and select **View Behavior Rule Tasks**.
2. In the **Behavior Rule Tasks** section, view the behavior rule task under the behavior rule. You can view the details of the task.

View the operational logs of a behavior rule task instance

1. In the **Behavior Rule Task Instances** section, click the target behavior, behavior rule, and behavior rule task instance in sequence. In the DAG in the right-side workspace, right-click the instance node and select **View Operational Log**.
2. On the **Operational Log** page, view the operational logs of the instance.

View the code of a behavior rule task instance

1. In the **Behavior Rule Task Instances** section, click the target behavior, behavior rule, and behavior rule task instance in sequence. In the DAG in the right-side workspace, right-click the instance node and select **View Node Script**.

2. On the **Node Script** page, view the code of the instance.

View the operation logs of a behavior rule task instance

1. In the **Behavior Rule Task Instances** section, click the target behavior, behavior rule, and behavior rule task instance in sequence. In the DAG in the right-side workspace, right-click the instance node and select **View Operations Log**.
2. In the **Operations Log** pane, view the operation logs of the instance. You can click the  icon in the **Details** column to view the operation details.

View the global DAG of the behavior rule task for which a behavior rule task instance was generated

1. In the **Behavior Rule Task Instances** section, click the target behavior, behavior rule, and behavior rule task instance in sequence. In the DAG in the right-side workspace, right-click the instance node and select **View Global Tasks**.
2. On the **Global Management** tab, view the behavior rule task for which the instance was generated in the **Recurring Tasks** section and the global DAG of the task in the right-side workspace.

View the global DAG of a behavior rule task instance

1. In the **Behavior Rule Task Instances** section, click the target behavior, behavior rule, and behavior rule task instance in sequence. In the DAG in the right-side workspace, right-click the instance node and select **View Global Task Instances**.
2. On the **Global Management** tab, view the instance in the **Recurring Task Instances** section and the global DAG of the instance in the right-side workspace.

Terminate a behavior rule task instance

> **Note** You can terminate a behavior rule task instance only when the instance is in the **Wait Submission** or **Running** state.

1. In the **Behavior Rule Task Instances** section, click the target behavior, behavior rule, and behavior rule task instance in sequence. In the DAG in the right-side workspace, right-click the instance node and select **Terminate**.
2. In the **Terminate** message, click **OK**.

Rerun a behavior rule task instance

> **Note**
>
> - You can rerun a behavior rule task instance only when the instance is in the **Success**, **Not Running**, or **Failed** state.
> - Use caution when you rerun a behavior rule task instance, because the data generated by the instance previously will be overwritten after the instance is rerun.

1. In the **Behavior Rule Task Instances** section, click the target behavior, behavior rule, and behavior rule task instance in sequence. In the DAG in the right-side workspace, right-click the instance node and select **Rerun and Resume Scheduling**.

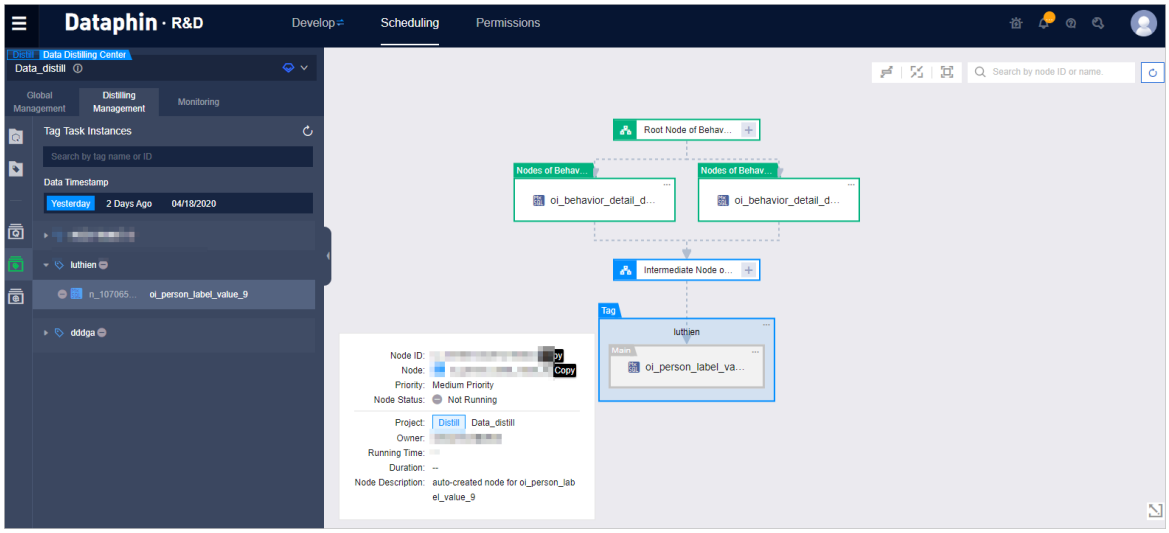
2. In the **Rerun and Resume Scheduling** message, click **OK**.

9.12.4.4. Tag task instances

This topic describes the operations that you can perform on tag task instances.

Tag Task Instances page

1. Go to the scheduling center. By default, the **Distilling Management** tab appears, as shown in the following figure.



2. On the left-side navigation submenu, click **Tag Task Instances**. The **Tag Task Instances** page appears.
   - In the left-side navigation pane, you can view and search for tags and their nodes. You can enter a tag name or tag ID in the search box in the upper-left corner to search for a tag task. When you search for a tag task, the tag ID must be exactly matched, whereas the tag name supports fuzzy match. The default data timestamp of the searched instances is yesterday. You can select **2 Days Ago** or a specific date to filter the search results.
   - In the left-side navigation pane, the tag task instances are displayed in two layers. The first layer displays the tag. The second layer displays the task instance node of the tag, including the instance status, type, ID, name, and running time of the node. Move the pointer over a node. The ID, name, owner, and running time of the node appear. In the left-side navigation pane, move the pointer over the icon of a tag to perform the following operations:
     - Select **Edit Tag**. On the **Change Tag** tab that appears, set the parameters as prompted. For more information, see Edit a factory tag.
     - Select **View Tag Tasks**. On the **Tag Tasks** page that appears, view the details of the task.
   - The color of a node box indicates the running status of the node. Green indicates that the node runs successfully. Red indicates that the node fails to run. Gray indicates that the node does not run. Blue indicates that the node is running. Purple indicates that the node is waiting to run. The color of a node group box indicates the running status of the node group. If all nodes in the node group run successfully, the node group appears in green. If

a node in the node group fails to run, the node group appears in red.

- The directed acyclic graph (DAG) in the workspace shows the node of the current tag, the intermediate nodes of related tags, the nodes of the behavior rules on which the current tag depends, and the common nodes of the upstream data distilling center related to the behavior rules. The **Tag** box is added outside the node of the current tag to display the tag information. By default, all nodes except the nodes of the behavior rules and the node of the current tag are hidden in node groups. You can click the Expand icon of a node group to view the nodes in the node group and their relationships in the DAG. In addition, the thumbnail of the DAG is available in the lower-right corner of the workspace.

Shortcut operation items

- Click the icon of the **Tag** box or right-click the **Tag** box to perform the following operations:
  - Select **Edit Tag**. On the **Change Tag** tab that appears, set the parameters as prompted. For more information, see Edit a factory tag.
  - Select **View Tag Tasks**. On the **Tag Tasks** page that appears, view the details of the task.
- Click the icon of a node (including the node of the current tag) or right-click the node to perform the following operations:
  - Select **View Operational Log**. On the **Operational Log** page that appears, you can view the operational logs of the node.
  - Select **View Node Script**. On the **Node Script** page that appears, you can view the script of the node, but you cannot edit it.
  - Select **View Operations Log**. In the **Operations Log** dialog box that appears, you can view the operation history of the node.
  - Select **View Global Tasks**. On the **Recurring Tasks** page that appears, you can view the global DAG of the node.
  - Select **View Global Task Instances**. On the **Recurring Task Instances** page that appears, you can view the global DAG of the node.
  - Select **Terminate** to terminate the node in the **Waiting** or **Running** state.
  - Select **Rerun and Resume Scheduling** to rerun the node in the **Success**, **Failed**, or **Not Running** state.

9.12.4.5. Retroactive data generation instances

The Retroactive Data Generation Instances section displays retroactive data generation instances that are generated when you generate retroactive data for tags and behavior rules. This topic describes the operations that you can perform on retroactive data generation instances.

Go to the Retroactive Data Generation Instances section

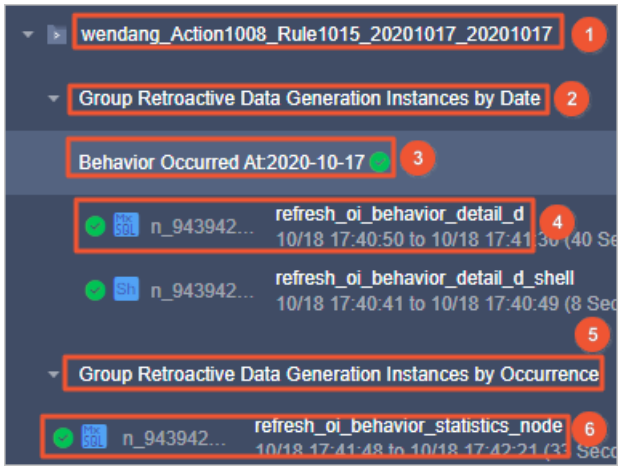
1. Log on to the Dataphin console.
2. Go to the **Distilling Management** tab.
   - If the project that you accessed last time is the **Data_distill** project, click **Scheduling and Management** in the middle section, or click **Enter** next to **Scheduling** in the upper-right corner of the Dataphin homepage.

- If the project that you accessed last time is not the **Data_distill** project, use one of the following methods to go to the **Distilling Management** tab:
  - a. On the Dataphin homepage, click **R&D** in the top navigation bar.
    b. On the **Develop** page, move the pointer over **Develop** in the top navigation bar and select **Distilling**.
    c. On the **Distilling** page, click **Scheduling** in the top navigation bar.
  - a. On the Dataphin homepage, click **Scheduling and Management** in the middle section, or click **Enter** next to **Scheduling** in the upper-right corner. The **Scheduling** page appears.
    b. Click the icon next to the project name in the upper-left corner, click the **Basic** tab, and then select the **Data_distill** project.

3. On the left-side navigation submenu, click the icon.
4. In the **Retroactive Data Generation Instances** section, view the retroactive data generation instances that are generated for tags and behavior rules.

   You can also search for retroactive data generation instances in the Retroactive Data Generation Instances section. If you click a retroactive data generation instance for a behavior rule or a tag in the Retroactive Data Generation Instances section, the DAG of the instance appears in the right-side workspace. The DAG shows the node of the current retroactive data generation instance and its relationships with other retroactive data generation instances for the same behavior rule or tag. The thumbnail of the DAG appears in the lower-right corner of the workspace. The **Retroactive Data Generation Instances** section contains the **Retroactive Data Generation Instance for Behavior Rule** and **Retroactive Data Generation Instance for Tag** tabs. You can view different instance information on the two tabs.

   - The following table describes the instance information that you can view on the **Retroactive Data Generation Instance for Behavior Rule** tab.



No.	Description
1	The name of the folder for storing retroactive data generation instances for a behavior rule. The name is in the format of Prefix_Behavior ID_Behavior rule ID_Start date for generating retroactive data_End date for generating retroactive data.

No.	Description
2	A type of retroactive data generation instances. ■ **Group Retroactive Data Generation Instances by Date**: This type of instances are run every day in the specified period. You can specify a date in the Group Retroactive Data Generation Instances by Date box in the DAG to filter specific instances of this type. ■ **Group Retroactive Data Generation Instances by Occurrence**: This type of instances are run only once. Dataphin runs this type of instances for a behavior rule only after all instances of the **Group Retroactive Data Generation Instances by Date** type are properly run for the behavior rule.
3	The data timestamp and overall running status of retroactive data generation instances of the **Group Retroactive Data Generation Instances by Date** type. ■ The overall running status is Success only when all the instances are properly run. ■ The overall running status is Failed if any instance failed. ■ The overall running status is Running if some instances are properly run and the others are running.
4	The display name of a retroactive data generation instance of the **Group Retroactive Data Generation Instances by Date** type. The display name consists of the running status of the instance, type of the corresponding behavior rule task, ID of the instance, and name of the instance.
5	A type of retroactive data generation instances.
6	The display name of a retroactive data generation instance of the **Group Retroactive Data Generation Instances by Occurrence** type. The display name consists of the running status of the instance, type of the corresponding behavior rule task, ID of the instance, and name of the instance.

- **The following table describes the instance information that you can view on the Retroactive Data Generation Instance for Tag tab.**

No.	Description
1	The name of the folder for storing retroactive data generation instances for a tag. The name is in the format of Prefix_Tag ID_End date for generating retroactive data.
2	The display name of a retroactive data generation instance for a tag. The display name consists of the running status of the instance, type of the corresponding tag task, ID of the instance, and name of the instance.

Search for retroactive data generation instances

In the **Retroactive Data Generation Instances** section, retroactive data generation instances are sorted in descending order of generation time. You can search for retroactive data generation instances by using one of the following methods:

- Enter an instance name in the search box to search for specific retroactive data generation instances. On the Retroactive Data Generation Instance for Behavior Rule tab, the instances whose data timestamp is the current day are found by default. On the Retroactive Data Generation Instance for Tag tab, the instances whose data timestamp is the previous day are found by default.
- On the Retroactive Data Generation Instance for Behavior Rule tab, click **Today** or **Yesterday** or select a date below **Retroactive Data Generation Date** to filter retroactive data generation instances. On the Retroactive Data Generation Instance for Tag tab, click Yesterday or 2 Days Ago or select a date below End Date to filter retroactive data generation instances.

View the operational logs of a retroactive data generation instance

1. In the **Retroactive Data Generation Instances** section, click the retroactive data generation instance whose operational logs you want to view. In the DAG in the right-side workspace, right-click the instance node and select **View Operational Log**.
2. On the **Operational Log** page, view the operational logs of the instance.

View the code of a retroactive data generation instance

1. In the **Retroactive Data Generation Instances** section, click the retroactive data generation instance whose code you want to view. In the DAG in the right-side workspace, right-click the instance node and select **View Node Script**.
2. On the **Node Script** page, view the code of the instance.

View the operation logs of a retroactive data generation instance

1. In the **Retroactive Data Generation Instances** section, click the retroactive data generation instance whose operation logs you want to view. In the DAG in the right-side workspace, right-click the instance node and select **View Operations Log**.
2. In the **Operations Log** pane, view the operation logs of the instance. You can click the icon in the **Details** column to view the operation details.

Terminate a retroactive data generation instance

Note You can terminate a retroactive data generation instance only when the instance is in the **Wait Submission** or **Running** state.

1. In the **Retroactive Data Generation Instances** section, click the retroactive data generation instance that you want to terminate. In the DAG in the right-side workspace, right-click the instance node and select **Terminate**.
2. In **Terminate** message, click **OK**.

Rerun a retroactive data generation instance

Note
- You can rerun a retroactive data generation instance only when the instance is in the **Success**, **Not Running**, or **Failed** state.
- Use caution when you rerun a retroactive data generation instance, because the data generated by the instance previously will be overwritten after the instance is rerun.

1. In the **Retroactive Data Generation Instances** section, click the retroactive data generation instance that you want to rerun. In the DAG in the right-side workspace, right-click the instance node and select **Rerun and Resume Scheduling**.
2. In the **Rerun and Resume Scheduling** message, click **OK**.

Rerun the downstream nodes of a retroactive data generation instance

1. In the **Retroactive Data Generation Instances** section, click the retroactive data generation instance whose downstream nodes you want to rerun. In the DAG in the right-side workspace, right-click the instance node and select **Rerun Downstream Nodes**.
2. In the **Rerun Downstream Nodes** dialog box, select the nodes to be rerun and click **OK**.

Set the running status of a retroactive data generation instance to Success and schedule the instance

Note You can set the running status of a retroactive data generation instance to Success and schedule the instance only when the instance is in the **Failed** state.

1. In the **Retroactive Data Generation Instances** section, click the retroactive data generation instance for which you want to set the running status to Success for scheduling. In the DAG in the right-side workspace, right-click the instance node and select **Set to Succeeded and Resume Scheduling**.
2. In the **Set to Succeeded and Resume Scheduling** message, click **OK**.

Forcibly rerun a retroactive data generation instance

1. In the **Retroactive Data Generation Instances** section, click the retroactive data generation instance that you want to forcibly rerun. In the DAG in the right-side workspace, right-click the instance node and select **Force Rerun**.
2. In the **Force Rerun** message, click **OK**.

> **Note** Use caution when you rerun a retroactive data generation instance, because the data generated by the instance previously will be overwritten after the instance is rerun.

Pause a retroactive data generation instance

1. In the **Retroactive Data Generation Instances** section, click the retroactive data generation instance that you want to pause. In the DAG in the right-side workspace, right-click the instance node and select **Pause**.
2. In the **Pause** message, click **OK**.

9.13. Monitoring and alerting

9.13.1. Alert records

When a monitored task triggers an alert, Dataphin pushes an alert notification to the specified recipients by using the notification method you specify in your task monitoring configuration. An alert record appears on the Alerts in Task page. You can view historical alerts on this page.

Search for and view alert records

1. On the Dataphin homepage, click **R&D** in the top navigation bar. On the R&D page, click **Scheduling** in the top navigation bar. On the page that appears, click **Monitoring** in the left-side navigation pane and click **Alerts in Task** on the left-side navigation submenu. If the current project is in Dev-Prod mode, you can only perform monitoring and alerting operations in Prod mode.
2. In the search box at the top of the workspace, you can enter keywords to search for alert records. Click the drop-down arrow to show more filter conditions. You can filter the search results by selecting filter conditions such as the alert cause, notification method, and notification status.

   Valid options of **Notification Status** include **Success**, **Sending**, and **Failed**.

   - **Success** indicates that an alert notification has been sent by using the specified notification method, and a receipt is returned.
   - **Sending** indicates that an alert notification has been sent by using the specified notification method, but no receipt is returned.
   - **Failed** indicates that one of the following errors occurs:
     - An alert notification cannot be sent by using the specified notification method.

       The error may result from one of the following causes: The email address or webhook URL has not been specified. The number of emails or DingTalk messages that the tenant can receive on the current day has reached the upper limit. The number of emails or DingTalk messages that the tenant can send on the current day has reached the upper limit. The specified recipient cannot be found in the contact information of the tenant because the selected recipient has been deleted.
     - An alert notification has been sent by using the specified notification method, but an error is reported.
     - A system error occurred. You can view the cause of the failure to obtain the detailed error message.

3. In the lower part of the workspace, you can view the search results, including the task name and task ID, monitoring type, alert cause, notification method, notification status, recipient, notification time, and available actions of each alert. By default, the alert records are sorted in descending order by notification time. You can click the icon to adjust the order of the alert records.
   - You can click the icon to view the new alert records.
   - You can click the icon to view the details of an alert.
   - You can move the pointer over the icon next to **Failed** of an alert record to view the cause of the failure.

   > **Note** If you have not configured the contact information for the recipient or the contact information is incorrect, **Failed** appears in the Notification Status column. You can move the pointer over the icon next to the notification status to view the cause of the failure.

Additional instructions

The maximum number of alert notifications that can be sent by using each notification method is limited. For more information, see Configure task monitoring.

> **Note** During the public preview, the monitoring and alerting feature of Dataphin is temporarily unavailable. You cannot configure the contact information, that is, pushing alert notifications is not supported.

9.13.2. Manage task monitoring configurations

This topic describes how to search for and view existing task monitoring configurations, enable and disable task monitoring, and modify or delete task monitoring configurations.

Search for and view existing task monitoring configurations

1. On the Dataphin homepage, click **R&D** in the top navigation bar. On the R&D page, click **Scheduling** in the top navigation bar. On the page that appears, click **Monitoring** in the left-side navigation pane and click **Task Monitoring Configuration** on the left-side navigation submenu.
2. On the Task Monitoring Configuration page:
   - In the search box at the top of the workspace, you can enter keywords to search for task monitoring configurations. Click the drop-down arrow to show more filter conditions. You can filter the search results by selecting the alert cause, notification method, alert notification recipient, and creator.
   - In the lower part of the workspace, you can view the search results, including the task name and task ID, alert cause, notification method, alert notification recipient, and creator of each task monitoring configuration.

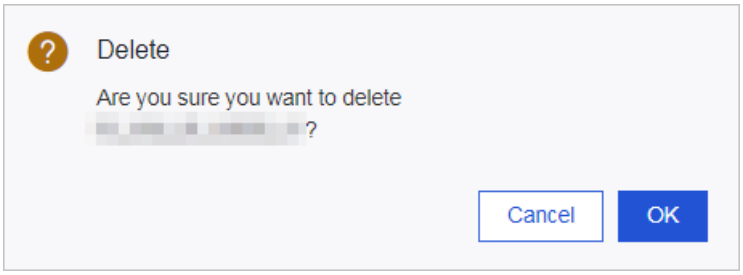
Enable and disable task monitoring

In the search result section, you can enable or disable monitoring for a specific task by turning on or off **Monitor Switch** for the target task monitoring configuration.

Modify or delete task monitoring configurations

In the search result section, click the **Change** icon in the **Actions** column for a task monitoring configuration. In the dialog box that appears, you can modify the alert cause, alert notification recipient, and notification method.

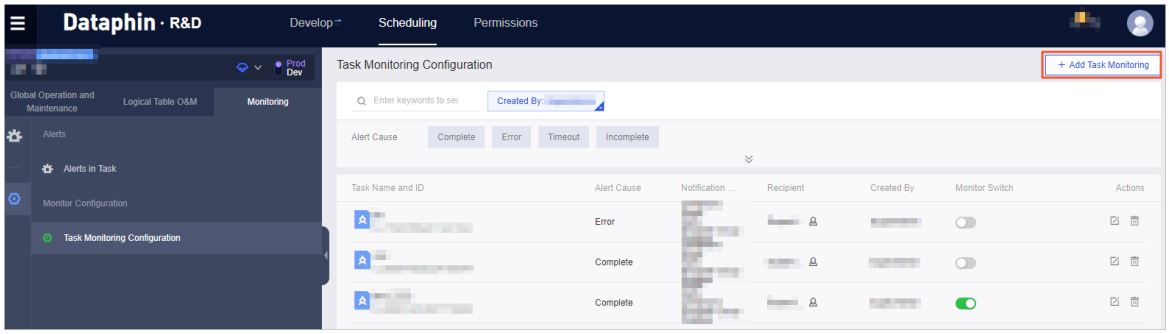
Click the **Delete** icon in the **Actions** column for a task monitoring configuration. A confirmation message appears, confirming whether you want to delete the task monitoring configuration.



9.13.3. Configure task monitoring

You can configure task monitoring to monitor the running status of tasks published to the production environment. This helps you know the task status in real time. This topic describes how to configure task monitoring.

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar. On the R&D page, click **Scheduling** in the top navigation bar. On the page that appears, click **Monitoring** in the left-side navigation pane and click **Task Monitoring Configuration** on the left-side navigation submenu.



> **Note** If the current project is in Dev-Prod mode, you must click the ▫ icon next to the project name in the left-side navigation pane to switch to the Prod mode. You can only perform monitoring and alerting operations in Prod mode.

3. On the Task Monitoring Configuration page, click **Add Task Monitoring** in the upper-right corner.
4. In the Add Task Monitoring dialog box that appears, set the parameters as prompted.
   - Select Task: the task to be monitored. You can select one or more tasks from the drop-down list for monitoring.

- Alert Cause: the trigger condition for the alert. You can select one of the following options: Error, Complete, Incomplete (until a certain time point), and Timeout (of specified minutes).
- Recipient: the user who receives the alert notification. You can specify the owner of the task or another user. One to three users can be specified at a time.
- Notification Method: the alert notification method. You can select Email, SMS, DingTalk Group Chatbot, or Cellphone.

  > Note
  > - A tenant can send a maximum of 100 messages by SMS, 2,000 messages by email, and 2,000 messages by DingTalk chatbot per day.
  > - A tenant can receive a maximum of 20 messages by SMS, 400 messages by email, and 400 messages by DingTalk chatbot per day.
  > - A tenant can send a maximum of 100 voice messages per day. Voice messages that are shorter than 1 minute is charged for 1 minute.

5. Click **OK**.

> Note During the public preview, the monitoring and alerting feature of Dataphin is temporarily unavailable. You cannot configure the contact information, that is, pushing alert notifications is not supported.

9.13.4. Alert rules for stream processing tasks

In Dataphin, you can configure alert rules to monitor the running status of stream processing tasks in the production environment. This topic describes how to create, modify, delete, enable, and disable alert rules for stream processing tasks.

Go to the Stream Processing Monitor Settings page

1. Log on to the Dataphin console.
2. Go to the **Monitoring** tab.
   - If the project that you accessed last time is in **Prod** or **Basic** mode, use one of the following methods to go to the **Monitoring** tab:
     - a. On the Dataphin homepage, click **R&D** in the top navigation bar.
       b. On the **Develop** page, click **Scheduling** in the top navigation bar.
       c. On the **Scheduling** page, click the **Monitoring** tab in the left-side navigation pane.
     - a. On the Dataphin homepage, click **Scheduling and Management** in the middle section, or click **Enter** next to **Scheduling** in the upper-right corner.
       b. On the **Scheduling** page, click the **Monitoring** tab in the left-side navigation pane.
   - If the project that you accessed last time is in **Dev** mode, use one of the following methods to go to the **Monitoring** page:

- a. On the Dataphin homepage, click **R&D** in the top navigation bar.
  b. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Prod** or **Basic** mode.
  c. On the **Develop** page, click **Scheduling** in the top navigation bar.
  d. On the **Scheduling** page, click the **Monitoring** tab in the left-side navigation pane.
- a. On the Dataphin homepage, click **Scheduling and Management** in the middle section, or click **Enter** next to **Scheduling** in the upper-right corner.
  b. On the **Scheduling** page, click the icon next to the project name in the upper-left corner and select a project in **Prod** or **Basic** mode.
  c. On the **Scheduling** page, click the **Monitoring** tab in the left-side navigation pane.

3. On the **Monitoring** tab, click the icon on the left-side navigation submenu. The **Stream Processing Monitor Settings** page appears.

   On the **Stream Processing Monitor Settings** page, you can filter alert rules for stream processing tasks by alert cause, notification method, recipient, and alert rule creator. You can also search for alert rules by entering a keyword of task names in the search box.In the lower part of the **Stream Processing Monitor Settings** page, you can view alert rules for stream processing tasks in detail, including the task name and ID, alert cause, notification method, recipient, alert rule creator, monitoring status, and actions that you can perform on each alert rule.

Parameter	Description
Task Name and ID	The name and ID of the stream processing task that is monitored based on the alert rule.
Alert Cause	The cause of alerts. Valid values: ○ **Excessively Long Delay** ○ **Exceeds Maximum TPS** ○ **Exceeds Specified Failure Frequency** ○ **Exceeds Specified Data Retention Period**
Notification Method	The method to notify the alert recipients. Valid values: ○ **Email** ○ **SMS** ○ **Cellphone** ○ **DingTalk Group Chatbot**
Recipient	The users to whom the alert notifications will be sent.
Created By	The user who created the alert rule.
Last Modified At	The time when the alert rule was last modified.

Parameter	Description
Monitor Switch	Indicates whether the alert rule is enabled for the task. ○ : The alert rule is enabled for the task. ○ : The alert rule is disabled for the task. You can click the switch to enable or disable the alert rule for the task. You can also click the icon next to the switch to delete the alert rule.
Actions	The actions that you can perform on the alert rule. Valid values: ○ You can click the icon to modify the alert rule. ○ You can click the icon to delete the alert rule.

Create an alert rule for a stream processing task

1. On the **Stream Processing Monitor Settings** page, click **Create Stream Processing Task Monitor** in the upper-right corner.
2. In the **Create Stream Processing Task Monitor** dialog box, set the parameters as required.

Section	Parameter	Description
Select Task	Task	The stream processing task to be monitored.
	Alert Causes	The alert cause of the alert rule. Click the icon next to **Alert Causes** to add an alert rule with another alert cause. You can configure the following alert rules for a stream processing task: ○ **Exceeds Specified Data Retention Period**: You must specify an upper limit for the queued time, in seconds. When the queued time exceeds this limit, an alert is triggered. ○ **Excessively Long Delay**: You must specify an upper limit for the processing delay, in seconds. When the processing delay exceeds this limit, an alert is triggered. ○ **Exceeds Maximum TPS**: You must specify a lower limit and an upper limit for the TPS. When the TPS is beyond the specified range, an alert is triggered. ○ **Exceeds Specified Failure Frequency**: You must specify an upper limit for the number of failures that occur in a minute. If the number of failures that occur in a minute exceeds this limit, an alert is triggered. You can click the icon next to an alert rule to delete the alert rule.

Section	Parameter	Description
Specify Alert Causes	Alerted Every	The time interval between alerts, in minutes. Valid values: 1 to 59.
	Time Range	The period during which the task is monitored. Valid values: ○ All Day ○ Specified
	Recipients	The users to whom the alert notifications will be sent. Valid values: ○ Owner: the owner of the stream processing task. ○ Custom: the specified users to whom the alert notifications will be sent. You can specify a maximum of five alert recipients for a stream processing task. ○ Shift Schedule: the shift schedule of users to whom the alert notifications will be sent. You can specify a maximum of one shift schedule.
	Notification Method	The method to notify the alert recipients. Valid values: ○ Email ○ SMS ○ Cellphone ○ DingTalk

Note

- For an Alibaba Cloud account, the system can send a maximum of 100 messages by SMS, 2,000 messages by email, and 2,000 messages by DingTalk chatbot per day.
- An Alibaba Cloud account can receive a maximum of 20 messages by SMS, 400 messages by email, and 400 messages by DingTalk chatbot per day.
- For an Alibaba Cloud account, the system can send a maximum of 100 voice messages per day. A voice message that is shorter than 1 minute is billed as 1 minute.

3. Click **OK**.

Modify an alert rule for a stream processing task

1. On the **Stream Processing Monitor Settings** page, find the alert rule that you want to modify and click the icon in the **Actions** column.
2. In the **Edit Stream Processing Task Monitor** dialog box, modify the parameters as required. For more information, see Create an alert rule for a stream processing task.
3. Click **OK**.

Delete alert rules for a stream processing task

1. On the **Stream Processing Monitor Settings** page, find the alert rules that you want to delete and click the icon in the **Actions** column.
2. In the **Tip** message, click **OK**.

Enable or disable an alert rule for a stream processing task

On the **Stream Processing Monitor Settings** page, find the alert rule that you want to enable or disable and click the or icon in the **Monitor Switch** column.

Delete an alert rule for a stream processing task

1. On the **Stream Processing Monitor Settings** page, find the alert rule that you want to delete and click the icon in the **Monitor Switch** column.
2. In the **Tip** message, click **OK**.

9.14. Data assets

9.14.1. Overview

This topic describes the Data Assets module of Dataphin and the three modes of viewing data assets, that is, the Global, Flow, and Structure modes.

Data asset overview

After development works such as data collection, integration, and processing are completed, you can manage data assets in a systematic way.

Based on the standards and methodology of data asset management, the Data Assets module of Dataphin allows you to take inventory of and evaluate the data assets in your enterprise, including:

- Automatically extracts and analyzes metadata, and creates a data asset dashboard. This helps enterprise managers discover and understand the value of data assets.
- Provides an end-to-end inventory check and analysis of computing, storage, security, and applications during data production. This helps you detect problems, propose and implement governance optimization schemes, reduce costs, and improve efficiency for data.
- Provides the Data Assets page for you to view the data modeling results and table details.

You can view data assets in **Global**, **Flow**, and **Structure** modes.

- The Global mode displays business units that contain a large amount of data in the form of planets and their respective data sizes.
- The Flow mode displays the entire process of data ingestion, integration, and output. This reveals the underlying potential capabilities of a Data Mid-End.
- The Structure mode displays components in different shapes to represent business entities and uses lines of different styles to represent relationships between these entities. This mode clearly shows the structure of data in a business unit.

Global mode

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the Data Assets page, click **Overview** in the top navigation bar.
4. On the **Overview** page, click **Global** in the upper-right corner.
5. The **Global** tab displays the total number of tasks, tables, and projects in Dataphin in the lower-right corner. It also displays the rankings of business units that contain a large amount of data, including the business unit name, data size, and proportion to the total data size.You can also move the pointer over a planet to view the statistics about the business unit, including the amount of used computing resources and storage size.

> **Note** The **Overview** page only displays information about the metadata of the production environment and the application data that has been processed.

Flow mode

On the **Overview** page, click **Flow** in the upper-right corner.

The **Flow** tab displays the data ingestion progress, the total number of tables, and data applications such as data query in a visual view.

- Move the pointer over **Data Ingestion Progress** to view the number of data sources.
- Move the pointer over **Total Tables** to view the statistics about tables from the perspectives of data standardization and data models.

Structure mode

On the **Overview** page, click **Structure** in the upper-right corner. On the **Structure** tab, click a business unit in the upper-right corner to view all the dimensions, business processes, and their relationships under this business unit.The **Structure** tab displays the following information in the upper-left corner:

- **Dimensions**: the types of dimensions. Dimensions are classified into common dimensions and other dimensions. Other dimensions include common dimensions by hierarchy, enumeration dimensions, and virtual dimensions.
- **Relation**: the relationships between dimensions.
  - indicates a parent-child relationship.
  -  indicates an association relationship.
- Search box: You can enter a dimension or business process name in the **Search** field or click the  icon next to **Search**, and select a dimension or business process from the drop-down list. The dimensions and business processes related to the selected dimension or business process appear.

You can use one of the following methods to view relationships between dimensions and between dimensions and business processes:

- Click a dimension. The dimensions and business processes related to this dimension are highlighted.
- Click a business process. The dimensions related to this business process are highlighted.
- Use the search box in the upper-left corner of the **Structure** tab to search for the desired

dimension or business process and view its related dimensions and business processes.

9.14.2. Map

9.14.2.1. View the asset map

An asset map summarizes the relationships between dimensions and business processes in a data domain of a business unit to show the structure of your enterprise data. In addition, the asset map allows you to efficiently and accurately search for and explore data based on features such as data search, access recording, and bookmarking.

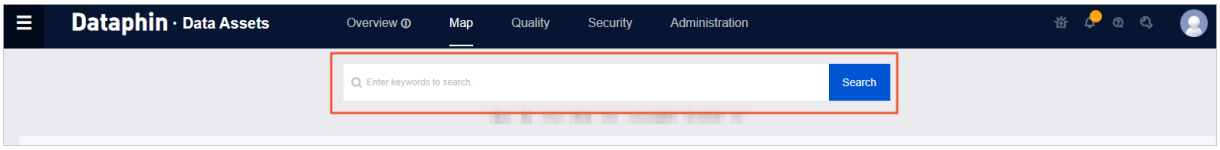
Map page

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar. The **Map** page appears by default.

   The Map page consists of the following four sections:

   - Search bar
   - Business Units section
   - My Data Assets section
   - Recommended section

Search bar



- You can enter a keyword in the search box to search for tables whose names contain the keyword in the development or production environment.
- By default, when you enter a keyword in the search box, 10 related tables and multiple related keywords that match the keyword appear in the drop-down list. You can view the names, display names, and descriptions of the related tables in the drop-down list.
- If you select a related table, the table details page appears. If you select a related keyword, the search results are updated based on the selected keyword.

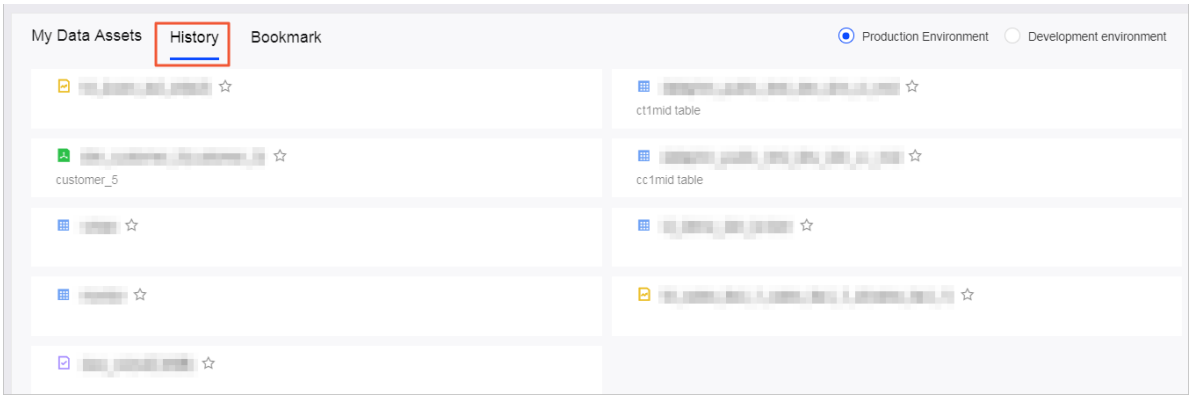
Business Units section

The **Business Units** section is below the search bar. In this section, the division of information echoes the asset overview. This section only displays the data of the production environment, including the business units, data domains, dimensions, and business processes.

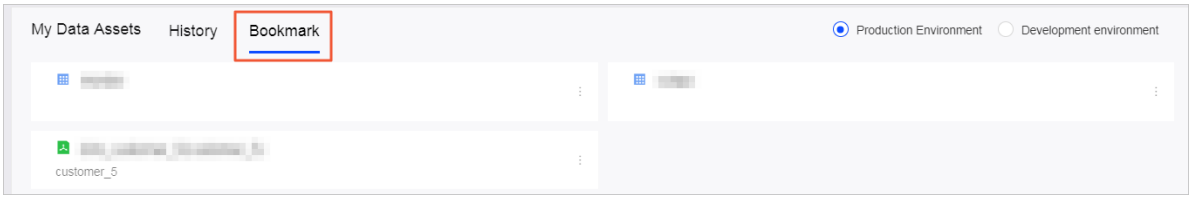
My Data Assets section

This section displays the data assets that you have accessed or bookmarked. You can switch between the development environment and production environment to view the access history and bookmarks. By default, the My Data Assets section displays the access history and bookmarks of the production environment.

- The **History** tab displays the 10 data assets that you recently accessed.

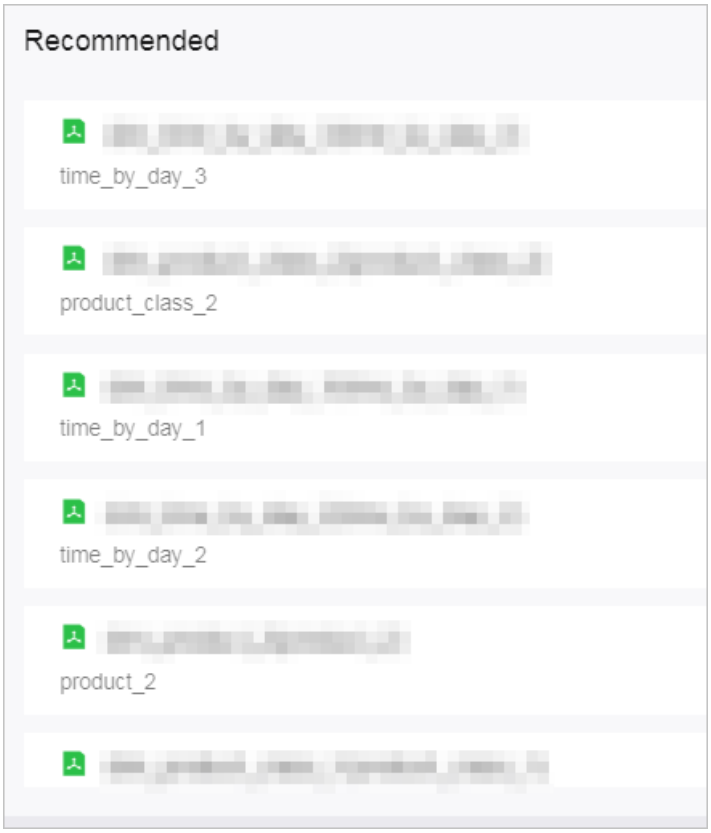


- The **Bookmark** tab displays the data assets that you bookmarked on the asset details page. The number of data assets that can be bookmarked is not limited.



Recommended section

This section displays the most popular tables, including their names, display names, and descriptions, based on the popularity of global user access.



Metadata

No search results will be returned if you query a table that is not created in Dataphin or a newly created table whose metadata has not been synchronized because of the latency of Dataphin in obtaining metadata. In this case, you can manually synchronize the metadata of the table to Dataphin.

1. On the **Map** page, click **Search** in the search bar.
2. On the page that appears, click the icon in the upper-right corner. The **Refresh Metadata** dialog box appears.
3. Set Project Name and Table Name and click **OK**.
   - **Project Name**: the name of the project to which the table belongs. You can view all projects of the current tenant in the drop-down list. Select one from the list.
   - **Table Name**: the name of the table whose metadata needs to be synchronized to Dataphin. You must enter an exact match to the table name.

     > **Note** Make sure that the table name is correct before you click **OK**.

9.14.2.2. View table details

This topic describes how to search for physical tables, logical tables, and stream metatables, and view table details.

Search for tables

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar. The **Map** page appears by default.
3. Enter a keyword in the search box and press Enter or click **Search**. Alternatively, select a dimension or business process in the Business Units section. The Search Results page appears.

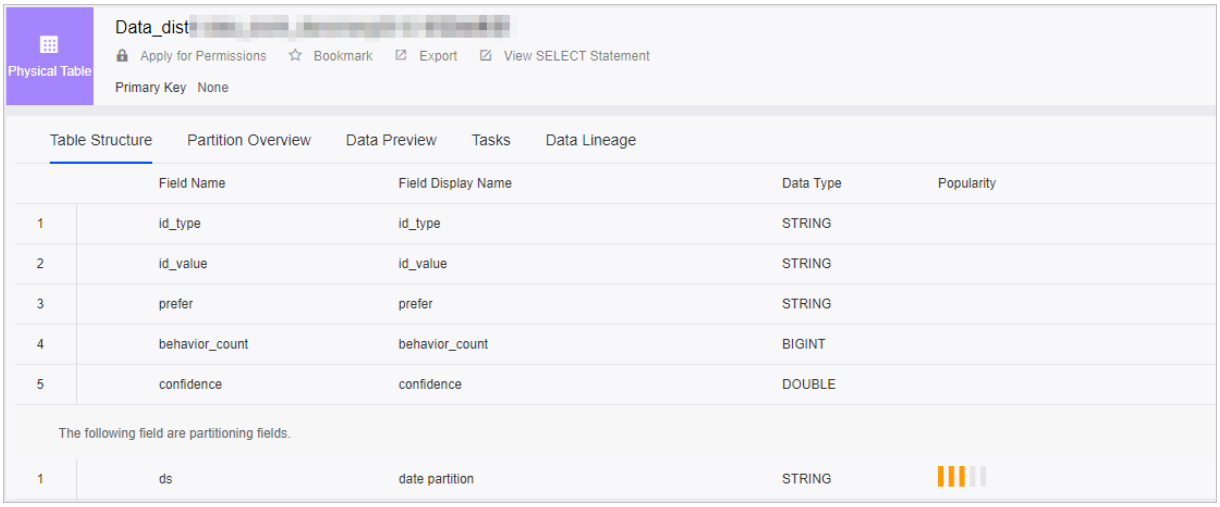
   The Search Results page provides the following information and features:

   - The left-side pane displays filter conditions and the right-side pane displays the tables that match the selected filter conditions. Filter conditions fall into the following two categories:
     - **Business Properties**: Filter conditions in this category are further classified by project, business unit, data domain, dimension, and business process.
     - **Data Properties**: Filter conditions in this category are further classified by environment, storage type, and table type, such as logical dimension table, logical fact table, and logical aggregate table.
   - You can select one or more filter conditions in the left-side pane to filter tables and update the search results in the right-side pane. By default, Dataphin displays only one row of filter conditions for each type. You can click the downwards arrow to view more filter conditions. You can click the name of a table in the right-side pane to go to the details page of the table.

View the details about a physical table

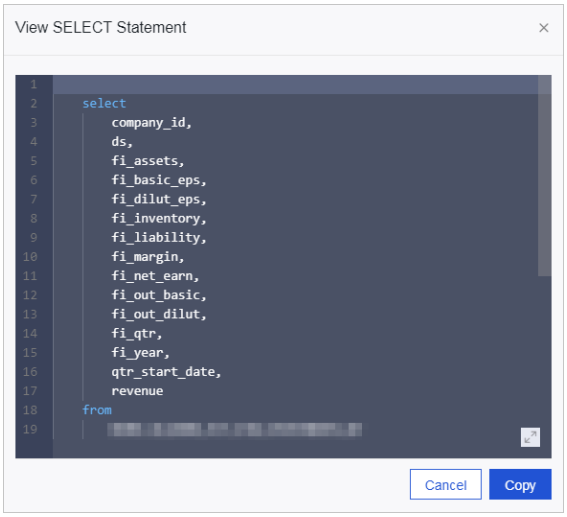
> **Note** The table details page varies with the table type.

On the Search Results page, click the name of a physical table. The details page of the table appears, as shown in the following figure.



- The upper-left part of the details page provides the following information and features:
  - Table type: The type of a table can be Logical Dimension Table, Logical Fact Table, Logical Aggregate Table, Physical Table, or Stream Metatable. In this example, the table type is **Physical Table**.
  - Table name: The table name is in the format of Business unit name. Table name. A maximum of 70 characters can be displayed for the name. The excess part is displayed as an ellipsis (...).
  - **Apply for Permissions**: Click Apply for Permissions. On the Apply for Physical Table Permissions tab, set the parameters to apply for required permissions.
  - **Bookmark** or Remove Bookmark: The action varies depending on whether the table is bookmarked.
    - The ☆ icon indicates that you have not bookmarked the table. You can click the ☆ icon to bookmark the table.
    - The ★ icon indicates that you have bookmarked the table. You can click the ★ icon to remove the table from your bookmarks.
  - **Export**: You can click **Export** to export the fields in the table to a CSV file.

- **View SELECT Statement**: Click **View SELECT Statement**. In the **View SELECT Statement** dialog box, you can view the SQL statement for querying the table data.



- In the right-side pane of the details page, you can view the basic information, access information, physical information, and update information about the table.

The lower-left part of the details page provides the following tabs:

- **Table Structure**: This tab displays the name, display name, data type, and popularity of the fields in the physical table.
- **Partition Overview**: This tab displays the partition information about the physical table.
- **Data Preview**: This tab displays the table content, including the name and records of each metric.

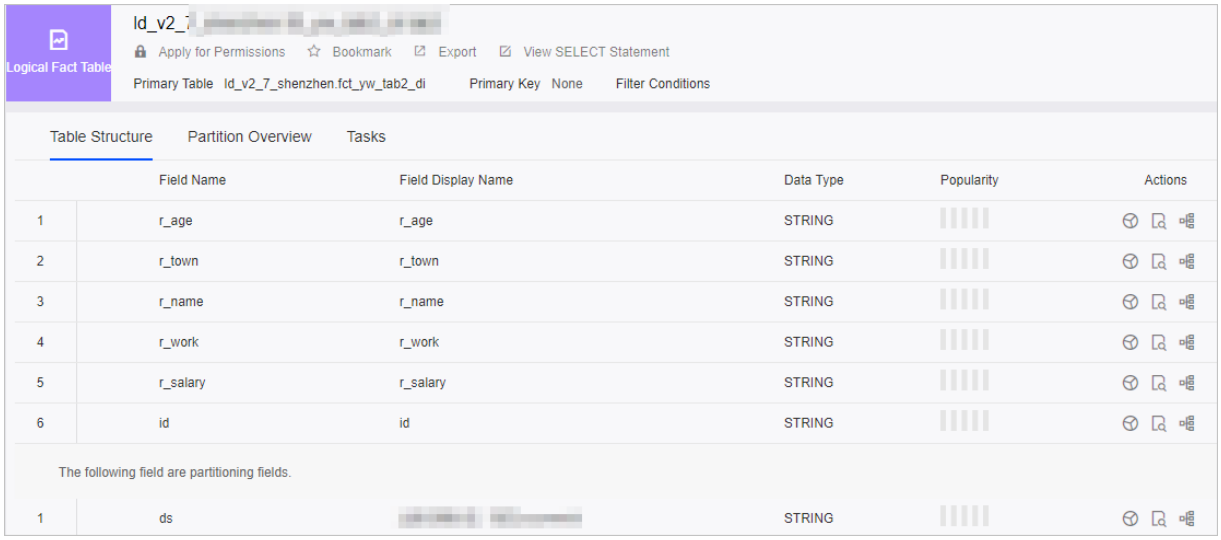
  > **Note** If you are not authorized to view the records, each record is de-identified with multiple asterisks (*****).

- **Tasks**: This tab displays the scheduling information about the tasks that are related to the physical table, including the ID, execution time in seconds, start time, and end time of each task.
  - You can click the icon in the **Task ID** column of a task to go to the **Recurring Task Instances** page. On this page, you can view the instances that have been generated for the task.
  - You can click the icon in the **Task ID** column of a task to go to the **Node Script** page. On this page, you can view the code of the task.
- **Data Lineage**: This tab displays the dependencies between tables.

View the details about a logical table

> **Note** This section describes how to view the details about a logical fact table. Follow the same procedure for other types of logical tables.

On the Search Results page, click the name of a logical fact table. The details page of the table appears, as shown in the following figure.

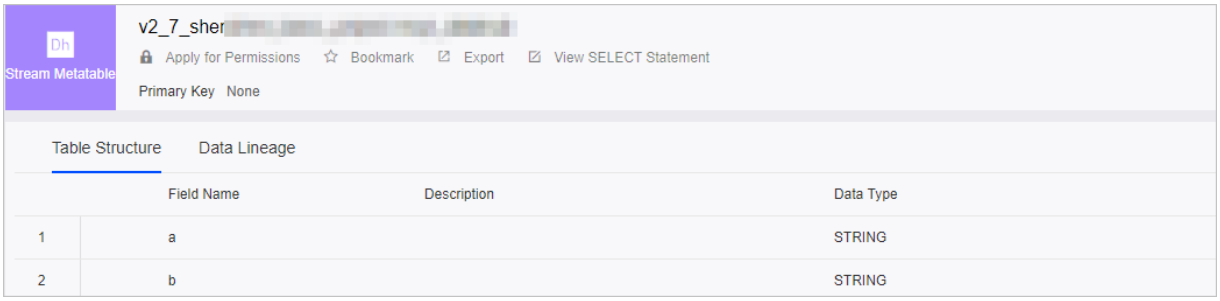


The details page consists of the upper-left part, lower-left part, and right-side pane.

- In the upper-left part, you can view the type, name, primary table, primary key, and filter conditions of the logical fact table. You can also perform the following actions on the logical fact table: **Apply for Permissions**, **Bookmark** or Remove Bookmark, **Export**, and **View SELECT Statement**.
- In the right-side pane, you can view the basic information, access information, physical information, and update information about the logical fact table.
- The **Table Structure** tab in the lower-left part displays the name, display name, data type, and popularity of the fields in the logical fact table. On this tab, you can perform the following operations:
  - Click the icon in the **Actions** column of a field. In the dialog box that appears, you can view the partitions, records, creation time, and update time of the field.
  - Click the icon in the **Actions** column of a field. In the dialog box that appears, you can view the numerical distribution and numerical interval distribution of the field, as well as the data records.
  - Click the icon in the **Actions** column of a field. In the dialog box that appears, you can view the data lineage of the field.
- The **Partition Overview** tab in the lower-left part displays the distribution of partitions for each field in the logical fact table. You can filter data by field or partition.
- The **Tasks** tab in the lower-left part displays the scheduling information about the tasks that are related to the logical fact table, including the ID, execution time in seconds, start time, and end time of each task. On this tab, you can perform the following operations:
  - Click the icon in the **Task ID** column of a task to go to the **Recurring Task Instances** page. On this page, you can view the instances that have been generated for the task.
  - Click the icon in the **Task ID** column of a task to go to the **Node Script** page. On this page, you can view the code of the task.

View the details about a stream metatable

On the Search Results page, click the name of a stream metatable. The details page of the table appears, as shown in the following figure.



The details page consists of the upper-left part, lower-left part, and right-side pane.

- By default, the upper-left part displays the type, name, and primary key of the stream metatable.
- In the right-side pane, you can view the basic information, access information, physical information, and update information about the stream metatable.
- The **Data Lineage** tab in the lower-left part displays the data lineage of the stream metatable.
- The **Table Structure** tab in the lower-left part displays the fields in the stream metatable.

  If you have the query permission on the table, you can view the first 10 fields in the table. If you do not have the query permission on the table, click **Apply for Permissions** to apply for permissions on the table. For more information, see Manage permissions on stream metatables.

9.14.3. Security

9.14.3.1. My permissions

9.14.3.1.1. Manage permissions on logical tables

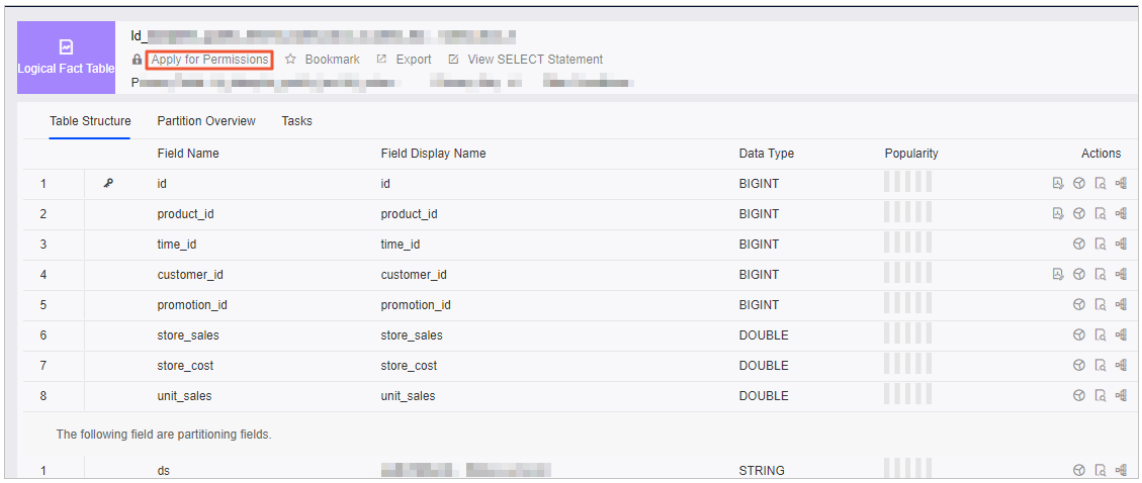
This topic describes how to apply for, query, renew, and remove permissions on logical tables.

Apply for permissions on a logical table

1. Log on to the Dataphin console.
2. Go to the **Logical Table Permissions** tab.
   i. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
   ii. On the **Data Assets** page, click **Security** in the top navigation bar.
   iii. On the **Permissions** page, click **Logical Table Permissions** under My Permissions in the left-side navigation pane.
3. On the **Logical Table Permissions** tab, go to the **Apply for Logical Table Permissions** tab by using one of the following methods:
   - Click **Apply for Logical Table Permissions** in the upper-right corner.
   - In the left-side navigation pane, move the pointer over **Logical Table Permissions** and

click the icon.

- In the left-side navigation pane, click the icon next to My Permissions and select **Logical Table Permissions**.
-



a. In the top navigation bar, click **Map**.

b. On the **Map** page, enter a keyword in the search box to search for tables whose names contain the keyword.

c. Find the logical table on which you want to apply for permissions and click the table name. On the details page that appears, click **Apply for Permissions** in the upper-left part.

4. On the **Apply for Logical Table Permissions** tab, perform the following operations in the configuration wizard:

i. In the **Select Data Objects** step, set the **Environment**, **Business Unit**, and **Logical Table** parameters.

ii. Click **Next**.

iii. In the **Apply for Permissions** step, set the parameters as required.

Parameter	Description
Authorized Fields	The fields on which you want to apply for permissions. Select fields by using one of the following methods: ■ Enter a keyword in the search box to search for the desired fields and select the fields. ■ Select fields from the field list of the logical table.
Permission Type	The permission that you want to apply for. By default, the value **Query** is selected and you cannot modify the setting.
Account Type	The accounts to be granted the permission that you are applying for. You can grant the permission to either or both of the personal account and project production account. ■ The personal account is used for data modeling and development in the development environment and publishing developed objects or tasks to the production environment. If you select **Personal Account**, you must also set the **Expiration Date** parameter. ■ The project production account is used to manage and run tasks that are submitted to the production environment. If you select **Project Production Account**, you must also set the **Project** parameter.
Reason for Application	The reason why you apply for the permission.

5. Click **Submit**.

Query the permissions on a logical table

1. On the **Logical Table Permissions** tab, find the logical table on which you want to query the permissions and click the table name in the **Data Object** column.
2. On the details page that appears, view the fields on which you have applied for permissions and the specific permissions.

Renew the permissions on a logical table

1. On the **Logical Table Permissions** tab, find the logical table on which you want to renew the permissions and click the table name in the **Data Object** column.
2. On the details page that appears, select the fields on which you want to renew permissions.
   - Enter a keyword in the search box to search for the desired fields and select the fields.
   - Select fields from the field list of the logical table.
3. In the lower part of the page, click **Extend Validity**.
4. In the **Apply for Permissions** step, set the parameters as required. For more information, see Apply for permissions on a logical table.
5. Click **Submit**.

Remove the permissions on a logical table

1. On the **Logical Table Permissions** tab, find the logical table on which you want to remove the permissions and click the icon in the **Actions** column.
2. In the **Remove Permissions** message, click **OK**.

9.14.3.1.2. Manage permissions on physical tables

This topic describes how to apply for, query, renew, and remove permissions on physical tables.

Apply for permissions on a physical table

1. Log on to the Dataphin console.
2. Go to the **Physical Table Permissions** tab.
   i. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
   ii. On the **Data Assets** page, click **Security** in the top navigation bar.
   iii. On the **Permissions** page, click **Physical Table Permissions** under My Permissions in the left-side navigation pane.
3. On the **Physical Table Permissions** tab, go to the **Apply for Physical Table Permissions** tab by using one of the following methods:
   - Click **Apply for Physical Table Permissions** in the upper-right corner.
   - In the left-side navigation pane, move the pointer over Physical Table Permissions and click the icon.
   - In the left-side navigation pane, click the Add icon next to My Permissions and select **Physical Table Permissions**.
   -

   a. In the top navigation bar, click **Map**.
   b. On the **Map** page, enter a keyword in the search box to search for tables whose names contain the keyword.
   c. Find the physical table on which you want to apply for permissions and click the table name. On the details page that appears, click **Apply for Permissions** in the upper-left part.

4. On the **Apply for Physical Table Permissions** tab, perform the following operations in the configuration wizard:
   i. In the **Select Data Objects** step, set the **Environment**, **Project**, and **Physical Tables** parameters.
   ii. Click **Next**.
   iii. In the **Apply for Permissions** step, set the parameters as required.

Parameter	Description
Authorized Fields	The fields on which you want to apply for permissions. Select fields by using one of the following methods: ■ Enter a keyword in the search box to search for the desired fields and select the fields. ■ Select fields from the field list of the physical table.
Permission Type	The permissions that you want to apply for. Valid values: ■ **Query** ■ **Write** ■ **Update** ■ **Delete**
Account Type	The accounts to be granted the permissions that you are applying for. You can grant the permissions to either or both of the personal account and project production account. ■ The personal account is used for data modeling and development in the development environment and publishing developed objects or tasks to the production environment. ■ The project production account is used to manage and run tasks that are submitted to the production environment.
Reason for Application	The reason why you apply for the permissions.

5. Click **Submit**.

Query the permissions on a physical table

1. On the **Physical Table Permissions** tab, find the physical table on which you want to query the permissions and click the table name in the **Data Object** column.
2. On the details page that appears, view the fields on which you have applied for permissions and the specific permissions.

Renew the permissions on a physical table

1. On the **Physical Table Permissions** tab, find the physical table on which you want to renew the permissions and click the table name in the **Data Object** column.
2. On the details page that appears, select the fields on which you want to renew permissions.
   - Enter a keyword in the search box to search for the desired fields and select the fields.

- Select fields from the field list of the physical table.

3. In the lower part of the page, click **Extend Validity**.
4. In the **Apply for Permissions** step, set the parameters as required. For more information, see Apply for permissions on a physical table.
5. Click **Submit**.

Remove the permissions on a physical table

1. On the **Physical Table Permissions** tab, find the physical table on which you want to remove the permissions and click the icon in the **Actions** column.
2. In the **Remove Permissions** message, click **OK**.

9.14.3.1.3. Manage permissions on stream metatables

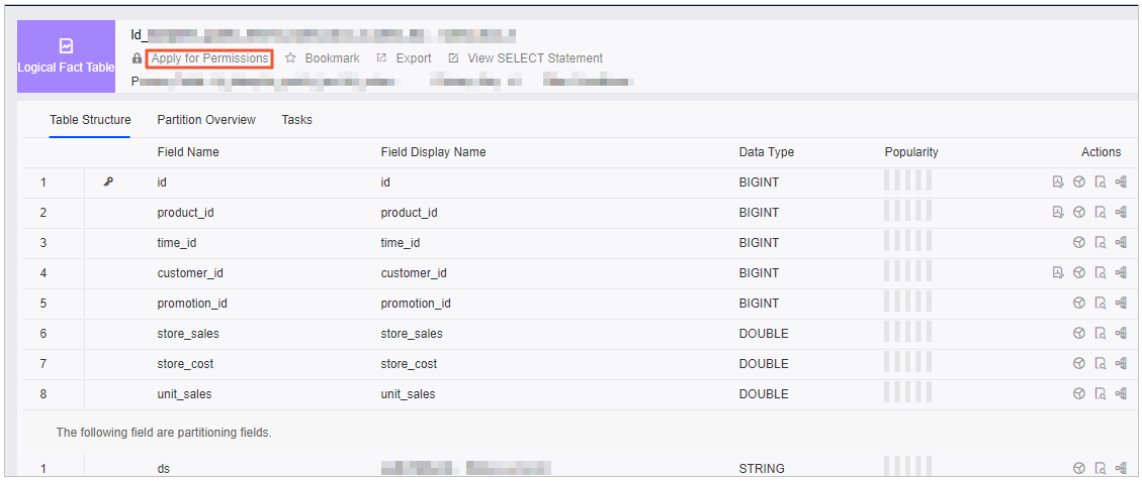
This topic describes how to apply for, query, renew, and remove permissions on stream metatables.

Context

A stream processing task in a project can reference a stream metatable in another project. If a stream processing task that you create needs to reference a stream metatable created by another user or in another project, you must apply for the query, write, update, or delete permission on the stream metatable.

Apply for permissions on a stream metatable

1. Log on to the Dataphin console.
2. Go to the **Stream Metatable Permissions** tab.
   i. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
   ii. On the **Data Assets** page, click **Security** in the top navigation bar.
   iii. On the **Permissions** page, click **Stream Metatable Permissions** under My Permissions in the left-side navigation pane.
3. On the **Stream Metatable Permissions** tab, go to the **Apply for Stream Metatable Permissions** tab by using one of the following methods:
   - Click **Apply for Stream Metatable Permissions** in the upper-right corner.
   - In the left-side navigation pane, move the pointer over Stream Metatable Permissions and click the icon.
   - In the left-side navigation pane, click the icon next to My Permissions and select **Stream Metadata Permissions**.
   - In the top navigation bar, click **Map**. On the **Map** page, enter a keyword in the search box to search for tables whose names contain the keyword. Find the stream metatable on which you want to apply for permissions and click the table name. On the details page that appears, click **Apply for Permissions** in the upper-left part.



4. In the **Select Data Objects** step, set the **Environment**, **Project**, and **Stream Metatables** parameters.
5. Click **Next**.
6. In the **Apply for Permissions** step, set the parameters as required.

Parameter	Description
Authorized Fields	The fields on which you want to apply for permissions. Select fields by using one of the following methods: ○ Enter a keyword in the search box to search for the desired fields and select the fields. ○ Select fields from the field list of the metatable.
Permission Type	The permissions that you want to apply for. Valid values: ○ **Query** ○ **Write** ○ **Update** ○ **Delete**
Account Type	The accounts to be granted the permissions that you are applying for. You can grant the permissions to either or both of the personal account and project production account. ○ The personal account is used for data modeling and development in the development environment and publishing developed objects or tasks to the production environment. ○ The project production account is used to manage and run tasks that are submitted to the production environment.
Reason for Application	The reason why you apply for the permissions.

7. Click **Submit**.

Query the permissions on a stream metatable

1. On the **Stream Metatable Permissions** tab, find the stream metatable on which you want to query the permissions and click the table name in the **Data Object** column.
2. On the details page that appears, view the fields on which you have applied for permissions and the specific permissions.

Renew the permissions on a stream metatable

1. On the **Stream Metatable Permissions** tab, find the stream metatable on which you want to renew the permissions and click the table name in the **Data Object** column.
2. On the details page that appears, select the fields on which you want to renew permissions.
   - Enter a keyword in the search box to search for the desired fields and select the fields.
   - Select fields from the field list of the metatable.
3. In the lower part of the page, click **Extend Validity**.
4. In the **Apply for Permissions** step, set the parameters as required. For more information, see Apply for permissions on a stream metatable.
5. Click **Submit**.

Remove the permissions on a stream metatable

1. On the **Stream Metatable Permissions** tab, find the stream metatable on which you want to remove the permissions and click the  icon in the **Actions** column.
2. In the **Remove Permissions** message, click **OK**.

9.14.3.1.4. Manage permissions on functions

This topic describes how to apply for and remove permissions on functions.

Context

When you use Dataphin for data warehouse modeling, you can use functions to improve the task development efficiency. You can manage the query permission on functions on the Function Permissions tab of Dataphin. If a task that you create needs to reference a function created by another user or in another project, you must apply for the query permission on the function.

Apply for the query permission on a function

1. Log on to the Dataphin console.
2. Go to the **Function Permissions** tab.
   i. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
   ii. On the **Data Assets** page, click **Security** in the top navigation bar.
   iii. On the **Permissions** page, click **Function Permissions** under My Permissions in the left-side navigation pane.
3. On the **Function Permissions** tab, go to the **Apply for Function Permissions** tab by using one of the following methods:
   - Click **Apply for Function Permissions** in the upper-right corner.
   - In the left-side navigation pane, click the  icon next to **Function Permissions**.

- In the left-side navigation pane, click the icon next to My Permissions and select Function Permissions.

4. On the **Apply for Function Permissions** tab, perform the following operations in the configuration wizard:
   i. In the **Select Data Objects** step, set the **Environment**, **Project**, and **UDF** parameters.
   ii. Click **Next**.
   iii. In the **Apply for Permissions** step, set the parameters as required.

Parameter	Description
Permission Type	The permission that you want to apply for. By default, the value **Query** is selected and you cannot modify the setting.
Account Type	The accounts to be granted the permission that you are applying for. You can grant the permission to either or both of the personal account and project production account. ■ The personal account is used for data modeling and development in the development environment and publishing developed objects or tasks to the production environment. If you select this option, you must also set the **Expiration Date** parameter. ■ The project production account is used to manage and run tasks submitted to the production environment. If you select this option, you must also set the **Project** parameter.
Reason for Application	The reason why you apply for the permission.

5. Click **Submit**.

Remove the query permission on a function

1. On the **Function Permissions** tab, find the function on which you want to remove the query permission and click the icon in the **Actions** column.
2. In the **Remove Permissions** message, click **OK**.

9.14.3.1.5. Manage permissions on data sources

This topic describes how to apply for and remove permissions on data sources.

Context

After you obtain the read and write permissions on a data source, you have the following permissions:

- Permissions to read and write physical tables in the data source but not existing fields in the tables. For more information about how to apply for the read and write permissions on existing fields in the physical tables, see Manage permissions on physical tables.
- Permission to read logical tables in the data source but not existing fields in the tables. For more information about how to apply for the read permission on existing fields in the logical tables, see Manage permissions on logical tables.

Apply for permissions on a data source

1. Log on to the Dataphin console.
2. Go to the **Data Source Permissions** tab.
   i. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
   ii. On the **Data Assets** page, click **Security** in the top navigation bar.
   iii. On the **Permissions** page, click **Data Source Permissions** under **My Permissions** in the left-side navigation pane.
3. On the **Data Source Permissions** tab, go to the **Apply for Data Source Permissions** tab by using one of the following methods:
   - Click **Apply for Data Source Permissions** in the upper-right corner.
   - In the left-side navigation pane, click the icon next to **Data Source Permissions**.
   - In the left-side navigation pane, click the icon next to My Permissions and select **Data Source Permissions**.
4. On the **Apply for Data Source Permissions** tab, set the parameters as required.
   i. In the **Select Data Objects** step, set the **Environment**, **Project**, and **UDF** parameters.
   ii. Click **Next**.
   iii. In the **Apply for Permissions** step, set the parameters as required.

Parameter	Description
Data Source	The data source on which you want to apply for permissions.
Permission Type	The permissions that you want to apply for. Valid values: **Read** and **Write**.
Account Type	The accounts to be granted the permissions that you are applying for. You can grant the permissions to either or both of the personal account and project production account. ■ The project production account is used to periodically schedule production tasks in the project. Dataphin uses this type of account to isolate users who have a personal account from the production environment. If you select this option, you must also set the **Project** parameter. ■ The personal account is used to perform operations related to data standardization, data modeling, and coding in the development environment. If you select this option, you must also set the **Expiration Date** parameter.
Reason for Application	The reason why you apply for the permissions.

5. Click **OK**.

Remove the permissions on a data source

1. On the **Data Source Permissions** tab, find the data source on which you want to remove the

permissions and click the icon in the **Actions** column.

2. In the **Remove Permissions** message, click **OK**.

9.14.3.1.6. Manage permissions on API operations

You can obtain permissions on API operations only after you activate the Services module. This topic describes how to apply for, query, and remove permissions on API operations.

Prerequisites

The Services module is activated.

Apply for permissions on an API operation

1. Log on to the Dataphin console.
2. Go to the **API Permissions** tab.
   i. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
   ii. On the **Data Assets** page, click **Security** in the top navigation bar.
   iii. On the **Permissions** page, click **API Permissions** under My Permissions in the left-side navigation pane.
3. Go to the **API Permission Request** page in Application Center of the Services module by using one of the following methods:
   - On the **API Permissions** tab, click **Apply for API Permissions** in the upper-right corner.
   - In the left-side navigation pane, click the icon next to **API Permissions**.
   - In the left-side navigation pane, click the icon next to My Permissions and select **API Permissions**.
4. On the **API Permission Request** page, set the parameters in the configuration wizard. For more information, see Apply for permissions on an API operation.

Query permissions on an API operation

1. On the **API Permissions** tab, find the API operation on which you want to query permissions and click the name in the **Data Object** column.
2. On the details page, view the permission information about the API operation.

Remove the permissions on an API operation

1. On the **API Permissions** tab, find the API operation on which you want to remove the permissions and click the icon in the **Actions** column.
2. In the **Remove Permissions** message, click **OK**.

9.14.3.1.7. Manage functionality permissions

This topic describes how to apply for and remove functionality permissions.

Apply for a functionality permission

1. Log on to the Dataphin console.
2. Go to the **Functionality Permissions** tab.
   i. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
   ii. On the **Data Assets** page, click **Security** in the top navigation bar.
   iii. On the **Permissions** page, click **Functionality Permissions** under **My Permissions** in the left-side navigation pane.
3. The **Functionality Permissions** tab does not provide the entry for you to apply for functionality permissions. You can apply for the corresponding functionality permissionif you are prompted to apply for the permission when you attempt to open a page, for example, the Overview page of the Data Assets module.
4. Click **Apply for Permission**.
5. In the **Apply for Functionality Permission** dialog box, set the **Expiration Date** and **Reason for Application** parameters.
6. Click **OK**.

Remove a functionality permission

1. On the **Functionality Permissions** tab, find the functionality on which you want to remove the permission and click the icon in the **Actions** column.
2. In the **Remove Permissions** message, click **OK**.

9.14.3.2. Managed permissions

9.14.3.2.1. Grant and revoke permissions on business units

This topic describes how to grant and revoke permissions on business units.

Grant permissions on a business unit to specific accounts

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the **Data Assets** page, click **Security** in the top navigation bar.
4. On the **Permissions** page, click **Business Unit Permissions** under Managed Permissions in the left-side navigation pane.
5. On the **Business Unit Permissions** tab, find the business unit on which you want to grant permissions to specific accounts and click the icon in the **Actions** column.
6. In the dialog box that appears, set the parameters as required.

Parameter	Description

Parameter	Description
Grant To	The accounts to which you want to grant permissions on the business unit. You can grant permissions on the business unit to either or both of the personal account and project production account. If you select an account from the **Personal Account** drop-down list, you must also set the **Expiration Date** parameter.
Logical Tables	The names of the logical tables on which you want to grant permissions to the specified accounts. You can select logical tables only in the current business unit.
Permission Type	The permissions to be granted. By default, the value **Query** is selected and you cannot modify the setting.
Reason for Grant of Permissions	The reason why you grant the permissions.

7. Click **OK**.

Revoke permissions on a business unit from a specific account

1. On the **Business Unit Permissions** tab, find the business unit on which you want to revoke permissions from a specific account and click the icon in the **Actions** column.
2. In the dialog box that appears, set the parameters as required.

Parameter	Description
Revoke From	The account from which you want to revoke permissions on the business unit.
Logical Tables	The names of the logical tables on which you want to revoke permissions from the specified account. You can select logical tables only in the current business unit.
Permission Type	The permissions that you want to revoke. By default, the value **Query** is selected and you cannot modify the setting.
Reason for Revocation of Permissions	The reason why you revoke the permissions.

3. Click **OK**.

9.14.3.2.2. Grant and revoke permissions on projects

This topic describes how to grant and revoke permissions on projects.

Grant permissions on a project to specific accounts

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.

3. On the **Data Assets** page, click **Security** in the top navigation bar.
4. On the **Permissions** page, click **Project Permissions** under Managed Permissions in the left-side navigation pane.
5. On the **Project Permissions** tab, find the project on which you want to grant permissions to specific accounts and click the icon in the **Actions** column.
6. In the dialog box that appears, set the parameters as required.

Parameter	Description
Grant To	The accounts to which you want to grant permissions on the project. You can grant permissions on the project to either or both of the personal account and project production account. If you select an account from the **Personal Account** drop-down list, you must also set the **Expiration Date** parameter.
Physical Tables	The names of the physical tables on which you want to grant permissions to the specified accounts. You can select physical tables only in the current project.
Permission Type	The permissions to be granted. Valid values: ○ **Query** ○ **Write** ○ **Update** ○ **Delete**
Reason for Grant of Permissions	The reason why you grant the permissions.

7. Click **OK**.

Revoke permissions on a project from a specific account

1. On the **Project Permissions** tab, find the project on which you want to revoke permissions from a specific account and click the icon in the **Actions** column.
2. In the dialog box that appears, set the parameters as required.

Parameter	Description
Revoke From	The account from which you want to revoke permissions on the project.
Physical Tables	The names of the physical tables on which you want to revoke permissions from the specified account. You can select physical tables only in the current project.
Permission Type	The permissions that you want to revoke.

Parameter	Description
Reason for Revocation of Permissions	The reason why you revoke the permissions.

3. Click **OK**.

9.14.3.2.3. Grant and revoke permissions on data sources

This topic describes how to grant and revoke permissions on data sources.

Grant permissions on a data source to specific accounts

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the **Data Assets** page, click **Security** in the top navigation bar.
4. On the **Permissions** page, click **Data Source Permissions** under **Managed Permissions** in the left-side navigation pane.
5. On the **Data Source Permissions** tab, find the data source on which you want to grant permissions to specific accounts and click the icon in the **Actions** column.
6. In the dialog box that appears, set the parameters as required.

Parameter	Description
Grant To	The accounts to which you want to grant permissions on the data source. You can grant permissions on the data source to either or both of the personal account and project production account. If you select an account from the **Personal Account** drop-down list, you must also set the **Expiration Date** parameter.
Permission Type	The permissions to be granted. Valid values: ○ **Read** ○ **Write**
Reason for Grant of Permissions	The reason why you grant the permissions.

7. Click **OK**.

Revoke permissions on a data source from a specific account

1. On the **Data Source Permissions** tab, find the data source on which you want to revoke permissions from a specific account and click the icon in the **Actions** column.
2. In the dialog box that appears, set the parameters as required.

Parameter	Description
Revoke From	The account from which you want to revoke permissions on the data source.
Permission Type	The permissions that you want to revoke.
Reason for Revocation of Permissions	The reason why you revoke the permissions.

3. Click **OK**.

9.14.3.2.4. Grant and revoke functionality permissions

This topic describes how to grant and revoke functionality permissions.

Grant a functionality permission to a specific account

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the **Data Assets** page, click **Security** in the top navigation bar.
4. On the **Permissions** page, click **Functionality Permissions** under **Managed Permissions** in the left-side navigation pane.
5. On the **Functionality Permissions** tab, find the functionality on which you want to grant the permission to a specific account and click the icon in the **Actions** column.
6. In the dialog box that appears, set the parameters as required.

Parameter	Description
Grant To	The account to which your want to grant the functionality permission.
Expiration Date	The period in which the functionality permission is valid for the specified account.
Reason for Grant of Permissions	The reason why you grant the functionality permission.

7. Click **OK**.

Revoke a functionality permission from a specific account

1. On the **Functionality Permissions** tab, find the functionality on which you want to revoke the permission from a specific account and click the icon in the **Actions** column.
2. In the dialog box that appears, set the parameters as required.

Parameter	Description

Parameter	Description
Revoke From	The account from which you want to revoke the functionality permission.
Reason for Revocation of Permissions	The reason why you revoke the functionality permission.

3. Click **OK**.

9.14.3.3. Owned permissions

9.14.3.3.1. Configure functionality permissions and transfer the ownership of functionality permissions

This topic describes how to configure functionality permissions and transfer the ownership of functionality permissions.

Configure a functionality permission

1. Log on to the Dataphin console.
2. Click **Data Assets** in the top navigation bar.
3. On the **Data Assets** page, click **Security** in the top navigation bar.
4. On the **Permissions** page, click **Functionality Permission Settings** under Owned Permissions in the left-side navigation pane.
5. On the **Functionality Permission Settings** tab, find the functionality for which you want to configure the permission and click the icon in the **Actions** column.
6. In the **Configure Permission Management** dialog box, specify the user to approve applications for this permission and specify the maximum validity period of the permission.
7. Click **OK**.

Transfer the ownership of a functionality permission

1. On the **Functionality Permission Settings** tab, find the functionality on which you want to transfer the ownership of the permission and click the icon in the **Actions** column.
2. In the **Transfer Permission Ownership** dialog box, specify the account to which you want to transfer the ownership of the functionality permission.
3. Click **OK**.

9.14.4. Data governance

9.14.4.1. Overview

On the Data Governance page of the Dataphin console, you can analyze resource consumption, control the overall computing and storage costs, and improve service efficiency.

To go to the Data Governance page, perform the following steps:

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the **Data Assets** page, click **Administration** in the top navigation bar. The Data Governance page appears.

The Data Governance page contains the following menus: **Resource Management**, **Governance Overview**, **Governance Console**, **Artifact Management**, and **Recycle Bin**.

- **Resource Management**: includes the **Resource Analysis** page. On the Resource Analysis page, you can view the trends of resource consumption, distribution of resource consumption, and overview of resource governance from a global perspective.
- **Governance Overview**: includes the **Analysis** and **Results** pages. On the **Analysis** page, you can view the diagnosis result of projects for the current tenant and the analysis result of artifacts to be optimized. On the **Results** page, you can view the analysis result of project governance performance. Then, you can evaluate the governance effect and promote the optimization of artifacts.
- **Governance Console**: includes the **My Governance** and **Project Governance** pages. On the **My Governance** page, you can manage and optimize tables or nodes in projects that are owned by the current account. On the **Project Governance** page, you can view the governance information about tables or nodes in projects in which the current account is involved as a member. You can also manage and optimize tables or nodes in projects that are owned by the current account.
- **Artifact Management**: includes the **Metadata Registration**, **Artifact Management**, **Push Management**, and **Task Management** pages. On these pages, you can create artifacts, use custom or system built-in artifacts to configure and initiate push tasks, view the running details and logs of push tasks and artifact tasks, and manage these tasks.
- **Recycle Bin**: allows you to view tables that you have deleted or unpublished in the governance console. Dataphin stores these tables temporarily to prevent misoperation on data.

9.14.4.2. Resource analysis

On the Resource Analysis page, you can view the trends of resource consumption, distribution of resource consumption, and overview of resource governance from a global perspective. This topic describes how to view the global metrics, health status of resources, trend analysis, and project analysis on the Resource Analysis page.

Go to the Resource Analysis page

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the **Data Assets** page, click **Administration** in the top navigation bar.
4. On the **Data Governance** page, click **Resource Analysis** under **Resource Management** in the left-side navigation pane.
5. On the **Resource Analysis** page, you can view the health status of resources, trend analysis, and project analysis.

Global metrics

Global metrics include the **Tables from Services**, **Instances**, **Data Tables**, **Projects**, **Developers**, and **Tables from Computing Engine** parameters.

Parameter	Description
Tables from Services	The number of tables that are synchronized from data sources of specific services to computing engines.
Instances	The total number of task instances with the specified data timestamp.
Data Tables	The total number of tables for the current tenant, including logical tables and physical tables of projects in the production environment and development environment.
Projects	The total number of projects for the current tenant, including projects in the production environment and development environment.
Developers	The total number of Dataphin users who have joined one or more projects of the tenant.
Tables from Computing Engine	The number of tables that are synchronized from computing engines to data sources of specific services.

Resource health status

You can view the health status of both computing resources and storage resources.

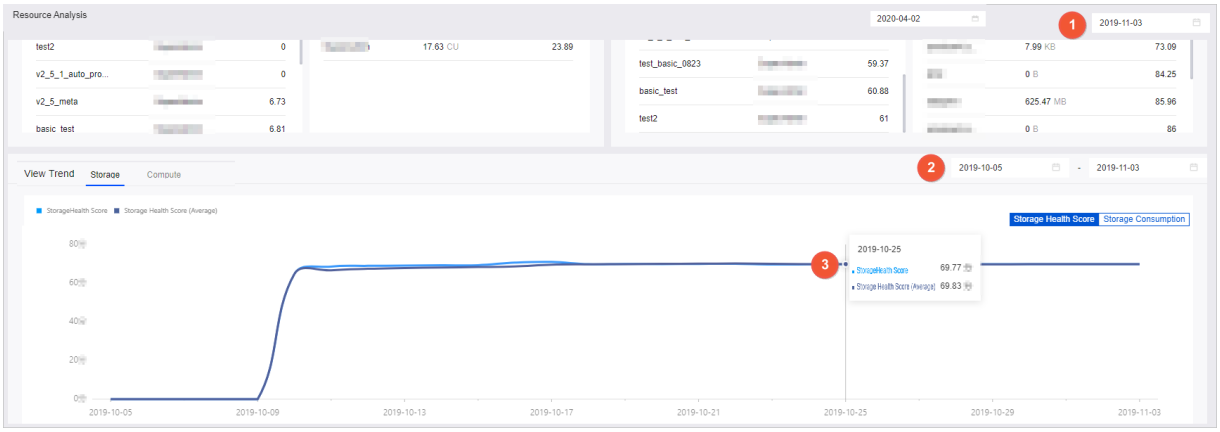
Parameter	Description
Compute Health Score	The score for the health status of computing resources with the specified data timestamp. The health scores are graded into the following three levels: • **High**: The health score is greater than or equal to 85. The message **Your score indicates that you excel in data asset management. Keep up the good work** is displayed. • **Medium**: The health score is greater than or equal to 60 and less than 85. The message **Your score is slightly higher than the threshold. We recommend that you continue to optimize data asset management** is displayed. • **Low**: The health score is less than 60. The message **Your score is lower than the threshold. We recommend that you optimize data asset management at your earliest opportunity** is displayed.

Parameter	Description
Consumed Compute Resources	The amount of consumed computing resources. Unit: CU, KCU, or CM. • 1 core × 60 seconds = 1 CM • 24 hours × 60 minutes × 1 CM = 1 CU • 1,000 CU = 1 KCU Different units are used in the following situations: • If the amount of consumed computing resources is less than 1,000 CM, the unit CM is used, for example, 987 CM. • If the amount of consumed computing resources is greater than 1,000 CM, the unit CU is used, for example, 0.83 CU, which equals to 1,200 CM. • If the amount of consumed computing resources is greater than 1,000 CU, the unit KCU is used, for example, 1.1 KCU, which equals to 1,100 CU. Note • The value is accurate to two decimal places. You can convert the consumption value to a new one with a larger unit as needed. • The amount of consumed computing resources is calculated based on the total execution time for which the CPU was dedicated to underlying tasks. For example, if a task occupies one CPU core and runs for one day, one CU is consumed.
Storage Health Score	The score for the health status of storage resources with the specified data timestamp.
Storage Consumption	The amount of consumed storage resources. Unit: byte, KB, MB, GB, TB, PB, EB, or ZB. Note - The following formulas describe the conversion from the unit of byte to the units of KB, MB, GB, TB, PB, EB, and ZB for the measurement of consumed storage resources: - 1024 B => 1 KB - 1024 * 1024 B => 1 MB - 1024 * 1024 * 1024 B => 1 GB - 1024 * 1024 * 1024 * 1024 B => 1 TB - 1024 * 1024 * 1024 * 1024 * 1024 B => 1 PB - 1024 * 1024 * 1024 * 1024 * 1024 * 1024 B => 1 EB - 1024 * 1024 * 1024 * 1024 * 1024 * 1024 * 1024 B => 1 ZB

Parameter	Description
Projects (Instant Optimization)	The top 10 projects with the lowest health scores in computing or those with the lowest health scores in storage.
Owners (Instant Optimization)	The top 10 owners with the lowest health scores in computing or those with the lowest health scores in storage.

Trend analysis

In the View Trend section, you can view information about global computing resources and storage resources in a specific time period, including the trends of the health score in storage, storage resource consumption, health score in computing, and computing resource consumption. The trend charts help you analyze data stability.



The base date, marked as 1 in the preceding figure, is displayed in the upper-right corner of the page. By default, the trend chart shows the trends of the corresponding data in the 30 days prior to the base date.

- Click the **Storage** tab in the **View Trend** section to view the trend chart of the health score in storage. By default, the trend chart shows the trends of the health score in storage and the average score in the 30 days prior to the base date.

  Move the pointer over a point of time in the chart. You can view the health score in storage corresponding to the specified date and the average score in the seven days prior to the specified date. The data stability is determined based on the difference between the health score in storage and the average score. A smaller difference indicates a higher data stability. For example, at the time point marked as 3 in the preceding figure, the health score in storage of October 25, 2019 is 69.77 and the average score in the seven days prior to October 25, 2019 is 69.83.

You can specify a time period, marked as 2 in the preceding figure, based on business requirements to view the corresponding trends of the health score in storage and the average score. For example, you can specify a time period from October 10, 2019 to October 15, 2019. The trend chart shows the trends of the health score in storage and the average score in this time period, as shown in the following figure. If you move the pointer over the time point of October 14, 2019 in the chart, the corresponding scores appear, that is, 69.23 for the health score in storage on October 14, 2019 and 68.12 for the average score in the seven days prior to October 14, 2019.

- On the Storage tab in the View Trend section, click **Storage Consumption** in the upper-right corner. By default, the trend chart shows the trends of storage resource consumption and the average consumption in the 30 days prior to the base date.

  > **Note** The data on the Storage Consumption chart is presented in the same way as that on the **Storage Health Score** chart.

- Click the **Compute** tab in the **View Trend** section to view the trend chart of the health score in computing. By default, the trend chart shows the trends of the health score in computing and the average score in the 30 days prior to the base date.

  > **Note** The data on the Compute Health Score chart is presented in the same way as that on the **Storage Health Score** chart.

- On the Compute tab in the View Trend section, click **Consumed Compute Resources** in the upper-right corner. By default, the trend chart shows the trends of computing resource consumption and the average consumption in the 30 days prior to the base date.

  > **Note** The data on the Consumed Compute Resources chart is presented in the same way as that on the **Storage Health Score** chart.

Project analysis

In the **Project Analysis** section, you can view the analysis result of projects. You can also filter projects to find a desired project and view the analysis result of the project. View the analysis result of projects in the following ways:

- View the analysis results of the projects that are displayed by default, as described in the following table.

Parameter	Description
Project Name	The name of the project.
Business Unit	The business unit to which the project belongs.
Instances	The number of task instances in the project, including instances of sync tasks and code tasks.
Data Tables	The number of tables in the project, including physical tables and logical tables.
Consumed Compute Resources	The amount of computing resources that are consumed by all tasks in the project. Unit: CU.
Consumed Storage Resources	The amount of storage resources that are consumed by all tables in the project.
Compute Health Score	The health score in computing of the project.
Storage Health Score	The health score in storage of the project.
Administrator	The administrator of the project.
Artifacts	The number of governance items to be optimized.

- Enter a keyword in the search box to search for projects whose names contain the keyword. You can also click the icon and set the **Environment** and **Business Unit** parameters to find desired projects and view the analysis result of these projects.

9.14.4.3. Governance overview

9.14.4.3.1. Governance analysis

On the Analysis page, you can view the diagnosis result of projects for the current tenant and the analysis result of artifacts to be optimized. This topic describes the information you can view on the Analysis page.

Go to the Analysis page

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the **Data Assets** page, click **Administration** in the top navigation bar.
4. On the **Data Governance** page, click **Analysis** under **Governance Overview** in the left-side navigation pane.
5. On the **Analysis** page, click the **Storage** and **Compute** tabs to view the health scores in storage and computing, score details, and project governance details.

   In the upper-right corner of the Analysis page, specify a base date to display the corresponding business data.

Resource categories

By default, the Analysis page displays the health score in storage and score details of projects for the current tenant. You can click the **Compute** tab on the **Analysis** page to view the health score in computing and score details. You can view the following information on the Storage or Compute tab:

- Click the **Storage** tab on the **Analysis** page. The health score in storage appears on the left of the page. The **Score Details** section on the right of the page displays the numbers of artifacts, optimized governance items, and tables to be optimized. The Score Details section also lists information about each artifact, as described in the following table.

Parameter	Description
Artifact Name	The name of the artifact. Artifacts for storage include Excessively Long Retention Period, No Management Policies Specified, Idle Physical Tables, Empty Table, No Management Policies Specified for Logical Tables, Idle Logical Tables, Empty Logical Table, and Logical Table Conversion (Empty Physical Tables).
Score Point Reduction	The points deducted for the occurrence of the artifact.
Storage Resources (To Be Optimized)	The amount of storage resources to be optimized.
Tables (To Be Optimized)	The number of tables to be optimized.

- Click the **Compute** tab on the **Analysis** page.**The health score in computing appears on the left of the page. The Score Details section on the right of the page displays the numbers of artifacts, optimized governance items, and nodes to be optimized.** The Score Details section also lists information about each artifact, as described in the following table.

Parameter	Description
Artifact Name	The name of the artifact. Artifacts for computing include Unread Output Table, Inappropriate Data Scanning, Unexpected Large Amounts of Data, Data Skew, Failed Task Node, No Imported Data, and No Input Data.
Score Point Reduction	The points deducted for the occurrence of the artifact based on the built-in health assessment model.
Compute Resources (To Be Optimized)	The amount of computing resources to be optimized.
Nodes (To Be Optimized)	The number of nodes to be optimized.

Project governance details

In the Project Governance Details section of the Storage and Compute tabs, you can view the governance information about each project in the corresponding business unit, such as the amount of consumed resources, the ratio of optimized governance items to total governance items, and the number of governance items to be optimized. You can click the **Compute** or **Storage** tab on the **Analysis** page to view the governance information about the computing resources or storage resources of projects. You can also filter projects to find a desired project and view the governance details of the project. View the governance details of projects in the following ways:

- Click the **Storage** tab to view the governance information about the storage resources of projects, as described in the following table.

Parameter	Description
Project Name	The name of the project.
Business Unit	The business unit to which the project belongs.
Administrator	The administrator of the project.
Consumed Storage Resources	The amount of storage resources that are consumed by all tables in the project.
Rate of Optimized Storage Resources	The ratio of optimized governance items to total governance items that were identified in the seven days prior to the date you specify in the upper-right corner of the page.
Artifacts	The number of governance items to be optimized in the project.
Actions	The entries for you to view data trends and health score rankings. ◦ Click the icon in the **Actions** column of a project. In the View Trend dialog box, you can view the trend chart of the health score in storage and storage resource consumption in the last 7 or 30 days. You can also move the pointer over a point of time in the chart to view the health score in storage and storage resource consumption of the specified date. ◦ Click the icon in the **Actions** column of a project. In the View Rankings dialog box, you can view the ratio of the storage resources that each table consumes in the project. You can also view the rankings of tables based on the storage resource consumption in descending order or based on the health score in storage in ascending order.

- Click the **Compute** tab to view the governance information about the computing resources of projects, as described in the following table.

Parameter	Description
Project Name	The name of the project.
Business Unit	The business unit to which the project belongs.
Administrator	The administrator of the project.

Parameter	Description
Consumed Compute Resources	The amount of computing resources that are consumed by all nodes in the project.
Rate of Optimized Compute Resources	The ratio of optimized governance items to total governance items that were identified in the seven days prior to the date you specify in the upper-right corner of the page.
Artifacts	The number of governance items to be optimized in the project.
Actions	The entries for you to view data trends and health score rankings. ○ Click the icon in the **Actions** column of a project. In the View Trend dialog box, you can view the trend chart of the health score in computing and computing resource consumption in the last 7 or 30 days. You can also move the pointer over a point of time in the chart to view the health score in computing and computing resource consumption of the specified date. ○ Click the icon in the **Actions** column of a project. In the View Rankings dialog box, you can view the ratio of the computing resources that each node consumes in the project. You can also view the rankings of nodes based on the computing resource consumption in descending order or based on the health score in computing in ascending order.

- Enter a keyword in the search box to search for projects whose names contain the keyword. You can also click the icon and set **Environment**, **Business Unit**, and **Owner** to find desired projects and view the governance details of these projects.

9.14.4.3.2. Governance results

On the Results page, you can view the analysis result of project governance performance. Then, you can evaluate the governance effect and promote the optimization of artifacts. This topic describes how to view the overall governance metrics, trends, and project governance details on the Results page.

Go to the Results page

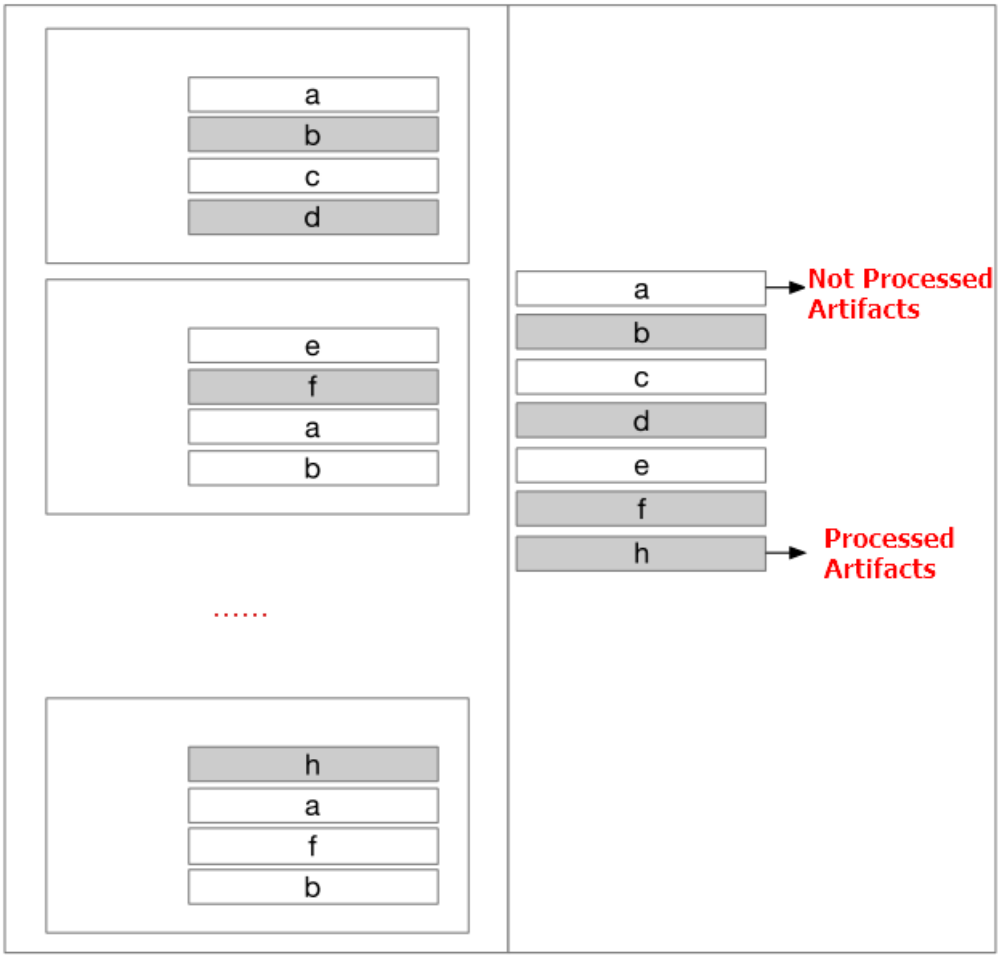
1. Log on to the Dataphin console.
2. Go to the **Data Governance** page.
   i. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
   ii. On the **Data Assets** page, click **Administration** in the top navigation bar.
3. On the **Data Governance** page, click **Results** under **Governance Overview** in the left-side navigation pane.

   In the upper-right corner of the **Results** page, specify a base date to display the corresponding business data. The Results page consists of the following sections: **Artifact Details**, **Saved Resources**, **View Trend**, and **Project Governance Details**.

Overall governance metrics

The overall governance metrics include two categories: **Artifact Details** and **Saved Resources**. The **Artifact Details** section displays the **Rate of Processed Resources** and **Processed Artifacts** metrics. The **Saved Resources** section displays the **Compute** and **Storage** metrics.

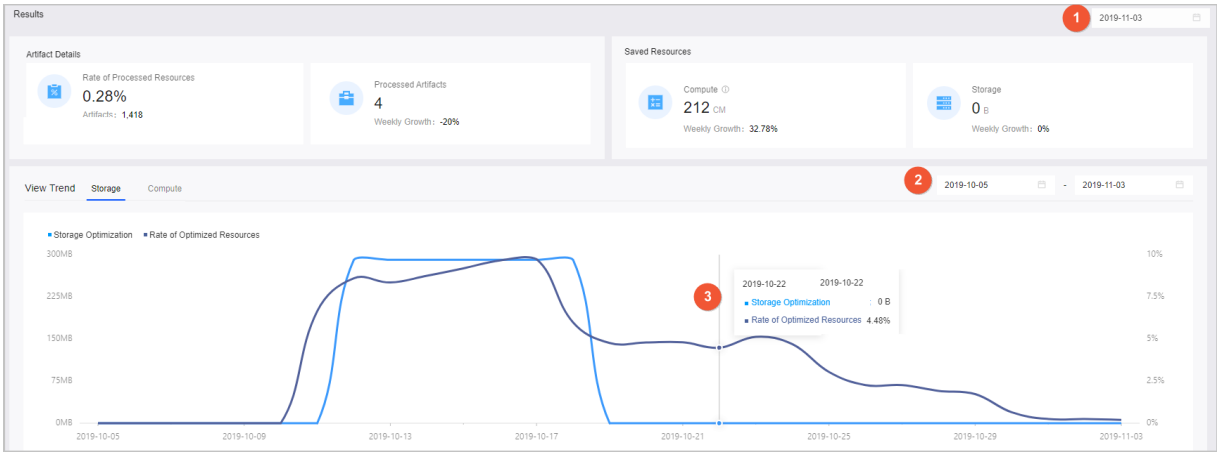
- **Rate of Processed Resources**: the ratio of optimized governance items to total governance items that were identified in the last seven days.



- **Processed Artifacts**: the number of governance items that were optimized in the last seven days.
- **Compute**: the amount of computing resources that have been saved by optimized governance items of the computing type.
- **Storage**: the amount of storage resources that have been saved by optimized governance items of the storage type.

Trend analysis

In the View Trend section, you can view information about global computing resources and storage resources in a specific time period, including the trends of the amount of saved resources and the ratio of optimized governance items to total governance items.

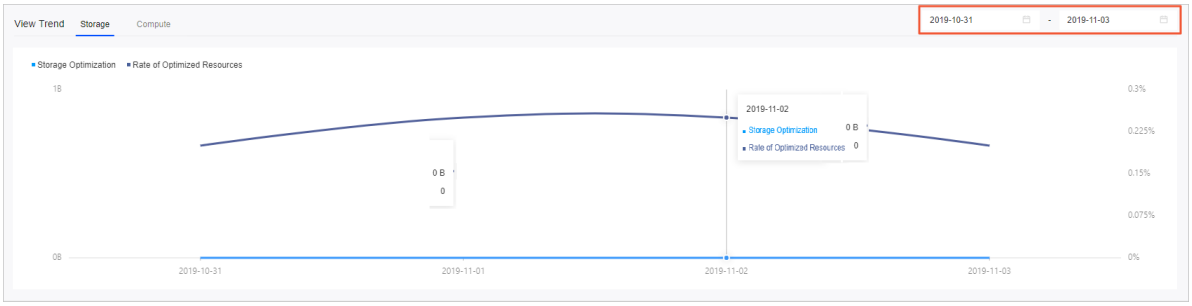


The base date, marked as 1 in the preceding figure, is displayed in the upper-right corner of the page. By default, the trend chart shows the trends of the corresponding data in the 30 days prior to the base date.

- Click the **Storage** tab in the **View Trend** section to view the trends of the amount of saved storage resources and the ratio of optimized governance items of the storage type to total governance items of the storage type in the 30 days prior to the base date.

  Move the pointer over a point of time in the chart. You can view the ratio of optimized governance items of the storage type to total governance items of the storage type corresponding to the specified date and the amount of storage resources that have been saved in the seven days prior to the specified date. For example, at the time point marked as 3 in the preceding figure, the amount of storage resources that have been saved in the seven days prior to October 22, 2019 is 0 bytes and the ratio of optimized governance items of the storage type to total governance items of the storage type on that day is 4.48%.

  You can specify a time period, marked as 2 in the preceding figure, based on business requirements to view the corresponding trends of the ratio of optimized governance items of the storage type to total governance items of the storage type and the amount of saved storage resources. For example, you can specify a time period from October 31, 2019 to November 3, 2019. The trend chart shows the trends of the ratio of optimized governance items of the storage type to total governance items of the storage type and the amount of saved storage resources in this time period, as shown in the following figure. If you move the pointer over the time point of November 2, 2019 in the chart, the corresponding data appears, that is, 0.0% for the ratio of optimized governance items of the storage type to total governance items of the storage type on November 2, 2019 and 0 bytes for the amount of storage resources that have been saved in the seven days prior to November 2, 2019.

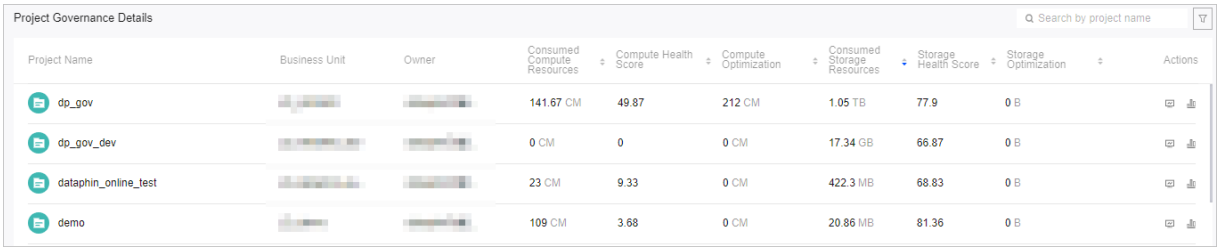


- Click the **Compute** tab in the **View Trend** section to view the trends of the amount of saved computing resources and the ratio of optimized governance items of the computing type to the total governance items of the computing type in the 30 days prior to the base date.

> **Note** The data on the Compute tab is presented in the same way as that on the Storage tab.

Project governance details

In the **Project Governance Details** section, you can view the governance information about each project in the corresponding business unit, such as the amount of consumed storage or computing resources, the health score in storage or computing, and the amount of saved storage or computing resources.



Parameter	Description
Project Name	The name of the project.
Business Unit	The business unit to which the project belongs.
Owner	The owner of the project.
Consumed Storage Resources	The amount of storage resources that are consumed by all tables in the project.
Storage Health Score	The health score in storage of the project.
Consumed Compute Resources	The amount of computing resources that are consumed to run MaxCompute tasks in the project, including SQL tasks that are created by developers and automatically generated by Dataphin.
Compute Health Score	The health score in computing of the project.

Parameter	Description
Storage Optimization	The amount of storage resources that have been saved in the project by optimized governance items of the storage type.
Compute Optimization	The amount of computing resources that have been saved in the project by optimized governance items of the computing type.
Actions	The entries for you to view data trends and health score rankings. • Click the icon in the **Actions** column of a project. In the View Trend dialog box, you can view the trend chart of the corresponding data in the last 7 or 30 days. ○ On the **Storage** tab, move the pointer over a point of time in the chart. You can view the health score in storage and storage resource consumption of the specified date. ○ Click the **Compute** tab. On the **Compute** tab, move the pointer over a point of time in the chart. You can view the health score in computing and computing resource consumption of the specified date. • Click the icon in the **Actions** column of a project. In the View Rankings dialog box, you can view the rankings of project owners based on their project governance performance. ○ On the **Storage** tab, you can view the rankings of project owners based on the health score in storage, amount of consumed storage resources, and amount of saved storage resources. 
Parameter	Description
	○ Click the **Compute** tab. On the Compute tab, you can view the rankings of project owners based on the health score in computing, amount of consumed computing resources, and amount of saved computing resources. 
Enter a keyword in the search box to search for projects whose names contain the keyword. You can also click the icon and set **Environment**, **Business Unit**, and **Owner** to find desired projects and view the governance details of these projects.

9.14.4.4. Governance console

In the governance console, you can view the governance information about tables or nodes in projects in which you are involved as a member. You can also manage and optimize tables or nodes in projects in which you are involved as an administrator.

As the administrator or developer of a project, you can filter tables or nodes that require optimization by selecting the governance scope, governance target, and artifact, and then view corresponding information and manage and optimize governance items in the governance console. The features provided on the **My Governance** page are similar to those on the **Project Governance** page. The following example demonstrates how to use the governance console. The **My Governance** page is used in this example.

Go to the My Governance page

1. Log on to the Dataphin console.
2. Go to the **My Governance** page.
   i. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
   ii. On the **Data Assets** page, click **Administration** in the top navigation bar.
   iii. On the **Data Governance** page, click **My Governance** under **Governance Console** in the left-side navigation pane.

iv. On the **My Governance** page, set the **Governance Scope**, **Governance Target**, and **Artifact** parameters to filter governance items.

Parameter	Description
Governance Scope	The business scope of the governance target. Valid values: **Storage** and **Compute**.
Governance Target	■ If you select **Storage** for the **Governance Scope** parameter, the valid values of the **Governance Target** parameter are **Physical Table** and **Logical Table**. ■ If you select **Compute** for the **Governance Scope** parameter, the value of the **Governance Target** parameter is fixed to **Task Node**.
Artifact	■ If you select **Storage** for the **Governance Scope** parameter and select **Physical Table** for the **Governance Target** parameter, the valid values of the **Artifact** parameter are **No Management Policies Specified**, **Empty Table**, **Idle Physical Tables**, **Excessively Long Retention Period**, and custom artifacts. ■ If you select **Storage** for the **Governance Scope** parameter and select **Logical Table** for the **Governance Target** parameter, the valid values of the **Artifact** parameter are **No Management Policies Specified for Logical Tables**, **Idle Logical Tables**, **Empty Logical Table**, **Logical Table Conversion (Empty Physical Tables)**, and custom artifacts. ■ If you select **Compute** for the **Governance Scope** parameter and select **Task Node** for the **Governance Target** parameter, the valid values of the **Artifact** parameter are **No Input Data**, **No Imported Data**, **Failed Task Node**, **Data Skew**, **Unexpected Large Amounts of Data**, **Inappropriate Data Scanning**, and **Unread Output Table**.

v. View the details of governance items.

- If you select **Storage** for the **Governance Scope** parameter and select **Physical Table** for the **Governance Target** parameter, you can view information about each physical table to be optimized.

Parameter	Description
Table Name	The name of the physical table.
Project Name	The name of the project to which the physical table belongs.
Business Unit	The business unit to which the physical table belongs.
Owner	The owner of the physical table.
Health Score	The health score of the physical table.
Storage Space	The size of MaxCompute storage resources that the physical table occupies.
Retention Period	The retention period of the physical table.
Number of Days (Accessed from First Day to Last Day in the Last 33 Days)	The number of visits to the physical table in the last 33 days.
Processing Status	The processing status of the node. Valid values: **Processed** and **Not Processed**.

- If you select **Storage** for the **Governance Scope** parameter and select **Logical Table** for the **Governance Target** parameter, you can view information about each logical table to be optimized.

Parameter	Description
Model Name	The name of the logical table.
Project Name	The name of the project to which the logical table belongs.
Business Unit	The business unit to which the logical table belongs.
Owner	The owner of the logical table.
Health Score	The health score of the logical table.
Storage Space	The size of MaxCompute storage resources that the logical table occupies.
Retention Period	The retention period of the logical table.
Environment	The environment to which the logical table belongs. Valid values: **Development** and **Production**.
Processing Status	The processing status of the node. Valid values: **Processed** and **Not Processed**.

- If you select **Compute** for the **Governance Scope** parameter and select **Task Node** for the **Governance Target** parameter, you can view information about each node to be optimized.

Parameter	Description
Node Name	The name of the node.
Node ID	The ID of the node.
Node Type	The type of the node.
Project Name	The name of the project to which the node belongs.
Owner	The owner of the node.
Health Score	The health score of the node.
CPU Consumption	The amount of computing resources that the node consumes.
Duration	The duration during which the node instance is run.
Processing Status	The processing status of the node. Valid values: **Processed** and **Not Processed**.

Manage physical tables

The supported actions on physical tables include **Move to Recycle Bin**, **Set Retention Period**, and **Pause Node**.

1. On the **My Governance** page, you can find physical tables to be optimized by using one of the following methods:
   - Select **Storage** for the **Governance Scope** parameter and select **Physical Table** for the **Governance Target** parameter to filter physical tables.
   - Click the icon next to **Select a project** and select a project to filter physical tables.
   - Enter a keyword in the search box to search for physical tables whose names contain the keyword.
   - Click the icon next to **All** and select All, Processed, or Not Processed to filter physical tables.
2. Manage physical tables by using one of the following methods:
   - Find the physical table that you want to manage and click the icon in the **Actions** column to move the physical table to the recycle bin.

     You can also select multiple physical tables and click **Move to Recycle Bin** in the lower part of the page to move them to the recycle bin. In the **Confirm** message, click **Confirm**. The selected physical tables are moved to the recycle bin.
   - Find the physical table that you want to manage and click the icon in the **Actions** column. In the **Set Retention Period** dialog box, set a retention period and click **OK**.

     You can also select multiple physical tables and click **Set Retention Period** in the lower part of the page. In the **Set Retention Period** dialog box, set a retention period and click **OK**. A retention period is set for the selected physical tables.
   - Find the physical table that you want to manage and click the icon in the **Actions** column. In the **Confirm** message, click **Confirm**. The system stops using this physical table.

     > **Note** The system does not allow you to resume a paused physical table.

Manage logical tables

Only the **Set Retention Period** action is supported on logical tables.

1. On the **My Governance** page, you can find logical tables to be optimized by using one of the following methods:
   - Select **Storage** for the **Governance Scope** parameter and select **Logical Table** for the **Governance Target** parameter to filter logical tables.
   - Click the icon next to **Select a project** and select a project to filter logical tables.
   - Enter a keyword in the search box to search for logical tables whose names contain the keyword.
   - Click the icon next to **All** and select All, Processed, or Not Processed to filter logical tables.
2. Find the logical table that you want to manage and click the icon in the **Actions** column. In

the **Set Retention Period** dialog box, set a retention period and click **OK**.

You can also select multiple logical tables and click **Set Retention Period** in the lower part of the page. In the **Set Retention Period** dialog box, set a retention period and click **OK**. A retention period is set for the selected logical tables.

Manage nodes

The supported actions on nodes include **Pause Node** and **Unpublish Node**.

1. On the **My Governance** page, you can find nodes to be optimized by using one of the following methods:
   - Select **Compute** for the **Governance Scope** parameter and select **Task Node** for the **Governance Target** parameter to filter nodes.
   - Click the icon next to **Select a project** to filter nodes.
   - Enter a keyword in the search box to search for nodes whose names contain the keyword.
   - Click the icon next to **All** and select All, Processed, or Not Processed to filter nodes.
2. Manage nodes by using one of the following methods:
   - Find the node that you want to manage and click the icon in the **Actions** column. In the **Confirm** message, click **Confirm**. The system stops running this node.

     > **Note** The system does not allow you to resume a paused node.

   - Find the node that you want to manage and click the icon in the **Actions** column. In the **Confirm** message, click **Confirm**. The node is not run in the production environment as scheduled.

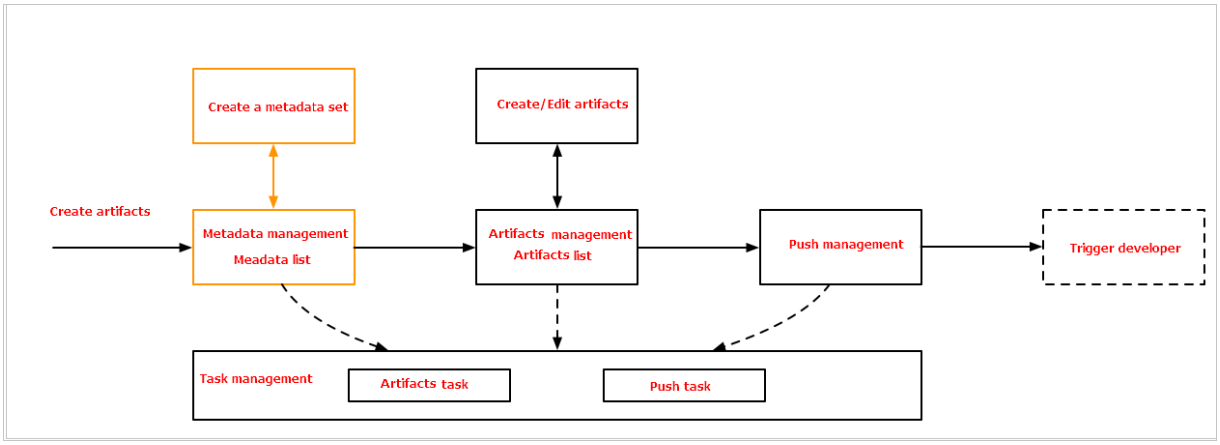
9.14.4.5. Artifact management

9.14.4.5.1. Overview

In the Artifact Management section, you can create and manage metadata sets, artifacts, and push tasks, view the running details and logs of push tasks and diagnosis tasks, and manage these tasks. In the Artifact Management section, you can create and manage custom artifacts and manage system built-in artifacts.

Artifact management Metadata management Push management Task management

Dataphin allows you to create custom artifacts based on your business requirements and use the governance settings in data asset management.



The following features are provided by Dataphin:

1. Metadata management: allows you to create and manage metadata sets required for data governance.
2. Artifact management: allows you to create and manage artifacts based on the configured metadata sets. Artifacts define the identification rules and policies for data governance.
3. Push management: allows you to create push tasks so that you can receive push notifications when occurrences of one or more specified artifacts are identified for the data objects, including tables and nodes, in the selected projects. The push notifications help to remind you to process the data objects that require optimization.
4. Task management: allows you to manage diagnosis tasks and push tasks.

9.14.4.5.2. Metadata registration

On the Metadata Registration page, you can create and manage metadata sets that are required for data governance. This topic describes how to create, edit, check, and delete metadata sets, and change owners of metadata sets.

Go to the Metadata Registration page

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the **Data Assets** page, click **Administration** in the top navigation bar.
4. On the **Data Governance** page, click **Metadata Registration** under **Artifact Management** in the left-side navigation pane.
5. On the **Metadata Registration** page, view information about registered metadata sets.

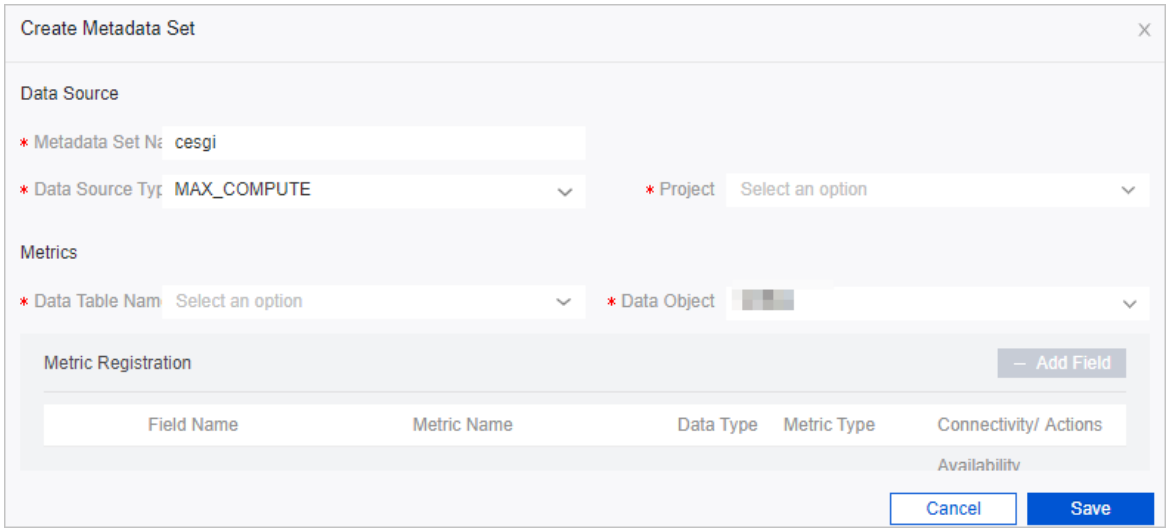
Parameter	Description
Metadata Set Name	The name of the metadata set.
Data Source Type	The type of the data source for the metadata set.
Data Object	The type of the data object that is managed based on the metadata set. Valid values: **Physical Table**, **Logical Table**, and **Task Node**.

Parameter	Description
Owner	The owner of the metadata set.
Metrics	The number of metrics that are registered in the metadata set.
Referenced by Artifacts	Indicates whether the metadata set is referenced and the number of times that the metadata set is referenced. For example, the value is Yes if you reference a metric in the metadata set when you create an artifact.
Check Status	The check result of the metadata set. Valid values: **Succeeded** and **Failed**. If any fields that the metadata set references are missing or the referenced table is renamed, the check fails. If all fields that the metadata set references exist and the metadata set can properly connect to the referenced table, the check is successful.

You can enter a keyword in the search box to search for metadata sets whose names contain the keyword. You can also click the icon and set the **Data Object**, **Data Source Type**, **Referenced Status**, and **Owner** parameters to filter metadata sets.

Create a metadata set

1. On the **Metadata Registration** page, click **Create Metadata Set** in the upper-right corner.
2. In the **Create Metadata Set** dialog box, set the parameters as required.



Section	Parameter	Description
	Metadata Set Name	The name of the metadata set. Limits: ○ The name must be 1 to 30 characters in length. ○ The name must be unique.

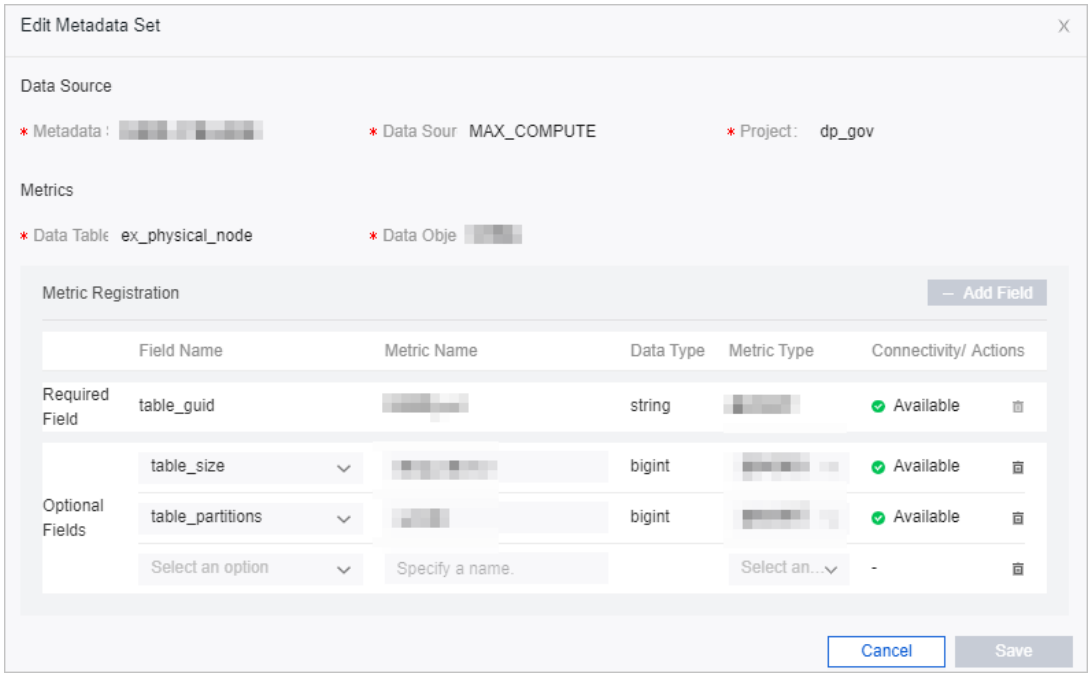
Section	Parameter	Description
Data Source	Data Source Type	The type of the data source for the metadata set. Select **MAX_COMPUTE**.
	Project	The data source of the metadata set. Select a computing engine from the drop-down list or search for it by entering a keyword in the search box. **Note** The drop-down list displays the computing engines that are created on the Planning page of the Dataphin console.
Metrics	Data Table Name	The table that is referenced by the metadata set. Select a table from the drop-down list or search for it by entering a keyword in the search box. **Note** Limits: ○ The drop-down list displays the physical tables, logical tables, and nodes that belong to the project of the selected computing engine. ○ You can create only one metadata set based on each table.
	Data Object	The type of the data object to be managed based on the metadata set. Valid values: **Physical Table**, **Logical Table**, and **Task Node**.
	Metric Registration	The metrics that are registered in the metadata set. At least one field of each table must be registered in the metadata set. You can click **Add Field** to add more fields. For more information, see Edit a metadata set.

3. Click **Save**. The metadata set is created.

Edit a metadata set

1. On the **Metadata Registration** page, find the metadata set that you want to edit and click the icon in the **Actions** column.
2. In the **Edit Metadata Set** dialog box, add or remove fields as required. The other parameters cannot be modified.
   - Add fields to the metadata set.

a. Click **Add Field** and set the parameters as required.



Parameter	Description
Field Name	The field to be used as a metric. Select a field from the drop-down list. **Note** The drop-down list displays the fields in the referenced table. Each field can be added only once.
Metric Name	The name of the metric.
Data Type	The data type of the field. Default value: **string**.
Metric Type	The type of the metric. Valid values: **Basic Attributes**, **Basic Metrics**, and **My Metrics**.
Connectivity/Availability	The connection status of the field. A field can be in the Available or Unavailable state. If a field in the **Metric Registration** section is in the Unavailable state, you cannot save the added fields.

b. Click **Save**. The fields are added to the metadata set.

- Delete a field from the metadata set.

  Find the field that you want to delete and click the icon in the **Actions** column to delete the field.

> **Note** Limits:
>
> - You cannot delete the first field in the **Required Field** section.
> - You cannot edit system metadata sets.

3. Click **Save**. The metadata set is modified.

Check a metadata set

On the Metadata Registration page, find the metadata set that you want to check and click the icon in the **Actions** column to check the metadata set.

Change the owner of a metadata set

1. On the Metadata Registration page, find the metadata set for which you want to change the owner and click the icon in the **Actions** column.To change the owners of multiple metadata sets at a time, select the metadata sets and click **Change Owner** in the lower part of the page.
2. In the **Change Owner** dialog box, select the user to whom you want to transfer the metadata set.
3. Click **Change Owner**. The metadata set is transferred to the specified user.

> **Note** Limits:
>
> - After the owner of a metadata set is changed, the original owner cannot modify the metadata set.
> - You can change the owner of a metadata set to any user of the current tenant.
> - You cannot change owners of system metadata sets.

Delete a metadata set

1. On the **Metadata Registration** page, find the metadata set that you want to delete, click the icon, and then select **Delete** in the **Actions** column.
2. In the **Delete Metadata Set** message, click **Confirm**.

> **Note** You cannot delete system metadata sets.

9.14.4.5.3. Artifact management

This topic describes how to create, edit, and delete artifacts.

Context

The following table describes the limits on operations related to artifact management.

Operation	Limit
Create an artifact	Limits on the role: • System built-in artifact: super administrator only • Custom artifact: super administrator and project administrator
Edit an artifact	Limits on the role: • System built-in artifact: super administrator only • Custom artifact: super administrator, project administrator, and artifact owner
View an artifact	This operation can be performed by all users.
Enable an artifact	Limits on the role: • System built-in artifact: super administrator only • Custom artifact: super administrator, project administrator, and artifact owner
Disable an artifact	Limits on the role: • System built-in artifact: super administrator only • Custom artifact: super administrator, project administrator, and artifact owner
Change the owner	Limits on the role: • System built-in artifact: super administrator only • Custom artifact: super administrator, project administrator, and artifact owner
Delete an artifact	Limits on the role: • System built-in artifact: super administrator only • Custom artifact: super administrator, project administrator, and artifact owner

Create an artifact

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the Data Assets page, click **Administration** in the top navigation bar.
4. On the Data Governance page, click **Artifact Management** under Artifact Management in the left-side navigation pane.
5. On the **Artifact Management** page, click **Create Artifact** in the upper-right corner.
6. On the **Create Artifact** page, set the parameters as required.

i. Select an artifact type.

Artifact type	Description
Custom artifact	The artifact that you can customize based on your business needs.
System built-in artifact	The artifact that can be created by the super administrator by using an Apsara Stack account. Dataphin pushes notifications for system built-in artifacts to all users.

ii. Set the basic parameters for the artifact.

Parameter	Description
Artifact Name	The name of the artifact. Dataphin has the following limits on the artifact name: ■ The name must be 1 to 20 characters in length. ■ The name must be unique.

Parameter	Description
Governance Target	The type of the data object to be managed. Valid values: ■ **Physical Table** After you select this option, display fields and governance operations are selected by default. You can clear some display fields and operations as required. The following display fields and operations are available: ■ Display fields: **Project Name**, **Business Unit**, **Owner**, **Health Score**, **Storage Space**, **Retention Period**, and **Number of Days (Accessed from First Day to Last Day in the Last 33 Days)** ■ Operations: **Move to Recycle Bin**, **Set Retention Period**, and **Pause Node** The selected display fields and operations will appear in the governance console. ■ **Logical Table** After you select this option, display fields and governance operations are selected by default. You can clear some display fields and operations as required. The following display fields and operations are available: ■ Display fields: **Project Name**, **Business Unit**, **Owner**, **Health Score**, **Storage Space**, and **Retention Period** ■ Only the **Set Retention Period** operation is supported. You cannot clear this operation. The selected display fields and operations will appear in the governance console. ■ **Task Node** After you select this option, display fields and governance operations are selected by default. You can clear some display fields and operations as required. The following display fields and operations are available: ■ Display fields: **Node ID**, **Node Type**, **Owner**, **Project Name**, **Health Score**, **CPU Consumption**, and **Duration** ■ Operations: **Pause Node** and **Unpublish Node** The selected display fields and operations will appear in the governance console.
Governance Scope	The business scope of the governance target. This parameter is automatically set based on the selected governance target. Valid values: **Compute** and **Storage**.
Description	The description of the artifact.

iii. Set rules for the artifact.

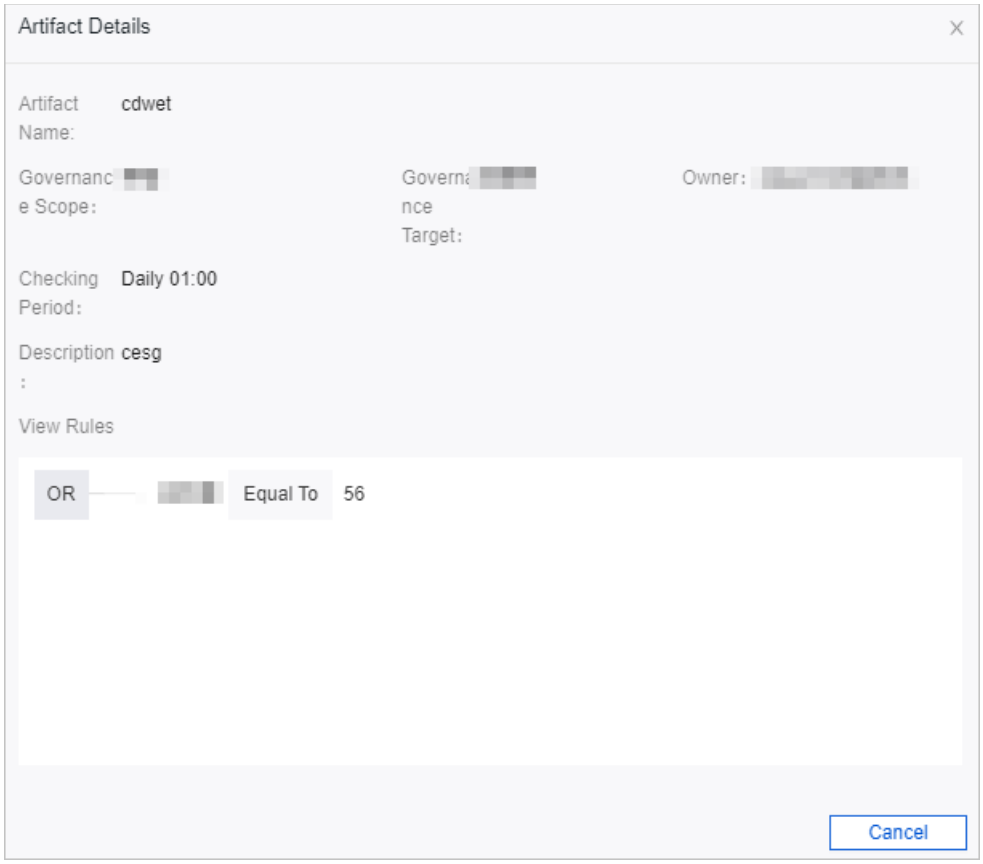
Section	Parameter	Description
Edit Rules	Governance Method	The method of setting rules for the artifact. You can use the codeless UI or code editor. ■ If you set the **Artifact Type** parameter to **Custom Artifact**, you can select **Create Custom Rules** or **Reference System Rules** in the **Configure Rules** section. ■ If you set the **Artifact Type** parameter to **General Artifact**, you can select only **Create Custom Rules** in the **Configure Rules** section.
	Code Editor	The custom SQL statements for setting rules for the artifact. If you set the **Governance Method** parameter to **Code Editor**, enter SQL statements in the code editor. Example: `select` `table_guid` `,business_name` `,is_important` `from` `physical_table_individuation` `where` `ds='${bizdate}'` `and business_name='tmall'` `and is_relation='Y'` `and table_size>100` **Note** This method uses SQL statements to customize rules based on the metrics of registered metadata sets. The artifact uses these rules to manage governance targets.

Section	Parameter	Description
Configure Rules	Create Custom Rules	To add rules, perform the following steps: a. To add an operator, click **Add Operator** and select **OR** or **AND**. b. To add a rule, click **Add Rule**, select a tag and a relational operator, and then enter a value. Parameter description: ■ Tags are registered metrics of metadata sets. ■ Relational operators include Greater Than, Greater Than or Equal To, Equal To, Less Than or Equal To, and Less Than. To remove an operator or a rule, click the icon next to the operator or rule.
	Reference System Rules	To reference the rules of a system built-in artifact, perform the following steps: a. Click **Reference System Rules**. b. In the **Reference System Rules** dialog box, select a system built-in artifact from the drop-down list. Note The system displays details of the selected system built-in artifact. c. Click **Confirm**.

7. Click **Submit**. The artifact is created.

View an artifact

1. On the **Artifact Management** page, find the artifact that you want to view and click the icon in the **Actions** column.
2. In the **Artifact Details** message, view the details of the artifact.



Edit an artifact

1. On the **Artifact Management** page, find the artifact that you want to edit and click the icon in the **Actions** column.
2. On the **Edit Artifact** page, modify the parameters for the artifact. For more information, see Create an artifact.

Enable an artifact

1. On the **Artifact Management** page, find the artifact that you want to enable and click the icon in the **Actions** column.
2. In the **Enable Artifact** message, click **Confirm**.

Disable an artifact

1. On the **Artifact Management** page, find the artifact that you want to disable and click the icon in the **Actions** column.
2. In the **Disable Artifact** message, click **Confirm**.

Change the owner of an artifact

1. On the **Artifact Management** page, find the artifact for which you want to change the owner and click the icon in the **Actions** column.
2. Select **Change Owner**.

3. In the **Change Owner** dialog box, select the user to whom you want to transfer the artifact.
4. Click **Confirm**.

> **Note** After the artifact is transferred to the selected user, the original owner cannot modify the artifact.

Delete an artifact

1. On the **Artifact Management** page, find the artifact that you want to delete and click the icon in the **Actions** column.
2. Select **Delete**.
3. In the **Delete Artifact** message, click **Confirm**.

9.14.4.5.4. Push management

Dataphin pushes governance results to you by using SMS messages, emails, and internal messages. This topic describes how to create, edit, and delete push tasks.

Go to the Push Management page

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the Data Assets page, click **Administration** in the top navigation bar.
4. On the **Data Governance** page, click **Push Management** under **Artifact Management** in the left-side navigation pane.
5. On the Push Management page, click the **As Owner** or **All** tab to view your push tasks or all push tasks.

Parameter	Description
Topic-based Push Task	The name of the push task.
Owner	The owner of the push task.
Start Date	The start date of the push task.
End Date	The end date of the push task.
Status	The status of the push task. Valid values: ○ **Publish** ○ **Pause** ○ **Unpublish**

You can enter a keyword in the search box to search for push tasks whose names contain the keyword. You can also click the icon and set **Status** to filter push tasks.

Create a push task

1. On the **Push Management** page, click **Create Push Task** in the upper-right corner.
2. On the **Create Push Task** page, set the parameters as prompted.
   i. Set the parameters in the **Push Task Settings** section.

Parameter	Description
Topic-based Push Task	The name of the push task.
Effective Time Range	The period during which the push task is effective.
Notification Time	The time for triggering the push task. ■ If you select **Specified Time**, select a date and the time for pushing governance results. ■ If you select **Recurrence**, select an interval and the time for pushing governance results.
Notification Methods	The methods for pushing governance results. Valid values: **SMS**, **Email**, and **Internal Message**.

   ii. Set the parameters in the **Push Data Settings** section.

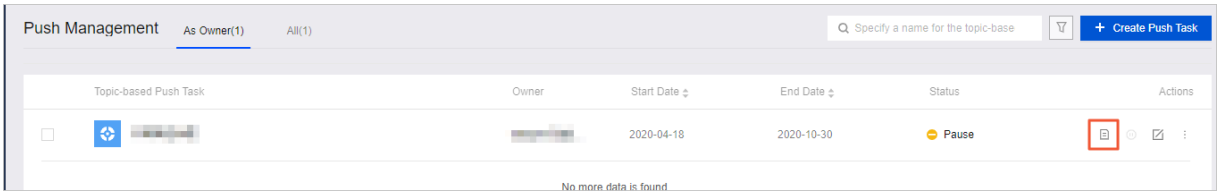
Button	Description
Create Artifact	If the artifacts you want are unavailable, click **Create Artifact** to create ones. For more information, see Create an artifact.
Add Existing Artifacts	To add an existing artifact, perform the following steps: a. Click **Add Existing Artifacts**. b. In the **Add Existing Artifacts** dialog box, find the artifact that you want to add in the **Available Artifacts** section and click the  icon to add it to the **Selected Artifacts** section. You can filter artifacts by using one of the following methods: ■ Enter a keyword in the search box to search for artifacts whose names contain the keyword. ■ Click the icon and set **Type**, **Owner**, and **Governance Target** to filter artifacts. c. Click **OK**.

   iii. Click **Next** in the **Push Data Settings** section.
   iv. Select a project and click **Test**.
3. Wait until the **Sent** message appears on the **Create Push Task** page, and click **Submit**.
4. In the **Submit Confirm** message, click **Confirm Submit**.

> **Note** By default, a new push task enters the Publish state after you submit it

View a push task

On the **Push Management** page, find the push task that you want to view and click the icon in the **Actions** column. In the **View Details** message, you can view the settings and involved artifacts and projects about the push task.



Edit a push task

1. On the **Push Management** page, find the push task that you want to edit and click the icon in the **Actions** column.
2. On the **Edit Push Task** page, set the parameters as prompted. For more information, see Create a push task.
3. Wait until the **Sent** message appears on the **Edit Push Task** page, and click **Submit**.
4. In the **Submit Confirm** message, click **Confirm Submit**.

Pause a push task

1. On the **Push Management** page, find the push task that you want to pause and click the icon in the **Actions** column.
2. In the **Pause Confirm** message, click **Confirm Pause**.

Change the owner of a push task

1. On the **Push Management** page, find the push task for which you want to change the owner, click the icon, and then select **Change Owner** in the **Actions** column.You can also select multiple push tasks and click **Change Owner** in the lower part of the page. In the **Change Owner** dialog box, select the user to whom you want to change the owner of the push tasks.
2. In the **Change Owner** dialog box, select the user to whom you want to transfer the push task.
3. Click **Confirm**.

> **Note**
> - After the owner of a push task is changed, the original owner cannot modify the push task.
> - You can transfer a push task to any user of the current tenant.

Delete a push task

1. On the **Push Management** page, find the push task that you want to delete, click the icon, and then select **Delete** in the **Actions** column.
2. In the **Delete Confirm** message, click **Confirm Delete**.

9.14.4.5.5. Task management

On the Task Management page, you can manage artifact tasks and push tasks. This topic describes how to view task details and task logs and rerun tasks.

Artifact tasks are used as examples in this topic. Follow the same procedures to manage push tasks.

Go to the Task Management page

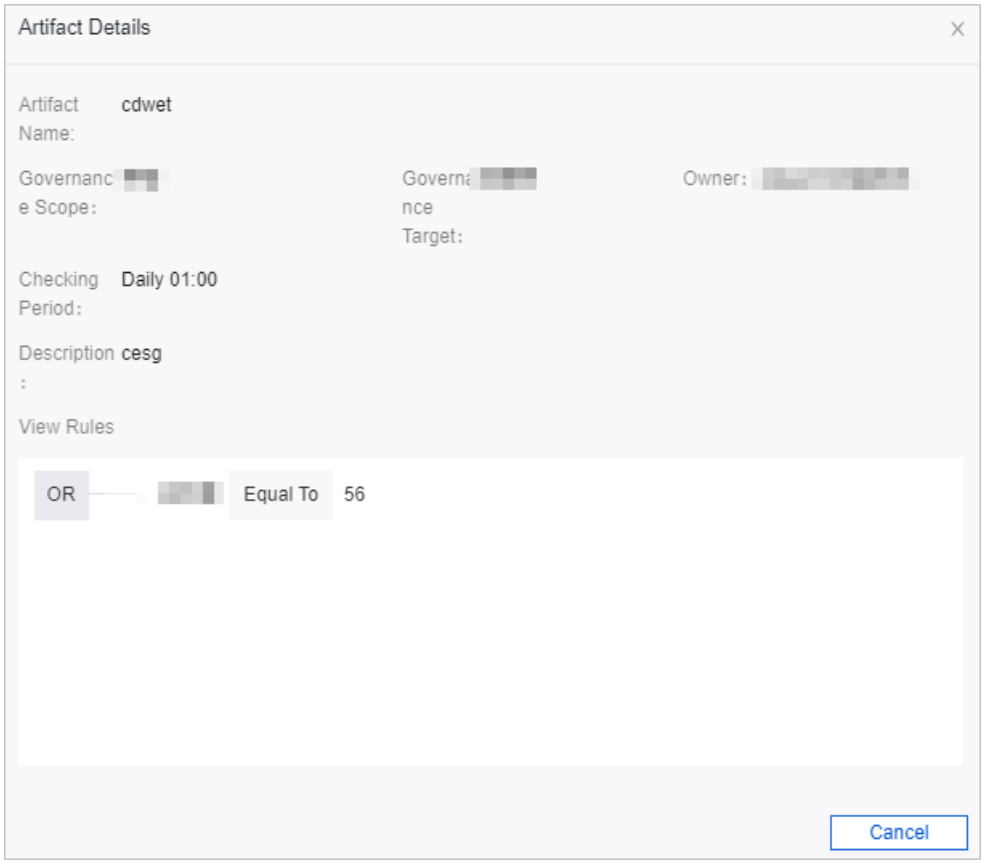
1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the **Data Assets** page, click **Administration** in the top navigation bar.
4. On the **Data Governance** page, click **Task Management** under Artifact Management in the left-side navigation pane.
5. On the **Task Management** page, click the **Push** or **Artifact** tab to view push tasks or artifact tasks.

Parameter	Description
Task Name	The name of the task.
Owner	The owner of the task.
Task Status	The running status of the task. Valid values: ○ **Succeeded** ○ **Failed** ○ **Initializing** ○ **Executing** ○ **Stopped**
Date Timestamp	The date on which the task is scheduled. The value of this parameter is the default value of the bizdate parameter.
Runtime	The period of time during which the task was run.

You can enter a keyword in the search box to search for tasks whose names contain the keyword. You can also click the icon and set **Owner**, **Data Timestamp**, **Runtime**, and **Task Status** to filter tasks.

View the details of a task

On the Task Management page, find the task that you want to view and click the icon in the Actions column. The View Details message appears.



Rerun a task

On the Task Management page, find the task that you want to rerun and click the icon in the Actions column to rerun the task. Then, the task enters the Executing state. After the task is rerun, the task enters the Succeeded state.

Pause a task

On the Task Management page, find the task that you want to pause and click the icon in the Actions column to pause the task.

View the logs of a task

On the Task Management page, find the task whose logs you want to view, click the icon, and then select View Log in the Actions column. The View Task Log message appears.

9.14.4.6. Recycle bin

To prevent misoperations on tables, Dataphin allows you to store deleted tables in the recycle bin for a short period of time. If a table is deleted by mistake, you can restore the table from the recycle bin. If a table is no longer required, you can clear the table from the recycle bin. This topic describes how to clear and restore tables in the recycle bin and view the operational logs of a table.

Go to the Tables page

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the Data Assets page, click **Administration** in the top navigation bar.
4. On the **Data Governance** page, click **Tables** under Recycle Bin in the left-side navigation pane.
5. On the **Tables** page, click the **To Be Processed**, **Processed**, or **All** tab to view pending tables, processed tables, or all tables that are moved to the recycle bin.

Parameter	Description
Table Name	The name of the table.
Project Name	The project to which the table belongs.
Table Type	The type of the table. Valid values: Physical Table and Logical Table.
Moved to Recycle Bin At	The date and time when the table is moved to the recycle bin, that is, the date and time when you delete the table in the governance console.
Processed At	The date and time when the table is processed in the recycle bin.
Status	The status of the table.

You can enter a keyword in the search box to search for tables whose names contain the keyword. You can also click the icon next to **All** and select a project to filter tables.

Clear a table

Tables cannot be restored after they are cleared from the recycle bin. Exercise caution when you perform this operation.

1. On the **Tables** page, find the table that you want to clear and click the icon in the **Actions** column.
2. In the **Clear Data** message, click **OK**.

Clear multiple tables

Tables cannot be restored after they are cleared from the recycle bin. Exercise caution when you perform this operation. You can clear multiple tables at a time.

1. On the **Tables** page, select multiple tables to be cleared and click **Clear** in the lower part of the page.
2. In the **Clear Data** message, click **OK**. If the status of the selected tables changes to

Succeeded, they are cleared from the recycle bin.

Restore a table

You can restore a table to the directory where the table was stored before it is moved to the recycle bin.

1. On the **Tables** page, find the table that you want to restore and click the icon in the **Actions** column.
2. In the **Restore Data** message, click **OK**.

Restore multiple tables

You can restore multiple tables to the directories where the tables were stored before they are moved to the recycle bin.

1. On the **Tables** page, select multiple tables that you want to restore and click **Restore** in the lower part of the page.
2. In the **Restore Data** message, click **OK**. If the status of the selected tables changes to **Succeeded**, they are restored from the recycle bin.

View the operational logs of a table

1. On the **Tables** page, find the table whose operational logs you want to view and click the icon in the **Actions** column.
2. In the **View Operations** message, view information about operations on the table, including the user who performed an operation, the time when the operation was performed, and the details of the operation.
3. Click **OK**.

9.14.5. Data quality

9.14.5.1. Overview

The Quality module of Dataphin provides a comprehensive data quality scheme that has various features. For example, you can configure quality rules to check data quality and use intelligent alerting.

Background information

As more demanding requirements for building, managing, and applying big data platforms emerge, Dataphin must adapt to more complex scenarios. The raw data from business systems may not meet specific requirements. To properly make business decisions based on data, you can configure quality rules in the Quality module of Dataphin to check the data quality, including the data timeliness, accuracy, integrity, consistency, and validity.

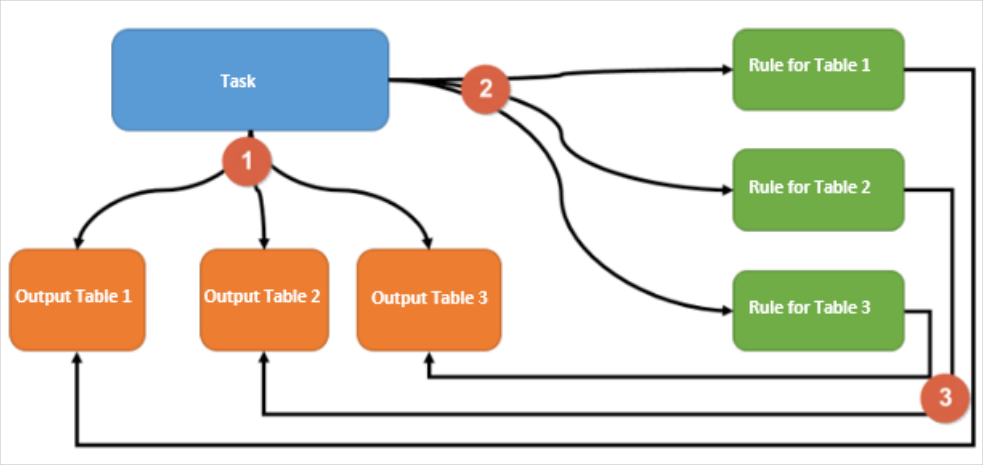
Features

You can use Quality to check the quality of various tables, trigger alerts, and generate quality reports.

The Quality module consists of the following submodules:

- **Quality Overview**: provides an overview of quality rule-based checks.
- **Quality Management**: allows you to configure quality rules. You can also view quality rules, check records, and quality reports.

The following figure shows the process of quality rule-based check.



9.14.5.2. Terms

This topic introduces the basic terms that are involved in the Quality module, such as the data object, quality rule, strong rule, and weak rule.

Term	Description
data object	An object that is managed in Quality. A data object can be a logical table or a physical table.
quality rule	A rule that is used to check the quality of a data object. A quality rule can check data quality at the granularity of fields. For example, you can configure a rule to monitor changes in the number of rows in a table at the ODS layer and check whether duplicate primary keys exist in the table.
strong rule	A rule whose check results affect the running of downstream nodes. If a data object fails a strong rule-based check, the system does not schedule downstream nodes of the current node where the data object resides. In addition, the system sets the status of the current node to failed and reports an alert to the specific alert recipients.
weak rule	A rule whose check results do not affect the running of downstream nodes. If a data object fails a weak rule-based check, the system does not forcibly stop scheduling downstream nodes of the current node, but only reports an alert to the specific alert recipients.
check record	A record that Quality generates after the quality of a data object is checked based on quality rules.
quality report	A report that Quality generates after the quality of a data object is checked based on quality rules. After the node where a data object resides is scheduled, Quality checks the quality of the updated data object based on the configured quality rules. Then, Quality generates a quality report that contains detailed results of the quality rule-based check.

Term	Description
partition expression	An expression that is used to define the data range to which a quality rule is applied.

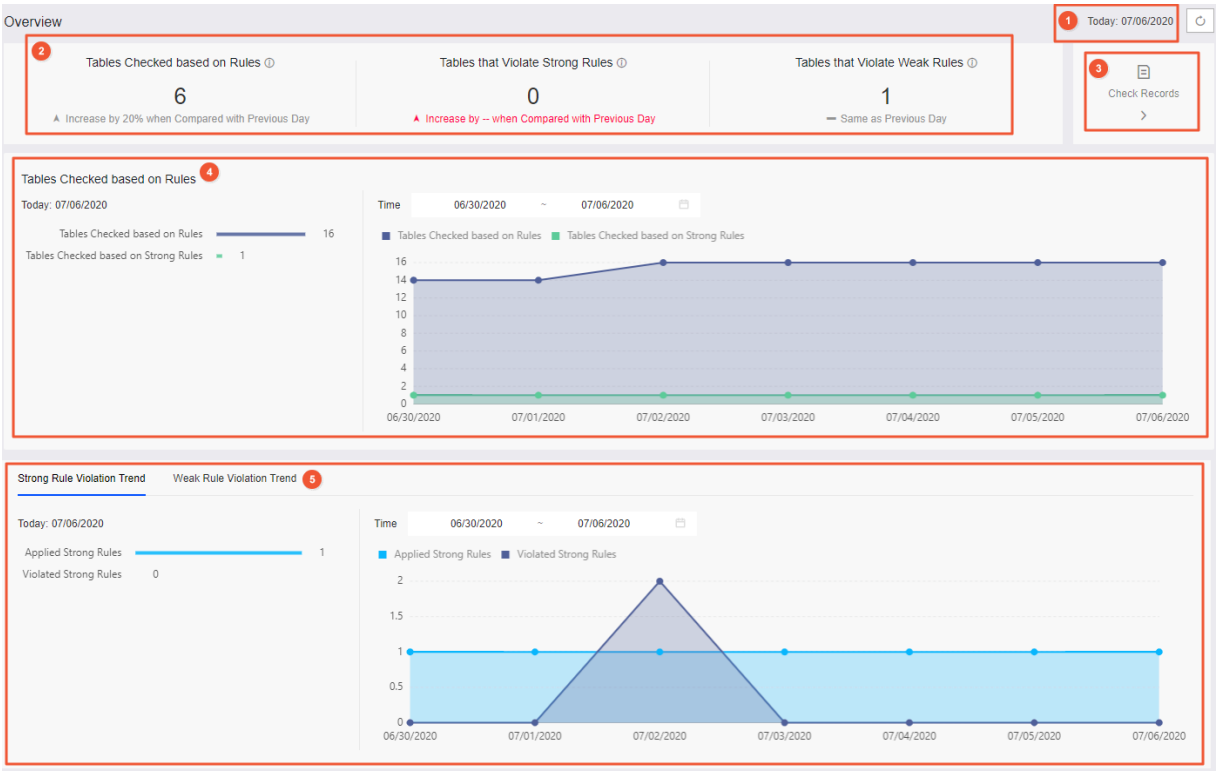
9.14.5.3. View statistics on the Overview page

The Overview page provides the overall results of quality rule-based checks on tables. It helps you properly identify and process abnormal check results.

To go to the **Overview** page, perform the following steps:

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the **Data Assets** page, click **Quality** in the top navigation bar.

On the **Overview** page, you can view the overall results of quality rule-based checks on tables.



No.	Description
1	Displays the date of the current day, which is used as the timestamp of data displayed on the Overview page.

No.	Description
2	• Displays the change in the number of tables that are checked based on quality rules on the current day, compared with that on the previous day. • Displays the change in the number of tables that fail strong rule-based checks on the current day, compared with that on the previous day. • Displays the change in the number of tables that fail weak rule-based checks on the current day, compared with that on the previous day.
3	Provides an entry for you to go to the Check Records page.
4	Displays the following data by default: • The number of tables that are checked based on quality rules on the current day and the trend within the latest seven days. • The number of tables that are checked based on strong rules on the current day and the trend within the latest seven days. Allows you to specify a time range within the last 30 days to view corresponding data.
5	• Displays the trend of statistics on strong rules, including: ◦ The number of strong rules that are used to check tables on the current day and the trend within the latest seven days. ◦ The number of strong rules that tables violate on the current day and the trend within the latest seven days. • Displays the trend of statistics on weak rules, including: ◦ The number of weak rules that are used to check tables on the current day and the trend within the latest seven days. ◦ The number of weak rules that tables violate on the current day and the trend within the latest seven days. Allows you to specify a time range within the last 30 days to view corresponding data.

9.14.5.4. Manage quality rules

9.14.5.4.1. View quality rules

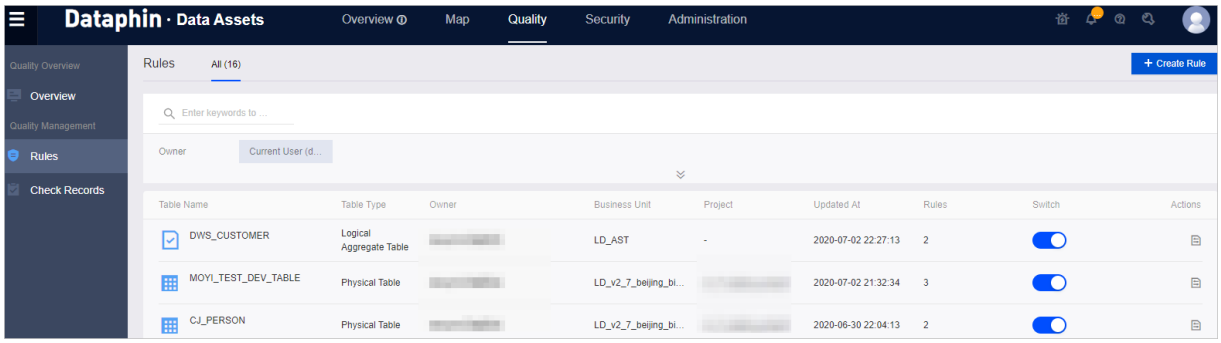
The Rules page displays information about quality rules that are configured for tables. This topic describes how to view quality rules and enable or disable quality rule-based check for tables.

Go to the Rules page

To go to the **Rules** page, perform the following steps:

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the Data Assets page, click **Quality** in the top navigation bar.
4. On the Quality page, click **Rules** in the left-side navigation pane.

On the Rules page, you can view information about quality rules that are configured for tables.



You can set **Owner**, **Business Unit**, **Project**, and **Table Type** to filter records. You can also enter a keyword in the search box to search for records of tables whose names contain the keyword.

Parameter	Description
Table Name	The name of the table for which quality rules are created.
Table Type	The type of the table. Valid values: • **Logical Aggregate Table** • **Logical Dimension Table** • **Logical Fact Table** • **Physical Table**
Owner	The owner of the table.
Business Unit	The business unit to which the table belongs. If the project to which a physical table belongs is not bound to a business unit, a hyphen (-) appears in the Business Unit column of the physical table.
Project	The project to which the table belongs.
Updated At	The last time when the quality rules of the table were updated.
Rules	The number of quality rules that are configured for the table.
Switch	Specifies whether quality rule-based check is enabled for the table. • indicates that quality rule-based check is enabled for the table. • indicates that quality rule-based check is disabled for the table.
Actions	The operations that you can perform on the table. You can click the icon in the **Actions** column to go to the **Rule Settings** page of the table.

View the settings of a rule

On the **Rules** page, find the table whose settings you want to view and click the icon in the **Actions** column. On the **Rule Settings** page, you can view the rule settings of the table.

Enable or disable quality rule-based check for a table

On the **Rules** page, find the table for which you want to disable or enable quality rule-based check and click the or icon in the **Switch** column.

9.14.5.4.2. Configure a quality rule

To properly manage data quality, you must configure quality rules. This topic describes how to configure a quality rule for a table.

Prerequisites

Tables are submitted or published to the production environment.

Step 1: Create a quality rule

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the **Data Assets** page, click **Quality** in the top navigation bar.
4. On the **Quality** page, click **Rules** in the left-side navigation pane.
5. On the **Rules** page, click **Create Rule** in the upper-right corner.
6. In the **Create Rule** dialog box, select a table and click **Configure**. You can select a table by using one of the following methods:
   - Click the icon and set **Business Unit**, **Project**, and **Table Type** to filter tables. Then, select the desired table from the drop-down list.
   - Click the arrow button. Enter a keyword in the search box to search for tables whose names contain the keyword and select the desired table.

Step 2: Configure alert information

After you configure alert information for a table, Alert Center reports alerts to the specified recipients if the table fails quality rule-based checks.

1. On the Rule Settings page of the table, click the icon in the **Alert Settings** section.
2. In the **Alert Settings** dialog box, set **Recipients** and **Methods** and click **OK**.

Step 3: Create a partition expression

A partition expression specifies the data range to which a group of quality rules are applied. You can create multiple partition expressions for a table and configure multiple quality rules under each partition expression, as shown in the following figure.

1. On the Rule Settings page of the table, click **Create Partition Expression** in the **Rule Settings** section.
2. In the **Create Partition Expression** dialog box, set **Type**, enter a partition expression, and then click **Save**.
   - If you set Type to a partition expression type that is built in Quality, the system automatically fills in the corresponding partition expression. The following table lists the partition expression types that are built in Quality and the corresponding partition

expressions.

Partition expression type	Partition expression
Last Day	ds='${yyyyMMdd}'
First Day of the Current Week	ds=tdBeginDate('${yyyyMMdd}', 'w', 'yyyyMMdd')
Last Day of the Current Week	ds=customEndDate('${yyyyMMdd}', 'w', '1', 0, 'yyyyMMdd')
First Day of the Current Month	ds=tdBeginDate('${yyyyMMdd}', 'm', 'yyyyMMdd')
Last Day of the Current Month	ds=customEndDate('${yyyyMMdd}', 'm', '01', 0, 'yyyyMMdd')
First Day of the Current Quarter	ds=tdBeginDate('${yyyyMMdd}', 'q', 'yyyyMMdd')
Last Day of the Current Quarter	ds=customEndDate('${yyyyMMdd}', 'q', '0101', 0, 'yyyyMMdd')
First Day of the Current Year	ds=tdBeginDate('${yyyyMMdd}', 'y', 'yyyyMMdd')
Last Day of the Current Year	ds=customEndDate('${yyyyMMdd}', 'y', '0101', 0, 'yyyyMMdd')
First Day of the Previous Month	ds=cBeginDate('${yyyyMMdd}', 'm', 'yyyyMMdd')
Last Day of the Previous Month	ds=cEndDate('${yyyyMMdd}', 'm', 'yyyyMMdd')
All Partitions	ds=ALL

- If you set Type to **Custom**, you must enter a partition expression, for example, `ds=${yyyyMM01}`.

After you create a partition expression, you can perform the following operations on it:

- Click the icon next to the partition expression to edit it.
- Click the icon next to the partition expression to delete it.

Step 4: Configure a quality rule

To configure a quality rule under a partition expression, perform the following steps:

1. On the Rule Settings page of the table, click **Create Rule** next to the partition expression.
2. In the **Create Rule** dialog box, set the parameters as prompted and click **Save**.The valid

values of the Rule Type parameter are **Template-based Rules** and **Custom Rules**.

- If you set Rule Type to **Template-based Rules**, you must set other parameters as described in the following table.

Parameter	Description
Object Name	The object to be checked based on the quality rule. The value of the **Object Name** parameter is in the `Table: Name of the current table` or `Field: Name of a field in the current table` format.
Strong or Weak Rule	The type of the quality rule. You can select Strong Rule or Weak Rule. ■ If you select **Strong Rule**, Alert Center reports an alert and the system blocks downstream nodes of the current node where the table resides when the specific object fails the rule-based check. ■ If you select **Weak Rule**, Alert Center reports an alert but the system does not block downstream nodes of the current node when the specific object fails the rule-based check.
Template	The check dimension of the quality rule. The valid values of the Template parameter vary based on the value you selected for the Object Name parameter. For more information, see Configuration table.
Trend	■ If the check type is fluctuation check, the valid values of the **Trend** parameter are **Absolute Value**, **Upward**, and **Downward**. ■ If the check type is comparison, the value of the **Trend** parameter is fixed to **Fixed Value**. For more information, see Configuration table.
Comparison Settings	The method for comparing the rule-based check result with the target value. You must specify a target value if the check type is comparison. The valid values of the **Comparison Method** parameter are **Greater Than Target Value**, **Greater Than or Equal To Target Value**, **Equal To Target Value**, **Less Than Target Value**, and **Less Than or Equal To Target Value**.
Fluctuation Threshold	The fluctuation threshold for the rule-based check result. The value of the **Threshold** parameter can range from 0.0 to 10.0.

Configuration table

Object name	Template	Trend	Configuration item	Check type
`Table: Name of the current table`	Compare the Target Table or Partition Size with that of Previous Day	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check

Object name	Template	Trend	Configuration item	Check type
Table: Name of the current table	Compare the Target Number of Table or Partition Rows with that of Previous Day	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Table: Name of the current table	Compare the Target Table or Partition Size with that of 7 Days Ago	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Table: Name of the current table	Compare the Target Number of Table or Partition Rows with that of 7 Days Ago	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Table: Name of the current table	Compare the Target Number of Table or Partition Rows with that of 30 Days Ago	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Table: Name of the current table	Compare the Target Number of Table or Partition Rows with that of Previous Day and that of 7 and 30 Days Ago	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Table: Name of the current table	Compare the Target Average Number of Table or Partition Rows with that of 7 Days Ago	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Table: Name of the current table	Compare the Target Average Number of Table or Partition Rows with that of 30 Days Ago	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check

Object name	Template	Trend	Configuration item	Check type
Table: Name of the current table	Number of Table Partitions	Fixed Value	Comparison Settings	Comparison
Table: Name of the current table	Check Fluctuations in the Number of Table Partitions	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Table: Name of the current table	Compare the Target Number of Table or Partition Rows with that of Previous Day, the First Day of this Month, and that of 7, 30 Days Ago	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Field: Name of a field in the current table	Compare the Target and the Expected Number of Unique Values	Fixed Value	Comparison Settings	Comparison
Field: Name of a field in the current table	Compare the Target Number of Unique Field Values with that of Previous Day and that of 7 and 30 Days Ago	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Field: Name of a field in the current table	Compare the Target Average Field Value with that of Previous Day and that of 7 and 30 Days Ago	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Field: Name of a field in the current table	Compare the Target Maximum Field Value with that of Previous Day	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check

Object name	Template	Trend	Configuration item	Check type
Field: Name of a field in the current table	Compare the Target Maximum Field Value with that of Previous Day and that of 7 and 30 Days Ago	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Field: Name of a field in the current table	Compare the Target Minimum Field Value with that of Previous Day	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Field: Name of a field in the current table	Compare the Target Minimum Field Value with that of Previous Day and that of 7 and 30 Days Ago	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Field: Name of a field in the current table	Compare the Target Sum of Field Values with that of Previous Day	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Field: Name of a field in the current table	Compare the Target Sum of Field Values with that of Previous Day and that of 7 and 30 Days Ago	Absolute Value, Upward, and Downward	Fluctuation Threshold	Fluctuation check
Field: Name of a field in the current table	Number of Null Field Values	Fixed Value	Comparison Settings	Comparison
Field: Name of a field in the current table	Rate of Null Values (Number of Null Values/Total Number of Rows)	Fixed Value	Comparison Settings	Comparison

Object name	Template	Trend	Configuration item	Check type
Field: Name of a field in the current table	Number of Duplicate Field Values	Fixed Value	Comparison Settings	Comparison
Field: Name of a field in the current table	Rate of Duplicate Field Values (Number of Duplicate Values/Total Number of Rows)	Fixed Value	Comparison Settings	Comparison

- **If you set Rule Type to Custom Rules, you must set other parameters as described in the following table.**

Parameter	Description
Rule Name	The name of the quality rule.
Details	The content of the quality rule. Example: `select` `  sum(value) as metric` `from` `  current_table ctb` `  left outer join related_table rtb on ctb.id = rtb.id` `where` `  ds = ${bizdate};`
Strong or Weak Rule	The type of the quality rule. You can select Strong Rule or Weak Rule. ■ If you select **Strong Rule**, Alert Center reports an alert and the system blocks downstream nodes of the current node where the table resides when the specific object fails the rule-based check. ■ If you select **Weak Rule**, Alert Center reports an alert but the system does not block downstream nodes of the current node when the specific object fails the rule-based check.
Check Type	The check type of the quality rule. The valid values of the **Check Type** parameter are **Compare Target Data with that of Previous Day**, **Compare Target Data with that of 7 Days Ago**, **Compare the Target Average Value with that of 7 Days Ago**, **Compare the Target Average Value with that of 30 Days Ago**, and **Compare with Fixed Value**.

Parameter	Description
Trend	■ If the check type is fluctuation check, the valid values of the **Trend** parameter are **Absolute Value**, **Upward**, and **Downward**. ■ If the check type is comparison, the value of the **Trend** parameter is fixed to **Fixed Value**.
Comparison Settings	The method for comparing the rule-based check result with the target value. You must specify a target value if the check type is comparison. The valid values of the **Comparison Method** parameter are **Greater Than Target Value**, **Greater Than or Equal To Target Value**, **Equal To Target Value**, **Less Than Target Value**, and **Less Than or Equal To Target Value**.
Fluctuation Threshold	The fluctuation threshold for the rule-based check result. The value of the **Threshold** parameter can range from 0.0 to 10.0.

3. Select the configured quality rule in the rule list and click **Test Run** in the lower part of the list. After the test is successful, turn on the switch for the quality rule. Then, the quality rule takes effect.The test run can in one of the following states:
   - **Pending**
   - **Succeeded**
   - **Failed**
   - **Running**

9.14.5.4.3. Modify a quality rule

To properly manage data quality, you must configure quality rules. This topic describes how to modify a quality rule for a table.

Prerequisites

A quality rule is configured for a table. For more information, see Configure a quality rule.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the **Data Assets** page, click **Quality** in the top navigation bar.
4. On the **Quality** page, click **Rules** in the left-side navigation pane.
5. On the **Rules** page, find the table for which you want to modify a quality rule and click the icon in the **Actions** column.
6. On the **Rule Settings** page, find the quality rule that you want to modify and click the icon in the **Actions** column.
7. In the **Change Rule** dialog box, modify the parameter settings as prompted. For more information, see Configure a quality rule.

8. Click **Save**.

9.14.5.4.4. Delete a quality rule

To properly manage data quality, you must configure quality rules. This topic describes how to delete a quality rule for a table.

Prerequisites

A quality rule is configured for a table. For more information, see Configure a quality rule.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the **Data Assets** page, click **Quality** in the top navigation bar.
4. On the **Quality** page, click **Rules** in the left-side navigation pane.
5. On the **Rules** page, find the table for which you want to delete a quality rule and click the icon in the **Actions** column.
6. On the **Rule Settings** page, find the quality rule that you want to delete and click the icon in the **Actions** column.
7. In the **Delete Rule** message, click **OK**.

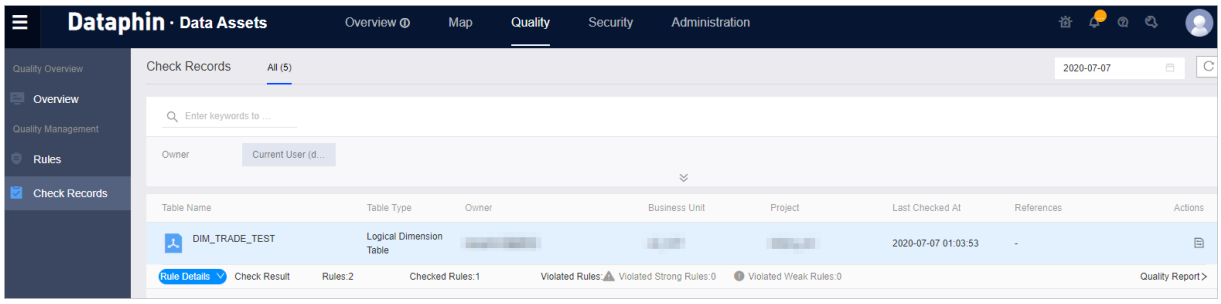
9.14.5.5. View check records

The Check Records page displays records of quality rule-based checks on tables. This topic describes how to view such records.

To go to the **Check Records** page, perform the following steps:

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Data Assets** in the top navigation bar.
3. On the **Data Assets** page, click **Quality** in the top navigation bar.
4. On the **Quality** page, click **Check Records** in the left-side navigation pane.

On the Check Records page, you can click the icon in the upper-right corner to select a date. Then, check records of that day appear on the page.



You can set **Owner**, **Business Unit**, **Project**, **Status**, **Table Type**, and **Rule Template** to filter check records. You can also enter a keyword in the search box to search for check records of tables whose names contain the keyword.

GUI element	Description
Table Name	The name of the table that Quality checked based on quality rules.
Table Type	The type of the table.
Owner	The owner of the table.
Business Unit	The business unit to which the table belongs.
Project	The project to which the table belongs.
Last Checked At	The last time when the table was checked based on quality rules.
References	The number of times that the table was referenced by tasks when the tasks were scheduled in the production environment.
Actions	The operations that you can perform on the table. You can click the icon in the Actions column to go to the Rule Settings page of the table, where you can: • View existing quality rules of the table. • Create quality rules for the table. For more information, see Configure a quality rule. • Modify existing quality rules of the table. For more information, see Configure a quality rule.
Rule Details	The details about quality rule-based checks on the table. You can click the icon next to **Rule Details** to view the details.

GUI element	Description
Check Result	The summary of quality rule-based checks on the table, including: • **Rules**: the number of quality rules that have been configured for the table. • **Checked Rules**: the number of quality rules that Quality used to check the table. • **Violated Rules**: ○ **Violated Strong Rules**: the number of strong rules that the table violated. ○ **Violated Weak Rules**: the number of weak rules that the table violated.
Quality Report	The quality report of the table. You can click **Quality Report** to go to the Quality Report page of the table. You can view information such as the quality analysis result, report details, and rule-based check instances on the page. For more information, see View a quality report.

9.14.5.6. View a quality report

After a task that references a table is scheduled in the production environment, Quality checks the quality of the updated table based on the quality rules configured for the table. Then, Quality generates a quality report that contains detailed results of the quality rule-based check. This topic describes how to view a quality report.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click Data Assets in the top navigation bar.
3. On the **Data Assets** page, click **Quality** in the top navigation bar.
4. The **Quality** page appears.
5. Go to the **Quality Report** page of a table by using one of the following methods:
   - a. On the Quality page, click **Rules** in the left-side navigation pane.
     b. On the **Rules** page, find the table whose quality report you want to view and click the icon in the **Actions** column.
     c. On the **Rule Settings** page of the table, click **Quality Report**.
   - a. On the Quality page, click **Check Records** in the left-side navigation pane.
     b. On the **Check Records** page, find the table whose quality report you want to view and click **Quality Report** under the table.
6. On the **Quality Report** page of the table, click the icon in the upper-right corner to select a date. Quality displays the quality report of the table on that day.

Parameter or section	Section	Parameter	Description
Table Details	N/A	Table	The name of the table.
		Business Unit	The business unit to which the table belongs.
		Project	The project to which the table belongs.
		Table Type	The type of the table. Valid values: ○ Logical Aggregate Table ○ Logical Dimension Table ○ Logical Fact Table ○ Physical Table
		Owner	The owner of the table.
		Task Node	The task that referenced the table in the production environment.
		Alert Recipients	The recipients to whom Alert Center reported alerts when the table failed quality rule-based checks.
Quality Analysis Report	N/A	Violated Rules	The number of quality rules that the table violated.
		Checked Rules	The total number of quality rules that are configured for the table and the number of quality rules that Quality used to check the table.
		Instance Execution Time	The time when the task that referenced the table was run in the production environment.
	N/A	Partition Expression	The partition expression of the table.
		Partition	The partition key value that is obtained based on the partition expression, for example, `DS=20200212`.
		Field Name	The name of the field for which a quality rule is configured under the partition expression.
		Rule Template Name	The template of the quality rule that is configured for the field.
		Strong or Weak Rule	The type of the quality rule.

Parameter or section	Section	Parameter	Description
Report Details	Field Check	Comparison Method	The method for comparing the quality rule-based check result with the specific fluctuation threshold or target value. ○ If the check type is fluctuation check, the valid values of the **Trend** parameter are **Absolute Value**, **Upward**, and **Downward**. ○ If the check type is comparison, the value of the **Trend** parameter is fixed to **Fixed Value**.
		Threshold	The fluctuation threshold of the field values.
		Status	The result of the quality rule-based check on the field.
		Details	The details about the field values. To view the value trend of the field, perform the following steps: i. Click the icon in the **Details** column of the field. ii. In the **Alert Trend** dialog box, specify a time range in the upper-right corner and view the value trend that appears. iii. Click **OK**.
	Custom Rule	Custom Rule Name	The name of the custom quality rule.
		Strong or Weak Rule	The type of the custom quality rule.
		Comparison Method	The method for comparing the custom quality rule-based check result with the specific fluctuation threshold or target value. ○ If the check type is fluctuation check, the valid values of the **Trend** parameter are **Absolute Value**, **Upward**, and **Downward**. ○ If the check type is comparison, the value of the **Trend** parameter is fixed to **Fixed Value**.
		Status	The result of the custom quality rule-based check on the field.

Parameter or section	Section	Parameter	Description
		Details	The details about the field values. To view the value trend of the field, perform the following steps: i. Click the icon in the **Details** column of the field. ii. In the **Alert Trend** dialog box, specify a time range in the upper-right corner and view the value trend that appears. iii. Click **OK**.
	Rule-based Check Instances	N/A	**Table Name**
Partition			The partition that Quality checked based on the quality rule.
Rule			The quality rule that Quality used to check the partition.
Owner			The owner of the table.
Date Timestamp			The data timestamp that Quality specified based on the partition.
Execution Time (Range)			The duration of the quality rule-based check.
Status			The result of the quality rule-based check. Valid values: ○ **Failed** ○ **Running** ○ **Succeeded**
Log			The operational logs of the quality rule-based check instance. You can click the icon in the **Log** column to view the operational logs of the quality rule-based check instance.

9.15. Theme-based data service

9.15.1. Ad hoc query

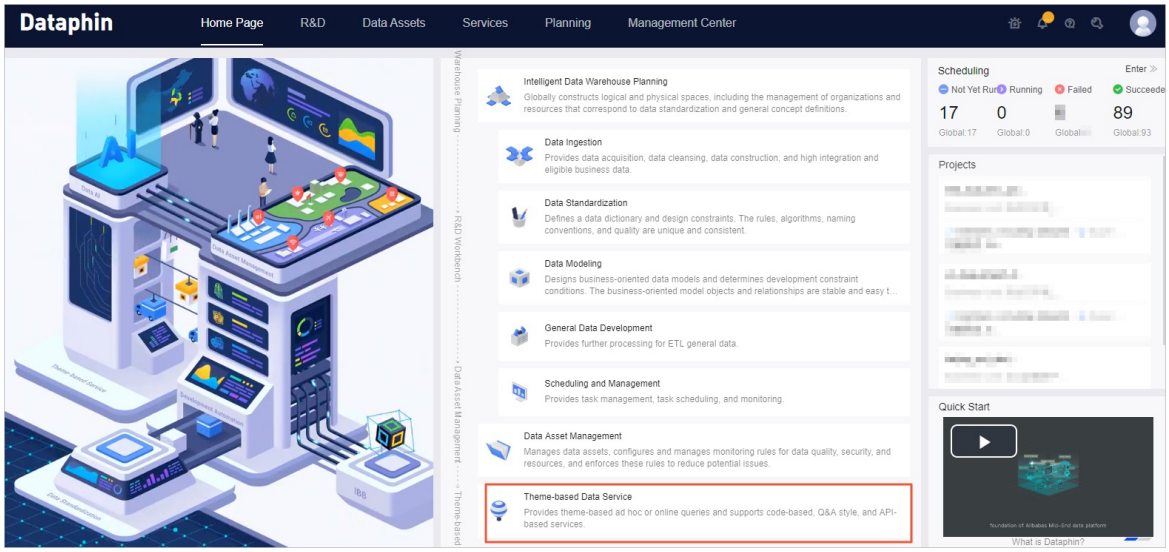
Dataphin provides the ad hoc query feature for you to query data.

Context

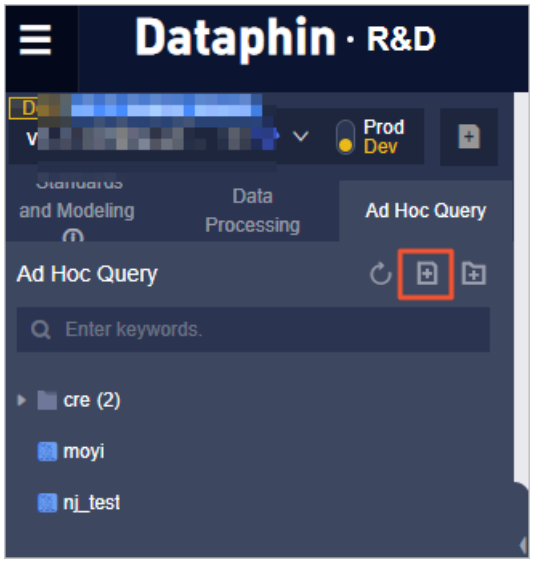
If your computing engine type is Hadoop, the Hive SQL syntax is supported in ad hoc queries. If your computing engine type is MaxCompute, the MaxCompute SQL syntax is supported in ad hoc queries. Dataphin can automatically identify and change the SQL syntax based on your computing engine type.

Procedure

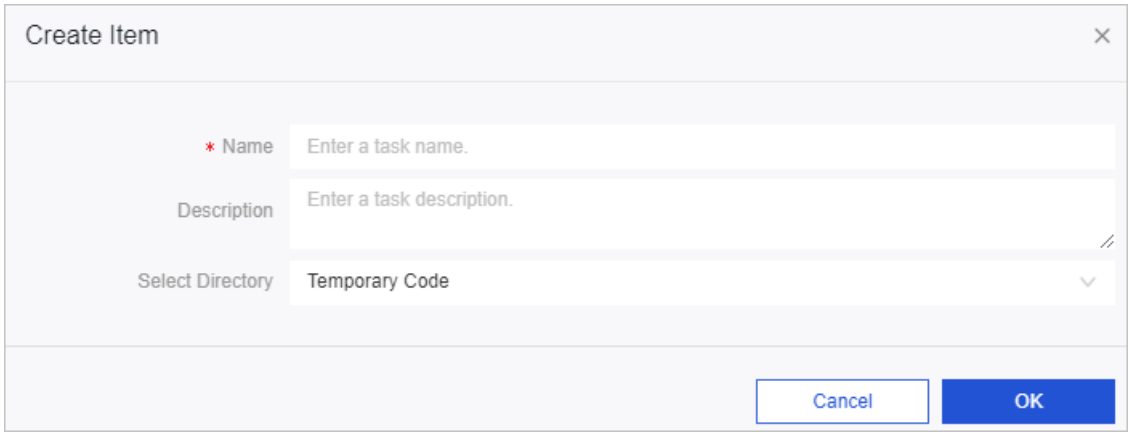
1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Theme-based Data Service** to go to the Ad Hoc Query tab.



3. On the Ad Hoc Query tab of the Develop tab, click the **Create Item** icon in the left-side navigation pane.



4. In the **Create Item** dialog box that appears, enter the task name and description, select a directory, and then click **OK**.



5. In the left-side ad hoc query task list, click the ad hoc query task that you created in the preceding step to go to the **Code Editor** tab.
6. Write SQL statements, click the **Save** icon, and then click **Run** in the upper-right corner.

> **Note** When you write SQL statements, reference table names in the format of *Project name.Table name*, for example, *demo.dim_qwe*.

7. After SQL statements are run, view the results on the **Result** tab.

9.16. Data services

9.16.1. Overview

As the last step in constructing a Data Mid-End based on Dataphin, the Services module provides data services in a uniform manner. In the Services module, Dataphin centrally manages data services. This effectively facilitates and secures the use of data services.

Data services API Service Workbench Administration
Dataphin is designed to build a uniform data service bus to help enterprises increase the value of their data assets while guaranteeing data reliability, security, and effectiveness. The Services module allows you to create API operations in the easy-to-use template wizard mode. This helps enterprises maximize the value of data applications that they create.

The Services module of Dataphin consists of the **API Service**, **Workbench**, and **Administration** pages.

- The **API Service** page lists all published API operations.
- The **Workbench** page is composed of **Development Center** and **Application Center**.
  - **Development Center** is designed for data service providers to develop services. It contains two modules: **Service Units** and **APIs**.

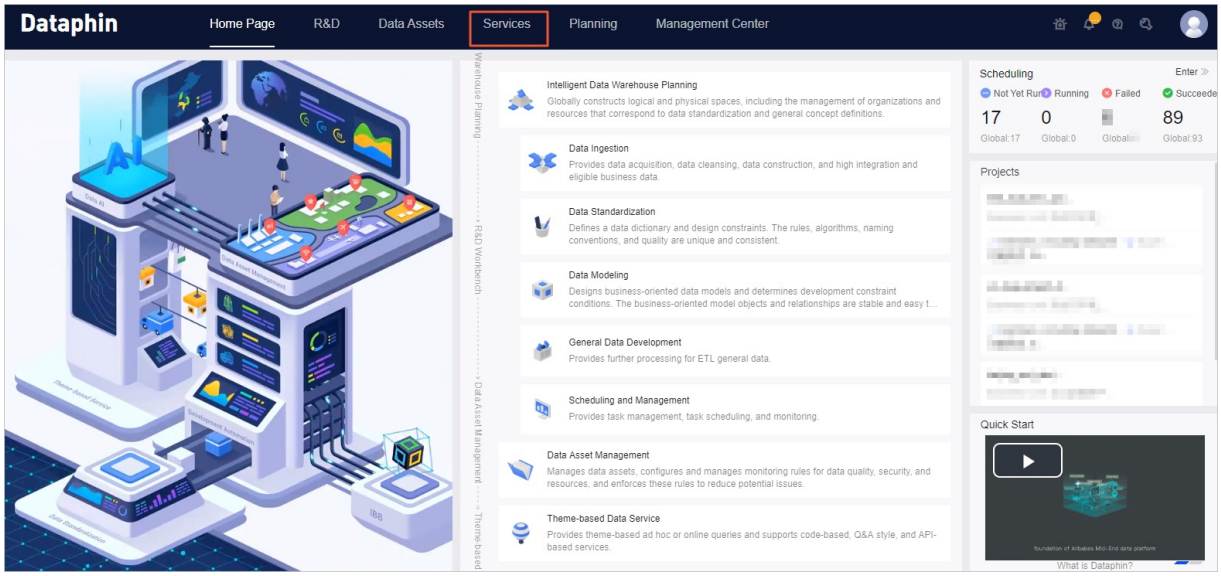
  - **Application Center** is designed for data service users to consume API services from applications. It contains two modules: **APIs** and **Applications**.

- The **Administration** page contains the following modules: **Member Management**, **Groups**, **Metadata Management**, **Monitoring**, **Network Configuration**, Call Examples, and Dataphin Data Sources. On this page, you can monitor and manage data services in a uniform manner.

In the Services module, you can develop, call, and monitor API operations.

Feature	Procedure
Develop API operations	1. Add a Dataphin user to the Services module as a **developer**. For more information, see Manage members. Note Only a developer can create API operations in the Services module. 2. Create a group. For more information, see Manage service unit groups. 3. Create a service unit. For more information, see Create a service unit. 4. Create an API operation. For more information, see Create an API operation. 5. Test the created API operation. For more information, see Test an API operation. 6. Publish the API operation. For more information, see Publish an API operation.
Call API operations	1. Add a Dataphin user to the Services module as an **application user**. For more information, see Manage members. Note Only an application user can call API operations in the Services module. 2. Create an application. For more information, see Create an application. 3. Apply for the permission to use an API operation. For more information, see API Service. 4. Debug the requested API operation. For more information, see Debug an API operation. 5. Call the API operation. For more information, see Manage call examples.
Monitor API operations	For more information about how to monitor API operations, see Monitor API operations.

Log on to the Dataphin console. On the Dataphin homepage, click Services in the top navigation bar. The Service page appears.



9.16.2. Terms

This topic describes the terms of the Services module in Dataphin, such as Dataphin data source, API operation, group, service unit, and application.

Term	Description
Dataphin data source	The data source that is created based on a table.
API operation	The API operation that is created by configuring a table.
Service unit	Allows you to manage the metadata of one or more tables in a uniform manner.
Application	The permission subject that allows members to consume data services, including calling API operations and using Dataphin data sources.
Group	Allows you to classify and manage data services and applications based on specific features or scenarios.
API Service page	The page that displays the API operations that you have published. It is the API market of Dataphin.
Metadata management	Allows you to configure and manage the schema mapping from NoSQL databases to relational databases to guarantee the consistency of data sources.
Network configuration	The network configuration for an application to access API operations and data sources. Network configuration includes the domain name configuration and the configuration of the Virtual Private Cloud (VPC) whitelist.

Term	Description
Call Examples page	The page that provides the instructions for calling API operations and using Dataphin data sources.

9.16.3. Configure the network

Before an application can call API operations and use Dataphin data sources, you must configure the network. Network configuration includes the domain name configuration and the configuration of the VPC whitelist. This topic describes how to enable and disable a second-level domain name, configure an independent domain name, and unbind an independent domain name to the current Apsara Stack tenant account.

Context

You can configure the network only by using an Apsara Stack tenant account.

Enable and disable a second-level domain name

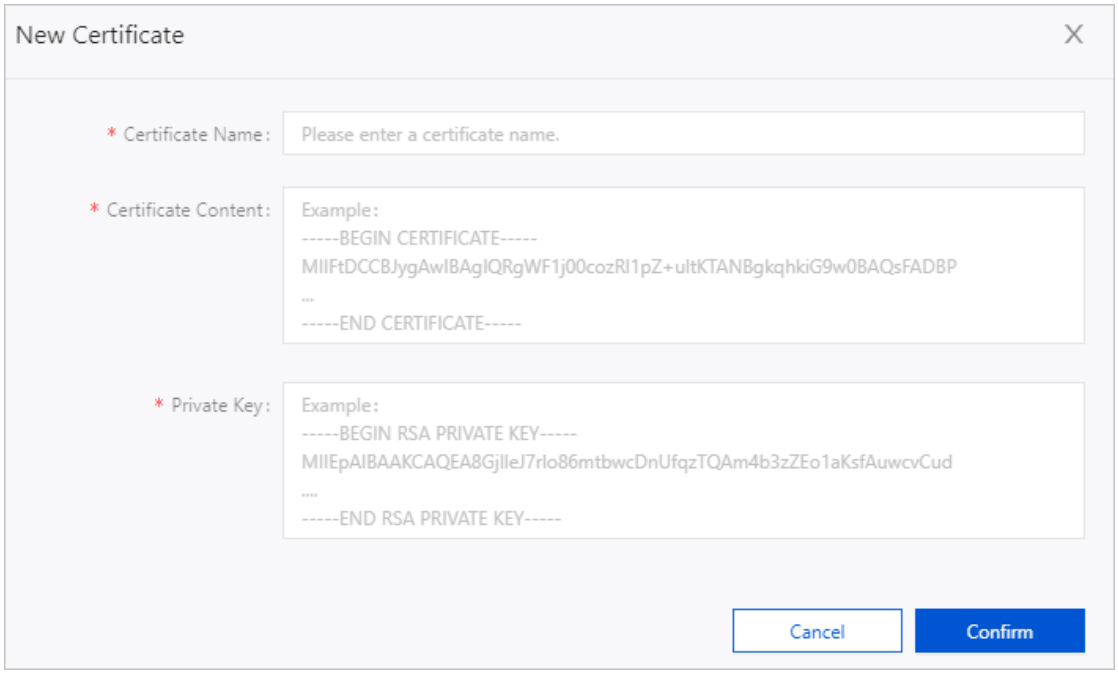
This section describes how to enable and disable the second-level domain name on the Internet. You can follow the same procedure to enable and disable the second-level domain name in a VPC.

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Services** in the top navigation bar.
3. On the Service page, click **Administration** in the top navigation bar.
4. On the Administration page, click **Network Configuration** in the left-side navigation pane.
5. Disable the second-level domain name.
   i. Click **Close the public domain second-level domain name** next to the domain name.
   ii. In the **Prompt** message, click **Confirm**.
6. Enable the second-level domain name.
   i. Click **Open the second-level domain name of the public network**.
   ii. In the **Prompt** message, click **Confirm**.

Configure an independent domain name

1. Bind an independent domain name to the current Apsara Stack tenant account.
   i. On the **Domain Configuration** tab, click **Bind Domain Name** in the upper-right corner of the **Independent Domain Name** section.
   ii. In the **Bind Domain Name** dialog box, enter a domain name.
   iii. Click **Confirm** to bind the independent domain name to the current Apsara Stack tenant account.
2. Bind an SSL certificate to the independent domain name.
   i. Click **Add** in the **SSL Certificate** column.

ii. In the **New Certificate** dialog box, enter a certificate name, the certificate content, and the private key as required.



Parameter	Description
Certificate Name	The name of the SSL certificate.
Certificate Content	The content of the SSL certificate. Enter the content based on the example on the page.
Private Key	The private key of the SSL certificate. Enter the private key based on the example on the page.

iii. Click **Confirm** to bind the SSL certificate.

Unbind an independent domain name

1. In the Independent Domain Name section, find the independent domain name that you want to unbind and click the icon in the Actions column.
2. In the message that appears, click **OK**.

9.16.4. Add a member

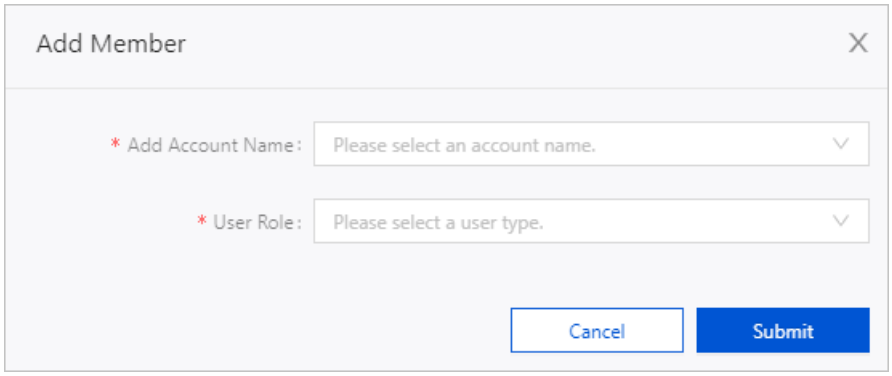
The Services module allows you to centrally manage the members who develop and use data services in Dataphin. This topic describes how to add a member to the Services module.

Context

A Dataphin user can access the Services module only after the user is added as a member with the **Developer** or **Application User** role. Only members can develop and use API operations and data sources.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Services** in the top navigation bar.
3. On the Service page, click **Administration** in the top navigation bar.
4. On the Administration page, click **Member Management** in the left-side navigation pane.
5. On the **Member Management** page, click **Add Member** in the upper-right corner.
6. In the **Add Member** dialog box, select the name of the account to be added as a member and the user type from the **Add Account Name** and **User Role** drop-down lists, respectively.



Parameter	Description
Add Account Name	The name of the account to be added as a member of the Services module.
User Role	The role to be assigned to each selected account. Valid values: ○ **Developer**: Developers provide data services and develop API operations. ○ **Application User**: Application users use data services and call API operations.

7. Click **Submit**.

The following table describes the operations that you can perform on the added members.

Operation	Description
Change the user role of a member	Click the icon in the **Actions** column to change the user role of a member.
Delete a member	○ Click the icon in the **Actions** column to delete a member from the Services module. ○ To delete multiple members at a time, select the members and click **Remove** in the upper-right corner of the **Member Management** page.

9.16.5. Develop API operations

9.16.5.1. Create a group

Dataphin allows you to manage service units and applications by group. This topic describes how to create a group for managing service units and applications.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Services** in the top navigation bar.
3. On the Service page, click **Administration** in the top navigation bar.
4. On the Administration page, click **Groups** in the left-side navigation pane.
5. On the **Service Unit** tab, click **Create Group** in the lower part of the group list.

6. Enter a name in the field that appears and click **OK**. A service unit group is created.
7. Click the **Application** tab. On the **Application** tab, click **Create Group** in the lower part of the group list. Enter a name in the field that appears and click **OK**. An application group is created.

   The following table describes the operations that you can perform on the created groups.

Operation	Description
Change the name of a group	Click the icon in the **Actions** column to change the name of a group.
Delete a group	Click the icon in the **Actions** column to delete a group.

9.16.5.2. Create a service unit

9.16.5.2.1. Create a metadata set

By using metadata, you can configure and manage the schema mapping from NoSQL databases to relational databases to ensure the consistency of data sources. This topic describes how to create metadata sets for HBase, Elasticsearch, and MongoDB data sources.

Context

Before you create a service unit based on an HBase, an Elasticsearch, or a MongoDB data source, you must create a metadata set for the corresponding data source.

Create a metadata set for an HBase data source

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Services** in the top navigation bar.
3. On the Service page, click **Administration** in the top navigation bar.
4. On the Administration page, click **Metadata Management** in the left-side navigation pane.
5. On the **Metadata Management** page, click **Create Metadata** in the upper-right corner.
6. On the **Create Metadata Set** page, specify a source table and add rowkeys and columns as required.

Section	GUI element	Description
Data Table Configuration	Physical Data Table	The configuration that specifies the source table. Select HBASE, a data source, and a physical table from the drop-down lists in sequence.
Rowkey Configuration	Delimiters	The delimiter used to separate different rowkeys.
	Rowkey Field Name	The name of the rowkey.
	Data Type	The data type of the rowkey.
	Row Key Description	The description of the rowkey.
	Actions	The operations that you can perform on the rowkey. You can click the icon in the **Actions** column to delete a field.
Column Field Configuration	Column Family Name	The name of the column family to which the column belongs.
	Column Qualifier Name	The name of the column.
	Data Type	The data type of the column.
	Description	The description of the column.
	Actions	The operations that you can perform on the column. You can click the icon in the **Actions** column to delete a column.

7. Click **Submit**.

Create a metadata set for an Elasticsearch data source

1. On the **Metadata Management** page, click **Create Metadata** in the upper-right corner.
2. On the **Create Metadata Set** page, specify a source table and add fields as required.

Section	GUI element	Description
Data Table Configuration	Physical Data Table	The configuration that specifies the source table. Select ES, a data source, and a physical table from the drop-down lists in sequence.
Field Configuration	Field Name	The name of the field. To configure a nested field, separate multiple field names with periods (.).
	Data Type	The data type of the field.
	Description	The description of the field.
	Actions	The operations that you can perform on the field. You can click the icon in the **Actions** column to delete a field.

3. Click **Submit**.

Create a metadata set for a MongoDB data source

The configurations for creating a metadata set for a MongoDB data source are similar to those for an Elasticsearch data source. For more information, see Create a metadata set for an Elasticsearch data source.

9.16.5.2.2. Create a service unit from a physical table

Dataphin allows you to create a service unit to manage the metadata of a physical table. This topic describes how to create a service unit from a physical table.

Prerequisites

- A service unit group is created. For more information, see Create a group.
- The corresponding metadata set is created if the source physical table resides in an HBase, an Elasticsearch, or a MongoDB data source. For more information, see Create a metadata set.

Context

The fields of a service unit can be referenced by multiple API operations.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Service Units** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **Workbench** in the top navigation bar.
   iii. In the left-side navigation pane, click **Service Units**.
3. On the **Service Units** page, click **Create Service Unit** in the upper-right corner. The Create Service Unit page appears.
4. Select a service unit type.
   i. In the Service Unit Type Selection step, select **Single Physical Table Service Unit**

i. In the Service Unit Type Selection step, select **Single Physical Table Service Unit**.

ii. Click **Next**.

5. Configure the service unit.

i. In the **Service Unit Basic Information Configuration** step, set the parameters as required.

Parameter	Description
Service unit name	The name of the service unit.
Service Unit Group	The group to which the service unit belongs.
Physical Data Table	The source table for the service unit. To specify a source table, perform the following steps: a. Select a data source type. b. Select a data source. c. Select a table.
Service unit description	The description of the service unit.

ii. Click **Next**.

6. Configure the fields of the service unit.

i. In the **Service Unit Field Configuration** step, configure the fields of the service unit as required.

ii. Click **Data Preview** to preview the data of the service unit to create.

iii. Click **Identify and Publish in the Staging Environment** to create and publish the service unit in the staging environment.

7. On the **Service Units** page, find the created service unit, move the pointer over the icon in the Actions column, and then select **Publish** to publish the service unit to the production environment.

The following table describes the operations that you can perform on the created service units.

Operation	Description
Modify the configuration of a service unit	Click the icon in the **Actions** column to modify the configuration of a service unit.

Operation	Description
Delete a service unit	Move the pointer over the More icon in the **Actions** column and select the icon to delete a service unit. **Note** ○ You can delete only unpublished service units. ○ To delete a service unit, you must be the owner of the service unit or the super administrator.
Unpublish a service unit	Move the pointer over the icon in the **Actions** column and select **Unpublish** to unpublish a service unit that has been previously published to the production environment.
Manage the members of a service unit	Click the icon in the **Actions** column. The Service Unit Member Management page of the service unit appears. ○ Click **Add Member**. In the Add Members to Service Unit dialog box, select the name of the account to be added as a member and the user type from the **Select Member** and **Select Role** drop-down lists, respectively. Then, click **Submit** to add a member to the service unit. ○ Click the icon in the **Actions** column and select a member from the Transfer Ownership To drop-down list to transfer the ownership of the service unit to the selected member. ○ Click the icon in the **Actions** column to delete a member from the service unit. ○ To delete multiple members at a time, select the members and click **Delete Members** in the upper-right corner.

9.16.5.2.3. Create a service unit from multiple physical tables

Dataphin allows you to create a service unit to manage the metadata of multiple physical tables. This topic describes how to create a service unit from multiple homogeneous or heterogeneous physical tables.

Prerequisites

- A service unit group is created. For more information, see Create a group.
- The corresponding metadata sets are created if the source physical tables reside in HBase, Elasticsearch, or MongoDB data sources. For more information, see Create a metadata set.

Context

The fields of a service unit can be referenced by multiple API operations.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Service Units** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **Workbench** in the top navigation bar.
   iii. In the left-side navigation pane, click **Service Units**.
3. On the **Service Units** page, click **Create Service Unit** in the upper-right corner. The Create Service Unit page appears.
4. Select a service unit type.
   i. In the Service Unit Type Selection step, select **Multiple Physical Table Service Unit**.
   ii. Click **Next**.
5. Configure the service unit.

i. In the **Service Unit Basic Information Configuration** step, set the parameters as required.

GUI element	Description
Service unit name	The name of the service unit.
Service Unit Group	The group to which the service unit belongs.
Service unit description	The description of the service unit.
Add Physical Table	To add a physical table, perform the following steps: a. In the Mounted Physical Table List section, click **Add Physical Table**. b. In the **Add Physical Table** dialog box, select a data source type, a data source, and a table in sequence to specify a source table. If the required data source is unavailable, click **Create Data Source** to go to the Planning page and create a data source. For more information, see Create a MaxCompute data source. c. In the **No field is selected** section, select the fields of the specified physical table as required and click the > icon to add the fields to the **Selected Field** section. To remove a field from the **Selected Field** section, select the field and click the < icon. d. Click **OK**.

By default, the system sets the first physical table that you add as the primary table. You can click the icon in the **Primary Table** column to change the primary table. You can also perform the following operations on the added physical tables:

- Click the icon in the **Actions** column to modify the configuration of a physical table.
- Click the icon in the **Actions** column to delete a physical table.

ii. Click **Next**.

6. Configure the fields of the service unit.

i. In the **Service Unit Field Configuration** step, configure the fields of the service unit as required.

Section	Parameter	Description
Service Unit Association Field Configuration	Service Unit Field	The name of the field in the service unit.
	Physical table name. Associated Field	The name of the association field. An association field is used to associate the physical tables that you added.
	Service Unit Association Field Type	The data type of the association field.
	Actions	The operations that you can perform on the association field. You can click the icon in the **Actions** column to delete a configured association field. **Note** You cannot delete the association field in the first line.
Service Unit Field Configuration	Service Unit Field Type	The data type of the field of the service unit. Dataphin automatically selects the data type of each field based on the data type of the field in the source table.
	Service Unit Field	The name of the field. Dataphin automatically generates the name for each field based on the name of the field in the source table.

ii. Click **Data Preview** to preview the data of the service unit to create.

iii. Click **Identify and Publish in the Staging Environment** to create and publish the service unit in the staging environment.

7. On the **Service Units** page, find the created service unit, move the pointer over the icon in the Actions column, and then select **Publish** to publish the service unit to the production environment.

   The following table describes the operations that you can perform on the created service units.

Operation	Description
Modify the configuration of a service unit	Click the icon in the **Actions** column to modify the configuration of a service unit.

Operation	Description
Delete a service unit	Move the pointer over the More icon in the **Actions** column and click the icon to delete a service unit. **Note** ◦ You can delete only unpublished service units. ◦ To delete a service unit, you must be the owner of the service unit or the super administrator.
Unpublish a service unit	Move the pointer over the icon in the **Actions** column and select **Unpublish** to unpublish a service unit that has been previously published to the production environment.
Manage the members of a service unit	Click the icon in the **Actions** column. The Service Unit Member Management page of the service unit appears. ◦ Click **Add Member**. In the Add Members to Service Unit dialog box, select the name of the account to be added as a member and the user type from the **Select Member** and **Select Role** drop-down lists, respectively. Then, click **Submit** to add a member to the service unit. ◦ Click the icon in the **Actions** column and select a member from the Transfer Ownership To drop-down list to transfer the ownership of the service unit to the selected member. ◦ Click the icon in the **Actions** column to delete a member from the service unit. ◦ To delete multiple members at a time, select the members and click **Delete Members** in the upper-right corner.

9.16.5.3. Create an API operation

9.16.5.3.1. Create an API operation in template wizard mode

Dataphin allows you to create an API operation by specifying a service unit and configuring the mapping between the fields of the service unit and the request and response parameters of the API operation on the GUI. This topic describes how to create an API operation in template wizard mode.

Prerequisites

- A service unit group is created. For more information, see Create a group.

- A service unit is created. For more information, see Create a service unit from multiple physical tables and Create a service unit from a physical table.

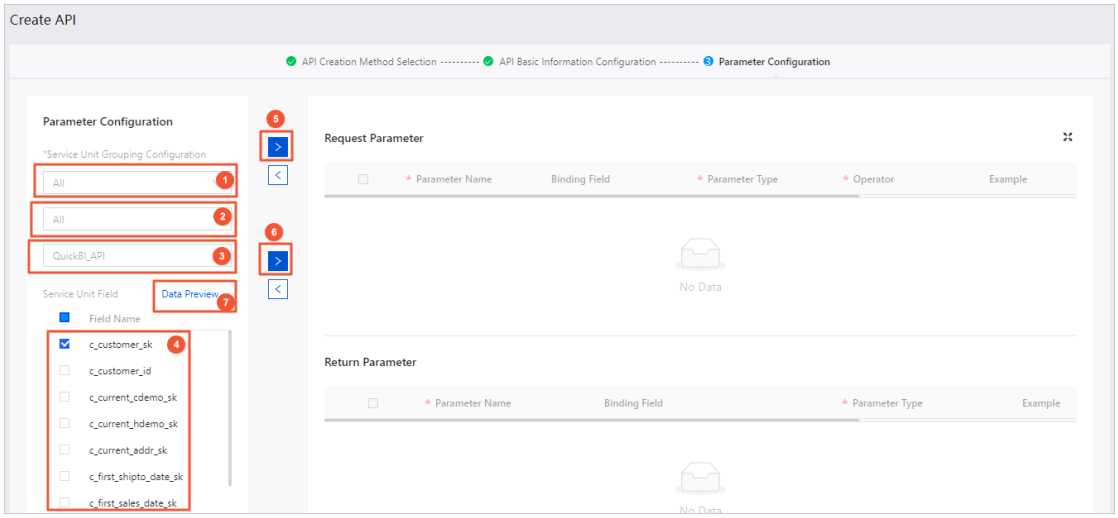
Procedure

1. Log on to the Dataphin console.
2. Go to the **APIs** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **Workbench** in the top navigation bar.
   iii. On the Workbench page, click **APIs** under **Development Center** in the left-side navigation pane.
3. On the APIs page, click **Create API** in the upper-right corner.
4. Select a creation method.
   i. In the **API Creation Method Selection** step, select **Template Wizard Mode**.
   ii. Click **Next**.
5. Configure the API operation.
   i. In the **API Basic Information Configuration** step, set the parameters as required

Parameter	Description
API Name	The name of the API operation. The name can contain letters, digits, and underscores (_).
Request Method	The method for calling the API operation. Valid values: ■ GET ■ LIST
Data Update Frequency	The frequency at which data is synchronized by using the API operation. Valid values: ■ Daily ■ Hourly ■ Minutely
Description	The description of the API operation.
Protocol	The protocol that is used by the API operation to synchronize data. Valid values: ■ HTTP ■ HTTPS

   ii. Click **Next Step**.
6. Configure the request and response parameters for the API operation.

i. In the **Parameter Configuration** step, set the parameters as required.



No.	GUI element	Description
1	Service Unit Grouping Configuration	Click the icon and select a service unit group.
2		Click the icon and select a service unit type.
3		Click the icon and select a service unit.
4	Service Unit Field	Select fields of the service unit.
5	N/A	After you complete the preceding configuration in sections marked as 1 to 4, click the icon marked as 5 to add the selected fields to the **Request Parameter** section. Then, set **Parameter Name**, **Parameter Type**, **Operator**, **Example**, **Description**, and **Required** for the added request parameters.
6	N/A	After you complete the preceding configuration in sections marked as 1 to 4, click the icon marked as 6 to add the selected fields to the **Return Parameter** section. Then, set **Parameter Name**, **Parameter Type**, **Example**, and **Description** for the added response parameters.
7	Data Preview	Click **Data Preview** to preview the data of the selected service unit.

ii. Click **Identify and Publish in the Staging Environment** to create and publish the API operation in the staging environment.

9.16.5.3.2. Create an API operation in custom SQL mode

Dataphin allows you to create an API operation by specifying a service unit and writing an SQL statement. Dataphin parses the request and response parameters of the API operation based on the SQL statement. This topic describes how to create an API operation in custom SQL mode.

Prerequisites

- A service unit group is created. For more information, see Create a group.
- A service unit is created. For more information, see Create a service unit from multiple physical tables and Create a service unit from a physical table.

Procedure

1. Log on to the Dataphin console.
2. Go to the **APIs** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **Workbench** in the top navigation bar.
   iii. On the Workbench page, click **APIs** under **Development Center** in the left-side navigation pane.
3. On the APIs page, click **Create API** in the upper-right corner.
4. Select a creation method.
   i. In the **API Creation Method Selection** step, select **Custom SQL Mode**.
   ii. Click **Next**.
5. Configure the API operation.

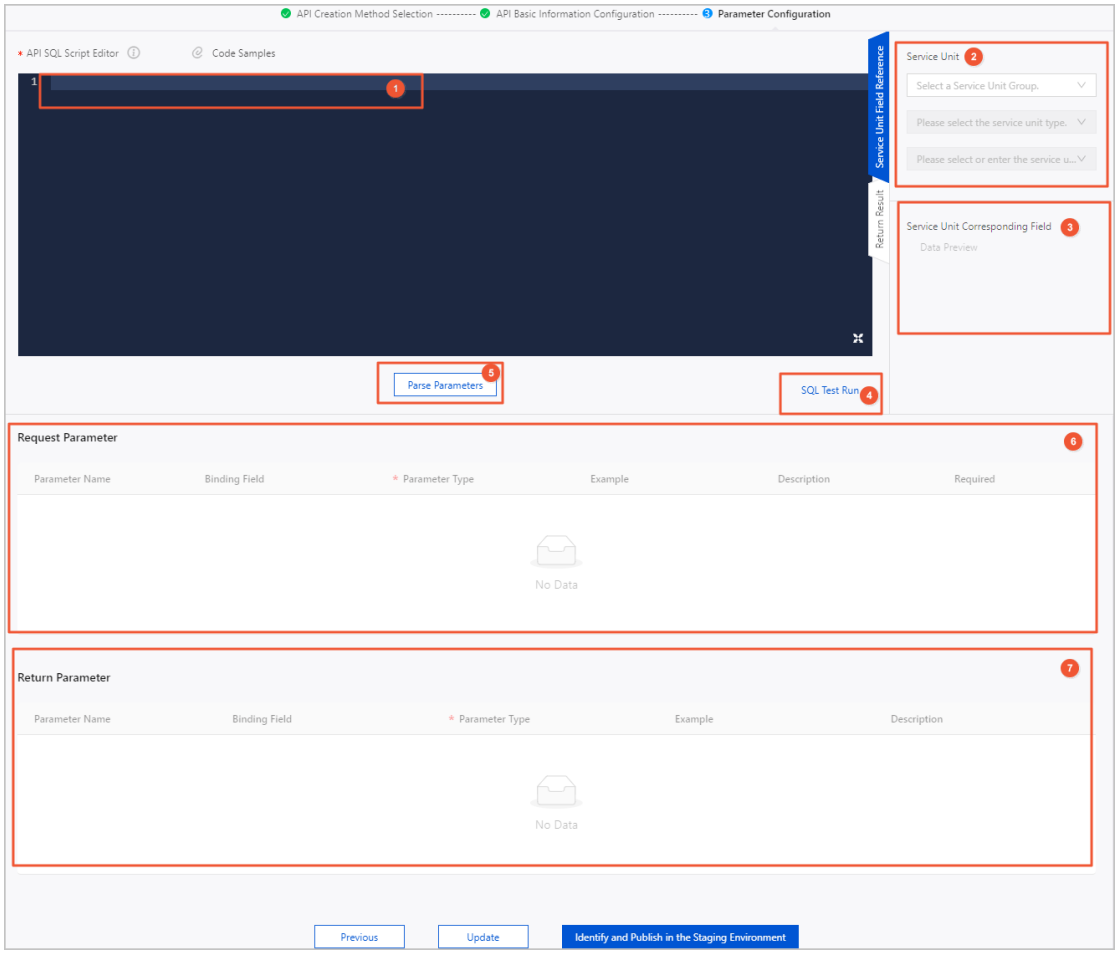
i. In the **API Basic Information Configuration** step, set the parameters as required

Parameter	Description
API Name	The name of the API operation. The name can contain letters, digits, and underscores (_).
Request Method	The method for calling the API operation. Valid values: ■ **GET** ■ **LIST**
Data Update Frequency	The frequency at which data is synchronized by using the API operation. Valid values: ■ **Daily** ■ **Hourly** ■ **Minutely**
Description	The description of the API operation.
Protocol	The protocol that is used by the API operation to synchronize data. Valid values: ■ **HTTP** ■ **HTTPS**

ii. Click **Next Step**.

6. Configure the request and response parameters for the API operation.

i. In the **Parameter Configuration** step, enter an SQL statement in the script editor and set the parameters as required.



No.	GUI element	Description
1	API SQL Script Editor	Enter an SQL statement in the **API SQL Script Editor** section. For example, you can enter the following statement: `select user_id,pid,city_id,activity_time from ads1578301726 where user_id=${user_id};` You can click the icon to view the limits on the SQL statement.
2	Service Unit	To specify a service unit, perform the following steps: a. Select a service unit group from the drop-down list. b. Select a service unit type from the drop-down list. c. Select a service unit from the drop-down list.

No.	GUI element	Description
3	Data Preview	Click **Data Preview** to preview the data of the selected service unit.
4	SQL Test Run	To run the SQL statement, perform the following steps: a. Click **SQL Test Run**. b. In the **Specify Request Parameters** dialog box, set **Test Run Input** to the value that you obtained when you previewed the data of the selected service unit. In this example, enter the value of the `user_id` field. c. Click **Confirm**. ■ If **SQL Status** appears as **Success**, the SQL syntax, computing engine, and database engine passed the validation checks. ■ If **SQL Status** appears as **Error**, the SQL syntax, computing engine, and database engine failed the validation checks.
5	Parse Parameters	Click **Parse Parameters** for the system to automatically generate request and response parameters based on the SQL statement that you entered in the **API SQL Script Editor** section.
6	Request parameters	Specify the following fields for the request parameters: ■ **Parameter Type** ■ **Example** ■ **Description** ■ **Required**
7	Return Parameter	Specify the following fields for the response parameters: ■ **Parameter Type** ■ **Example** ■ **Description**

ii. Click **Identify and Publish in the Staging Environment** to create and publish the API operation in the staging environment.

9.16.5.4. Test an API operation

You can publish an API operation to the production environment only after it passes the test in the staging environment. This topic describes how to test an API operation.

Prerequisites

An API operation is created. For more information, see Create an API operation in template wizard mode and Create an API operation in custom SQL mode.

Context

You can test API operations only in the staging environment. We recommend that you test API operations before you publish them to the production environment.

Procedure

1. Log on to the Dataphin console.
2. Go to the **APIs** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **Workbench** in the top navigation bar.
   iii. On the Workbench page, click **APIs** under **Development Center** in the left-side navigation pane.
3. On the **APIs** page, find the API operation that you want to test.
   - You can filter API operations by selecting a service unit or service unit group from the corresponding drop-down list.
   - Alternatively, you can enter a keyword in the search box to filter API operations whose names contain the keyword.
4. Move the pointer over the icon in the Actions column and select **Test**.
5. On the **API Test** page, enter the input values for API-specific request parameters based on the example values in the **API Request Parameters** section. Enter the input values for common request parameters based on the example values in the **Public Request Parameter List** section. Select response parameters as required in the **Optional Response Parameters** section. Then, select a protocol from the **Protocol** drop-down list.
6. Click **Test**.
7. After the test is completed, view the test results of the API operation in the **Test Results** section. You can also click **View Error Code Table** in the lower part of the page to view error codes and their descriptions.

9.16.5.5. Publish an API operation

API operations can be called only after they are published to the production environment. The API Service page lists the API operations that have been published. This topic describes how to publish an API operation.

Prerequisites

An API operation is created. For more information, see Create an API operation in template wizard mode and Create an API operation in custom SQL mode.

Procedure

1. Log on to the Dataphin console.
2. Go to the **APIs** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.

ii. On the Service page, click **Workbench** in the top navigation bar.

iii. On the Workbench page, click **APIs** under **Development Center** in the left-side navigation pane.

3. On the **APIs** page, find the API operation that you want to publish.
   - You can filter API operations by selecting a service unit or service unit group from the corresponding drop-down list.
   - Alternatively, you can enter a keyword in the search box to filter API operations whose names contain the keyword.
4. Move the pointer over the icon in the Actions column and select **Publish**.
5. In the message that appears, click **OK** to publish the API operation to the production environment.

9.16.5.6. Unpublish an API operation

This topic describes how to unpublish an API operation.

Prerequisites

An API operation is published. For more information, see Publish an API operation.

Context

If you find an API operation inappropriate, you can unpublish it. Unpublished API operations do not appear on the API Service page. After you unpublish an API operation, you can delete it from Development Center. For more information about how to delete an API operation, see Delete an API operation.

Procedure

1. Log on to the Dataphin console.
2. Go to the **APIs** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **Workbench** in the top navigation bar.
   iii. On the Workbench page, click **APIs** under **Development Center** in the left-side navigation pane.
3. On the **APIs** page, find the API operation that you want to unpublish.
   - You can filter API operations by selecting a service unit or service unit group from the corresponding drop-down list.
   - Alternatively, you can enter a keyword in the search box to filter API operations whose names contain the keyword.
4. Move the pointer over the icon in the Actions column and select **Unpublish**.

> **Note** You can only unpublish API operations that are not being used by any application.

5. In the message that appears, click **OK**.

9.16.5.7. Delete an API operation

This topic describes how to delete an API operation from Development Center.

Prerequisites

An API operation is published. For more information, see Publish an API operation.

Procedure

1. Log on to the Dataphin console.
2. Go to the **APIs** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **Workbench** in the top navigation bar.
   iii. On the Workbench page, click **APIs** under **Development Center** in the left-side navigation pane.
3. On the **APIs** page, find the API operation that you want to delete.
   - You can filter API operations by selecting a service unit or service unit group from the corresponding drop-down list.
   - Alternatively, you can enter a keyword in the search box to filter API operations whose names contain the keyword.
4. Move the pointer over the icon in the Actions column and select **Delete**.

   > **Note** You can only delete API operations that are not being used by any application.

5. In the message that appears, click **OK**.

9.16.6. Use and manage an API operation

9.16.6.1. Create an application

You must use applications to call API operations in the Services module. An application supports multiple API operations. This topic describes how to create an application.

Prerequisites

An application group is created. For more information, see Create a group.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Applications** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **Workbench** in the top navigation bar.

iii. On the Workbench page, click **Applications** under **Application Center** in the left-side navigation pane.

3. On the **Applications** page, click **Create Application** in the upper-right corner.
4. In the **Create Application** dialog box, set the **Application Group** and **Application Name** parameters as required.
5. Click **Confirm**.The following table describes the operations that you can perform on the created applications.

Operation	Description
Modify the configuration of an application	Click the icon in the **Actions** column to modify the configuration of an application.
Manage the members of an application	Click the icon in the **Actions** column. The Application Member Management page of the application appears. ○ Click **Add Member**. In the Add Member dialog box, select the name of the account to be added as a member and the user type from the **Member Name** and **Select Role** drop-down lists, respectively. Then, click **Submit** to add a member to the application. ■ The members of an application can apply for permissions on API operations for the application and call the API operations that the application is authorized to access. ■ The administrator of an application can apply for permissions on API operations for the application, call the API operations that the application is authorized to access, and remove API operations from the application. ○ Click the icon in the **Actions** column and select a member from the Transfer Ownership To drop-down list to transfer the ownership of the application to the selected member. ○ Click the icon in the **Actions** column to delete a member from the application. ○ To delete multiple members at a time, select the members and click **Remove** in the upper-right corner.
Go to the API Service page	Click the icon in the **Actions** column. The API Service page appears, where you can view the published API operations.
Delete an application	Click the icon in the **Actions** column to delete an application.
View the key and secret of an application	On the **Applications** page, view the key and secret of an application in the **AppKey** and **AppSecret** columns, respectively.

9.16.6.2. View an API operation

Before you apply for permissions on an API operation for an application, we recommend that you view the details of the API operation and determine whether it meets your business requirements. This topic describes how to view an API operation on the API Service page.

Prerequisites

An API operation is published. For more information, see Publish an API operation.

Procedure

1. Log on to the Dataphin console.
2. Go to the **API Service** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **API Service** in the top navigation bar.
3. On the **API Service** page, find the API operation that you want to view and click **API Documentation** in the **Documentation** column.
4. On the **API Documentation** page, view the information in the **Basic Information**, **API Request Parameters**, **Public Request Parameter List**, and **Response Parameters** sections and determine whether the API operation meets your business requirements.

9.16.6.3. Apply for permissions on an API operation

Before you call an API operation by using an application, the application must be authorized to access the API operation. This topic describes how to apply for the permission to query fields of an API operation for an application.

Prerequisites

An application is created. For more information, see Create an application.

Procedure

1. Log on to the Dataphin console.
2. Go to the **API Service** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **API Service** in the top navigation bar.
3. On the API Service page, find the API operation on which you want to apply for permissions and click **Request Now** in the **Request Status** column.
4. In the Select Application and API step of the **API Permission Request** wizard, set the **Application** and **API** parameters as required.
5. Click **Next**.
6. In the **Apply for API Permissions** step, set the parameters as required.

Section	Parameter	Description

Section	Parameter	Description
Object Information	N/A	In this section, you can view the names of the application and API operation, and the groups to which they belong.
Authorized Fields	N/A	Select the fields on which you want to apply for permissions. You can enter a keyword in the search box to search for the fields whose names contain the keyword.
Permission Configuration	Validity Period	The validity period of the query permission. Valid values: ○ **30 Days** ○ **90 Days** ○ **180 Days** ○ **Long-term** ○ **Custom Expiration Date** Dataphin allows only application users of an application to apply for the permission to query fields of an API operation for the application.
	Reason for Application	The reason for applying for the permission to query fields of the API operation.

7. Click **OK**.

9.16.6.4. Debug an API operation

Before you call an API operation by using an application, you must debug the API operation to ensure data security and stability. This topic describes how to debug an API operation.

Prerequisites

- An application is granted the query permission on the API operation that you want to debug. For more information, see Apply for permissions on an API operation.
- The key and secret of the application that is granted the query permission are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **APIs** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **Workbench** in the top navigation bar.
   iii. On the Workbench page, click **APIs** under **Application Center** in the left-side navigation pane.
3. Find the API operation that you want to debug and click the icon in the **Actions** column.

   The **API Debugging** page appears.
4. On the **API Debugging** page, set the parameters as required.

Section	Parameter	Description
API Request Parameters	Input Value	The value of the required request parameter for debugging the API operation.
Public Request Parameter List	Input Value	The value of the common request parameter for debugging the API operation. ○ **Input Value of appkey**: the key of the application for debugging the API operation. ○ **Input Value of appsecret**: the secret of the application for debugging the API operation.
Response Parameters	Protocol	In the Response Parameters section, select the response parameters and the protocol to be used for the debugging as required.

5. Click **Debug**.
6. After the debugging is completed, view the result in the **Results** section. You can also click **View Error Code Table** in the lower part of the page to view error codes and their descriptions.If the debugging fails, you can go to the APIs page to remove the API operation from the application. To remove an API operation, find the API operation and click the icon in the **Actions** column. In the message that appears, click **OK**. You can also apply for permissions on specific fields of an API operation on the APIs page. To apply for field permissions, find the API operation and click the icon in the **Actions** column. On the **API Permission Request** page, set the parameters as required and click OK.

9.16.6.5. Call an API operation

This topic describes how to use an application to call an API operation that has been published to the production environment.

Prerequisites

- The network is configured. For more information, see Configure the network.
- An application is granted the query permission on an API operation. For more information, see Apply for permissions on an API operation.
- The key and secret of the application are obtained. For more information, see Create an application.
- The API operation is debugged. For more information, see Debug an API operation.

Context

You can call an API operation by using Services SDK for Java or Postman. We recommend that you use Services SDK for Java to call an API operation. You can use Postman only when you debug or develop an API operation.

Procedure

1. Log on to the Dataphin console.

2. Go to the **Call Examples** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the **Service** page, click **Administration** in the top navigation bar.
   iii. On the **Administration** page, click **Call Examples** in the left-side navigation pane.
3. On the **API Call Examples** tab, view the sample code for using Services SDK for Java to call an API operation.
4. Click **Download SDK** in the upper-right corner to download the code package.
5. Modify the downloaded code based on the instructions on the **API Call Examples** tab. Then, you can call the API operation by using the specified application.

9.16.7. Monitor an API operation

Dataphin monitors API requests on a daily basis. You can view the statistics of the API operations that you have published on the Monitoring page. This topic describes how to view the request details of, set a request limit on, and configure alert rules for an API operation.

View the request details of an API operation

1. Log on to the Dataphin console.
2. Go to the **Monitoring** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **Administration** in the top navigation bar.
   iii. On the Administration page, click **Monitoring** in the left-side navigation pane.
3. On the **Monitoring** page, click **Details** in the **Actions** column of the API operation whose details you want to view. On the API Monitoring page, you can view the statistics of the API requests in the last hour.

Set a request limit on an API operation

> **Note** To set a request limit on an API operation, you must be the developer of the API operation or the super administrator.

1. On the **Monitoring** page, click **Limit** in the **Actions** column of the API operation on which you want to set a request limit.
2. In the **Configure API Call Limit** dialog box, set the parameters as required.

GUI element	Description
Limit Status	Specifies whether to set a request limit on the API operation.
Time Unit	The time granularity of the request limit to be set on the API operation. Valid values: ○ **hour** ○ **sec** ○ **min** ○ **day**

GUI element	Description
API Call Limit	The maximum number of API requests that can be handled at the specified granularity. Assume that your enterprise has purchased the default specification for the Services module, which supports handling 500 API requests per second. In this case, if you set **Time Unit** to **sec**, you must specify a value less than or equal to 500 for the **API Call Limit** parameter.
Application Call Limit	The maximum number of API requests sent by each involved application that can be handled at the specified granularity. Note the following rules when you set the **Application Call Limit** parameter: ○ The specified value of **Application Call Limit** applies to all the applications that are authorized to access the API operation. ○ The value of **Application Call Limit** must be less than or equal to that of **API Call Limit**. ○ The **API Call Limit** parameter has a higher priority than the **Application Call Limit** parameter. Assume that the request limit on an API operation is 1,000 requests per second and that on each of the three applications that are authorized to access the API operation is 500 requests per second. The sum of the permitted requests per second for the three applications exceeds the request limit on the API operation. However, with a higher priority, the request limit on the API operation determines the upper limit of requests. ○ If you set **Application Call Limit** to a value greater than that of **API Call Limit**, an error message is returned.
Add Application	Click **Add Application** and set the **Application** and **Call Limit** parameters to set a different request limit on a specific application. You can also click the  icon in the **Actions** column of an application to remove the request limit from the application.Note the following rules when you set the **Call Limit** parameter: ○ The value of **Call Limit** for a specific application must be less than or equal to that of **API Call Limit**. ○ The **Call Limit** parameter of a specific application has a higher priority than the **Application Call Limit** parameter. Assume that the request limit on a specific application is 0 or 200 API requests per second and that on each of the other applications that are authorized to access the same API operation is 100 API requests per second. In this case, with a higher priority, the request limit on the specific application determines the upper limit of requests for itself. ○ If you set the **Call Limit** parameter of a specific application to a value greater than that of **API Call Limit**, an error message is returned.

3. Click **OK**.

Configure alert rules for an API operation

1. On the **Monitoring** page, click **Alert** in the **Actions** column of the API operation for which you want to configure alert rules.

2. On the **Alert** page, click **Create Rule** in the upper-right corner.
3. Set the parameters as required.

Parameter	Description
Monitoring Metric	The metric to be monitored for the API operation. Valid values: ○ **Number of Calls**: the total number of API requests per unit time. ○ **Average Response time**: the average response time of API requests per unit time. The average response time equals the total time for processing the API requests divided by the total number of API requests. ○ **Failed Calls (Percentage)**: the ratio of the number of failed API requests to the total number of API requests per unit time. ○ **Calls During Offline (Percentage)**: the ratio of the number of API requests that failed due to connection interruptions to the total number of API requests per unit time.
Time Unit	The time interval at which monitoring data is queried. Valid values: **1min**, **5min**, **10min**, **30min**, and **60min**.
Operator	The comparison operator that is used to compare the value of the monitored metric with the specified value of **Trigger Threshold**. Valid values: <=, <, >, >=, =, != .
Trigger Threshold	The threshold cross which an alert will be triggered.
Notification	The method that is used to send alert notifications to the recipient. Valid values: ○ **Email** ○ **Cellphone** ○ **SMS** ○ **DingTalk**
Recipient	The user to receive alert notifications.
Silent Period	The period of time in which an alert notification is not sent repeatedly. This helps avoid notification redundancy.

4. Click **OK**.On the Alert page, you can view the basic information about the selected API operation and the alert rules that have been created for the API operation. You can perform the following operations on existing alert rules:
   - Click the  icon in the **Actions** column of an alert rule to modify the rule.
   - Click the  icon in the **Actions** column of an alert rule to delete the rule.

9.16.8. Create a Dataphin data source

In the Services module, you can create Dataphin data sources from logical or physical tables for applications to access. This topic describes how to create a Dataphin data source.

Context

After you create Dataphin data sources from logical or physical tables, you can further develop these data resources based on the specific business scenarios. This allows you to enjoy a secure, stable, and easy-to-use data sharing service at low costs.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Dataphin Data Sources** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **Administration** in the top navigation bar.
   iii. On the Administration page, click **Dataphin Data Sources** in the left-side navigation pane.
3. On the **Dataphin Data Sources** page, click **Create Data Source** in the upper-right corner.
4. On the **Create Data Source** page, set the parameters as required.

Section	Parameter	Description
Basic Information	Data Source Name	The name of the data source to create.
	Data Source Description	The description of the data source.
Logical Table Selection	Unselected Logical Tables	Lists the logical tables that you are authorized to access. To specify the tables for creating the data source, select the tables and click the > icon to move the tables to the Selected Logical Tables section.
	Selected Logical Tables	Lists the logical tables that you specify for creating the data source. To remove tables from the list, select the tables and click the < icon to move the tables to the Unselected Logical Tables section.
Physical Table Selection	Unselected Physical Tables	Lists the physical tables that you are authorized to access. To specify the tables for creating the data source, select the tables and click the > icon to move the tables to the Selected Logical Tables section.
	Selected Physical Tables	Lists the physical tables that you specify for creating the data source. To remove tables from the list, select the tables and click the < icon to move the tables to the Unselected Physical Tables section.

Section	Parameter	Description
Computing Space	Select Project for Data Source Computing	The Dataphin project for the computing work of the data source to be created.

5. Click **Create Data Source**. After the data source is created, it appears on the Dataphin Data Sources page. This page lists the data sources that applications can use.The following table describes the operations that you can perform on the created data sources.

Operation	Description
Modify the configuration of a data source	Click the icon in the **Actions** column to modify the configuration of a data source.
Delete a data source	Click the icon in the **Actions** column to delete a data source.

9.16.9. Use and manage a Dataphin data source

9.16.9.1. View a Dataphin data source

Before you use a Dataphin data source, we recommend that you view the details of the data source and determine whether it meets your business requirements. This topic describes how to view a Dataphin data source.

Prerequisites

A Dataphin data source is created. For more information, see Create a Dataphin data source.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Dataphin Data Sources** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **Administration** in the top navigation bar.
   iii. On the Administration page, click **Dataphin Data Sources** in the left-side navigation pane.
3. On the Dataphin Data Sources page, find the data source that you want to view and click the icon in the **Actions** column. The **View Data Source** page appears.
4. On the **View Data Source** page, view the information in the **Basic Information**, **Logical Table Information**, **Physical Table Information**, and **Computing Space Information** sections and determine whether the data source meets your business requirements.

9.16.9.2. Use a Dataphin data source

Dataphin provides the JDBC interface for you to use Dataphin data sources. You must download the JAR package of the Dataphin JDBC driver and import the JAR package by using a JDBC client or by writing Java code. Then, you can use Dataphin data sources. This topic describes how to use a Dataphin data source.

Prerequisites

- A Dataphin data source that meets your business requirements is found. For more information, see View a Dataphin data source.
- The network is configured. For more information, see Configure the network.
- The permission to query the Dataphin data source is granted by the super administrator.
- The JDBC URL of the Dataphin data source is granted by the super administrator.
- The **AccessKey** of the Dataphin data source is obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Call Examples** page.
   i. On the Dataphin homepage, click **Services** in the top navigation bar.
   ii. On the Service page, click **Administration** in the top navigation bar.
   iii. On the Administration page, click **Call Examples** in the left-side navigation pane.
3. On the **Call Examples** page, click the **Dataphin Data Source Usage Examples** tab.
4. On the Dataphin Data Source Usage Examples tab, click **Download JDBC JAR Package** in the upper-right corner to download the Dataphin JDBC driver.
5. Use a JDBC client or write Java code based on the instructions on the **Dataphin Data Source Usage Examples** tab to use the data source.

10.Elasticsearch (on ECS)

10.1. What is Elasticsearch?

Elasticsearch is a distributed search and data analytics service based on Lucene. It provides a distributed multi-tenant search engine that supports full text queries. This engine is based on a RESTful Web interface. Elasticsearch is developed based on Java. It is released as an open source product that complies with the Apache license terms and conditions. Elasticsearch is a mainstream search engine for enterprises. Elasticsearch is designed to serve cloud computing for real-time search. It is stable, reliable, fast, and easy to install and use.

Apsara Stack Elasticsearch provides two open source versions: Elasticsearch V5.5.3 and Elasticsearch V6.3.2. Apsara Stack Elasticsearch is designed to serve users in data search, data analytics, and other scenarios. Based on open source Elasticsearch, Apsara Stack Elasticsearch also supports enterprise-class permission management.

The default plug-ins provided by Apsara Stack Elasticsearch include but are not limited to the following:

- **IK analyzer**: an open source and lightweight Chinese analysis kit based on Java. The IK analyzer plug-in is very popular in open source communities for Chinese tokenization.
- **Smart Chinese analysis plug-in**: the default Lucene Chinese tokenizer.
- **ICU analysis plug-in**: a Lucene ICU tokenizer. ICU is a set of stable, tested, powerful, and easy to use libraries, providing Unicode and globalization support for applications.
- **Japanese (Kuromoji) analysis plug-in**: a Japanese tokenizer.
- **Stempel (Polish) analysis plug-in**: a French tokenizer.
- **Mapper attachments type plug-in**: an attachment-type plug-in which can parse files of different types into strings based on the Tika library.

10.2. Quick start

This topic shows you how to create an Elasticsearch instance based on ECS. It covers creating a VPC, creating a security group, creating an ECS instance, creating an Elasticsearch instance, and connecting to an Elasticsearch instance.

Create an Elasticsearch instance based on ECS

After you create an Elasticsearch instance, a VPC, and an ECS instance (in the same region as the Elasticsearch instance), the ECS instance can be used as the client. Then you can deploy a user program or run the curl command.

> **Note** If your Elasticsearch instance and ECS instance share the same VPC and region but reside in different zones, you must create a VSwitch in the zone where the ECS instance resides to ensure that the ECS instance can connect to your Elasticsearch instance.

10.2.1. Log on to the Elasticsearch console

This topic describes how to log on to the Elasticsearch console.

Prerequisites

.

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password used to log on to the console from the operations administrator.

   > **Note** When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters.
   > - Digits.
   > - Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Products** > **Big Data** > **Elasticsearch**.
5. Specify **Organization** and **Region** and click **Elasticsearch**.

10.2.2. Create an Elasticsearch cluster

This topic describes how to create an Elasticsearch cluster.

Prerequisites

- A Virtual Private Cloud (VPC) and a VSwitch are created.

  For more information, see the "Quick start" topic in Apsara Stack Virtual Private Cloud User Guide.
- Elastic Compute Service (ECS) instances are sufficient.

Precautions

Before you create an Elasticsearch cluster, you must understand the main data sources of the Elasticsearch cluster. This helps you better plan the size and allocation of disk space.

If you specify a small disk size, Elasticsearch cluster logs occupy a relatively large proportion of disk space. An Elasticsearch cluster mainly stores the following types of data:

- User data that has been pushed to the Elasticsearch cluster.
- Index replicas. You can specify the number of replicas for each index but must make sure that each index has a minimum of one replica.

Procedure

1. Log on to the Elasticsearch console.
2. On the page that appears, click **Create**.
3. Specify the required parameters.

Type	Parameter	Description
Region	Region	The region where the cluster is deployed.
	Zone	An Elasticsearch cluster can be deployed across zones. You may find multiple available zones from the **Zone** drop-down list. Select one or more appropriate zones as needed.
Cluster	Version	Valid values: 5.5.3 and 6.3.2.
	Network Type	The value of this parameter can only be VPC.
	VPC	Select the same VPC as your ECS instances.
	VSwitch	Select the same VSwitch as your ECS instances.
	Specification Family	Valid values: Local SATA, Local SSD, and Cloud Disk.
	Instance Specification	◦ Local SATA 16-Core 64 GB and 8-Core 32 GB ◦ Local SSD 16-Core 64 GB and 8-Core 32 GB ◦ Cloud Disk 16-Core 64 GB, 8-Core 32 GB, and 4-Core 16 GB
	Count	The number of data nodes. You must purchase a minimum of two data nodes. A cluster that contains only two data nodes has a high risk of split-brain. Therefore, exercise caution when you set this parameter.
	Dedicated Master Node	To improve the stability of your cluster, we recommend that you purchase dedicated master nodes. Dedicated master nodes support the following specifications: 4-Core 16 GB, 8-Core 32 GB, and 16-Core 64 GB. Standard SSDs are supported for storage.
	Client Node	For CPU-intensive services, we recommend that you purchase client nodes to share the CPU overheads of data nodes. This further improves the computing performance and service stability of your cluster. For example, if a large number of aggregation operations are performed, you can use client nodes to share the overheads. Client nodes support the following specifications: 4-Core 16 GB, 8-Core 32 GB, and 16-Core 64 GB. Ultra disks are supported for storage.

Type	Parameter	Description
	Warm Node	If your business includes both of the following index types, we recommend that you purchase warm nodes to implement the hot-warm architecture. This architecture improves the computing performance and service stability of your cluster. ◦ Frequently queried or written indexes ◦ Infrequently queried or written indexes, typically indexes of records Warm nodes support the following specifications: 4-Core 16 GB, 8-Core 32 GB, and 16-Core 64 GB. Ultra disks are supported for storage. You can select Warm Node on the buy page or configuration upgrade page to purchase warm nodes. After you purchase nodes, the system adds `-Enode.attr.box_type` to their startup parameters. ◦ Data nodes: -Enode.attr.box_type=hot ◦ Warm nodes: -Enode.attr.box_type=warm
Storage Note This parameter can be configured only when the Specification Family parameter is set to Cloud Disk.	Disk Type	Standard SSDs and ultra disks are supported. ◦ A standard SSD provides a maximum of 2,048 GiB of storage space. Standard SSDs are ideal for online data analytics and searches that require high IOPS and fast responses. ◦ An ultra disk provides a maximum of 5,120 GiB of storage space. Ultra disks are cost-effective and are ideal for scenarios such as logging and analyzing large amounts of data. Ultra disks with the storage space greater than 2,560 GiB cannot be resized because these disks are designed to run in disk arrays or RAID 0.
	Storage Space per Data Node	The storage space of each data node. It depends on the disk type. Unit: GiB. If the disk type is SSD Cloud Disk, the maximum value of this parameter is 2048. If the disk type is Ultra Disk, the maximum value of this parameter is 5120. If the volume of the data that you want to store exceeds 2,048 GiB, you can set this parameter to 2560, 3072, 3584, 4096, 4608, or 5120. If the storage space of the disk for a purchased cluster is less than 2,048 GiB, you can resize the disk to a maximum of 2,048 GiB.
	Username	The value of this parameter can only be elastic.

Password Type	Parameter	Description
	Password	The password of the Elasticsearch cluster. This password is also used to log on to the Kibana console.

4. Click **Create**.

   You can then find the cluster in the cluster list. When **Active** is displayed for the cluster, the cluster is created.

10.2.3. Access an Elasticsearch cluster

This topic describes how to access an Elasticsearch cluster. You can access an Elasticsearch cluster from an Elastic Compute Service (ECS) instance or the Kibana console.

Prerequisites

You have completed the following operations:

- Create an Elasticsearch cluster.
- Create an ECS instance that resides in the same Virtual Private Cloud (VPC), region, and zone as the Elasticsearch cluster.
- Obtain the internal endpoint and Kibana console URL of the Elasticsearch cluster.

  You can log on to the Elasticsearch console, find the target cluster on the Instances page, and click its ID in the **Instance ID/Name** column. Then, obtain the preceding information from the **Basic Information** page.

Use an ECS instance to access an Elasticsearch cluster

1. Log on to the ECS instance over SSH and install the cURL tool.

   > **Note** For information about other methods that are used to log on to an ECS instance, see the "Quick start" topic in Elastic Compute Service (ECS) of Alibaba Cloud Apsara Stack Enterprise V3.12.0 User Guide - Cloud Essentials and Security.

2. Run the following command to connect to the internal endpoint of the Elasticsearch cluster:

   ```
   curl http://<HOST>:<PORT>
   ```

   - Set `<HOST>` to the internal endpoint of the Elasticsearch cluster. You can obtain the internal endpoint from the Basic Information page of the cluster.
   - Set `<PORT>` to the port number of the Elasticsearch cluster. You can obtain the port number from the Basic Information page the cluster. The default port is 9200.

   If the connection is established, the result shown in the following figure is returned.

```
[root@iZ7t                    ~]# curl http://es-cn-d                    .elasticsea
rch.aliyun-inc.com:9200
{
  "name" : "k7d3r4E",
  "cluster_name" : "es-cn-d                    ",
  "cluster_uuid" : "Fmo                    ",
  "version" : {
    "number" : "5.5.3",
    "build_hash" : "9305a5e",
    "build_date" : "2017-09-07T15:56:59.599Z",
    "build_snapshot" : false,
    "lucene_version" : "6.6.0"
  },
  "tagline" : "You Know, for Search"
}
```

Use the Kibana console to access an Elasticsearch cluster

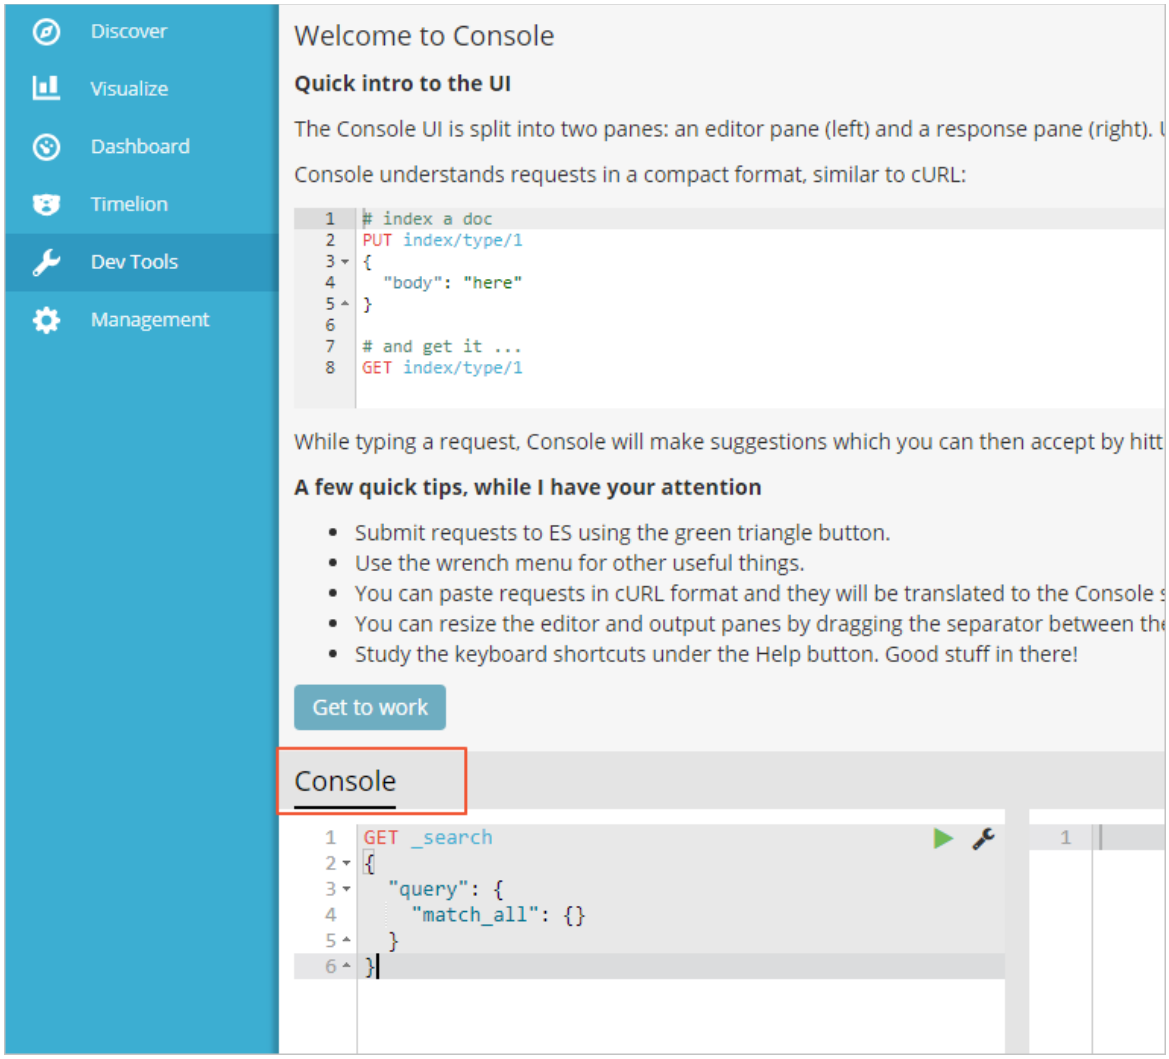
1. Enter the URL of the Kibana console in the address bar of your browser.

   > **Notice** The server where your browser is located must reside in the same VPC as the Elasticsearch cluster.

2. On the page that appears, enter the username and password and click Log in.

   The username is elastic. The password is the one that is specified when you create the Elasticsearch cluster.

3. In the left-side navigation pane, click **Dev Tools**.
4. On the **Console** tab, run the `GET /` command to access the Elasticsearch cluster.



10.3. Manage clusters

This topic describes how to manage Elasticsearch clusters. Elasticsearch provides management features, such as **Kibana console**, **cluster restart**, and **refresh**.

10.3.1. Log on to the Kibana console

This topic describes how to log on to the Kibana console of an Elasticsearch cluster. Elasticsearch provides the Kibana console for you to scale your businesses. The Kibana console is seamlessly integrated into Elasticsearch. It allows you to view the status of your Elasticsearch cluster in real time and manage the cluster.

1. Log on to the Elasticsearch console.
2. Find the target cluster and click its ID in the **Instance ID/Name** column.
3. On the **Basic Information** page, obtain the **Kibana console URL**. Then, enter the URL in the address bar of your browser.

> **Notice** The server where your browser is located must reside in the same Virtual Private Cloud (VPC) as the Elasticsearch cluster.

4. On the page that appears, enter the username and password and click Log in.

   The username is elastic. The password is the one that is specified when you create the Elasticsearch cluster.

10.3.2. Restart an Elasticsearch cluster

This topic describes how to restart an Elasticsearch cluster. Two restart methods are supported: Restart and Force Restart. You can select a method based on your business scenario.

Precautions

- If the disk usage of an Elasticsearch cluster exceeds 85%, the status of the cluster may become abnormal (indicated by the color yellow or red). In this case, you must perform a forced restart.
- If the cluster is abnormal, we recommend that you do not perform the following operations on the cluster: node addition, node capacity expansion, disk resizing, restart, password reset, and configuration update. Perform these operations only after the status of the cluster becomes normal (indicated by the color green).
- If you update the configuration of an abnormal cluster that contains two or more nodes and the cluster remains in the Initializing state, submit a ticket.
- If a cluster contains only one node, services may become unavailable when you update the cluster configuration, restart or scale out/in the cluster, or reset the password of the cluster. In this case, create another Elasticsearch cluster and migrate your services to the new cluster.

Procedure

1. Log on to the Elasticsearch console.
2. Find the target cluster and click its ID in the **Instance ID/Name** column.
3. On the **Basic Information** page, click **Restart Instance**.
4. In the **Restart Instance** dialog box, select a restart method.
   - **Restart**: This restart method does not affect the services of your cluster but is time-consuming. Before you select this method, make sure that each index of the cluster has a minimum of one replica.
   - **Force Restart**: This restart method may cause unstable services on your cluster but saves time.
5. Click **OK**.

> **Notice** Before the restart, make sure that the cluster is in a normal state. During the restart, the CPU utilization and memory usage of nodes in the cluster experience a surge. This may affect the stability of your services for a short period of time.

10.3.3. Refresh the information of an Elasticsearch cluster

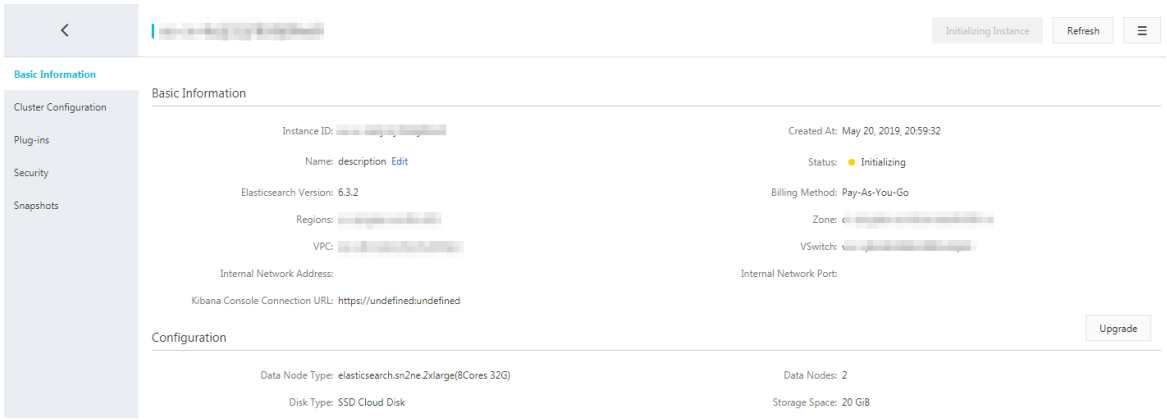
This topic describes how to refresh the information of an Elasticsearch cluster. If part of the information in the console, such as the status of a newly created Elasticsearch cluster, is not refreshed in time, the console may fail to display the information. In this case, you can manually refresh the page to obtain the latest status.

1. Log on to the Elasticsearch console.
2. Find the target cluster and click its ID in the **Instance ID/Name** column.
3. In the upper-right corner of the **Basic Information** page, click **Refresh**.

10.3.4. View the basic information of an Elasticsearch cluster

This topic describes how to view the basic information of an Elasticsearch cluster.

1. Log on to the Elasticsearch console.
2. Find the target cluster and click its ID in the **Instance ID/Name** column.
3. On the **Basic Information** page, view the basic information of the cluster.



Parameter	Description
Instance ID	The unique ID of the cluster.
Created At	The time when the cluster was created.
Name	The name of the cluster. By default, the name of a cluster is the same as its ID. Cluster names are configurable. You can search for clusters by name.
Status	The status of the cluster. A cluster has the following states: **Active** (green), **Initializing** (yellow), **Unhealthy** (red), **Paused** (red), and **Expired** (gray).
Elasticsearch Version	The version of the cluster. Valid values: **5.5.3** and **6.3.2**.
Region	The region where the cluster resides.
Zone	The zone where the cluster resides.

Parameter	Description
VPC	The Virtual Private Cloud (VPC) where the cluster resides.
VSwitch	The VSwitch to which the cluster belongs.
Internal Network Address	The internal endpoint of the cluster. You can use an Elastic Compute Service (ECS) instance to connect to the internal endpoint of the cluster. Make sure that the ECS instance resides in the same VPC as the cluster.
Internal Network Port	The port used to connect to the cluster over an internal network. Elasticsearch supports the following ports: ○ Port 9200 for HTTP ○ Port 9300 for TCP
Kibana Console Connection URL	The URL of the Kibana console of the cluster. You can use an ECS instance to connect to the URL. Make sure that the ECS instance resides in the same VPC as the cluster.

Note You can also view the cluster configuration information on the Basic Information page. The information includes the data node specifications, number of data nodes, disk type, and storage space. You can determine whether to upgrade the cluster configuration based on the information and your business plan.

10.3.5. Upgrade the configuration of an Elasticsearch cluster

Apsara Stack Elasticsearch allows you to upgrade the specifications, storage space per node, and number of nodes for an Elasticsearch cluster. You cannot downgrade the configuration of an Elasticsearch cluster. This topic describes how to upgrade the configuration of an Elasticsearch cluster.

Procedure

1. Log on to the Elasticsearch console.
2. Find the target cluster and click its ID in the **Instance ID/Name** column.
3. In the lower-right corner of the **Basic Information** page, click **Upgrade**.
4. On the **Update Configuration** page, modify the cluster configuration.

   For information about parameters on this page, see Create an Elasticsearch cluster.

> Notice
>
> - For each upgrade, you can modify only one of the following items: specifications, storage space per node, and the number of nodes.
> - If your business requires a cluster configuration upgrade, evaluate your Elasticsearch cluster before the upgrade.

5. Click **Confirm Change**.

10.3.6. Configure an Elasticsearch cluster

10.3.6.1. Configure synonyms

You can configure synonyms for the synonym dictionary of an Apsara Stack Elasticsearch cluster. After you configure a tokenizer, new indexes in the cluster are tokenized based on the latest synonym dictionary. This topic describes how to configure synonyms.

Description

> Notice
>
> - After you upload a synonym dictionary file to an Elasticsearch cluster, the system does not restart the cluster. The system sends the synonym dictionary file to all nodes in the cluster. The time that is required for the file to take effect depends on the number of nodes in the cluster.
> - For example, the index-aliyun index is created based on the aliyun.txt synonym dictionary file. If you have uploaded a new synonym dictionary file to overwrite the existing aliyun.txt file, the index-aliyun index cannot automatically load the new dictionary file. If you want the index to automatically load the new dictionary file, we recommend that you disable the index before the upload and then enable the index after the upload. If an index that is created before the uploaded synonym dictionary file takes effect needs to use synonyms, you must reindex the data in the index and configure synonyms.

You can use a filter to configure synonyms. Sample code:

```
PUT /test_index
{
  "settings": {
    "index" : {
      "analysis" : {
        "analyzer" : {
          "synonym" : {
            "tokenizer" : "whitespace",
            "filter" : ["synonym"]
            }
          },
          "filter" : {
            "synonym" : {
              "type" : "synonym",
               "synonyms_path" : "analysis/synonym.txt",
               "tokenizer" : "whitespace"
             }
           }
         }
        }
     }
}
```

- `filter` : specifies a `synonym` filter that contains the `analysis/synonym.txt` path. This path indicates the location of config.
- `tokenizer` : specifies a tokenizer that tokenizes synonyms. It is set to `whitespace` by default. Additional settings:
  - `ignore_case` : The default value is false.
  - `expand` : The default value is true.

Two synonym formats are supported: Solr and WordNet.

- Solr synonyms

  Configuration example:

```
# Blank lines and lines starting with pound are comments.
# Explicit mappings match any token sequence on the LHS of "=>"
# and replace with all alternatives on the RHS.  These types of mappings
# ignore the expand parameter in the schema.
# Examples:
i-pod, i pod => ipod,
sea biscuit, sea biscit => seabiscuit
# Equivalent synonyms may be separated with commas and give
# no explicit mapping.  In this case the mapping behavior will
# be taken from the expand parameter in the schema.  This allows
# the same synonym file to be used in different synonym handling strategies.
# Examples:
ipod, i-pod, i pod
foozball , foosball
universe , cosmos
lol, laughing out loud
# If expand==true, "ipod, i-pod, i pod" is equivalent
# to the explicit mapping:
ipod, i-pod, i pod => ipod, i-pod, i pod
# If expand==false, "ipod, i-pod, i pod" is equivalent
# to the explicit mapping:
ipod, i-pod, i pod => ipod
# Multiple synonym mapping entries are merged.
foo => foo bar
foo => baz
# is equivalent to
foo => foo bar, baz
```

You can also define synonyms in the filter, but you must use `synonyms` rather than `synonyms_path`. Example:

```
PUT /test_index
{
  "settings": {
    "index" : {
      "analysis" : {
        "filter" : {
          "synonym" : {
            "type" : "synonym",
            "synonyms" : [
              "i-pod, i pod => ipod",
              "begin, start"
            ]
          }
        }
      }
    }
}
```

We recommend that you use `synonyms_path` to define large synonym sets in the filter. Using `synonyms` to define large synonym sets increases the size of your cluster.

- WordNet synonyms

  Configuration example:

```
PUT /test_index
{
  "settings": {
    "index" : {
      "analysis" : {
        "filter" : {
          "synonym" : {
            "type" : "synonym",
            "format" : "wordnet",
            "synonyms" : [
              "s(100000001,1,'abstain',v,1,0).",
              "s(100000001,2,'refrain',v,1,0).",
              "s(100000001,3,'desist',v,1,0)."
            ]
          }
        }
      }
    }
  }
}
```

You can also use `synonyms_path` to define WordNet synonyms.

Use a synonym dictionary file to configure synonyms

1. Log on to the Elasticsearch console.
2. Find the target cluster and click its ID in the **Instance ID/Name** column.
3. In the left-side navigation pane of the page that appears, click **Cluster Configuration**.
4. Upload a synonym dictionary file.
   i. Click **Synonym Dictionary Configuration**.
   ii. In the **Synonym Dictionary Configuration** pane, select the mode to upload a synonym dictionary file and click **Upload**. Then, select the .txt file that is generated based on the preceding rules.
   iii. Click **Save**.

   After the state of the Elasticsearch cluster becomes Active, you can use the synonym dictionary file. In this example, the `aliyun_synonyms.txt` file is uploaded. The file contains `begin, start` .
5. Configure and test the synonym dictionary.
   i. Log on to the Kibana console.

   For more information, see Log on to the Kibana console.
   ii. In the left-side navigation pane, click **Dev Tools**.

iii. On the **Console** tab, run the following command to create an index:

```
PUT aliyun-index-test
{
"index": {
 "analysis": {
  "analyzer": {
   "by_smart": {
    "type": "custom",
    "tokenizer": "ik_smart",
    "filter": ["by_tfr","by_sfr"],
    "char_filter": ["by_cfr"]
   },
   "by_max_word": {
    "type": "custom",
    "tokenizer": "ik_max_word",
    "filter": ["by_tfr","by_sfr"],
    "char_filter": ["by_cfr"]
   }
  },
  "filter": {
   "by_tfr": {
    "type": "stop",
    "stopwords": [" "]
   },
   "by_sfr": {
    "type": "synonym",
    "synonyms_path": "analysis/aliyun_synonyms.txt"
   }
  },
  "char_filter": {
   "by_cfr": {
    "type": "mapping",
    "mappings": ["| => |"]
   }
  }
 }
}
}
```

iv. Run the following command to configure the title synonym field:

```
PUT aliyun-index-test/_mapping/doc
{
"properties": {
 "title": {
   "type": "text",
   "index": "analyzed",
   "analyzer": "by_max_word",
   "search_analyzer": "by_smart"
 }
}
}
```

v. Run the following command to verify synonyms:

```
GET aliyun-index-test/_analyze
{
"analyzer": "by_smart",
"text":"begin"
}
```

If the command is successfully executed, the following result is returned:

```
{
"tokens": [
 {
   "token": "begin",
   "start_offset": 0,
   "end_offset": 5,
   "type": "ENGLISH",
   "position": 0
 },
 {
   "token": "start",
   "start_offset": 0,
   "end_offset": 5,
   "type": "SYNONYM",
   "position": 0
 }
]
}
```

vi. Run the following commands to add data for further testing:

```
PUT aliyun-index-test/doc/1
{
"title": "Shall I begin?"
}
```

```
PUT aliyun-index-test/doc/2
{
"title": "I start work at nine."
}
```

vii. Run the following command to perform a query test:

```
GET aliyun-index-test/_search
{
 "query" : { "match" : { "title" : "begin" }},
 "highlight" : {
    "pre_tags" : ["<red>", "<bule>"],
    "post_tags" : ["</red>", "</bule>"],
    "fields" : {
       "title" : {}
    }
 }
}
```

If the command is successfully executed, the following result is returned:

```
{
"took": 11,
"timed_out": false,
"_shards": {
 "total": 5,
 "successful": 5,
 "failed": 0
},
"hits": {
 "total": 2,
 "max_score": 0.41048482,
 "hits": [
  {
    "_index": "aliyun-index-test",
    "_type": "doc",
    "_id": "2"
```

```
    "_id": "2",
    "_score": 0.41048482,
    "_source": {
      "title": "I start work at nine."
    },
    "highlight": {
      "title": [
        "I <red>start</red> work at nine."
      ]
    }
  },
  {
    "_index": "aliyun-index-test",
    "_type": "doc",
    "_id": "1",
    "_score": 0.39556286,
    "_source": {
      "title": "Shall I begin?"
    },
    "highlight": {
      "title": [
        "Shall I <red>begin</red>?"
      ]
    }
  }
 ]
}
}
```

Reference synonyms and use the IK dictionary for word splitting

1. Configure the `my_synonym_filter` synonym filter and a synonym dictionary.
2. Configure the `my_synonyms` analyzer and use the `ik_smart` IK analyzer to split words.

   The `ik_smart` IK analyzer splits words and converts all letters into lowercase.

```
PUT /my_index
{
 "settings": {
    "analysis": {
       "analyzer": {
          "my_synonyms": {
             "filter": [
                "lowercase",
                "my_synonym_filter"
             ],
             "tokenizer": "ik_smart"
          }
       },
       "filter": {
          "my_synonym_filter": {
             "synonyms": [
                "begin,start"
             ],
             "type": "synonym"
          }
       }
    }
 }
}
```

3. Run the following command to configure the title synonym field:

```
PUT /my_index/_mapping/doc
{
"properties": {
 "title": {
   "type": "text",
   "index": "analyzed",
   "analyzer": "my_synonyms"
 }
}
}
```

4. Run the following command to verify synonyms:

```
GET /my_index/_analyze
{
 "analyzer":"my_synonyms",
 "text":"Shall I begin?"
}
```

If the command is successfully executed, the following result is returned:

```
{
"tokens": [
 {
  "token": "shall",
  "start_offset": 0,
  "end_offset": 5,
  "type": "ENGLISH",
  "position": 0
 },
 {
  "token": "i",
  "start_offset": 6,
  "end_offset": 7,
  "type": "ENGLISH",
  "position": 1
 },
 {
  "token": "begin",
  "start_offset": 8,
  "end_offset": 13,
  "type": "ENGLISH",
  "position": 2
 },
 {
  "token": "start",
  "start_offset": 8,
  "end_offset": 13,
  "type": "SYNONYM",
  "position": 2
 }
]
}
```

5. Run the following commands to add data for further testing:

```
PUT /my_index/doc/1
{
"title": "Shall I begin?"
}
```

```
PUT /my_index/doc/2
{
"title": "I start work at nine."
}
```

6. Run the following command to perform a query test:

```
GET /my_index/_search
{
"query" : { "match" : { "title" : "begin" }},
"highlight" : {
 "pre_tags" : ["<red>", "<bule>"],
 "post_tags" : ["</red>", "</bule>"],
 "fields" : {
    "title" : {}
 }
}
}
```

If the command is successfully executed, the following result is returned:

```
{
"took": 11,
"timed_out": false,
"_shards": {
 "total": 5,
 "successful": 5,
 "failed": 0
},
"hits": {
 "total": 2,
 "max_score": 0.41913947,
 "hits": [
  {
   "_index": "my_index",
   "_type": "doc",
   "_id": "2"
```

```
    "_id": "2",
    "_score": 0.41913947,
    "_source": {
      "title": "I start work at nine."
    },
    "highlight": {
      "title": [
        "I <red>start</red> work at nine."
      ]
    }
  },
  {
    "_index": "my_index",
    "_type": "doc",
    "_id": "1",
    "_score": 0.39556286,
    "_source": {
      "title": "Shall I begin?"
    },
    "highlight": {
      "title": [
        "Shall I <red>begin</red>?"
      ]
    }
  }
 ]
}
}
```

10.3.6.2. Perform configurations on YML files

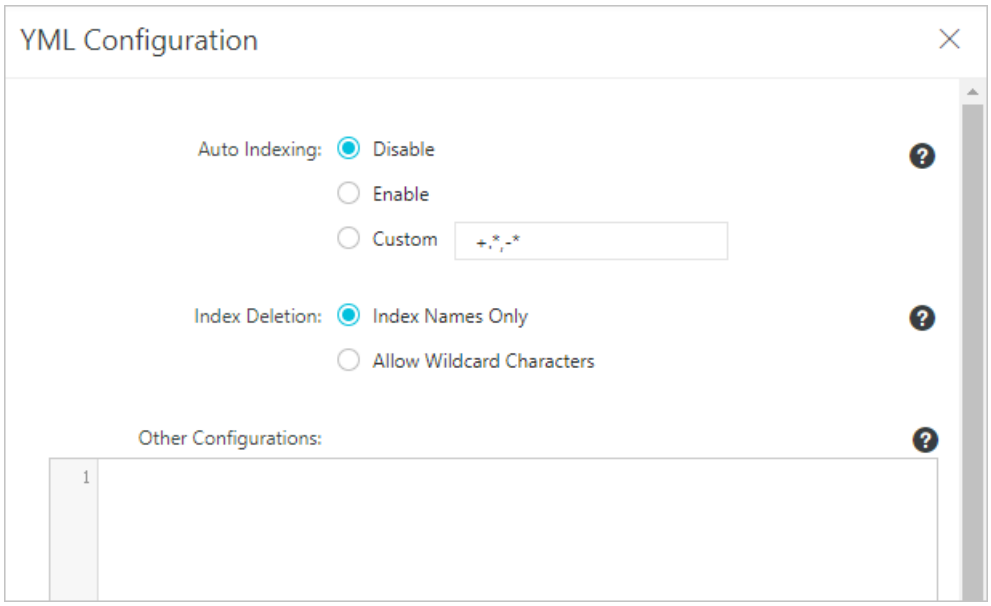
10.3.6.2.1. Configure a YML file

The YML file contains the configuration of an Elasticsearch cluster. You can use the file to modify the configuration of the cluster. This topic describes how to configure a YML file.

Procedure

1. Log on to the Elasticsearch console.
2. Find the target cluster and click its ID in the **Instance ID/Name** column.
3. In the left-side navigation pane of the page that appears, click **Cluster Configuration**.
4. On the page that appears, click **Modify Configuration** on the right side of **YML Configuration**.

5. In the **YML Configuration** pane, specify the required parameters.



Parameter	Description
Auto Indexing	This parameter specifies whether to automatically create an index when a new document is uploaded to an Elasticsearch cluster but no index has been created. Valid values: ○ Disable: The system does not automatically create an index. This value is the default value. ○ Enable: The system automatically creates an index. **Notice** We recommend that you disable Auto Indexing because indexes created by this feature may not meet your business requirements. ○ Custom: The system automatically creates a custom index. For example, if you specify `-an*,+a,-*`, the system automatically creates only indexes whose names start with a, except indexes whose names start with an.
Index Deletion	○ Index Names Only: When you delete an index, you must specify its name. ○ Allow Wildcard Characters: You can use wildcards to delete multiple indexes at a time. **Notice** You cannot restore the indexes that have been deleted. Exercise caution when you specify this parameter.

Parameter	Description
Other Configurations	The following content lists some supported configuration items. For more information, see YML configuration parameters. ○ http.cors.enabled ○ http.cors.allow-origin ○ http.cors.max-age ○ http.cors.allow-methods ○ http.cors.allow-headers ○ http.cors.allow-credentials ○ reindex.remote.whitelist ○ action.auto_create_index ○ action.destructive_requires_name Notice You can reindex data from a remote Elasticsearch cluster that is specified in a remote reindex whitelist. You can reindex data from all versions of remote Elasticsearch clusters. This feature allows you to migrate index data from an Elasticsearch cluster of an earlier version to an Elasticsearch cluster of the newly released version. For more information, see Reindex data from a remote Elasticsearch cluster.

10.3.6.2.2. YML configuration parameters

This topic describes the YML configuration parameters supported by Elasticsearch. These configuration parameters support only the static configuration mode but not the hot deployment mode. For configurations to take effect, you must add the configurations to the elasticsearch.yml file.

Parameters

Parameter	Description

Parameter	Description
http.cors.enabled	The cross-origin resource sharing (CORS) configuration item. This item is used to specify whether to allow browsers on other origins to access Elasticsearch. • If you set the value to `true`, CORS is enabled, and Elasticsearch can process `OPTIONS CORS` requests. • If the origin in a request is declared in `http.cors.allow-origin`, Elasticsearch returns a response that has the `Access-Control-Allow-Origin` header included. • The default value is `false`. If you set the value to `false`, CORS is disabled. In this case, Elasticsearch ignores the origin in the request header and returns a response that does not have the `Access-Control-Allow-Origin` header included. • If a client cannot send a pre-flight request that has origin information included in the request header or does not verify the `Access-Control-Allow-Origin` header in the response that is returned from the server, the cross-origin security is compromised. • If CORS is disabled for Elasticsearch, a client can send only an OPTIONS request to check whether the Access-Control-Allow-Origin header exists.
http.cors.allow-origin	The origin configuration item. This item specifies the origins from which requests are allowed. By default, no origins are allowed. • If you add a forward slash (`/`) to the start and end of the value, this item is considered as a regular expression. • This allows you to use regular expressions to support HTTP and HTTPS requests. For example, `/https?:\/\/localhost(:[0-9]+)?/` indicates that Elasticsearch responds to all requests that match the regular expression. • The asterisk (`*`) is a valid character but considered as a security risk. This is because the asterisk indicates that an Elasticsearch cluster is open to all origins. We recommend that you do not use asterisks.
http.cors.max-age	Browsers can send OPTIONS requests to query the CORS configuration. This item specifies the cache time of the retrieved CORS configuration. The default value is 1728000 seconds (20 days).
http.cors.allow-methods	The item that is used to configure the request method. Valid values: `OPTIONS, HEAD, GET, POST, PUT, and DELETE`.
http.cors.allow-headers	The item that is used to configure the request header. Valid values: `X-Requested-With, Content-Type, and Content-Length`.

Parameter	Description
http.cors.allow-credentials	The credential configuration item. This item specifies whether Elasticsearch is allowed to return the `Access-Control-Allow-Credentials` header. If you set the value to `true`, Elasticsearch is allowed to return the header. The default value is `false`.
reindex.remote.whitelist	The remote reindex whitelist of the current cluster. This whitelist contains the addresses of remote hosts that can be used to access the current cluster. An address in the whitelist can be a combination of host and port. Separate the configurations of multiple hosts with commas (,), such as `otherhost:9200,another:9200,127.0.10.**:9200,localhost:**`. You can use only the host and port to configure security policies because the whitelist ignores the protocol information.
action.auto_create_index	The configuration item for auto index creation. If you set the value to `false`, the auto index creation feature is disabled.
action.destructive_requires_name	This item specifies whether to specify the name of an index when you delete the index. The default value is `false`. If you set the value to false, you can use a regular expression or the `_all` parameter to delete indexes. If you set the value to `true`, you must specify the names of the indexes you want to delete. In this case, you cannot use `_all` or wildcards.

10.3.6.2.3. Reindex data from a remote Elasticsearch cluster

This topic describes how to reindex data from a remote Elasticsearch cluster that is specified in a remote reindex whitelist. This feature is applicable to all versions of remote Elasticsearch clusters. It allows you to reindex data from an Elasticsearch cluster of an earlier version to an Elasticsearch cluster of the newly released version.

You can call the reindex operation to reindex data. Example:

```
POST _reindex
{
 "source": {
  "remote": {
   "host": "http://otherhost:9200",
   "username": "user",
   "password": "pass"
  },
  "index": "source",
  "query": {
   "match": {
    "test": "data"
   }
  }
 },
 "dest": {
  "index": "dest"
 }
}
```

Note Reindexing from a remote cluster does not support manual slicing or automatic slicing.

- The value of the `host` parameter must include the protocol, domain name, and port number, such as http://otherhost:9200.
- `username` and `password` are optional. If the remote Elasticsearch cluster needs to use the basic authorization scheme, specify the username and password. If you use the basic authorization scheme, we recommend that you use the HTTPS protocol. Otherwise, the password is transmitted as a text.
- The reindex operation can be called remotely only after the remote host address is declared in the *elasticsearch.yaml* configuration file by using the `reindex.remote.whitelist` attribute. `reindex.remote.whitelist` can use host-port pairs. Separate multiple pairs with commas (,), such as, otherhost:9200, another:9200, 127.0.10.**:9200, localhost:**. You can use only the host and port to configure security policies because the whitelist ignores the protocol information.
- If the host is already added to the whitelist, the query is directly sent to the remote Elasticsearch cluster without verification or modification.

Indexing from a remote Elasticsearch cluster uses on-heap buffer. The default maximum batch size is 100 MB. If the index on the remote cluster contains large documents, you must adjust the batch size to a small value.

In the following example, the batch size is 10, which is the minimum value.

```
POST _reindex
{
 "source": {
  "remote": {
   "host": "http://otherhost:9200"
  },
  "index": "source",
  "size": 10,
  "query": {
   "match": {
    "test": "data"
   }
  }
 },
 "dest": {
  "index": "dest"
 }
}
```

- `socket_timeout` is used to set the timeout period for socket read. The default value is 30s.
- `connect_timeout` is used to set the connection timeout period. The default value is 1s.

In the following example, socket_timeout is set to 1m and connect_timeout is set to 10s.

```
POST _reindex
{
 "source": {
  "remote": {
   "host": "http://otherhost:9200",
   "socket_timeout": "1m",
   "connect_timeout": "10s"
  },
  "index": "source",
  "query": {
   "match": {
    "test": "data"
   }
  }
 },
 "dest": {
  "index": "dest"
 }
}
```

10.3.7. Configure plug-ins

Plug-ins extend the capabilities of Apsara Stack Elasticsearch in data pre-processing and analytics. You can use built-in plug-ins or upload custom plug-ins based on your requirements. This topic describes how to configure a plug-in.

Go to the plug-in configuration page

1. Log on to the Elasticsearch console.
2. Find the target cluster and click its ID in the **Instance ID/Name** column.
3. In the left-side navigation pane, click **Plug-ins**.

Built-in plug-ins

The following table lists the built-in plug-ins for Elasticsearch on the Plug-ins page.

Plug-in	Description
analysis-icu	The ICU analysis plug-in for Elasticsearch. This plug-in integrates the ICU module of Lucene into Elasticsearch and adds ICU analysis components.
analysis-ik	The IK analysis plug-in for Elasticsearch.

Plug-in	Description
analysis-kuromoji	The Japanese (Kuromoji) analysis plug-in for Elasticsearch. This plug-in integrates the Kuromoji analysis module of Lucene into Elasticsearch.
analysis-phonetic	The phonetic analysis plug-in for Elasticsearch. This plug-in integrates the phonetic token filter into Elasticsearch.
analysis-pinyin	The pinyin analysis plug-in for Elasticsearch.
analysis-smartcn	The smart Chinese analysis plug-in for Elasticsearch. This plug-in integrates the smart Chinese analysis module of Lucene into Elasticsearch.
elasticsearch-repository-oss	The plug-in allows you to use Apsara Stack Object Storage Service (OSS) to store Elasticsearch snapshots.
gab-paas-plugin	None.
ingest-attachment	The ingest processor for Elasticsearch. This plug-in uses Apache Tika to extract content.
ingest-geoip	The ingest processor for Elasticsearch. This plug-in queries geographic data in MaxMind databases based on IP addresses.
ingest-user-agent	The ingest processor for Elasticsearch. This plug-in extracts information from a user agent.
mapper-murmur3	When you create an index and store these values in the index, this plug-in allows you to compute the hash values of fields.
mapper-size	This plug-in allows you to take note of the sizes of documents before they are compressed when you create an index.
repository-hdfs	This plug-in provides support for Hadoop Distributed File System (HDFS) repositories.
search-guard-6	This plug-in provides the access control feature for Elasticsearch.

The analysis-ik plug-in allows you to use the standard update or rolling update method to update IK dictionaries. For more information, see Standard update of IK dictionaries and Rolling update of IK dictionaries.

Standard update of IK dictionaries

The standard update method requires Elasticsearch to perform a rolling restart for an Elasticsearch cluster to update dictionaries. Elasticsearch sends the uploaded dictionary file to all nodes in the cluster, modifies the `IKAnalyzer.cfg.xml` file, and then restarts the nodes to load the file.

You can use the standard update method to update the IK main dictionary and stopword list. In the standard update pane, you can check the built-in main dictionary `SYSTEM_MAIN.dic` and the built-in stopword list `SYSTEM_STOPWORD.dic`.

- If you want to update the built-in main dictionary, upload a dictionary file named `SYSTEM_MAIN.dic`.
- If you want to update the built-in stopword list, upload a dictionary file named `SYSTEM_STOPWORD.dic`.

1. Go to the plug-in configuration page.
2. On the page that appears, find the analysis-ik plug-in and click **Standard Update** in the Actions column.
3. In the **Plug-ins** pane, click **Configure**.
4. Click **Upload DIC File** and select a local file to upload.

   > Note
   > - By default, a .dic file needs to be uploaded. You can also choose to upload an OSS file.
   > - If the content of a dictionary stored in OSS changes, you must manually upload the dictionary file again.

5. In the lower part of the pane, select **This operation will restart the instance. Continue?** and click **Save**.

   Then, the system performs a rolling start for the Elasticsearch cluster.

6. After the cluster is restarted, log on to the Kibana console of the Elasticsearch cluster and run the following command to check whether the new dictionaries take effect.

   For more information about how to log on to the Kibana console, see Use the Kibana console to access an Elasticsearch cluster.

   ```
   GET _analyze
   {
   "analyzer": "ik_smart",
   "text": ["Tokens in the new dictionaries"]
   }
   ```

   > Note
   > - You cannot delete the built-in main dictionary and stopword list.
   > - The standard update operation requires Elasticsearch to perform a rolling restart for the cluster.
   > - You can perform the standard update operation only when the cluster is healthy.

Rolling update of IK dictionaries

If the content of a dictionary file changes, you can use this method to update the dictionaries on all nodes in an Elasticsearch cluster. After you upload the latest dictionary file, all nodes in the Elasticsearch cluster automatically load the file.

If the dictionary file list changes when you perform a rolling update, the system performs a rolling restart for your Elasticsearch cluster to reload the dictionary configuration. For example, when you upload a new dictionary file or delete an existing dictionary file, the changes are synchronized to the `IKAnalyzer.cfg.xml` file.

The procedure of a rolling update is similar to that of a standard update. If you upload a dictionary file for the first time, you must modify the `IKAnalyzer.cfg.xml` file. Elasticsearch needs to perform a rolling restart to reload the configuration file. Subsequently, if you upload a dictionary file with the same name, Elasticsearch does not perform a rolling restart for the update to take effect.

1. Go to the plug-in configuration page.
2. On the page that appears, find the analysis-ik plug-in and click **Rolling Update** in the Actions column.
3. In the **Plug-ins** pane, click **Configure**.
4. Click **Upload DIC File** and select a local file to upload.

   > **Note**
   > - By default, a .dic file needs to be uploaded. You can also choose to upload an OSS file.
   > - If the content of a dictionary stored in OSS changes, you must manually upload the dictionary file again.

5. In the lower part of the pane, select **This operation will restart the instance. Continue?** and click **Save**.

   After you click Save, the system performs a rolling restart for the cluster. After the cluster is restarted, the new dictionaries take effect.

If you want to add tokens to or remove tokens from the new dictionaries, perform the following steps to modify the `a_10words.dic` file: In the rolling update pane, delete the existing `a_10words.dic` file and upload a new dictionary file. The new dictionary file must have the same name. This operation changes the content of the existing dictionary file in the cluster and uploads a new file that has the same name. Elasticsearch does not need to perform a rolling restart on the cluster for the update to take effect. You can directly click **Save**.

The analysis-ik plug-in on the nodes of the Elasticsearch cluster automatically loads the dictionary file. The time that is required to load the dictionary file varies depending on the nodes. It requires about two minutes for all nodes to load the dictionary file. To verify the new dictionaries, you can log on to the Kibana console of the Elasticsearch cluster and run the following command multiple times:

```
GET _analyze
{
"analyzer": "ik_smart",
"text": ["Tokens in the new dictionaries"]
}
```

> **Note** You cannot use the rolling update method to modify the built-in main dictionary. If you want to modify the built-in main dictionary, you must use the standard update method.

10.3.8. Configure security settings

You can reset the password of your Elasticsearch cluster, modify the Kibana whitelist, and modify the VPC whitelist. This topic describes how to configure security settings.

Go to the security configuration page

1. Log on to the Elasticsearch console.
2. Find the target cluster and click its ID in the **Instance ID/Name** column.
3. In the left-side navigation pane, click **Security**.

Reset the password of an Elasticsearch cluster

> **Notice** This operation only resets the password of the elastic account. We recommend that you do not use the elastic account to log on to your Elasticsearch cluster.

1. Go to the security configuration page.
2. Click **Reset** next to **Elasticsearch Instance Password**.
3. In the **Reset** pane, enter a new password and confirm the password.
4. Click **OK**.

   Then, the new password takes effect within about five minutes. The new password will be used to log on to the Kibana console and access the Elasticsearch cluster.

   > **Note** The password reset does not restart the Elasticsearch cluster.

Modify a Kibana whitelist

1. Go to the security configuration page.
2. Click **Update** next to **Kibana Whitelist**.
3. In the **Edit Kibana Whitelist** pane, enter IP addresses.

   You can enter both IP addresses and CIDR blocks. For example, enter `192.168.0.1` or `192.168.0.0/24`. Separate multiple IP addresses or CIDR blocks with commas (,). You can enter `127.0.0.1` to deny requests from all IPv4 addresses or enter `0.0.0.0/0` to allow requests from all IPv4 addresses.

   If your Elasticsearch cluster is deployed in the China (Hangzhou) region, you can add IPv6 addresses to the whitelist. For example, enter `2401:b180:1000:24::5` or `2401:b180:1000::/48`. Enter `::1` to deny requests from all IPv6 addresses or `::/0` to allow requests from all IPv6 addresses.

> Note You can use only a server that resides in the same VPC as your Elasticsearch cluster to log on to the Kibana console.

4. Click **OK**.

Modify a VPC whitelist

1. Go to the security configuration page.
2. Click **Update** next to **VPC Whitelist**.
3. In the **Edit VPC Whitelist** pane, enter IP addresses.

   You can enter both IP addresses and CIDR blocks. For example, enter `192.168.0.1` or `192.168.0.0/24`. Separate multiple IP addresses or CIDR blocks with commas (,). You can enter `127.0.0.1` to deny requests from all IPv4 addresses or enter `0.0.0.0/0` to allow requests from all IPv4 addresses.

   > Note
   > - By default, requests from all IPv4 addresses within the VPC in which the Elasticsearch cluster resides are allowed.
   > - The VPC whitelist is used to control access from IP addresses within VPCs.

4. Click **OK**.

10.3.9. Back up data

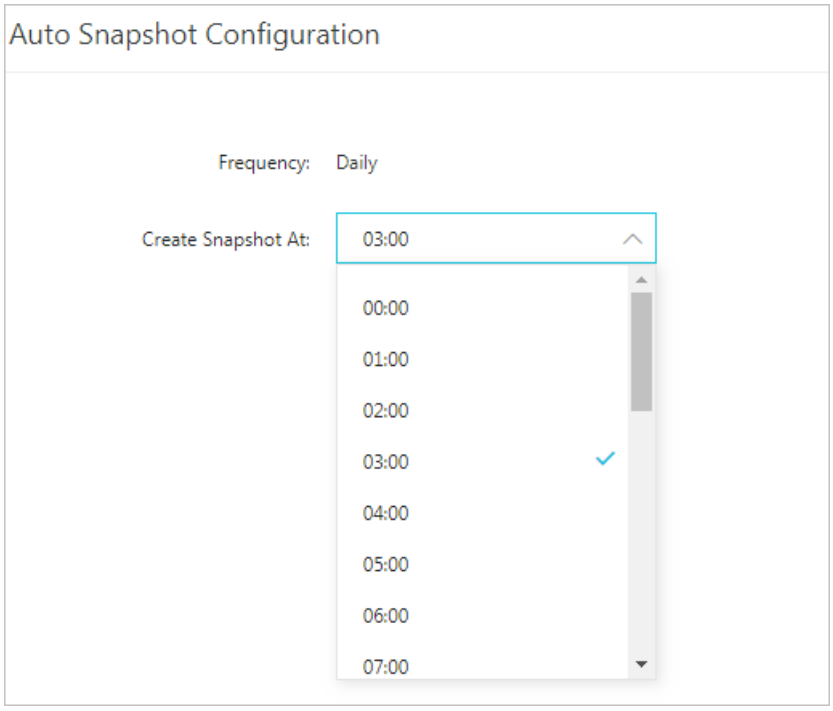
10.3.9.1. Enable and configure the auto snapshot feature

The auto snapshot feature allows you to specify the snapshot creation period and time. After you specify them, the system automatically creates snapshots. This topic describes how to enable and configure the auto snapshot feature.

1. Log on to the Elasticsearch console.
2. Find the target cluster and click its ID in the **Instance ID/Name** column.
3. In the left-side navigation pane, click **Snapshots**.
4. Turn on the **Auto Snapshot** switch. This switch is turned on by default.

   > Notice After the auto snapshot feature is enabled, the system uses the system time of the region where your Elasticsearch cluster resides to create snapshots. Do not perform snapshot operations when the system is creating snapshots.

5. Click **Modify Configuration** on the right side of **Snapshots (Free Trial)**.
6. In the **Auto Snapshot Configuration** pane, set **Create Snapshot At**.



- **Frequency**: The value of this parameter is Daily.
- **Create Snapshot At**: specifies the hour for creating a snapshot every day. Valid values: 00:00 to 23:00.

7. Click **Save**.

10.3.9.2. Query snapshot status

After you enable the auto snapshot feature, you can call the snapshot operation to query the status of snapshots. This topic describes how to query the status of snapshots.

> **Note** You can run all the commands provided in this topic in the Kibana console. For information about how to log on to the Kibana console, see Access an Elasticsearch cluster.

Query all snapshots

Run the following command to query information about all snapshots that are stored in the aliyun_auto_snapshot repository:

```
GET _snapshot/aliyun_auto_snapshot/_all
```

If the command is successfully executed, the following result is returned:

```
{
 "snapshots": [
  {
   "snapshot": "<yourSnapshotName>",
   "uuid": "n7YIayyZTm2hwg8BeW****",
   "version_id": 5050399,
```

```
    "version": "5.5.3",
    "indices": [
      ".kibana"
    ],
    "state": "SUCCESS",
    "start_time": "2018-06-28T01:22:39.609Z",
    "start_time_in_millis": 1530148959609,
    "end_time": "2018-06-28T01:22:39.923Z",
    "end_time_in_millis": 1530148959923,
    "duration_in_millis": 314,
    "failures": [],
    "shards": {
      "total": 1,
      "failed": 0,
      "successful": 1
    }
  },
  {
    "snapshot": "<yourSnapshotName>",
    "uuid": "frdl1YFzQ5Cn5xN9ZW****",
    "version_id": 5050399,
    "version": "5.5.3",
    "indices": [
      ".kibana"
    ],
    "state": "SUCCESS",
    "start_time": "2018-06-28T01:25:00.764Z",
    "start_time_in_millis": 1530149100764,
    "end_time": "2018-06-28T01:25:01.482Z",
    "end_time_in_millis": 1530149101482,
    "duration_in_millis": 718,
    "failures": [],
    "shards": {
      "total": 1,
      "failed": 0,
      "successful": 1
    }
  }
 ]
}
```

The state field indicates the status of a snapshot. A snapshot can be in one of the following states:

- `IN_PROGRESS` : The snapshot is being created.
- `SUCCESS` : The snapshot is created, and all shards are stored.
- `FAILED` : The snapshot fails to be created because some shards cannot be stored.
- `PARTIAL` : The snapshot is created, but a minimum of one shard fails to be stored.
- `INCOMPATIBLE` : The snapshot is incompatible with the Elasticsearch cluster version.

Query a specified snapshot

Run the following command to query information about a specified snapshot that is stored in the aliyun_auto_snapshot repository:

```
GET _snapshot/aliyun_auto_snapshot/<snapshot>/_status
```

Replace `<snapshot>` with the name of the snapshot, such as `<yourSnapshotName>` .

If the command is successfully executed, the following result is returned:

```
{
 "snapshots": [
  {
   "snapshot": "<yourSnapshotName>",
   "repository": "aliyun_auto_snapshot",
   "uuid": "n7YIayyZTm2hwg8BeWbydA",
   "state": "SUCCESS",
   "shards_stats": {
    "initializing": 0,
    "started": 0,
    "finalizing": 0,
    "done": 1,
    "failed": 0,
    "total": 1
   },
   "stats": {
    "number_of_files": 4,
    "processed_files": 4,
    "total_size_in_bytes": 3296,
    "processed_size_in_bytes": 3296,
    "start_time_in_millis": 1530148959688,
    "time_in_millis": 77
   },
   "indices": {
```

```
    ".kibana": {
     "shards_stats": {
      "initializing": 0,
      "started": 0,
      "finalizing": 0,
      "done": 1,
      "failed": 0,
      "total": 1
     },
     "stats": {
      "number_of_files": 4,
      "processed_files": 4,
      "total_size_in_bytes": 3296,
      "processed_size_in_bytes": 3296,
      "start_time_in_millis": 1530148959688,
      "time_in_millis": 77
     },
     "shards": {
      "0": {
       "stage": "DONE",
       "stats": {
        "number_of_files": 4,
        "processed_files": 4,
        "total_size_in_bytes": 3296,
        "processed_size_in_bytes": 3296,
        "start_time_in_millis": 1530148959688,
        "time_in_millis": 77
       }
      }
     }
    }
   }
 ]
}
```

10.3.9.3. Restore data from automatic snapshots

If you enable the auto snapshot feature for an Elasticsearch cluster, the system creates snapshots for the cluster every day. You can call the restore operation to restore data to the cluster from the created snapshots. This topic describes how to restore data from automatic snapshots.

> **Note** You can run all the commands provided in this topic in the Kibana console. For information about how to log on to the Kibana console, see Access an Elasticsearch cluster.

Background information

- The first snapshot is a full copy of the data in an Elasticsearch cluster. Subsequent snapshots store only incremental data. Therefore, it requires longer time to create the first snapshot than a subsequent snapshot.
- The system stores automatic snapshots that are created only within the last five days.
- A snapshot does not store monitoring data generated by an Elasticsearch cluster, such as indexes with the prefix `.monitoring` or `.security_audit`.
- An automatic snapshot repository is created when the first snapshot is created.

Query all snapshot repositories

Run the following command to query all snapshot repositories:

```
GET _snapshot
```

If the command is successfully executed, the following result is returned:

```
{
 "aliyun_auto_snapshot": {
  "type": "oss",
  "settings": {
   "compress": "true",
   "base_path": "xxxx",
   "endpoint": "xxxx"
  }
 }
}
```

- aliyun_auto_snapshot: the name of the repository.
- type: the storage where snapshots are stored.
- compress: indicates whether compression is enabled. The value true indicates that the metadata of indexes is compressed during snapshot creation.
- base_path: the location of snapshots in Object Storage Service (OSS).
- endpoint: the endpoint of the OSS bucket.

The auto snapshot feature also supports the following default parameters that are not displayed:

- `max_snapshot_bytes_per_sec:40mb` : The maximum speed for snapshot creation on a single node is 40 MB/s.
- `max_restore_bytes_per_sec:40mb` : The maximum speed for data restoration on a single node is 40 MB/s.
- `chunk_size: Max 1Gb` : During snapshot creation, a large index is divided into multiple parts. The maximum size of each part is 1 GB.

Query all snapshots

Run the following command to query information about all snapshots that are stored in the aliyun_auto_snapshot repository:

```
GET _snapshot/aliyun_auto_snapshot/_all
```

If the command is successfully executed, the following result is returned:

```
{
 "snapshots": [
  {
   "snapshot": "<yourSnapshotName>",
   "uuid": "MMRniVLPRAiawSCm8D****",
   "version_id": 5050399,
   "version": "5.5.3",
   "indices": [
    "index_1",
    ".security",
    ".kibana"
   ],
   "state": "SUCCESS",
   "start_time": "2018-06-27T01:16:01.009Z",
   "start_time_in_millis": 1530062161009,
   "end_time": "2018-06-27T01:16:05.632Z",
   "end_time_in_millis": 1530062165632,
   "duration_in_millis": 4623,
   "failures": [],
   "shards": {
    "total": 12,
    "failed": 0,
    "successful": 12
   }
  }
 ]
}
```

Restore indexes from a snapshot

You can call the `_restore` operation to restore indexes from snapshots.

- Run the following command to restore all indexes from a specified snapshot that is stored in the aliyun_auto_snapshot repository. The restoration task is executed at the backend.

  ```
  POST _snapshot/aliyun_auto_snapshot/<snapshot>/_restore
  ```

  Replace `<snapshot>` with the name of the snapshot, such as `<yourSnapshotName>`.

- Run the following command to restore all indexes from a specified snapshot that is stored in the aliyun_auto_snapshot repository. Then, wait until the restoration task is complete.

The `_restore` operation runs restoration tasks asynchronously. An Elasticsearch cluster immediately returns a response if the _restore operation can be executed. The restoration task is executed at the backend. You can specify the `wait_for_completion` parameter to enable the cluster to return a response only after the restoration task is complete.

```
POST _snapshot/aliyun_auto_snapshot/<snapshot>/_restore?wait_for_completion=true
```

Replace `<snapshot>` with the name of the snapshot, such as `<yourSnapshotName>`.

- Run the following command to restore specified indexes from a specific snapshot that is stored in the aliyun_auto_snapshot repository, and rename the restored indexes. The restoration task is executed at the backend.

```
POST _snapshot/aliyun_auto_snapshot/<snapshot>/_restore
{
"indices": "index_1",
"rename_pattern": "index_(.+)",
"rename_replacement": "restored_index_$1"
}
```

  - <snapshot>: Replace it with the name of the snapshot, such as `<yourSnapshotName>`.
  - indices: the name of the index you want to restore.
  - rename_pattern: optional. This parameter specifies the regular expression that is used to match the name of the index you want to restore.
  - rename_replacement: optional. This parameter specifies the regular expression that is used to rename a matched index.

10.3.9.4. Commands for creating snapshots and restoring data

You can call the snapshot operation to back up or restore data for your Apsara Stack Elasticsearch cluster. The snapshot operation retrieves the status and data of your cluster and then stores them to a shared repository.

The first snapshot is a full copy of the data in a cluster. Subsequent snapshots store only incremental data. Therefore, when you create subsequent snapshots, the system only needs to add data to or remove data from the snapshots. This means that it requires less time to create a subsequent snapshot than the first snapshot.

Precautions

- This topic uses the following markers to provide descriptions for code: <1>, <2>, and <3>. Remove these markers when you run the code.
- You can run the code provided in this topic in the Kibana console of your Elasticsearch cluster. For more information, see Access an Elasticsearch cluster.

Create a repository

```
PUT _snapshot/my_backup
{
  "type": "oss",
   "settings": {
      "endpoint": "http://oss-cn-hangzhou-internal.aliyuncs.com", <1>
      "access_key_id": "xxxx",
      "secret_access_key": "xxxxxx",
      "bucket": "xxxxxx", <2>
      "compress": true,
      "base_path": "snapshot/" <3>
   }
}
```

- <1>: The `endpoint` parameter specifies the internal endpoint of the OSS bucket.
- <2>: The bucket parameter specifies the name of an OSS bucket that has been created.
- <3>: The base_path parameter specifies the path of the repository. The default value is the root directory.

Set the size of each part

When you upload large volumes of data to an OSS bucket, you can use the `chunk_size` parameter to set the size of each part. This allows you to upload the data in multiple parts.

```
POST _snapshot/my_backup/ <1>
{
   "type": "oss",
   "settings": {
      "endpoint": "http://oss-cn-hangzhou-internal.aliyuncs.com",
      "access_key_id": "xxxx",
      "secret_access_key": "xxxxxx",
      "bucket": "xxxxxx",
      "chunk_size": "500mb",
      "base_path": "snapshot/" <2>
   }
}
```

- <1>: Use the POST method instead of the PUT method. The POST method updates repository settings.
- <2>: The base_path parameter specifies the path of the repository. The default value is the root directory.

Query repository information

```
GET _snapshot
```

You can also use the `GET _snapshot/my_backup` command to query the information of a specified repository.

Create snapshots

The following command is a basic command that is used to create a snapshot:

```
PUT _snapshot/my_backup/snapshot_1
```

This command creates the `snapshot_1` snapshot for all open indexes. The snapshot is stored in the `my_backup` repository. After you run the command, the system immediately returns a response while the snapshot is created at the backend.

If you want the system to return a response after it creates the snapshot, add the `wait_for_completion` parameter to the command.

```
PUT _snapshot/my_backup/snapshot_1? wait_for_completion=true
```

After you run the command, the system does not return a response until the snapshot is created. If the size of the index is large, the response is returned after a longer period of time.

Create a snapshot for specified indexes

By default, a snapshot contains all open indexes. For Kibana, when you create a snapshot, you may want to ignore all diagnostic indexes (the `.kibana` indexes) because of limited disk space. To create a snapshot for specified indexes, run the following command:

> **Notice** A repository stores multiple snapshots. Each snapshot is a copy of all indexes, specified indexes, or a single index in a cluster. When you create a snapshot, make sure that the snapshot name is unique.

```
PUT _snapshot/my_backup/snapshot_2
{
  "indices": "index_1,index_2"
}
```

The preceding command creates a snapshot only for the `index1` and `index2` indexes.

Query snapshot information

In some cases, you may need to query snapshot information. For example, a snapshot name containing a date is hard to remember, such as `backup_2014_10_28`.

To query the information of a snapshot, send a `GET` request that contains both the repository name and snapshot name. Example:

```
GET _snapshot/my_backup/snapshot_2
```

The following response contains detailed information of the snapshot:

```
{
"snapshots": [
  {
    "snapshot": "snapshot_2",
    "indices": [
      ".marvel_2014_28_10",
      "index1",
      "index2"
    ],
    "state": "SUCCESS",
    "start_time": "2014-09-02T13:01:43.115Z",
    "start_time_in_millis": 1409662903115,
    "end_time": "2014-09-02T13:01:43.439Z",
    "end_time_in_millis": 1409662903439,
    "duration_in_millis": 324,
    "failures": [],
    "shards": {
      "total": 10,
      "failed": 0,
      "successful": 10
    }
  }
]
}
```

You can replace the snapshot name in the preceding command with `_all` to query all snapshots in the repository. Example:

```
GET _snapshot/my_backup/_all
```

Delete a snapshot

You can specify a repository name and a snapshot name, and send a `DELETE` request to delete the specified snapshot. Example:

```
DELETE _snapshot/my_backup/snapshot_2
```

> **Notice**
>
> - You can only use the DELETE operation to delete snapshots. A snapshot is associated with other backup files. Some of the files may also be used by other snapshots. The DELETE operation does not delete files that are still being used by other snapshots. It only deletes files that are associated with the deleted snapshot and are not used by other snapshots.
> - If you choose to manually delete a snapshot, you may delete files that are associated with snapshots by mistake. This may cause data loss.

Monitor snapshot creation progress

The `wait_for_completion` parameter provides a simple method for you to monitor the progress of a snapshot creation task. However, this parameter is not suitable for snapshot creation tasks of medium-size Elasticsearch clusters. You can use one of the following methods to query detailed information about a snapshot:

- Send a `GET` request with the snapshot name specified. Example:

  ```
  GET _snapshot/my_backup/snapshot_3
  ```

  If the system is still creating the snapshot when you run the preceding command, the information of the creation task is returned, such as the time when the snapshot creation task started and the duration.

  > **Notice** The preceding command shares a thread pool with the command used to create a snapshot. Therefore, if you create a snapshot for large shards, the preceding command has to wait until the resources that are used by the snapshot creation command in the thread pool are released.

- Call the _status operation to query the snapshot status.

  ```
  {
  "snapshots": [
    {
      "snapshot": "snapshot_3",
      "repository": "my_backup",
      "state": "IN_PROGRESS", <1>
      "shards_stats": {
        "initializing": 0,
        "started": 1, <2>
        "finalizing": 0,
        "done": 4,
        "failed": 0,
        "total": 5
      },
      "stats": {
  ```

```
    "number_of_files": 5,
    "processed_files": 5,
    "total_size_in_bytes": 1792,
    "processed_size_in_bytes": 1792,
    "start_time_in_millis": 1409663054859,
    "time_in_millis": 64
  },
  "indices": {
    "index_3": {
      "shards_stats": {
        "initializing": 0,
        "started": 0,
        "finalizing": 0,
        "done": 5,
        "failed": 0,
        "total": 5
      },
      "stats": {
        "number_of_files": 5,
        "processed_files": 5,
        "total_size_in_bytes": 1792,
        "processed_size_in_bytes": 1792,
        "start_time_in_millis": 1409663054859,
        "time_in_millis": 64
      },
      "shards": {
        "0": {
          "stage": "DONE",
          "stats": {
            "number_of_files": 1,
            "processed_files": 1,
            "total_size_in_bytes": 514,
            "processed_size_in_bytes": 514,
            "start_time_in_millis": 1409663054862,
            "time_in_millis": 22
          }
        },
        ...
```

- <1>: The status of the snapshot. If a snapshot is being created, the value of the field is `IN_PROGRESS`.
- <2>: The number of shards that are being transmitted. If the value 1 is returned, a shard of the snapshot is being transmitted, and the other four shards have been transmitted.

  The value of the `shards_stats` parameter contains the status of the snapshot. It also contains statistics about each index and shard. This parameter allows you to learn the detailed information of the snapshot creation progress. A shard can be in one of the following states:

  - `INITIALIZING`: The shard is verifying the status of the cluster to check whether the shard can be stored in a snapshot. In most cases, this process is fast.
  - `STARTED`: Data is being transmitted to the repository.
  - `FINALIZING`: The data transmission process is complete. The shard is sending snapshot metadata.
  - `DONE`: The snapshot is created.
  - `FAILED`: An error occurred during the snapshot creation. The shard, index, or snapshot cannot be processed. You can view logs for more information.

Cancel a snapshot

To cancel a snapshot, run the following command when the snapshot is being created:

```
DELETE _snapshot/my_backup/snapshot_3
```

This command stops the snapshot creation process and deletes the snapshot that is being created from the repository.

Restore indexes from a snapshot

To restore indexes from a snapshot, run the command that is used in the "Create a repository" section on the Elasticsearch cluster that stores these indexes. You can use one of the following methods to restore indexes from a snapshot:

- To restore indexes from a specified snapshot, append the `_restore` parameter to the snapshot name in the command to run. Example:

  ```
  POST _snapshot/my_backup/snapshot_1/_restore
  ```

  After you run this command, the system restores all indexes in the snapshot. For example, if the `snapshot_1` snapshot contains five indexes, all these indexes are restored to the Elasticsearch cluster. You can also specify the indexes that you want to restore. For more information, see Create a snapshot for specified indexes.
- Restore specified indexes and rename the indexes. If you only want to verify or process the data in indexes and do not need to overwrite the data, use this method to restore the indexes.

```
POST /_snapshot/my_backup/snapshot_1/_restore
{
 "indices": "index_1", <1>
 "rename_pattern": "index_(.+)", <2>
 "rename_replacement": "restored_index_$1" <3>
}
```

In this example, the `index_1` index is restored to your Elasticsearch cluster and renamed `restored_index_1`.

- <1>: The system only restores the `index_1` index from the snapshot.
- <2>: The system searches for the index that is being restored and matches the index name with the provided pattern.
- <3>: The system renames the matching index.

- If you want the system to return a response after it restores the index, add the `wait_for_completion` parameter to the command.

```
POST _snapshot/my_backup/snapshot_1/_restore? wait_for_completion=true
```

After you call the _restore operation, the system immediately returns a response and restores the index at the backend. If you want the operation to return the result after the restore process is complete, add the `wait_for_completion` parameter.

Monitor index restoration progress

> **Note** Restoring data from a repository applies the existing restoration mechanism in Elasticsearch. Restoring shards from a repository is the same as restoring data from a node.

You can call the recovery operation to monitor the progress of an index restoration task.

- Monitor a specified index that is being restored.

```
GET restored_index_3/_recovery
```

The recovery operation is a general-purpose operation. It shows the status of the shards that are being transmitted to your cluster.

- Monitor all indexes on the cluster. This may include shards that are irrelevant to the restoration process.

```
GET /_recovery/
```

The following content shows the sample response:

```
{
"restored_index_3" : {
 "shards" : [ {
  "id" : 0,
```

```
  "type" : "snapshot", <1>
  "stage" : "index",
  "primary" : true,
  "start_time" : "2014-02-24T12:15:59.716",
  "stop_time" : 0,
  "total_time_in_millis" : 175576,
  "source" : { <2>
    "repository" : "my_backup",
    "snapshot" : "snapshot_3",
    "index" : "restored_index_3"
  },
  "target" : {
    "id" : "ryqJ5lO5S4-lSFbGntkEkg",
    "hostname" : "my.fqdn",
    "ip" : "10.0. **.**",
    "name" : "my_es_node"
  },
  "index" : {
    "files" : {
      "total" : 73,
      "reused" : 0,
      "recovered" : 69,
      "percent" : "94.5%" <3>
    },
    "bytes" : {
      "total" : 79063092,
      "reused" : 0,
      "recovered" : 68891939,
      "percent" : "87.1%"
    },
    "total_time_in_millis" : 0
  },
  "translog" : {
    "recovered" : 0,
    "total_time_in_millis" : 0
  },
  "start" : {
    "check_index_time" : 0,
    "total_time_in_millis" : 0
  }
}]
```

```
}
}
```

- <1>: The `type` parameter indicates the type of restoration. The value `snapshot` indicates that the shard is being restored from a snapshot.
- <2>: The `source` parameter indicates the source snapshot and repository.
- <3>: The `percent` parameter indicates the progress of the restoration task. The value `94.5%` indicates that 94.5% of the shard files are restored.

The response lists all indexes that are being restored and the shards in these indexes. Each shard has statistics about the start or end time, duration, restoration progress, and bytes transmitted.

Cancel index restoration

To cancel index restoration, you only need to delete the indexes that are being restored. A restoration process is a shard restoration process. You can call the DELETE operation to modify the status of the cluster and cancel the restoration process. Example:

```
DELETE /restored_index_3
```

If you run the preceding command when the `restored_index_3` index is being restored, the system stops the restoration and deletes the data that has been restored to the cluster. For more information, see Snapshot And Restore.

Use a snapshot to migrate data

To use a snapshot to migrate data from an Elasticsearch cluster to another, follow these steps:

1. Back up a snapshot to OSS.
2. Create a snapshot repository on the destination cluster. The repository must use the OSS bucket that stores the snapshot.
3. Set the `base_path` parameter to the path of the snapshot.
4. Run the data restoration command on the destination cluster.

> **Note** These steps provide a simple solution to snapshot-based data migration. For more information, see Use a snapshot stored in OSS to migrate Elasticsearch data.

10.4. Manage documents

10.4.1. Create a document

This topic describes how to use Elasticsearch to create a document.

Access an Elasticsearch cluster and send a POST request to create a document in the cluster.

```
curl -XPOST http://<HOST>:<PORT>/my_index/my_type -d '{"title": "One", "tags": ["ruby"]}'
```

- `<HOST>`: the internal endpoint of the Elasticsearch cluster.
- `<PORT>`: the internal port of the Elasticsearch cluster. The default port is 9200.
- `my_index`: the name of the index, which can be customized.
- `my_type`: the type of the document, which can be customized.

> **Note**
>
> - Each document has an ID and a type. The response contains the ID and type of the document. If you do not specify an ID or type when you create a document, the system automatically generates one for the document.
> - If you enable the Auto Indexing feature and the specified index name does not exist, the system automatically creates an index when creating the document. The Auto Indexing feature is disabled by default. For information about how to enable this feature, see Configure a YML file.

If the command is successfully executed, the following result is returned:

```
{
  "_index": "my_index",
  "_type": "my_type",
  "_id": "AV4JIvi15ny3i8DCdK1H",
  "_version": 1,
  "result": "created",
  "_shards": {
    "total": 2,
    "successful": 1,
    "failed": 0
  },
  "created": true
}
```

10.4.2. Update a document

This topic describes how to use Elasticsearch to update a document.

Access an Elasticsearch cluster and send a POST request to update a document in the cluster.

```
curl -XPOST http://<HOST>:<PORT>/my_index/my_type/<doc_id>
```

- `<HOST>`: the internal endpoint of the Elasticsearch cluster.
- `<PORT>`: the internal port of the Elasticsearch cluster. The default port is `9200`.
- `my_index`: the name of the index.

- `my_type` : the type of the document.
- `<doc_id>` : the ID of the document.

Example:

```
curl -XPOST http://<HOST>:<PORT>/my_index/my_type/AV4JIVI15NY3I8DCDK1H
-d '{"title": "FOUR UPDATED", "TAGS": ["RUBY", "PHP"]}'
```

If the command is successfully executed, the following result is returned:

```
{
   "_index": "my_index",
   "_type": "my_type",
   "_id": "AV4JIvi15ny3i8DCdK1H",
   "_version": 2,
   "result": "updated",
   "_shards": {
      "total": 2,
      "successful": 1,
      "failed": 0
   },
   "created": false
}
```

10.4.3. Retrieve a document

This topic describes how to use Elasticsearch to retrieve a document.

Access an Elasticsearch cluster and send a GET request to retrieve a document in the cluster.

Example:

```
curl -XGET http://<HOST>:<PORT>/my_index/my_type/AV4JIVI15NY3I8DCDK1H
```

- `<HOST>` : the internal endpoint of the Elasticsearch cluster.
- `<PORT>` : the internal port of the Elasticsearch cluster. The default port is `9200` .
- `my_index` : the name of the index.
- `my_type` : the type of the document.
- `AV4JIVI15NY3I8DCDK1H` : the ID of the document.

If the command is successfully executed, the following result is returned:

```
{
  "_INDEX" : "MY_INDEX",
  "_TYPE" : "MY_TYPE",
  "_ID" : "AV4JIVI15NY3I8DCDK1H",
  "_VERSION" : 2,
  "EXISTS" : TRUE,
  "_SOURCE" : {
  "TITLE": "FOUR UPDATED", "TAGS": ["RUBY", "PHP"]
  }
```

10.4.4. Search for documents

This topic describes how to use Elasticsearch to search for documents.

Access an Elasticsearch cluster and send a GET or POST request to search for documents in the cluster. You can specify URI parameters in the request. Examples:

```
curl -XGET http://<HOST>:<PORT>/_search
curl -XGET http://<HOST>:<PORT>/{index_name}/_search
curl -XGET http://<HOST>:<PORT>/{index_name}/{type_name}/_search
```

To search for documents in which the title field contains the T keyword, run the following command:

```
curl -XGET http://<HOST>:<PORT>/my_index/my_type/_search?q=title:T*
```

- `<HOST>` : the internal endpoint of the Elasticsearch cluster.
- `<PORT>` : the internal port of the Elasticsearch cluster. The default port is `9200` .
- `my_index` : the name of the index.
- `my_type` : the type of the document.

10.4.5. Perform a complex search

This topic describes how to use Elasticsearch to perform a complex search.

Access an Elasticsearch cluster and send a POST request to perform a complex search on documents in the cluster. Example:

```
$ curl -XPOST http://<HOST>:<PORT>/my_index/my_type/_search?pretty=true -d '{
"query": {
   "query_string": {"query": "*"}
},
"facets": {
   "tags": {
      "terms": {"field": "tags"}
   }
}}'
```

- `<HOST>`: the internal endpoint of the Elasticsearch cluster.
- `<PORT>`: the internal port of the Elasticsearch cluster. The default port is `9200`.
- `my_index`: the name of the index.
- `my_type`: the type of the document.

> **Note** The `?pretty=true` parameter is used to make the result easier to understand.

10.4.6. Delete a document

This topic describes how to use Elasticsearch to delete a document.

Access an Elasticsearch cluster and call the DELETE operation to delete a document in the cluster.

Delete a document with its ID specified

```
curl -XDELETE http://<HOST>:<PORT>/my_index/my_type/{ID}
```

- `<HOST>`: the internal endpoint of the Elasticsearch cluster.
- `<PORT>`: the internal port of the Elasticsearch cluster. The default port is `9200`.
- `my_index`: the name of the index.
- `my_type`: the type of the document.
- `ID`: the ID of the document.

Delete a specified type of documents

```
curl -XDELETE http://<HOST>:<PORT>/my_index/my_type/
```

- `<HOST>`: the internal network endpoint of the Elasticsearch cluster.
- `<PORT>`: the internal port of the Elasticsearch cluster. The default port is `9200`.

- `my_index` : the name of the index.
- `my_type` : the type of the documents.

Delete documents in a specified index

```
curl -XDELETE http://<HOST>:<PORT>/{my_index}
```

- `<HOST>` : the internal endpoint of the Elasticsearch cluster.
- `<PORT>` : the internal port of the Elasticsearch cluster. The default port is `9200` .
- `my_index` : the name of the index.

10.5. Elasticsearch test

After you create an Elasticsearch instance, you can log on to the Kibana console integrated into the Elasticsearch console and test the search function on the Dev Tools page. You can also run the curl command in an ECS instance that meets the requirements to perform the test.

10.5.1. Use a curl command to access an Elasticsearch cluster over port 9200

This topic describes how to use a curl command to access an Elasticsearch cluster over port 9200.

The following example shows how to access an Elasticsearch cluster, with its username and password specified:

```
curl -u username:password 'http://<HOST>:9200/filebeat/my_type/'?pretty -d '{"title": "One", "tags": [
"ruby"]}'
```

If the command is successfully executed, the following result is returned:

```
{
 "_index" : "filebeat",
 "_type" : "my_type",
 "_id" : "AV-bTkaTwdiHxfaSqlAt",
 "_version" : 1,
 "result" : "created",
 "_shards" : {
  "total" : 2,
  "successful" : 2,
  "failed" : 0
 },
 "created" : true
}
```

The following example shows how to access an Elasticsearch cluster, with its username and password not specified:

```
curl http://<HOST>:9200/index_name/type_name -XPOST -d '{"title": "One", "tags": ["ruby"]}'
```

10.5.2. Use Python to access an Elasticsearch cluster over port 9200

This topic describes how to use Python to access an Elasticsearch cluster over port 9200.

```
from elasticsearch import Elasticsearch, RequestsHttpConnection
import certifi
es = Elasticsearch(
    ['<HOST>'],
    http_auth=('username', 'password'),
    port=9200,
    use_ssl=False
)
res = es.index(index="my_index", doc_type="my_type", id=1, body={"title": "One", "tags": ["ruby"]})
print(res['created'])
res = es.get(index="my-index", doc_type="my-type", id=1)
print(res['_source'])
```

10.5.3. Use Java REST Client to access an Elasticsearch cluster over port 9200

This topic describes how to use Java REST Client to access an Elasticsearch cluster over port 9200 and provides related precautions.

Precautions

- The open source Elasticsearch team no longer maintains Transport Client. We recommend that you do not use Transport Client to access an Elasticsearch cluster. If you use Transport Client 5.5.3 to access an Elasticsearch cluster, the system displays the "NoNodeAvailableException" error message. We recommend that you use Java Low Level REST Client to access an Elasticsearch cluster.
- Java REST Client described in this topic is applicable only to Elasticsearch V5.5.3 clusters. For more information about how to use Java REST Client to access an Elasticsearch V6.3.2 cluster, see Java REST Client 6.3.2.
- The version of Java REST Client must be the same as that of your Elasticsearch cluster.

Prerequisites

- An Elasticsearch cluster is created, and the Auto Indexing feature is enabled for the cluster.

  For more information, see Create an Elasticsearch cluster and Configure a YML file.
- The relevant JDK is installed, and environment variables are configured. The JDK version must be 1.8 or later.

Sample code

```
import org.apache.http.HttpEntity;
import org.apache.http.HttpHost;
import org.apache.http.auth.AuthScope;
import org.apache.http.auth.UsernamePasswordCredentials;
import org.apache.http.client.CredentialsProvider;
import org.apache.http.entity.ContentType;
import org.apache.http.impl.client.BasicCredentialsProvider;
import org.apache.http.impl.nio.client.HttpAsyncClientBuilder;
import org.apache.http.nio.entity.NStringEntity;
import org.apache.http.util.EntityUtils;
import org.elasticsearch.client.Response;
import org.elasticsearch.client.RestClient;
import org.elasticsearch.client.RestClientBuilder;
import java.io.IOException;
import java.util.Collections;
public class RestClientTest {
   public  static void main(String[]args){
      final CredentialsProvider credentialsProvider = new BasicCredentialsProvider();
```

```
        credentialsProvider.setCredentials(AuthScope.ANY,
                new UsernamePasswordCredentials("<USER NAME>", "<PASSWORD>"));
        RestClient restClient = RestClient.builder(new HttpHost("<HOST>", 9200))
                .setHttpClientConfigCallback(new RestClientBuilder.HttpClientConfigCallback() {
                    @Override
                    public HttpAsyncClientBuilder customizeHttpClient(HttpAsyncClientBuilder httpClientBuilder
) {
                        return httpClientBuilder.setDefaultCredentialsProvider(credentialsProvider);
                    }
                }).build();
        try {
            //index a document
            HttpEntity entity = new NStringEntity("{\n\"user\" : \"kimchy\"\n}", ContentType.APPLICATION_JS
ON);
            Response indexResponse = restClient.performRequest(
                    "PUT",
                    "/index/type/123",
                    Collections. <String, String>emptyMap(),
                    entity);
            //search a document
            Response response = restClient.performRequest("GET", "/index/type/123",
                    Collections.singletonMap("pretty", "true"));
            System.out.println(EntityUtils.toString(response.getEntity()));
        } catch (IOException e) {
            e.printStackTrace();
        }
    }
}
```

- `<USER NAME>` : the username of your Elasticsearch cluster.
- `<PASSWORD>` : the password of your Elasticsearch cluster.
- `<HOST>` : the internal endpoint of your Elasticsearch cluster. You can obtain the endpoint from the Basic Information page of the cluster.

11.Elasticsearch (on k8s)

11.1. What is Apsara Stack Elasticsearch?

Open source Elasticsearch is a Lucene-based, distributed, real-time search and analytics engine. It is a product released under the Apache License. Elasticsearch is a popular search engine for enterprises. It provides distributed services, allowing you to store, query, and analyze large amounts of datasets in near real time. Elasticsearch is typically used as a basic engine or technology to support complex queries and high-performance applications.

Apsara Stack Elasticsearch provides fully-managed Elasticsearch services. It supports multiple versions of open source Elasticsearch and is compatible with all open source Elasticsearch features. Apsara Stack Elasticsearch offers an optimized kernel and provides the multi-tenancy, high availability, and auto scaling features. In addition to the features of open source Elasticsearch, Apsara Stack Elasticsearch allows you to create a cluster in a visualized manner, use Migration Assistant to migrate data, manage repositories, create snapshots, manage plug-ins, and perform O&M operations.

11.2. Quick start

11.2.1. Log on to the Elasticsearch console

This topic describes how to log on to the Elasticsearch console.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password used to log on to the console from the operations administrator.

   > **Note** When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters.
   > - Digits.
   > - Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Products** > **Big Data** > **Elasticsearch(k8s)**.

5. Specify **Organization** and **Region** and click **Elasticsearch(k8s)**.

11.2.2. Access an Elasticsearch cluster

You can access an Elasticsearch cluster from an Elastic Compute Service (ECS) instance or the Kibana console.

Prerequisites

- Operations and maintenance (O&M) personnel have created an Elasticsearch cluster under your organization.

  For more information, see Elasticsearch Operations and Maintenance Guide.
- An ECS instance is created. The ECS instance must reside in the same Virtual Private Cloud (VPC), Kubernetes cluster, region, and zone as the Elasticsearch cluster.

Use an ECS instance to access an Elasticsearch cluster

1. Log on to the ECS instance over SSH and install the cURL tool.

   > **Note** For more information about other logon methods, see ECS User Guide.

2. Run the following command to connect to the internal endpoint of the Elasticsearch cluster.

   ```
   curl http://<HOST>:<PORT>
   ```

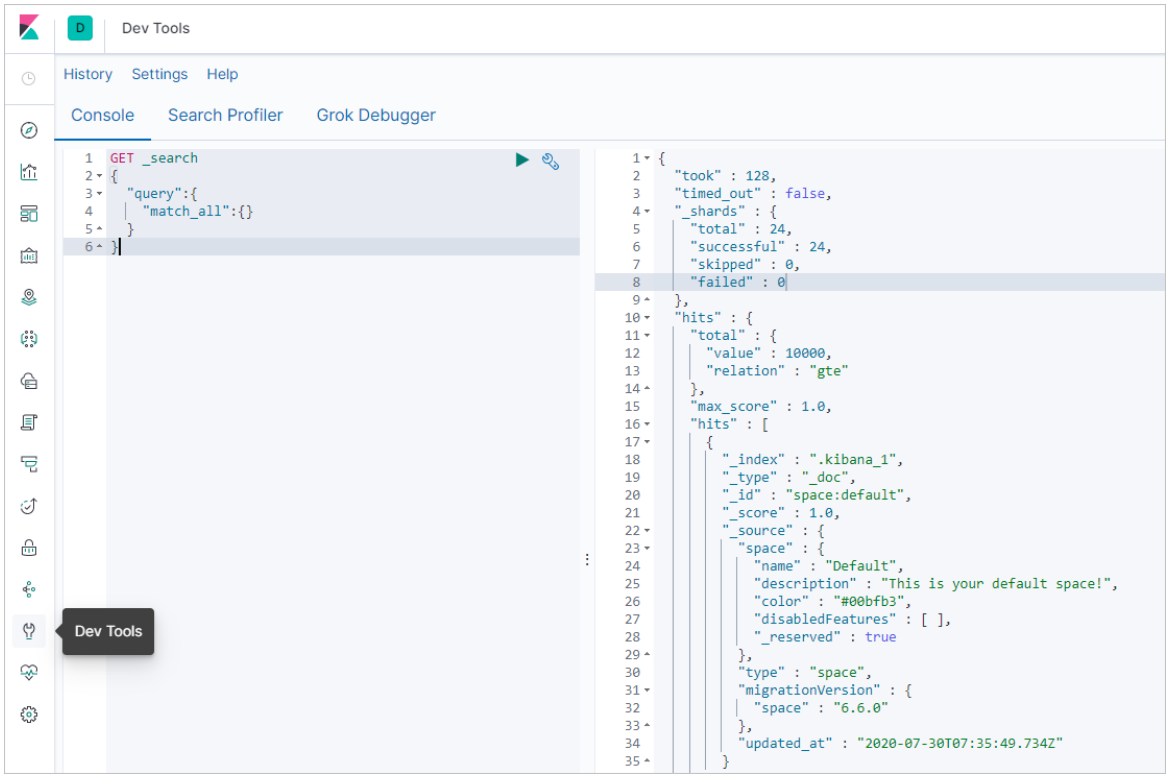
   - `<HOST>`: the internal endpoint of the Elasticsearch cluster. You can obtain the information from the Basic Information page of the cluster.

     > **Note** To go to the Basic Information page, log on to the Elasticsearch console, find the cluster, and click its ID in the Instance ID/Name column.

   - `<PORT>`: the internal port of the Elasticsearch cluster. You can obtain the information from the Basic Information page. The default port is 9200.

Use the Kibana console to access an Elasticsearch cluster

1. Log on to the Elasticsearch console.
2. Find the target cluster and click its ID in the **Instance ID/Name** column.
3. In the left-side navigation pane, click **Data Visualization**.
4. Click **Console** in the Kibana section.
5. On the page that appears, enter the username and password and click **Log in**.The username is elastic. You can obtain the password from O&M personnel.
6. In the left-side navigation pane, click the **Dev Tools** icon. On the **Console** tab, run the command shown in the following figure.

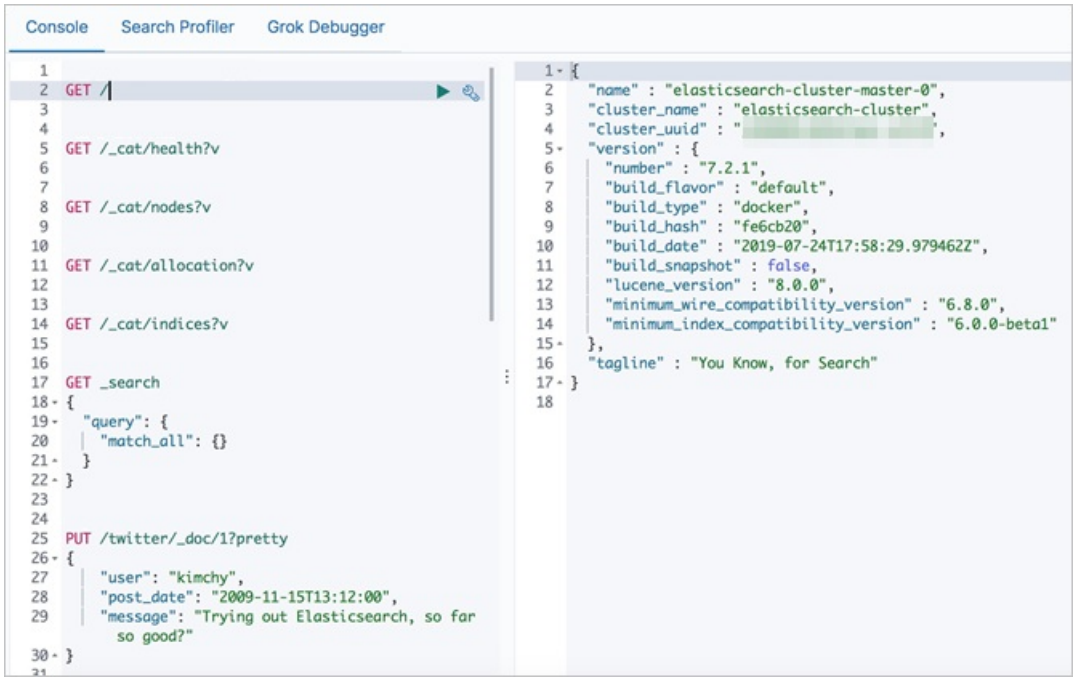


11.2.3. View the information of an Elasticsearch cluster

This topic describes how to view the information of an Elasticsearch cluster from the Kibana console.

Procedure

1. Access your Elasticsearch cluster from the Kibana console.For more information, see Access an Elasticsearch cluster.
2. Run the following commands to view the basic information of the cluster.



- View the version of the cluster

  ```
  GET /
  ```

- View the health status of the cluster

  ```
  GET /_cat/health?v
  ```

- View the information of nodes in the cluster

  ```
  GET /_cat/nodes?v
  ```

- View JVM heap memory

  ```
  GET /_nodes/stats/jvm?pretty
  ```

- View information of disks

  ```
  GET /_cat/allocation?v
  ```

- View information of indexes

  ```
  GET /_cat/indices?v
  ```

11.2.4. Create an index

Before you use Elasticsearch to process documents, you must create an index. This topic describes how to create an index.

Procedure

1. Access your Elasticsearch cluster from the Kibana console.For more information, see Access an Elasticsearch cluster.

2. Run the following command to create an index:

```
PUT my_index?include_type_name=true
{
  "settings" : {
    "index" : {
      "number_of_shards" : "5",
      "number_of_replicas" : "1"
    }
  },
  "mappings" : {
    "_doc" : {
      "properties" : {
        "post_date": {
          "type": "date"
        },
        "tags": {
          "type": "keyword"
        },
        "title" : {
          "type" : "text",
          "analyzer" : "cjk"
        }
      }
    }
  }
}
```

Notice

- The preceding command is only for your reference. You can customize the parameters as needed. For more information, see open source Elasticsearch documentation.
- You can configure the YML configuration file of your Elasticsearch cluster to enable the Auto Indexing feature. After this feature is enabled, when you create a document, the system automatically creates an index for the document. Auto Indexing is used only for testing purposes. We recommend that you do not use this feature in production.
- Mapping types are deprecated in Elasticsearch V7.0.0 and later. Versions earlier than Elasticsearch V7.0.0 still support mapping types. For more information, see open source Elasticsearch documentation.

In the preceding example, an index named `my_index` is created, and the type of the index is `_doc`. The index is split into five shards, has one replica for each shard, and uses the `cjk` analyzer.

If the command is successfully executed, the following result is returned:

```
{
 "acknowledged" : true,
 "shards_acknowledged" : true,
 "index" : "my_index"
}
```

11.2.5. Manage documents

11.2.5.1. Create a document

This topic describes how to use Elasticsearch to create a document.

Procedure

1. Access your Elasticsearch cluster from the Kibana console.For more information, see Access an Elasticsearch cluster.
2. Run the following command to create a document:

```
curl -XPUT http://<HOST>:<PORT>/<index_name>/_doc/<ID>
{
 "<field_name>": "<value>"
}'
```

   - `<HOST>`: the endpoint of the Elasticsearch cluster.
   - `<PORT>`: the port of the Elasticsearch cluster. The default port is 9200.
   - `<index_name>`: the name of the index.
   - `_doc`: the type of the index. The index type of Elasticsearch V7.0 and later must be `_doc`.
   - `<ID>`: the ID of the document.
   - `<field_name>`: the name of the field.
   - `value`: the value of the field.

   Examples:

```
curl -XPUT http://localhost:9200/my_index/_doc/1?pretty' -d '
{
 "title": "One",
 "tags": ["ruby"],
 "post_date":"2009-11-15T13:00:00"
}'
```

```
curl -XPUT http://localhost:9200/my_index/_doc/2?pretty' -d '
{
 "title": "Two",
 "tags": ["ruby"],
 "post_date":"2009-11-15T14:00:00"
}'
```

If the commands are successfully executed, the following results are returned:

```
{
 "_index" : "my_index",
 "_type" : "_doc",
 "_id" : "1",
 "_version" : 1,
 "result" : "created",
 "_shards" : {
  "total" : 2,
  "successful" : 2,
  "failed" : 0
 },
 "_seq_no" : 0,
 "_primary_term" : 1
}
```

```
{
 "_index" : "my_index",
 "_type" : "_doc",
 "_id" : "2",
 "_version" : 1,
 "result" : "created",
 "_shards" : {
  "total" : 2,
  "successful" : 2,
  "failed" : 0
 },
 "_seq_no" : 1,
 "_primary_term" : 1
}
```

For more information, see open source Elasticsearch documentation.

11.2.5.2. Update a document

This topic describes how to use Elasticsearch to update a document.

Procedure

1. Access your Elasticsearch cluster from the Kibana console.For more information, see Access an Elasticsearch cluster.
2. Run one of the following commands to update a document:

   Update a whole document

   ```
   curl -XPUT http://<HOST>:<PORT>/<index_name>/_doc/<ID>
   {
    "<field_name>": "<value>"
   }'
   ```

   Make partial updates to a document

   ```
   curl -XPOST http://<HOST>:<PORT>/<index_name>/_update/<ID>
   {
    "script" : {
        "source": "ctx._source.<field_name> = '<value>'"
    }
   }'
   ```

   - `<HOST>` : the endpoint of the Elasticsearch cluster.
   - `<PORT>` : the port of the Elasticsearch cluster. The default port is `9200` .

- `<index_name>`: the name of the index.
- `_doc`: the type of the index.
- `<ID>`: the ID of the document.
- `<field_name>`: the name of the field.
- `value`: the value of the field.

Examples:

- Update a whole document

```
curl -XPUT http://localhost:9200/my_index/_doc/1?pretty' -d '
{
  "title": "One World One Dream",
  "tags": ["ruby"],
  "post_date":"2009-11-15T13:00:00"
}'
```

If the command is successfully executed, the following result is returned:

```
{
  "_index" : "my_index",
  "_type" : "_doc",
  "_id" : "1",
  "_version" : 2,
  "result" : "updated",
  "_shards" : {
    "total" : 2,
    "successful" : 2,
    "failed" : 0
  },
  "_seq_no" : 1,
  "_primary_term" : 1
}
```

- Make partial updates to a document

```
curl -XPOST http://localhost:9200/my_index/_update/1?pretty' -d '
{
    "script" : {
        "source": "ctx._source.title='One World'"
    }
}'
```

If the command is successfully executed, the following result is returned:

```
{
  "_index" : "my_index",
  "_type" : "_doc",
  "_id" : "1",
  "_version" : 5,
  "result" : "updated",
  "_shards" : {
    "total" : 2,
    "successful" : 2,
    "failed" : 0
  },
  "_seq_no" : 4,
  "_primary_term" : 1
}
```

You can also call the update operation to update documents. For more information, see open source Elasticsearch documentation.

11.2.5.3. Retrieve a document

This topic describes how to use Elasticsearch to retrieve a document.

Procedure

1. Access your Elasticsearch cluster from the Kibana console.For more information, see Access an Elasticsearch cluster.
2. Run the following command to retrieve a document:

   ```
   curl -XGET http://<HOST>:<PORT>/<index_name>/_doc/<ID>
   ```

   - `<HOST>` : the endpoint of the Elasticsearch cluster.
   - `<PORT>` : the port of the Elasticsearch cluster.
   - `<index_name>` : the name of the index.
   - `_doc` : the type of the index.
   - `<ID>` : the ID of the document.

   Example:

   ```
   curl -XGET http://localhost:9200/my_index/_doc/1
   ```

   If the command is successfully executed, the following result is returned:

```
{
 "_index" : "my_index",
 "_type" : "_doc",
 "_id" : "1",
 "_version" : 5,
 "_seq_no" : 4,
 "_primary_term" : 1,
 "found" : true,
 "_source" : {
  "title" : "One World",
  "tags" : [
   "ruby",
   "blue"
  ],
  "post_date" : "2009-11-15T13:00:00"
 }
}
```

For more information, see open source Elasticsearch documentation.

11.2.5.4. Search for documents

This topic describes how to use Elasticsearch to search for documents.

Procedure

1. Access your Elasticsearch cluster from the Kibana console.For more information, see Access an Elasticsearch cluster.
2. Run the following command to search for documents. URI parameters in the command are used to specify the object you want to search.

   ```
   curl -XGET http://<HOST>:<PORT>/_search
   curl -XGET http://<HOST>:<PORT>/<index_name>/_search
   ```

   - `<HOST>` : the endpoint of the Elasticsearch cluster.
   - `<PORT>` : the port of the Elasticsearch cluster. The default port is 9200.
   - `<index_name>` : the name of the index.

   To search for documents in which the title field contains the T keyword, run the following command:

   ```
   curl -XGET http://localhost:9200/my_index/_search?q=title:T*
   ```

   If the command is successfully executed, the following result is returned:

```
{
 "took" : 689,
 "timed_out" : false,
 "_shards" : {
  "total" : 5,
  "successful" : 5,
  "skipped" : 0,
  "failed" : 0
 },
 "hits" : {
  "total" : {
   "value" : 1,
   "relation" : "eq"
  },
  "max_score" : 1.0,
  "hits" : [
   {
    "_index" : "my_index",
    "_type" : "_doc",
    "_id" : "2",
    "_score" : 1.0,
    "_source" : {
     "title" : "Two",
     "tags" : [
      "ruby"
     ],
     "post_date" : "2009-11-15T14:00:00"
    }
   }
  ]
 }
}
```

For more information, see open source Elasticsearch documentation.

11.2.5.5. Perform a complex search

This topic describes how to use Elasticsearch to perform a complex search.

Procedure

1. Access your Elasticsearch cluster from the Kibana console.For more information, see Access an Elasticsearch cluster.

2. Run the following command to perform a complex search:

```
curl -XGET http://<HOST>:<PORT>/<index_name>/_search?pretty=true -d '
{
  "query" : {
    ""
  }
}'
```

- `<HOST>` : the endpoint of the Elasticsearch cluster.
- `<PORT>` : the port of the Elasticsearch cluster. The default port is 9200.
- `<index_name>` : the name of the index.
- `query` : the request body.

> **Note** `?pretty=true` is used to make the returned result easier to understand.

Examples:

- Search based on a time range

```
curl -XGET http://localhost:9200/my_index/_search?pretty=true -d '
{
  "query" : {
    "range" : {
      "post_date" : { "from" : "2009-11-15T13:00:00", "to" : "2009-11-15T14:00:00" }
    }
  }
}'
```

If the command is successfully executed, the following result is returned:

```
{
 "took" : 1,
 "timed_out" : false,
 "_shards" : {
  "total" : 5,
  "successful" : 5,
  "skipped" : 0,
  "failed" : 0
 },
 "hits" : {
  "total" : {
   "value" : 2,
   "relation" : "eq"
```

```
    "relation" : "eq"
  },
  "max_score" : 1.0,
  "hits" : [
   {
    "_index" : "my_index",
    "_type" : "_doc",
    "_id" : "2",
    "_score" : 1.0,
    "_source" : {
     "title" : "Two",
     "tags" : [
      "ruby"
     ],
     "post_date" : "2009-11-15T14:00:00"
    }
   },
   {
    "_index" : "my_index",
    "_type" : "_doc",
    "_id" : "1",
    "_score" : 1.0,
    "_source" : {
     "title" : "One World",
     "tags" : [
      "ruby"
     ],
     "post_date" : "2009-11-15T13:00:00"
    }
   }
  ]
 }
}
```

- Search based on a keyword

```
curl -XGET "http://localhost:9200/my_index/_search?pretty=true" -H 'Content-Type: application
/json' -d'
{
   "query" : {
   "simple_query_string" : {
      "query": "One +(python | ruby) -Two",
      "fields": ["title^5", "tags"],
      "default_operator": "or"
   }
 }
}'
```

If the command is successfully executed, the following result is returned:

```
{
 "took" : 1,
 "timed_out" : false,
 "_shards" : {
  "total" : 5,
  "successful" : 5,
  "skipped" : 0,
  "failed" : 0
 },
 "hits" : {
  "total" : {
   "value" : 1,
   "relation" : "eq"
  },
  "max_score" : 2.2378674,
  "hits" : [
   {
    "_index" : "my_index",
    "_type" : "_doc",
    "_id" : "1",
    "_score" : 2.2378674,
    "_source" : {
     "title" : "One World",
     "tags" : [
      "ruby"
     ],
     "post_date" : "2009-11-15T13:00:00"
    }
   }
  ]
 }
}
```

For more information, see open source Elasticsearch documentation.

11.2.5.6. Perform statistical analytics

This topic describes how to use Elasticsearch to perform statistical analytics on documents.

Procedure

1. Access your Elasticsearch cluster from the Kibana console.For more information, see Access an Elasticsearch cluster.

2. Run the following command to perform statistical analytics on documents:

```
curl -XPOST http://<HOST>:<PORT>/<index_name>/_search?pretty=true -d '
{
 "size": 0,
 "aggs": {
  "group_by_tags": {
   "terms": {
    "field": "tags"
   }
  }
 }
}'
```

- `<HOST>` : the endpoint of the Elasticsearch cluster.
- `<PORT>` : the port of the Elasticsearch cluster. The default port is 9200.
- `<index_name>` : the name of the index.

> **Note** `?pretty=true` is used to make the returned result easier to understand.

Example:

```
curl -XPOST http://localhost:9200/my_index/_search?pretty=true -d '
{
 "size": 0,
 "aggs": {
  "group_by_tags": {
   "terms": {
    "field": "tags"
   }
  }
 }
}'
```

If the command is successfully executed, the following result is returned:

```
{
 "took" : 1,
 "timed_out" : false,
 "_shards" : {
  "total" : 5,
  "successful" : 5,
  "skipped" : 0,
  "failed" : 0
 },
 "hits" : {
  "total" : {
   "value" : 2,
   "relation" : "eq"
  },
  "max_score" : null,
  "hits" : [ ]
 },
 "aggregations" : {
  "group_by_tags" : {
   "doc_count_error_upper_bound" : 0,
   "sum_other_doc_count" : 0,
   "buckets" : [
    {
     "key" : "ruby",
     "doc_count" : 2
    }
   ]
  }
 }
}
```

11.2.5.7. Delete a document

This topic describes how to use Elasticsearch to delete a document.

Procedure

1. Access your Elasticsearch cluster from the Kibana console.For more information, see Access an Elasticsearch cluster.
2. Run the following command to delete a document:

```
curl -XDELETE http://<HOST>:<PORT>/<index_name>/_doc/<ID>
```

- `<HOST>` : the endpoint of the Elasticsearch cluster.
- `<PORT>` : the port of the Elasticsearch cluster. The default port is 9200.
- `<index_name>` : the name of the index.
- `_doc` : the type of the index.
- `<ID>` : the ID of the document.

Example:

```
curl -XDELETE http://localhost:9200/my_index/_doc/2
```

If the command is successfully executed, the following result is returned:

```
{
  "_index" : "my_index",
  "_type" : "_doc",
  "_id" : "2",
  "_version" : 2,
  "result" : "deleted",
  "_shards" : {
    "total" : 2,
    "successful" : 2,
    "failed" : 0
  },
  "_seq_no" : 4,
  "_primary_term" : 1
}
```

For more information, see open source Elasticsearch documentation.

11.2.6. Delete an index

This topic describes how to call the delete operation for Elasticsearch to delete an index.

Procedure

1. Access your Elasticsearch cluster from the Kibana console.For more information, see Access an Elasticsearch cluster.
2. Run the following command to delete an index:

```
curl -XDELETE http://<HOST>:<PORT>/<index_name>
```

- `<HOST>` : the endpoint of the Elasticsearch cluster.
- `<PORT>` : the port of the Elasticsearch cluster. The default port is 9200.
- `<index_name>` : the name of the index.

Example:

```
curl -XDELETE http://localhost:9200/my_index
```

If the command is successfully executed, the following result is returned:

```
{
  "acknowledged" : true
}
```

For more information, see open source Elasticsearch documentation.

11.3. Manage clusters

11.3.1. Customize a cluster list

You can customize columns that are displayed in a cluster list. This makes it easy for you to view cluster information. This topic describes how to customize the columns.

Procedure

1. Log on to the Elasticsearch console.
2. In the upper-right corner of the **Elasticsearch Instances** page, click the  icon.
3. In the **Select Filters** dialog box, select columns as needed.
4. Click **OK**.
   The system then displays the cluster list based on the selected items.

11.3.2. Export a cluster list

You can export the list of Elasticsearch clusters based on selected columns. This topic describes how to export a cluster list.

Procedure

1. Log on to the Elasticsearch console.
2. In the upper-right corner of the **Elasticsearch Instances** page, click the  icon.
3. In the **Export** dialog box, specify **Export Mode** and **Translate Heading**, and select the columns that you want to export.
   - **Export Mode**: the mode used to export the cluster list. Valid values: All and Selected. Default value: All.
   - **Translate Heading**: specifies whether to translate headings. Valid values: Yes and No. Default value: Yes. If you set this parameter to Yes, exported headings are in Chinese. If you set this parameter to No, exported headings are in English, such as Instance ID and Instance Name.
   - **Custom**: Select columns that you want to export.

4. Click OK.

11.3.3. Refresh the information of a cluster

If the information of an Elasticsearch cluster, such as its status, is not refreshed in time in the console, you can manually refresh the page to obtain the up-to-date information. This topic describes how to refresh the information of an Elasticsearch cluster.

Procedure

1. Log on to the Elasticsearch console.
2. Use one of the following methods to refresh the information of a cluster:
   - On the Elasticsearch Instances page, click the icon in the upper-right corner.
   - On the Elasticsearch Instances page, find the target cluster and click its ID in the **Instance ID/Name** column. On the **Basic Information** page, click **Refresh** in the upper-right corner.

11.3.4. View the basic information of an Elasticsearch cluster

On the Basic Information page of an Elasticsearch cluster, you can view the information of the cluster, such as the ID, name, internal endpoint, and status. This topic describes how to view the basic information of a cluster.

Procedure

1. Log on to the Elasticsearch console.
2. Find the target cluster and click its ID in the **Instance ID/Name** column.
3. On the **Basic Information** page, view the basic information of the cluster.

Section	Parameter	Description
Basic Information section	Instance ID	The unique ID of the cluster.
	Name	The name of the cluster. By default, the name of a cluster is the same as its ID. Cluster names are configurable. You can search for clusters by name.
	Version	Valid values: 6.3.2, 6.7.0, 6.8.2, 7.2.1, and 7.4.0.
	Region	The region where the cluster resides.
	Zone	The zone where the cluster resides.
	Internal Network Address	The internal endpoint of the cluster. In a Virtual Private Cloud (VPC), you can use the internal endpoint to access the cluster.

Section	Parameter	Description
	Internal Network Port	Elasticsearch supports the following ports: ○ Port 9200 for HTTP ○ Port 9300 for TCP
Instance Statistics	Status	The status of the cluster. A cluster has the following states: Active (green), Initializing (yellow), Unhealthy (red), Paused (red), and Expired (gray).
	Created At	The time when the cluster was created.
Configuration Info	None	The configuration of the cluster. You must specify the configuration when you create the cluster. Related configuration items include Data Nodes, Dedicated Master Nodes (optional), Client Nodes (optional), and Kibana Nodes. For more information, see Elasticsearch Operations and Maintenance Guide.

11.3.5. Log on to the Kibana console

Apsara Stack Elasticsearch provides the Kibana console for you to scale your businesses. The Kibana console is a part of the Elastic ecosystem and is seamlessly integrated into Elasticsearch. This allows you to view the status of your Elasticsearch cluster in real time and manage the cluster. This topic describes how to log on to the Kibana console.

Procedure

1. Log on to the Elasticsearch console.
2. Find the target cluster and click its ID in the **Instance ID/Name** column.
3. In the left-side navigation pane, click **Data Visualization**.
4. In the **Kibana** section of the page that appears, click **Console**.
5. On the page that appears, enter the username and password and click **Log in**The username is elastic. The password is the one that is specified when the cluster is created. You can obtain the password from operations and maintenance (O&M) personnel.

11.3.6. Create a snapshot and restore data

You can call the snapshot operation to back up or restore data for your Apsara Stack Elasticsearch cluster. The snapshot operation retrieves the status and data of your cluster and stores them to a shared repository.

The first snapshot is a full copy of the data in a cluster. Subsequent snapshots store only incremental data. When you create a subsequent snapshot, the system only adds data to or removes data from the previous snapshot. This means that it requires less time to create a subsequent snapshot than the first snapshot.

Precautions

- This topic uses the following markers to provide descriptions for code: <1>, <2>, and <3>. Remove these markers before you run the code.
- You can run all the commands provided in this topic in the Kibana console of your Elasticsearch cluster. For more information, see Log on to the Kibana console.

Create a repository

```
PUT _snapshot/my_backup
{
  "type": "oss",
   "settings": {
      "endpoint": "http://oss-cn-hangzhou-internal.aliyuncs.com", <1>
      "access_key_id": "xxxx",
      "secret_access_key": "xxxxxx",
      "bucket": "xxxxxx", <2>
      "compress": true,
      "base_path": "snapshot/" <3>
   }
}
```

- <1>: The `endpoint` parameter specifies the internal endpoint of an Object Storage Service (OSS) bucket.
- <2>: The bucket parameter specifies the name of the OSS bucket.
- <3>: The base_path parameter specifies the path of the repository. The default value is the root directory.

Set the size of each part

You can upload large volumes of data to an OSS bucket in multiple parts. When you upload the data, you can use the `chunk_size` parameter to set the size of each part. Example:

```
POST _snapshot/my_backup/ <1>
{
   "type": "oss",
   "settings": {
      "endpoint": "http://oss-cn-hangzhou-internal.aliyuncs.com",
      "access_key_id": "xxxx",
      "secret_access_key": "xxxxxx",
      "bucket": "xxxxxx",
      "chunk_size": "500mb",
      "base_path": "snapshot/" <2>
   }
}
```

- <1>: Use the POST method instead of the PUT method. The POST method updates repository settings.
- <2>: The base_path parameter specifies the path of the repository. The default value is the root directory.

Query repository information

```
GET _snapshot
```

You can also use the `GET _snapshot/my_backup` command to query the information of a specified repository.

Create a snapshot for all open indexes

The following command is a basic command that is used to create a snapshot:

```
PUT _snapshot/my_backup/snapshot_1
```

This command creates a snapshot named `snapshot_1` for all open indexes and stores the snapshot in a repository named `my_backup`. After you run the command, the system immediately returns a response and creates the snapshot at the backend.

If you want the system to return a response after the snapshot is created, specify the `wait_for_completion` parameter in the command. Example:

```
PUT _snapshot/my_backup/snapshot_1?wait_for_completion=true
```

After you run the command, the system does not return a response until the snapshot is created. If the size of an index is large, the response is returned after a longer period of time.

Create a snapshot for specified indexes

By default, a snapshot contains all open indexes. If Kibana is used when you create a snapshot, you may want to ignore all diagnostic indexes (the `.kibana` indexes) because of limited disk space. To create a snapshot for specified indexes, run the following command.

> **Notice** A repository stores multiple snapshots. Each snapshot is a copy of all indexes, specified indexes, or a single index in a cluster. When you create a snapshot, make sure that the snapshot name is unique.

```
PUT _snapshot/my_backup/snapshot_2
{
  "indices": "index_1,index_2"
}
```

The preceding command creates a snapshot only for the `index1` and `index2` indexes.

Query snapshot information

In some cases, you may need to query snapshot information. For example, a snapshot name that contains a date is hard to remember, such as `backup_2014_10_28`.

To query the information of a snapshot, send a `GET` request that contains both the repository name and snapshot name. Example:

```
GET _snapshot/my_backup/snapshot_2
```

The response contains detailed information of the snapshot:

```
{
"snapshots": [
  {
    "snapshot": "snapshot_2",
    "indices": [
      ".marvel_2014_28_10",
      "index1",
      "index2"
    ],
    "state": "SUCCESS",
    "start_time": "2014-09-02T13:01:43.115Z",
    "start_time_in_millis": 1409662903115,
    "end_time": "2014-09-02T13:01:43.439Z",
    "end_time_in_millis": 1409662903439,
    "duration_in_millis": 324,
    "failures": [],
    "shards": {
      "total": 10,
      "failed": 0,
      "successful": 10
    }
  }
]
}
```

You can replace the snapshot name in the preceding command with `_all` to query all snapshots in the repository. Example:

```
GET _snapshot/my_backup/_all
```

Delete a snapshot

You can specify a repository name and a snapshot name in a `DELETE` request to delete the specified snapshot. Example:

```
DELETE _snapshot/my_backup/snapshot_2
```

> **Notice**
>
> - You can delete snapshots only by calling the DELETE operation. A snapshot is associated with other backup files. Some of the files may also be used by other snapshots. The DELETE operation does not delete files that are still being used by other snapshots. It deletes only the files that are associated with deleted snapshots and are no longer used by other snapshots.
> - If you choose to manually delete a snapshot, you may delete files that are used by other snapshots. This can cause data loss.

Monitor snapshot creation progress

The `wait_for_completion` parameter provides a simple method for you to monitor the progress of a snapshot creation task. However, this parameter is not suitable for snapshot creation tasks of medium-size Elasticsearch clusters. You can use one of the following methods to query detailed information about a snapshot:

- Send a `GET` request with the snapshot name specified. Example:

  ```
  GET _snapshot/my_backup/snapshot_3
  ```

  If the system is creating the snapshot when you run the preceding command, the information of the creation task is returned, such as the start time and duration of the task.

  > **Notice** The preceding command shares a thread pool with the command used to create a snapshot. Therefore, if you create a snapshot for large shards, the preceding command has to wait until the resources that are used by the snapshot creation command in the thread pool are released.

- Call the status operation to query the snapshot status.

  ```
  {
  "snapshots": [
    {
      "snapshot": "snapshot_3",
      "repository": "my_backup",
      "state": "IN_PROGRESS", <1>
      "shards_stats": {
        "initializing": 0,
        "started": 1, <2>
        "finalizing": 0,
        "done": 4,
  ```

```
    "failed": 0,
    "total": 5
  },
  "stats": {
    "number_of_files": 5,
    "processed_files": 5,
    "total_size_in_bytes": 1792,
    "processed_size_in_bytes": 1792,
    "start_time_in_millis": 1409663054859,
    "time_in_millis": 64
  },
  "indices": {
    "index_3": {
      "shards_stats": {
        "initializing": 0,
        "started": 0,
        "finalizing": 0,
        "done": 5,
        "failed": 0,
        "total": 5
      },
      "stats": {
        "number_of_files": 5,
        "processed_files": 5,
        "total_size_in_bytes": 1792,
        "processed_size_in_bytes": 1792,
        "start_time_in_millis": 1409663054859,
        "time_in_millis": 64
      },
      "shards": {
        "0": {
          "stage": "DONE",
          "stats": {
            "number_of_files": 1,
            "processed_files": 1,
            "total_size_in_bytes": 514,
            "processed_size_in_bytes": 514,
            "start_time_in_millis": 1409663054862,
            "time_in_millis": 22
          }
        },
```

```
            ...
```

- <1>: the status of the snapshot. If a snapshot is being created, the value of the field is `IN_PROGRESS`.
- <2>: the number of shards that are being transmitted. If the value 1 is returned, a shard is being transmitted to the snapshot, and the other four shards have been transmitted.

  The value of the `shards_stats` parameter contains the status of the snapshot and the statistics about each index and shard. This parameter allows you to obtain the detailed information of the snapshot creation progress. A shard can be in one of the following states:

  - `INITIALIZING`: The shard is verifying the status of the cluster to check whether the shard can be stored in a snapshot. In most cases, this process is fast.
  - `STARTED`: Data is being transmitted to the repository.
  - `FINALIZING`: Data is transmitted, and the shard is sending snapshot metadata.
  - `DONE`: A snapshot is created for the shard.
  - `FAILED`: An error occurred during the snapshot creation. The shard, index, or snapshot cannot be processed. You can view logs for more information.

Cancel a snapshot

To cancel a snapshot, run the following command when the snapshot is being created:

```
DELETE _snapshot/my_backup/snapshot_3
```

This command stops the snapshot creation process and deletes the snapshot that is being created from the repository.

Restore indexes from a snapshot

To restore indexes from a snapshot, run the command that is used in the "" section on the Elasticsearch cluster that stores these indexes. You can use one of the following methods to restore indexes from a snapshot:

- To restore indexes from a specified snapshot, append the `_restore` parameter to the snapshot name in the command to run. Example:

  ```
  POST _snapshot/my_backup/snapshot_1/_restore
  ```

  After you run this command, the system restores all indexes in the snapshot. For example, if the `snapshot_1` snapshot contains five indexes, all these indexes are restored to the related Elasticsearch cluster. You can also specify the indexes that you want to restore. For more information, see the "" section.
- Restore specified indexes and rename the indexes. If you only want to verify or process the data in indexes and do not want to overwrite the data, use this method to restore the indexes.

```
POST /_snapshot/my_backup/snapshot_1/_restore
{
 "indices": "index_1", <1>
 "rename_pattern": "index_(.+)", <2>
 "rename_replacement": "restored_index_$1" <3>
}
```

In this example, the `index_1` index is restored to your Elasticsearch cluster and renamed `restored_index_1`.

- <1>: The system restores only the `index_1` index from the snapshot.
- <2>: The system searches for the index that is being restored and matches the index name with the provided index pattern.
- <3>: The system renames the matched index.

- If you want the system to return a response after it restores the index, specify the `wait_for_completion` parameter in the command. Example:

  ```
  POST _snapshot/my_backup/snapshot_1/_restore?wait_for_completion=true
  ```

  After you call the restore operation, the system immediately returns a response and restores the index at the backend. If you want the system to return a response after the index is restored, specify the `wait_for_completion` parameter.

Monitor index restoration progress

> **Note** Restoring data from a repository applies the existing restoration mechanism in Elasticsearch. Restoring shards from a repository is the same as restoring data from a node.

You can call the recovery operation to monitor the progress of an index restoration task.

- Monitor the restoration of a specified index.

  ```
  GET restored_index_3/_recovery
  ```

  The recovery operation is a general-purpose operation that shows the status of the shards that are being transmitted to your cluster.

- Monitor the restoration of all indexes on the cluster. This may include shards that are irrelevant to the restoration process.

  ```
  GET /_recovery/
  ```

  Sample response:

  ```
  {
  "restored_index_3" : {
   "shards" : [ {
    "id" : 0,
  ```

```
  "type" : "snapshot", <1>
  "stage" : "index",
  "primary" : true,
  "start_time" : "2014-02-24T12:15:59.716",
  "stop_time" : 0,
  "total_time_in_millis" : 175576,
  "source" : { <2>
    "repository" : "my_backup",
    "snapshot" : "snapshot_3",
    "index" : "restored_index_3"
  },
  "target" : {
    "id" : "ryqJ5lO5S4-lSFbGntkEkg",
    "hostname" : "my.fqdn",
    "ip" : "10.0. **.**",
    "name" : "my_es_node"
  },
  "index" : {
    "files" : {
      "total" : 73,
      "reused" : 0,
      "recovered" : 69,
      "percent" : "94.5%" <3>
    },
    "bytes" : {
      "total" : 79063092,
      "reused" : 0,
      "recovered" : 68891939,
      "percent" : "87.1%"
    },
    "total_time_in_millis" : 0
  },
  "translog" : {
    "recovered" : 0,
    "total_time_in_millis" : 0
  },
  "start" : {
    "check_index_time" : 0,
    "total_time_in_millis" : 0
  }
}]
```

```
}
}
```

- <1>: The `type` parameter indicates the type of restoration. The value `snapshot` indicates that the shard is being restored from a snapshot.
- <2>: The `source` parameter indicates the source snapshot and repository.
- <3>: The `percent` parameter indicates the progress of the restoration task. The value `94.5%` indicates that 94.5% of the shard files are restored.

The response lists all indexes that are being restored and the shards in these indexes. Each shard has statistics about the start or end time, duration, restoration progress, and bytes transmitted.

Cancel index restoration

To cancel index restoration, you only need to delete the indexes that are being restored. A restoration process is a shard restoration process. You can call the DELETE operation to modify the status of a cluster and cancel index restoration. Example:

```
DELETE /restored_index_3
```

If you run the preceding command when the `restored_index_3` index is being restored, the system stops the restoration and deletes the data that has been restored to your cluster. For more information, see Snapshot And Restore.

Use a snapshot to migrate data

To use a snapshot to migrate data from an Elasticsearch cluster to another, perform the following steps:

1. Back up a snapshot to OSS.
2. Create a snapshot repository on the destination cluster. The repository must use the OSS bucket that stores the snapshot.
3. Set the `base_path` parameter to the path of the snapshot.
4. Run the data restoration command on the destination cluster.

> **Note** These steps provide a simple solution to snapshot-based data migration. For more information, see Use a snapshot stored in OSS to migrate Elasticsearch data.

11.4. Use plug-ins

11.4.1. Use the a-pack-xdcr plug-in to replicate data across Elasticsearch clusters

This topic describes how to use the a-pack-xdcr plug-in for Elasticsearch to replicate data across Elasticsearch clusters in different data centers. This implements remote disaster recovery. Only Elasticsearch V6.7.0 and V6.8.2 clusters support this plug-in.

Prerequisites

- The a-pack-xdcr plug-in is installed on the source and destination Elasticsearch clusters.

  You can contact O&M personnel to install the plug-in. For more information, see Elasticsearch Operations and Maintenance Guide.

- The IP address of the source Elasticsearch cluster is obtained.

  You can obtain the IP address and port number of the source Elasticsearch cluster by running the `kubectl get svc -n <elasticsearch namespace>` command on the relevant Kubernetes server. You can also obtain the information from O&M personnel.

Context

Elasticsearch provides the cross data center replication (XDCR) feature. It allows you to replicate data across Elasticsearch clusters to implement remote high availability (HA). Core link applications must be able to withstand the impact of service interruptions in data centers or regions. The native capabilities of XDCR can meet disaster recovery and HA requirements across data centers without requiring additional technologies. You can use the XDCR feature to replicate data to data centers that are located in close proximity to users or application servers. This reduces latency and costs. For example, you can replicate product lists or reference datasets to 20 or more data centers around the world to minimize the distance between data and application servers.

Procedure

1. Log on to the Kibana console of the destination Elasticsearch cluster.For more information, see Log on to the Kibana console.
2. In the left-side navigation pane, click **Dev Tools**.
3. On the **Console** tab, run the following command to create a remote repository in the destination Elasticsearch cluster and connect the repository to the source Elasticsearch cluster:

```
PUT _cluster/settings
{
"persistent": {
"cluster": {
    "remote": {
      "leader": {
        "seeds": [
          "<your cluster IP>:<your cluster port>"
        ]
      }
    }
}
}
}
```

Note Replace <your cluster IP> with the IP address of the source cluster. Replace <your cluster port> with the port number of the source cluster. In most cases, the port number is 9300.

4. Run the following command to replicate data in an index:

```
PUT _xdcr/leader/<your_index>
```

Note Replace <your_index> with the name of the index whose data you want to replicate.

5. Run the following command to view the status of the replication task:

```
GET _cat/xdcr?v
```

If the command is successfully executed, the following result is returned.

index	repository	shard	localSeqNo	remoteSeqNo
twitter	leader	4	1	1
twitter	leader	1	0	0
twitter	leader	2	7	7
twitter	leader	3	3	3
twitter	leader	0	-1	-1

> **Note** index indicates the index name. repository indicates the destination cluster. shard indicates the index shard. localSeqNo indicates the maximum sequence number of the source cluster. remoteSeqNo indicates the maximum sequence number of the destination cluster.

6. Run the following command to view replicated data:

```
GET /<your_index>/_search
```

> **Note** Replace `<your_index>` with the name of the index that stores the replicated data.

11.4.2. Use the opendistro_sql plug-in to query cluster data by executing SQL statements

This topic describes how to use the opendistro_sql plug-in for Elasticsearch to query data in an Elasticsearch cluster by executing SQL statements.

Prerequisites

The opendistro_sql plug-in is installed. You can contact O&M personnel to install the plug-in. For more information, see Elasticsearch Operations and Maintenance Guide.

Procedure

1. Log on to the Kibana console of your Elasticsearch cluster.For more information, see Log on to the Kibana console.
2. In the left-side navigation pane, click **Dev Tools**.
3. On the **Console** tab, run one of the following commands to query cluster data by executing SQL statements.Elasticsearch supports the following SQL query syntax:

> **Note** Replace `<your_index>` in the following code with the name of the index whose data you want to query.

   - Syntax for an SQL query in a GET request

```
GET _opendistro/_sql?sql=select * from <your_index> limit 50
```

   - Syntax for an SQL query in a POST request

```
POST _opendistro/_sql
{
 "query": "SELECT * FROM <your_index> LIMIT 50"
}
```

   - Syntax for an SQL query with the CSV format specified for the data to return

```
POST _opendistro/_sql?format=csv
{
 "query": "SELECT * FROM <your_index> LIMIT 50"
}
```

Note

- For more information about SQL syntax, see SQL.
- If you want to execute Java code by using SQL statements, download the JDBC driver at https://github.com/opendistro-for-elasticsearch/sql-jdbc.

11.4.3. Use the bsearch_querybuilder plug-in to construct query conditions

This topic describes how to use the bsearch_querybuilder plug-in for Elasticsearch to construct query conditions in Kibana. This plug-in implements visualized data queries. Only Kibana V6.7.0 and V6.8.2 support this plug-in.

Prerequisites

The bsearch_querybuilder plug-in is installed. You can contact O&M personnel to install the plug-in. For more information, see Elasticsearch Operations and Maintenance Guide.

Procedure

1. Log on to the Kibana console of your Elasticsearch cluster.For more information, see Log on to the Kibana console.
2. In the left-side navigation pane, click **Discover**. On the page that appears, click **Query** in the upper-right corner.

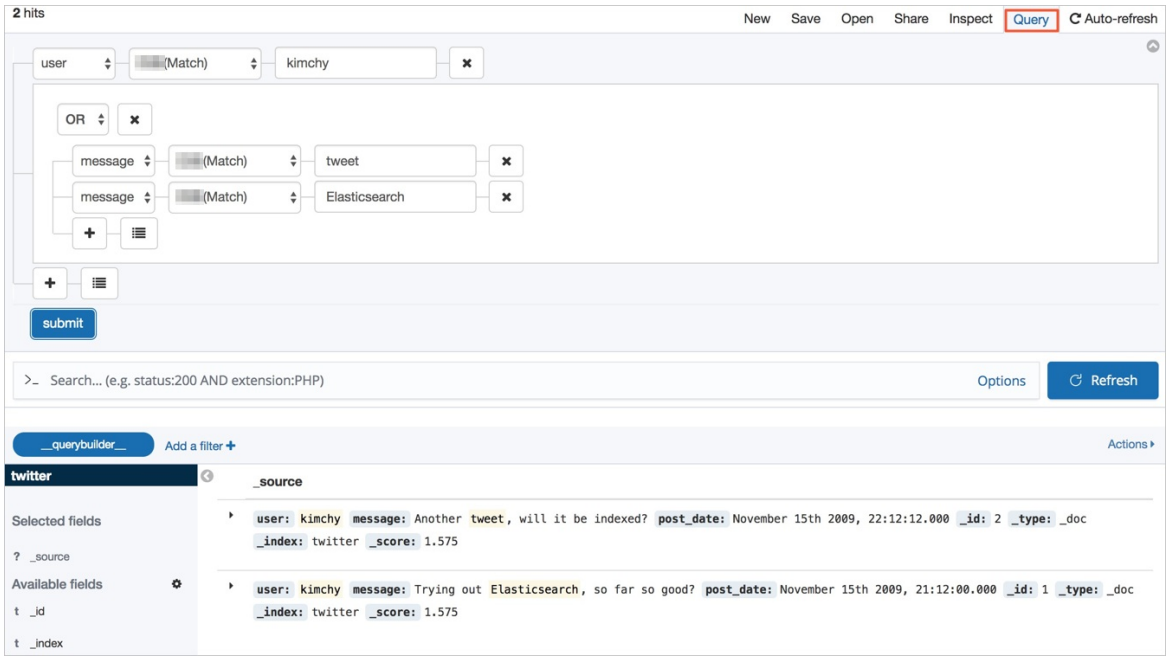
   Notice

   - Before you create a query, make sure that you have created an index pattern. To create an index pattern in the Kibana console, click **Management** in the left-side navigation pane. On the page that appears, click **Index Patterns** in the Kibana section. Then, click **Create index pattern** and create an index pattern as prompted.
   - If the bsearch_querybuilder plug-in is installed, but **Query** is not displayed in the Kibana console, the plug-in may not take effect. In this case, you must run the `kubectl delete deployments elasticsearch-cluster-kibana -n <your_es_namespace>` command on the relevant Kubernetes server to restart Kibana.

3. On the page that appears, specify query conditions and filters.Click the + icon to add a query condition. Click the ☰ icon to add a filter for the query condition. Click the ✖

icon to delete a query condition or filter.

The following figure shows a query example. In this example, the user condition is set to kimchy, and the type filters are set to tweet and Elasticsearch.



4. Click **submit**.

11.4.4. Use alerting plug-ins to implement alerting for an Elasticsearch cluster

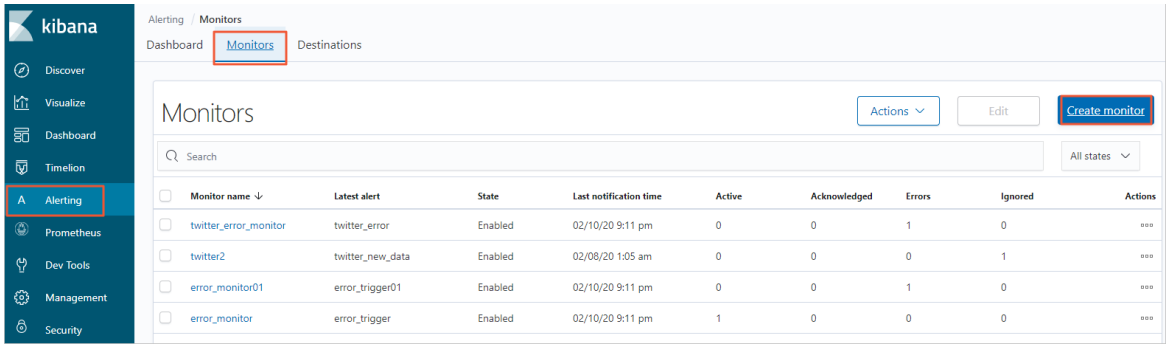
This topic describes how to use the alerting plug-ins of Elasticsearch and Kibana to implement alerting for an Elasticsearch cluster. You can configure alerts and customize alert thresholds and conditions for the cluster. The system sends alert notifications if the alert conditions are met.

Prerequisites

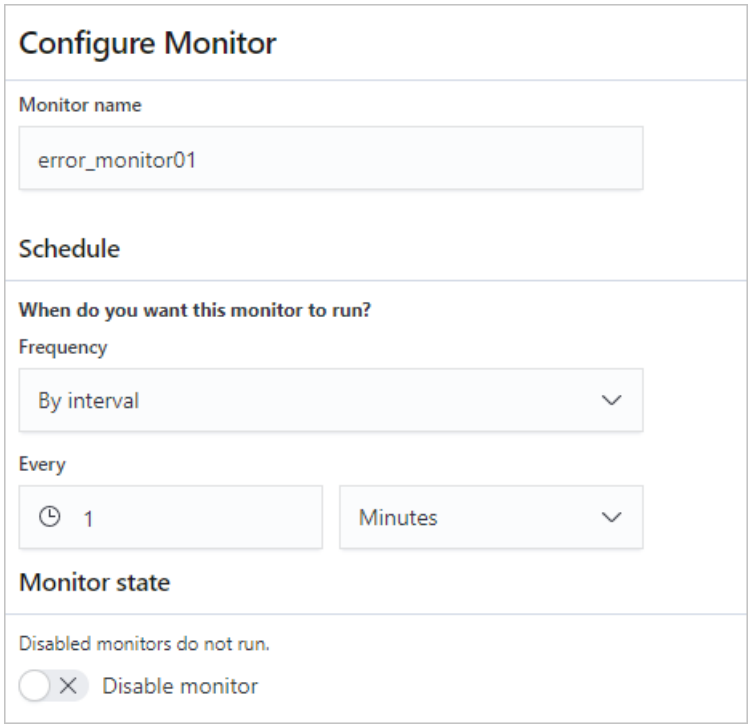
The opendistro_alerting plug-in for Elasticsearch and the opendistro-alerting plug-in for Kibana are installed. You can contact O&M personnel to install the plug-ins. For more information, see Elasticsearch Operations and Maintenance Guide.

Procedure

1. Log on to the Kibana console of your Elasticsearch cluster.For more information, see Log on to the Kibana console.
2. In the left-side navigation pane, click **Alerting**.
3. On the page that appears, click the **Monitors** tab.
4. In the upper-right corner of the tab, click **Create Monitor**.



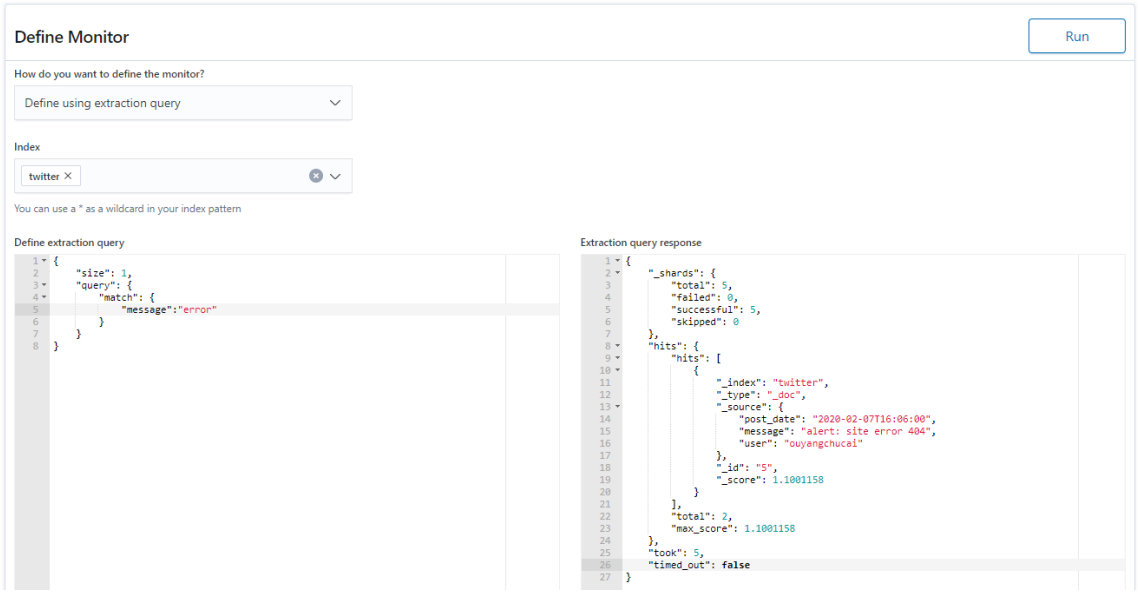
5. On the page that appears, specify the required parameters.



In this example, the name of the monitor is error_monitor01, and the monitor runs once a minute.

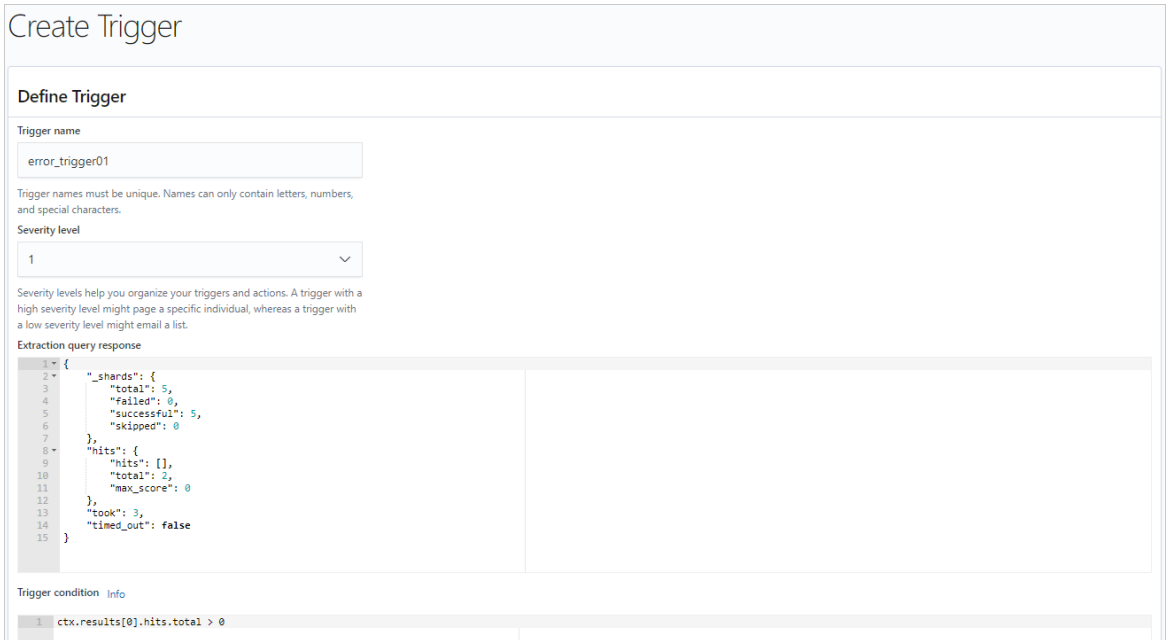
6. Define the monitor.Elasticsearch allows you to use visual images or specific query statements to define a monitor.
   - If you want to use visual images to define the monitor, you must specify an **index** and a **time field**.
   - If you want to use specific query statements to define the monitor, specify an **index** and query conditions. Then, click **Run** and view results. This method is used in this topic.

The following figure shows the query condition. This query is to obtain data that includes the error keyword from messages.



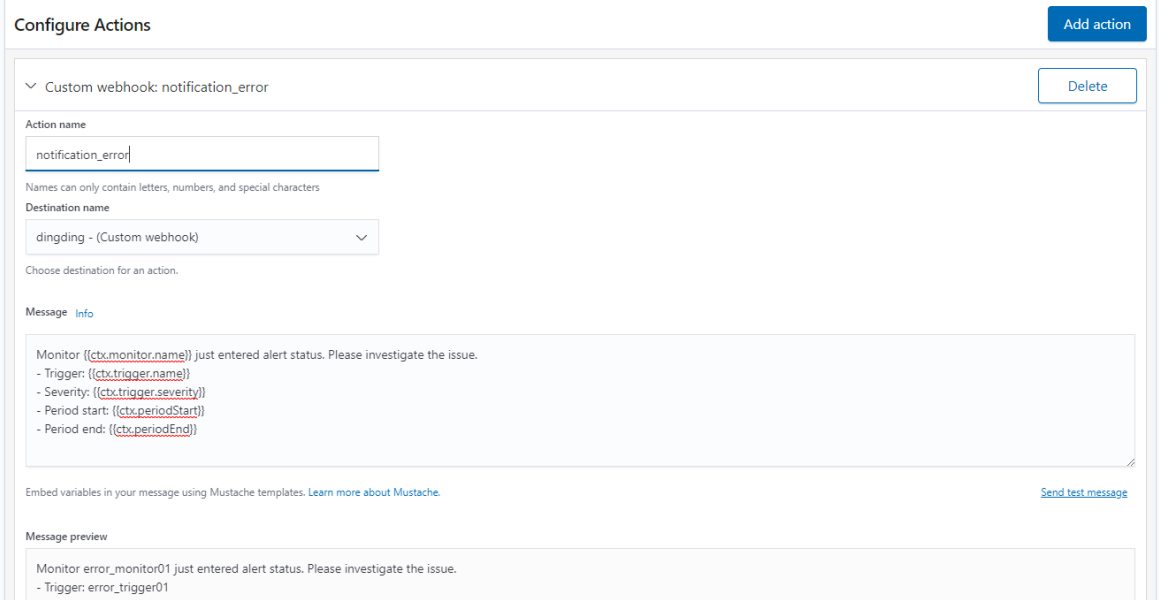
```
{
  "size": 1,
  "query": {
    "match": {
      "message":"error"
    }
  }
}
```

7. Click **Create**.
8. On the **Create Trigger** page, define and configure an alert trigger.



Parameter	Description
Trigger name	The name of the trigger.
Severity level	The severity of the trigger.
Extraction query response	The query response. This is specified in the alert definition and cannot be modified.
Trigger condition	The condition to trigger the alert. You can modify the condition based on your business requirements. For example, the condition is `ctx.results[0].hits.total > 0`. This indicates that an alert is reported when the number of returned entries is greater than 0.

9. Configure an alert notification.In the **Configure Actions** section, specify the required parameters.



Parameter	Description
Action name	The name of the notification.
Destination name	The destination address of the notification. In most cases, the address is a URL.
Message	The content of the notification. The content can be modified based on your requirements.
Message preview	The notification preview. This cannot be modified.

10. Click **Create**.
11. On the Alerting page, click the **Dashboard** tab to view the newly created alert.
