The Instances page lists all Hologres instances purchased by your Apsara Stack tenant account. On this page, you can view the instance status, change instance configurations, and create instances. You can also click an instance name to go to the instance details page where you can manage objects in the instance, including databases and users.

Instances

Log on to the Apsara Stack console. In the top navigation bar, choose **Products** > **Interactive Analytics** to go to the Hologres console. In the Hologres console, click **Instance List** in the left-side navigation pane. The following figure shows the Instance List page.

1. **New engine instance button**

   On the Instance List page, click **New engine instance**. In the New engine instance dialog box, enter an instance name and select the instance specifications to create a Hologres instance.

2. **Search box**

   If you have purchased multiple Hologres instances, you can enter a keyword of an instance name in the search box to find the target instance.

3. **Running status column**

   The Running status column displays the running status of each Hologres instance. An instance can be in one of the following states:

   - Normal operation: The instance is running as expected.
   - Creating: The payment is successful, and Hologres is creating the instance. You must wait for 3 to 5 minutes.
   - Shutdown: The instance has been suspended and you cannot connect to it.

Operation column

The Operation column provides the following buttons for you to manage a Hologres instance:

1. **Management**

   Find the target instance and click **Management** in the Operation column. On the page that appears, you can view and manage objects in the instance, including databases and users.

2. **Change configuration**

   If your instance cannot meet your business needs or your instance has a large amount of surplus resources, you can click **Change configuration** in the Operation column. In the **Change configuration** dialog box, upgrade or downgrade your instance configurations based on your business needs.

3. **Shutdown**

   Find the target instance and click **Shutdown** in the **Operation** column to suspend the instance. You cannot connect to the suspended instance.

2.6.6.3. Manage instances

This topic describes how to view and change instance configurations, select a network type, and select a connection method on the Basic information page in the Hologres console.

View and change instance configurations

In the Hologres console, click **Instance List** in the left-side navigation pane. In the instance list, find the target instance and click **Management** in the **Operation** column. The Basic information page displays basic information about a Hologres instance, including the instance name, instance ID, region, instance version, billing method, instance specification, and creation time.

If you need to change the instance specifications, click **Change configuration.** In the Change configuration dialog box, upgrade or downgrade the instance specifications based on your business needs.

Select a network type

The following table lists the supported network type.

Network type	Domain name	Scenario
Internal network	`<instancename>-cn-<region>-internal.hologres.aliyuncs.com:80`	Select this network type when you want to connect to the Hologres instance by using the classic network, without charges on the Internet traffic.

Select a connection method

Hologres is compatible with PostgreSQL. You can connect to a Hologres instance from the PostgreSQL client or over JDBC interfaces by using ETL or BI tools.

The Connection Methods section offers methods for you to use common development tools to connect to a Hologres instance. You can select a development tool and connection method based on your business needs and preference.

1. **Connect from the PostgreSQL client**

   To connect to a Hologres instance from the PostgreSQL client, use the following connection string:

   ```
   PGUSER=<AccessId> PGPASSWORD=<AccessKey> psql -p <Port> -h <Endpoint> -d <Database>
   ```

2. **Connect over JDBC**

   To connect to a Hologres instance over JDBC, use the following connection string:

   ```
   postgres://<AccessId>:<AccessKey>@<Endpoint>:<Port>/<database>? preferQueryMode=simple&tcpKeepAlive=true
   ```

2.6.6.4. Manage users

This topic describes how to manage users on the User Management page in the Hologres console.

Overview

In the Hologres console, click **Instance List** in the left-side navigation pane. In the instance list, find the target instance and click **Management** in the **Operation** column. On the page that appears, click **User Management**. On the User Management page, you can manage users on a Hologres instance without executing cumbersome SQL statements. For example, you can add and delete users and grant permissions to users on this page.

After you create a Hologres instance with your Apsara Stack tenant account, this account becomes a superuser of the instance. A superuser has all permissions on the Hologres instance. By default, the User Management page displays only the information of the Apsara Stack tenant account that creates the Hologres instance. The information of a Resource Access Management (RAM) user appears on this page only after you use the Apsara Stack tenant account to add it to the instance.

Column	Description	Remarks
Members	Displays the usernames of the Apsara Stack tenant account and RAM users on the Hologres instance.	Generally, a username appears in the xxx format.
Cloud account	Displays the account IDs of users on the Hologres instance.	N/A
Type	Displays the roles assigned to users on the Hologres instance.	The user can be a superuser or normal user.

Add a user

On the User Management page, you can create RAM users on a Hologres instance without executing the SQL CREATE statement.

Click **Add new user**. In the Add new user dialog box, select existing RAM users under your Apsara Stack tenant account to add them to the Hologres instance. If no RAM user exists under your Apsara Stack tenant account, create a RAM user first.

When you add a RAM user, you can assign the superuser or normal user role to the user.

- Superuser: A superuser has all permissions on the Hologres instance without the need for additional authorization.
- Normal user: A normal user cannot view or manage any objects on the Hologres instance, including databases, schemas, and tables. A normal user must be authorized before it can view and manage objects in the instance. We recommended that you go to the DB management page to grant permissions to RAM users as required. Alternatively, you can use SQL statements to grant permissions to RAM users.

Delete a user

Find the target user on the User Management page and click **Delete** in the Operation column to delete the user from the Hologres instance. A deleted user has no access to the Hologres instance.

2.6.6.5. Manage databases

This topic describes how to manage databases on the DB management page in the Hologres console.

Overview

In the Hologres console, click **Instance List** in the left-side navigation pane. In the instance list, find the target instance and click **Management** in the **Operation** column. On the page that appears, click **DB management**. On the DB management page, you can manage all databases on the current Hologres instance. You can create databases, select a permission management mode for the databases, and view database information.

> **Note** A default database named postgres is automatically created after you create a Hologres instance. This database is provided for management purposes only and does not appear on the DB management page. This database is allocated with limited resources. Create databases on this page based on your business needs.

Create a database

Hologres allows you to create a database with one click on the graphical user interface (GUI), eliminating the need for SQL operations.

Click **New Database**. In the New Database dialog box, enter a name for the database and set the Simple permissions model parameter to Open or Close. To simplify authorization, we recommend that you set the Simple permissions model parameter to Open.

Hologres provides two permission models for you to authorize users in a convenient way.

- Standard PostgreSQL authorization: Compatible with PostgreSQL, Hologres provides a permission model that is exactly the same as the standard PostgreSQL authorization model. You can authorize RAM users by using the standard PostgreSQL GRANT statement.
- SPM: Backed by the understanding of customers' business and its practical experience, Alibaba Cloud introduced a simple permission model (SPM) to Hologres to simplify the management of user permissions. The SPM is a coarse-grained model that authorizes users by user group.

After a database is created, you can use a development tool to connect to the database to analyze data.

Authorize a user

After the SPM is enabled for a new database, you can authorize RAM users with one click in the Hologres console. Perform the following steps:

1. **Open the Permission management right-side pane.**

   Find the target RAM user and click **User authorization** in the Operation column. You can grant permissions to a RAM user by adding the user to the desired user group.

2. **Add a RAM user to a user group.**

   In the Permission management right-side pane, click **Add authorization**. In the Add authorization dialog box, select the account to which you want to grant permissions, select the desired user group below Permissions policy, and then click **OK**.

Revoke permissions

If the SPM is enabled for your database, you can revoke the permissions of a RAM user with one click in the Hologres console.

On the instance details page, click **DB management**. On the DB management page, find the target database and click **User authorization** in the Operation column. In the Permission management right-side pane, find the target RAM user and click **Delete authorization** in the Operation column.

Delete a database

On the DB management page, find the database no longer required and click Delete in the Operation column to delete the database. After a database is deleted, data in the database is also deleted and cannot be recovered.

2.7. Realtime Analysis

2.7.1. Overview

Integrated with DataWorks, DataAnalysis supports creating MaxCompute tables in tabular mode, collaboratively editing workbooks and performing statistical analysis, and generating and sharing visual reports. These features enable data developers and business staff to quickly analyze data.

Go to DataAnalysis

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > DataAnalysis**.
3. On the **Home** page of DataAnalysis, click **Experience now** to go to the Web Excel page.

Features

- **Workbook**

  You can create and edit workbooks. Workbooks support basic operations such as addition, subtraction, multiplication, and division, and multiple data processing methods, including functions, classification, and aggregation. In addition, you can edit workbooks collaboratively with other users online and create pivot tables for further analysis.

- **Visual report**

  You can create and design visual reports by dragging, dropping, and configuring controls without running SQL statements.

- **Dimension table**

  You can create MaxCompute tables in tabular mode by one click without running SQL statements and edit MaxCompute tables collaboratively with other users online.

  - You can create a MaxCompute table in tabular mode.

- You can import data into a MaxCompute table by one click.

2.7.2. Workbook

2.7.2.1. Create a workbook

This topic describes how to create a workbook. After a workbook is created, you can rename, clone, delete, or change the owner of the workbook.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page, click  in the upper-left corner and choose **All Products** > **DataAnalysis**.
3. On the DataAnalysis homepage, click **Experience Now**.
4. On the **Web Excel** page, click  in the **New Spreadsheet** section.

   > **Note** If you have created workbooks, you can search for a workbook by entering its name in the search box in the **All Spreadsheets** section. Then, click the workbook name in the **File Name** column to go to the workbook editing page.

5. In the **New spreadsheet** dialog box, enter a name in the **File Name** field.
6. Click **OK**.

Result

After the workbook is created, it appears in the **All Spreadsheets** section. In this section, you can view all created workbooks. In addition, you can rename, clone, delete, or change the owner of a workbook.

- Find the target workbook and click **Rename** in the Operation column. In the **Rename** dialog box, enter the new name in the **File Name** field and click **OK**.
- Find the target workbook and click **Change Owner** in the Operation column. In the **Change Owner** dialog box, select an owner from the New Owner drop-down list and click **OK**.
- Find the target workbook and click **Clone** in the Operation column. The cloned workbook appears in the workbook list. The name of the cloned workbook contains the _copy suffix.
- Find the target workbook and click **Delete** in the Operation column. In the **Delete** message, click **OK**.

2.7.2.2. Edit a workbook

This topic describes how to edit a workbook. For example, you can import data to, export data from, and share a workbook, create a pivot table in a workbook, and use the data profiling feature.

Go to the workbook editing page

1. Log on to the DataWorks console.

2. On the DataStudio page, click in the upper-left corner and choose **All Products** > **DataAnalysis**.
3. On the DataAnalysis homepage, click **Experience Now**. The **Web Excel** page appears.
4. In the **All Spreadsheets** section of the **Web Excel** page, click the name of the target workbook in the **File Name** column.After you create a workbook, the workbook editing page appears.

Apply a template to a workbook or save a workbook as a template

You can apply an existing template to the current workbook by performing the following steps:

1. In the upper-right corner of the workbook editing page, choose **Template** > **Import Template**.
2. In the **Import Template** dialog box, select a file to be used as a template for the current workbook.

   > **Note** The data of the selected template will overwrite that of the current workbook.

3. Click **OK**.

You can save the current workbook as a template by performing the following steps:

1. In the upper-right corner of the workbook editing page, choose **Template** > **Save as Template**.
2. In the **Template settings** dialog box, set the **Type**, **Name**, and **Description** parameters.

   > **Notice** The template name can be up to 256 characters in length and the template description can be up to 1,024 characters in length.

3. Click **OK**.

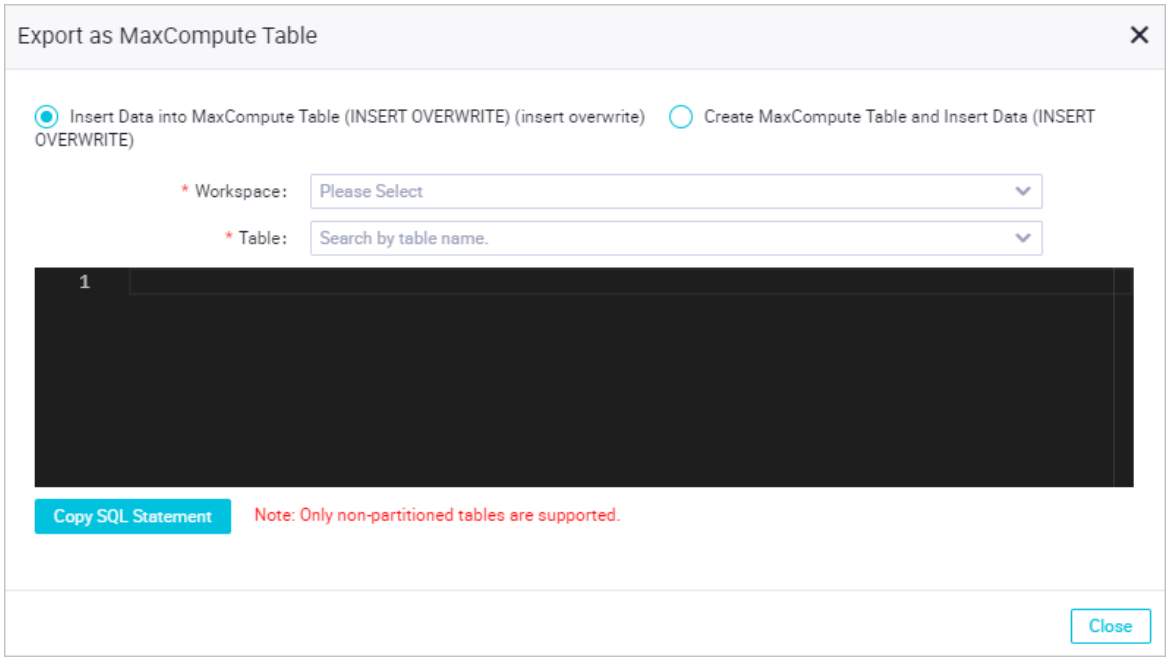
Import data to a workbook

1. In the upper-right corner of the workbook editing page, click **Import**.
2. In the Open dialog box, find and select a local file to be imported and click **Open**. The data in the local file is imported to the current workbook.

   > **Note** You can only import data from Excel files.

Export data from a workbook to a MaxCompute table

1. In the upper-right corner of the workbook editing page, choose **Export** > **Generate MaxCompute Build Table Statement**.
2. In the **Export as MaxCompute Table** dialog box, set relevant parameters.



Insert mode	Parameter	Description
Insert Data into MaxCompute Table (INSERT OVERWRITE) (insert overwrite)	**Workspace**	The workspace to which the MaxCompute table belongs.
	Table	The MaxCompute table to which you want to insert data.
Create MaxCompute Table and Insert Data (INSERT OVERWRITE)	**Workspace**	The workspace to which the MaxCompute table belongs.
	Table Name	The name of the MaxCompute table. Make sure that the table name has not been used. You can click **Check Duplicate Names** to check whether the table name exists.

3. After the parameters are set, click **Copy SQL Statement**.

> **Notice** Only non-partitioned tables are supported.

Create a pivot table

1. On the workbook editing page, select the data for which you want to create a pivot table and click **Pivot** in the upper-right corner.
2. In the **Create Pivot Table** dialog box, set relevant parameters.

   Specify the range of the data to be analyzed. You can set the **Choose Data** parameter to **Select Range** or **Use External Data Store** as needed.

   - If you select **Select Range**, select the cells in the workbook for which you want to create a

pivot table. The value of the **Range** field changes based on the selected cells.

> **Note** This parameter is available only when you select **Select Range**.

- If you select **Use External Data Store**, set the **Type** parameter first. You can set the Type parameter to **Mysql** or **Data Services**.
  - If you select **Mysql**, set the parameters described in the following table.

Parameter	Description
Choose Data	The range of the data to be analyzed. Select **Use External Data Store**.
Type	The type of the data source. Select **Mysql**.
Workspace	The workspace where the MySQL data store resides.
Data Store	The name of the connection to the data store. To create a connection to a data store, perform the following steps: Click the **Workspace Manage** icon in the upper-right corner. On the page that appears, click **Data Source** in the left-side navigation pane. On the Data Source page, create a connection to a data store.
Table	The table for which you want to create a pivot table.

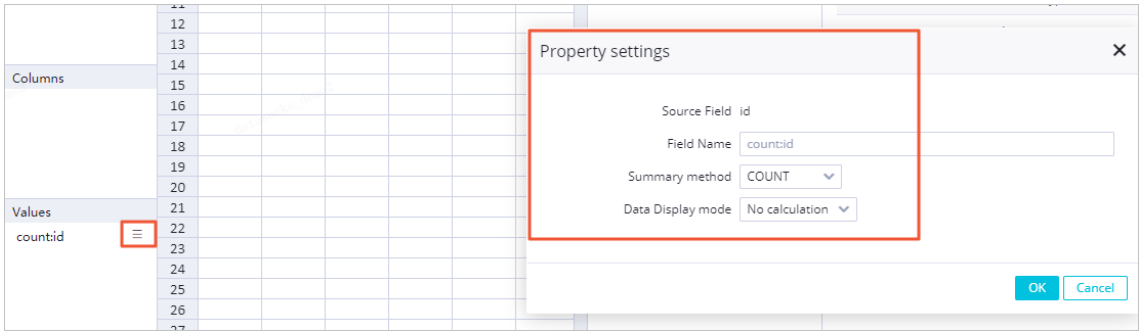
  - If you select **Data Services**, set the parameters described in the following table.

Parameter	Description
Choose Data	The range of the data to be analyzed. Select **Use External Data Store**.
Type	The type of the data source. Select **Data Services**.
Workspace	The workspace where the API of DataService Studio resides.
API Group	The API group to which the API belongs.
API	The API to be used as the data source.

3. Click **OK**. The pivot table editing page appears.This topic takes the pivot table for a selected range of data as an example.
   - **Data Source**: the range that you specified in the previous step.
   - **Pivot Table Fields**: the names of the fields that you selected in the previous step.
   - **Rows**: Drag fields from the Pivot Table Fields section to the **Rows** section. Each value of

the field added to the **Rows** section occupies a row in the pivot table.

- **Columns**: Drag fields from the Pivot Table Fields section to the **Columns** section. Each value of the field added to the **Columns** section occupies a column in the pivot table.
- **Values**: Click the property setting icon for a field in the **Values** section. In the Property settings dialog box, set the **Summary method** and **Data Display mode** parameters. By default, the **Field Name** parameter cannot be modified.



Parameter	Description
Source Field	The name of the selected source field.
Field Name	The name of the field that appears in the pivot table. The name is in the format of **Aggregation method:Source field name**.
Summary method	The aggregation method. Valid values: **SUM**, **COUNT**, **MAX**, **MIN**, and **AVG**.
Data Display mode	The mode for displaying the data. Valid values: **No calculation** and **Percentage of Total**.

- **Filters**: Drag fields from the Pivot Table Fields section to the Filters section. In the right-side pivot table display area, you can select the fields to filter data.

Download a workbook

In the upper-right corner of the workbook editing page, click **Download** to download the workbook to a local directory.

Share a workbook

In the upper-right corner of the workbook editing page, click **Share**. In the dialog box that appears, set the sharing mode.

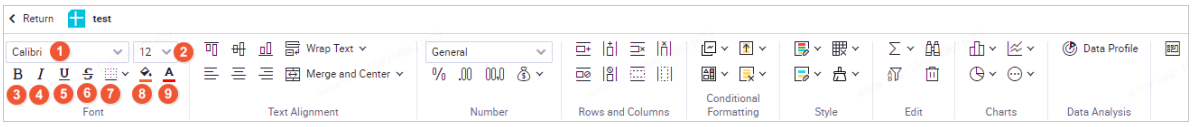
You can share the workbook in the following ways:

- **Link**: Click **Copy Link** and send the copied URL to other users as needed.
- **Users with Edit Access**: Click **Add** in the **Users with Edit Access** section. In the dialog box that appears, select the users to whom you want to grant the edit permission and click **OK**.
- **Visible to All**: To allow all users to view the workbook, turn on the **Visible to All** switch.
- **Users with Read Access**: To allow only specific users to view the workbook, turn off the **Visible to All** switch and click **Add** in the **Users with Read Access** section. In the dialog box that appears, select the users to whom you want to grant the read-only permission and click **OK**.

> **Note** If the system notifies you that the number of users to whom you want to grant the read-only permission reaches the upper limit, you can upgrade the DataWorks edition.

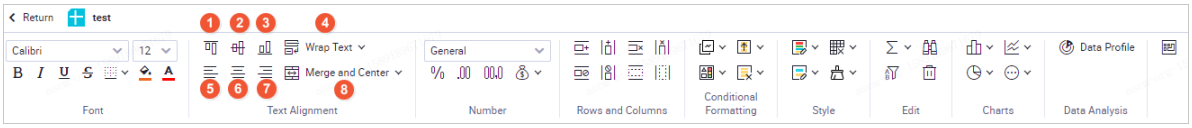
Menu bar

- **Font**



No.	Feature	Description
①	Font	Select a font type from the drop-down list as needed.
②	Font Size	Select a font size from the drop-down list as needed.
③	Bold	Set text in bold.
④	Italic	Set text in italic.
⑤	Underline	Underline text.
⑥	Strikethrough	Add a strikethrough to text.
⑦	Borders	Add borders to cells.
⑧	Background Color	Specify the background color of cells.
⑨	Text Color	Change the text color.

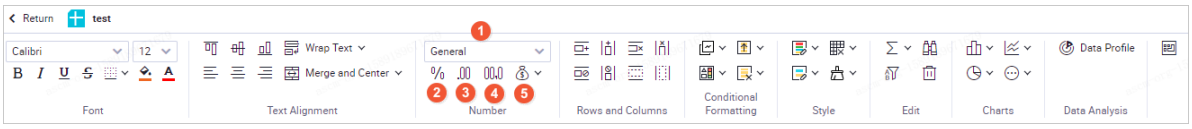
- **Text Alignment**



No.	Feature	Description
①	Top Align	Align text vertically to the top.
②	Middle Align	Align text vertically to the center.
③	Bottom Align	Align text vertically to the bottom.
④	Wrap Text	Display long text in multiple lines in a cell.

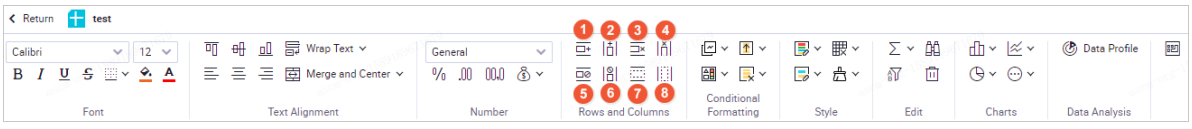
No.	Feature	Description
⑤	Align Left	Align text horizontally to the left.
⑥	Center	Align text horizontally to the center.
⑦	Align Right	Align text horizontally to the right.
⑧	Merge and Center	Merge multiple cells to one cell and center the content in the cell.

- **Number**



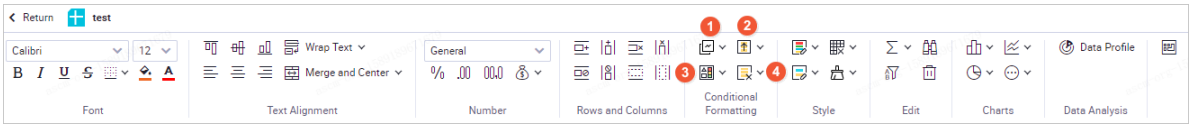
No.	Feature	Description
①	Data Type	Specify the type of data held in cells. You can select General, Number, Currency, Short Date, Long Date, Time, Percentage, Fraction, Scientific, and Text from the drop-down list.
②	Percentage	Apply the percentage format to numbers.
③	Two Decimal Places	Round numbers to two decimal places.
④	1000 Separator	Display numbers with thousands separators, for example, 1,005.
⑤	Currency	Add a currency sign to numbers. The following currency signs are supported: yuan sign (¥), dollar sign ($), pound sign (£), euro sign (€), and franc sign (Fr).

- **Rows and Columns**



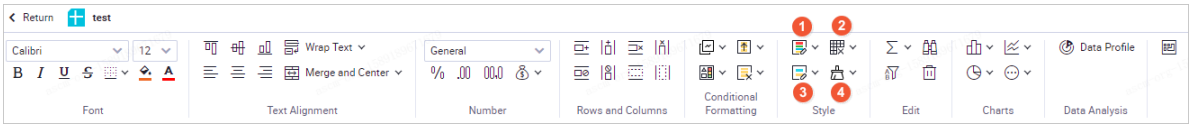
No.	Feature	Description
①	Insert Row	Insert a row to the workbook.
②	Insert Column	Insert a column to the workbook.
③	Delete Row	Delete rows from the workbook.
④	Delete Column	Delete columns from the workbook.
⑤	Lock Row	Lock the rows before the selected row in the workbook.
⑥	Lock Column	Lock the columns before the selected column in the workbook.
⑦	Hide Row	Hide rows in the workbook.
⑧	Hide Column	Hide columns in the workbook.

- **Conditional Formatting**



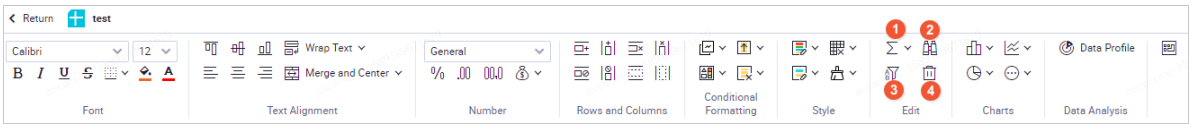
No.	Feature	Description
①	Highlight cell rules	Specify the rules for highlighting cells.
②	Data Bar/Color Scale	Format cells by using data bars and color scales.
③	Icon Set	Format cells by using icon sets. The icon sets include directional icons, shapes, indicators, and rating icons.
④	Clear Rule	Clear the formatting. You can select **Clear Rules from Selected Cells** or **Clear Rules from Entire Sheet** from the drop-down list.

- **Style**



No.	Feature	Description
①	Apply table style	Apply a predefined table style to cells.
②	Delete	Remove the applied table style.
③	Cell Style	Apply a cell style to cells.
④	Clear	Clear the content or style in cells. You can select **Clear All**, **Clear Content**, or **Clear Style** from the drop-down list.

- **Edit**



No.	Feature	Description
①	AutoSum	Select an aggregation method. You can select **Sum**, **Average**, **Count Numbers**, **Max**, or **Min** from the drop-down list.
②	Search	Click **Search** or press **Ctrl+F** to open the search box.
③	Sort and Filter	Filter data and sort data in ascending or descending order.
④	Clear	Clear the content in cells.

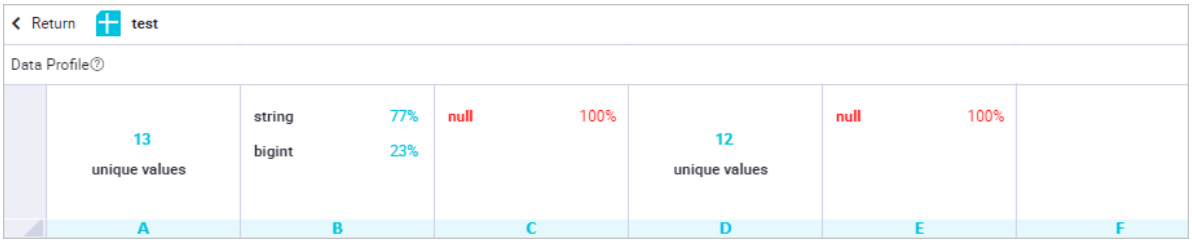
- **Charts**

  - **Column Chart**: After you click the **Column Chart** icon, you can select **Column Chart**, **Stacked Column Chart**, or **100% Stacked Column Chart**.
  - **Line Chart**: After you click the **Line Chart** icon, you can select **Line Chart**, **Stacked Line Chart**, **100% Stacked Line Chart**, **Line Chart with Markers**, **Stacked Line Chart with Markers**, or **100% Stacked Line Chart with Markers**.
  - **Pie Chart**: After you click the **Pie Chart** icon, you can select **Pie Chart** or **Doughnut Chart**.
  - **More**: After you click the **More** icon, you can view more chart types, including area charts, bar charts, scatter charts, and stock charts.

- **Data Profile**

The data profiling feature allows you to analyze the quality, structure, distribution, and statistics of the data. It also allows you to preview, profile, process, analyze, and visualize data. The data profiling feature analyzes data by column and allows you to view the distribution of data types and values of each column.

Select the data to be analyzed and click **Data Profile**. The data profiling feature displays the data type and value distribution of each column above the editing area in the form of charts and rich text.



Simple mode:

- For a column whose values are of the STRING or DATE type: The simple mode displays the values ranking top 2 based on frequency and their respective percentages, and the percentage of other values in the form of rich text. If the number of value types exceeds 50% of the total number of values, the simple mode displays the number of unique values.
- For a column whose values are of the INTEGER or FLOAT type: The simple mode displays the value distribution in the form of a histogram.
- For a column whose values are of the BOOLEAN type: The simple mode displays the proportions of different values in the form of pie charts.
- For a column whose values are of two or more data types: The simple mode displays the proportions of different data types in the form of pie charts. In addition, the system reminds you that the current column has dirty data. After the dirty data is cleared, the simple mode displays the data in one of the preceding forms based on the data type.
- For a column whose values are null values: The simple mode displays the percentage of null values in red.

Click **Detailed Mode** in the upper-right corner. In the **Data Profile** dialog box, you can view the profiling result of each column.

Detailed mode:

- For a column whose values are of the STRING or DATE type: The detailed mode displays the number of fields, the numbers and percentages of unique values, valid values, and null values, and the numbers of occurrences of the values ranking top 5 based on frequency.
- For a column whose values are of the INTEGER or FLOAT type: The detailed mode displays the number of fields, the numbers and percentages of unique values, valid values, zeros, and null values, the numbers of occurrences of the values ranking top 5 based on frequency, the statistics, and a histogram.
- For a column whose values are of the BOOLEAN type: The detailed mode displays the number of fields, the numbers and percentages of unique values, zeros, and null values, the numbers of occurrences of the values ranking top 5 based on frequency, and a pie chart.

> **Note** The system considers the true and false strings and the 0 and 1 integers as values of the BOOLEAN type.

- **List of Shortcut Keys**

  Click  to view the shortcut keys for different features.

2.7.3. Report

2.7.3.1. Create a report

This topic describes how to create a report. After a report is created, you can rename or delete the report.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page, click  in the upper-left corner and choose **All Products** > **DataAnalysis**.
3. On the DataAnalysis homepage, click **Experience Now**.
4. On the **Web Excel** page, click **Report** in the top navigation bar.
5. Click in the **New Report** section.Alternatively, click a template in the **New Report** section to create a report.

   > **Note** If you have created reports, you can search for a report by entering its name in the search box in the **All Reports** section. Then, click the report name in the **File Name** column to go to the report editing page.

6. In the **New Report** dialog box, set the **Report Name** and **Report Description** parameters.
7. Click **OK**.

Result

After the report is created, it appears in the **All Reports** section. In this section, you can view all created reports. In addition, you can rename or delete a report.

- To rename a report, perform the following steps: Find the target report and click **Rename** in the Operation column. In the **Rename** dialog box, enter the new name in the **File Name** field and click **OK**.
- To delete a report, perform the following steps: Find the target report and click **Delete** in the Operation column. In the **Delete** message, click **OK**.

2.7.3.2. Edit a report

This topic describes how to edit, preview, save, share, and release a report, and save a report as a template.

Procedure

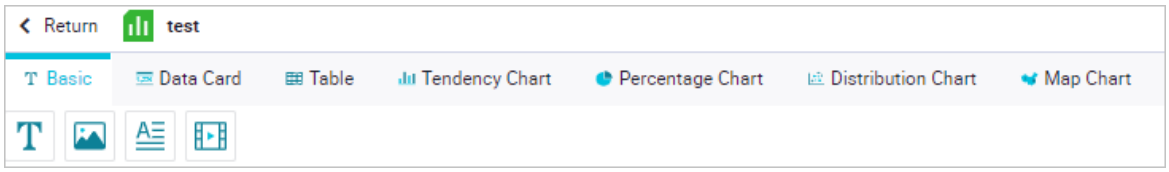
1. Go to the Report page.
   i. Log on to the DataWorks console.

ii. On the DataStudio page, click in the upper-left corner and choose **All Products** > **DataAnalysis**.

iii. On the DataAnalysis homepage, click **Experience Now**.

iv. On the **Web Excel** page, click **Report** in the top navigation bar.

2. Go to the report editing page.Use one of the following methods to go to the report editing page:
   - After you create a report, the report editing page appears.
   - In the **All Reports** section of the Report page, click the name of the target report in the **File Name** column.
3. Drag controls from the menu bar to the canvas. In this topic, the **Bar Chart** control on the **Tendency Chart** tab is dragged to the current report.You can drag a control from the menu bar to the canvas to use the control as a component in the report.

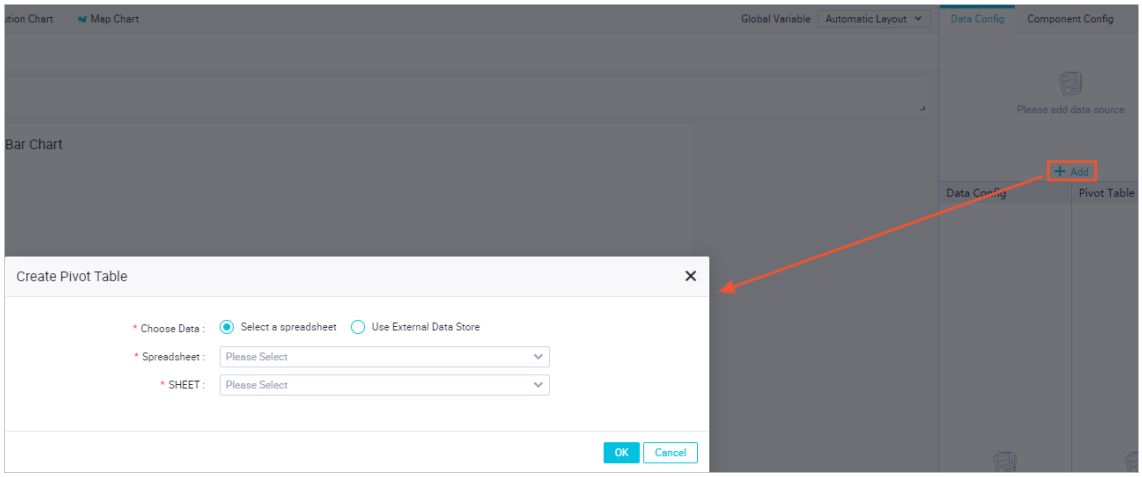


4. Click the **Bar Chart** component. Then, select a data store on the **Data Config** tab of the configuration section.If the required data store is added, click the name of the data store on the **Data Config** tab.

   If you need to add a data store, click **Add** on the **Data Config** tab. In the **Create Pivot Table** dialog box, set relevant parameters and click **OK**.

   You can set the Choose Data parameter to Select a spreadsheet or Use External Data Store.

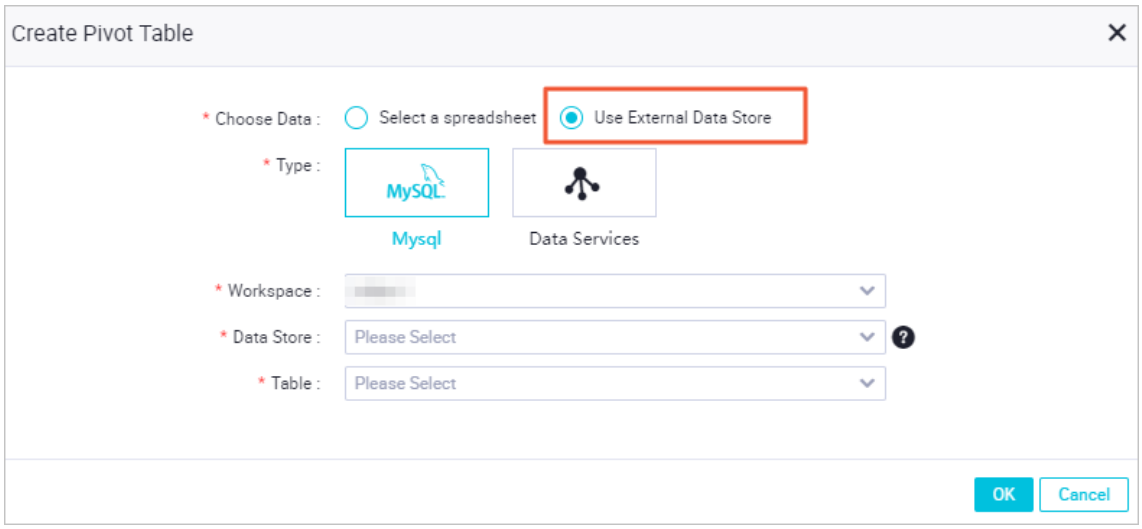
   - **Select a spreadsheet**: You can select an editable worksheet in a workbook of the current user as the data store.



Parameter	Description
Choose Data	The range of the data to be analyzed. Select **Select a spreadsheet**.

Parameter	Description
Spreadsheet	The workbook from which the data is analyzed. Select a workbook from the **Spreadsheet** drop-down list.
SHEET	The worksheet of which the data is analyzed. Select a worksheet from the **SHEET** drop-down list.

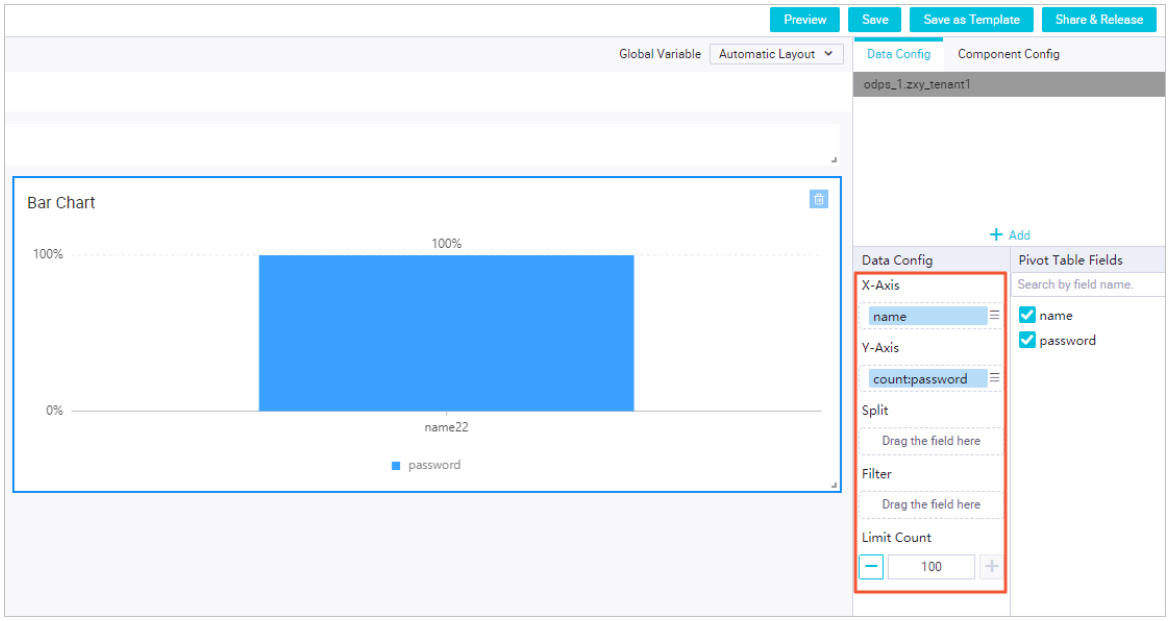
- **Use External Data Store**: You can select a MySQL data store or the API of DataService Studio.



Parameter	Description
Choose Data	The range of the data to be analyzed. Select **Use External Data Store**.
Type	The type of the data source. Valid values: **Mysql** and **Data Services**.
Workspace	The workspace where the MySQL data store resides.
Data Store	The name of the connection to the data store. To create a connection to a data store, perform the following steps: Click the **Workspace Manage** icon in the upper-right corner. On the page that appears, click **Data Source** in the left-side navigation pane. On the Data Source page, create a connection to a data store. **Note** This parameter is available only when you set the Type parameter to **Mysql**.

Parameter	Description
Table	The table of which the data is analyzed. Note This parameter is available only when you set the Type parameter to Mysql.
API Group	The API group to which the API belongs. Note This parameter is available only when you set the Type parameter to Data Services.
API	The API to be used as the data source. Note This parameter is available only when you set the Type parameter to Data Services.

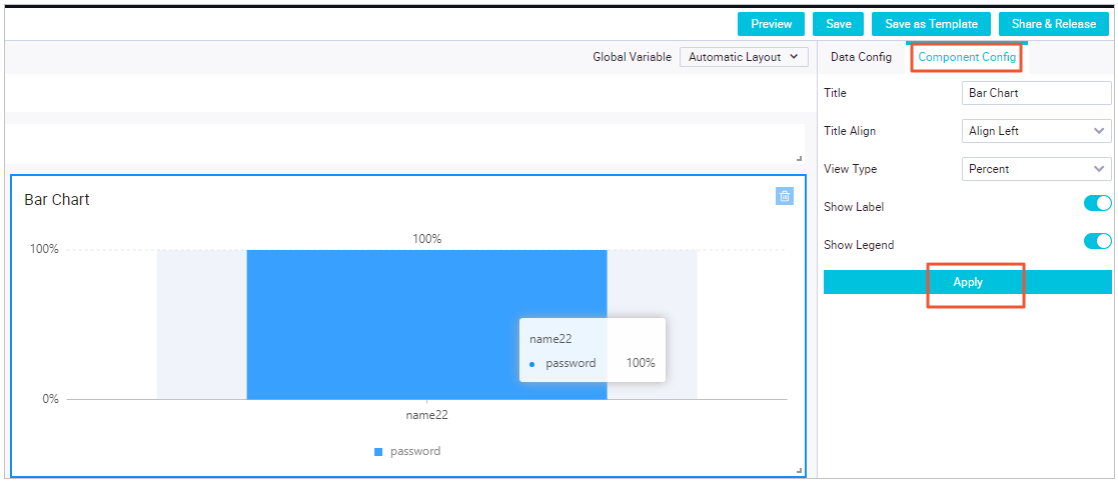
5. Select fields as statistical items.The fields that are required vary with the chart type. For example, you must specify the X-axis, Y-axis, split, and filter fields for a column chart by dragging fields from the **Pivot Table Fields** section to the **Data Config** section. You can also specify the number of vertical columns that can appear in the column chart.



Multiple charts can use the same data store. They can use the data store in different ways without affecting each other. A chart can use only one data store. When you click a chart and drag fields from the Pivot Table Fields section to the Data Config section, the chart is associated with the data store.

6. Configure the information about the column chart.
   i. On the canvas, click the **Bar Chart** component.
   ii. Click the **Component Config** tab in the right-side configuration section.

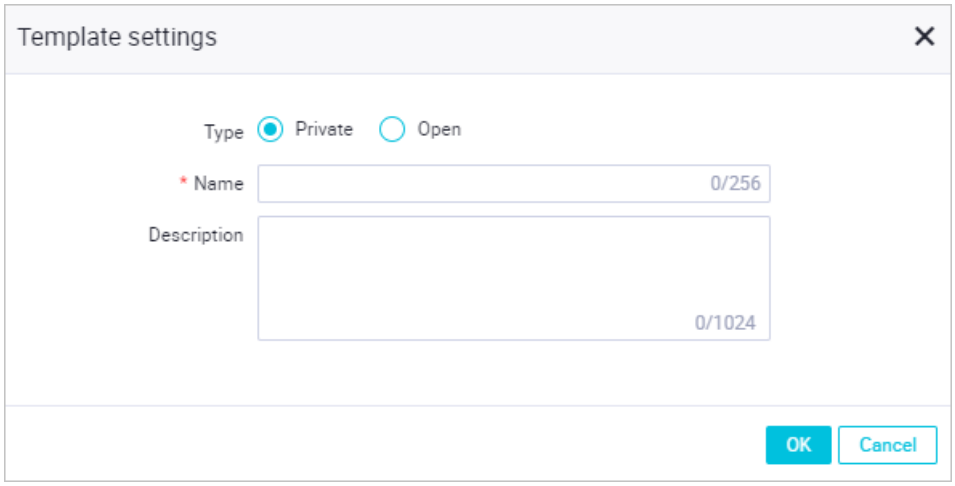
iii. On the **Component Config** tab, set relevant parameters.



Parameter	Description
Title	The title of the component.
Title Align	The alignment of the chart title. Valid values: **Align Left**, **Align Center**, and **Align Right**.
View Type	The display mode of vertical columns. Valid values: **Stack**, **Parallel**, and **Percent**.
Show Label	Specifies whether to display labels for the component.
Show Legend	Specifies whether to display legends for the component.

7. Click **Apply**.
8. Return to the **Report** page or preview, save, share, or release the report as needed.
   - **Return**: You can click **Return** in the upper-left corner to return to the **Report** page. On the Report page, you can view other reports and go to the report editing page of other reports.
   - **Preview**: You can click **Preview** in the upper-right corner to preview the report.
   - **Save**: You can click **Save** in the upper-right corner to save the report, so that you can open and edit the saved report next time.
   - **Save as Template**: You can save a report as a template, so that you can create a report based on the template. Perform the following steps to save a report as a template:
     a. On the report editing page, click **Save as Template** in the upper-right corner.
     b. On the **Preview** page, click **Next Step (Template setup)**.

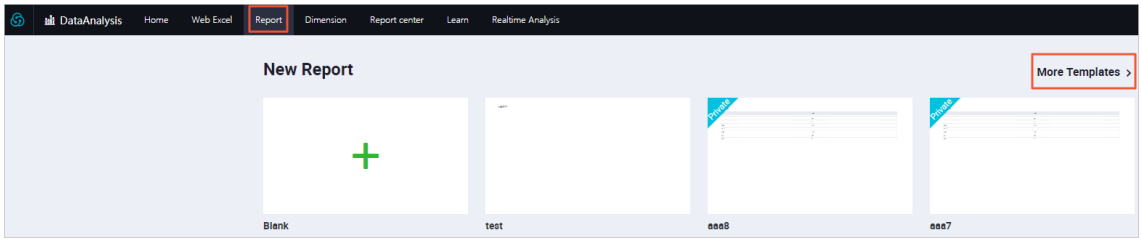
c. In the **Template settings** dialog box, set relevant parameters.



Parameter	Description
Type	Specifies whether to show or hide the template for other users. Valid values: **Private** and **Open**.
Name	The name of the template. The name can be up to 256 characters in length.
Description	The description of the template. The description can be up to 1,024 characters in length.

d. Click **OK**.

After you save the report as a template, you can click the template in the New Report section of the **Report** page to create a report.



- **Share & Release**: You can click **Share & Release** in the upper-right corner to share and release the report. You can share the report with specified users or all users. If you need to share the report to specific users, click **Add** to specify the users.

2.7.4. Go to the report center

On the Data analysis report center page, you can view the visualized report solution that DataAnalysis provides.

Procedure

1. Log on to the DataWorks console.

2. On the **DataStudio** page, click in the upper-left corner and choose **All Products** > **DataAnalysis**.
3. In the top navigation bar of the DataAnalysis page, click **Report center** to go to the **Data analysis report center** page.

2.7.5. Go to the learning center

On the Data analytics Learning Center page, you can view relevant materials and learn about DataAnalysis.

Procedure

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click in the upper-left corner and choose **All Products** > **DataAnalysis**.
3. In the top navigation bar of the DataAnalysis page, click **Learn** to go to the **Data analytics Learning Center** page.

2.8. Administration

2.8.1. Overview

Generally, developers need to test workflows and nodes on the Operation Center page.

As a key tool for routine O&M, Operation Center enables you to manage and maintain the workflows and nodes that you have committed. The Operation Center service consists of four modules: Dashboard, Nodes, Node Instances, and Monitor.

- **Dashboard**: enables you to view and manage all global nodes of DataWorks. It displays various information, including **Instances**, **Instances Run Today**, **Node Runtime**, **Instances Run in the Last Month**, **Nodes with Errors in the Last Month**, and **Node Types** of the current workspace.
- **Nodes**: provides **Recurring** and **Manually Triggered**.
- **Node Instances**: provides **Recurring**, **Manually Triggered**, **Smoke Test** and **Retroactive**. You can manage them in a list view or DAG.
  - The list view displays the running status of nodes in a list. You can add multiple alerts at a time, change owners, and add nodes to baselines.
  - In the DAG, you can maintain and manage the running status of nodes and their dependencies on ancestor and descendant nodes. You can also perform operations, such as retroactive data generation and rerun, for a single node.
- **Monitor**: provides **Baseline Instances**, **Baselines**, **Events**, **Alert Triggers**, and **Alerts**.

2.8.2. Dashboard

The Dashboard page provides information about the node running status, the trend of the number of nodes that were run, the node running time, and the nodes with errors.

Go to the Dashboard page

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Operation Center**. By default, the **Dashboard** page appears.

The **Dashboard** page consists of the following sections: **Instances**, **Instances Run Today**, **Node Runtime**, **Nodes with Errors In the Last Month**, **Instances Run In the Last Month**, and **Node Types**.

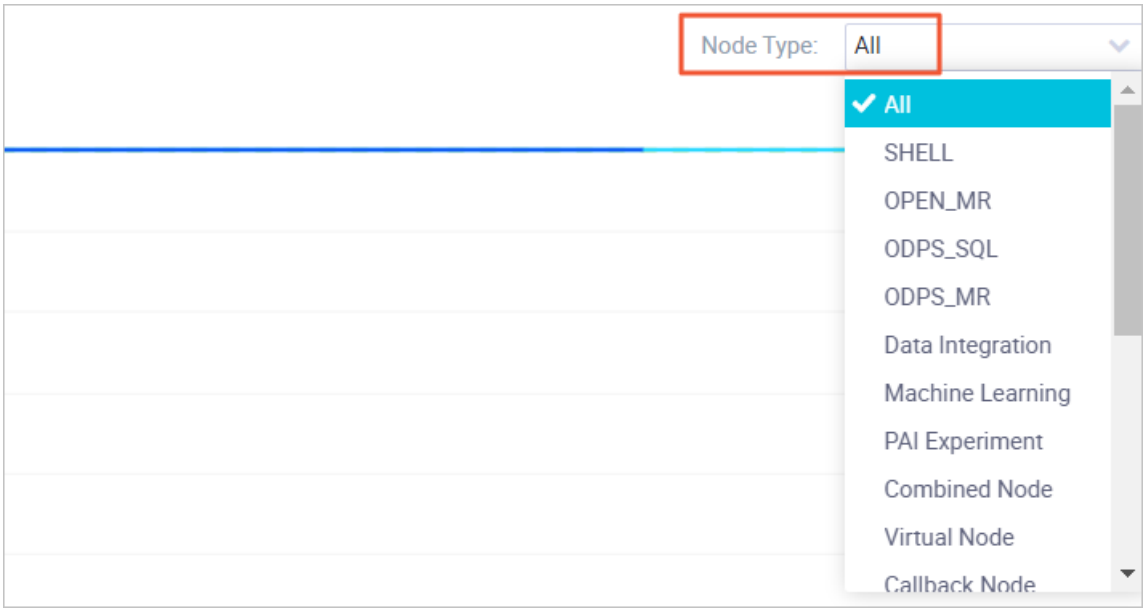
> **Note**
> - Pending (Schedule): the instances whose scheduled time has not arrived. These instances will be automatically run when their scheduled time arrives.
> - Pending (Resources): the instances whose scheduled time has arrived. These instances are waiting for scheduling resources.

View the summary of instance running

The **Instances** section displays the numbers of auto triggered node instances that were run today and yesterday, as well as the historical average. If the deviations among the three numbers are large, an exception occurred during a specific period of time. Further check and analysis are required.

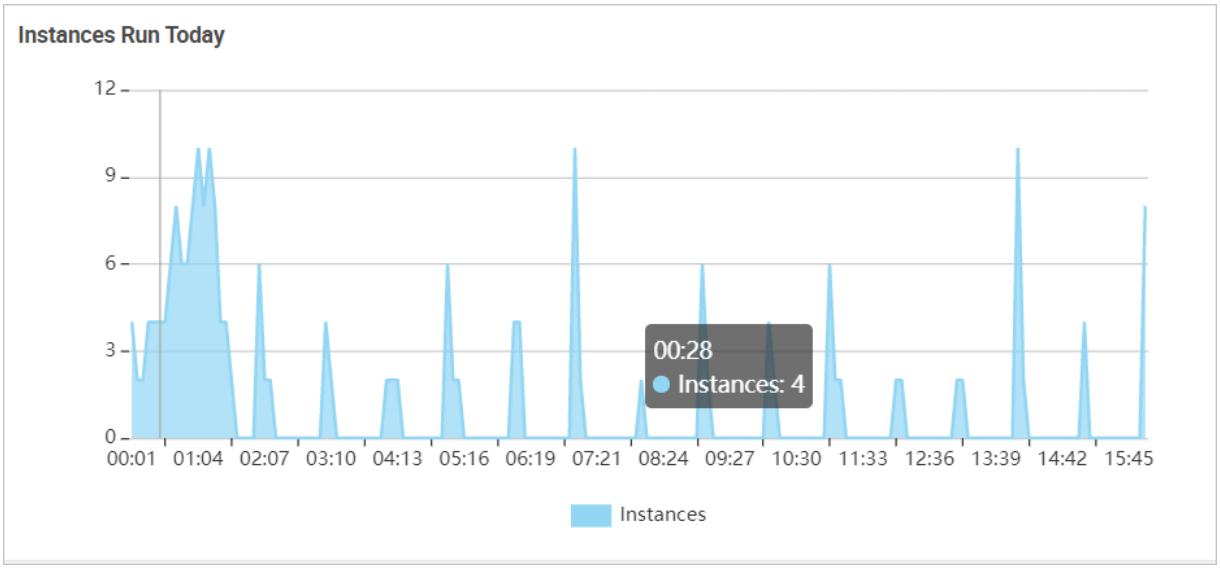
The statistical chart on the right of the Instances section shows three lines in different colors, representing the numbers of instances completed between 00:00 and 23:00 of today and yesterday, as well as the historical average. You can also view the number and proportion of instances in the pie chart on the left.

In the upper-right corner of the statistics chart, you can select a node type from the **Node Type** drop-down list to view statistics on the specified type of nodes.



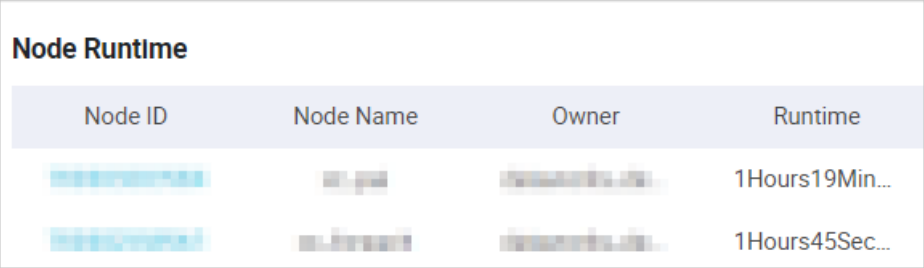
View the statistics on instances run today

The **Instances Run Today** section displays the numbers of node instances that were running at different time points of the current day. In the chart, you can find the time point when peak concurrency occurred and the maximum number of concurrent nodes. Based on the information, you can determine whether to avoid node scheduling at the peak hours and adjust the scheduling time of nodes.



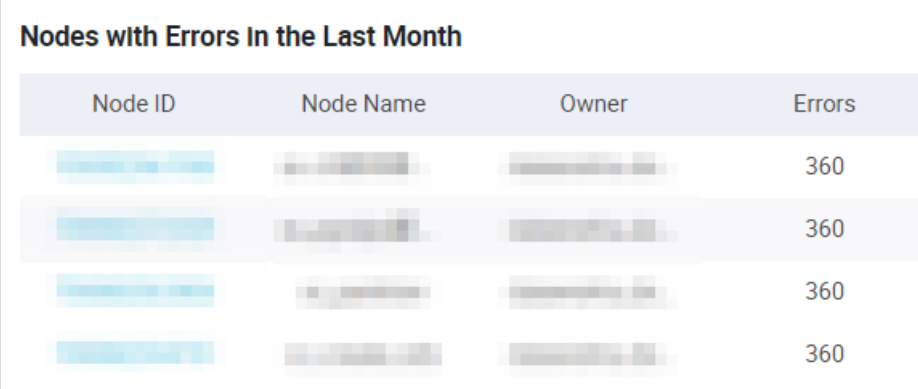
View the rankings of nodes based on their running time

The **Node Runtime** section displays nodes with a specified timestamp in the current workspace by their running time. By default, this section displays the top 10 nodes in descending order of their running time. You can view **Node ID**, **Node Name**, **Owner**, and **Runtime** of each node.



View the rankings of nodes with errors in the last month

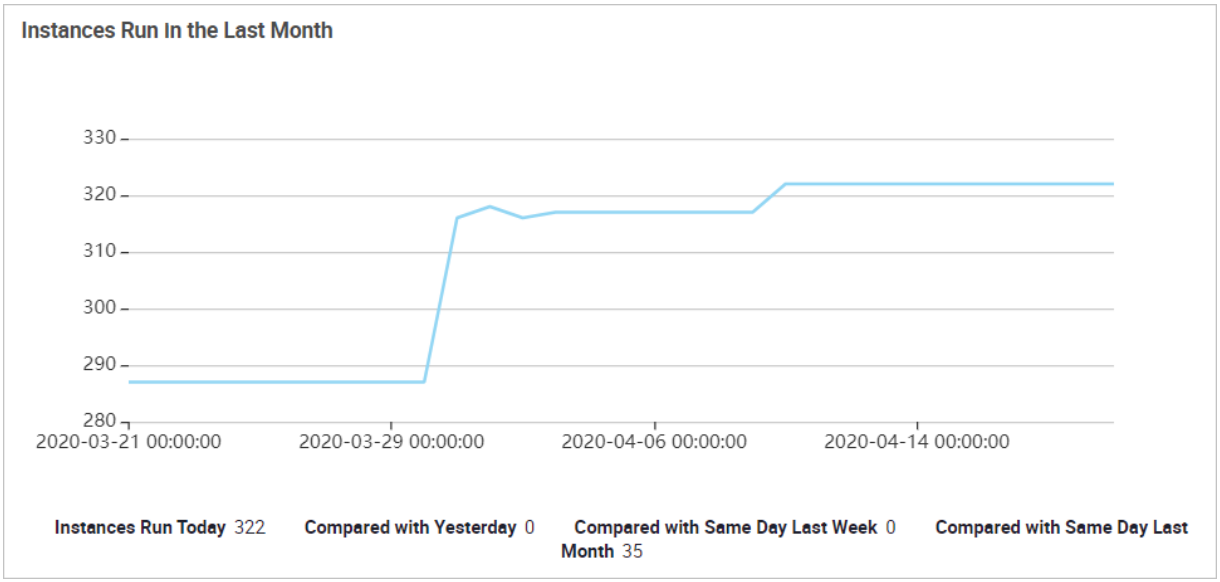
The **Nodes with Errors In the Last Month** section displays the top 10 nodes with the most errors in the last month. You can view **Node ID**, **Node Name**, **Owner**, and **Errors** of each node.



You can click a node ID to go to the node details page.

View the trend of the number of instances that were run

The **Instances Run In the Last Month** section displays the number of instances that were run today, comparison with yesterday, comparison with the same day last week, and comparison with the same day last month.



View the node distribution by node type

In the **Node Types** section, you can move the pointer over a sector of the pie chart to view the number and proportion of nodes of the specific type.

2.8.3. Auto triggered node O&M

2.8.3.1. Manage auto triggered nodes

Auto triggered nodes are automatically run as scheduled after they are committed to the scheduling system.

> **Note**
>
> - By default, the auto triggered node list displays nodes in all the workflows created by the current account.
> - After you commit a node, the scheduling system automatically generates and runs an instance of the node at 23:30 the next day. If you commit a node after 23:30, the scheduling system generates and runs an instance of the node on the third day.
> - Do not perform any operations on the **Workspace name_root** node, which is the root node of the workspace. All instances of auto triggered nodes depend on this node. If this node is frozen, instances of auto triggered nodes cannot be run.

Manage auto triggered nodes in the node list

The Cycle Task page displays auto triggered nodes that are committed to the scheduling system in a list.

Operation	Description
Filter	Find required nodes by setting parameters in the red box marked with 1 in the preceding figure. You can search for nodes by node name or node ID and set the **Node Type**, **Owner**, **My Nodes**, **Modified Today**, and **Frozen** parameters to filter nodes. **Note** When you search for nodes by node name, the search result is affected by other filter conditions you specified. Only the nodes that meet both the specified search condition and other filter conditions are returned in the search result.
DAG	Click **DAG** in the Actions column of a node to view the directed acyclic graph (DAG) of the node. You can view the node information, such as properties, operations logs, and code, in the DAG.
Test	Click **Test** in the Actions column of a node to test the node. For more information, see Manage test instances.
Patch Data	Click **Patch Data** in the Actions column of a node and select an item from the drop-down list to generate retroactive data for the node. For more information, see Manage retroactive instances.

Operation	Description
More operations	Click **More** in the Actions column of a node to perform more operations on the node. You can perform the following operations on the node: • Select **Freeze** to freeze the node. After the node is frozen, DataWorks can still generate instances of the node, but does not run the instances of the node and its descendant instances. • Select **Unfreeze** to unfreeze the node. After the node is unfrozen, DataWorks can normally run the instances of the node and its descendant instances. • Select **View Instances** to view the instances of the node. • Select **Configure Alert Trigger** to configure alert triggers for the node. • Select **Change Owner** to change the owner of the node. • Select **Add to Baseline** to add the node to a baseline. • Select **Change Resource Group** to change the resource group used to run the node if multiple resource groups exist in the workspace. • Select **Configure Data Quality Rules** to configure rules for monitoring the data quality of the node. • Select **View Lineage** to view the lineage of the node. • Select **View Ancestor and Descendant Nodes** to go to the **Node Information** page, where you can view node information on the **Ancestor Nodes** and **Descendant Nodes** tabs.
Batch operations	Select multiple nodes and click a button in the red box marked with 3 in the preceding figure to perform batch operations. The buttons include **Configure Alert Trigger**, **Change Owner**, **Change Resource Group**, **Add to Baseline**, **Freeze**, **Unfreeze**, and **Delete**.

Manage auto triggered nodes in a DAG

Click the name of a node or **DAG** in the Actions column to view the DAG of the node. In the DAG, you can right-click the node to perform related operations.

Operation	Description
Show Ancestor Nodes or **Show Descendant Nodes**	View ancestor or descendant nodes at one or more levels. If the workflow contains three or more nodes, the DAG displays only the current node and hides its ancestor and descendant nodes.
View Node Details	Go to the **Node Information** page to view the node information, including the input table, output table, ancestor nodes, and descendant nodes.
View Code	View the code of the node.
Edit Node	Go to the DataStudio page to modify the node.
View Instances	View the instances of the node.
View Lineage	View the lineage of the node.

Operation	Description
Test	Go to the **Smoke Test** dialog box. Set the **Smoke Test Instance Name** and **Data Timestamp** parameters and click **OK**. Then, the Test Instance page appears.
Run	Select **Current Node Retroactively**, **Current and Descendant Nodes Retroactively**, or **Mass Nodes Retroactively**.
Freeze	Pause the scheduling of the node.
Unfreeze	Resume the scheduling of the node after it is frozen.
Configure Data Quality Rules	Configure rules for monitoring the data quality of the node.

2.8.3.2. Manage auto triggered node instances

Auto triggered node instances are snapshots taken for auto triggered nodes that are run.

An instance is generated each time when an auto triggered node is run as scheduled. You can manage auto triggered node instances. For example, you can view the running status of instances, and stop, rerun, and unfreeze instances.

> **Note** DataWorks regularly generates instances for auto triggered nodes. Each generated instance runs the latest code. If you modify and recommit the node code after instances are generated, the instances that have not been run will run the latest code.

Manage auto triggered node instances in the instance list

You can manage auto triggered node instances in the instance list. For example, you can check operational logs, rerun instances, and stop running instances.

Operation	Description
Filter	Find required instances by setting parameters in the red box marked with 1 in the preceding figure. You can search for instances by node name or node ID and set the following parameters to filter instances: **Data Timestamp**, **Node Type**, **Run At**, **Solution**, **Workflow**, **Region**, **Engine type**, **Engine instance**, **Baseline**, **Owner**, **Recurrence**, **Status**, **My Nodes**, **My Nodes with Errors**, **My Incomplete Nodes**, and **Re-run node**. > **Note** By default, the data timestamp is set to the previous day of the current day.
Stop	Stop the instance. You can stop instances only when they are in the **Pending (Resource)** or **Running** state. After you perform this operation, the instance enters the **Failed** state.

Operation	Description
Rerun	Rerun the instance. After the instance is rerun, its descendant instances will be run as scheduled. Perform this operation if an instance fails or it is not run as scheduled. Note This operation applies only to instances in the Pending (Ancestor), Successful, or Failed state.
Rerun Descendant Nodes	Rerun the instance and its descendant instances. You must specify the instances to rerun. After they are run, their descendant instances will be run as scheduled. This operation applies to data recovery. Note You can select instances only in the Pending (Ancestor), Successful, or Failed state. The value No appears in the Meet Rerun Condition column of instances in other states, and you cannot select the instances.
Set Status to Successful	Set the status of the instance to Successful and run its descendant instances as scheduled. You can perform this operation if an instance fails. Note This operation applies only to failed instances but not workflows.
Freeze	Freeze the instance if it is in the Running state.
Unfreeze	Unfreeze the instance after it is frozen. • If the instance is not run, DataWorks automatically runs this instance after its ancestor instances are run. • If all the ancestor instances have been run, the instance is directly set to Failed. You must manually rerun the instance.
Batch operations	Select multiple instances and click a button in the red box marked with 3 in the preceding figure to perform batch operations. The buttons include Stop, Rerun, Set Status to Successful, Freeze, and Unfreeze.

Manage auto triggered node instances in a DAG

Click the name of an instance or DAG in the Actions column to view the directed acyclic graph (DAG) of the instance. In the DAG, you can right-click the instance to perform related operations.

Operation	Description
Show Ancestor Nodes or Show Descendant Nodes	View ancestor or descendant instances at one or more levels. If a workflow contains three or more instances, the DAG displays only the current instance and hides its ancestor and descendant instances.

Operation	Description
View Runtime Log	View the operational logs of the instance if it is in the Running, Successful, or Failed state.
View Code	View the code of the instance.
Edit Node	Go to the DataStudio page to modify the node to which the instance belongs.
View Lineage	View the lineage of the instance.
More operations	View more instance information on the **General**, **Context**, **Runtime Log**, **Operation Log**, and **Code** tabs.
Stop	Stop the instance if it is in the Pending (Resource) or Running state. After you perform this operation, the instance enters the Failed state.
Rerun	Rerun the instance. After the instance is rerun, its descendant instances will be run as scheduled. Perform this operation if an instance fails or it is not run as scheduled. **Note** This operation applies only to instances in the **Pending (Ancestor)**, **Successful**, or **Failed** state.
Rerun Descendant Nodes	Rerun the instance and its descendant instances. You must specify the instances to rerun. After they are run, their descendant instances will be run as scheduled. This operation applies to data recovery. **Note** You can select instances only in the **Pending (Ancestor)**, **Successful**, or **Failed** state. The value No appears in the **Meet Rerun Condition** column of instances in other states, and you cannot select the instances.
Set Status to Successful	Set the status of the instance to Successful and run its descendant instances as scheduled. You can perform this operation if an instance fails. **Note** This operation applies only to failed instances but not workflows.
Resume	Continue to run the instance after it fails.
Emergency Operations	Perform emergency operations, including **Delete Dependencies**, **Change Priority**, and **Force Rerun**. Perform these operations in emergency only. These operations take effect only on the current instance for one time. Select **Delete Dependencies** to delete dependencies of the current instance. You can perform this operation so that you can start the current instance when the ancestor instances fail and the current instance does not depend on the data of the ancestor instances.

Operation	Description
Freeze	Freeze the instance if it is in the Running state.
Unfreeze	Unfreeze the instance after it is frozen. • If the instance is not run, DataWorks automatically runs this instance after its ancestor instances are run. • If all the ancestor instances have been run, the instance is directly set to Failed. You must manually rerun the instance.

2.8.3.3. Manage retroactive instances

DataWorks runs retroactive instances to generate retroactive data for auto triggered nodes. You can manage retroactive instances. For example, you can view the running status of instances, and stop, rerun, or unfreeze instances.

Limits

- When DataWorks generates retroactive data in a period of time for a node, if one instance of the node fails on a day, the retroactive instance for that day is also set to Failed. DataWorks will not run instances of this node for the next day. To sum up, DataWorks runs instances of a node on a day only when all its instances of the previous day are successful.
- For a self-dependent auto triggered node, if the first instance for which retroactive data needs to be generated has a last-cycle instance on the previous day but the last-cycle instance is not run, the retroactive instance cannot be triggered. If the first instance for which retroactive data needs to be generated does not have a last-cycle instance on the previous day, the retroactive instance is directly triggered.
- DataWorks generates alerts only for auto triggered node instances.
- If an auto triggered node has an instance in the Running state, its retroactive or test instance can start to run only after this auto triggered node instance is run.
- If both an auto triggered node instance and a retroactive instance are running for a node at the same time, you must stop the retroactive instance to ensure proper running of the auto triggered node instance.

Go to the page for configuring retroactive instances

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Operation Center**.
3. In the left-side navigation pane, choose **Cycle Task Maintenance > Cycle Task**.
4. On the page that appears, click the rightward arrow in the middle to show the Actions column in the node list. Find the target node, click **Patch Data** in the Actions column, and then select a mode for generating retroactive data.

   You can also right-click the target node in the directed acyclic graph (DAG), move the pointer over **Run**, and then select a mode for generating retroactive data.

Generate retroactive data for the current node

1. Find the target node, click **Patch Data** in the Actions column, and then select **Current Node**

Retroactively.

2. In the **Patch Data** dialog box, set the parameters.

Parameter	Description
Retroactive Instance Name	The name of the retroactive instance. DataWorks automatically generates a name, which can be changed.
Data Timestamp	The data timestamp of the retroactive instance.
Node	The name of the node for which you want to generate retroactive data. You cannot change the name.
Parallelism	Specifies whether to generate multiple retroactive instances at a time. ○ If you select **Disable**, only one retroactive instance is generated. The retroactive instance is run multiple times based on the data timestamp in sequence. ○ If you select **2 Parallel Groups**, **3 Parallel Groups**, **4 Parallel Groups**, or **5 Parallel Groups**, multiple retroactive instances are generated. The retroactive instances are run based on the data timestamp in parallel or in sequence. ■ If the number of days in the data timestamp is smaller than the number of parallel groups, the retroactive instances are run in parallel. For example, the data timestamp is from January 11 to January 13, and you select 4 Parallel Groups. In this case, three retroactive instances are generated for each day in the data timestamp, and the three retroactive instances are run in parallel. ■ If the number of days in the data timestamp is greater than the number of parallel groups, some instances must be run multiple times in sequence while others are run in parallel. For example, the data timestamp is from January 11 to January 13, and you select 2 Parallel Groups. In this case, two retroactive instances are generated. They are run in parallel for once, and one of them must be run for a second time.

3. Click **OK**.

Generate retroactive data for the current and descendant nodes

1. Find the target node, click **Patch Data** in the Actions column, and then select **Current and Descendant Nodes Retroactively.**
2. In the **Patch Data** dialog box, set the parameters, including **Nodes.**

Parameter	Description
Retroactive Instance Name	The name of the retroactive instance. DataWorks automatically generates a name, which can be changed.

Parameter	Description
Data Timestamp	The data timestamp of the retroactive instance.
Parallelism	Specifies whether to generate multiple retroactive instances at a time. ○ If you select **Disable**, only one retroactive instance is generated. ○ If you select **2 Parallel Groups**, **3 Parallel Groups**, **4 Parallel Groups**, or **5 Parallel Groups**, multiple retroactive instances are generated.
Nodes	The nodes for which you want to generate retroactive data. You can set **Node Name** and **Node Type** to filter nodes.

3. Click **OK**.

Generate retroactive data for a large number of nodes

1. Find the target node, click **Patch Data** in the Actions column, and then select **Mass Nodes Retroactively**.
2. In the **Patch Data** dialog box, set the parameters. The following table describes the parameters for generating retroactive data for a large number of nodes.

Parameter	Description
Retroactive Instance Name	The name of the retroactive instance. DataWorks automatically generates a name, which can be changed.
Data Timestamp	The data timestamp of the retroactive instance. **Note** We recommend that you do not set this parameter to a long range. Otherwise, the retroactive instance may be delayed due to insufficient resources.
Parallelism	Specifies whether to generate multiple retroactive instances at a time. ○ If you select **Disable**, only one retroactive instance is generated. ○ If you select **2 Parallel Groups**, **3 Parallel Groups**, **4 Parallel Groups**, or **5 Parallel Groups**, multiple retroactive instances are generated.
Nodes	○ If you select the **Current Node** check box, retroactive instances are generated for the current node and its descendant nodes. ○ If you clear the **Current Node** check box, the current node is dry-run and retroactive instances are generated for its descendant nodes.

Parameter	Description
Workspaces	The workspaces of the nodes for which DataWorks needs to generate retroactive data. Select workspaces under **Available Workspaces** and add them to **Selected Workspaces**. Fuzzy match is supported when you search for workspaces under Available Workspaces.
Node Whitelist	The nodes outside the selected workspaces, for which DataWorks needs to generate retroactive data. **Note** You can search for nodes by node ID.
Node Blacklist	The nodes inside the selected workspaces, for which DataWorks does not need to generate retroactive data. **Note** You can search for nodes by node ID.

3. Click **OK**.

Manage retroactive instances in the instance list

Operation	Description
Filter	Find required instances by specifying filter conditions. You can search for instances by node name or node ID and set the following parameters to filter instances: **Retroactive Instance Name**, **Node Type**, **Owner**, **Run At**, **Data Timestamp**, **Engine type**, **Engine instance**, **Baseline**, and **My Nodes**. **Note** By default, the data timestamp is set to the previous day of the current day.
DAG	View the DAG of the instance. You can view the running result of the instance in the DAG.
Stop	Stop the instance. You can stop instances only when they are in the **Pending (Resource)** or **Running** state. After you perform this operation, the instance enters the **Failed** state.
Rerun	Rerun the instance.
Rerun Descendant Nodes	Rerun the descendant instances of the instance.
Freeze	Pause the scheduling of the instance.
Recover	Resume the scheduling of the instance after it is paused.

Operation	Description
View Lineage	View the lineage of the instance.

Manage retroactive instances in a DAG

Click the name of an instance or DAG in the Actions column to view the DAG of the instance. In the DAG, you can right-click the instance to perform related operations.

> Note After you click Refresh in the upper-right corner, the DAG of the instance is refreshed, but the operational logs are not.

Operation	Description
Show Ancestor Nodes or Show Descendant Nodes	Show ancestor or descendant instances at one or more levels. If a workflow contains three or more instances, the DAG displays only the current instance and hides its ancestor and descendant instances.
View Runtime Log	View the operational logs of the instance if it is in the Running, Successful, or Failed state.
View Code	View the code of the instance.
Edit Node	Go to the DataStudio page to modify the node to which the instance belongs.
View Lineage	View the lineage of the instance.
Stop	Stop the instance. You can stop instances only when they are in the Pending (Resource) or Running state. After you perform this operation, the instance enters the Failed state.
Rerun	Rerun the instance if it is in the Failed or an abnormal state.
Rerun Descendant Nodes	Rerun all the descendant instances of the instance.
Set Status to Successful	Set the status of the instance to Successful and run its descendant instances as scheduled. You can perform this operation if an instance fails. > Note This operation applies only to failed instances but not workflows.
Emergency Operations	Perform emergency operations in emergency only. Emergency operations take effect only on the current instance for one time. Select Delete Dependencies to delete dependencies of the current instance. You can perform this operation so that you can start the current instance when the ancestor instances fail and the current instance does not depend on the data of the ancestor instances.

Operation	Description
Freeze	Pause the scheduling of the instance.
Unfreeze	Resume the scheduling of the instance after it is paused.

2.8.3.4. Manage test instances

Test instances are generated when you test auto triggered nodes. You can manage test instances.

Go to the Test Instance page

1. Log on to the DataWorks console.
2. Click  in the upper-left corner and choose **All Products > Operation Center**.
3. In the left-side navigation pane, choose **Cycle Task > Test Instance**. The Test Instance page appears, where you can view the list and directed acyclic graphs (DAGs) of test instances.

Manage test instances in the instance list

You can manage test instances in the instance list. For example, you can rerun, freeze, or unfreeze instances, set the status of instances to Successful, view the lineage of instances, and check operational logs.

Operation	Description
Filter	Find required instances by specifying filter conditions. You can search for instances by node name or node ID and set the following parameters to filter instances: **Node Type**, **Owner**, **Run At**, **Data Timestamp**, **Status**, **Region**, **Engine type**, **Engine instance**, **Baseline**, **My Nodes**, **Tested by Me Today**, and **Frozen**.
Stop	Stop the instance. You can stop instances only when they are in the **Pending (Resource)** or **Running** state. After you perform this operation, the instance enters the **Failed** state.
Rerun	Rerun the instance. After the instance is rerun, its descendant instances will be run as scheduled. Perform this operation if an instance fails or it is not run as scheduled. Note This operation applies only to instances in the **Pending (Ancestor)**, **Successful**, or **Failed** state.
More operations	Click **More** in the Actions column and then select an operation. The operations include **Set Status to Successful**, **Freeze**, **Unfreeze**, **View Lineage**, and **View Runtime Log**.

Operation	Description
Batch operations	Select multiple instances and click a button in the lower part of the instance list to perform batch operations. The buttons include **Stop**, **Rerun**, **Set Status to Successful**, **Freeze**, and **Unfreeze**.

Manage test instances in a DAG

Click the name of an instance or **DAG** in the Actions column to view the DAG of the instance. In the DAG, you can right-click the instance to perform related operations.

Operation	Description
View Runtime Log	View the operational logs of the instance if it is in the Running, Successful, or Failed state.
View Code	View the code of the instance.
Edit Node	Go to the **DataStudio** page to modify the node to which the instance belongs.
View Lineage	View the lineage of the instance.
Stop	Stop the instance. You can stop instances only when they are in the **Pending (Resource)** or **Running** state. After you perform this operation, the instance enters the **Failed** state.
Rerun	Rerun the instance. After the instance is rerun, its descendant instances will be run as scheduled. Perform this operation if an instance fails or it is not run as scheduled. Note This operation applies only to instances in the **Pending (Ancestor)**, **Successful**, or **Failed** state.
Set Status to Successful	Set the status of the instance to **Successful** and run its descendant instances as scheduled. You can perform this operation if an instance fails. Note This operation applies only to failed instances but not workflows.
Freeze	Pause the scheduling of the instance.
Unfreeze	Resume the scheduling of the instance after it is frozen. • If the instance is not run, DataWorks automatically runs this instance after its ancestor instances are run. • If all the ancestor instances have been run, the instance is directly set to Failed. You must manually rerun the instance.

2.8.4. Manually triggered node O&M

2.8.4.1. Manage manually triggered nodes

Manually triggered nodes are nodes whose scheduling type is set to manual before they are committed to the scheduling system.

> Note After a manually triggered node is committed to the scheduling system, it will run only after it is manually triggered.

Manage manually triggered nodes in the node list

The manually triggered node list displays manually triggered nodes that are committed.

Operation	Description
Filter	Find required nodes by specifying filter conditions. You can search for nodes by node name and set the **Owner**, **My Nodes**, and **Modified Today** parameters to filter nodes. > Note When you search for nodes by node name, the search result is affected by other filter conditions you specified. Only nodes that meet both the specified search condition and other filter conditions are returned in the search result.
DAG	Click **DAG** in the Actions column of a node to view the directed acyclic graph (DAG) of the node. You can view the node information, such as the code and lineage, in the DAG.
Run	Click **Run** in the Actions column of a node to run the node. Manually triggered node instances are generated.
View Instances	Click **View Instances** in the Actions column of a node to go to the **Manual Instance** page, where you can view the instances of the node.
More operations	Choose **More** > **Change Owner** in the Actions column of a node to change the owner of the node.
Batch operations	Select multiple nodes and click **Change Owner** in the lower part of the page to change the owner of the nodes.

Manage manually triggered nodes in a DAG

Click the name of a node or **DAG** in the Actions column to view the DAG of the node. In the DAG, you can right-click the node to perform related operations.

Operation	Description
View Code	View the code of the node.
Edit Node	Go to the **DataStudio** page to modify the node.

Operation	Description
View Instances	View the instances of the node.
View Lineage	View the lineage of the node.
Run	Run the node. After you click Run, manually triggered node instances are generated.
Change Resource Group	Change the resource group where the node is run.

2.8.4.2. Manage manually triggered node instances

DataWorks generates manually triggered node instances from manually triggered nodes. Manually triggered nodes do not have node dependencies. They must be run manually.

> **Notice** DataWorks generates alerts only for auto triggered node instances when they fail to be run.

Go to the page for managing manually triggered node instances

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Operation Center**.
3. In the left-side navigation pane, choose **Trigger Task Maintenance > Trigger Instance**. The Trigger Instance page appears, where you can view the list and directed acyclic graphs (DAGs) of manually triggered instances.

Manage manually triggered node instances in the instance list

Operation	Description
Filter	Find required instances by specifying filter conditions. You can search for instances by instance name and set the **Owner**, **Data Timestamp**, and **Run At** parameters to filter instances.
DAG	Click **DAG** in the Actions column to view the DAG of the instance. You can view the running result of the instance in the DAG.
Stop	Click **Stop** to stop the instance if it is in the Running state.
Rerun	Rerun the instance.
Batch stop	Select multiple instances and click **Stop** to stop the selected instances at a time.

Manage manually triggered node instances in a DAG

Click the name of an instance or **DAG** in the Actions column to view the DAG of the instance. In the DAG, you can right-click the instance to perform related operations.

Note A manually triggered node instance does not have dependencies, so only the current instance appears in the DAG.

Operation	Description
View Runtime Log	View the operational logs of the instance if it is in the Running, Successful, or Failed state.
View Code	View the code of the instance.
Edit Node	Go to the DataStudio page to modify the node to which the instance belongs.
View Lineage	View the lineage of the instance.
Stop	Stop the instance.
Rerun	Rerun the instance if it is in the Failed or an abnormal state.

2.8.5. MaxCompute engine O&M

DataWorks Operation Center allows you to view the jobs, quota groups, and projects of MaxCompute.

Prerequisites

A MaxCompute engine is added on the **Project Management** page.

Go to the MaxCompute page

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Operation Center**.
3. In the left-side navigation pane, choose **Engine Maintenance > MaxCompute**. The **Job Queue** tab appears by default.You can view the jobs, quota groups, and projects of MaxCompute.

View jobs

On the **Job Queue** tab, you can view the total number of jobs and numbers of jobs in the **Running**, **Waiting for Resources**, and **Initializing** states.

You can set the **QuotaGroup** and **Project** parameters to filter jobs. You can view the following parameters of each job: **Instance**, **Execution Time**, **CPU Usage (Minimum/Maximum)**, **Memory Usage (Minimum/Maximum)**, **Priority**, **Node**, **Submitted By**, **Project**, **Type**, **Quota Group**, **Cluster**, **Status**, and **Start Time**.

View quota groups

On the **MaxCompute** page, click the **Quotas** tab.

On the **Quotas** tab, you can view the following parameters of each quota group: **Project**, **Quota Group**, **Default**, **Cluster**, **Minimum CPU (cores)**, **Maximum CPU (cores)**, **Minimum Memory (bytes)**, **Maximum Memory (bytes)**, and **Projects**.

You can click the name of a quota group to view the resource usage information about the quota group.

View projects

On the **MaxCompute** page, click the **Projects** tab.

On the **Projects** tab, you can view the following parameters of each project: **Project**, **Owner**, **Cluster**, **Quota Group**, **Storage Used**, **Storage Quota**, **Storage Usage**, and **Files**.

2.8.6. Monitor

2.8.6.1. Overview

The Monitor module is a node monitoring and analysis system of DataWorks. Based on monitoring rules and node running status, the Monitor module determines whether, when, and how to trigger an alert, and whom an alert is sent to. It automatically selects the most appropriate alerting time, notification methods, and recipients.

The Monitor module provides you with the following benefits:

- Improves your efficiency on configuring monitoring rules.
- Prevents invalid alerts from bothering you.
- Automatically covers all important nodes for you.

General monitoring systems cannot meet the requirement of DataWorks. The reasons are as follows:

- DataWorks has numerous nodes, so it is difficult for you to find out the nodes to be monitored. Some DataWorks businesses have a large number of nodes, and dependencies between the nodes are complex. Even if you know the most important node, it is difficult to find all ancestor nodes of the node and monitor them all. In this case, if you simply monitor all nodes, a large number of invalid alerts may be generated. In consequence, you may miss those useful alerts.
- The alerting method varies with nodes. For example, some monitoring tasks require the relevant nodes to run for more than one hour before triggering alerts, while other monitoring tasks require the relevant nodes to run for more than two hours. It is extremely complex to set a monitoring node for each node, and it is difficult to predict the alert threshold value for each node.
- The alerting time varies with nodes. For example, an alert for an unimportant node can be sent after you start working in the morning. An alert for an important node needs to be sent immediately when an error occurs. General monitoring systems cannot tell the importance of each node.
- Different alerts require different operations to turn off.

The Monitor module provides comprehensive monitoring and alerting logic. You only need to provide the node name of your business. Then, the Monitor module automatically monitors the entire process of your node and creates standard alert triggers for the node. In addition, you can customize alerting triggers by completing basic settings.

Currently, the Monitor module has been used for monitoring all important businesses of Alibaba Group. Its full-path monitoring function guarantees the overall data output of all important businesses of Alibaba Group. In addition, it supports analyzing ancestor and descendant node paths to promptly detect risks and provide O&M advice for business departments. These functions of the Monitor module have guaranteed the long-term high stability of businesses in Alibaba Group.

2.8.6.2. Feature description

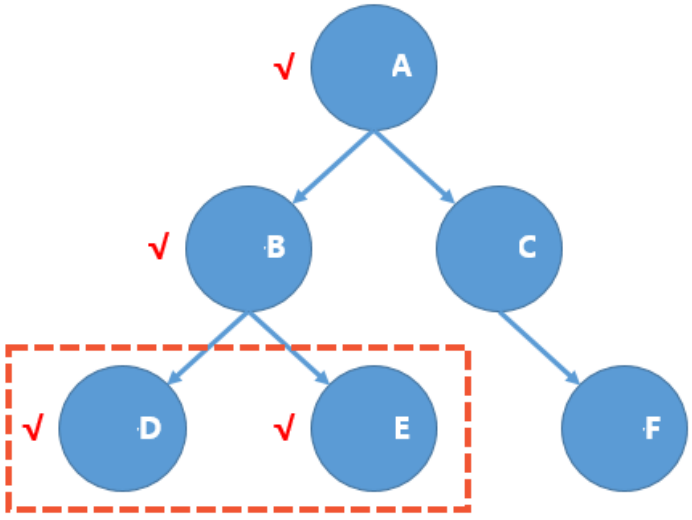
2.8.6.2.1. Baseline alert and event alert

This topic describes the functional logic of baseline alerts and event alerts from the aspects of monitoring scope, node capturing, alert object judgment, alerting time judgment, notification methods, and alert escalation.

Monitoring scope

A baseline is a management unit of a group of nodes, that is, a node group. You can specify nodes to monitor in a baseline.

After a baseline is monitored, all nodes of the baseline and its ancestor nodes are monitored. The Monitor module does not monitor all nodes by default. A node is monitored only when it has descendant nodes that are added to a monitoring baseline. If no descendant nodes are added to a monitoring baseline, the Monitor module does not report any alert even if the node fails.



As shown in the preceding figure, assume that DataWorks has only six nodes, and nodes D and E belong to a monitoring baseline. Nodes D and E and all their ancestor nodes are monitored by the Monitor module. That is, any error or slowdown on node A, B, D, or E will be detected by the Monitor module. However, nodes C and F are not monitored by the Monitor module.

Node capturing

After the nodes to be monitored are specified, if a monitored node incurs an exception, the Monitor module generates an event. All alert decisions are based on the analysis of this event. Two types of node exceptions are available. You can choose **Events** > **Event Type** to view them.

- **Error**: indicates that a node fails to run.
- **Slow**: indicates that the running time of a node is significantly longer than the average

running time of the node in the past periods.

> **Note** If a node times out and then encounters an error, two events are generated.

Alerting time judgment

Buffer, an important concept in the Monitor module, refers to the maximum time period that a node can be delayed. The latest start time of a node is obtained by subtracting the average uptime from the baseline time.

The baseline time of baseline A is 05:00, you must set the latest start time of node E to 04:10. This time is calculated by subtracting the average uptime of node F (20 minutes) and node E (30 minutes) from the baseline time 05:00. This time is also the latest completion time of node B in baseline A.

To ensure that the baseline time of baseline B is 06:00, you must set the latest completion time of node B to 04:00. This time, which is earlier than 04:10, is calculated by subtracting the average uptime of node D (2 hours) from the baseline time 06:00. To meet the baseline time of both baseline A and baseline B, you must set the latest completion time of node B to 04:00.

The latest completion time of node A is 02:00, which is calculated by subtracting the average uptime of node B (2 hours) from 04:00. The latest start time of node A is 01:50, which is calculated by subtracting the average uptime of node A (10 minutes) from 02:00. If node A fails to run before 01:50, it is probable that baseline A is broken.

If node A fails to run at 01:00, its buffer is 50 minutes, which is the difference between 01:00 and 01:50. As demonstrated in this example, buffer reflects the degree of caution for a node exception.

Baseline alert

Baseline alerting is an additional feature developed for baselines that are enabled. Each baseline must provide an alert buffer and committed time. Baseline alerting is the action of notifying the preset alert recipient three times at the interval of 30 minutes when the baseline completion time estimated by the Monitor module exceeds the alert buffer.

Notification method

Currently, baseline alerts are sent to the baseline owner by default. On the **Alert Triggers** page, you can find **Global Baseline Alert Trigger**, click **View Details**, and change the alert trigger method and the alerting action.

Gantt chart function

The Gantt chart function reflects the key path of a node. The function is provided by the **Baseline Instances** module of Monitor.

> **Note** The key path is the slowest upstream link that causes the node to be completed at this time point.

2.8.6.2.2. Custom alert trigger

Alert trigger customization is a lightweight monitoring function of the Monitor module.

You can customize all monitoring alert triggers by setting the following parameters:

- Objects: You can specify nodes, baselines, and workspaces as objects.
- Trigger Condition: Valid values include Completed, Uncompleted, Error, Uncompleted Cycle, and Overtime.
- Notification Method: Valid values include SMS and Email.
- Maximum Alerts: This parameter indicates the maximum number of alert reporting times. If the number of alerting times exceeds the preset threshold, no alerts are generated.
- Minimum Alert Interval: This parameter indicates the minimum time interval at which DataWorks reports alerts.
- Quiet Hours: This parameter indicates the specified period during which no alerts are reported.
- Recipient: This parameter indicates the person who receives alerts. You can set this parameter to the node owner or another recipient.

A monitoring rule uses the following five alert trigger conditions: Completed, Uncompleted, Error, Uncompleted Cycle, and Overtime.

- **Completed**

  A completion alert can be set for nodes, baselines, and workspaces. Once all nodes of the preset objects are completed, the completion alert is reported. If you set a completion alert for a baseline, the alert is reported when all nodes of the baseline are completed.

- **Uncompleted**

  You can set alerts for nodes, baselines, or workspaces that are not completed at a certain time point. For example, if you require that a baseline be completed at 10:00, an alert containing a list of uncompleted nodes is reported once a node in the baseline is not completed at the specified time.

- **Error**

  An error alert can be set for nodes, baselines, and workspaces. Once a node has an error, an alert containing detailed node error information is sent to the recipient.

- **Uncompleted Cycle**

  For the monitoring rules of hourly scheduled nodes, you can separately specify the uncompleted time points in different periods.

- **Overtime**

  An overtime alert can be set for nodes, baselines, and workspaces. Once a monitored node of the preset object is not completed within the specified time, an alert is reported.

2.8.6.3. Instructions

2.8.6.3.1. Baseline instances

On the Baseline Instances page, you can view the information about a baseline.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Operation Center**. The **Operation Center** page appears.
3. On the Operation Center page, choose **Monitor > Baselines** in the left-side navigation pane. On the **Baselines** page, create a baseline. For more information abut how to create a

baseline, see Create a baseline.

> Note If you have created a baseline, skip this step and directly go to the Baseline Instances page to perform subsequent operations.

4. In the left-side navigation pane, choose Monitor > Baseline Instances. The Baseline Instances page appears. On this page, you can search for baseline instances by condition, such as the data timestamp, owner name or ID, event ID, workspace, and baseline name. You can also click View Details, Handle, and View Gantt Chart in the Actions column to perform corresponding operations on a baseline.

   > Note After creating a baseline, you must enable the baseline so that a baseline instance can be generated.

   A baseline can be in the one of the following four states:

   - Normal: All nodes in the baseline are completed before the alerting time.
   - Alerting: One or more nodes in the baseline are not completed at the alerting time but the committed completion time has not arrived.
   - Overtime: One or more nodes in the baseline are not completed at the committed completion time.
   - Others: All nodes in the baseline are paused or the baseline is not associated with any node.

   You can click View Details, Handle, and View Gantt Chart in the Actions column to perform corresponding operations on a baseline.

   - View Details: Click View Details to go to the Baseline Instance Details page.

     On the Baseline Instance Details page, you can view the general information, critical path, baseline instance information, history graph, and relevant events.

     > Note
     > - In the preceding figure, the data timestamp is `one day before the system time`.
     > - When you create a baseline, you can select By the Day Interval or By the Hour Interval. The Cycle parameter appears as the advanced settings of the Committed Time parameter only when you select By the Hour Interval.

   - Handle: Click Handle to pause the alert generated by the baseline when the baseline is being handled.
   - View Gantt Chart: Click View Gantt Chart to view the critical paths of nodes.

2.8.6.3.2. Baselines

You can create and define baselines on the Baselines page.

Create a baseline

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and

choose **All Products** > **Operation Center**. The **Operation Center** page appears.

3. On the Operation Center page, choose **Monitor** > **Baselines** in the left-side navigation pane.
4. On the **Baselines** page, click **Create Baseline** in the upper-right corner.

> Note Currently, only workspace administrators can create baselines.

5. In the **Create Baseline** dialog box that appears, set the parameters and click **OK**.

Parameter	Description
Baseline Name	The name of the baseline.
Workspace	The workspace of the node associated with the baseline.
Owner	The name or ID of the owner.
Recurrence	Specifies whether the baseline detects nodes by day or hour. ○ **By the Day Interval**: Select this option for nodes scheduled by day. ○ **By the Hour Interval**: Select this option for nodes scheduled by hour.
Nodes	○ **Node**: the node associated with the baseline. Enter the name or ID of a node, and then click the icon on the right to add the node. You can add multiple nodes. ○ **Workflow**: the workflow associated with the baseline. Enter the name or ID of a workflow, and then click the icon on the right to add the workflow. We recommend that you only add the last node of a workflow instead of all nodes.
Priority	The priority of the baseline. A baseline with a higher priority is scheduled first. Currently, the only available priority value is 1.
Estimated Completion Time	The completion time of the node estimated based on the average running time of the node during previous scheduling. If no historical data is available, the message **The completion time cannot be estimated due to a lack of historical data** appears.
Committed Time	The time point when a node should be completed. An alert is triggered if the node is not completed until the time point obtained by subtracting the alert margin threshold from the committed completion time.

Parameter	Description
Margin Threshold	The interval before an alert is triggered. For example, set Committed Time to 3:30 and Margin Threshold to 10 minutes. An alert is triggered if the node is not completed at 3:20. Assume that the average running time of the node is 30 minutes. If the node is not started at 2:50, an alert is triggered. **Note** The average running time of a node can be calculated based on the data of the last 15 days.

6. After a baseline is created, click **Enable** in the Actions column to enable the baseline.

   You can click **View Details**, **Change**, **Enable**, Disable, or **Delete** in the Actions column to perform the corresponding operation on a baseline.

   - **View Details**: Click **View Details** to view the basic information about the baseline.
   - **Change**: Click **Change** to modify the baseline.
   - **Enable** or Disable: Click Enable or Disable to enable or disable the baseline. A baseline instance can be generated only when the corresponding baseline is enabled.
   - **Delete**: Click **Delete** to delete the baseline.

Add a node to a baseline

By default, all nodes in the production environment are in the default baseline of each workspace. When you create a baseline, you actually move nodes from the default baseline to the baseline that you create.

Note A node must belong to a baseline, so you cannot directly remove nodes from the default baseline. Instead, you can create a baseline to move nodes from the default baseline to the new baseline. When you delete a baseline that you create, you actually move the nodes in the baseline to the default baseline.

To change the baseline of a node, perform one of the following operations:

- On the **Baselines** page, click **Create Baseline** in the upper-right corner. Then, create a baseline by following the instructions in the Create a baseline section.
- In the left-side navigation pane, choose Nodes > **Recurring**. On the page that appears, find the node and choose **More** > **Add to Baseline** in the Actions column.

2.8.6.3.3. Events

On the Events page, you can view all events related to slowdown or errors.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products** > **Operation Center**.
3. On the Operation Center page, choose **Monitor** > **Events** in the left-side navigation pane. The **Events** page appears.

You can search for events by condition, such as the event owner, time when an event was detected, event status, event type, and name or ID of a node or node instance.

In the search results, each event is displayed in a row and associated with a node that encounters errors. The worst baseline indicates a baseline with the minimum margin among the baselines affected by an event.

- Click **View Details** in the Actions column of an event. You can view the event occurrence time, alert time, clearance time, historical runtime logs of the node, and detailed node logs.

  You can assign an alert recipient. After you click **View Alerts**, the alert details page corresponding to the event appears. Affected baselines are all descendant baselines affected by the node associated with the event. You can observe descendant baselines and the impact on these baselines and analyze node logs to identify the causes of the event.
- If you click **Handle**, DataWorks records the event handling operation and pauses the alert for the event when the event is being handled.
- If you click **Ignore**, DataWorks keeps the event ignorance record and permanently stops the alert for the event.

2.8.6.3.4. Alert triggers

This topic describes how to customize alert triggers on the Alert Triggers page.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Operation Center**.
3. On the Operation Center page, choose **Monitor > Alert Triggers** in the left-side navigation pane. The **Alert Triggers** page appears.
4. On the Alert Triggers page, click **Create Custom Trigger** in the upper-right corner.
5. In the **Create Custom Trigger** dialog box that appears, set relevant parameters.

Parameter	Description
Trigger Name	The name of the custom alert trigger.
Object Type	The granularity of monitored objects. Valid values: **Node** and **Workflow**.
Objects	The monitored object. Enter the name or ID of a node or workflow and click the icon on the right to add the object.
Trigger Condition	The condition for triggering an alert. Valid values: **Completed**, **Uncompleted**, **Error**, **Uncompleted Cycle**, and **Overtime**.
Maximum Alerts	The maximum number of alert reporting times. If the number of alert reporting times exceeds the preset threshold, no alerts are reported.
Minimum Alert Interval	The minimum time interval at which DataWorks reports an alert.

Parameter	Description
Quiet Hours	The specified period during which no alerts are reported.
Notification Method	The method of reporting alerts. Valid values: **Email** and **SMS**.
Recipient	The person who receives alerts. You can set this parameter to the node owner or another recipient.
DingTalk Chatbot	The DingTalk chatbot to receive alerts.

6. Click **OK** to create the alert trigger.

   On the **Alert Triggers** page, you can click **View Details** in the Actions column of an alert trigger to view the details of the alert trigger.

2.8.6.3.5. Alert information

You can view all alerts on the Alerts page.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Operation Center**.
3. On the Operation Center page, choose **Monitor > Alerts** in the left-side navigation pane. The **Alerts** page appears.

   You can search for alerts by condition, such as the alert trigger ID or name, recipient, alert time, notification method, and alert trigger type.

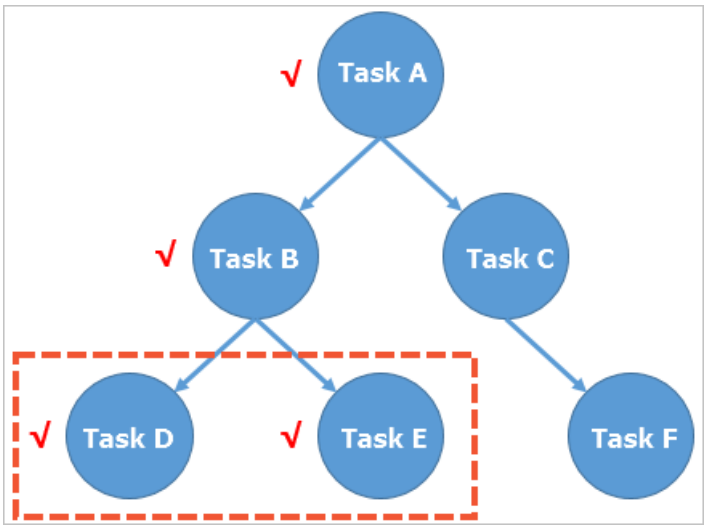
   You can also view alert details such as the notification method and status. To view more alert details, find the target alert and click **View Details** in the Actions column.

2.8.6.4. FAQ

This topic describes the FAQ about the Monitor service.

What can I do if I do not need to receive alerts for a node?

After you create and enable a monitoring baseline, the Monitor service monitors all nodes in the baseline and their ancestor nodes. If a node in the baseline or an ancestor node of the baseline affects data generation of the monitored nodes in the baseline, the Monitor service reports an alert to the node owner.



As shown in the preceding figure, assume that DataWorks has only six nodes, and Nodes D and E belong to a monitoring baseline. The Monitor service monitors Nodes D and E and all their ancestor nodes. Namely, the Monitor service will detect any error or slowdown on Node A, B, D, or E. Nodes C and F are not monitored by the Monitor service.

Nodes A and B are ancestor nodes of Nodes D and E and may affect data generation of the monitored nodes in the baseline. When an error or slowdown occurs on Node A or B, the Monitor service reports an alert to the node owner.

If you do not need to receive alerts for a node, use the following methods:

- If the owners of Nodes D and E do not need to receive alerts, contact the baseline owner to remove Nodes D and E from the baseline.
- If the owner of Node A or B does not need to receive alerts, contact the owners of Nodes D and E to delete the dependency of Nodes D and E on Node A or B.

Why is no alert reported for a baseline in the Overtime state?

Baseline monitoring is controlled by the baseline switch and enabled for nodes. If all nodes are running properly, no alert will be triggered even in the Overtime state. This is because all the nodes are running properly and the Monitor service cannot determine which node has an error. Overtime is a baseline state, indicating that a node is still not completed after the committed time.

If the baseline still enters the Overtime state when all nodes are running properly, consider the following reasons:

- The baseline time is not properly set.
- The node dependency is not properly configured.

Can I disable the Monitor service from reporting an alert for a node that slows down?

The Monitor service reports a node slowdown alert only when a node meets both of the following conditions:

- The node is an ancestor node of an important baseline.
- Compared with its historical performance, the node does slow down.

You can view the descendant baseline affected by the node on the **Event Management** page. Then, you can confirm the impact with the party whose monitoring baseline contains descendant nodes of your node.

- If the node slowdown has a minor impact, you can ignore the alert.
- If the node slowdown has a major impact, maintain your node properly.

Why do I fail to receive an alert for an error node?

The Monitor service reports an alert only for specified nodes when an error occurs. An alert is reported for an error node only when the node meets one of the following conditions:

- The node is an ancestor node of a baseline that has been enabled.
- An alert trigger has been customized.

What can I do if I receive an alert at night?

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click  in the upper-left corner and choose **All Products > Operation Center**.
3. In the left-side navigation pane, choose **Alarm > Event Management**.
4. On the **Event Management** page, disable the event alert. Disable the event alert in one of the following ways:
   - Handle the event that triggers an alert.
     a. Find the target event and click **Handle** in the Actions column.
     b. In the **Handle Event** dialog box, set the **Handling Time** parameter.
     c. Click **OK**.

     > **Note** DataWorks records the event handling operation and pauses alerting for the event when the event is being handled.

   - Ignore the event that triggers an alert.
     a. Find the target event and click **Ignore** in the Actions column.
     b. In the **Ignore Event** message, click **OK**.

     > **Note** DataWorks records the event ignoring operation and permanently stops alerting for the event.

2.9. Security Center

2.9.1. Overview

Security Center provides flexible permission management features. It allows you to request permissions and handle permission requests on the graphical user interface (GUI), and view and manage permissions. Security Center not only improves data security but also facilitates data permission management.

Log on to the DataWorks console. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Security Center**. The **Security Center** page appears.

Security Center consists of the following modules: **My Permissions**, **Authorizations**, and **Approval Center**.

Currently, Security Center provides the following features:

- Self-service permission request: Users can select the required tables to quickly initiate a permission request online. This online request mode is more efficient than the original mode in which users need to contact administrators offline.
- Permission management: Administrators can view the users who have permissions on database tables and revoke permissions as required. Users can also revoke unnecessary permissions themselves.
- Permission request approval: Before granting permissions to users, administrators approve permission requests initiated by users. This implements a visual and process-based permission management system, and supports reviewing the approval process.

In Security Center, you can view permissions on all the tables in an organization, request and revoke table permissions, and approve or reject permission requests.

Each operation in Security Center applies to all the workspaces of a tenant in standard mode and basic mode.

2.9.2. My Permissions

On the My Permissions page, you can view your table and field permissions in a workspace, and request or revoke table and field permissions.

View table and field permissions

1. Move the pointer over the DataWorks icon in the upper-left corner, and click **Security Center**. In the left-side navigation pane, click **My Permissions**. The **Table** tab appears.
2. On this tab, you can select a workspace and specify the environment (for a workspace in standard mode) to view all the tables of the workspace in the specified environment. You can also enter a table name in the search box to search for required tables in fuzzy match mode.

   You can view the names and owners of tables in the workspace, view your permissions on the tables, and request or revoke table and field permissions.

Request table and field permissions

1. Select the tables and fields on which you want to request permissions.
   - Request permissions on a table or some fields in the table

     Select the required fields on which you have no permissions in a table and choose **More > Request Permission** in the Actions column.

Alternatively, choose **More** > **Request Permission** in the Actions column for a table without selecting any fields to request permissions on all the fields in the table.

> **Note** You can request permissions on fields only in a workspace with LabelSecurity enabled. If LabelSecurity is disabled for a workspace, you can request permissions only on tables in this workspace.

- Request permissions on multiple tables and fields

  Select all the required tables and fields and click **Request Permission**.

  > **Note** You can also click **Request Permission** without selecting any tables or fields, and then select the required tables and fields in the **Table Permission Request** dialog box.

2. Set the parameters in the **Table Permission Request** dialog box.

Parameter	Description
Workspace	The name of the workspace, which is automatically entered based on the information you specified on the My Permissions page. You can change the workspace as required.
Environment	The environment of the workspace.
MaxCompute Project	The name of the MaxCompute project.
Grant To	The account for which you request permissions. You can request permissions for the current account or a production account of another workspace you joined.
Reason for Request	The reason why you request permissions.
Objects Requested	The tables on which you request permissions. The tables that you select on the previous page are displayed. You can add tables or delete existing tables as required.

3. After the configuration is completed, click **Submit**. If you do not want to request the permissions, click **Cancel**.

Revoke permissions

You can revoke table and field permissions.

- Revoke field permissions

> Note
> - You can revoke permissions on fields only in a workspace with LabelSecurity enabled.
> - To revoke permissions on all the fields in a table, you can directly revoke the permissions on the table.

i. Choose **More** > **Revoke Field Permission** in the **Actions** column for the table on which you want to revoke permissions.
ii. In the **Revoke Field Permission** dialog box, select the fields on which you want to revoke permissions.
iii. Click **OK**.

- Revoke table permissions
  i. Choose **More** > **Revoke Permission** in the **Actions** column for the table on which you want to revoke permissions.
  ii. In the **Revoke Permission** dialog box, select the permissions you want to revoke.
  iii. Click **OK**.

2.9.3. Authorizations

On the Authorizations page, a workspace administrator can view the accounts that have permissions on tables and fields in each workspace, and revoke unnecessary table and field permissions.

You can move the pointer over the DataWorks icon in the upper-left corner, and click **Security Center**. In the left-side navigation pane, click **Authorizations**. On the **Table** tab that appears, you can view and search for tables in workspaces of the current organization.

On the Table tab, you can select a workspace and specify the environment (for a workspace in standard mode) to view all the tables of the workspace in the specified environment. You can also enter a table name in the search box to search for required tables in fuzzy match mode.

View accounts that have permissions on a table

On the **Table** tab of the **Authorizations** page, click the plus sign (+) in front of a table to view all the accounts that have permissions on the table.

Revoke table permissions

Click **Revoke Permission** in the Actions column for an account to revoke the permissions of the account on the current table.

View field permissions

Click **View Field Permissions** in the Actions column for an account to view the permissions of the account on the fields in the current table.

Revoke field permissions

If LabelSecurity is enabled for the workspace, select fields on the Field Permissions page and click **Revoke Field Permissions** to revoke the permissions on the fields.

2.9.4. Approval Center

On the Approval Center page, you can view your requests and their status, view and handle the requests pending your approval, and view the requests that you have handled.

My Requests

1. Move the pointer over the DataWorks icon in the upper-left corner, and click **Security Center**. In the left-side navigation pane, click **Approval Center**. On the Approval Center page, click the **My Requests** tab.

   On this tab, you can view the information about each of your requests, including **Object Type**, **Workspace**, **Status**, **MaxCompute Project**, **Request Time**, and **Table**.

   > **Note** If a request contains permission requests for tables that belong to different owners, Security Center automatically splits the request into multiple requests by table owner.

2. Click **View** in the Actions column to view the details about a request.

Pending My Approval

1. On the **Approval Center** page, click the **Pending My Approval** tab.

   On this tab, you can view the requests pending your approval. If a request is pending your approval, a red dot appears next to Approval Center and Pending My Approval to remind you.

   You can view the information about each of requests pending your approval, including **Object Type**, **Grant To**, **Request Time**, **Workspace**, **MaxCompute Project**, and **Table**.

2. Click **Handle** in the Actions column to view the details about a request and handle it on the Request Details page. The request details include the progress and objects requested.
3. Enter your comments and click Approve or Reject as required.

Handled by Me

1. On the **Approval Center** page, click the **Handled by Me** tab.

   On this tab, you can view the information about each request that you have handled, including **Object Type**, **Grant To**, **Result**, **Workspace**, **MaxCompute Project**, **Table**, and **Request Time**.

2. Click **View** in the Actions column to view the details about a request. The request details include the progress and objects requested.

2.9.5. FAQ

This topic describes the frequently asked questions (FAQs) about the Security Center service of DataWorks.

- Q: What permissions can I request in Security Center?

  A: In Security Center, you can request permissions on tables in DataWorks workspaces in the development environment and production environment.

- Q: What is the relationship between Data Management and Security Center?

  A: Security Center is a product that upgrades and replaces the permission and security features in Data Management. You can choose **Security Center** > **My Permissions** to view the permissions requested or granted by using the `odpscmd grant` command in **Data Management**.

  If you want to request other permissions and handle permission requests on the GUI, go to **Security Center** and perform operations as required. The **Data Management** service does not support permission request and approval any more.

- Q: Why cannot I select fields when I request permissions?

  A: If LabelSecurity is enabled for a workspace, you can request permissions on fields in this workspace. If LabelSecurity is disabled for a workspace, you can request permissions only on tables in this workspace.

- Q: Who will handle my request?

  A: Your request is handled by a workspace administrator or a table owner. After either of them approves or rejects your request, the request is closed.

- Q: Why do I find two requests on the **My Requests** page after I submit only one request?

  A: The tables in your request belong to two owners. In this case, Security Center automatically splits your request into two by table owner.

- Q: I request permissions on a field for one month only. Why does the validity period of the permissions become permanent after my request is approved?

  A: The security level of this field is zero or not higher than the security level of your account.

- Q: Why do I obtain permissions on some tables and fields on which I have not requested any permissions?

  A: The possible causes are as follows:

  - An administrator has granted the permissions to you by running commands in the DataWorks console.
  - After your request is approved in Security Center, Security Center also grants you the permissions on fields whose security level is zero or not higher than the security level of your account, even though you have not requested the permissions.

- Q: Why does a request disappear from the **Pending My Approval** tab before I handle it?

  A: Another workspace administrator or the table owner has approved or rejected the request. The request is closed and no longer needs to be handled.

- Q: What can I do if the message "An error occurred in the MaxCompute project" appears when I specify the workspace and environment?

  A: Send the error message and error code to a workspace administrator for troubleshooting.

- Q: Why do I fail to revoke permissions on a field?

  A: You can revoke permissions only on the fields whose security level is higher than the security level of your account.

- Q: Why do I fail to request permissions by using my tenant account?

  A: By default, a tenant account has all permissions. Therefore, you do not need to request permissions for your tenant account. The tenant account hides unnecessary operations such as permission request. This does not affect the use of the tenant account.

- Q: In **Security Center**, can I view the permission request and approval records of **Data Management**?

  A: Security Center and Data Management have not synchronized permission request and approval records yet. You need to go to **Data Management** to view the permission request and approval records of Data Management.

- Q: Can I revoke permissions based on the request records in Security Center?

  A: Currently, Security Center is not the only service that provides authorization. To facilitate permission revocation, the Authorizations page in Security Center provides an access control list (ACL) of all users, regardless of the authorization channel. You can revoke any granted permissions without using the request records.

- Q: A permission request submitted in **Data Management** has not been approved yet. Do I need to submit it again in Security Center?

  A: Security Center and Data Management have not synchronized permission request and approval records yet. You need to submit the permission request again in Security Center.

- Q: How do I specify the LabelSecurity parameter for fields?

  A: You need to go to **Data Map** to set the LabelSecurity parameter for fields.

2.10. Data Quality

2.10.1. Overview

DataWorks provides a Data Quality service for you to control the data quality of disparate connections. In Data Quality, you can check data quality, configure alert notifications, and manage connections.

Relying on DataWorks, Data Quality provides a comprehensive data quality solution that has various features. For example, you can detect data, compare data, monitor data quality, and use intelligent alerting.

Data Quality monitors data in datasets. Currently, it allows you to monitor MaxCompute tables and DataHub topics. When offline MaxCompute data changes, Data Quality checks data and blocks nodes if it detects exceptions. This prevents nodes from being affected. In addition, Data Quality allows you to manage the check result history so that you can analyze and evaluate the data quality.

For streaming data, Data Quality uses DataHub to monitor data streams and sends alert notifications to subscribers if it detects stream discontinuity. You can also set the alert severity such as warning and error alerts, and the alert frequency to minimize repeated alerts.

The following figure shows the monitoring flowchart in Data Quality.

> **Note** Data Quality monitors the quality of data from MaxCompute and DataHub datasets. To use Data Quality features, you need to create tables and write data to the tables.
>
> You can create MaxCompute tables and write data to the tables in the MaxCompute console or in the DataWorks console.

Log on to the DataWorks console. Click the DataWorks icon in the upper-left corner and choose **All Products** > **Data Quality** to go to the **Data Quality** page.

2.10.2. Features

2.10.2.1. Dashboard

As the homepage of Data Quality, the Dashboard page displays an overview of alerts and blocks for subscribed nodes. You can set filter conditions to view the required alerts and blocks.

Card	Description
My MaxCompute Partition Subscriptions	Displays the number of MaxCompute partitions with alerts or blocks and the number of normal MaxCompute partitions on the current day. You can click this card to go to the Search by Node page for the MaxCompute connection and view alert details.
My DataHub Topic Subscriptions	Displays the number of DataHub topics with alerts and the number of normal DataHub topics on the current day. You can click this card to go to the Search by Node page for the DataHub connection and view alert details.
Current task alarm condition	Displays alerts for MaxCompute and DataHub connections of the current workspace on the current day.
Current task blocking situation	Displays blocks for the MaxCompute connection of the current workspace on the current day.
Task Alarm Situation Trend	Displays the trend chart of alerts for MaxCompute and DataHub connections. You can view the alert trend in the past 7 or 30 days, or a custom time period within the past three months.
Task Blocking Situation Trend Graph	Displays the trend chart of blocks for MaxCompute and DataHub connections. You can view the block trend in the past 7 or 30 days, or a custom time period within the past three months.

2.10.2.2. My Subscriptions

The My Subscriptions page displays all nodes subscribed by your account.

Go to the My Subscriptions page

Currently, Data Quality allows you to monitor MaxCompute tables and DataHub topics. You can select a connection on the **My Subscriptions** page and search for subscribed nodes of the connection.

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Data Quality**.
3. In the left-side navigation pane, click **My Subscriptions**. The **My Subscriptions** page appears.

Subscribed MaxCompute connections

On the **My Subscriptions** page, select **MaxCompute** from the connection drop-down list in the upper-left corner. All the subscribed MaxCompute connections appear.

- You can click a partition expression on the right to go to the **Rules** page. For more information,

see MaxCompute monitoring.

- You can click **View Check Results** in the Actions column for a partition expression to go to the Search by Node page.
- Data Quality supports the following four notification methods: **Email**, **Email and SMS**, **DingTalk Chatbot**, and **DingTalk Chatbot @ALL**.
- You can click **Cancel Subscription** to unsubscribe from the connection.

Subscribed DataHub connections

On the **My Subscriptions** page, select **DataHub** from the connection drop-down list in the upper-left corner. All the subscribed DataHub connections appear.

- After you click **Alerts** for a topic, the **Alerts** page appears, allowing you to view detailed information about the rule alert.
- You can click **Notification Method** for a topic to change the notification method of the rule alert.
- You can click **Cancel Subscription** in the Actions column for a topic to unsubscribe from the topic.

2.10.2.3. Configure monitoring rules

Data Quality can monitor data in the MaxCompute, DataHub, and E-MapReduce data stores. This topic describes how to configure a rule for monitoring a table or topic.

Go to the Monitoring Rules page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Quality**.
3. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane. On the Monitoring Rules page, you can select ODPS, Datahub, or EMR from the Engine/Data Source drop-down list.
   - If you select ODPS or EMR, all tables in the current MaxCompute or E-MapReduce data store appear. You can also switch to another data store or enter a keyword in the search box to search for topics or tables.
   - If you select Datahub, all topics and dimension tables in the current DataHub data store appear. You can also switch to another data store or enter a keyword in the search box to search for topics or tables.
4. Find the target table or topic and click **View Monitoring Rules** in the Actions column. The rule configuration page for the table or topic appears.

   Data Quality allows you to configure template rules and custom rules for a table or topic.

   > **Note** Before you configure a template rule for a table, you must configure a partition filter expression.

Create a template rule

1. Click **View Monitoring Rules** in the Actions column of a table or topic.

2. On the rule configuration page that appears, click the partition filter expression for which you want to configure a template rule. Then, click **Create rules**. In the Create rules right-side pane, the **Template Rules** tab appears.

   On the **Template Rules** tab, click **Add Monitoring Rule** or **Quick Create** to create a template rule.

   - **Click Add Monitoring Rule.**

     Set parameters in the rule configuration section that appears, as described in the following table.

Parameter	Description
Rule Name	The name of the rule.
Rule Type	The type of the rule. Valid values: Rule Type and Soft. ■ If you select Rule Type, error alerts are reported and descendant nodes are blocked, whereas warning alerts are reported but descendant nodes are not blocked. ■ If you select Soft, error alerts are reported but descendant nodes are not blocked, whereas warning alerts are not reported and descendant nodes are not blocked.
Field	The fields to be monitored. You can select **All Fields in Table** or select a field of a numeric type or non-numeric type.
Template	The template to apply to the rule. Data Quality supports 37 rule templates. **Note** You can set field-specific rules of the average value, accumulated value, minimum value, and maximum value only for numeric fields.
Comparison Method	The comparison method of the rule. Valid values: **Absolute Value**, **Raise**, and **Drop**.

Parameter	Description
Thresholds	■ You can calculate the fluctuation by using the following formula: Fluctuation = (Sample - Baseline)/Baseline ■ You can calculate the fluctuation variance only for numeric fields such as BIGINT and DOUBLE fields by using the following formula: Fluctuation variance = (Sample - Baseline)/Standard deviation Note The sample and baseline are defined in the following way: ■ Sample: the sample value for the current day. For example, if you need to check the fluctuation of table rows on an SQL node in a day, the sample is the number of table rows on the current day. ■ Baseline: the comparison value from the previous N days. Examples: ■ If you need to check the fluctuation of table rows on an SQL node in a day, the baseline is the number of table rows on the previous day. ■ If you need to check the fluctuation of the average number of table rows on an SQL node in seven days, the baseline is the average number of table rows in the last seven days. You can set **Warning Threshold** and **Error Threshold** to monitor data at different severities: ■ If the fluctuation does not exceed the warning threshold, Data Quality determines that data is normal. ■ If the fluctuation exceeds the warning threshold but does not exceed the error threshold, Data Quality reports a warning alert. ■ If the fluctuation exceeds the error threshold, Data Quality reports an error alert. ■ If you do not specify the warning threshold, Data Quality reports error alerts or normal based on the monitoring result. ■ If you do not specify the error threshold, Data Quality reports warning alerts or normal based on the monitoring result. ■ If you specify neither the warning threshold nor the error threshold, Data Quality reports error alerts if it detects anomalies. However, you must specify at least one of the two thresholds. If you specify neither of them, Data Quality applies default values, namely, 10% for the warning threshold and 50% for the error threshold.

- **Click Quick Create.**

Set parameters in the rule configuration section that appears, as described in the following table.

Parameter	Description
Rule Name	The name of the rule.
Field	The fields to be monitored. You can select **All Fields in Table** or a specific field of a numeric type or non-numeric type.
Trigger	The trigger condition of the rule. If you select All Fields in Table for the Field parameter, **The number of rows is greater than 0** is selected by default.

3. Click **Batch Create**.

Create a custom rule

If template rules do not meet your requirements for monitoring the data quality, you can create custom rules.

1. Click **View Monitoring Rules** in the Actions column of a table or topic.
2. On the rule configuration page that appears, click the partition filter expression for which you want to configure a custom rule. Then, click **Create rules**. In the Create rules right-side pane, the **Template Rules** tab appears.
3. Click the **Custom Rules** tab. On the **Custom Rules** tab, click **Add Monitoring Rule** or **Quick Create** to create a custom rule.
   - **Click Add Monitoring Rule.**

     Set parameters in the rule configuration section that appears, as described in the following table.

Parameter	Description
Rule Name	The name of the rule.
Field	The fields to be monitored. You can select **All Fields in Table**, **SQL Statement**, or a specific field. ■ If you select All Fields in Table or a specific field, you can specify the WHERE clause to customize filter conditions based on business requirements. ■ If you select SQL Statement, you can customize the SQL logic to set a rule. The return value is the value in a row of a column.

Parameter	Description
Rule Type	The type of the rule. Valid values: Rule Type and Soft. ■ If you select Rule Type, error alerts are reported and descendant nodes are blocked, whereas warning alerts are reported but descendant nodes are not blocked. ■ If you select Soft, error alerts are reported but descendant nodes are not blocked, whereas warning alerts are not reported and descendant nodes are not blocked.
Sampling Method	The statistical function. Valid values: **count** and **count/table_count**.
Filter	The filter condition of the rule. For example, if you need to query partitions of the table based on a specific data timestamp, you can specify `pt=$[yyyymmdd-1]` as the filter condition.
Check type	The threshold type of the rule. Valid values: **Numeric type** and **Fluctuation**.
Comparison Method	The comparison method of the rule. If you set Check type to Numeric type, the values that are optional for this parameter include **Greater Than**, **Greater Than or Equal To**, **Equal To**, **Unequal To**, **Less Than**, and **Less Than or Equal To**.
Verification Method	The verification method of the rule. If you set Check type to Numeric type, you can only set this parameter to **Compare with a specified value**.
Expected Value	The expected value of the rule.
Description	The description of the rule.

- **Click Quick Create.**

  Set parameters in the rule configuration section that appears, as described in the following table.

Parameter	Description
Rule Name	The name of the rule.
Trigger	The type of the rule. You can select only **Values Duplicated in Multiple Fields**.
Field	The fields to be monitored.

Associate a custom node with Data Quality monitoring rules

Before you associate a custom node with Data Quality monitoring rules, make sure that the custom node is created and committed to the production environment. For more information, see Create a custom node type.

You can use one of the following methods to associate a custom node with Data Quality monitoring rules:

- Associate a custom node with Data Quality monitoring rules on the Data Quality page.
  i. Log on to the DataWorks console.
  ii. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Quality**.
  iii. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane.
  iv. Select the target data store from the Engine/Data Source drop-down list, find the target table or topic, and then click **View Monitoring Rules** in the Actions column.
  v. On the rule configuration page that appears, click the partition filter expression for which monitoring rules are configured.
  vi. Click **Manage Linked Nodes**.
  vii. In the **Manage Linked Nodes** dialog box, select the target workspace, enter the ID or name of the custom node, and then click **Create**.
- Associate a custom node with Data Quality monitoring rules on the Operation Center page.
  i. Log on to the DataWorks console.
  ii. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Operation Center**.
  iii. In the left-side navigation pane, choose **Cycle Task Maintenance > Cycle Task**.
  iv. Find the target node and choose **More > Configure Data Quality Rules** in the Actions column.
  v. In the **Configure Data Quality Rules** dialog box, set the **Workspace**, **Table Name**, **Engine type**, **Engine instance**, and **Partition Expression** parameters, and click **Add**.

2.10.2.4. View monitoring results

The Node Query page displays the monitoring results of rules. After monitoring rules are triggered, you can go to the Node Query page to view the monitoring results of the rules.

Go to the Node Query page

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click  in the upper-left corner and choose **All Products > DataAnalysis**.
3. On the Data Quality page, click **Node Query** in the left-side navigation pane.On the **Node Query** page, you can set parameters, such as the **Engine/Data Source**, **Status**, and **My Subscriptions** parameters, to filter nodes and view the monitoring results.

View the monitoring results of E-MapReduce and MaxCompute tables

GUI element	Description
Engine/Data Source	The name of the compute engine. In this example, select **EMR** or **ODPS**.

GUI element	Description
Engine/Database Instance	The E-MapReduce instance or MaxCompute project where the desired tables reside.
Status	The monitoring result of rules. Pay attention to partitions that trigger alerts or blocks.
Data Timestamp	The data timestamp.
My Subscriptions	Specifies whether to display only monitoring results of tables that you subscribed to.
Run At	The time when rules were triggered.
Table Name	The name of the table whose monitoring results you want to view.
Node	The node that triggered rules.
Details	Click **Details** in the **Actions** column of a table. On the page that appears, you can perform the following operations on each rule configured for the table: • Click **View History Check Results** in the Actions column of a rule to view the monitoring result history of the rule. • Enter comments on a rule based on the execution status of the rule. Perform the following steps to enter comments on a rule: i. Click **Problem Handling** in the Actions column of the rule. ii. In the **Problem Handling** dialog box, set the **Handling Method** and **Comments** parameters. iii. Click **OK**. **Notice** You can only use the problem handling feature in DataWorks Enterprise Edition or higher. • Click **Handling Logs** in the Actions column of a rule to view the processing history of the rule.
Rules	Click **Rules** in the Actions column of a table to go to the rule configuration page for the table. On this page, you can view partition filter expressions and rules configured for the table, and modify the rules as required. For more information, see MaxCompute monitoring.
View Log	Click **View Log** in the Actions column of a table to view the operational logs of rules configured for the table.
View Statistics	Click **View Statistics** in the Actions column of a table to view rule execution information about the table, including the number of rows and the table size.

View the monitoring results of DataHub topics

GUI element	Description
Engine/Data Source	The name of the compute engine. In this example, select Datahub.
Configure a data source	The name of the DataHub connection.
Status	The monitoring result of rules. Pay attention to topics that trigger alerts or blocks.
Topic	The name of the topic whose monitoring results you want to view.
My Subscriptions	Specifies whether to display only monitoring results of topics that you subscribed to.
Clear	Click Clear to clear the filter conditions you specified.
View Log	Click View Log in the Actions column of a topic to view the operational logs of rules configured for the topic.
Alerts	Click Alerts in the Actions column of a topic. On the Alerts page, you can view details about alerts triggered by the topic. On the Alerts page, you can click Close in the Actions column of an alert. In the message that appears, click OK to disable the alert.

2.10.2.5. Report Template Management

On the Report Template Management page, you can create a template of data quality reports. DataWorks can periodically generate and send data quality reports based on the template.

Create a report template

1. Log on to the DataWorks console. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose All Products > Data Quality.
2. On the Data Quality page that appears, choose Configuration > Report Template Management in the left-side navigation pane. The Report Template Management page appears.
3. Click Create Report Template. On the Create Report Template page that appears, set required parameters.

Section	Parameter	Description
	Name	The name of the report template.

Section	Parameter	Description
Basic settings	**Sending Cycle**	The interval at which reports are sent. Valid values: **Every Day**, **Every Week**, **Every Month**, and **Do Not Send**. If you set Sending Cycle to Every Week or Every Month, you also need to specify the specific day on which reports are sent.
	Timespan	The number of days before the current day. DataWorks generates reports based on the data of those days. The maximum value of this parameter is 30.
Statistics of Rule Configuration The Statistics of Rule Configuration section displays metrics about rule configuration for offline data and real-time data. You can select metrics based on your needs.	**Offline data**	The metrics about rule configuration for tables in the workspace. The metrics include **Table count**, **Partition expression count**, **Count of rule on offline data**, and **Rule coverage on tables**. The Rule coverage on tables metric indicates the ratio of tables for which quality monitoring rules are configured.
	Realtime data	The metrics about rule configuration for topics in the workspace. The metrics include **Topic count**, **Count of rule on realtime data**, **Count of rule on cut off data**, **Rule coverage on topic**, **Count of rule on delayed data**, and **Count of customized rule**. The Rule coverage on topic metric indicates the ratio of topics for which quality monitoring rules are configured.

Section	Parameter	Description
Statistics of Rule Execution The Statistics of Rule Execution section displays metrics about rule running for offline data and real-time data. You can select metrics based on your needs. Quality reports display the selected metrics in charts.	**Offline data**	The metrics about rule running for tables in the workspace. The metrics are classified into the following types: **About rules**, **About partitions**, and **About tables**.
	Realtime data	The metrics about rule running for topics in the workspace. The metrics are classified into the following types: **About messages**, **About alarms**, and **About cut-offs**.
Manage Subscriptions	**Subscription Method**	The method used to notify report subscribers of new reports. Currently, DataWorks sends emails to notify report subscribers of new reports.
	Recipient	The recipient of report notifications. You can add multiple recipients.
	Actions	The operations that you can perform on the subscription. You can click **Save** or **Cancel** in the Actions column of a subscription to save or cancel the subscription.
	Add Subscription	The button that allows you to add a subscription.

4. Click **Save** in the upper-right corner. A template of data quality reports is generated.

Preview a report template

After creating a report template, you can click **Preview** in the upper-right corner of the Create Report Template page to view the display format of reports generated based on this template.

> **Note** If report subscribers view reports through email notifications, they can only view the reports in tables. If they view reports on the Data Quality page, they can view reports in tables or charts.

2.10.2.6. Manage rule templates

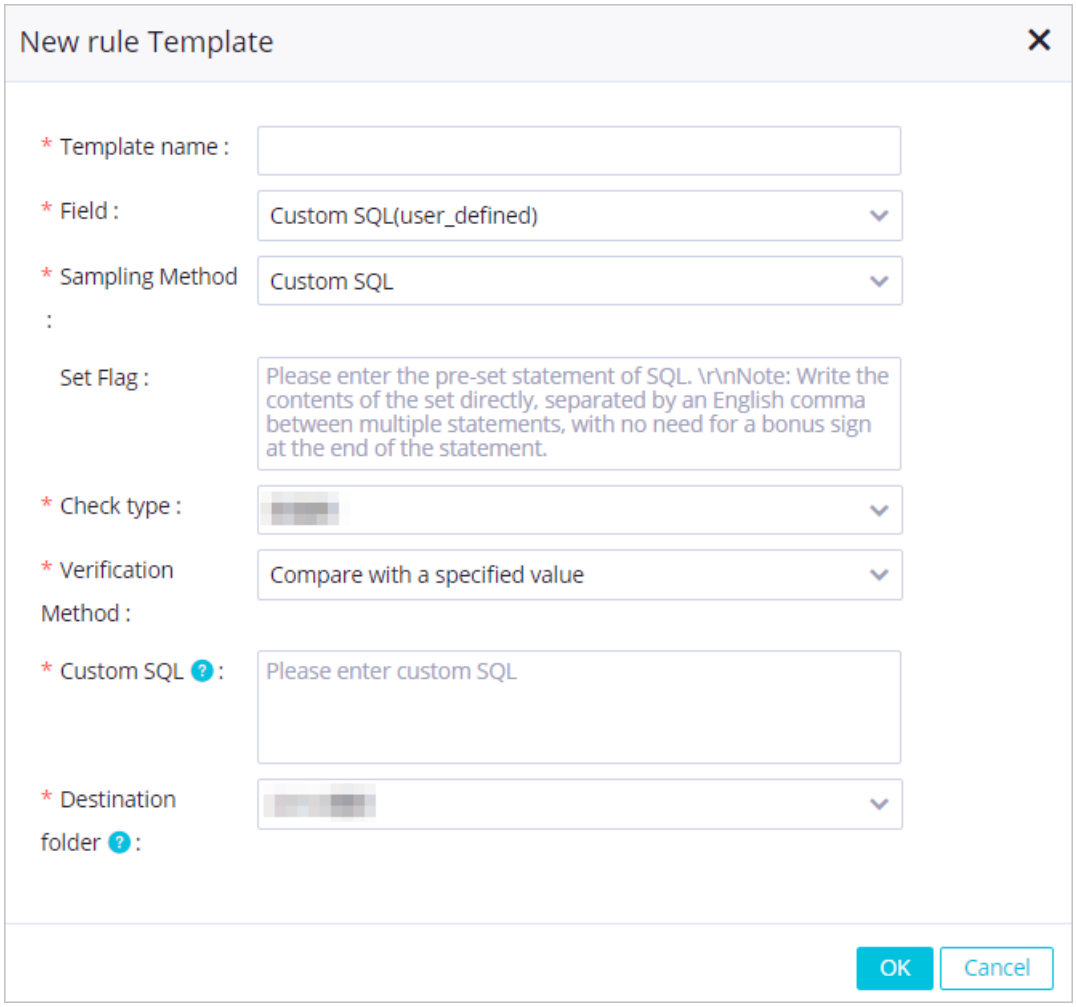
In Data Quality, you can manage a set of custom rule templates and use the rule templates to improve the efficiency of rule configuration.

Context

You can create a rule template on the **Rule Templates** and **Monitoring Rules** pages. After the rule template is created, you can manage and use it.

Create a rule template on the Rule Template Management page

1. Log on to the DataWorks console.
2. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Quality**.
3. On the Data Quality page, choose **Configuration > Rule Templates** in the left-side navigation pane.
4. On the Rule Templates page, click and select **Create Folder**.
5. In the **Create Folder** dialog box, set the **Name** and **Location** parameters and click **OK**.
6. Right-click the folder name and select **Create Rule Template**. You can also rename or delete a folder.
7. In the **Create Rule Template** dialog box, set relevant parameters.



Parameter	Description
Template Name	The name of the rule template.
Field	The fields to be monitored and the statistical function. You can only set the two parameters to **Custom SQL**.
Sampling Method	
Set Flag	The `SET` clause of the SQL statement for querying the field to be monitored. **Note** Separate multiple statements with commas (,). You do not need to add a semicolon (;) at the end of each statement.
Check type	The threshold type of the rule. Valid values: **Numeric type** and **Fluctuation**.
Verification Method	The verification method of the rule template. The verification methods that can be selected vary with the threshold type. ○ If you set the **Check type** parameter to **Numeric type**, you can only set this parameter to **Compare with a specified value**. ○ If you set the **Check type** parameter to **Fluctuation**, the values that are optional for this parameter include **Compare the current value with the average value of the last 7 days**, **Compare the current value with the average value of the last 30 days**, **Compare the current value with the value 1 day before**, **Compare the current value with the value 7 days before**, **Compare the current value with the value 30 days before**, **The variance between the current value and the value 7 days before**, **The variance between the current value and the value 30 days before**, **Compare with the value 1, 7, and 30 days before** and **Compare with the value of the previous cycle**.
Custom SQL	The custom SQL statement. You can use ${tableName} as the table name.
Location	The name of the folder to which you want to store the custom rule template.

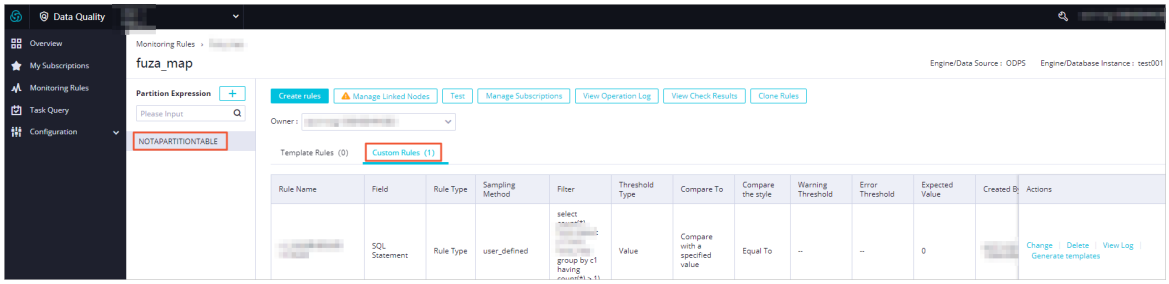
8. Click **OK**.

Create a rule template on the Monitoring Rules page

1. Go to the **Data Quality** page.
2. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane.
3. On the Monitoring Rules page, select the compute engine or data store, find the target table or topic, and then click **View Monitoring Rules** in the Actions column.

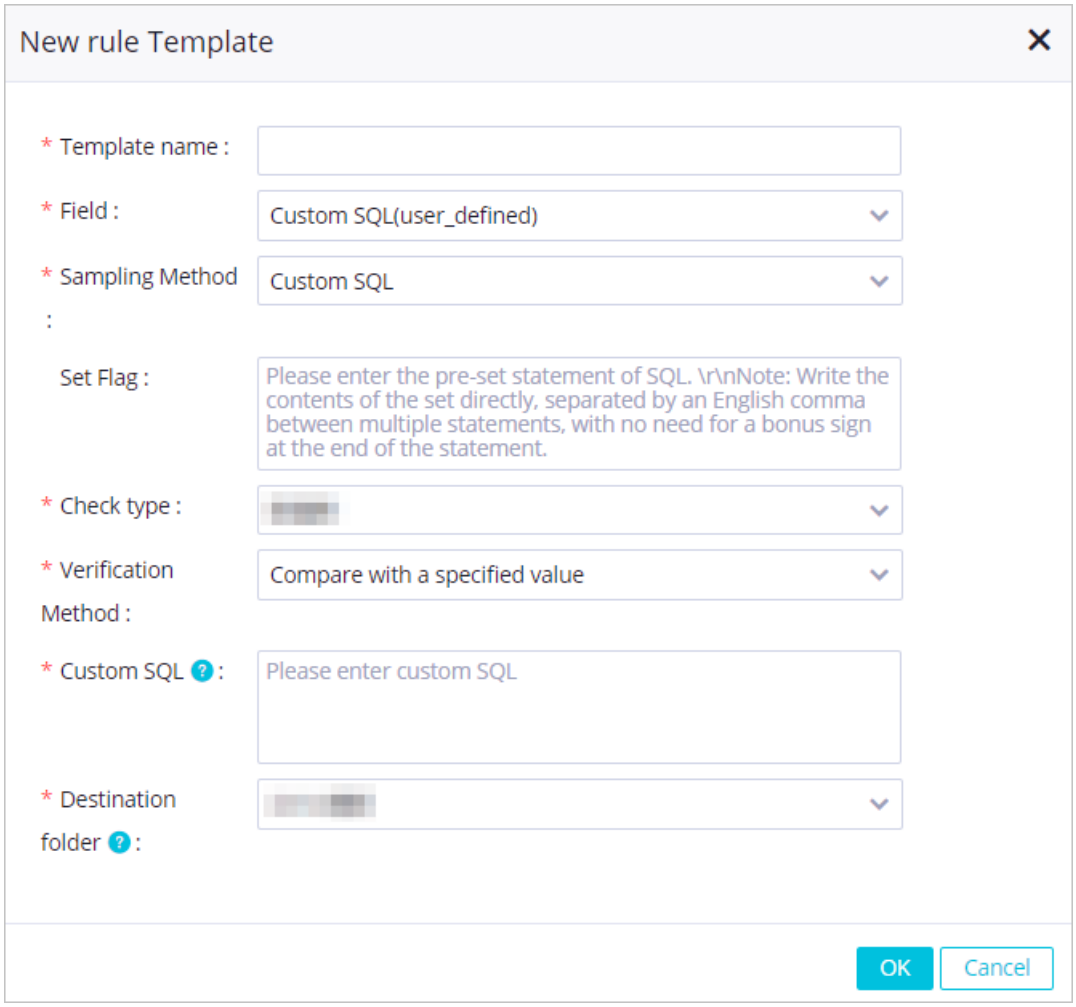
   Note This topic uses a MaxCompute table as an example.

4. Click a partition filter expression and then click the **Custom Rules** tab.



Note For more information about how to create custom rules, see **Custom rules**.

5. On the **Custom Rules** tab, find the target custom rule and click **Generate Template** in the **Actions** column.
6. In the **Create Template** dialog box, set relevant parameters.



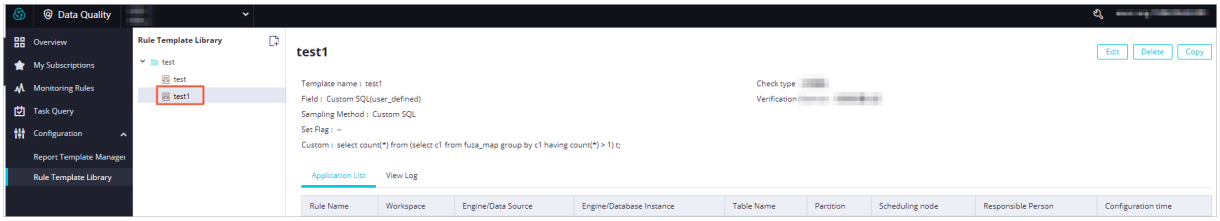
Parameter	Description
Template Name	The name of the rule template.
Field	The fields to be monitored and the statistical function. You can only set the two parameters to **Custom SQL**.
Sampling Method	

Parameter	Description
Set Flag	The `SET` clause of the SQL statement for querying the field to be monitored. **Note** Separate multiple statements with commas (,). You do not need to add a semicolon (;) at the end of each statement.
Check type	The threshold type of the rule. Valid values: **Numeric type** and **Fluctuation**.
Verification Method	The verification method of the rule template. The verification methods that can be selected vary with the threshold type. ○ If you set the **Check type** parameter to **Numeric type**, you can only set this parameter to **Compare with a specified value**. ○ If you set the **Check type** parameter to **Fluctuation**, the values that are optional for this parameter include **Compare the current value with the average value of the last 7 days**, **Compare the current value with the average value of the last 30 days**, **Compare the current value with the value 1 day before**, **Compare the current value with the value 7 days before**, **Compare the current value with the value 30 days before**, **The variance between the current value and the value 7 days before**, **The variance between the current value and the value 30 days before**, **Compare with the value 1, 7, and 30 days before** and **Compare with the value of the previous cycle**.
Custom SQL	The custom SQL statement. You can use ${tableName} as the table name.
Location	The name of the folder to which you want to store the custom rule template.

7. Click **OK**.
8. In the left-side navigation pane, choose **Configuration** > **Rule Templates** to view the created rule template.

Manage an existing rule template

On the Rule Templates page, you can click the name of a rule template to go to the template details page. On this page, you can view, edit, delete, or copy the rule template.



Action	Description

Action	Description
View	You can view the parameter configuration, the rules that use the rule template, and logs of the rule template: • The **Application List** tab displays the rules that use the rule template. • The **View Log** tab displays the logs of operations performed on the rule template, including the user who performed each operation, the time when each operation was performed, and the operation details.
Edit	Click **Edit** in the upper-right corner. In the **Edit Rule Template** dialog box, modify the required parameters, and click **OK**.
Delete	Click **Delete** in the upper-right corner. In the **Delete Template** message, click **OK**.
Copy	Click **Copy** in the upper-right corner. In the **Copy Rule Template** dialog box, set the **Template Name** and **Location** parameters and click **OK**.

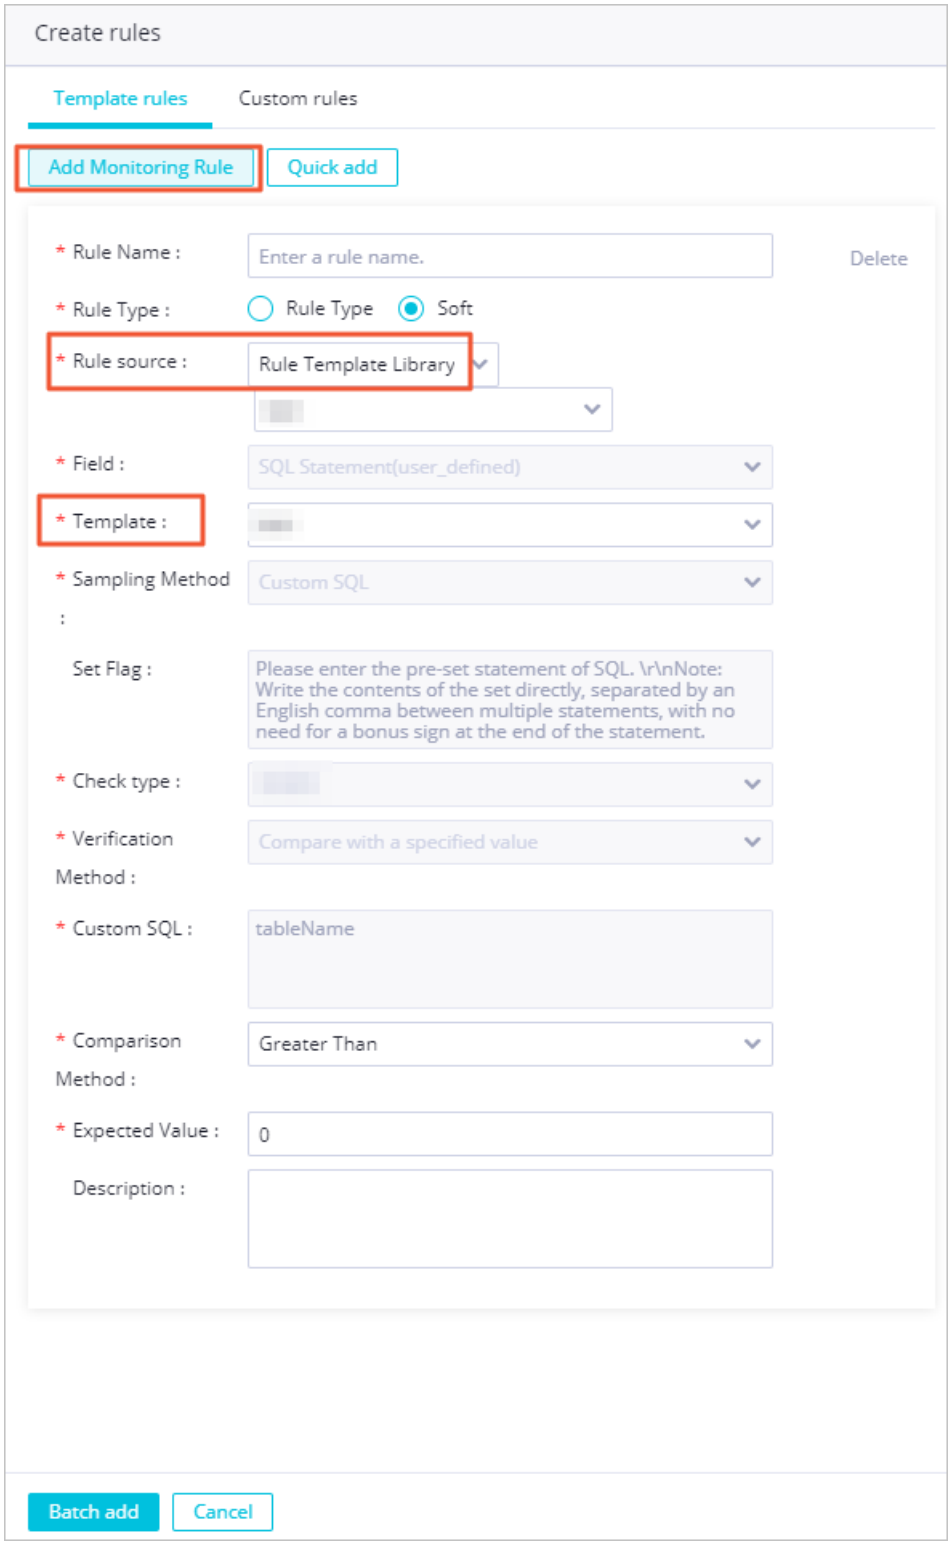
Use a rule template

When you create a monitoring rule, you can select a custom rule template to create the rule based on the rule template.

1. Go to the **Data Quality** page.
2. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane.
3. On the Monitoring Rules page, select the compute engine or data store, find the target table or topic, and then click **View Monitoring Rules** in the Actions column.

   > **Note** This topic uses a MaxCompute table as an example.

4. Click a partition filter expression and click the **Custom Rules** tab.
5. On the **Template Rules** tab of the **Create rules** right-side pane, click **Add Monitoring Rule**.
6. Set the parameters for the rule. Specifically, set the **Rule Source** parameter to **Rule Templates** and select a rule template. For more information about the parameter description, see Rules.



7. Click **Batch Create**.

2.10.3. User guide

2.10.3.1. Configure monitoring rules for MaxCompute

The Monitoring Rules page is the most important part of Data Quality, where you can configure rules to monitor data in E-MapReduce, MaxCompute, and DataHub. This topic describes how to configure monitoring rules for MaxCompute.

Add a MaxCompute connection

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration**.
3. On the Data Integration page, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
4. Click **Add Connection** in the upper-right corner to add a MaxCompute connection.

Select the MaxCompute connection

1. On the current page, click  in the upper-left corner and choose **All Products > Data Quality**.
2. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane.
3. Select **ODPS** from the **Engine/Data Source** drop-down list to display all tables in the MaxCompute data store.You can search for a table by table name. Fuzzy search based on the initial letters of a table name is supported.
4. Find the target table and click **View Monitoring Rules** in the Actions column.

Configure a partition filter expression

In Data Quality, you must configure rules based on a partition filter expression:

- To configure rules for a non-partitioned table, you can specify NOTAPARTITIONTABLE as the partition filter expression.
- To configure rules for a partitioned table, you can specify a data timestamp expression, such as $[yyyymmdd], or a regular expression as the partition filter expression.

On the rule configuration page of a table, click + next to **Partition Expression** to add a partition filter expression.

You can create a partition filter expression or select a recommended partition filter expression.

- Create a partition filter expression

  In the **Add Partition** dialog box, enter a partition filter expression that conforms to the syntax as required. For a non-partitioned table, select **NOTAPARTITIONTABLE** from the recommended partition filter expressions.

  - For a table with only one partition, follow the format: Partition key=Partition value. The partition value can be either a constant or a system parameter. You must configure partition expressions by using the last partition.
  - For a table with multiple partitions, follow the format: Partition key 1\=Partition value/Partition key 2=Partition value/Partition key N=Partition value. Each partition value can be either a constant or a system parameter. You must use brackets [ ] to indicate a parameter, such as $[yyyymmdd-N].

The data timestamp configured in a partition filter expression also determines the recurrence of the partition filter expression. For example, if the data timestamp is the date of five days ago, the partition filter expression is triggered every five days. The following table describes supported partition filter expressions.

Partition filter expression	Description
dt=$[yyyymmdd-N]	Indicates N days before.
dt=$[yyyymm01-1]	Indicates the first day of each month.
dt=$[yyyymm01-Nm]	Indicates the first day of the month that is N months before the current month.
dt=$[yyyymmld-1]	Indicates the last day of each month.
dt=$[yyyymmld-1m]	Indicates the last day of the month that is N months before the current month.
dt=$[hh24miss-1/24]	Indicates one hour before the hour specified by the data timestamp.
dt=$[hh24miss-30/24/60]	Indicates half an hour before the hour specified by the data timestamp.
$[yyyymmdd]	Indicates the data timestamp.
$[yyyymmdd-1]	Indicates one day before the data timestamp of the current instance.
$[yyyymmddhh24miss]	Indicates the data timestamp of the current instance. Follow the `yyyymmddhh24miss` format by understanding the following format description: ◦ yyyy indicates a four-digit year. ◦ mm indicates a two-digit month. ◦ dd indicates a two-digit day. ◦ hh24 indicates a two-digit hour (24-hour clock). ◦ mi indicates two-digit minutes. ◦ ss indicates two-digit seconds.
NOTAPARTITIONTABLE	Indicates the partition filter expression of a non-partitioned table.

- Select a recommended partition filter expression

  This section uses the dt partition as an example to describe how to select a recommended partition filter expression. We recommend that you specify a regular expression as the partition filter expression for a dynamic partitioned table.

  i. In the **Add Partition** dialog box, click the Partition Expression field. A drop-down list appears to show you the partition filter expressions recommended by Data Quality.

  - Select a recommended partition filter expression if it meets your expectation.

- Specify a custom partition filter expression if no recommended partition filter expressions meet your expectation.

ii. After you enter a partition expression, click **Verify**. Data Quality uses the current time, that is, the data timestamp, to calculate data and verify the partition filter expression.

iii. Click **OK**.

If you need to delete a partition filter expression, move the pointer over the partition filter expression and click the **Delete** icon to delete the partition filter expression. When you delete a partition filter expression, all rules configured based on the partition filter expression are also deleted.

Link a partition filter expression to a node

To monitor the quality of data involved in a node, you need to link a partition filter expression to the node.

- The Manage Linked Nodes dialog box lists all committed nodes. Data Quality allows you to link a partition filter expression to a node in another workspace.
- Before you link a partition filter expression to a node in another workspace, make sure that you are an administrator, a developer, or an administration expert in the two workspaces.

You can link a partition filter expression to one or more nodes. After nodes are linked, Data Quality can automatically monitor linked nodes.

> **Note** Data Quality allows you to flexibly link a partition filter expression to a node. You can select a node that is not related to your table.

1. On the rule configuration page of a table, click **Manage Linked Nodes**.
2. In **Manage Linked Nodes** dialog box, enter the name of the node that you want to link to the partition filter expression.
3. Click **Create**.

Create a rule

The Monitoring Rules page is the most important part of Data Quality, where you can create rules for your tables.

Data Quality allows you to create template rules and custom rules as needed. If you need to create a template rule or a custom rule, you can click **Add Monitoring Rule** or **Quick Create**. For more information, see Rules.

After rules are configured, you can click **Batch Create** to save all the configured rules for the current partition filter expression.

Creation method	Parameter	Description
	Rule Name	The name of the rule.

Creation method	Parameter	Description
Add Monitoring Rule	Rule Type	The type of the rule. Valid values: • **Rule Type**: If a node reaches the error threshold, Data Quality reports an error alert and determines that the node fails. If a node reaches the warning threshold, Data Quality reports a warning alert and determines that the node is successful. • **Soft**: If a node reaches the error threshold, Data Quality reports an error alert and determines that the node is successful. If a node reaches the warning threshold, Data Quality does not report a warning alert and determines that the node is successful.
	Auto-Generated Threshold	You can use the dynamic threshold feature only in DataWorks Enterprise Edition or higher.
	Rule Source	The source of the rule. Valid values: **Built-in Template** and **Rule Templates**.
	Field	The fields to be monitored. You can select **All Fields in Table** or a specific field. If you select a field, you can apply the rule to the specified field in the table. **Note** In this example, select All Fields in Table and set other parameters for the table-specific rule.
	Template	• If you set **Rule Source** to **Built-in Template**, the built-in table-specific rules appear. • If you set **Rule Source** to **Rule Templates**, you must set parameters, such as **Sampling Method** and **Set Flag**.
	Comparison Method	The comparison method of the rule. Valid values: **Absolute Value**, **Raise**, and **Drop**.
	Thresholds	The warning threshold and error threshold of the fluctuation. You can adjust the slider to specify thresholds or directly enter thresholds.
	Description	The description of the rule.
	Rule Name	The name of the rule.

Creation method	Parameter	Description
Quick Create	Field	The fields to be monitored. You can select All Fields in Table or a specific field. If you select a field, you can apply the rule to the specified field in the table.
	Trigger	• The trigger condition of the rule. If you select All Fields in Table for the Field parameter, you can set this parameter to The number of columns is greater than 0 or Table row number dynamic threshold. Notice You can use the dynamic threshold feature only in DataWorks Enterprise Edition or higher. • If you select a field for the Field parameter, you can select The field value already exists, Null Field, or Unique value dynamic threshold. Notice You can use the dynamic threshold feature only in DataWorks Enterprise Edition or higher.

Test rules

After rules are configured for a partition filter expression, you can test all these rules and view the test results.

Note You can manually run these rules to test their configuration and notification methods. We recommend that you test rules as required.

1. On the rule configuration page of a table, click **Test**.
2. In the **Test** dialog box, set the **Data Timestamp** parameter.

Parameter	Description
Partition	The partition filter expression for which rules are run. The actual partition key varies with the data timestamp. For a non-partitioned table, use NOPARTITIONTABLE as the partition filter expression.
Data Timestamp	The data timestamp for testing rules. The default value is the current time.

3. Click **Test**.
4. In the Test dialog box, click **The test is complete. Click to view the results** to view the test results on the **Node Query** page.

Manage subscriptions

By default, Data Quality sends notifications to the user who created a partition filter expression. You can add other users so that Data Quality sends notifications to them.

1. On the rule configuration page of a table, click **Manage Subscriptions**.
2. In the **Manage Subscriptions** dialog box, specify the notification method and notification receiver.Data Quality supports the following four methods: **Email**, **Email and SMS**, **DingTalk Chatbot**, and **DingTalk Chatbot @ALL**.

   > **Note** Add a DingTalk chatbot and obtain a webhook URL. Then, copy the webhook URL to the Manage Subscriptions dialog box.

3. Click **Save**.

View operational logs

On the rule configuration page of a table, click **View Operation Log**. In the **Operations Logs** right-side pane, you can view the information about each operation, including the user who performed the operation, the time when the operation was performed, and the operation details.

The **Details** column displays the details of each operation performed on the current partition filter expression, including the rule configuration details.

View check results

On the rule configuration page of a table, click **View Check Results** to go to the **Node Query** page. On this page, you can view the check results for all rules under the current partition filter expression.

Clone rules

1. On the rule configuration page of a table, click **Clone Rules**.
2. In **Clone Rules** dialog box, set the **Target Expression** parameter.
3. Select **Clone Subscribers** or **Change Table Names in Custom Rules** as required.
4. Click **Clone**.

2.10.3.2. Configure monitoring rules for DataHub

The Monitoring Rules page is the most important part of Data Quality, where you can configure rules to monitor data in E-MapReduce, MaxCompute, and DataHub. This topic describes how to configure monitoring rules for DataHub.

Context

DataHub monitoring supports the following features:

- Templates for monitoring stream discontinuity and data latency
- Stream processing features, such as custom Flink SQL, dimension table JOIN, multi-stream JOIN, and window functions

Procedure

1. Add a DataHub connection.
   i. Log on to the DataWorks console.
   ii. On the **DataStudio** page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration**.
   iii. On the Data Integration page, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
   iv. Click **Add Connection** in the upper-right corner to add a DataHub connection.
2. Select the DataHub connection.
   i. On the current page, click  in the upper-left corner and choose **All Products > Data Quality**.
   ii. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane.
   iii. Select **Datahub** from the **Engine/Data Source** drop-down list and select the DataHub connection. All the topics in the selected DataHub data store appear.

Parameter	Description
Configure Flink Resources	After you add a connection, click Configure Flink Resources to configure Flink and Log Service resources related to the connection.
Topics	The Topics tab lists all topics in the DataHub data store. You can click the following buttons in the Actions column for a topic: ■ **View Monitoring Rules**: Click it to create rules for the topic. You can create template rules and custom rules as needed. ■ **Manage Subscriptions**: Click it to view and modify subscribers to the current topic, and change the notification method. You can configure the DingTalk chatbot notification method. The changed notification method takes effect for all subscribers to the topic.

Parameter	Description
Dimension Tables	When you create custom rules for a topic, you can create dimension tables and use the JOIN clause to join dimension tables. If the collected data streams lack some fields for a dimension table, you must supplement fields to data streams before data analysis and declare the dimension table in Data Quality. DataHub supports the dimension tables of ApsaraDB for HBase, Lindorm, ApsaraDB for RDS, Tablestore, Taobao Distributed Data Layer (TDDL), and MaxCompute. Flink SQL does not design the DDL syntax for dimension tables. You can use the standard CREATE TABLE statement. However, you must add `period for system_time` to specify the period of a dimension table and declare that the dimension table stores time-varying data. **Note** When you declare a dimension table, you must specify the primary key. When you join a dimension table with another table, the ON condition must contain an equivalence condition that includes the primary key of either table.

iv. Click the **Topics** tab. Find the target topic and click **View Monitoring Rules** in the Actions column.

3. On the rule configuration page of the topic, click **Create rules**.
4. Create a monitoring rule.In Data Quality, you can create template rules and custom rules as needed.
   - Click **Create Template Rule**. Two templates are available: **Data Delay** and **Stream Discontinuity**.

     For example, you can select **Data Delay** for Template Type.

Parameter	Description
Rule Name	The name of the rule. The name can be up to 255 characters in length.
Field Type	The fields to be monitored. By default, the field type is All Fields in Table.

Parameter	Description
Template Type	■ **Data Delay**: monitors the interval between the time when data is generated and the time when data is written to DataHub based on the data timestamp field. If the interval exceeds a specified threshold, an alert is generated. Note ■ Before you configure a stream discontinuity rule, you must activate Realtime Compute in Flink and create a project. ■ The data timestamp field supports two data types: TIMESTAMP and STRING (yyyy -MM -dd H dd HH:mm:ss). ■ **Stream Discontinuity**: monitors the period during which no data is written to DataHub. If the period exceeds a specified threshold, an alert is generated.
Alerts Threshold	The maximum number of alerts generated for data latency. Data Quality reports an alert when the number of alerts generated for data latency exceeds this threshold. This parameter only takes effect when you select Data Delay for Template Type.
Data Timestamp Field	The data timestamp field of the topic for which the rule is created. This field supports two data types: TIMESTAMP and STRING (yyyy-MM-dd HH:mm:ss). This parameter only takes effect when you select Data Delay for Template Type.
Alert Frequency	The interval for reporting an alert. You can set the alert interval to 10 minutes, 30 minutes, 1 hour, or 2 hours.
Warning Threshold	The warning threshold, in seconds. The value must be an integer and less than the error threshold.
Error Threshold	The error threshold, in seconds. The value must be an integer and greater than the warning threshold.

- If template rules do not meet your requirements for monitoring the data quality of DataHub topics, you can click **Create Custom Rule** to create a rule as required.

  Note
  - The field in the SELECT clause must be a column. Ensure that you can compare the field values with the warning and error thresholds.
  - The FROM clause must include the current topic and all its columns.

Parameter	Description

Parameter	Description
Rule Name	The name of the rule. The name must be unique in the topic and can be up to 20 characters in length.
Script	The custom SQL script, which is used to set a rule. The return value of the SELECT clause must be unique. You can refer to the following sample statements: ■ Use a simple SQL statement. `select id as a from zmr_tst02;` ■ Join the topic and a dimension table named test_dim. `select e.id as eid` `from zmr_test02 as e` `join test_dim for system_time as of proctime() as w` `on e.id=w.id` ■ Join the topic and another topic named dp1test_zmr01. `select count(newtab.biz_date) as aa` `from (select o.*` `from zmr_test02 as o` `join dp1test_zmr01 as p` `on o.id=p.id)newtab` `group by id.biz_date,biz_date_str,total_price,'timestamp'`
Warning Threshold	The warning threshold, in minutes. The value must be an integer and less than the error threshold.
Error Threshold	The error threshold, in minutes. The value must be an integer and greater than the warning threshold.
Minimum Alert Interval	The minimum interval for reporting an alert, in minutes.
Description	The description of the rule.

5. Click **Batch Create** to add the created rules to the topic.
   - **View Log**: Click it to view the operational logs of rules.

- **Manage Subscriptions**: Click it to view and modify subscribers to the current rule, and change the notification method. The changed notification method takes effect for all subscribers to the rule.

  Data Quality supports the following four methods: **Email**, **Email and SMS**, **DingTalk Chatbot**, and **DingTalk Chatbot @ALL**.

  > **Note** Add a DingTalk chatbot and obtain a webhook URL. Then, copy the webhook URL to the Manage Subscriptions dialog box.

2.11. Data Map

2.11.1. Overview

Developed based on Data Management, Data Map uses roles to control the permissions for using different features, such as the permissions for creating and previewing data. Data Map helps you build a better enterprise-level knowledge base.

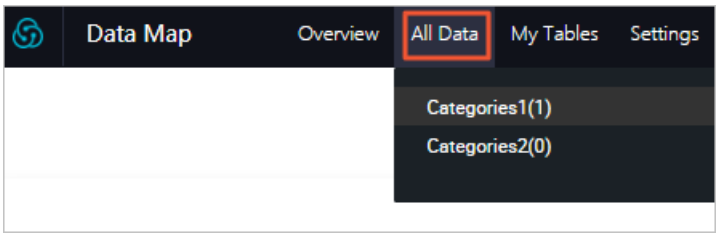
On the homepage of Data Map, you can enter keywords to search for tables by name. You can also click a table in any of the following sections to view the table data: **Recently Viewed Tables**, **Recently Read Tables**, **Most Viewed Tables**, and **Most Read Tables**.

- If you prefer a powerful search engine, go to the homepage to search for data.

  > **Note** The homepage appears by default when you access **Data Map**. To return to the homepage from other pages, click **Data Map** in the upper-left corner.

- If you need to find tables by project or cluster, click **All Data** in the top navigation bar. On the All Data page, you can view tables on the **MaxCompute** and **E-MapReduce** tabs. On the MaxCompute tab, you can perform the following operations on a table: **Add to Favorites**, **Apply for Permission**, **View Lineage**, and **View DDL Statement**.

  If you have added tables to categories, move the pointer over **All Data** in the top navigation bar and select a category. Tables in the category appear. For more information, see Manage categories and configure workspace permissions.

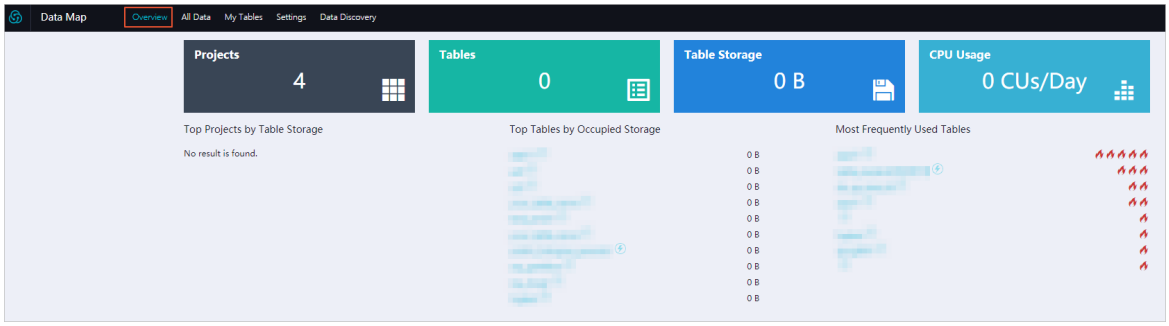
- If you need to view the overall data of the current tenant, click **Overview** in the top navigation bar. For more information, see View overall data.
- If you need to modify tables owned by yourself, click **My Tables** in the top navigation bar. For more information, see View and manage data and data permissions.
- If you are a category administrator or workspace administrator and need to modify the workspace configuration or global categories, click **Settings**. For more information, see Manage categories and configure workspace permissions.

2.11.2. View overall data

This topic describes how to view the overall data of a tenant on the Overview page.

Procedure

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Data Map(Data Management)**. The homepage of Data Map appears.
3. Click **Overview** in the top navigation bar. The **Overview** page displays offline statistics of the tenant.



> **Note** The Overview page displays statistics of the previous day.

Section	Description
Projects	The total number of projects of the tenant.
Tables	The total number of tables of the tenant.
Table Storage	The total storage occupied by all tables of the tenant.
CPU Usage	The number of compute units (CUs) consumed by the tenant in one day. One CU is equivalent to the computing resources consumed by one fully loaded CPU core in one day.
Top Projects by Table Storage	The top projects that occupy the most storage space under the tenant.

Section	Description
Top Tables by Occupied Storage	The top tables that occupy the most storage space under the tenant. You can click a table name to go to the details page of the table. Note The logical storage space occupied by projects and tables is collected in a T+1 manner. The numbers next to the project and table names indicate the sizes of the occupied logical storage space. The project storage volume includes the table storage volume, storage volumes of resources, data in the recycle bin, and other system files. Therefore, the project storage volume is larger than the table storage volume. The table storage volume is charged based on the logical storage rather than the physical storage.
Most Frequently Used Tables	The most frequently referenced tables of the tenant. You can click a table name to go to the details page of the table.

2.11.3. View and manage data and data permissions

You can view and manage data on the Owned by Me, Managed by Me as Workspace Administrator, Managed by Tenant Account, and My Favorites pages. This topic describes how to view and manage data and data permissions.

Context

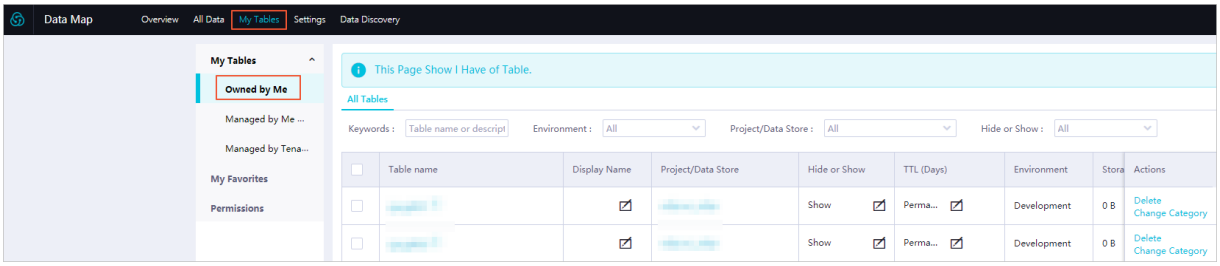
Data Map updates data one day after the data is generated. If you need to query real-time data, we recommend that you use SQL statements.

Go to the My Tables page

1. Log on to the DataWorks console.
2. Click  in the upper-left corner and choose **All Products > Data Map(Data Management)**. The homepage of Data Map appears.
3. In the top navigation bar, click **My Tables**. By default, the **My Tables > Owned by Me** page appears.

View and manage data on the Owned by Me page

On the **Owned by Me** page, you can search for data by keyword, environment, project or data store, and visibility. You can also view the details about a table and perform relevant operations on the table.

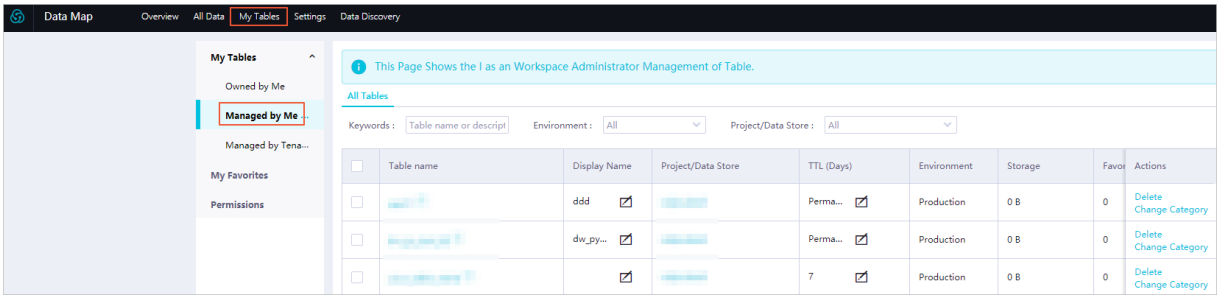


GUI element	Description
Table name	The name of the table. You can click a table name to go to the table details page.
Display Name	The display name of the table. You can click in the **Display Name** column of a table to change the display name of the table.
Project/Data Store	The project or data store where the table resides.
Hide or Show	Indicates whether the table is hidden. You can click in the **Hide or Show** column of a table to hide or show the table. **Note** If you hide a table, the **Apply for Permissions** button does not appear on the details page of the table.
TTL (Days)	The TTL of the table, which is the same as that you set when you create the table.
Environment	The environment to which the table belongs. Valid values: **Development** and **Production**.
Storage	The amount of data that is stored in the table.
Favorites	The number of times that users add the table to favorites.
Views in Last 30 Days	The number of times that users view the table in the last 30 days.
Created At	The time when the table was created.
Actions	The operations that you can perform on the table. You can click **Delete** or **Change Category** in the Actions column of a table to delete the table or change the category of the table.

GUI element	Description
Edit, Change Owner, Delete, and Change Category	The operations that you can perform on multiple tables at a time. You can select tables and then click **Edit**, **Change Owner**, **Delete**, or **Change Category** to modify the tables, change the table owners, delete the tables, or change the categories of the tables.

View and manage data on the Managed by Me as Workspace Administrator page

In the left-side navigation pane, click **Managed by Me as Workspace Administrator**. On the page that appears, you can search for data by keyword, project or data store, and environment. You can also view the details about a table and perform relevant operations on the table.

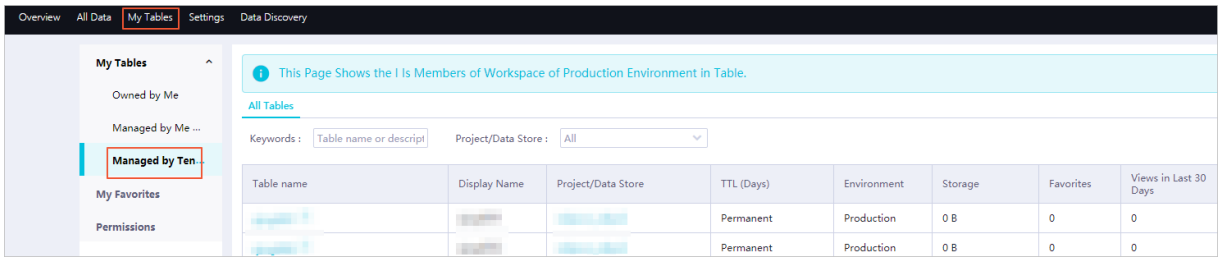


GUI element	Description
Table name	The name of the table. You can click a table name to go to the table details page.
Display Name	The display name of the table. You can click in the **Display Name** column of a table to change the display name of the table.
Project/Data Store	The project or data store where the table resides.
TTL (Days)	The TTL of the table, which is the same as that you set when you create the table.
Environment	The environment to which the table belongs. Valid values: **Development** and **Production**.
Storage	The amount of data that is stored in the table.
Favorites	The number of times that users add the table to favorites.
Views in Last 30 Days	The number of times that users view the table in the last 30 days.
Created At	The time when the table was created.
Actions	The operations that you can perform on the table. You can click **Delete** or **Change Category** in the Actions column of a table to delete the table or change the category of the table.

GUI element	Description
Edit, Change Owner, Delete, and Change Category	The operations that you can perform on multiple tables at a time. You can select tables and then click **Edit**, **Change Owner**, **Delete**, or **Change Category** to modify the tables, change the table owners, delete the tables, or change the categories of the tables.

View data on the Managed by Tenant Account page

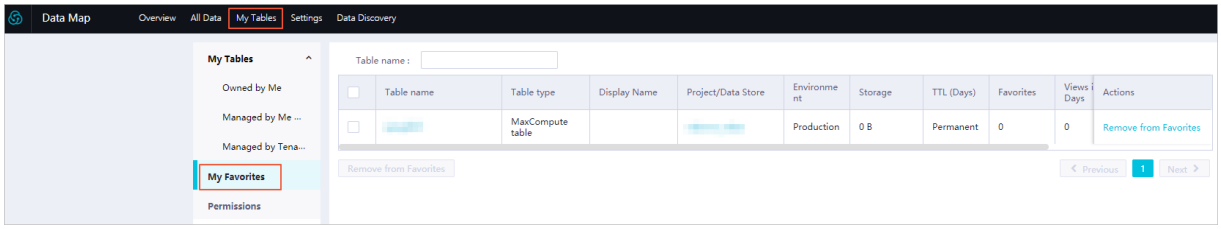
In the left-side navigation pane, click **Managed by Tenant Account**. On the page that appears, you can search for data by keyword and project or data store. You can also view the details about a table and perform relevant operations on the table.



GUI element	Description
Table name	The name of the table. You can click a table name to go to the table details page.
Display Name	The display name of the table. You can click in the **Display Name** column of a table to change the display name of the table.
Project/Data Store	The project or data store where the table resides. Tables have different suffixes when they are deployed in different environments. For example, **_dev** indicates the development environment.
TTL (Days)	The TTL of the table, which is the same as that you set when you create the table.
Environment	The environment to which the table belongs. Valid values: **Development** and **Production**.
Storage	The amount of data that is stored in the table.
Favorites	The number of times that users add the table to favorites.
Views in Last 30 Days	The number of times that users view the table in the last 30 days.
Created At	The time when the table was created.

View data on the My Favorites page

In the left-side navigation pane, click **My Favorites**. On the page that appears, you can view the tables that you have added to favorites.



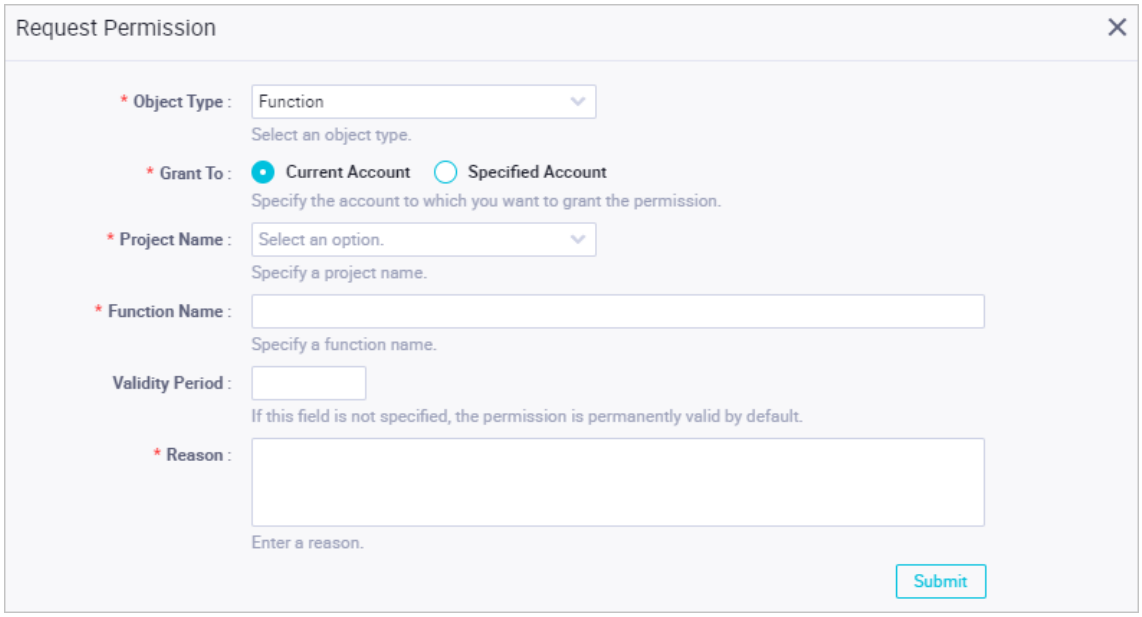
You can click **Remove from Favorites** in the Actions column of a table to remove the table from your favorites.

View and manage data permissions

In the left-side navigation pane, click **Permissions**. On the Permissions page, you can view and manage data permissions.

You can click **Apply function and resource permissions** in the upper-right corner of the **Permissions** page to request permissions. You can also view permission requests on the **To Be Approved**, **Submitted by Me**, and **Handled by Me** tabs.

- **Apply function and resource permissions**
  i. On the Permissions page, click **Apply function and resource permissions** in the upper-right corner.
  ii. In the **Request Permission** dialog box, set the parameters as required. The following table describes the parameters for requesting permissions.



Parameter	Description
Object Type	The type of object on which you want to request permissions. Valid values: **Function** and **Resources**.

Parameter	Description
Grant To	The account to which the permissions will be granted. Valid values: **Current Account** and **Specified Account**. ■ If you select **Current Account**, the permissions will be granted to you after the request is approved. ■ If you select **Specified Account**, you must also specify the **Account** parameter. The permissions will be granted to the specified account after the request is approved.
Project Name	The name of the MaxCompute project that contains the target function or resource.
Function Name or Resource Name	The full name of the function or resource in the project. If the resource is a file, enter the full name of the file, including the file name extension. Example: my_mr.jar.
Validity Period	The validity period of the permissions, in days. If this parameter is not specified, the permissions are permanently valid. After the validity period expires, the system automatically revokes the permissions.
Reason	The reason why you request the permissions.

- **To Be Approved**

  If you are the workspace administrator, you can go to the **To Be Approved** tab. On the tab, you can view and approve the requests for permissions on all objects such as tables, resources, and functions in the workspace.

- **Submitted by Me**

  Click the **Submitted by Me** tab on the **Permissions** page.

  You can view the permission requests that you have submitted on this tab.

- **Handled by Me**

  If you are the workspace administrator, you can go to the **Handled by Me** tab on the **Permissions** page.

  On the **Handled by Me** tab, you can view the permission requests that you have handled for all objects such as tables, resources, and functions in the workspace.

2.11.4. Manage categories and configure workspace permissions

This topic describes how to manage categories and configure workspace permissions on the Settings page.

Go to the Settings page

1. Log on to the DataWorks console.
2. Click  in the upper-left corner and choose **All Products > Data Map(Data Management)**. The

homepage of Data Map appears.

3. In the top navigation bar, click **Settings**. The **Manage Categories** page appears by default.

Manage categories

Only tenant administrators have permissions to create categories and add tables to the categories on the **Manage Categories** page. For more information about how to assign the tenant administrator role to a user, see Member management.

To manage categories as a tenant administrator, perform the following steps:

1. On the **Manage Categories** page, move the pointer over **Categories** and click + to create a level-1 category.
2. Move the pointer over the name of the level-1 category and click + to create a level-2 category.Use the same method to create more categories. DataWorks allows you to create categories at a maximum of four levels. You can change category names and delete categories.
   - To change the name of a category, move the pointer over the category name, click , enter a new name in the field that appears, and then press Enter.
   - To delete a category, move the pointer over the category name and click . In the **Delete Category** message, click **OK**.
3. Add tables to and remove tables from a category.
   - To add tables to a category, select the category and click **Add Tables** in the upper-right corner. In the dialog box that appears, select the required tables and click **Add Tables**.

   - To remove a table from a category, select the category, find the target table, and then

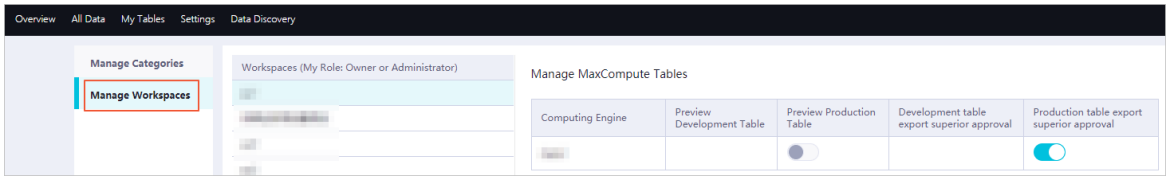
click **Remove from Category** in the Actions column. In the message that appears, click **OK**.

> **Note** To remove multiple tables from a category, select the category, select the target tables, and then click **Remove from Category** in the lower part of the table list.

Configure workspace permissions

To configure workspace permissions on the Settings page, perform the following steps:

1. In the left-side navigation pane, click **Manage Workspaces**.
2. Click the name of the target workspace.
3. In the **Manage MaxCompute Tables** section, configure the permissions on the workspace.You can turn on or off the **Preview Development Table** and **Preview Production Table** switches as required.



> **Note** If the workspace is in basic mode, you can turn on or off only the **Preview Production Table** switch.

2.11.5. View table details

2.11.5.1. View the details of a table

This topic describes how to go to the details page of a table and view the details about the table, such as the basic information, output information, and lineage information.

Go to the details page of a table

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Data Map(Data Management)**. The homepage of Data Map appears.
3. In the top navigation bar, click **All Data**.
4. On the All Data page, click a tab as required.
5. On the tab that appears, click the name of the table you want to view.On the details page that appears, you can view the basic information, business information, permission information, technical information, detailed information (including the fields, partitions, and change history), output information, lineage information, reference records, and usage notes of the table. You can also preview data in the table.

View basic information

In the **Basic Information** section, you can view the numbers of reads, favorites, and views. You can also check the output nodes, MaxCompute project name, region to which the current workspace belongs, region to which the engine belongs, owner, creation time, time-to-live (TTL), storage capacity, description, and tags of the table, and whether the table is partitioned.

You can perform the following operations in this section:

- View the code of the output node of the table: Click **View Code** next to **Output Node**. On the **Operation Center** page, view the node code.
- View the details about the MaxCompute project: Click the MaxCompute project name. On the page that appears, view the details about the MaxCompute project to which the table belongs.
- Edit the description of the table: Click next to **Description**, enter a description in the field that appears, and then click .
- Add a tag to or remove a tag from the table: Click next to **Label**, enter a tag name in the field that appears, and then press **Enter**.

  To remove a tag from the table, move the pointer over the tag and click the **Remove** icon.

View business information

In the **Business Information** section, you can view the DataWorks workspace name, environment type, and category of the table.

In this section, you can click the workspace name next to **DataWorks Workspace** to view the details about the workspace to which the table belongs.

View permission information

In the **Permission Information** section, you can view your permissions on the table.

To modify your permissions on the table, perform the following steps:

1. Click **More** in the upper-right corner of the **Permission Information** section.
2. In the **Apply for Data Permissions** dialog box, set the **Grant To**, **Validity Period**, and **Reason** parameters as required.

   > **Note** If you do not set the **Validity Period** parameter, the permissions that you request will be permanently valid after your request is approved.

3. Click **Commit**.

View technical information

In the **Technical Information** section, you can view the technical type, last time when the DDL statement was modified, last time when the data was modified, last time when the data was viewed, and compute engine information.

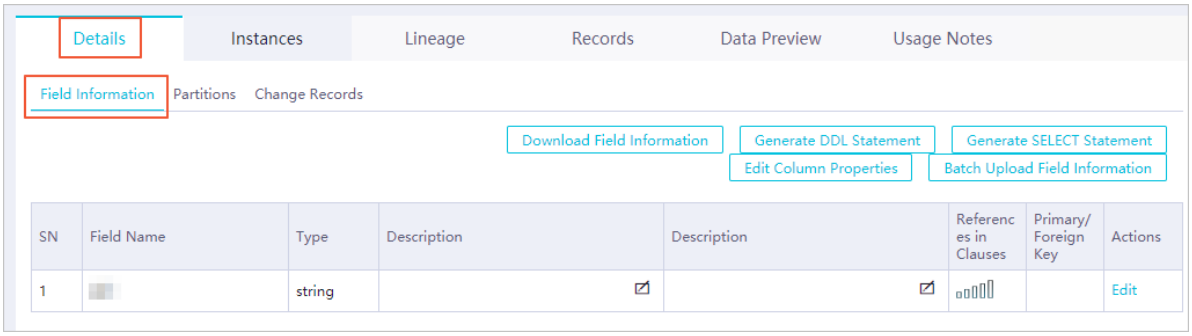
In this section, you can click **Click to View** next to **Compute Engine Information**. In the **Compute Engine Information** dialog box, you can view or copy the information about the compute engine.

View detailed information

The **Details** tab contains the following tabs: **Field Information**, **Partitions**, and **Change Records**.

- **Field Information tab**

  On the **Field Information** tab, you can view the name, data type, description, business description, and popularity of fields. You can also check whether a field is a primary key or foreign key.



Button	Description
Edit Column Properties	Click this button, modify the field description and business description, and then click **Save** or **Cancel** as needed.
Batch Upload Field Information	Click this button and drag the local file to be uploaded to the **Batch Upload Field Information** dialog box.
Download Field Information	Click this button to download the field information of the current table.
Generate DDL Statement	Click this button. In the **Generate DDL Statement** dialog box, view or copy the DDL statement used to create the current table.
Generate SELECT Statement	Click this button. In the **Generate SELECT Statement** dialog box, view or copy the `SELECT` statement for querying data in the current table.

- **Partitions tab**

  On the **Partitions** tab, you can view the name, number of records, storage capacity, creation time, and last update time of each partition in the current table.

- **Change Records tab**

  On the **Change Records** tab, you can view the description, type, granularity, time, and operator of changes performed on the current table.

  On this tab, you can also select a change type from the drop-down list in the upper-left corner to filter the table changes.

  Change types include **Create Table**, **Modify Table**, **Delete Table**, **Add Partition**, **Delete Partition**, **Change Owner**, and **Modify Lifecycle**.

View output information

If the table data periodically changes with the corresponding node, you can view the change status and data that is continuously updated on the **Instances** tab.

On this tab, you can also click **Code** or **Logs** in the **Actions** column of a node to view the code or logs of the node.

View lineage information

On the Lineage tab, you can view the source and destination of data and manage the lineage information with ease.

The **Lineage** tab contains the following tabs: **Table Lineage**, **Field Lineage**, and **Impact Analysis**.

- **Table Lineage** tab: On this tab, you can search for the ancestor and descendant tables of the current table based on the globally unique identifier (GUID).
- **Field Lineage** tab: On this tab, you can select a field from the **Field Name** drop-down list to view the lineage information of the field.
- **Impact Analysis** tab: On this tab, you can query the node that generates a lineage and the full link of the lineage based on information such as the field, node type, table name, project name, and table owner.

You can perform the following operations on the query result:

- Click **Download** to download the query result to your local computer.
- Click **Email**. In the **Notify by Email** dialog box, set the required parameters and click **OK**. In this way, you can configure DataWorks to send email notifications to owners of the descendant tables of the current table.

View reference records

The **Records** tab contains the following tabs: **Foreign Key References** and **Access Statistics**.

- **Foreign Key References** tab: On this tab, you can check the number of users who reference the current table.
- **Access Statistics** tab: On this tab, you can view the reference records in a line chart.

Preview data

On the **Data Preview** tab, you can preview the data of the current table.

> **Notice** Only authorized users can preview tables in the production environment. If you do not have the required permissions, click **Apply Now**.

View usage notes

On the **Instructions** tab, you can edit usage notes, check the historical versions of the usage notes, and view the business description of data.

2.11.5.2. Request table permissions

This topic describes how to request table permissions on the Data Map or Security Center page.

Go to the details page of a table

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Data Map(Data Management)**. The homepage of Data Map appears.

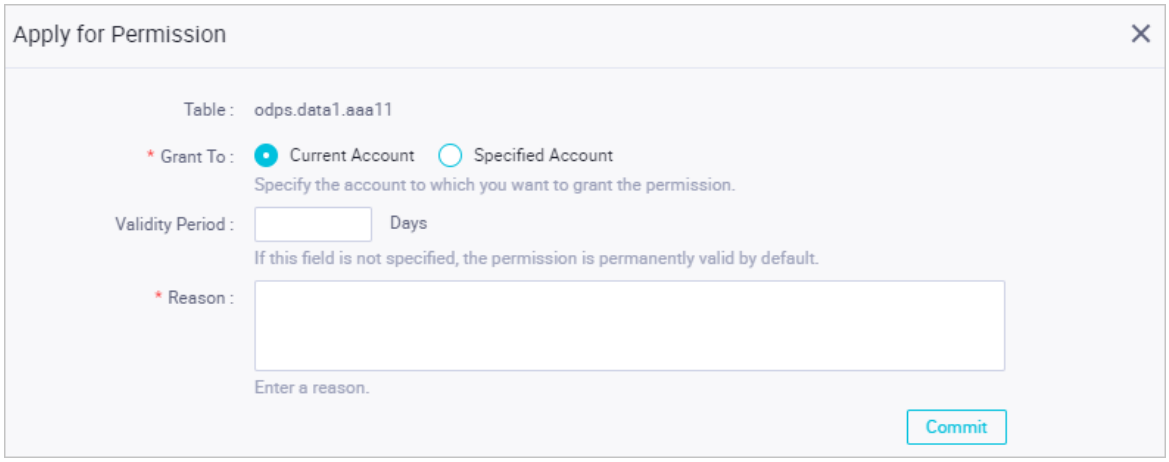
3. In the top navigation bar, click **All Data**.
4. On the All Data page, click a tab as required.
5. On the tab that appears, click the name of the table on which you want to request permissions.

Request table permissions

1. On the table details page, click **Apply for Permission**.

   > **Note** If a table is hidden, the **Apply for Permissions** button does not appear on the details page of the table.

2. In the **Apply for Permission** dialog box, set the parameters as required. The following table describes the parameters for requesting table permissions.



Parameter	Description
Table	The table on which you want to request permissions. You cannot change the default value.
Grant To	The type of the account to which the permissions will be granted. Valid values: **Current Account** and **Specified Account**.
Username	The username of the account to which the permissions will be granted. > **Note** This parameter is available only when you set the **Grant To** parameter to **Specified Account**.
Validity Period	The validity period of the permissions. If you do not set this parameter, the permissions are permanently valid.
Reason	The reason why you request the permissions. Enter a reason for faster approval.

3. Click **Commit**.

View the request status

1. Click in the upper-left corner and choose **All Products > Data Map(Data Management)**. The homepage of Data Map appears.
2. In the top navigation bar, click **My Tables**.
3. On the My Tables page, click **Permissions** in the left-side navigation pane.
4. On the page that appears, click the **Submitted by Me** tab.
5. Find the target request record and click **View** in the Actions column. The request details appear.

2.11.5.3. Add a table to favorites

This topic describes how to add a table to or remove it from favorites, and view the tables added to favorites.

Procedure

1. Log on to the DataWorks console.
2. Go to the details page of a table and click **Add to Favorites** in the upper-left corner.
3. In the top navigation bar, click **My Tables**.
4. On the **My Tables** page, click **My Favorites** in the left-side navigation pane. On the page that appears, you can view all the tables that you have added to favorites and remove tables from favorites. To remove a table from favorites, find the table in the table list and click **Remove from Favorites** in the Actions column.

2.12. Data Asset Management

2.12.1. Go to the Data Asset Management page

Data Asset Management provides you with an overview of your data assets. Data Asset Management requires that data be synchronized by using Data Integration and processed by using DataStudio before you manage your tables and APIs stored in your business system and DataWorks.

Context

Data Asset Management controls the permissions of users independently. You must grant the permissions on the Project Management page because Data Asset Management is a tenant-level feature.

Data Asset Management allows you to view the metadata collected in Data Map. You can also perform basic management operations on the metadata. For example, you can change the business classes and add business descriptions for metadata tables.

Procedure

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Project Management**. The Project Management page appears.

3. In the left-side navigation pane, click **Member Management**. On the Member Management page, you can assign the following roles to members: **Data Asset Management-Asset Manager**, **Data Asset Management-Class Manager**, and **Data Asset Management-Home Visitor**.
4. Click in the upper-left corner and choose **All Products > Data Asset Management** to manage data assets in Data Asset Management. The following table describes the permissions of each role.

Role	Permission
Data Asset Management-Asset Manager	In the top navigation bar of the **Data Asset Management** page, click the **Assets** tab. On the Assets tab, you can manage data assets, such as adding business units and classes. You can also add data assets to a class.
Data Asset Management-Class Manager	In the top navigation bar of the **Data Asset Management** page, click the **Classes** tab. On the Classes tab, you can view the data assets of each class.
Data Asset Management-Home Visitor	In the top navigation bar of the **Data Asset Management** page, click the **Home** tab. On the Home tab, you can view the statistics of data assets of different classes and business units.

2.12.2. Asset manager

Asset managers can view the information about data assets.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Asset Management**.
3. On the **Home** page that appears, enter keywords in the search box and click **Search**.
4. On the search results page that appears, click the **Tables**, **File**, or **API** tab to view details and apply for permissions.

   You can click the **Classes** tab in the top navigation bar to filter data assets by class.

2.12.3. Asset user

Asset users can access Data Asset Management to perform operations such as searching for assets, applying for permissions, and using assets.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Asset Management**.
3. On the **Home** page that appears, enter keywords in the search box and click **Search**.
4. On the search results page that appears, click the **Tables**, **File**, or **API** tab to view details and apply for permissions.

You can click the **Classes** tab in the top navigation bar to filter data assets by class.

2.12.4. Asset administrator

Asset administrators can manage assets and authorizations in Data Asset Management.

> **Note** You can submit a ticket to apply for the asset administrator role.
>
> An administrator can grant the administrator role to common users. An administrator can perform any operations in Data Asset Management, and no approval is required.

Go to the Assets tab

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Asset Management**.
3. In the top navigation bar, click the **Assets** tab.

   Under the **Assets** tab, you can click **Data Management**, **Classes**, or **Business Management** in the left-side navigation pane to manage your data assets accordingly.

Manage data

In the left-side navigation pane, you can click **Data Management** and then **Tables**, **Files**, or **APIs** to manage tables, files, or APIs.

- **Manage tables**

  In the left-side navigation pane, choose **Data Management > Tables** to go to the **Tables** page.

  On the Tables page, you can view, edit, publish, or delete a table.

  - Click the name of a table to view table details.
  - Click **Edit** in the Actions column of a table. In the Edit dialog box that appears, you can edit the configuration of the table.
  - Move the pointer over **Publish** in the Actions column of a table. In the dialog box that appears, click **Publish**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

    > **Note** You can search for a published table in Data Asset Management.

  - Move the pointer over **Delete** in the Actions column of a table. In the dialog box that appears, click **Delete**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

    > **Note** You cannot search for a deleted table in Data Asset Management.

- **Manage files**

  In the left-side navigation pane, choose **Data Management > Files** to go to the **Files** page.

On the **File Management** page that appears, you can upload a file. Then, you can view, edit, download, or delete the file.

- In the upper-right corner, click **Upload File**. In the **Upload File** dialog box that appears, click **Add File**. In the Add dialog box that appears, select the file to be uploaded and click **Open**. Alternatively, you can drag and drop a file to the **Upload File** dialog box. Then, click **Next**.

  > Note
  > - To upload a file, make sure that the size of the file does not exceed 50 MB.
  > - You can only upload a file with one of the following file name extensions:
  >
  >   3DX, 7Z, A3D, ATX, AVI, BMP, SV, DBF, DOC, DOCX, DWG, EPS, ESP, FREELIST, GDB, GDBINDEXES, GDBTABLE, GDBTABLX, GIF, GZ, HTM, HTML, IVE, JPEG, JPG, LOCK, LSP, LST, MP3, MP4, MPJ, OSG, OSGB, PDF, PNG, PPT, PPTX, PRJ, PSD, RAR, S3C, SBN, SBX, SCP, SHP, SPX, TFW, TIF, TIFF, TTF, TXT, WAV, WL, WP, WT, XLS, XLSX, ZIP, XML, SHX, and SKP

- Click the name of a file to view file details.
- Click **Edit** in the Actions column of a file. In the Edit dialog box that appears, you can edit the configuration of the file.
- Move the pointer over **Publish** in the Actions column of a file. In the dialog box that appears, click **Publish**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

  > Note You can search for a published file in Data Asset Management.

- Move the pointer over **Delete** in the Actions column of a file. In the dialog box that appears, click **Delete**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

  > Note You cannot search for a deleted file in Data Asset Management.

- Click **Download** in the Actions column of a file to download the file.

  > Note Before downloading a file, apply for the download permission.

- **Manage APIs**

  In the left-side navigation pane, choose **Data Management** > **APIs** to go to the **APIs** page.

  On the **APIs** page, you can edit, publish, or delete an API.

  - Click **Edit** in the Actions column of an API. In the **Edit** dialog box that appears, you can edit the configuration of the API. Then, click **Submit**.

- Move the pointer over **Publish** in the Actions column of an API. In the dialog box that appears, click **Publish**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

  > **Note** You can search for a published API in Data Asset Management.

- Move the pointer over **Delete** in the Actions column of an API. In the dialog box that appears, click **Delete**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

  > **Note** You cannot search for a deleted API in Data Asset Management.

Manage classes

1. In the left-side navigation pane, click **Classes** to go to the **Classes** page.

   On the Classes page, you can import or export a class.

2. Click the icon. In the **Add Class** dialog box that appears, set relevant parameters and click **OK** to add a level-1 class

Parameter	Description
Name	The name of the class, which can be up to 128 characters in length.
Code	The code of the class. This parameter cannot be left empty.
Description	The description of the class.
Confidential	Specifies whether the class is confidential. Valid values: **Yes** and **No**.
Share	Specifies whether to share the class. Valid values: **Yes**, **Conditional**, and **No**.

   To create a subclass under a class, click the icon next to the class.

3. Click a class. On the page that appears, click the **Tables** tab.
4. Click **Add Table**. In the **Add Table** dialog box that appears, select the tables to be added to the class and click **OK**.

   You can add files and APIs to a class in the same way.

   To change the class of a table, click **Modify Class** in the Actions column. In the **Change Class** dialog box that appears, change the class as needed.

Manage business

In the left-side navigation pane, you can click **Business Management** and then **Business Units**, **Business Systems**, or **Connections** to manage business units, business systems, or connections.

> **Note** Connections belong to a business system, and business systems belong to a business unit.
>
> - A business system with connections cannot be deleted.
> - A business unit with business systems cannot be deleted.

- **Manage business units**

  In the left-side navigation pane, choose **Business Management** > **Business Units** to go to the **Business Units** page.

  Click the icon. In the **Add Business Unit** dialog box that appears, set relevant parameters and click **OK** to add a business unit.

Parameter	Description
Name	The name of the business unit. This parameter cannot be left empty.
Code	The code of the business unit. By default, the code cannot be modified.
Description	The description of the business unit.
Confidential	Specifies whether the business unit is confidential. Valid values: **Yes** and **No**.
Share	Specifies whether to share the business unit. Valid values: **Yes**, **Conditional**, and **No**.
Business system included	Select the business systems to be added to the business unit and click the > icon.

  To create a sub-business unit under a business unit, click the icon next to the business unit.

- **Manage business systems**

  In the left-side navigation pane, choose **Business Management** > **Business Systems** to go to the **Business Systems** page.

  On the Business Systems page, you can add a business system. Then, you can view, edit, or delete the business system.

  - Click **Add Business System**. In the **Basic information** dialog box that appears, set relevant parameters and click **Submit**.
  - Click **View** in the Actions column of a business system to view its details.
  - Click **Edit** in the Actions column of a business system. In the **Business System Properties** dialog box that appears, you can edit the configuration of the business system.
  - Click **Delete** in the Actions column of a business system. In the **Delete business system** dialog box that appears, click **OK** to delete the business system.

- **Manage connections**

  In the left-side navigation pane, choose **Business Management** > **Connections** to go to the **Connections** page.

  On the **Connections** page, you can view the information of connections. The connection information includes the connection name, the number of tables, the owner, the business system to which the connection belongs, the data type, and the update time. You can also edit the configuration of a connection.

2.12.5. Manage authorizations

Under the Permissions tab, you can view permissions in different states on the Submitted by Me, To Be Handled, Handled by Me, and My Permissions pages respectively.

Go to the Permissions tab

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products** > **Data Asset Management**.
3. In the top navigation bar, click the **Permissions** tab.

   Under the **Permissions** tab, you can view permissions in different states on the **Submitted by Me**, **To Be Handled**, **Handled by Me**, and **My Permissions** pages respectively.

Submitted by Me

In the left-side navigation pane, click **Submitted by Me**.

On the **Submitted by Me** page, you can view request details or cancel requests submitted by you. To resubmit a request that was not approved, find the target request and click **Reapply**.

To Be Handled

In the left-side navigation pane, click **To Be Handled**. On the To Be Handled page, you can view request details and approve or reject requests.

Handled by Me

In the left-side navigation pane, click **Handled by Me** to view requests handled by you.

My Permissions

In the left-side navigation pane, click **My Permissions**. On the My Permissions page, you can view your permissions on tables, files, and APIs respectively.

2.12.6. Perform cross-tenant authorization

Authorization logic

The logic of authorization within a tenant and that of cross-tenant authorization are as follows:

- Authorization within a tenant: An access control list (ACL) is used for authorization. You need to add the applicant to the corresponding workspace and then grant permissions to the applicant as requested.

- Cross-tenant authorization: A package is used for authorization. First, check whether the workspace where the requested resources reside has a package.
  - If the workspace does not have a package, create a package and add the requested resources to the package. Then, install the package in the workspace where the requested resources are used.

    After that, use an ACL to grant permissions to the applicant as requested.
  - If the workspace has a package, add the requested resources to the package.

  If the requested resources need to be shared with multiple workspaces, install the package in all these workspaces. If the workspace where the requested resources reside has multiple packages, install all of them in the workspaces where the requested resources are used.

Procedure

1. Log on to the DataWorks console. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Asset Management**.
2. On the **Asset Portal** tab, enter the name of the table that belongs to another tenant in the search box and click **Search**.
3. On the **Asset Category** tab that appears, click the name of the found table on the **Tables** tab. The details page of the table appears.

   On the details page, you can view details about the table, including the basic information, business information, physical information, and field information.
4. Click **Request Permission** in the upper-right corner. The **Table Permission Request** page appears.
5. Set parameters on the **Table Permission Request** page.

Parameter	Description
Target Workspace	The workspace where the table is to be used.
Environment	The type of the environment where the table is to be used. If the selected workspace is in standard mode, you need to set this parameter to Development or Production.
Home Workspace	The workspace where the table resides. This parameter is automatically set.
Home Tenant	The tenant to which the table belongs. This parameter is automatically set.
Grant To	The account for which permissions on the table are requested. Valid values: **Current Account** and **System Account for Production Environment**.
Requested Period	The period in which the requested permissions are valid.

Parameter	Description
Reason for Request	The reason why you request the permissions. To improve the review efficiency, we recommend that you describe the reason in detail.
Objects Requested	The tables you want to use. By default, the current table is selected. You can select other tables.

6. After the configuration is completed, click **Submit**.

   After you submit the request, click **Approval Management** in the top navigation bar and then click **Submitted by Me**. You can view the review progress on the page that appears.

   - If you want to revoke a request, click **Revoke** in the Actions column of the request.
   - If you want to submit a revoked or rejected request again, click **Reapply** in the Actions column of the request.

7. Log on to the DataWorks console as the table owner, go to the **Approval Management** tab and click **To Be Handled**. On the page that appears, review the request information and click **Agree**.

   After clicking **Agree**, click **Approval Management** in the top navigation bar and click **Handled by Me**. On the page that appears, you can view your authorization records and revoke specific authorizations.

2.13. Organization management

2.13.1. Member management

1. Log on to the DataWorks console as a workspace administrator.
2. Move your pointer over the DataWorks icon in the upper-left corner, and click **Project Management**.
3. Click **Member Management** in the left-side navigation bar. The **Members** page appears.
4. You can enter a member name or logon name in the search box to search for a member to be added or removed from the current organization.
   - Assign a role

     To assign a role to a member, click the **Roles** drop-down list next to the member, and select the role to be assigned.

     To unassign a role from a member, click **x** next to the role.
   - Remove a member from an organization

     Click **Delete** next to the member, and click **OK** in the **Remove from Tenant** dialog box that appears.

2.13.2. Resource groups

2.13.2.1. About scheduling resources

You can use the Scheduling Resource page to create, configure, and edit a scheduling resource.

A scheduling resource is an object within an organization. A dedicated scheduling resource may contain multiple physical machines or ECS instances that are used to implement a specific task.

1. Log on to the DataWorks console.
2. In the left-side navigation pane, choose **Organization Management > Scheduling Resources**.

> **Note** On the **Scheduling Resources** page, the tenant administrator can create a dedicated scheduling resource, and edit an existing scheduling resource.

2.13.2.2. Change the workspace of scheduling resources

You can change the workspace of dedicated scheduling resources that have been created and configured.

Procedure

To change the workspace of dedicated scheduling resources, the tenant administrator performs the following operations:

1. Log on to the DataWorks console as a tenant administrator.
2. Choose **Organization Management > Scheduling Resources**.
3. On the page that appears, enter a scheduling resource name for a fuzzy search to find the target scheduling resource.
4. Click **Change Workspace**.
5. Click **OK**.

2.13.3. Configure the compute engine

Currently, DataWorks only supports MaxCompute as its compute engine. All business flows and nodes in a workspace are run on the MaxCompute project associated to the workspace.

Example

> **Note** Tenant administrators can modify the settings for MaxCompute projects. The following settings are changeable: the project description, whether to use the MaxCompute project owner account to run MaxCompute jobs, the account used for running MaxCompute jobs, and the AccessKey of the account.

Assume that the account used for running MaxCompute jobs is no longer available, for example, because the account owner has resigned. If Run MaxCompute Task Using MaxCompute Owner Account is not selected, the tenant administrator needs to immediately modify the account used for running MaxCompute jobs and its AccessKey so that tasks can properly run in the workspace that uses the corresponding MaxCompute project.

Procedure

You can modify the account used for running MaxCompute jobs and its AccessKey as follows:

1. Log on to the DataWorks console as a tenant administrator. For more information, see Log

on to the DataWorks console.

2. Choose **Project Management** > **Compute Engine**.
3. In the search box on the **Project Management** > **Compute Engine** page, enter the compute engine name. Fuzzy search is supported.
4. Find the target compute engine, and click **Configure** in the Actions column.
5. In the **Configure Compute Engine** dialog box, specify the Alibaba Cloud Account and the AccessKey.

   > **Note** You can also select Run MaxCompute Task Using MaxCompute Owner Account or create a new Alibaba Cloud account.

6. Click **Submit**.

2.14. Data Service

2.14.1. Overview

With Data Service, you can manage all your table APIs after you create new APIs or register existing APIs. You can also easily publish your APIs to API Gateway. Together with API Gateway, Data Service provides a secure, stable, low-cost, and easy-to-use data sharing service.

Data Service adopts a serverless architecture and allows you to develop table APIs without thinking about infrastructure such as compute resources. Data Service supports automatic scaling for compute resources, which significantly reduces your OPEX.

Create an API

In Data Service, you can quickly create APIs based on tables in relational databases or NoSQL databases using a visual wizard. It takes only a few minutes to configure a data API, and coding is not required. You can also create APIs by specifying SQL scripts. The script mode supports advanced functions such as associative tables, complex criteria, and aggregate functions.

Register an API

You can register existing RESTful APIs to Data Service for unified API management. Four request methods and three data formats are supported. The four request methods are GET, POST, PUT, and DELETE. The three data formats are tables, JSON, and XML.

API Gateway

API Gateway provides API lifecycle management services, including API publishing, management, maintenance, and monetization. It enables low-risk, simple, cost-effective, and fast microservice integration, front and back end separation, and system integration. You can use API Gateway to share functions and data with your partners and third-party developers.

API Gateway supports authorization, authentication, flow control, and billing for Data Service.

2.14.2. Terms

This section introduces terms of Data Service.

Name	Description
Data source	Indicates database links. Data Service accesses data through data sources. Data sources are configured in Data Integration.
Create an API	Creates APIs based on data tables.
Register an API	Registers existing APIs to Data Service for unified management.
Wizard mode	Guides you through the procedure of API creation. This method is suitable for beginners who want to create simple APIs. You do not need to write any code.
Script mode	Allows you to create APIs by writing SQL scripts. This method supports associative tables, complex queries, and aggregate functions. This method is suitable for experienced developers who want to create complex APIs.
API group	Indicates a set of APIs for a specific scenario or for consuming a specific service. An API group is the smallest group unit in Data Service, and the smallest unit for API Gateway management. API groups are published in Alibaba Cloud API Marketplace as API products.
API Gateway	Indicates a hosted service provided by Alibaba Cloud to manage APIs. API Gateway supports API lifecycle management, permission management, access management, and traffic control.

2.14.3. Manage tags

This topic describes how to create, add, view, and remove tags for an API.

DataService Studio allows you to add tags to APIs when you manage workflows and create, register, and deploy APIs. This topic uses the scenario of creating an API in the codeless UI as an example. Tags allow you to efficiently classify and search for APIs. You can maintain only one tag list in a workspace, and cannot use the tag list of a workspace in another workspace.

> **Note**
>
> - Each API supports zero to five tags. That is, you can add no tags to an API at all or add a maximum of five tags to an API.
> - The name of a tag can contain letters, digits, and underscores (_), and cannot exceed 20 characters in length.

Create a tag for an API

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All Products > Data Service**.
2. On the Service Development tab, move the pointer over  and choose **API > Generate API**.
3. In the **Generate API** dialog box, set the API mode parameter to Wizard Mode and enter a tag in the **Label** field.

If the tag you entered does not exist in the current workspace, Add <Tag> appears in the drop-down list. Click Add <Tag> to create the tag for the API.

4. Set other parameters and click **OK**. The tag is created for the API and appears in the tag list of the current workspace.

Add an existing tag to an API

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All Products** > **Data Service**.
2. On the Service Development tab, move the pointer over  and choose **API** > **Generate API**.
3. In the **Generate API** dialog box, set the API mode parameter to Wizard Mode and click a blank area or the downward arrow in the **Label** field. Tags in the current workspace appear in a drop-down list.
4. Click the required tag, set other parameters, and then click **OK**. The tag is added to the API.

View tags of an API

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All Products** > **Data Service**.
2. On the **Service Development** tab, double-click the name of the target API in the API list.
3. In the right-side navigation pane, click **Properties**. Then you can view the tags of the API in the **Label** column.

   > **Note** You can also create, add, and remove tags for the API in the Properties pane.

   If an API is published, you can also perform the following steps to view the tags of the API:

   i. In DataService Studio, click **Service Management** in the upper-right corner.

   ii. Click **Manage APIs** in the left-side navigation pane. On the page that appears, click the **APIs of Published** tab and click the name of the target API. The **API Details** page appears.

   iii. View the tags of the API under **Label** in the **API Basic Information** section.

Remove a tag from an API

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All Products** > **Data Service**.
2. On the **Service Development** tab, double-click the name of the target API in the API list.
3. In the right-side navigation pane, click **Properties**. Then, you can view the tags of the API in the **Label** column.
4. Click  next to the tag to remove.
5. Click **Publish** in the upper-right corner. The tag is removed from the API.

Search for APIs by tag

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All Products** > **Data Service**.

2. On the **Service Development** tab, click **Service Management** in the upper-right corner.
3. Click **Manage APIs** in the left-side navigation pane. On the page that appears, click the **APIs of Published** tab and view the tags of each API in the **Label** column.

   If an API has multiple tags and some of them are hidden, click **...** to show all the tags.
4. On the **APIs of Published** tab, click **Advanced Search**.
5. Enter a tag in the **Label** field to search for all APIs associated with the tag.

   > **Note** You can search for APIs based on multiple tags.

2.14.4. Manage business processes and objects under business processes

2.14.4.1. Manage business processes

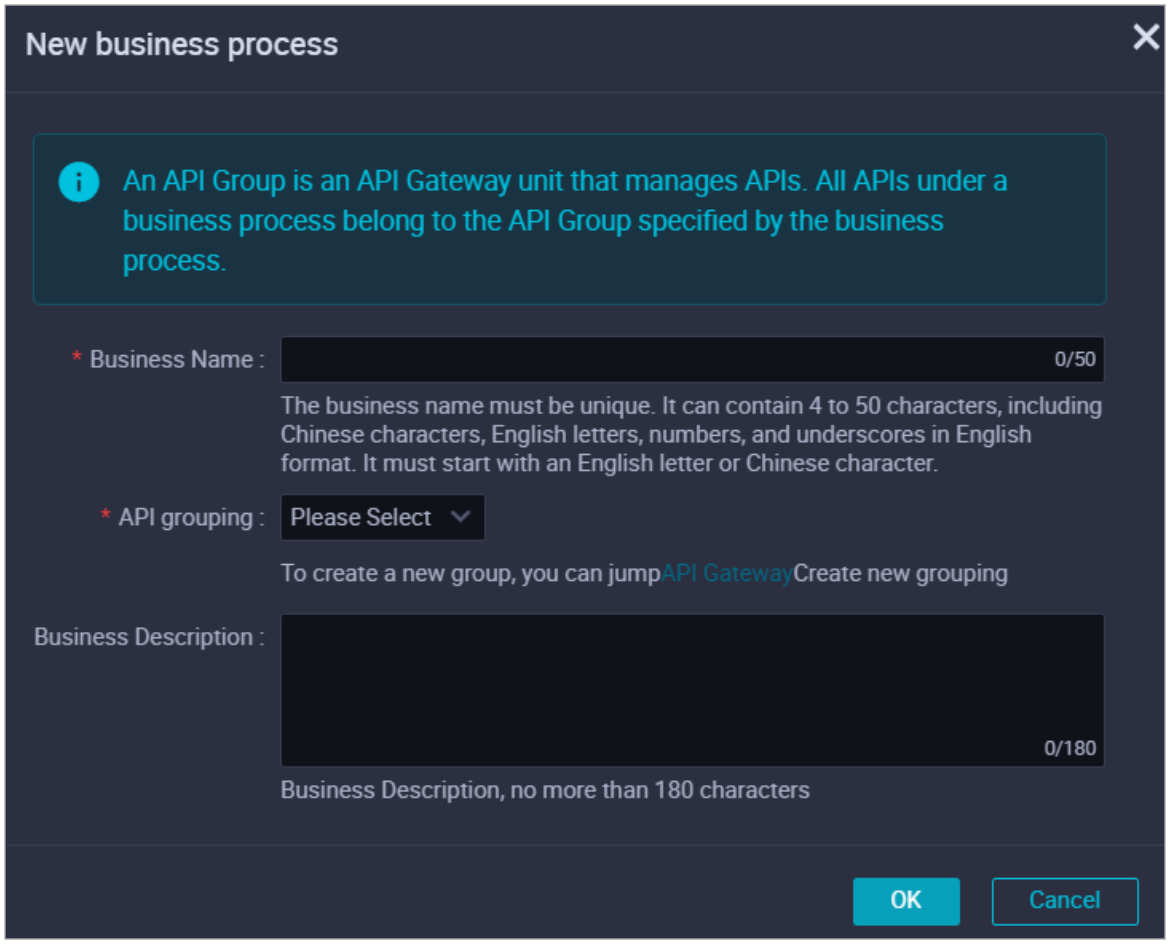
This topic describes how to create, modify, and delete a business process.

Context

DataWorks allows you to organize different types of resources in a business process. This helps you analyze data by business. Each business process contains APIs, functions, and workflows.

Create a business process

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, move the pointer over  and select **Business process**.
4. In the **New business process** dialog box, set the parameters as required.

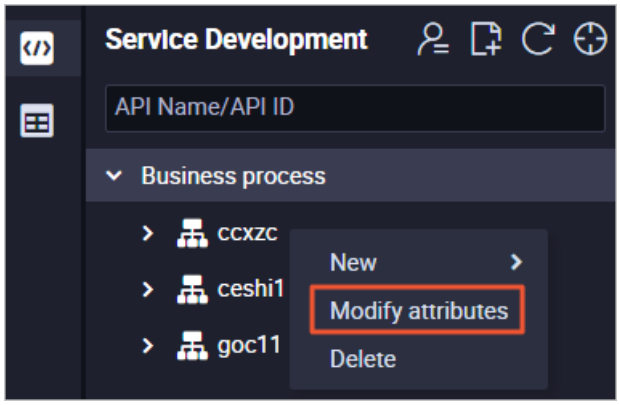


Parameter	Description
Business Name	The name of the business process. ○ The name can contain letters, digits, and underscores (_). ○ The name must start with a letter. ○ The name must be 4 to 50 characters in length. ○ The name must be unique in the workspace to which the business process belongs.
API Group	The API group to which the APIs under the business process belong. An API group is the API management unit of API Gateway. You can select an API group from the drop-down list. DataService Studio creates a default API group named in the Workspace name_default format for each user. If you need to create an API group, click **API Gateway** in the note to go to the API Gateway console and create an API group.
Business Description	The description of the business process. The description can be up to 180 characters in length.

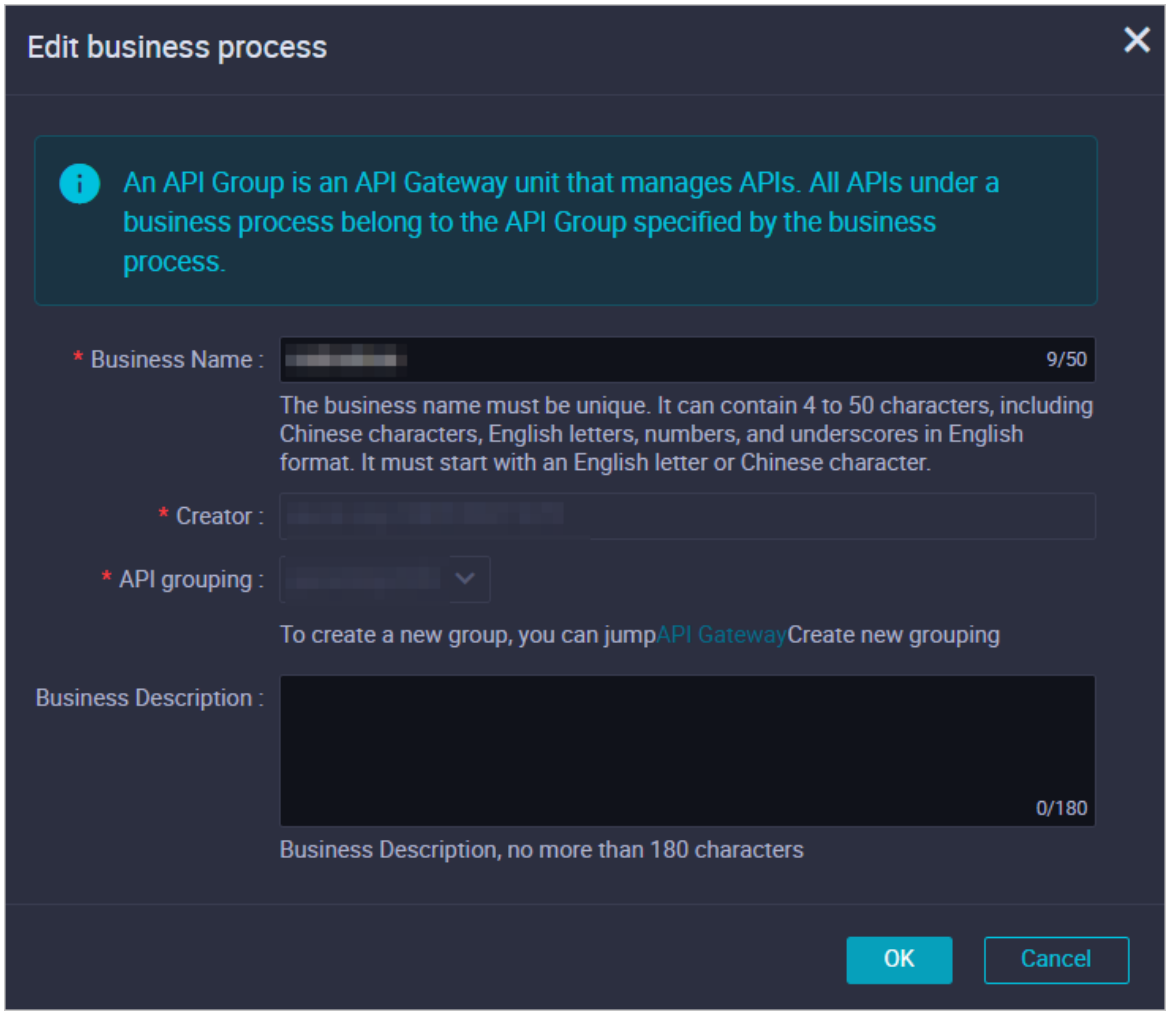
5. Click **OK**.After the business process is created, you can view it in the business process list.

Modify a business process

1. On the **Service Development** tab, right-click the name of the target business process and select **Modify attributes**.



2. In the **Edit business process** dialog box, modify the **Business Name** and **Business Description** parameters as required.

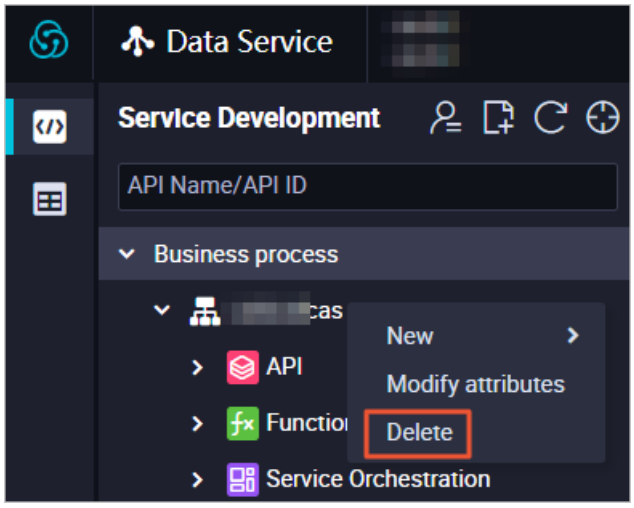


> **Note** You cannot modify the **Creator** or **API Group** parameter of a business process.

3. Click **OK**.

Delete a business process

1. On the **Service Development** tab, right-click the name of the target business process and select **Delete**.



2. In the message that appears, click **OK**.

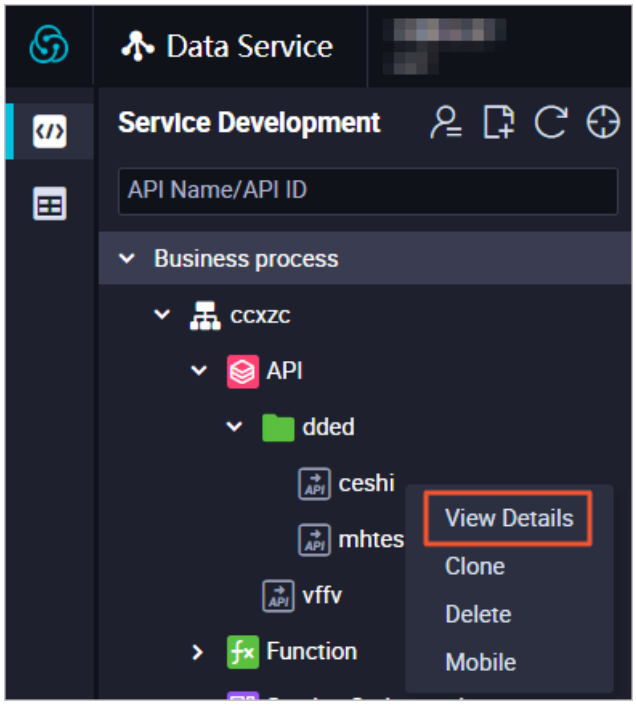
> **Note**
> - You can delete only business processes that do not contain any objects such as APIs, functions, or workflows.
> - If you need to delete a business process that contains such objects, delete the objects before you delete the business process.

2.14.4.2. Manage APIs

This topic describes how to view, clone, delete, and move APIs.

View an API

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, right-click the name of the target API and select **View Details**.

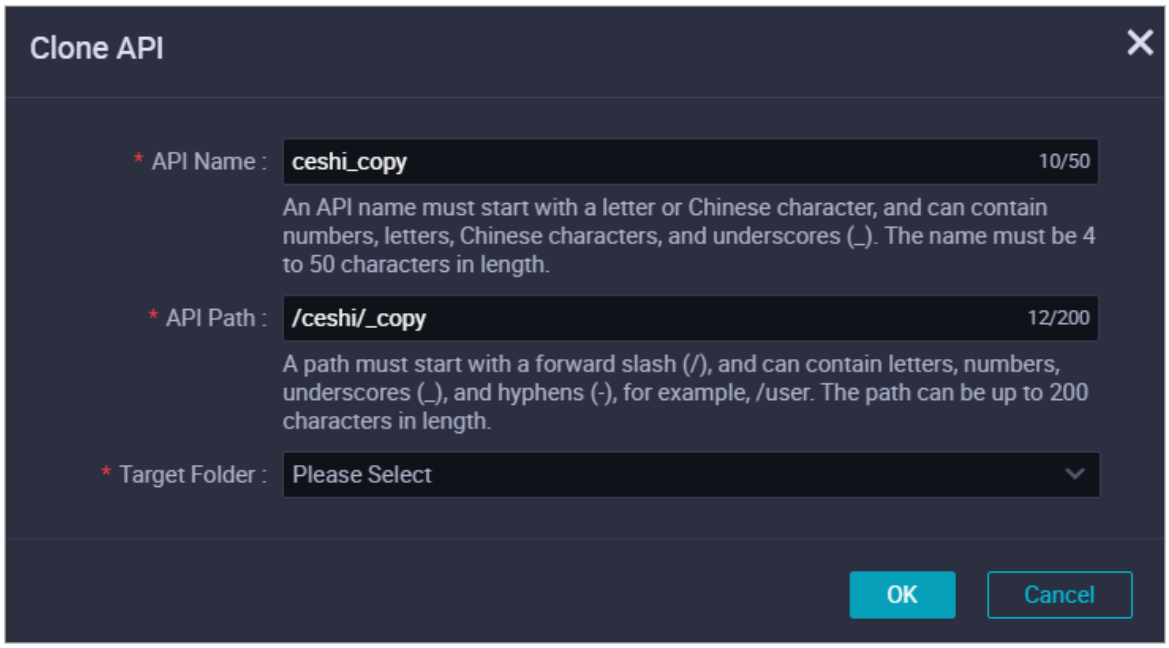


Note The View Details option appears only in the shortcut menu of an API that has been published. If an API has not been published, double-click the API to go to the configuration tab of the API. Then, click Properties in the right-side navigation pane to view its basic information.

Clone an API

You can clone an API to a specified directory in the directory tree.

1. On the **Service Development** tab, right-click the name of the target API and select **Clone**.
2. In the **Clone API** dialog box, set the parameters as required.



Parameter	Description
API Name	The name of the cloned API. It must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.
API Path	The path for storing the cloned API, for example, */user*. The path can contain letters, digits, underscores (_), and hyphens (-). It must start with a forward slash (/) and can be up to 200 characters in length.
Target Folder	The directory for storing the cloned API.

3. Click **OK**.

Delete an API

You can delete only APIs that have not been published. To delete APIs that have been published, you must unpublish them first.

1. Optional. Unpublish the target API. If the API to be deleted is in the Unpublished state, skip this step.
   i. Go to the **Service Development** tab and click **Service Management** in the upper-right corner.

   ii. On the page that appears, click the **APIs of Published** tab, find the target API, and then click **Unpublish** in the Actions column.
   iii. In the **Unpublish API** message, click **OK**.
   iv. Click **Service Development** in the upper-right corner to return to the **Service Development** tab.
2. On the **Service Development** tab, right-click the name of the target API and select **Delete**.
3. In the **Delete API** message, click **OK**.

> **Note** Deleted APIs cannot be recovered. Use caution when you delete an API.

Move an API to another directory

You can move only APIs that have not been published. To move APIs that have been published, you must unpublish them first.

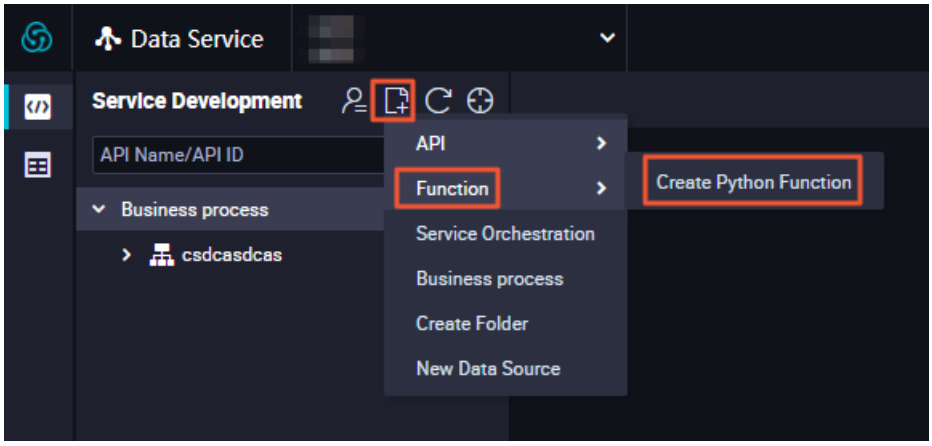
1. On the **Service Development** tab, right-click the name of the target API and select **Mobile**.
2. In the **Modify file path** dialog box, set the **Target Folder** parameter.
3. Click **OK**.

2.14.4.3. Manage functions

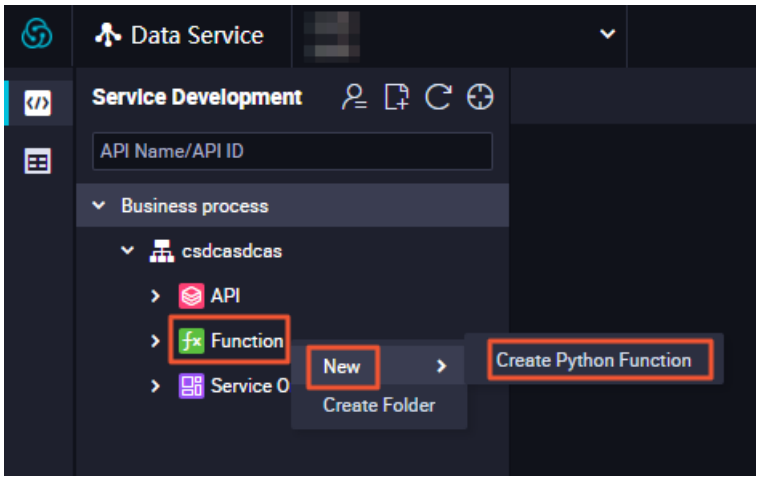
This topic describes how to create, clone, delete, and move Python functions.

Create a function

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Data Service**.
3. Move the pointer over and choose **Function > Create Python Function**.

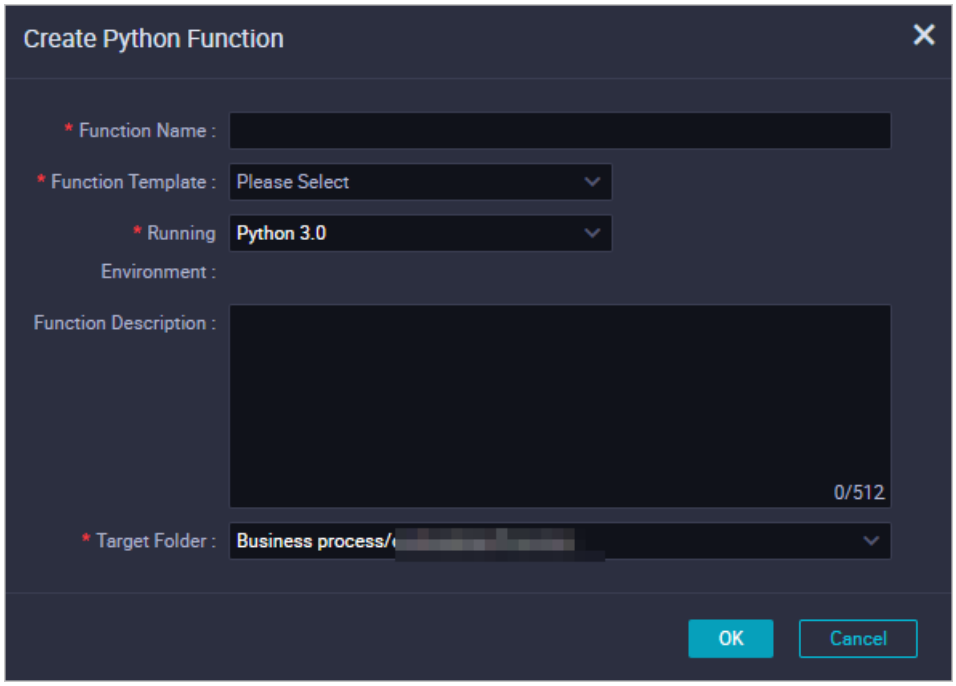


You can also click a business process, right-click **Function**, and then choose **New > Create Python Function**.



> **Notice** DataService Studio allows you to create only Python functions.

4. In the **Create Python Function** dialog box, set the parameters as required.

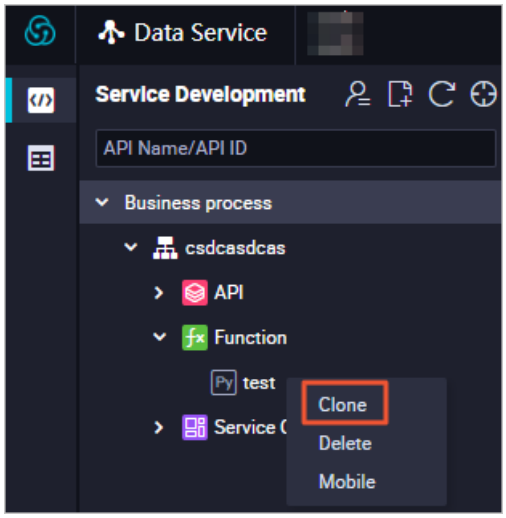


Parameter	Description
Function Name	The name of the function to create, which can be up to 256 characters in length.
Function Template	The template used to create the function. Set the value to Python3 Standard v1.
Running Environment	The runtime environment of the function. Set the value to Python 3.0.
Function Description	The description of the function. The description can be up to 512 characters in length.
Target Folder	The directory for storing the function.

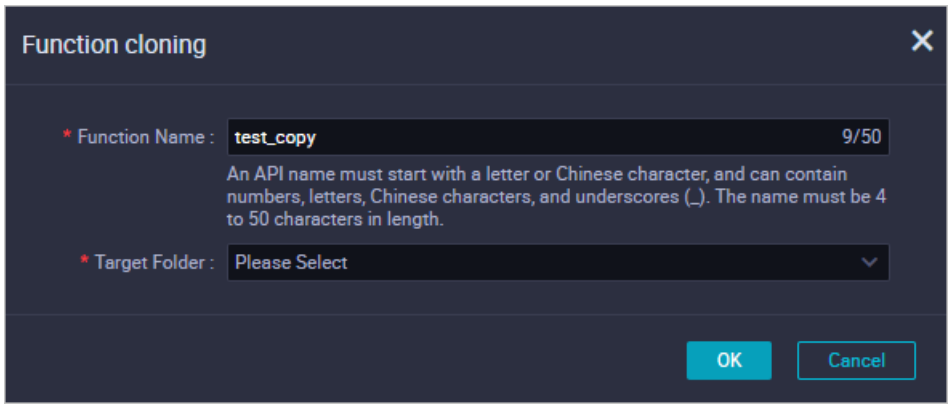
5. Click **OK**.
6. On the configuration tab of the function, configure the function.
   i. In the **Edit Code** section, enter the function code.
   ii. In the **Environment Configuration** section, set the **Memory** and **Function Timeout** parameters.
7. Click Save icon in the toolbar.

Clone a function

1. On the **Service Development** tab, right-click the name of the target function and select **Clone**.



2. In the **Function cloning** dialog box, set the **Function Name** and **Target Folder** parameters.

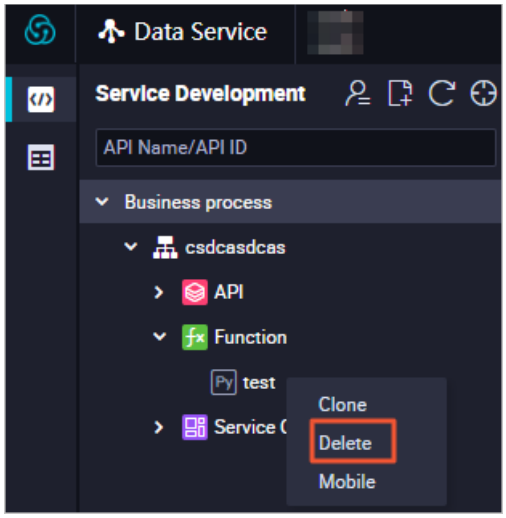


> **Note** The name of the function must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.

3. Click **OK**.

Delete a function

1. On the **Service Development** tab, right-click the name of the target function and select **Delete**.

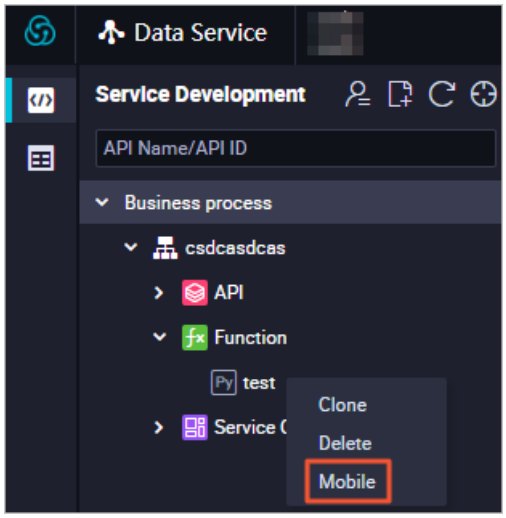


2. In the message that appears, click **OK**.

> **Note** You can delete only functions that are not referenced by APIs. You must remove the function from the filters of the APIs that reference the function before you can delete the function.

Move a function to another directory

1. On the **Service Development** tab, right-click the name of the target function and select **Mobile**.



2. In the **Modify file path** dialog box, set the **Target Folder** parameter.
3. Click **OK**.

2.14.4.4. Manage workflows

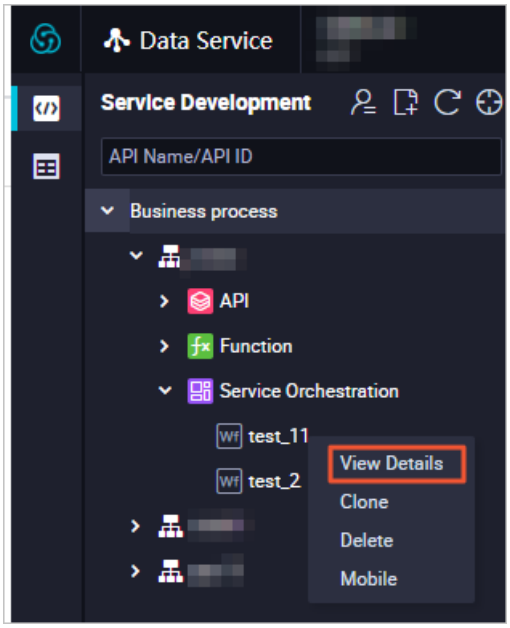
This topic describes how to view, clone, delete, and move a workflow.

Prerequisites

Workflows are created and published. For more information, see Use workflows.

View a workflow

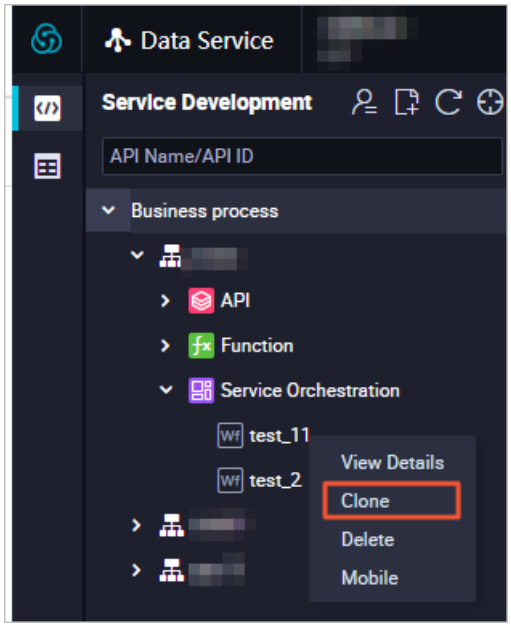
1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Data Service**.
3. On the Service Development tab, right-click the name of the target workflow and select **View Details**.



> **Note** The View Details option appears only in the shortcut menu of a workflow that has been published. If a workflow has not been published, double-click the workflow to go to the configuration tab of the workflow. Then, click **Properties** in the right-side navigation pane to view its basic information.

Clone a workflow

1. On the **Service Development** tab, right-click the name of the target workflow and select **Clone**.



2. In the **Clone API** dialog box, set the parameters as required.

Parameter	Description
API Name	The name of the cloned workflow. It must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.
API Path	The path for storing the cloned workflow, for example, */user*. The path can contain letters, digits, underscores (_), and hyphens (-). It must start with a forward slash (/) and can be up to 200 characters in length.
Target Folder	The directory for storing the cloned workflow.

3. Click **OK**.

Delete a workflow

You can delete only workflows that have not been published. To delete workflows that have been published, you must unpublish them first.

1. Optional. Unpublish the target workflow. If the workflow to be deleted is in the Unpublished state, skip this step.
   i. Go to the **Service Development** tab and click **Service Management** in the upper-right corner.

   ii. On the page that appears, click the **APIs of Published** tab, find the target API, and then click **Unpublish** in the Actions column.
   iii. In the **Unpublish API** message, click **OK**.

iv. Click **Service Development** in the upper-right corner to return to the **Service Development** tab.

2. On the **Service Development** tab, right-click the name of the target workflow and select **Delete**.
3. In the **Delete API** message, click **OK**.

> **Note** Deleted workflows cannot be recovered. Use caution when you delete a workflow.

Move a workflow to another directory

You can move only workflows that have not been published. To move workflows that have been published, you must unpublish them first.

1. On the **Service Development** tab, right-click the name of the target workflow and select **Mobile**.
2. In the **Modify file path** dialog box, set the **Target Folder** parameter.
3. Click **OK**.

2.14.5. Create an API

In Data Service, you can quickly create APIs based on tables in relational databases or NoSQL databases using a visual wizard. It takes only a few minutes to configure a data API, and coding is not required.

You can also create APIs by specifying SQL scripts. The script mode supports advanced functions such as associative tables, complex criteria, and aggregate functions.

The differences between the wizard mode and script mode are described as follows:

Differences between the wizard mode and script mode

Category	Description	Wizard mode	Script mode
Query object	Queries a single table from one data source	Supported	Supported
	Queries associative tables from one data source	Not supported	Supported
Search condition	Searches for an exact number	Supported	Supported
	Searches for a range of numbers	Not supported	Supported
	Matches an exact string	Supported	Supported
	Performs fuzzy search for strings	Supported	Supported

Category	Description	Wizard mode	Script mode
	Sets required and optional parameters	Supported	Supported
Query result	Returns the field value	Supported	Supported
	Performs a mathematical calculation for field values	Not supported	Supported
	Performs an aggregate operation on field values	Not supported	Supported
	Displays results with pagination	Supported	Supported

2.14.5.1. Configure connections

DataService Studio allows you to obtain table schemas and query data through APIs from connections.

> **Note** Before generating an API, make sure that you have configured the relevant connections.

You can click **Connections** on the **Data Integration** page to configure connections. The following table lists the available connection types and supported configuration modes.

Connection name	Create an API in the codeless UI	Create an API in the code editor
ApsaraDB for RDS	Supported	Supported
DRDS	Supported	Supported
ApsaraDB for MySQL	Supported	Supported
ApsaraDB for PostgreSQL	Supported	Supported
ApsaraDB for SQL Server	Supported	Supported
Oracle	Supported	Supported
AnalyticDB	Supported	Supported
Table Store	Supported	Not supported
MongoDB	Supported	Not supported

2.14.5.2. Create an API in the codeless UI

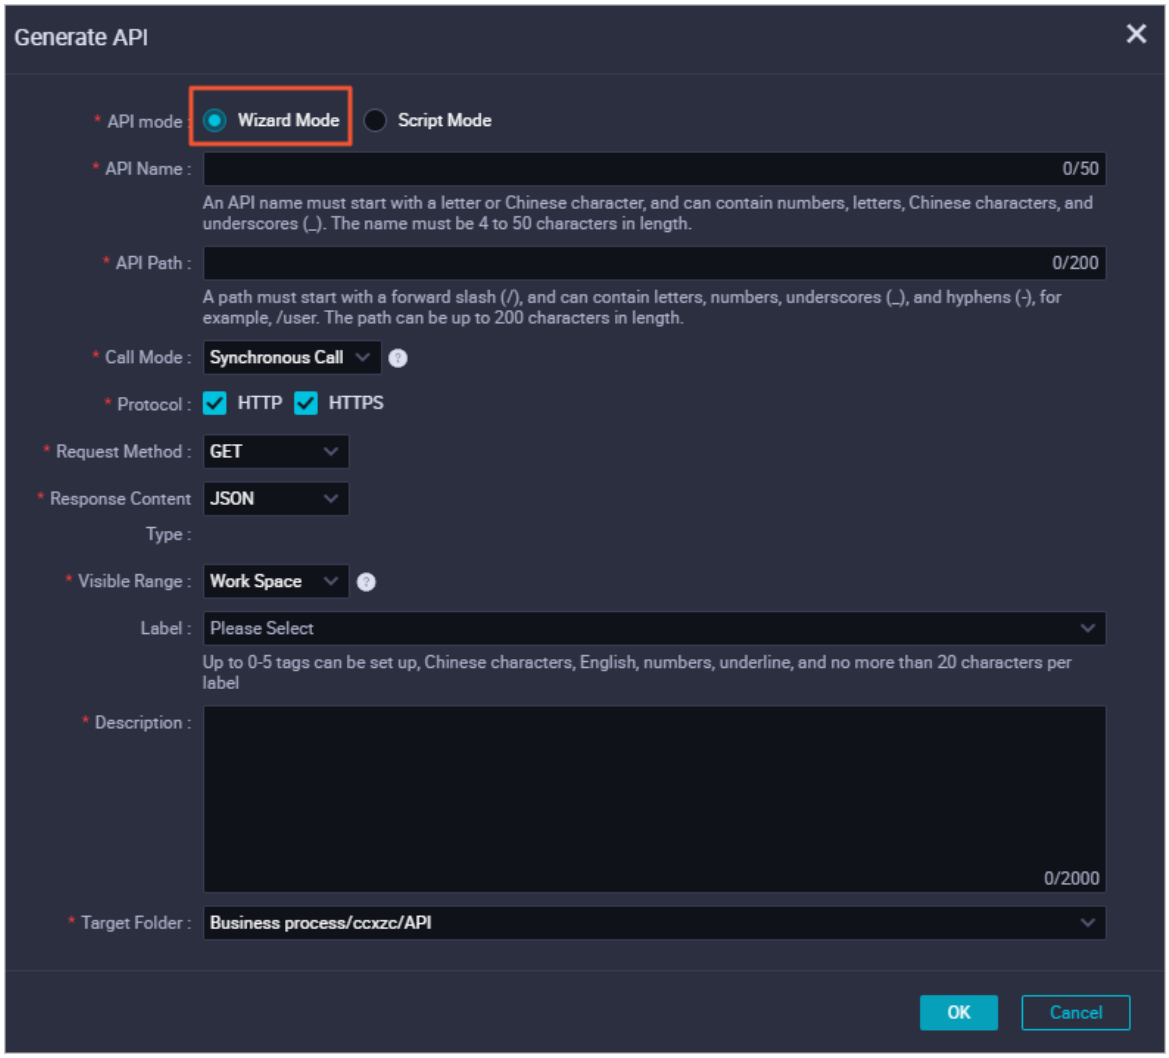
DataWorks allows you to create APIs by setting parameters in the codeless UI without the need to write code. This topic describes how to create an API in the codeless UI.

Prerequisites

Connections are configured on the **Data Source** page. For more information, see Configure data sources.

Create an API

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, move the pointer over and choose **API > Generate API**.You can also click a business process, right-click **API**, and then choose **New > Generate API**.
4. In the **Generate API** dialog box, set the parameters as required.



Parameter	Description
API mode	The mode for creating the API. Valid values: **Wizard Mode** and **Script Mode**. In this example, select **Wizard Mode**.
API Name	The name of the API. The name must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.
API Path	The path for storing the API, for example, */user*.
Call Mode	The mode for calling the API. Valid values: **Synchronous Call** and **Asynchronous Call**. ○ If you set this parameter to **Synchronous Mode**, the API returns results immediately after it is called. The synchronous mode is most commonly used. ○ If you set this parameter to **Asynchronous Mode**, the API returns the RequestID parameter immediately after it is called. The API caller can then obtain the call result from a message queue based on the request ID.
Protocol	The protocol used by the API. Valid values: **HTTP** and **HTTPS**.
Request Method	The request method used by the API. Valid values: **GET** and **POST**.
Response Content Type	The return type of the API. Set the value to **JSON**.
Visible Range	The visibility of the API. Valid values: ○ **Work Space**: The API is visible to all members in the current workspace. ○ **Private**: The API is visible only to its owner and permissions on the API cannot be granted to other users. **Note** If you set the Visible Range parameter to Private, the API is visible only to you in the directory tree. It is hidden to other members of the workspace.
Label	The tag of the API. Select one or more tags from the drop-down list. For more information, see Manage tags. **Note** You can set at most five tags for an API.
Description	The description of the API, which can be up to 2,000 characters in length.
Target Folder	The directory for storing the API.

5. Click **OK**.

Configure the API

1. Double-click the API in the directory tree. On the configuration tab that appears, set the **Datasource Type**, **Datasource Name**, and **Table Name** parameters in the **Select Table** section.

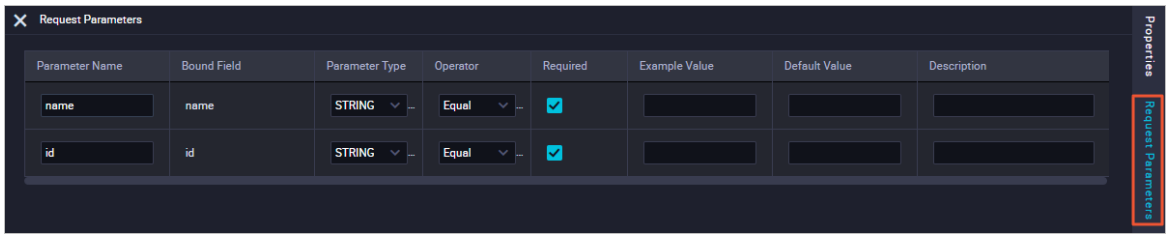
   > **Note**
   > - Before you select a table for an API, you must configure a connection in Data Integration. You can enter a table name in the Table Name field to search for the desired table.
   > - After you create an API, the table configuration tab automatically appears for you to select a table for the API.

2. In the **Environment Configuration** section, set the **Memory** and **Function Timeout** parameters.
3. In the **Select Parameters** section, set the request and response parameters for the API.After you select a table in the Select Table section, all fields in the table appear in the **Select Parameters** section. Select the required fields and select the check boxes in the **Set as Req Param** and **Set as Resp Param** columns as required.

   To sort the data returned by the API based on a field, click **Add to field sort** in the Actions column of the field to add it to the **Sort field** section.

   The sorting feature allows you to specify the fields based on which the parameters returned by the API are sorted. A field with a smaller sequence number in the Sort field section has a higher priority in sorting. You can click **Move up** or **Move down** to adjust the sequence of a field. You can specify the sorting mode for each field by selecting **Ascending order** or **Descending order** in the Sort column.

4. In the right-side navigation pane, click **Request Parameters**. In the Request Parameters pane, set the parameters as required.

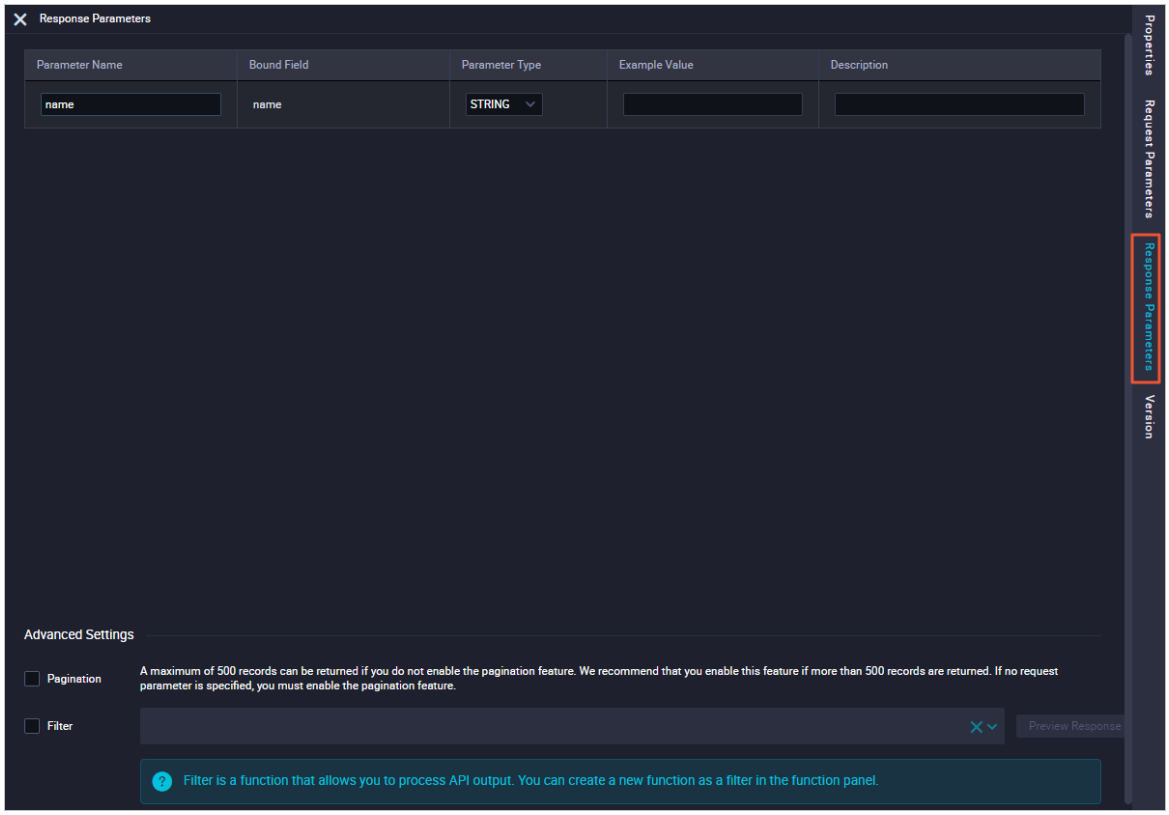


Parameter	Description
Parameter Name	The name of the request parameter. The name can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter and can be up to 64 characters in length.
Bound Field	The field to be bound to the request parameter. You cannot change the value.
Parameter Type	The type of the request parameter. Valid values: **STRING**, **INT**, **LONG**, **FLOAT**, **DOUBLE**, and **BOOLEAN**.
Operator	The operator that is used to associate or compare the value of the request parameter with the specified value. You can select one of the following operators: ○ **Equal**: The value of the request parameter is equal to the specified value. ○ **LIKE**: The value of the request parameter matches the specified pattern. ○ **IN**: The value of the request parameter is in the specified range. ○ **NOT IN**: The value of the request parameter is out of the specified range. ○ **NOT LIKE**: The value of the request parameter does not match the specified pattern. ○ **! =**: The value of the request parameter is not equal to the specified value. ○ **>**: The value of the request parameter is greater than the specified value. ○ **<**: The value of the request parameter is less than the specified value. ○ **>=**: The value of the request parameter is greater than or equal to the specified value. ○ **<=**: The value of the request parameter is less than or equal to the specified value.
Required	Specifies whether the request parameter is required.
Example Value	The sample value of the request parameter.
Default Value	The default value of the request parameter.
Description	The description of the request parameter.

To preprocess the request parameters of the API, select **Use prefilter** in the **Advanced Settings** section. For more information, see Use prefilters.

> **Note**
>
> - To enhance the matching efficiency, set an indexed field as a request parameter.
> - To make it easier for API callers to know the details about the API, we recommend that you specify information such as the sample value, default value, and description for each parameter of the API.

5. In the right-side navigation pane, click **Response Parameters**. In the Response Parameters pane, set the parameters as required.



Parameter	Description
Parameter Name	The name of the response parameter. The name can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter and can be up to 64 characters in length.
Bound Field	The field to be bound to the response parameter. You cannot change the value.
Parameter Type	The type of the response parameter. Valid values: **STRING**, **INT**, **LONG**, **FLOAT**, **DOUBLE**, and **BOOLEAN**.
Example Value	The sample value of the response parameter.
Description	The description of the response parameter.

You can select **Pagination** and **Filter** in the **Advanced Settings** section.

Select Pagination based on your needs.

- If you do not select **Pagination**, the API returns a maximum of 2,000 records by default.
- If the API may return more than 2,000 records, we recommend that you select **Pagination**.

The following common parameters are available when Pagination is selected:

- Common request parameters
  - pageNum: the number of the page to return.
  - pageSize: the number of entries to return on each page.
- Common response parameters
  - pageNum: the page number of the returned page.
  - pageSize: the number of entries returned per page.
  - totalNum: the total number of returned entries.

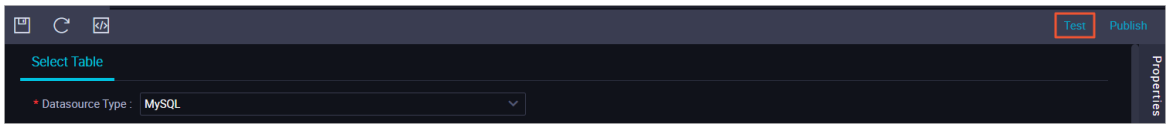
If you need to process the query results returned by the API, select **Filter**.

> **Note**
>
> - Field values are returned in the response as they are in the table.
> - Request parameters are optional for an API. If you do not specify any request parameters for an API, you must select **Pagination**.

6. Click Save icon in the toolbar.

Test the API

1. After you save the settings of the API, click **Test** in the upper-right corner.



2. In the **Test APIs** dialog box, click **Test** to send an API request.The request and response details appear on the right. If the API fails the test, check the error message, modify the API settings accordingly, and test the API again.

   You can select **Save the correct response example automatically** as required.

> **Note**
>
> - The system automatically generates sample failure responses and error codes when it tests an API. However, the system does not automatically generate sample success responses.
>
> To allow the system to save the success test result as a sample success response, you must select **Save the correct response example automatically** before you perform the test. If the response contains sensitive data that must be de-identified, you can manually edit the response.
> - The sample success response is an important reference for API callers, and therefore must be configured.
> - The Call Latency value is the latency of the current API request, which is used to evaluate the API performance. If the latency is long, consider optimizing the database.

3. After the API is tested, close the **Test APIs** dialog box and click **Publish** in the upper-right corner of the configuration tab.

Switch from the codeless UI to the code editor

On the configuration tab of an API, you can switch from the codeless UI to the code editor.

1. Go to the **Service Development** tab and double-click the target API. The configuration tab of the API appears.
2. Click in the toolbar.
3. In the message that appears, click **OK**. Then, you can view the SQL statements of the API in the **Edit query SQL** section.

> **Notice**
>
> - DataService Studio allows you to switch only from the codeless UI to the code editor.
> - After you switch from the codeless UI to the code editor, you cannot switch back to the codeless UI.

2.14.5.3. Create an API in the code editor

To meet the requirements of advanced data query, DataService Studio allows you to create an API by writing an SQL script in the code editor. DataService Studio supports table join queries, complex queries, and aggregate functions. This topic describes how to create an API in the code editor.

Prerequisites

Connections are configured on the **Data Source** page. For more information, see Configure data sources.

Create an API

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, move the pointer over and choose **API > Generate API**.You can also click a workflow, right-click **API**, and then choose **New > Generate API**.
4. In the **Generate API** dialog box, set the parameters as required.

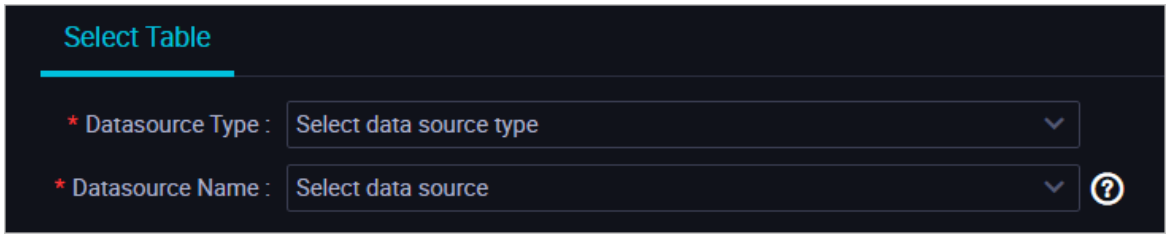
Parameter	Description
API mode	The mode for creating the API. Valid values: **Wizard Mode** and **Script Mode**. In this example, select **Script Mode**.
API Name	The name of the API. The name must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.
API Path	The path for storing the API, for example, */user*.
Call Mode	The mode for calling the API. Valid values: **Synchronous Call** and **Asynchronous Call**. ○ If you set this parameter to **Synchronous Mode**, the API returns results immediately after it is called. The synchronous mode is most commonly used. ○ If you set this parameter to **Asynchronous Mode**, the API returns the RequestID parameter immediately after it is called. The API caller can then obtain the call result from a message queue based on the request ID.
Protocol	The protocol used by the API. Valid values: **HTTP** and **HTTPS**.
Request Method	The request method used by the API. Valid values: **GET** and **POST**.
Response Content Type	The return type of the API. Set the value to **JSON**.
Visible Range	The visibility of the API. Valid values: ○ **Work Space**: The API is visible to all members in the current workspace. ○ **Private**: The API is visible only to its owner and permissions on the API cannot be granted to other users. **Note** If you set the Visible Range parameter to Private, the API is visible only to you in the directory tree. It is hidden to other members of the workspace.

Parameter	Description
Label	The tag of the API. Select one or more tags from the drop-down list. For more information, see Manage tags. Note You can set at most five tags for an API.
Description	The description of the API, which can be up to 2,000 characters in length.
Target Folder	The directory for storing the API.

5. Click **OK**.

Configure the API

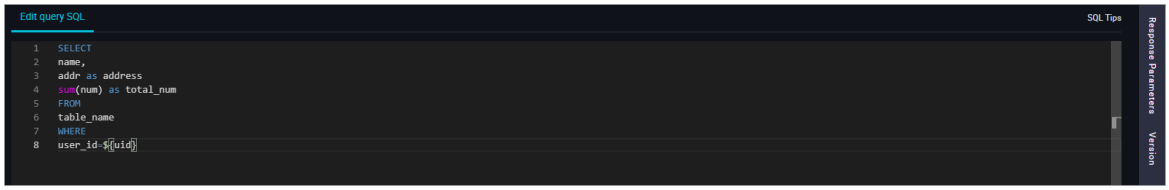
1. Double-click the API. On the configuration tab that appears, set the **Datasource Type** and **Datasource Name** parameters in the **Select Table** section.



Note You must configure a connection in Data Integration in advance. You can enter a keyword in the Table Name field to search for the desired table.

2. In the **Environment Configuration** section, set the **Memory** and **Function Timeout** parameters.

3. In the **Edit query SQL** section, enter the SQL statement for querying data.

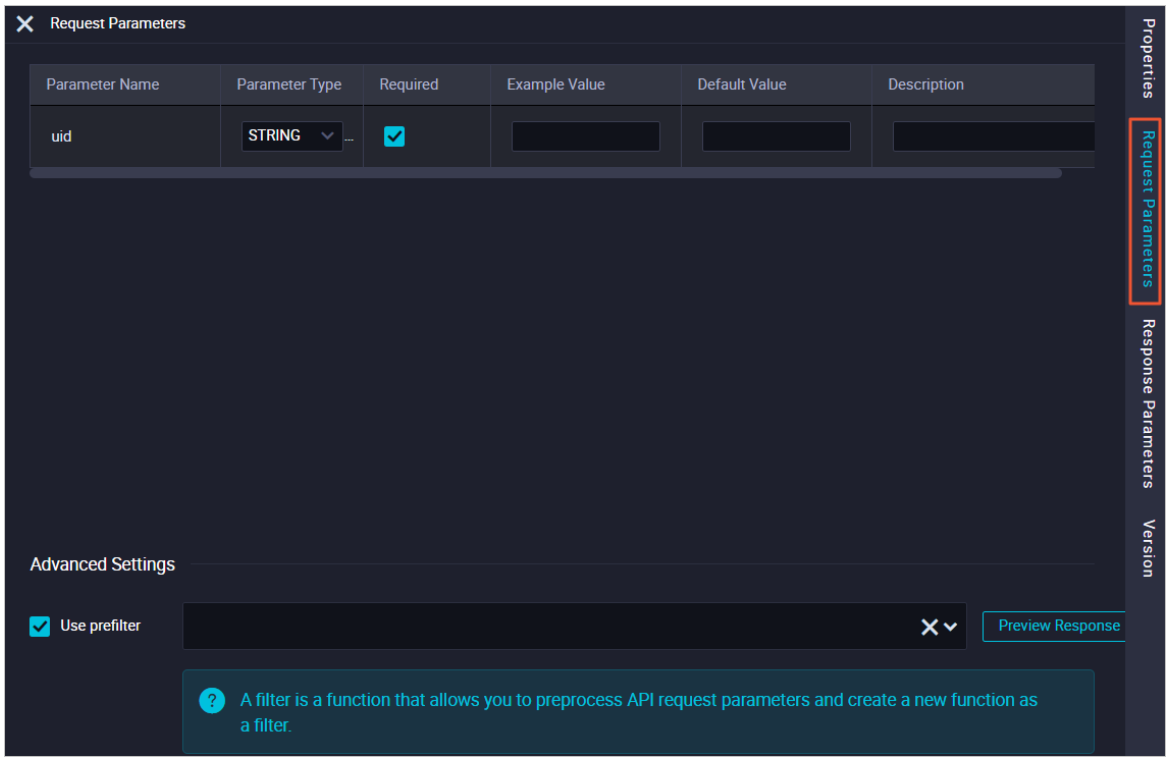


Note The SELECT clause specifies the parameters that the API returns. The WHERE clause specifies the request parameters of the API. You must use ${} to interpolate a request parameter.

Follow these rules when you enter the SQL statement:

- You can enter only one SQL statement in the script editor.
- Only the SELECT clause is supported. Other clauses such as INSERT, UPDATE, and DELETE are not supported.
- The clause `SELECT \*` is not supported. You must specify the columns to be queried.
- Single-table queries, table join queries, and nested queries under the same connection are supported.
- If the name of the column that the SELECT clause specifies has a table prefix, for example, t.name, you must create an alias for the corresponding response parameter, for example, t.name as name.
- If you use an aggregate function, such as min, max, sum, or count, you must create an alias for the corresponding response parameter, for example, `sum(num) as total\_num`.
- ${param} in the SQL statement and that in character strings are regarded as request parameters and replaced. If an escape character \ is placed before ${param}, ${param} is processed as a common string.
- ${param} cannot be enclosed in single quotation marks (' '). For example, `'${id}'` and `'abc ${xyz}123'` are not allowed. If necessary, you can use `concat('abc', ${xyz}, '123')` instead.
- Parameters cannot be configured as optional.
- ${param} is not allowed in comments. For example, --${id} is not allowed.

4. In the right-side navigation pane, click **Request Parameters**. In the Request Parameters pane, set the parameters as required.

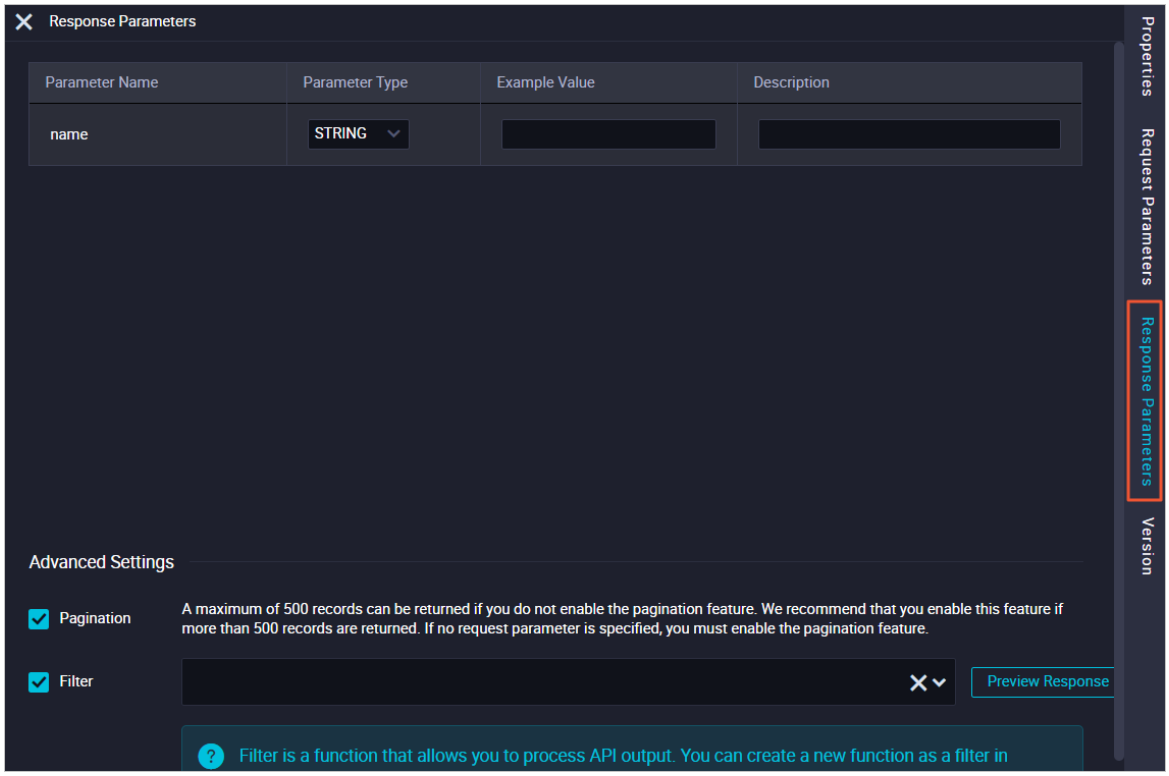


Parameter	Description
Parameter Name	The name of the request parameter. The name can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter and can be up to 64 characters in length.
Parameter Type	The type of the request parameter. Valid values: **STRING**, **INT**, **LONG**, **FLOAT**, **DOUBLE**, and **BOOLEAN**.
Required	Specifies whether the request parameter is required.
Example Value	The sample value of the request parameter.
Default Value	The default value of the request parameter.
Description	The description of the request parameter.

To preprocess the request parameters of the API, select Use prefilter in the Advanced Settings section. For more information, see Use prefilters.

> **Note**
>
> - To enhance the matching efficiency, set an indexed field as a request parameter.
> - To make it easier for API callers to know the details about the API, we recommend that you specify information such as the sample value, default value, and description for each parameter of the API.

5. **In the right-side navigation pane, click Response Parameters. In the Response Parameters pane, set the parameters as required.**



Parameter	Description
Parameter Name	The name of the response parameter. The name can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter and can be up to 64 characters in length.
Parameter Type	The type of the response parameter. Valid values: **STRING**, **INT**, **LONG**, **FLOAT**, **DOUBLE**, and **BOOLEAN**.
Example Value	The sample value of the response parameter.
Description	The description of the response parameter.

You can select **Pagination** and **Filter** in the **Advanced Settings** section.

Select Pagination based on your needs.

- If you do not select **Pagination**, the API returns a maximum of 2,000 records by default.
- If the API may return more than 2,000 records, we recommend that you select **Pagination**.

The following common parameters are available when Pagination is selected:

- Common request parameters
  - pageNum: the number of the page to return.
  - pageSize: the number of entries to return on each page.
- Common response parameters
  - pageNum: the page number of the returned page.
  - pageSize: the number of entries returned per page.
  - totalNum: the total number of returned entries.

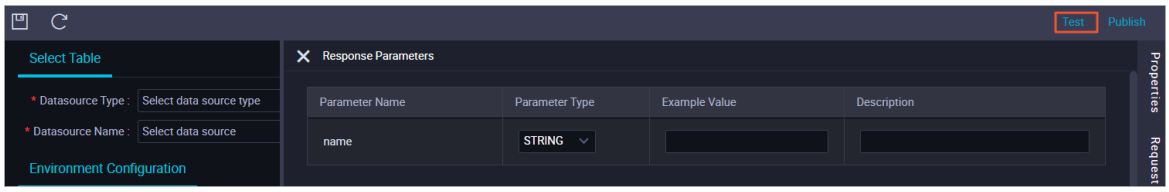
If you need to process the query results returned by the API, select **Filter**.

> **Note**
> - Field values are returned in the response as they are in the table.
> - Request parameters are optional for an API. If you do not specify any request parameters for an API, you must select **Pagination**.

6. Click Save icon in the toolbar.

Test the API

1. After you save the settings of the API, click **Test** in the upper-right corner.



2. In the **Test APIs** dialog box, click **Test** to send an API request.The request and response details appear on the right. If the API fails the test, check the error message, modify the API

settings accordingly, and test the API again.

You can select **Save the correct response example automatically** as required.

> **Note**
>
> - The system automatically generates sample failure responses and error codes when it tests an API. However, the system does not automatically generate sample success responses.
>
>   To allow the system to save the success test result as a sample success response, you must select **Save the correct response example automatically** before you perform the test. If the response contains sensitive data that must be de-identified, you can manually edit the response.
> - The sample success response is an important reference for API callers, and therefore must be configured.
> - The Call Latency value is the latency of the current API request, which is used to evaluate the API performance. If the latency is long, consider optimizing the database.

3. After the API is tested, close the **Test APIs** dialog box and click **Publish** in the upper-right corner of the configuration tab.

2.14.5.4. Use filters

2.14.5.4.1. Use prefilters

A prefilter is a function that is used to process request parameters of APIs. You can specify one or more prefilters to customize the request content for APIs. This topic describes the limits of prefilters, the built-in function template provided by the system, and how to create functions and use them as prefilters.

Context

Prefilters have the following limits:

- Only Python 3.0 functions can be used as prefilters.
- Prefilters support importing only the following modules: json, time, random, pickle, re, and math.
- The function name of a prefilter must be `def handler(event,context):` .

Function template

The system provides the following built-in function template:

```
# -*- coding: utf-8 -*-

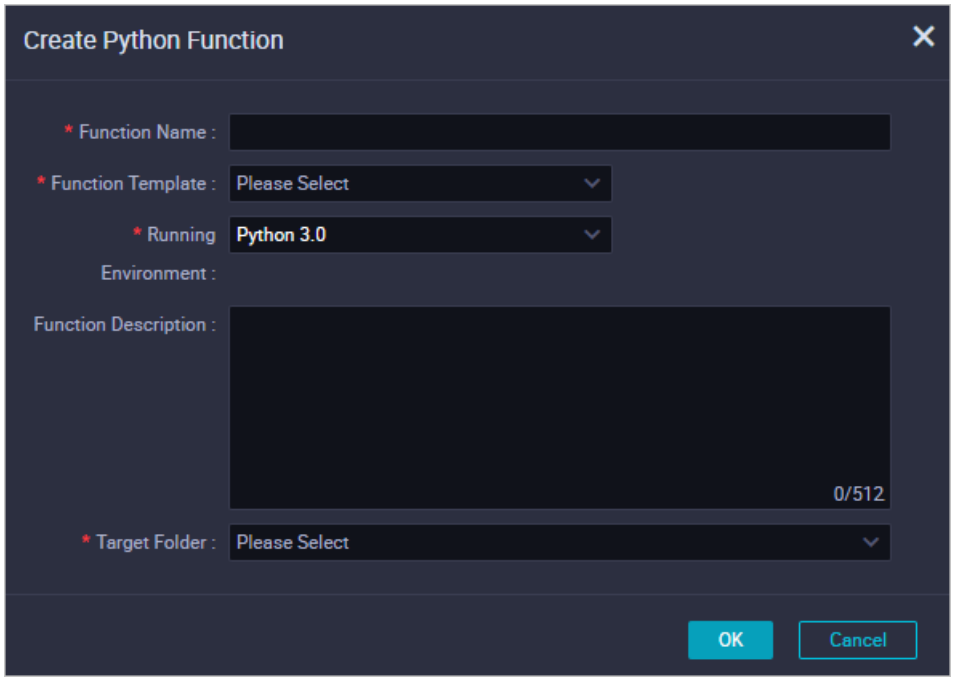
# event (str) : in filter it is the API result, in other cases, it is your param
# context : some environment information, temporarily useless
# import module limit: json,time,random,pickle,re,math
# do not modify function name
import json
def handler(event,context):
# load str to json object
obj = json.loads(event) # Convert the string specified by the event parameter to a JSON object.
# add your code here
# end add
return obj
```

You can modify the function template to write your own function. You can modify the names of the input parameters as needed.

```
Parameter 1 [context]: the context of calling APIs. The value is of the STRING type. This parameter is n
ot in use and is left empty.
Parameter 2 [event]: the result data returned by APIs or the preceding filter. The value is of the STRIN
G type.
```

Create a Python function

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, move the pointer over  and choose **Function > Create Python Function**. You can also click a workflow, right-click **Function**, and then choose **New > Create Python Function**.
4. In the **Create Python Function** dialog box, set the parameters as required.

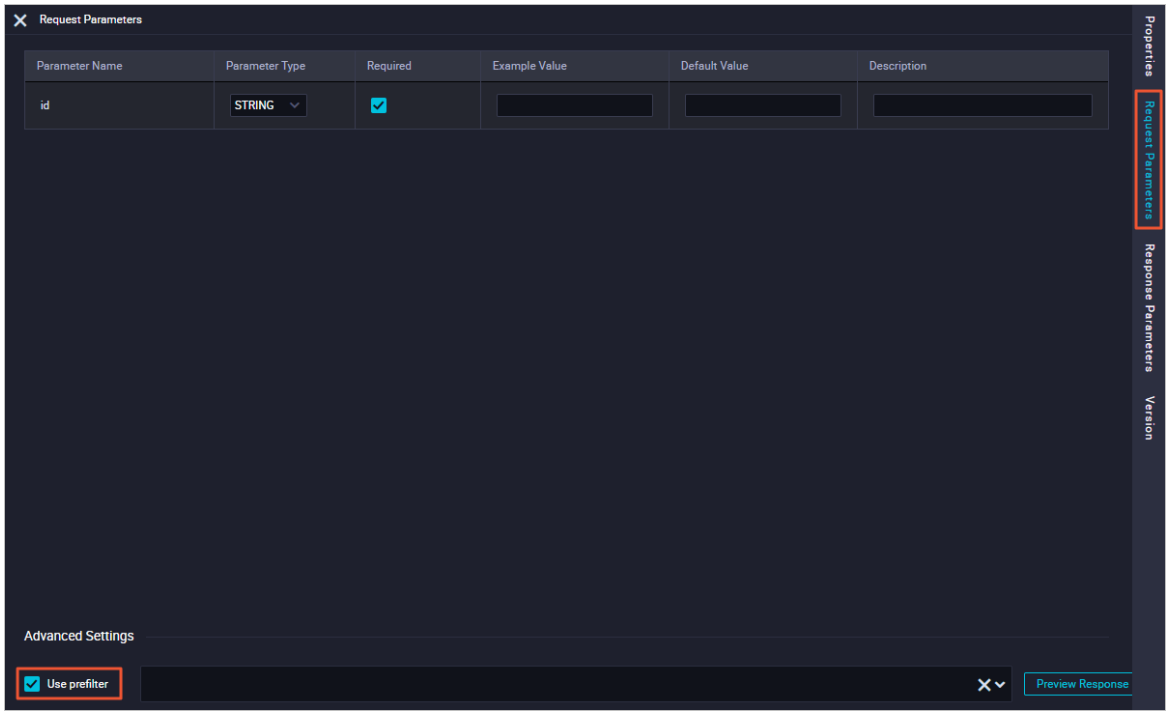


Parameter	Description
Function Name	The name of the function to create, which can be up to 256 characters in length.
Function Template	The template used to create the function. Set the value to Python3 Standard v1.
Running Environment	The runtime environment of the function. Set the value to Python 3.0.
Function Description	The description of the function.
Target Folder	The directory for storing the function.

5. Click **OK**.

Use prefilters

1. On the **Service Development** tab, double-click the target API.
2. On the configuration tab that appears, click **Request Parameters** in the right-side navigation pane.
3. In the **Request Parameters** pane, select **Use prefilter** in the **Advanced Settings** section.



4. Select functions from the **Use prefilter** drop-down list.

   > **Note** A prefilter is a function that is used to process request parameters of APIs. You can create a function and use it as a prefilter.

5. Click **Preview Response** to view the processing results of the prefilters.

2.14.5.4.2. Use post filters

A post filter is a function that is used to process the results returned by APIs. You can specify one or more post filters to process the results returned by APIs. This topic describes the limits of post filters, the built-in function template provided by the system, and how to create functions and use them as post filters.

Context

Post filters have the following limits:

- Only Python 3.0 functions can be used as post filters.
- Post filters support importing only the following modules: json, time, random, pickle, re, and math.
- The function name of a post filter must be `def handler(event,context):` .

Function template

The system provides the following built-in function template:

```
# -*- coding: utf-8 -*-

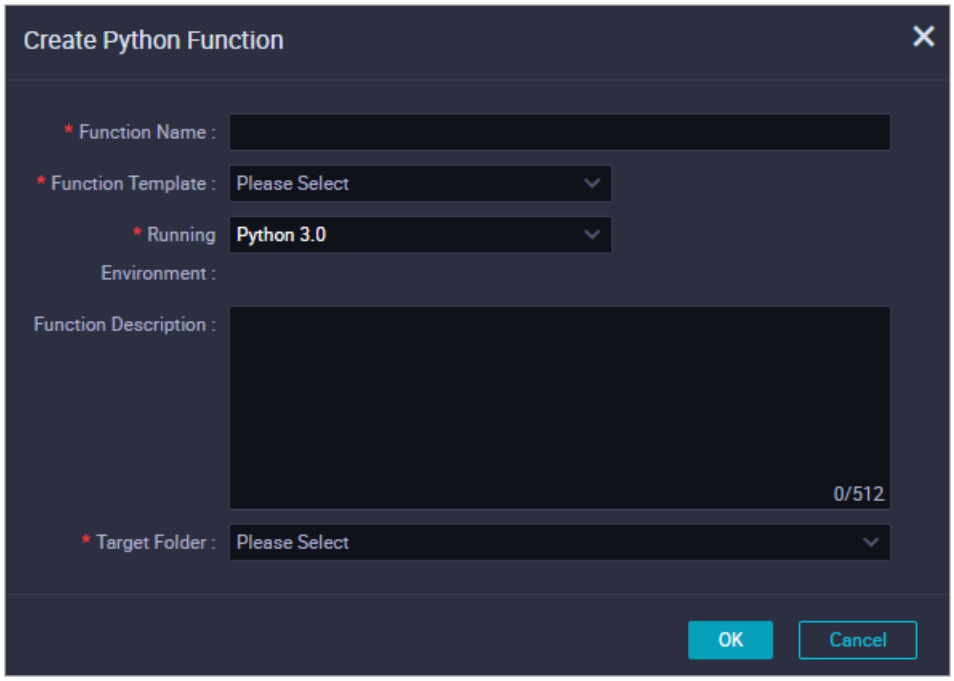
# event (str) : in filter it is the API result, in other cases, it is your param
# context : some environment information, temporarily useless
# import module limit: json,time,random,pickle,re,math
# do not modify function name
import json
def handler(event,context):
# load str to json object
obj = json.loads(event) # Convert the string specified by the event parameter to a JSON object.
# add your code here
# end add
return obj
```

You can modify the function template to write your own function. You can modify the names of the input parameters as needed.

```
Parameter 1 [context]: the context of calling APIs. The value is of the STRING type. This parameter is n
ot in use and is left empty.
Parameter 2 [event]: the result data returned by APIs or the preceding filter. The value is of the STRIN
G type.
```

Create a Python function

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, move the pointer over and choose **Function > Create Python Function**. You can also click a workflow, right-click **Function**, and then choose **New > Create Python Function**.
4. In the **Create Python Function** dialog box, set the parameters as required.

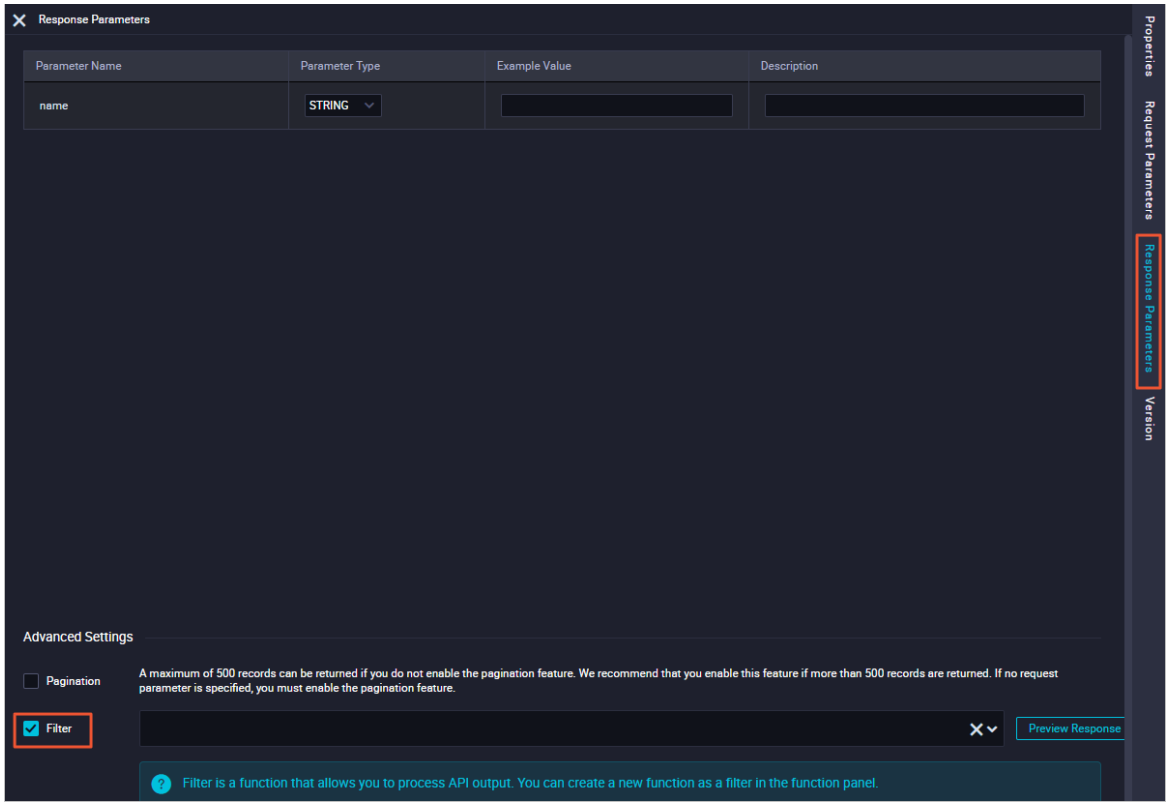


Parameter	Description
Function Name	The name of the function to create, which can be up to 256 characters in length.
Function Template	The template used to create the function. Set the value to Python3 Standard v1.
Running Environment	The runtime environment of the function. Set the value to Python 3.0.
Function Description	The description of the function.
Target Folder	The directory for storing the function.

5. Click **OK**.

Use post filters

1. On the **Service Development** tab, double-click the target API.
2. On the configuration tab that appears, click **Response Parameters** in the right-side navigation pane.
3. In the **Response Parameters** pane, select **Filter** in the **Advanced Settings** section.



4. Select functions from the **Filter** drop-down list.

   > **Note** A post filter is a function that is used to process the results returned by APIs. You can create a function and use it as a post filter.

5. Click **Preview Response** to view the processing results of the post filters.

2.14.6. Register APIs

This topic describes how to register APIs and manage and publish them to API Gateway together with APIs created based on data tables.

Currently, DataService Studio allows you to register only RESTful APIs. Supported request methods include GET, POST, PUT, and DELETE. Supported data types include forms, JSON data, and XML data.

Create a group

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products** > **DataService Studio**.
3. Go to the **Service Development** page, right-click **Service List**, and then select **New API Group**.
4. In the **Create API Group** dialog box that appears, enter values for **Group Name** and **Description**.
5. Click **OK**.

Configure basic API information

1. Right-click the new group and select **Register API**.
2. In the **Create API** dialog box that appears, set each parameter.

Configuration item	Description
API Name	The name must be 4 to 50 characters in length. It must start with a letter and can contain letters, digits, and underscores (_).
API Group	An API group is a collection of APIs for a specific feature or scenario. It is also the minimum API management unit of API Gateway. To create an API group, move the pointer over the **Create** icon and select **New API Group**.
API Path	API Path is the alias of Backend Service Path. APIs with different API paths can share the same backend service path and backend service host. Parameters defined in Backend Service Path must also be defined in brackets in API Path.
Protocol	Currently, HTTP and HTTPS are supported.
Request Method	You can select GET, POST, PUT, or DELETE as the request method. The parameters to be configured vary with the request method.
Return Type	Currently, JSON and XML return types are supported.
Description	The description of the API.

3. After configuring the basic API information, click **OK** to go to the API parameter configuration page.

Configure API parameters

On the API parameter configuration page, you need to define the backend service, request parameters, response content, and error codes.

Configuration item	Description
Define the back-end Service	• **Backend Service Host**: Enter the host of the API. The host must start with http:// or https://, and cannot contain the path. • **Backend Service Path**: Enter the path of the API. Place parameter names in brackets, for example, /user/[userid]. In the next step, parameters defined in Backend Service Path are automatically added to the request parameter list. • **Backend timeout**: Set the backend timeout period.

Configuration item	Description
Define Request Parameters	• **Parameter Type:** The available request parameter locations (Path, Header, Query, or Body) vary with the request method. • **Constant Parameters:** A constant parameter is fixed and is invisible to the caller. You do not have to specify the constant parameters when calling an API. Instead, the constant parameters and their values are automatically sent to the backend service. This is useful when you want to set a parameter to a fixed value and hide the parameter value from the caller. • **Request Body Definition:** This configuration item is available only when the request method is POST or PUT. You can enter the body description in Request Body Definition. It is equivalent to an example of the request body so that API callers can refer to the format of the request body. The content type of the request body can be JSON or XML. **Note** If a parameter has been defined in both the request body and the request parameter list, the parameter value in the request body takes priority.
Define Response Content	You can enter a successful response example or an error response example for API callers to refer to when writing the return parse code.
Error Codes	Enter the common errors and solutions in API calling. This enables API callers to troubleshoot and solve these errors. **Note** To ensure that the API is easily used by the callers, provide complete API parameter information if possible, especially the parameter sample values, default values, and sample responses.

Test the API

After you have configured and saved the API parameters, click **Test** in the upper-right corner to go to the API test page.

Set the parameters and click **Test** to send an API request. The request and response details are displayed on the right. If the test fails, check carefully the error message, make modifications accordingly, and test the API again.

Pay attention to the settings of the successful response example in the configuration process. When testing an API, the system automatically generates error response examples and error codes. However, successful response examples are not automatically generated. To enable the system to save the test result as the successful response example, you need to select **Save as Successful Response Example** before performing the test. If the response contains sensitive data that must be masked, you can manually edit the response.

> Note
>
> - The successful response example is an important reference for API callers, and therefore must be configured.
> - The Call Latency value is the latency of the current API request, which is used to evaluate the API performance. If the latency is long, consider optimizing the database.

After the API test is passed, return to the **Service Development** page, and click **Publish** to generate an API.

2.14.7. Test APIs

This topic describes how to test APIs.

When creating and registering an API, you can test the API. The system also provides an independent API test feature, which allows you to test APIs online.

1. Go to the **DataService Studio** page and click **Service Management** in the upper-right corner.
2. Click **Test API** in the left-side navigation pane.
3. Select the API to be tested, set the parameters, and then click **Test**.

> Note
>
> - The API Test page provides only online API testing. You cannot update or save the successful response example for an API on this page. To update the successful response example for an API, click the API name in the API list to enter the API edit mode. Then, update the successful response example for the API in the API testing step.
> - You must test an API before publishing it.

2.14.8. Publish APIs

API Gateway provides API lifecycle management services, including API publishing, management, maintenance, and monetization. It helps you easily and quickly aggregate microservices, separate the frontend from the backend, and integrate systems at low costs and low risks, making features and data available to partners and developers.

API Gateway provides permission management, traffic control, access control, and metering services. The services make it easy for you to create, monitor, and secure APIs. Therefore, we recommend that you publish the APIs that have been created and registered in DataService Studio to API Gateway. DataService Studio and API Gateway are interconnected, which allows you to publish APIs to API Gateway easily.

Publish APIs to API Gateway

Before publishing an API, you must activate API Gateway and register and test the API.

After the API passes the test, click **Publish** in the upper-right corner to publish the API to API Gateway.

The system automatically registers the API with API Gateway during the publish process. The system also creates a group in API Gateway with the same name as the API group to which the API belongs in DataService Studio and publishes the API in this group. After the API is published, you can access the API Gateway console to view API details or configure bandwidth throttling, access control, and other features.

If you generate an API to be called by your own application, you need to create an application in API Gateway, authorize the application to use the API, and enable the application to call the API by using AppKey and AppSecret. For more information, see *API Gateway documentation* . API Gateway also provides SDKs for mainstream programming languages to help you quickly integrate the API into your own application.

2.14.9. Call APIs

This topic describes how to call an API after this API is published on API Gateway.

API Gateway provides the SDKs for authorizing and calling APIs. You can authorize yourself, your associates, or third parties to use APIs. If you want to call an API, perform the following operations.

Three conditions for calling an API

The following three conditions must be met to call an API:

- API: The API that you call is clearly defined by API parameters.
- App: The app that you use to call the API has a key pair that uniquely identifies you. The key pair consists of the AppKey and AppSecret.
- Relationship between the API and app: If you want to call an API by using an app, the app must have the permission to call this API. This permission is granted through authorization.

Procedure

1. Obtain the API documentation.

   The method of obtaining the API documentation varies depending on how you obtain the API. You can obtain the API by purchasing it from the marketplace, or you are authorized to use the API for free.

2. Create an app.

   The app identifies you when you call the API. Each app has a key pair: AppKey and AppSecret, which are equivalent to an account and the corresponding password.

3. Obtain the permission to call the API.

   Authorization means granting the app the permission to call an API. Your app must be authorized to call the API. The authorization method varies depending on how you obtain the API.

4. Call the API.

   You can edit an HTTP or HTTPS request to call the API. Before calling the API, you can use examples of calling APIs in multiple languages in the API Gateway console to test the call.

You can call APIs after you passed the quick authentication or encrypted signature authentication.

Click **API call**. The AppCode and AppKey that are synchronized from API Gateway are available on the page that appears. You can perform **copy** and **reset** operations on them. For more information about API Gateway, see *API Gateway documentation* .

2.14.10. Use workflows

The workflow feature, also called service orchestration, provides a composite API service. This topic describes the benefits of workflows and how to use workflows.

In DataService Studio, a workflow is represented as a directed acyclic graph (DAG). By dragging and dropping nodes to a DAG, you can arrange APIs and functions in a serial, parallel, or branch structure based on the business logic.

When you run a workflow to call APIs, DataWorks runs the nodes in the workflow in sequence, passes parameters among the nodes, and automatically changes the status of each node. The workflow feature simplifies the process of calling multiple APIs or functions and reduces the cost of development and maintenance. This allows you to focus on business development.

Benefits

- Reduced cost of combining multiple APIs

  By dragging and dropping nodes to a DAG, you can arrange APIs and functions in a serial, parallel, or branch structure without writing code. This reduces the cost of developing APIs.

- Higher performance in calling APIs and functions

  A workflow allows you to call multiple APIs and functions in a container. Compared with writing code to call APIs and functions, the workflow feature reduces the latency of calling APIs and functions.

- Serverless architecture

  The workflow feature adopts a serverless architecture. A serverless architecture supports automatic resource scaling based on business needs. You can focus on the business logic, without worrying about the runtime environment.

Obtain values of request and response parameters

DataService Studio uses JSONPath to obtain parameter values. JSONPath is a query language that allows you to extract data from JSON files.

For example, three nodes are run in the following order: A, B, and then C. Node C needs to use the response parameters of nodes A and B.

- Response parameter of node A: {"namea":"valuea"}

  Expression for obtaining the value of the response parameter of node A: ${A.namea}

- Response parameter of node B: {"nameb":"valueb"}

  Expression for obtaining the value of the response parameter of node B: $.nameb or ${B.nameb}

The built-in start node provides request parameters for the whole workflow. Assume that a request parameter of a workflow is {"namewf":"valuewf"}. All nodes of the workflow can obtain the value of the request parameter by using the ${START.namewf} expression.

Set parameters

Request parameters:

- If you do not specify a value for a request parameter of a node, DataService Studio obtains the value of the same parameter in the first layer of the JSON string returned by the parent node, and assigns the value to the request parameter. If no value is specified for a request parameter of the first node, DataService Studio obtains the value of the same parameter in the request parameters of the workflow.
- If you specify a value for a request parameter, DataService Studio uses the value that you set.
- If you need to use the value of the specified parameter returned by a specified ancestor node, obtain the value by using a JSONPath expression.

Common JSONPath expressions for obtaining parameter values:

- $.: obtains response parameters of the parent node.
- $.param: obtains the value of the param parameter returned by the parent node. To allow you to obtain response parameters of any ancestor nodes, DataService Studio enhances JSONPath expressions.
- ${NODEID1}: obtains response parameters of the node whose ID is NODEID1.
- ${START}: obtains request parameters of the workflow, which are response parameters of the start node.
- ${NODEID1.param}: obtains the value of the param parameter returned by the node whose ID is NODEID1.

JSONPath expressions for setting response parameters of a node:

- $.: sets response parameters of the current node.
- $.param: sets the param parameter to be returned by the current node.
- ${NODEID1.param}: sets the param parameter returned by the node whose ID is NODEID1.

Example

Add a connection before you create and use a workflow. In this example, a MySQL connection is used.

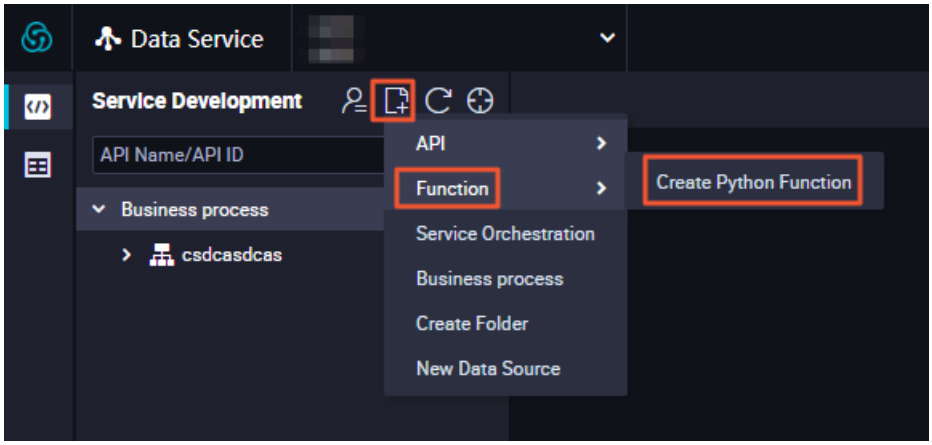
1. Register an API.

   In this example, create an API by using the registration method. For more information, see Register an API.

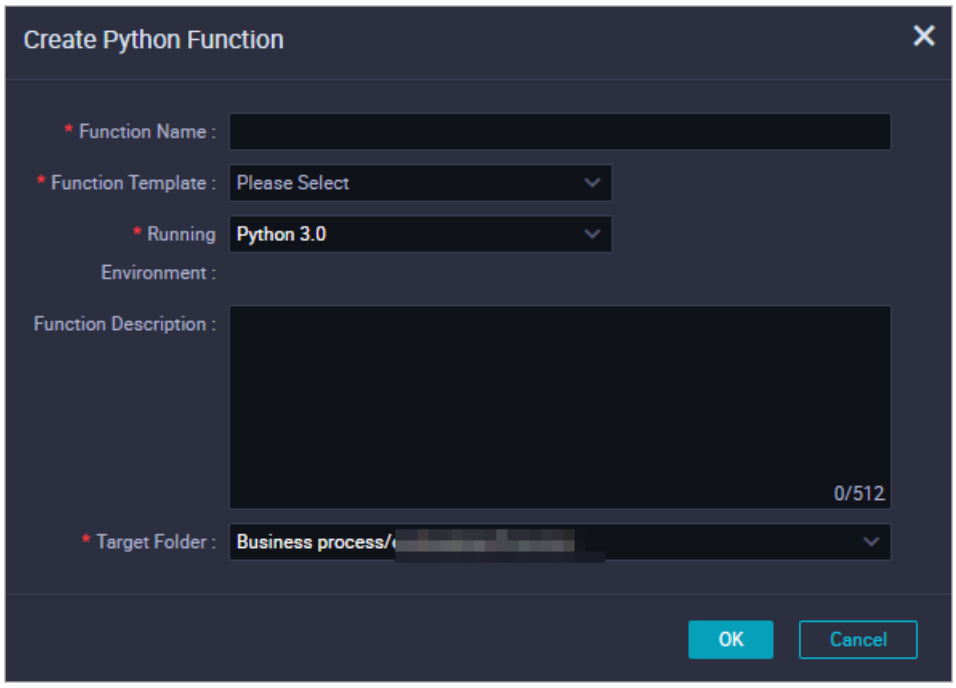
2. Register a function. For more information, see Create a function.

   In this example, create a Python function as a branch node to process the result data of the parent node.

i. Go to the **Service Development** tab, move the pointer over and choose **Function** > **Create Python Function**.



ii. In the **Create Python Function** dialog box, set the parameters as required.



Parameter	Description
Function Name	The name of the function to create, which can be up to 256 characters in length.
Function Template	The template used to create the function. Set the value to Python3 Standard v1.
Running Environment	The runtime environment of the function. Set the value to Python 3.0.
Function Description	The description of the function. The description can be up to 512 characters in length.
Target Folder	The directory for storing the function.

iii. Click **OK**.

iv. On the configuration tab of the function, configure the function.

a. In the **Edit Code** section, enter the function code.

```
# -*- coding: utf-8 -*-
# event (str) : in filter it is the API result, in other cases, it is your param
# context : some environment information, temporarily useless
# import module limit: json,time,random,pickle,re,math
import json
def handler(event,context):
    # load str to json object
    obj = json.loads(event)
    # add your code here
    # end add
    return obj
```

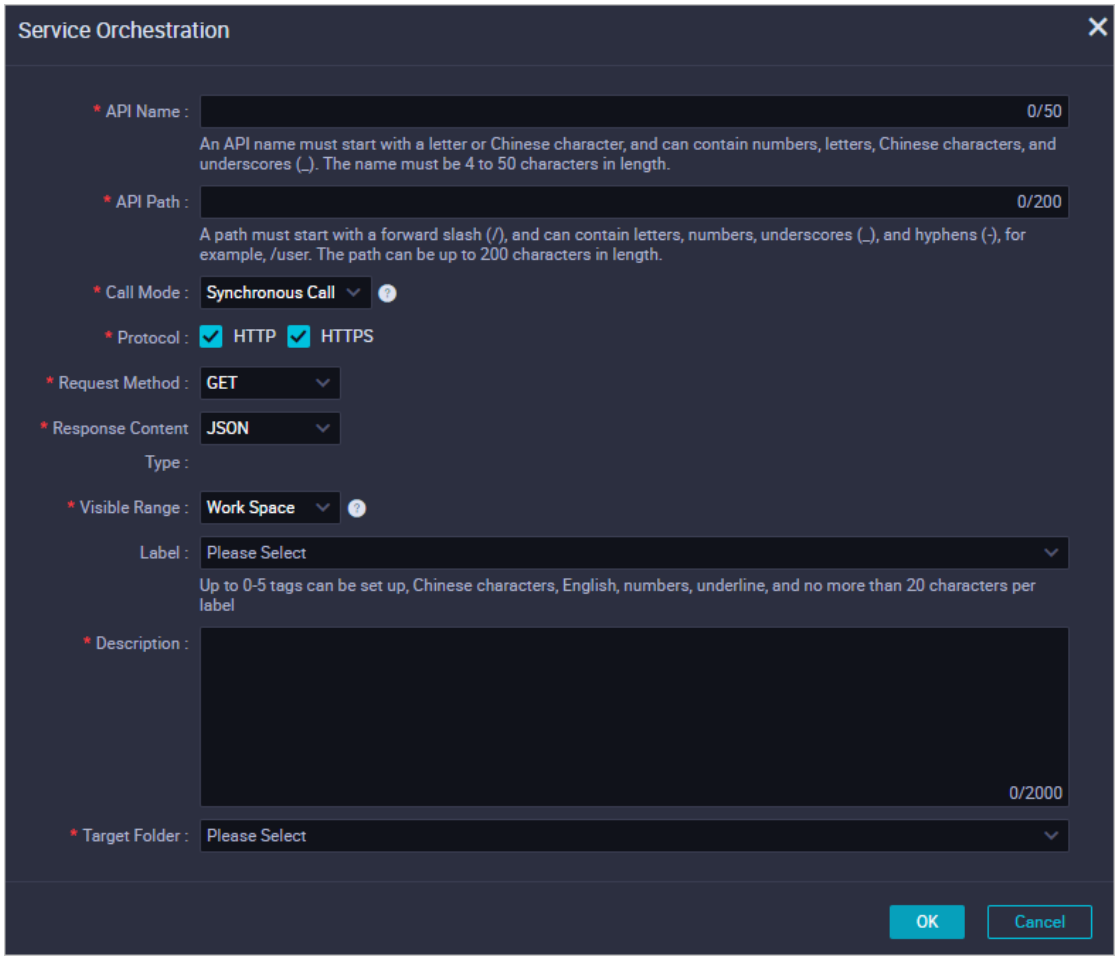
b. In the **Environment Configuration** section, set the **Memory** and **Function Timeout** parameters.

v. Click Save icon in the toolbar.

3. Create a workflow.

i. On the **Service Development** tab, move the pointer over and select **Service Orchestration**.

ii. In the **Service Orchestration** dialog box, set the parameters as required.



Parameter	Description
API Name	The name of the workflow. The name must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.
API Path	The path for storing the workflow, for example, */user*.
Call Mode	The mode for calling the API to be arranged in the workflow. Valid values: **Synchronous Call** and **Asynchronous Call**. ■ If you set this parameter to **Synchronous Mode**, the API returns results immediately after it is called. The synchronous mode is most commonly used. ■ If you set this parameter to **Asynchronous Mode**, the API returns the RequestID parameter immediately after it is called. The API caller can then obtain the call result from a message queue based on the request ID.
Protocol	The protocol used by the API. Valid values: **HTTP** and **HTTPS**.
Request Method	The request method used by the API. Valid values: **GET** and **POST**.
Response Content Type	The return type of the API. Set the value to **JSON**.

Parameter	Description
Visible Range	The visibility of the workflow. Valid values: ■ **Work Space**: The workflow is visible to all members in the current workspace. ■ **Private**: The workflow is visible only to its owner and permissions on the workflow cannot be granted to other users. Note If you set the Visible Range parameter to Private, the workflow is visible only to you in the directory tree. It is hidden to other members of the workspace.
Label	The tag of the workflow. Select one or more tags from the drop-down list. For more information, see Manage tags. Note You can set at most five tags for a workflow.
Description	The description of the workflow, which can be up to 2,000 characters in length.
Target Folder	The directory for storing the workflow.

iii. Click **OK**.

4. Configure the workflow.

i. On the configuration tab of the workflow, drag and drop nodes and connect them as required.

ii. Double-click the **API1** node to edit the node. Select the API that you registered earlier as the API to be called in the node.

Select **set output results** and enter `{"user_id":"$.data[0].id"}` .

Use JSONPath expressions to set response parameters. The syntax for obtaining the value of a parameter is ${NodeA.namea}, which is the same as that for setting request parameters. `{" user_id":"$.data[0].id"}` assigns the value of the id parameter of the first element in the data array to the user_id parameter. Then, the API1 node returns {"user_id":"value"} in JSON format.

iii. Double-click the **PYTHON1** node to edit the node. Select the function that you created earlier as the function to be called in the node.

iv. Double-click the **SWITCH2** node to edit the node. In the right-side pane that appears, click **Set branch conditions**. In the Set branch conditions dialog box, enter conditional expressions based on the response parameter of the parent node. For example, you can enter expressions in the `${Node ID. Parameter}>1` or `$. Parameter>1` format. Conditional expressions support the following operators: ==, ! =, >=, >, <=, <, &&, !, (), +, -, *, /, and %.

In this example, the user_id parameter is the response parameter of the API1 node and is used as the request parameter of the SWITCH2 node.

```
Branch node 1: $.user_id != 1, indicating that the branch node 1 is run if the value of the user
_id parameter is not 1.
Branch node 2: $.user_id == 1, indicating that the branch node 2 is run if the value of the user
_id parameter is 1.
```

v. Double-click the end node and then click the **Response Parameters** tab on the right side to set response parameters.

5. Click **Test** in the upper-right corner.
6. In the **Test APIs** dialog box, set the parameters as required and click **OK**.

   You can view the test result after the workflow is tested.

2.14.11. Manage versions

This topic describes how to manage versions of APIs, workflows, and functions in Data Service.

You can view and compare historical versions of APIs, workflows, and functions. Data Service generates a version record each time an API, a workflow, or a function is published.

View historical versions

1. Log on to the DataWorks console. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > DataService Studio**.
2. On the **Service Development** page that appears, double-click the name of the target API in the API list.

   > **Note** You can also click Function or Table in the left-side navigation pane and double-click the name of a workflow or function to manage its versions.

3. In the right-side navigation pane, click **Version**. In the **Version** dialog box that appears, view historical versions of the API.

Parameter	Description
API ID	The ID of the API. Each API ID is unique.
Version	The version of the API. A version is generated each time the API is published. V1 indicates version 1 and V2 indicates version 2. The version number is incremented by 1 each time.

Parameter	Description
The Author	The user who published the version.
Submitted Date	The time when the version was published. The time is accurate to second.
Status	The status of the version. Value values: ○ **Release**: indicates that the version of the API is the latest version. ○ **Off-Line**: indicates that the version of the API is a historical version.
Actions	The operations that you can perform on the version. The **Actions** column is only available for API and workflow versions. You can click **API Details** of a version to go to the details page of the version. The **Actions** column is unavailable for function versions.

Compare historical versions

In the **Version** dialog box, select two versions to compare, and click **Contrast**. In the **History Version Contrast** dialog box that appears, compare the code and parameters of the two versions.

2.14.12. FAQ

This topic provides answers to commonly asked questions about DataService Studio.

- Q: Do I need to activate the API Gateway service?

  A: API Gateway provides you with high-performance and highly available API hosting services. If you need to make your APIs available to others, activate the API Gateway service first.

- Q: Where can I add and change connections?

  A: After you log on to the DataWorks console, click the DataWorks icon in the upper-left corner and choose **All Products** > **Data Integration** to go to the **Data Integration** page. In the left-side navigation pane, choose **Sync Resources** > **Connections**. On the page that appears, perform the relevant configuration. DataService Studio automatically reads data from the connections that you have configured.

- Q: What is the role of an API group in DataService Studio? What is the relationship between an API group in DataService Studio and an API group in API Gateway?

  A: An API group is a set of APIs specific to a feature or scenario. It is the smallest organization unit in DataService Studio, which is similar to an API group in API Gateway. An API group in DataService Studio is equivalent to an API group in API Gateway. After you publish an API from DataService Studio to API Gateway, API Gateway automatically creates an API group with the same name.

- Q: How can I configure an API group appropriately?

A: Typically, an API group includes APIs that provide similar features or resolve a specific issue. For example, a weather API group can include APIs that are used to check the weather by city and by longitude and latitude.

- Q: How many API groups can I create?

  A: An Alibaba Cloud account can create up to 100 API groups.

- Q: When do I need to enable the pagination feature for an API call so that its return results can be displayed on multiple pages?

  A: By default, an API call returns a maximum of 2,000 records. If an API call may return more than 2,000 records, enable the pagination feature. If you do not specify any request parameters, the API call usually returns a large number of records and the pagination feature is automatically enabled.

- Q: Do APIs created by DataService Studio support POST requests?

  A: APIs created by DataService Studio support GET and POST requests.

- Q: Do APIs created by DataService Studio support the HTTPS protocol?

  A: APIs created by DataService Studio support both HTTP and HTTPS protocols.

2.15. Stream Studio

2.15.1. Overview

Built on Alibaba Cloud Realtime Compute, which is based on Apache Flink, Stream Studio allows you to develop real-time computing nodes in directed acyclic graph (DAG) mode or SQL mode. You can switch between the two modes to edit the code or drag and drop components and configure them in a visual way.

As an ideal platform for developing real-time computing nodes, Stream Studio has the following features:

- Supports developing nodes in DAG mode. You can perform drag and drop components to configure real-time computing nodes.
- Supports developing nodes in SQL mode. You can edit the code to configure real-time computing nodes.
- Supports switching between the DAG mode and the SQL mode for you to easily check SQL operators.
- Supports using Function Studio to create and publish user-defined functions (UDFs) online in exclusive mode.
- Supports smart diagnosis for real-time computing nodes to facilitate online troubleshooting.

2.15.2. Bind a Realtime Compute project

1. Log on to the DataWorks console.
2. Click the **Project Manage** icon in the upper-right corner. The **Project Management** page appears.
3. On the **Project Management** page, click **Add Compute Engine** in the **Compute Engine** section, and select **Add engine service**.
4. Enter the name of the Blink engine to be added and click **Bind**.

2.15.3. Create a real-time computing node

This topic describes how to create a real-time computing node and develop data in Stream Studio.

Prerequisites

A workflow is created. You can create real-time computing nodes and develop data under an existing workflow.

Procedure

After a workflow is created, you can create real-time computing nodes under the workflow. By default, data is developed for a real-time computing node in directed acyclic graph (DAG) mode.

1. Right-click the workflow that you have created and select **Create task**.
2. In the **Create Node** dialog box that appears, set the parameters and click **Submit**.
3. Develop data in DAG mode on the **Components** page.

   The Components page includes the following four sections:

   - Component list section: In this section, you can view the list of available components. You can click **Components** on the left-side navigation submenu to go to the Components page and view the list.
   - DAG section: In this section, you can drag and drop components to the DAG and connect them. To configure the dependency between two components, click and hold the highlighted dot at the bottom of a component and move the pointer to link this component with a descendant component. A DAG corresponds to a real-time computing node.
   - Parameter configuration section: Double-click a component in the DAG. Then, you can set the related parameters in this section.
   - Toolbar section: In this section, you can click the icons to perform the save, submit, steal lock, pre-compilation, test, stop, reload, and format operations respectively.

   When you configure the DAG, you can right-click a component and select an operation from the menu that appears to perform it on the selected component. Available operations include **Rename**, **View schema**, **Delete node**, **View error message**, **New component group**, and **Copy**.

2.15.4. Get started with Stream Studio

This topic uses an example to describe how to use Stream Studio to develop and manage a real-time computing node. Stream Studio allows you to create, configure, publish, run, stop, and unpublish a real-time computing node.

Prerequisites

A Realtime Compute project is bound to the current DataWorks workspace.

Context

- Data store: a Datahub table with a created topic, which contains the `m_name, id, m_type, and t`

`ag` fields.

> **Note** The Datahub topic must be created in advance.

- Data processing: splits the tag field by using the `semicolon (;)` as the delimiter to the color, mode, and weight fields.
- Output data: writes the `id, m_type, and weight` fields to a Log Service table.

> **Note** The Log Service project and Logstore must be created in advance.

Procedure

1. Log on to the DataWorks console. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Stream Studio**.
2. Create a workflow.
   i. On the Stream Studio homepage, click **New business process**.

      You can also move the pointer over the **Create** icon and click **Business process**.

   ii. In the **Create business process** dialog box that appears, set the **Business Name** and **Description** parameters.

   iii. Click **New**.
3. Create a real-time computing node.
   i. Right-click the workflow that you have created and select **Create task**.

   ii. In the **Create node** dialog box that appears, set the relevant parameters.

   iii. Click **Submit**. The **Components** page appears.

   iv. On the left-side navigation submenu, click **Resource Reference** and select **PUBLIC_COMMON**.

   > **Note** If this option is not selected, the message shown when you use the **FixedFieldsSplit** component.
   >
   > You can also go to the Resource Reference page to configure the reference resources after this message appears.
4. Configure the created real-time computing node.

   On the left-side navigation submenu, click **Components**. The **Components** page appears.

   i. Configure the data store of the node on the **Components** page.

      a. Drag and drop the Datahub component in the Data Source section to the directed acyclic graph (DAG).

      b. Click the Datahub component and set the parameters as needed on the **Parameter configuration** tab that appears.

Parameter	Description

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name. If this parameter is not specified, the real table name is used.
table schema	The custom fields and attribute fields to be returned. Click **Custom**. In the **Select field** dialog box that appears, click **+ Add** and enter the name and type of the output field. Then, click **OK**.
endPoint	The endpoint used to access Datahub. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to read data from Datahub. It corresponds to the accessId parameter in the WITH clause of the CREATE TABLE statement.
accessKey	The AccessKey secret used to read data from Datahub. It corresponds to the accessKey parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the Datahub project from which data is to be read. It corresponds to the project parameter in the WITH clause of the CREATE TABLE statement.
topic	The name of the Datahub topic from which data is to be read. It corresponds to the topic parameter in the WITH clause of the CREATE TABLE statement.
startTime	The beginning of the time range when data is read. It corresponds to the startTime parameter in the WITH clause of the CREATE TABLE statement.
maxRetryTimes	The maximum number of retries for reading data from Datahub. It corresponds to the maxRetryTimes parameter in the WITH clause of the CREATE TABLE statement. Default value: *20*.
retryIntervalMs	The retry interval at which data is read. It corresponds to the retryIntervalMs parameter in the WITH clause of the CREATE TABLE statement. Unit: milliseconds. Default value: *1,000*.
batchReadSize	The number of data records that are read at a time. It corresponds to the batchReadSize parameter in the WITH clause of the CREATE TABLE statement. Default value: *10*.
lengthCheck	The rule for checking the number of fields parsed from a row of data. It corresponds to the lengthCheck parameter in the WITH clause of the CREATE TABLE statement. Default value: *NONE*.

Parameter	Description
columnErrorDebug	Specifies whether to enable debugging. It corresponds to the columnErrorDebug parameter in the WITH clause of the CREATE TABLE statement. If you turn on this switch, logs about parsing errors are returned. You can view the node details Operation Center.

ii. Configure the data operator.

a. Drag and drop the **FixedFieldsSplit** component to the DAG to split the tag field.

b. Click and hold the highlighted dot at the bottom of the **Datahub** component and move the pointer to link this component with the **FixedFieldsSplit** component.

c. Click the **FixedFieldsSplit** component and set the field to tag and the column separator to semicolon (;) on the Parameter configuration tab that appears.

d. Click **Custom** for the Add column parameter. In the **Select field** dialog box that appears, click + Add and enter the name and type of the output field. Then, click **OK**.

e. Drag and drop the **Select** component to the DAG. Click and hold the highlighted dot at the bottom of the **FixedFieldsSplit** component and move the pointer to link this component with the **Select** component.

f. Click the **Select** component and click **0 Field has been selected** on the **Parameter configuration** tab that appears.

g. In the dialog box that appears, select the fields to be returned and click **OK**.

iii. Configure the result table.

This example uses the LogService component as the destination.

a. Drag and drop the **LogService** component to the DAG. Click and hold the highlighted dot at the bottom of the **Select** component and move the pointer to link this component with the **LogService** component.

b. Click the **LogService** component and set the parameters as needed on the **Parameter configuration** tab that appears.

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name. If this parameter is not specified, the real table name is used.
Output Field	The fields to be returned. Click **0 Field has been selected** for the Output Field parameter. In the dialog box that appears, select the fields to be returned and click **OK**.
endPoint	The endpoint used to access Log Service. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the Log Service project to which data is to be written. It corresponds to the project parameter in the WITH clause of the CREATE TABLE statement.
topic	The name of the Log Service topic to which data is to be written. It corresponds to the topic parameter in the WITH clause of the CREATE TABLE statement.
source	The name of the Log Service table to which data is to be written. It corresponds to the source parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to access Log Service. It corresponds to the accessId parameter in the WITH clause of the CREATE TABLE statement.
accessKey	The AccessKey secret used to access Log Service. It corresponds to the accessKey parameter in the WITH clause of the CREATE TABLE statement.
mode	The mode of data writing. It corresponds to the mode parameter in the WITH clause of the CREATE TABLE statement. Default value: *random*.
logStore	The name of the Logstore in the Log Service project to which the data is to be written. It corresponds to the logStore parameter in the WITH clause of the CREATE TABLE statement.

iv. Switch between the DAG mode and SQL mode.

Stream Studio allows you to configure a real-time computing node in both DAG mode and SQL mode. You can switch between these two modes.

By default, you configure a node in DAG mode. You can click **Switch to SQL mode** in the upper-right corner to switch to the SQL mode.

In SQL mode, you can click **Switch to DAG mode** in the upper-right corner to switch back to the DAG mode.

v. Configure the execution plan.

a. Click **Execution Plan** on the right-side navigation submenu to generate an execution plan.

b. Click **Save execution plan**.

5. Publish the real-time computing node.

You can publish the real-time computing node that you have configured. Click **Save** and then click **Submit** to publish the node.

i. Click **Save** and then click **Submit**. If you have not saved the node, a message appears, indicating that you must save it.

ii. In the **Submit New version** dialog box that appears, enter the remarks for the node and click **OK**.

iii. After you publish the node, you can go to the **OAM** page to view the node status and manage the node.

6. Perform O&M on the real-time computing node.

Click **OAM** in the upper-right corner to perform O&M on the real-time computing node.

i. Start the real-time computing node.

Find the real-time computing node that you have created in the node list and click **Start** to start the node.

You can set a custom start time for the real-time computing node based on your business requirement.

After starting the real-time computing node, you can click the node name to view its running status. If the real-time computing node is started properly, it enters the **Run** state.

ii. Stop and unpublish the real-time computing node.

a. Click **Stop** to stop the real-time computing node.

b. After the real-time computing node is stopped, click **Offline** to unpublish it.

Result

Now you have created, configured, published, run, stopped, and unpublished a real-time streaming node.

2.15.5. Configure components

2.15.5.1. Source tables

2.15.5.1.1. Datahub

Datahub is a real-time data distribution platform that is designed to process streaming data. It provides a channel for the Apsara Stack DTplus platform to process big data.

Realtime Compute typically uses Datahub to store source and result tables for streaming data processing. Data Transmission Services (DTS) and the Internet of Things (IoT) also use Datahub to access big data platforms. Datahub stores streaming data that can be used as input data for Realtime Compute.

Parameter configuration

Parameter	Description	Remarks
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.	None
table schema	The custom fields and attribute fields to be read from Datahub.	None
endPoint	The consumer endpoint.	None
accessId	The AccessKey ID used to read data from Datahub.	None
accessKey	The AccessKey secret used to read data from Datahub.	None
project	The name of the Datahub project from which data is to be read.	None
topic	The name of the Datahub topic from which data is to be read.	None
startTime	The beginning of the time range when data is read.	The format is `yyyy-MM-dd hh:mm:ss`.
maxRetryTimes	The maximum number of retries for reading data from Datahub.	None
retryIntervalMs	The retry interval at which data is read. Unit: milliseconds.	None
batchReadSize	The number of data records that are read at a time.	None

Parameter	Description	Remarks
lengthCheck	The rule for checking the number of fields parsed from a row of data.	Valid values: *SKIP*, *EXCEPTION*, and *PAD*. Default value: SKIP. • *SKIP*: skips a data record when the number of fields in the data record is not the specified one. • *EXCEPTION*: throws an exception when the number of fields in the data record is not the specified one. • *PAD*: pads fields in sequence. Pad a field with null when the field does not exist.
columnErrorDebug	Specifies whether to enable debugging. If you turn on this switch, logs about parsing errors are returned.	None
BLOB	Specifies whether the type of data read from Datahub is BLOB.	None
Data Quality	Specifies whether to open the Data Quality page to view related monitoring nodes.	None

Field type mapping

The following table lists the mapping between Datahub and Realtime Compute data types. We recommend that you declare the type mapping in the DDL statement.

Datahub data type	Realtime Compute data type
BIGINT	BIGINT
DOUBLE	DOUBLE
TIMESTAMP	BIGINT
BOOLEAN	BOOLEAN
DECIMAL	DECIMAL

Attribute fields

You can obtain the attribute field indicating the system time at which each data record is written to Datahub.

Field	Description
System Time	The system time at which each data record is written to Datahub.

2.15.5.1.2. Log Service

As an all-in-one real-time data logging service, Log Service allows you to quickly finish tasks such as data ingestion, consumption, delivery, query, and analysis without any extra development work. This can help you improve O&M and operational efficiency, and build up the capability to process large amounts of logs in the data technology era.

Log Service stores streaming data that can be used as input data for Realtime Compute.

The data format of Log Service is consistent with JSON. Example:

```
{
  "a": 1000,
  "b": 1234,
  "c": "li"
}
```

Parameter configuration

Parameter	Description	Remarks
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.	None
table schema	The custom fields and attribute fields to be read from Log Service.	None
endPoint	The consumer endpoint.	Log Service endpoints
accessId	The AccessKey ID used to read data from Log Service.	None
accessKey	The AccessKey secret used to read data from Log Service.	None
project	The name of the Log Service project from which data is to be read.	None
logStore	The name of the Logstore under the Log Service project.	None

Parameter	Description	Remarks
consumerGroup	The name of the consumer group.	You can specify a custom consumer group name. The format of the name is not fixed.
startTime	The beginning of the time range when the log data is consumed.	None
heartBeatIntervalMills	Optional. The heartbeat interval at which the client sends heartbeat messages. Unit: milliseconds.	None
maxRetryTimes	The maximum number of retries for reading data from Log Service.	None
columnErrorDebug	Specifies whether to enable debugging. If you turn on this switch, logs about parsing errors are returned.	None

Field type mapping

The following table lists the mapping between Log Service and Realtime Compute data types. We recommend that you declare the type mapping in the DDL statement.

Log Service data type	Realtime Compute data type
STRING	VARCHAR

Attribute fields

Currently, Log Service supports the following three attribute fields by default. You can also specify other custom fields.

Field	Description
`__source__`	Specifies a log source.
`__topic__`	Specifies a log topic.
`__timestamp__`	Specifies the time when a logged event occurs.

Note

- Currently, Log Service does not support the MAP type.
- We recommend that you define the fields in the same order as the fields in the preceding table. Unordered fields are also supported.
- If the input data is in JSON format, define the delimiter and use the built-in function JSON_VALUE to parse the JSON value. Otherwise, the parsing fails and the following error is returned:

```
2017-12-25 15:24:43,467 WARN [Topology-0 (1/1)] com.alibaba.blink.streaming.connectors.common.source.parse.DefaultSourceCollector - Field missing error, table column number: 3, data column number: 3, data field number: 1, data: [{"lg_order_code":"LP00000005","activity_code":"TEST_CODE1","occur_time":"2017-12-10 00:00:01"}]
```

- The batchGetSize value must not exceed 1,000. Otherwise, an error occurs.
- The batchGetSize parameter specifies the number of log items read at a time in a log group. If both the size of a single log item and the batchGetSize value are too large, frequent garbage collection (GC) may be triggered. To avoid this, you must set batchGetSize parameter to a smaller value.

2.15.5.2. Dimension tables

2.15.5.2.1. ApsaraDB for RDS

ApsaraDB for Relational Database Service (RDS) offers stable, reliable, and scalable cloud database services.

Parameter configuration

Parameter	Description	Remarks
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.	None
url	The URL of the RDS instance.	None
tableName	The name of the dimension table.	None
userName	The username used to access RDS.	None
password	The password used to access RDS.	None
Output Field	The fields to be returned to the descendant component.	None

Parameter	Description	Remarks
maxRetryTimes	The maximum number of retries for reading data from RDS.	None
Cache Policy	The policy for caching data.	Valid values: *None*, *LRU*, and *ALL*.
primaryKey	The primary key field of the output fields.	• You must specify the primary key when you declare the dimension table. • When you join a dimension table with another table, the ON condition must contain an equivalence condition that includes the primary key of either table. • The primary key in RDS or Distribute Relational Database Service (DRDS) is the primary key or unique index column of an RDS or DRDS dimension table.

Note

- RDS and DRDS provide the following three cache policies:
  - **None**: indicates that no data is cached.
  - **LRU**: indicates that the recently used data is cached.

    When this cache policy is used, you must set the cacheSize and cacheTTLMs parameters.
  - **ALL**: indicates that all data is cached.

  Before Realtime Compute runs a node, it loads all data in the remote table to the memory. Then Realtime Compute searches the cache for data in all subsequent dimension table query operations. In the case of a cache miss, the corresponding data does not exit. All data is cached again after the cache expires. The ALL cache policy applies to scenarios where the remote table is small but there are a large number of missing keys. When this cache policy is used, you must set the cacheTTLMs and cacheReloadTimeBlackList parameters.
- When the cache policy is set to ALL, Realtime Compute reloads data asynchronously. Therefore, you must increase the memory of the JOIN operator. The size of the increased memory is twice the data size of the remote table.
- When the cache policy is set to ALL, pay special attention to the memory of the JOIN operator to prevent out of memory (OOM) errors.

2.15.5.2.2. Table Store

Table Store is a distributed NoSQL database service built on Alibaba Cloud Apsara system. It is designed to provide high availability and data reliability.

Parameter configuration

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
instanceName	The ID of the Table Store instance.
tableName	The name of the dimension table.
Output Field	The fields to be returned to the descendant component.
endPoint	The endpoint used to access Table Store. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to read data from Table Store.
accessKey	The AccessKey secret used to read data from Table Store.
Cache Policy	The policy for caching data. Valid values: **None** and **LRU**.
primaryKey	The primary key field of the output fields.

2.15.5.2.3. MaxCompute

This topic describes the parameter configuration, field type mapping, and metrics of a MaxCompute dimension table.

Parameter configuration

Parameter	Description	Remarks
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.	None
endPoint	The endpoint used to access MaxCompute. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.	None

Parameter	Description	Remarks
tunnelEndpoint	The endpoint of the Tunnel service. It corresponds to the tunnelEndPoint parameter in the WITH clause of the CREATE TABLE statement.	This parameter is required for a MaxCompute dimension table deployed in a Virtual Private Cloud (VPC).
project	The name of the MaxCompute project to which the dimension table belongs.	None
accessId	The AccessKey ID used to read data from MaxCompute.	None
accessKey	The AccessKey secret used to read data from MaxCompute.	None
Output Field	The fields to be returned to the descendant component.	None
partition	The partition name of the MaxCompute dimension table.	None
maxRowCount	The maximum number of data records that can be read from the MaxCompute dimension table	None
Cache Policy	The policy for caching data.	Default value: **ALL**.
cacheSize	The maximum number of data records that can be cached.	This parameter is required if you set the Cache Policy parameter to `LRU`. Default value: 100,000.
cacheTTLMs	The time interval at which the cache is refreshed. It corresponds to the cacheTTLMs parameter in the WITH clause of the CREATE TABLE statement. Units: milliseconds.	This parameter specifies the cache refresh interval when the Cache Policy parameter is set to `ALL`. The cache is not refreshed by default.

Parameter	Description	Remarks
cacheReloadTimeBlackList	Optional. The time period during which the cache is not refreshed. This parameter is valid when the Cache Policy parameter is set to `ALL`. During the time period specified by this parameter, for example, the Double 11 Shopping Festival, the cache is not refreshed.	This parameter is left empty by default. If you want to set this parameter, specify the time period in the format shown in the following example: `2017-10-24 14:00 -> 2017-10-24 15:00, 2017-11-10 23:30 -> 2017-11-11 08:00` Separate multiple time periods with commas (,). Separate the start and end time for a time period with the string "->".
primaryKey	The primary key field of the output fields.	None

Field type mapping

MaxCompute data type	Realtime Compute data type
TINYINT	TINYINT
SMALLINT	SMALLINT
INT	INT
BIGINT	BIGINT
FLOAT	FLOAT
DOUBLE	DOUBLE
BOOLEAN	BOOLEAN
DATETIME	TIMESTAMP
TIMESTAMP	TIMESTAMP
VARCHAR	VARCHAR
STRING	STRING
DECIMAL	DECIMAL
BINARY	VARBINARY

Metrics

When you join the dimension table to another table, you can view metrics such as the correlation degree and cache hit ratio. You can use K-Monitor to view the metrics.

Query statement	Description
fetch qps	Queries the total number of queries per second (QPS) against the dimension table, including hits and misses. The metric name is `blink.projectName.jobName.dimJoin.fetchQPS`.
fetchHitQPS	Queries the number of hits (in QPS) against the dimension table, including cache hits and hits against the physical dimension table. The metric name is `blink.projectName.jobName.dimJoin.fetchHitQPS`.
cacheHitQPS	Queries the number of cache hits (in QPS) against the dimension table. The metric name is `blink.projectName.jobName.dimJoin.cacheHitQPS`.
dimJoin.fetchHit	Queries the correlation degree of the dimension table and the table to which the dimension table is joined. The metric name is `blink.projectName.jobName.dimJoin.fetchHit`.
dimJoin.cacheHit	Queries the cache hit ratio of the dimension table. The metric name is `blink.projectName.jobName.dimJoin.cacheHit`.

Note

- We recommend that you use Realtime Compute V2.1.1 and later.
- To use a MaxCompute dimension table, you must grant the read permission to the account for accessing MaxCompute.
- When you declare a dimension table, you must specify the primary key. When you join a dimension table with another table, the ON condition must contain an equivalent condition that includes the primary key of either table.
- The primary key value for each row of a MaxCompute dimension table must be unique. Otherwise, the duplicate records are removed.
- If the dimension table is a partitioned table, Realtime Compute does not currently support writing the partition key column to the schema.
- When the cache policy is set to ALL, Realtime Compute reloads data asynchronously. Therefore, you must increase the memory of the JOIN operator. The size of the increased memory is twice the data size of the remote table.
- The following failover message may appear when you run a node:

```
RejectedExecutionException: Task
java.util.concurrent.ScheduledThreadPoolExecutor$ScheduledFutureTas,
```

Generally, this message appears because dimension table joining in Realtime Compute V1.x has certain issues. We recommend that you upgrade Realtime Compute to V2.1.1 or later. If you want to continue using the existing version, we recommend that you pause the node and resume it after troubleshooting. To troubleshoot the failover, check the specific error information that was generated for the first failover record in the failover history.

2.15.5.3. Data operators

2.15.5.3.1. Filter

The Filter component allows you to configure filter conditions. It corresponds to the WHERE clause in SQL statements.

Parameter configuration

Enter the filter expression to configure this component. The filter expression supports functions and operators (=, <>, >, >=, <, and <=), for example, `city = 'Beijing'` .

2.15.5.3.2. GroupBy

The GroupBy component corresponds to the GROUP BY clause in SQL statements.

Parameter configuration

Parameter	Description
Select grouping field	The fields based on which data is grouped. You can specify multiple fields.
Output Field	The fields to be returned, that is, the fields to be selected. You can specify the fields in the same way that you configure the Select component.

2.15.5.3.3. Join

The Join component corresponds to the JOIN clause in SQL statements.

Parameter configuration

Parameter	Description
JoinMode	The JOIN mode to be used. Valid values: INNER JOIN, LEFT OUTER JOIN, RIGHT OUTER JOIN, and FULL OUTER JOIN.
expression	The JOIN expression. An equijoin is supported, for example, leftId = rightId AND limit = 0, whereas a non-equijoin is not supported.
Select Field	The fields to be returned, that is, the fields to be selected.

2.15.5.3.4. Select

The Select component allows you to configure the fields to be returned and supports field expressions. It corresponds to SELECT statements.

Parameter configuration

Select or configure the output fields in the Select field dialog box.

You can select fields to be returned in the **Field list** section and set an alias for a field in the **Field alias** column. To set a field expression, click the Edit icon next to the target field name. In the Edit dialog box that appears, enter the required SQL statement.

2.15.5.3.5. UDTF

The UDTF component allows you to configure custom functions. It corresponds to the UDTF clause in SQL statements.

Parameter configuration

Parameter	Description
JoinMode	The JOIN mode for the custom function. Only *INNER JOIN* and *LEFT OUTER JOIN* are supported. • *INNER JOIN*: returns an empty result set when the UDTF clause returns no result. • *LEFT OUTER JOIN*: returns the NULL string when the UDTF clause returns no result.
Select function	The name of the function that the current node references. To reference a function for the current node, upload the related resources on the Resource Reference page and select the target resource.
parameter expression	The input parameters and output parameters of the referenced function.
Output Field	The fields to be returned. You can configure the name, alias, and expression of each field.

2.15.5.3.6. UnionAll

The UnionAll component corresponds to the UNION ALL clause in SQL statements.

Parameter configuration

No parameter configuration is required.

2.15.5.3.7. Dynamic column splitting

Dynamic column splitting allows you to split data records with a dynamic number of columns.

Example

Input data:

```
k1=v1,k2=v2,k3=v3,k4=v4
```

In the preceding example, the data is stored in key-value pairs in the format of key=value. Different data records may have different numbers of key-value pairs, that is, they may have different numbers of columns. In this case, you can use the first-level delimiter, which is comma (,) in the preceding example, to split the data to different key-value pairs. Then, you can use the secondary-level delimiter, which is equal sign (=) in the preceding example, to split each key-value pair to the key and value.

Parameter configuration

Parameter	Description
Select Field	The name of the field to split.
first level column delimiter	The delimiter used to split the field at the first level. Default value: \u0001.
secondary level column delimiter	The delimiter used to split the field at the secondary level. Default value: \u0002.
Add column	The fields that store the split data. Specify a key for each field. An alias is allowed.

2.15.5.3.8. Static column splitting

Static column splitting allows you to split data records with fixed columns that are separated by a fixed delimiter.

Example

You can use commas (,) as the delimiter to split the following data to four new columns, that is, 1111, 2222, 3333, and 4444.

```
1111,2222,3333,4444
```

The static column splitting method is applicable to data records with fixed columns that are separated by a fixed delimiter.

Parameter configuration

Parameter	Description
Select Field	The name of the field to split.
column separator	The delimiter used to split the field. You can use full-width characters or half-width characters as needed.

Parameter	Description
Add column	The fields that store the split data. Specify a key and a sequence number for each field. An alias is allowed.

2.15.5.3.9. Row splitting

Row splitting allows you split a row to multiple rows based on a field by using the specified delimiter.

Example

The following table lists the input data.

id	num
1	1,2

Split the row to multiple rows based on the num field by using the comma (,) as the delimiter, and place the split data in the new field new_num. The following table lists the output data.

id	num	new_num
1	1,2	1
1	1,2	2

Parameter configuration

Parameter	Description	Remarks
Select Field	The name of the field to split.	This parameter is set to num in the preceding example.
Field separator	The delimiter used to split the field. Default value: (\n).	This parameter is set to comma (,) in the preceding example.
Define new column name	The name of the new field that stores the split data.	This parameter is set to new_num in the preceding example.

2.15.5.4. Result tables

2.15.5.4.1. Datahub

Datahub is a real-time data distribution platform that is designed to process streaming data. It provides a channel for the Apsara Stack DTplus platform to process big data. Datahub works with multiple Apsara Stack services to provide an end-to-end data processing solution. Realtime Compute typically uses Datahub to store source and result tables for streaming data processing.

Parameter configuration

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
Output Field	The fields to be returned.
endPoint	The endpoint used to access DataHub. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the Datahub project to which data is to be written. It corresponds to the project parameter in the WITH clause of the CREATE TABLE statement.
topic	The name of the Datahub topic to which data is to be written. It corresponds to the topic parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to access Datahub. It corresponds to the accessId parameter in the WITH clause of the CREATE TABLE statement.
accessKey	The AccessKey secret used to access Datahub. It corresponds to the accessKey parameter in the WITH clause of the CREATE TABLE statement.
maxRetryTimes	The maximum number of retries for writing data to DataHub. It corresponds to the maxRetryTimes parameter in the WITH clause of the CREATE TABLE statement.
batchSize	The number of data records that are written at a time. It corresponds to the batchSize parameter in the WITH clause of the CREATE TABLE statement.
batchWriteTimeoutMs	The interval at which the cache is cleared. It corresponds to the batchWriteTimeoutMs parameter in the WITH clause of the CREATE TABLE statement.
maxBlockMessages	The maximum number of data blocks that are written at a time. It corresponds to the maxBlockMessages parameter in the WITH clause of the CREATE TABLE statement.

Field type mapping

The following table lists the mapping between Datahub and Realtime Compute data types. We recommend that you declare the type mapping in the DDL statement.

Datahub data type	Realtime Compute data type
BIGINT	BIGINT
DOUBLE	DOUBLE
TIMESTAMP	BIGINT
BOOLEAN	BOOLEAN
DECIMAL	DECIMAL

2.15.5.4.2. Log Service

As an all-in-one real-time data logging service, Log Service allows you to quickly finish tasks such as data ingestion, consumption, delivery, query, and analysis without any extra development work. This can help you improve O&M and operational efficiency, and build up the capability to process large amounts of logs in the data technology era.

Parameter configuration

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
Output Field	The fields to be returned.
endPoint	The endpoint used to access Log Service. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the Log Service project to which the data is to be written. It corresponds to the project parameter in the WITH clause of the CREATE TABLE statement.
primaryKey	The primary key field of the output fields.
source	The name of the log source. It corresponds to the source parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to access Log Service.
accessKey	The AccessKey secret used to access Log Service.

Parameter	Description
mode	The mode of data writing. It corresponds to the mode parameter in the WITH clause of the CREATE TABLE statement. Default value: `random`. If you set this parameter to `partition`, data is written by partition.
logStore	The name of the Logstore in the Log Service project to which the data is to be written.

2.15.5.4.3. ApsaraDB for RDS

Alibaba Cloud ApsaraDB for Relational Database Service (RDS) offers stable, reliable, and scalable cloud database services.

Parameter configuration

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
Output Field	The fields to be written to the RDS table.
url	The URL used to access RDS. It corresponds to the url parameter in the WITH clause of the CREATE TABLE statement.
tableName	The name of the RDS table to which data is to be written. It corresponds to the tableName parameter of the WITH clause in the CREATE TABLE statement.
userName	The username used to access RDS. It corresponds to the userName parameter in the WITH clause of the CREATE TABLE statement.
password	The password used to access RDS. It corresponds to the password parameter in the WITH clause of the CREATE TABLE statement.
maxRetryTimes	The maximum number of retries for writing data to RDS. It corresponds to the maxRetryTimes parameter in the WITH clause of the CREATE TABLE statement.
batchSize	The number of data records that are written at a time. It corresponds to the batchSize parameter in the WITH clause of the CREATE TABLE statement.

Parameter	Description
bufferSize	The buffer size after data deduplication. It corresponds to the bufferSize parameter in the WITH clause of the CREATE TABLE statement. You can only use this parameter when the primary key is defined.
flushIntervalMs	The interval at which the data cache is cleared. Unit: milliseconds. It corresponds to the flushIntervalMs parameter in the WITH clause of the CREATE TABLE statement.
excludeUpdateColumns	The fields that will not be updated when Realtime Compute updates data records with the same primary key value. It corresponds to the excludeUpdateColumns parameter in the WITH clause of the CREATE TABLE statement.
ignoreDelete	Specifies whether to skip DELETE operations. It corresponds to the ignoreDelete parameter in the WITH clause of the CREATE TABLE statement.
partitionBy	Specifies the partitioning rule for the result table. Before writing data to the result table, Realtime Compute performs a Hash partitioning based on a partition key. The data records with the same key are then distributed to the same operator. It corresponds to the partitionBy parameter in the WITH clause of the CREATE TABLE statement.
primaryKey	The primary key field of the output fields.

Field type mapping

RDS data type	Realtime Compute data type
TEXT	VARCHAR
BYTE	VARCHAR
INTEGER	INT
LONG	BIGINT
DOUBLE	DOUBLE
DATE	VARCHAR
DATETIME	VARCHAR
TIMESTAMP	VARCHAR

RDS data type	Realtime Compute data type
TIME	VARCHAR
YEAR	VARCHAR
FLOAT	FLOAT
DECIMAL	DECIMAL
CHAR	VARCHAR

JDBC connection parameters

Parameter	Description	Default value	Since version (JDBC driver)
useUnicode	Specifies whether to use the Unicode character set. If you want to set the characterEncoding parameter to gb2312 or gbk, this parameter must be set to true.	*false*	1.1g
characterEncoding	Specifies the character encoding when the useUnicode parameter is set to true. You can set this parameter to gb2312 or gbk.	*false*	1.1g
autoReconnect	Specifies whether to automatically re-establish a connection when the connection to the database is unexpectedly interrupted.	*false*	1.1
autoReconnectForPools	Specifies whether to use the reconnection policy for a database connection pool.	*false*	3.1.3
failOverReadOnly	Specifies whether to set the connection to read-only after the database is automatically reconnected.	*true*	3.0.12

Parameter	Description	Default value	Since version (JDBC driver)
maxReconnects	Specifies the maximum number of reconnection attempts allowed if the autoReconnect parameter is set to true.	*3*	1.1
initialTimeout	Specifies the interval between two reconnection attempts if the autoReconnect parameter is set to true. Unit: seconds.	*2*	1.1
connectTimeout	Specifies the timeout period when you use a socket connection to access the database server. Unit: millisecond. The default value of 0 indicates no timeout (only works on JDK V1.4 and later).	*0*	3.0.1
socketTimeout	The timeout period for a socket operation (read or write). Unit: milliseconds. The default value of 0 indicates no timeout.	*0*	3.0.1

FAQ

- Q: When output data is written to an RDS table, is a new data record generated in the table? If not, is the result table updated based on the primary key value?

  A: If a primary key is defined in the DDL statement, the result table is updated by using the statement: `INSERT INTO tablename(field1,field2, field3, ...) VALUES(value1, value2, value3, ...) ON DUP LICATE KEY UPDATE field1=value1,field2=value2, field3=value3, ...;` . For a data record, if the value of the primary key field does not exist, the record is inserted to the table as a new row. If the value of primary key field exists, the original row in the table is updated. If no primary key is declared in the DDL statement, output data is added to the result table by using the `INSERT INTO` statement.

- Q: How can I perform GROUP BY operations based on the unique index of an RDS table?

A: An RDS table has only one auto-increment primary key, which cannot be declared as the primary key in the DDL statement of a real-time computing node. If you want to perform GROUP BY operations based on the unique index of the RDS table, declare the unique index in the Primary Key() element of the DDL statement.

2.15.5.4.4. Table Store

Table Store is a distributed NoSQL database service built on the Apsara distributed operating system of Alibaba Cloud. Based on data sharding and load balancing technologies, Table Store has high performance in scaling out and handling concurrent transactions. You can use Table Store to store and query large amounts of structured data.

Parameter configuration

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
Output Field	The fields to be written to the Table Store table.
instanceName	The name of the Table Store instance. It corresponds to the instanceName parameter in the WITH clause of the CREATE TABLE statement.
tableName	The name of the Table Store table to which data is to be written. It corresponds to the tableName parameter in the WITH clause of the CREATE TABLE statement.
endPoint	The endpoint used to access Table Store. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to access Table Store. It corresponds to the accessId parameter in the WITH clause of the CREATE TABLE statement.
accessKey	The AccessKey secret used to access Table Store. It corresponds to the accessKey parameter in the WITH clause of the CREATE TABLE statement.
valueColumns	The names of fields to be inserted to the result table. Separate multiple names with commas (,).
bufferSize	The buffer size after data deduplication. It corresponds to the bufferSize parameter in the WITH clause of the CREATE TABLE statement.
batchWriteTimeoutMs	The timeout period for writing data to Table Store. Unit: milliseconds. It corresponds to the batchWriteTimeoutMs parameter in the WITH clause of the CREATE TABLE statement.

Parameter	Description
batchSize	The maximum number of retries for writing data to Table Store. It corresponds to the batchSize parameter of the WITH clause in the CREATE TABLE statement.
retryIntervalMs	The retry interval at which data is written. It corresponds to the retryIntervalMs parameter in the WITH clause of the CREATE TABLE statement.
ignoreDelete	Specifies whether to skip DELETE operations. It corresponds to the ignoreDelete parameter in the WITH clause of the CREATE TABLE statement.
primaryKey	The primary key field of the output fields.

Field type mapping

Table Store data type	Realtime Compute data type
INTEGER	BIGINT
STRING	VARCHAR
BOOLEAN	BOOLEAN
DOUBLE	DOUBLE

2.15.5.4.5. MaxCompute

Realtime Compute supports creating a MaxCompute table as the result table.

Parameter configuration

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
tableName	The name of the MaxCompute table to which data is to be written.
Output Field	The fields to be written to the MaxCompute table.
endPoint	The endpoint used to access MaxCompute. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.

Parameter	Description
tunnelEndPoint	The endpoint of the Tunnel service, which is required for a MaxCompute project deployed in a Virtual Private Cloud (VPC). It corresponds to the tunnelEndPoint parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the MaxCompute project to which data is to be written. It corresponds to the project parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to access MaxCompute. It corresponds to the accessId parameter in the WITH clause of the CREATE TABLE statement.
accessKey	The AccessKey secret used to access MaxCompute. It corresponds to the accessKey parameter in the WITH clause of the CREATE TABLE statement.
partition	The partitions to which the data is to be written. It corresponds to the partition parameter in the WITH clause of the CREATE TABLE statement. This parameter must be specified for a partitioned table. For example, if the partition name of a table is `ds=20180905`, you can specify the parameter as `` `partition` = 'ds=20180905' ``. Separate multiple levels of partitions with commas (,), for example, `` `partition` = 'ds=20180912,dt=xxxyyy' ``.

Note Realtime Compute writes cached data to a MaxCompute table every time when a checkpoint is reached.

Field type mapping

MaxCompute data type	Realtime Compute data type
TINYINT	TINYINT
SMALLINT	SMALLINT
INT	INT
BIGINT	BIGINT
FLOAT	FLOAT

MaxCompute data type	Realtime Compute data type
DOUBLE	DOUBLE
BOOLEAN	BOOLEAN
DATETIME	TIMESTAMP
TIMESTAMP	TIMESTAMP
VARCHAR	VARCHAR
STRING	STRING
DECIMAL	DECIMAL
BINARY	VARBINARY

FAQ

Q: Does a real-time computing node clear the result table before it writes data to the MaxCompute sink that is in Stream mode when `isOverwrite` is set to `true`?

A: The `isOverwrite` parameter is set to `true` by default. That is, a real-time computing node clears the result table and result data before it writes data to the sink. Every time a real-time computing node starts or resumes after being paused, it clears data of the existing result table or the result partition before it writes data. Certain data may be lost when data is cleared after a paused real-time computing node is resumed.

2.15.5.5. FAQ

This topic describes the frequently asked questions (FAQs) about Stream Studio.

Q: What computing engine do I need to activate before using Stream Studio?

A: You must first activate Realtime Compute because Stream Studio is a development platform based on Realtime Compute.

Q: Where can I create a Realtime Compute project? How do I bind the project to Stream Studio?

A: You can create a Realtime Compute project in the Realtime Compute console. After a project is created, you can bind it to an existing DataWorks workspace in the DataWorks console or directly create a workspace and bind the project to it. After the Realtime Compute project is bound to your workspace, you can develop real-time computing nodes in Stream Studio.

Q: What are the advantages of the directed acyclic graph (DAG) mode in Stream Studio? What are the similarities and differences between the DAG mode and SQL mode?

A: Stream Studio supports both the DAG mode and the SQL mode to develop real-time computing nodes. In DAG mode, you can perform drag-and-drop operations on components to configure real-time computing nodes without writing code. In this mode, what you see is what you get. You can also switch to the SQL mode to configure nodes by writing SQL statements.

Q: What types of SQL does Stream Studio support?

A: Realtime Compute is based on Apache Flink. Therefore, Stream Studio supports Flink SQL.

2.16. Graph Studio

2.16.1. Overview

Graph Compute is a next-generation one-stop platform for graph data management and analysis. Based on Graph Compute, Graph Studio provides an all-in-one R&D platform for Graph Compute. This topic describes how to use Graph Compute through Graph Studio.

Graph Compute allows you to model, import, and modify graph data and use the standard Gremlin language of Apache TinkerPop to query graph data. It also supports common graph analysis algorithms. Graph Compute features fast data loading, auto scaling, millisecond-level query latency, hybrid compute engines for online and offline graph computing, and shared data storage. You can use Graph Compute to easily build graph applications with large amounts of relational data.

Graph Studio provides graph application developers with all-in-one R&D services, including instance modeling, data import, data query, visualized analysis, instance management, and node O&M.

> **Note** You must bind a Graph Compute instance to your DataWorks workspace to use Graph Studio. The message shown in the following figure appears if you have not bound a Graph Compute instance to the current workspace. Bind a Graph Compute instance accordingly.

- Instance modeling: allows you to create vertices and edges to design a graph schema for your Graph Compute instance. You can configure the vertices, edges, and their attributes flexibly.
- Data import: allows you to create automatic sync nodes to import data to vertices and edges. You can schedule the sync nodes flexibly to automatically update data. Currently, you can import data stored in MaxCompute tables to Graph Compute. For more information, see Data import.
- Data query: allows you to use the standard Gremlin language of Apache TinkerPop to query graph data. For more information, see Data query.
- Node O&M: allows you to quickly filter and view the details of sync nodes. For more information, see Node O&M.

2.16.2. Instance modeling

During instance modeling, you can create vertices and edges to design a graph schema for your Graph Compute instance in visual mode or tabular mode.

Go to the Model Design page

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Graph Studio**.
3. On the Graph Studio page, click **Model Design**.

Visual mode

On the **Model Design** page, click the Graph Compute instance for which you want to design a schema. By default, the tab for designing the schema in **visual mode** appears.

- Create a vertex

  You can drag and drop the vertex icon to the canvas and set vertex parameters to create a vertex.

  Drag and drop the  icon to the canvas. In the right-side **Add To** dialog box that appears, set parameters as required and click **Save**.

Parameter	Description
Types	The type of the item to create. Valid values: **Point** and **Side**.
Type Name	The name of the vertex. A vertex name can contain letters, digits, and underscores (_). It can be up to 128 characters in length. **Note** The name of each vertex in the same Graph Compute instance must be unique.
Display Name	The display name of the vertex.
Remarks	The description of the vertex.
Display Color	The default color of the vertex in visual mode. Default value: *green*.
Display Size	The default size of the vertex in visual mode. Default value: *M*.
Display Content	The display content of the vertex in visual mode. Default value: the value of the **Type Name** parameter.
Attribute Configuration	You can view the name, type, description, default value, and primary key of each property of the vertex. You can click **+New Attribute** to add a property for the vertex. **Note** You can delete a property that has not been saved.

- Create an edge

  i. Move the pointer over the vertex where you want to create an edge. The  icon appears.

  ii. Drag and drop the  icon to the target vertex to connect to. In the right-side **Add To** dialog box that appears, set parameters as required.

Parameter	Description
Types	The type of the item to create. Valid values: **Point** and **Side**.

Parameter	Description
Type Name	The name of the edge. Note The name of each edge in the same Graph Compute instance must be unique.
Display Name	The display name of the edge.
Display Color	The default color of the edge in visual mode. Default value: *primary*.
Display Content	The display content of the edge in visual mode. Default value: the value of the *Type Name* parameter.
Remarks	The description of the edge.
Attribute Configuration	You can view the name, type, description, and default value of each property of the edge and perform operations on the properties. You can click **+New Attribute** to add a property for the edge.
Relationship Configuration	You must select two vertices from the created ones to set them as the source and target vertices of the edge. You can click **+Add Point-Edge Relationship** to add a vertex-edge connection for the edge as required. Note An edge can have multiple vertex-edge connections.

iii. Click **Save** to create the edge.

- Modify a vertex

Note Note the following limits when you modify a vertex:

- You cannot change the name of the vertex, but you can change the description, display color, display size, and display content of it.
- You cannot add a property as the primary key to the vertex.
- You cannot delete the primary key property from the vertex. The corresponding sync node may fail after you delete a property from the vertex. In this case, you must manually modify the node. Delete a property with caution.
- You can only change the description of existing properties for the vertex.

i. Click a vertex that you want to modify. The **Overview** dialog box appears on the right side.

ii. Click **Edit**. In the **Update** dialog box that appears, change the parameter configuration.

iii. Verify that the settings are correct and click **Save**.

- Modify an edge

> **Note** Note the following limits when you modify an edge:
>
> - You cannot change the name of the edge, but you can change the description, display color, and display content of it.
> - You can only change the description of existing properties for the edge.
> - You can add or delete properties for the edge. However, make sure that at least one vertex-edge connection exists.
> - The corresponding sync node may fail after you modify properties or vertex-edge connections of the edge. In this case, you must manually modify the node. Modify properties or vertex-edge connections with caution.

i. Click an edge that you want to modify. The **Overview** dialog box appears on the right side.

ii. Click **Edit**. In the **Update** dialog box that appears, change the parameter configuration.

iii. Verify that the settings are correct and click **Save**.

- Delete a vertex or an edge

i. Right-click a vertex or an edge that you want to delete.

ii. Select **Delete**.

iii. In the **Note** dialog box that appears, click **OK**.

Tabular mode

On the **Model Design** page, click the Graph Compute instance for which you want to design a schema. By default, the tab for designing the schema in **visual mode** appears.

Click **Tabular Mode** in the upper-right corner to switch to the tabular mode.

- Create a vertex

  In this mode, you can set relevant parameters to create a vertex.

  i. Move the pointer over the + icon and click **New Point**.

     You can also click **Add To** in the **Model Design** section to create a vertex.

  ii. In the **Add To** dialog box that appears, set parameters as required. For more information about the parameters, see the parameter description for the visual mode.

  iii. After the configuration is completed, click **Save**.

- Create an edge

  i. Move the pointer over the + icon and click **New Side**.

     You can also click **Add To** in the **Model Design** section to create an edge.

  ii. In the **Add To** dialog box that appears, set parameters as required. For more information about the parameters, see the parameter description for the visual mode.

  iii. After the configuration is completed, click **Save**.

- Modify a vertex

  Click **Change Settings** in the Actions column of a vertex that you want to modify. In the **Update** dialog box that appears, change the parameter configuration as required and click **Save**.

> **Note** Note the following limits when you modify a vertex:
>
> - You cannot change the name of the vertex, but you can change the description, display color, display size, and display content of it.
> - You cannot add a property as the primary key to the vertex.
> - You cannot delete the primary key property from the vertex. The corresponding sync node may fail after you delete a property from the vertex. In this case, you must manually modify the node. Delete a property with caution.
> - You can only change the description of existing properties for the vertex.

- Modify an edge

  Click **Change Settings** in the Actions column of an edge that you want to modify. In the **Update** dialog box that appears, change the parameter configuration as required and click **Save**.

> **Note** Note the following limits when you modify an edge:
>
> - You cannot change the name of the edge, but you can change the description, display color, and display content of it.
> - You can only change the description of existing properties for the edge.
> - You can add or delete properties for the edge. However, make sure that at least one vertex-edge connection exists.
> - The corresponding sync node may fail after you modify properties or vertex-edge connections of the edge. In this case, you must manually modify the node. Modify properties or vertex-edge connections with caution.

2.16.3. Data import

Currently, Graph Studio only allows you to import data stored in MaxCompute tables to Graph Compute.

Go to the Data Import page

After you create a vertex or an edge, a corresponding sync node is automatically generated for the vertex or edge. You can import data stored in MaxCompute tables to the vertex or edge in **visual mode** or **tabular mode**. Follow these steps to open the data import page in the visual mode and tabular mode respectively:

- **Visual mode**

  Open the Graph Compute instance. The tab for importing data in **visual mode** appears by default, where you can import data to vertices and edges.

  - Import data to a vertex: Right-click a vertex and select **Data Import**.
  - Import data to an edge: Right-click an edge, select **Data Import**, and then click a vertex-edge connection.

- **Tabular mode**

  Open the Graph Compute instance. The tab for importing data in visual mode appears by default. Click **Tabular Mode** in the upper-right corner switch to the tabular mode. Click **Data Import** in the Actions column of a vertex or an edge to import data.

Configure the sync node

After you select or click **Data Import** for a vertex or an edge, the **DataStudio** page appears.

- Import data to a vertex
  i. Configure the source and destination connections for the sync node.

     Set Connection in the **Source** section to ODPS and specify the MaxCompute table and partitions from which data is imported. The Connection parameter in the **Target** section is set to the target vertex of the Graph Compute instance by default.

  ii. Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right. You can click **Add** to add a field or move the pointer over a field and click the **Delete** icon to delete the field.

  iii. Configure the channel.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read and write data to data storage within a single sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The servers on which nodes are run. If an excessively large number of nodes are run on the default resource group, some nodes may be delayed due to insufficient resources. In this case, you can add a custom resource group.

  iv. Configure the node properties.

     Click the **Properties** tab in the right-side navigation pane. On the **Properties** tab that appears, set the parameters. For more information, see Schedule.

  v. Commit the node.

     After you set the properties, click **Save** in the tool bar to commit the node to the development environment. After you commit the node to the development environment, the node is unlocked.

  vi. Deploy the node.

     For more information, see Deploy.

  vii. Test the node in the production environment.

     For more information, see Recurring tasks.

- Import data to an edge

The procedure of importing data to an edge is similar to that of importing data to a vertex. The difference is that you must specify a target vertex-edge connection to which data is imported. In addition, you must specify the primary keys of the source and destination vertices connected by the edge For more information, see Import data to a vertex.

> **Note** If you want to delete a vertex or an edge from a schema, you must also manually delete it from the sync node.

2.16.4. Data query

Graph Studio allows you to use the graph traversal language, Gremlin, of Apache TinkerPop to query graph data.

Create a graph query node

1. Go to the Graph Studio page. In the left-side navigation pane, click **Data Query**.
2. On the Data Query page, move the pointer over the **Create** icon and choose **Create > Graph Query**.
3. In the **Create Node** dialog box that appears, set the **Diagram Example**, **Location**, **Node Name** parameters.
4. Click **Submit** to create the graph query node.
5. Enter and run the Gremlin query statement in the editor. The query result is returned.

View the query results

The following figure shows the query results of running the `g.V().limit(10)` statement.

As shown in the preceding figure, the results section provides three tabs to display the query results in graph mode, display the query results in tabular mode (in the form of an Excel file), and display operational logs, respectively. By default, operational logs appear when you run the graph query node. If the query results contain vertices or edges, they are provided in graph mode. Otherwise, the query results are provided in tabular mode.

- Graph mode

  In graph mode, vertices or edges are provided in a graph so that you can clearly view them. You can click a vertex or an edge to view its detailed information and properties.

- Tabular mode

  In tabular mode, the detailed information and properties of each vertex or edge are provided in a table.

- Operational logs

  The log tab displays the operational logs generated when you run the Gremlin statement in the graph query node.

2.16.5. Node O&M

The Operation and Maintenance page displays all sync nodes of a Graph Compute instance, so that you can view the data update status.

Click **Operation and Maintenance** in the upper-right corner to go to the corresponding page. You can also filter sync nodes by instance name, vertex or edge name, running status, node type, and data timestamp to find the required sync node and view its details.

2.17. Data Protection

2.17.1. Overview

Data Protection is a data security management platform. It can be used to detect data assets, detect sensitive data, classify data, de-identify data, monitor data access behavior, report alerts, and audit risks.

Data Protection provides security management services for MaxCompute.

Access Data Protection

1. Log on to the DataWorks console.
2. On the DataWorks page that appears, click the icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now** to go to the Data Protection page.

Features

Data Protection provides the following features:

- Intelligent sensitive data detection

  Data Protection automatically detects an enterprise's sensitive data based on self-training models and algorithms, and clearly displays statistics on data types, volume, and visitors. It also recognizes custom data types.

- Accurate data classification: Data Protection allows you to classify data and create custom levels for better data management.
- Flexible data de-identification

  Data Protection provides diverse and configurable methods for dynamic data de-identification.

- Risky behavior monitoring and auditing

  Data Protection uses various correlation analysis algorithms to detect risky behavior. It also provides alerts and supports visualized auditing for detected risks.

2.17.2. Configure rules for defining sensitive data

This topic describes how to configure rules for defining sensitive data.

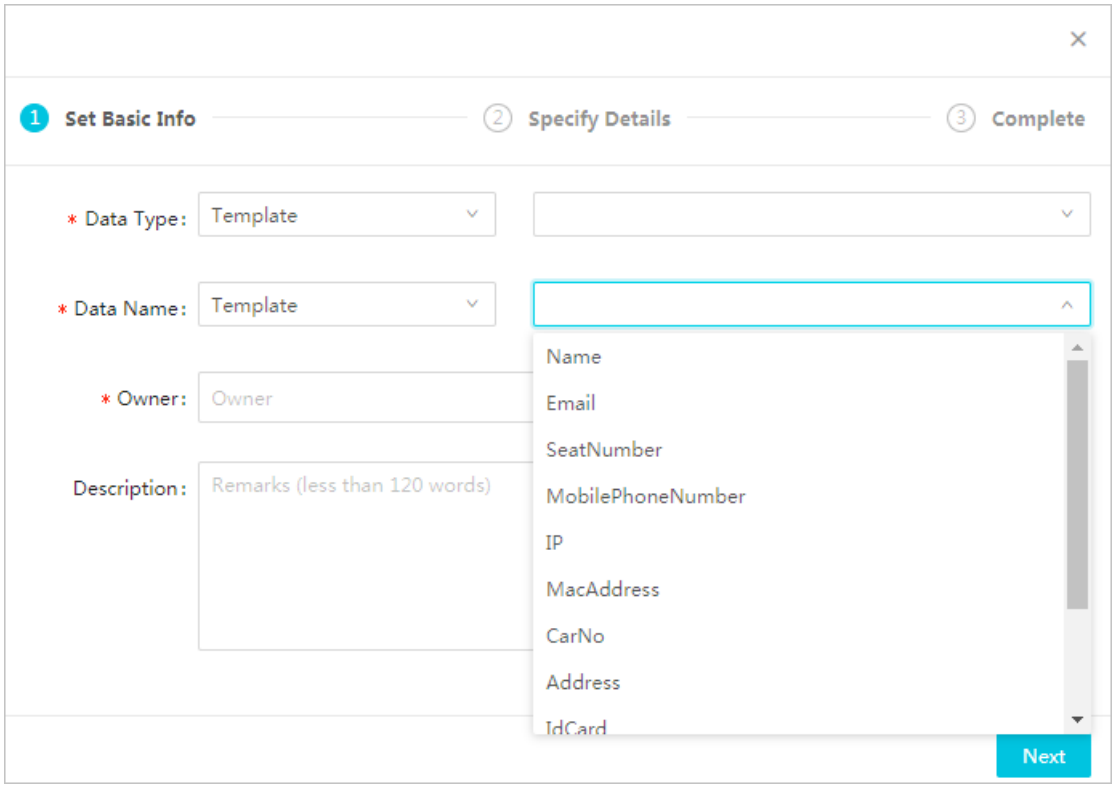
Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now** to go to the **Data Security Guard** page.
4. In the left-side navigation pane, choose **Management > Data Definition**. On the Data

Recognition Rules page that appears, click **Create Rule**.

5. In the dialog box that appears, set parameters in the **Set Basic Info** step.

   You can create a template-based identification rule or a custom identification rule.



Parameter	Description
Data Type	The category of the rule. You can select Template or Custom from the Data Type drop-down list. ○ If you select **Template**, you can select **Personal Information**, **Merchant Information**, or **Company Information** from the right drop-down list. ○ If you select **Custom**, you can enter a data type.
Data Name	○ If you select **Template** from the drop-down list, you can select a built-in identification rule template from the right drop-down list. You can select **Email**, **SeatNumber**, **MobilePhoneNumber**, **IP**, **MacAddress**, **CarNo**, **PostCode**, **IdCard**, or **BankCard**. ○ If you select **Custom**, you can enter a data name.
Owner	The owner of the rule.
Description	The description of the rule.

6. Click **Next**. Set the **Level** and **Data Definition** parameters.

Parameter	Description
Level	The security level of the sensitive data to which the rule is applied. If the existing security levels cannot meet your needs, click **Levels** in the left-side navigation pane to change the level settings.
Content Scanning	Specifies whether to enable content scanning. This option is selected by default for all the built-in data identification templates. ○ If you select a template, you cannot modify the identification rule, but you can verify the accuracy of the identification rule. ○ If you select regular expression matching, you can customize the identification rule.
Field Scanning	Specifies whether to enable field scanning. This approach provides two matching methods: exact matching and fuzzy matching of field names. Multiple-field matching is supported, and the relationship between the fields is OR.

7. Click **Next**. After you confirm the configuration, click **Save and Apply**.

> **Note** When you create a rule to define sensitive data, note the following:
> - The rule name must be unique.
> - The content scanning and field scanning configuration must be unique.
> - You can only view the sensitive data that is detected based on the data identification rule one day after the rule takes effect.

2.17.3. View the distribution of sensitive data

On the next day after you configure and activate sensitive data identification rules as a data security administrator, you can access Data Recognition to view the distribution of sensitive data.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. In the left-side navigation pane, click **Data Recognition**. On the Data Recognition page that appears, you can view the overall data distribution and field details.

2.17.4. View the information about data activities

On the next day after you configure and activate sensitive data identification rules as a data security administrator, you can access Data Activities to view related activity statistics, trend, and details.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. In the left-side navigation pane, click **Data Activities** to go to the **Data Activities** page.

The Data Activities page allows you to view the information of each activity that involves sensitive data. On the Manipulations and Queries tab, you can view the statistics, trend, user, and details of data access activities. On the Export tab, you can view the statistics and details of data export.

2.17.5. View the data audited as risky

Data activities are audited manually or based on the risk identification rules and AI-based identification rules. The Data Risks page displays data activities that are audited as risky. You can comment audit results as required.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now** to go to the **Data Security Guard** page.
4. In the left-side navigation pane, click **Data Risks** to filter and view the data audited as risky as needed.

2.17.6. Manage the data security levels

When creating a rule, you can specify a security level for the data to which the rule applies. On the Levels page, you can create and delete security levels. You can also modify the priority of each security level and manage rules by security level.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now** to go to the **Data Security Guard** page.
4. In the left-side navigation pane, choose **Management > Levels**.

   On the **Levels** page, you can create and delete security levels. You can also modify the priority of each security level and manage rules by security level.

Operation	Description
Create a security level	Click **Create Level**. Specify the security level name and operator.
Manage rules by security level	Find the target security level and click the  icon in the Actions column. In the Manage Rules by Level dialog box that appears, you can select a rule and adjust its security level.
Delete a security level	Find the target security level and click the  icon in the Actions column. In the dialog box that appears, click **Delete**.
Modify the priority of a security level	Find the target security level. Drag and drop the  icon in the Actions column.

2.17.7. Manage data that is incorrectly detected

On the Manual Check page, you can manually correct the sensitive data that is incorrectly detected by rules. For example, you can delete incorrectly detected data, change the type of the detected data, and delete or recover data in batches.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now** to go to the **Data Security Guard** page.
4. In the left-side navigation pane, choose **Management > Manual Check**.

   On the Manual Check page, you can delete incorrectly detected data, change the type of the detected data, and delete or recover data in batches.

   - To delete a data record that is incorrectly detected, turn off the switch in the Status column of the data record.

     > **Note** You can recover data records that you have deleted.

   - To change the type of a data record, click the edit icon next to the name of the target rule and select a rule.

     > **Note** You can only select a rule that has been configured in DataWorks.

   - To delete or recover multiple data records at the same time, you can select the data records and click **Remove** or **Recover**.

2.17.8. Customize de-identification rules

This topic describes how to customize de-identification rules in Data Security Guard so that DataWorks can dynamically de-identify the results of ad hoc queries.

Prerequisites

Sensitive data detection rules are created and data security levels are specified. For more information, see Configure rules for defining sensitive data and Manage the data security levels.

Go to the Data Masking page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now**.
4. In the left-side navigation pane, choose **Management > Data Masking**.

   The **Data Masking** page has two tabs: **Data Masking** and **Whitelist**.

Customize de-identification rules in Data Security Guard

1. Set the **Masking Scene** parameter to **Global Config (_default_scene_code)** and click **Create**

Rule in the upper-right corner.

2. In the **Create Rule** dialog box, set the **Rule**, **Owner**, and **Method** parameters.

   > **Note** Data Security Guard provides three methods for de-identifying ID card numbers and email addresses, including **Pseudonymisation**, **Hashing**, and **Masking Out**. For other types of data, Data Security Guard only provides the **Hashing** and **Masking Out** methods.

   - **Pseudonymisation**

     This method replaces the text of a data record with an artificial pseudonym of the same data type. If you select this method, specify a security domain. Rules with different security domains generate different pseudonyms for the same data record.

   - **Hashing**

     If you select this method, specify a security domain. Rules with different security domains generate different hash values for the same data record.

   - **Masking Out**

     This method uses asterisks (*) to mask specified parts of a data record. It is commonly used.

Parameter	Description
Recommended	You can select recommended policies to mask data of common types such as ID card numbers and bank card numbers.
Custom	You can flexibly specify whether to mask the specified number of characters at the first, middle, or last part of a data record.

3. Click **OK**.
4. On the **Data Masking** tab of the **Data Masking** page, set the status of the de-identification rule to **Active** or **Inactive**.

   You can click the **Test** icon in the Actions column of the rule to test whether it works.

5. Click the **Whitelist** tab. On the Whitelist tab, click **Add Account**.
6. In the **Add Account** dialog box, set the **Rule**, **Account**, **Effective From**, and To parameters. For more information about user groups, see Manage user groups.

   > **Note** If you query data beyond the time range specified for the whitelist, the query results will be de-identified.

7. Click **Save**.

Verify the de-identification effect in DataWorks

After you create and configure de-identification rules, DataWorks dynamically de-identifies the results of queries in your workspace based on the rules.

> Note You must first turn on Mask Data in Page Query Results for your workspace in the DataWorks console.

2.17.9. Manage user groups

You can create a user group on the GroupManagement page and reference it in a de-identification whitelist. You can also copy, edit, and delete user groups on the GroupManagement page.

Go to the GroupManagement page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now**.
4. In the left-side navigation pane, choose **Management > GroupManagement**. The GroupManagement page appears.

Create a user group

1. On the **GroupManagement** page, click **Create Group** in the upper-right corner.
2. In the **Create Group** dialog box that appears, set the parameters described in the following table.

Parameter	Description
Name	Enter the name of the user group. > Note The name of the user group must be unique.
Owner	Enter the owner of the user group.
Source Type	Specify the source of accounts in the user group. Valid values: ○ **Text**: If you select this option, click **Upload File** next to **Source File**, select a local file to upload, and then click **Open**. ○ **Select Existing Accounts**: If you select this option, select the accounts to add next to **Add Members** and click >.

3. Click **Save**.

Copy a user group

On the **GroupManagement** page, find the target user group and click  in the Actions column.

An identical user group is generated.

> Note
>
> - The name of the generated user group contains the -copy suffix. You can click to change the name.
> - You can only copy the content but not the dependencies of a user group.

Edit a user group

To edit an existing user group, follow these steps:

1. On the **GroupManagement** page, find the target user group and click in the Actions column.
2. In the **Edit Group** dialog box that appears, modify parameters such as **Name**, **Owner**, and **Source Type**.
3. Verify the settings and click **Save**.

Delete a user group

To delete a user group, find the user group on the GroupManagement page and click **Delete** in the Actions column. In the dialog box that appears, click **Delete**.

> Note You cannot delete a user group that is referenced in a de-identification whitelist.
>
> If you still want to delete the user group, delete the user group from the corresponding de-identification whitelist first.

2.18. App Studio

2.18.1. Overview

App Studio is a tool designed to help you develop data products. It comes with a rich set of front-end components that you can drag and drop to simply and quickly build front-end apps.

With App Studio, you do not need to download and install a local integrated development environment (IDE) or configure and maintain environment variables. Instead, you can use a browser to write, run, and debug apps and enjoy the same programming experience as that in a local IDE. App Studio also allows you to publish apps online.

Advantages

App Studio has the following core advantages:

- Data development anytime, anywhere

  You do not need to download and install a local IDE or configure and maintain environment variables. Instead, you can use a browser to develop data in your office, at home, or anywhere that you can connect to the network.
- Editor with complete features

App Studio provides a browser-based editor that allows you to easily write, run, and debug projects. When you enter the code, App Studio provides code hinting, code completion, and repair suggestions. You can also find all references and the definition of a method to automatically generate code.

- Online debugging

  App Studio comes with all breakpoint types and operations of a local IDE. It supports thread switching and filtering, variable checking and watching, remote debugging, and hot code replacement.

- Multi-feature terminal

  You can directly access the runtime environment, which is currently built based on CentOS as the base image. The multi-feature terminal supports all bash commands, including vim and other interactive commands.

- Collaborative coding

  You and your team members can use App Studio to share the development environment for collaborative coding. Currently, App Studio allows a maximum of eight users to edit the same file of a project online concurrently, improving work efficiency. In the future, the collaborative coding component will support chatting, bullet screen messages, code annotations, videos, and other features to make teamwork efficient and pleasant.

- Plug-in system

  App Studio supports business plug-ins, tool plug-ins, and language plug-ins.

  - App Studio allows you to customize any required menu or add any service portal based on your business needs.
  - You can customize project management processes, project types, and templates dedicated to your business.
  - You can develop common tools, such as enhanced Git features, code rule scanning, keyboard shortcuts, enhanced editing features, and code snippets, and integrate them into App Studio.
  - You can use language plug-ins to enrich the languages supported by App Studio, enabling App Studio to serve users with more languages while addressing your own business needs.

- Visual building

  App Studio provides a WYSIWYG designer that has rich components and deeply integrates DataService Studio and DataStudio. Among all components of DataWorks, you can call DataWorks API operations only in App Studio. In addition to calling the API operations, you can quickly build front-end apps by dragging and dropping components and configuring them in the WYSIWYG designer based on the santa file system, developing web apps without code.

- Rich templates and flexible project management

  App Studio provides rich project templates, allowing you to develop your project accordingly with fewer steps and higher efficiency. You can also save your project as a template for future development and use, or share it with other users.

2.18.2. Get started with App Studio

To build a data portal, engineers need to develop data, build backend services, and develop front-end pages. This topic describes the basic features of App Studio and how to use App Studio.

Originally, DataWorks is mainly used by data engineers to implement offline or streaming data development. As DataWorks becomes increasingly easy to use, many roles such as algorithm engineers, BI analysts, operators, and product managers who are familiar with SQL can use DataWorks to develop data.

App Studio helps different types of users quickly build webpages for data viewing and apps for data query.

Go to the App Studio page

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products** > **App Studio**. The **Projects** page appears.

Create a front-end project

App Studio provides complete front-end development capabilities that allow you to develop front-end projects in the same way as in a local integrated development environment (IDE). Without the need to master or understand any new concepts, you can create front-end projects in App Studio and develop HTML, CSS, JavaScript, and React files in a way that you are familiar with.

1. Create a project based on the sample project.
   i. Go to the **App Studio** page and click **Projects** in the left-side navigation pane. On the Projects page, click **Create Project from Code**.
   ii. On the **Create Project** page, set the **Name** and **Description** parameters, and set the runtime environment to **react-demo**.

   > Note
   > - The name of the project must start with a letter and can contain digits, letters, underscores (_), and hyphens (-).
   > - The description of the project can be 2 to 500 characters in length.

   iii. After the configuration is completed, click **Submit**.
2. Set running parameters.

   In the upper-right corner, choose **Edit Config** > Edit Configurations. In the **Run/Debug Configurations** dialog box that appears, set the required parameter. Select the instance type and specify the port number as required. You can use the default configuration unless otherwise required. Then, click **OK**.

Parameter	Description
Install Cmd	The command used to install the dependency, for example, npm install.
Start Cmd	The command used to start the app, for example, npm start.

Parameter	Description
Environment Variables	The environment variables.
Initialize Script	The path of the script used to initialize a container in the code library.
PORT	The port of the Elastic Compute Service (ECS) instance. Default value: 3000.
ECS Instance	The instance type. Valid values: 1vCPU 2GMemory, 2vCPU 3GMemory, 4vCPU 8GMemory, and 8vCPU 16GMemory.

3. Run the project.

   Click the Run icon in the upper-right corner to run the project. Currently, you can run the `tnpm start` command to start front-end projects. You can seamlessly run projects with *webpack-dev-server* configured.

   During project running, you can view the dependency installation and app startup logs. After the project running is completed, the Preview tab appears in the right-side navigation pane. You can edit and save the code in real time. The edited code takes effect immediately.

4. Access the project.

   Click the **Preview** tab in the right-side navigation pane, and click the arrow next to the access link to open the project.

   In App Studio, you can edit and develop front-end projects in the same way as in a local IDE. App Studio supports code completion, method signature, refactoring, and redirection for HTML, CSS, LESS, SCSS, JavaScript, TypeScript, JSX, and TSX files. In addition, you can develop front-end projects based on templates without the need to build any environment or download any dependency.

Create a backend project

1. Create a project based on the sample project.
   i. Go to the **App Studio** page and click **Projects** in the left-side navigation pane. On the Projects page, click **Create Project from Code**.
   ii. On the **Create Project** page, set the **Name** and **Description** parameters, and set the runtime environment to **springboot**.
   - The name of the project must start with a letter and can contain digits, letters, underscores (_), and hyphens (-).
   - The description of the project can be 2 to 500 characters in length.

   iii. After the configuration is completed, click **Submit**.
2. Set running parameters.

   In the upper-right corner, choose **Edit Config** > Edit Configurations. In the **Run/Debug Configurations** dialog box that appears, set the required parameter and then click **OK**.

Parameter	Description
Main class	Select the main method. If no main method is available, check whether your project has a main method.
VM options	The virtual machine (VM) options.
Program arguments	The app parameters.
Environment Variables	The environment variables.
JRE	The Java runtime environment (JRE). By default, this parameter cannot be modified.
PORT	The port of the ECS instance. Default value: *7001*.
ECS Instance	The instance type. Valid values: **1vCPU 2GMemory**, **2vCPU 3GMemory**, **4vCPU 8GMemory**, and **8vCPU 16GMemory**.
Pre-Launch Option	The commands to be run before the project is run. You can specify up to three commands.
Enable Hot Code	Specifies whether to enable hot code replacement.

You can click **Add** on the left of the Run/Debug Configurations dialog box to add multiple configurations for running.

3. Run the project.

   Click the Run icon in the upper-right corner to run the project.

   The first time that the project is run takes a longer time because App Studio needs to allocate the ECS instance and initialize the language service. After the running is completed, the Runtime tab appears, showing the access link.

4. Access the project.

   Click **Open Link** to access the project.

Append /testapi to the link and refresh the page.

Understand App Studio

The following operations are supported for created projects:

- Top navigation bar
  - **Project**

    From the Project menu, you can configure the project or view detailed information by selecting **Character Set** or **Project Information**. Provided information about the current project includes the ID specified by **Project ID**, name specified by **Project Name**, type specified by **Project Type**, creation time specified by **Created At**, and **UUID**.

  - **File**

    From the File menu, you can create a file or open a recently created file by selecting **Create File** or **Re-Open Most Recent Files**.

  - **Edit**

    From the Edit menu, you can perform common editing operations. To search all the code in the project and open the related file, select Find in Path.

- **Version**

  From the Version menu, you can select **Switch Branch**, **View Changes**, **Submit**, **View Log**, **Connect to Remote Repo**, and **Merge Abort**.

  - **Switch Branch**

    In the Check Out Branch dialog box, you can click **+Create Branch** to create a local branch and push it to the remote repo. You can click a local branch and select **checkout** from the shortcut menu on the right to switch to the branch. You can also select **merge** to merge the selected branch to the current branch.

    You can click a remote branch and select **check out as a new local branch** from the shortcut menu on the right to check out the remote branch locally. Then rename the branch. You can also select **merge** to merge the selected branch to the current branch.

  - **View Changes**

    Click **View Changes** to view the list of edited files on a local branch in the right-side navigation pane.

  - **Submit**

    Click Submit to commit edits on a local branch for staging. You must enter the commit information.

  - **View Log**

    On the Log page, you can view all commit records of branches and filter them.

  - **Connect to Remote Repo**

    You can associate a new project with a remote repo for version control.

- **View**

  You can click **Toggle Full Screen** or press **Esc** on the keyboard to enter or exit the full screen mode of the page. You can also click **Hide Sidebar** or **Hide Status Bar** to hide the right-side navigation pane or the status bar. If they are hidden, you can click Show Sidebar or Show Status Bar to show them respectively.

- **Debug**

  - If you create a front-end project, you can set running parameters and add custom images.
  - App Studio supports Java-based debugging. In addition to setting running parameters and adding custom images, you can perform many other operations for debugging backend projects. You can also perform full or incremental builds and compile the Main.java file.

- **Settings**

  From the Settings menu, you can set the Git configuration to import the Git code to create a project. You can also configure your preference and shortcut keys.

- **Deploy**

  You can choose **Deploy** > **Download Source Code** to download the source code.

- **Template**

  You can choose **Template** > **Manage Templates** to go to the **My Templates** page to manage templates.

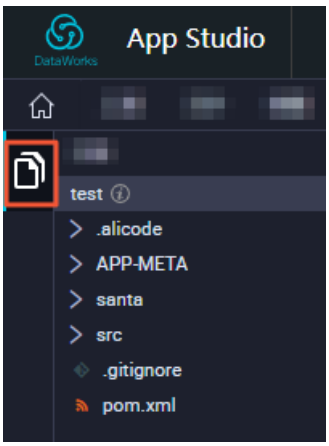
- Left-side navigation pane

- Entry

  Click the icon framed in red. The project section appears.

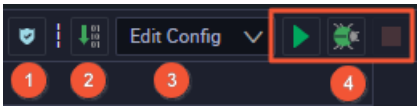
- Edit section

  Double-click a file that you want to edit. In the Edit section that appears, right-click the code section to perform the following operations.



Action	Description
Go to Definition	Navigates to the definition page.
Peek Definition	Previews the definition.
Find All References	Searches for all references.
Workspace Symbol	Searches for a symbol in the project.
Go to Symbol...	Navigates to the symbol in the project.
Generate...	Generates the code.
Rename Symbol	Renames the symbol.
Change All Occurrences	Changes the name of all occurrences of a symbol throughout the file.
Format Document	Formats the file.
Cut	Cuts the file.
Copy	Copies the file.
Command Palette	Goes to the command palette.

- Icons in the upper-right corner



No.	Feature
1	Alibaba Coding Guidelines
2	Build Program. You can perform this operation only when the project is running or being debugged.
3	Run/Debug Configurations. You can set parameters for running or debugging the project.
4	Operations on the project, including running, debugging, or stopping the project.

- Bottom bar

  - OUT tab

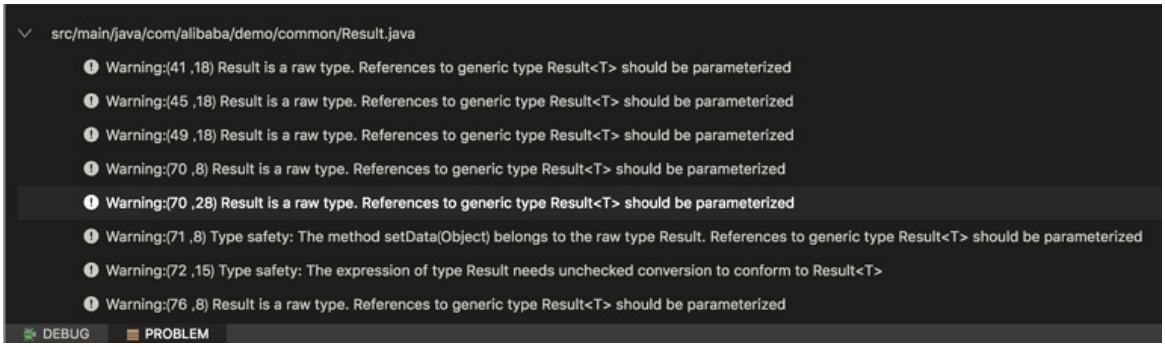
    You can click the OUT tab to view the output.

  - RUN or DEBUG tab

    If you click the Run or Debug icon for a project, this tab appears, showing the progress and information of the project.

  - PROBLEM tab

    If you click the Run or Debug icon for a project that has a problem, this tab appears.



- Terminal tab

  When running or debugging a project, you can click the Terminal tab and run bash or vim commands on the ECS instance.

- Version Control tab

  You can click the Version Control tab to view the logs and history of the project.

2.18.3. Navigation pane

2.18.3.1. View and manage projects

You can create and manage projects on the Projects page.

Go to the App Studio page and click Projects in the left-side navigation pane. On the page that appears, you can view projects that you have created. For more information about how to create template-based and code-based projects, see Project management.

Click a project to go to the project editing page. You can also click **Create Template** of a project to create a template based on the project.

Create a template

1. Click **Create Template** of a project.
2. In the **Create Template** dialog box that appears, set each parameter.

Parameter	Description
Name	The name of the template.
Description	The description of the template.
Class	The class of the template.

3. After the configuration is completed, click **OK**.

2.18.3.2. View and manage templates

You can view all templates created based on projects on the Templates page.

Click a template to go to the template details page. Then, click **Code Editor** to view the project code that this template is based on.

You can also click **Create Project** of a template to create a project based on this template.

2.18.4. Project management

This topic describes how to create and manage projects.

You can create a template-based or code-based project.

Create a template-based project

1. Go to the App Studio page and click Projects in the left-side navigation pane. On the **Projects** page, click **Create Project from Template**.
2. On the **Create Project** page, specify **Name** and **Description**, and select a template.

   > **Note**
   > - You can select a custom template or a template provided by the system.
   > - All projects created by using templates support WYSIWYG development.

3. After the configuration is completed, click **Submit**.

Create a code-based project

You can create a project by running code. App Studio provides code templates for three types of runtime environments. Select a code template as required.

1. Go to the App Studio page and click Projects in the left-side navigation pane. On the **Projects** page, click **Create Project from Code**.
2. On the **Create Project** page, specify **Name** and **Description**, and select a template.
3. After the configuration is completed, click **Submit**.

View and manage projects

You can view the created projects on the **Projects** page.

You can click a project name to go to the project editing page. You can also click **Create Template** of a project to create a template based on the project.

> **Note** You can view projects shared by others but cannot create templates based on those projects.

2.18.5. Code editing

2.18.5.1. Overview

Code editing supports common IDE features, such as automatic completion, code hinting, syntax diagnosis, and global content search.

The following tables list the basic and advanced features that App Studio supports in different languages.

Basic feature	Java	Python	JavaScript and TypeScript
Completion	Supported	Supported	Supported
Hover	Supported	Supported	Supported
Diagnostics	Supported	Supported	Supported
SignatureHelp	Supported	Supported	Supported
Definition	Supported	Supported	Supported
References	Supported	Supported	Supported
Implementation	Supported (coming soon)	Not supported	Not supported
DocumentHighlight	Supported	Supported	Supported
DocumentSymbol	Supported	Supported	Supported
WorkspaceSymbol	Supported	Supported	Supported
CodeAction	Supported (Alibaba Java Guidelines coming soon)	Supported	Supported
CodeLens	References implementation	Not supported	Not supported
Formatting	Supported	Supported	Not supported
RangeFormatting	Supported	Not supported	Not supported
FindInPath	Supported	Supported	Supported

Advanced feature	Java	Python	JavaScript and TypeScript
Rename	Supported	Supported	Supported
WorkspaceEdit	Supported	Not supported	Not supported
UnitTest (quick start)	Supported	Not supported	Not supported
MainClass	Supported	Not supported	Not supported
MainClassQuickStart	Not supported	Not supported	Not supported
ListModules	Supported	Not supported	Not supported

Advanced feature	Java	Python	JavaScript and TypeScript
Generate	Constructor Override Getter and Setter Implement	Not supported	Not supported

2.18.5.2. Generate code snippets

Currently, App Studio supports the Java class constructor, getter and setter methods, override methods of the parent class that a child class inherits, and API methods to be implemented.

Entry

Perform either of the following operations to generate the Java code:

- Right-click the code section and select **Generate**.
- Press Command+M on the keyboard. The Java code is automatically generated.

Constructor

On the Generate menu, click **Constructor**.

Select the fields to be included in the constructor and click **OK**.

The constructor that contains the initialization statement of the fields is generated.

Getter and setter methods

Generate the getter and setter methods in a way similar to the constructor.

> **Note** If a Java class does not have any field or the Java class is overwritten by the @data annotation of lombok, the getter or setter method is not required for the Java class. In this case, the Getter, Setter, and Getter And Setter options do not appear on the Generate menu.

Override methods

Click Override Methods on the Generate menu. All methods that can be overridden are listed in the Generate Code dialog box.

Select a method. The corresponding method is generated.

2.18.5.3. Run UT

App Studio currently supports unit testing (UT), including automatically generating UT code, detecting the entry for UT, running UT code, and displaying the UT result.

Automatically generate UT code

Open the target file, right-click the code editing section, select **Generate** and then click **Create Test**. The UT class file and UT code are automatically generated in the test directory.

Detect the entry for UT

> Note
>
> - UT class files must be stored in the *src/test/java* directory. A Java UT class file that is not stored in this directory cannot be identified as the Java UT class.
> - For a method annotated with @Test annotation, Run Test appears, indicating the entry for UT.

After the Java UT class file is created, add the **@Test** annotation of `org.junit.Test` to the corresponding sample UT method.

Run UT code

Click the Run icon in the upper-right corner. The sample UT starts.

2.18.5.4. Find in Path

App Studio provides the Find in Path feature to support global content search.

Move the pointer over **Edit** in the top navigation bar and select **Find in Path**.

You can select **Match Case**, **Words**, **Regex**, and **File Mask** as required. If you select File Mask, you must also select a file name extension from the right drop-down list to search in files of the specified type.

You can also search for content in the specified project, module, or directory.

After selecting a file, you can locate the searched content in the file and open the file in the editor.

2.18.6. Debugging

2.18.6.1. Configuration and startup

You can configure the entry method, start debugging, and set breakpoints to debug an app.

Configure the entry method

Parameter	Description
Main class	The entry method (which is the main method) you want to start. You can select a value from the drop-down list.
VM options	The parameters for starting a Java Virtual Machine (JVM), for example, -D, -Xms, and -Xmx.
Program arguments	The startup parameter, which is obtained by the args parameter in the main method.

Parameter	Description
Environment Variables	The environment variables.
JRE	The Java runtime environment. Default value: *1.8 - SDK*.
PORT	The port you want to expose in the app, for example, classic port 7001 or port 8080 for Spring Boot-based projects.
ECS Instance	The type of the ECS instance used for debugging.
Enable Hot Code	This configuration takes effect only in Run mode. By default, the HotCode2 plug-in that Alibaba Cloud provides is used.

Start debugging

Move the pointer over **Debug** in the top navigation bar and click **Start Debugging**.

The first startup is slower, because the system needs to prepare the runtime environment and download Maven dependencies for you. When you restart debugging, App Studio skips this process and provides user experience similar to that in a local IDE.

2.18.6.2. Online debugging

App Studio supports the online debugging of Java apps and Spring Boot-based web projects.

Before online debugging, you must configure the entry method and start debugging. For more information, see Configuration and startup.

Exposed services

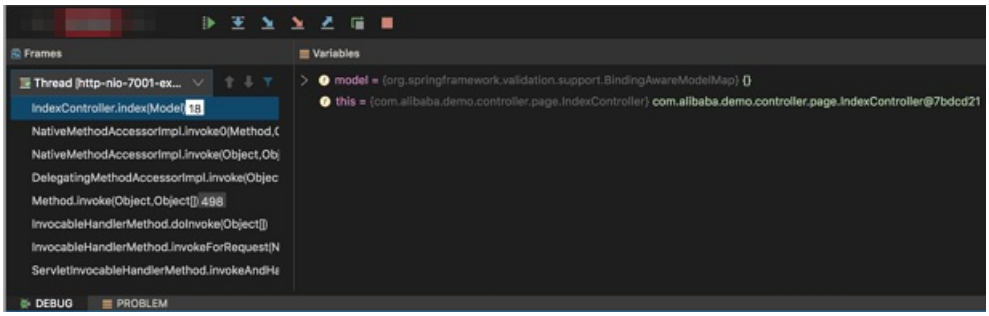
After your app is started, two basic services are provided. You can click the link next to Backend to debug the back-end Java code.

Panel introduction

- Output

  The Output panel displays the standard output, excluding System.in, of all apps. It supports the ANSI color and guarantees consistent experience as a local terminal.

- Call Stack

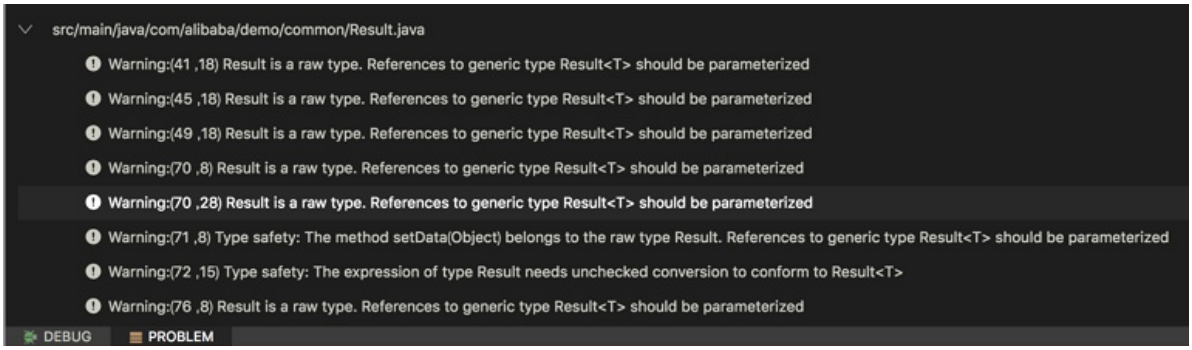


- Breakpoint

  The Breakpoint panel displays the breakpoints that are currently set. For more information about the breakpoint types and usage, see Breakpoint types.

- PROBLEM

  The **PROBLEM** panel displays compilation problems of apps. You can click a record to go to the corresponding line in the file.



2.18.6.3. Breakpoint types

App Studio supports normal line breakpoints, method breakpoints, and exception breakpoints.

Normal line breakpoint

You can click the blank section next to a line in the current file to generate a breakpoint for that line. The breakpoint also appears on the Breakpoint panel.

Method breakpoint

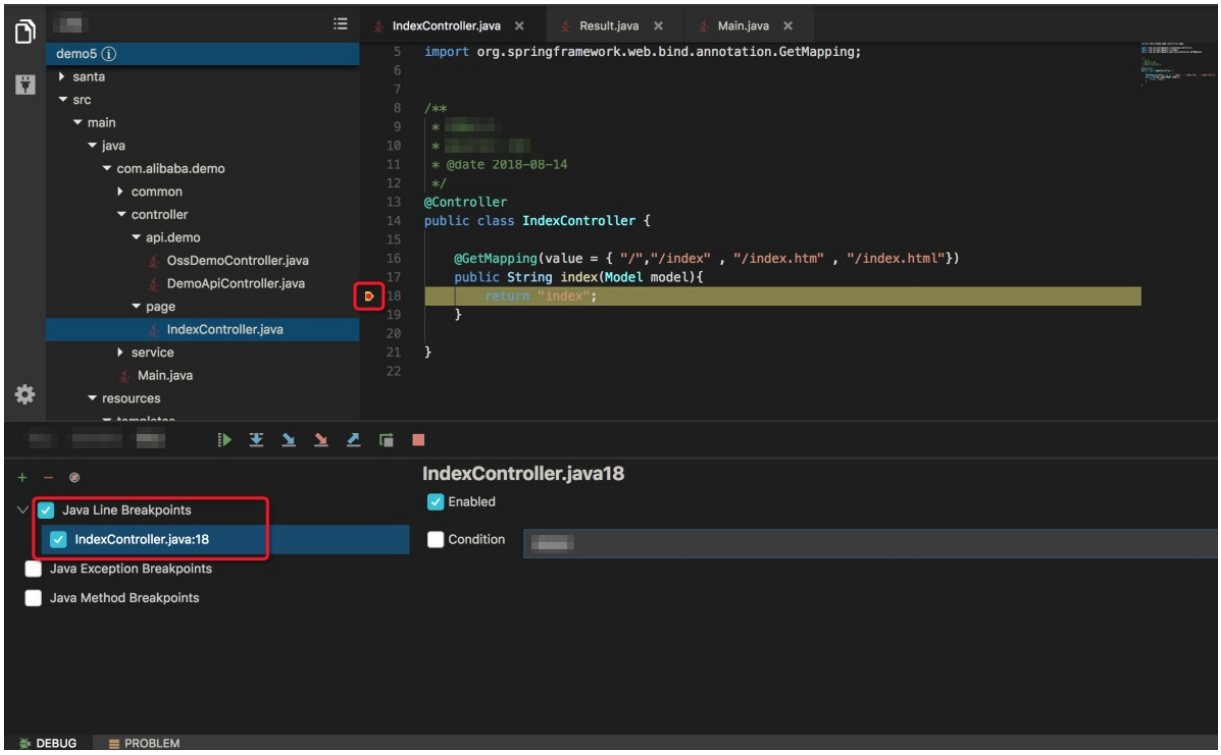
Different from a line breakpoint or an exception breakpoint, a method breakpoint triggers two events, namely, entry and exit. You can manually add a method breakpoint, or set a breakpoint at the place where the method is defined.

If the method breakpoint is triggered, the program stops when stepping into or out of the method.

Exception breakpoint

If an exception breakpoint is set, the program stops when encountering the exception.

As shown in the following figure, after index is triggered, the program stops in line 23 because **NullPointerException** appears.



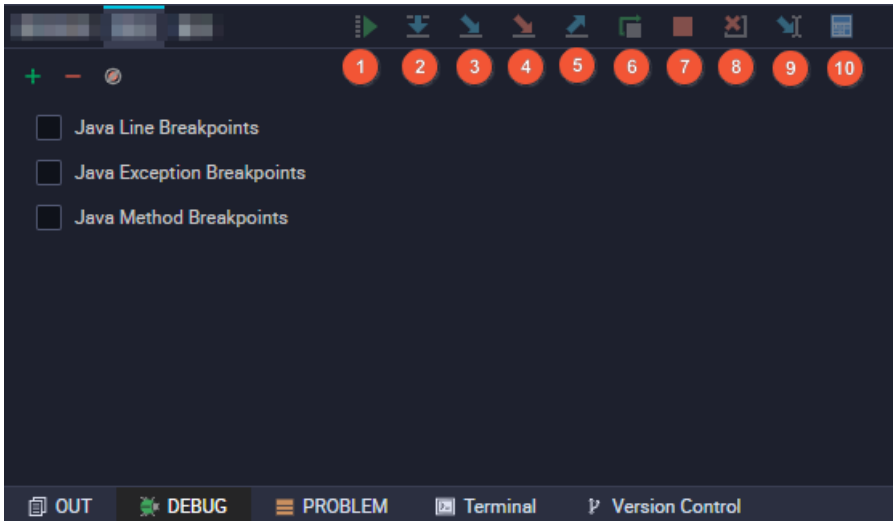
2.18.6.4. Breakpoint operations

The Breakpoint panel displays the breakpoints that are currently set. This topic describes how to operate breakpoints.

Breakpoints can be classified into normal line breakpoints, method breakpoints, and exception breakpoints. For more information, see Breakpoint types.

Debugging buttons

You can perform the debugging operations by clicking the following buttons listed in the table:



No.	Feature	Description
1	**Continue**	Resumes the current breakpoint to continue the current thread.
2	**Step Over**	Runs to the next line.
3	**Step Into**	Steps into a method.
4	**Force Step Into**	Forcibly steps into a method of a class not to be stepped into. Different from **Step Into**, **Force Step Into** enables you to step into a method from a built-in Java library.
5	**Step Out**	Steps out of the current method.
6	**Restart**	Currently, the **Restart** button is not perfect enough and may not be able to clean up the program. This button is being optimized.
7	**Stop**	Stops debugging.
8	**Drop Frame**	Deletes the current stack and returns to the previous method.
9	**Run to Cursor**	Runs to the current line of code. You can set a temporary breakpoint in a line.
10	**Evaluate Expression**	Calculates an expression.

2.18.6.5. Terminal

You can start multiple terminals in App Studio.

The **Terminal** tab appears in the lower part of the page.

App Studio supports common shell commands such as **ls** and **cat** and interactive commands such as **vi** and **top**.

2.18.6.6. Hot code replacement

Using the hot code replacement feature, you can edit the running code of an app and make the edits effective without restarting the app.

For example, after you edit the code while debugging a Spring Boot-based app, you do not need to restart the app. The edited code takes effect once it is saved. App Studio supports this feature by default.

App Studio also supports hot code replacement while an app is running. To trigger hot code replacement, you only need to save the file without installing any plug-in or manually compiling the file.

If you are editing the code in Debug mode, App Studio automatically deletes the current running stack and returns to the method entry.

Configure hot code replacement in Run mode

Enable hot code replacement on the Run/Debug Configurations page.

After you click Run or Debug, the output information of the HotCode2 plug-in appears on the OUT tab.

Save the file after editing it.

Configure hot code replacement in Debug mode

You can use the native Java Debug Interface (JDI) to enable hot code replacement in Debug mode. However, due to Java Virtual Machine (JVM) restrictions, hot code replacement is unavailable when a method is added to or deleted from a class. You can save the file to trigger hot code replacement.

> **Note** The native JVM supports hot code replacement for operations such as adding or deleting a class. However, hot code replacement is unavailable when you change the class structure.

2.18.7. WYSIWYG designer

2.18.7.1. Get started with the WYSIWYG designer

This topic describes basic operations in the WYSIWYG designer, including creating a project and building a visual page.

Create a project

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > App Studio**. The **Projects** page appears.
3. Click **Projects** in the left-side navigation pane. On the page that appears, click **Create Project from Code**.
4. On the **Create Project** page, set the **Name** and **Description** parameters, and set **Select the runtime environment** to **appstudio**.
5. After the configuration is completed, click **Submit**.

Build a visual page

Open a project created by using the WYSIWYG designer. Go to the *santa/pages* directory in your project.

Double-click a .santa file to go to the WYSIWYG designer. For example, you can double-click the file named *home.santa*.

You can also right-click **pages** and choose **Create > Template** to develop the page based on a template.

The WYSIWYG designer consists of the component menu and operation panel.

- Component menu

The component menu lists all components that the WYSIWYG designer presets, including **layout components**, **basic components**, **form components**, **chart components**, and **advanced components**.

Select a component from the component menu and drag and drop it to the visual operation section. Click the component. The **Component Settings** panel appears on the right.

On the **Component Settings** panel, you can configure the component on the **Properties**, **Style**, and **Advance** tabs.

- Operation panel

  You can click the corresponding icon on this panel to **undo an operation**, **redo an operation**, **preview the rendering result**, **enable the code mode**, **use the global style**, **configure the navigation**, **configure a global data flow**, **deploy as a template**, and **save edits**.

  Click the **Configure Navigation** icon in the upper-right corner to go to the navigation configuration page. For more information, see Navigation configuration.

Configure a global data flow

For more information about how to configure a global data flow, see Global data flow.

On the Component Settings panel, you can configure the component on the **Properties**, **Style**, and **Advance** tabs.

- Configure component properties

  On the Properties tab, you can visually configure component properties.

  Based on the rules for configuring component properties, a visual form is generated on the Properties tab. After you configure component properties in this form, the WYSIWYG designer re-renders the component in the visual operation section based on the new properties. You can view the rendering results of the component with different properties in real time.

- Configure component styles

  On the Style tab, you can configure the styles of a component.

  A visual panel for configuring common styles is provided on the Style tab. On this panel, you can customize the basic styles of a component, including the layout, text, background, border, and effect.

  After you add or modify the component styles on this tab, the WYSIWYG designer collects all the style settings and re-renders the component in the visual operation section based on the new component style. You can view the component configuration effect in real time.

- Configure association between components

  On the Advanced Settings tab, you can configure association between components.

  Select a component in the visual operation section and click the **Advance** tab. The properties of the selected component are listed on the left of the tab. Click the Magnifier icon on the right and select the component to be associated to your selected component.

  The properties of the associated component appear on the right of the tab.

  Select a property, for example, searchParams, in the left property list and connect it to a property, for example, requestParams, in the right property list.

In this way, any change of the searchParams parameter of the left component is transferred to the requestParams parameter of the right component in real time. This achieves property-based association between the two components.

Configure the code mode

By using the code mode, you can implement complex interactions in a more advanced way. For more information, see Code mode.

Save, preview, run, and hot code replacement

For more information, see Save, preview, run, and hot code replacement.

2.18.7.2. Code mode

By using the code mode, you can implement complex interactions in a more advanced way.

Click the **Code Mode** icon in the upper-right corner of the operation panel to enable the code mode.

The WYSIWYG designer uses domain-specific language (DSL) at the intermediate layer to switch between the visualization mode and code mode. DSL can be considered as a simplified version of React. The DSL syntax is basically the same as the React syntax.

As shown in the code section in the preceding figure, DSL uses a tag to describe a component. The tag properties are the component properties. The property value can be of a simple data type such as a string or a number. The property value can also be an expression. You can enter `state.xxx` to obtain data from the global data flow.

The code mode has the following features:

- If you drag and drop a component or configure the component properties in the visualization section, the edits are updated in the code in real time.
- If you edit the code in the code section, the edits are updated in the visualization section in real time.
- The drag-and-drop operation and component property configuration in the visualization section and code edits in the code section can be converted between each other.

2.18.7.3. DSL syntax

Domain-specific language (DSL) is a component-based language developed based on the features of React JSX and Vue templates and is more suitable for UI layout design.

JSX

The DSL syntax is similar to the JSX syntax in the React.render method. The following section provides a brief description of JSX:

- You can use `{}` to switch an HTML scope to a JavaScript scope. In a JavaScript scope, you can write any valid JavaScript expression. The return value appears on the page, for example, `<div>{'Hello' + ' Relim'}</div>`.

> **Note** You can write any JavaScript expressions such as computing statements or literals in `{}`.

- An HTML tag is used to switch a JavaScript scope to an HTML scope, for example, `{<div>Hello Relim</div>}`.
- The HTML scope and JavaScript scope can be nested, for example, `{<div>{'Hello' + ' Relim'}</div>}`.

Valid JavaScript expressions

```
// Computing statements
{aaa} // √ Variable aaa must be defined.
{aaa * 111} // √
{1 == 1 ? 1 : 0} // √
{/^123/.test(aa)} // √
{[1,2,3].join('')} // √
{(()=>{return 1})()} // The self-executing function. √

// Literals
{1}
{true}
{[11,22,33]} // √
{{aa:"11",bb:"22"}} // √
{()=>1} // Describe a function, which is valid but meaningless. √
```

> **Note** If certain complex logic must be implemented by multiple computing statements rather than only one statement, you can wrap the logic in a self-executing function, which must be a valid expression. The following statements provide an example:

```
{(function(){
    // Sum the even digits of a number array.
    var input = [1,2,3,4,5,6,7,8,9,10];
    var temp = input.filter(i => i % 2 == 0)
    return temp.reduce((buf, cur) => buf + cur, 0)
})()}
```

Invalid JavaScript expressions

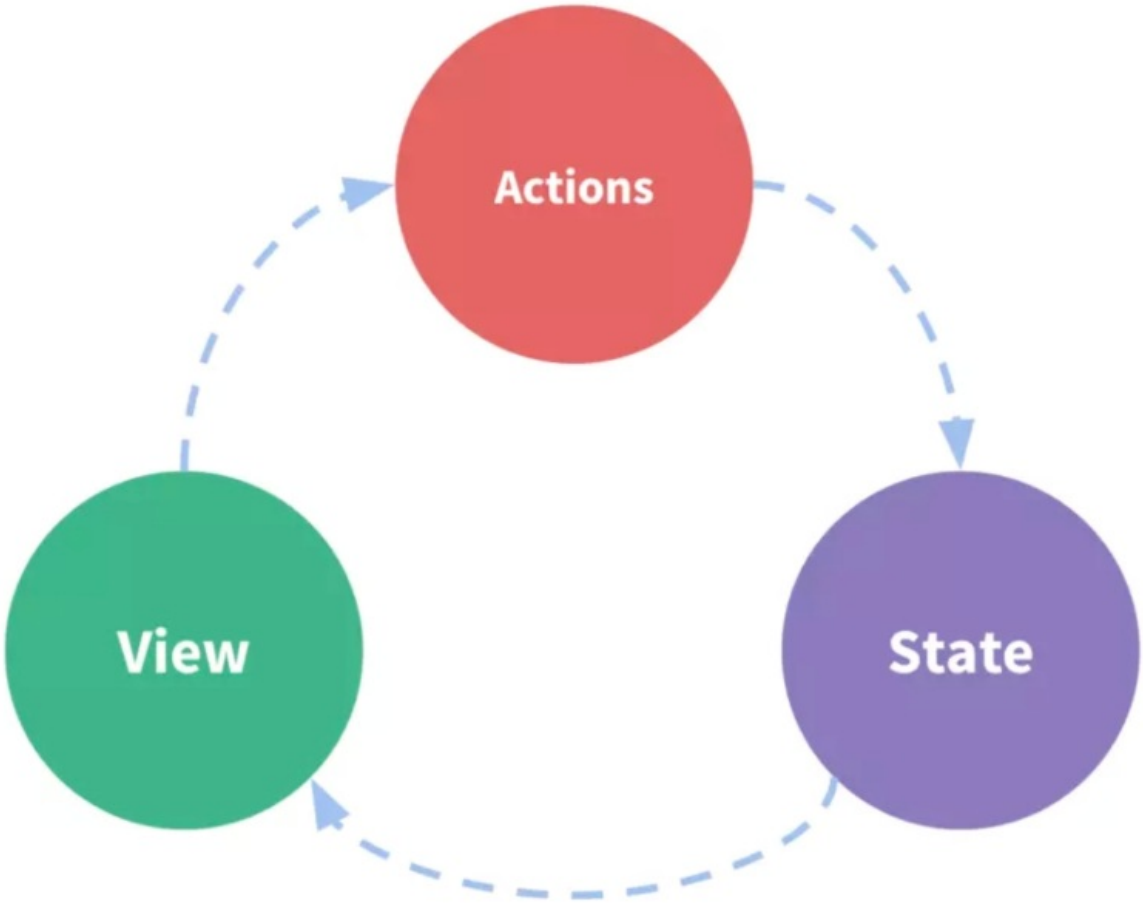
```
{ var a = 1 } // The value assignment statement.
{ aaa * 111; 2} // Multiple statements separated with semicolons (;).
```

2.18.7.4. Global data flow

A global data flow is used for front-end data management. For multiple components that need to share a state, it is difficult to transfer the state among them. To resolve this issue, you can extract the shared state and use a global data flow to transfer it to all related components.

Principles

In a global data flow, global data is transferred in a globally unique way. Once the data declared in global data changes, the data flow shown in the following figure is executed.



1. A component triggers an action when, for example, a user clicks the component.
2. The action triggers global data changes.
3. Upon the global data changes, components that reference the global state are automatically re-rendered.

Scenarios

A global data flow is applicable to the association of two or more components on a page. You can refine public data into global data for unified management, and then use a global data flow to associate two or more components.

Configure a global data flow

1. Click the **Global Data Flow Settings** icon in the upper-right corner of the operation panel.

2. In the **Global Data Flow Settings** dialog box that appears, set **Variable Name** and **Value**.
   - The variable value can be a number, character string, or JSON string.
   - If the variable value is declared as an API endpoint, data obtained from the API is automatically used as the value of the variable name.
3. Click **Save**.

Use a global data flow

- Obtain global data

  Use `state.name` in the component to obtain global data.

  ```
  <Input value={state.name} />
  ```

- Modify global data

  Use the $setState() method in the component to modify global data.

  ```
  <Input onChange={value => $setState({ name: value })} />
  ```

  Note You must use the $setState() method to modify global data. If you use `state.name = 'new value'`, re-rendering cannot be triggered.

2.18.7.5. Save, preview, run, and hot code replacement

In the WYSIWYG designer, you can perform operations such as saving edits, previewing the rendering result, running an app, or making edits in hot code replacement mode.

Save edits

The WYSIWYG designer periodically saves your edits. You can also click the **Save** icon in the upper-right corner of the operation panel to save edits.

Preview the rendering results

In the WYSIWYG designer, code in the operation section is in the editable status. However, special processing is added for the editable status of some components. For these components, you can run the rendering logic only when the app is running. To preview the rendering result, click the Preview icon in the upper-right corner of the operation panel.

Run an app

In the WYSIWYG designer, you can open and edit only one santa file at a time. To view the effect of the entire app,

click the Run Program icon on the Debug panel of App Studio to run the app.

Make edits in hot code replacement mode

If you are not satisfied with any page after running the app, you can edit the code in the WYSIWYG designer and save the edits.

The edited code takes effect on the running page in hot code replacement mode.

2.18.7.6. Navigation configuration

This topic describes how to configure the site navigation in the WYSIWYG designer.

The WYSIWYG designer provides each app with a public page header, a public bottom bar, and public sidebars, where you can configure various menus and themes. You can also specify whether to display the public header, bottom bar, and sidebars as required.

Click the **Navigation Settings** icon in the upper-right corner of the operation panel to go to the page for configuring the navigation of an app.

Configure the public header

You can configure the public header based on your business requirements.

Parameter	Description
Enabled	Specifies whether to display the public header.
Theme	The theme of the public header. You can select a dark or light theme.
Logo Image	The logo image of the site. You can enter an image URL or upload a local image.
Title	The title of the site.
Fix to Page Top	Specifies whether to fix the public header to the top of the page. If you turn on this switch, the public header stays at the top of the page when the page scrolls.
Menu Items	The menu items such as the link name and link URL that are displayed in the public header.

Configure the sidebars

You can configure the sidebars based on your business requirements.

Parameter	Description
Enabled	Specifies whether to display the sidebars.
Theme	The theme of the sidebars. You can select a dark or light theme.
Enable Folding	Specifies whether the sidebar menus can be hidden.

2.19. Workspace management

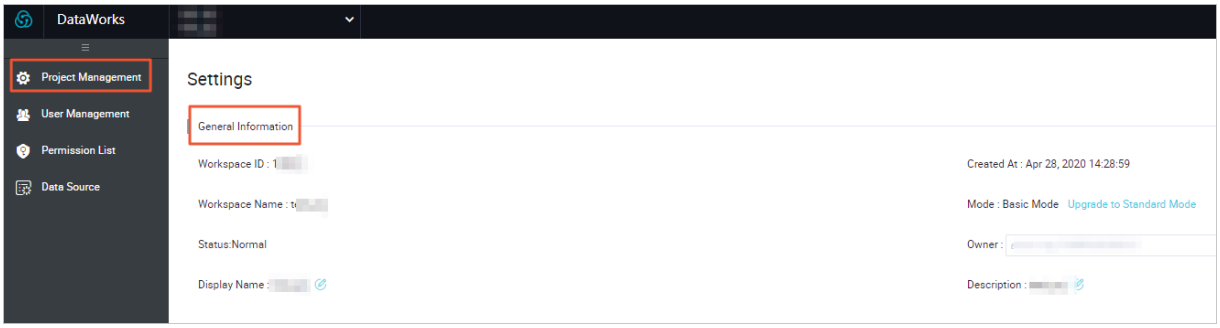
2.19.1. Configure a workspace

On the Project Management page of a workspace, you can manage and configure the workspace.

Go to the Project Management page

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click in the upper-right corner.
3. On the **Project Management** page, configure the workspace as required in the **Basic properties**, **Scheduling properties**, **Security Settings**, and **Compute Engine information** sections.

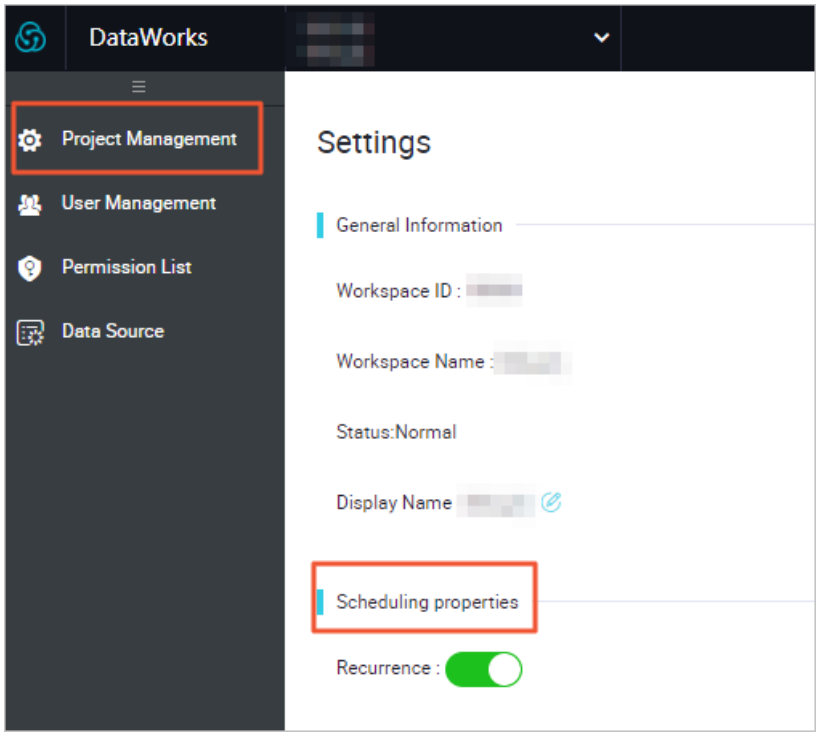
Basic properties section



Parameter	Description
Workspace ID	The ID of the workspace.
Workspace name	The name of the workspace. The name must start with a letter and can contain only letters and digits. It is not case-sensitive. It uniquely identifies the workspace and cannot be changed after the workspace is created.
Status	The status of the workspace.
Display name	The display name that is used to identify the workspace. It can contain only letters and digits. You can change the display name as required.
Creation date	The time when the workspace was created, which cannot be changed.
Mode	The mode of the workspace. Valid values: **Basic Mode** and **Standard Mode**.
The head of	The owner of the workspace. The owner of the workspace cannot be changed.
Description	The description of the workspace, which provides comments on the workspace. You can modify the description as required. The description can be up to 128 characters in length and can contain letters, special characters, and digits.

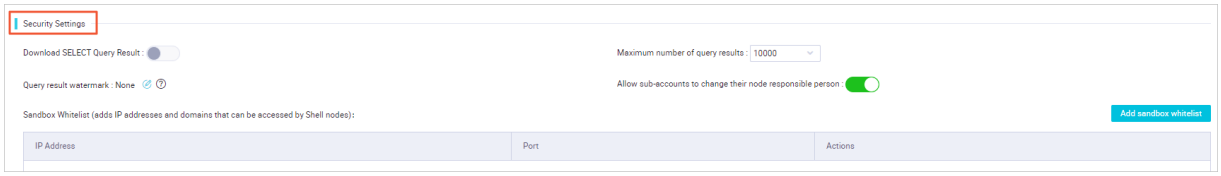
Scheduling properties section

In the **Scheduling properties** section, you can specify whether to enable the recurrence feature for the current workspace.



Recurring nodes can be run in this workspace only after you turn on the **Enable scheduling cycle** switch.

Security Settings section



Parameter	Description
Allow download of select results	Specifies whether to allow workspace members to download data query results in DataStudio. If you turn on this switch, workspace members can download data query results returned by SELECT statements in DataStudio.
Maximum number of query results	The maximum number of data records that can be returned for each query. Valid values: **10**, **100**, **500**, **1000**, **5000**, and **10000**. Default value: **10000**. Assume that you set the **Maximum number of query results** parameter to **1000**. Go to the **DataStudio** page 5 minutes later. In the left-side navigation pane, click **Ad-Hoc Query**. On the Ad-Hoc Query tab, create an ODPS SQL node and run the node to query data in a table that has more than 1,000 data records. 1,000 records are returned.
Query result watermark	Specifies whether to display watermarks for the query results.

Parameter	Description
Allow sub-accounts to change their own node owners	Specifies whether to allow RAM users to change the owner for their nodes.
Sandbox whitelist (configure IP addresses or domain names that shell tasks can access)	The whitelist of IP addresses and domain names that a Shell node run on the default resource group can access.

To add an IP address to the whitelist, perform the following steps:

1. In the **Security Settings** section, click **Add sandbox whitelist**.
2. In the **Add sandbox whitelist** dialog box, enter the IP address and port number in the **Address** and **Port** fields respectively.
3. Click **Confirm**.

Computing Engine information section

DataWorks supports the following types of compute engines: MaxCompute, E-MapReduce, Realtime Compute, and Graph Compute.

MaxCompute

1. Click the **MaxCompute** tab in the **Compute Engine information** section. On this tab, you can view the information about all available MaxCompute instances in the current workspace.
2. Click **Add instances**.
3. In the **Add MaxCompute engine** dialog box, set the **MaxCompute project name** and **MaxCompute access identity** parameters.
4. Click **Confirm**.

E-MapReduce

1. Click the **E-MapReduce** tab in the **Computing Engine information** section. On this tab, you can view the information about all available E-MapReduce clusters in the current workspace.
2. Click **Add instances**.
3. In the **New EMR cluster** dialog box, set relevant parameters.

Parameter	Description
Instance display name	The display name of the E-MapReduce cluster to be added.
Region	The region where the current workspace resides.
Access ID	The AccessKey ID of the account that is authorized to access the E-MapReduce cluster.
Access Key	The AccessKey secret of the account that is authorized to access the E-MapReduce cluster.
Cluster ID	The ID of the E-MapReduce cluster.

Parameter	Description
EmrUserID	The ID of the user who created the E-MapReduce cluster.
Project ID	The ID of the project in the E-MapReduce cluster.
YARN resource queue	The name of the resource queue in the E-MapReduce cluster. Unless otherwise specified, set the value to *default*.
Endpoint	The endpoint of the E-MapReduce cluster. You can obtain the endpoint from the E-MapReduce console.

4. Click **Confirm**.

Realtime Compute

1. Click the **Real-time computing** tab in the **Computing Engine information** section. On this tab, you can view the information about all available Realtime Compute projects in the current workspace.
2. Click **Add engine service**.
3. In the **New Blink engine** dialog box, set the **Enter the Realtime Compute project name to add** parameter.

> **Notice** A Realtime Compute project can be bound to only one DataWorks workspace. After a Realtime Compute project is bound to a DataWorks workspace, the Realtime Compute project cannot be used in other DataWorks workspaces. After you bind a Realtime Compute project to a workspace, you cannot unbind it. Use caution when you bind a Realtime Compute project.

4. Click **Binding**.

Graph Compute

1. Click the **GraphCompute** tab in the **Computing Engine information** section.
2. Click **Bind a GraphCompute instance**.

> **Notice** A Graph Compute instance can be bound to only one DataWorks workspace. After a Graph Compute instance is bound to a DataWorks workspace, the instance cannot be used in other DataWorks workspaces.

3. In the **Bind a GraphCompute instance** dialog box, set relevant parameters.

Parameter	Description
Instance display name	The display name of the Graph Compute instance to be bound to the workspace.
GraphCompute instance name	The name of the Graph Compute instance.

4. Click **Binding**.

2.19.2. Manage workspace members

This topic describes how to add and delete members and change the roles of members on the User Management page.

Go to the User Management page

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click in the upper-right corner.
3. In the left-side navigation pane, click **User Management**.You can view the information about each member in the following columns on the **User Management** page:
   - **Members**: the display name of the Apsara Stack tenant account or RAM user that the member uses to log on to DataWorks.
   - **Cloud account**: the Apsara Stack tenant account or RAM user that the member uses to log on to DataWorks.
   - **Role**: the roles of the member in the current DataWorks workspace. A member can have one or more of the following roles: workspace owner, workspace administrator, developer, administration expert, deployment expert, visitor, and security expert.

     > **Note** The workspace administrator can assign roles to RAM users as required. You can click **Permission List** in the left-side navigation pane to view the specific permissions of different member roles.

   - **Join TIME**: the time when the member was added to the workspace.
   - **Operation**: the operation that you can perform on the member. You can delete all members except the workspace owner from the workspace.

Add members

1. On the **User Management** page, click **Add Member** in the upper-right corner.
2. In the **Add Member** dialog box, select one or more accounts to add in the **Account to be added** list.
3. Click **>** to move the selected accounts to the **Added account** list.
4. Select the roles next to **Batch role setting**. You can select one or more of the following roles: **Space Administrator**, **Development**, **Operation & Maintenance (O & M)**, **Deployment**, **Visitors**, and **Security Administrator**.
5. Click **Confirm**.

Remove a member

1. On the **User Management** page, find the target member and click **Delete** in the Operation column.
2. In the **Member remove this workspace** message, click **OK**.

Assign a role to a member

Click the drop-down list in the **Role** column of the member and select the role to be assigned.

Revoke a role from a member

Click x next to the role in the Role column.

2.19.3. Permission list

DataWorks provides seven roles: workspace owner, workspace administrator, developer, administration expert, deployment expert, visitor, and security expert. You cannot grant the role of the workspace owner to other workspace members. This topic describes the permissions of these roles. In the following tables, Yes indicates that a role has the corresponding permission, and No indicates that a role does not have the corresponding permission.

Data management

Permission	Workspace owner	Workspace administrator	Developer	Administration expert	Deployment expert	Visitor	Security expert
Delete self-created tables	Yes	Yes	Yes	No	No	No	No
Specify categories for self-created tables	Yes	Yes	Yes	No	No	No	No
View favorite tables	Yes	Yes	Yes	No	No	No	No
Create tables	Yes	Yes	Yes	No	No	No	No
Unhide self-created tables	Yes	Yes	Yes	No	No	No	No
Modify the schemas of self-created tables	Yes	Yes	Yes	No	No	No	No
View self-created tables	Yes	Yes	Yes	No	No	No	No
View the content of self-submitted permission requests	Yes	Yes	Yes	No	No	No	No
Hide self-created tables	Yes	Yes	Yes	No	No	No	No
Specify the time-to-live (TTL) for self-created tables	Yes	Yes	Yes	No	No	No	No
Request permissions on tables created by others	Yes	Yes	Yes	No	No	No	No
Delete tables	No	Yes	Yes	No	No	No	No
Update tables	No	Yes	Yes	No	No	No	No

Permission	Workspace owner	Workspace administrator	Developer	Administration expert	Deployment expert	Visitor	Security expert
Preview data	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Preview table data of other organizations	Yes	Yes	No	No	No	No	No

Deployment management

Permission	Workspace owner	Workspace administrator	Developer	Administration expert	Deployment expert	Visitor	Security expert
Create deployment tasks	Yes	Yes	Yes	Yes	No	No	No
View the list of deployment tasks	Yes	Yes	Yes	Yes	Yes	Yes	No
Delete deployment tasks	Yes	Yes	Yes	Yes	No	No	No
Run deployment tasks	Yes	Yes	No	Yes	Yes	No	No
View the content of deployment tasks	Yes	Yes	Yes	Yes	Yes	Yes	No

Buttons

Permission	Workspace owner	Workspace administrator	Developer	Administration expert	Deployment expert	Visitor	Security expert
Button: Stop	Yes	Yes	Yes	No	No	No	No
Button: Format	Yes	Yes	Yes	No	No	No	No
Button: Edit	Yes	Yes	Yes	No	No	No	No
Button: Run	Yes	Yes	Yes	No	No	No	No

2.19.4. Manage connections

Connections are used to configure readers and writers during data integration. On the Data Source page of a workspace, you can view and add connections.

Procedure

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click  in the upper-right corner.
3. In the left-side navigation pane, click **Data Source**. On the **Data Source** page, you can filter connections by conditions such as **Connect To** and **Connection Name**.

   Click **Add Connection** in the upper-right corner to add a connection. For more information, see Data sources.

3.Realtime Compute

3.1. What is Realtime Compute?

Realtime Compute is a big data processing platform that analyzes streaming data in real time based on Apsara Stack. You can create streaming data analysis and computing jobs by using Alibaba Cloud Flink SQL. When you use Flink SQL, you do not need to develop the underlying logic for streaming data processing.

As the demands for high data timeliness and operability increase, software systems need to process more data in less time. In traditional models for big data processing, online transaction processing (OLTP) and offline data analysis are separately performed at different times.

Realtime Compute is designed to respond to the increasing demand for the timeliness of data processing. The business value of data decreases as time passes by. Therefore, data must be computed and processed as soon as possible after it is generated. Traditional models for big data processing follow the scheduled processing mode, which accumulates and processes data in a computing cycle that can last hours or even days. These models cannot satisfy the growing demand for real-time big data processing. Batch processing cannot meet the business requirements in scenarios in which an extremely low processing delay is required. These scenarios include real-time big data analysis, early warning and risk control, real-time forecasting, and financial transactions. Realtime Compute enables real-time processing over data streams. With Realtime Compute, you can shorten the data processing delay, easily implement real-time computational logic, and greatly reduce computing costs. This helps you meet business requirements for real-time processing of big data.

Streaming data

Big data can be viewed as a series of discrete events. These discrete events form event streams or data streams along a timeline. Streaming data is continuously generated from thousands of data sources and is typically sent in data records. Streaming data has a smaller scale than offline data. Each type of data is produced as a stream of events. Streaming data includes a wide variety of data, such as the log files generated by your mobile or web applications, online purchases, in-game player activities, information from social networks, financial trade centers, geospatial services, and telemetry data from connected devices in data centers.

Realtime Compute has the following advantages:

- Real-time and unbounded data streams

  Realtime Compute processes data streams in real time. Streaming data is continuously generated from data sources and is subscribed and consumed in chronological order. Data streams continuously flow into the Realtime Compute system. For example, when Realtime Compute processes data streams from website visit logs, the log data streams continuously enter the Realtime Compute system as long as the website is online. In Realtime Compute, unbounded data streams are processed in real time.

- Continuous and efficient computing

  Realtime Compute is an event-driven system in which unbounded event or data streams continuously trigger real-time computations. Each streaming data record triggers a computational task. Realtime Compute performs continuous and real-time computations over data streams.

- Real-time integration of streaming data

Realtime Compute writes the computing result of each streaming data record into the target data store in real time. For example, the system directly writes the data of a computed report to an ApsaraDB for RDS instance for report display. Realtime Compute continuously writes the results into the target data store in real time. Therefore, Realtime Compute can be viewed as a data source that generates data streams for the target data store.

3.2. Quick start

3.2.1. Log on to the Realtime Compute console

This topic describes how to log on to the Realtime Compute console.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password used to log on to the console from the operations administrator.

   > **Note** When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters.
   > - Digits.
   > - Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, move the pointer over Products and click **Realtime Compute**.
5. Specify **Organization** and **Region**.
6. Click **Blink**.

3.2.2. Real-time security monitoring

3.2.2.1. Overview

With the wide application of digital technologies, every industry is facing the ever-increasing demand for data security, especially for real-time monitoring and alerting. To monitor streaming data and report alerts in real time, you need to ensure that the data is accurate and is processed instantly after it has been generated. To address these challenges, Realtime Compute allows you to perform JOIN operations on source tables of streaming data and dimension tables that include blacklists. The following sections describe a use case of real-time monitoring and alerting.

3.2.2.2. Preparations

Before proceeding with the development process in the Realtime Compute console, you must create a source table and a result table in the upstream and downstream data stores, respectively. You must also upload data to the source table.

Context

To simplify operations, this example organizes incoming streaming data based on a table: datahub_IpPlace.

datahub_IpPlace

Field name	Data type	Description
name	VARCHAR	The name
Place	VARCHAR	The place

The rds_dim dimension table is described as follows.

rds_dim

Field name	Data type	Description
name	VARCHAR	The name
Place	VARCHAR	The place

A result table named rds_IpPlace is obtained after a JOIN operation is performed on the datahub_IpPlace and rds_dim tables. This result table is described as follows.

rds_IpPlace

Field name	Data type	Description
name	VARCHAR	The name
Place	VARCHAR	The place

Create source and result tables

Procedure

1. Log on to the DataHub console. For more information, see the "Log on to the DataHub

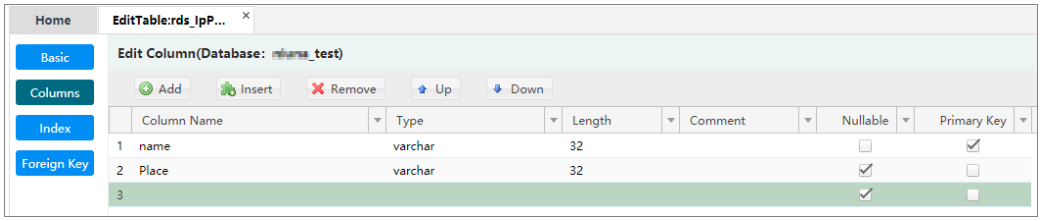
console" section in *DataHub User Guide*.

2. Create a project. For more information, see the "Create projects" section in *DataHub User Guide*.
3. On the page that shows the project details, create a topic. The following figure shows the schema of the source table. For more information, see the "Create a topic" section in *DataHub User Guide*.
4. Create an ApsaraDB for RDS instance. For more information, see the "Create an instance" section in *ApsaraDB for RDS User Guide*.
5. On the **Instances** page of the ApsaraDB for RDS console, click the target instance name.
6. On the **Basic Information** page, click **Log On to DB**.
7. Log on to the RDS database, and create a result table in the database.

   Log on to the database

   
   Dimension table schema

   
   Result table schema

8. Upload data to DataHub.

Log on to the **DataHub** console. In the left-side navigation pane, click **Data Acquisition**, and then click **Upload File**. On the page that appears, double-click the project, click the target DataHub topic, and then click **Select File** to upload data. For more information, see the "Upload local files" section in *DataHub User Guide*.

9. Write data into the rds_dim dimension table.
   i. Log on to the RDS database. In the top navigation bar, choose **SQL Operations** > **SQL Window**.
   ii. On the **SQL Window** tab, enter the following code.

```
insert into 'rds_dim'('name','Place') VALUES('test01','beijing')
```

   iii. On the **SQL Window** tab, click **execute**.

3.2.2.3. Develop a job

After you create source and result tables in external data stores, you must register the data stores in the Realtime Compute console and create references to the source and result tables. After the data stores are registered, you can proceed with the development process.

Procedure

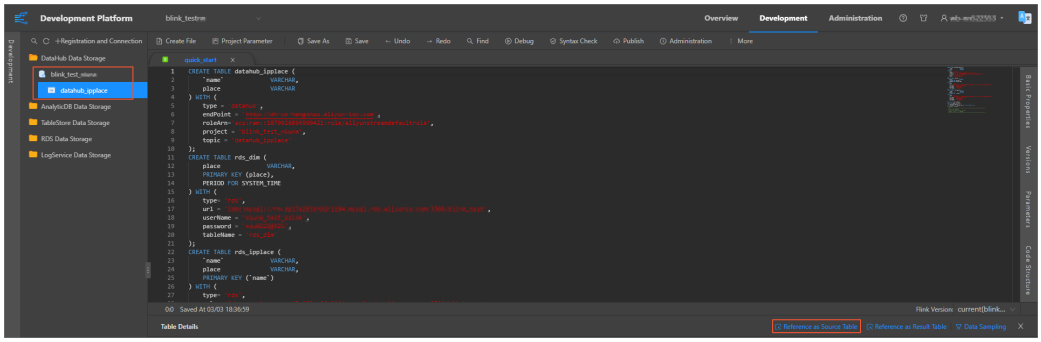
1. Log on to the Realtime Compute console to go to the homepage of Realtime Compute.
2. In the top navigation bar, click Development.
3. On the top of the page that appears, click the **Create File** icon.

Parameter description

Parameter	Description
File Name	The name of the file. The name must be 3 to 64 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a lowercase letter.
File Type	The type of the file. Valid values: FLINK_STREAM / SQL and FLINK_STREAM / DATASTREA.
Storage Path	The folder where the job SQL file is located. You can click the folder icon on the right side of an existing folder and create a subfolder.

4. Select DataHub as the data store for a source table. You can use the DataHub parameter settings and schema information that are automatically generated on the Data Storage tab. For more information, see Register a DataHub project.

   Use DataHub as the data store for a source table



5. Double-click a DataHub project in the **DataHub Data Storage** folder.
6. On the top of the section that appears, click **Reference as Source Table**.
7. Create a reference to the ApsaraDB for RDS dimension table. You must specify the required parameters and the table schema. Dimension tables cannot be registered on the Storage tab. The following sample code demonstrates how to create an ApsaraDB for RDS dimension table:

```
create table rds_input (
   place varchar,
   `name` varchar,
   primary key (place),
   period for system_time
) with (
   type = 'rds',
   url = 'yourURL',
   tableName = 'yourTableName',
   password = 'yourPassword'
);
```

8. Select RDS as the data store for the result table. You can use the RDS parameter settings and schema information that are automatically generated on the Data Storage tab. For more information, see Register an RDS instance.
9. To use RDS to store the result table, double-click the RDS Data Storage folder, double-click the target database, and then double-click the target table. On the top of the section that appears, click **Reference as Result Table**.
10. Edit SQL statements that implement the computing logic in the code editor.

```
INSERT INTO rds_output
SELECT
   t.`name`,
   w.place
FROM datahub_input1 as t
JOIN rds_intput FOR SYSTEM_TIME AS OF PROCTIME() as w
ON t.place = w.place
```

11. Click **Debug**.

12. Click **Publish**. After the computing logic is verified during the debugging, click **Publish** on the Development page to publish the job SQL file. Then, you can view the job on the Administration page of the Realtime Compute console and manage the job in the production environment, such as starting the job.

3.2.2.4. Administration

After you create and publish the job SQL file on the **Development** page, you can manage the job on the **Administration** page. For example, you can start, suspend, terminate, publish, or unpublish the job.

Procedure

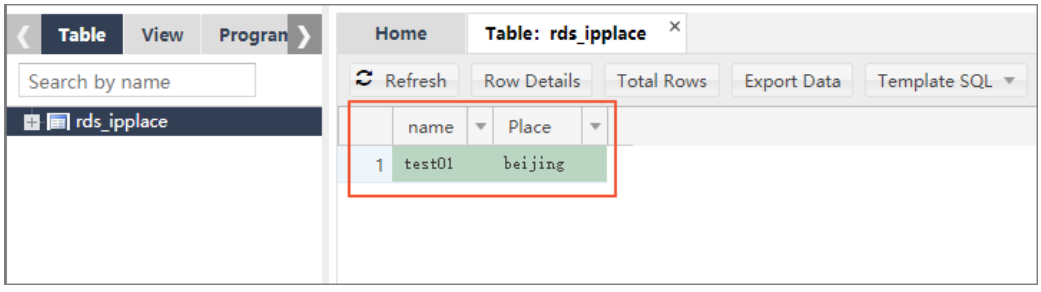
1. Go to the **Administration** page of the Realtime Compute console.
   i. Log on to the Realtime Compute console.
   ii. In the top navigation bar, click **Administration**.
2. Click **Start** for the `bj_dim_join` job.
3. Specify the **Start Time for Reading Data** parameter. The start time for reading data is also known as the start offset. The source data store remains connected to Realtime Compute for only a short period of time. Therefore, we recommend that you specify a time that is earlier than the current time.

   The Start Time for Reading Data parameter specifies the start time for reading data from the source data store.

Parameter	Description
Start Time for Reading Data	Specifies the start time for reading data from the source data store.
Enable Auto Upgrade	Specifies whether to enable auto upgrade.
Upgrade Time	Specifies the upgrade time range.
Offset	Specifies the range of data that is to be updated.

4. Click **OK** to start the job.
5. View the output data in the ApsaraDB for RDS data store.

   View the output data in the RDS data store



3.2.3. Frequently used words

3.2.3.1. Overview

Statistical analysis of frequently used words is widely applied in diverse fields, including the analysis of frequently used words in search engines, forums, and tags. For example, you can easily view the latest and most frequently searched words in microblogging websites through real-time statistics. Statistical analysis of frequently used words is, at its core, a simple word count job. In word count jobs for streaming data, real-time processing logic is used to analyze and display frequently used words in real time.

If you are new to working with big data computing, a word count job is for you to easily get started. The word count job in big data computing is similar to a `Hello, World!` program that is often the first program that a developer learns to write. The following topics take a word count job in Realtime Compute as an example to describe how to create a word count job based on real-time processing logic. This example helps you quickly get familiar with basic Flink SQL syntax and basic operations of Realtime Compute jobs, such as creating an SQL file for a job and publishing the job.

3.2.3.2. Code development

This topic uses a word count job as an example to describe how to create a Realtime Compute job.

Prerequisites

Before creating a word count job, a source table named stream_source and a result table named stream_result are created in external data stores. The stream_source table includes only one column. The column is named word and its data type is STRING. The stream_result table includes two columns. One column is named word and its data type is STRING. The other column is named cnt and its data type is BIGINT. The two tables are registered in Realtime Compute.

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.
3. Right-click the folder where you want to store the job file.
4. Click **Create File**, and the **Create File** page appears.
5. On the page that appears, set the following parameters:
   - File Name: Set the value to `wordcount`.
   - File Type: Set the value to FLINK_STREAM/SQL.
   - Storage Path: Keep the default setting.
6. Enter the following code in the code editor.

> **Note** In the SQL statements for the word count job, the STRING data type for the referenced table must be declared as the VARCHAR data type.

```
 create table stream_source (word varchar);
create table stream_result (word varchar, cnt bigint);
insert into
   stream_result
select
   t.word,
   count (1)
from
   stream_source t
group by
   t.word;
```

The following section explains the SQL code.

Line 1 creates a reference to the stream_source source table.

> **Note** Streaming data continuously enters Realtime Compute and triggers stream processing procedures. Each streaming data record or each batch of data from the stream_source table triggers a stream processing procedure.

Line 2 creates a reference to the stream_result result table. The stream_result table stores the computing results of the word count job.

> **Note** Realtime Compute does not have built-in components for data storage, and the result data is stored in external data stores, such as ApsaraDB for RDS and Tablestore. This line of code creates a reference to a result table that contains the result data.

Lines 5 through 11 implement the computing logic: Realtime Compute reads data from the stream_source table and counts how often words occur based on incoming data records.

> **Note** Flink SQL supports most standard SQL statements. This allows you to easily and cost-effectively adopt Realtime Compute for stream processing.

The method of performing a word count job for stream processing is similar to that for batch processing. The word count job for stream processing continuously processes unbounded data streams until the job is terminated.

3.2.3.3. Code debugging

Realtime Compute provides a powerful debugging feature to verify SQL statements. You can debug Realtime Compute jobs by simulating data stores where streaming data, static data, and result data are stored.

> **Note**
>
> - To avoid negative impacts on online data stores, Realtime Compute is not allowed to read data from these data stores during the debugging process. Before debugging, you must prepare test data for input tables.
> - The outputs of INSERT operations are exported only to local screens. This does not affect online systems.

Debugging method

1. On the top of the **Development** page, click **Debug**.
2. On the page that appears, click **Download Template** and edit the template based on your debugging rules.

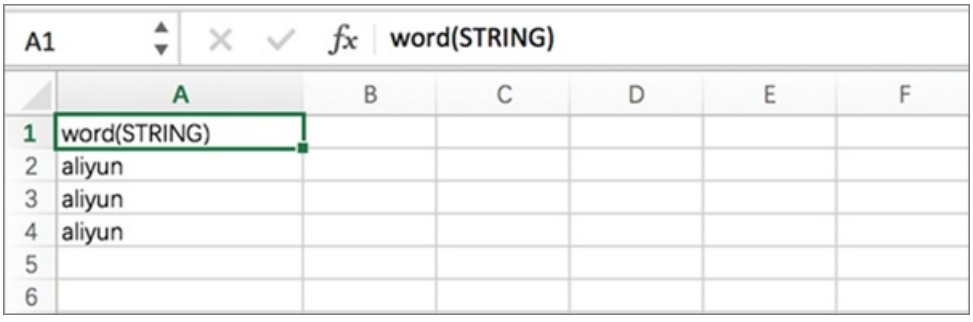
   > **Note** The file that is uploaded for debugging must meet the following requirements:
   >
   > - The file size cannot exceed 1 MB, and the file contains maximum of 1,000 records.
   > - The file must use UTF-8 encoding.
   > - Commas (,) cannot be used in test data, because the file uses the comma-separated values (CSV) format.
   > - Numeric values can be displayed only in the general format, and cannot be displayed in the scientific notation format.

3. Click **Upload** to upload the file.
4. Click **OK**.
5. View the debugging result in the output window.

Sample file for debugging the word count job

> **Note** The file for debugging is in the CSV format. We recommend that you use the following software applications to open and modify the template:
>
> - Excel for Windows users.
> - Vim or Sublime Text for MacOS users. We do not recommend that you use Number because it adds unnecessary fields when you modify CSV files.

Sample file for debugging the word count job



Test data

You can download test data and upload the data on the **Debug File** page.

> **Note** The *test data for statistical analysis of frequently used words* is unavailable for download in a PDF file. You can contact system administrators to download the test data.

View the debugging result

Real-time computing is triggered by data streams. Each data record from the stream_source table triggers a stream processing procedure. After each procedure is complete, a computing result is exported. The test file contains three data records. After each data record reaches Realtime Compute, a stream processing procedure is triggered. Therefore, a total of three data records are displayed on the screen. Realtime Compute uses the following computing logic:

- The first data record (aliyun) reaches Realtime Compute. This is the first time that the system has detected the word "aliyun." Therefore, the computing result is `<aliyun, 1>`, which is displayed on the screen.
- The second data record (aliyun) reaches Realtime Compute. The system detects an existing record of `<aliyun, 1>` and increases the value by one. Therefore, the computing result is `<aliyun, 2>`, which is displayed on the screen.
- The third data record (aliyun) reaches Realtime Compute. The system detects an existing record of `<aliyun, 2>` and increases the value by one. Therefore, the computing result is `<aliyun, 3>`, which is displayed on the screen.

The third computing result `<aliyun, 3>` is considered as the final output of the debugging. Another sample of test data is provided for you to test the debugging feature. You can use different samples of test data and view the debugging outputs.

3.2.3.4. Administration

After the SQL file has been verified, you can publish the SQL file for the job on the **Administration** page of Realtime Compute. Then, you can start the job. The job runs on a Realtime Compute cluster.

Procedure

1. On the **Development** page, click **Publish**. The **Publish New Version** dialog box appears.
2. In the **Resource Configuration** step, click **Next**.
3. In the **Check** step, click **Next**.
4. In the **Publish File** step, click **Publish**.
5. On the **Administration** page, view the published word count job.
6. Click **Start** in the **Actions** column of the word count job. The **Start** dialog box appears.
7. Specify **Start Time of Reading Data** and click **OK**. Then, the job runs on a Realtime Compute cluster.

Result

After the job is started, click the job name. The **Overview** page appears.

FAQ

Q: Why does the word count job have no input or output while it is running on the distributed compute clusters of Realtime Compute?

A: When you created the `my_source` and `my_result` tables, you did not specify the data storage type of the referenced data source. In this scenario, the source table is considered to be a random table of strings or digits, and the result table is considered to be discarded data.

3.2.4. Big screen service for the Tmall Double Eleven Global Shopping Festival

3.2.4.1. Overview

During Double 11, a big screen shows the total sales volume of Alibaba Group in real time. The big screen service is a highlight for the shopping festival.

Stream processing for the big screen service was previously based on Apache Storm that is an open source distributed real-time computation system. The Apache Storm-based development process took around one month. The application of Flink SQL reduces the period for the development of the big screen service to three days. The underlying layer of Realtime Compute removes the Apache Storm modules that are designed for execution optimization and troubleshooting. This achieves a higher processing efficiency for Realtime Compute jobs.

3.2.4.2. Scenario description

The streaming data input for the Tmall big screen service is the transaction data from the Tmall platform. The incoming transaction data is organized based on a two-dimensional table: `tmall_trade_detail`.

Field	Type	Description
tid	BIGINT	The order ID.
buyer_uid	BIGINT	The buyer ID.
seller_uid	BIGINT	The seller ID.
gmtdate	TIMESTAMP	The time when the order is completed.
payment	DOUBLE	The order amount.

Realtime Compute calculates two metrics based on the preceding table: the total number of orders and the total order amount up to the current time. The two metrics are written to an online RDS system and displayed on a big screen in real time. The online RDS system is used to store the result table: `tmall_trade_state`.

Field	Type	Description

Field	Type	Description
gmtdate	VARCHAR(16)	The date when the order is completed.
trade_count	BIGINT	The total number of orders.
trade_sum	DOUBLE	The total order amount.

The following topics describe how to build an end-to-end solution for the Tmall big screen service in around 10 minutes.

3.2.4.3. Preparations

Before editing Flink SQL statements for a Realtime Compute job, you must register data stores for source tables and result tables in Realtime Compute. This topic uses DataHub as an example to describe how to register a data store in Realtime Compute.

Create a DataHub topic

1. Log on to the DataHub console. For more information, see the "Log on to the DataHub console" section in *DataHub User Guide*.
2. If one or more projects have been created, click **View** in the **Actions** column for the target project. If no projects have been created, click **Create Project** to create a project and click **View** in the **Actions** column.
3. On the page that appears, click **Create Topic**.
4. Configure the topic based on the schema of the tmall_trade_state RDS table in the "Scenario description" section.

After performing these steps, you can edit Flink SQL statements for the Realtime Compute job.

Upload data to DataHub

You can upload data to the DataHub topic that you have created. To do this, follow these steps. Log on to the **DataHub** console. You can upload data to the DataHub topic that you have created. To do this, follow these steps:

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Data Acquisition**.
3. Click **Upload File**.
4. On the page that appears, double-click the target project and click the target DataHub topic.
5. Click **Select File** to select a file.
6. Click **Upload**.

To simplify the test procedure, you can use thetest data about the Double 11. You can download the data and then upload it to the DataHub topic for data collection.

3.2.4.4. Register a data store

The data store registration feature of Realtime Compute allows you to easily register DataHub topics, create tables, and reference data stores. To register a data store, follow these steps:

Procedure

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click the **Storage** tab.
4. Click the **DataHub Data Storage** folder.
5. On the top of the page, click **+Registration and Connection**.
6. Register a DataHub project in Realtime Compute. For more information about parameter settings, see Register a DataHub project.

   If you use ApsaraDB for RDS for MySQL to store the result data for data visualization, you must register an RDS data store in Realtime Compute. For more information, see Register an RDS instance.

3.2.4.5. Development

After the data has been collected to Realtime Compute, you can continue to edit Flink SQL statements.

1. Create a reference to the source.

   To create references to the DataHub source table and RDS result table, click Data Storage in the left-side navigation pane of the **Development** page in the Realtime Compute console, and perform the following operations:

   - Find the target DataHub topic, and click **Reference as Source Table**. Realtime Compute automatically parses the schema of the topic and adds the corresponding SQL statements to the **Development** page.
   - Find the target RDS table, and click **Reference as Result Table**. Realtime Compute automatically parses the schema of the table and adds the corresponding SQL statements to the **Development** page.

2. Edit Flink SQL statements.

   If you have created the DataHub topic and RDS table as described in the previous topics, the Flink SQL code for the tmall_d11 job can be executed directly. Otherwise, change the names of the DataHub topic and RDS table based on the topic and table that you have created. The sample code is as follows:

```
replace into tmall_trade_state
  select
    from_unixtime(FLOOR(tmall_trade_detail.gmtdate/1000), 'yyyy-MM-dd') as gmt_date,
    count(tid) as trade_count,
    sum(payment) as trade_sum
  from
    tmall_trade_detail
  group by
    from_unixtime(FLOOR(tmall_trade_detail.gmtdate/1000), 'yyyy-MM-dd');
```

Note You can modify the information about tables and fields as required.

3. Debug the Flink SQL code.

   The data during the Double 11 Shopping Festival is available for testing. To debug the code, download the test data and upload the data on the **Development** page for debugging.

4. Publish the SQL file for the tmall_d11 job.

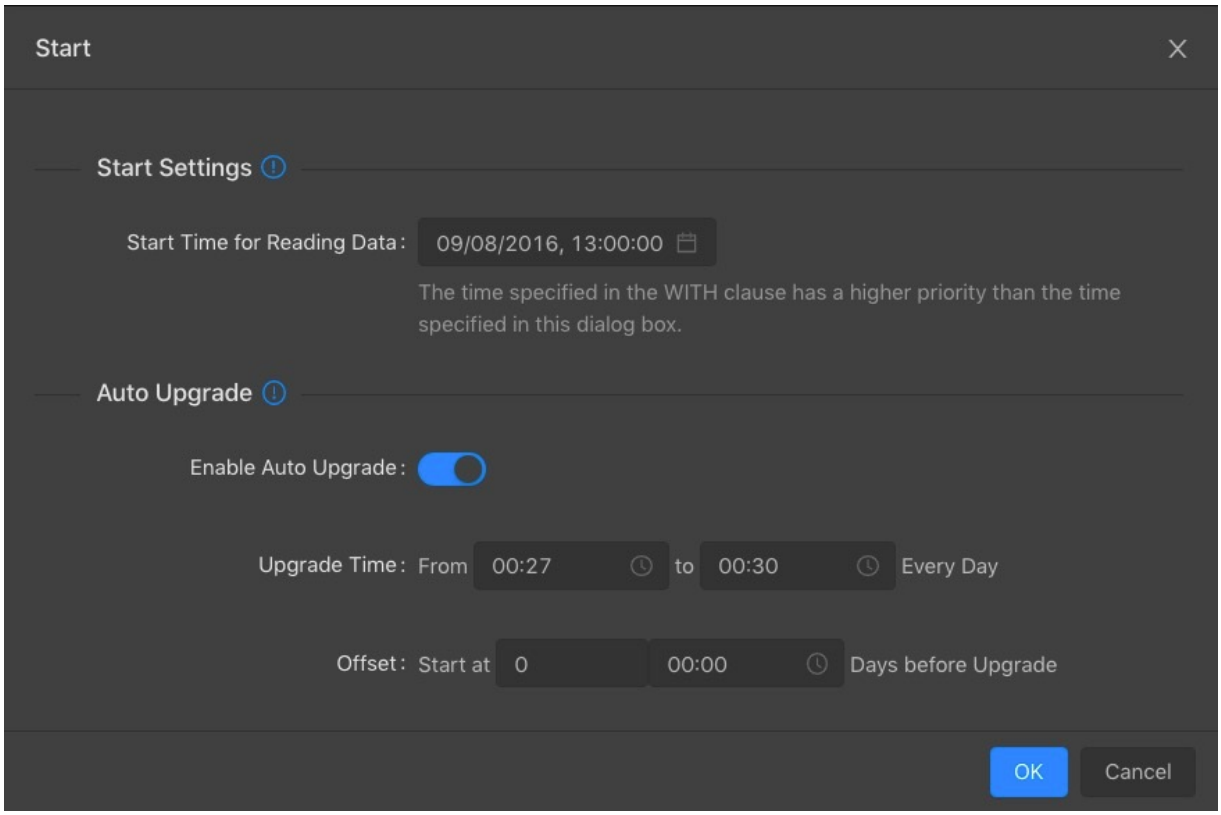
   After the computational logic has been verified in the debugging phase, click **Publish** on the **Development** page to publish the SQL file for the tmall_d11 job. Then, you can view the tmall_d11 job on the **Administration** page of the Realtime Compute console, and manage the job in the production environment, such as starting the job.

3.2.4.6. Administration

On the **Administration** page, you can click **Start** in the **Actions** column and specify the parameters on the page that appears to start a stream processing job, for example, the tmall_d11 job.

Note After you click **Start**, a dialog box is displayed. In the dialog box, you can specify the start time for reading data from the source data store.

The specified start time must be earlier than the file upload time. For example, the start time can be one hour earlier than the file upload time. In the Double 11 use case, the current time is 14:10, and 10 minutes have elapsed since the source data is uploaded. Therefore, the start time is set to 13:00.



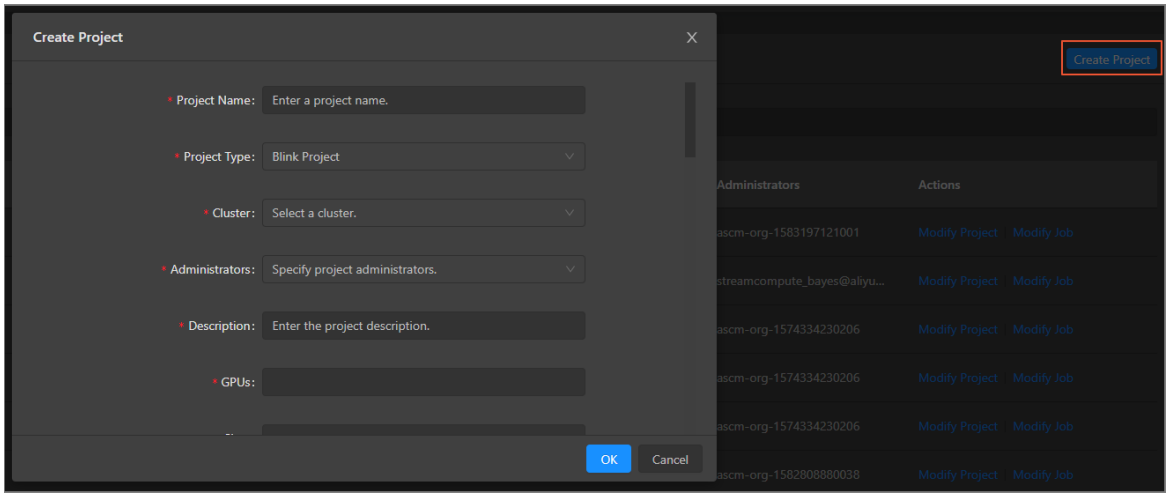
You can check the result data in the ApsaraDB for RDS data store after the job runs as expected. In the result table, five transactions and a turnover of CNY 500 are displayed. This is consistent with the source data for testing. In this way, an end-to-end verification is performed to check the SQL code.

3.3. Project management

This topic describes how to create and search for a project.

Create a project

1. Log on to the Realtime Compute console.
2. In the top navigation bar, move the pointer over your profile picture and click **Project Management**.
3. In the upper-right corner of the **Projects** page, click **Create Project**.
4. Configure the project information.



Parameter description

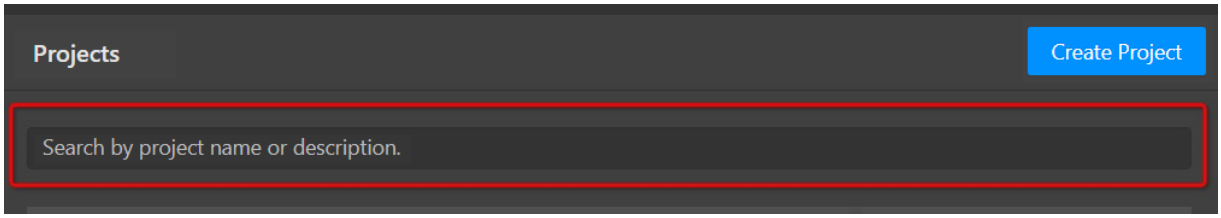
Parameter	Description
Project Name	The name of the project.
Project Type	The type of the project. **Blink Project** is selected by default.
Cluster	The cluster on which the jobs in the project run.
Description	The description of the project.
GPUs	The number of GPUs that are used by the project.
Slots	The number of compute units (CUs) that are used by the project. One CU is assigned with one CPU core and 4 GB memory.
Alert Methods	The methods in which alerts are sent when errors occur during job running. You can receive alerts by using text messages or TradeManager messages.
File Types	The supported file types. You can keep the default setting.
Storage Types	The supported data store types. You can keep the default setting.
Max Data Stores	The maximum number of data stores that can be registered in Realtime Compute. You can keep the default setting.
Max File Versions	The maximum number of code versions for an SQL file. You can keep the default setting.
Max Folders	The maximum number of folders that can be created in the project. You can keep the default setting.
Max Folder Levels	The maximum number of folder levels in the project. You can keep the default setting.
Max Files	The maximum number of job SQL files that can be created in the project. You can keep the default setting.

Parameter	Description
Max Resources	The maximum number of JAR files and DICTIONARY resources that can be uploaded. You can keep the default setting.
Max Referenced Resources	The maximum number of JAR files and DICTIONARY resources that can be referenced. You can keep the default setting.
Monitoring and Alerting	Specifies whether to enable the monitoring and alerting feature. You can keep the default setting.
Data Collection	Specifies whether to collect data while a job is running. You can keep the default setting.
Data Display	Specifies whether to display data. You can keep the default setting.
Metastore	Specifies whether to display metadata. You can keep the default setting.
Data Storage	Specifies whether to enable data store registration. This feature is enabled by default. You can keep the default setting.
Engine	Specifies whether to display the engine. You can keep the default setting.
Online Logs	Specifies whether to record the job running logs. This feature is enabled by default. You can keep the default setting.
Resource Management	Specifies whether resources such as JAR files can be uploaded. This feature is enabled by default. You can keep the default setting.
Switch Version	Specifies whether to enable the job version switch feature. This feature is enabled by default. You can keep the default setting.
Project Protection	Specifies whether to enable the project lock feature. You can keep the default setting.

5. Click **OK**.

Search for a project

On the **Projects** page, enter a keyword or full name of a project in the search box to find the project.



3.4. Data storage

3.4.1. Overview

This chapter describes data storage systems supported by Realtime Compute.

3.4.2. Overview

3.4.2.1. Overview

To facilitate data storage management, you can register data storage resources on the Realtime Compute development platform. This enables you to leverage the advantages of the one-stop Realtime Compute service. In Realtime Compute, you can manage multiple data storage systems, such ApsaraDB for RDS, and Table Store. With this one-stop management service, you no longer have to navigate across multiple management consoles of different storage systems.

3.4.2.2. Types

Realtime Compute supports both streaming data storage and static data storage.

Streaming data storage

Streaming data storage systems provide inputs and outputs for downstream Realtime Compute jobs.

Streaming data storage

Storage system	Input	Output
DataHub	Supported	Supported
Log Service	Supported	Supported
MQ	Supported	Supported

Static data storage

Static data storage systems provide outputs for downstream Realtime Compute jobs and allow you to perform association queries.

Static data storage

Storage system	Dimension table	Output
ApsaraDB for RDS	Supported	Supported
Table Store	Supported	Supported

3.4.2.3. Registration and usage

This topic describes how to register and use external data stores in Realtime Compute.

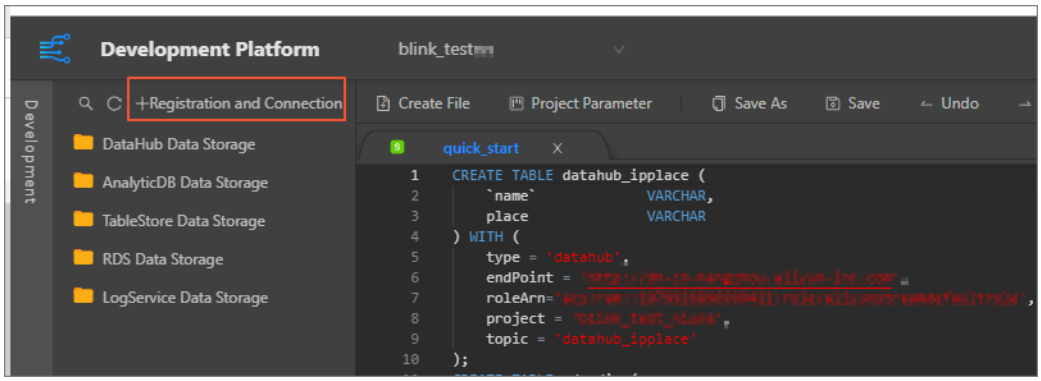
> **Note** If a job requires the use of the data stores owned by another Apsara Stack tenant account, you can write DDL statements to reference the data stores. In the DDL statements, you must specify the AccessKey ID and AccessKey secret of the account. In this scenario, you cannot use the codeless UI to manage the data stores.

Register a data store

To register a data store, follow these steps:

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane of the page that appears, click the **Storage** tab. Select the folder for the data store that you want to register. Then, click **+Registration and Connection**.

   Register a data store



4. In the dialog box that appears, configure the required parameters and click **OK**.

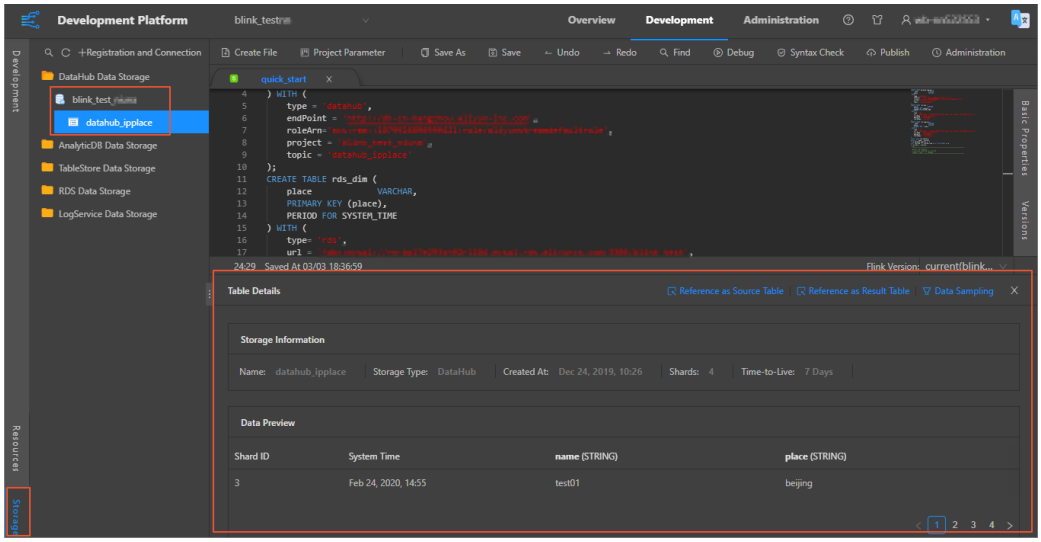
> **Note** After you enable the data store registration feature, you can only register data stores that are owned by your organization.

Preview data from a data store

Realtime Compute provides the data preview feature for each registered data store. To preview data, click the **Storage** tab and double-click the folder of the target data store in the left-side navigation pane. The following example shows how to preview data from a DataHub data store.

1. Log on to the Realtime Compute console. In the top-navigation bar, click Development. On the page that appears, click the **Storage** tab and double-click the **DataHub Data Storage** folder.
2. Double-click the target project and then the target topic to view the details.

   Table details



Use the auto DDL generation feature

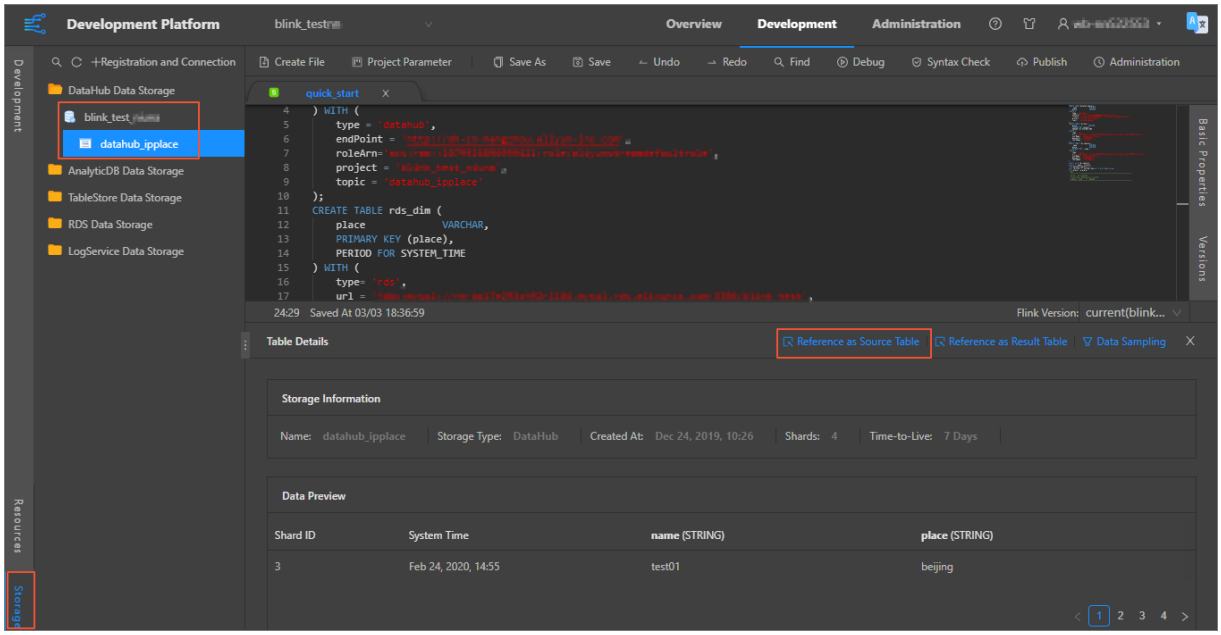
You must declare tables from external data stores before you can reference these tables. The following example shows how to reference a source table that contains streaming data:

```
CREATE TABLE in_stream( a varchar, b varchar, c timeStamp) with ( type='datahub', endPoint='http://dh-cn-hangzhou.aliyuncs.com', project='blink_test', topic='ip_count02', accessId='LTAIYtaf******', accessKey='gUqyVwfkK2vfJI7jF90******');
```

The field names in the table that is referenced on the Development page must be the same as those in the DataHub topic. You must declare the field data types in the code based on the field type mapping between DataHub and Realtime Compute to ensure that Realtime Compute can identify the data. Realtime Compute offers the auto DDL generation feature. The following section describes how to use this feature.

1. In the left-side navigation pane of the **Development** page, click the **Storage** tab.
2. On the **Storage** tab, navigate through cascaded folders and nodes to find the target table. Then, double-click the name of the target table.
3. In the **Table Details** pane that appears, click **Reference as Source Table**, **Reference as Result Table**, or **Reference as Dimension Table** as required. Then, you can obtain the DDL statements that are automatically generated to reference the target table.

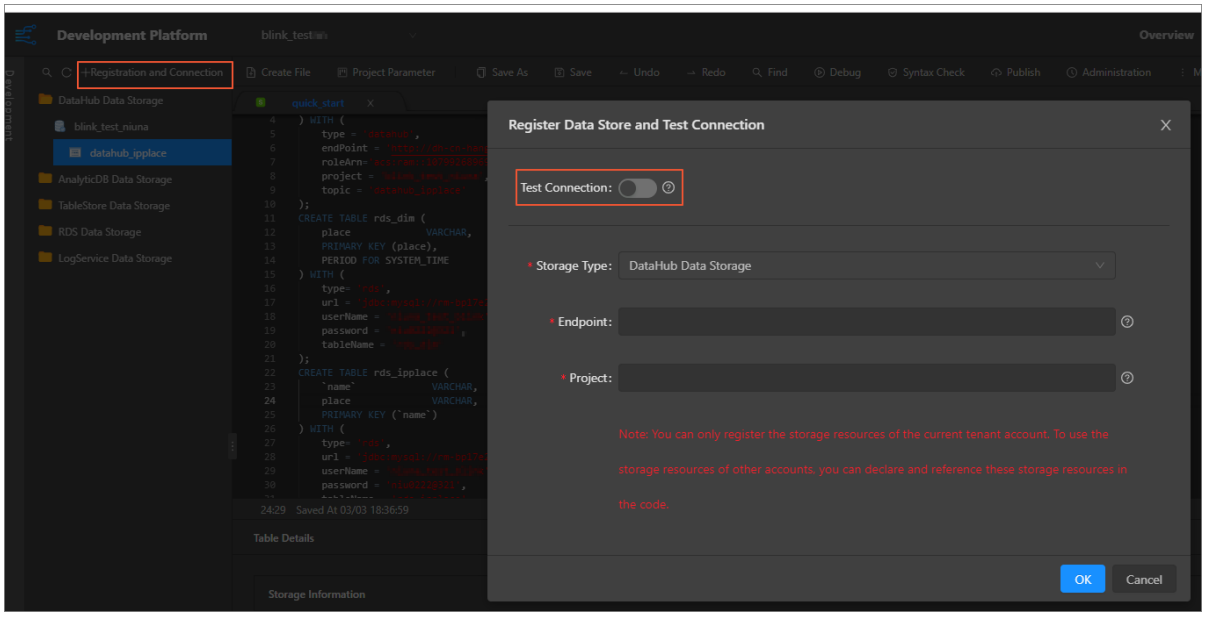
To reference a source table, log on to the Realtime Compute console and open the target SQL file on the Development page. Click the Storage tab, select the table for reference, and then click **Reference as Source Table**. The required DDL statements are displayed on the current page.



Test network connection

Realtime Compute offers the network connection test feature for data stores. This feature allows you to test the connection between Realtime Compute and a target data store. To enable the network connection test feature, follow these steps:

1. In the left-side navigation pane of the **Development** page, click the **Storage** tab.
2. In the upper-right corner of the **Storage** tab, click **+Registration and Connection**.
3. In the **Register Data Store and Test Connection** dialog box, turn on **Test Connection**.



Example: Reference data stores owned by another level-1 organization

You can only register and use data stores that are owned by your level-1 organization. To use data stores that are owned by another level-1 organization, write DDL statements to create a reference to these data stores. For example, if a user from Organization A wants to use the data stores owned by Organization B, the user can enter the following DDL statements:

```
CREATE TABLE in_stream( a varchar, b varchar, c timeStamp) with ( type='datahub', endPoint='http://dh-cn-hangzhou.aliyuncs.com', project='blink_test', topic='ip_count02', accessId='AccessKey ID authorized by Organization B users', accessKey='AccessKey secret authorized by Organization B users');
```

3.4.3. Register a DataHub data store

DataHub, an Alibaba Cloud streaming data service, is a real-time data distribution platform designed to process streaming data. You can publish and subscribe to applications for streaming data in DataHub and distribute the data to other platforms. DataHub allows you to analyze streaming data and build applications based on the streaming data. Realtime Compute often uses DataHub to store source and result tables that contain streaming data.

Register a DataHub project

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click the **Storage** tab.
4. Right-click the **DataHub Data Storage** folder and select **Register Data Store** to register a DataHub project in Realtime Compute.

Parameter description

Parameter	Description
Test Connection	Specifies whether to enable the network connection test feature. Network connection tests are automatically performed on data stores that can be registered in Realtime Compute. To test the connection between Realtime Compute and data stores that cannot be registered, turn on the Test Connection switch.
Storage Type	The type of the data store. DataHub Data Storage is selected by default.
Endpoint	The endpoint of DataHub. The endpoint of DataHub varies with regions. For more information about endpoints, contact your administrator. **Note** To specify this parameter for Apsara Stack, contact your Apsara Stack administrator to obtain the endpoint of DataHub.
Project	The name of the DataHub project. **Note** You can only register DataHub projects that are owned by your level-1 organization. For example, if DataHub Project A is owned by Organization A, users from Organization B cannot register Project A in Realtime Compute.

Parameter	Description
AccessKey ID	The AccessKey ID of the current account.
AccessKey Secret	The AccessKey secret of the current account. The AccessKey secret enables Realtime Compute to access the DataHub project.

Scenarios

DataHub is a streaming data storage system that can be used to store source and result tables. However, it cannot be used to store dimension tables for Realtime Compute.

FAQ

Q: Why am I unable to register a DataHub project in Realtime Compute?

A: Realtime Compute uses a storage software development kit (SDK) to access different data stores. The Storage tab in the Realtime Compute console only helps you manage data from different data stores. You can perform the following operations to troubleshoot registration errors:

- Check whether you have created a DataHub project and have the permissions to access the project. You can log on to the DataHub console and check whether you can access the project.
- Check whether you are the project owner. You can only register DataHub projects that are owned by your level-1 organization. For example, if DataHub Project A is owned by Organization A, users from Organization B cannot register Project A in Realtime Compute.
- Check whether you have specified the correct DataHub endpoint and project name.
- Check whether you have specified a classic network endpoint for the Endpoint parameter. If you specify a VPC endpoint, the DataHub project will fail to be registered.
- Check whether you have registered the DataHub project. Realtime Compute provides a registration check mechanism to prevent duplicate registration.

Q: Why does Realtime Compute only support time-based sampling?

A: DataHub stores streaming data, and you can only specify time parameters in the API. Therefore, Realtime Compute supports only time-based sampling.

3.4.4. Register a Log Service data store

Log Service (previously known as SLS) provides an end-to-end solution for log management. You can use Log Service to easily collect, subscribe to, dump, and query large amounts of log data. Realtime Compute can integrate with Log Service to process logs. This eliminates the need of data migration.

Register a Log Service project

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click the **Storage** tab.
4. Right-click the **LogService Data Storage** folder and select **Register Data Store** to register a Log Service project in Realtime Compute.

Parameter description

Parameter	Description
Test Connection	Specifies whether to enable the network connection test feature. Network connection tests are automatically performed on data stores that can be registered in Realtime Compute. To test the connection between Realtime Compute and data stores that cannot be registered, turn on the Test Connection switch.
Storage Type	The type of the data store. LogService Data Storage is selected by default.
Endpoint	The endpoint of Log Service. The endpoint of Log Service varies with regions. Note For more information about the endpoint of Log Service, contact the Apsara Stack system administrator.
Project	The name of the Log Service project. Note You can only register Log Service projects that are owned by your level-1 organization. For example, if Log Service Project A is owned by Organization A, users from Organization B cannot register Project A in Realtime Compute.
AccessKey ID	The AccessKey ID of the current account.
AccessKey Secret	The AccessKey secret of the current account. The AccessKey secret enables Realtime Compute to access the Log Service project.

Scenarios

Log Service is a streaming data storage system that can be used to store source tables and result tables. However, it cannot be used to store dimension tables for Realtime Compute.

FAQ

- Q: Why am I unable to register a Log Service project in Realtime Compute?

  A: Realtime Compute uses a storage software development kit (SDK) to access different data stores. The Storage tab in the Realtime Compute console only helps you manage data from different data stores. You can perform the following operations to troubleshoot registration errors:

  - Check whether you have created a Log Service project and have the permissions to access the project. You can log on to the Log Service console and check whether you can access the project.

- Check whether you are the project owner. You can only register Log Service projects that are owned by your level-1 organization. For example, if Log Service Project A is owned by Organization A, a user from Organization B cannot register Project A in Realtime Compute.
- Check whether you have specified the correct Log Service endpoint and project name.

  > **Note** The endpoint must start with http and cannot end with a forward slash (/). For example, *http://cn-hangzhou.log.aliyuncs.com* is correct, and *http://cn-hangzhou.log.aliyuncs.com/* is incorrect.

- Check whether you have registered the Log Service project. Realtime Compute provides a registration check mechanism that prevents duplicate registration.

- Q: Why does Realtime Compute support only time-based sampling?

  A: Log Service stores streaming data, and you can only specify time parameters in the API. Therefore, Realtime Compute supports only time-based sampling.

  > **Note** To use the search feature of Log Service, log on to the Log Service console.

3.4.5. Register a Tablestore data store

Tablestore is a NoSQL database service that is based on the Apsara distributed system. Tablestore allows you to store and access large amounts of structured data in real time. Tablestore features massive data storage and low access delays, which makes it suitable to store dimension tables and result tables for Realtime Compute.

Register a Tablestore instance

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click the **Storage** tab.
4. Right-click **TableStore Data Storage** and select **Register Data Store**. In the dialog box that appears, register a Tablestore instance in Realtime Compute.

Parameters

Parameter	Description
Test Connection	Specifies whether to enable the network connection test feature. Network connection tests are automatically performed on data stores that can be registered in Realtime Compute. To test the connection between Realtime Compute and data stores that cannot be registered, turn on the **Test Connection** switch.
Storage Type	The type of the data store. **TableStore Data Storage** is selected by default.
Endpoint	The endpoint of the Tablestore instance. You must enter the internal endpoint of the Tablestore instance. You can log on to the Tablestore console to view the internal endpoint of the instance.

Parameter	Description
Instance Name	The name of the Tablestore instance.
AccessKey ID	The AccessKey ID of the current account.
AccessKey Secret	The AccessKey secret of the current account. The AccessKey secret enables Realtime Compute to access the Tablestore instance.

3.4.6. Register an RDS data store

This topic describes how to register and use an ApsaraDB for RDS data store in Realtime Compute.

RDS overview

RDS offers a stable, reliable, and scalable online database service. Based on the Apsara distributed system and high performance SSD storage, RDS supports a wide range of engines, such as MySQL, PostgreSQL, and Postgres Plus Advanced Server (PPAS, highly compatible with Oracle). Realtime Compute supports the following RDS engines: MySQL and PostgreSQL.

The performance of Tablestore in high concurrency scenarios where large amounts of data need to be processed is higher than that of RDS. The performance of RDS is restricted by the limits of relational models. Therefore, RDS is often used to store result tables for Realtime Compute. In low concurrency scenarios where a small number of data needs to be processed, RDS can be used to store dimension tables.

> **Note** Realtime Compute uses relational databases, such as ApsaraDB RDS for MySQL, to store result data. Distributed Relational Database Service (DRDS) and RDS connectors are used. If Realtime Compute frequently writes data into a DRDS or RDS table, deadlocks may occur. In scenarios that require high queries per second (QPS), high transactions per second (TPS), or highly concurrent write operations, we recommend that you do not use DRDS or RDS to store the result tables of Blink jobs. To prevent deadlocks, we recommend that you use Tablestore to store result tables.

Register an RDS instance

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click the **Storage** tab.
4. Right-click **RDS Data Storage**, and select **Register Data Store**. In the dialog box that appears, register an RDS instance in Realtime Compute.

Parameters

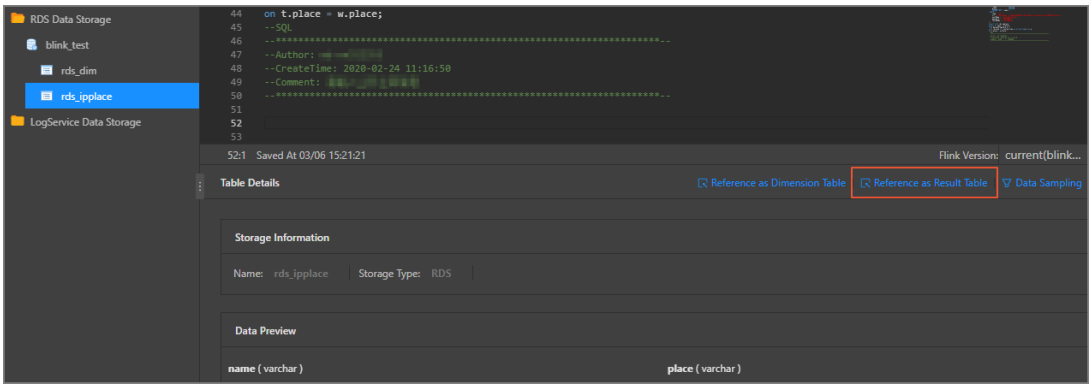
Parameter	Description

Parameter	Description
Test Connection	Specifies whether to enable the network connection test feature. Network connection tests are automatically performed on data stores that can be registered in Realtime Compute. To test the connection between Realtime Compute and data stores that cannot be registered, turn on the **Test Connection** switch.
Storage Type	The type of the data store. **RDS Data Storage** is selected by default.
URL	The connection URL of the RDS database.
DBName	The name of the RDS database to be accessed by Realtime Compute. **Note** This parameter specifies the RDS database name instead of the RDS instance name. RDS uses whitelists for access control to ensure system security. The IP addresses of the Realtime Compute console and worker nodes must be added to RDS whitelists. Otherwise, Realtime Compute may fail to connect to RDS. For more information, see Specify whitelist settings.
User Name	The username that you use to log on to the RDS database.
Password	The password that you use to log on to the RDS database.
Engine	The type of the RDS database. Valid values: ○ **mysql** ○ **postgresql** ○ **sqlserver**

Reference an RDS table as a result table

After you register an RDS data store, double-click the RDS database, double-click the RDS table that you want to reference as a result table, and then click **Reference as Result Table**.

Reference an RDS table as a result table



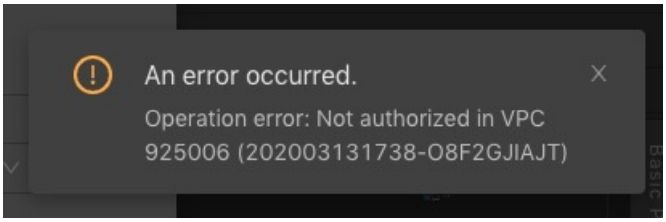
After you click **Reference as Result Table**, Realtime Compute automatically generates the corresponding DDL statements on the current page.

Result

```
31      place             VARCHAR,
32      PRIMARY KEY (`name`)
33  ) WITH (
34      type= 'rds',
35      url = '[redacted]',
36      userName = '[redacted]',
37      password = '[redacted]',
38      tableName = '[redacted]'
39  );
```

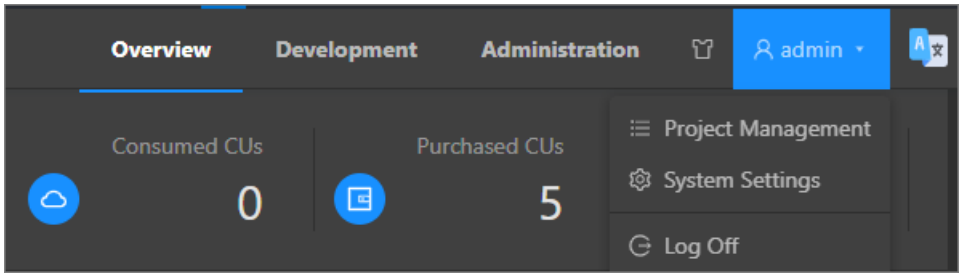
If the following error message appears, troubleshoot and rectify the fault as follows.

Error message



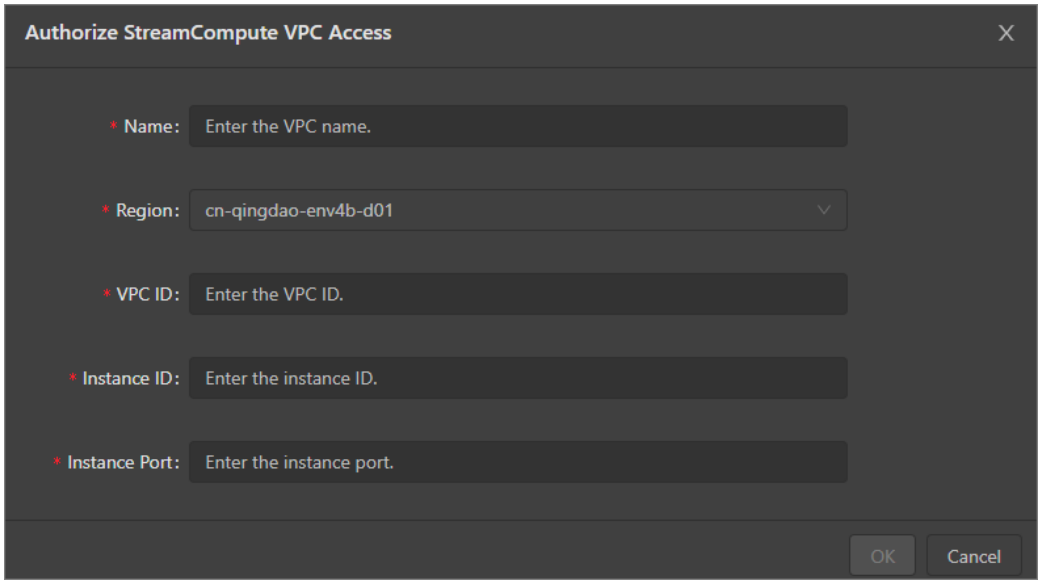
The error occurs because a VPC (not a classic network) was selected when you created the RDS instance. To rectify this fault, follow these steps:

1. Move the pointer over the administrator icon, as shown in the following figure.



2. Click **System Settings**.
3. In the left-side navigation pane, click **VPC Access Authorization**.
4. Click **Add Authorization**. The **Authorize StreamCompute VPC Access** page appears.

Authorization



Parameters

Parameter	Description
Name	The name of the VPC.
Region	The region where RDS resides.
VPC ID	The ID of the VPC.
Instance ID	The ID of the RDS instance. You can log on to the RDS console and view the instance ID. Instance information Instance Port	The access port for the RDS instance. To view the internal port number, log on to the RDS console, click the target instance ID or name in the **Instance ID/Name** column. On the page that appears, view the internal port number in the Basic Information section.

5. Register the target RDS instance. You must specify the required parameters during the registration.

You can only register data storage resources that are owned by your level-1 organization. For example, if RDS Instance A is owned by Organization A, a user from Organization B cannot register RDS Instance A in the Realtime Compute console. To use Instance A in a stream processing job, the user from Organization B must use SQL code to create a reference to Instance A.

> **Note** If you want to use the RDS storage resources owned by your level-1 organization, we recommend that you do not use SQL code to create a reference to these resources.

The user from Organization B must also specify the following parameters in the WITH clause based on the information of Instance A: url, userName, password, and tableName.

Configuration

```
CREATE TABLE datahub_output (
    id            varchar
) WITH (
    type= 'rds',
    url = '[redacted]',
    userName = '[redacted]',
    password = '[redacted]',
    tableName = 'datahub_output'
);
```

To use RDS storage resources by writing SQL code, the user from Organization B must specify whitelist settings.

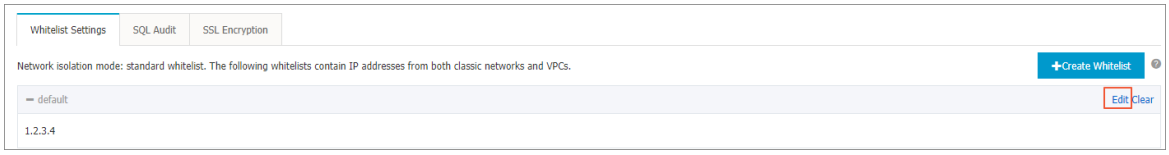
Specify whitelist settings

Some data stores use whitelists for access control to ensure high-level security. These data stores allow access only from the IP addresses that are added to the whitelists. This prevents unauthorized Apsara Stack services from accessing data in these data stores. For example, a newly created RDS database denies all access. You must add IP addresses to the RDS database whitelists to allow access to the database.

RDS can be accessed from both external and internal networks. To enable Realtime Compute to access RDS, you must add the CIDR blocks of Realtime Compute to RDS whitelists.

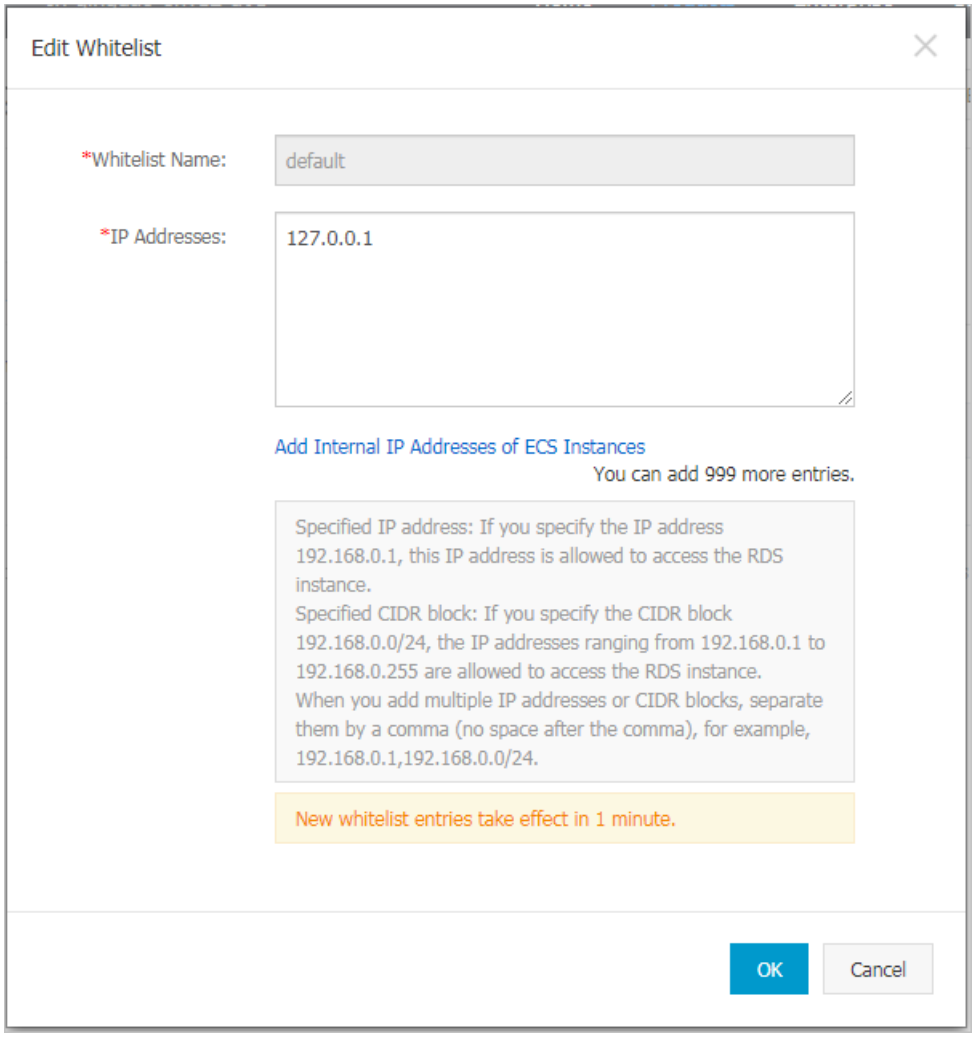
To do this, follow these steps:

1. Log on to the ApsaraDB for RDS console.
2. On the **Instances** page, click the ID of an instance in the **Instance ID/Name** column.
3. In the left-side navigation pane, click **Data Security**.
4. On the **Whitelist Settings** tab, click **Edit** corresponding to the **default** whitelist.



> **Note**
>
> - To connect an ECS instance to an RDS instance by using an internal endpoint, you must make sure that the two instances are in the same region and have the same network type. Otherwise, the connection fails.
> - You can also click **Create Whitelist** to create a new whitelist.

5. In the **Edit Whitelist** dialog box that appears, specify the IP addresses or CIDR blocks that are used to access the instance, and then click **OK**.



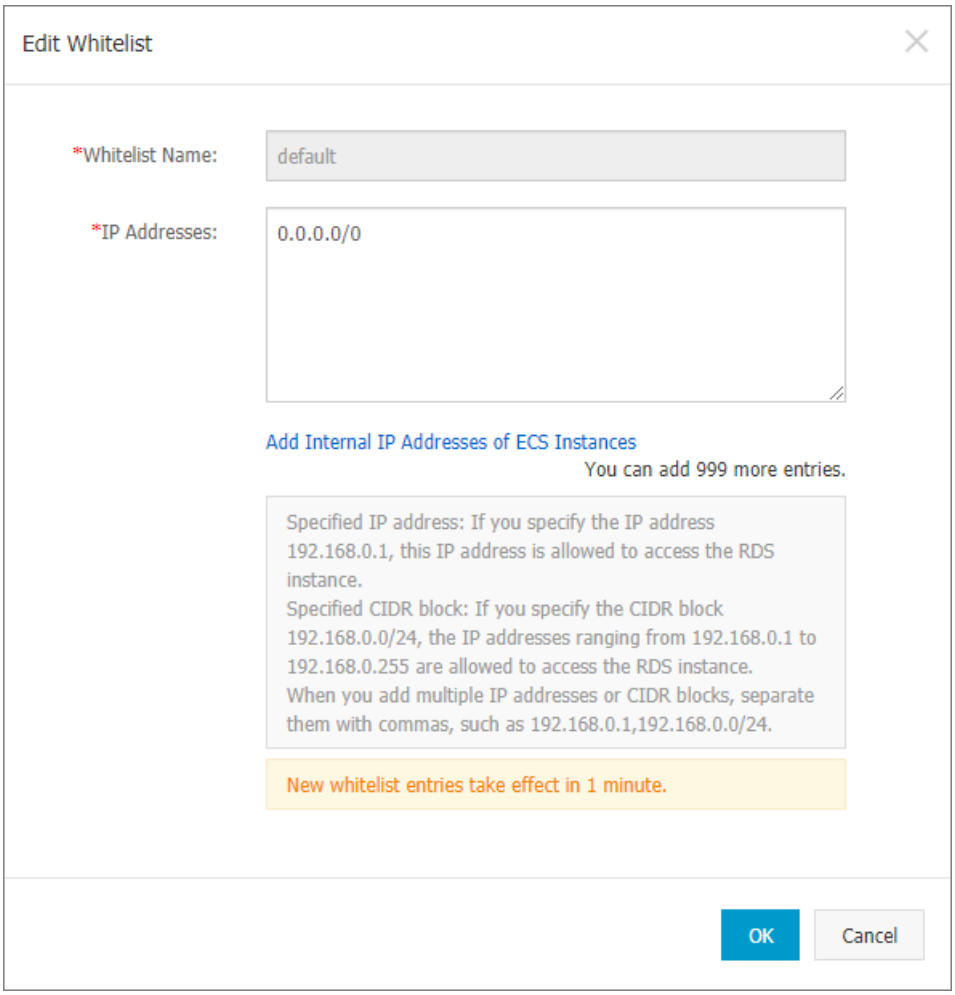
- If you specify the 10.10.10.0/24 CIDR block, IP addresses in the 10.10.10.X format are allowed to access the RDS instance.
- If you want to add multiple IP addresses or CIDR blocks, separate entries with commas (without spaces), such as 192.168.0.1,172.16.213.9.
- After you click **Add Internal IP Addresses of ECS Instances**, the IP addresses of all the ECS instances under your Apsara Stack account are displayed. You can select the required IP addresses to add to the whitelist.

> **Note** If you add a new IP address or CIDR block to the **default** whitelist, the default address 127.0.0.1 is automatically deleted.

Troubleshooting

- Fault description

A stack exception occurs while the system is running, as shown in the following figure.



- Solution

  Add the IP address of your region to an RDS whitelist. For more information, see Specify whitelist settings.

3.5. Data development

3.5.1. Create a job

This topic describes how to create a Realtime Compute job.

Procedure

1. Log on to the Realtime Compute console.
2. Click **Development Platform**.
3. Click **Development** in the top navigation bar.
4. Click **Create File** in the toolbar.
5. In the **Create File** dialog box, specify the required fields.

Field	Description
File Name	The name of the file. The specified name must be 3 to 64 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a lowercase letter.
File Type	The type of the file. Valid values: FLINK_STREAM/SQL and FLINK_STREAM/DATASTREAM.
Storage Path	The folder of the file. You can click the icon on the right side of an existing folder and create a subfolder.

6. Click **OK**.

3.5.2. Development

3.5.2.1. SQL code assistance

The development platform of Realtime Compute offers a complete set of SQL tools in the integrated development environment (IDE). These tools provide the following features to help you with Flink SQL-based development:

- Syntax check

  On the **Development** page of Realtime Compute, the revised script is automatically saved. When the script is saved, an SQL syntax check is automatically performed. If a syntax error is detected, the **Development** page shows the row and column where the error is located, and the cause of the error.

- Intelligent code completion

  When you enter SQL statements on the **Development** page of Realtime Compute, auto completion popups about keywords, built-in functions, tables, or fields are automatically displayed.

- Syntax highlighting

  Flink SQL keywords are highlighted in different colors to differentiate data structures.

3.5.2.2. SQL code version management

Realtime Compute provides key features that help you complete development tasks, such as coding assistance and code version management. A new code version is generated each time you publish a job SQL file. The code version management feature allows you to track code changes and roll back to an earlier version if required.

- Manage code versions

  On the **Development** page, you can manage Flink SQL code versions. A new code version is generated each time you publish a job SQL file. You can use the code version management feature to track versions, modify the code, and roll the code back to an earlier version.

  On the **Versions** tab on the right side of the **Development** page, click **More** in the **Actions** column to manage code versions.

  - **Compare**: Check the differences between the current version and an earlier version.

- **Rollback**: Roll back to an earlier version.
- **Delete**: Delete an earlier version.
- **Locked**: Lock the current version.

> **Note** You cannot submit a new version before you unlock the SQL file.

- Delete code versions

  A snapshot of a code version is created each time you submit an SQL file for publishing a job. This allows you to track code changes. The maximum number of code versions has been specified. If you use Apsara Stack, a maximum of 20 code versions can be published. To find out the maximum number of code versions in other environments, contact the system administrator. If the number of code versions reaches the upper limit, an error message is displayed to alert you to delete one or more earlier versions.

  In this scenario, you must delete one or more earlier versions before you publish new versions. To do this, click the **Versions** tab on the right side of the **Development** page, click **More** in the **Actions** column, and select **Delete** to delete expired versions that are no longer needed.

3.5.2.3. Data store management

The Development page of the Realtime Compute console provides an easy and effective method to manage data stores. For example, you can register external data stores to reference the data stores.

- Data preview

  The **Development** page of Realtime Compute allows you to preview data from a wide range of data stores. Data preview allows you to analyze the characteristics of upstream and downstream data, identify key business logic, and complete development tasks with high efficiency.

- Auto DDL generation

  Realtime Compute provides the auto DDL generation feature. The system can automatically generate DDL statements to reference data stores that can be registered in Realtime Compute. This feature provides a simple method to edit SQL statements for stream processing jobs. This improves overall efficiency and reduces errors when you manually enter SQL statements.

3.5.3. Debug job code

The Realtime Compute development platform provides a simulated running environment where you can customize uploaded data, simulate operations, and check outputs.

After you write the SQL code that implements the computing logic, follow these steps to debug the code:

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click **Development**.
4. On the **Development** tab, double-click the target folder and file name to open the job file.
5. In the top menu bar, click **Syntax Check**.

> **Note** You can use the syntax check feature to check whether the SQL file includes syntax errors. Error messages are displayed for syntax errors.

6. In the top menu bar, click **Debug**. On the **Debug File** page, debug your SQL code.

   The test data for debugging can be acquired by using either of the following two methods:

   - Upload local data.
     a. Click **Download Template**.
     b. Prepare test data based on the template.
     c. Click **Upload**. After the file is uploaded, you can view the uploaded data in the data preview section.
   - Sample online data.
     a. Click **Random Online Data Sampling** or **Sequential Online Data Sampling**.
     b. View the sampled data in the data preview section.

7. Click **OK**.
8. In the output window, view the debugging result.

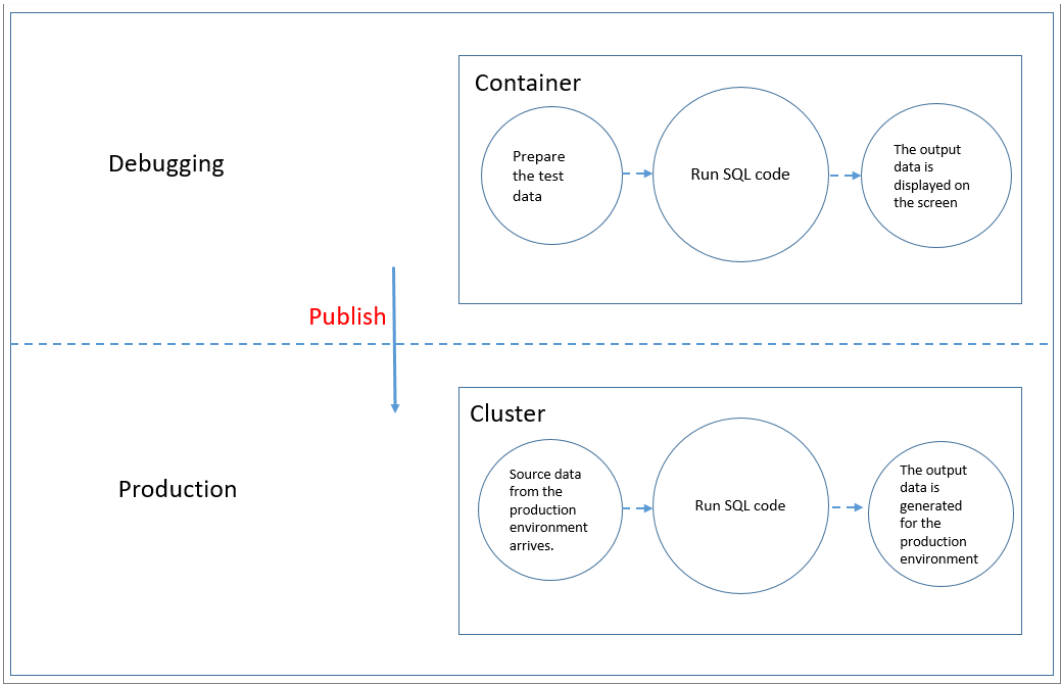
The debugging feature of Realtime Compute provides the following functions:

- Enables isolation between debugging and production environments.

  In the debugging environment, the Flink SQL code runs in a separate container, and computing result data is only displayed on the screen of the **Development** page. In this way, the debugging does not affect the running jobs and data stores in the production environment.

  In the debugging phase, result data is not written to external data stores. In the production environment, failures may occur due to format errors when result data is written to the target data stores. Such failures cannot be identified or prevented in the debugging phase, and can be detected only while jobs are running. For example, failures may occur in the production environment if your result data is too long. This occurs when the result data is written to a result table in ApsaraDB for RDS and the length of character strings reaches the upper limit for an RDS table. The Realtime Compute team is working on support for writing result data to external data stores in the production environment. This allows you to effectively simulate the production environment and resolve more issues in the debugging phase.

  Isolation between debugging and production environments



- Supports the customization of test data.

  In the debugging environment, Realtime Compute does not read data from source data stores, such as DataHub topics that store source tables and RDS instances that store dimension tables. You must create a set of test data and upload the test data on the **Development** page.

  To make the debugging feature easy to use, Realtime Compute provides a template of test data for each type of job. You can download the template and enter your test data.

  > **Note** We recommend that you use the templates to prevent errors.

- Specifies a separator.

  A comma (,) is used as the separator in files for debugging by default. An example of a file for debugging is described as follows:

  ```
  id,name,age
  1,alicloud,13
  2,stream,1
  ```

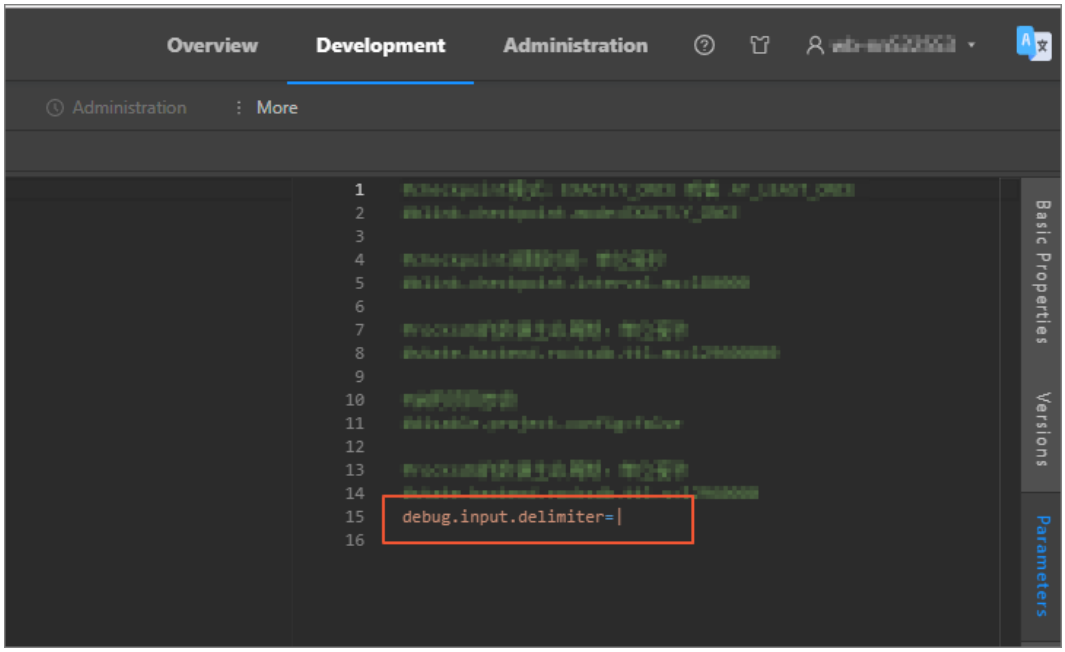
  If the separator is not specified, a comma (,) is used to separate fields. If you need to use a JSON string as the field data and the string contains commas (,), you must specify another character as the separator.

  > **Note** Realtime Compute allows you to specify a character as the separator, but not a multi-character string, such as aaa.

  ```
  id|name|age
  1|alicloud|13
  2|stream|1
  ```

In this example, specify the debug.input.delimiter parameter as follows: `debug.input.delimiter=|`.

Specify a separator



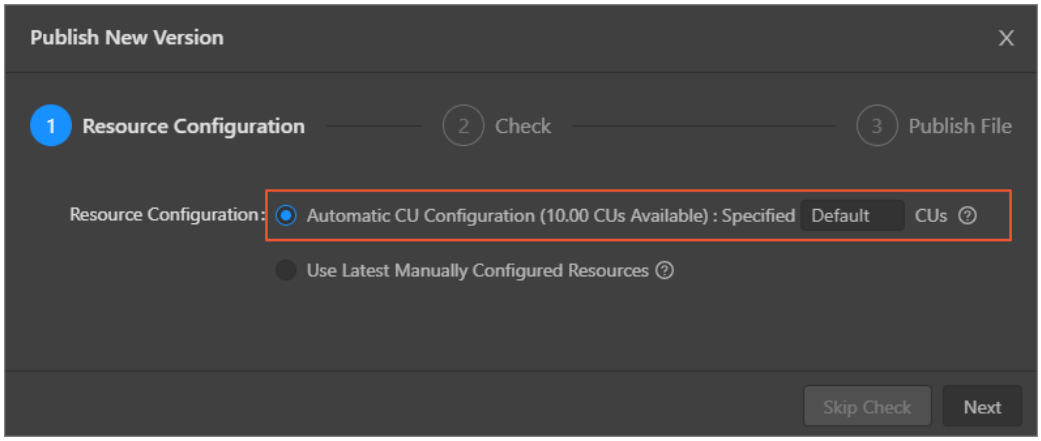
3.5.4. Publish a job SQL file

After you have created and debugged a job Flink SQL file, you can publish the SQL file and manage the job in the production environment.

Procedure

1. Log on to the Realtime Compute console.
2. In the top navigation bar, Click **Development**.
3. In the top menu bar, click **Publish**.
4. In the dialog box that appears, select **Automatic CU Configuration**. If you are performing automatic configuration for the first time, we recommend that you use the default number of CUs. Click **Next**.

   Configure resources



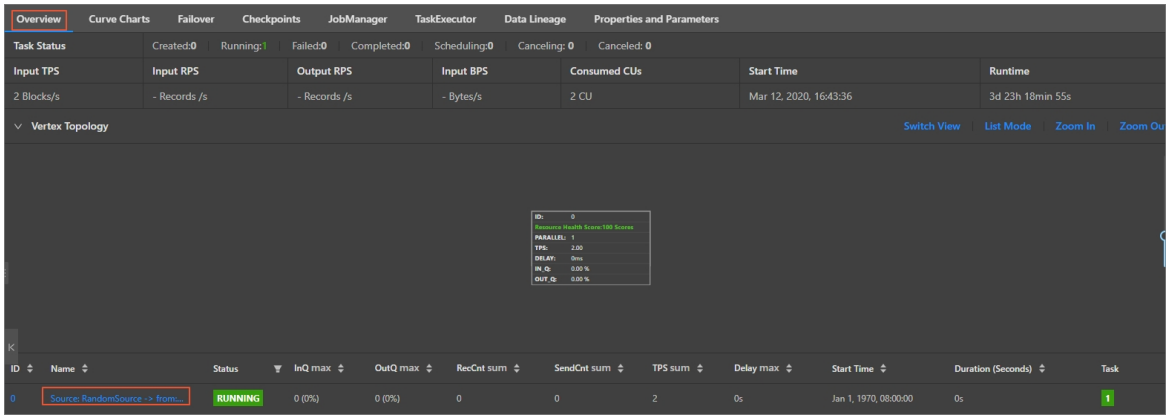
5. Check the data. After the check is completed, click **Next**.
6. Click **Publish**.
7. Go to the **Administration** page to start the job.
   i. In the top navigation bar, click **Administration**.
   ii. On the **Administration** page, find the target job, and click **Start** in the **Actions** column.

3.5.5. View logs

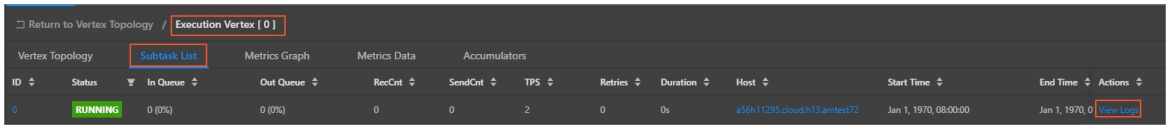
You can view job logs to check the job run information. This topic describes how to view job logs.

Procedure

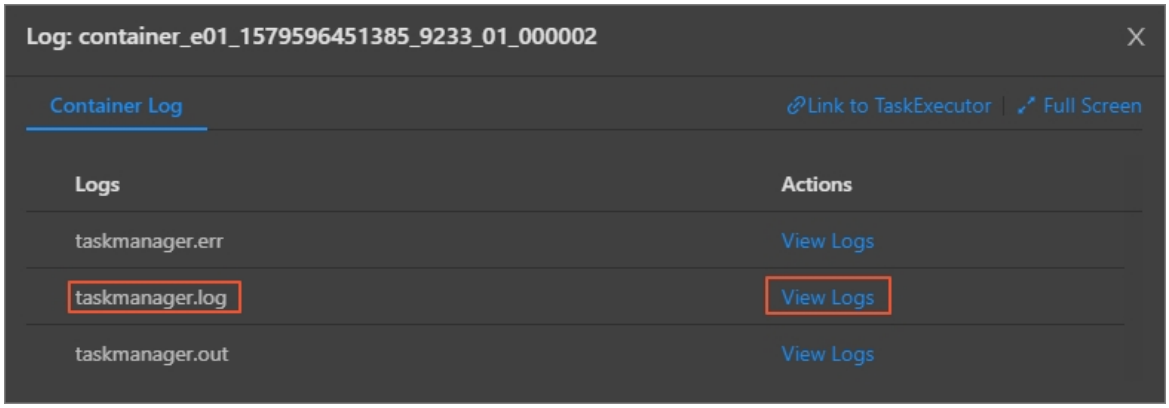
1. Go to the **Administration** page in Realtime Compute.
   i. Log on to the Realtime Compute console.
   ii. In the top navigation bar, click **Administration**.
   iii. On the **Jobs** page that appears, click the target job name in the **Job Name** column.
2. At the bottom of the **Overview** page, click the name of the target vertex.



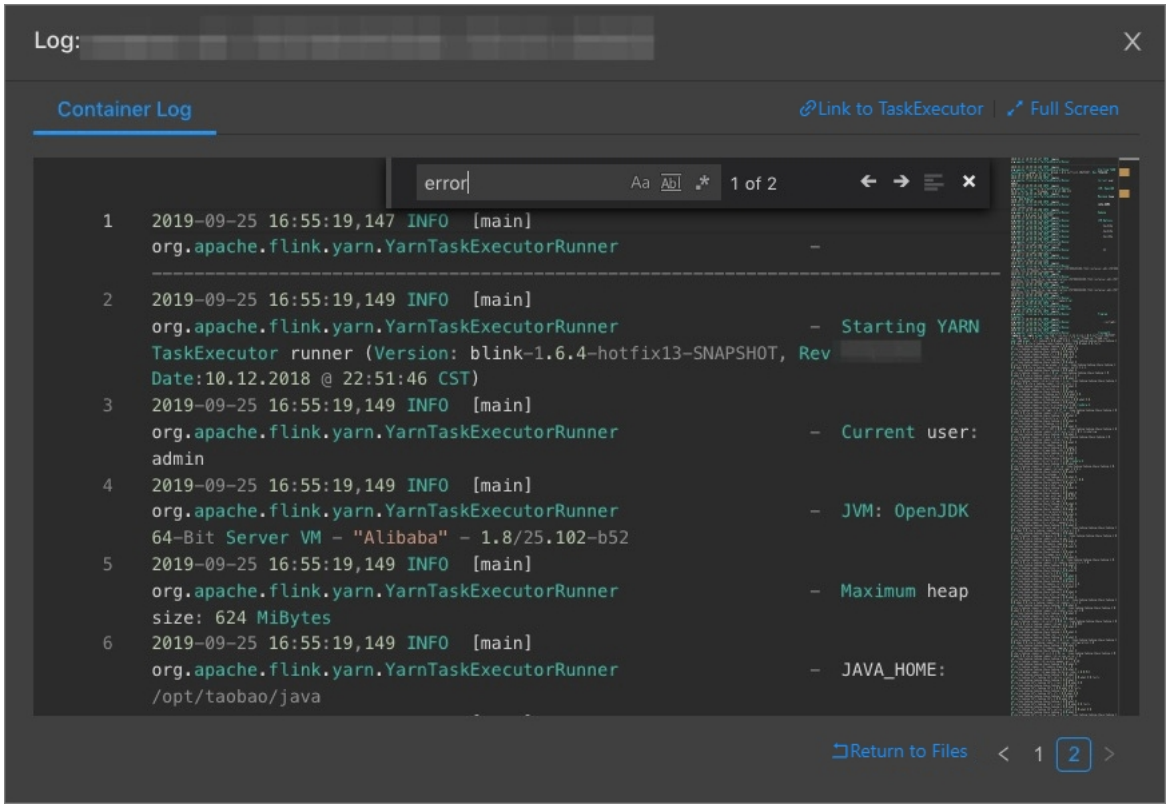
3. On the **Execution Vertex** page, click the **Subtask List** tab, and click **View Logs** in the **Actions** column.



4. In the **Log** dialog box that appears, click **View Logs** for **taskmanager.log** in the **Actions** column.



5. On the **Container Log** tab, view the log entries.



Note You can press **Ctrl+F** for Windows or **Cmd+F** for MacOS to search for specified log entries. We recommend that you view the logs from the last page. The first `error` log entry describes the root cause of the job error.

4.Machine Learning Platform for AI

4.1. What is machine learning?

Machine learning is a process of using statistical algorithms to learn large amounts of historical data and generate an empirical model to provide business strategies.

Apsara Stack Machine Learning Platform for AI is a set of data mining, modeling, and prediction tools. It is developed based on MaxCompute (also known as ODPS). Machine Learning Platform for AI supports the following functions:

- Provides an all-in-one algorithm service covering algorithm development, sharing, model training, deployment, and monitoring.
- Allows you to complete the entire procedure of an experiment either through the GUI or by running PAI commands. This function is typically intended for data mining personnel, analysts, algorithm developers, and data explorers.
- In Apsara Stack, Machine Learning Platform for AI runs on MaxCompute. Machine Learning Platform for AI allows you to call algorithms to decouple the applications and compute engines after you have deployed algorithm packages in MaxCompute clusters.
- Provides various algorithms and reliable technical support, providing more options to resolve service issues. In the Data Technology (DT) era, you can use Machine Learning Platform for AI to implement data-driven services.

Machine Learning Platform for AI can be applied in the following scenarios:

- Marketing: commodity recommendations, user profiling, and precise advertising.
- Finance: loan delivery prediction, financial risk control, stock trend prediction, and gold price prediction.
- Social network sites (SNSs): microblog leader analysis and social relationship chain analysis.
- Text: news classification, keyword extraction, text summarization, and text analysis.
- Unstructured data processing: image classification and image text extraction through OCR.
- Other prediction cases: rainfall forecast and football match result prediction.

Machine learning can be divided into three types:

- Supervised learning: Each sample has an expected value. You can create a model and map input feature vectors to target values. Typical examples of this learning mode include regression and classification.
- Unsupervised learning: No samples have a target value. This learning mode is used to discover potential regular patterns from data. Typical examples of this learning mode include simple clustering.
- Reinforcement learning: This learning mode is complex. A system constantly interacts with the external environment to obtain external feedback and determines its own behavior to achieve a long-term optimization of targets. Typical examples of this learning mode include AlphaGo and driverless vehicles.

4.2. Quick start

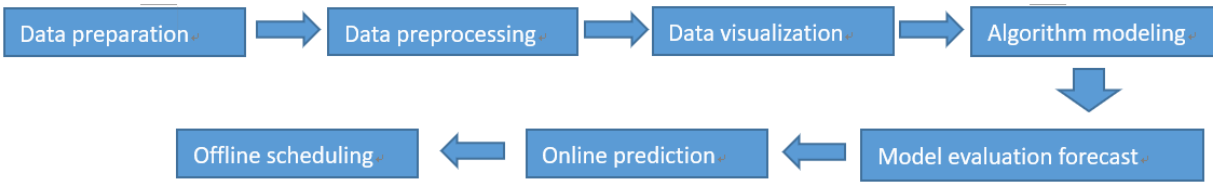
4.2.1. Overview

This topic describes how to perform data preparation, data preprocessing, data visualization, algorithm modeling, model prediction and evaluation, online prediction, and DataWorks task scheduling to set up a machine learning experiment.

> **Note** This document covers Apsara Stack Machine Learning Platform for AI, online model service, and deep learning framework. The online model service and deep learning framework are not basic functions of Apsara Stack Machine Learning Platform for AI and must be purchased separately.

For more information, see Machine learning experiment creation flowchart.

Machine learning experiment creation flowchart



1. Data preparation

   Import target data into the Apsara Stack Machine Learning Platform for AI console.

2. Data preprocessing

   Perform data processing, including SQL-based conversion, normalization, and standardization, to ensure that all data has the same dimensions.

3. Data visualization

   Display data in charts to view the features of the data and the distribution of the values. This serves as the basis for model algorithm selection.

4. Algorithm modeling

   Use machine learning algorithms to train data and ultimately build a model.

5. Model evaluation forecast

   Make predictions from and evaluate the model, and use the prediction results to create business development strategies.

6. Online prediction

   Use online prediction to deploy the generated model and adjust your business strategy based on the prediction results.

7. Offline scheduling

   Deploy experiments in DataStudio and run them on a regular basis.

4.2.2. Log on to Apsara Stack Machine Learning Platform for AI

This topic describes how to log on to Apsara Stack Machine Learning Platform for AI.

Prerequisites

- Before logging on to the ASCM console, make sure that you have obtained the IP address or domain name of the ASCM console from the deployment personnel. The URL used to access the ASCM console is in the following format: https://[IP address or domain name of the ASCM console].
- We recommend that you use the Google Chrome browser.

Procedure

1. Enter the address into the address bar of your web browser, and then press Enter.
2. Enter your username and password. Obtain the username and password for logging on to the console from the operations administrator.

   > **Note** The first time you are logging on to ASCM, you must follow the instructions to change the password of your account. For security concerns, your password must meet the minimum complexity requirements: The password must be 8 to 20 characters in length and must contain two or more types of the following characters: letters, digits, and special characters such as exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

3. Click **Login** to log on to ASCM.
4. In the top menu bar, choose **Products** > **Machine Learnig Platform for AI** to open the portal of Machine Learning Platform for AI.
5. Select an organization, and then click **PAI**.

   > **Note** If this is the first time that you log on to the Machine Learning Platform for AI console, you must perform the following tasks:
   >
   > i. Add an organization
   >
   > Create an organization to manage resource sets and resources in the resource sets.
   >
   > ii. Create a user
   >
   > Administrators can create users and attach different roles to users for permission control.
   >
   > iii. Create a resource set
   >
   > Create a resource set before you apply for resources.
   >
   > iv. Add a member to a resource set
   >
   > Add users to the resource set as members.
   >
   > v. In the top menu bar of ASCM, choose **Products** > **Big Data** > **MaxCompute**, and then create a **task account** and **MaxCompute project**.
   >
   > a. Create a task account: set the **Organization** to the one created in step 1.
   >
   > b. Create a MaxCompute project: set the **Organization** to the one created in step 1, set the **Resource Set** to the one created in step 2, and set the **Task Account** to the one that you have created.
   >
   > vi. Create a DataWorks workspace. In the **Advanced Settings** section, set **MaxCompute Project Name** to the project created in the preceding step.

4.2.3. Data preparation

This topic describes how to import data into the Apsara Stack Machine Learning Platform for AI console for modelling.

Prerequisites

Make sure that you have created a MaxCompute project and imported table data into the project. You can download the data from .

Procedure

1. Log on to the Apsara Stack Machine Learning Platform for AI console and click **Experiments** in the left-side navigation pane.
2. On the **Experiments** page, right-click **My Experiments** and choose **New Experiment** from the shortcut menu. In the dialog box that appears, enter the experiment name and description. Click **Create** to go to the **Components** page.
3. In the **Components** list, click **Data Source/Target**, and drag and drop the **Read MaxCompute Table** onto the canvas.
4. Click the **Read MaxCompute Table** component and configure its parameters. Enter the MaxCompute table name in **Table Name** in the right-side configuration pane.
5. In the right-side parameter setting pane, click **Column Information** to view the column name, data type, and the first 100 rows of data in the input table.

4.2.4. Data preprocessing

This topic describes how to perform data preprocessing by using methods such as normalization, SQL scripts, and data splitting.

Prerequisites

Before data preprocessing, make sure that you have completed data preparation.

Procedure

1. Log on to the Apsara Stack Machine Learning Platform for AI console and click **Components** in the left-side navigation pane.
2. In the **Components** list, click **Tools**. Drag and drop the **SQL Script** component onto the canvas. Click **Data Preprocessing**. Drag and drop the **Normalization** component onto the canvas, and connect the components.
3. Click the **SQL Script** component and click the right-side **Parameters** tab. In the **SQL Script** input box, enter the following SQL scripts to convert the features from string type to numeric type.

```
select age,
(case sex when 'male' then 1 else 0 end) as sex,
(case cp when 'angina' then 0  when 'notang' then 1 else 2 end) as cp,
trestbps,
chol,
(case fbs when 'true' then 1 else 0 end) as fbs,
(case restecg when 'norm' then 0  when 'abn' then 1 else 2 end) as restecg,
thalach,
(case exang when 'true' then 1 else 0 end) as exang,
oldpeak,
(case slop when 'up' then 0  when 'flat' then 1 else 2 end) as slop,
ca,
(case thal when 'norm' then 0  when 'fix' then 1 else 2 end) as thal,
(case status  when 'sick' then 1 else 0 end) as ifHealth
from  ${t2};
```

4. Click the **Normalization** component and select all fields to normalize the numeric features to values ranging from 0 to 1.
5. Click **Data Preprocessing**. Drag and drop the **Split** component onto the canvas and set **Split Ratio** to **0.7**.

> **Note** This step splits data into two parts: 70% of the data is used as the model training set, and 30% of the data is used as the model prediction set.

4.2.5. Data visualization

This topic describes how to view the features and value distribution by using statistical analysis components.

Prerequisites

Before data visualization, make sure that you have completed data preprocessing.

Procedure

1. Log on to the Apsara Stack Machine Learning Platform for AI console and click **Components** in the left-side navigation pane.
2. In the **Components** list, click **Statistical Analysis**. Drag and drop the **Whole Table Statistics** component onto the canvas. Connect the components, and click **Run** at the bottom of the canvas.
3. After the experiment stops running, right-click **Whole Table Statistics** and choose **View Data** from the shortcut menu. The analysis report is displayed.

4.2.6. Algorithm modeling

This topic describes how to perform feature training and generate models by using the machine learning components.

Prerequisites

Before algorithm modeling, ensure that you have completed data preprocessing and learned the data characteristics and value distribution through data visualization.

Procedure

1. Log on to the Apsara Stack Machine Learning Platform for AI console and click **Components** in the left-side navigation pane.
2. In the **Components** list, choose **Machine Learning** > **Binary Classification**. Drag and drop the **Binary Logistic Regression** component onto the canvas, and connect the corresponding components and data streams.
3. Click the component, and select 13 feature columns from **Training Feature Columns** in the right-side **Column Settings** pane. All parameters use the default settings.
4. Click **Run**.
5. Click **Models** in the left-side navigation pane to view the generated model.

4.2.7. Model prediction evaluation

This topic describes how to use a model to make predictions and evaluate its results by using the prediction and evaluation components.

Prerequisites

Before evaluating the prediction, make sure that you have completed algorithm modeling and generated a machine learning model from the experiment.

Procedure

1. Log on to the Apsara Stack Machine Learning Platform for AI console and click **Components** in the left-side navigation pane.
2. In the **Components** list, click **Machine Learning**. Drag and drop the **Prediction** component onto the canvas, and connect the corresponding components and data streams.
3. Choose **Machine Learning** > **Evaluation**. Drag and drop the **Binary Classification Evaluation** component onto the canvas and connect the corresponding components and data streams.
4. Click **Run** in the upper-left corner of the canvas. During the running process, select a component and click the **Developer Tool** ( ) icon in the lower-right corner of the canvas to view the running status of the component.
5. Right-click the **Binary Classification Evaluation** component and choose **View Evaluation Report** from the shortcut menu to generate the ROC curve of the LR model trained with different parameters.

4.2.8. DataWorks task scheduling

After you have run all nodes in an experiment, you can deploy the experiment to DataWorks and schedule DataWorks to periodically run the experiment. This topic uses air quality prediction as an example scenario.

Prerequisites

Before scheduling an experiment, you must make sure that you have successfully run all nodes in the experiment and that the experiment is deployed to DataWorks.

Procedure

1. Log on to the Apsara Stack Machine Learning Platform for AI console. Click **Experiments** in the left-side navigation pane.
2. Click the **My Experiments** tab and select an experiment to navigate to the canvas.

   > **Notice** Make sure all components have been run in the experiment. A green check means that the component is running correctly.

3. In the upper-left corner of the canvas, choose **Deploy > Schedule DataWorks Tasks** to go to DataStudio.
4. In the DataStudio console, choose **Create > Algorithm > Machine Learning Platform for AI**, and then create a Machine Learning experiment node.
5. In the **Create Node** dialog box, enter the node name, select the target folder, and click **Submit**.

   > **Notice** You must select a target folder for the algorithm type.

   After the experiment node is created.
6. Select the experiment from the drop-down list.
7. Configure task scheduling parameters, including the recurrence, input, and output parameters.
8. Click **Submit**. The task will be executed the next day.
9. Click **Administration** in the upper-right corner to go to the administration page. You can view the status of the machine learning task and the system log. You can also perform other operations such as adding retroactive data and testing the experiment.

4.3. Online model service (must be activated separately)

4.3.1. Deploy an online model service

This topic describes how to deploy the generated experiment model through the online model service. You can adjust your business strategy anytime based on predicted results.

Prerequisites

Before deploying the online model service, make sure that the preceding steps are completed and the components are running properly. A green check means that the component is running

correctly.

Procedure

1. Log on to the Apsara Stack Machine Learning for AI console and click **Experiments** in the left-side navigation pane.
2. Click the **My Experiments** tab and select an experiment to navigate to the canvas.

   > **Notice** Make sure that the selected experiment is running properly. A green check means that the component is running correctly.

3. In the upper-left corner of the canvas, choose **Deploy** > **Online Model Service**.
4. Select the model to deploy and click **Next**.
5. Select a deployment mode. You can select one of the following modes:
   - New Service
   - Add Existing Service Version
   - Create Blue-green Deployment

4.3.2. Create a service

This topic describes how to use the **New Service** mode to deploy online prediction services.

Procedure

1. Complete Preparations for online model prediction.
2. Set **Processes** and **Quota**.

   > **Note** **Processes** determines the maximum number of concurrently running programs. **Quota** determines the running speed and the parameters such as RT and QPS.

3. Click **Deploy**. It takes several minutes to create the model.
4. After the model is created, click the model name to view information about the model invocation.
5. Click the icons under **Monitor** to view statistics about QPS, response, RT, traffic, CPU utilization, memory usage, and daily invocation.
6. > **Note** Perform this step when resources are insufficient and need to be expanded.

   Click **Update** to expand resources.
7. Click **Online Debugging** in the upper-right corner of the page and select the current model.

4.3.3. Add an existing service version

This topic describes how to use the **Add Existing Service Version** mode to deploy online prediction services.

Prerequisites

Before you use the **Add Existing Service Version** mode to deploy online prediction services, ensure that you have deployed one version of online prediction services through the New Service mode.

Procedure

1. Complete Preparations for online model prediction.
2. Select **Add Existing Service Version**.
3. Select a deployed model. It takes several minutes to add a version.
4. After the model is deployed, select the added version from the **Current Version** drop-down list.

4.3.4. Create a blue-green deployment

This topic describes how to use the **Create Blue-green Deployment** mode to deploy online prediction services.

Prerequisites

Before you use the **Create Blue-green Deployment** mode to deploy online prediction services, ensure that you have deployed two versions of online prediction services through the New Service and Add Existing Service Version modes.

Context

In the blue-green deployment mode, you can deploy and test the target version without stopping the source version. After confirming that the target version is running normally, switch all traffic to the target version. Blue-green deployment is safe and does not interrupt services.

Procedure

1. Complete Preparations for online model prediction.
2. Select the deployed model service and click **Deploy**. The deployment may take several minutes.
3. Click **Switch Traffic** and adjust the ratio of traffic forwarded to the two models. The initial ratio is 100% for both models.
4. Perform online debugging.
   i. Click **Online Debugging** in the upper-right corner of the page and select the deployed model.
   ii. Enter data (feature input) in **Body**. For example, the body information of the logistic regression model for heart disease prediction is as follows:

   ```
   [{"sex":0,"cp":0,"fbs":0,"restecg":0,"exang":0,"slop":0,"thal":0,"age":0,"trestbps":0,"chol":0,"th
   alach":0,"oldpeak":0,"ca":0}]
   ```

   iii. Click **Run** and check the result.

4.4. Components

4.4.1. Overview

This topic describes how to use and configure machine learning components. When building a machine learning experiment, you can select components based on the features of existing data to generate a model and make accurate predictions for your business.

Each component has one or more input or output ports. You can move the pointer over the ports to view their descriptions and connect the components.

4.4.2. Data source and target

This topic describes components in the **Data Source/Target** category, such as the Read MaxCompute Table and Write MaxCompute Table components.

Read MaxCompute tables

You can use the Read MaxCompute Table component to read MaxCompute tables. By default, this component reads data of the current project. If you want to read data from tables in another project for which you have access, you can prefix the table name with the project name in the `project name. table name` format. For example, `tianchi_project.weibo_data`. After you specify the input table, the system reads the structural data of the table. You can click the **Column Information** tab to view the data. This component does not support views.

If the selected input table is a partitioned table, the back end automatically selects the Partition checkbox. You can select or configure partition parameters. Only one partition can be selected. If you do not select the Partition checkbox or do not specify the partition parameters, the whole table is selected. If the input table is non-partitioned, the Partition checkbox cannot be selected.

Write MaxCompute tables

You can use the Write MaxCompute Table component to write data to tables in the current project or tables in other projects. This component can write data to partitions. Partitions must be created for the table in the MaxCompute console before this component can write data to the partitions. You can set the table lifecycle measured in days.

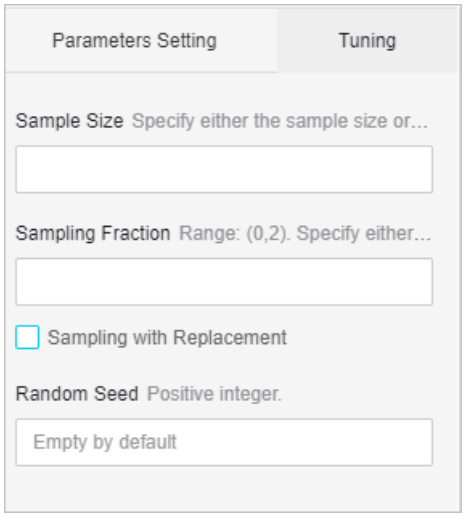
4.4.3. Data preprocessing

4.4.3.1. Sampling and filtering

4.4.3.1.1. Random sampling

Data is sampled randomly and independently. You can specify a ratio or quantity of samples to be taken and choose whether to enable sampling with replacement.

Parameter settings



PAI command

```
Pai -name sample
-project algo_public
-DinputTableName=wbpc
-DoutputTableName=wpbc_sample
-Dratio=0.3;
```

Algorithm parameters

Parameters

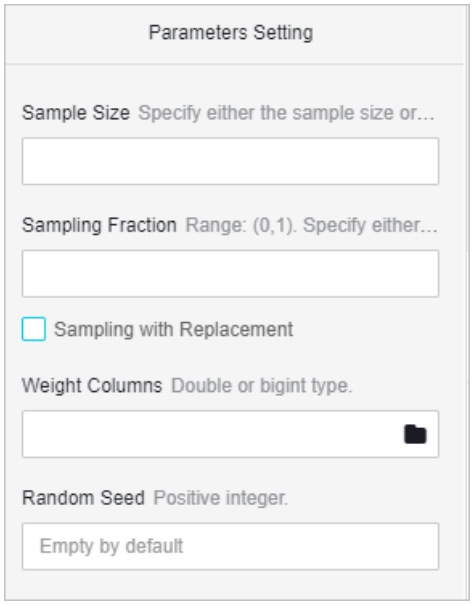
Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.

Parameter	Description	Valid values	Default value
ratio	Required. The sampling fraction.	(0, 1)	-
outputTableName	Required. The name of the output table.	-	-
outputTablePartition	Optional. The partition of the output table.	-	The output table is a non-partitioned table by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer in the range of [1, 3650]	No lifecycle is set by default.

4.4.3.1.2. Weighted sampling

Sample data is collected based on weights. The weight column must be of double or int type. Data is sampled based on the value of its corresponding weight. For example, data with a col value of 1.2 has a higher probability to be sampled than data with a col value of 1.0.

Parameter settings



Parameter settings

Parameter	Description
Sample Size	You can specify the number of samples to be taken, which is 10,000 by default. For sampling without replacement, the number of samples cannot be greater than the number of data entries.
Sampling Fraction	You can use either the Sample Size or Sampling Fraction parameter. You can choose sampling with or without replacement, the latter of which is used by default. Select the checkbox to enable sampling with replacement.

Parameter	Description
Weight Columns	You can select a weight column from the drop-down list. The weight column can be of the double or bigint type.
Random Seed	The random seed, which is a positive integer. This parameter is empty by default.

- You can choose sampling with or without replacement, the latter of which is used by default. Select the checkbox to enable sampling with replacement.
- You can specify the number of samples to be taken, which is 10,000 by default.

  > **Note** For sampling without replacement, the number of samples cannot be greater than the number of data entries.

- You can select a weight column from the drop-down list. The weight column can be of the double or bigint type.

PAI command

```
PAI -name WeightedSample
-project algo_public
-DprobCol="previous"
-DsampleSize="500"
-DoutputTableName="test2"
-DinputPartitions="pt=20150501"
-DinputTableName="bank_data_partition";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
replace	Indicates whether sampled data is replaced. If this parameter is set to true, data is replaced after it is sampled. If this parameter is set to false, data is not replaced after it is sampled.
probCol	The columns to be weighted. Each value indicates the weight of an entry. Normalization is not required.
sampleSize	The number of samples to be taken. For sampling without replacement, the number of samples cannot be greater than the number of data entries.

Parameter	Description
outputTableNames	The name of the output table. Separate multiple table names with commas (,).
inputPartitions	Optional. The partitions selected from the input table for training. If no partitions are specified, the entire table is selected.
inputTableName	The name of the input table.
replace	Optional. This parameter indicates whether sampled data is replaced. If this parameter is set to true, data is replaced after it is sampled. If this parameter is set to false, data is not replaced after it is sampled.

4.4.3.1.3. Filtering and mapping

You can filter data based on filtering expressions and rename columns.

Parameter settings

1. Use the WHERE condition to filter data similar to how it would function in an SQL statement.

   Filtering conditions: Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), less than or equal to (<=) signs, as well as like and rlike.

2. Rename columns.

PAI command

```
PAI -name Filter
-project algo_public
-DoutTableName="test_9"
-DinputPartitions="pt=20150501"
-DinputTableName="bank_data_partition"
-Dfilter="age>=40";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
outTableName	The name of the output table.
inputPartitions	Optional. The partitions selected from the input table for training. If no partitions are specified, the entire table is selected.

Parameter	Description
inputTableName	The name of the input table.
filter	The WHERE condition to filter data. Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), less than or equal to (<=) signs, as well as like and rlike.

4.4.3.1.4. Stratified sampling

Stratified sampling is a statistical computing method. It works by dividing a population into several strata based on specified features, performing random sampling at each stratum, and creating a sample collection.

Parameter settings

Parameter	Description
Column Settings	Stratification Column: Required. Samples are stratified based on this column.
Parameter Settings	Sampling Fraction/Sample Size: Required. A value less than 1 represents the sampling fraction per stratum. A value greater than 1 represents the number of samples at each stratum.
	Other Sampling Configurations: Optional. This parameter allows you to collect different numbers of samples at different strata.
	Random Seed: Optional. Valid values: 1, 2, 3, 4, 5, 6, and 7.

PAI command

```
Pai -name sample
-project algo_public
-DinputTableName=wbpc
-DoutputTableName=wpbc_sample
-DstrataColName="label"
-DsampleSize="A:200,B:300,C:500"
-DrandomSeed=1007
-Dlifecycle=30
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.
strataColName	Required. The stratification column.	-	-
outputTableName	Required. The name of the output table.	-	-
sampleSize	Optional. An integer value that specifies the number of samples taken from each stratum. A string value must be in the `strata0:n0,strata1:n1....` format. Each item in the string represents the number of samples to be taken from the corresponding stratum.	-	

Parameter	Description	Valid values	Default value
sampleRatio	Optional. A decimal value from 0 to 1 that represents the ratio of data for each stratum to be sampled. A string value must be in the `strata0:r0,strata1:r1,...` format. Each item in the string represents the sampling fraction for the corresponding stratum.	-	-
randomSeed	Optional. The number of random seeds.	-	0
lifecycle	Optional. The lifecycle of the output table.	A positive integer in the range of [1, 3650]	No lifecycle is set by default.
coreNum	Optional. The number of cores.	-	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	-	Automatically calculated.

4.4.3.2. Data merge

4.4.3.2.1. Join

This component merges two tables by associating the information in the tables and outputting the specified columns. This component is similar to the JOIN statement of SQL.

Parameter settings

- Join types: left join, internal join, right join, and full join.
- Only the equation condition is supported.
- You can manually add or delete join conditions.

PAI command

No PAI command is available.

4.4.3.2.2. Merge columns

You can merge data of two tables by column. The two tables must have the same number of rows.

Parameter settings

Procedure

1. Select input columns from the left table.
2. Select input columns from the right table.

   When merging columns:

   - The two tables must have the same number of rows.
   - The names of output columns selected from the left and right tables cannot be the same.
   - When selecting an output column, you can change its name.
   - If no output columns are selected from the left or right table, the whole table is selected. In this case, if **Automatically Rename Output Columns** is selected, the duplicate columns are renamed and then output.

PAI command

```
PAI -name AppendColumns
-project algo_public
-DoutputTableColNames="petal_length,petal_width,petal_length2,petal_width2"
-DautoRenameCol="false"
-DoutputTableName="pai_temp_770_6840_1"
-DinputTableNames="iris_twopartition,iris_twopartition"
-DinputPartitionsInfoList="dt=20150125/dp=20150124;dt=20150124/dp=20150123"
-DselectedColNamesList="petal_length,petal_width;sepal_length,sepal_width";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
outputTableColNames	The names of the columns in the new table. The column names must be separated with commas (,). If autoRenameCol is set to true, this parameter is ignored.
autoRenameCol	Optional. This parameter specifies whether to automatically rename the columns in the output table. If the value is true, the columns are renamed. If the value is false, the columns are not renamed. Default value: false.
outputTableName	The name of the output table.
inputTableNames	The name of the input table. Separate multiple table names with commas (,).

Parameter	Description
inputPartitionsInfoList	Optional. A list of partitions selected from the corresponding input tables. Partitions of the same table must be separated with commas (,) and partitions of different tables must be separated with semicolons (;).
selectedColNamesList	The names of selected columns. The names of columns in the same table must be separated with commas (,) and the names of columns in different tables must be separated with semicolons (;).

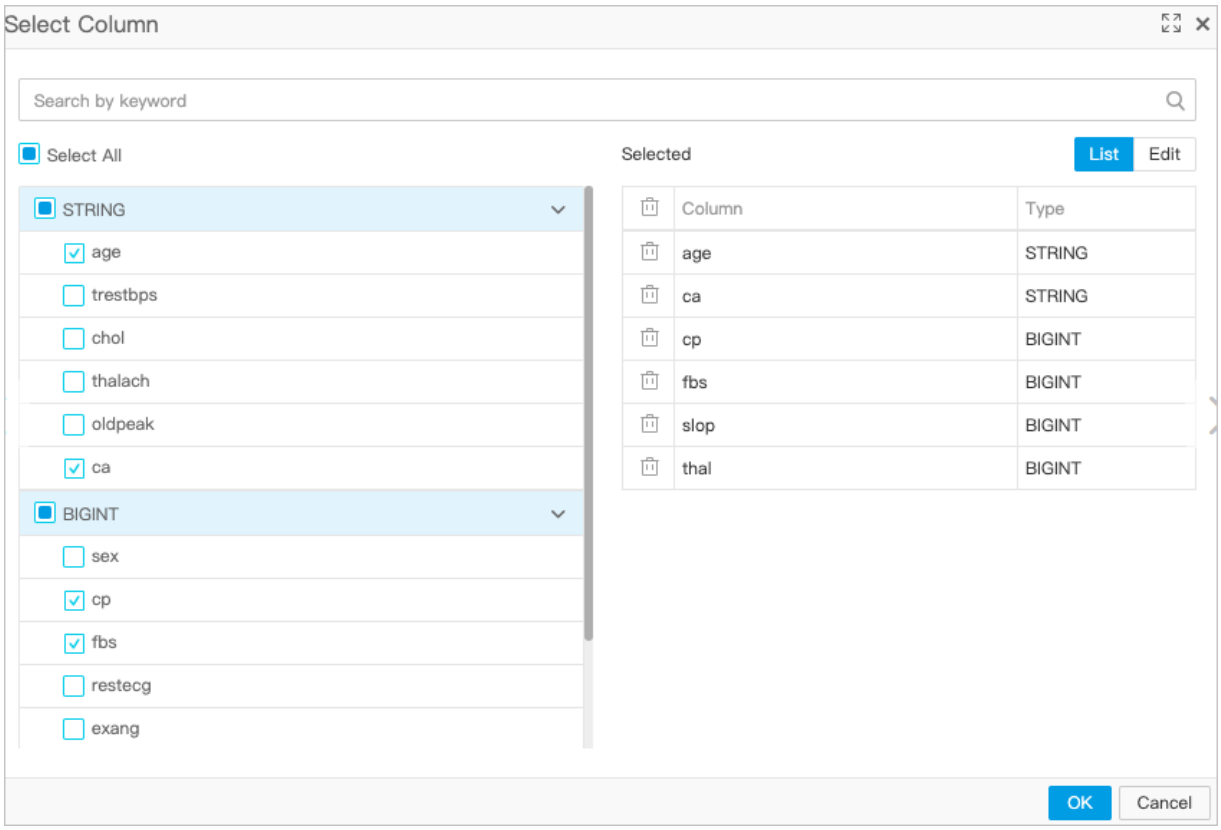
4.4.3.2.3. Merge rows (UNION)

To merge the data of two tables by row, the quantity and data type of the output columns selected from the left and right tables must be the same. The function is integrated with the UNION and UNION ALL functions.

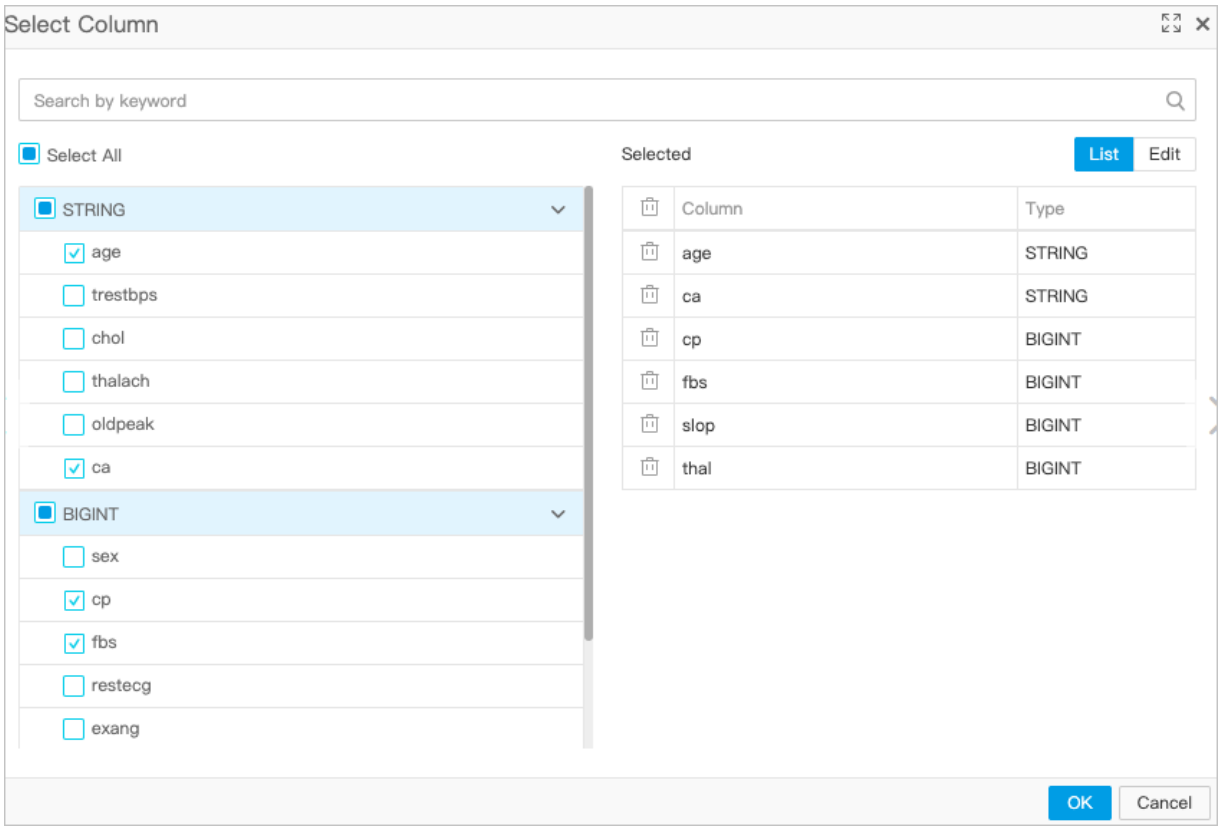
Parameter settings

- During the merge process, the numbers of columns selected from the left and right tables must be the same, and the data types of the corresponding columns must be the same.
- You can enter conditions in the text box by which to filter and select columns. The whole table is selected by default. Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), and less than or equal to (<=) signs, as well as like and rlike.
- **Remove Duplicates** is selected by default. When this option is selected, duplicate rows in the output table are removed.

The following figure shows the union columns selected from the left table.



The following figure shows the union columns selected from the right table.



PAI command

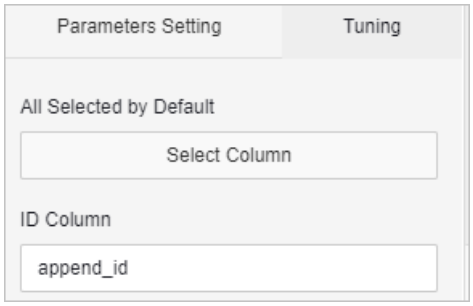
No PAI command is available.

4.4.3.3. Others

4.4.3.3.1. Add ID column

You can append an ID column to a table as the first column and save the table as a new table.

Parameter settings



PAI command

```
PAI -name AppendId
-project algo_public
-DIDColName="append_id"
-DoutputTableName="test_11"
-DinputTableName="bank_data"
-DselectedColNames="age,campaign,cons_conf_idx,cons_price_idx,emp_var_rate,euribor3m,nr_employ
ed,pdays,poutcome,previous,y";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
IDColName	The name of the appended ID column. ID numbers start from 0 and increment by one. Example: 0, 1, 2, 3, ...
outputTableName	The name of the output table.
inputTableName	The name of the input table.

Parameter	Description
selectedColNames	The names of the columns to be retained. Separate multiple columns with commas (,).

4.4.3.3.2. Split

This component is used to split an input table or a partition based on a specified ratio, and output two tables from two output ports.

Algorithm component

Parameter settings

- The Split component has two output ports.
- In Parameter settings, if the splitting fraction is set to 0.7, the left output port outputs 70% of the data and the right output port outputs 30% of the data.

PAI command

```
pai -name split -project algo_public
    -DinputTableName=wbpc
      -Doutput1TableName=wpbc_split1
    -Doutput2TableName=wpbc_split2
    -Dfraction=0.25;
```

Parameter settings

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.
output1TableName	Required. The name of output table 1.	-	-

Parameter	Description	Valid values	Default value
output1TablePartition	Optional. The partitions in output table 1.	-	Output table 1 is a non-partitioned table by default.
output2TableName	Required. The name of output table 2.	-	-
output2TablePartition	Optional. The partitions in output table 2.	-	Output table 2 is a non-partitioned table by default.
fraction	Required. The portion of data diverted to output table 1.	(0, 1)	-
lifecycle	Optional. The lifecycle of the output table.	A positive integer in the range of [1, 3650]	No lifecycle is set by default.

4.4.3.3.3. Missing value imputation

This component replaces a null value or a specified value with the maximum, minimum, average, or custom value. A list of values is defined to impute the missing values in an input table with the specified values.

- This component can replace a numeric null value with the maximum, minimum, average, or custom value.
- This component can also replace a null string, empty string, null and empty string, or specified value with a custom value.
- The missing values to be imputed can be null strings, empty strings, or custom values. If you choose empty strings, the data type of the target column must be string.

The parameters for the two input ports are as follows:

- inputTableName: the name of the input table for which to replace missing data.
- inputParaTableName: the name of the input configuration table that contains parameters generated by the missing value imputation node. Based on this parameter, configuration parameters in one table can be applied to a new table.

Parameters for the two output ports are as follows:

- outputTableName: the name of the imputed output table.
- outputParaTableName: the name of the output configuration table, which can be applied to other datasets.
- Columns to Impute: the names of the columns for which to replace missing values.
- Original Value: the values to be replaced.
- Replaced With: the replacement values.

PAI command

```
PAI -name FillMissingValues
    -project algo_public
    -Dconfigs="poutcome,null-empty,testing" \
    -DoutputTableName="test_3"
    -DinputPartitions="pt=20150501"
    -DinputTableName="bank_data_partition";
```

Algorithm parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
inputTablePartitions	Optional. The partitions selected from the input table for training.	Partition name	The whole table is selected by default.
outputTableName	Required. The name of the output table.	Table name	N/A

Parameter	Description	Valid value	Default value
configs	Required. The configurations for missing value imputation. Example: `col1, null, 3.14; col2, empty, hello; col3, empty-null, world`, where *null* indicates a null value and *empty* indicates an empty string. If you choose to use empty strings to fill the target columns, the data type of the target column must be string. The variables used to specify the replacement value as maximum, minimum, and average are max, min, and mean respectively. If you want to impute a custom value to the target column, use a user-defined variable in the `col4,user-defined,str,str123` format.	N/A	N/A
outputParaTableName	Required. The name of the output configuration table.	Table name	N/A
inputParaTableName	Optional. The name of the input configuration table.	Table name	No input configuration table is set by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	A positive integer	Automatically calculated.

Examples

Test data

- SQL statement to generate data:

```
drop table if exists fill_missing_values_test_input;
create table fill_missing_values_test_input(
  col_string string,
  col_bigint bigint,
  col_double double,
  col_boolean boolean,
  col_datetime datetime);
insert overwrite table fill_missing_values_test_input
select
  *
from
(
  select
    '01' as col_string,
    10 as col_bigint,
    10.1 as col_double,
    True as col_boolean,
    cast('2016-07-01 10:00:00' as datetime) as col_datetime
  from dual
  union all
    select
      cast(null as string) as col_string,
      11 as col_bigint,
      10.2 as col_double,
      False as col_boolean,
      cast('2016-07-02 10:00:00' as datetime) as col_datetime
    from dual
  union all
    select
      '02' as col_string,
      cast(null as bigint) as col_bigint,
      10.3 as col_double,
      True as col_boolean,
      cast('2016-07-03 10:00:00' as datetime) as col_datetime
    from dual
  union all
    select
      '03' as col_string,
      12 as col_bigint,
```

```
        cast(null as double) as col_double,
        False as col_boolean,
        cast('2016-07-04 10:00:00' as datetime) as col_datetime
    from dual
  union all
    select
      '04' as col_string,
      13 as col_bigint,
      10.4 as col_double,
      cast(null as boolean) as col_boolean,
      cast('2016-07-05 10:00:00' as datetime) as col_datetime
    from dual
  union all
    select
      '05' as col_string,
      14 as col_bigint,
      10.5 as col_double,
      True as col_boolean,
      cast(null as datetime) as col_datetime
    from dual
) tmp;
```

```

4.4.3.3.4. Normalization

You can normalize one or more columns in a table and save the generated data to a new table.

Linear function transformation is supported. The transformation expression is `y=(x-MinValue)/(MaxValue-MinValue)`.

MaxValue and *MinValue* indicate the maximum and minimum values of the sample respectively.

- Click **Columns** to select the columns to be normalized. Double and bigint types are supported.
- You can choose whether to retain the original columns. If you select the corresponding checkbox, the original columns will be retained. Processed columns will be renamed.

PAI command

```
PAI -name normalize_wf
-project algo_public
-DkeepOriginal="true"
-DoutputTableName="test_4"
-DinputPartitions="pt=20150501"
-DinputTableName="bank_data_partition"
-DselectedColNames="emp_var_rate,euribor3m";
```

Algorithm parameters

Parameters

Parameter	Description	Default value

Parameter	Description	Default value
inputTableName	Required. The name of the input table.	N/A
selectedColNames	Optional. The names of columns selected from the input table.	All columns are selected by default.
inputTablePartitions	Optional. The partitions selected from the input table for training.	The whole table is selected by default.
outputTableName	Required. The name of the output table.	N/A
outputParaTableName	Required. The name of the output configuration table.	N/A
inputParaTableName	Optional. The name of the input configuration table.	No input configuration table is set by default.
outputPMMLTableName	Required. The name of the output PMML table.	N/A
keepOriginal	Optional. This parameter specifies whether to retain the original columns. If `keepOriginal` is set to true, processed columns are renamed with the `normalized_` prefix and the original columns are retained and their data overwritten. If `keepOriginal` is set to false, all columns are retained but not renamed.	false
lifecycle	Optional. The lifecycle of the output table.	No lifecycle is set by default.
coreNum	Optional. The number of cores.	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	Automatically calculated.

4.4.3.3.5. Standardization

You can standardize one or more columns in a table and save the generated data to a new table.

- The formula used for standardization is `(X - Mean)/(Standard deviation)` .
  - Mean: The mean of samples.

- Standard deviation: The standard deviation of samples. This variable is used when samples are used to calculate the total deviation. To make the calculated value closer to the mean, you must moderately increase the calculated standard deviation by using the formula $\frac{1}{N-1}$.
- The formula for calculating the standard deviation of samples:

$$S = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}(X_i - \bar{X})^2}$$

$\bar{X}$ represents the mean of samples X1, X2, ..., Xn.

- You can choose whether to retain the original columns. If you select the corresponding checkbox, the original columns will be retained. Processed columns will be renamed.
- Click **Columns** and select columns to be standardized. Double and bigint types are supported.

PAI command

```
PAI -name Standardize
-project algo_public
-DkeepOriginal="false"
-DoutputTableName="test_5"
-DinputTablePartitions="pt=20150501"
-DinputTableName="bank_data_partition"
-DselectedColNames="euribor3m,pdays"
```

Standardization component

Parameters for the two input ports are as follows:

- inputTableName: the name of the input table to be standardized.
- inputParaTableName: the name of the input configuration table that contains the parameters generated by the standardization node. You can use an input configuration table to apply the configuration parameters of one table to a new table.

Parameters for the two output ports are as follows:

- outputTableName: the name of the standardized output table.
- outputParaTableName: the name of the output parameter table, which can be applied to other datasets.

Standardization parameters

The corresponding algorithm parameter for Reserve Original Columns is `keepOriginal`.

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
selectedColNames	Optional. The names of columns selected from the input table.	-	All columns are selected by default.
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.
outputTableName	Required. The name of the output table.	-	-
outputParaTableName	Required. The name of the output configuration table.	-	-
outputPartition	Optional. The partitions in the output table.	-	-
inputParaTableName	Optional. The name of the input configuration table.	-	No input configuration table is set by default.
keepOriginal	Optional. This parameter specifies whether to retain the original columns. If this parameter is set to true, the original columns are retained and the column name is suffixed with `_orig`.	true and false	false
lifecycle	Optional. The lifecycle of the output table.	-	No lifecycle is set by default.
coreNum	Optional. The number of cores.	-	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	-	Automatically calculated.

Examples

```
drop table if exists standardize_test_input;
create table standardize_test_input(
col_string string,
col_bigint bigint,
col_double double,
col_boolean boolean,
col_datetime datetime);
insert overwrite table standardize_test_input  select     * from  (
select       '01' as col_string,
10 as col_bigint,
10.1 as col_double,
True as col_boolean,
cast('2016-07-01 10:00:00' as datetime) as col_datetime    from dual    union all
select          cast(null as string) as col_string,
11 as col_bigint,
10.2 as col_double,
False as col_boolean,
cast('2016-07-02 10:00:00' as datetime) as col_datetime       from dual    union all
select
'02' as col_string,
cast(null as bigint) as col_bigint,
10.3 as col_double,
True as col_boolean,
cast('2016-07-03 10:00:00' as datetime) as col_datetime       from dual    union all
select          '03' as col_string,
12 as col_bigint,

4.4.3.3.6. KV to Table

This component is used to convert KV pairs to a table. The key is converted to a table column, while the value is converted to a column value in the corresponding row.

KV table format definition:

- A key is the index of a column. Key values can be of the bigint or double types.
- A KV table can be input in the sparse format to algorithm components such as logistic and linear regression.
- Keys must be of the string type. You can input a key_map table to the KV to Table component to map keys to columns. This component outputs a key_map table that contains all key-column mappings after conversion, regardless of whether you input a key_map table.

kv
1:10;2:20;3:30

key_map table format definition: a table that contains index-to-column mappings and data type information. The data types of the col_name, col_index, and col_datatype columns must be string. The default data type of the col_datatype column is double if not specified.

col_name	col_index	col_datatype
col1	1	bigint
col2	2	double

PAI command

```
PAI -name KVToTable
    -project algo_public
    -DinputTableName=test
    -DoutputTableName=test_out
    -DoutputKeyMapTableName=test_keymap_out
    -DkvColName=kv;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	The table cannot be empty.
kvColName	Required. The name of the KV column.	Only one column can be selected.	-
outputTableName	Required. The name of the output table.	Table name	-
outputKeyMapTableName	Required. The name of the output index table.	Table name	-
inputKeyMapTableName	Optional. The name of the input index table.	Table name	No input index table is set by default.
appendColName	Optional. The name of the appended column.	Multiple columns can be selected.	No column is appended by default.
inputTablePartitions	Optional. The partitions selected from the input table.	Partition name	No partition is specified by default.
kvDelimiter	Optional. The delimiter used to separate keys and values.	Symbol	The default delimiter is a semicolon (;).
itemDelimiter	Optional. The delimiter used to separate key-value pairs.	Symbol	The default delimiter is a comma (,).
top1200	Optional. This parameter specifies whether to output the first 1,200 columns.	true and false	Default value: true. If the value is false, an error is returned when the number of columns reaches the upper limit.

Parameter	Description	Valid values	Default value
lifecycle	Optional. The lifecycle of the output table.	An integer greater than or equal to -1.	Default value: -1. This value indicates that no lifecycle is set.
coreNum	Optional. The number of cores.	An integer greater than 0.	Default value: -1. This value indicates that the number of instances is determined by the amount of input data.
memSizePerCore	Optional. The memory size of each core.	(100, 65536)	Default value: -1. This value indicates that the memory size is determined by the amount of input data.

Examples

SQL statement to generate data:

```
drop table if exists test;
  create table test as
   select
    *
   from
   (
    select '1:1,2:2,3:-3.3' as kv from dual
    union all
    select '1:10,2:20,3:-33.3' as kv from dual
   ) tmp;
```

PAI command

```
PAI -name KVToTable
  -project algo_public
  -DinputTableName=test
  -DoutputTableName=test_out
  -DoutputKeyMapTableName=test_keymap_out
  -DkvColName=kv;
```

Output

The output table is shown as follows.

```
+------------+------------+------------+
| kv_1     | kv_2     | kv_3     |
+------------+------------+------------+
| 1.0      | 2.0      | -3.3     |
| 10.0     | 20.0     | -33.3    |
+------------+------------+------------+
```

The output mapping table is shown as follows.

```
+------------+------------+------------+
| col_name   | col_index  | col_type   |
+------------+------------+------------+
| kv_1     | 1        | double    |
| kv_2     | 2        | double    |
| kv_3     | 3        | double    |
+------------+------------+------------+
```

Input and output restrictions

Converted columns include appended columns and columns converted from KV pairs. The KV columns are output before the appended columns. MaxCompute supports a maximum of 1,200 columns. When the number of columns exceeds the maximum value, and top1200 is set to true, only the first 1,200 columns are output. If top1200 is set to false, an error is returned. The number of input data entries cannot exceed 100 million.

Restrictions and guidelines

- If a key_map table is input, columns are converted from the keys that exist in both the key_map and key-value tables.
- The converted column type can only be numeric.
- If a key_map table is input, the data type of the converted key column is the same as that of the key_map table. If no key_map table is input, the data type of the converted key column is double.
- If a key_map table is not input, the name of the converted key column is in the format of 'kv column name+""+key'. An error is returned if the key contains any of the following characters: %&()*+-. /;<>=?
- If an appended column is specified and the name of the appended column is the same as that of the converted key column, an error is returned indicating a column name conflict.
- If a row contains multiple keys, the values are added.
- A column name can contain up to 128 characters. If more than 128 characters are entered, only the first 128 characters are kept.

4.4.3.3.7. Table to KV

This component is used to convert data tables to KV tables. Null values in the table to be converted are not displayed in the KV table. You can specify columns to be retained in the new table. These columns will remain unchanged.

PAI command

```
PAI -name TableToKV
    -project algo_public
    -DinputTableName=maple_tabletokv_basic_input
    -DoutputTableName=maple_tabletokv_basic_output
    -DselectedColNames=col0,col1,col2
    -DappendColNames=rowid;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
selectedColNames	Optional. The names of selected columns from the input table.	The column type must be bigint or double.	The whole table is selected by default.
appendColNames	Optional. The names of columns to remain unchanged. These columns are written in the output table without any changes.	Multiple columns can be selected.	-
outputTableName	Required. The name of the output KV table.	Table name	-

Parameter	Description	Valid values	Default value
kvDelimiter	Optional. The delimiter used to separate keys and values.	Symbol	The default delimiter is a colon (:).
itemDelimiter	Optional. The delimiter used to separate key-value pairs.	Symbol	The default delimiter is a comma (,).
convertColToIndexId	Optional. This parameter specifies whether to convert columns into IDs.	0 and 1	0
inputKeyMapTableName	Optional. The name of the input index table. This parameter takes effect only in the case of `convertColToIndexId=1`. If this parameter is not specified, IDs are automatically generated.	Table name	No input index table is set by default.
outputKeyMapTableName	The name of the output index table. This parameter is required only in the case of `convertColToIndexId=1`.	Table name	The default value is determined by convertColToIndexId.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

Example 1

Data generation

rowid	kv
0	col0:1,col1:1.1,col2:2
1	col0:0,col1:1.2,col2:3
2	col0:1,col1:2.3
3	col0:1,col1:0.0,col2:4

PAI command

```
PAI -name TableToKV
    -project algo_public
    -DinputTableName=maple_tabletokv_basic_input
    -DoutputTableName=maple_tabletokv_basic_output
    -DselectedColNames=col0,col1,col2
    -DappendColNames=rowid;
```

Output

The output table is shown as follows.

maple_tabletokv_basic_output

rowid:bigint	kv:string
0	1:1.1,2:2
1	1:1.2,2:3
2	1:2.3
3	1:0.0,2:4

Example 2

PAI command

```
PAI -name TableToKV
    -project projectxlib4 -DinputTableName=maple_tabletokv_basic_input
    -DoutputTableName=maple_tabletokv_basic_output
    -DselectedColNames=col0,col1,col2 -DappendColNames=rowid
    -DconvertColToIndexId=1
    -DinputKeyMapTableName=maple_test_tabletokv_basic_map_input
    -DoutputKeyMapTableName=maple_test_tabletokv_basic_map_output;
```

Output

The output table is shown as follows.

maple_test_tabletokv_basic_map_output

col_name:string	col_index:string	col_datatype:string
col1	1	bigint
col2	2	double

Restrictions and guidelines

- If a key_map table is input, columns are converted from the keys that exist in both the key_map and key-value tables.
- If a key_map table is input and its type is different from the input table, the output key_map table uses the type specified by the user.
- The type of the columns that need to be converted into KV pairs in the input table must be bigint or double.

4.4.4. Feature engineering

4.4.4.1. Feature transformation

4.4.4.1.1. PCA

You can use principal component analysis (PCA) to reduce dimensionality.

- For more information about the PCA algorithm, see Wikipedia.
- This component supports the dense data format.

PAI command

```
PAI -name PrinCompAnalysis
-project algo_public
-DinputTableName=bank_data
-DeigOutputTableName=pai_temp_2032_17900_2
-DprincompOutputTableName=pai_temp_2032_17900_1
-DselectedColNames=pdays,previous,emp_var_rate,cons_price_idx,cons_conf_idx,euribor3m,nr_employ
ed
-DtransType=Simple
-DcalcuType=CORR
-DcontriRate=0.9;
```

Algorithm parameters

Parameters

Parameter	Description	Default value
inputTableName	Required. The name of the input table for PCA.	-
eigOutputTableName	Required. The name of the output table that contains eigenvectors and eigenvalues.	-
princompOutputTableName	Required. The name of the output table after PCA dimensionality reduction.	-
selectedColNames	Required. The names of feature columns that are involved in the PCA procedure.	-
transType	Optional. The method used to transform the original table to the principal component table. Valid values: Simple, Sub-Mean, and Normalization.	Simple
calcuType	Optional. The eigendecomposition mode of the original table. Valid values: CORR, COVAR_SAMP, and COVAR_POP.	CORR
contriRate	Optional. The ratio of information to be retained after dimensionality reduction.	0.9
remainColumns	Optional. The columns retained from the original table after dimensionality reduction.	-

Sample PCA output

Table after dimensionality reduction,shows a sample table after dimensionality reduction.

Eigenvalues and eigenvectors,shows the eigenvalues and eigenvectors.

4.4.4.2. Feature importance evaluation

4.4.4.2.1. Linear model feature importance

You can evaluate the quality of a linear algorithm model based on the predicted and actual output results such as the indicators and residual histogram. Indicators include SST, SSE, SSR, R2, R, MSE, RMSE, MAE, MAD, MAPE, count, yMean, and predictMean.

PAI command

```
pai -name regression_evaluation
-project algo_public
-DinputTableName=input_table
-DyColName=y_col
-DpredictionColName=prediction_col
-DindexOutputTableName=index_output_table
-DresidualOutputTableName=residual_output_table
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training.	-	All partitions in the input table are selected by default.
yColName	Required. The name of the expected dependent variable column in the input table. It must be a numerical value.	-	-
predictionColName	Required. The name of the predicted dependent variable column. It must be a numerical value.	-	-
indexOutputTableName	Required. The name of the regression indicator output table.	-	-
residualOutputTableName	Required. The name of the residual histogram output table.	-	-
intervalNum	Optional. The number of intervals to divide the histogram over.	-	100
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	-	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	-	Automatically calculated.

Output

The output table is in JSON format. Field description describes the JSON fields.

Field description

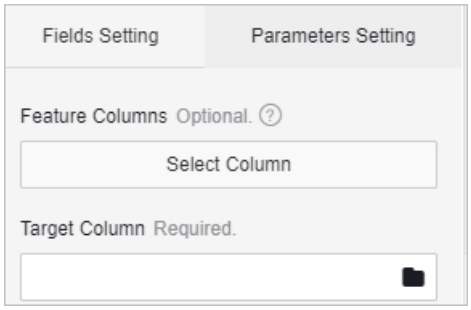
Field	Description

Field	Description
SST	Total sum of squares.
SSE	Sum of squared errors.
SSR	Sum of squares due to regression.
R2	Coefficient of determination.
R	Coefficient of multiple correlation.
MSE	Mean squared error.
RMSE	Root-mean-square error.
MAE	Mean absolute error.
MAD	Mean absolute difference.
MAPE	Mean absolute percentage error.
count	Number of rows.
yMean	Mean of expected dependent variables.
predictionMean	Mean of prediction results.

4.4.4.2.2. Random forest feature importance

You can calculate the importance of features in a random forest model.

Column settings



PAI command

```
pai -name feature_importance
-project algo_public
-DinputTableName=input
-DoutputTableName=output
-Dlabel=label
-DmodelName=model
```

Algorithm parameters

Parameters

Parameter	Description	Default value
inputTableName	Required. The name of the input table.	-
outputTableName	Required. The name of the output table.	-
labelColName	Required. The name of the label column.	-
modelName	Required. The name of the input model.	-
featureColNames	Optional. The names of feature columns selected from the input table.	All columns except the label column are selected by default.
inputTablePartitions	Optional. The partitions selected from the input table.	The whole table is selected by default.
lifecycle	Optional. The lifecycle of the output table.	No lifecycle is set by default.
coreNum	Optional. The number of cores.	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	Automatically calculated.

4.4.5. Statistical analysis

4.4.5.1. Data pivoting

This component allows you to view the distributions of feature values, feature columns, and label columns. Data can be analyzed more efficiently when you know its features. This component supports dense and sparse formats.

PAI command

```
PAI -name fe_meta_runner -project algo_public
-DinputTable="pai_dense_10_10"
-DoutputTable="pai_temp_2263_20384_1"
-DmapTable="pai_temp_2263_20384_2"
-DselectedCols="pdays,previous,emp_var_rate,cons_price_idx,cons_conf_idx,euribor3m,nr_employed,age,campaign,poutcome"
-DlabelCol="y"
-DcategoryCols="previous"
-Dlifecycle="28"-DmaxBins="5" ;
```

Algorithm parameters

Parameter	Description	Required	Default value
inputTable	The name of the input table.	Yes	N/A
inputTablePartitions	The partitions selected from the input table.	No	N/A
outputTable	The name of the output table.	Yes	N/A
mapTable	The output mapping table. The Data Pivoting component maps String and Int type data for machine learning to use for training.	Yes	N/A
selectedCols	The columns selected from the input table.	Yes	N/A
categoryCols	The columns specified to process Int or Double type columns as enumeration features.	No	null
maxBins	The maximum number of intervals for equal-distance division of continuous features.	No	100
isSparse	Indicates whether the features are in sparse format.	No	false

Parameter	Description	Required	Default value
itemSpliter	The delimiter used to separate sparse feature items.	No	","
kvSpliter	The delimiter used to separate keys and values.	No	":"
lifecycle	The lifecycle of the output table. Unit: days.	No	28

4.4.5.2. Whole table statistics

This component analyzes a table or selected columns of a table.

Parameter settings

In the Input Columns box, select the columns of the table to be analyzed. By default, all columns are selected. You can enter filtering conditions for the selected columns in the condition text box. Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), and less than or equal to (<=) signs, as well as like and rlike.

PAI command

```
PAI -name SimpleSummary
-project algo_public
-DsummaryColNames="euribor3m,pdays"
-DoutputTableNames="pai_temp_667_6017_1"
-DinputTableName="bank_data"
-Dfilter="age>40";
```

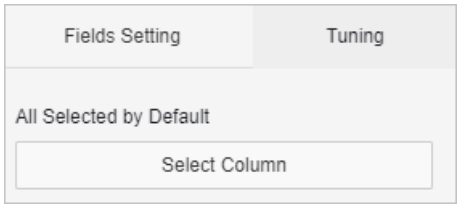
Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
summaryColNames	The columns that require analysis. Separate the columns with commas(,).
outputTableNames	The names of the output tables generated after the system performs the whole table statistics operation.
inputTableName	The name of the input table.
filter	The filtering conditions. Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), and less than or equal to (<=) signs, as well as like and rlike.

4.4.5.3. Correlation coefficient matrix

The correlation coefficient is a measure of the correlation between columns in a matrix. The valid range of values for this parameter is [-1, 1]. The count equals the number of non-zero elements in two successive columns.

Column settings



PAI command

```
PAI -name corrcoef
-project algo_public
-DinputTableName=maple_test_corrcoef_basic12x10_input
-DoutputTableName=maple_test_corrcoef_basic12x10_output
-DcoreNum=1
-DmemSizePerCore=110
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartition	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions are selected by default.
outputTableName	Required. A list of output table names.	Table name	-
selectedColNames	Optional. The names of columns selected from the input table.	Column name	All columns are selected by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each node. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

Examples

Data generation describes the data generation result.

Data generation

col0:double	col1:bigint	col2:double	col3:bigint	col4:double	col5:bigint	col6:double	col7:bigint	col8:double	col9:double

4.4.5.4. Covariance

In probability theory and statistics, covariance is a measure of the joint variability of two random variables. Variance is a special case of covariance where the two measured variables are the same. If the expected values are E(X) = μ and E(Y) = v, the covariance between real-number random variables X and Y is cov(X, Y) = E((X - μ) (Y - v)).

PAI command

```
PAI -name cov
    -project algo_public
    -DinputTableName=maple_test_cov_basic12x10_input
    -DoutputTableName=maple_test_cov_basic12x10_output
    -DcoreNum=6
    -DmemSizePerCore=110;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-

Parameter	Description	Valid values	Default value
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
outputTableName	Required. A list of output table names.	Table name	-
selectedColNames	Optional. The names of columns selected from the input table.	Column name	All columns are selected by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each node. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

4.4.5.5. Empirical probability density chart

An empirical distribution is an estimated non-parametric distribution of probability in scenarios where accurate parametric distributions cannot be made.

The algorithm uses kernel distribution to estimate the probability density of sample data. Similar to a histogram, the algorithm generates functions to describe the distribution of sample data. However, kernel distribution is different in that it overlays the contributions of all parts to generate a smooth and continuous distribution curve, while a histogram only generates discrete descriptions. When kernel distribution is used, the probability density of non-sample data points is not 0, but an overlay of weighted probability density of all sampling points in a certain kernel distribution. In this document, the kernel distribution used is Gaussian distribution.

- For more information about kernel distribution, see Wikipedia.
- For more information about empirical distribution, see Wikipedia.

PAI command

```
PAI -name empirical_pdf
-project algo_public
-DinputTableName="test_data"
-DoutputTableName="test_epdf_out"
-DfeatureColNames="col0,col1,col2"
-DinputTablePartitions="ds='20160101'"
-Dlifecycle=1
-DintervalNum=100
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
outputTableName	Required. The name of the output table.	Table name	-
featureColNames	Required. The names of input columns.	Multiple columns of the double or bigint type can be selected.	-
labelColName	Optional. The name of the input label column.The feature column is stratified based on the label values in the label column.	Only one column of the bigint or string type can be selected. The number of label values cannot exceed 100.	No input label column is set by default.
inputTablePartitions	Optional. The partitions selected from the input table.	Partition name	All partitions are selected by default.
intervalNum	The number of calculation intervals. The larger the number, the higher the accuracy.	[1, 1E14)	Default value: -1. This value indicates that the number of intervals is determined based on the range of data values for each column.
lifecycle	The lifecycle of the output table.	A positive integer	Default value: -1. This value indicates that no lifecycle is set.

Parameter	Description	Valid values	Default value
coreNum	Optional. The number of cores.	A positive integer	Default value: -1. This value indicates that the number of instances is determined based on the volume of input data.
memSizePerCore	Optional. The memory size of each core.	A positive integer in the range of [1024, 65536]	Default value: -1. This value indicates that the memory size is determined based on the volume of input data.

Examples

SQL statement to generate data:

```
drop table if exists epdf_test;
create table epdf_test as
select
 *
from
(
 select 1.0 as col1 from dual
  union all
 select 2.0 as col1 from dual
  union all
 select 3.0 as col1 from dual
  union all
 select 4.0 as col1 from dual
  union all
 select 5.0 as col1 from dual
) tmp;
```

PAI command

```
PAI -name empirical_pdf
-project algo_public
-DinputTableName=epdf_test
-DoutputTableName=epdf_test_out
-DfeatureColNames=col1;
```

Input description

You can select multiple columns to be calculated. You can select a label column and stratify the columns by label. For example, if the label column contains labels 0 and 1, the columns that need to be calculated are stratified into two groups. One group only contains columns with label 0 and the other group only contains columns with label 1. The probability density for each group is then calculated. If no label column is selected, all feature columns are calculated.

Output description

This component outputs a diagram and a result table. The columns in the result table are as follows. If no label column is selected, NULL is output in the label column.

Column name	Data type
colName	string
label	string
x	double
pdf	double

Output table:

```
+------------+------------+------------+------------+
| colname    | label      | x          | pdf        |

```

Input and output restrictions

The maximum number of label columns that can be specified is 100.

4.4.5.6. Chi-square goodness of fit test

This component is used to determine the differences between the observed frequencies and the expected frequencies for each classification of a single multiclass classification nominal variable. The null hypothesis assumes that the observed frequencies and the expected frequencies are consistent.

PAI command

```
PAI -name chisq_test
    -project algo_public
    -DinputTableName=pai_chisq_test_input
    -DcolName=f0
    -DprobConfig=0:0.3,1:0.7
    -DoutputTableName=pai_chisq_test_output0
    -DoutputDetailTableName=pai_chisq_test_output0_detail
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
colName	Required. The name of the column that requires a chi-square test.	Column name	-
outputTableName	Required. The name of the output table.	Table name that has not been used	-
outputDetailTableName	Required. The name of the output detail table.	Table name that has not been used	-
inputTablePartitions	Optional. The partitions selected from the input table.	Partition list	All partitions are selected by default.
probConfig	Optional. The class probability configuration.	The configuration is stored in a key-value pair format: `class:probability`. The sum of all probabilities is 1.	All classes have the same probability by default.

Examples

Testing data

```
create table pai_chisq_test_input as
select * from
(
 select '1' as f0,'2' as f1 from dual
 union all
 select '1' as f0,'3' as f1 from dual
 union all
 select '1' as f0,'4' as f1 from dual
 union all
 select '0' as f0,'3' as f1 from dual
 union all
 select '0' as f0,'4' as f1 from dual
)tmp;
```

PAI command

```
PAI -name chisq_test
   -project algo_public
   -DinputTableName=pai_chisq_test_input
   -DcolName=f0
   -DprobConfig=0:0.3,1:0.7
   -DoutputTableName=pai_chisq_test_output0
   -DoutputDetailTableName=pai_chisq_test_output0_detail
```

Output description

Output table outputTableName is a JSON array containing only one row and one column.

```
{
   "Chi-Square": {
      "comment": "Pearsons chi-square test",
      "df": 1,
      "p-value": 0.75,
      "value": 0.2380952380952381
   }
}
```

Output table outputDetailTableName includes the following columns: data source class (**f0** or **f1**), observed frequency (**observed**), expected frequency (**expected**), and standard residuals (`residuals = (observed - expected)/sqrt (expected)`).

f0	f1	observed	expected	residuals
0	2	0.0	0.4	-0.6324555320336759
0	3	1.0	0.8	0.22360679774997894

4.4.5.7. Chi-square test of independence

This component verifies whether two factors (each having two or more classes) are mutually independent. The null hypothesis is that two factors are independent of each other.

PAI command

```
PAI -name chisq_test
    -project algo_public
    -DinputTableName=pai_chisq_test_input
    -DxColName=f0
    -DyColName=f1
    -DoutputTableName=pai_chisq_test_output2
    -DoutputDetailTableName=pai_chisq_test_output2_detail
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
xColName	Required. The name of the column that requires a chi-square test.	Column name	-
yColName	Required. The name of the column that require a chi-square test.	Column name	-
outputTableName	Required. The name of the output table.	Table name that has not been used	-
outputDetailTableName	Required. The name of the output detail table.	Table name that has not been used	-

Parameter	Description	Valid values	Default value
inputTablePartitions	Optional. The partitions selected from the input table.	Partition list	All partitions are selected by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Examples

- Testing data

```
create table pai_chisq_test_input as
select * from
(
select '1' as f0,'2' as f1 from dual
union all
select '1' as f0,'3' as f1 from dual
union all
select '1' as f0,'4' as f1 from dual
union all
select '0' as f0,'3' as f1 from dual
union all
select '0' as f0,'4' as f1 from dual
)tmp;
```

- PAI command

```
PAI -name chisq_test
  -project algo_public
  -DinputTableName=pai_chisq_test_input
  -DxColName=f0
  -DyColName=f1
  -DoutputTableName=pai_chisq_test_output2
  -DoutputDetailTableName=pai_chisq_test_output2_detail
```

- Output description

  Output table outputTableName is a JSON array containing only one row and one column.

```
{
  "Chi-Square": {
    "comment": "Pearsons chi-square test",
    "df": 2,
    "p-value": 0.75,
    "value": 0.8333333333333334
  }
}
```

Output table outputDetailTableName has the following columns:

Column name	Description
xColName	Class
yColName	Class
observed	Observed frequency
expected	Expected frequency
residuals	Residuals = (observed - expected)/sqrt (expected)

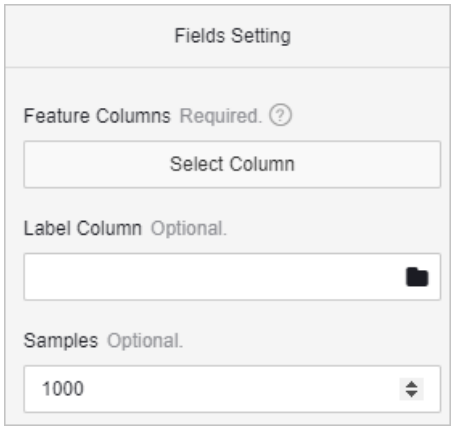
Data:

f0	f1	observed	expected	residuals
0	2	0.0	0.4	-0.6324555320336759
0	3	1.0	0.8	0.22360679774997894
0	4	1.0	0.8	0.22360679774997894
1	2	1.0	0.6000000000000001	0.5163977794943221
1	3	1.0	1.2000000000000002	-0.1825741858350555
1	4	1.0	1.2000000000000002	-0.1825741858350555

4.4.5.8. Scatter plot

In regression analysis, this component outputs a scatter plot that shows the distribution of data points in a Cartesian coordinate system.

Column settings



PAI command

```
PAI -name scatter_diagram
-project algo_public
-DselectedCols=emp_var_rate,cons_price_rate,cons_conf_idx,euribor3m
-DsampleSize=1000
-DlabelCol=y
-DmapTable=pai_temp_2447_22859_2
-DinputTable=scatter_diagram
-DoutputTable=pai_temp_2447_22859_1
```

Parameters

Parameter	Description	Default value
inputTable	Required. The name of the input table.	-
inputTablePartitions	Optional. The partitions selected from the input table.	-
outputTable	Required. The name of the output table that stores the samples.	-
mapTable	Required. The name of the output table that stores the maximum value, minimum value, and enumeration values of each feature.	-
selectedCols	Required. The columns selected from the input table from which to draw a scatter plot. A maximum of five features can be selected.	-
labelCol	Optional. An Int or String column to serve as the enumeration label column.	No enumeration label column is set by default.

Parameter	Description	Default value
sampleSize	Optional. The number of samples to collect from the input data.	1000
lifecycle	Optional. The lifecycle of the output table measured in days.	28

Examples

Input data

```
create table scatter_diagram as select emp_var_rate,cons_price_rate, cons_conf_idx,euribor3m,y from pai_bank_data limit 10
```

Parameters

emp_var_rate	cons_price_rate	cons_conf_idx	euribor3m	y
1.4	93.918	-42.7	4.962	0

1.1	93.994	-36.4	4.858	0
1.4	93.444	-36.1	4.963	0

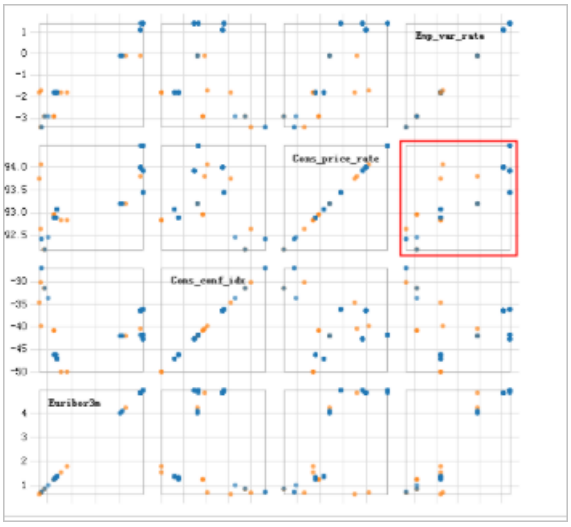
Parameter settings

Scatter plot configuration: select **select emp_var_rate**, **cons_price_rate**, **cons_conf_idx**, and **euribor3m** as the feature columns, and select **y** as the label column.

Output



You can view the distribution of classification tags between every two features in the scatter plot.

4.4.5.9. Two-sample T-test

A two-sample T-test is composed of an independent sample T-test and a paired sample T-test. Two samples independent of each other are called independent samples. An independent sample T-test checks whether two samples are significantly different from each other. The T-test is based on the premise that two samples are independent of each other and come from two normally distributed populations. A paired sample T-test checks whether the mean values from two paired populations are significantly different from each other.

PAI command

```
PAI -name t_test
    -project algo_public
    -DxTableName=pai_t_test_all_type
    -DxColName=col1_double
    -DxTablePartitions=ds=2010/dt=1
    -DyTableName=pai_t_test_all_type
    -DyColName=col1_double
    -DyTablePartitions=ds=2010/dt=1
    -DoutputTableName=pai_t_test_out
    -Dalternative=less
    -Dmu=47
    -DconfidenceLevel=0.95
    -Dpaired=False
    -DvarEqual=True
```

Parameters

Parameter	Description	Valid values	Default value
xTableName	Required. The name of input table x.	Table name	-
xTablePartitions	Optional. The partitions selected from input table x for testing, in the format of `Partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
xColName	Required. The column selected from table x for testing.	Column name. The type must be double or bigint.	-
yTableName	Required. The name of input table y.	Table name	-
yTablePartitions	Optional. The partitions selected from input table y for testing, in the format of `Partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.

Parameter	Description	Valid values	Default value
yColName	Required. The name of the column selected from table y for testing.	Column name. The type must be double or bigint.	-
paired	Optional. A value of True indicates that it is a paired sample T-test. A value of False indicates that it is an independent sample T-test.	True and False	False
alternative	Optional. The alternative hypothesis.	two.sided, less, and greater	two.sided
mu	Optional. The hypothesized mean.	double	0
varEqual	Optional. This parameter indicates whether two population variances are equal.	True and False	False
confidenceLevel	Optional. The confidence level.	0.8, 0.9, 0.95, 0.99, 0. 995, and 0.999	0.95
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each node. Unit: MB.	A positive integer in the range of [1024, 65536].	Automatically calculated.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Custom resources

Note

- For a regular table, we recommend that you do not set coreNum and memSizePerCore, and instead allow the default values to be used automatically.
- If you do not have sufficient compute resources, use the following code to calculate the amount of compute resources needed:

```
def CalcCoreNumAndMem(row, centerCount, kOneCoreDataSize=1024):
  """Calculates the number of nodes and memory size needed for each node.
    Args:
      row: the number of rows in the input table.
      col: the number of columns in the input table.
      kOneCoreDataSize: the amount of data needed to be calculated per node. Unit: MB. The value m
ust be a positive integer. Default value: 1024.
    Return:
      coreNum, memSizePerCore
    Example:
      coreNum, memSizePerCore = CalcCoreNumAndMem(1000,99, 100, kOneCoreDataSize=2048)

  """
  kMBytes = 1024.0 * 1024.0
  #Number of compute nodes
  coreNum = max(1, int(row * 2 * 8 / kMBytes / kOneCoreDataSize))
  #Memory size per node = Data volume
  memSizePerCore = max(1024,  int(kOneCoreDataSize*2))
  return coreNum,  memSizePerCore
```

Examples

- SQL statement to generate data:

```
create table pai_test_input as
select * from
(
 select 1 as f0,2 as f1 from dual
 union all
 select 1 as f0,3 as f1 from dual
 union all
 select 1 as f0,4 as f1 from dual
 union all
 select 0 as f0,3 as f1 from dual
 union all
 select 0 as f0,4 as f1 from dual
)tmp;
```

- PAI command

```
PAI -name t_test
    -project algo_public
    -DxTableName=pai_test_input
    -DxColName=f0
    -DyTableName=pai_test_input
    -DyColName=f1
    -DyTablePartitions=ds=2010/dt=1
    -DoutputTableName=pai_t_test_out
    -Dalternative=less
    -Dmu=47
    -DconfidenceLevel=0.95
    -Dpaired=False
    -DvarEqual=True
```

- Output description

  The output table is a JSON array containing only one row and one column.

```
{
    "AlternativeHypthesis": "difference in means not equals to 0",
    "ConfidenceInterval": "(-2.5465, -0.4535)",
    "ConfidenceLevel": 0.95,
    "alpha": 0.05000000000000004,
    "df": 19,
    "mean of the differences": -1.5,
    "p": 0.008000000000000007,
    "t": -3
}
```

Input and output restrictions

The input and output are not limited.

4.4.5.10. One-sample T-test

A one-sample T-test verifies whether the mean of a normally distributed population differs significantly from a target value. A T-test is performed based on the condition that the sample population is normally distributed.

PAI command

```
PAI -name t_test -project algo_public
    -DxTableName=pai_t_test_all_type
    -DxColName=col1_double
    -DoutputTableName=pai_t_test_out
    -DxTablePartitions=ds=2010/dt=1
    -Dalternative=less
    -Dmu=47
    -DconfidenceLevel=0.95
```

Algorithm parameters

Parameter	Description	Valid values	Default value
xTableName	Required. The name of input table x.	Table name	-
xColName	Required. The column selected from table x for testing.	Column name. The type must be double or bigint.	-
outputTableName	Required. The name of the output table.	Table name that has not been used	-
xTablePartitions	Optional. The partitions selected from input table x.	Partition list	All partitions are selected by default.
alternative	Optional. The alternative hypothesis.	two.sided, less, and greater	two.sided
mu	Optional. The hypothesized mean.	double	0
confidenceLevel	Optional. The confidence level.	0.8, 0.9, 0.95, 0.99, 0.995, and 0.999	0.95

Output description

The output table is a JSON array containing only one row and one column.

```
{
   "AlternativeHypthesis": "mean not equals to 0",
   "ConfidenceInterval": "(44.72234194006504, 46.27765805993496)",
   "ConfidenceLevel": 0.95,
   "alpha": 0.05,
   "df": 99,
   "mean": 45.5,
   "p": 0,
   "stdDeviation": 3.919647479510927,
   "t": 116.081867662439
}
```

4.4.5.11. Lorenz curve

The Lorenz curve is a graph to illustrate the distribution of wealth across a population. The X axis represents the total population arranged from least wealthy to most wealthy, while the Y axis represents the total wealth. If this graph is a straight line, it indicates perfectly equal distribution of wealth. The Gini coefficient is calculated by taking the area between the equal distribution curve and the actual Lorenz curve for a population as a fraction of the total area beneath the equal distribution curve. As the distribution of wealth becomes less equal, the Gini coefficient will increase, whereas a population with equal distribution of wealth will have a Gini coefficient of 0.

To study the distribution of income among a population, American statistician Max Otto Lorenz proposed the famous Lorenz curve in 1905. In 1921, Italian economist Corrado Gini defined the Gini coefficient as a measure of inequality in a population based on the Lorenz curve.

PAI command

```
PAI -name LorenzCurve
   -project algo_public
   -DinputTableName=maple_test_lorenz_basic10_input
   -DcolName=col0
   -DoutputTableName=maple_test_lorenz_basic10_output -DcoreNum=20
   -DmemSizePerCore=110;
```

Parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
outputTableName	Required. The name of the output table.	Table name that has not been used	N/A

Parameter	Description	Valid value	Default value
colName	Optional. The column name. Separate multiple columns with commas (,).	Column name	The whole table is selected by default.
N	The number of quantiles.	N/A	100
inputPartitions	Optional. The partitions selected from the input table for training, in the `partition_name=value` format. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

4.4.5.12. Normality test

This component is used to determine whether observed values are normally distributed.

This component consists of three test methods: Anderson-Darling test (see Wikipedia), Kolmogorov-Smirnov test (see Wikipedia), and Q-Q plot (see Wikipedia). You can use one or more methods as needed.

Algorithm description:

- Original hypothesis H0: The observed values are normally distributed. H1: The observed values are not normally distributed.
- The KS p-value calculation method progressively calculates CDF of KS distribution regardless of the sample size. For more information, see Wikipedia.
- If the sample size is greater than 1000, the Q-Q plot method collects samples to calculate and output plots. This means that the data points in plots do not necessarily cover all samples.

PAI command

```
PAI -name normality_test
    -project algo_public
    -DinputTableName=test
    -DoutputTableName=test_out
    -DselectedColNames=col1,col2
    -Dlifecycle=1;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
outputTableName	Required. The name of the output table.	Table name that has not been used	-
selectedColNames	Optional. The names of selected columns.	Multiple double or bigint type columns can be selected.	-
inputTablePartitions	Optional. The partitions selected from the input table.	Partition name	All partitions are selected by default.
enableQQplot	Optional. This parameter specifies whether to use the Q-Q plot.	true and false	true
enableADtest	Optional. This parameter specifies whether to perform the Anderson-Darling test.	true and false	true
enableKStest	Optional. This parameter specifies whether to perform the Kolmogorov-Smirnov test.	true and false	true

Parameter	Description	Valid values	Default value
lifecycle	Optional. The lifecycle of the output table.	An integer greater than or equal to -1	Default value: -1. This value indicates that no lifecycle is set.
coreNum	Optional. The number of cores.	An integer greater than 0	Default value: -1. This value indicates that the number of instances is determined by the amount of input data.
memSizePerCore	Optional. The memory size of each core.	(100, 65536)	Default value: -1. This value indicates that the memory size is determined by the amount of input data.

Examples

- **SQL statement to generate data:**

```
drop table if exists normality_test_input;
  create table normality_test_input as
  select
   *
  from
  (
   select 1 as x from dual
    union all
   select 2 as x from dual
    union all
   select 3 as x from dual
    union all
   select 4 as x from dual
    union all
   select 5 as x from dual
    union all
   select 6 as x from dual
    union all
   select 7 as x from dual
    union all
   select 8 as x from dual
    union all
   select 9 as x from dual
    union all
   select 10 as x from dual
  ) tmp;
```

- **PAI command**

```
PAI -name normality_test
  -project projectxlib4
  -DinputTableName=normality_test_input
  -DoutputTableName=normality_test_output
  -DselectedColNames=x
  -Dlifecycle=1;
```

- **Input description**

  Input format: select the columns that need to be calculated. The columns must be of the double or bigint type.

- **Output description**

  A diagram and a result table are output. The columns in the result table are as follows. The result table has two partitions:

- `p='test'` shows the result of the AD or KS test. Data is output when *enableADtest* or *enableKStest* is set to true.
- `p='plot'` shows the Q-Q plot data. When *enableQQplot* is set to true, data is output and the columns that meet the `p='test'` condition are reused. In the case of `p='plot'`, the *testvalue* column records the original observed data (x axis of the Q-Q plot), and the *pvalue* column records the expected data that is normally distributed (y axis of the Q-Q plot).

Output table:

```
+------------+------------+------------+------------+------------+
| colname    | testname   | testvalue  | pvalue     | p          |
+------------+------------+------------+------------+------------+
| x          | NULL       | 1.0        | 0.8173291742279805 | plot       |
| x          | NULL       | 2.0        | 2.470864450785345 | plot       |
| x          | NULL       | 3.0        | 3.5156067948020056 | plot       |
| x          | NULL       | 4.0        | 4.3632330349313095 | plot       |
| x          | NULL       | 5.0        | 5.128868067945126 | plot       |
| x          | NULL       | 6.0        | 5.871131932054874 | plot       |
| x          | NULL       | 7.0        | 6.6367669650686905 | plot       |
| x          | NULL       | 8.0        | 7.4843932051979944 | plot       |
| x          | NULL       | 9.0        | 8.529135549214654 | plot       |
| x          | NULL       | 10.0       | 10.182670825772018 | plot       |
| x          | Anderson_Darling_Test | 0.1411092332197832 | 0.9566579606430077 | test       |
| x          | Kolmogorov_Smirnov_Test | 0.09551932503797644 | 0.9999888659426232 | test       |
+------------+------------+------------+------------+------------+
```

Column name	Data type	Definition
colName	string	Column name
testname	string	Test name
testvalue	double	Test value on the x axis of the Q-Q plot
pvalue	double	Test p value on the y axis of the Q-Q plot
p	double	Partition name

4.4.5.13. Percentile

This component calculates the percentile of the values in a column.

Parameter settings

Select the column to be analyzed. Only the double and bigint types are supported.

PAI command

```
PAI -name Percentile
-project algo_public
-DoutputTableName="pai_temp_666_6014_1"
-DcolName="euribor3m"
-DinputTableName="bank_data";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
outputTableName	The name of the output table automatically generated after the system performs the percentile calculation.
colName	The column selected for percentile calculation. Only the numeric type is supported.
inputTableName	The name of the input table.

4.4.5.14. Pearson coefficient

This component calculates the Pearson correlation coefficient of two numeric columns in an input table or a partition, and saves the result to the output table.

Component description

- The component has only two parameters: input column 1 and input column 2. Enter the names of the two columns for which the Pearson correlation coefficient is calculated.
- After you run the component, right-click the component and choose **View Analytics Report** from the shortcut menu.
- The Pearson correlation coefficient is listed in the row.

PAI command

```
pai -name pearson
-project algo_test
-DinputTableName=wpbc
-Dcol1Name=f1
-Dcol2Name=f2
-DoutputTableName=wpbc_pear;
```

Algorithm prameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	The partitions selected from the input table for calculation.	The parameter value must be in the `partition_name=value` format. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	All partitions in the input table are selected by default.
col1Name	Required. The name of input column 1.	Column name	-
col2Name	Required. The name of input column 2.	Column name	-
outputTableName	Required. The name of the output table.	Table name	-

4.4.5.15. Histogram

This component analyzes data in a column and outputs a histogram.

Parameter settings

- Select the columns to be analyzed. Only the double and bigint types are supported.
- View the analysis report.
- You can adjust the step and move the slider to view the entire histogram.

4.4.6. Machine learning

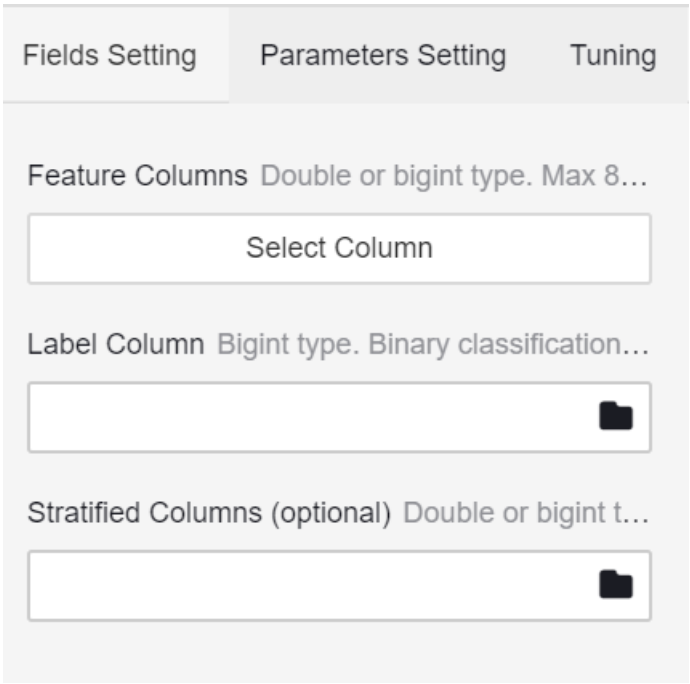
4.4.6.1. Binary classification

4.4.6.1.1. GBDT binary classification

This component is used for binary classification based on GBDT regression and sorting. Values greater than the threshold value are considered positive samples, while values that are less than or equal to the threshold value are considered negative samples.

Procedure

1. Drag and drop the GBDT Binary Classification component onto the canvas for training and set the parameters, as shown in the following figure.



Parameters

Parameter	Description
Feature Columns	The double and bigint types are supported. A maximum of 800 columns can be specified.
Label Column	You can select all columns except the input column. The values must be of the binary type.
Stratification Column	Optional. The whole table is selected by default. The double and bigint types are supported.

2. You can change the data type of the input columns.

   The input columns of GBDT binary classification only support the continuous type and are processed in the same way as the discrete type.

3. Set the parameters.

Parameters

Parameter	Description
Metric Type	The normalized discounted cumulative gain (NDCG) and discounted cumulative gain (DCG).
Trees	Valid values: [1,10000]. Default value: 500.
Learning Rate	Valid values: (0, 1). Default value: 0.05.
Training Sample Fraction	Valid values: (0, 1). Default value: 0.6.
Training Feature Fraction	Valid values: (0, 1). Default value: 0.6.
Maximum Leaves	The value must be an integer in the range of [2, 1000]. Default value: 32.
Testing Data Fraction	Valid values: [0, 1]. Default value: 0.0.
Maximum Tree Depth	The value must be an integer in the range of [1, 11]. Default value: 11.
Minimum Samples per Leaf Node	The value must be an integer in the range of [100, 1000]. Default value: 500.
Random Seed	The value must be an integer in the range of [0, 10]. Default value: 0.
Maximum Splits per Feature	Valid values: [1, 1000]. Default value: 500.

4. View the output. For more information, see the description of the Random forest component.

> Note
>
> - GBDT and GBDT_LR have different default types of loss functions. The default loss function of GBDT is regression loss:mean squared error loss. The default loss function of GBDT_LR is logistic regression loss. The system automatically writes the default loss function for GBDT_LR.
> - For GBDT binary classification, the label column must be of the binary type. String type data is not supported.
> - When connecting the ROC curve component, set the prediction component parameters and select a base value.

PAI command (F/L setup settings are not used)

```
PAI -name GBDT_LR
-project algo_public
-DfeatureSplitValueMaxSize="500"
-DrandSeed="0"
-Dshrinkage="0.5"
-DmaxLeafCount="32"
-DlabelColName="y"
-DinputTableName="bank_data_partition"
-DminLeafSampleCount="500"
-DgroupIDColName="nr_employed"
-DsampleRatio="0.6"
-DmaxDepth="11"
-DmodelName="xlab_m_GBDT_LR_21208"
-DmetricType="2"
-DfeatureRatio="0.6"
-DinputTablePartitions="pt=20150501"
-DtestRatio="0.0"
-DfeatureColNames="age,previous,cons_conf_idx,euribor3m"
-DtreeCount="500";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
featureSplitValueMaxSize	Optional. The maximum number of splits per feature. Valid values: [1, 1000]. Default value: 500.
randSeed	Optional. The number of random seeds. The value must be an integer in the range of [0, 10]. Default value: 0.
shrinkage	Optional. The learning rate. Valid values: (0, 1). Default value: 0.05.
maxLeafCount	Optional. The maximum number of leaves. The value must be an integer in the range of [2, 1000]. Default value: 32.
labelColName	The name of the label column selected from the input table.
inputTableName	The name of the input table for training.

Parameter	Description
minLeafSampleCount	Optional. The minimum number of samples per leaf node. The value must be an integer in the range of [100, 1000]. Default value: 500.
groupIDColName	Optional. The name of the stratification column. The whole table is considered as a stratum by default.
sampleRatio	Optional. The fraction of samples collected for training. Valid values: (0, 1). Default value: 0.6.
maxDepth	Optional. The maximum depth of a tree. The value must be an integer in the range of [1, 11]. Default value: 11.
modelName	The name of the output model.
metricType	Optional. The type of a metric. Valid values: 0 and 1. 0 represents normalized discounted cumulative gain (NDCG) and 1 represents discounted cumulative gain (DCG).
featureRatio	Optional. The fraction of features collected for training. Valid values: (0, 1). Default value: 0.6.
inputTablePartitions	Optional. The partitions selected from the input prediction table. If no partitions are specified, the whole table is selected.
testRatio	Optional. The fraction of testing samples. Valid values: [0, 1]. Default value: 0.0.
featureColNames	The names of feature columns selected from the input table for training.
treeCount	Optional. The number of trees. Valid values: [1, 10000]. Default value: 500.

4.4.6.1.2. Linear SVM

Support-vector machines (SVMs) are developed based on the VC dimension theory and the structural risk minimization principle.

This linear SVM version is not implemented using the kernel function. For more information, see Trust Region Method for L2-SVM at http://www.csie.ntu.edu.tw/~cjlin/papers/logistic.pdf. This algorithm only supports binary classification.

Procedure

1. Configure column settings.
   - Feature Columns: You can select a feature column of the bigint or double type.
   - Label Column: The data type of the label column can be bigint, double, or string. This component only supports binary classification.
2. Set parameters.

Parameters

Parameter	Description
Positive Sample Label	Optional. The value of the positive sample. If this parameter is not specified, the system randomly selects a value. We recommend that you specify this parameter when the positive and negative samples are significantly different.
Positive Penalty Factor	Optional. The weight of the positive sample. Valid values: (0, +∞). Default value: 1.0.
Negative Penalty Factor	Optional. The weight of the negative sample. Valid values: (0, +∞). Default value: 1.0.
Convergence Coefficient	Optional. The convergence deviation. Valid values: (0, 1). Default value: 0.001. Note If no base value is specified, Positive Penalty Factor and Negative Penalty Factor must be set to the same value.

3. View the output. For more information, see the description of the Random Forest component.

PAI command (F/L setup settings are not used)

```
PAI -name LinearSVM
-project algo_public
-DnegativeCost="1.0"
-DmodelName="xlab_m_LinearSVM_6143"
-DpositiveCost="1.0"
-Depsilon="0.001"
-DlabelColName="y"
-DfeatureColNames="pdays,emp_var_rate,cons_conf_idx"
-DinputTableName="bank_data"
-DpositiveLabel="0";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
negativeCost	Optional. The weight of the negative sample. It is the penalty factor of the negative sample. Valid values: (0, +∞). Default value: 1.0.

Parameter	Description
modelName	The name of the output model.
positiveCost	Optional. The weight of the positive sample. It is the penalty factor of the positive sample. Valid values: (0, +∞). Default value: 1.0.
epsilon	Optional. The convergence coefficient. Valid values: (0, 1). Default value: 0.001.
labelColName	The name of the label column.
featureColNames	The names of feature columns selected from the input table for training.
inputTableName	The name of the input table for training.
positiveLabel	Optional. The value of the positive sample. If this parameter is not specified, the system randomly selects a value.

4.4.6.1.3. Logistic regression for binary classification

Binary classification is a classic logistic regression method. Logistic regression on the algorithm platform supports multiclass classification. The logistic regression component supports two data types: sparse and dense.

Parameter settings

Parameters

Parameter	Description
Regularization Type	Optional. The type of regularization. Valid values: *L1*, *L2*, and *None*. Default value: *L1*.
Maximum Iterations	Optional. The maximum number of L-BFGS iterations. Default value: 100.
Regularization Coefficient	Optional. The regularization coefficient. Default value: 1.0. If regularizedType is set to *None*, this parameter is ignored.
Minimum Convergence Deviance	Optional. The condition to terminate L-BFGS. This is the log-likelihood deviation between two iterations. Default value: *1.0e-06*.

The logistic regression component outputs a model, which is available in the model list.

Model name format: `Experiment Name + "-" + Component Name + "model"` .

PAI command (F/L setup settings are not used)

```
PAI -name LogisticRegression
-project algo_public
-DmodelName="xlab_m_logistic_regression_6096"
-DregularizedLevel="1"
-DmaxIter="100"
-DregularizedType="l1"
-Depsilon="0.000001"
-DlabelColName="y"
-DfeatureColNames="pdays,emp_var_rate"
-DgoodValue="1"
-DinputTableName="bank_data";
```

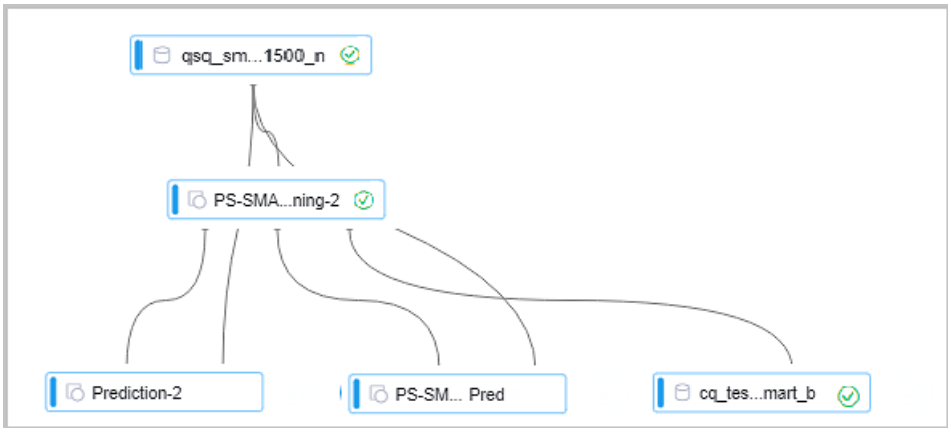
Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
modelName	The name of the output model.
regularizedLevel	Optional. The regularization coefficient. Default value: 1.0. If regularizedType is set to *None*, this parameter is ignored.
maxIter	Optional. The maximum number of L-BFGS iterations. Default value: 100.
regularizedType	Optional. The type of regularization. Valid values: *L1*, *L2*, and *None*. Default value: *L1*.
epsilon	Optional. The convergence deviation. It is the condition to terminate L-BFGS. This is the log-likelihood deviation between two iterations. Default value: *1.0e-06*.
labelColName	The name of the label column selected from the input table.
featureColNames	The names of feature columns selected from the input table for training.
goodValue	Optional. The base value. For binary classification, specify the label value of the training coefficient. If this parameter is not specified, the system randomly selects a value.
inputTableName	The name of the input table for training.

4.4.6.1.4. PS-SMART binary classification

A parameter server (PS) is used to train a large number of models online and offline. Scalable Multiple Additive Regression Tree (SMART) is an implementation of Gradient Boosting Decision Tree (GBDT) on PS. PS-SMART can run training tasks containing up to tens of billions of samples and hundreds of thousands of features on thousands of nodes. It also supports failover for high stability. PS-SMART supports various data formats, training targets, evaluation targets, output feature importance, and histogram approximation for training acceleration.

Quick start



As shown in the figure, a PS-SMART binary classification model is learned based on training data. The model has three output ports:

- Output model: offline model, which is connected to the unified prediction component. This model does not support the output of leaf node numbers.
- Output model table: a binary table that is not readable and is used to ensure compatibility with the PS-SMART prediction component. The table supports the output of leaf node numbers, which ensures higher efficiency, less resource consumption, and higher stability.
- Output feature importance table: lists the importance of each feature. Three importance types are supported. For more information, see Parameters.

PAI command

- Training

```
PAI -name ps_smart
    -project algo_public
    -DinputTableName="smart_binary_input"
    -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
    -DoutputTableName="pai_temp_24515_545859_2"
    -DoutputImportanceTableName="pai_temp_24515_545859_3"
    -DlabelColName="label"
    -DfeatureColNames="f0,f1,f2,f3,f4,f5"
    -DenableSparse="false"
    -Dobjective="binary:logistic"
    -Dmetric="error"
    -DfeatureImportanceType="gain"
    -DtreeCount="5";
    -DmaxDepth="5"
    -Dshrinkage="0.3"
    -Dl2="1.0"
    -Dl1="0"
    -Dlifecycle="3"
    -DsketchEps="0.03"
    -DsampleRatio="1.0"
    -DfeatureRatio="1.0"
    -DbaseScore="0.5"
    -DminSplitLoss="0"
```

- Prediction

```
PAI -name prediction
    -project algo_public
    -DinputTableName="smart_binary_input";
    -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
    -DoutputTableName="pai_temp_24515_545860_1"
    -DfeatureColNames="f0,f1,f2,f3,f4,f5"
    -DappendColNames="label,qid,f0,f1,f2,f3,f4,f5"
    -DenableSparse="false"
    -Dlifecycle="28"
```

Parameters

- Data parameters

Command option	Parameter	Description	Valid values	Remarks
featureColNames	Feature Columns	The names of feature columns selected from the input table for training.	If the column name is in dense format, it must be of the bigint or double type. If the column name is in sparse KV format, it must be a string, and its keys and values must be numeric.	Required
labelColName	Label Column	The name of the label column selected from the input table.	The column name can be of either string or numeric type, but only numeric data can be stored in the columns. For example, in binary classification, the column value can be 0 or 1.	Required
weightCol	Weight Column	This column specifies the weight of each sample.	The column name can be of the numeric type.	Optional. Default value: null.
enableSparse	Use Sparse Format	This parameter specifies whether the data in the input table is in sparse format, in which key-value pairs are separated by spaces whereas keys and values are separated by colons (:), for example, 1:0.3 3:0.9.	[true, false]	Optional. Default value: false.
inputTableName	Input Table Name	N/A	N/A	Required

Command option	Parameter	Description	Valid values	Remarks
modelName	Output Model Name	N/A	N/A	Required
outputImportanceTableName	Output Feature Importance Table Name	N/A	N/A	Optional. Default value: null.
inputTablePartitions	Input Table Partitions	N/A	N/A	Optional. The parameter value must be in ds=1/pt=1 format.
outputTableName	Output Model Table Name	The output table is a MaxCompute table that uses the binary format and is not readable. The prediction component that comes with SMART can be used to generate leaf node numbers.	String	Optional
lifecycle	Output Table Lifecycle	N/A	Positive integer	Optional. Default value: 3.

- Algorithm parameters

Command option	Parameter	Description	Valid values	Remarks
objective	Objective Function Type	The objective function type affects learning and must be selected properly. Select **binary:logistic** for binary classification.	N/A	Required
metric	Evaluation Indicator Type	Evaluation indicators in the training set, which are exported to stdout of the coordinator in a logview.	logloss, error and auc	Optional. Default value: null.

Command option	Parameter	Description	Valid values	Remarks
treeCount	Trees	The number of trees. The training time is proportional to this number.	Positive integer	Optional. Default value: 1.
maxDepth	Maximum Tree Depth	The maximum depth of a tree. We recommend that you set this value to 5, which means the tree can contain up to 32 leaf nodes.	A positive integer in the range of [1, 20]	Optional. Default value: 5.
sampleRatio	Data Sampling Fraction	The data sampling rate when trees are built. The sample data is used to build a weak learner to accelerate training.	(0, 1]	Optional. The default value is 1.0, which means data sampling is disabled.
featureRatio	Feature Sampling Fraction	The feature sampling rate when trees are built. The sample features are used to build a weak learner to accelerate training.	(0, 1]	Optional. The default value is 1.0, which means feature sampling is disabled.
l1	L1 Penalty Coefficient	This parameter determines the number of leaf nodes. The greater the value, the less the leaf nodes. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 0.

Command option	Parameter	Description	Valid values	Remarks
l2	L2 Penalty Coefficient	This parameter determines the size of a leaf node. The greater the value, the more evenly the leaf nodes are distributed. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 1.0.
shrinkage	Learning Rate	N/A	(0, 1]	Optional. Default value: 0.3.
sketchEps	Sketch-based Approximate Precision	The threshold for selecting quantiles when you build a sketch. The number of buckets is O(1.0/sketchEps). The smaller the parameter value, the more buckets are generated. Typically, you do not need to modify this value.	(0, 1)	Optional. Default value: 0.03.
minSplitLoss	Minimum Split Loss Change	The minimum split loss changes required for splitting a node. The greater the value, the more conservatively the node splits.	Non-negative real number	Optional. Default value: 0.

Command option	Parameter	Description	Valid values	Remarks
featureNum	Features	The number of features or the maximum feature ID. Specify this parameter for resource usage estimation.	Positive integer	Optional
baseScore	Global Offset	Original predicted values of all samples.	Real number	Optional. Default value: 0.5.
featureImportanceType	Feature Importance Type	The type of feature importance. **weight** indicates the number of times that a feature splits. **gain** indicates information gain brought by the feature. **cover** indicates the number of samples that the feature covers on the splitting nodes.	**weight**, **gain**, and **cover**	Optional. Default value: **gain**.

- Note
  - Specify different values for the objective parameter in different learning models. On the binary classification Web GUI, the objective function is automatically specified and invisible to users. On the command line, set the objective parameter to `binary:logistic`.
  - Mappings between metrics and objective functions are: **logloss** for **negative loglikelihood for logistic regression**, **error** for **binary classification error**, and **auc** for **Area under curve for classification**.

Execution optimization

Command option	Parameter	Description	Valid values	Remarks
coreNum	Cores	The number of cores. The greater the value, the faster the computing algorithm runs.	Positive integer	Optional. Automatically calculated.

Command option	Parameter	Description	Valid values	Remarks
memSizePerCore	Memory Size per Core (MB)	The memory size of each core, where 1024 represents 1 GB of memory.	Positive integer	Optional. Automatically calculated.

Example

- Data generation

  The following example uses data in dense format.

```
drop table if exists lm_test_input;
create table smart_binary_input lifecycle 3 as
select
*
from
(
select 0.72 as f0, 0.42 as f1, 0.55 as f2, -0.09 as f3, 1.79 as f4, -1.2 as f5, 0 as label from dual
union all
select 1.23 as f0, -0.33 as f1, -1.55 as f2, 0.92 as f3, -0.04 as f4, -0.1 as f5, 1 as label from dual
union all
select -0.2 as f0, -0.55 as f1, -1.28 as f2, 0.48 as f3, -1.7 as f4, 1.13 as f5, 1 as label from dual
union all
select 1.24 as f0, -0.68 as f1, 1.82 as f2, 1.57 as f3, 1.18 as f4, 0.2 as f5, 0 as label from dual
union all
select -0.85 as f0, 0.19 as f1, -0.06 as f2, -0.55 as f3, 0.31 as f4, 0.08 as f5, 1 as label from dual
union all
select 0.58 as f0, -1.39 as f1, 0.05 as f2, 2.18 as f3, -0.02 as f4, 1.71 as f5, 0 as label from dual
union all
select -0.48 as f0, 0.79 as f1, 2.52 as f2, -1.19 as f3, 0.9 as f4, -1.04 as f5, 1 as label from dual
union all
select 1.02 as f0, -0.88 as f1, 0.82 as f2, 1.82 as f3, 1.55 as f4, 0.53 as f5, 0 as label from dual
union all
select 1.19 as f0, -1.18 as f1, -1.1 as f2, 2.26 as f3, 1.22 as f4, 0.92 as f5, 0 as label from dual
union all
select -2.78 as f0, 2.33 as f1, 1.18 as f2, -4.5 as f3, -1.31 as f4, -1.8 as f5, 1 as label from dual
) tmp;
```

- Training

  Configure the training data and training components, as shown in Quick start. Select the label column as the target column and columns f0, f1, f2, f3, f4, f5 as feature columns.

- You do not need to set the number of features because this number is calculated automatically by the algorithm. If you have a large number of features and want the algorithm to accurately estimate the amount of required resources, specify the actual number of features.
- To accelerate the training, set the number of cores on the execution optimization page. The greater the number, the faster the algorithm runs. Typically, you do not need to enter the memory size per core because the algorithm can accurately calculate the memory size. The PS algorithm starts to run only when all hosts have obtained the required resources. Therefore, you may need to wait for a longer period of time when the cluster is busy and resources are requested in large volumes.
- You can view the output values of the metrics in the stdout of the coordinator in a logview (HTTP link starting with http://logview.odps.aliyun-inc.com:8080/logview). A single PS-SMART training job can contain multiple tasks, and therefore multiple logviews are created. Select the logview whose name starts with PS to view the output of the PS job.

- Prediction
  - Use the unified prediction component

    The model generated after training is saved in binary format and can be used for prediction. Configure the input model and test data for the prediction component, as shown in Quick start.

    If the dense format is used, you only need to select feature columns. (All columns are selected by default, and extra columns do not affect the prediction.) If the KV format is used, set the data format to sparse format and select the correct delimiter. In the SMART model, key-value pairs are separated by space characters. Therefore, the delimiter must be set to space or \u0020 (escape expression of spaces).

    In the "prediction_detail" column, value 1 indicates a positive sample, and value 0 indicates a negative sample. The values following 0 and 1 indicate the probabilities of the corresponding classes.

- Use the PS-SMART prediction component

  The output model table obtained after training is saved in binary format and can be used by the PS-SMART prediction component for prediction. Configure the input model and test data for the prediction component, as shown in Quick start. Set the required parameters, including the data format, feature columns, target column, and number of classes. The ID column can only be a string type column other than a feature column or a target column. The loss function must be set to binary:logistic.

  The **prediction_score** column lists probabilities of predicted positive samples. A sample is predicted as a positive sample if its score is greater than 0.5. Otherwise, it is predicted as a negative sample. The **leaf_index** column lists the predicted leaf node numbers. Each sample has N numbers, where N is the number of decision trees. Each tree is mapped to a number, which indicates the leaf node number of the sample on this tree.

  > Note
  >
  > - The output model table is a binary table that is not readable and is used to support the PS-SMART prediction component. The table provides outputs such as leaf node numbers and evaluation indicators. However, the output table has strict requirements on data formats, which negatively affects user experience. This component is being continually improved, and may be replaced by another component in the future.
  > - A string type column must be selected as the label column. You can enter strings in the column but cannot be blank or NULL. A feature column can be converted to the string type by using the data type conversion component.
  > - The loss function must be explicitly set to **binary:logistic**. By default, the function does not work.

- View feature importance

  To view feature importance, you can export the third output port to an output table, or right-click **PS-SMART training component** and choose **View Data > Output Feature Importance Table** from the shortcut menu.

order	id	value
1	0	0.5690338015556335
2	1	0.21714292466640472
3	4	0.21382322907447815

  In the table, the ID column lists the numbers of input features. In this example, the data is in dense format. The input features are **f0,f1,f2,f3,f4,f5**. Therefore, ID 0 represents f0 and ID 4 represents f4. If the KV format is used, the IDs represent keys in key-value pairs. Each value indicates a feature importance type. The default value is **gain**, indicating the sum of information gains brought by a feature in the model. The preceding figure shows only three features because only these three features are used during the tree split process. In this case, the importance of unused features is 0.

FAQ

- Q: Does PS_SMART support non-numerical features and tags?
- A: No.

- Q: What is the scale of features supported by PS-SMART? Can we use large-scale 0-1 features?
- A: Although PS-SMART supports tasks that contain hundreds of thousands of features, such tasks consume large amounts of resources and run slowly. Therefore, we recommend that you do not use such a large number of features. The GBDT algorithm is suitable for training with continuous features. The categorical features require one-hot coding to filter out infrequent features before they can be used for training. The continuous numerical features can be used for training with the GBDT algorithm directly. Discretization is not recommended for numerical features.
- Q: Why is the result different every time although the SMART algorithm has the same data and the same parameter settings?
- A: The PS-SMART algorithm applies randomness in many scenarios. For example, the data_sample_ratio and fea_sample_ratio items introduce data and feature sampling respectively. In addition, the PS-SMART algorithm uses histograms to show similarity. When multiple workers run in a cluster in distributed mode, local sketches are merged to global sketches in a random order. Although different merging orders result in different tree structures, this does not introduce too much variation to the output model. Therefore, it is normal situation to obtain different results after the algorithm runs multiple times with the same data and same parameter settings.

> Note
>
> - The target column in a PS-SMART binary classification model supports only numerical values (0 for negative samples and 1 for positive samples). Even if values in the MaxCompute table are strings, they are saved as numerical values. If the classification target is a type string similar to **Good** or **Bad**, convert it to 1 or 0.
> - In the key-value format, feature IDs must be positive integers, and feature values must be real numbers. If feature IDs are strings, use the serialization component to serialize them. If the feature values are classification type strings, perform feature engineering, such as discretization.

4.4.6.2. Multiclass classification

4.4.6.2.1. KNN

The KNN algorithm is used to resolve classification issues. For a row in the prediction table, this component selects K entries nearest to the row from the training table. It then assigns the row to the class that is most common among the K entries.

PAI command

```
PAI -name knn
    -DtrainTableName=pai_knn_test_input
    -DtrainFeatureColNames=f0,f1
    -DtrainLabelColName=class
    -DpredictTableName=pai_knn_test_input
    -DpredictFeatureColNames=f0,f1
    -DoutputTableName=pai_knn_test_output
    -Dk=2;
```

Parameters

Parameter	Description	Valid value	Default value
trainTableName	Required. The name of the training table.	Table name	N/A
trainFeatureColNames	Required. The names of feature columns selected from the training table.	Column name	N/A
trainLabelColName	Required. The name of the label column selected from the training table.	Column name	N/A
trainTablePartitions	Optional. The partitions selected from the training table.	Partition name	All partitions are selected by default.
predictTableName	Required. The name of the prediction table.	Table name	N/A
outputTableName	Required. The name of the output table.	Table name	N/A
predictFeatureColNames	Optional. The names of feature columns selected from the prediction table.	Column name	N/A
predictTablePartitions	Optional. The partitions selected from the prediction table.	Partition name	All partitions are selected by default.

Parameter	Description	Valid value	Default value
appendColNames	Optional. The names of columns appended to the output table from the prediction table.	Column name	N/A
outputTablePartition	Optional. The partitions in the output table.	Partition name	The output table is non-partitioned by default.
k	Optional. The number of the nearest neighbors.	A positive integer in the range of [1, 1000]	100
enableSparse	Optional. This parameter specifies whether the data in the input table is in sparse format.	true and false	false
itemDelimiter	Optional. The delimiter used to separate key-value pairs when the data in the input table is in sparse format.	Symbol	The default delimiter is a space.
kvDelimiter	Optional. The delimiter used to separate keys and values when the data in the input table is in sparse format.	Symbol	The default delimiter is a colon (:).
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 20000].	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Examples

- **Test data**

```
create table pai_knn_test_input as
select * from
(
 select 1 as f0,2 as f1, 'good' as class from dual
 union all
 select 1 as f0,3 as f1, 'good' as class from dual
 union all
 select 1 as f0,4 as f1, 'bad' as class from dual
 union all
 select 0 as f0,3 as f1, 'good' as class from dual
 union all
 select 0 as f0,4 as f1, 'bad' as class from dual
)tmp;
```

- **PAI command**

```
PAI -name knn
    -DtrainTableName=pai_knn_test_input
    -DtrainFeatureColNames=f0,f1
    -DtrainLabelColName=class
    -DpredictTableName=pai_knn_test_input
    -DpredictFeatureColNames=f0,f1
    -DoutputTableName=pai_knn_test_output
    -Dk=2;
```

- **Output description**

f0	f1	prediction_result	prediction_score	prediction_detail
1	4	bad	1.0	{"bad": 1}
0	4	bad	1.0	{"bad": 1}
0	3	bad	0.5	{ "bad": 0.5, "good": 0.5}
1	3	good	1.0	{"good": 1}
1	2	good	1.0	{"good": 1}

  - f0 and f1: the appended columns in the output table.
  - prediction_result: the classification result.
  - prediction_score: the probabilities for the classification result.
  - prediction_detail: the latest K conclusions and their probabilities.

4.4.6.2.2. Logistic regression for multiclass classification

Logistic regression of Apsara Stack Machine Learning Platform for AI supports multiclass classification. The logistic regression component supports two data formats: sparse and dense.

Parameter settings

Parameters

Parameter	Description
Regularization Type	Optional. The type of regularization. Valid values: *L1*, *L2*, and *None*. Default value: *L1*.
Max Iterations	Optional. The maximum number of L-BFGS iterations. Default value: 100.
Regularization Coefficient	Optional. The regularization coefficient. Default value: 1.0. If regularizedType is set to *None*, this parameter is ignored.
Minimum Convergence Deviance	Optional. The condition to terminate L-BFGS. This is the log-likelihood deviance between two iterations. Default value: *1.0e-06*.

The logistic regression component outputs a model, which is available in the model list.

Model naming format: `Experiment Name + "-" + Component Name + "model"` .

PAI command (F/L setup settings are not used)

```
PAI -name LogisticRegression
-project algo_public
-DmodelName="xlab_m_logistic_regression_6096"
-DregularizedLevel="1"
-DmaxIter="100"
-DregularizedType="l1"
-Depsilon="0.000001"
-DlabelColName="y"
-DfeatureColNames="pdays,emp_var_rate"
-DgoodValue="1"
-DinputTableName="bank_data";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
modelName	The name of the output model.
regularizedLevel	Optional. The regularization coefficient. Default value: 1.0. If regularizedType is set to *None* , this parameter is ignored.

Parameter	Description
maxIter	Optional. The maximum number of L-BFGS iterations. Default value: 100.
regularizedType	Optional. The type of regularization. Valid values: *L1*, *L2*, and *None*. Default value: *L1*.
epsilon	Optional. The convergence deviation. It is the condition to terminate L-BFGS. This is the loglikelihood deviation between two iterations. Default value: *1.0e-06*.
labelColName	The name of the label column selected from the input table.
featureColNames	The names of feature columns selected from the input table for training.
goodValue	Optional. The base value. For multiclass classification, specify the label value of the training coefficient. If this parameter is not specified, the system randomly selects a value.
inputTableName	The name of the input table for training.

4.4.6.2.3. Random forest

A random forest is a classifier that contains multiple decision trees. Its output class is decided by the mode of individual tree output classes.

Procedure

1. Drag and drop the Random Forest component onto the canvas and select columns.

Parameters

Parameter	Description
Feature Columns	Optional. All columns except the label and weight columns are selected by default.
Excluded Columns	Optional. This parameter is used to exclude specified columns from training. This parameter is mutually exclusive with featureColNames.
Columns Forced to Convert	Optional. The default feature parsing rules are as follows: ○ Parse columns of string, boolean, and datetime types to discrete columns. ○ Parse columns of double and bigint types to contiguous columns. ○ Set the *forceCategorical* parameter to parse bigint type columns to categorical columns.
Weight Columns	Optional. You can select all columns except the input and label columns. The double and bigint types are supported.
Label Column	You can select all columns except the input column. The bigint, double, and string types are supported.

2. Set the parameters of the Random Forest component.

Parameters

Parameter	Description
Trees	The number of trees in the forest. Valid values: (0, 1000).
Single-tree Algorithm Type	Optional. The algorithm type of each tree in the forest. Valid values: id3, c4.5, and cart. If the forest has n trees and the condition is `algorithmTypes = a,b`, then `[0,a)` indicates `id3`, `[a,b)` indicates `cart`, and `[b,n)` indicates `c4.5`. If this parameter is set to [2, 4] for a forest with five trees, [0, 1) indicates the ID3 algorithm, [2, 3) indicates the CART algorithm, and 4 indicates the C4.5 algorithm. If the value is None, the algorithms are evenly allocated across the forest.
Random Features per Tree	The number of features selected randomly. Valid values: 1 to N. N indicates the number of features.
Minimum Samples per Leaf Node	Optional. The minimum number of samples per leaf node. The value must be a positive integer no less than 2.
Minimum Fraction of Samples on Leaf Node to Samples on Parent Node	The minimum fraction of samples on a leaf node to samples on a parent node. A value of -1 indicates that no limit is set. Default value: -1. Valid values: [0, 1].
Maximum Tree Depth	The maximum depth of a tree. -1 indicates a completely grown tree. Valid values: [1, ∞).
Random Samples Input per Tree	The number of random samples input per tree. Valid values: (1000, 1000000].

Note

- With improvement of the bagging method, the Random Forest component builds a forest without correlated trees in the big cube. Random forests are similar to the boosting method in many aspects, particularly their training processes.
- For the growth of a single tree, this method provides the id3, cart, and c4.5 options. The treeNum parameter is used to specify the number of trees in the forest, in the range of [1, 1000]. The structure of a single tree can be controlled based on the edited template. You can use other parameters to specify the minimum number of samples per leaf node, the minimum fraction of samples on a leaf node to samples on a parent node, and the maximum depth of a tree.
- Each row in the weight column corresponds to a sample and indicates the proportion of this sample in training. If the age column is selected as the weight column, the sample in the row with a higher weight value in the age column has a higher proportion during the training.
- The "input table is empty!" error may occur in the following situations: The sampling fraction is too small, which means that the value of maxRecordSize is too small, or the input table is empty.

PAI command (F/L setup settings are not used)

```
PAI -name RandomForests
-project algo_public
-DmodelName="xlab_m_random_forests_6036"
-DrandomColNum="1.0"
-DlabelColName="campaign"
-DmaxTreeDeep="10"
-DmaxRecordSize="100000"
-DfeatureColNames="age,pdays,previous,emp_var_rate,cons_price_idx,cons_conf_idx,euribor3m,nr_em
ployed"
-DisFeatureContinuous="1,1,1,1,1,1,1,1"
-DminNumPer="-1"
-DminNumObj="2"
-DinputTableName="bank_data"
-DweightColName="y"
-DtreeNum="10";
```

Parameters

Parameter	Description
name	The name of the component.

Parameter	Description
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
modelName	The name of the output model.
randomColNum	Optional. The random attribute type. This parameter specifies the number of features randomly selected each time a single tree is generated. *-1* indicates `log2N`. Valid values: 1 to N. N indicates the number of features.
labelColName	The name of the label column selected from the input table.
maxTreeDeep	Optional. The maximum depth of a tree. *-1* indicates a completely grown tree. Valid values: [1, ∞].
maxRecordSize	Optional. The maximum number of samples per tree. Valid values: (1000, 1000000). *-1* indicates 100000.
featureColNames	The names of feature columns selected from the input table for training.
isFeatureContinuous	Specifies whether the feature for subsequent columns is continuous or discrete. *1* indicates that the feature column data is continuous, while *0* indicates that the feature column data is discrete. *1,0,0* indicates that values are continuous in the first feature column and discrete in the second and third feature columns. The number of values corresponds to the feature length.
minNumPer	Optional. The minimum fraction of samples on a leaf node to samples on a parent node. A value of *-1* indicates that no limit is set. Valid values: [0.0, 1.0].
minNumObj	Optional. The minimum number of samples per leaf node.
inputTableName	The name of the input table for training.
weightColName	Optional. The name of the weight column selected from the input table. If there is no weight column, set this parameter to *None*. If there is any weight column, the value of weightColName is greater than 0.
treeNum	The number of trees. Valid values: (0, 1000).

4.4.6.2.4. Naive Bayes

Naive Bayes classifier is a simple probabilistic classifier based on applying Bayes theorem with strong independence assumptions between the features. A probabilistic model that can more accurately describe this potential is called an independent feature model.

Component description

Component parameter settings (For more information, see the description of the Random Forest component.)

PAI command

```
PAI -name NaiveBayes
-project algo_public
-DmodelName="xlab_m_NaiveBayes_23772"
-DinputTablePartitions="pt=20150501"
-DlabelColName="poutcome"
-DfeatureColNames="age,previous,cons_conf_idx,euribor3m"
-DisFeatureContinuous="1,1,1,1"
-DinputTableName="bank_data_partition";
```

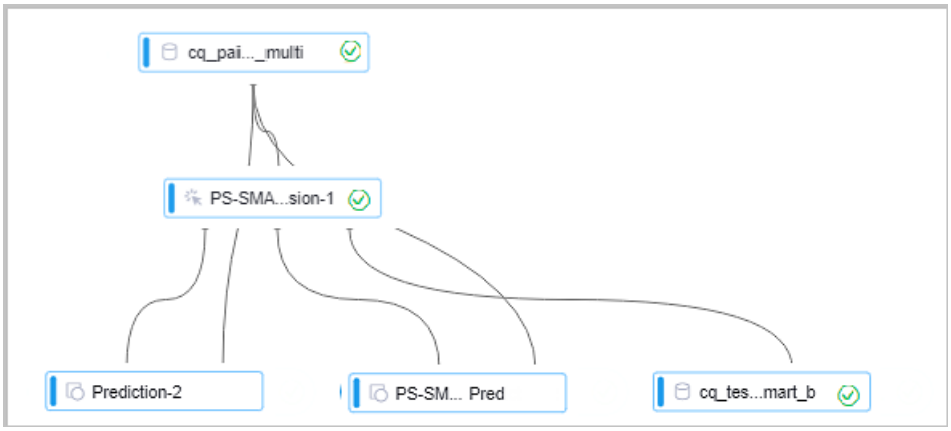
Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
modelName	The name of the model generated by training.
inputTablePartitions	Optional. The partitions selected from the input prediction table. If no partitions are specified, the entire table is selected.
labelColName	The name of the label column selected from the input table.
featureColNames	The names of feature columns selected from the input table for training.
isFeatureContinuous	Specifies whether the feature for subsequent columns is continuous or discrete. *1* indicates that the feature column data is continuous, while *0* indicates that the feature column data is discrete. *1,0,0* indicates that values are continuous in the first feature column and discrete in the second and third feature columns. The number of values corresponds to the feature length.
inputTableName	The name of the input table.

4.4.6.2.5. PS-SMART multiclass classification

A parameter server (PS) is used to train a large number of models online and offline. Scalable Multiple Additive Regression Tree (SMART) is an implementation of Gradient Boosting Decision Tree (GBDT) on PS. PS-SMART can run training tasks containing up to tens of billions of samples and hundreds of thousands of features on thousands of nodes. It also supports failover for high stability. PS-SMART supports various data formats, training targets, evaluation targets, output feature importance, and histogram approximation for training acceleration.

Quick start



As shown in the figure, a PS-SMART multiclass classification model is learned based on training data. The model has three output ports:

- Output model: offline model, which is connected to the unified prediction component. This model does not support the output of leaf node numbers.
- Output model table: a binary table that is not readable and is used to support the PS-SMART prediction component. The table provides outputs such as leaf node numbers and assessment metrics. However, the output table has strict requirements on data formats, which negatively affects user experience. This component is being continually improved, and may be replaced by another component in the future.
- Output feature importance table: lists the importance of each feature. Three importance types are supported. For more information, see Parameters.

PAI command

- Training

```
PAI -name ps_smart
    -project algo_public
    -DinputTableName="smart_multiclass_input"
    -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
    -DoutputTableName="pai_temp_24515_545859_2"
    -DoutputImportanceTableName="pai_temp_24515_545859_3"
    -DlabelColName="label"
    -DfeatureColNames="features"
    -DenableSparse="true"
    -Dobjective="multi:softprob"
    -Dmetric="mlogloss"
    -DfeatureImportanceType="gain"
    -DtreeCount="5";
    -DmaxDepth="5"
    -Dshrinkage="0.3"
    -Dl2="1.0"
    -Dl1="0"
    -Dlifecycle="3"
    -DsketchEps="0.03"
    -DsampleRatio="1.0"
    -DfeatureRatio="1.0"
    -DbaseScore="0.5"
    -DminSplitLoss="0"
```

- Prediction

```
PAI -name prediction
    -project algo_public
    -DinputTableName="smart_multiclass_input";
    -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
    -DoutputTableName="pai_temp_24515_545860_1"
    -DfeatureColNames="features"
    -DappendColNames="label,features"
    -DenableSparse="true"
    -DkvDelimiter=":"
    -Dlifecycle="28"
```

Parameters

- Data parameters

Command option	Parameter	Description	Valid values	Remarks
featureColNames	Feature Column	The names of feature columns selected from the input table for training.	If the column name is in dense format, it must be of the bigint or double type. If the column name is in sparse KV format, it must be a string, and its keys and values must be numeric.	Required
labelColName	Label Column	The name of the label column selected from the input table.	The column name can be of either string or numeric type, but only numeric data can be stored in the columns. For multiclass classification, column values can be 0, 1, 2, ..., n-1, where n is the number of classes.	Required
weightCol	Weight Column	This column specifies the weight of each sample.	The column name can be of the numeric type.	Optional. Default value: null.
enableSparse	Use Sparse Format	This parameter specifies whether the data in the input table is in sparse format, in which key-value pairs are separated by spaces whereas keys and values are separated by colons (:), for example, 1:0.3 3:0.9.	true, false	Optional. Default value: false.
inputTableName	Input Table Name	N/A	N/A	Required

Command option	Parameter	Description	Valid values	Remarks
modelName	Output Model Name	N/A	N/A	Required
outputImportanceTableName	Output Feature Importance Table Name	N/A	N/A	Optional. Default value: null.
inputTablePartitions	Input Table Partitions	N/A	N/A	Optional. The parameter value must be in ds=1/pt=1 format.
outputTableName	Output Model Table	The output table is a MaxCompute table that uses the binary format and is not readable. The prediction component that comes with SMART can be used to generate leaf node numbers.	String	Optional
lifecycle	Output Table Lifecycle	N/A	Positive integer	Optional. Default value: 3.

- Algorithm parameters

Command option	Parameter	Description	Valid values	Remarks
classNum	Classes	The number of classes in multiclass classification. If the number of classes is n, the label column name can be 0, 1, 2, ..., or n-1.	A non-negative integer, greater than or equal to 3.	Required

Command option	Parameter	Description	Valid values	Remarks
objective	Objective Function Type	The objective function type affects learning and must be selected properly. Set it to **multi:softprob** for multiclass classification.	N/A	Required
metric	Evaluation Indicator Type	Evaluation indicators in the training set, which are exported to stdout of the coordinator in a logview.	**mloglossmerror**	Optional. Default value: null.
treeCount	Trees	The number of trees. The training time is proportional to this number.	Positive integer	Optional. Default value: 1.
maxDepth	Maximum Decision Tree Depth	The maximum depth of a tree. We recommend that you set this value to 5, which means the tree can contain up to 32 leaf nodes.	A positive integer in the range of [1, 20].	Optional. Default value: 5.
sampleRatio	Data Sampling Fraction	The data sampling rate when trees are built. The sample data is used to build a weak learner to accelerate training.	(0, 1]	Optional. The default value is 1.0, which means data sampling is disabled.

Command option	Parameter	Description	Valid values	Remarks
featureRatio	Feature Sampling Fraction	The feature sampling rate when trees are built. The sample features are used to build a weak learner to accelerate training.	(0, 1]	Optional. The default value is 1.0, which means feature sampling is disabled.
l1	L1 Penalty Coefficient	This parameter determines the number of leaf nodes. The greater the value, the fewer the leaf nodes. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 0.
l2	L2 Penalty Coefficient	This parameter determines the size of a leaf node. The greater the value, the more evenly the leaf nodes are distributed. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 1.0.
shrinkage	Learning Rate	N/A	(0, 1]	Optional. Default value: 0.3.

Command option	Parameter	Description	Valid values	Remarks
sketchEps	Sketch-based Approximate Precision	The threshold for selecting quantiles when you build a sketch. The number of buckets is O(1.0/sketchEps). The smaller the parameter value, the more buckets are generated. Typically, you do not need to modify this value.	(0, 1)	Optional. Default value: 0.03.
minSplitLoss	Minimum Split Loss	The minimum split loss changes required for splitting a node. The greater the value, the more conservatively the node splits.	Non-negative real number	Optional. Default value: 0.
featureNum	Features	The number of features or the maximum feature ID. Specify this parameter for resource usage estimation.	Positive integer	Optional
baseScore	Global Offset	Original predicted values of all samples.	Real number	Optional. Default value: 0.5.

Command option	Parameter	Description	Valid values	Remarks
featureImportanceType	Feature Importance Type	The type of feature importance. **weight** indicates the number of times that a feature splits. **gain** indicates information gain brought by the feature. **cover** indicates the number of samples that the feature covers on the splitting nodes.	**weight**, **gain**, and **cover**	Optional. Default value: **gain**.

- Note
  - Specify different values for the objective parameter in different learning models. On the multiclass classification Web GUI, the objective function is automatically specified and invisible to users. On the command line, set the objective parameter to `multi:softprob`.
  - Mappings between metrics and objective functions are: **mlogloss** for **multiclass negative log likelihood**, and **merror** for **multiclass classification error**.
- Execution optimization

Command option	Parameter	Description	Valid values	Remarks
coreNum	Cores	The number of cores. The greater the value, the faster the computing algorithm runs.	Positive integer	Optional. Automatically calculated.
memSizePerCore	Memory Size per Core (MB)	The memory size of each core, where 1024 represents 1 GB of memory.	Positive integer	Optional. Automatically calculated.

Example

- Data generation

  The following example uses data in sparse KV format.

```
drop table if exists smart_multiclass_input;
create table smart_multiclass_input lifecycle 3 as
select
*
from
(
select 2 as label, '1:0.55 2:-0.15 3:0.82 4:-0.99 5:0.17' as features from dual
   union all
select 1 as label, '1:-1.26 2:1.36 3:-0.13 4:-2.82 5:-0.41' as features from dual
   union all
select 1 as label, '1:-0.77 2:0.91 3:-0.23 4:-4.46 5:0.91' as features from dual
   union all
select 2 as label, '1:0.86 2:-0.22 3:-0.46 4:0.08 5:-0.60' as features from dual
   union all
select 1 as label, '1:-0.76 2:0.89 3:1.02 4:-0.78 5:-0.86' as features from dual
   union all
select 1 as label, '1:2.22 2:-0.46 3:0.49 4:0.31 5:-1.84' as features from dual
   union all
select 0 as label, '1:-1.21 2:0.09 3:0.23 4:2.04 5:0.30' as features from dual
   union all
select 1 as label, '1:2.17 2:-0.45 3:-1.22 4:-0.48 5:-1.41' as features from dual
   union all
select 0 as label, '1:-0.40 2:0.63 3:0.56 4:0.74 5:-1.44' as features from dual
   union all
select 1 as label, '1:0.17 2:0.49 3:-1.50 4:-2.20 5:-0.35' as features from dual
) tmp;
```

The data has five dimensions of features.

- Training

  Configure the training data and training components, as shown in Quick start. Select the label column as the target column and the features column as the feature column.

  - You do not need to set the number of features because this number is calculated automatically by the algorithm. If you have a large number of features and want the algorithm to accurately estimate required resources, specify the actual number of features.
  - To accelerate the training, set the number of cores on the execution optimization page. The greater the number, the faster the algorithm runs. Typically, you do not need to enter the memory size per core because the algorithm can accurately calculate the memory size. The PS algorithm starts to run only when all hosts have obtained the required resources. Therefore, you may need to wait for a longer time when the cluster is busy and resources are requested in large volumes.

- You can view the output values of the metrics in the stdout of the coordinator in a logview (HTTP link starting with http://logview.odps.aliyun-inc.com:8080/logview). A single PS-SMART training job can contain multiple tasks, which creates multiple logviews. Select the logview whose name starts with PS to view the output of the PS job.

Then, perform operations in the logview.

- Prediction
  - Use the unified prediction component

    The model generated after training is saved in binary format and can be used for prediction. Configure the input model and test data for the prediction component, as shown in Quick start.

    If the dense format is used, you only need to select feature columns. (All columns are selected by default, and extra columns do not affect the prediction.) If the KV format is used, set the data format to sparse format and select the correct delimiter. In the SMART model, key-value pairs are separated with spaces. Therefore, the delimiter must be set to space or \u0020 (escape expression of spaces).

    In the **prediction_detail**column, values 0, 1, and 2 indicate classes, and the values following them indicate probabilities of the corresponding classes. The **predict_result** column lists the selected classes with the highest probability, and the **predict_score** column lists the probability of each selected class.

  - Use the PS-SMART prediction component

    The output model table obtained after training is saved in binary format and can be used by the PS-SMART prediction component for prediction. Configure the input model and test data for the prediction component, as shown in Quick start. Set the required parameters, including the data format, feature columns, target column, and number of classes. The ID column can only be a string type column other than a feature column or a target column. The loss function must be explicitly set to **multi:softprob**.

    The **score_class_k** columns list probabilities of class k. The class with the highest probability is the predicted class. The **leaf_index** column lists the predicted leaf node numbers. Each sample has N × M numbers, where N is the number of decision trees, and M is the number of classes. In this example, each sample has 15 numbers (5 × 3 = 15). Each tree is mapped to a number, which indicates the leaf node number of the sample on this tree.

    > **Note**
    > - The output model table is a binary table that is not readable and is used to support the PS-SMART prediction component. The table provides outputs such as leaf node numbers and evaluation indicators. However, the output table has strict requirements on data formats, which negatively affects user experience. This component is being continually improved, and may be replaced by another component in the future.
    > - A string type column must be selected as the label column. You can enter strings in the column but cannot be blank or NULL. A feature column can be converted to the string type by using the data type conversion component.
    > - The loss function must be explicitly set to **multi:softprob**. By default, the loss function does not work.

- View feature importance

  To view feature importance, you can export the third output port to an output table, or right-click **PS-SMART training component** and choose **View Data > Output Feature Importance Table** from the shortcut menu.The following figure shows the output feature importance table.

order	id	value
1	1	0.276059627532959
2	3	0.20854459702968597
3	4	0.31002077460289
4	5	0.20537501573562622

  In the table, the ID column lists the numbers of input features. In this example, the data is in KV format, and the IDs represent keys in key-value pairs. If the dense format is used and input features are **f0,f1,f2,f3,f4,f5**, ID 0 represents f0 and ID 4 represents f4. Each value indicates a feature importance type. The default value is **gain**, indicating the sum of information gains brought by a feature in the model. The preceding figure shows only four features because only these four features are used during the tree split process. In this case, the importance of unused features is 0.

FAQ

- Q: Does PS_SMART support non-numerical features and tags?
- A: No.
- Q: What is the scale of features supported by PS-SMART? Can we use large-scale 0-1 features?
- A: Although PS-SMART supports tasks that contain hundreds of thousands of features, such tasks consume large amounts of resources and run slowly. Therefore, we recommend that you do not use a large number of features. The GBDT algorithm is suitable for training with continuous features. The categorical features require one-hot coding (to filter out infrequent features) before they can be used for training. The continuous numerical features can be used for training with the GBDT algorithm directly. Discretization is not recommended for numerical features.
- Q: Why is the result different every time although the SMART algorithm has the same data and the same parameter settings?
- A: The PS-SMART algorithm applies randomness in many scenarios. For example, the data_sample_ratio and fea_sample_ratio items introduce data and feature sampling respectively. In addition, the PS-SMART algorithm uses histograms to show similarity. When multiple workers run in a cluster in distributed mode, local sketches are merged to global sketches in a random order. Although different merging orders result in different tree structures, this does not introduce too much variation to the output model. Therefore, it is normal situation to obtain different results after the algorithm runs multiple times with the same data and same parameter settings.

Note

- The target column in a PS-SMART multiclass classification model supports only positive integer IDs (class numbers are 0, 1, 2, ..., n-1, where n is the number of classes). Even if the values in the MaxCompute table are strings, they are saved as numerical values. If the classification target is a type string similar to **Good**, **Medium**, or **Bad**, convert it into a numeric value (0, 1, 2, ..., n-1).
- In the key-value format, feature IDs must be positive integers, and feature values must be real numbers. If feature IDs are strings, use the serialization component to serialize them. If the feature values are classification type strings, perform feature engineering, such as discretization.

4.4.6.3. K-means clustering

K-means clustering is a widely used algorithm that is used to divide n objects into k clusters while maintaining high similarity within each cluster. Similarity is calculated based on the average value of objects in a cluster. This algorithm is similar to the expectation maximization algorithm for calculating mixed normality distribution, as both algorithms try to find the natural clustering center in data. K-means clustering randomly selects k objects. Each object represents the average value or center of a cluster. Based on its distance from each cluster center, each remaining object is then assigned to the nearest cluster and the average value of each cluster is re-calculated. This process is repeated until the criterion function converges. This algorithm assumes that object properties are from the spatial vector. Its objective is to minimize the sum of the mean square deviance inside each group.

Parameter settings

Parameters

Parameter	Description
Clusters	The number of clusters. Default value: 10.
Distance Measurement Method	Valid values: *euclidean*, *cityblock* (the sum of absolute deviations), and *cosine*. Default value: euclidean.
Initial Centroid Location	Valid values: *sample* (randomly selected), *topk* (first K rows), *uniform* (evenly distributed and randomly generated), *matrix* (an initial centroid table must be specified), and *kmpp* (k-means++ initialization). Default value: sample.
Maximum Iterations	The maximum number of iterations. Default value: 100.
Minimum Iteration Precision	The minimum iteration precision. Default value: 0.0.

Procedure

1. After running the K-means Clustering component, you can view the cluster center table.

Cluster center table: The number of columns in this table is equal to the total number of columns selected from the input table. The number of rows is equal to the number of clusters, with each row representing a cluster center location.

2. Right-click the target table and choose **View Data** to view the cluster index table (idxTablename).
   - Cluster index table: The number of rows is equal to the total number of rows in the input table. The value in each row represents the cluster index of the point in the corresponding row of the input table.
   - The names of all columns are displayed. A classification marking column is appended to the table.
   - 0, 1, 2, 3 are classification IDs.
   - You can also use the table name generated by PAI command to view the cluster center table, cluster index table, and cluster count table in IDE.

Note If *matrix* is selected as the initial centroid location, you must define the initial centroid table, with the same columns as the original table. The number of rows is the same as the number of clusters. When you prepare the table, configure k centers and use SQL or MapReduce for sampling, or select another method based on your requirements.

PAI command

```
PAI -name KMeans
-project algo_public
-DcenterCount="10"
-DidxTableName="bank_data_index"
-DdistanceType="euclidean"
-DappendColsIndex="0,1,2,3,4,5,6,7,8,9,10"
-DcenterTableName="pai_temp_3300_27298_3"
-Dloop="100"
-DclusterCountTableName="pai_temp_3300_27298_2"
-DinitCentersMethod="sample"
-Daccuracy="0.0"
-DinputTableName="bank_data"
-DselectedColNames="cons_conf_idx,emp_var_rate,euribor3m,pdays,previous";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.

Parameter	Description
centerCount	The number of clusters. The value must be an integer. Default value: 10.
idxTableName	The name of the output cluster index table. The number of rows is equal to the total number of rows in the input table. The value in each row represents the cluster index of the point in the corresponding row of the input table.
distanceType	Optional. The method used to measure the distance. Valid values: euclidean, cityblock, and cosine. Default value: euclidean.
appendColsIndex	Optional. The name of the ID column appended to the output table. No ID column is appended to the output table by default.
centerTableName	The name of the output cluster center table. The number of columns in this table is equal to the total number of columns selected from the input table. The number of rows is equal to the number of clusters, with each row representing a cluster center location.
loop	Optional. The maximum number of iterations. The value must be an integer. Default value: 100.
clusterCountTableName	The name of the cluster point count table. The number of rows is equal to the number of clusters, which indicates the total number of cluster points in the class in each clustering centroid row.
initCentersMethod	Optional. The method used to determine the initial centroid location. The options include sample (randomly selected), topk (first K rows), uniform (evenly distributed and randomly generated), matrix (an initial centroid table must be specified), and kmpp (k-means++ initialization). Default value: sample.
accuracy	The minimum iteration precision. Default value: 0.0.
inputTableName	The name of the input table.
selectedColNames	The names of columns selected from the input table, which are separated with commas (,). Only double type is supported.
initCenterTableName	Optional. The name of the table that stores the initial center values. This table is not required unless initCentersMethod is set to *matrix*.

4.4.6.4. Regression

4.4.6.4.1. GBDT regression

Gradient boosting decision tree (GBDT) is an iterative decision tree algorithm based on multiple decision trees. The final output is the sum of conclusions of all trees. GBDT can be applied to almost all regression models (linear or nonlinear) and has a wider scope of application than logistic regression that is only applicable to linear regression.

For more information, see A Regression Framework for Learning Ranking Functions Using Relative Relevance Judgments. For more information, see GBDT binary classification.

PAI command

```
PAI -name gbdt
-project algo_public
-DfeatureSplitValueMaxSize="500"
-DlossType="0"
-DrandSeed="0"
-DnewtonStep="0"
-Dshrinkage="0.05"
-DmaxLeafCount="32"
-DlabelColName="campaign"
-DinputTableName="bank_data_partition"
-DminLeafSampleCount="500"
-DsampleRatio="0.6"
-DgroupIDColName="age"
-DmaxDepth="11"
-DmodelName="xlab_m_GBDT_83602"
-DmetricType="2"
-DfeatureRatio="0.6"
-DinputTablePartitions="pt=20150501"
-Dtau="0.6"
-Dp="1"
-DtestRatio="0.0"
-DfeatureColNames="previous,cons_conf_idx,euribor3m"
-DtreeCount="500"
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
featureColNames	Optional. The names of feature columns selected from the input table for training.	Column name	All columns are selected by default.

Parameter	Description	Valid values	Default value
labelColName	Optional. The name of the label column selected from the input table.	Column name	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions are selected by default.
modelName	Required. The name of the output model.	-	-
outputImportanceTableName	Optional. The name of the output feature importance table.	-	-
groupIDColName	Optional. The name of the stratification column.	Column name	The whole table is selected by default.
lossType	Optional. The loss function type. The function types include *0: GBRANK*, *1:LAMBDAMART_DCG*, *2: LAMBDAMART_NDCG*, *3: LEAST_SQUARE*, and *4: LOG_LIKELIHOOD*.	0, 1, 2, 3, and 4	0
metricType	Optional. The type of metrics. *0(NDCG)* indicates the normalized discounted cumulative gain, *1 (DCG)* indicates the discounted cumulative gain, and *2 (AUC)* is applicable only to 0/1 label.	0, 1, and 2	2

Parameter	Description	Valid values	Default value
treeCount	Optional. The number of trees.	[1, 10000]	500
shrinkage	Optional. The learning rate.	(0, 1]	0.05
maxLeafCount	Optional. The maximum number of leaves. This value must be an integer.	[2, 1000]	32
maxDepth	Optional. The maximum depth of a tree. This value must be an integer.	[1, 11]	11
minLeafSampleCount	Optional. The minimum number of samples on a leaf node. This value must be an integer.	[100, 1000]	500
sampleRatio	Optional. The fraction of training samples.	(0, 1]	0.6
featureRatio	Optional. The fraction of training features.	(0, 1]	0.6
tau	Optional. The Tau parameter in gbrank loss.	[0, 1]	0.6
p	Optional. The p parameter in gbrank loss.	[1, 10]	1
randSeed	Optional. The random seed.	[0, 10]	0
newtonStep	Optional. This parameter specifies whether to use the Newton method.	0 and 1	1
featureSplitValueMaxSize	Optional. The maximum number of splits per feature.	[1, 1000]	500
lifecycle	Optional. The lifecycle of the output table.	-	No lifecycle is set by default.

Examples

SQL statement to generate data:

```
drop table if exists gbdt_ls_test_input;
create table gbdt_ls_test_input as select     * from (
select        cast(1 as double) as f0,
cast(0 as double) as f1,
cast(0 as double) as f2,
cast(0 as double) as f3,
cast(0 as bigint) as label    from dual    union all
select          cast(0 as double) as f0,
cast(1 as double) as f1,
cast(0 as double) as f2,
cast(0 as double) as f3,
cast(0 as bigint) as label    from dual    union all
select          cast(0 as double) as f0,
cast(0 as double) as f1,
cast(1 as double) as f2,
cast(0 as double) as f3,
cast(1 as bigint) as label    from dual    union all
select          cast(0 as double) as f0,
cast(0 as double) as f1,
cast(0 as double) as f2,
cast(1 as double) as f3,
cast(1 as bigint) as label    from dual    union all
select          cast(1 as double) as f0,
cast(0 as double) as f1,
cast(0 as double) as f2,
cast(0 as double) as f3,
cast(0 as bigint) as label    from dual    union all
select          cast(0 as double) as f0,
cast(1 as double) as f1,
cast(0 as double) as f2,
cast(0 as double) as f3,
cast(0 as bigint) as label    from dual ) a;
```

PAI command

- Training:

```
drop offlinemodel if exists gbdt_ls_test_model;
PAI -name gbdt
-project algo_public
-DfeatureSplitValueMaxSize="500"
-DlossType="3"
-DrandSeed="0"
-DnewtonStep="1"
-Dshrinkage="0.5"
-DmaxLeafCount="32"
-DlabelColName="label"
-DinputTableName="gbdt_ls_test_input"
-DminLeafSampleCount="1"
-DsampleRatio="1"
-DmaxDepth="10"
-DmetricType="0"
-DmodelName="gbdt_ls_test_model"
-DfeatureRatio="1"
-Dp="1"
-Dtau="0.6"
-DtestRatio="0"
-DfeatureColNames="f0,f1,f2,f3"
-DtreeCount="10"
```

- Prediction:

```
drop table if exists gbdt_ls_test_prediction_result;
PAI -name prediction
-project algo_public
-DdetailColName="prediction_detail"
-DmodelName="gbdt_ls_test_model"
-DitemDelimiter=","
-DresultColName="prediction_result"
-Dlifecycle="28"
-DoutputTableName="gbdt_ls_test_prediction_result"
-DscoreColName="prediction_score"
-DkvDelimiter=":"
-DinputTableName="gbdt_ls_test_input"
-DenableSparse="false"
-DappendColNames="label"
```

Input description

gbdt_ls_test_input

f0	f1	f2	f3	label
1.0	0.0	0.0	0.0	0
0.0	0.0	1.0	0.0	1
0.0	0.0	0.0	1.0	1
0.0	1.0	0.0	0.0	0
1.0	0.0	0.0	0.0	0
0.0	1.0	0.0	0.0	0

Output description

gbdt_ls_test_prediction_result

label	prediction_result	prediction_score	prediction_detail
0	NULL	0.0	{"label": 0}
0	NULL	0.0	{"label": 0}
1	NULL	0.9990234375	{"label": 0.9990234375}
1	NULL	0.9990234375	{"label": 0.9990234375}
0	NULL	0.0	{"label": 0}
0	NULL	0.0	{"label": 0}

4.4.6.4.2. Linear regression

This component is used to resolve regression issues and analyze the linear relationship between a dependent variable and multiple independent variables. Certain columns from an input table are selected as feature columns and one column is selected as the label column for linear regression training and linear regression model generation.

PAI command

```
PAI -name linearregression
    -project algo_public
    -DinputTableName=lm_test_input
    -DfeatureColNames=x
    -DlabelColName=y
    -DmodelName=lm_test_input_model_out;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
modelName	Required. The name of the output model.	-	-
outputTableName	Optional. The name of the output model evaluation table.	This parameter must be specified when enableFitGoodness is set to *true*.	-
labelColName	Required. The name of the label column.	The name must be a double or bigint type value. Only one column can be specified.	-
featureColNames	Required. The name of the feature column.	The name must be a double or bigint type value in dense format, or a string type value in sparse format. Multiple columns can be specified.	-
inputTablePartitions	Optional. The partitions selected from the input table for training.	-	No partitions are selected by default.
maxIter	Optional. The maximum number of iterations.	-	100
epsilon	Optional. The minimum likelihood deviance.	-	0.000001

Parameter	Description	Valid values	Default value
enableSparse	Optional. This parameter specifies whether the data is in sparse format.	true and false	false
enableFitGoodness	Optional. This parameter specifies whether to perform model evaluation. Model evaluation can be performed using a variety of metrics, including R-squared, adjusted R-Squared, Akaike information criterion, degrees of freedom, residual standard deviation, and deviation.	true and false	false
enableCoefficientEstimate	Optional. This parameter specifies whether to estimate the regression coefficient. The metrics of this parameter are value t, value p, and confidence interval [2.5%, 97.5%]. This parameter takes effect only when enableFitGoodness is set to *true*. This parameter is ignored when enableFitGoodness is set to *false*.	true and false	false
itemDelimiter	Optional. The delimiter used to separate key-value pairs. This parameter takes effect only when enableSparse is set to *true*.	-	Use spaces on command lines and use commas (,) on webpages.

Parameter	Description	Valid values	Default value
kvDelimiter	Optional. The delimiter used to separate keys and values. This parameter takes effect only when enableSparse is set to *true*.	-	The default delimiter is a colon (:).
lifecycle	Optional. The lifecycle of the output table.	An integer greater than or equal to -1	Default value: -1. This value indicates that no lifecycle is set.
coreNum	Optional. The number of cores.	An integer larger than 0	Default value: -1. This value indicates that the number of instances is determined by the amount of input data.
memSizePerCore	Optional. The memory size of each core.	(100, 65536)	Default value: -1. This value indicates that the memory size is determined by the amount of input data.

Examples

- SQL statement to generate data:

```
drop table if exists lm_test_input;
    create table lm_test_input as
    select
     *
    from
    (
     select 10 as y, 1.84 as x1, 1 as x2, '0:1.84 1:1' as sparsecol1 from dual
      union all
     select 20 as y, 2.13 as x1, 0 as x2, '0:2.13' as sparsecol1 from dual
      union all
     select 30 as y, 3.89 as x1, 0 as x2, '0:3.89' as sparsecol1 from dual
      union all
     select 40 as y, 4.19 as x1, 0 as x2, '0:4.19' as sparsecol1 from dual
      union all
     select 50 as y, 5.76 as x1, 0 as x2, '0:5.76' as sparsecol1 from dual
      union all
     select 60 as y, 6.68 as x1, 2 as x2, '0:6.68 1:2' as sparsecol1 from dual
      union all
     select 70 as y, 7.58 as x1, 0 as x2, '0:7.58' as sparsecol1 from dual
      union all
     select 80 as y, 8.01 as x1, 0 as x2, '0:8.01' as sparsecol1 from dual
      union all
     select 90 as y, 9.02 as x1, 3 as x2, '0:9.02 1:3' as sparsecol1 from dual
      union all
     select 100 as y, 10.56 as x1, 0 as x2, '0:10.56' as sparsecol1 from dual
    ) tmp;
```

- PAI command

```
PAI -name linearregression
    -project algo_public
    -DinputTableName=lm_test_input
    -DlabelColName=y
    -DfeatureColNames=x1,x2
    -DmodelName=lm_test_input_model_out
    -DoutputTableName=lm_test_input_conf_out
    -DenableCoefficientEstimate=true
    -DenableFitGoodness=true
    -Dlifecycle=1;
pai -name prediction
    -project algo_public
    -DmodelName=lm_test_input_model_out
    -DinputTableName=lm_test_input
    -DoutputTableName=lm_test_input_predict_out
    -DappendColNames=y;
```

- Output description:
  - When enableFitGoodness is set to *true*, partitions specified by `p='goodness'` are created in the model evaluation table. The output metrics are *R-squared*, *adjusted R-Squared*, *Akaike information criterion*, *degrees of freedom*, *residual standard deviation*, and *deviation*.
  - When enableCoefficientEstimate is set to *true*, partitions specified by `p='coefficient'` are created in the model evaluation table. The table contains the intercepts and the *name*, *coefficient*, *t-score*, *p-value*, and *confidence interval [2.5%, 97.5%]* of the features.

- Output model evaluation table: lm_test_input_conf_out.

colname	value	tscore	pvalue	confidenceinterval	p
Intercept	-6.42378496687763	-2.2725755951390028	0.06	{"2.5%": -11.964027, "97.5%": -0.883543}	coefficient

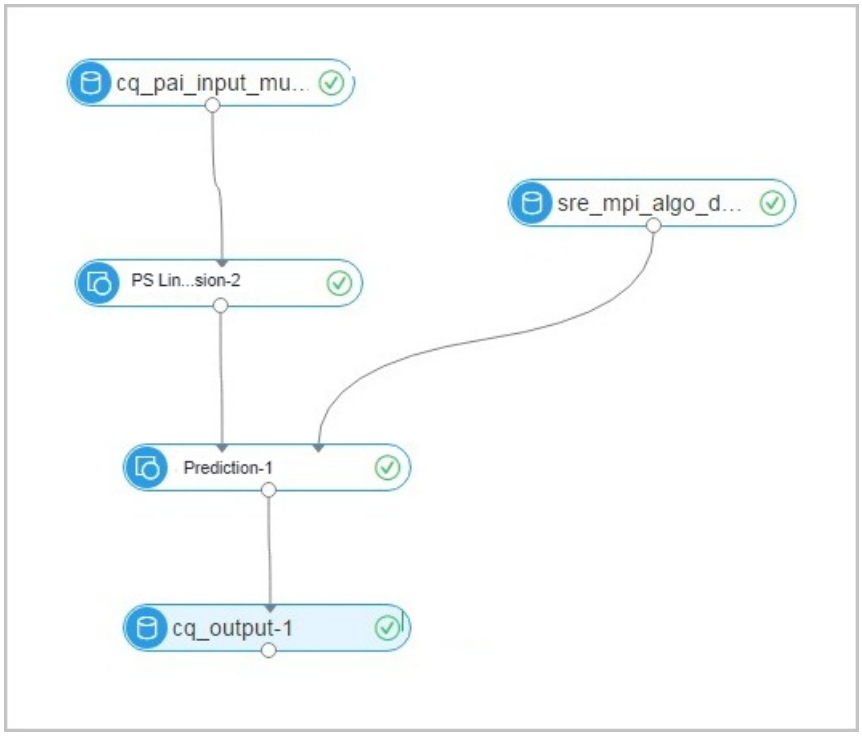
4.4.6.4.3. PS linear regression

Linear regression is a classic regression algorithm used to analyze the linear relationship between a dependent variable and multiple independent variables. Parameter servers (PSs) are used to run large amounts of training tasks online and offline. Parameter servers can use hundreds of billions of samples to efficiently train billions of feature models. The PS linear regression model can run training tasks with hundreds of billions of samples and billions of features, and supports L1 and L2 regular expressions.

Quick start



PAI command

- **Training**

```
PAI -name ps_linearregression
    -project algo_public
    -DinputTableName="lm_test_input"
    -DmodelName="linear_regression_model"
    -DlabelColName="label"
    -DfeatureColNames="features"
    -Dl1Weight=1.0
    -Dl2Weight=0.0
    -DmaxIter=100
    -Depsilon=1e-6
    -DenableSparse=true
```

- **Prediction**

```
drop table if exists logistic_regression_predict;
PAI -name prediction
    -DmodelName="linear_regression_model"
    -DoutputTableName="linear_regression_predict"
    -DinputTableName="lm_test_input"
    -DappendColNames="label,features"
    -DfeatureColNames="features"
    -DenableSparse=true
```

Parameters

- **Data parameters**

Command option	Parameter	Description	Valid values	Default value
featureColNames	Feature Columns	Required. The names of feature columns selected from the input table for training.	If a column name is in dense format, it must be of the bigint or double type. If the column name is in sparse KV format, it must be a string.	-
labelColName	Label Column	Required. The name of the label column selected from the input table.	The column name must be of the bigint or double type.	-
enableSparse	Use Sparse Format	Optional. If you choose to use the sparse KV format, do not use feature ID 0. We recommend that the feature IDs start from 1.	true and false	false
itemDelimiter	KV Pair Delimiter	Optional. The delimiter used to separate key-value pairs when data in the input table is in sparse format.	Symbol	The default delimiter is a space.

Command option	Parameter	Description	Valid values	Default value
kvDelimiter	KV Delimiter	Optional. The delimiter used to separate keys and values when data in the input table is in sparse format.	Symbol	The default delimiter is a colon (:).
inputTableName	Input Table Name	Required.	Table name	-
modelName	Output Model Name	Required.	Model name	-
inputTablePartitions	Input Table Partitions	Optional.	Partition name	The parameter value must be in the ds=1/pt=1 format.
enableModelIo	Output to Offline Model	Optional. When this parameter is set to false, the data is output to a MaxCompute table where you can view model weights.	true and false	true

- **Algorithm parameters**

Command option	Parameter	Description	Valid values	Default value
l1Weight	L1 Weight	Optional. The L1 regularization coefficient. The larger this value is, the fewer non-zero elements a model has. To overfit the model, set this parameter to a larger value.	A non-negative real number	1.0

Command option	Parameter	Description	Valid values	Default value
l2Weight	L2 Weight	Optional. The L2 regularization coefficient. The larger this value is, the smaller the absolute values of the model parameters are. To overfit the model, set this parameter to a larger value.	A non-negative real number	0
maxIter	Maximum Iterations	Optional. The maximum number of LBFGS/OWL-QN iterations. Value 0 indicates that no limit is set.	A non-negative integer	100
epsilon	Minimum Convergence Deviance	Optional. The mean of the relative loss change rates in ten iterations, which is used as a condition to determine whether to terminate the optimization algorithm. The smaller this value is, the stricter the condition is, and the longer the algorithm runs.	A real number between 0 and 1	1.0e-06

Command option	Parameter	Description	Valid values	Default value
modelSize	Largest Feature ID	Optional. The largest feature ID among all feature IDs (feature dimension). It can be larger than the actual largest feature ID. The larger this value is, the higher the memory usage is. If you leave this parameter empty, the system starts an SQL task to calculate the largest feature ID automatically.	A non-negative integer	0

Note Both the maximum iterations and minimum convergence deviance determine when the algorithm stops. If both parameters are set, the algorithm stops when one of the conditions is met.

- **Execution optimization**

Command option	Parameter	Description	Valid values	Default value
coreNum	Cores	Optional. The number of cores. The larger this value is, the faster the computing algorithm runs.	A positive integer	Automatically allocated.
memSizePerCore	Memory Size per Core (MB)	Optional. The memory size of each core, where 1024 represents 1 GB of memory.	A positive integer	Automatically allocated. Typically, you do not need to set this parameter because the algorithm can accurately estimate the memory size required.

Examples

- **Data generation**

  The following example uses data in sparse KV format:

```
drop table if exists lm_test_input;
create table lm_test_input as
select
*
from
(
select 2 as label, '1:0.55 2:-0.15 3:0.82 4:-0.99 5:0.17' as features from dual
   union all
select 1 as label, '1:-1.26 2:1.36 3:-0.13 4:-2.82 5:-0.41' as features from dual
   union all
select 1 as label, '1:-0.77 2:0.91 3:-0.23 4:-4.46 5:0.91' as features from dual
   union all
select 2 as label, '1:0.86 2:-0.22 3:-0.46 4:0.08 5:-0.60' as features from dual
   union all
select 1 as label, '1:-0.76 2:0.89 3:1.02 4:-0.78 5:-0.86' as features from dual
   union all
select 1 as label, '1:2.22 2:-0.46 3:0.49 4:0.31 5:-1.84' as features from dual
   union all
select 0 as label, '1:-1.21 2:0.09 3:0.23 4:2.04 5:0.30' as features from dual
   union all
select 1 as label, '1:2.17 2:-0.45 3:-1.22 4:-0.48 5:-1.41' as features from dual
   union all
select 0 as label, '1:-0.40 2:0.63 3:0.56 4:0.74 5:-1.44' as features from dual
   union all
select 1 as label, '1:0.17 2:0.49 3:-1.50 4:-2.20 5:-0.35' as features from dual
) tmp;
```

  The feature IDs start from 1, and the maximum feature ID is 5.

- **Training**

  Configure the training data and training components based on Quick start. Select the label column as the target column and features column as the feature column. Then, select the sparse data format.

  - You can retain the default value 0 for the largest feature ID. The algorithm can start an SQL task to calculate the largest feature ID automatically. If you do not want to start the SQL task, enter a value greater than 5. This value indicates the number of feature columns in dense format and indicates the largest feature ID in KV format.

  - To accelerate the training, you can set the number of cores on the tuning page. The larger the number is, the faster the algorithm runs. Typically, you do not need to enter the memory size per core because the algorithm can accurately calculate the memory size. The PS algorithm starts to run only when all hosts have obtained the resources. Therefore, you may need to wait a longer period of time when the cluster is busy and resources are requested in large volume.

- **Prediction**

  The model generated after training is saved in binary format and can be used for prediction. Configure the input settings (model and testing data) for the prediction component and set parameters based on Quick start.

  Select the KV format for training and set a correct delimiter. When the KV format is used, key-value pairs are separated by spaces. Therefore, the delimiter must be set to space or `\u0020` (the escape expression of space).

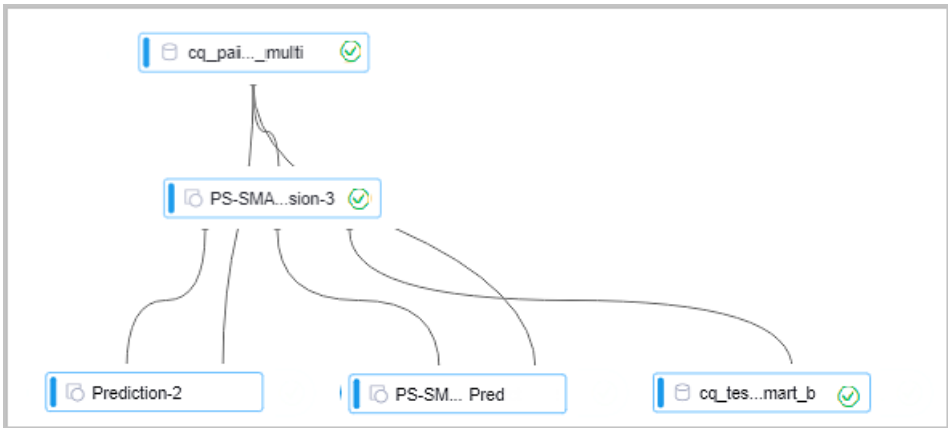
Restrictions and guidelines

In the key-value format, feature IDs must be positive integers, and feature values must be real numbers. If feature IDs are strings, use the serialization component to serialize them. If the feature values are classification type strings, perform feature engineering, such as discretization.

4.4.6.4.4. PS-SMART regression

A parameter server (PS) is used to train a large number of models online and offline. Scalable Multiple Additive Regression Tree (SMART) is an implementation of Gradient boosting decesion tree （GBDT） on PS. PS-SMART can run training tasks containing up to tens of billions of samples and hundreds of thousands of features on thousands of nodes. It also supports failover for high stability. PS-SMART supports various data formats, training targets, evaluation targets, output feature importance, and histogram approximation for training acceleration.

Quick start



As shown in the figure, a PS-SMART regression model is learned based on training data. The model has three output ports:

- Output model: offline model, which is connected to the unified prediction component. This model does not support the output of leaf node numbers.
- Output model table: a binary table that is not readable and is used to ensure compatibility with the PS-SMART prediction component. The table provides outputs such as leaf node

numbers and evaluation metrics. However, the output table has strict requirements on data formats, which negatively affects user experience. This component is being continually improved, and may be replaced by another component in the future.

- Output feature importance table: lists the importance of each feature. Three importance types are supported. For more information, see Parameters.

PAI command

- Training

```
PAI -name ps_smart
    -project algo_public
    -DinputTableName="smart_regression_input"
    -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
    -DoutputTableName="pai_temp_24515_545859_2"
    -DoutputImportanceTableName="pai_temp_24515_545859_3"
    -DlabelColName="label"
    -DfeatureColNames="features"
    -DenableSparse="true"
    -Dobjective="reg:linear"
    -Dmetric="rmse"
    -DfeatureImportanceType="gain"
    -DtreeCount="5";
    -DmaxDepth="5"
    -Dshrinkage="0.3"
    -Dl2="1.0"
    -Dl1="0"
    -Dlifecycle="3"
    -DsketchEps="0.03"
    -DsampleRatio="1.0"
    -DfeatureRatio="1.0"
    -DbaseScore="0.5"
    -DminSplitLoss="0"
```

- Prediction

```
PAI -name prediction
    -project algo_public
    -DinputTableName="smart_regression_input";
    -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
    -DoutputTableName="pai_temp_24515_545860_1"
    -DfeatureColNames="features"
    -DappendColNames="label,features"
    -DenableSparse="true"
    -Dlifecycle="28"
```

Parameters

- Data parameters

Command option	Parameter	Description	Valid values	Remarks
featureColNames	Feature Column	The names of feature columns selected from the input table for training.	If the column name is in dense format, it must be of the bigint or double type. If the column name is in sparse KV format, it must be a string, and its keys and values must be numeric.	Required
labelColName	Label Column	The name of the label column selected from the input table.	The column name can be of either string or numeric type, but only numeric data can be stored in the columns. For example, the column value can be 0 or 1 for regression.	Required
weightCol	Weight Column	This column specifies the weight of each sample.	The column name can be of the numeric type.	Optional. Default value: null.

Command option	Parameter	Description	Valid values	Remarks
enableSparse	Use Sparse Format	This parameter specifies whether the data in the input table is in sparse format, in which key-value pairs are separated by spaces whereas keys and values are separated by colons (:), for example, 1:0.3 3:0.9.	true, false	Optional. Default value: false.
inputTableName	Input Table Name	N/A	N/A	Required
modelName	Output Model Name	N/A	N/A	Required
outputImportanceTableName	Output Feature Importance Table Name	N/A	N/A	Optional. Default value: null.
inputTablePartitions	Input Table Partitions	N/A	N/A	Optional. The parameter value must be in ds=1/pt=1 format.
outputTableName	Output Model Table Name	The output table is a MaxCompute table that uses the binary format and is not readable. The prediction component that comes with SMART can be used to generate leaf node numbers.	String	Optional
lifecycle	Output Table Lifecycle	N/A	Positive integer	Optional. Default value: 3.

- Algorithm parameters

Command option	Parameter	Description	Valid values	Remarks
objective	Objective Function Type	The objective function type affects learning and must be selected properly. Multiple loss functions are available for regression. For more information, see the notes.		Required. The default type is Linear regression.
metric	Evaluation Indicator Type	Evaluation indicators in the training set, which must correspond to the objective function type and are exported to stdout of the coordinator in a logview. For more information, see the following notes and samples.		Optional. Default value: null.
treeCount	Trees	The number of trees. The training time is proportional to this number.	Positive integer	Optional. Default value: 1.
maxDepth	Maximum Decision Tree Depth	The maximum depth of a tree. We recommend that you set this value to 5, which means the tree can contain up to 32 leaf nodes.	A positive integer in the range of [1, 20]	Optional. Default value: 5.

Command option	Parameter	Description	Valid values	Remarks
sampleRatio	Data Sampling Fraction	The data sampling rate when trees are built. The sample data is used to build a weak learner to accelerate training.	(0, 1]	Optional. The default value is 1.0, which means data sampling is disabled.
featureRatio	Feature Sampling Fraction	The feature sampling rate when trees are built. The sample features are used to build a weak learner to accelerate training.	(0, 1]	Optional. The default value is 1.0, which means feature sampling is disabled.
l1	L1 Penalty Coefficient	This parameter determines the number of leaf nodes. The greater the value, the fewer the leaf nodes. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 0.
l2	L2 Penalty Coefficient	This parameter determines the size of a leaf node. The greater the value, the more evenly the leaf nodes are distributed. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 1.0.
shrinkage	Learning Rate	N/A	(0, 1]	Optional. Default value: 0.3.

Command option	Parameter	Description	Valid values	Remarks
sketchEps	Sketch-based Approximate Precision	The threshold for selecting quantiles when you build a sketch. The number of buckets is O(1.0/sketchEps). The smaller the parameter value, the more buckets are generated. Typically, you do not need to change this value.	(0, 1)	Optional. Default value: 0.03.
minSplitLoss	Minimum Split Loss	The minimum split loss changes required for splitting a node. The greater the value, the more conservatively the node splits.	Non-negative real number	Optional. Default value: 0.
featureNum	Features	The number of features or the maximum feature ID. Specify this parameter for resource usage estimation.	Positive integer	Optional
baseScore	Global Offset	Original predicted values of all samples.	Real number	Optional. Default value: 0.5.

Command option	Parameter	Description	Valid values	Remarks
featureImportanceType	Feature Importance Type	The type of feature importance. **weight** indicates the number of times that a feature splits. **gain** indicates information gain brought by the feature. **cover** indicates the number of samples that the feature covers on the splitting nodes.	**weight**, **gain**, and **cover**	Optional. Default value: **gain**.
tweedieVarPower	Tweedie Distribution Index	Tweedie distribution index indicates the relationship between the variance and mean. For example, $Var(y) ~ E(y)^tweedie_variance_power$.	(1, 2)	Optional. Default value: 1.5.

- Note
  - Specify different values for the objective parameter in different learning models. The regression Web GUI provides multiple objective functions.

    reg:linear (Linear regression) // The range of label numbers is (-∞, +∞).
    reg:logistic (Logistic regression) // The range of label numbers is [0, 1].
    count:poisson (Poisson regression for count data, output mean of poisson distribution) // Label numbers must be greater than 0.
    reg:gamma (Gamma regression for modeling insurance claims severity, or for any outcome that might be [gamma-distributed](https://en.wikipedia.org/wiki/Gamma_distribution#Applications)) // Label numbers must be greater than 0.
    reg:tweedie (Tweedie regression for modeling total loss in insurance, or for any outcome that might be [Tweedie-distributed](https://en.wikipedia.org/wiki/Tweedie_distribution#Applications).) // Label numbers must be greater than or equal to 0.

- Metrics for these objective functions are:

  rmse (rooted mean square error, corresponding to objective reg:linear)
  mae (mean absolute error, corresponding to objective reg:linear)
  poisson-nloglik (negative loglikelihood for poisson regression, corresponding to objective count:poisson)
  gamma-deviance (Residual deviance for gamma regression, corresponding to objective reg:gamma)
  gamma-nloglik (Negative log-likelihood for gamma regression, corresponding to objective reg:gamma)
  tweedie-nloglik (tweedie-nloglik@1.5, negative log-likelihood for Tweedie regression, at a specified value of the tweedie_variance_power parameter)

- Execution optimization

Command option	Parameter	Description	Valid values	Remarks
coreNum	Cores	The number of cores. The greater the value, the faster the computing algorithm runs.	Positive integer	Optional. Automatically allocated.
memSizePerCore	Memory Size per Core (MB)	The memory size of each core, where 1024 represents 1 GB of memory.	Positive integer	Optional. Automatically allocated.

Example

- Data generation

  The following example uses data in sparse KV format.

```
drop table if exists smart_regression_input;
create table smart_regression_input as
select
*
from
(
select 2.0 as label, '1:0.55 2:-0.15 3:0.82 4:-0.99 5:0.17' as features from dual
   union all
select 1.0 as label, '1:-1.26 2:1.36 3:-0.13 4:-2.82 5:-0.41' as features from dual
   union all
select 1.0 as label, '1:-0.77 2:0.91 3:-0.23 4:-4.46 5:0.91' as features from dual
   union all
select 2.0 as label, '1:0.86 2:-0.22 3:-0.46 4:0.08 5:-0.60' as features from dual
   union all
select 1.0 as label, '1:-0.76 2:0.89 3:1.02 4:-0.78 5:-0.86' as features from dual
   union all
select 1.0 as label, '1:2.22 2:-0.46 3:0.49 4:0.31 5:-1.84' as features from dual
   union all
select 0.0 as label, '1:-1.21 2:0.09 3:0.23 4:2.04 5:0.30' as features from dual
   union all
select 1.0 as label, '1:2.17 2:-0.45 3:-1.22 4:-0.48 5:-1.41' as features from dual
   union all
select 0.0 as label, '1:-0.40 2:0.63 3:0.56 4:0.74 5:-1.44' as features from dual
   union all
select 1.0 as label, '1:0.17 2:0.49 3:-1.50 4:-2.20 5:-0.35' as features from dual
) tmp;
```

Feature IDs are numbered starting from 1, and the maximum feature ID is 5.

- Training

  Select the label column as the target column and the features column as the feature column.

  - You do not need to set the number of features because this number is calculated automatically by the algorithm. If you have a large number of features and want the algorithm to accurately estimate the amount of required resources, specify the actual number of features.
  - To accelerate the training, set the number of cores on the execution optimization page. The greater the number, the faster the algorithm runs. Typically, you do not need to enter the memory size per core because the algorithm can accurately calculate the memory size. The PS algorithm starts to run only when all hosts have obtained the required resources. Therefore, you may need to wait for a longer time when the cluster is busy and resources are requested in large volumes.

- You can view the output values of the metrics in the stdout of the coordinator in a logview (HTTP link starting with http://logview.odps.aliyun-inc.com:8080/logview). A single PS-SMART training job can contain multiple tasks, and therefore multiple logviews are created. Select the logview whose name starts with PS to view the output of the PS job.

- Prediction
  - Use the unified prediction component

    The model generated after training is saved in binary format and can be used for prediction. Configure the input model and test data for the prediction component, as shown in Quick start.

    If the dense format is used, you only need to select feature columns. (All columns are selected by default, and extra columns do not affect the prediction.) If the KV format is used, set the data format to sparse format and select the correct delimiter. In the SMART model, key-value pairs are separated with spaces. Therefore, the delimiter must be set to space or \u0020 (escape expression of spaces).

  - Use the PS-SMART prediction component

    The output model table obtained after training is saved in binary format and can be used by the PS-SMART prediction component for prediction. Configure the input model and test data for the prediction component, as shown in Quick start. Set the required parameters, including the data format, feature columns, target column, and number of classes. The ID column can only be a string type column other than a feature column or a target column. The loss function must be explicitly set to the objective function used for training.

    The **prediction_score** column lists the predicted values. The **leaf_index** column lists the predicted leaf node numbers. Each sample has N numbers, where N is the number of decision trees. Each tree is mapped to a number, which indicates the leaf node number of the sample on this tree.

    > **Note**
    > - The output model table is a binary table that is not readable and is used to support the PS-SMART prediction component. The table provides outputs such as leaf node numbers and evaluation indicators. However, the output table has strict requirements on data formats, which negatively affects user experience. This component is being continually improved, and may be replaced by another component in the future.
    > - A string type column must be selected as the label column. You can enter strings in the column but cannot be blank or NULL. A feature column can be converted to the string type by using the data type conversion component.
    > - The loss function must be explicitly set to the objective function used for training. By default, the loss function does not work.

- View feature importance

To view feature importance, you can export the third output port to an output table, or right-click **PS-SMART training component** and choose **View Data > Output Feature Importance Table** from the shortcut menu.

order	id	value
1	1	0.14059734344482422
2	4	0.8594027161598206

In the table, the ID column lists the numbers of input features. In this example, the data is in KV format and the IDs represent keys in key-value pairs. If the dense format is used and input features are **f0,f1,f2,f3,f4,f5**, ID 0 represents f0, and ID 4 represents f4. Each value indicates a feature importance type. The default value is **gain**, indicating the sum of information gains brought by a feature in the model. The preceding figure shows only two features because only these two features are used during the tree split process. In this case, the importance of unused features is 0.

FAQ

- Q: Does PS_SMART support non-numerical features and tags?
- A: No.
- Q: What is the scale of features supported by PS-SMART? Can we use large-scale 0-1 features?
- A: Although PS-SMART supports tasks that contain hundreds of thousands of features, such tasks consume large amounts of resources and run slowly. Therefore, we recommend that you do not use a large number of features. The GBDT algorithm is suitable for training with continuous features. The categorical features require one-hot coding (to filter out infrequent features) before they can be used for training. The continuous numerical features can be used for training with the GBDT algorithm directly. Discretization is not recommended for numerical features.
- Q: Why is the result different every time although the SMART algorithm has the same data and the same parameter settings?
- A: The PS-SMART algorithm applies randomness in many scenarios. For example, the data_sample_ratio and fea_sample_ratio items introduce data and feature sampling respectively. In addition, the PS-SMART algorithm uses histograms to show similarity. When multiple workers run in a cluster in distributed mode, local sketches are merged to global sketches in a random order. Although different merging orders result in different tree structures, this does not introduce too much variation to the output model. Therefore, it is normal situation to obtain different results after the algorithm runs multiple times with the same data and same parameter settings.

> **Note**
>
> - The target column in a PS-SMART regression model supports only numerical values. Even if values in the MaxCompute table are strings, they are saved as numerical values.
> - In the key-value format, feature IDs must be positive integers, and feature values must be real numbers. If feature IDs are strings, use the serialization component to serialize them. If feature values are classification type strings, perform feature engineering, such as discretization.

4.4.6.5. Collaborative filtering (etrec)

etrec is an item-based collaborative filtering algorithm that takes two input columns and provides the top N items that have the highest similarity.

Set the user and item columns.

- You can configure three similarity types.
- topN indicates the first N items with the highest similarity.
- Calculation method: the method used to calculate items that appear multiple times.

PAI command

```
PAI -name pai_etrec
-project algo_public
-DsimilarityType="wbcosine"
-Dweight="1"
-DminUserBehavior="2"
-Dlifecycle="28"
-DtopN="2000"
-Dalpha="0.5"
-DoutputTableName="etrec_test_result"
-DmaxUserBehavior="500"
-DinputTableName="etrec_test_input"
-Doperator="add"
-DuserColName="user"
-DitemColName="item"
```

Parameters

Parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	N/A	N/A
userColName	Required. The name of the input table column selected as the user column.	N/A	N/A
itemColName	The name of the input table column selected as the item column.	N/A	N/A

Parameter	Description	Valid value	Default value
payloadColName	Optional. The name of the input table column selected as the payload column.	N/A	No payload column is set by default.
inputTablePartitions	Optional. The partitions selected from the input table for training.	N/A	The whole table is selected by default.
outputTableName	Required. The name of the output table.	N/A	N/A
outputTablePartition	Optional. The partitions in the output table.	N/A	The output table is non-partitioned by default.
similarityType	Optional. The type of similarity.	wbcosine, asymcosine, and jaccard	wbcosine
topN	Optional. N items with the highest similarity.	[1, 10000]	2000
minUserBehavior	Optional. The minimum user behavior.	[2,)	2
maxUserBehavior	Optional. The maximum user behavior.	[2, 100000]	500
itemDelimiter	Optional. The delimiter used to separate items in the output table.	N/A	The default delimiter is a space.
kvDelimiter	Optional. The delimiter used to separate keys and values in the output table.	N/A	The default delimiter is a colon (:).
alpha	Optional. The value of the smoothing factor for asymcosine.	N/A	0.5
weight	Optional. The weight used for asymcosine.	N/A	1.0
operator	Optional. The action to be performed when the same items exist for one user.	add, mul, min, and max	add

Parameter	Description	Valid value	Default value
lifecycle	Optional. The lifecycle of the output table.	N/A	1

Examples

- SQL statement to generate data:

```
drop table if exists etrec_test_input;
create table etrec_test_input as select * from
(
select cast(0 as string) as user,
cast(0 as string) as item from dual
union all
select cast(0 as string) as user,
cast(1 as string) as item from dual
union all
select cast(1 as string) as user,
cast(0 as string) as item from dual
union all
select cast(1 as string) as user,
cast(1 as string) as item from dual ) a;
```

- PAI command

```
drop table if exists etrec_test_result;
PAI -name pai_etrec
-project algo_public
-DsimilarityType="wbcosine"
-Dweight="1"
-DminUserBehavior="2"
-Dlifecycle="28"
-DtopN="2000"
-Dalpha="0.5"
-DoutputTableName="etrec_test_result"
-DmaxUserBehavior="500"
-DinputTableName="etrec_test_input"
-Doperator="add"
-DuserColName="user"
-DitemColName="item"
```

- Input description

etrec_test_input

User	Item
0	0
0	1
1	0
1	1

- Output description

etrec_test_result

Item ID	Similarity
0	1:1
1	0:1

4.4.6.6. Evaluation

4.4.6.6.1. Regression model evaluation

You can evaluate a regression model based on the predicted and actual results. Indicators include SST, SSE, SSR, R2, R, MSE, RMSE, MAE, MAD, MAPE, count, yMean, and predictMean.

PAI command

```
Pai -name regression_evaluation
-project algo_public
-DinputTableName=input_table
-DyColName=y_col
-DpredictionColName=prediction_col
-DoutputTableName=output_table;
```

Parameters

Parameter	Description	Default value
inputTableName	Required. The name of the input table.	-
inputTablePartitions	Optional. The partitions selected from the input table for training.	All partitions of the input table are selected by default.

Parameter	Description	Default value
yColName	Required. The name of the original dependent variable column in the input table. It must be a numerical value.	-
predictionColName	Required. The name of the predicted dependent variable column. It must be a numerical value.	-
outputTableName	Required. The name of the output table.	-
inputTablePartitions	Optional. The partitions selected from the input table.	-
lifecycle	Optional. The lifecycle of the output table.	No lifecycle is set by default.

Output

The following table describes the JSON columns.

Column description

Column	Description
SST	The sum of squares total.
SSE	The sum of squares error.
SSR	The sum of squares regression.
R2	The coefficient of determination.
R	The coefficient of multiple correlations.
MSE	The mean squared error.
RMSE	The root-mean-square error.
MAE	The mean absolute error.
MAD	The mean absolute difference.
MAPE	The mean absolute percentage error.
count	The number of rows.
yMean	The mean of original dependent variables.
predictionMean	The mean of prediction results.

4.4.6.6.2. Clustering model evaluation

You can evaluate clustering models, including metrics and icons, based on raw data and clustering models.

PAI command

```
PAI -name cluster_evaluation
-project algo_public
-DinputTableName=pai_cluster_evaluation_test_input
-DselectedColNames=f0,f3
-DmodelName=pai_kmeans_test_model
-DoutputTableName=pai_ft_cluster_evaluation_out;
```

Parameters

Parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
selectedColNames	Optional. The names of columns selected from the input table for evaluation. The column names must be separated with commas (,). The column names must be the same as the feature names saved in the model.	Column name	All columns are selected by default.
inputTablePartitions	Optional. The partitions selected from the input table for evaluation, in the `name1=value1/name2=value2` format. Separate multiple partitions with commas (,).	N/A	All partitions are selected by default.
enableSparse	Optional. This parameter specifies whether data in the input table is in sparse format.	true and false	false

Parameter	Description	Valid value	Default value
itemDelimiter	Optional. The delimiter used to separate key-value pairs when data in the input table is in sparse format.	N/A	The default delimiter is a space.
kvDelimiter	Optional. The delimiter used to separate keys and values when data in the input table is in sparse format.	N/A	The default delimiter is a colon (:).
modelName	Required. The name of the input clustering model.	Model name	N/A
outputTableName	Required. The name of the output table.	Table name	N/A
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Evaluation formula

The Calinski-Harabasz metric is also known as the variance ratio criterion (VRC), which is defined as follows:

$$VRC_k = \frac{SS_B}{SS_W} \times \frac{(N-k)}{(k-1)},$$

- SS_B represents the inter-clustering variance. The definition is as follows:

  $$SS_B = \sum_{i=1}^{k} n_i \|m_i - m\|^2,$$

  - k represents the number of cluster centers.
  - m_i represents the center of cluster i.
  - m represents the mean of the input data.

- SS_W represents the intra-clustering variance. The definition is as follows:

  $$SS_W = \sum_{i=1}^{k} \sum_{x \in c_i} \|x - m_i\|^2,$$

  - k represents the number of cluster centers.
  - x represents a data point.
  - c_i represents the number i cluster.

- m_i represents the center of cluster i.

- `N` represents the total number of records. `k` represents the number of cluster centers.

Examples

- Test data

```
create table if not exists pai_cluster_evaluation_test_input
as select * from ( select 1 as id,
1 as f0,2 as f3 from dual union all
select 2 as id, 1 as f0,3 as f3 from dual union all
select 3 as id, 1 as f0,4 as f3 from dual union all
select 4 as id, 0 as f0,3 as f3 from dual union all
select 5 as id, 0 as f0,4 as f3 from dual )tmp;
```

- Clustering model building

```
pai -name kmeans
-project algo_public
-DinputTableName=pai_cluster_evaluation_test_input
-DselectedColNames=f0,f3
-DcenterCount=3
-Dloop=10
-Daccuracy=0.00001
-DdistanceType=euclidean
-DinitCenterMethod=random
-Dseed=1
-DmodelName=pai_kmeans_test_model
-DidxTableName=pai_kmeans_test_idx
```

- PAI command

```
PAI -name cluster_evaluation
-project algo_public
-DinputTableName=pai_cluster_evaluation_test_input
-DselectedColNames=f0,f3
-DmodelName=pai_kmeans_test_model
-DoutputTableName=pai_ft_cluster_evaluation_out;
```

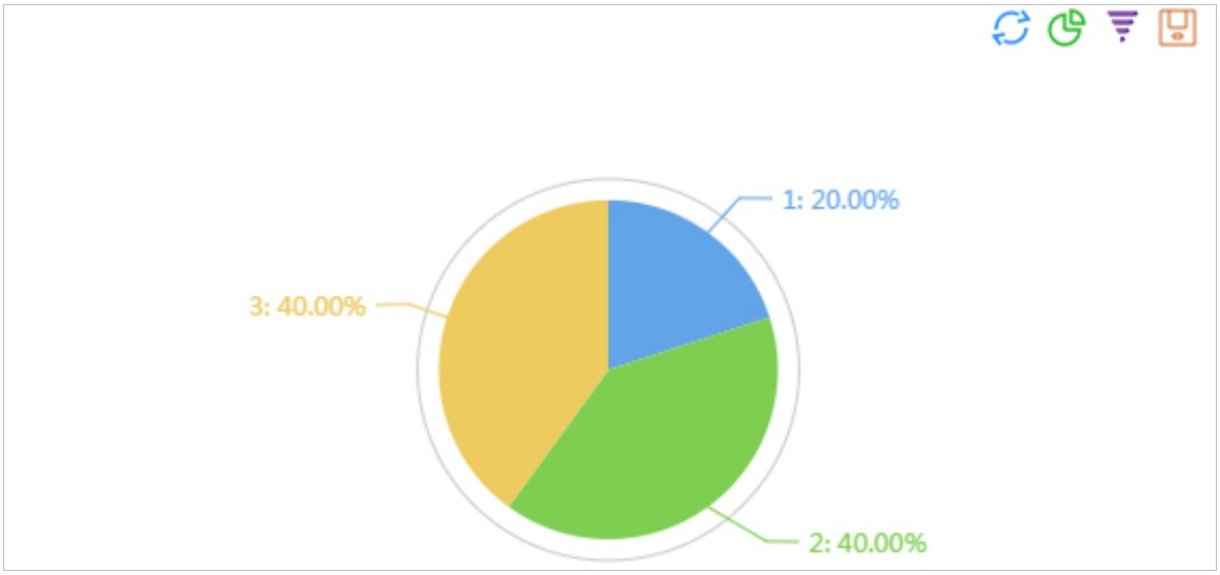
- Output description

Output table (outputTableName)

Column	Description
count	The total number of records.
centerCount	The number of cluster centers.
calinhara	The Calinski Harabasz metric.
clusterCounts	The number of points included in each cluster.

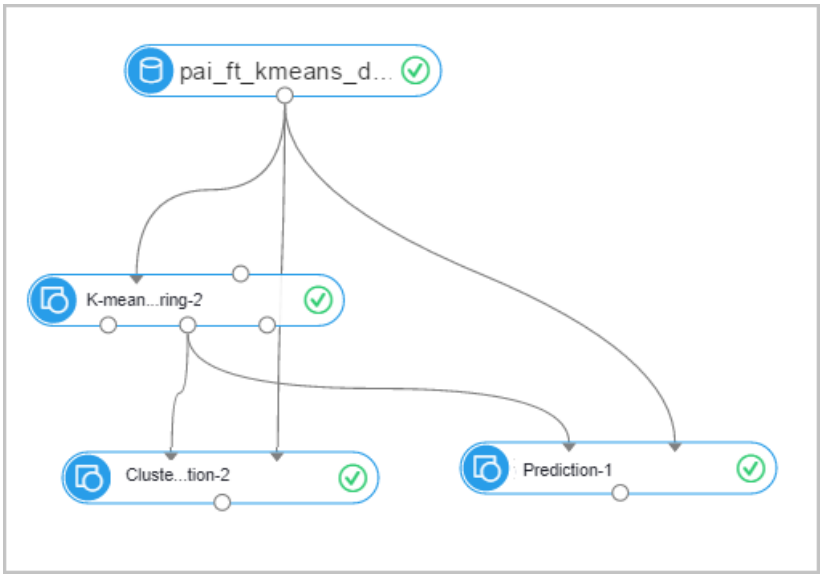
PaiWeb demonstration

Clustering model evaluation



PaiWeb-Pipeline

PaiWeb-Pipeline



4.4.6.6.3. Binary classification evaluation

You can evaluate a regression algorithm model based on its predicted and actual results. The metrics include MSE, MAE, and MAPE.

PAI command

```
pai -name evaluation
-DinputTableName=input_table
-DlabelColName=label_name
-DpredictionColName=prediction_score
-DoutputTableName=output_table;
```

Algorithm parameters

Parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	N/A	N/A
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	N/A	All partitions of the input table are selected by default.
labelColName	Required. The name of the original label column in the input table. It must be a numerical value.	N/A	N/A
predictionColName	Required. The name of the label column in the prediction result table. It must be a numerical value.	N/A	N/A
outputTableName	Required. The name of the output table.	N/A	N/A
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Output table

Output column description

Column	Description
MSE	The mean square error, which is used to measure the mean error and evaluate data changes. The smaller the MSE, the more accurately a prediction model describes the test data.

Column	Description
MAE	The mean absolute error, which is used to measure the mean difference between the predicted value and the actual value.
MAPE	The mean absolute percentage error, which is used to measure prediction accuracy. The value is expressed in percentage. If MAPE is set to 15, the mean absolute percentage error is 15%.

4.4.6.6.4. Confusion matrix

The Confusion Matrix component is a visualization tool typically used in supervised learning. This tool is used to calculate the classification accuracy of a confusion matrix model by comparing its results with measured values.

Procedure

1. Configure the confusion matrix parameters.

   The default settings are typically used. You can also select a target column and a prediction probability column. A prediction probability column is the target column generated by the Prediction component.

2. Connect the Confusion Matrix component and the Prediction component.

   > **Note** The parent node of the Confusion Matrix component must be a Prediction component. You can perform confusion matrix analysis only when a classification model is used.

3. Right-click the Confusion Matrix component and choose **View Evaluation Report**.

PAI command

```
PAI -name confusionmatrix
-project algo_public
-DoutputTableName="pai_temp_2954_24178_1"
-DlabelColName="age"
-DpredictionColName="prediction_result"
-DinputTableName="pai_temp_2954_24176_1";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.

Parameter	Description
outputTableName	The name of the output table.
labelColName	The name of the label column selected from the input table.
predictionColName	The name of the prediction result column.
inputTableName	The name of the input table for predicting results.

4.4.6.6.5. Multiclass classification evaluation

You can evaluate a multiclass classification model based on its predicted and actual results. The indicators include accuracy, kappa, and F1-Score.

Component description

The Multiclass Classification Evaluation component must be connected to a Prediction component and does not support regression models.

PAI command

```
PAI -name MultiClassEvaluation -project algo_public
    -DinputTableName="test_input"
    -DoutputTableName="test_output"
    -DlabelColName="label"
    -DpredictionColName="prediction_result"
    -Dlifecycle=30;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training.	-	All partitions of the input table are selected by default.
labelColName	Required. The name of the original label column in the input table. It must be a numerical value.	-	-
predictionColName	Required. The name of the label column in the prediction result table. It must be a numerical value.	-	-

Parameter	Description	Valid values	Default value
outputTableName	Required. The name of the output table.	-	-
predictionColName	Optional. The name of the probability column that lists prediction results. It must be in the {"A":0.2,"B":0.3} format.	-	-
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

4.4.6.7. Prediction

The Prediction component is used to make model-based predictions. The component has two inputs (training model and prediction data) and one output (prediction result). Conventional data mining algorithms often use this component for prediction.

Procedure

1. Connect all components.
2. Configure column settings.

Parameters

Parameter	Description
Feature Columns	The feature columns used for prediction. All feature columns are selected by default.
Reserved Columns	The columns reserved and exported to the prediction result.
Output Result Column	The default value is used.
Output Score Column	The default value is used.
Output Detail Column	The default value is used.

> **Note** Feature columns must be selected if data is in sparse format such as `k1:v1,k2:v2`.

3. After you configure the preceding parameters, right-click the Prediction component and choose **View Data** from the shortcut menu.

   The following three columns are appended to the prediction data:

   - predict_result: the prediction result column.
   - predict_score: the probability score in prediction results. This column is only appended

onto the outputs of binary classification models.

- predict_detail: the prediction result of each category. This column is only appended onto the outputs of binary classification models.

PAI command

```
PAI -name Prediction
-project algo_public
-DdetailColName="prediction_detail"
-DsplitCharacteristic="2"
-DappendColNames="age,campaign,pdays,previous,poutcome,emp_var_rate,cons_price_idx,cons_conf_
idx,euribor3m,nr_employed,y"
-DmodelName="xlab_m_random_forests_6036"
-DresultColName="prediction_result"
-DoutputTableName="pai_temp_675_6048_1"
-DscoreColName="prediction_score"
-DinputTableName="bank_data";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
detailColName	Optional. The name of the detail column in the output table. The default value is prediction_detail.
splitCharacteristic	Optional. The type of classification. The value *1* indicates binary classification. The value *2* indicates multiclass classification.
appendColNames	Optional. The names of columns in the input prediction table to be appended to the output table.
modelName	The name of the random forest model.
resultColName	Optional. The name of the result column in the output table. The default value is *prediction_result*.
outputTableName	The name of the output prediction table.
scoreColName	Optional. The name of the score column in the output table. The default value is *prediction_score*.
inputTableName	The name of the input prediction table.

4.4.7. Deep learning (must be activated separately)

4.4.7.1. Activate deep learning

The deep learning service is not a basic function of Apsara Stack Machine Learning Platform for AI. You must purchase it separately.

If you have already deployed the deep learning service, activate it by using the following procedure:

1. Log on to the Apsara Stack Machine Learning Platform for AI console.
2. Click **Settings** in the left-side navigation pane.
3. Click **General**. Under **Deep Learning**, select **Enable GPU Compute**.

4.4.7.2. Read OSS buckets

When using the **Read OSS Bucket** component on Machine Learning Platform for AI, you must assign the default system role **AliyunODPSPAIDefaultRole** to your DTplus service account. OSS buckets can be correctly read and written by algorithms of the machine learning platform only when the role is correctly assigned.

> **Note** The machine learning platform shares service accounts with MaxCompute, because it runs on the MaxCompute framework. During authorization, you must assign the default role to your MaxCompute service account.

You can use RAM authorization to grant OSS access permissions to Machine Learning Platform for AI. Click **Settings** to grant permission to read and write OSS data. For more information, see RAM authorization.

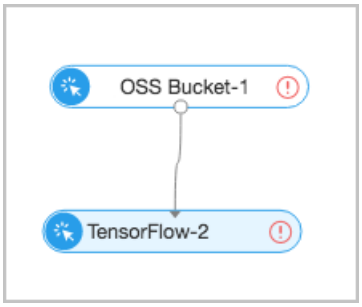
RAM authorization

1. Log on to the Machine Learning Platform For AI console, click **Settings** in the left-side navigation pane, and select **General**.
2. Under **OSS Authorization**, select **Authorize Machine Learning Platform for AI to access my OSS resources.**
3. The following page is displayed. Click **Click here to authorize access in RAM.** The RAM page is displayed.
4. Click **I Agree.**

Note To view details about the AliyunODPSPAIDefaultRole policy, log on to the RAM console. The default role AliyunODPSPAIDefaultRole contains the following permission information.

Permission (Action)	Description
oss:PutObject	Upload a file or folder object.
oss:GetObject	Obtain a file or folder object.
oss:ListObjects	Query file information.
oss:DeleteObjects	Delete an object.

5. Go back to the machine learning page and click **Refresh**. RAM information is automatically recorded to the components.
6. Use the deep learning framework. Connect the **Read OSS Bucket** component to the corresponding deep learning component to obtain permissions to read and write OSS data.



4.4.7.3. TensorFlow 1.4

TensorFlow (TF) is an open-source machine learning framework. It is easy to use for algorithm developers. The TF framework is integrated into Apsara Stack Machine Learning Platform for AI. You can write code and adjust computing resources flexibly by using the TF compute engine. The TF computing engine is a Graphics Processing Unit (GPU) cluster.

Parameters

- Parameter settings

Parameter settings

Parameter	Description
Python Code Files	The program execution files. Multiple files can be packaged and uploaded in the tar.gz format.
Primary Python File	Optional. The primary file in a compressed code file package.
Data Source Directory	The path of data sources. You can select Object Storage Service (OSS) data sources.

Parameter	Description
Configuration File Hyperparameters and Custom Parameters	Machine Learning Platform for AI Tensorflow allows you to use commands to pass in hyperparameter settings and try different learning rates and batch sizes during model testing.
Output Directory	The path of the output model.

- Tuning

  You can specify the number of GPUs based on the complexity of jobs.

PAI command

> **Note** You do not need to set all parameters. For the definitions of these parameters, see Parameters. We recommend that you do not directly copy the following command.

```
PAI -name tensorflow_ext140
-Dbuckets="oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist/"
-DgpuRequired="100"
-Darn="acs:ram::166408185518****:role/aliyunodpspaidefaultrole"
-Dscript="oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist_ext.py";
```

The following table lists the descriptions of the parameters.

Parameters

Parameter	Description	Valid values	Default value
script	Required. The TF algorithm file. This file can be a single file or compressed as a tar.gz format package.	oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist_ext.py	N/A
entryFile	Optional. The name of the primary Python file. If the script is a compressed package in the tar.gz format, this parameter is required.	train.py	Null

Parameter	Description	Valid values	Default value
buckets	Required. The input OSS buckets. You can specify multiple buckets separated with commas (,). Each bucket must end with a forward slash (/).	oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist/	Null
arn	Required. The Alibaba Cloud Resource Name (ARN) of an OSS object.	N/A	Null
gpuRequired	Required. This parameter indicates the number of GPUs to be used.	200	100
checkpointDir	Optional. The TF checkpoint directory.	oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist/	Null
cluster	Optional.	A JSON format value. Quotation marks must be escaped.	Null
hyperParameters	Optional. The path of the command line hyperparameters.	oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist/hyper_parameters.txt	Null

- script and entryFile are used to specify the TF algorithm script to be executed. If the algorithm is complex and divided into multiple files, you can package the files into a tar.gz file and use entryFile to specify the primary Python file.
- checkpointDir is used to specify the OSS path to be written by algorithms. You must specify the OSS path when you save TensorFlow models.
- buckets is used to specify the OSS path to be read by algorithms. To use OSS, you must specify arn.
- Distributed Machine Learning Platform for AI TensorFlow supports cluster. You can use cluster to specify the number of parameter servers and workers. cluster is in JSON format, and the quotation marks must be escaped. The JSON code must contain two keys: ps and worker. Both the ps and worker parameters contain count, gpu, cpu, and memory.

Keyword	Description	Default value	Remarks

Keyword	Description	Default value	Remarks
count	Required. The number of parameter servers or workers.	-	None
gpu	Optional. The number of GPUs allocated to each parameter server or worker. 100 represents a single GPU card.	For parameter servers, the default value is 0. For workers, the default value is 100.	If the number of GPUs allocated to each worker is set to 0, Machine Learning Platform for AI will reset the value to 100 to ensure the task is scheduled properly.
cpu	Optional. The number of CPUs allocated to each parameter server or worker. 100 represents a single CPU card.	600	None
memory	The memory size allocated to each parameter server or worker. 100 represents 100 MB.	30000	None

Examples

The MNIST digit classification set is a set of handwritten digits 1 through 9 that contains training and test sets for machine learning models.

1. Upload the Python execution files and training datasets to OSS. In this case, create a bucket on OSS in China (Shanghai) and name the bucket as tfmnist001. Upload the Python script and training data.
2. Drag and drop the **Read OSS Bucket** and **TensorFlow** components onto the canvas to create the following experiment. Set the region for the OSS bucket and configure RAM authorization.
3. Set the TensorFlow parameters. Set the paths for **Python Code Files**, **Primary Python File**, and **Data Source Directory**.
4. Click **Run** and wait for the experiment to complete running.
5. Right-click the **TensorFlow** component and view the running log.

4.4.8. Time series

4.4.8.1. x13_arima

Autoregressive Integrated Moving Average Model (ARIMA) is a well-known time series prediction method defined by Box and Jenkins in the early 1970s. This model is also called the Box-Jenkins model or the Box-Jenkins method. x13-arima is an ARIMA algorithm for seasonal adjustment based on the open-source X-13ARIMA-SEATS algorithm.

PAI command

```
pai -name x13_arima
    -project algo_public
    -DinputTableName=pai_ft_x13_arima_input
    -DseqColName=id
    -DvalueColName=number
    -Dorder=3,1,1
    -Dstart=1949.1
    -Dfrequency=12
    -Dseasonal=0,1,1
    -Dperiod=12
    -DpredictStep=12
    -DoutputPredictTableName=pai_ft_x13_arima_out_predict
    -DoutputDetailTableName=pai_ft_x13_arima_out_detail
```

Algorithm parameters

Parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
inputTablePartitions	Optional. The partitions selected from the input table for training, in the `partition_name=value` format. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
seqColName	Required. The name of the time series column.	Column name	This parameter is only used to sort the column specified by valueColName. The value does not affect the calculated results.

Parameter	Description	Valid value	Default value
valueColName	Required. The name of the value column.	Column name	N/A
groupColNames	Optional. The name of the stratification column. Separate multiple columns with commas (,), such as `col0,col1;` . A time series is created for each stratum.	Column name	N/A
order	Required. *p*, *d*, and *q* indicate the autoregressive coefficient, difference, and moving regression coefficient, respectively.	*p*, *d*, and *q* must be non-negative integers in the range of [0, 36].	N/A
start	Optional. The start date of a time series.	A string in the `year.seasonal` format, such as 1986.1 For more information, see the time series format section.	1.1
frequency	Optional. The frequency of a time series. Unit: months/year	A positive integer in the range of (0, 12) For more information, see the time series format section.	12
seasonal	Optional. *sp*, *sd*, and *sq* indicate the seasonal autoregressive coefficient, seasonal difference, and seasonal moving regression coefficient, respectively.	*sp*, *sd*, and *sq* must be non-negative integers in the range of [0, 36].	*seasonal* is not set by default.
period	Optional. The seasonal period.	A number in the range of (0, 100]	frequency
maxiter	Optional. The maximum number of iterations.	A positive integer	1500

Parameter	Description	Valid value	Default value
tol	Optional. The degree of tolerance.	A double type value	1e-5
predictStep	Optional. The number of prediction items.	A number in the range of (0, 365]	12
confidenceLevel	Optional. The prediction confidence level.	A number in the range of (0, 1)	0.95
outputPredictTableName	Required. The name of the output prediction table.	Table name	N/A
outputDetailTableName	Required. The name of the output detail table.	Table name	N/A
outputTablePartition	Optional. The partition in the output table.	Partition name	The output table is non-partitioned by default.
coreNum	Optional. The number of cores.	A positive integer used with memSizePerCore	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Time series format

- The start and frequency parameters specify the two time dimensions of data (valueColName): TS1 and TS2.
- The frequency parameter indicates the data frequency within a period, which equals the frequency of TS2 in each TS1.
- The start parameter must be in the `n1.n2` format. This indicates that the start date is the N2 TS2 in the N1 TS1.

Unit time	TS1	TS2	Frequency	Start date
12 months/year	Year	Month	12	1949.2 indicates the second month of year 1949.

Unit time	TS1	TS2	Frequency	Start date
Four quarters/year	Year	Quarter	4	1949.2 indicates the second quarter of year 1949.
Seven days/week	Day	Week	7	1949.2 indicates the second day of the1949th week.
1	Any time unit	1	1	1949.1 indicates the 1949th (year, day, or hour).

Example: value=[1,2,3,5,6,7,8,9,10,11,12,13,14,15]

- `start=1949.3` and `frequency=12` indicate that the data frequency is monthly, and the prediction start date is 1950.06.

Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
1949			1	2	3	4	5	6	7	8	9	10
1950	11	12	13	14	15							

- `start=1949.3` and `frequency=4` indicate that the data frequency is quarterly, and the prediction start date is 1953.02.

Year	Qtr1	Qtr2	Qtr3	Qtr4
1949			1	2
1950	3	4	5	6
1951	7	8	9	10
1952	11	12	13	14
1953	14			

- `start=1949.3` and `frequency=7` indicate that the data frequency is daily, and the prediction start date is 1951.04.

Week	Sun	Mon	Tue	Wed	Thu	Fri	Sat
1949			1	2	3	4	5

Week	Sun	Mon	Tue	Wed	Thu	Fri	Sat
1950	6	7	8	9	10	11	12
1951	13	14	15				

- `start=1949.1` and `frequency=1` indicate that the prediction start date is 1963.00 regardless of the time unit used.

Cycle	p1
1949	1
1950	2
1951	3
1951	4
1952	5
1953	6
1954	7
1955	8
1956	9

1958	11
1959	12
1960	13
1961	14
1962	15

Examples

- Data used for testing: AirPassengers. The data set contains the number of passengers for international airlines each month from 1949 to 1960. It can be downloaded from https://stat.ethz.ch/R-manual/R-devel/library/datasets/html/AirPassengers.html .

```
create table pai_ft_x13_arima_input(id bigint,number bigint);
tunnel upload data/airpassengers.csv pai_ft_x13_arima_input -h true;
```

- PAI command

```
pai -name x13_arima
  -project algo_public
  -DinputTableName=pai_ft_x13_arima_input
  -DseqColName=id
  -DvalueColName=number
  -Dorder=3,1,1
  -Dseasonal=0,1,1
  -Dstart=1949.1
  -Dfrequency=12
  -Dperiod=12
  -DpredictStep=12
  -DoutputPredictTableName=pai_ft_x13_arima_out_predict
  -DoutputDetailTableName=pai_ft_x13_arima_out_detail
```

- Output description
  - The columns of the output table specified by outputPredictTableName are as follows.

Column	Description
pdate	The prediction date.
forecast	The prediction result.
lower	The lower threshold of the prediction result when the confidence level is specified (default value: 0.95).
upper	The upper threshold of the prediction result when the confidence level is specified (default value: 0.95).

Output data

1	196101	444.445401291661	422.354385657496	466.536416925825

4.4.8.2. x13_auto_arima

ARIMA is described in x13_arima. The x13_auto_arima algorithm includes a process of automatic model selection.

The x13_auto_arima selection process is as follows:

- **Default model estimation**

  In the case of `frequency = 1`, the default model is `(0,1,1)`.

  In the case of `frequency > 1`, the default model is `(0,1,1)(0,1,1)`.

- **Identification of differencing orders**

  Skip this step if you have configured diff and SeasonalDiff.

  Use `Unit root test (wiki )` to determine the difference d and the seasonal difference D.

- **Identification of ARMA model orders**

  Select the optimal model based on BIC (wiki). The maxOrder and maxSeasonalOrder parameters are used in this step.

- **Comparison of identified model with default model**

  Use Ljung-Box Q statistic(wiki) to compare the models. If both models are unacceptable, use the `(3,d,1)(0,D,1)` model.

- **Final model checks**

PAI command

```
pai -name x13_auto_arima
    -project algo_public
    -DinputTableName=pai_ft_x13_arima_input
    -DseqColName=id
    -DvalueColName=number
    -Dstart=1949.1
    -Dfrequency=12
    -DpredictStep=12
    -DoutputPredictTableName=pai_ft_x13_arima_out_predict2
    -DoutputDetailTableName=pai_ft_x13_arima_out_detail2
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-

Parameter	Description	Valid values	Default value
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
seqColName	Required. The name of the time series column.	Column name	This parameter is only used to sort valueColNames. It is not relevant to the calculated output.
valueColName	Required. The name of the value column.	Column name	-
groupColNames	Optional. The name of the stratification column. Separate multiple columns with commas (,), such as `col0,col1;`. A time series is created for each group.	Column name	-
start	Optional. The start date of a time series.	A string in the format of `year.seasonal`, such as 1986.1 For more information, see the time series format section.	1.1
frequency	Optional. The frequency of a time series.	A positive integer in the range of (0, 12) For more information, see the time series format section.	The frequency is 12 months/year by default.

Parameter	Description	Valid values	Default value
maxOrder	Optional. The maximum values of p and q.	A positive integer in the range of [0, 4]	2
maxSeasonalOrder	Optional. The seasonal maximum values of p and q.	A positive integer in the range of [0, 2]	1
maxDiff	Optional. The maximum value of differential d.	A positive integer in the range of [0, 2]	2
maxSeasonalDiff	Optional. The maximum value of seasonal differential d.	A positive integer in the range of [0, 1]	1
diff	Optional. The differential d.	A positive integer in the range of [0, 2] If both diff and maxDiff are set, maxDiff is ignored. If diff is set, then seasonalDiff must also be set.	Default value: -1. This value indicates that diff is not specified by default.
seasonalDiff	Optional. The seasonal differential d.	A positive integer in the range of [0, 1] If both seasonalDiff and maxSeasonalDiff are set, maxSeasonalDiff is ignored.	Default value: -1. This value indicates that seasonalDiff is not specified by default.
maxiter	Optional. The maximum number of iterations.	A positive integer	1500
tol	Optional. The degree of tolerance.	A double type value	1e-5
predictStep	Optional. The number of prediction items.	A number in the range of (0, 365]	12
confidenceLevel	Optional. The prediction confidence level.	A number in the range of (0, 1)	0.95

Parameter	Description	Valid values	Default value
outputPredictTableName	Required. The name of the output prediction table.	Table name	-
outputDetailTableName	Required. The name of the output detail table.	Table name	-
outputTablePartition	Optional. The partitions in the output table.	Partition name	No partition is specified by default.
coreNum	Optional. The number of cores.	A positive integer used with memSizePerCore	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Time format

- The start and frequency parameters specify the two time dimensions of data (valueColName): TS1 and TS2.
- The frequency parameter indicates the data frequency within a period, which equals the frequency of TS2 in each TS1.
- The start parameter is in the format of `n1.n2`. This indicates that the start date is the N2 TS2 in the N1 TS1.

Unit time	ts1	ts2	Frequency	Start date
12	Year	Month	12	1949.2 indicates the second month of year 1949.
4	Year	Quarter	4	1949.2 indicates the second quarter of year 1949.
7	Day	Week	7	1949.2 indicates the second day of a week in year 1949.

Unit time	ts1	ts2	Frequency	Start date
1	Any time unit	1	1	1949.1 indicates the 1949th (year, day, or hour).

For example, value=[1,2,3,5,6,7,8,9,10,11,12,13,14,15].

- `start=1949.3` and `frequency=12` indicate that the data frequency is monthly, and the prediction start date is 1950.06.

Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
1949			1	2	3	4	5	6	7	8	9	10
1950	11	12	13	14	15							

- `start=1949.3` and `frequency=4` indicate that the data frequency is quarterly, and the prediction start date is 1953.02.

Year	Qtr1	Qtr2	Qtr3	Qtr4
1949			1	2
1950	3	4	5	6
1951	7	8	9	10
1952	11	12	13	14
1953	14			

- `start=1949.3` and `frequency=7` indicate that the data frequency is daily, and the prediction start date is 1951.04.

Week	Sun	Mon	Tue	Wed	Thu	Fri	Sat
1949			1	2	3	4	5
1950	6	7	8	9	10	11	12
1951	13	14	15				

- `start=1949.1` and `frequency=1` indicate that the end date is 1963.00.

Period	p1
1949	1

summary	Storage details.

4.4.9. Text analysis

4.4.9.1. Word splitting

Based on Alibaba Word Segmenter (AliWS), this component performs word splitting on documents specified by columns. Segmented words are separated with spaces. If you have set the part-of-speech (POS) tagging or semantic tagging parameters, the component outputs the word splitting results, POS tagging results, and semantic tagging results. Forward slashes `(/)` are used as delimiters for POS tagging. Vertical bars `(|)` are used as delimiters for semantic tagging. Only Chinese Taobao word segmentation and Internet word segmentation are supported.

Parameter settings

Word segmentation algorithms: CRF and UNIGRAM.

Parameters

Parameter	Description
Recognition Options	Specifies whether to recognize nouns with special meanings during word splitting.
Merge Options	Considers the terms used in certain industries as a whole without splitting.
Tokenizer	Allows you to select the Taobao word segmentation or Internet word segmentation. Taobao word segmentation is recommended.
Pos Tagger	Specifies whether to mark the part of speech for each word. If this parameter is specified, the part of speech for each word is marked in the output.

Examples

The following input table consists of the id column (document IDs) and the text column (document content).

PAI command

```
pai -name split_word
-project algo_public
-DinputTableName=doc_test
-DselectedColNames=content1,content2
-DoutputTableName=doc_test_split_word
-DinputTablePartitions="region=cctv_news"
-DoutputTablePartition="region=news"
-Dtokenizer=TAOBAO_CHN
-DenableDfa=true
-DenablePersonNameTagger=false
-DenableOrgnizationTagger=false
-DenablePosTagger=false
-DenableTelephoneRetrievalUnit=true
-DenableTimeRetrievalUnit=true
-DenableDateRetrievalUnit=true
-DenableNumberLetterRetrievalUnit=true
-DenableChnNumMerge=false
-DenableNumMerge=true
-DenableChnTimeMerge=false
-DenableChnDateMerge=false
-DenableSemanticTagger=true
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	The name of the input table.	-	-
selectedColNames	The names of the columns selected from the input table for word segmentation.	Separate multiple columns with commas (,).	-
outputTableName	The name of the output table.	-	-

Parameter	Description	Valid values	Default value
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.
outputTablePartition	The partition in the output table.	-	The output table is non-partitioned by default.
tokenizer	The type of the classifier.	TAOBAO_CHN and INTERNET_CHN	Default value: TAOBAO_CHN. *TAOBAO_CHN* represents Taobao word segmentation. *INTERNET_CHN* represents Internet word segmentation.
enableDfa	Specifies whether to enable simple entity recognition.	true and false	true
enablePersonNameTagger	Specifies whether to enable personal name recognition.	true and false	false
enableOrgnizationTagger	Specifies whether to enable organization name recognition.	true and false	false
enablePosTagger	Specifies whether to enable part-of-speech tagging.	true and false	false
enableTelephoneRetrievalUnit	Specifies whether to enable retrieval unit configuration for telephone number recognition.	true and false	true

Parameter	Description	Valid values	Default value
enableTimeRetrievalUnit	Specifies whether to enable retrieval unit configuration for time ID recognition.	true and false	true
enableDateRetrievalUnit	Specifies whether to enable retrieval unit configuration for date ID recognition.	true and false	true
enableNumberLetterRetrievalUnit	Specifies whether to enable retrieval unit configuration for number and letter recognition.	true and false	true
enableChnNumMerge	Specifies whether to merge Chinese numbers into a retrieval unit.	true and false	false
enableNumMerge	Specifies whether to merge regular numbers into a retrieval unit.	true and false	true
enableChnTimeMerge	Specifies whether to merge Chinese time into a semantic unit.	true and false	false
enableChnDateMerge	Specifies whether to merge Chinese dates into a semantic unit.	true and false	false
enableSemanticTagger	Specifies whether to enable semantic tagging.	true and false	false

4.4.9.2. Deprecated word filtering

Deprecated word filtering is a preprocessing method in text analysis. This method is used to filter out the noise in word splitting results, such as of, yes, and ah.

Parameter settings

The left and right input ports are as follows:

- Input table, which is a word splitting result table for filtering. Parameter: inputTableName
- Deprecated word table, which is a one-column table with each row containing a deprecated word. Parameter: noiseTableName

PAI command

```
PAI -name FilterNoise
-project algo_public
-DinputTableName="test_input"
-DnoiseTableName="noise_input"
-DoutputTableName="test_output"
-DselectedColNames="words_seg1,words_seg2"
-Dlifecycle=30
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	All partitions in the input table are selected by default.
noiseTableName	Required. The name of the deprecated word table.	A one-column table with each row containing a deprecated word	-
noiseTablePartitions	Optional. The partitions selected from the deprecated word table.	-	All partitions in the table are selected by default.
outputTableName	Required. The name of the output table.	-	-
selectedColNames	Required. The name of the column to be filtered. Separate multiple columns with commas (,).	-	-
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of (0, 65536)	Automatically calculated.

4.4.9.3. String similarity

String similarity calculation is a basic operation in machine learning that is used in information retrieval, natural language processing, and bioinformatics. This algorithm supports five methods to calculate similarity: Levenshtein distance, longest common substring, string subsequence kernel, cosine, and simhash_hamming. It also supports two input methods: string-to-string calculation and top N calculation.

PAI command

```
PAI -name string_similarity
-project algo_public
-DinputTableName="pai_test_string_similarity"
-DoutputTableName="pai_test_string_similarity_output"
-DinputSelectedColName1="col0"
-DinputSelectedColName2="col1";
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
outputTableName	Required. The name of the output table.	-	-
inputSelectedColName1	Optional. The name of the first column for similarity calculation.	-	By default, the first string type column in the table is selected.
inputSelectedColName2	Optional. The name of the second column for similarity calculation.	-	The second string type column in the table is selected by default.
inputAppendColNames	Optional. The names of columns appended to the output table.	-	No column is appended by default.
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	The whole table is selected by default.

Parameter	Description	Valid values	Default value
outputColName	Optional. The name of the similarity column in the output table. The column name can be up to 128 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.	-	output
method	Optional. The similarity calculation method.	levenshtein, levenshtein_sim, lcs, lcs_sim, ssk, cosine, simhash_hamming, simhash_hamming_sim, minhash_sim, and hash_jaccard_sim	levenshtein_sim
lambda	Optional. The weight of the matching string. This parameter takes effect when similarityType is set to ssk.	(0, 1)	0.5
k	Optional. The length of the substring. This parameter takes effect when similarityType is set to ssk or cosine.	(0, 100)	2
kVec	Optional. The number of MinHash instances.	A positive integer	2
b	Optional. The number of buckets.	A positive integer	1
seed	Optional. The random seed used in a MinHash instance.	A positive integer	0
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of (0, 65536)	Automatically calculated.

Examples

- SQL statement to generate data:

```
create table pai_ft_string_similarity_input
as select * from
(select 0 as id, "Beijing" as col0,
"Beijing" as col1 from dual union all
select 1 as id,
"Beijing" as col0,
"Beijing Shanghai" as col1 from dual union all
select 2 as id,
"Beijing" as col0,
"Beijing Shanghai Hongkong" as col1 from dual )tmp;
```

- PAI command

```
PAI -name string_similarity
-project sre_mpi_algo_dev
-DinputTableName=pai_ft_string_similarity_input
-DoutputTableName=pai_ft_string_similarity_output
-DinputSelectedColName1=col0
-DinputSelectedColName2=col1
-Dmethod=simhash_hamming
-DinputAppendColNames=col0,col1;
```

- Output description
  - Output obtained by using the simhash_hamming method:

col0	col1	output
beijing	beijing	0
beijing	beijing shanghai	6
beijing	beijing shanghai xianggang	13

  - Output obtained by using the simhash_hamming_sim method:

col0	col1	output
beijing	beijing	1
beijing	beijing shanghai	0.90625
beijing	beijing shanghai xianggang	0.796875

4.4.9.4. Convert row, column, and value to KV pair

This component converts rows, columns, and values into KV pairs. A row, column, and value set is defined as XXD or XXL, where X can represent any type, D represents Double, and L represents Bigint. The row, column, and value set is converted into KV format (row, [col_id:value]). The row and value types are consistent with the original input data. The col_id type is Bigint, and the column is mapped to col_id based on the index table.

PAI command

```
PAI -name triple_to_kv
-project algo_public
-DinputTableName=test_data
-DoutputTableName=test_kv_out
-DindexOutputTableName=test_index_out
-DidColName=id
-DkeyColName=word
-DvalueColName=count
-DinputTablePartitions=ds=test1
-DindexInputTableName=test_index_input
-DindexInputKeyColName=word
-DindexInputKeyIdColName=word_id
-DkvDelimiter=:
-DpairDelimiter=;
-Dlifecycle=3
```

Parameters

Parameters

Parameter	Description	Default value
inputTableName	Required. The name of the input table.	The input table cannot be empty.
idColName	Required. The name of the column to be retained after the table is converted into a KV table.	-
keyColName	Required. The name of the key column in the KV table.	-
valueColName	Required. The name of the value column in the KV table.	-
outputTableName	Required. The name of the output KV table.	-

Parameter	Description	Default value
indexOutputTableName	Required. The name of the index table for the output keys.	-
indexInputTableName	Optional. The name of the input index table.	No index table is set by default. The table cannot be empty and it does not need to contain indexes for all of the output keys.
indexInputKeyColName	Optional. The name of the key column in the input index table.	No key column is specified by default. This parameter is required if indexInputTableName is set.
indexInputKeyIdColName	Optional. The name of the index column in the input index table.	No index column is specified by default. This parameter is required if indexInputTableName is set.
inputTablePartitions	Optional. The partitions in the input table.	No partition is specified by default. Only one partition can be input.
kvDelimiter	Optional. The delimiter used to separate the key and value.	The default delimiter is a colon (:).
pairDelimiter	Optional. The delimiter used to separate KV pairs.	The default delimiter is a semicolon (;).
lifecycle	Optional. The lifecycle of the output table.	No lifecycle is set by default.
coreNum	Optional. The number of cores.	-1
memSizePerCore	Optional. The memory size of each core. Valid values: 100 to 65536.	-1

Examples

- SQL statement to generate data:

```
drop table if exists triple2kv_test_input;
create table triple2kv_test_input as
select       *     from
(      select '01' as id, 'a' as word,
10 as count from dual        union all
select '01' as id, 'b' as word,
20 as count from dual        union all
select '01' as id, 'c' as word,
30 as count from dual        union all
select '02' as id,
'a' as word,
100 as count from dual        union all
select '02' as id, 'd' as word,
200 as count from dual        union all
select '02' as id, 'e' as word,
300 as count from dual     ) tmp;
```

- PAI command

```
PAI -name triple_to_kv
-project algo_public
-DinputTableName=triple2kv_test_input
-DoutputTableName=triple2kv_test_input_out
-DindexOutputTableName=triple2kv_test_input_index_out
-DidColName=id
-DkeyColName=word
-DvalueColName=count
-Dlifecycle=1;
```

Input description

Input table

Input description

id	word	count
01	a	10
01	b	20
01	c	30

Output description

- The output KV table is as follows, where custom KV delimiters can be used.

Output description

id	key_value
01	1:10;2:20;3:30

- The output index table that contains indexes for the words is as follows.

Output index table

key	key_id
a	1
b	2
c	3

4.4.9.5. String similarity - Top N

String similarity calculation is a basic operation in machine learning that is used in information retrieval, natural language processing, and bioinformatics. This algorithm supports five methods to calculate similarity: Levenshtein distance, longest common substring, string subsequence kernel, cosine, and simhash_hamming. It also supports two input methods: string-to-string calculation and top N calculation.

PAI command

```
PAI -name string_similarity_topn
-project algo_public
-DinputTableName="pai_test_string_similarity_topn"
-DoutputTableName="pai_test_string_similarity_topn_output"
-DmapTableName="pai_test_string_similarity_map_topn"
-DinputSelectedColName="col0"
-DmapSelectedColName="col1";
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
mapTableName	Required. The name of the mapping table.	-	-
outputTableName	Required. The name of the output table.	-	-

Parameter	Description	Valid values	Default value
inputSelectedColName	Optional. The name of the column selected from the left table for similarity calculation.	-	The first string type column in the table is selected by default.
mapSelectedColName	Optional. The name of the column selected from the mapping table for similarity calculation. The similarities between each row in the left table and all strings in the mapping table are calculated, and the top N entries are output.	-	The first string type column in the table is selected by default.
inputAppendColNames	Optional. The names of columns appended to the output table from the input table.	-	No column is appended by default.
inputAppendRenameColNames	Optional. The aliases of columns appended to the output table from the input table. This parameter takes effect when inputAppendColNames is specified.	-	No alias is specified by default.
mapAppendColNames	Optional. The names of columns appended to the output table from the mapping table.	-	No column is appended by default.
mapAppendRenameColNames	Optional. The aliases of columns appended to the output table from the mapping table.	-	No alias is specified by default.
inputTablePartitions	Optional. The partitions selected from the input table.	-	The whole table is selected by default.
mapTablePartitions	Optional. The partitions in the mapping table.	-	The whole table is selected by default.

Parameter	Description	Valid values	Default value
outputColName	Optional. The name of the similarity column in the output table. The column name can be up to 128 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.	-	output
method	Optional. The similarity calculation method.	levenshtein_sim, lcs_sim, ssk, cosine, simhash_hamming_sim, minhash_sim, and hash_jaccard_sim	levenshtein_sim
lambda	Optional. The weight of the matching string. This parameter takes effect when similarityType is set to ssk.	(0, 1)	0.5
k	Optional. The length of the substring. This parameter takes effect when similarityType is set to ssk or cosine.	(0, 100)	2
kVec	Optional. The number of MinHash instances.	A positive integer	2
b	Optional. The number of buckets.	A positive integer	1
seed	Optional. The random seed used in a MinHash instance.	A positive integer	0
topN	Optional. The number of similarity maximums to be output.	(0, +∞)	10
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.

Parameter	Description	Valid values	Default value
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of (0, 65536)	Automatically calculated.

Examples

- SQL statement to generate data:

```
create table pai_ft_string_similarity_topn_input
as select * from
(select 0 as id,
"Beijing" as col0 from dual union all
select 1 as id,
"Beijing Shanghai" as col0 from dual union all
select 2 as id,
"Beijing Shanghai Hongkong" as col0 from dual )tmp;
```

- PAI command

```
PAI -name string_similarity_topn
-project sre_mpi_algo_dev
-DinputTableName=pai_ft_string_similarity_topn_input
-DmapTableName=pai_ft_string_similarity_topn_input
-DoutputTableName=pai_ft_string_similarity_topn_output
-DinputSelectedColName=col0
-DmapSelectedColName=col0
-DinputAppendColNames=col0
-DinputAppendRenameColNames=input_col0
-DmapAppendColNames=col0
-DmapAppendRenameColNames=map_col0
-Dmethod=simhash_hamming_sim;
```

- Output.

input_col0	map_col0	output
beijing	beijing	1
beiji beijing	beijing shanghai	0.90625
beijing	beijing shanghai xianggang	0.796875
beijing shanghai	beijing shanghai	1
beijing shanghai	beijing	0.90625
beijing shanghai	beijing shanghai xianggang	0.828125
beijing shanghai xianggang	beijing shanghai xianggang	1
beijing shanghai xianggang	beijing shanghai	0.828125
beijing shanghai xianggang	beijing	0.796875

4.4.9.6. N-gram counting

N-gram counting is a step in language model training. N-grams are generated based on words.The number of the corresponding N-grams in all corpora is counted. The N-gram counting model counts the number of N-grams in all documents rather than in a single document. For more information, see ngram-count.

PAI command

```
PAI -name ngram_count
    -project algo_public
    -DinputTableName=pai_ngram_input
    -DoutputTableName=pai_ngram_output
    -DinputSelectedColNames=col0
    -DweightColName=weight
    -DcoreNum=2
    -DmemSizePerCore=1000;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
outputTableName	Required. The name of the output table.	Table name	N/A
inputSelectedColNames	Optional. The names of columns selected from the input table.	Column name	The first character type column is selected by default.
weightColName	Optional. The name of the weight column.	Column name	1

Parameter	Description	Valid values	Default value
inputTablePartitions	Optional. The partitions selected from the input table.	Partition name	The whole table is selected by default.
countTableName	Optional. The name of the former N-gram counting output table. This table is merged into the output result.	Table name	N/A
countWordColName	Optional. The name of the word column in the counting table.	Column name	The second column is selected by default.
countCountColName	Optional. The name of the counting column in the counting table.	Column name	The third column is selected by default.
countTablePartitions	Optional. The partitions in the counting table.	Partition name	N/A
vocabTableName	Optional. The name of the bag-of-words table. The words that are not contained in the bag-of-words table are marked with \<unk\>.	Table name	N/A
vocabSelectedColName	Optional. The name of the bag-of-words column.	Column name	The first character type column is selected by default.
vocabTablePartitions	Optional. The partitions in the bag-of-words table.	Partition name	N/A
order	Optional. The maximum length of N-grams.	N/A	3
lifecycle	Optional. The lifecycle of the output table.	A positive integer	N/A
coreNum	Optional. The number of cores.	A positive integer	N/A
memSizePerCore	Optional. The memory size of each core.	A positive integer	N/A

4.4.9.7. Text summarization

Automatic summarization uses computers to automatically extract summaries from a source document. A summary is a simple, concise, and short document that completely and accurately describes the content of a certain document. This TextRank-based algorithm generates summaries by extracting existing sentences in the document.

PAI command

```
PAI -name TextSummarization
-project algo_public
-DinputTableName="test_input"
-DoutputTableName="test_output"
-DdocIdCol="doc_id"
-DsentenceCol="sentence"
-DtopN=2
-Dlifecycle=30;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	All partitions in the input table are selected by default.
outputTableName	Required. The name of the output table.	-	-
docIdCol	Required. The name of the document ID column.	-	-
sentenceCol	Required. The sentence column.	Only one column can be specified.	-
topN	Optional. The top N key sentences to be output.	-	3
similarityType	Optional. The method used to calculate sentence similarity.	lcs_sim, levenshtein_sim, cosine, and ssk	lcs_sim

Parameter	Description	Valid values	Default value
lambda	Optional. The weight of the matching string. This parameter takes effect when similarityType is set to ssk.	(0, 1)	0.5
k	Optional. The length of the substring. This parameter takes effect when similarityType is set to ssk or cosine.	(0, 100)	2
dampingFactor	Optional. The damping factor.	(0, 1)	0.85
maxIter	Optional. The maximum number of iterations.	[1, +]	100
epsilon	Optional. The convergence coefficient.	(0, ∞)	0.000001
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	A positive integer	Automatically calculated.

The sentence similarity options are as follows:

- lcs_sim: The formula is `1.0 - (Length of the longest common subsequence)/max(len(A), len(B))`.
- levenshtein_sim: The formula is `1.0 - (Levenshtein distance)/max(len(A), len(B))`.
- cosine: See `Lodhi, Huma; Saunders, Craig; Shawe-Taylor, John; Cristianini, Nello; Watkins, Chris (2002). "Text classification using string kernels". Journal of Machine Learning Research: 419-444`.
- ssk: See `Leslie, C.; Eskin, E.; Noble, W.S. (2002), The spectrum kernel: A string kernel for SVM protein classification 7, pp. 566-575`.

Note `A` and `B` indicate two strings, and `len(A)` indicates the length of string A.

Output format description

The output table contains the doc_id and abstract columns, as shown in Output table example.

Output table example

doc_id	abstract
1000894	In 2008, the Shanghai Stock Exchange published disclosure guidelines for the corporate social responsibility of listed companies. Three types of companies were urged to disclose their CSR reports, and other qualified listed companies were encouraged to voluntarily disclose their CSR reports. In 2012, a total of 379 listed companies making up a 40% of all listed companies disclosed CSR reports. Of those companies, 305 were mandated to disclose CSR reports and and 75 voluntarily disclosed CSR reports. According to Hu Ruyin, Shanghai Stock Exchange will explore how to expand the scope of CSR report disclosure, revise and refine the guidelines on disclosure of the CSR reports, and encourage more organizations to promote CSR product innovation.

4.4.9.8. Keyword extraction

Keyword extraction is one of the important technologies in natural language processing. It is used to extract keywords from a document. This algorithm is based on TextRank, a variation of the PageRank algorithm used to describe the relationship between webpages. This algorithm uses the relationship between certain words to construct a network, calculate the importance of each word, and determine words with larger weights as keywords.

PAI command

```
PAI -name KeywordsExtraction
-DinputTableName=maple_test_keywords_basic_input
-DdocIdCol=docid -DdocContent=word
-DoututTableName=maple_test_keywords_basic_output
-DtopN=19;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-

Parameter	Description	Valid values	Default value
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions are selected by default.
outputTableName	Required. The name of the output table.	-	-
docIdCol	Required. The name of the document ID column.	Only one column can be specified.	-
docContent	Required. The word column.	Only one column can be specified.	-
topN	Optional. The number of top N keywords to be output. If this number is smaller than the number of keywords, all keywords are output.	-	5
windowSize	Optional. The window size of the TextRank algorithm.	-	2
dumpingFactor	Optional. The damping factor of the TextRank algorithm.	-	0.85
maxIter	Optional. The maximum number of iterations of the TextRank algorithm.	-	100
epsilon	Optional. The convergence residual threshold of the TextRank algorithm.	-	0.000001

Parameter	Description	Valid values	Default value
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

Examples

The words in the input table are separated with spaces, and deprecated words and all punctuations are filtered out.

Examples

docid: string	word: string
doc0	The blended-wing-body aircraft is a new direction for the future development in the aviation field Many research institutions inside and outside China have carried out research on the blended-wing-body aircraft while its fully automated shape optimization algorithm has become a new hot topic Based on the existing research achievements inside and outside China common modeling and flow solver tools have been analyzed and compared The geometric modeling grid flow field solver and shape optimization modules have been designed The pros and cons between different algorithms have been compared to achieve the optimized shape of the blended-wing-body aircraft in the conceptual design stage Geometric modeling and grid generation module are achieved based on the transfinite interpolation algorithm and spline based grid generation method The flow solver module includes the finite difference solver the finite element solver and the panel method solver The finite difference solver includes mathematical modeling of the potential flow the derivation of the Cartesian grid based variable step length difference scheme Cartesian grid generation and indexing algorithm the Cartesian grid based Neumann boundary conditions expression form derivation are achieved based on finite element difference solver The aerodynamic parameters of a two-dimensional

docid: string	word: string
	airfoil are calculated based on the finite difference solver The finite element solver includes potential flow modeling based on the variational principle of the finite element theory the derivation of the two-dimensional finite element Kutta conditional least squares based speed solving algorithm Gmsh based two-dimensional field grid generator of airfoil with wakes design The aerodynamic parameters of a two-dimensional airfoil are calculated based on the finite element solver The panel method solver includes modeling and automatic wake generation the design of the three-dimensional flow solver of the blended-wing-body drag estimation based on the Blasius solution solver implemented in the Fortran language a mixed compilation of Python and Fortran OpenMP and CUDA based acceleration algorithm The aerodynamic parameters of a three-dimensional wing body are calculated based on the panel method solver The shape optimization module includes free form deformation algorithm genetic algorithms differential evolution algorithm Aircraft surface area calculation algorithm is based on the moments integration algorithm The volume of an aircraft calculation algorithm is based on VKT data visualization format tool

PAI command

```

4.4.9.9. Sentence splitting

You can split sentences in a document by punctuation. This component is used to preprocess text summarizations. It splits text such that each row contains only a single sentence.

PAI command

```
PAI -name SplitSentences
-project algo_public
-DinputTableName="test_input"
-DoutputTableName="test_output"
-DdocIdCol="doc_id"
-DdocContent="content"
-Dlifecycle=30
```

Parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	All partitions in the input table are selected by default.
outputTableName	Required. The name of the output table.	-	-
docIdCol	Required. The name of the document ID column.	-	-
docContent	Required. The name of the document content column.	Only one column can be specified.	-
delimiter	Optional. A set of characters used to determine the end of a sentence.	-	The default delimiter set contains the period (.), question mark (!), and exclamation mark (?).
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	A positive integer	Automatically calculated.

Output format description

The output table contains the doc_id and sentence columns, as shown in Output table example.

Output table example

doc_id	sentence
1000894	In 2008, the Shanghai Stock Exchange published disclosure guidelines for the corporate social responsibility of listed companies. Three types of companies were urged to disclose their CSR reports, and other qualified listed companies were encouraged to voluntarily disclose their CSR reports.

doc_id	sentence
1000894	In 2012, a total of 379 listed companies making up a 40% of all listed companies disclosed CSR reports. Of those companies, 305 were mandated to disclose CSR reports and and 75 voluntarily disclosed CSR reports.

4.4.9.10. Semantic vector distance

You can calculate the extension words or sentences of the specified words or sentences based on the calculated semantic vectors, such as word vectors calculated by the Word2Vec component. The extension words or sentences are a set of vectors closest to a certain vector. The following example shows how to generate a list of words that are most similar to the word that you entered based on the word vectors calculated by the Word2Vec component.

PAI command

```
PAI -name SemanticVectorDistance
-project algo_public
-DinputTableName="test_input"
-DoutputTableName="test_output"
-DidColName="word"
-DvectorColNames="f0,f1,f2,f3,f4,f5"
-Dlifecycle=30
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	All partitions in the input table are selected by default.
outputTableName	Required. The name of the output table.	-	-
idTableName	Optional. The name of the vector ID table for vector calculation. The table contains only one column and each row stores a vector ID.	-	No vector ID table is specified by default. This means that all vectors in the input table are calculated.

Parameter	Description	Valid values	Default value
idTablePartitions	Optional. The partitions selected from the ID table for calculation.	-	All partitions are selected by default.
idColName	Required. The name of the ID column.	-	3
vectorColNames	Optional. A list of vector column names, such as f1, f2,...	-	-
topN	Optional. The number of the closest vectors to output.	[1, +∞]	5
distanceType	Optional. The distance calculation method.	euclidean, cosine, and manhattan	euclidean
distanceThreshold	Optional. The distance threshold. Only the distances between two vectors that do not exceed this threshold are output.	(0, +∞)	∞
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	A positive integer	Automatically calculated.

Examples

The output table contains the original_id, near_id, distance, and rank columns.

original_id	near_id	distance	rank
hello	hi	0.2	1
hello	xxx	xx	2
Man	Woman	0.3	1
Man	xx	xx	2
..	...	...	...

4.4.9.11. Document similarity

This algorithm calculates the similarity between two text documents by comparing the similarities of documents or sentences separated by spaces. This algorithms functions similar to how the similarity of strings is calculated.

PAI command

```
PAI -name doc_similarity
-project algo_public
-DinputTableName="pai_test_doc_similarity"
-DoutputTableName="pai_test_doc_similarity_output"
-DinputSelectedColName1="col0"
-DinputSelectedColName2="col1"
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
outputTableName	Required. The name of the output table.	-	-
inputSelectedColName1	Optional. The name of the first column for similarity calculation.	-	By default, the first string type column in the table is selected.
inputSelectedColName2	Optional. The name of the second column for similarity calculation.	-	The name of the second string type column in the table is selected by default.
inputAppendColNames	Optional. The names of columns appended to the output table.	-	No column is appended by default.
inputTablePartitions	Optional. The partitions selected from the input table.	-	The whole table is selected by default.

Parameter	Description	Valid values	Default value
outputColName	Optional. The name of the similarity column in the output table. The column name can be up to 128 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.	-	output
method	Optional. The similarity calculation method.	levenshtein, levenshtein_sim, lcs, lcs_sim, ssk, cosine, simhash_hamming, and simhash_hamming_sim	levenshtein_sim
lambda	Optional. The weight of the matching word pair. This parameter takes effect if similarityType is set to ssk.	(0, 1)	0.5
k	Optional. The length of the substring. This parameter takes effect if similarityType is set to ssk or cosine.	(0, 100)	2
kVec	Optional. The number of MinHash instances.	A positive integer	2
b	Optional. The number of buckets.	A positive integer	1
seed	Optional. The random seed used in a MinHash instance.	A positive integer	0
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of (0, 65536)	Automatically calculated.

Examples

- SQL statement to generate data:

```
drop table if exists pai_doc_similarity_input;
create table pai_doc_similarity_input as
select * from (
select 0 as id,
"Beijing and Shanghai" as col0,
"Beijing and Shanghai" as col1 from dual union all
select 1 as id,
"Beijing and Shanghai" as col0,
"Beijing, Shanghai, and Hong Kong" as col1 from dual )tmp;
```

- PAI command

```
drop table if exists pai_doc_similarity_output;
PAI -name doc_similarity
-project algo_public
-DinputTableName=pai_doc_similarity_input
-DoutputTableName=pai_doc_similarity_output
-DinputSelectedColName1=col0
-DinputSelectedColName2=col1
-Dmethod=levenshtein_sim
-DinputAppendColNames=id,col0,col1;
```

- Input description: pai_doc_similarity_input

ID	col0	col1
1	Beijing and Shanghai	Beijing, Shanghai, and Hong Kong
0	Beijing and Shanghai	Beijing and Shanghai

- Output description: pai_doc_similarity_output

ID	col0	col1	Output
1	Beijing and Shanghai	Beijing, Shanghai, and Hong Kong	0.6666666666666667
0	Beijing and Shanghai	Beijing and Shanghai	1.0

4.4.9.12. PMI

Mutual information (MI) is a measure of information in the information theory. It can be regarded as the amount of information contained in a random variable about another variable, or the reduction in uncertainty of a random variable due to the known random variable.

This algorithm is used to count the co-occurrence of all words in several documents and calculate the point mutual information（PMI）. PMI definition: `PMI(x,y)=ln(p(x,y)/(p(x)p(y)))=ln(#(x,y)D/(#x#y))`.

- `#(x,y)` indicates the number of pair(x,y).
- D indicates the total number of pairs.
- If x and y appear in the same window, the output is #x+=1;#y+=1;#(x,y)+=1.

PAI command

```
PAI -name PointwiseMutualInformation
    -project algo_public
    -DinputTableName=maple_test_pmi_basic_input
    -DdocColName=doc
    -DoutputTableName=maple_test_pmi_basic_output
    -DminCount=0
    -DwindowSize=2
    -DcoreNum=1
    -DmemSizePerCore=110;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
outputTableName	Required. The name of the output table.	Table name	-
docColName	Required. The name of the document column after word splitting, where words are separated with spaces.	Column name	-
windowSize	Optional. The window size. For example, the value 5 refers to the five words adjacent on the right of the current word. Words that appear in the window are considered related to the current word.	[1, sentence length]	The whole row is selected by default.

Parameter	Description	Valid values	Default value
minCount	The minimum word truncation frequency. Words that appear for a number of times less than this value are filtered out.	[0, 2e63]	5
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

Examples

- **Data generation**

doc:string
w1 w2 w3 w4 w5 w6 w7 w8 w8 w9
w1 w3 w5 w6 w9
w0
w0 w0
w9 w1 w9 w1 w9

- **PAI command**

```
PAI -name PointwiseMutualInformation
    -project algo_public
    -DinputTableName=maple_test_pmi_basic_input
    -DdocColName=doc
    -DoutputTableName=maple_test_pmi_basic_output
    -DminCount=0
    -DwindowSize=2
    -DcoreNum=1
    -DmemSizePerCore=110;
```

- **Output description**

4.4.9.13. Word frequency statistics

Based on the word splitting results, this component outputs the words in their original order and calculates the frequency that a word occurs in the document (docContent) specified by the document ID column (docId).

Parameter settings

Input parameters: docId column and docContent column generated by the Word Splitting component.

Two output parameters:

- Output port 1: The output table contains the id, word, and count columns.

  count: indicates the frequency that a word occurs in each document.

- Output port 2: The output table contains the id and word columns.

  The table output by the second output port lists words in order of occurrence in the document. The table does not calculate the frequency of the occurrence. Therefore, a word may have multiple table entries in the same document. The output table format is compatible with the Word2Vec component.

Examples

In the Alibaba Cloud word splitting data, the two columns in the output table are used as the input parameters for word frequency calculation.

- Select the docId column: id.
- Select the docContent column: After the word frequency calculation is performed, the result is displayed by output port 1 on this component.

PAI command

```
pai -name doc_word_stat
-project algo_public
-DinputTableName=doc_test_split_word
-DdocId=id
-DdocContent=content
-DoutputTableNameMulti=doc_test_stat_multi
-DoutputTableNameTriple=doc_test_stat_triple
-DinputTablePartitions="region=cctv_news"
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	The name of the input table.	-	-
docId	The name of the document ID column.	Only one column can be specified.	-
docContent	The name of the document content column.	Only one column can be specified.	-

Parameter	Description	Valid values	Default value
outputTableNameMulti	The name of the output table that lists words in the document content after word splitting. Documents are specified by the docId column and their contents are specified by the docContent column. The words are listed in the order that they occur within the documents.	-	-
outputTableNameTriple	The name of the output table that lists the words and the frequency of the occurrence of these words in the documents. The documents are specified by the docId column and their contents are specified by the docContent column.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.

4.4.9.14. TF-IDF

Term frequency-inverse document frequency (TF-IDF) is typically used as a weighting technology in information retrieval and text mining. TF-IDF is a statistical method to evaluate the importance of a word for a document in a collection or corpus. The importance of a word increases as the frequency that it occurs within the document increases. The importance decreases as the frequency that the word occurs in the corpus increases. TF-IDF is frequently used by search engines as a tool in scoring and ranking the correlation between documents and user queries.

- For more information, see TF-IDF in Wikipedia.
- The TF-IDF component is used to calculate the TF-IDF value of each word that appears in a collection of documents based on word frequency statistics.

Examples

The output table in the example of the word frequency statistics component is used as the input table for the TF-IDF component. The corresponding parameter settings are as follows:

- Select the document ID column: id
- Select the word column: word
- Select the word count column: count

The output table contains the following columns: docid, word, word_count (frequency that a certain word occurs in the current document), total_word_count (total number of words in the current document), doc_count (total number of documents that contain the current word), total_doc_count (total number of documents), tf, idf.

PAI command

```
pai -name tfidf
-project algo_public
-DinputTableName=rgdoc_split_triple_out
-DdocIdCol=id
-DwordCol=word
-DcountCol=count
-DoutputTableName=rg_tfidf_out;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	Optional. The partitions selected from the input table for word splitting.	This value must be in the `partition_name=value` format. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	All partitions in the input table are selected by default.
docIdCol	Required. The name of the document ID column.	Only one column can be specified.	-
wordCol	Required. The name of the word column.	Only one column can be specified.	-
countCol	Required. The name of the count column.	Only one column can be specified.	-
outputTableName	Required. The name of the output table.	Table name	-

Parameter	Description	Valid values	Default value
outputTablePartition	The partitions in the output table.	Partition name	The output table is non-partitioned by default.

4.4.9.15. PLDA

Latent Dirichlet Allocation (LDA) is a topic model that outputs the topic of a document. It outputs the topic of each document based on probability distribution. LDA is an unsupervised learning algorithm that does not require a manually tagged training set. Instead, it only requires a set of documents and the number of topics (k). It is used in text mining, including text topic recognition, text classification, and text similarity calculation.

Parameter settings

Parameters

Parameter	Description
Topics	The number of topics output by LDA.
Alpha	The AlphaPrior Dirichlet distribution parameter of `P(z/d)` .
Beta	The AlphaPrior Dirichlet distribution parameter of `P(w/z)` .
Burn-in Iterations	The number of burn-in iterations. The parameter value must be less than the total number of iterations. The default value is 100.
Total Iterations	Optional. The total number of iterations. The parameter value must be a positive integer. The default value is 150.

Note z represents topics, w represents words, and d represents documents.

Input and output settings

- Input:

  The data must be in the sparse matrix format. For more information about the format, see the data format description section. You can use the Convert Row, Column, and Value to KV Pair component to convert the data. Input format as shows the following picture.

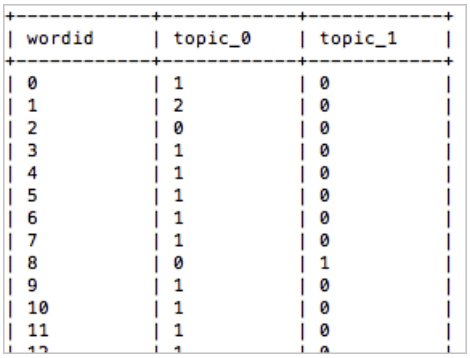
```
| id          | features |
+-------------+----------+
| 2           | 38:3.0,39:1.0,40:3.0,41:1.0,42:1.0,43:2.0,44:1.0,45:1.0,46:1.0,47:1.0,48:1.0,49:2.0,50:1.0,51:1.0,52:1.0,53:1.0,54:1.0,55:1.0,5
6:1.0,57:1.0,58:1.0,59:1.0,60:1.0,61:1.0,62:1.0,63:1.0,64:1.0,65:1.0,66:1.0,67:1.0,68:1.0,69:1.0,70:1.0,71:1.0,72:1.0,73:1.0,74:1.0,75:1.0,76:
1.0,77:2.0 |
| 1           | 0:1.0,1:2.0,3:1.0,4:1.0,5:1.0,6:1.0,7:1.0,8:1.0,9:1.0,10:1.0,11:1.0,12:1.0,13:1.0,14:2.0,15:1.0,16:1.0,17:1.0,18:1.0,19:1.0,20:
1.0,21:1.0,22:1.0,23:1.0,24:1.0,25:1.0,26:1.0,27:1.0,28:1.0,29:1.0,30:1.0,31:1.0,32:1.0,33:1.0,34:1.0,35:1.0,36:2.0,39:2.0,77:3.0 |
+-------------+----------+
```

  - Column 1: the ID of a document.
  - Column 2: KV data of the word and how frequently it occurs.

- Output:

The following tables are generated in sequence: topic-word frequency contribution table, P(w/z) table, P(z/w) table, P(d/z) table, P(z/d) table, and P(z) table.

The following picture shows the output format of the topic-word frequency contribution table.



wordid	topic_0	topic_1
0	1	0
1	2	0
2	0	0
3	1	0
4	1	0
5	1	0
6	1	0
7	1	0
8	0	1
9	1	0
10	1	0
11	1	0

PAI command

```
pai -name PLDA
-project algo_public
-DinputTableName=lda_input
-DtopicNum=10
-topicWordTableName=lda_output;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	Optional. The partitions selected from the input table for word splitting.	This value must be in the `partition_name=value` format. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	All partitions in the input table are selected by default.
selectedColNames	Optional. The names of the columns selected from the input table for LDA.	Separate multiple columns with commas (,).	All columns in the input table are selected by default.

Parameter	Description	Valid values	Default value
topicNum	Required. The number of topics.	[2, 500]	-
kvDelimiter	Optional. The delimiter used to separate the key and value.	Space, comma (,), and colon (:)	The default delimiter is a colon (:).
itemDelimiter	Optional. The delimiter used to separate keys.	Space, comma (,), and colon (:)	The default delimiter is a space.
alpha	Optional. The prior Dirichlet distribution parameter of P(z/d).	(0, ∞)	0.1
beta	Optional. The prior Dirichlet distribution parameter of P(w/z).	(0, ∞)	0.01
topicWordTableName	Required. The name of the topic-word frequency contribution table.	Table name	-
pwzTableName	Optional. The name of the P(w/z) table.	Table name	No P(w/z) table is output by default.
pzwTableName	Optional. The name of the P(z/w) table.	Table name	No P(z/w) table is output by default.
pdzTableName	Optional. The name of the P(d/z) table.	Table name	No P(d/z) table is output by default.
pzdTableName	Optional. The name of the P(z/d) table.	Table name	No P(z/d) table is output by default.
pzTableName	Optional. The name of the P(z) table.	Table name	No P(z) table is output by default.
burnInIterations	Optional. The number of burn-in iterations.	A positive integer	This value must be smaller than the total number of iterations. The default value is 100.
totalIterations	Optional. The number of iterations.	A positive integer	150

4.4.9.16. Word2Vec

Word2Vec is an open-source algorithm used to convert words into vectors. By training neural networks, Word2Vec can map words to K-dimensional space vectors and map word vectors to semantics.

For information about the Google Word2Vec toolkit, visit https://code.google.com/p/word2vec/.

Parameter settings

- Dimension of Word Features: We recommend a value from 0 to 1000.
- Downsampling Threshold: We recommend a value from 1e-3 to 1e-5.
- Input: inputs a word column and a vocabulary.
- Output: generates a word vector table and a vocabulary.

PAI command

```
pai -name Word2Vec
-project algo_public
-DinputTableName=w2v_input
-DwordColName=word
-DoutputTableName=w2v_output;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	Optional. The partitions selected from the input table for word splitting.	The parameter value must be in the `partition_name=value` format. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	All partitions in the input table are selected by default.
wordColName	Required. The name of the word column. Each row in the word column contains a single word. `</s>` is used to break lines in the corpus.	Column name	-

Parameter	Description	Valid values	Default value
inVocabularyTableName	Optional. The name of the input word list, which contains the wordcount output of inputTableName.	Table name	Word count is performed for the input table by default.
inVocabularyPartitions	Optional. The partitions in the input word list.	Partition name	By default, all partitions in the table specified by inVocabularyTableName are selected.
layerSize	Optional. The dimension of word features.	0 to 1000	100
cbow	Optional. The language model.	1: cbow. 0: skip-gram.	0
window	Optional. The size of the word window.	A positive integer	5
minCount	Optional. The minimum frequency of word truncation.	A positive integer	5
hs	Optional. This parameter specifies whether to use hierarchical softmax.	1: Hierarchical softmax is used. 0: Hierarchical softmax is not used.	1
negative	Optional. The negative sampling.	0: Negative sampling is unavailable. Recommended value range: 5 to 10.	0
sample	Optional. The downward sampling threshold.	0 or smaller values: downward sampling is unavailable. Recommended value range: 1e-3 to 1e-5.	0
alpha	Optional. The initial learning rate.	A value greater than 0	0.025
iterTrain	Optional. The number of training iterations.	A value greater than or equal to 1	1

Parameter	Description	Valid values	Default value
randomWindow	Optional. This parameter specifies whether to randomly set the size of the window.	1: The window size is randomly generated.The window size value will range from 1 to 5. 0: The window size is determined by the window parameter.	1
outVocabularyTableName	Optional. The name of the output word list.	Table name	No Output Word List is generated by default.
outVocabularyPartition	Optional. The partition in the output word list.	Partition name	The output word list is non-partitioned by default.
outputTableName	Required. The name of the output table.	Table name	-
outputPartition	Optional. The information about partitions in the output table.	Partition name	The output table is non-partitioned by default.

4.4.10. Network analysis

4.4.10.1. K-core

The k-core of a graph is the largest subgraph in which every vertex is connected to at least k other vertices within the subgraph. The coreness of a vertex is k if it belongs to the k-core but is not included in the (k+1)-core. Therefore, the coreness of a vertex whose degree is 1 must be 0. The graph coreness is equal to that of the vertex with the largest coreness.

Parameter settings

k: Required. The value of the coreness. Default value: 3.

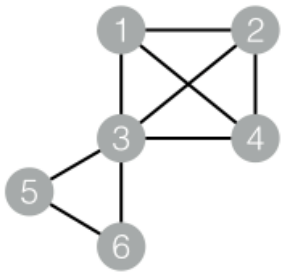
Examples - Testing data

SQL statement to generate data:

```
drop table if exists KCore_func_test_edge;
create table KCore_func_test_edge as
select * from (
select '1' as flow_out_id,
'2' as flow_in_id from dual   union all
select '1' as flow_out_id,
'3' as flow_in_id from dual   union all
select '1' as flow_out_id,
'4' as flow_in_id from dual   union all
select '2' as flow_out_id,
'3' as flow_in_id from dual   union all
select '2' as flow_out_id,
'4' as flow_in_id from dual   union all
select '3' as flow_out_id,
'4' as flow_in_id from dual   union all
select '3' as flow_out_id,
'5' as flow_in_id from dual   union all
select '3' as flow_out_id,
'6' as flow_in_id from dual   union all
select '5' as flow_out_id,
'6' as flow_in_id from dual )tmp;
```

Graph structure shows the group structure.

Graph structure



Set K to 2. Output shows the output.

Output

```
+-------+-------+
| node1 | node2 |
+-------+-------+
| 1     | 2     |
| 1     | 3     |
| 1     | 4     |
| 2     | 1     |
| 2     | 3     |
| 2     | 4     |
| 3     | 1     |
| 3     | 2     |
| 3     | 4     |
| 4     | 1     |
| 4     | 2     |
| 4     | 3     |
+-------+-------+
```

PAI command

```
pai -name KCore
-project algo_public
-DinputEdgeTableName=KCore_func_test_edge
-DfromVertexCol=flow_out_id
-DtoVertexCol=flow_in_id
-DoutputTableName=KCore_func_test_result
-Dk=2;
```

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the edge table.	Yes	-
toVertexCol	The end vertex column in the edge table.	Yes	-
outputTableName	The name of the output table.	Yes	-
outputTablePartitions	The partitions in the output table.	No	-

Parameter	Description	Required	Default value
lifecycle	The lifecycle of the output table.	No	-
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096
splitSize	The data split size.	No	64
k	The number of cores.	Yes	3

4.4.10.2. Single-source shortest path

The single-source shortest path (SSSP) refers to the shortest path between a vertex and all other vertices as calculated by the Dijkstra algorithm.

Parameter settings

Start Vertex ID: Required. The ID of the start vertex used to calculate the shortest paths.

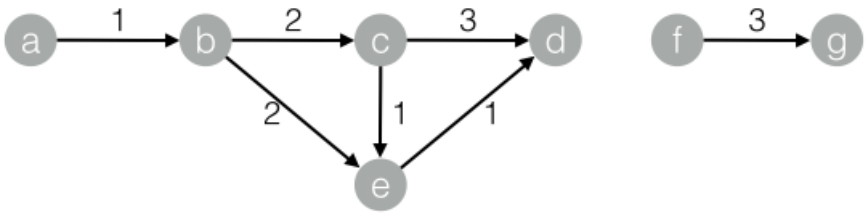
Examples - Testing data

SQL statement to generate data:

```
drop table if exists SSSP_func_test_edge;
create table SSSP_func_test_edge
as select
flow_out_id,flow_in_id,edge_weight from (
select "a" as flow_out_id,
"b" as flow_in_id,
1.0 as edge_weight from dual    union all
select "b" as flow_out_id,
"c" as flow_in_id,
2.0 as edge_weight from dual    union all
select "c" as flow_out_id,
"d" as flow_in_id,
1.0 as edge_weight from dual    union all
select "b" as flow_out_id,
"e" as flow_in_id,
2.0 as edge_weight from dual    union all
select "e" as flow_out_id,
"d" as flow_in_id,
1.0 as edge_weight from dual    union all
select "c" as flow_out_id,
"e" as flow_in_id,
1.0 as edge_weight from dual    union all
select "f" as flow_out_id,
"g" as flow_in_id,
3.0 as edge_weight from dual    union all
select "a" as flow_out_id,
"d" as flow_in_id,
4.0 as edge_weight from dual ) tmp ;
```

Graph structure shows the graph structure.

Graph structure



Output

```
+------------+------------+------------+--------------+
| start_node | dest_node  | distance   | distance_cnt |
+------------+------------+------------+--------------+
| a          | b          | 1.0        | 1            |
| a          | c          | 3.0        | 1            |
| a          | d          | 4.0        | 3            |
| a          | a          | 0.0        | 0            |
| a          | e          | 3.0        | 1            |
+------------+------------+------------+--------------+
```

PAI command

```
pai -name SSSP
-project algo_public
-DinputEdgeTableName=SSSP_func_test_edge
-DfromVertexCol=flow_out_id
-DtoVertexCol=flow_in_id
-DoutputTableName=SSSP_func_test_result
-DhasEdgeWeight=true
-DedgeWeightCol=edge_weight
-DstartVertex=a;
```

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	-
toVertexCol	The end vertex column in the input edge table.	Yes	-
outputTableName	The name of the output table.	Yes	-
outputTablePartitions	The partitions in the output table.	No	-
lifecycle	The lifecycle of the output table.	No	-

Parameter	Description	Required	Default value
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096
splitSize	The data split size.	No	64
startVertex	The ID of the start vertex.	Yes	-
hasEdgeWeight	Specifies whether the edges in the input edge table have weights.	No	false
edgeWeightCol	The edge weight column in the input edge table.	No	-

4.4.10.3. PageRank

The PageRank algorithm is used to sort and calculate the rankings of web pages based on their link sources.

Features

The basic principle of the PageRank algorithm is as follows: The more web pages that direct to a web page, the more importance or higher quality the web page has. In addition to the number of links directing to a web page, the weight of the web page and the number of outgoing links are also considered during page ranking. For a social network of users, the edge weight is an important factor in addition to the influence of the users. For example, a Sina Weibo user is more likely to have influence on their family, friends, classmates, and colleagues than they will on followers with a weaker relationship. In the social network, the edge weight is equivalent to the user-to-user relationship strength index. The PageRank formula with connection weight is as follows:

$$W(A) = (1 - d) + d * (\sum_{i} W(i) * C(Ai))$$

In the formula, W(i) represents the weight of node i, C(A,i) represents the link weight, and d represents the damping coefficient. W is the influence index of each user and represents the node weight after the algorithm iteration becomes stable.

Parameter settings

Maximum Iterations: Optional. The number of iterations performed before the algorithm automatically converges. Default value: 30.

Examples - Testing data

SQL statement to generate data:

```
drop table if exists PageRankWithWeight_func_test_edge;
create table PageRankWithWeight_func_test_edge
as select * from (
select 'a' as flow_out_id,
'b' as flow_in_id,
1.0 as weight from dual    union all
select 'a' as flow_out_id,
'c' as flow_in_id,
1.0 as weight from dual    union all
select 'b' as flow_out_id,

-DmaxIter 100;
```

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	-
toVertexCol	The end vertex column in the input edge table.	Yes	-
outputTableName	The name of the output table.	Yes	-
outputTablePartitions	The partitions in the output table.	No	-
lifecycle	The lifecycle of the output table.	No	-
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096
splitSize	The data split size.	No	64

Parameter	Description	Required	Default value
hasEdgeWeight	Specifies whether the edges in the input edge table have weights.	No	false
edgeWeightCol	The edge weight column in the input edge table.	No	-
maxIter	The maximum number of iterations.	No	30

4.4.10.4. Label propagation clustering

Graph clustering is used to divide a graph into subgraphs based on the topology of the graph so that the links between the nodes in a subgraph are more than the links between the subgraphs. The label propagation algorithm (LPA) is a graph-based semi-supervised machine learning algorithm. The labels of a node (community) depend on those of the neighboring nodes. The degree of dependence is determined by the similarity between nodes. Data becomes stable by iterative propagation update.

Parameters

Maximum Iterations: Optional. The maximum number of iterations. Default value: 30.

Examples - Testing data

SQL statement to generate data:

```
drop table if exists LabelPropagationClustering_func_test_edge;
create table LabelPropagationClustering_func_test_edge
as select * from (
select '1' as flow_out_id,
'2' as flow_in_id,
0.7 as edge_weight from dual    union all
select '1' as flow_out_id,
'3' as flow_in_id,
0.7 as edge_weight from dual    union all
select '1' as flow_out_id,
'4' as flow_in_id,
0.6 as edge_weight from dual    union all
select '2' as flow_out_id,
'3' as flow_in_id,
0.7 as edge_weight from dual    union all
select '2' as flow_out_id,
'4' as flow_in_id,
```

```
0.6 as edge_weight from dual    union all
select '3' as flow_out_id,
'4' as flow_in_id,
0.6 as edge_weight from dual    union all
select '4' as flow_out_id,
'6' as flow_in_id,

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	-
toVertexCol	The end vertex column in the input edge table.	Yes	-
inputVertexTableName	The name of the input vertex table.	Yes	-
inputVertexTablePartitions	The partitions in the input vertex table.	No	The whole table is selected by default.
vertexCol	The vertex column in the input vertex table.	Yes	-
outputTableName	The name of the output table.	Yes	-

Parameter	Description	Required	Default value
outputTablePartitions	The partitions in the output table.	No	-
lifecycle	The lifecycle of the output table.	No	-
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096
splitSize	The data split size.	No	64
hasEdgeWeight	Specifies whether the edges in the input edge table have weights.	No	false
edgeWeightCol	The edge weight column in the input edge table.	No	-
hasVertexWeight	Specifies whether the vertices in the input vertex table have weights.	No	false
vertexWeightCol	The vertex weight column in the input vertex table.	No	-
randSelect	Specifies whether the maximum label value is to be randomly selected.	No	false
maxIter	The maximum number of iterations.	No	30

4.4.10.5. Label propagation classification

Label propagation classification is a semi-supervised classification algorithm. It uses the label information of labeled nodes to predict the label information for unlabeled nodes.

Features

During algorithm execution, the labels of each node are propagated to the neighboring nodes based on the similarity between the nodes. In each step of propagation, a node updates its labels based on the labels of the neighboring nodes so that the node is more similar to the neighboring nodes. The higher the similarity, the more labeling influences the neighboring nodes have on that node, and the easier it is for the labels to be propagated. During label propagation, the labels of the labeled data remain unchanged. These labels serve as sources for propagation to the unlabeled data.

After the iterations end, the probability distributions of similar nodes tend to be similar. These nodes can be classified into the same category. This completes the label propagation.

Parameter settings

Damping factor: The default value is 0.8. Convergence factor: The default value is 0.000001.

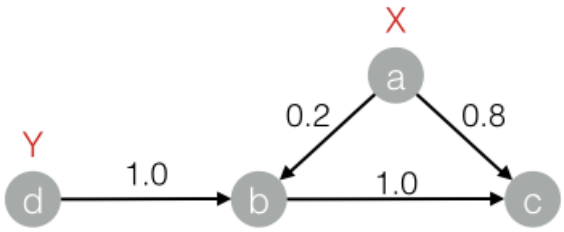
Examples - Testing data

SQL statement to generate data:

```
drop table if exists LabelPropagationClassification_func_test_edge;
create table LabelPropagationClassification_func_test_edge
as select * from (
select 'a' as flow_out_id,
'b' as flow_in_id,
0.2 as edge_weight from dual    union all
select 'a' as flow_out_id,
'c' as flow_in_id,
0.8 as edge_weight from dual    union all
select 'b' as flow_out_id,
'c' as flow_in_id,
1.0 as edge_weight from dual    union all
select 'd' as flow_out_id,
'b' as flow_in_id,
1.0 as edge_weight from dual )tmp ;
drop table if exists LabelPropagationClassification_func_test_node;
create table LabelPropagationClassification_func_test_node
as select * from (
select 'a' as node,
'X' as label,
1.0 as label_weight from dual    union all
select 'd' as node,
'Y' as label,
1.0 as label_weight from dual )tmp ;
```

Graph structure shows the graph structure.

Graph structure



Output

node	tag	weight
a	X	1.0
b	X	0.16667
b	Y	0.83333
c	X	0.53704
c	Y	0.46296
d	Y	1.0

PAI command

-DfromGroupCol=group_out_id
-DtoVertexCol=flow_in_id
-DtoGroupCol=group_in_id
-DoutputTableName=Modularity_func_test_result;
```

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	-
fromGroupCol	The start vertex group in the input edge table.	Yes	-
toVertexCol	The end vertex column in the input edge table.	Yes	-
toGroupCol	The end vertex group in the input edge table.	Yes	-
outputTableName	The name of the output table.	Yes	-
outputTablePartitions	The partitions in the output table.	No	-
lifecycle	The lifecycle of the output table.	No	-
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096
splitSize	The data split size.	No	64

4.4.10.7. Maximum connected subgraph

In an undirected graph G, vertex A is connected to vertex B if a path exists between the two vertices. Graph G contains several subgraphs. Each vertex is connected to other vertices in the same subgraph. Vertices in different subgraphs are not connected. In this case, the subgraphs of graph G are called maximum connected subgraphs.

Features

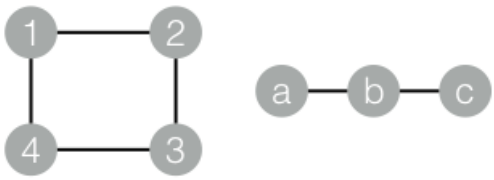
Examples - Testing data

SQL statement to generate data:

```
drop table if exists MaximalConnectedComponent_func_test_edge;
create table MaximalConnectedComponent_func_test_edge
as select * from (
select '1' as flow_out_id,
'2' as flow_in_id from dual   union all
select '2' as flow_out_id,
'3' as flow_in_id from dual   union all
select '3' as flow_out_id,
'4' as flow_in_id from dual   union all
select '1' as flow_out_id,
'4' as flow_in_id from dual   union all
select 'a' as flow_out_id,
'b' as flow_in_id from dual   union all
select 'b' as flow_out_id,
'c' as flow_in_id from dual )tmp;
drop table if exists MaximalConnectedComponent_func_test_result;
create table MaximalConnectedComponent_func_test_result (   node string,   grp_id string );
```

Graph structure shows the graph structure.

Graph structure



Output

node	grp_id
1	4
2	4
3	4
4	4
a	c
b	c
c	c

PAI command

```
pai -name MaximalConnectedComponent
-project algo_public
-DinputEdgeTableName=MaximalConnectedComponent_func_test_edge

-DtoVertexCol=flow_in_id
-DoutputTableName=MaximalConnectedComponent_func_test_result;
```

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	-
toVertexCol	The end vertex column in the input edge table.	Yes	-
outputTableName	The name of the output table.	Yes	-
outputTablePartitions	The partitions in the output table.	No	-
lifecycle	The lifecycle of the output table.	No	-
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096
splitSize	The data split size.	No	64

4.4.10.8. Vertex clustering coefficient

This coefficient is used to calculate the peripheral density of a vertex in an undirected graph G. The density of a star network is 0, and that of a fully meshed network is 1.

Parameter settings

maxEdgeCnt: Optional. If the node degree is larger than the value of this parameter, sampling is required. Default value: 500.

Examples - Testing data

SQL statement to generate data:

```
drop table if exists NodeDensity_func_test_edge;
create table NodeDensity_func_test_edge
as select * from (
select '1' as flow_out_id,
'2' as flow_in_id from dual   union all

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.

Parameter	Description	Required	Default value
fromVertexCol	The start vertex column in the input edge table.	Yes	-
toVertexCol	The end vertex column in the input edge table.	Yes	-
outputTableName	The name of the output table.	Yes	-
outputTablePartitions	The partitions in the output table.	No	-
lifecycle	The lifecycle of the output table.	No	-
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096
splitSize	The data split size.	No	64

4.4.11. Tools

4.4.11.1. SQL script

You can use the SQL script editor to write SQL statements.

1. Drag and drop the **SQL Script** component onto the canvas.
2. Connect the input table to the **SQL Script** component, and then click **SQL Script**. The following configuration pane is displayed.
3. Write an SQL script in the text box.
   - An SQL script supports one to four inputs and one output.
   - You can write only one SQL statement.
   - The input data is automatically mapped to tables t1 through t4. You can directly call ${t1}, ${t2}, ${t3}, and ${t4} without specifying the table names.
   - The sample SQL script calculates the number of rows in the input table.

4.4.12. Financials

4.4.12.1. Binning

The Binning component performs data binning based on equal-width or equal-frequency.

PAI command

```
PAI -name binning
    -project algo_public
    -DinputTableName=input
    -DoutputTableName=output
```

Parameters

Parameter	Description	Valid value	Default
inputTableName	Required. The name of the input table.	Table name	N/A
outputTableName	Required. The name of the output table.	Table name	N/A
selectedColNames	Optional. The names of columns selected from the input table for data binning.	Column name	All columns are selected, except for the label column.
labelColumn	Optional. The name of the column that stores the labels.	Column name	No label column is selected.
validTableName	Required when the binning mode (binningMethod) is set to auto. The name of the table used for calibration.	Table name	No table is specified for calibration.
validTablePartitions	Optional. The partitions selected from the calibration table.	Partition name	The whole table is selected.
inputTablePartitions	Optional. The partitions selected from the input table.	Partition name	The whole table is selected.
inputBinTableName	Optional. The name of the input binning table.	Table name	No binning table is specified.
selectedBinColNames	Optional. The names of the columns selected from the binning table.	Column name	No column is selected.

Parameter	Description	Valid value	Default
positiveLabel	Optional. The value used to represent positive samples.	N/A	1
nDivide	Optional. The number of bins.	A positive integer	10
colsNDivide	Optional. The numbers of bins customized for specified columns. Example: col0:3,col2:5. Columns specified in the colsNDivide parameter but not included in the selectedColNames parameter are also processed by the Binning component. For example, if selectedColNames is set to col0,col1 and colsNDivide is set to col0:3,col2:5, data binning is perform based on col0:3,col1:10,col2:5.	N/A	No custom binning rule is specified.
isLeftOpen	Optional. The type of the interval, which can be left-open, right-closed or left-closed, right-open.	true and false	true
stringThreshold	Optional. The discrete value threshold. Values below this threshold are put into other bins.	N/A	No discrete value threshold is set.
colsStringThreshold	Optional. The thresholds for specified columns. Specify the values in the same format of the colsNDivide parameter.	N/A	No threshold is set.

Parameter	Description	Valid value	Default
binningMethod	Optional. The binning mode.	quantile (equal-frequency), bucket (equal-width), and auto (automatic binning). If you select auto, monotonic binning is used based on equal-frequency.	quantile
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size per core.	A positive integer	Automatically calculated.

Constraints

Binning constraints must be used together with the Scorecard Training component. You can add constraints to the weight of each dummy variable when the Binning component discretizes features and transforms them into dummy variables. The definitions of the constraints are as follows:

- Ascending order: adds weights to the dummy variables of a feature based on the index values in ascending order. This means that dummy variables with higher index values have larger weights.
- Descending order: adds weights to the dummy variables of a feature based on the index values in descending order. This means that dummy variables with lower index values have lighter weights.
- Same weight: the weights of two dummy variables of a feature must be the same.
- Set weight to 0: sets the weight of a dummy variable to 0.
- Set weight to a specified value: sets the weight of a dummy variable to a floating point value.
- WOE order: adds weights to the dummy variables of a feature based on the WOE values in ascending order. This means that dummy variables with higher WOE values have larger weights.

4.4.12.2. Data conversion

Parameters

Parameter	Description
inputFeatureTableName	Required. The name of the input feature table.
inputBinTableName	Required. The name of the binning result table.

Parameter	Description
inputFeatureTablePartitions	Optional. The partitions selected from the feature table. By default, all partitions are selected.
outputTableName	Required. The name of the output table.
featureColNames	Optional. The names of the features selected from the input feature table. By default, all columns are selected.
metaColNames	Optional. The names of the columns to be reserved in the output table without data conversion. By default, no column is reserved. You can specify columns such as label and sample_id.
transformType	Optional. The type of data conversion. Valid values: normalize (normalization), dummy (discretization), and woe (WOE transformation). The default is dummy.
itemDelimiter	Optional. The delimiter used to separate features. By default, commas (,) are used. Only data discretization supports this parameter.
kvDelimiter	Optional. The delimiter used to separate keys and values. By default, colons (:) are used. Only data discretization supports this parameter.
lifecycle	Optional. The lifecycle of the output table. By default, no lifecycle is set.
coreNum	Optional. The number of cores. By default, the number of cores is automatically calculated.
memSizePerCore	Optional. The memory size per core in megabytes. By default, the memory size per core is automatically calculated.

instance

PAI command

```
PAI -name data_transform
-project algo_public
-DinputFeatureTableName=feature_table
-DinputBinTableName=bin_table
-DoutputTableName=output_table
-DmetaColNames=label
-DfeatureColNames=feaname1,feaname2
```

Normalization

The Normalization component transforms variable values to a scale of 0 to 1. Missing values are imputed with zeros. The algorithm is as follows:

```
if feature_raw_value == null or feature_raw_value == 0 then
   feature_norm_value = 0.0
else
   bin_index = FindBin(bin_table, feature_raw_value)
   bin_width = round(1.0 / bin_count * 1000) / 1000.0
   feature_norm_value = 1.0 - (bin_count - bin_index - 1) * bin_width
```

Output format

Normalization and WOE conversion tables output regular tables.

Dummy variable conversion in discretization outputs a table that contains KV pairs. The output variables are in the format of [${feaname}]\_bin\_${bin_id}. Taking variable sns as an example:

- If the variable sns is put into the second bin, the output variable is `[sns]_bin_2`.
- If the variable sns does not have a value, it is put into an empty bin. The output variable is `[sns]_bin_null`.
- If the variable sns has a value but it cannot be put into any of the predefined bins, it is put into the else bin. The output variable is `[sns]_bin_else`.

4.4.12.3. Scorecard training

The scorecard is a modeling tool widely used for credit score evaluation. It uses binning to discretize variables, and then uses linear models (logistic regression or linear regression) to train a model. The model training process includes feature selection and score transformation. The scorecard also allows you to add constraints to the variables during model training.

> **Note** If you use the scorecard without binning, the entire model training process is equivalent to logistic regression or linear regression.

Feature engineering

The main difference between the scorecard and normal linear models is that the scorecard performs feature engineering before it trains linear models. The Scorecard component provides two methods for feature engineering. You must use binning to discretize the features first no matter which method you choose. One of the methods is to use one hot encoding to encode the variable binning results, and then generate N dummy variables. N represents the number of bins. The other method is to use Weight of Evidence (WOE) transformation. It replaces the original value of a variable with the WOE value of the bin where the variable is placed.

> **Note** You can add constraints for each variable when you transform variables to dummy variables.

Score transformation

In the credit score evaluation scenario, you must use linear transformation to transform the odds of the samples in the prediction results to credit scores as follows:

```
log(odds) = \sum(wx) = a scaled_score + b
```

The parameters in the formula are as follows:

- scaledValue: specifies a base point to be scaled.
- odds: specifies an odd level.
- pdo: specifies the points to double the odds.

For example, if the scaledValue, odds, and pdo parameters are set to 800, 50, and 25, the two vectors that determine the score scale are as follows:

```
log(40) = a * 800 + b
log(80) = a * 825 + b
```

Calculate the values of a and b, and then perform a linear transformation to obtain the scores.

The scaling information is specified in JSON format by using the -Dscale parameter as follows:

```
{"scaledValue":800,"odds":50,"pdo":25}
```

The three parameters must be set at the same time.

Add constraints

You can add constraints for variables during scorecard training. You can set the score of a bin to a fixed value, set a proportion between the scores of two bins, or limit the scores of bins. For example, you can sort the scores of the bins by WOE. The implementation of constraints depends on the underlying optimization algorithms with constraints. You can set a constraint in the Binning component. After you set the parameters, the component generates a constraint in JSON format, and then passes the constraint to the component connected to it. The supported constraints are as follows:

- <: sorts the weights of the variables in ascending order.
- >: sorts the weights of the variables in descending order.
- =: sets the weights of the variables to a fixed value.
- %: sets a proportion between the weights of two variables.
- UP: sets an upper limit for the weights of the variables.
- LO: sets a lower limit for the weights of the variables.

A constraint is stored in a table as a JSON string. The table contains only one row and one column.

```
{
  "name": "feature0",
  "<": [
    [0,1,2,3]
  ],
  ">": [
    [4,5,6]
  ],
  "=": [
    "3:0","4:0.25"
  ],
  "%": [
    ["6:1.0","7:1.0"]
  ]
}
```

Built-in constraints

Every original variable has a default constraint. The average score of the population in a variable must be 0. Based on this constraint, the scaled_weight in the intercept options of the scorecard model equals the average score of the entire population.

Optimization algorithms

In the advanced options of the Scorecard component, you can select optimization algorithms to be used in model training. The supported optimization algorithms are as follows:

- L-BFGS
- Newton's Method
- Barrier Method
- SQP

L-BFGS is a first-order optimization algorithm for processing large amounts of feature data. Newton's Method is a classic tier-2 optimization algorithm. It is fast in regression and accurate. However, it is not suitable for processing large amounts of feature data because it needs to calculate the second-order Hessian Matrix. The two algorithms do not have any constraints. When these algorithms are selected, the system automatically ignores the constraints.

If you do not want the system to ignore the constraints, select Barrier Method or SQP. Barrier Method and SQP are second-order optimization algorithms. When no constraint is set, they are equivalent to Newton's Method. Barrier Method and SQP have minor differences in performance and accuracy. We recommend that you choose SQP. If you are not familiar with optimization algorithms, we recommend that you choose the Auto-selected by default option. The system will automatically select an optimization algorithm based on the amount of the data and the constraints.

Feature selection

The Scorecard component supports stepwise feature selection. Stepwise is a combination of forward selection and backward selection. Each time the system selects a new variable by forward selection and adds it to the model, it must perform a backward selection. The backward selection starts with the variables in the model, and eliminates the ones with significance not meeting the requirements. Stepwise feature selection supports various types of target functions and feature transformation methods. Therefore, stepwise feature selection also supports multiple selection standards. Currently, the following standards are supported:

- Marginal contribution: It can be applied to all target functions and feature engineering methods.
- Score test: It only supports WOE transformation and logistic regression without feature engineering.
- F test: It only supports WOE transformation and linear regression without feature engineering.

Marginal contribution

The marginal contribution is the difference between the target functions of Model A without Variable X and target functions of Model B with Variable X after both models are trained. It is the marginal contribution of Variable X to all the other variables in Model B. In the scenario of transforming variables to dummy variables by feature engineering, the marginal contribution of Variable X is the difference between the target functions of all dummy variables in Model A without Variable X and target functions of all dummy variables in Model B with Variable X. Therefore, using marginal contribution to select features is supported by all feature engineering methods.

Marginal contribution makes feature selection more open-ended. It is not restricted to a certain type of models. Only variables that contribute to the target functions are passed to the model. Marginal contribution has certain disadvantages when compared with statistical significance. Typically, statistical significance chooses 0.05 as its threshold. Marginal contribution does not provide a recommended threshold for beginners. We recommend that you set the threshold to 10E-5.

Score test

Score test is only suitable for feature selection in logistic regression. During a forward selection, a model with only intercept options is trained first. In each subsequent regression, the score chi-squares of the variables that have not been passed to the model are calculated. The variable with the largest score chi-square is passed to the model. The P-value corresponds to the largest score chi-square is also calculated based on chi-square distribution. If the P-value is greater than the given SLENTRY value, feature selection is complete.

After the forward selection is complete, a backward selection is performed for the variable passed to the model. The Wald chi-square of the variable and the corresponding P-value are calculated. If the P-value is greater than the given SLSTAY value, the variable is removed from the model. The system then starts a new regression.

F test

F test is only suitable for feature selection in linear regression. During a forward selection, a variable with only intercept options is trained first. In each subsequent regression, the F-values of the variables that have not been passed to the model are calculated. F-value calculation is similar to marginal contribution calculation. Both of them need to train two models to calculate the F-value of a variable. The F-value fits the F distribution. The corresponding P-value can be calculated based on the probability density function of the F distribution. If the P-value is greater than the given SLENTRY value, the variable is not passed to the model, and the forward selection is complete.

The backward selection process uses the F-value to calculate the significance of the variable in a way similar to a score test.

Forcibly selected variables

Before you perform feature selection, you can specify variables to be forcibly passed to the model. The specified variables are passed to the model regardless of their significance. No forward selection or backward selection is performed for these variables.

The number of regressions and significance levels (SLENTRY and SLSTAY) are defined by using a JSON string in the -Dselected parameter as follows:

```
{"max_step":2, "slentry": 0.0001, "slstay": 0.0001}
```

If the -Dselected parameter is left empty or max_step is set to 0, no feature selection is performed.

Model report

The Scorecard component outputs data to a model report. The model report contains basic model evaluation statistics, such as the binning information, binning constraints, WOE values, and marginal contribution information. The following table lists the fields contained in the model report:

Field	Type	Description
feaname	string	The name of the feature.
binid	bigint	The ID of a bin.
bin	string	The description of the bin, which indicates the interval of the bin.
constraint	string	The constraints of the bin specified for model training.
weight	double	The weight of a binning variable. For a non-scorecard model without binning, this field indicates the weight of a model variable.

Field	Type	Description
scaled_weight	double	For score transformation in scorecard training, this field indicates the score linearly transformed from the weight of a binning variable.
woe	double	A statistical indicator. It indicates the WOE value of a bin in the training set.
contribution	double	A statistical indicator. It indicates the marginal contribution value of a bin in the training set.
total	bigint	A statistical indicator. It indicates the total number of samples in a bin in the training set.
positive	bigint	A statistical indicator. It indicates the number of positive samples in a bin in the training set.
negative	bigint	A statistical indicator. It indicates the number of negative samples in a bin in the training set.
percentage_pos	double	A statistical indicator. It indicates the proportion between positive samples in a bin and total positive samples in the training set.
percentage_neg	double	A statistical indicator. It indicates the proportion between negative samples in a bin and total negative samples in the training set.
test_woe	double	A statistical indicator. It indicates the WOE value of a bin in the testing set.
test_contribution	double	A statistical indicator. It indicates the marginal contribution value of a bin in the testing set.

Field	Type	Description
test_total	bigint	A statistical indicator. It indicates the total number of samples in a bin in the testing set.
test_positive	bigint	A statistical indicator. It indicates the number of positive samples in a bin in the testing set.
test_negative	bigint	A statistical indicator. It indicates the number of negative samples in a bin in the testing set.
test_percentage_pos	double	A statistical indicator. It indicates the proportion between positive samples in a bin and total positive samples in the testing set.
test_percentage_neg	double	A statistical indicator. It indicates the proportion between negative samples in a bin and total negative samples in the testing set.

Algorithm parameters

Parameter	Description	Valid value	Default
inputTableName	Required. The input table that contains features.	N/A	N/A
inputTablePartitions	Optional. The partitions selected from the input table.	N/A	The whole table is selected.
inputBinTableName	Optional. The binning result table. If this parameter is set, the system automatically discretizes the original features based on the binning rules in the binning result table.	N/A	N/A

Parameter	Description	Valid value	Default
featureColNames	Optional. The names of feature columns selected from the input table.	N/A	All columns in the input table are selected by default, except for the label column.
labelColName	Required. The names of the target columns.	N/A	N/A
outputTableName	Required. The name of the output table.	N/A	N/A
inputConstraintTableName	Optional. A constraint. The constraint is a JSON string stored in a cell of a table.	N/A	
optimization	Optional. The optimization algorithm.	lbfgs, newton, barrier_method, sqp, and auto. Currently, only the sqp and barrier_method algorithms support constraints. If you set the value to auto, the system automatically selects an optimization algorithm based on the input data and corresponding parameters. We recommend that you set the value to auto if you are unfamiliar with the listed optimization algorithms.	auto
loss	Optional. The type of the loss function.	logistic_regression and least_square.	logistic_regression
iterations	Optional. The maximum number of regressions.	N/A	100
l1Weight	Optional. The weight of the L1 regularization parameter. Currently, only lbfgs supports l1weight.	N/A	0

Parameter	Description	Valid value	Default
l2Weight	Optional. The weight of the L2 regularization parameter.	N/A	0
m	Optional. The number of regressions performed by L-BFGS. Only L-BFGS supports this parameter.	N/A	10
scale	Optional. The weight scaling information of the scorecard.	N/A	Null
selected	Optional. Feature selection in scorecard training.	N/A	Null
convergenceTolerance	Optional. The convergence tolerance.	N/A	1e-6
positiveLabel	Optional. The category of positive samples.	N/A	1
lifecycle	Optional. The lifecycle of the output table.	N/A	No lifecycle is set.
coreNum	Optional. The number of vCores.	N/A	Automatically calculated.
memSizePerCore	Optional. The memory size per core.	N/A	Automatically calculated.

4.4.12.4. Scorecard prediction

The Scorecard Prediction component predicts credit scores based on the input data. It uses a model generated by a model training component. Supported model training components include the Scorecard Training, Logistic Regression for Binary Classification (in the Financials folder), and Linear Regression (in the Financials folder) components.

Input parameters

The Scorecard Prediction component has the following parameters:

- **Feature Column**: specifies the feature columns to be used for predicting credit scores. By default, all columns are selected.
- **Columns Reserved in Result Table**: specifies the columns to be appended to the prediction result table without any changes, such as the ID column and target column.

- **Output Variable Score**: specifies whether to output the score of each variable. The final score equals the score in the intercept option plus the scores of all variables.

Score table

The following is an example of the score table output by the component.

The first column churn is the column appended to the result table from the input table. The data in this column does not affect the prediction results. The remaining three columns display the prediction results. The definitions of these columns are as follows:

Column name	Type	Description
prediction_score	Double	The predicted scores column. In a linear model, the feature values and model weight values are summed up or multiplied to obtain the predicted scores. In a scorecard model, if score transformation is performed, the transformed scores are input into this column.
prediction_prob	Double	The probability values of positive samples in binary classification. The probability values are transformed from the original scores (before score transformation) by using the sigmoid function.
prediction_detail	String	The probability values of positive and negative samples described in JSON strings. Value 0 represents negative and value 1 represents positive. Example: { “0” :0.1813110520,” 1” :0.8186889480}.

PAI command

```
pai -name=lm_predict
    -project=algo_public
    -DinputFeatureTableName=input_data_table
    -DinputModelTableName=input_model_table
    -DmetaColNames=sample_key,label
    -DfeatureColNames=fea1,fea2
    -DoutputTableName=output_score_table
```

Algorithm parameters

Parameter	Description	Valid value	Default
inputFeatureTableName	Required. The name of the input table that stores feature data.	N/A	N/A
inputFeatureTablePartitions	Optional. The partitions selected from the input table.	N/A	The whole table is selected.
inputModelTableName	Required. The name of the model table.	N/A	N/A
featureColNames	Optional. The names of the feature columns selected from the input table.	N/A	All columns are selected.
metaColNames	Optional. The names of the columns to be reserved in the result table.	N/A	The meta column is excluded. You can specify columns such as label and sample_id.
outputFeatureScore	Optional. It specifies whether to output variable scores to the result table.	true and false	false
outputTableName	Required. The name of the result table.	N/A	N/A
lifecycle	Optional. The lifecycle of the result table.	N/A	No lifecycle is set.
coreNum	Optional. The number of cores.	N/A	Automatically calculated.
memSizePerCore	Optional. The memory size per core.	N/A	Automatically calculated.

4.4.12.5. PSI

Population stability index (PSI) is an important metric to identify a shift in two samples of a population. For example, you can use it to measure whether the changes in the population within two months are stable. A PSI value smaller than 0.1 indicates insignificant changes. A PSI value between 0.1 and 0.25 indicates minor changes. A PSI value greater than 0.25 indicates major changes in the population.

When the changes in a population over time are unstable, you can use charts to identify the changes. You can use binning to discretize variables into multiple bins, calculate the number and proportion of the samples in each bin, and then display the statistics in a chart, as shown in the following figure.

This method can directly show whether a variable in two samples changes significantly. However, the shift in these changes cannot be measured by using this method. This means that the population stability cannot be automatically monitored. To resolve this issue, you can use the PSI component. Before you use the PSI component, you must use the Binning component to discretize the data. The formula for calculating PSI values is as follows:

Examples

The following figure shows a use case of the PSI component. The PSI component is connected to the Binning component and two sample datasets. You only need to specify the columns for PSI calculation in the PSI component.

Result

PAI command

```
PAI -name psi
-project algo_public
-DinputBaseTableName=psi_base_table
-DinputTestTableName=psi_test_table
-DoutputTableName=psi_bin_table
-DinputBinTableName=pai_index_table
-DfeatureColNames=fea1,fea2,fea3
-Dlifecycle=7
```

Algorithm parameters

Parameter	Description	Valid value	Default
inputBaseTableName	Required. The name of the base table. The shift of the population is calculated based on the samples in the base and test tables.	N/A	N/A
inputBaseTablePartitions	Optional. The partitions in the base table.	N/A	The whole table is selected.
inputTestTableName	Required. The name of the test table. The shift of the population is calculated based on the samples in the base and test tables.	N/A	N/A
inputTestTablePartitions	Optional. The partitions in the test table.	N/A	The whole table is selected.

Parameter	Description	Valid value	Default
inputBinTableName	Required. The name of the binning result table.	N/A	N/A
featureColNames	Optional. The features specified for PSI calculation.	N/A	All features are selected.
outputTableName	Required. The name of the output table (PSI statistics).	N/A	N/A
lifecycle	Optional. The lifecycle of the output table.	N/A	No lifecycle is set.
coreNum	Optional. The number of cores.	N/A	Automatically calculated.
memSizePerCore	Optional. The memory size per core.	N/A	Automatically calculated.

4.5. OpenAPI

4.5.1. Query PMML models

Operation name

ListPMMLModels

Description

You can call this operation to query PMML models by project ID, experiment ID, or owner.

Request parameters

Parameter	Type	Required	Example	Description
OnwerId	String	Yes	11769368777159105	The UID of a model owner.
ProjectId	Long	Yes	10009	The ID of a project.
ExperimentId	Long	No	4294	The ID of an experiment.

Parameter	Type	Required	Example	Description
Action	String	Yes	ListPMMLModels	The operation that you want to perform. Set the value to ListPMMLModels.

Response parameters

Parameter	Type	Description
Experiments	List<ExperimentModelInfo>	An array of experiment properties returned.
Experiment	ExperimentModelInfo	The returned experiment information.
ExpId	Long	The ID of the experiment to which the models belong.
Models	List<ModelInfo >	An array of model properties returned.
Model	ModelInfo	The returned model information.
Name	String	The display name of the model.
Owner	String	The ID of the model owner.
Description	String	The description of the model.
ModelId	String	The ID of the model.
ModelName	String	The name of the underlying model generated by the corresponding algorithm.
CreateTime	Date	The time when the model was generated.
ExperimentId	String	The ID of the experiment from which the model is generated.
UpdateTime	Date	The time when the model was updated.
Project	String	The name of the project to which the model belongs.
ProjectId	String	The ID of the project to which the model belongs.

Action	String	The name of the API operation.
AccessKeyId	String	The AccessKey ID provided to you by Alibaba Cloud.
Signature	String	The signature string.
SignatureMethod	String	The signing method.
SignatureVersion	String	The version of the signature encryption algorithm.
SignatureNonce	String	A unique, random number used to prevent replay attacks.
Timestamp	String	The timestamp of the request.
Version	String	The version number of the API. The value must be in the YYYY-MM-DD format.
Format	String	The language of the response.

Sample requests

```

4.5.2. Query detailed information about a PMML model

Operation name

DescribePMMLMode

Description

You can call this operation to query detailed information about a model.

Request parameters

Parameter	Type	Required	Example	Description
ModelId	Integer	Yes	6200	The ID of the model.
Action	String	Yes	DescribePMMLMode	The operation that you want to perform. Set the value to DescribePMMLMode.

Response parameters

Parameter	Type	Description
Models	List<ModelInfo >	An array of model properties returned.
Model	ModelInfo	Detailed information about the model.
Name	String	The display name of the model.
Owner	String	The ID of the model owner.
Description	String	The description of the model.
ModelId	String	The ID of the model.
ModelName	String	The name of the underlying model generated by the algorithm.
CreateTime	Date	The time when the model was generated.
ExperimentId	String	The ID of the experiment from which the model is generated.
UpdateTime	Date	The time when the model was updated.
Project	String	The name of the project to which the model belongs.
ProjectId	String	The ID of the project to which the model belongs.

Sample requests

```
http://pop.pai.idst.inter.env8d.com/?Action=DescribePMMLMode&ModelId=6200&<Common request parameters>
```

Sample responses

4.5.3. Download PMML models

4.5.3.1. Generate a download URL for a model

Operation name

GeneratePMMLModelUrl

Description

You can call this operation to generate a download URL for a PMML model. The API call is executed asynchronously. After you call this operation, the system creates a download URL generation task in the background, and returns the task ID to you. You can then use the task ID to query the status of the task. If the task is successfully executed, the URL (OSS endpoint) of the model is returned.

Request parameters

Parameter	Type	Required	Example	Description
ModelId	Integer	Yes	6200	The ID of the model.
Action	String	Yes	GeneratePMMLModelUrl	The operation that you want to perform. Set the value to GeneratePMMLModelUrl.

Response parameters

Parameter	Type	Description
Data	Data	The returned data.
JobId	String	The ID of the download URL generation task.

Sample requests

```
http://pop.pai.idst.inter.env8d.com/?Action=GeneratePMMLModelUrl&ModelId=6200&<Common request parameters>
```

Sample responses

```
<GeneratePMMLModelUrlResponse>
<Data>
<JobId>
asynUploadModel2Oss_395fd769-1568-4015-8aa8-a56b2e0da11c
</JobId>
</Data>
<RequestId>0a9481861569501305435669 7d0059</RequestId>
<ErrMsg>Successful</ErrMsg>
<ErrCode>success</ErrCode>
</GeneratePMMLModelUrlResponse>{
 "GeneratePMMLModelUrlResponse": {
   "Data": {
    "JobId": "
asynUploadModel2Oss_395fd769-1568-4015-8aa8-a56b2e0da11c
"
   },
   "RequestId": "0a9481861569501305435669 7d0059",
   "ErrMsg": "Successful",
   "ErrCode": "success"
 }
}
```

4.5.3.2. Query a model URL generation task

Operation name

QueryAsynJobStatus

Description

You can call this operation to query the status of a URL generation task. If the task is successfully executed, the URL (OSS endpoint) of the model is returned.

Request parameters

Parameter	Type	Required	Example	Description

Parameter	Type	Required	Example	Description
JobId	String	Yes	asynUploadModel2Oss_395fd769-1568-4015-8aa8-a56b2e0da11c	The ID of the task to be queried. The task ID is returned after you call the GeneratePMMLModelUrl operation.
Action	String	Yes	QueryAsynJobStatus	The operation that you want to perform. Set the value to QueryAsynJobStatus.

Response parameters

Parameter	Type	Description
Data	Data	The returned data.
Status	String	The status of the task. Valid values: done, failed, and running.
Info	String	The URL of the model is returned if the task is successfully executed. An error message is returned if the system fails to execute the task.

Sample requests

```
http://pop.pai.idst.inter.env8d.com/?Action=QueryAsynJobStatus&JobId=asynUploadModel2Oss_395fd769-1568-4015-8aa8-a56b2e0da11c&<Common request parameters>
```

Sample responses

 }
}
```

4.5.4. SDKs

Alibaba Cloud SDKs

```
https://developer.aliyun.com/sdk?spm=5176.10695662.1kquk9v2l.2.1e734735x9Gptc&aly_as=m3lFQpXP<
dependency>
<groupId>com.aliyun</groupId>
<artifactId>aliyun-java-sdk-core</artifactId>
<version>{$version}</version></dependency>
```

SDK use case

Example: call an RPC API operation.

```
import com.aliyuncs.CommonRequest;
import com.aliyuncs.CommonResponse;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.profile.DefaultProfile;
public class Sample {
    public static void main(String[] args) {
        // Create a default ACS client and initialize it.
        DefaultProfile profile = DefaultProfile.getProfile(
            "<your-region-id>",         // The region ID.
            "<your-access-key-id>",     // The AccessKey ID.
            "<your-access-key-secret>"); // The AccessKey secret.
        IAcsClient client = new DefaultAcsClient(profile);
        // Create an API request and configure parameters.
        CommonRequest request = new CommonRequest();
        request.setDomain("ecs.aliyuncs.com");
        request.setVersion("2014-05-26");
        request.setAction("DescribeInstanceStatus");
        request.putQueryParameter("PageNumber", "1");
        request.putQueryParameter("PageSize", "30");
        try {
            CommonResponse response = client.getCommonResponse(request);
            System.out.println(response.getData());
        } catch (ServerException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        } catch (ClientException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        }
    }
}
```

Example: call an RESTful API operation.

```
import com.aliyuncs.CommonRequest;
import com.aliyuncs.CommonResponse;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.profile.DefaultProfile;
public class Sample {
    public static void main(String[] args) {
        // Create a default ACS client and initialize it.
        DefaultProfile profile = DefaultProfile.getProfile(
            "<your-region-id>",         // The region ID.
            "<your-access-key-id>",     // The AccessKey ID.
            "<your-access-key-secret>"); // The AccessKey secret.
        IAcsClient client = new DefaultAcsClient(profile);
        // Create an API request and configure parameters.
        CommonRequest request = new CommonRequest();
        request.setDomain("cs.aliyuncs.com");
        request.setVersion("2015-12-15");
        request.setUriPattern("/clusters");
        try {
            CommonResponse response = client.getCommonResponse(request);
            System.out.println(response.getData());
        } catch (ServerException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        } catch (ClientException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        }
    }
}
```

SDK parameters

The domain must be in the pop.${pai_domain} format. Set the pai_domain parameter to the domain shown in the Machine Learning Platform for AI.

The version must be 2019-09-25.

The Action string specifies an API operation.

The QueryParameter string specifies API request parameters, excluding the action parameter.

Example:

```
CommonRequest request = new CommonRequest();
request.setDomain("pop.${pai_domain}");
request.setVersion("2019-09-25");
request.setAction("DescribePMMLMode");
request.putQueryParameter("ModelId", "***");
```

4.6. EAS user guide

4.6.1. EAS overview

Elastic Algorithm Service (EAS) allows you to deploy machine learning models, such as PMML, PAI-OfflineModel, TensorFlow, and Caffe models, as services. You can also develop custom online services based on the API standards defined by EAS. You can simply use a JSON file to describe the service that you want to deploy, such as the path of the model, the region where the service is deployed, and the resources used by the service. After the JSON file is prepared, you can use the eascmd client or Alibaba Cloud SDK for Java to deploy it as an online service. The service can be accessed from the production environment and Internet. EAS supports various regions and different types of hardware resources (CPUs and GPUs).

4.6.2. Client

You can use the eascmd client to create, delete, view, and modify services. The eascmd client is stored in the Object Storage Service (OSS) bucket eas-utils. You can use wget or curl to download eascmd.

4.6.3. User authentication

Deployed model services use JSON Web Token (JWT) for user authentication. You can run the following command in eascmd to configure the AccessKey information.

```
./eascmd64 config -i <AccessKeyId> -k <AccessKeySecret> -e {{Domain name of EAS}}
//New users can use the admin account to pass authentication.
./eascmd64 config -i admin -k admin -e {{Domain name of EAS}}
```

4.6.4. Upload files

When you create a service, you must specify the HTTP addresses of the model and processor files. You can store the model and processor files on any HTTP servers.

4.6.5. Create a service

You can run the `create` command to create a service. When you create a service, you must specify the HTTP URLs of the model and processor files to be used by the service. You can upload the files to Object Storage Service (OSS) and specify their OSS paths.

```
eascmd create [service_desc_json]
```

The service_desc_json file contains service information and metadata configurations. The metadata configurations only contain cluster deployment information, such as the region where the cluster is deployed and the required resources. Example:

> **Note** When you run the test command to debug the service, the metadata configurations are ignored.

```
{
 "name": "mnist_saved_model_example",
 "generate_token": "true",
 "model_path": "http://eas-data.oss-cn-shanghai.aliyuncs.com/models%2Fmnist_saved_model.tar.gz",
 "processor": "tensorflow_cpu",
 "metadata": {
  "instance": 1,
  "cpu": 1,
 }
}
```

The parameters in the JSON file are described as follows:

Key	Value
name	The name of the service. Service names are unique inside each region. You can specify the region in the metadata configurations.
generate_token	Specifies whether to generate a token. If the value is set to true, you must add the token to the HTTP header of the request that you send to the service. If the value is set to false, the service is accessible to the public. No authentication is required.
token	Optional. The token used for authenticating requests sent to the service. If you do not specify a token, the generate_token parameter automatically generates a token.
model_path	The path of the model file. For more information, see the note under this table.

Key	Value
model_entry	Optional. The input file of the model. If no input file is specified, the file specified by the model_path parameter is used. You can specify arbitrary files in this parameter. The path of the primary file will be passed to the Load() function in the processor.
model_config	Optional. The configuration of the model. The configuration can be in any text format. The configuration is passed to the second parameter of the LoadWithConfig() function in the processor.
processor	Optional. The built-in processor used to make predictions. When this parameter is specified, the processor_path, processor_entry, processor_mainclass, and processor_type parameters are ignored.
processor_path	Optional. The path of the processor. Only custom processors support this parameter. For more information about processor packages, see the note under this table.
processor_entry	The primary file of the processor. It contains the implementations of the Load() and Process() functions. This parameter is required when you develop a custom processor using the C or C++ language.
processor_mainclass	The primary file of the processor. It defines the main class in Java. This parameter is required when you develop a custom processor using Java.
processor_type	Optional. The language used to develop the processor. Only custom processors support this parameter. Currently, only C++, Java, and Python are supported.
metadata	The metadata of the service.

Note model_path and processor_path specify the inputs of the model and processor in the format of HTTP URLs or OSS paths. When you use the test command to debug the service on your local machine, local paths are supported.

When HTTP URLs are used, the required files must be packaged in the tar.gz, tar.bz2, or ZIP format.

Metadata descriptions

Category	Parameter	Description
Common options	workers	Optional. The number of threads used by each instance to process requests in parallel. The default is 5.
	instance	The number of instances launched by the service.
	CPU	The number of CPUs required by each instance.
	gpu	The number of GPUs required by each instance.
	resource	The name of the resource group. If your service uses CPU resources, ignore this parameter. Supported GPU resource groups are P4_4CORE and P4_8CORE.
Advanced parameter (use with caution)	rpc.batching	Optional. It specifies whether to enable batching at the server end for GPU optimization. The default is false.
	rpc.keepalive	Optional. The maximum amount of time that it takes to process a single request. When the time expires, the server end returns a 408 error and disconnects from the client. The default is 5000 milliseconds.
	rpc.io_threads	Optional. The number of threads used by each instance to handle network inputs and outputs. The default is 4.
	rpc.max_batch_size	Optional. The maximum size of each batch when batching is enabled. The default is 16.
	rpc.max_batch_timeout	Optional. The maximum timeout of each batch when batching is enabled. The default is 50 milliseconds.

Category	Parameter	Description
	rpc.max_queue_size	Optional. The maximum size of the queue. The default is 64. When the queue is full, the server end returns a 450 error and closes the connection. The queue can prevent the server from being overloaded. It also can notify the client to send the request to other instances when the current instance is busy. For a queue that produces a long response time, you can set the size of the queue to a smaller value to prevent large amounts of pending requests from timing out.
	rpc.worker_threads	Optional. The number of threads used by each instance to process requests in parallel. This parameter is the same as the workers parameter. The default is 5.

Example:

```
{
 ...
"metadata": {
  "cpu": 4,
"rpc.max_queue_size": 32,
...
 }
```

```
$ eascmd create pmml.json
[RequestId]: 1651567F-8F8D-4A2B-933D-F8D3E2DDEB2D

```

4.6.6. Local debugging

Before you deploy the service to the cluster, you can use the local debugging feature to start a local service for debugging. This feature requires a Docker container and Internet access. You must install Docker on the machine where eascmd runs, and then run the following command to debug the service.

```
sudo eascmd test [service_desc_json]
```

Specify the JSON file used to deploy the service in this command. The following example shows how to run this command:

```
[xingke.***@mac-3:~/code/go/src/easgo]$ bin/eascmd test tf.json
[OK] Pulling image: registry.cn-shanghai.aliyuncs.com/eas/eas-worker-amd64:0.1.4

[2019-02-24 00:16:27] [172.17.0.2] Fetching processor from [http://eas-data.oss-cn-shanghai.aliyuncs.com/eas-pmml-processor-0.1-jar-with-dependencies.jar]
[2019-02-24 00:16:28] [172.17.0.2] ----------------------------SERVICE LOG-------------------------------
...
[2019-02-24 00:16:30] [172.17.0.2] [INFO] Token: [WIzMFW5Jb8kckYj****]
...
[2019-02-24 00:16:30] [172.17.0.2] [INFO] Service start successfully
```

In this example, the command starts a local TensorFlow model service. The endpoint of the service is http://localhost:6942/api/predict/savedmodel_exanple.

4.6.7. Modify configurations

You can specify the -D parameter in the modify command to modify the metadata configurations, such as the instance, CPU, and memory configurations.

```
eascmd modify [service_name] -Dmetadata.[attr_name]=[attr_value]
```

For example, you can run the following command to set the number of instances to 10.

```
eascmd modify service_test -Dmetadata.instance=10
```

You can set multiple properties at a time. For example, you can set the number of instances to 10 and the memory size to 2,000 MB.

```
eascmd modify service_test -Dmetadata.instance=10 -Dmetadata.memory=2000
```

4.6.8. Modify a service

You can run the modify command to modify a deployed service.

```
eascmd modify [service_name] -s [service_desc_json]
```

> **Note** You cannot use this command to modify the region where the service is deployed. Note: If you only want to modify the resources used by the service, specify the metadata configurations in the service description file.

4.6.9. Delete a service

You can run the delete command to delete a service.

```
eascmd delete [service_name]
```

When you delete a service, you must specify the service name and the region where the service is deployed.

Examples:

```
$ eascmd delete savedmodel_exanple
Are you sure to delete the service [savedmodel_exanple] in [cn-shanghai]? [Y/n]
[RequestId]: 1651567F-8F8D-4A2B-933D-F8D3E2DDEB2D
[OK] Service [savedmodel_exanple] in region [cn-shanghai] is terminating
[OK] Service is terminating
[OK] Service is terminating
[OK] Service was deleted successfully
```

4.6.10. Switch service version

You can run the desc command to view the version of the current service and the latest version, and run the version command to switch the service to a version earlier than the latest version.

```
eascmd version [service_name] [version_id]
```

4.6.11. View service list

You can run the list(ls) command to view all services deployed by the current user.

```
$ eascmd ls
[RequestId]: 83945D4EED3E-4D35-A989-831E6BBA39F
+--------------------------+-------------+----------+--------------------+--------------------+---------+--------+-
---------------------------------------+
|     SERVICENAME      |  REGION   | INSTANCE |    CREATETIME     |    UPDATETIME     | STATUS  | WEIGH

```

4.6.12. View service information

You can run the desc command to view detailed information about a deployed service.

```
eascmd desc [service_name]
```

Examples:

```
$ eascmd desc mnist_saved_model_example
+--------------------+-----------------------------------------------------------------------------------------------------

|             | "tensorflow_cpu"                                                              |
|             | }
```

4.6.13. View service processes

You can run the showworkers(w) command to view the status of the service processes.

```
eascmd w [service_name]
```

Examples:

```
$ eascmd w mnist_saved_model_example
[RequestId]: 4E905404-E617-4BD8-85D6-EC5C6A0D0211
+--------------+---------------+--------------------+----------+---------+-------+--------+
|   INNERIP    |    HOSTIP     |     STARTAT        | RESTARTS | STATUS  | READY | REASON |
+--------------+---------------+--------------------+----------+---------+-------+--------+
| 172.24.5.183 | 192.168.65.121 | 2019-02-21 16:35:58 |       0 | Running | [1/1] |       |
+--------------+---------------+--------------------+----------+---------+-------+--------+
```

4.6.14. Call the prediction service

To call a prediction service, you must use the HTTP URL generated when the prediction service is created. The URLs for local testing and online prediction are generated in the same format. The only difference is that they use different hosts. When you send a request to the URL, you must add a token to the HTTP header of the request. The token is generated when you create an image. The following example shows how to call the prediction service from curl. PMML model prediction:

```
$ curl http://{{The domain of EAS}}/api/predict/pmml_example -H 'Authorization: NGE3MzM4YmRhODZj
MTE2NmZjZjNlNTJlNDgyNzM3YzdjMmIwOD****==' -d '[{}]'
[{"prediction_score":0.0902926730924553}]
```

The processor defines the formats of the input and output of the prediction service.

4.6.15. Use Java or C++ to develop a model service

4.6.15.1. What are processors

Processors are program packages that contain the prediction logic. User requests are processed by processors and then returned to clients. A processor contains the logic for loading models and making predictions upon user requests. Machine Learning Platform for AI supports general processors: PMML and TensorFlow. If you want to customize the prediction logic, you must follow the processor development standards to develop a processor.

You can develop a processor in C, C++, and Java languages without the need to use an SDK. You only need to define the relevant classes and functions to develop a processor. This makes it easy for you to debug the processor offline.

4.6.15.2. C/C++ processor

If you use a C or C++ processor, you must define functions Load() and Process(). Function Load() is used to load the model during the initialization process. Function Process() is used to process service calls and return the processing results to clients. The two functions are declared as follows:

```
void *initialize(const char *model_entry, const char *model_config, int *state)
```

Parameter	Type	Description
model_entry	Input parameter	Specifies a model file. This parameter corresponds to the model_entry parameter in the configuration file when you deploy a model service. You can specify a file name or directory, for example, randomforest.pmml or ./model.
model_config	Input parameter	Specifies the custom model configurations. This parameter corresponds to the model_config parameter in the configuration file when you deploy a model service.
state	Output parameter	Indicates whether the model is loaded. Value 0 indicates that the model has been loaded.
N/A	Returned value	The momery address of the user-defined model variable. The value can be any data type.

```
int process(void *model_buf, const void *input_data, int input_size,
        void **output_data, int *output_size)
```

Parameter	Type	Description
model_buf	Input parameter	Specifies the memory address of the model returned by function initialize().
input_data	Input parameter	Specifies the input data. String data and binary data are supported.
input_size	Output parameter	Specifies the size of the input data.
output_data	Output parameter	The data returned by the processor. You must allocate heap memory to the processor. The model will automatically release the memory.
output_size	Output parameter	The size of the data returned by the processor.
N/A	Returned value	If value 0 or 200 is returned, the model service is successfully called. This parameter can return HTTP error codes to clients. If the processor cannot recognize the HTTP error code, it automatically converts it to HTTP error code 400.

Examples

In the following example, no model data is loaded. The prediction service directy returns the request to the client.

```
#include <stdio.h>
#include <string.h>
extern "C" {
    void *initialize(const char *model_entry, const char *model_config, int *state)
    {
        *state = 0;
        return NULL;
    }
    int process(void *model_buf, const void *input_data, int input_size,
            void **output_data, int *output_size)
    {
        if (inputSize == 0) {
            const char *errmsg = "input data should not be empty";
            *outputData = strndup(errmsg, strlen(errmsg));
            *outputSize = strlen(errmsg);
            return 400;
        }
        *outputData = strndup((char *)inputData, inputSize);
        *outputSize = inputSize;
        return 200;
    }
}
```

The processor does not load any model data. It directly returns the input data to the client. You can use Makefile to compile the processor into a .so file.

```
CC=g++
CCFLAGS=-I./ -D_GNU_SOURCE -Wall -g -fPIC
LDFLAGS= -shared -Wl,-rpath=. /

OBJS=processor.o
TARGET=libpredictor.so

all: $(TARGET)

$(TARGET): $(OBJS)
    $(CC) -o $(TARGET) $(OBJS) $(LDFLAGS) -L./

%.o: %.cc
    $(CC) $(CCFLAGS) -c $< -o $@

clean:
    rm -f $(TARGET) $(OBJS)
```

If the processor is reliant on other .so files, package these files with the processor.so file, and then deploy the package.

4.6.15.3. Java processor

The Java processor also uses functions Load() and Process() besides constructors. You only need to define one class for the Java processor. The class is defined as follows:

```
package com.alibaba.eas;

import java.util.*;

public class TestProcessor {
  public TestProcessor(String modelEntry, String modelConfig) {
    /* Passes a model file name to the class and initializes the model. */
  }

  public void Load() {
    /* Loads the model information based on the specified model file name */
  }

  public String Process(String input) {
    /* Preprocesses the input data and outputs the processing results. Currently, only string type data c
an be input and output */
  }

  public static void main(String[] args) {
    /* The main function is optional. It can be used for debugging on your local host. */
  }
}
```

If an exception occurs, the system automatically captures the exception, and returns an error message to the client. An HTTP 400 status code is also returned to the client. You can also customize the logic for capturing exceptions and return an error message to your client as follows:

```
try{
} catch (com.alibaba.fastjson.JSONException e) {
  throw new RuntimeException("bad json format, " + e.getMessage());
}
```

4.7. AutoML (must be activated separately)

4.7.1. Automatic parameter tuning with AutoML

This topic describes the automatic parameter tuning feature of AutoML.

Parameter

1. Log in to machine learning console. In the left-side navigation pane, click **Experiments**.

2. Click an experiment to go to the canvas of the experiment.

   > **Note** This topic uses air quality prediction as an example.

3. In the upper-left corner of the canvas, choose **Auto ML > Auto Parameter Tuning**.
4. On the **Auto Parameter Tuning** page, select an algorithm for parameter tuning, and click **Next**.

   > **Note** You can select only one algorithm to tune at a time.

5. In the **Configure Parameter Tuning** module, set the **Parameter Tuning Method** parameter and click **Next**.

   Alibaba Cloud Machine Learning Platform for AI provides four **parameter tuning methods**. For more information, see Parameter adjustment method.

6. In the **Configure Model Output** module, set the model output parameters and click **Next**.

Parameter	Description
Evaluation Criteria	You can select one evaluation standard from the following four dimensions: **AUC**, **F1-score**, **PRECISION**, and **RECALL**.
Saved Models	You can save up to five models. The system ranks models based on the **Evaluation Criteria** setting you select and save the top ranked models according to the number entered in the **Saved Models** field.
Pass Down Model	This switch is turned on by default. If the switch is turned off, the model generated by the default parameters of the current component are passed down to the node of the subsequent component. If the switch is turned on, the optimal model generated by automatic parameter tuning are passed down to the node of the subsequent component.

7. In the upper-left corner of the canvas, click **Run** to run the automatic parameter tuning algorithm, as shown in the following figure.

   > **Note** After the preceding configuration is complete, the Auto ML switch of the related algorithm is turned on. You can turn the switch on or off as needed.

8. Right-click a model component and choose **Edit AutoML Parameters** from the shortcut menu to modify its AutoML configuration parameters.

Output model display

1. During parameter tuning, right-click the target model component and choose **Parameter Tuning Details** from the shortcut menu.
2. On the **AutoML-Parameter Tuning Details** page, click the **Metrics** tab to view the current

tuning progress and the running status of each model.

3. You can sort candidate models according to indicators (**AUC**, **F1-score**, **Accuracy**, and **Recall Rate**).
4. In the **View Details** column, you can click **Log** or **Parameter** to view the logs and parameters of each candidate model.

Parameter tuning effect display

1. On the **AutoML-Parameter Tuning Details** page, you can click the **Charts** tab to view the **Model Evaluation and Comparison** and **Hyperparameter Iteration Result Comparison** charts.
2. You can view the growth trend of the evaluation indicators of updated parameters in the **Hyperparameter Iteration Result Comparison** chart.

Model storage

1. Log in to machine learning console. In the left-side navigation pane, click **Models**.
2. Click **Experiment Model** to open the experiment model folder.
3. Click the corresponding experiment folder to view the model saved with Auto ML.
4. (Optional) You can apply a model to other experiments by dragging the model to the canvas of the target experiment.

4.7.2. Parameter tuning methods

AutoML supports four parameter tuning methods.

Evolutionary Optimizer

Principle:

1. Randomly selects A parameter candidate sets (where A indicates the **number of exploration samples**).
2. Takes the N parameter candidate sets with higher evaluation indicators as the parameter candidate sets of the next iteration.
3. Continues the exploration within R times (where R indicates the **convergence coefficient**) as the standard deviation range around these parameters to explore new parameter sets. The new parameter sets replace the last A-N parameter sets by the evaluation indicator in the previous round.
4. Iterates the exploration for M rounds (where M indicates the **number of explorations**) until the optimal parameter set is found, according to the preceding logic.

Based on the preceding principle, the final number of models is A + (A - N) × M.

> **Note** The first value of N is A/2 - 1. During iteration, the default value is A/2 - 1 (rounded up).

Parameter	Description

Parameter	Description
Data Splitting Ratio	Splits input data sources into training and evaluation sets. 0.7 indicates that 70% of the data is used for model training and 30% for evaluation.
Exploration Samples	The number of parameter sets of each iteration. The higher the number, the greater the accuracy, the larger the calculation. This parameter must be set to a positive integer in the range of 5 to 30.
Explorations	The number of iterations. The higher the number of iterations, the greater the search accuracy, the larger the calculation. This parameter must be set to a positive integer in the range of 1 to 10.
Convergence Coefficient	Tunes the exploration ranges (R times the standard deviation range search). The smaller the range, the faster the convergence (however, optimal parameters may be missed). Valid values: 0.1 to 1 (one floating point after the decimal point).

Note You must enter the tuning range for each parameter. If the current parameter range is not configured, the parameter range is set by default.

Random Search

Principle:

1. Randomly selects a value for each parameter within the parameter range.
2. Enters random values into a set of parameters for model training.
3. Performs M rounds (where M indicates the number of iterations) and then sorts the output models.

Parameter	Description
Data Splitting Ratio	Splits input data sources into training and evaluation sets. 0.7 indicates that 70% of the data is used for model training and 30% for evaluation.
Iterations	The number of searches in the configured range. Valid values: 2 to 50.

Note You must enter the tuning range for each parameter. If the current parameter range is not configured, the parameter range is set by default.

Grid Search

Principle:

1. Splits the value range of each parameter into N segments (where N indicates the number of split grids).
2. Randomly takes a value from the N segments. Assuming that there are M parameters, N^M parameter sets can be combined.
3. According to the N^M parameter sets, N^M models are generated by training. The models are then sorted.

Parameter	Description
Data Splitting Ratio	Splits input data sources into training and evaluation sets. 0.7 indicates that 70% of the data is used for model training and 30% for evaluation.
Grids	The number of split grids. Valid values: 2 to 10.

Note You must enter the tuning range for each parameter. If the current parameter range is not configured, the parameter range is set by default.

Custom Parameters

- You can enumerate parameter candidate sets. The system then helps score all the combinations of the candidate sets.
- You can define enumeration ranges and separate parameters with commas (,). If the ranges are not configured, the default ranges of parameters are tuned.

4.8. Terms and acronyms

4.8.1. Terms

This topic lists the basic terms used in machine learning.

experiment

A user-created data mining workflow.

project

The basic object in MaxCompute. A project is also known as a workspace. A project contains other objects, such as tables and instances.

component

The minimum operating unit that you can invoke and execute on Apsara Stack Machine Learning Platform for AI. You can use components to import and export data, process data, analyze data, train models, and make predictions.

4.8.2. Acronyms

This topic describes the acronyms used in the Machine Learning Platform for AI User Guide.

MaxCompute

MaxCompute (formerly known as ODPS) is a data processing platform developed by Alibaba Cloud for large-scale data warehousing. MaxCompute can store and compute structured data in batches to meet the requirements of most big data modeling and analysis scenarios.

MaxCompute source and target tables

Tables are data storage objects in MaxCompute. Similar to relational database tables, tables in MaxCompute have a two-dimensional logical structure. A source table is the input of an algorithm node, while a target table is the output of an algorithm node.

5.E-MapReduce (EMR)

5.1. What is E-MapReduce?

E-MapReduce is a managed cluster platform that simplifies running big data frameworks, such as Hadoop, Spark, Kafka, and Storm. E-MapReduce provides you with one-stop big data processing and analysis services, such as managing clusters, jobs, and data.

E-MapReduce is a service that is based on ZStack and uses open-source Apache Hadoop and Spark to process and analyze vast amounts of data. You can use components, such as Apache Hive, Apache Pig, and HBase, in the Hadoop and Spark ecosystems to process and analyze data. You can also use E-MapReduce to import and export data from Alibaba Cloud data stores and databases, such as OSS and ApsaraDB for RDS.

5.2. Introduction

5.2.1. Instructions

Before you use the E-MapReduce service, familiarize yourself with information such as the software configuration of the EMR cluster and the procedure for deploying the service.

5.2.2. Introduction

5.2.2.1. Software configuration

You need to install an operating system and big data components on each ECS instance in an E-MapReduce cluster.

5.2.2.2. Software environment

Software requirements lists the software requirements.

Software requirements

Software	Description
Operating system	CentOS 7 64-bit kernel-3.10.0-693.2.2.el7.x86_64
JDK	OpenJDK 1.8.0

5.2.2.3. Supported components

This topic lists the components of EMR and the supported versions.

Components

Component	Version
Hadoop	2.8.5

Component	Version
Hive	3.1.1
Tez	0.9.1
Spark	2.4.3
Oozie	5.1.0
Hue	4.4.0
Zeppelin	0.8.1
Sqoop	1.4.7
ZooKeeper	3.5.5
Kafka	1.1.1
HBase	1.4.9
Phoenix	4.14.1
Presto	0.22.1
Flink	1.7.2
Ranger	1.2.0
Flume	1.8.0

5.2.2.4. Introduction to components

This section introduces the big data components that can run on an EMR cluster.

Component	Description
Hadoop	• YARN: supports task scheduling and cluster resource management. • HDFS: a distributed file system.
Hive	A Hadoop-based offline data processing system that provides an SQL-like interface to query data. Hive uses tables to store and manage data.
Spark	An in-memory distributed computing framework that supports offline and real-time computing, SQL statements, and machine learning.

Component	Description
Oozie	A job scheduler that supports workflow orchestration by building a directed acyclic graph (DAG). It supports multiple types of jobs.
Hue	A visualized platform used to manage open source components, such as Hadoop, Hive, Oozie, and HBase.
Sqoop	A tool designed to transfer data between HDFS and relational databases.
ZooKeeper	An open source distributed application coordination service. It is an open source implementation of Chubby provided by Google and is an important component of Hadoop and HBase. ZooKeeper solves the consistency problem of distributed applications. Its services include configuration maintenance, domain name services, distributed synchronization, and group services.
Kafka	A distributed messaging system that features high throughput, scalability, reliability, and performance. It is used in real-time computing, log processing, and data aggregation.
HBase	An open source, distributed, and column-oriented database. It is a component of the Apache Hadoop project. Different from typical relational databases, HBase is designed to store unstructured data. HBase is column-oriented rather than row-oriented.
Phoenix	Provides SQL-like statements for you to analyze HBase data.
Presto	A distributed SQL query engine that retrieves large datasets from one or more data sources.

5.2.3. Introduction

5.2.3.1. Deployment

This topic describes available deployment modes for a cluster and supported cluster services.

5.2.3.2. Deployment modes

This topic describes the available deployment modes for an E-MapReduce cluster.

E-MapReduce supports the following deployment modes:

- Hybrid

E-MapReduce supports full-cluster hybrid deployment mode, which means that all components can be deployed in one cluster. Each node in the cluster can provide more than one service.

- Independent

  Only one service is deployed on each E-MapReduce cluster.

5.2.3.3. Supported services

This topic describes services that you can deploy on an EMR cluster.

For more information about services supported by EMR, see List of services.

List of services

Service	Component	Deployment
Hadoop HDFS	NameNode	Deployed on a master node. In a high-availability (HA) cluster, NameNode is deployed on two master nodes.
	DataNode	Deployed on a core node.
	ZKFC	Deployed on a master node. In an HA cluster, ZKFC is deployed on two master nodes.
	JournalNode	• In a non-HA cluster, JournalNode is deployed on a master node, first core node, and second core node. • In an HA cluster, JournalNode is deployed on two master nodes and the first-created core node.
	KMS	Deployed on a master node. Only supports single-node deployment.
	HttpFS	Deployed on a master node. Only supports single-node deployment.
Hadoop YARN	ResourceManager	Deployed on a master node. In an HA cluster, NameNode is deployed on two master nodes.
	NodeManager	Deployed on core nodes.
	JobHistory	Deployed on a master node. Only supports single-node deployment.

Service	Component	Deployment
	TimeLineServer	Deployed on a master node. Only supports single-node deployment.
	WebAppProxyServer	Deployed on a master node. Only supports single-node deployment.
Hive	HiveServer	Deployed on a master node. In an HA cluster, HiveServer is deployed on two master nodes.
	HiveMetaStore	Deployed on the master node. In an HA cluster, HiveMetaStore is deployed on two master nodes.
Spark	JobHistory	Deployed on a master node. Only supports single-node deployment.
Ganglia	GMond	Deployed on all nodes to collect information.
	GMetad	Deployed on a master node. Only supports single-node deployment.
HBase	HMaster	Deployed on a master node. In an HA cluster, HMaster is deployed on two master nodes.
	HRegionServer	Deployed on core nodes.
	ThriftServer	Deployed on a master node. Only supports single-node deployment.
ZooKeeper	ZooKeeper	• In a non-HA cluster, JournalNode is deployed on a master node, first core node, and second core node. • In an HA cluster, JournalNode is deployed on two master nodes and the first core node.
Hue	Hue	Deployed on a master node. In an HA cluster, Hue is deployed on two master nodes.

Service	Component	Deployment
Oozie	Oozie	Deployed on a master node. In an HA cluster, Oozie is deployed on two master nodes.
HAS	HASServer	Deployed on the master node. In an HA cluster, HASServer is deployed on two master nodes.
Knox	Knox	Deployed on the master node. In an HA cluster, Knox is deployed on two master nodes.

5.3. Log on to the E-MapReduce console

This topic describes how to log on to the E-MapReduce console.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Context

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password used to log on to the console from the operations administrator.

   > **Note** When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters.
   > - Digits.
   > - Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Products** > **Big Data** > **E-MapReduce**.
5. Set Organization and **Region** and click **EMR** to go to the E-MapReduce console.

5.4. Cluster planning and configuration

5.4.1. Cluster planning

5.4.1.1. Gateway clusters

Gateway clusters can serve as a separate job submission node for Hadoop clusters. When you create a gateway cluster, you must associate it with an existing cluster. This facilitates operations on the associated cluster.

A gateway cluster is an independent cluster that consists of multiple instances with the same configurations. Clients, such as Hadoop (HDFS+YARN), Hive, Spark, and Sqoop clients, are deployed on the cluster.

If no gateway cluster is created, jobs of a Hadoop cluster are submitted on the master or core instance of the Hadoop cluster, which consumes the resources of this cluster. After a gateway cluster is created, you can use it to submit jobs of the cluster associated with this gateway cluster. This way, the jobs do not occupy the resources of the associated cluster, and the stability of the master and core instances, especially the master instance, in the associated cluster is improved.

Each gateway cluster can have an independent configuration environment. For example, you can create multiple gateway clusters for one cluster that is shared by multiple departments to meet their business requirements.

5.4.1.2. Disaster recovery in E-MapReduce clusters

This article will introduce disaster recovery of data and dervices in E-MapReduce clusters

Data

HDFS stores the data of each file in blocks, with each block holding multiple copies (three by default). HDFS also makes sure that these copies are stored in different frameworks. In most situations, HDFS stores the first copy in the local framework, the second in the same framework as the first but in different nodes, and the last copy in a different framework.

HDFS scans the data copies regularly. If it finds that a data copy has been lost, HDFS makes another to make sure the number of copies is stable. If a node that stores a copy has been lost, HDFS makes another node to recover the data in that node. In Alibaba Cloud, if you use cloud disks, each cloud disk has three data copies in the back-end. If any of them has an issue, the copies exchange and recover data to ensure reliability.

HDFS is a highly reliable file storage system that can store massive amounts of data. Based on the features of Alibaba Cloud, HDFS can also make backups of the data stored in OSS, providing even greater data reliability.

Services

The core components of HDFS guarantee high availability by making sure that there are at least two nodes to back each other up, such as YARN, HDFS, HiveServer, or Hive Meta. In this way, whenever a node experiences an issue, the nodes can exchange and recover data to ensure that services are not impacted.

5.4.2. Configure clusters

5.4.2.1. Create a cluster

This topic describes how to create an E-MapReduce (EMR) cluster.

Go to the cluster creation page

1. Log on to the E-MapReduce console.
2. Click **Cluster Wizard**.

Configure cluster information

Configure software, hardware, and basic parameters as guided by the wizard.

> **Notice** After a cluster is created, you cannot modify its parameters except for the cluster name. Make sure that all parameters are correct when you create a cluster.

1. Configure software parameters.

Parameter	Description
EMR Version	The major version of EMR. The major version of EMR is a complete open source software environment. It can be regularly updated based on updates made to the internal component software. The major version of EMR is also updated with Hadoop-related software. Clusters of an earlier version cannot be automatically updated to a later version.
Cluster Type	The type of the cluster you want to create. EMR supports the following types of clusters: ○ **Hadoop**: Hadoop clusters provide multiple ecosystem components, such as Hadoop, Hive, Spark, Spark Streaming, Flink, Storm, Presto, Impala, Oozie, and Pig. Hadoop, Hive, and Spark are semi-hosted services and are used to store and compute large-scale distributed data offline. Spark Streaming, Flink, and Storm provide stream computing. Presto and Impala are used for interactive queries. For more information about these components, see the Services section of the Status tab on the Clusters and Services page. ○ **Kafka**: Kafka clusters serve as a semi-hosted, distributed message system with high throughput and scalability. Kafka clusters provide a comprehensive service monitoring system that maintains cluster stability. Kafka clusters are professional, reliable, and secure. You do not need to deploy or maintain these clusters. These clusters are used in scenarios such as log collection and monitoring data aggregation. They can also be used for offline data processing, stream computing, and real-time data analysis. ○ **Druid**: Druid clusters provide a semi-hosted, real-time, and interactive analytic service. These clusters can query big data within milliseconds and ingest data in multiple ways. You can use Druid clusters with services such as EMR Hadoop, EMR Spark, Object Storage Service (OSS), and ApsaraDB for RDS to build a flexible and stable system for real-time queries.

Parameter	Description
Required Services	The default components required for a specific cluster type. After a cluster is created, you can add, start, or stop services on the cluster management page.
Optional Services	The other components that you can specify as required. The relevant service processes for the components you specify are started by default. **Note** The more components you specify, the higher instance specifications a cluster requires to handle the components. You must select the instance type that matches the number of components you specified when you configure the hardware. Otherwise, the cluster may have insufficient resources to run the components.
Advanced Settings	○ **Kerberos Mode**: specifies whether to enable Kerberos authentication for the cluster. This mode is disabled by default because it is not required by clusters created for common users. ○ **Custom Software Settings**: customizes software settings. You can use a JSON file to customize the parameters of basic components required for a cluster, such as Hadoop, Spark, and Hive.

2. Configure hardware parameters.

Section	Parameter	Description
Network Settings	**Zone**	The zone where a cluster is created. Zones are different geographical areas located in the same region. They are interconnected by an internal network. The instance types and disks that are available for you to create a cluster depend on the selected zone. Networks of zones are isolated from each other. If your business requires a low-latency network, we recommend that you deploy instances in the same zone. However, if the zone has insufficient instances, a cluster may fail to be created.
	Network Type	The network type of a cluster. The Virtual Private Cloud (VPC) network type is selected by default.
	VPC	The VPC selected in the region where your cluster resides.
	VSwitch	The VSwitch selected in the zone where your cluster and VPC reside. If no VSwitch is available in the zone, create one.

Section	Parameter	Description
	Security Group Name	The security group to which you want to add your cluster. Only the security groups that you create in EMR are available in the drop-down list. To create a security group, you can directly enter a name in the Security Group Name field. The name must be 2 to 64 characters in length and can contain only letters, digits, underscores (_), and hyphens (-). It must start with a letter.
High Availability	High Availability	Specifies whether to enable the high availability mode. By default, this mode is disabled. In this case, the cluster has only one master node. If the high availability mode is enabled, two master nodes are created in a Hadoop cluster to ensure the availability of the ResourceManager and NameNode processes. HBase clusters support high availability. In the original high availability mode, an HBase cluster uses a core node as the backup of the master node. If you enable the high availability mode described here, an HBase cluster uses two master nodes to achieve high availability, which is more secure and reliable.

Section	Parameter	Description
Instance	Configuration	◦ Node type: ▪ **Master Instance**: runs control processes, such as ResourceManager and NameNode. ▪ **Core Instance**: stores all data of the cluster. You can add core nodes as needed after the cluster is created. ▪ **Task Instance**: improves the computing capabilities of the cluster and stores no data. No task node is configured by default. You can add task nodes as required. ◦ Instance type: Select an instance type for each node type as needed. ◦ Data disk type: Data disk types include standard SSD and ultra disk. Data disk types that are available for you to create the cluster vary with the selected zone and instance type. By default, data disks are released after the cluster is released. For a compute node with local disks, the data disk type is selected by default and cannot be changed. ◦ Data disk size: Valid values: 40 to 32768. Unit: GB. If you use a local disk, the size of the local disk is set by the system and cannot be modified. ◦ Node quantity: You can set the number of nodes of each type as needed. A cluster with the high availability mode disabled must contain three nodes at least. If the high availability mode is enabled, another master node must be added to the cluster.

3. Configure basic parameters.

Section	Parameter	Description
Basic Information	**Cluster Name**	The name of the cluster. The name must be 1 to 64 characters in length and can contain only letters, digits, hyphens (-), and underscores (_).
	Assign Public Network IP	This feature is disabled by default.

Section	Parameter	Description
	Password	The password used to log on to the master node. The password must be 8 to 30 characters in length and contain letters, digits, and special characters. The following special characters are supported: ! @ # $ % ^ & *
Advanced Settings	**Permission Settings**	The RAM roles that allow applications running in a cluster to access other Alibaba Cloud services. You can use the default RAM roles. ○ **EMR Role**: The value is fixed to AliyunEMRDefaultRole and cannot be changed. This RAM role authorizes a cluster to access other Alibaba Cloud services, such as ECS and OSS. ○ **ECS Role**: You can also assign an application role to a cluster. Then, EMR applies for a temporary AccessKey pair when applications running on the compute nodes of that cluster access other Alibaba Cloud services, such as OSS. This way, you do not need to manually enter an AccessKey pair. You can grant the application role access permissions on specific Alibaba Cloud services as required.
	Bootstrap Actions	Optional. You can configure bootstrap actions to run custom scripts before a cluster starts Hadoop.

Confirm the creation

Verify that the configuration is correct and click **Create**.

5.4.2.2. Cluster list and details

This topic describes the parameters in the cluster list, parameters on the cluster details page, and supported cluster operations.

Cluster list

The Cluster Management tab displays the basic information about all of your clusters and the operations supported by each cluster.

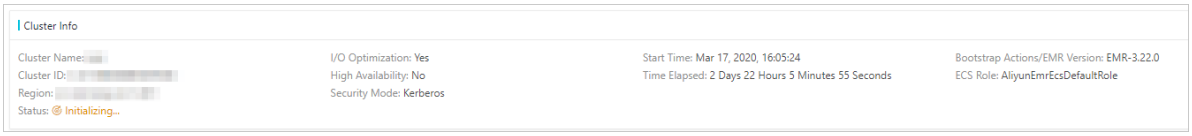
Parameter	Description
Cluster ID/Name	The ID and name of the cluster. Move your pointer over a cluster name and click the icon to modify the cluster name.
Cluster Type	The type of the cluster. Hadoop, Kafka, and Druid cluster types are supported.

Parameter	Description
Status	The status of the cluster. If a cluster experiences an exception, such as a creation failure, error information appears in this column. You can move the pointer over the Help icon next to the error information to view detailed error information.
Created At	The time when the cluster was created.
Time Elapsed	The duration from the point of creation to the current time. After the cluster is released, the time is no longer measured.
Actions	The operations that can be performed on the cluster. The supported operations include: • **Manage**: Go to the Clusters and Services page. • **Details**: View detailed information about the cluster on the Cluster Overview page.

Cluster details

The Cluster Overview page displays detailed information about the cluster and consists of four sections: Cluster Info, Software Info, Network Info, and Instance Info.

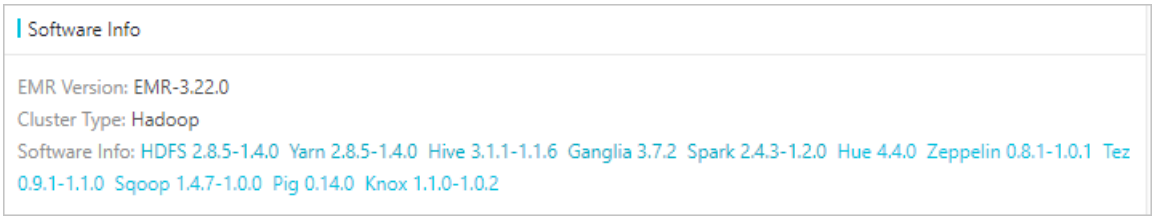
- Cluster Info



Parameter	Description
Cluster Name	The name of the cluster.
Cluster ID	The ID of the cluster.
Region	The region where the cluster resides.
Status	The status of the cluster.
I/O Optimization	Specifies whether I/O optimization is enabled.
High Availability	Specifies whether high availability is enabled.
Security Mode	The security mode. The software of the cluster starts in Kerberos security mode.
Start Time	The time when the cluster was created.
Time Elapsed	The duration from the point of creation to the current time.
Bootstrap Actions/EMR Version	Information about custom scripts and software configuration.

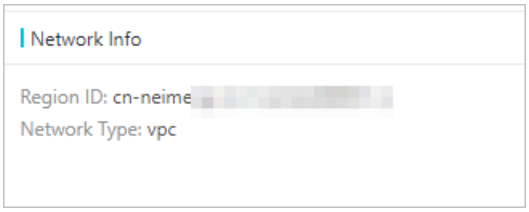
Parameter	Description
ECS Role	The ECS application role. You can assign an application role to a cluster. This way, EMR applies for a temporary AccessKey pair when applications running on the compute nodes of the cluster access other Alibaba Cloud services, such as OSS. You do not need to manually enter an AccessKey pair. You can grant the application role access permissions on specific Alibaba Cloud services as required.

- Software Info



Parameter	Description
EMR Version	The major version of EMR.
Cluster Type	The type of the cluster.
Software Info	All user-installed applications and their versions.

- Network Info



Parameter	Description
Region ID	The zone where the cluster resides, such as cn-hangzhou-b. The value is also the ID of the zone where the ECS instance resides.
Network Type	The network type of the cluster.

- Instance Info

Master instance group information

Parameter	Description
Instances	The current number of instances, and the number of instances that you have requested. Theoretically, the two values are the same. However, the current number is less than the requested number during the cluster creation process.
CPU	The number of CPU cores of a single instance.
Memory	The memory capacity of a single instance.
Data Disk Type	The data disk type and data disk capacity of a single instance.
ECS instances	The information about ECS instances in a master instance group. ○ **ECS ID**: the ID of the ECS instance. ○ **Deployment Status**: the deployment status of the ECS instance. Valid values: Initializing, Normal, and Scaling out. ○ **Public Network IP**: the public IP address of the ECS instance. ○ **Internal Network IP**: the internal IP address of the ECS instance, which can be accessed by all instances in the cluster. ○ **Created At**: the creation time of the ECS instance.

Core instance group information

Parameter	Description
Instances	The current number of instances, and the number of instances that you have requested.
CPU	The number of CPU cores of a single instance.
Memory	The memory capacity of a single instance.
Data Disk Type	The data disk type and data disk capacity of a single instance.
ECS instances	The information about ECS instances in a master instance group. ○ **ECS ID**: the ID of the ECS instance. ○ **Deployment Status**: the deployment status of the ECS instance. Valid values: Initializing, Normal, and Scaling out. ○ **Public Network IP**: the public IP address of the ECS instance. ○ **Internal Network IP**: the internal IP address of the ECS instance, which can be accessed by all instances in the cluster. ○ **Created At**: the creation time of the ECS instance.

5.4.2.3. View the running status of services

This topic describes how to view the running status of the services deployed in a cluster, such as HDFS and YARN, on the Clusters and Services page.

1. Log on to the E-MapReduce console.
2. Find the target cluster and click the **cluster ID**.
3. In the Services section of the **Clusters and Services** page, view the status of services.

   The following figure shows the list of services.

   If a service, such as Storm, is not selected when you create the cluster, it is not displayed in the Services section.

   You can click the name of a service to view its details, including the running status, deployment topology, configurations, and historical configuration modifications. A service may be in the **Normal** or **Error** state.

5.4.2.4. Create a gateway cluster

A gateway cluster is composed of ECS instances that reside in the same internal network as an EMR cluster. You can use a gateway cluster to achieve load balancing and security isolation and to submit jobs to the EMR cluster.

Create a gateway cluster in the EMR console

A gateway cluster can be associated only with an EMR Hadoop cluster. Before you create a gateway cluster, make sure that you have created an EMR Hadoop cluster. To create a gateway cluster, perform the following steps:

1. Log on to the E-MapReduce console.
2. In the upper-right corner of the page that appears, click **Create Gateway**.
3. On the **Create Gateway** page, specify the required parameters.
   - **Cluster Name**: the name of the gateway cluster. The name must be 1 to 64 characters in length and can contain only letters, digits, hyphens (-), and underscores (_).
   - **Assign Public Network IP**: specifies whether the gateway cluster is assigned an elastic IP address.
   - **Password**: the password used to log on to the gateway cluster. The password must be 8 to 30 characters in length and must contain uppercase letters, lowercase letters, digits, and special characters.

     The following special characters are supported:

     ! @ # $ % ^ & *
   - **Billing Method**: the billing method of the gateway cluster. The default value is **Pay-As-You-Go**. The system charges you for the gateway cluster on an hourly basis.
   - **Associated Cluster**: the EMR cluster associated with the gateway cluster. The gateway cluster submits jobs to this EMR cluster. The gateway cluster is automatically configured with the same Hadoop environment as the EMR cluster.
   - **Zone**: the zone where the associated cluster resides.
   - **Network Type**: the network type of the associated cluster.
   - **VPC**: the VPC to which the associated cluster belongs.
   - **VSwitch**: the VSwitch you want the gateway cluster to use. Select the VSwitch that corresponds to the zone and VPC.
   - **Security Group Name**: the name of the security group to which the associated cluster belongs.
   - **Gateway Instance**: the available ECS instance types in the current region.
   - **System Disk Type**: the type of the system disks you want the gateway cluster to use. System disk types include standard SSDs and ultra disks. By default, the system disks are released after the relevant cluster is released.
   - **Disk Size**: the size of each system disk. Unit: GiB. Valid values: 40 to 500. Default value: 300.
   - **Data Disk Type**: the type of the data disks you want the gateway cluster to use. Data disk types include standard SSDs and ultra disks. By default, the data disks are released after the relevant cluster is released.
   - **Disk Size**: the size of each data disk. Unit: GiB. Valid values: 200 to 4000. Default value: 300.
   - **Count**: the number of data disks. Valid values: 1 to 10.
4. Click **Create** to save the configurations.

   The created gateway cluster appears in the cluster list. The value of **Status** is **Idle**.

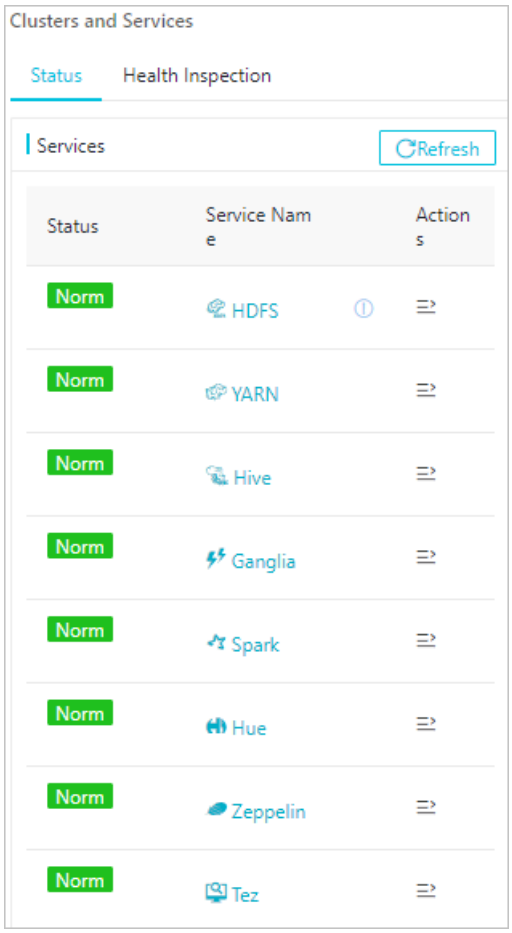
5.4.3. Third-party software

5.4.3.1. Configure parameters for components

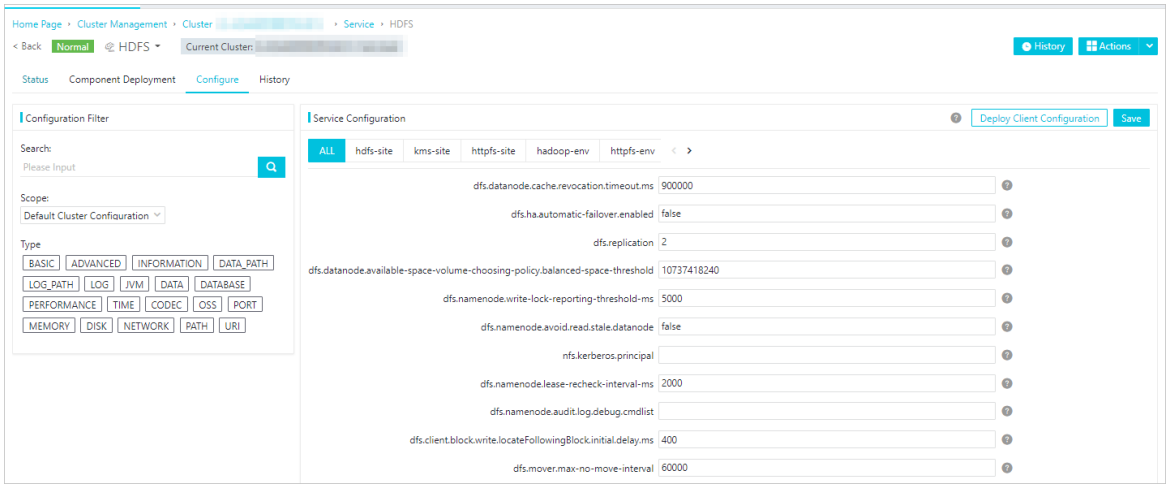
EMR allows you to configure parameters and change parameter settings for components such as HDFS, YARN, Spark, Kafka, and Druid.

Change the parameter settings of an existing component

1. Log on to the E-MapReduce console.
2. Find the target cluster and click its ID.
3. In the Services section, click the component for which you want to change a parameter setting, such as **HDFS**.



4. On the HDFS page, click the **Configure** tab.



5. In the **Configuration Filter** section, enter the parameter whose setting you want to change in the search box and click the search icon. You can also specify Scope and Type for the search.
6. In the Service Configuration section, find the target parameter and change its setting. If the parameter does not exist, click the tab that corresponds to the component. Then, in the upper-right corner of the tab, click **Custom Configuration**. In the dialog box that appears, specify the required parameters and click OK.

   - Key: the name of the parameter
   - Value: the value of the parameter
   - Description: the description of the parameter
7. In the upper-right corner of the Service Configuration section, click **Save**. If you want to synchronize the new setting to the gateway cluster associated with the current cluster, select the gateway cluster in the Synchronize to Associated Gateway Cluster section of the **Confirm Changes** dialog box.

Then, make the setting take effect by following the instructions provided in Make configurations take effect.

Make configurations take effect

- Client configuration
  i. After you change the setting of a client configuration parameter, click **Deploy Client Configuration** in the upper-right corner of the Service Configuration section. The **Cluster Activities** dialog box appears.
  ii. Set Target Nodes to Matching Nodes or Designated Node.
  iii. Enter the reason for the change in the Description field.

iv. Click **OK**.

You can click **History** in the upper-right corner of the HDFS page to view the execution status and progress.

- Server configuration

> **Note** After you change the setting of a server configuration parameter, you must restart the current component.

i. In the upper-right corner of the Service Configuration section, click **Deploy Client Configuration**. The **Cluster Activities** dialog box appears.

ii. Specify Target Nodes.

iii. Enter the reason for the change in the Description field.

iv. Click **OK**.

You can click **History** in the upper-right corner of the HDFS page to view the execution status and progress.

Roll back parameter settings

To roll back a parameter setting, perform the following steps:

1. Log on to the E-MapReduce console.
2. Find the target cluster and click its ID.
3. In the Services section, click the component for which you want to change a parameter setting, such as **HDFS**.
4. On the HDFS page, click the **History** tab.
5. Find the target parameter and click **Roll Back** in the Actions column.

Then, make the parameter setting take effect by following the instructions provided in Make configurations take effect.

6.DataHub

6.1. What is DataHub?

DataHub collects, stores, and processes streaming data, allowing you to analyze streaming data and build applications based on the streaming data.

DataHub is a platform designed to process streaming data. You can publish and subscribe to streaming data in DataHub and distribute the data to other platforms. DataHub allows you to analyze streaming data and build applications based on the streaming data.

DataHub collects, stores, and processes streaming data from mobile devices, applications, website services, and sensors. You can use your own applications or Apsara Stack Realtime Compute to process streaming data in DataHub, such as real-time website access logs, application logs, and events. The processing results such as alerts and statistics presented in graphs and tables are updated in real time.

Based on the Apsara system of Alibaba Cloud, DataHub features high availability, low latency, high scalability, and high throughput. DataHub is seamlessly integrated with Realtime Compute, allowing you to use SQL to analyze streaming data.

DataHub can also distribute streaming data to Apsara Stack services such as MaxCompute and Object Storage Service (OSS).

DataHub supports the following features:

- **Data queue**: DataHub automatically generates a cursor for each record in a shard, which can be considered as a logical data queue. The cursor is a unique sequence of numbers. You can improve the performance of a topic by increasing the number of shards in the topic.
- **Offset-based data consumption**: DataHub saves consumption offsets for applications. You can resume data consumption from a saved consumption offset when your application fails.
- **Data synchronization**: Data in DataHub can be automatically synchronized to other Apsara Stack services, including MaxCompute, OSS, AnalyticDB, ApsaraDB RDS for MySQL, Tablestore, and Elasticsearch.
- **Scalable topics**: DataHub allows you to scale in or out topics by splitting or merging shards.

6.2. Usage notes

Before you use DataHub, get familiar with the limits on specific features.

The following table describes the limits of DataHub.

Limits

Item	Limit	Description
Active shards per topic	(0,256]	Each topic can contain up to 256 active shards.
Shards	(0,512]	You can create up to 512 shards in each topic.
HTTP request body size	Up to 4 MB	The size of the HTTP request body cannot exceed 4 MB.

Item	Limit	Description
String size	Up to 1 MB	The size of a string cannot exceed 1 MB.
Merge and split operations on new shards	5s	You cannot merge a shard with another shard or split the shard within the 5s after the shard is created.
Queries per second (QPS)	Up to 5,000	The write QPS limit for each shard is 5,000. Multiple queries in one batch are considered as one query.
Throughput	Up to 5 MB/s	Each shard provides a throughput of up to 5 MB/s.
Projects	Up to 100	You can create up to 100 projects with each account.
Topics per project	Up to 1,000	You can create up to 1,000 topics in each project. Contact the administrator if you need to create more topics.
Time-to-live (TTL) of records	[1,7]	The TTL of each record in a topic ranges from one to seven days.

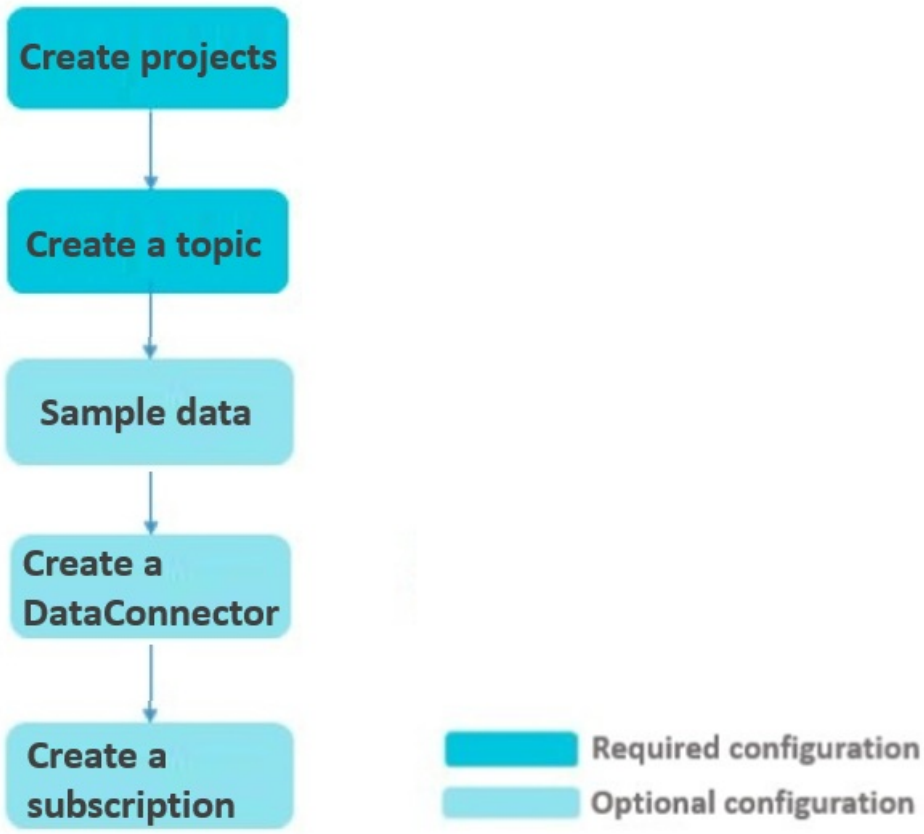
6.3. Quick Start

6.3.1. Overview

This topic describes the procedure of using DataHub.

Procedure shows the procedure of using DataHub.

Procedure



1. Create projects.

   A project is an organizational unit in DataHub and contains one or more topics. When you use DataHub, you must create a project first.

2. Create a topic.

   A topic is the smallest unit for data subscription and publication. You can use topics to distinguish different types of streaming data.

3. Optional. Sample data.

   DataHub supports data sampling. You can sample data of a specific shard.

4. Optional. Create a DataConnector.

   You can synchronize real-time data from DataHub to other data warehouses by using DataConnectors so that you can analyze and process historical data.

5. Optional. Create a subscription.

   The subscription feature of DataHub supports saving consumption offsets on the server and allows applications to resume data consumption from saved consumption offsets. In addition, DataHub supports resetting offsets to ensure that data can be consumed at least once.

6.3.2. Log on to the DataHub console

This topic describes how to log on to the DataHub console by using Google Chrome.

Prerequisites

Before you log on to the DataHub console, make sure that the following prerequisites are met:

- The IP address or domain name of the Apsara Stack console is obtained from deployment engineers.

  The URL used to access the Apsara Stack console is in the following format: https://IP address or domain name of the Apsara Stack console.
- Google Chrome is upgraded to version 42.0.0 or later.

Procedure

1. In the address bar, enter the URL used to log on to the Apsara Stack console and press Enter.
2. Enter your username and password.

   Obtain the username and password for logging on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Stack console for the first time, you must change the password as instructed. For security concerns, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two types of the following characters: letters, digits, and special characters such as exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).
3. Click **Login** to go to the Apsara Stack console homepage.
4. In the top navigation bar, choose **Products** > **Big Data** > **DataHub** to go to the DataHub console. The **Overview** page appears.

6.3.3. Create a project

A project is an organizational unit in DataHub and contains one or more topics. When you use DataHub, you must create a project first. This topic describes how to create a project in the DataHub console.

Prerequisites

An Apsara Stack tenant account is created.

Background information

- DataHub projects are independent from MaxCompute projects. Projects you created in MaxCompute cannot be used in DataHub.
- You can create up to 100 projects with each account.

Procedure

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, click **Create Project**. On the Create Project page, set parameters in the Region and Basic Settings sections and click **Submit**.

6.3.4. Create a topic

A topic is the smallest unit for data subscription and publication. You can use topics to distinguish different types of streaming data. This topic describes how to create a topic in the DataHub console.

Prerequisites

A project is created.

Background information

You can create up to 1,000 topics in each project. Contact the administrator if you need to create more topics.

Procedure

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click **View** in the Operate column.
3. On the project details page, click **Create Topic**.
4. In the Create Topic dialog box, set relevant parameters and click **Create**.

> **Note** DataHub allows you to directly create a topic or create a topic by importing a table schema from MaxCompute.

6.3.5. Sample data

DataHub supports data sampling. You can sample data of a specific shard. This topic describes how to sample data in the DataHub console.

Prerequisites

A project and a topic are created and data is written to the topic.

Background information

Before you sample data, you must specify the start time and the maximum number of records that you want to sample.

Procedure

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click View in the Operate column. On the project details page, find the target topic and click **View** in the Operate column.
3. On the Shard List tab of the topic details page, find the target shard and click **Sample** in the Operate column.
4. In the dialog box that appears, specify the start time and the maximum number of records that you want to sample and click **Sample**. DataHub samples the records that are written to the shard after the specified time and displays the sampled records in the table below

Sample.

6.3.6. Create a DataConnector

You can synchronize real-time data from DataHub to other data warehouses by using DataConnectors so that you can analyze and process historical data. This topic describes how to create a DataConnector in the DataHub console.

Prerequisites

A project and a topic are created and data is written to the topic.

Background information

You can synchronize data from DataHub to MaxCompute, AnalyticDB, ApsaraDB RDS for MySQL, Tablestore, OSS, and Elasticsearch.

Procedure

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click View in the Operate column. On the project details page, find the target topic and click **View** in the Operate column.
3. On the topic details page, click **Connector**. In the Create connector dialog box, select the data warehouse to which data is synchronized.
4. In the Create connector dialog box, set relevant parameters and click **Create**.

6.3.7. Create a subscription

The subscription feature of DataHub supports saving consumption offsets on the server and allows applications to resume data consumption from saved consumption offsets. In addition, DataHub supports resetting offsets to ensure that data can be consumed at least once. This topic describes how to create a subscription in the DataHub console.

Prerequisites

A project and a topic are created and data is written to the topic.

Procedure

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click View in the Operate column. On the project details page, find the target topic and click **View** in the Operate column.
3. On the topic details page, click **Subscription**. In the Create subscription dialog box, set relevant parameters and click **Create**.

6.4. Access Control

6.4.1. Overview

DataHub allows you to improve data security by granting different permissions to Apsara Stack tenant accounts and RAM user accounts.

DataHub uses Resource Access Management (RAM) for access control. Only users that have been granted the required permissions can access the resources in your department. By default, users do not have permission to access resources in your department. This topic describes how access control for DataHub is achieved by using RAM.

> **Note** An Apsara Stack tenant account is owned by a department and requires no authorization. A RAM user account must be granted permissions by the tenant account.

6.4.2. DataHub resources in RAM

The DataHub resources in RAM are project, topic, and subscription. Subscription is the action that you specify an application to read and process the records in DataHub. DataHub supports RAM authorization of project, topic, and subscription. RAM authorization is not supported at the shard level.

In RAM, each resource type has a general description and each specific object of the resource type has a description. For example, the description of a project that resides in a certain region is *acs:dhs:$region:$accountid:projects/$projectName*. *$region, $accountid, and $projectName* indicate the region that the project resides, the user ID, and the project name.

Resource description

Resource type	Description
SingleProject	acs:dhs:$region:$accountid:projects/$projectName
AllProject	acs:dhs:$region:$accountid:projects/*
SingleTopic	acs:dhs:$region:$accountid:projects/$projectName/topics/$topicName
AllTopic	acs:dhs:$region:$accountid:projects/$projectName/topics/*
SingleSubscription	acs:dhs:$region:$accountid:projects/$projectName/topics/$topicName/subscriptions/$subId
AllSubscription	acs:dhs:$region:$accountid:projects/$projectName/topics/$topicName/subscriptions/*

6.4.3. API

DataHub provides application programming interfaces (APIs) for projects, topics, shards, subscriptions, and records. Before you can call the API operations, you must grant corresponding permissions to the RAM user by using RAM authorization policies.

The RAM authorization policy and resource type for each API operation is described as follows:

API operations for projects

API operations for projects

Operation name	RAM authorization policy	Resource type
CreateProject	dhs:CreateProject	AllProject
ListProject	dhs:ListProject	AllProject
DeleteProject	dhs:DeleteProject	SingleProject
GetProject	dhs:GetProject	SingleProject
UpdateProject	dhs: UpdateProject	SingleProject

API operations for topics

API operations for topics

Operation name	RAM authorization policy	Resource type
CreateTopic	dhs:CreateTopic	AllTopic
ListTopic	dhs:ListTopic	AllTopic
DeleteTopic	dhs:DeleteTopic	SingleTopic
GetTopic	dhs:GetTopic	SingleTopic
UpdateTopic	dhs: UpdateTopic	SingleTopic

API operations for subscriptions

API operations for subscriptions

Operation name	RAM authorization policy	Resource type
CreateSubscription	dhs:CreateSubscription	AllSubscription
ListSubscription	dhs:ListSubscription	AllSubscription
DeleteSubscription	dhs:DeleteSubscription	SingleSubscription
GetSubscription	dhs:GetSubscription	SingleSubscription
UpdateSubscription	dhs: UpdateSubscription	SingleSubscription
CommitOffset	dhs:CommitOffset	SingleSubscription
GetOffset	dhs:GetOffset	SingleSubscription

API operations for shards

API operations for shards

Operation name	RAM authorization policy	Resource type
ListShard	dhs:ListShard	SingleTopic
MergeShard	dhs:MergeShard	SingleTopic
SplitShard	dhs:SplitShard	SingleTopic

API operations for shards

API operations for shards

Operation name	RAM authorization policy	Resource type
PutRecords	dhs:PutRecords	SingleTopic
GetRecords	dhs:GetRecords	SingleTopic
GetCursor	dhs:GetRecords	SingleTopic

6.4.4. Conditions

This section describes conditions that can be applied to the RAM authorization policies for DataHub.

Conditions that can be applied to the RAM authorization policies for DataHub are as follows:

RAM authorization policy conditions for DataHub

Condition keyword	Description	Valid value
acs:SourceIp	The IP address range that can access the specified object.	Any valid IP address. Wildcard masks are supported.
acs:SecureTransport	Indicates whether HTTPS is used to access the specified object.	true/false
acs:MFAPresent	Indicates whether the specified object can be accessed by multiple clients.	true/false
acs:CurrentTime	The time that the specified object can be accessed.	This keyword must be described in ISO 8601 format.

6.4.5. Sample RAM authorization policy content

6.4.5.1. AliyunDataHubFullAccess

This section describes how to set the AliyunDataHubFullAccess policy content.

The authorization policy content can be set as follows:

```
{
 "Version": "1",
 "Statement": [
  {
   "Action": "dhs:*",
   "Resource": "*",
   "Effect": "Allow"
  }
 ]
}
```

6.4.5.2. AliyunDataHubReadOnlyAccess

This section describes how to set the AliyunDataHubReadOnlyAccess policy content.

The authorization policy content can be set as follows:

```
{
 "Version": "1",
 "Statement": [
  {
   "Action": ["dhs:List*", "dhs:Get*"],
   "Resource": "*",
   "Effect": "Allow"
  }
 ]
}
```

6.5. Data Acquisition

6.5.1. Overview

In addition to SDK and local file uploads, DataHub supports various data acquisition tools to help you quickly collect data to DataHub.

This section describes how to acquire data by using Fluentd, Logstash, and Oracle GoldenGate (OGG).

6.5.2. Fluentd

This topic describes how to install and use the DataHub plug-in for Fluentd.

Developed based on the open-source data collector Fluentd, the DataHub plug-in for Fluentd is easy to install and is used to write the collected data to DataHub.

Install the DataHub plug-in for Fluentd

- Install the plug-in by using RubyGems

```
gem install fluent-plugin-datahub
```

> **Notice** We recommend that you change the gem source to https://ruby.taobao.org/.

- Install the plug-in by using a local installation package

  The agent must be installed in Linux. Before you install the agent, install Ruby. For users who have not installed Fluentd, a full installation package for installing both Fluentd and DataHub plug-in is provided. For users who have installed Fluentd, an installation package of the DataHub plug-in is provided.

  - If you have not installed Fluentd, download the full installation package and run the following commands to install Fluentd with the DataHub plug-in:

    > **Notice** Fluentd 0.12.23 is provided in the full installation package.

    ```
    $ tar -xzvf fluentd-with-datahub-0.12.23.tar.gz
    $ cd fluentd-with-dataHub
    $ sudo sh install.sh
    ```

  - If you have installed Fluentd, download the installation package of the DataHub plug-in for Fluentd and run the following command to install the plug-in.

    ```
    $ sudo gem install --local fluent-plugin-dataHub-0.0.2.gem
    ```

Use cases

Case 1: Collect CSV files

This example shows how to write the incremental content of a Comma-Separated Values (CSV) file to DataHub in quasi-real time by using the DataHub plug-in for Fluentd. The following CSV file is used in this example:

```
0,qe614c760fuk8judu01tn5x055rpt1,true,100.1,14321111111
1,znv1py74o8ynn87k66o32ao4x875wi,true,100.1,14321111111
2,7nm0mtpgo1q0ubuljjjx9b000ybltl,true,100.1,14321111111
3,10t0n6pvonnan16279w848ukko5f6l,true,100.1,14321111111
4,0ub584kw88s6dczd0mta7itmta10jo,true,100.1,14321111111
5,1ltfpf0jt7fhvf0oy4lo8m3z62c940,true,100.1,14321111111
6,zpqsfxqy9379lmcehd7q8kftntrozb,true,100.1,14321111111
7,ce1ga9aln346xcj761c3iytshyzuxg,true,100.1,14321111111
8,k5j2id9a0ko90cykl40s6ojq6gruyi,true,100.1,14321111111
9,ns2zcx9bdip5y0aqd1tdicf7bkdmsm,true,100.1,14321111111
10,54rs9cm1xau2fk66pzyz62tf9tsse4,true,100.1,14321111111
```

Each line is a record to be written to DataHub. Columns are separated by commas (,). Save the CSV file as /temp/test.csv on the local computer. The following table shows the schema of the DataHub topic to which the CSV file is written.

DataHub topic schema

Field	Data type
id	BIGINT
name	STRING
gender	BOOLEAN
salary	DOUBLE
my_time	TIMESTAMP

After you edit the Fluentd configuration file based on the CSV file and topic schema, run the following command to start Fluentd to write the CSV file to DataHub:

```
${FLUENTD_HOME}/fluentd-with-dataHub/bin/fluentd -c fluentd_test.conf
```

Use the following Fluentd configuration file in this example:

```
<source>
  @type tail
  path /xxx/yyy (Specify the path of the CSV file.)
  tag test1
  format csv
  keys id,name,gender,salary,my_time
</source>

<match test1>
  @type dataHub
  access_id your_app_id
  access_key your_app_key
  endpoint http://ip:port
  project_name test_project
  topic_name fluentd_performance_test_1
  column_names ["id", "name", "gender", "salary", "my_time"]
  flush_interval 1s
  buffer_chunk_limit 3m
  buffer_queue_limit 128
  dirty_data_continue true
  dirty_data_file /xxx/yyy (Specify the path of the dirty record file.)
  retry_times 3
  put_data_batch_size 1000
</match>
```

Case 2: Collect Log4j logs

The following format of Log4j logs is used in this example:

```
11:48:43.439 [qtp1847995714-17] INFO  AuditInterceptor - [c2un5sh7cu52ek6am1ui1m5h] end /web/v1/p
roject/tefe4mfurtix9kwwyrvfqd0m/node/0m0169kapshvgc3ujskwkk8g/health GET, 4061 ms
```

Use the following Fluentd configuration file in this example:

```
<source>
  @type tail
  path bayes.log
  tag test
  format /(? <request_time>\d\d:\d\d:\d\d.\d+)\s+\[(? <thread_id>[\w\-]+)\]\s+(? <log_level>\w+)\s+(
? <class>\w+)\s+-\s+\[(? <request_id>\w+)\]\s+(? <detail>.+)/
</source>

<match test>
  @type dataHub
  access_id your_access_id
  access_key your_access_key
  endpoint http://ip:port
  project_name test_project
  topic_name dataHub_fluentd_out_1
  column_names ["thread_id", "log_level", "class"]
</match>
```

Parameter description

Input configuration

Parameter	Description
tag test1	The tag, which is mapped to the destination information by using the specified regular expression.
format csv	The format of the file from which data is collected.
keys id,name,gender,salary,my_time	The columns to be collected from the CSV file. The column names must be the same as those in the schema of the destination DataHub topic.

Output configuration

Parameter	Description
shard_id 0	The ID of the shard to which all records are written. By default, all records are written to the shard by polling. The default ID is 0.
shard_keys ["id"]	The column used as the shard key. Hashed shard key values are used as indexes for writing data.
flush_interval 1	The interval between data flushes. The default value is 60s.

Parameter	Description
buffer_chunk_limit 3m	The maximum size of a chunk. Unit: k or m, which indicates KB or MB. We recommend you set the maximum size to 3 MB.
buffer_queue_limit 128	The maximum length of the chunk queue. Both the buffer_chunk_limit and buffer_queue_limit parameters determine the size of the buffer. The default value is 128 MB.
put_data_batch_size 1000	The number of records to be written to DataHub at a time. In this example, 1,000 records are written to DataHub each time.
retry_times 3	The number of retries for writing data to DataHub. Default value: 3.
retry_interval 3	The retry interval at which data is written. Unit: seconds. Default value: 3.
dirty_data_continue true	Specifies whether to ignore dirty records. The value true indicates that the plug-in retries the operation for a specified number of times before it writes the dirty records to the dirty record file.
dirty_data_file /xxx/yyy	The directory where the dirty record file is stored.
column_names ["id"]	The name of the columns to be written to DataHub.

6.5.3. Logstash

This topic describes how to install and use Logstash to import data to DataHub and export data from DataHub.

Logstash is a distributed log collection framework. It is often used with Elasticsearch and Kibana, known as the ELK Stack, for log data analysis. To support a wider variety of data inputs, DataHub offers Output and Input plug-ins for data transfer with Logstash. By using Logstash, you can access more than 30 types of data sources in the Logstash open source community, such as files, Syslog logs, Redis logs, Log4j logs, Apache logs, and NGINX logs. Logstash also supports filter plug-ins for customizing the fields to be transferred. This topic demonstrates how to use Logstash with DataHub.

Install Logstash and DataHub plug-ins

Java Runtime Environment (JRE) 7 or later is required to run Logstash. If the JRE version does not meet the requirement, several features of Logstash are unavailable. You can install Logstash and DataHub plug-ins with one click by downloading and decompressing the software package or install Logstash and DataHub plug-ins separately.

- Install Logstash and DataHub plug-ins with one click: Download the software package.

  Run the following commands to decompress the package and go to the software directory:

```
$ tar -xzvf logstash-with-datahub-2.3.0.tar.gz
$ cd logstash-with-datahub-2.3.0
```

- Install Logstash and DataHub plug-ins separately
  - Install Logstash. For more information, see the documentation on the official website of Logstash.
  - Install the DataHub Output plug-in for Logstash. You can use this plug-in to import data to DataHub.
  - Install the DataHub Input plug-in for Logstash. You can use this plug-in to export data from DataHub.

Use cases

Case 1: Collect Log4j logs

This example shows how to collect unstructured Log4j logs and derive a structure out of the logs by using Logstash. The following format of Log4j logs is used in this example:

```
20:04:30.359 [qtp1453606810-20] INFO  AuditInterceptor - [13pn9kdr5tl84stzkmaa8vmg] end /web/v1/project/fhp4clxfbu0w3ym2n7ee6ynh/statistics? executionName=bayes_poc_test GET, 187 ms
```

In this example, you can derive a structure out of the logs and transfer the data to DataHub. The following table shows the schema of the DataHub topic to which the Log4j logs are written.

DataHub topic schema

Field	Data type
request_time	STRING
thread_id	STRING
log_level	STRING
class_name	STRING
request_id	STRING
detail	STRING

Use the following configuration of the Logstash task in this example:

```
input {
    file {
        path => "${APP_HOME}/log/bayes.log"
        start_position => "beginning"
    }
}

filter{
    grok {
        match => {
          "message" => "(? <request_time>\d\d:\d\d:\d\d\.\d+)\s+\[(? <thread_id>[\w\-]+)\]\s+(? <log_le
vel>\w+)\s+(? <class_name>\w+)\s+\-\s+\[(? <request_id>\w+)\]\s+(? <detail>.+)"
        }
    }
}

output {
    datahub {
        access_id => "Your accessId"
        access_key => "Your accessKey"
        endpoint => "Endpoint"
        project_name => "project"
        topic_name => "topic"
        #shard_id => "0"
        #shard_keys => ["thread_id"]
        dirty_data_continue => true
        dirty_data_file => "/Users/ph0ly/trash/dirty.data"
        dirty_data_file_max_size => 1000
    }
}
```

Case 2: Collect CSV files

This example shows how to use Logstash to collect CSV files. The following CSV file is used in this example:

```
1111,1.23456789012E9,true,14321111111000000,string_dataxxx0,
2222,2.23456789012E9,false,14321111111000000,string_dataxxx1
```

The following table shows the schema of the DataHub topic to which the CSV file is written.

DataHub topic schema

Field	Data type
col1	BIGINT
col2	DOUBLE
col3	BOOLEAN
col4	TIMESTAMP
col5	STRING

Use the following configuration of the Logstash task in this example:

```
input {
  file {
    path => "${APP_HOME}/data.csv"
    start_position => "beginning"
  }
}

filter{
  csv {
    columns => ['col1', 'col2', 'col3', 'col4', 'col5']
  }
}

output {
  datahub {
    access_id => "Your accessId"
    access_key => "Your accessKey"
    endpoint => "Endpoint"
    project_name => "project"
    topic_name => "topic"
    #shard_id => "0"
    #shard_keys => ["thread_id"]
    dirty_data_continue => true
    dirty_data_file => "/Users/ph0ly/trash/dirty.data"
    dirty_data_file_max_size => 1000
  }
}
```

Case 3: Consume data from DataHub

Use the following configuration of the Logstash task in this example:

```
input {
  datahub {
    access_id => "Your accessId"
    access_key => "Your accessKey"
    endpoint => "Endpoint"
    project_name => "test_project"
    topic_name => "test_topic"
    interval=> 5
    #cursor => {
    #   "0"=>"20000000000000000000000003110091"
    #   "2"=>"20000000000000000000000003110091"
    #   "1"=>"20000000000000000000000003110091"
    #   "4"=>"20000000000000000000000003110091"
    #   "3"=>"20000000000000000000000003110000"
    #}
    shard_ids => []
    pos_file => "/home/admin/logstash/logstash-2.3.0/pos_file"
  }
}

output {
  file {
    path => "/home/admin/logstash/logstash-2.3.0/output"
  }
}
```

Start Logstash

Run the following command to start Logstash:

```
$LOGSTASH_HOME/bin/logstash -f <The preceding configuration file> -b 256
```

> **Note** -f is followed by the path of the configuration file. -b is followed by the number of records transferred to DataHub at a time. Default value: 125.

Parameters

The following table describes the parameters of the DataHub Output plug-in.

Parameters of the DataHub Output plug-in

Parameter	Description
access_id	Required. The AccessKey ID of your Apsara Stack tenant account.
access_key	Required. The AccessKey secret of your Apsara Stack tenant account.
endpoint	Required. The endpoint used to access DataHub.
project_name	Required. The name of the DataHub project.
topic_name	Required. The name of the DataHub topic.
retry_times	Optional. The maximum number of retries. The value -1 indicates unlimited retries. The value 0 indicates no retries. A value greater than 0 indicates the specified number of retries. Default value: -1.
retry_interval	Optional. The interval between retries. Unit: seconds. Default value: 5.
shard_keys	Optional. The key of the shard. The hash of the key value is used to map the ID of the shard to which the records are written. If the shard_keys and shard_id parameters are not specified, the system polls the shards to decide which shard the records are written to.
shard_id	Optional. The ID of the shard where records are written. If the shard_keys and shard_id parameters are not specified, the system polls the shards to decide which shard the records are written to.
dirty_data_continue	Optional. Specifies whether to ignore dirty records. The value true indicates that dirty records are to be ignored. Default value: false. If you set the value to true, you must specify the dirty_data_file parameter.
dirty_data_file	Optional. The name of the dirty record file. The dirty record file is divided into .part 1 and .part 2. The most recent records are stored in .part 2.
dirty_data_file_max_size	Optional. The maximum size of the dirty record file. This value is for reference only.

The following table describes the parameters of the DataHub Input plug-in.

Parameters of the DataHub Input plug-in

Parameter	Description
access_id	Required. The AccessKey ID of your Apsara Stack tenant account.
access_key	Required. The AccessKey secret of your Apsara Stack tenant account.
endpoint	Required. The endpoint used to access DataHub.
project_name	Required. The name of the DataHub project.
topic_name	Required. The name of the DataHub topic.

Parameter	Description
retry_times	Optional. The maximum number of retries. The value -1 indicates unlimited retries. The value 0 indicates no retries. A value greater than 0 indicates the specified number of retries. Default value: -1.
retry_interval	Optional. The interval between retries. Unit: seconds. Default value: 5.
shard_ids	Optional. The shards in which records are to be consumed. If this parameter is not specified, records in all the shards are consumed.
cursor	Optional. The sequence number of the record from which the consumption begins. The consumption starts from the earliest record by default.
pos_file	Required. The checkpoint file, which is used to reset the consumption offset.

6.5.4. Oracle GoldenGate

This topic describes how to install and use Oracle GoldenGate (OGG).

OGG is a tool for log-based structured data replication across heterogeneous environments. It is used for data backup between primary and secondary Oracle databases. It is also used to synchronize data from Oracle databases to other databases such as IBM Db2 and MySQL databases. OGG must be deployed in the source and destination databases. It is composed of the following components: Manager, Extract, data pump, Collector, and Replicat.

- Manager is the control process of OGG. A Manager process must be running on the source and destination databases. It is responsible for starting, stopping, and monitoring other processes.
- Extract is a process that captures data from the source database or transaction logs. You can configure the Extract process for initial data loads and incremental data synchronization. For initial data loads, Extract captures a set of data directly from their source objects. To keep source data synchronized to the destination database, Extract captures incremental DML and DDL operations after the initial data loading has taken place. This topic describes incremental data synchronization.
- A data pump is a secondary Extract group within the source OGG configuration. In a typical configuration with a data pump, the primary Extract group writes to a trail on the source database. The data pump reads the trail and sends the DML or DDL operations over the network to a remote trail on the destination database.
- Collector is a process on the destination database, which receives data from the source database and generates trail files.
- Replicat is a process that reads the trail on the destination database, reconstructs the DML or DDL operations, and then applies them to the destination database.

The DataHub agent for OGG offers the Replicat feature that applies the updated data to DataHub by analyzing the trail. The data in DataHub is processed in real time by using Realtime Compute and can be archived into MaxCompute.

The following example shows how to synchronize incremental data from an Oracle database to DataHub and process the data in DataHub.

Install OGG

Prerequisites:

- You have installed the Oracle database client.
- You have obtained the OGG installation package for the source database. We recommend that you use OGG V12.1.2.1.
- You have obtained the OGG Adapters installation package for the destination database. We recommend that you use OGG Application Adapters 12.1.2.1.
- You have installed Java 7.

Follow these steps to install OGG:

1. Install OGG for the source database.
   i. Extract the OGG installation package for the source database and the following directories appear:

```
drwxr-xr-x install
drwxrwxr-x response
-rwxr-xr-x runInstaller
drwxr-xr-x stage
```

   ii. Install dependencies in response/oggcore.rsp. The OGG response file template is as follows:

```
oracle.install.responseFileVersion=/oracle/install/rspfmt_ogginstall_response_schema
#The installation option, which must reflect the installed Oracle version. Specify ORA11g for i
nstalling OGG for Oracle Database 11g.
INSTALL_OPTION=ORA11g
#The location in which OGG is installed.
SOFTWARE_LOCATION=/home/oracle/u01/ggate
#Indicates whether to start the Manager after installation.
START_MANAGER=false
#The port number of the Manager process.
MANAGER_PORT=7839
#The location of the Oracle database.
DATABASE_LOCATION=/home/oracle/u01/app/oracle/product/11.2.0/dbhome_1
#The location that stores the inventory files. This parameter is not required to be configured.
INVENTORY_LOCATION=
#The UNIX group of the inventory directory. In this example, OGG is installed by using the ogg
_test Oracle account. You can also create a dedicated account for OGG as necessary.
UNIX_GROUP_NAME=oinstall
```

iii. Run the following command to install OGG:

```
runInstaller -silent -responseFile {YOUR_OGG_INSTALL_FILE_PATH}/response/oggcore.rsp
```

> **Note**
>
> In this example, OGG is installed in */home/oracle/u01/ggate* and the installation logs are stored in */home/oracle/u01/ggate/cfgtoollogs/oui*. The OGG installation is complete when the following message appears in the silentInstall{time}.log file:
>
> ```
> The installation of Oracle GoldenGate Core was successful.
> ```

iv. Run the following command and enter `CREATE SUBDIRS` as required to create OGG directories:

```
/home/oracle/u01/ggate/ggsci
```

2. Perform Oracle configurations in the source database.

   Navigate to *sqlplus: sqlplus / as sysdba* as the database administrator and complete the following configurations:

```
#Create a tablespace.
create tablespace ATMV datafile '/home/oracle/u01/app/oracle/oradata/uprr/ATMV.dbf' size 100
m autoextend on next 50m maxsize unlimited;

 #Create a user named ogg_test. The password is also set to ogg_test.
create user ogg_test identified by ogg_test default tablespace ATMV;

 #Grant required privileges to ogg_test.
grant connect,resource,dba to ogg_test;

 #Check whether supplemental logging is enabled for the database.
Select SUPPLEMENTAL_LOG_DATA_MIN, SUPPLEMENTAL_LOG_DATA_PK, SUPPLEMENTAL_LOG_DATA
_UI, SUPPLEMENTAL_LOG_DATA_FK, SUPPLEMENTAL_LOG_DATA_ALL from v$database;

 #If the result is NO, enable supplemental logging.
alter database add supplemental log data;
alter database add supplemental log data (primary key, unique,foreign key) columns;
 #Enable rollback.
alter database drop supplemental log data (primary key, unique,foreign key) columns;
alter database drop supplemental log data;

 #Enable all column logging at the database level. Note: Even when all column logging is enabled,
only primary key columns are logged for a delete operation.
```

```
ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (ALL) COLUMNS;
 #Enable the forced logging mode.
alter database force logging;
 #Run the marker_setup.sql script.
@marker_setup.sql
 #Run the ddl_setup.sql script.
@ddl_setup.sql
 #Run the role_setup.sql script.
@role_setup.sql
 #Grant the GGS_GGSUSER_ROLE to ogg_test.
grant GGS_GGSUSER_ROLE to ogg_test;
 #Run the ddl_enable.sql script to enable the DDL trigger.
@ddl_enable.sql
 #Run the ddl_pin script to improve the performance of the DDL trigger.
@ddl_pin ogg_test
 #Run the sequence.sql script.
@sequence.sql
#
alter table sys.seq$ add supplemental log data (primary key) columns;
```

3. Configure the Manager process on the source database.

   Start the Oracle GoldenGate Software Command Interface (GGSCI) and perform the following steps:

   i. Run the following command to configure the Manager process:

   ```
   edit params mgr
   PORT 7839
   DYNAMICPORTLIST  7840-7849
   USERID ogg_test, PASSWORD ogg_test
   PURGEOLDEXTRACTS ./dirdat/*, USECHECKPOINTS, MINKEEPDAYS 7
   LAGREPORTHOURS 1
   LAGINFOMINUTES 30
   LAGCRITICALMINUTES 45
   PURGEDDLHISTORY MINKEEPDAYS 3, MAXKEEPDAYS 7
   PURGEMARKERHISTORY MINKEEPDAYS 3, MAXKEEPDAYS 7
   ```

   ii. Run the following command to start the Manager process. The logs are stored in ggate/dirrpt.

   ```
   start mgr
   ```

iii. Run the following command to check whether the Manager process is running:

```
info mgr
```

iv. Run the following command to view the Manager parameter file:

```
view params mgr
```

4. Configure the Extract process on the source database.

   Start the GGSCI and perform the following steps:

   i. Run the following command to configure the Extract process. In the following example, the group name of the process is extract.

```
edit params extractEXTRACT extract
SETENV (NLS_LANG="AMERICAN_AMERICA.AL32UTF8")
DBOPTIONS   ALLOWUNUSEDCOLUMN
USERID ogg_test, PASSWORD ogg_test
REPORTCOUNT EVERY 1 MINUTES, RATE
NUMFILES 5000
DISCARDFILE ./dirrpt/ext_test.dsc, APPEND, MEGABYTES 100
DISCARDROLLOVER AT 2:00
WARNLONGTRANS 2h, CHECKINTERVAL 3m
EXTTRAIL ./dirdat/st, MEGABYTES 200
DYNAMICRESOLUTION
TRANLOGOPTIONS CONVERTUCS2CLOBS
TRANLOGOPTIONS RAWDEVICEOFFSET 0
DDL &
INCLUDE MAPPED OBJTYPE 'table' &
INCLUDE MAPPED OBJTYPE 'index' &
INCLUDE MAPPED OBJTYPE 'SEQUENCE' &
EXCLUDE OPTYPE COMMENT
DDLOPTIONS  NOCROSSRENAME  REPORT
TABLE    OGG_TEST.*;
SEQUENCE  OGG_TEST.*;

GETUPDATEBEFORES
```

   ii. Run the following command to add an Extract process. Replace extract in the following command with your actual group name.

```
add ext extract,tranlog, begin now
```

iii. Run the following command to delete an Extract process. In the following example, the process name is DP_TEST.

```
delete ext DP_TEST
```

iv. Run the following command to create a trail, associate the trail with the Extract group named extract, and set the maximum file size in the trail to 200 megabytes:

```
add exttrail ./dirdat/st,ext extract, megabytes 200
```

v. Run the following command to start the Extract process. The logs are stored in ggate/dirrpt.

```
start extract extract
```

Note After the Extract process configuration is complete, you can view the changes to the database in the files stored in the *ggate/dirdat* directory.

5. Create a DEFGEN parameter file.

i. Start the GGSCI in the source database. In GGSCI, run the following command to create a DEFGEN parameter file and copy the file to the dirdef directory in the destination database:

```
edit params defgen
DEFSFILE ./dirdef/ogg_test.def
USERID ogg_test, PASSWORD ogg_test
table OGG_TEST. *;
```

ii. Run the following command from the shell to create a DEFGEN parameter file named ogg_test.def:

```
./defgen paramfile ./dirprm/defgen.prm
```

6. Install and configure OGG in the destination database.

i. Extract the OGG installation package to the destination database.

ii. Copy the dirdef/ogg_test.def file in the source database to dirdef of the destination database.

iii. Start the GGSCI and run the following command to create the default directories of OGG:

```
create subdirs
```

iv. Run the following command to configure the Manager process:

```
edit params mgr
PORT 7839
DYNAMICPORTLIST  7840-7849
PURGEOLDEXTRACTS ./dirdat/*, USECHECKPOINTS, MINKEEPDAYS 7
LAGREPORTHOURS 1
LAGINFOMINUTES 30
LAGCRITICALMINUTES 45
PURGEDDLHISTORY MINKEEPDAYS 3, MAXKEEPDAYS 7
PURGEMARKERHISTORY MINKEEPDAYS 3, MAXKEEPDAYS 7
```

v. Run the following command to start the Manager process:

```
start mgr
```

7. Configure a data pump in the source database.

Start the GGSCI and perform the following steps:

i. Run the following command to configure a data pump:

```
edit params pump
EXTRACT pump
RMTHOST xx.xx.xx.xx, MGRPORT 7839, COMPRESS
PASSTHRU
NUMFILES 5000
RMTTRAIL ./dirdat/st
DYNAMICRESOLUTION
TABLE    OGG_TEST.*;
SEQUENCE  OGG_TEST.*;
```

ii. Run the following command to create a data-pump Extract process. The process reads from the specified trail.

```
add ext pump,exttrailsource ./dirdat/st
```

iii. Run the following command to create a trail and set the maximum file size in the trail to 200 megabytes:

```
add rmttrail ./dirdat/st,ext pump,megabytes 200
```

iv. Run the following command to start the data pump:

```
start pump
```

Note After the data pump is started, you can view the trail files in the dirdat directory of the destination database.

8. Install and configure the DataHub agent for OGG.
   i. Run the following command to configure the *JAVA_HOME and LD_LIBRARY_PATH* environment variables and specify the configurations in the ~/.bash_profile:

```
export JAVA_HOME=/xxx/xxx/jrexx
export LD_LIBRARY_PATH=${LD_LIBRARY_PATH}:$JAVA_HOME/lib/amd64:$JAVA_HOME/lib/amd64/server
```

   ii. After the environment variables are configured, restart the Manager process in the destination database.
   iii. Download the DataHub agent for OGG and extract the installation package.
   iv. Modify the javaue.properties and log4j.properties files in the conf sub-directory of the installation directory and replace {YOUR_HOME} with the target path of the extracted files:

```
gg.handlerlist=ggdatahub
gg.handler.ggdatahub.type=com.aliyun.odps.ogg.handler.datahub.DatahubHandler
gg.handler.ggdatahub.configureFileName={YOUR_HOME}/datahub-ogg-plugin/conf/configure.xml
goldengate.userexit.nochkpt=false
goldengate.userexit.timestamp=utc
gg.classpath={YOUR_HOME}/datahub-ogg-plugin/lib/*
gg.log.level=debug
jvm.bootoptions=-Xmx512m -Dlog4j.configuration=file:{YOUR_HOME}/datahub-ogg-plugin/conf/log4j.properties -Djava.class.path=ggjava/ggjava.jar
```

   v. Modify the configure.xml file in the conf sub-directory of the installation directory as follows:

```
<? xml version="1.0" encoding="UTF-8"? >
<configue>

  <defaultOracleConfigure>
    <! --(Required) The Oracle database system identifier (SID).-->
    <sid>100</sid>
    <! --The schema of the Oracle table, which can be overwritten by oracleSchema in the column mappings. At least one of them must be specified.-->
    <schema>ogg_test</schema>
  </defaultOracleConfigure>

  <defalutDatahubConfigure>
    <! --(Required) The endpoint of DataHub.-->
    <endPoint>YOUR_DATAHUB_ENDPOINT</endPoint>
    <! --The DataHub project, which can be overwritten by datahubProject in the column map
```

```
pings. At least one of them must be specified.-->
        <project>YOUR_DATAHUB_PROJECT</project>

sId in the column mappings. At least one of them must be specified.-->
        <accessId>YOUR_DATAHUB_ACCESS_ID</accessId>
        <! --The AccessKey Secret for accessing DataHub, which can be overwritten by datahubA
ccessKey in the column mappings. At least one of them must be specified.-->
        <accessKey>YOUR_DATAHUB_ACCESS_KEY</accessKey>
        <! --The column in DataHub that indicates the data update type, which can be overwritte
n by ctypeColumn in the column mappings.-->
        <ctypeColumn>optype</ctypeColumn>
        <! -- The column in DataHub that indicates the data update time, which can be overwritte
n by ctimeColumn in the column mappings.-->
        <ctimeColumn>readtime</ctimeColumn>
        <! -- The column in DataHub that indicates the sequence number of the updated data, w
hich can be overwritten by cidColumn in the column mappings. The sequence number increase
s as more data are updated, but may not be consecutive.-->
        <cidColumn>record_id</cidColumn>
    </defalutDatahubConfigure>

    <! --The approach to handling errors. If an error occurs, the system either ignores the error
and continues running or retries the operation repeatedly.-->

    <! --(Optional) The maximum number of records operated at one time. Default value: 1000.-
->
    <batchSize>1000</batchSize>

    <! --(Optional) The format that the timestamp is converted into. Default: yyyy-MM-dd HH:m
m:ss.-->
    <defaultDateFormat>yyyy-MM-dd HH:mm:ss</defaultDateFormat>

    <! --(Optional) Indicates whether the system needs to ignore dirty records. Default value: f
alse.-->
    <dirtyDataContinue>true</dirtyDataContinue>

    <! --(Optional) The dirty record file name. Default value: datahub_ogg_plugin.dirty-->
    <dirtyDataFile>datahub_ogg_plugin.dirty</dirtyDataFile>

    <! --(Optional) The maximum size of the dirty record file. Unit: MB. Default value: 500.-->
    <dirtyDataFileMaxSize>200</dirtyDataFileMaxSize>
```

```
  <! --(Optional) The maximum number of retries if an error occurs. -1: Unlimited. 0: No retrie
s. n: The number of retries. Default value: -1.-->
  <retryTimes>0</retryTimes>

  <! --(Optional) The interval between retries. Unit: milliseconds. Default value: 3000.-->
  <retryInterval>4000</retryInterval>

  <! --(Optional) The checkpoint file name. Default value: datahub_ogg_plugin.chk.-->
  <checkPointFileName>datahub_ogg_plugin.chk</checkPointFileName>

  <mappings>
    <mapping>
      <! --The schema of the Oracle table.-->
      <oracleSchema></oracleSchema>
      <! --(Required) The Oracle table name.-->
      <oracleTable>t_person</oracleTable>
      <! --The DataHub project name.-->
      <datahubProject></datahubProject>
      <! --The AccessKey ID for accessing DataHub.-->
      <datahubAccessId></datahubAccessId>
      <! --The AccessKey Secret for accessing DataHub.-->
      <datahubAccessKey></datahubAccessKey>
      <! --(Required) The DataHub topic name.-->
      <datahubTopic>t_person</datahubTopic>
      <ctypeColumn></ctypeColumn>
      <ctimeColumn></ctimeColumn>
      <cidColumn></cidColumn>
      <columnMapping>
        <! --
        src: (Required) The column names in the Oracle table.
        dest: (Required) The column names in the DataHub topic.
        destOld: (Optional) The DataHub topic column that records the data before it is upd
ated.
        isShardColumn: (Optional) Indicates whether the shard ID is generated based on th
e hash key value, which can be overwritten by shardId. Default value: false.
        isDateFormat: Indicates whether the timestamp is converted into a string based on
dateFormat. Default value: true. If you set the value to false, the data type in the source dat
abase must be long.
        dateFormat: The format that the timestamp is converted into. If this parameter is lef
t blank, the default format is used.
        -->
```

```
            <column src="id" dest="id" isShardColumn="true"  isDateFormat="false" dateFormat
="yyyy-MM-dd HH:mm:ss"/>
            <column src="name" dest="name" isShardColumn="true"/>
            <column src="age" dest="age"/>
            <column src="address" dest="address"/>
            <column src="comments" dest="comments"/>
            <column src="sex" dest="sex"/>
            <column src="temp" dest="temp" destOld="temp1"/>
        </columnMapping>

        <! --(Optional) The ID of the shard prioritized to be written into.-->
        <shardId>1</shardId>
      </mapping>
   </mappings>
</configue>
```

vi. Run the following command in GGSCI to start the DataHub writer:

```
edit params dhwriter
extract dhwriter
getEnv (JAVA_HOME)
getEnv (LD_LIBRARY_PATH)
getEnv (PATH)
CUSEREXIT ./libggjava_ue.so CUSEREXIT PASSTHRU INCLUDEUPDATEBEFORES, PARAMS "{YOUR_
HOME}/datahub-ogg-plugin/conf/javaue.properties"
sourcedefs ./dirdef/ogg_test.def
table OGG_TEST. *;
```

vii. Run the following command to add a DataHub writer:

```
add extract dhwriter, exttrailsource ./dirdat/st
```

viii. Run the following command to start the writer:

```
start dhwriter
```

Use case

For example, you have an Oracle table that stores order information. The table has three columns. The column names are oid, pid, and num, which indicate order ID, product ID, and product quantity. You can synchronize incremental data to DataHub by using the DataHub agent for OGG. The steps are as follows:

> **Note** Before performing incremental data synchronization, you must synchronize existing data from the source table to MaxCompute by using DataX.

1. Create a topic in DataHub. The schema of the topic is as follows:

```
string record_id, string optype, string readtime, bigint oid_before, bigint oid_after, bigint pid_befo
re, bigint pid_after, bigint num_before, bigint num_after
```

2. Make sure that you have completed the deployment of the DataHub agent for OGG. Then configure the column mappings as follows:

```
<ctypeColumn>optype</ctypeColumn>
        <ctimeColumn>readtime</ctimeColumn>
        <cidColumn>record_id</cidColumn>
        <columnMapping>
          <column src="oid" dest="oid_after" destOld="oid_before" isShardColumn="true"/>
          <column src="pid" dest="pid_after" destOld="pid_before"/>
          <column src="num" dest="num_after" destOld="num_before"/>
        </columnMapping>
```

> **Note** The optype parameter indicates the type of the data update. Valid values of the optype parameter are I, D, and U, which represent an insert, delete, and update operation, respectively. The readtime parameter indicates the time of the data update.

3. When the agent can run properly, data updates are synchronized from the source table to DataHub.

6.6. Data Archive

6.6.1. Overview

You can synchronize real-time data from DataHub to other data warehouses by using DataConnectors so that you can analyze and process historical data.

The following topics describe how to synchronize data from DataHub to MaxCompute.

6.6.2. Archive to MaxCompute

6.6.2.1. Create a DataConnector

This topic describes how to create a DataConnector to synchronize data from DataHub to MaxCompute.

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click View in the Operate column. On the project details page, find the target topic and click **View** in the Operate column.
3. On the topic details page, click **Connector**. In the Create connector dialog box, select the data warehouse to which data is synchronized.
4. In the Create connector dialog box, set relevant parameters and click **Create**.

Note

The following table describes the parameters of the DataConnector for synchronizing data from DataHub to MaxCompute.

Parameter	Description
Project Name	The name of the MaxCompute project to which data in the topic is synchronized.
Table Name	The name of the MaxCompute table to which data in the topic is synchronized.
AccessID and AccessKey	The AccessKey pair used to access MaxCompute. The AccessKey pair must belong to a RAM user that has CreateInstance, Desc, and Alter permissions on the MaxCompute table.
Partition Mode	The method used to create partitions. Valid values: SYSTEM_TIME, EVENT_TIME, USER_DEFINE, and META_TIME. If you select SYSTEM_TIME, partitions are created based on the recording time. If you select EVENT_TIME, partitions are created based on the value of the event_time field. When you create the topic, you must define a field named event_time for the topic and set its data type to TIMESTAMP. The value of the event_time field must be accurate to microseconds. If you select USER_DEFINE, partitions are created based on the user-defined partition key.
Partition Config	The format of the time based on which partitions are created. This parameter takes effect only when you set the Partition Mode parameter to SYSTEM_TIME, EVENT_TIME, or META_TIME.
Time Range	The interval of creating partitions. This parameter takes effect only when you set the Partition Mode parameter to SYSTEM_TIME, EVENT_TIME, or META_TIME. The minimum value is 15 minutes.
Timezone	The time zone of the time based on which partitions are created. This parameter takes effect only when you set the Partition Mode parameter to SYSTEM_TIME, EVENT_TIME, or META_TIME.
Start Time	The time when data synchronization starts.

6.6.2.2. View data synchronization details

This section describes how to view data synchronization details after a DataConnector is created.

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click **View** in the Operate column.
3. On the project details page, find the target topic and click **View** in the Operate column.
4. On the topic details page, click the **Connector** tab. On the Connector tab, find the target DataConnector and click **View** in the Operate column.

> **Notice** You can restart or stop a DataConnector. Exercise caution when you perform the operations.

6.7. Metric statistics

This topic describes how to view the metric statistics of a topic in DataHub.

In the DataHub console, you can view the metric statistics of topics in quasi-real-time, such as QPS and throughput. The following metrics are available:

- Read and write QPS
- Read and write records per second (RPS)
- Read and write throughput, measured in KB per second
- Read and write latency, measured in microseconds per request

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click **View** in the Operate column.
3. On the project details page, find the target topic and click **View** in the Operate column.
4. On the topic details page, click the **Metric Statistics** tab.

You can view the metric statistics for a specified time range.

6.8. Data subscription

6.8.1. Overview

Resumable consumption is required in scenarios where you consume data in DataHub topics and want to resume the consumption from the time when your application fails. If you need to resume consumption, you must save the current consumption offset and make sure that the service for saving consumption offsets supports high availability. This increases the complexity of developing applications. The subscription feature of DataHub supports saving consumption offsets to the server to solve the preceding problem. You only need to enable this feature and add a few lines of code to your application to obtain a consumption offset maintenance service with high availability.

In addition, the subscription feature allows you to reset consumption offsets. This ensures that the data can be consumed at least once. For example, if an error occurs when your application processes the data consumed in a specific time period and you need to consume the data again, you can reset the consumption offset without restarting the application. Your application automatically consumes data from the specified consumption offset.

6.8.2. Create a subscription

You can create subscriptions only in the DataHub console. Make sure that your account is authorized to subscribe to topics of the specified project.

Perform the following steps to create a subscription:

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the

target project and click View in the Operate column. On the project details page, find the target topic and click **View** in the Operate column.

3. On the topic details page, click **Subscription**. In the Create subscription dialog box, set relevant parameters and click **Create**.
4. After the subscription is created, click the **Subscription List** tab on the topic details page to view the subscriptions of the topic.

> **Note** You can click **Reset** or **Delete** in the Operate column of a subscription.
>
> - **Reset**: resets the consumption offset of the subscription to the required time. Specify the time in the *mm-dd-yyyy HH:MM:SS* format.
> - **Delete**: permanently deletes the subscription, including all consumption offsets that are saved for the subscription.

6.8.3. Use case

The subscription feature allows you to save consumption offsets. You can use the read and write capabilities of DataHub with the capability of saving consumption offsets in scenarios where you must save consumption offsets after data is read.

The following sample code is used for reference only.

```
// The following sample code consumes data from a saved consumption offset and submit consumptio
n offsets during consumption.
public void offset_consumption(int maxRetry) {
    String endpoint = "<YourEndPoint>";
    String accessId = "<YourAccessId>";
    String accessKey = "<YourAccessKey>";
    String projectName = "<YourProjectName>";
    String topicName = "<YourTopicName>";
    String subId = "<YourSubId>";
    String shardId = "0";
    List<String> shardIds = Arrays.asList(shardId);
    // Create a DataHub client.
    DatahubClient datahubClient = DatahubClientBuilder.newBuilder()
        .setDatahubConfig(
            new DatahubConfig(endpoint,
                // Specify whether to enable binary data transmission. The server of V2.12 or later sup
ports binary data transmission.
                new AliyunAccount(accessId, accessKey), true))
        .build();
    RecordSchema schema = datahubClient.getTopic(projectName, topicName).getRecordSchema();
    OpenSubscriptionSessionResult openSubscriptionSessionResult = datahubClient.openSubscriptionS
ession(projectName, topicName, subId, shardIds);
    SubscriptionOffset subscriptionOffset = openSubscriptionSessionResult.getOffsets().get(shardId);
```

```
    // 1. Obtain the cursor of the record at the current consumption offset. If the record expired or the r
ecord is not consumed, obtain the cursor of the first record within the TTL of the topic.
    String cursor = "";
    // If the sequence number is smaller than 0, the record is not consumed.
    if (subscriptionOffset.getSequence() < 0) {
        // Obtain the cursor of the first record within the TTL of the topic.
        cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.OLDEST).getCurs
or();
    } else {
        // Obtain the cursor of the next record.
        long nextSequence = subscriptionOffset.getSequence() + 1;
        try {
            // If the SeekOutOfRange error is returned after you obtain the cursor based on the sequence
number, the record expired.
            cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.SEQUENCE, nex
tSequence).getCursor();
        } catch (SeekOutOfRangeException e) {
            // Obtain the cursor of the first record within the TTL of the topic.
            cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.OLDEST).getCu
rsor();
        }
    }
    // 2. Read records and save consumption offsets. In this example, you read tuple records and save c
onsumption offsets each time 1,000 records are read.
    long recordCount = 0L;
    // Read 1,000 records each time.
    int fetchNum = 1000;
    int retryNum = 0;
    int commitNum = 1000;
    while (retryNum < maxRetry) {
        try {
            GetRecordsResult getRecordsResult = datahubClient.getRecords(projectName, topicName, shar
dId, schema, cursor, fetchNum);
            if (getRecordsResult.getRecordCount() <= 0) {
                // If no records can be read, pause the thread for 1s and continue to read records.
                System.out.println("no data, sleep 1 second");
                Thread.sleep(1000);
                continue;
            }
            for (RecordEntry recordEntry : getRecordsResult.getRecords()) {
                // Consume data
```

```
            // Consume data.
            TupleRecordData data = (TupleRecordData) recordEntry.getRecordData();
            System.out.println("field1:" + data.getField("field1") + "\t"
                + "field2:" + data.getField("field2"));
            // Save the consumption offset after the data is consumed.
            recordCount++;
            subscriptionOffset.setSequence(recordEntry.getSequence());
            subscriptionOffset.setTimestamp(recordEntry.getSystemTime());
            // commit offset every 1000 records
            if (recordCount % commitNum == 0) {
              // Submit the consumption offset.
              Map<String, SubscriptionOffset> offsetMap = new HashMap<>();
              offsetMap.put(shardId, subscriptionOffset);
              datahubClient.commitSubscriptionOffset(projectName, topicName, subId, offsetMap);
              System.out.println("commit offset successful");
            }
          }
          cursor = getRecordsResult.getNextCursor();
        } catch (SubscriptionOfflineException | SubscriptionSessionInvalidException e) {
          // The subscription session is exited. The Offline exception indicates that the subscription is of
fline. The SessionChange exception indicates that the subscription is consumed by other clients.
          e.printStackTrace();
          throw e;
        } catch (SubscriptionOffsetResetException e) {
          // The consumption offset is reset. You must obtain the version information of the consumption
offset again.
          SubscriptionOffset offset = datahubClient.getSubscriptionOffset(projectName, topicName, subI
d, shardIds).getOffsets().get(shardId);
          subscriptionOffset.setVersionId(offset.getVersionId());
          // After the consumption offset is reset, you must obtain the cursor of the record at the consu
mption offset again. The method for obtaining the cursor depends on the method of resetting the con
sumption offset.
          // If both the sequence number and timestamp are specified to reset the consumption offset, y
ou can obtain the cursor based on the sequence number or the timestamp.
          // If only the sequence number is specified to reset the consumption offset, you can obtain the
cursor only based on the sequence number.
          // If only the timestamp is specified to reset the consumption offset, you can obtain the cursor
only based on the timestamp.
          // Generally, preferentially obtain the cursor based on the sequence number. If the cursor faile
d to be obtained based on the sequence number or the timestamp, obtain the cursor of the earliest re
cord.
```

```
            cursor = null;
            if (cursor == null) {
                try {
                    long nextSequence = offset.getSequence() + 1;
                    cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.SEQUENCE,
nextSequence).getCursor();
                    System.out.println("get cursor successful");
                } catch (DatahubClientException exception) {
                    System.out.println("get cursor by SEQUENCE failed, try to get cursor by SYSTEM_TIME");
                }
            }
            if (cursor == null) {
                try {
                    cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.SYSTEM_TI
ME, offset.getTimestamp()).getCursor();
                    System.out.println("get cursor successful");
                } catch (DatahubClientException exception) {
                    System.out.println("get cursor by SYSTEM_TIME failed, try to get cursor by OLDEST");
                }
            }
            if (cursor == null) {
                try {
                    cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.OLDEST).g
etCursor();
                    System.out.println("get cursor successful");
                } catch (DatahubClientException exception) {
                    System.out.println("get cursor by OLDEST failed");
                    System.out.println("get cursor failed!!") ;
                    throw e;
                }
            }
        } catch (LimitExceededException e) {
            // limit exceed, retry
            e.printStackTrace();
            retryNum++;
        } catch (DatahubClientException e) {
            // other error, retry
            e.printStackTrace();
            retryNum++;
        } catch (Exception e) {
            e.printStackTrace();
```

```
            System.exit(-1);
        }
    }
}
```

Note

- When you start the application for the first time, your application consumes data from the earliest record. During the running of the application, you can refresh the Subscription List tab in the console.
- If you reset the consumption offset by clicking Reset in the console during the consumption, your application automatically detects the change of the consumption offset and consumes data from the specified consumption offset. When the application catches OffsetResetedException, the application calls the getSubscriptionOffset method to query the latest consumption offset from the server. Then, the application can consume data from the latest consumption offset.
- Note that a shard in a subscription cannot be consumed by multiple threads or processes at the same time. Otherwise, the consumption offset submitted by a thread is overwritten by that submitted by another thread and the server cannot determine to which thread the saved consumption offset belongs. In this case, the server throws OffsetSessionChangedException. We recommend that you exit the subscription session to check whether data is repeatedly consumed if this exception is caught.

6.9. Collaborative consumption

6.9.1. Note

DataHub-client-library encapsulates the Java SDK and integrates the consumer for collaborative consumption and the producer for distributing data evenly among shards.

6.9.2. Overview

Offset-based data consumption

The offset-based data consumption feature allows you to save consumption offsets to the server. A consumption offset consists of the sequence number of a record and the timestamp when the record is written to DataHub.

You can create a subscription for a topic and submit the consumption offset to the server after specific data is consumed. When you application starts the next time, the application can obtain the consumption offset from the server and consume data from the next record. The consumption offsets must be saved on the server so that your application can consume data from a submitted consumption offset after shards are reallocated. This is a prerequisite for collaborative consumption.

You do not need to manually submit consumption offsets in the consumer. You only need to specify the interval of submitting consumption offsets in the configurations of the consumer. The system considers that the previous records are consumed when it reads records. If the interval of submitting consumption offsets is exceeded, the system submits a consumption offset again. If the consumption offset fails to be submitted and your application is interrupted, the consumption offset may fail to be submitted in time. In this case, your application may repeatedly consume specific data.

Collaborative consumption

The collaborative consumption feature automatically allocates shards when multiple consumers consume a topic at the same time. This feature simplifies the data processing of clients.

> **Note** Manual shard allocation is difficult because multiple consumers may reside on different machines. If multiple consumers that subscribe to the same topic are in the same consumer group, a shard can be allocated to only one consumer in the consumer group.

Example:

Assume that A, B, and C are three consumer instances and the topic has 10 shards.

1. When the consumer instance A is started at first, 10 shards are allocated to it.
2. When the other two consumer instances are started, the shards are reallocated in the following way: four to A, three to B, and three to C.
3. When one of the shards consumed by the consumer instance A is split into two and the two shards are released after consumption, the shards are reallocated in the following way: four to A, four to B, and three to C.
4. When the consumer instance C is stopped, the shards are reallocated in the following way: six to A and five to B.

Heartbeat

You must use the heartbeat feature to notify the server of the status of consumer instances. If the server has not received heartbeats from a consumer instance after the specified interval, the server considers that the consumer instance is stopped. When the status of a consumer instance changes, the server reallocates shards. The server returns the new allocation plan in heartbeat requests. Therefore, the client takes time to detect reallocation of shards.

6.9.3. Maven dependencies and JDK

Maven dependencies

```
<dependency>
    <groupId>com.aliyun.datahub</groupId>
    <artifactId>datahub-client-library</artifactId>
    <version>1.0.6-public</version>
</dependency>
```

JDK

```
jdk: >= 1.7
```

6.9.4. Use case

The following sample code is for reference only.

Initialize the producer

```
String endpoint = "http://dh-cn-hangzhou.aliyuncs.com";
String accessId = "<YourAccessKeyId>";
String accessKey = "<YourAccessKeySecret>";
String projectName = "<YourProjectName>";
String topicName = "<YourTopicName>";
ProducerConfig config = new ProducerConfig(endpoint, accessId, accessKey);
Producer producer = new Producer(projectName, topicName, config);
```

Write data to DataHub

```
RecordSchema schema = new RecordSchema();
schema.addField(new Field("field1", FieldType.STRING));
schema.addField(new Field("field2", FieldType.BIGINT));
List<RecordEntry> recordEntries = new ArrayList<>();
for (int cnt = 0; cnt < 10; ++cnt) {
    RecordEntry entry = new RecordEntry();
    entry.addAttribute("key1", "value1");
    entry.addAttribute("key2", "value2");
    TupleRecordData data = new TupleRecordData(schema);
    data.setField("field1", "testValue");
    data.setField("field2", 1);
    entry.setRecordData(data);
    recordEntries.add(entry);
}
int maxRetry = 3;
while (true) {
    try {
        producer.send(records, maxRetry);
        break;
    } catch (MalformedRecordException e) {
        // malformed RecordEntry
    } catch (InvalidParameterException e) {
        // invalid param
    } catch (ResourceNotFoundException e) {
        // project, topic or shard not found, sometimes caused by split/merge shard
    } catch (DatahubClientException e) {
        // network or other exceptions exceeded retry limit
    }
}
// close before exit
producer.close();
```

Initialize the consumer

```
String endpoint = "http://dh-cn-hangzhou.aliyuncs.com";
String accessId = "<YourAccessKeyId>";
String accessKey = "<YourAccessKeySecret>";
String projectName = "<YourProjectName>";
String topicName = "<YourTopicName>";
String SubId = "<YourSubscriptionId>";
// 1. If you need to use the collaborative consumption feature, specify the subscription ID.
ConsumerConfig config = new ConsumerConfig(endpoint, accessId, accessKey);
Consumer consumer = new Consumer(projectName, topicName, SubId, config);
// 2. If you need to use the offset-based data consumption feature instead of the collaborative consu
mption feature, specify the subscription ID and the shards to be read by the consumer.
List<String> assignment = Arrays.asList("0", "1", "2");
ConsumerConfig config = new ConsumerConfig(endpoint, accessId, accessKey);
Consumer consumer = new Consumer(projectName, topicName, SubId, assignment, config);
// 3. If you do not need to use the collaborative consumption feature nor the offset-based data consu
mption feature, specify the subscription ID, the shards to be read by the consumer, and the consumpti
on offset.
Map<String, Offset> offsetMap = new HashMap<>();
// If both the sequence number and timestamp are specified but the sequence number is invalid, obtai
n the cursor based on the timestamp.
offsetMap.put("0", new Offset(100, 1548573440756L));
// If only the sequence number is specified, obtain the cursor based on the sequence number.
offsetMap.put("1", new Offset().setSequence(1));
// If only the timestamp is specified, obtain the cursor based on the timestamp.
offsetMap.put("2", new Offset().setTimestamp(1548573440756L));
ConsumerConfig config = new ConsumerConfig(endpoint, accessId, accessKey);
Consumer consumer = new Consumer(projectName, topicName, SubId, offsetMap, config);
```

Read data from DataHub

```
int maxRetry = 3;
boolean stop = false;
while (! stop) {
    try {
        while (true) {
            RecordEntry record = consumer.read(maxRetry);
            if (record ! = null) {
                TupleRecordData data = (TupleRecordData) record.getRecordData();
                System.out.println("field1:" + data.getField(0) + ", field2:" + data.getField("field2"));
            }
        }
    } catch (SubscriptionSessionInvalidException | SubscriptionOffsetResetException e) {
        // subscription exception, will not recover
        // print some log or just use a new consumer
        consumer.close();
        consumer = new Consumer(TEST_PROJECT, TEST_TOPIC, TEST_SUB_ID, config);
    } catch (ResourceNotFoundException | InvalidParameterException e) {
        // - project, topic, shard, subscription not found
        // - seek out of range
        // - sometimes shard operation cause ResourceNotFoundException
        // should make sure if resource exists, print some log or just exit
    } catch (DatahubClientException e) {
        // - network or other exception exceed retry limit
        // can just sleep and retry
    }
}
// close before exit
consumer.close();
```

6.9.5. Usage notes

A consumer or producer cannot access DataHub by using multiple threads. If you need to use multiple threads, specify a different consumer or producer for each thread.

7.Quick BI

7.1. What is Quick BI?

This topic describes the concept and features of Quick BI.

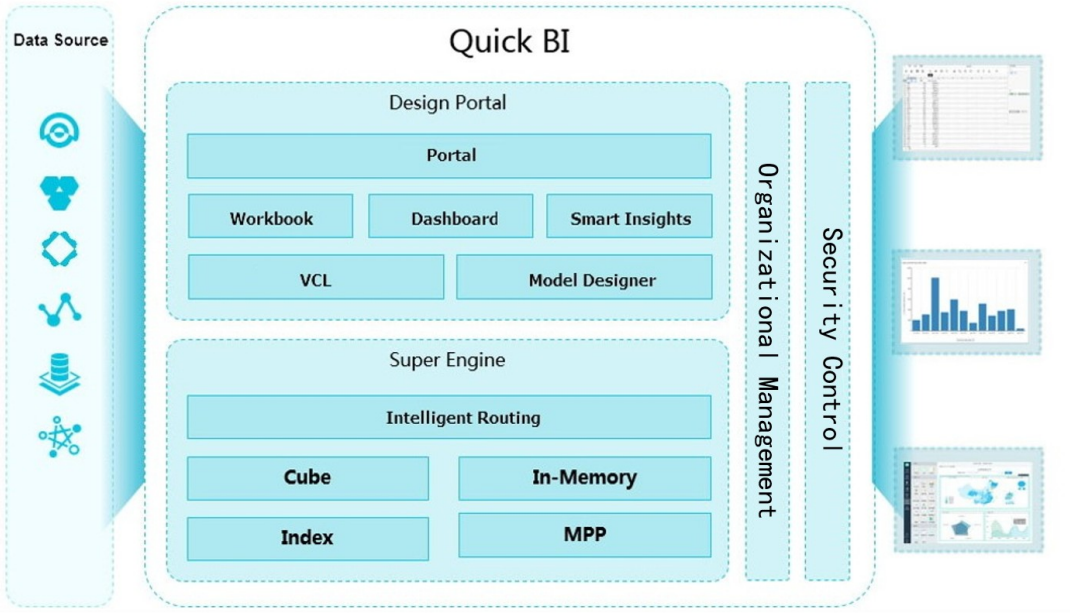
Quick BI is a flexible and lightweight self-service Business Intelligence (BI) tool based on cloud computing. It supports a wide range of data sources:

- MaxCompute (formerly known as ODPS) and ApsaraDB for RDS
- User-created MySQL and SQL Server databases that are hosted on ECS
- VPC data sources

Quick BI analyzes large amounts of data in real time and returns results within seconds. You do not need to preprocess the data. Quick BI analyzes terabytes of incremental data on a daily basis.

With an intelligent data modeling tool and a variety of visual chart tools, Quick BI significantly reduces data acquisition costs and makes it easier for you to use Quick BI features. This allows you to easily complete data analysis, self-service data acquisition, business data query, and report making.

Architecture



7.2. Log on to the Quick BI console

This topic describes how to log on to the Quick BI console.

Prerequisites

- Before logging on to the ASCM console, make sure that you have obtained the IP address or domain name of the ASCM console from the deployment personnel. The URL used to access the ASCM console is in the following format: https://[IP address or domain name of the ASCM console].

- We recommend that you use the Google Chrome browser.

Context

If you are using a RAM account, you can use the domain name to log on to the Quick BI console. If you are using an Apsara Stack tenant account, log on to the Quick BI console by performing the following steps:

Procedure

1. In the address bar, enter the access address of the Apsara Stack Cloud Management (ASCM) console, and press Enter.
2. Enter your username and password.

   Obtain the username and password for logging on to the console from the operations administrator.

   > **Note** When you log on to the ASCM console for the first time, you must change the password of your username as prompted. Due to security concerns, your password must meet the minimum complexity requirements: The password must be 8 to 20 characters in length and must contain at least two of the following character types: uppercase letters, lowercase letters, digits, and special characters such as exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

3. Click **Login** to go to the homepage of the ASCM console.
4. In the top navigation bar, choose **Product** > **Big Data** and click **Quick BI**.
5. Select an organization and a region from the drop-down lists and click **QuickBI** or **Quick BI Console** to go to the **Quick BI** system.
   - You can click **QuickBI** to go to the product page.
   - You can click **Quick BI Console** to go to the settings page. You can manage organization members and workspaces on this page.

     > **Note** If you use this method, the Apsara Stack tenant account quickbi_admin@aliyun.com is used to log on to the Quick BI console no matter which department you select.

7.3. Data modeling

7.3.1. Data modeling

Data modeling visualizes data and allows you to quickly identify and extract information. It also helps you make correct decisions based on data trends.

Steps of data modeling:

1. Create a data source.
2. Create a dataset.

7.3.2. Data sources

7.3.2.1. Overview of data sources

Datasets, workbooks, dashboards, and BI portals are all created based on data sources. Quick BI supports both cloud data sources and user-created data sources.

Cloud data sources include:

- MaxCompute
- MySQL
- SQL Server
- AnalyticDB for MySQL 2.0
- HybridDB for MySQL
- AnalyticDB for PostgreSQL
- PostgreSQL
- PPAS
- Hive
- Data Lake Analytics
- Distribute Relational Database Service (DRDS)
- Presto
- AnalyticDB for MySQL 3.0
- PolarDB for MySQL

> Note VPCs only support MySQL and SQL Server data sources.

User-created data sources include:

- MySQL
- SQL Server
- PostgreSQL
- Oracle
- Hive
- Vertica
- IBM DB2 LUW
- SAP IQ (SybaseIQ)
- SAP HANA
- Presto

> Note You cannot check SQL Server data sources by using views.

7.3.2.2. Cloud data sources

7.3.2.2.1. Add the IP addresses of a Quick BI cluster to a database whitelist

This topic describes how to add the IP addresses of a Quick BI cluster to a database whitelist.

Prerequisites

The Quick BI service is purchased.

Context

Before you add some data sources in the Quick BI console, you must first query available IP addresses of machines and add them to a whitelist of ApsaraDB for RDS.

Procedure

1. Log on to the Apsara Infrastructure Management Framework console.Make sure that you have obtained the URL of the Apsara Stack Operations (ASO) console, and the username and password used for logging on to the console from a deployment engineer or administrator.
   i. Open a browser, enter the URL in the address bar, and press Enter. The URL is in the format of *region-id*.aso.*intranet-domain-id*.com.

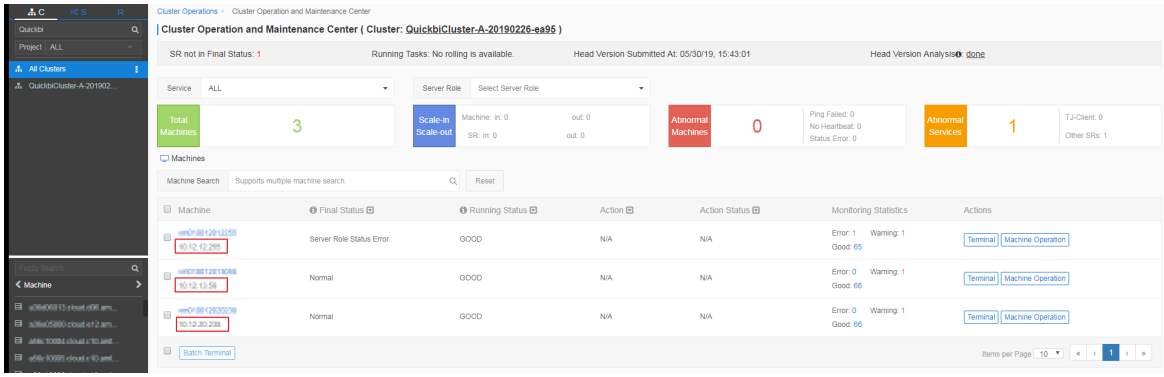
      > **Note** We recommend that you use the Google Chrome browser.
      >
      > You can select a language from the drop-down list in the upper-right corner.

   ii. Enter the correct username and password.
      - The following user roles are available by default:
        - security administrator: the user who has the permissions to manage other users or roles
        - auditor: the user who has the permissions to view audit logs
        - sysadmin: the user who has the permissions that security administrators and auditors do not have
      - When you log on to the ASO console for the first time, you must change the password of your username as prompted.

        For security concerns, your password must contain the following characters:
        - Letters
        - Digits
        - Special characters, such as exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

        The password must be 10 to 20 characters in length.

   iii. Click **Log On** to go to the **ASO** console.
   iv. In the left-side navigation pane, choose **Products** > **Product List**. Click **Apsara Infrastructure Management Framework**.
2. On the homepage of the Apsara Infrastructure Management Framework console, enter the keywords of the name of the target Quick BI cluster in the search box, select the target cluster from the drop-down list, and then click **Operations** next to the cluster.
3. You can view the IP addresses of the Quick BI cluster on the **Machines** tab.



What's next

Add the IP addresses to an ApsaraDB for RDS whitelist.

Before you add the IP addresses to the ApsaraDB for RDS whitelist, change the last octet of all the addresses to 0/24. For example, if an IP address is 10.10.10.10, change it to 10.10.10.0/24. For information about how to add an IP address to an ApsaraDB for RDS whitelist, see "Configure a whitelist" in ApsaraDB for RDS User Guide.

7.3.2.2.2. Add a cloud MaxCompute data source

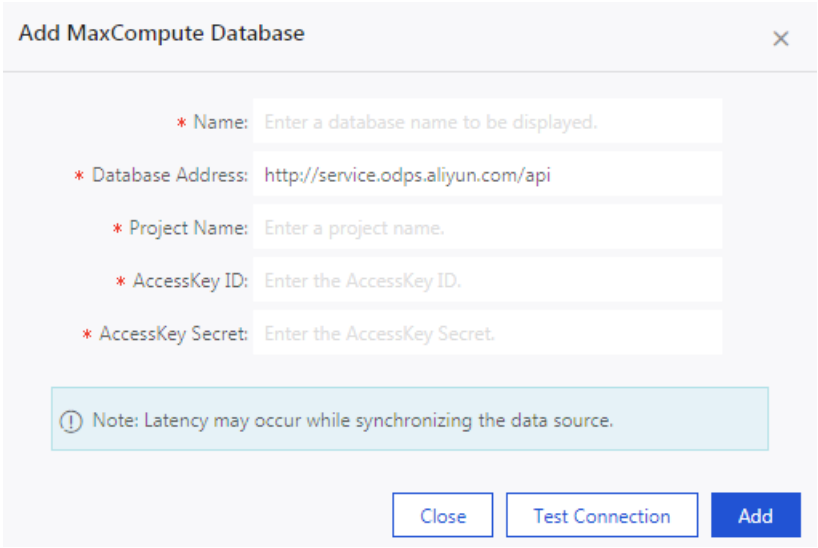
This topic describes how to add a cloud MaxCompute data source.

Prerequisites

- A MaxCompute (formerly known as ODPS) project is created in the big data computing service console.
- Parameter settings for connecting to the MaxCompute data source are obtained.

Procedure

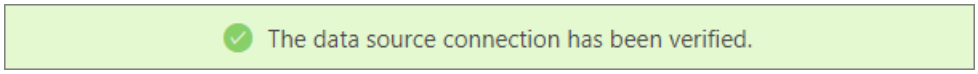
1. Create a data source.
2. Click **MaxCompute**. In the **Add MaxCompute Database** dialog box that appears, set the following parameters.



3. Set the parameters for connecting to the data source.

Parameter	Description
Name	The name of the data source that you want to display.
Database Address	The default database address.
Project Name	The name of the MaxCompute project.
AccessKey ID	The AccessKey ID used to identify a visitor.
AccessKey Secret	The AccessKey secret of the account that purchased the data source instance. The AccessKey secret is used to encrypt the signature string on the client and decrypt the signature string on the server for authentication. Keep the AccessKey secret confidential.

4. Click **Test Connection** to perform a data source connectivity test.



5. After the connection is established, click **Add**.

   After the data source is added, the Data Sources page appears. Tables under the data source are listed on the right side of the page.

7.3.2.2.3. Add a cloud data source ApsaraDB RDS for MySQL

This topic describes how to add a cloud data source ApsaraDB RDS for MySQL.

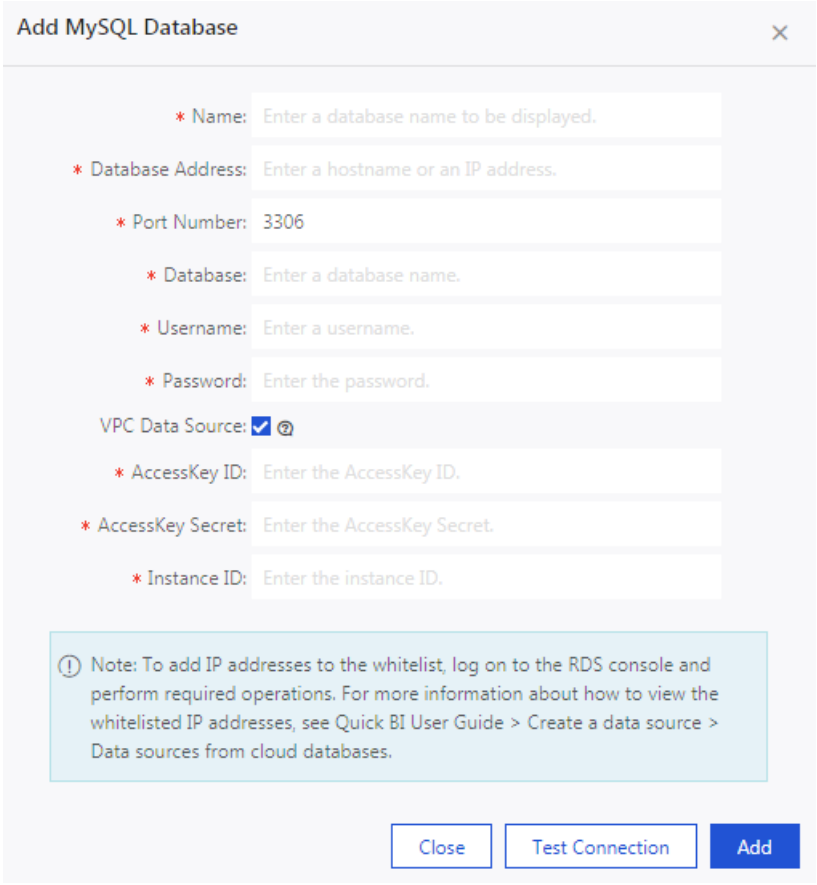
Prerequisites

1. An ApsaraDB RDS for MySQL instance is created. For information about how to create an ApsaraDB for RDS instance, see "Create an instance" in ApsaraDB for RDS User Guide.
2. Available IP addresses of machines are obtained and added to a whitelist of the ApsaraDB for RDS instance. For information about how to query the IP addresses, see Add the IP addresses of a Quick BI cluster to a database whitelist. For information about how to add the IP addresses to a whitelist of the ApsaraDB for RDS instance, see "Configure a whitelist" in ApsaraDB for RDS User Guide.
3. Parameter settings used to connect to the cloud data source ApsaraDB RDS for MySQL are obtained.

Procedure

1. Create a data source.
2. Click the **MySQL** card and configure the required parameters in the dialog box that appears.

   Add a cloud data source ApsaraDB RDS for MySQL



> **Note** If the data source is connected over a VPC, select **VPC Data Source** and configure the required parameters.

Parameter	Description
Name	The name of the data source, which is user-defined.
Database Address	The hostname or IP address of the database that is used as the data source.
Port Number	The port that you use to access the database. Default value: 3306.
Database	The name of the database that you want to access.
Username	The username that you use to access the database.
Password	The password that you use to access the database. > **Note** If you do not know the username and password, contact the data warehouse administrator.
AccessKey ID	The AccessKey ID that you use to purchase the database instance.

Parameter	Description
AccessKey Secret	The AccessKey secret that you use to purchase the database instance.
Instance ID	The ID of the database instance.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **Add**.

   After a data source is added, you cannot add it again. If you attempt to add a data source for the second time, an error message appears.

7.3.2.2.4. Add a cloud data source ApsaraDB RDS for SQL Server

This topic describes how to add a cloud data source ApsaraDB RDS for SQL Server.

Prerequisites

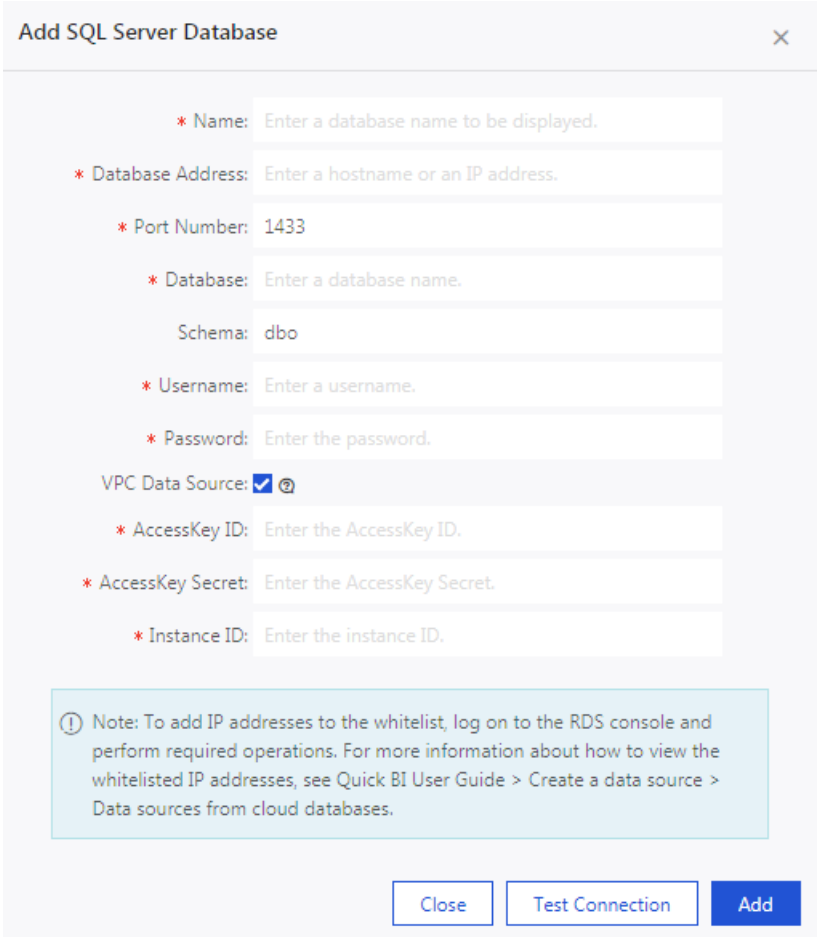
1. An ApsaraDB RDS for SQL Server instance is created. For information about how to create an ApsaraDB for RDS instance, see "Create an instance" in ApsaraDB for RDS User Guide.
2. Available IP addresses of machines are obtained and added to a whitelist of the ApsaraDB for RDS instance. For information about how to query the IP addresses, see Add the IP addresses of a Quick BI cluster to a database whitelist. For information about how to add the IP addresses to a whitelist of the ApsaraDB for RDS instance, see "Configure a whitelist" in ApsaraDB for RDS User Guide.
3. Parameter settings used to connect to the cloud data source ApsaraDB RDS for SQL Server are obtained.

Context

The method of using an ApsaraDB RDS for SQL Server database as a data source is similar to that of using an ApsaraDB RDS for MySQL database as a data source. The only difference is that you must set the Schema parameter when you use an ApsaraDB RDS for SQL Server database as a data source.

Procedure

1. Create a data source.
2. Click the **SQL Server** card and configure the required parameters in the dialog box that appears.



Note If the data source is connected over a VPC, select **VPC Data Source** and configure the required parameters.

Parameter	Description
Name	The name of the data source, which is user-defined.
Database Address	The hostname or IP address of the database that is used as the data source.
Port Number	The port that you use to access the database. Default value: 1433.
Database	The name of the database that you want to access.
Schema	The database schema. Default value: dbo.
Username	The username that you use to access the database.
Password	The password that you use to access the database.
AccessKey ID	The AccessKey ID that you use to purchase the database instance.

Parameter	Description
AccessKey Secret	The AccessKey secret that you use to purchase the database instance.
Instance ID	The ID of the database instance.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **Add**.

7.3.2.2.5. Add an AnalyticDB for MySQL 2.0 data source

This topic describes how to add an AnalyticDB for MySQL 2.0 data source.

Prerequisites

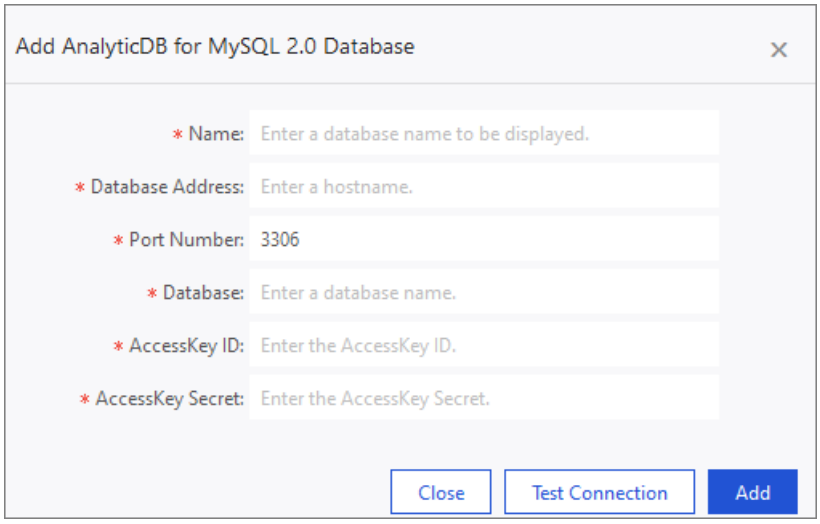
An AnalyticDB database is created in the AnalyticDB console, and parameter settings used to connect to the AnalyticDB data source are obtained. For information about how to create an AnalyticDB database, see "Create a database" in AnalyticDB for MySQL User Guide.

Context

AnalyticDB for MySQL is formerly known as AnalyticDB.

Procedure

1. On the Data Sources page, click Create Data Source in the upper-right corner. For more information, see Create a data source.
2. On the Add Data Source page, click the Cloud Data Sources tab. Then, click **AnalyticDB for MySQL 2.0** and set the parameters for connecting to the data source in the dialog box that appears.



Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.

Parameter	Description
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database.
Database	The name of the database to which you want to access.
AccessKey ID	The AccessKey ID used to identify a visitor.
AccessKey Secret	The AccessKey secret is used to encrypt the signature string on the client and decrypt the signature string on the server for authentication. Keep the AccessKey secret confidential.

3. Click **Test Connection** to test connectivity with the data source.
4. After the connection is established, click **Add**.

7.3.2.2.6. Add a cloud HybridDB for MySQL data source

This topic describes how to add a cloud HybridDB for MySQL data source.

Prerequisites

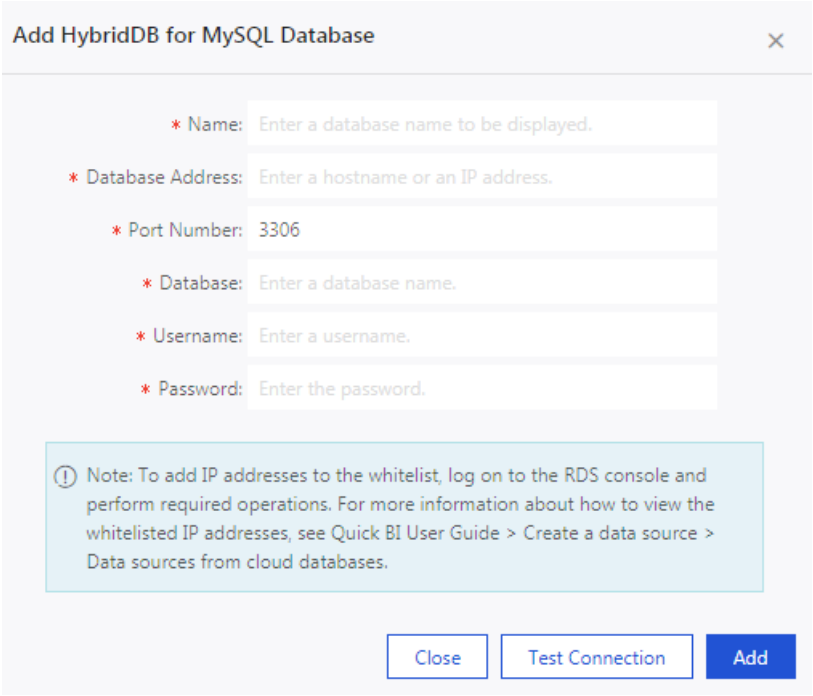
1. A HybridDB for MySQL instance is created.
2. The available machine IP addresses are obtained and added to a whitelist of the HybridDB for MySQL instance. For information about how to query the available IP addresses, see Add the IP addresses of a Quick BI cluster to a database whitelist.
3. Parameter settings used to connect to the HybridDB for MySQL data source are obtained.

Context

The procedure for adding a HybridDB for MySQL data source is similar to that for adding an SQL Server data source. The only difference is that the default port is the port specific to HybridDB for MySQL.

Procedure

1. Create a data source.
2. Click **HybridDB for MySQL** and set the parameters for connecting to the data source in the dialog box that appears.



Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 3306.
Database	The name of the database to which you want to access.
Username	The username used to access the database.
Password	The password of the database user.

3. Click **Test Connection** to test the data source connectivity.
4. After the connection is established, click **Add**.

7.3.2.2.7. Add a cloud AnalyticDB for PostgreSQL data source

This topic describes how to add a cloud AnalyticDB for PostgreSQL data source.

Prerequisites

1. An AnalyticDB for PostgreSQL instance is created. For information about how to create an AnalyticDB for PostgreSQL instance, see "Create an instance" in AnalyticDB for PostgreSQL User Guide.
2. The available machine IP addresses are obtained and added to a whitelist of the AnalyticDB

for PostgreSQL instance. For information about how to query the available IP addresses, see Add the IP addresses of a Quick BI cluster to a database whitelist. For information about how to add the IP addresses to a whitelist of the AnalyticDB for PostgreSQL instance, see "Configure a whitelist" in AnalyticDB for PostgreSQL User Guide.

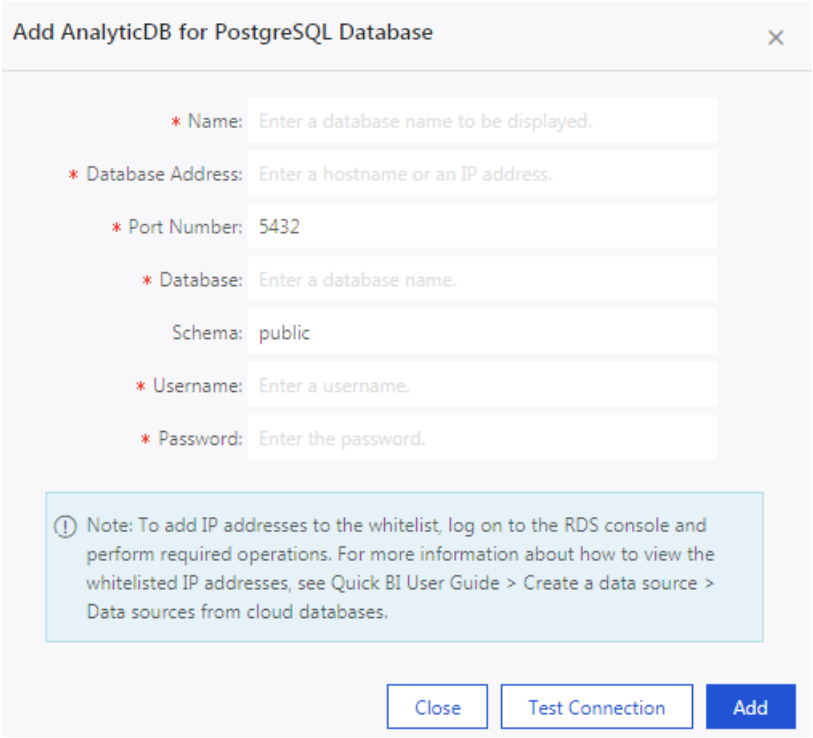
3. Parameter settings used to connect to the AnalyticDB for PostgreSQL data source are obtained.

Context

The procedure for adding an AnalyticDB for PostgreSQL data source is similar to that for adding an SQL Server data source. The only difference is that the default port is the port specific to AnalyticDB for PostgreSQL.

Procedure

1. Create a data source.
2. Click **AnalyticDB for PostgreSQL** and set the parameters for connecting to the data source in the dialog box that appears.



Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 5432.
Database	The name of the database to which you want to access.
Schema	The default value is Public.

Parameter	Description
Username	The username used to access the database.
Password	The password of the database user.

3. Click **Test Connection** to test the data source connectivity.
4. After the connection is established, click **Add**.

7.3.2.2.8. Add a cloud data source AnalyticDB for PostgreSQL

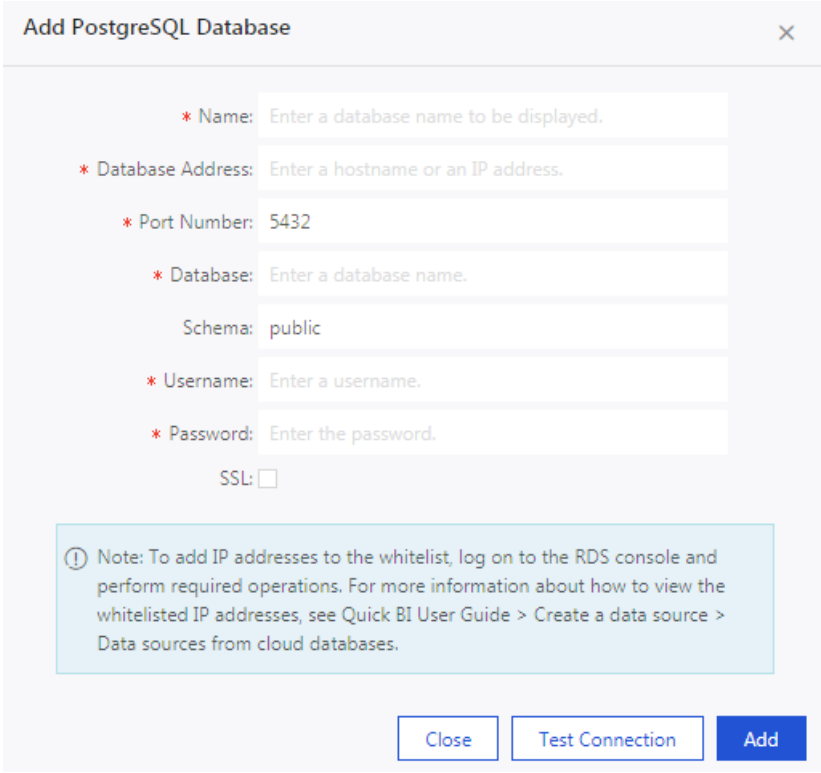
This topic describes how to add a cloud data source AnalyticDB for PostgreSQL.

Prerequisites

1. An RDS for PostgreSQL instance is created. For information about how to create an ApsaraDB for RDS instance, see "Create an instance" in ApsaraDB for RDS User Guide.
2. Available IP addresses of machines are obtained and added to a whitelist of the ApsaraDB for RDS instance. For information about how to query the IP addresses, see Add the IP addresses of a Quick BI cluster to a database whitelist. For information about how to add the IP addresses to a whitelist of the ApsaraDB for RDS instance, see "Configure a whitelist" in ApsaraDB for RDS User Guide.
3. Parameter settings used to connect to a cloud data source AnalyticDB for PostgreSQL are obtained.

Procedure

1. Create a data source.
2. Click the **PostgreSQL** card and configure the required parameters in the dialog box that appears.



Note After you select the **SSL** option, the data source supports the interactive query service MaxCompute Lightning provided by MaxCompute.

Parameter	Description
Name	The name of the data source, which is user-defined.
Database Address	The hostname or IP address of the database that is used as the data source.
Port Number	The port that you use to access the database. Default value: 5432.
Database	The name of the database that you want to access.
Schema	The database schema. Default value: public.
Username	The username that you use to access the database.
Password	The password that you use to access the database.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **Add**.

7.3.2.2.9. Add a cloud PPAS data source

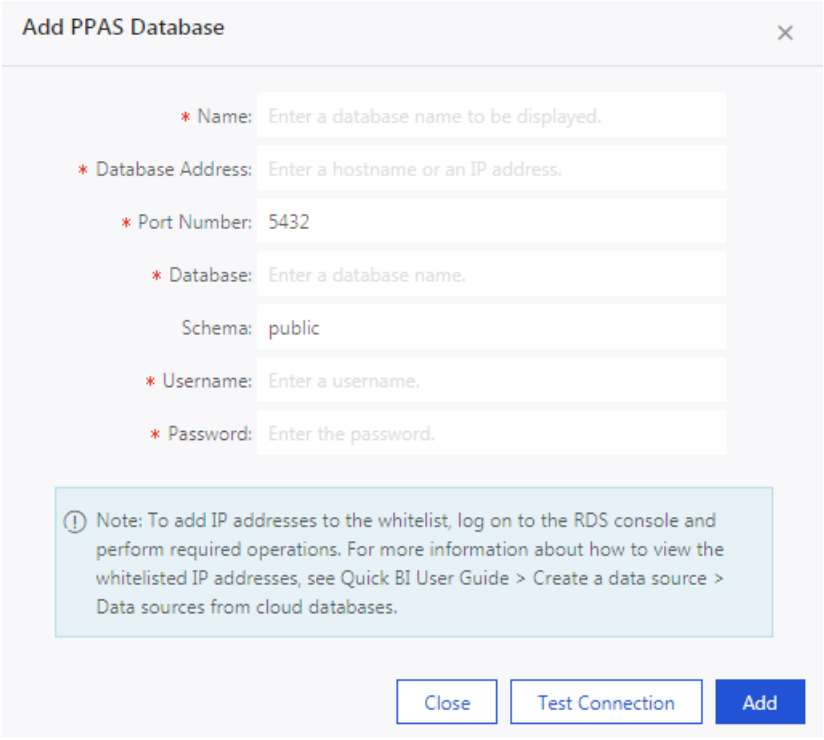
This topic describes how to add a cloud PPAS data source.

Prerequisites

1. An RDS for PPAS instance is created. For information about how to create an ApsaraDB for RDS instance, see "Create an instance" in ApsaraDB for RDS User Guide.
2. The available IP addresses are obtained and added to a whitelist of the ApsaraDB for RDS instance. For information about how to query the IP addresses, see Add the IP addresses of a Quick BI cluster to a database whitelist. For information about how to add the IP addresses to a whitelist of the ApsaraDB for RDS instance, see "Configure a whitelist" in ApsaraDB for RDS User Guide.
3. Parameter settings used to connect to the PPAS data source are obtained.

Procedure

1. Create a data source.
2. Click **PPAS** and set the parameters for connecting to the data source in the dialog box that appears.



Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port	The port number of the database. The default port is 5432.
Database	The name of the database to which you want to access.
Schema	The default value is Public.

Parameter	Description
Username	The username used to access the database.
Password	The password of the database user.

3. Click **Test Connection** to test the data source connectivity.
4. After the connection is established, click **Add**.

7.3.2.2.10. Add a cloud Hive data source

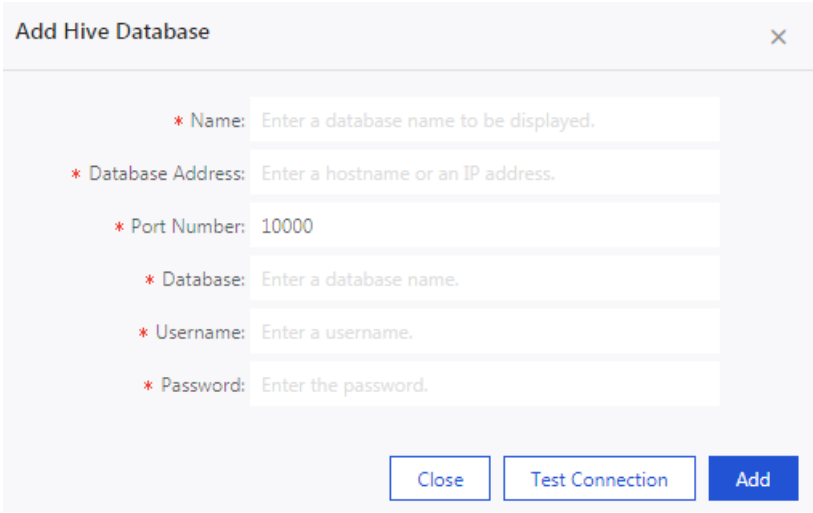
This topic describes how to add a cloud Hive data source.

Prerequisites

Parameter settings used to connect to the Hive data source are obtained.

Procedure

1. Create a data source.
2. Click **Hive** and set the parameters for connecting to the data source in the dialog box that appears.



Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 10000.
Database	The name of the database to which you want to access.
Username	The username used to access the database.

Parameter	Description
Password	The password of the database user.

3. Click **Test Connection** to test the data source connectivity.
4. After the connection is established, click **Add**.

7.3.2.2.11. Add a cloud data source Data Lake Analytics

This topic describes how to add a cloud data source Data Lake Analytics (DLA).

Prerequisites

Parameter settings used to connect to the cloud data source DLA are obtained.

Procedure

1. Create a data source.
2. Click the **Data Lake Analytics** card and configure the required parameters in the dialog box that appears.

Parameter	Description
Name	The name of the data source, which is user-defined.
Database Address	The hostname or IP address of the database that is used as the data source.
Port Number	The port that you use to access the database. Default value: 10000.
Database	The name of the database that you want to access.
Username	The username that you use to access the database.
Password	The password that you use to access the database.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **Add**.

7.3.2.2.12. Add a cloud DRDS data source

This topic describes how to add a cloud Distributed Relational Database Service (DRDS) data source.

Prerequisites

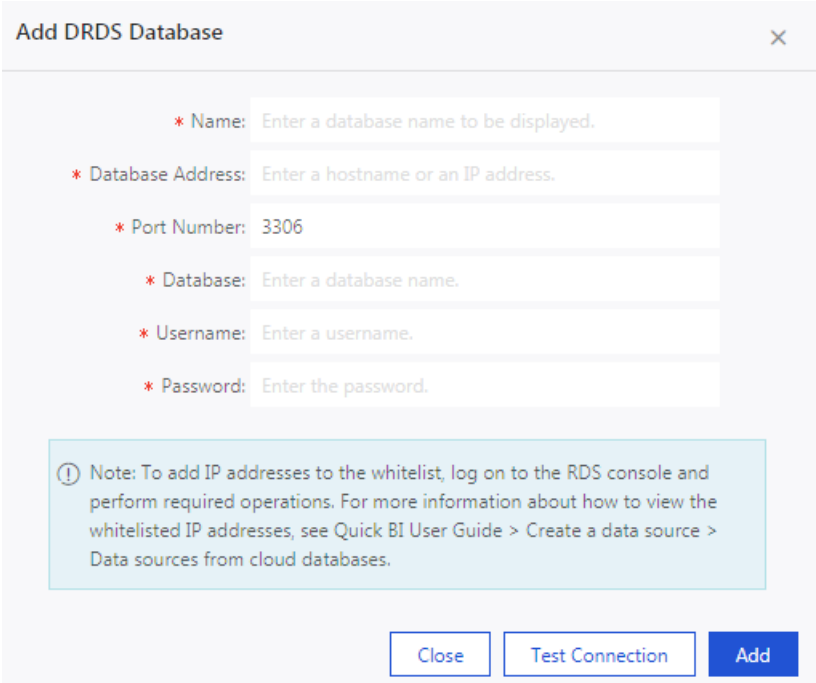
1. A DRDS instance is created. For information about how to create a DRDS instance, see "Create an instance" in ApsaraDB for RDS User Guide.
2. The available IP addresses are obtained and added to a whitelist of the DRDS instance. For information about how to query the IP addresses, see Add the IP addresses of a Quick BI

cluster to a database whitelist. For information about how to add the IP addresses to a whitelist of the DRDS instance, see "Configure a whitelist" in ApsaraDB for RDS User Guide.

3. Parameter settings used to connect to the DRDS data source are obtained.

Procedure

1. Create a data source.
2. Click **DRDS** and set the parameters for connecting to the data source in the dialog box that appears.



Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 3306.
Database	The name of the database to which you want to access.
Username	The username used to access the database.
Password	The password of the database user.

3. Click **Test Connection** to test the data source connectivity.
4. After the connection is established, click **Add**.

7.3.2.2.13. Add a cloud Presto data source

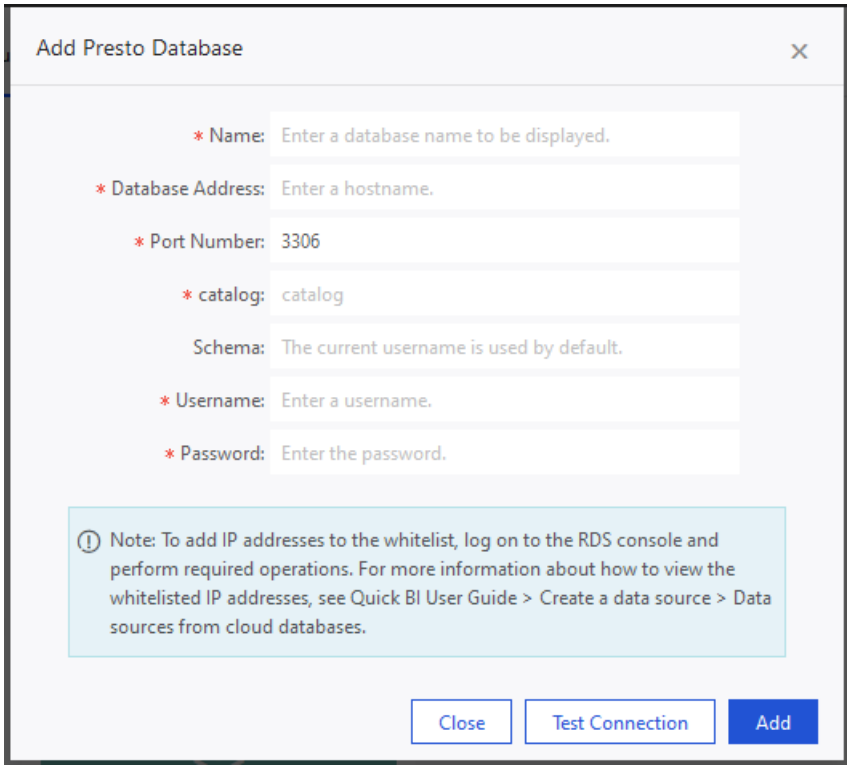
This topic describes how to add a cloud Presto data source.

Prerequisites

Parameter settings used to connect to the Presto data source are obtained.

Procedure

1. On the Data Sources page, click Create Data Source in the upper-right corner. For more information, see Create a data source.
2. On the Add Data Source page, click the Cloud Data Sources tab. Then, click **Presto** and set the parameters for connecting to the data source in the dialog box that appears.



Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 3306.
catalog	The name of the data source that you want to use Presto to query.
Schema	The current logon username is used by default.
Username	The username used to access the database.
Password	The password used to access the database.

3. Click **Test Connection** to test connectivity with the database.

4. After the connection is established, click **Add**.

7.3.2.2.14. Add a cloud data source AnalyticDB for MySQL V3.0

This topic describes how to add a cloud data source AnalyticDB for MySQL V3.0.

Prerequisites

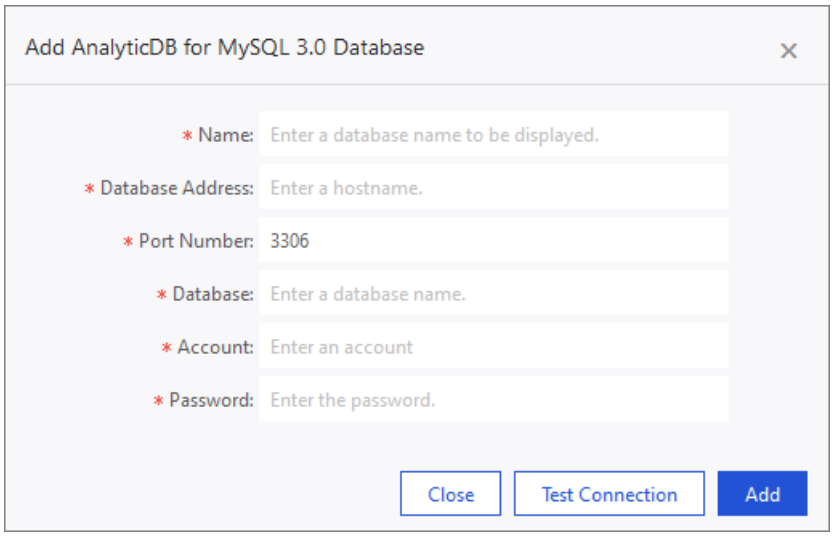
An AnalyticDB for MySQL V3.0 database is created in the AnalyticDB for MySQL console, and parameter settings for connecting to the database are obtained. For information about how to create an AnalyticDB for MySQL V3.0 database, see "Create a database" in AnalyticDB for MySQL User Guide.

Context

AnalyticDB for MySQL is formerly known as AnalyticDB.

Procedure

1. Create a data source.
2. Click the **AnalyticDB for MySQL 3.0** card and configure the required parameters in the dialog box that appears.



Parameter	Description
Name	The name of the data source, which is user-defined.
Database Address	The hostname or IP address of the database that is used as the data source.
Port Number	The port that you use to access the database.
Database	The name of the database that you want to access.
Username	The username that you use to access the database.

Parameter	Description
Password	The password that you use to access the database.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **Add**.

7.3.2.2.15. Add a cloud data source PolarDB for MySQL

This topic describes how to add a cloud data source PolarDB for MySQL.

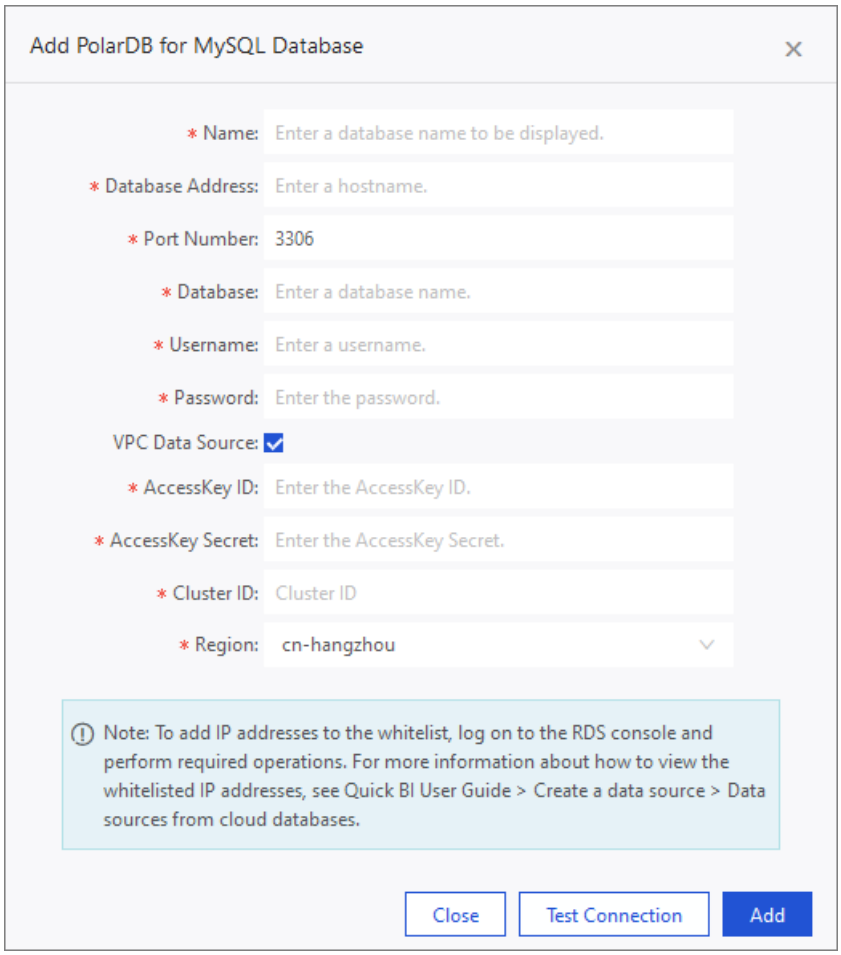
Prerequisites

Parameter settings used to connect to the cloud data source PolarDB for MySQL are obtained.

Procedure

1. Create a data source.
2. Click the **PolarDB for MySQL** card and configure the required parameters in the dialog box that appears.

> **Note** If the data source is connected over a VPC, select VPC Data Source and configure the required parameters.



Parameter	Description
Name	The name of the data source, which is user-defined.
Database Address	The hostname or IP address of the database that is used as the data source.
Port Number	The port that you use to access the database. Default value: 3306.
Database	The name of the database that you want to access.
Username	The username that you use to access the database.
Password	The password that you use to access the database.
AccessKey ID	The AccessKey ID that you use to purchase the database instance.
AccessKey Secret	The AccessKey secret that you use to purchase the database instance.
Cluster ID	The ID of the cluster.
Region	The region where the instance resides.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **Add**.

7.3.2.3. User-created data sources

7.3.2.3.1. Add a user-created MySQL data source

This topic describes how to add a user-created MySQL data source.

Prerequisites

Parameter settings used to connect to the MySQL database are obtained.

Context

The procedure for configuring a user-created MySQL data source is similar to that for configuring an ApsaraDB RDS for MySQL data source. You must perform the following operations to open the specific port of the firewall to allow Quick BI to access the MySQL database:

1. Run the following command to open the configuration file of the firewall:

```
vi /etc/sysconfig/iptables
```

2. Add the following command to the configuration file:

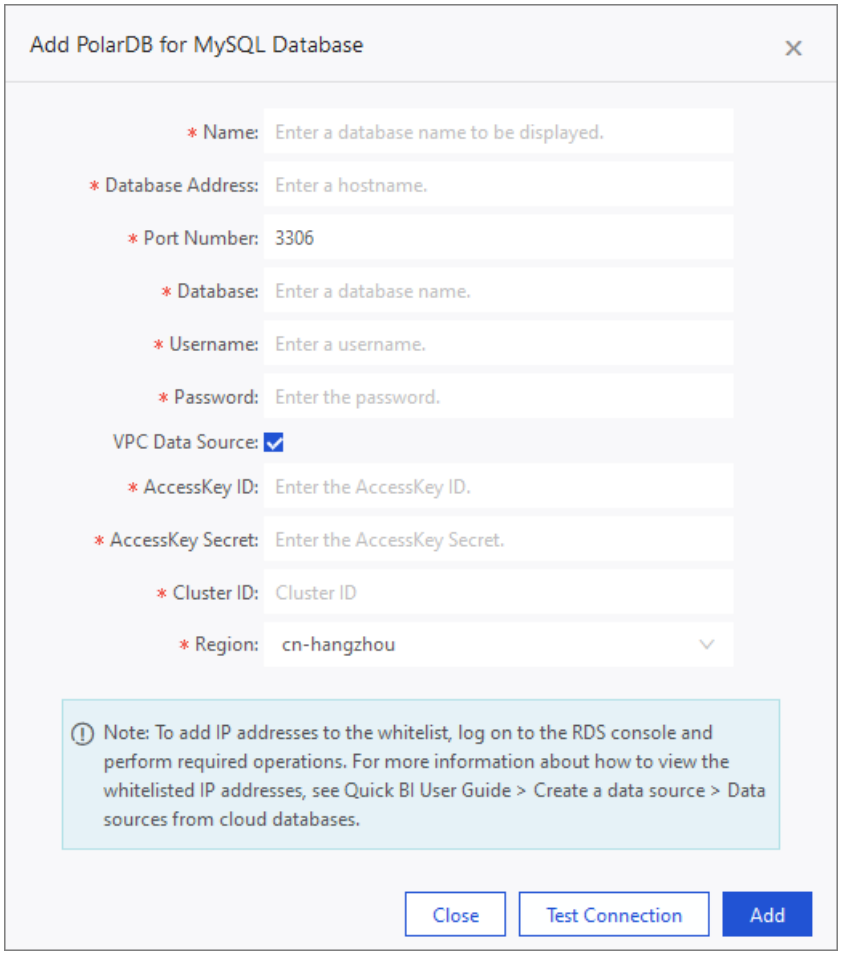
```
-A RH-Firewall-1-INPUT -m state -state NEW -m tcp -p tcp -dport 3306 -j ACCEPT
```

3. Restart the iptables service after the configuration is complete.

```
service iptables restart
```

Procedure

1. Go to the Add Data Source page. For more information, see Add a data source.
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click **MySQL** and configure the parameters for connecting to the database in the dialog box that appears.



> **Note** If you select ssh, you can access the database by using an SSH tunnel.

Parameter	Description
Name	The name of the data source.
Database Address	The hostname or IP address of the database.
Port	The port that you use to access the database. Default value: 3306.
Database	The name of the database that you want to access.
Username	The username that you use to access the database.

Parameter	Description
Password	The password that you use to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username that you use to access the SSH host.
SSH Password	The password that you use to access the SSH host.
SSH Port Number	The port number that you use to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **Add**.

7.3.2.3.2. Add a user-created SQL Server data source

This topic describes how to add a user-created SQL Server data source.

Prerequisites

Parameter settings used to connect to the SQL Server database are obtained.

Context

The procedure for configuring a user-created SQL Server data source is similar to that for configuring an ApsaraDB RDS for SQL Server data source. You must perform the following operations to open the specified port of the firewall to allow Quick BI to access the SQL Server database:

1. Run the following command to open the configuration file of the firewall:

   ```
   vi /etc/sysconfig/iptables
   ```

2. Add the following command to the configuration file:

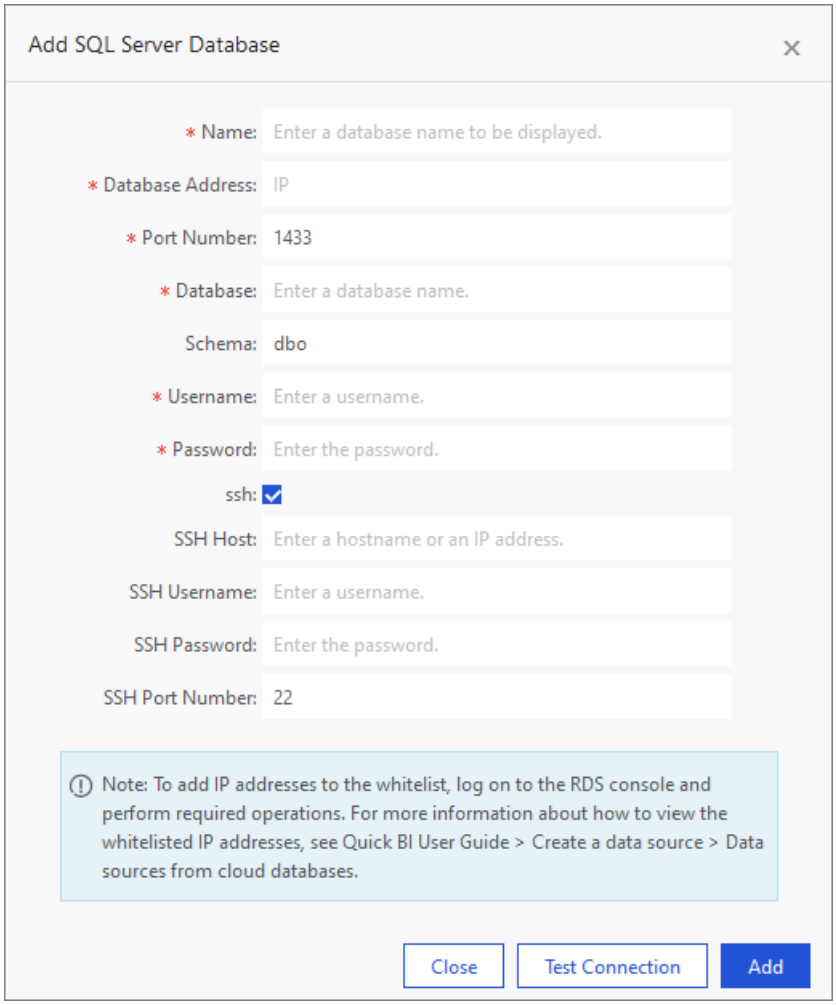
   ```
   -A RH-Firewall-1-INPUT -m state -state NEW -m tcp -p tcp -dport 3306 -j ACCEPT
   ```

3. After the configuration is complete, run the following command to restart the iptable service:

   ```
   service iptables restart
   ```

Procedure

1. Go to the Add Data Source page. For more information, see Add a data source.
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click the **SQL Server** card and configure the parameters for connecting to the database in the dialog box that appears.



Note If you select ssh, you can access the data source by using an SSH tunnel.

Parameter	Description
Name	The name of the data source.
Database Address	The hostname or IP address of the database.
Port	The port that you use to access the database. Default value: 1433.
Database	The name of the database that you want to access.
Schema	The database schema. Default value: dbo.
Username	The username that you use to access the database.
Password	The password that you use to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username that you use to access the SSH host.

Parameter	Description
SSH Password	The password that you use to access the SSH host.
SSH Port Number	The port number that you use to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **Add**.

> **Note** You cannot add a data source that has been added. If you attempt to add it again, an error message appears.

7.3.2.3.3. Add a user-created PostgreSQL data source

This topic describes how to add a user-created PostgreSQL data source.

Prerequisites

Parameter settings used to connect to the PostgreSQL database are obtained.

Context

The procedure for configuring a user-created PostgreSQL data source is similar to that for configuring an ApsaraDB RDS for PostgreSQL data source. You must perform the following operations to open the specified port of the firewall to allow Quick BI to access the PostgreSQL database:

1. Run the following command to open the configuration file of the firewall:

```
vi /etc/sysconfig/iptables
```

2. Add the following command to the configuration file:

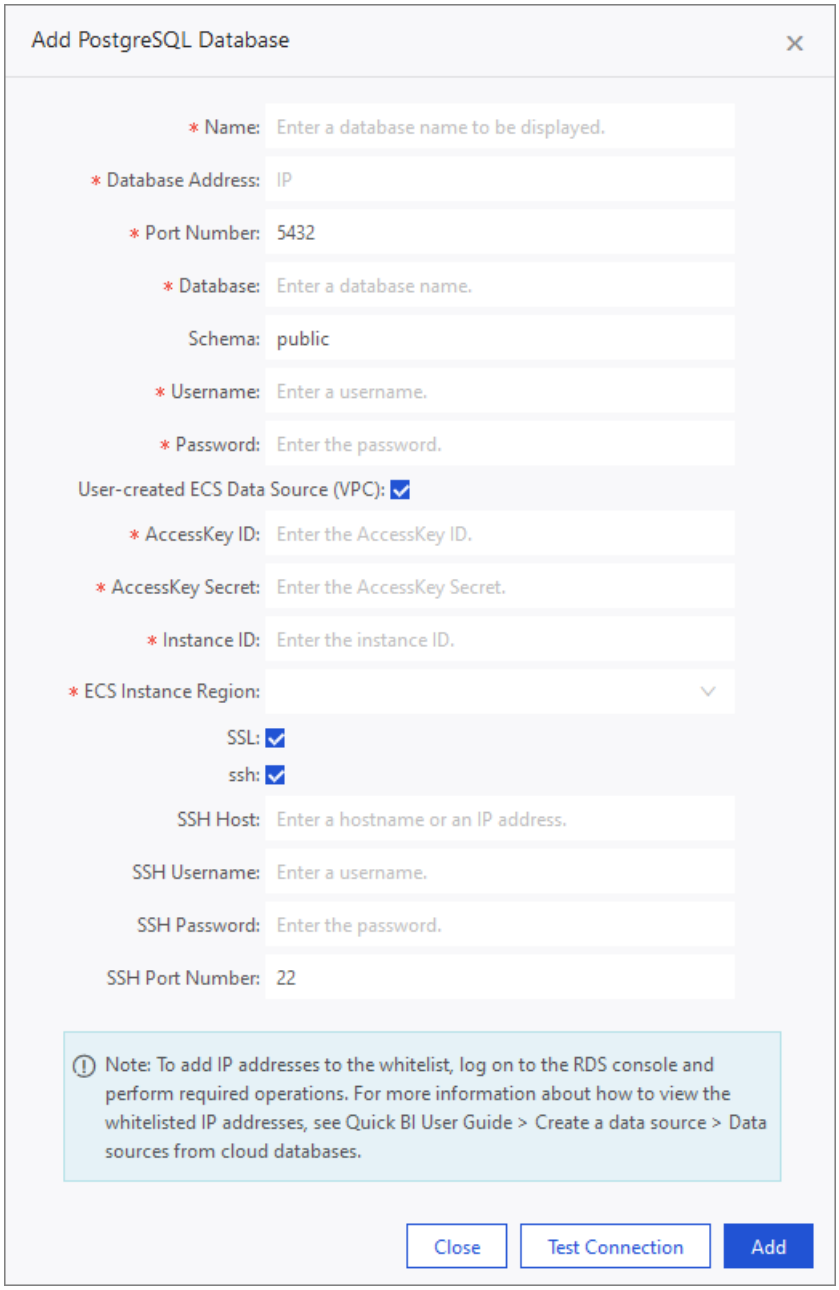
```
-A RH-Firewall-1-INPUT -m state -state NEW -m tcp -p tcp -dport 3306 -j ACCEPT
```

3. After the configuration is complete, run the following command to restart the iptable service:

```
service iptables restart
```

Procedure

1. Go to the Add Data Source page. For more information, see Add a data source.
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click the **PostgreSQL** card and configure the parameters for connecting to the database in the dialog box that appears.



Note If the data source is connected over a VPC, select **User-created ECS Data Source (VPC)** and specify required parameters. If you select **SSL**, MaxCompute Lightning is supported. If you select **ssh**, you can access the data source by using an SSH tunnel.

Parameter	Description
Name	The name of the data source.
Database Address	The hostname or IP address of the database.
Port	The port that you use to access the database. Default value: 5432.

Parameter	Description
Database	The name of the database that you want to access.
Schema	The database schema. Default value: public.
Username	The username that you use to access the database.
Password	The password that you use to access the database.
AccessKey ID	The AccessKey ID that you use to purchase the database instance.
AccessKey Secret	The AccessKey secret that you use to purchase the database instance.
Instance ID	The ID of the database instance.
ECS Instance Region	The region where the data source is located.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username that you use to access the SSH host.
SSH Password	The password that you use to access the SSH host.
SSH Port Number	The port number that you use to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **Add**.

7.3.2.3.4. Add a user-created Oracle data source

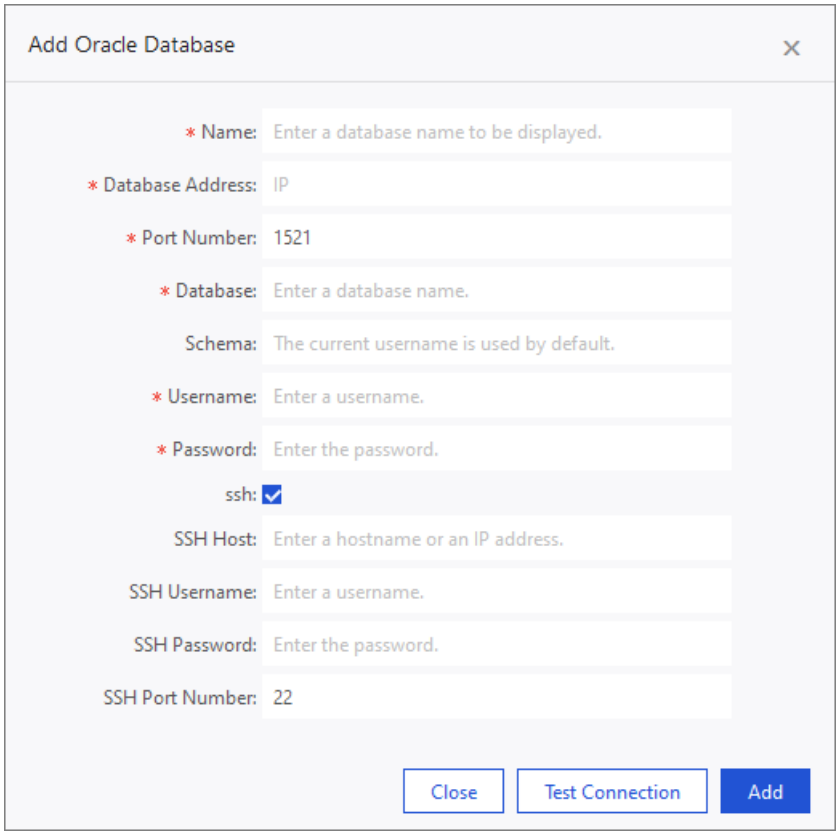
This topic describes how to add a user-created Oracle data source.

Prerequisites

Parameter settings used to connect to the Oracle database are obtained.

Procedure

1. Go to the Add Data Source page. For more information, see Add a data source.
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click the **Oracle** card and configure the parameters for connecting to the database in the dialog box that appears.



Note If you select ssh, you can access the data source by using an SSH tunnel.

Parameter	Description
Name	The name of the data source.
Database Address	The hostname or IP address of the database.
Port	The port that you use to access the database. Default value: 1521.
Database	The name of the database that you want to access.
Schema	The database schema. Default value: public.
Username	The username that you use to access the database.
Password	The password that you use to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username that you use to access the SSH host.
SSH Password	The password that you use to access the SSH host.
SSH Port Number	The port number that you use to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **Add**.

7.3.2.3.5. Add a user-created Hive data source

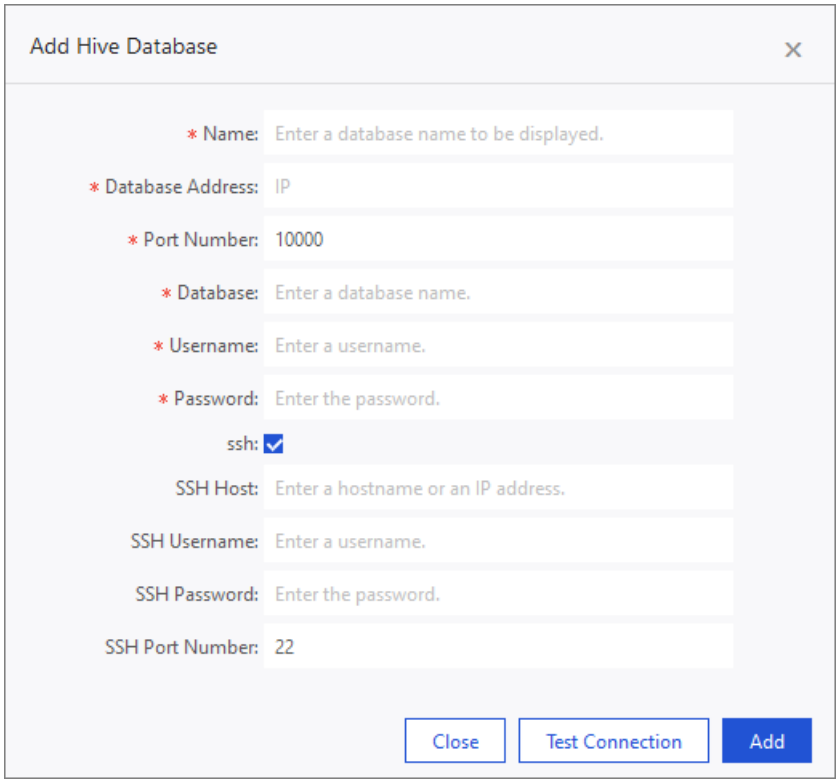
This topic describes how to add a user-created Hive data source.

Prerequisites

Parameter settings for connecting to the Hive data source are obtained.

Procedure

1. On the Data Sources page, click Create Data Source in the upper-right corner. For more information, see Create a data source.
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click **Hive** and set the parameters for connecting to the data source in the dialog box that appears.



Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 10000.
Database	The name of the database to which you want to access.

Parameter	Description
Username	The username used to access the database.
Password	The password used to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username used to access the SSH host.
SSH Password	The password used to access the SSH host.
SSH Port Number	The port number used to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the connection is established, click **Add**.

7.3.2.3.6. Add a user-created Vertica data source

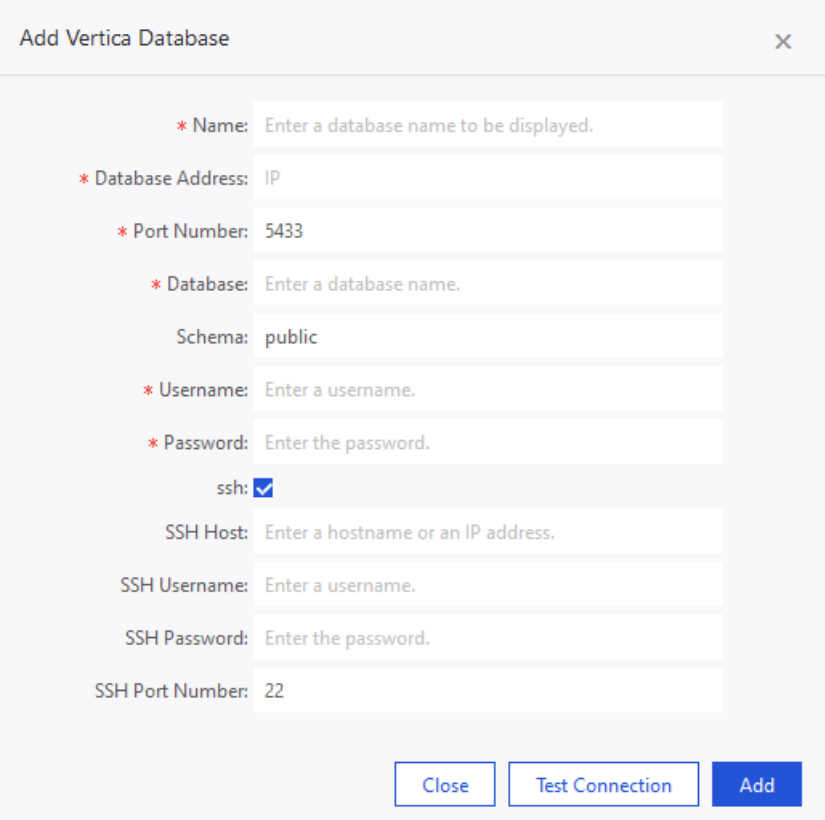
This topic describes how to add a user-created Vertica data source.

Prerequisites

Parameter settings for connecting to the Vertica data source are obtained.

Procedure

1. On the Data Sources page, click Create Data Source in the upper-right corner. For more information, see Create a data source.
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click **Vertica** and set the parameters for connecting to the data source in the dialog box that appears.



Parameter	Description
Name	The name to be displayed for the connected data source.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 5433.
Database	The name of the database to which you want to access.
Schema	The schema of the database. The default value is public.
Username	The username used to access the database.
Password	The password used to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username used to access the SSH host.
SSH Password	The password used to access the SSH host.
SSH Port Number	The port number used to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the connection is established, click **Add**.

7.3.2.3.7. Add a user-created IBM DB2 LUW data source

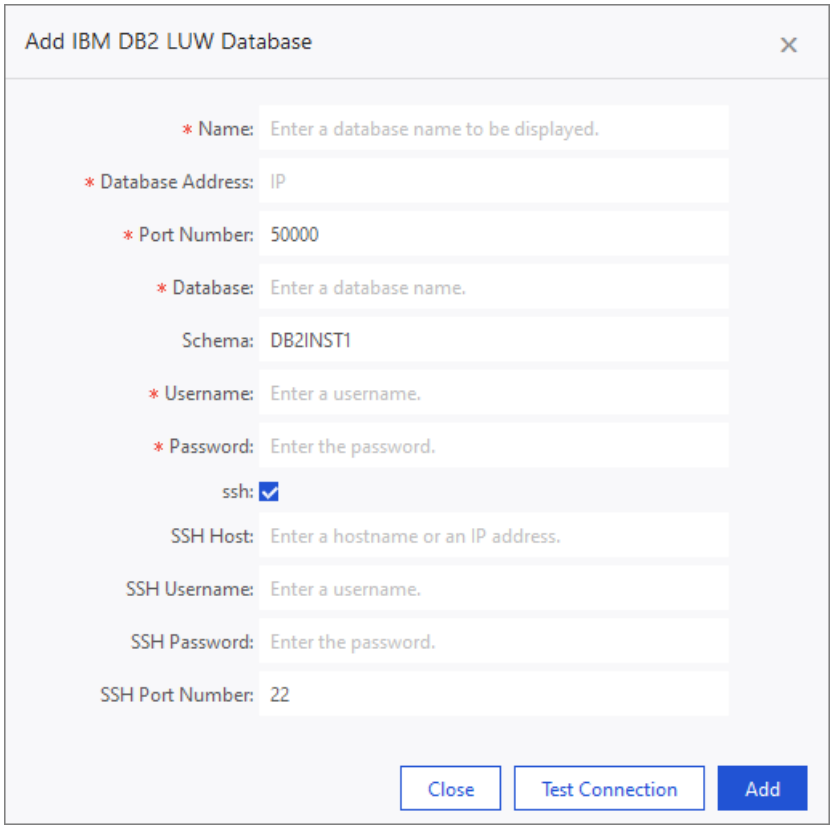
This topic describes how to add a user-created IBM DB2 LUW data source.

Prerequisites

Parameter settings for connecting to the IBM DB2 LUW data source are obtained.

Procedure

1. On the Data Sources page, click Create Data Source in the upper-right corner. For more information, see Create a data source.
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click **IBM DB2 LUW** and set the parameters for connecting to the data source in the dialog box that appears.



Parameter	Description
Name	The name to be displayed for the connected data source.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 50000.
Database	The name of the database that you want to access.
Schema	The schema of the database. The default value is DB2INST1.

Parameter	Description
Username	The username used to access the database.
Password	The password used to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username used to access the SSH host.
SSH Password	The password used to access the SSH host.
SSH Port Number	The port number used to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the data source.
4. After the connection is established, click **Add**.

7.3.2.3.8. Add a user-created SAP IQ (Sybase IQ) data source

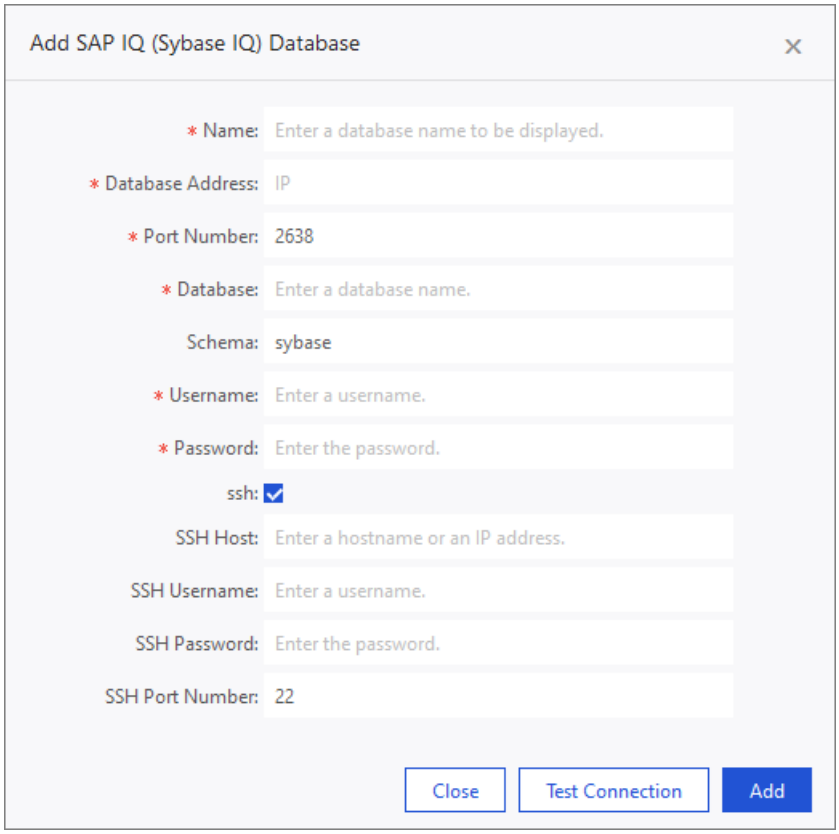
This topic describes how to add a user-created SAP IQ (Sybase IQ) data source.

Prerequisites

Parameter settings for connecting to the SAP IQ (Sybase IQ) data source are obtained.

Procedure

1. On the Data Sources page, click Create Data Source in the upper-right corner. For more information, see Create a data source.
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click **SAP IQ (Sybase IQ)** and set the parameters for connecting to the data source in the dialog box that appears.



Parameter	Description
Name	The name to be displayed for the connected data source.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 2638.
Database	The name of the database that you want to access.
Schema	The schema of the database. The default value is sybase.
Username	The username used to access the database.
Password	The password used to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username used to access the SSH host.
SSH Password	The password used to access the SSH host.
SSH Port Number	The port number used to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the data source.
4. After the connection is established, click **Add**.

7.3.2.3.9. Add a user-created SAP HANA data source

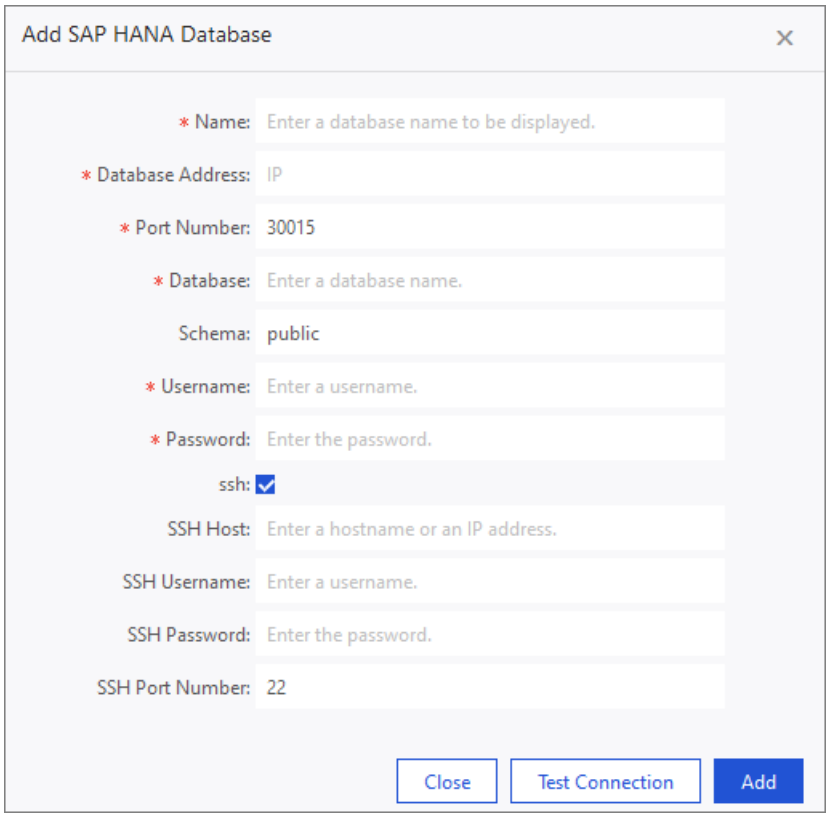
This topic describes how to add a user-created SAP HANA data source.

Prerequisites

Parameter settings used to connect to the SAP HANA database are obtained.

Procedure

1. Go to the Add Data Source page. For more information, see Add a data source.
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click the **SAP HANA** card and configure the parameters for connecting to the database in the dialog box that appears.



> **Note** If you select ssh, you can access the database by using an SSH tunnel.

Parameter	Description
Name	The name of the data source.
Database Address	The hostname or IP address of the database.
Port	The port that you use to access the database. Default value: 30015.
Database	The name of the database that you want to access.

Parameter	Description
Schema	The database schema. Default value: public.
Username	The username that you use to access the database.
Password	The password that you use to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username that you use to access the SSH host.
SSH Password	The password that you use to access the SSH host.
SSH Port Number	The port number that you use to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **Add**.

7.3.2.3.10. Add a user-created Presto data source

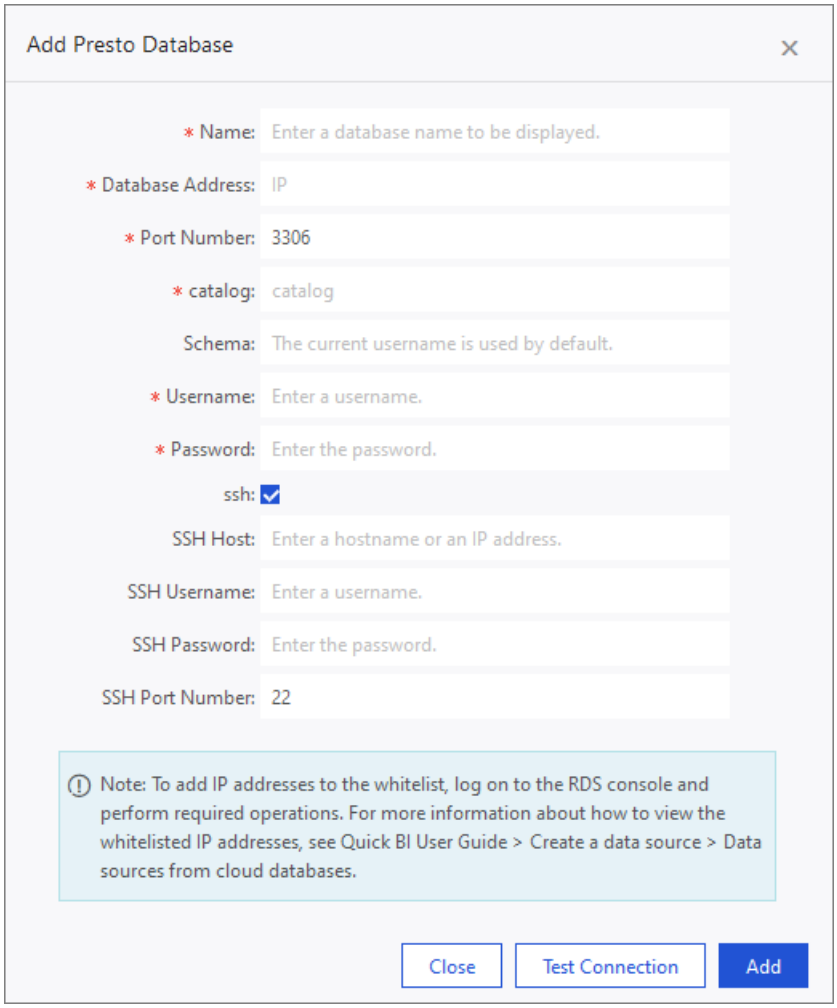
This topic describes how to add a user-created Presto data source.

Prerequisites

Parameter settings for connecting to the Presto data source are obtained.

Procedure

1. On the Data Sources page, click Create Data Source in the upper-right corner. For more information, see Create a data source.
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click **Presto** and set the parameters for connecting to the data source in the dialog box that appears.



Note If you select ssh, you can access the data source by using an SSH tunnel.

Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 3306.
catalog	The name of the data source that you want to use Presto to query.
Schema	The current logon username is used by default.
Username	The username used to access the database.
Password	The password used to access the database.
SSH Host	The hostname or IP address of the SSH host.

Parameter	Description
SSH Username	The username used to access the SSH host.
SSH Password	The password used to access the SSH host.
SSH Port Number	The port number used to access the SSH host. Set the value to 22.

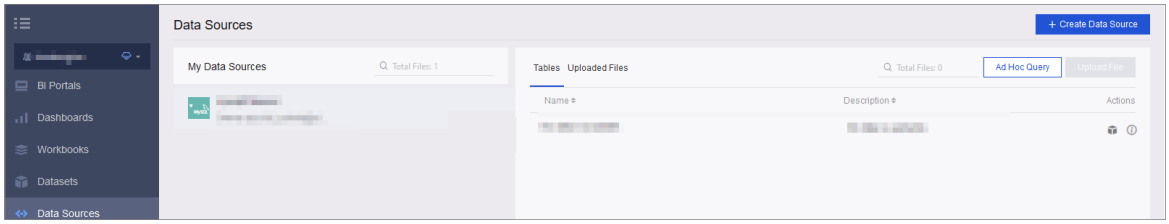
3. Click **Test Connection** to test connectivity with the data source.
4. After the connection is established, click **Add**.

7.3.2.4. List of data sources

This topic describes the basic information about the Data Sources page.

1. Log on to the Quick BI console.
2. Click the Workspace tab. In the left-side navigation pane, click **Data Sources**.

   On this page, you can manage data sources. For example, you can **create**, **edit**, and **delete** a data source.



7.3.2.5. Create a data source

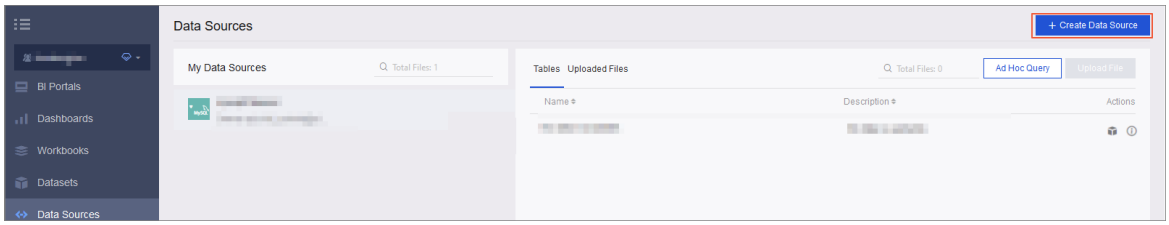
This topic describes how to create a data source.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane of the Workspace page, click **Data Sources**.
4. In the upper-right corner of the Data Sources page, click **Create Data Source**.



5. In the **Add Data Source** dialog box that appears, select a data source.
   - If you want to add a cloud data source, click the **Cloud Data Sources** tab.

- If you want to add a user-created data source, click the **User-created Data Sources** tab.

6. Select the data source type. In the dialog box that appears, enter the information required for connecting to the data source, and click **Add**.

7.3.2.6. Edit a data source

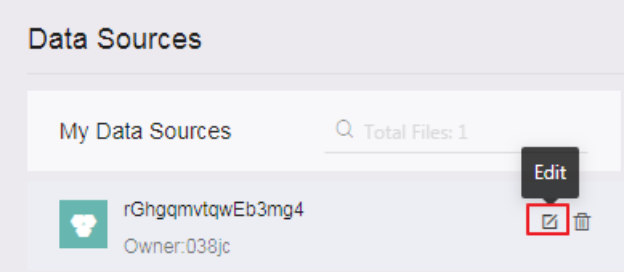
This topic describes how to edit a data source.

Prerequisites

- The Quick BI service is purchased.
- A data source is created.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.
4. Find the data source that you want to edit in the data source list.
5. Click the icon and edit the data source.



7.3.2.7. Delete a data source

This topic describes how to delete a data source.

Prerequisites

- The Quick BI service is purchased.
- A data source is created.

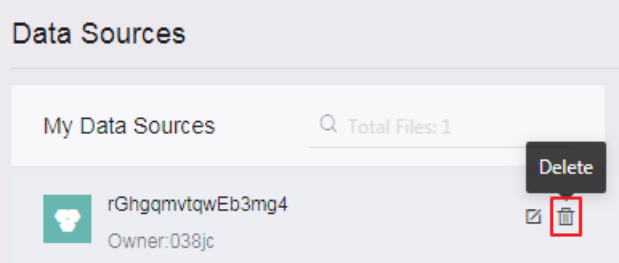
Context

If you have created datasets based on a data source, you cannot delete the data source.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.

4. Find the data source that you want to delete in the data source list.
5. Click the icon to delete the data source.



7.3.2.8. Search for a data source

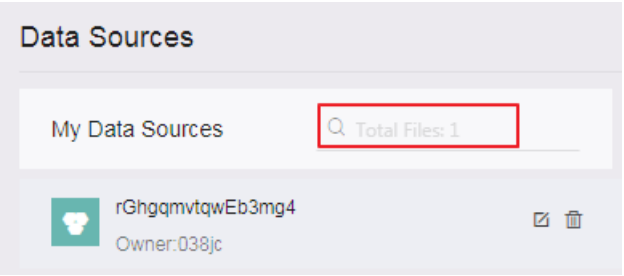
This topic describes how to search for a data source.

Prerequisites

- The Quick BI service is purchased.
- A data source is created.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.
4. On the Data Sources page, enter a keyword of the data source that you want to search for in the search box.



5. Click the icon.

7.3.2.9. Search for a table under a data source

This topic describes how to search for a specific table under a data source.

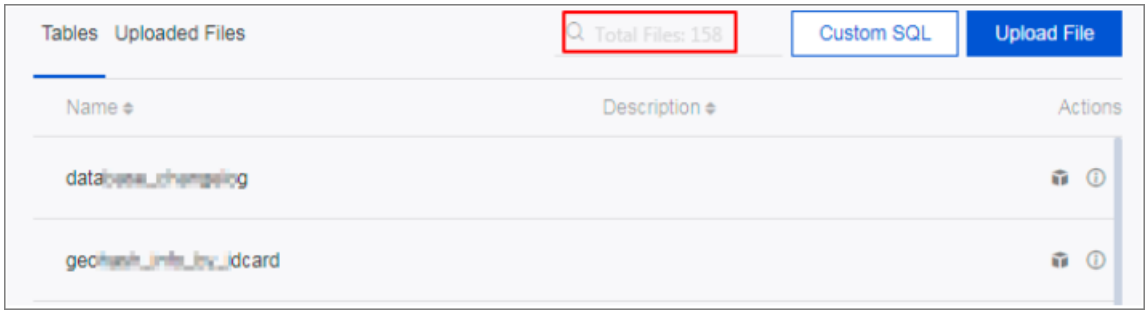
Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.

3. In the left-side navigation pane, click **Data Sources**.
4. Select the target data source. All tables under the data source are listed in the right-side part of the page.
5. Enter a keyword of the table that you want to search in the search box.



6. Click the icon.

7.3.2.10. View the details of a table under a data source

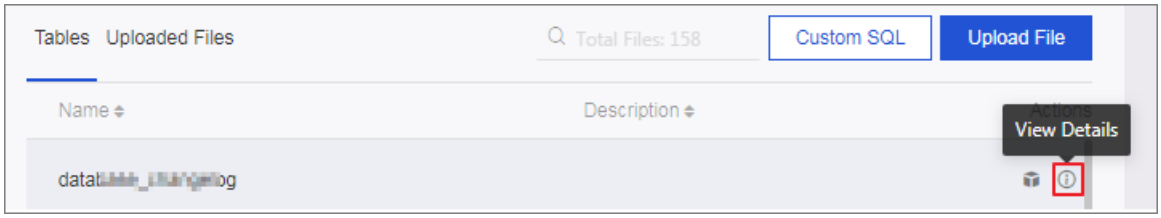
Quick BI allows you to view the tables and table details under a data source.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.
4. Select the target data source. All tables under the data source are listed in the right-side part of the page.
5. Find the table whose details you want to view and click the icon in the Actions column.



7.3.3. Datasets

7.3.3.1. Overview of datasets

You can use tables from data sources to create datasets. The following topics describe common operations on datasets, for example, create, edit, and query a dataset.

You can use one of the following three methods to create a dataset:

- Create a dataset from a data source.

- Create a dataset by uploading a file.
- Create a dataset by using an SQL statement for ad hoc query.

7.3.3.2. Create datasets

7.3.3.2.1. Create a dataset based on a data source

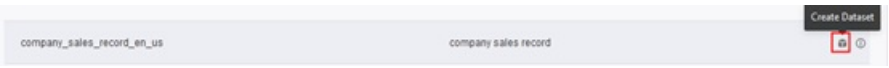
This topic describes how to create a dataset based on a data source.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.
4. On the Data Sources page, click the target data source. All tables under the data source are listed in the right-side part of the page.
5. Find the target table and click the icon in the Actions column.



After the dataset is created, the **Datasets** page appears. The new dataset is displayed on the My Items tab and marked with NEW.

7.3.3.2.2. Create a dataset by uploading a file

This topic describes how to create a dataset by uploading a file.

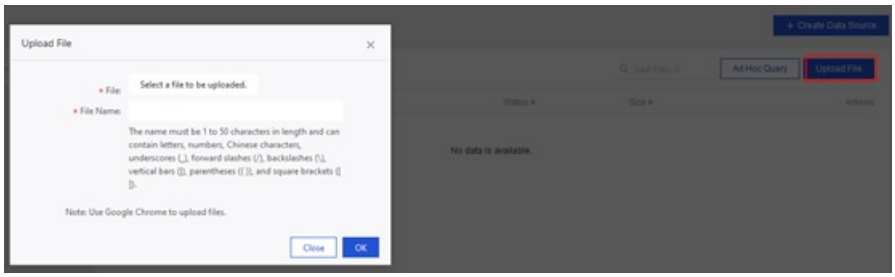
Prerequisites

- The Quick BI service is purchased.
- A data source is created.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.

4. On the Data Sources page, click a data source, and then click **Upload File** in the upper-right corner of the page.
5. In the **Upload File** dialog box, select the target file, enter a file name, and then click **OK**.



> **Note** After the file is uploaded, the Uploaded Files page appears.

6. On the Uploaded Files page, find the file you uploaded and click the icon in the Actions column to create a dataset.

7.3.3.2.3. Create a dataset by using an SQL statement for ad hoc query

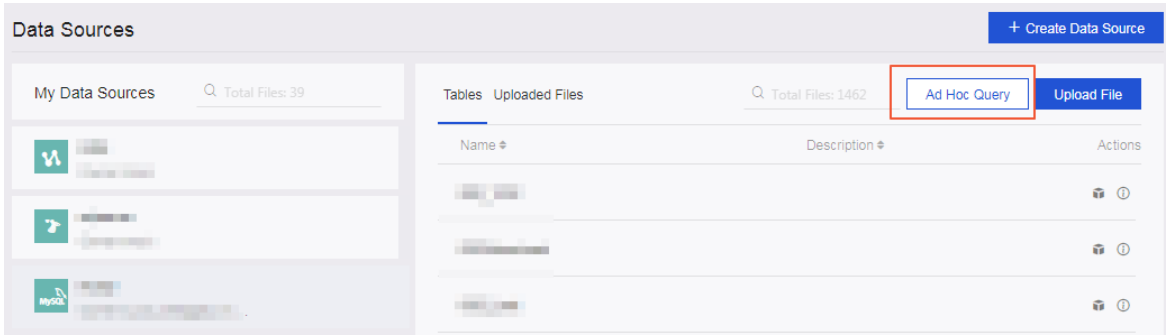
This topic describes how to create a dataset by using an SQL statement for ad hoc query to implement some complex logic for data modeling. Ad hoc queries support dynamic parameter passing to SQL statements. Modeling analysis based on dynamic parameter passing to SQL statements increases the depth of scenarios supported by Quick BI. This meets the requirements of complex data analysis scenarios.

Prerequisites

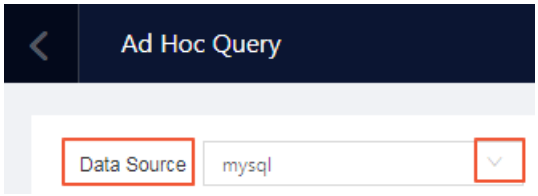
The Quick BI service is purchased.

Create a dataset by using an SQL statement for ad hoc query

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane of the Workspace page, click **Data Sources**.
4. In the upper-right corner of the **Data Sources** page, click **Ad Hoc Query**.



5. On the **Ad Hoc Query** page that appears, specify the data source.



6. Enter an SQL statement.

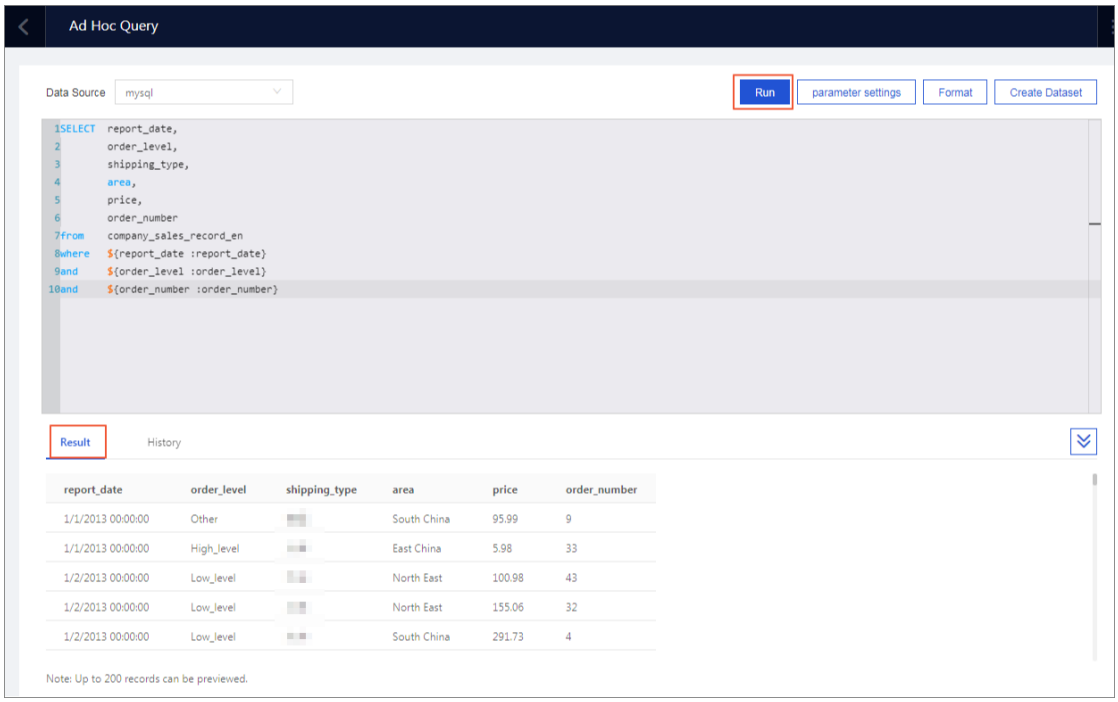
   Sample SQL statement:

```
SELECT  report_date,
        order_level,
        shipping_type,
        area,
        price,
        order_number
from    company_sales_record
where   ${report_date :report_date}
and     ${order_level :order_level}
and     ${order_number :order_number}
```

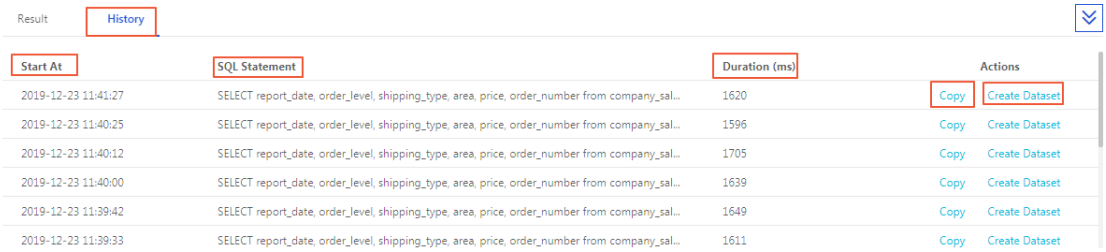
7. Click **Run** to execute the SQL statement.

   You can view the execution results on the Result tab.

   i. Click the **Result** tab.



ii. Click the **History** tab to view the execution time, SQL statement, and time consumed by the ad hoc query.



- Click **Copy** to copy the SQL statement and paste it into the SQL statement input box.
- Click **Create Dataset**. A dataset is created by using the historical SQL statement.
- Click to hide the execution results.

SQL statements for ad hoc queries support dynamic parameter passing and placeholders. When you create an SQL model, you can append SQL parameters to the WHERE clause in the format of $ {Physical field name:Parameter alias}. The parameters can be referenced by the filter bar widget.

> **Note** Parameter fields are not displayed in the dataset, but are displayed in the filter bar widget.

Sample SQL statement:

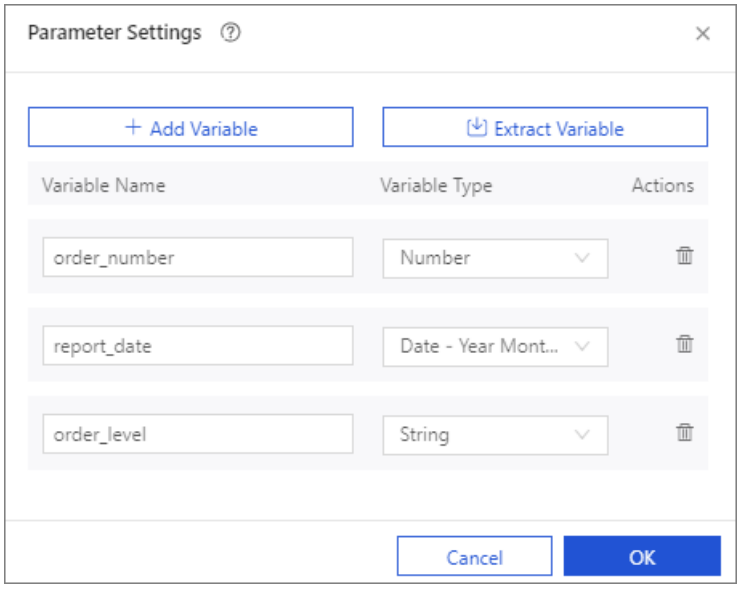
```
SELECT  report_date,
      order_level,
      shipping_type,
      area,
      price,
      order_number
from   company_sales_record
where   ${report_date :report_date}
and     ${order_level :order_level}
and     ${order_number :order_number}
```

8. Before you execute SQL statements, you can set and format parameters. After the SQL statements are executed, you can create datasets.

i. Click **parameter settings**. In the dialog box that appears, configure the parameters.

   You can add variables and modify variable types. Five variable types are supported: String, Number, Date -Year Month Date, Date -Year Month, and Date -Year.

   - Click **New parametric variables** to add parameter aliases and variable types. A parameter alias must be added to the WHERE clause in the SQL statement in the format of ${Physical field name:Parameter variable name}.
   - Click **Fast extraction** to obtain the parameter aliases in the SQL statement. The default variable type is String, which can be changed.



ii. Click **Format** to format the SQL statement.

iii. Click **Create Dataset** to create a dataset based on the query results of the current SQL statement.

For information about how to use the parameters in the filter bar widget, see Use SQL statement parameters in the Filter Bar widget.

7.3.3.3. Specify a method to name dimensions and measures

Quick BI creates datasets based on the metadata of physical tables and converts fields in the physical tables to dimensions or measures in the datasets. The names of dimensions and measures are automatically generated. They can be the names or descriptions of the fields in the physical tables.

Prerequisites

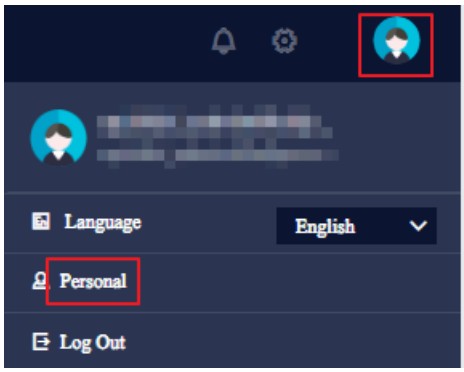
The Quick BI service is purchased.

Context

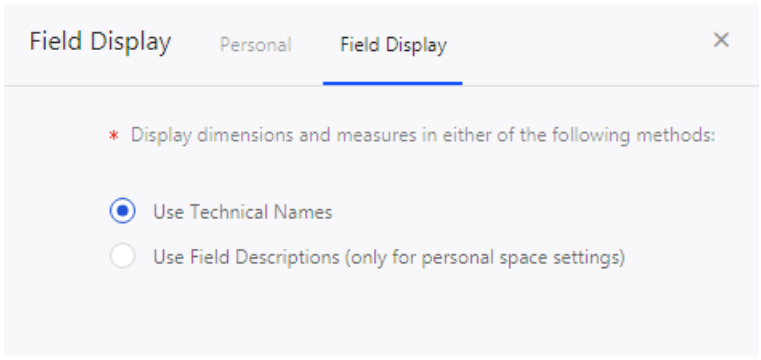
You can move the pointer over the profile picture and specify a method to name dimensions and measures in datasets. Dimensions and measures in datasets are named based on your setting.

Procedure

1. Log on to the Quick BI console.
2. Move the pointer over the profile picture in the upper-right corner and select **Personal**.



3. In the **Personal** dialog box, click the **Display** tab and select a method to name dimensions and measures in datasets.



7.3.3.4. Edit a dataset

7.3.3.4.1. Edit a dimension

If the data type of a field in a dataset table is String or Date/Time, the field is classified as a dimension by the system. You can edit the field in the Dimensions list.

Prerequisites

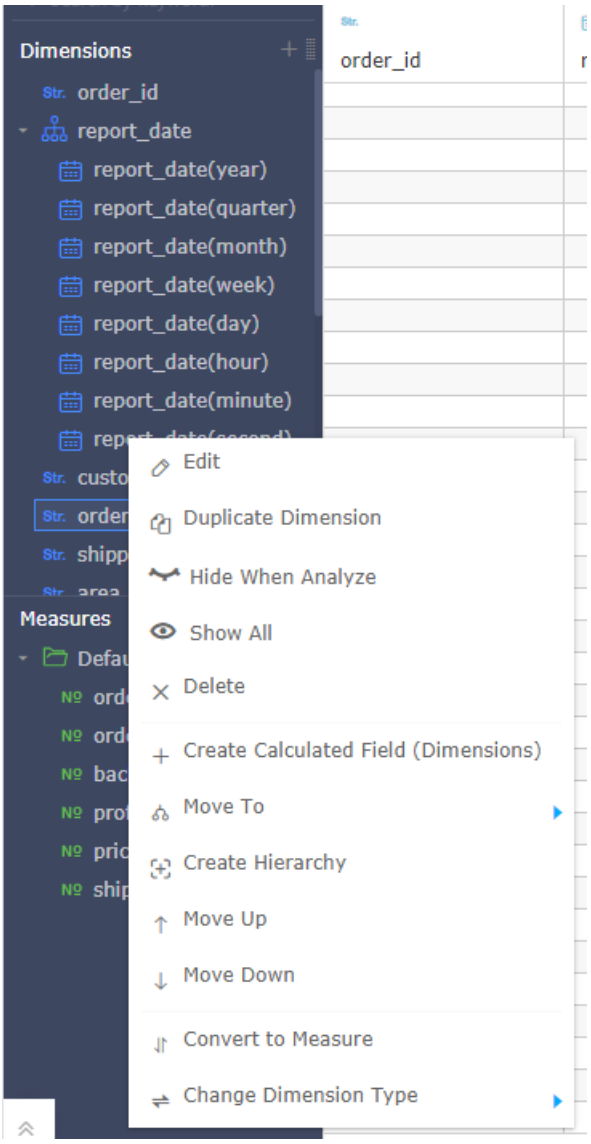
The Quick BI service is purchased.

A dataset is created.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the Datasets page, find the target dataset and click the icon in the Actions column to go to the dataset edit page.
5. Find the target field in the Dimensions list.

6. Right-click the field and select the operation you want to perform.



- **Edit**: Edit the name and description of the dimension.

  When you edit a week dimension, you can configure the first day of a week.
- **Duplicate Dimension**: Duplicate the dimension. The name of the duplicate dimension ends with **Duplicate**.
- **Hide When Analyze**: Hide the dimension as required.
- **Show All**: Show all dimensions.
- **Delete**: Delete the dimension.
- **Create Calculated Field (Dimensions)**: Create a dimension and customize its calculation method.
- **Move To**: Move the dimension to an existing hierarchy for drilling.
- **Create Hierarchy**: Add the dimension field to a new hierarchy.
- **Move Up/Move Down**: Move the dimension. You can drag or right-click the dimension to move it.

- **Convert to Measure**: Convert the dimension to a measure.
- **Change Dimension Type**: Switch the dimension type among Date/Time (Source Format), Geo, String, and Number.

  For example, you must change the data type of the province and city dimensions to Geo when you create a bubble map or colored map. Otherwise, the map cannot be created.

  > **Note** You can duplicate, hide, and delete dimensions at different hierarchy levels.

7.3.3.4.2. Edit a measure

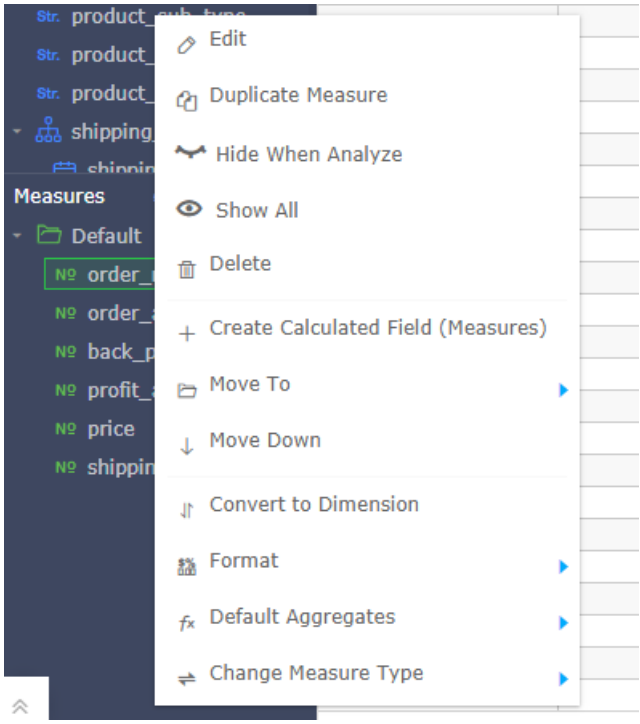
If the data type of a field in a dataset table is Number, the field is classified as a measure by default. You can edit the field in the Measures list.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the Datasets page, click the target dataset to go to the dataset edit page.
5. Find the target field in the Measures list.
6. Right-click the field and select the operation that you want to perform on the field as required.



- Edit: Edit the name and description of the measure.
- Duplicate Measure: Duplicate the measure. The name of the duplicate measure ends with Duplicate.
- Hide When Analyze: Hide the measure as required.
- Show All: Show all measures.
- Delete: Delete the measure.
- Create Calculated Field (Measures): Create a measure and customize its calculation method.
- Move To: Move the measure to an existing folder.
- Move Up/Move Down: Move the measure. You can drag or right-click the measure to move it.
- Convert to Dimension: Convert the measure to a dimension.
- Format: Specify the number format.
- Default Aggregates: Specify the aggregate function, such as SUM, MAX, or MIN.
- Change Measure Type: Switch the measure type between String and Number.

7.3.3.4.3. Toolbar and shortcut menu

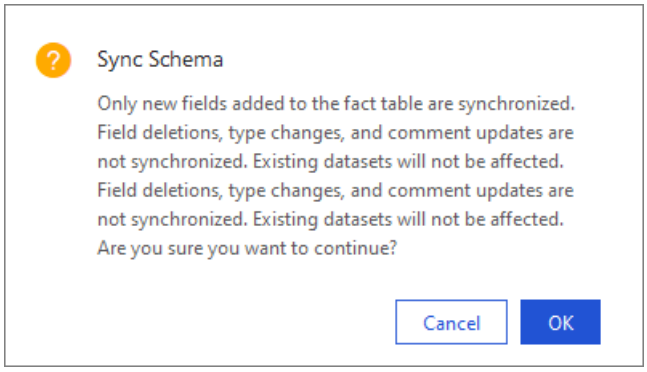
On the dataset edit page, Quick BI provides a toolbar and a shortcut menu for you to edit a dataset and create reports.

Toolbar

- Lock: provides a lock mechanism. Multiple users can edit a dataset at the same time. If you want to modify a dataset, you must first lock the dataset and refresh the page to update the dataset. Then, make and save the modifications. If you modify the dataset without refreshing the page, the changes made by other users are overwritten.
- Sync Schema: synchronizes the new fields in an online physical table to the dataset that is created based on the physical table.

  However, if a field is modified or deleted from the physical table, the field in the dataset remains unchanged.

  Sync Schema

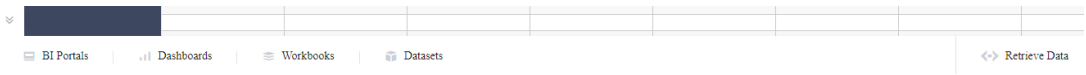
- Refresh Preview: refreshes the dataset for preview. If you want to view the latest data, save the dataset and click Refresh Preview.
- Set Filter: filters out unnecessary data in the dataset to prevent full table scan.
- Save As: saves the current dataset as a new dataset. This function allows you to duplicate or back up a dataset.
- Save: saves the dataset.

  After you add new fields, delete fields, or convert between dimensions and measures in a dataset, you must save the dataset. Then, you can refresh the page to view the updated dataset.

Shortcut menu

On the dataset edit page, click the icon in the lower-left corner to expand the shortcut menu.

Shortcut menu

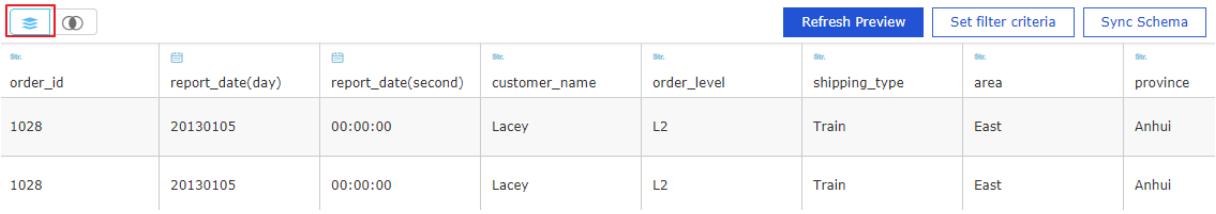


- Dashboards: You can click **Dashboards** to open the **Create Dashboard** dialog box.
- Workbooks: You can click **Workbooks** to go to the page for creating and editing a workbook.
- Datasets: You can click **Datasets** to go to the page for creating a dataset.
- BI Portals: You can click **BI Portals** to go to the page for creating and editing a BI portal.
- Retrieve Data: You can click **Retrieve Data** to go to the page for creating a data source.

7.3.3.4.4. Preview data

This topic describes how to preview data on the dataset edit page.

Click the icon to preview data.



order_id	report_date(day)	report_date(second)	customer_name	order_level	shipping_type	area	province
1028	20130105	00:00:00	Lacey	L2	Train	East	Anhui
1028	20130105	00:00:00	Lacey	L2	Train	East	Anhui

7.3.3.4.5. Join tables

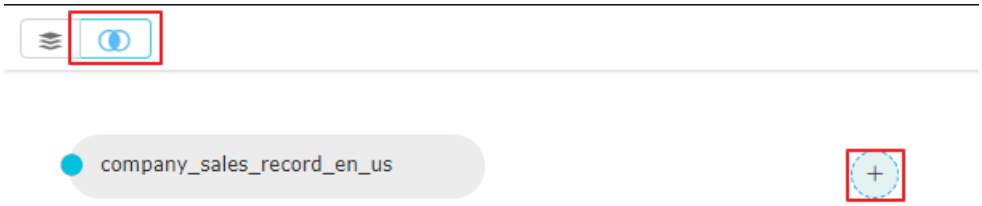
This topic describes how to join tables when you edit a dataset.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the Datasets page, click the target dataset to go to the dataset edit page. The dataset

company_sales_record is used as an example.

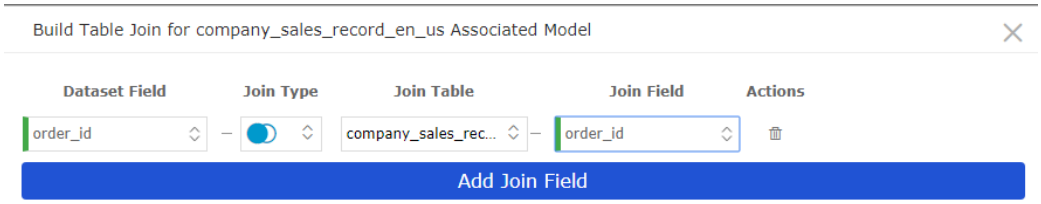
5. Click the **Join** icon ( ) to switch to the Table Join mode.



6. Click the plus sign (+). The **Build Table Join for company_sales_record Associated Model** dialog box appears. Quick BI supports five-layer horizontal join, as shown in the following figure.

7. Select the fields that are used to join tables and specify a join type.

Build a table join model



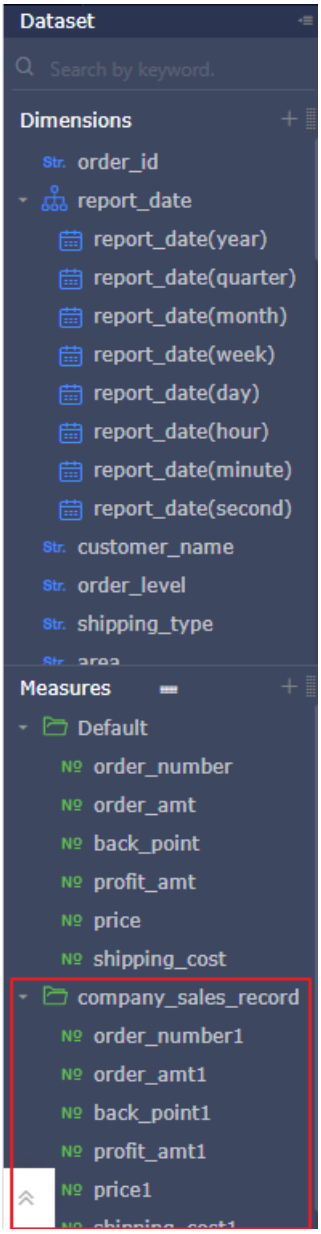
Quick BI supports the following join types:

- Inner Join ( ): returns records with the same join fields in two tables.
- Left Outer Join ( ): returns all records in the left table and records in the right table that have the same join fields as the left table.
- All Join ( ): returns all records in two tables.

> **Note** MySQL data sources do not support the All Join type.

8. Click **Add Join Field** to add multiple join fields.
9. Click **OK** to save the model.

10. Click **Save**.
11. After the model is saved, click the preview icon ( ) to switch to the preview mode, and then click **Refresh Preview** to view the join results of the tables.



7.3.3.4.6. Calculated fields

7.3.3.4.6.1. Overview

Quick BI allows you to create fields from existing fields in data sources by using SQL functions. The new fields are referred to as calculated fields.

When you create a calculated field, take note of the following points:

- Fields that are created from the Dimensions list are classified as calculated dimensions. Fields that are created from the Measures list are classified as calculated measures.

- In the Expression field, you can select any functions or expressions supported by the current data source.
- You must enter the function name. The field name must be enclosed in a pair of brackets. You can enter the entire field name, or enter a left bracket ([) and select the required field from the displayed field list. You can also double-click the target field in the Dimensions or Measures list to add the field to the Expression field. Correct SQL expressions are highlighted.
- When you specify an SQL expression for a calculated field, do not use full-width punctuation marks. If an error occurs, check whether you have entered full-width punctuation marks in the expression field.
- After you create the calculated field, save the dataset and then refresh it to show the calculated field.
- You cannot use a calculated field in the expression of another calculated field. If a field is deleted from the physical table, a calculated field whose expression uses the deleted field becomes invalid.

7.3.3.4.6.2. Rules for using calculated fields

This topic describes the rules for using calculated fields.

- Calculated fields not using aggregate functions can be used as dimensions, or as measures after you specify the aggregate method. Calculated fields using aggregate functions can only be used as measures, and cannot be converted to dimensions.
- You can set the data type for a calculated field. Currently, you can set the data type of dimension fields to Number, Text, or Date/Time, and set the data type of measure fields to Number or Text.
- Similar to dimensions and measures generated by the original fields in a data source, dimensions and measures generated by calculated fields can be used in rows, columns, and filters, and can be selected on the Data tab for charts and maps. You can also convert a calculated field from dimension to measure or from measure to dimension.

> **Note** If you use the SUM or AVG aggregate function in an expression of a calculated field whose data type is Text and values are text data, an error occurs due to a failure in data type conversion.

7.3.3.4.6.3. Types of calculated measures

A calculated field in the measure category is a calculated measure. Calculated measures are classified into common measures and aggregate measures based on the expression type.

The following table lists differences between common measures and aggregate measures.

Common measure	Aggregate measure
Expressions exclude aggregate functions.	Expressions include aggregate functions.
You can change the aggregation method.	You cannot change the aggregation method.
You can convert common measures to dimensions.	You cannot convert aggregate measures to dimensions.

Common measure	Aggregate measure
No aggregate functions are supported.	Supported aggregate functions: SUM, AVG, MIN, MAX, COUNT, and COUNT DISTINCT.

You can use the COUNT or COUNT DISTINCT function that has dimensions as its parameters to form a deduplicated aggregate measure.

For example, to calculate the average purchase price per user, you can use the following expression: sum(purchase price)/countd(user ID). To calculate the proportion of order costs to order prices, you can use sum(order cost)/sum(order price) but not avg(order cost/order price).

> **Note** Common measures cannot be used with aggregate measures. For example, sum(order cost)/order price is incorrect.

7.3.3.4.6.4. Expressions of calculated fields

This topic describes functions and arithmetic operations of calculated fields.

Aggregation methods

- To calculate the total order price: sum([order_amt])
- To calculate the average order price: avg([order_amt])
- To calculate the maximum order price: max([order_amt])
- To calculate the minimum order price: min([order_amt])
- To count the number of customers: count([customer_name])
- To count the number of unique customers: count(distinct [customer_name])

Basic operations

order_cost = ([order_amt] - [profit_amt])/100

Substring

Substring([customer_name],1,1)

Group values of a measure by using the CASE WHEN statement

- Group orders based on the order price

  CASE WHEN [order_amt] < 500 THEN 'small order' WHEN [order_amt] >= 500 AND [order_amt] < 2000 Then 'medium order' WHEN [order_amt] >= 2000 AND [order_amt] < 5000 THEN 'big order' ELSE 'large order' END

- Group dimension members by using the CASE WHEN statement. In this example, provinces are classified into a specific physical region.

  CASE WHEN [province] in ('Heilongjiang', 'Liaoning', 'Jilin') THEN 'Northeast' ELSE [province] END

- Calculate a measure by using a complex expression: order price per customer

  sum([order_amt])/count(distinct[customer_name])

- Add a UNIX timestamp

from_unixtime([order_id] + 1234567890)

- Locate different days in a month

  day([order date])

  Returns a number in the range of 1 to 31.

- Locate different hours in a day

  hour([report_date])

  Returns a number in the range of 0 to 23.

- Calculate the advertisement conversion rate

  CASE WHEN sum([Views]) > 0 THEN sum([Conversion times])/sum([Views]) ELSE 0 END

  The following example is an incorrect expression: sum(CASE WHEN [Views] > 0 THEN [Conversion times]/[Views] ELSE 0 END). For metrics that indicate rates, you must perform the sum operation before the division operation.

7.3.3.4.6.5. Add a calculated field

This topic describes how to add a calculated field.

Prerequisites

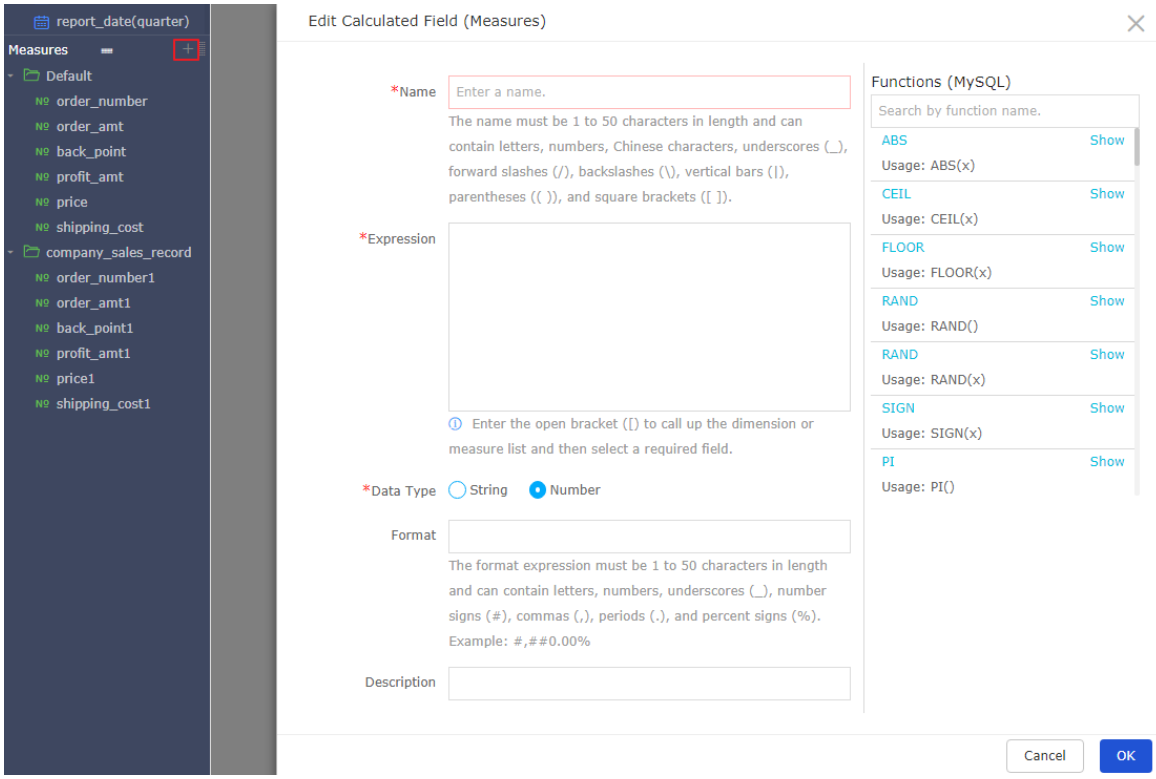
For information about the usage and expressions of calculated fields, see Rules for using calculated fields and Expressions of calculated fields.

Context

The following example uses the company_sales_record dataset to calculate the average profit of orders.

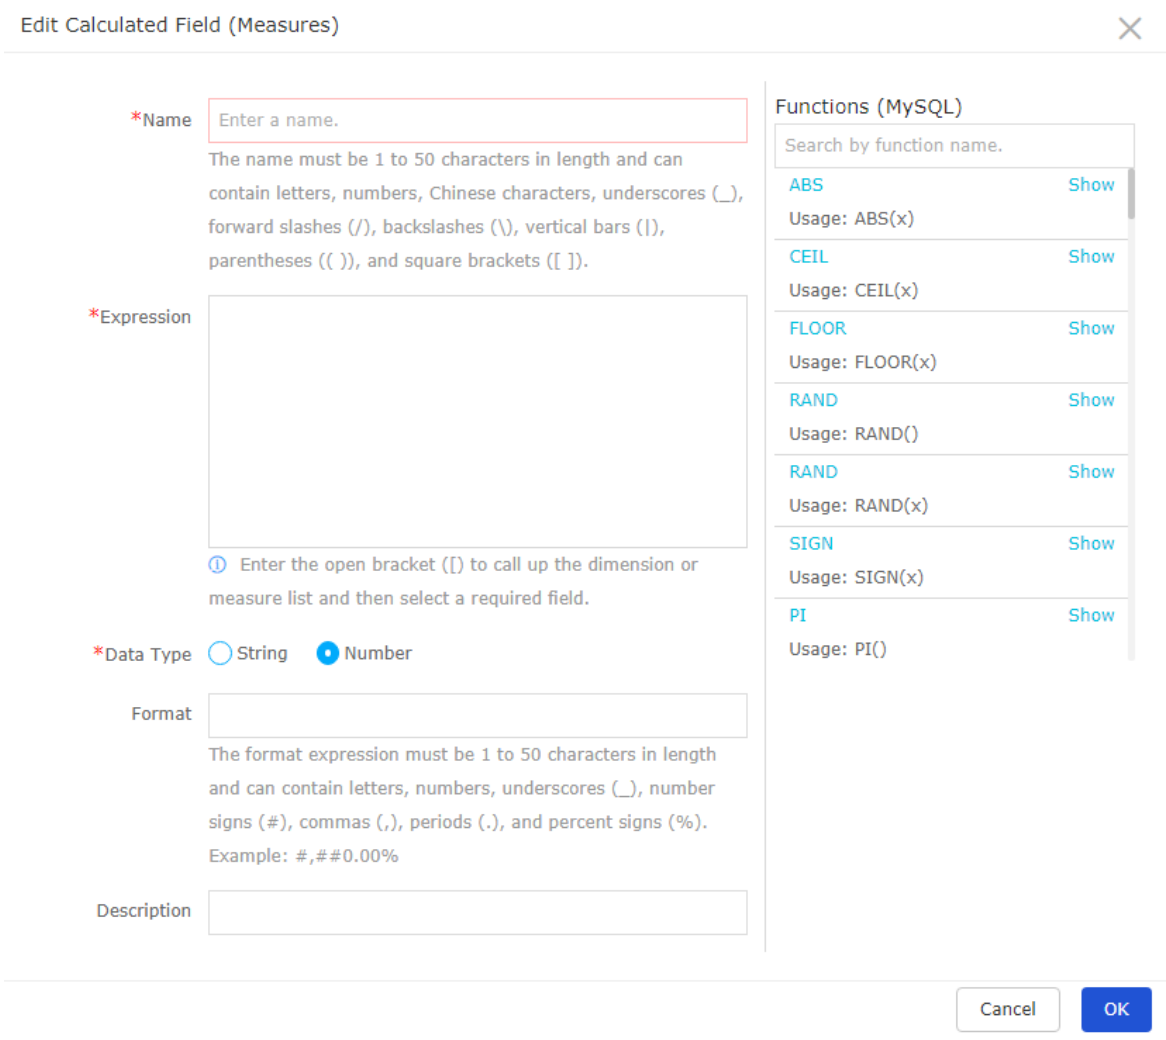
Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane of the Workspace page, click **Datasets**.
4. On the Datasets page, click the company_sales_record dataset.
5. In the Measures list, click the plus sign (+). The **Edit Calculated Field (Measures)** dialog box appears.



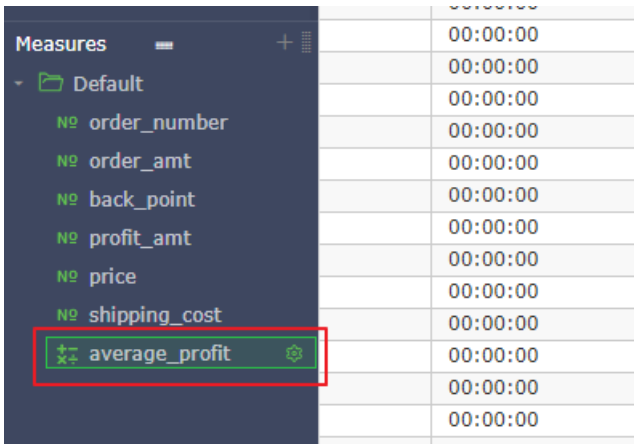
6. Enter the measure name and expression.

   If you want to calculate the average profit of orders, enter an expression to divide the total profit of the orders by the order quantity.



Note You must use an English IME to enter the expression.

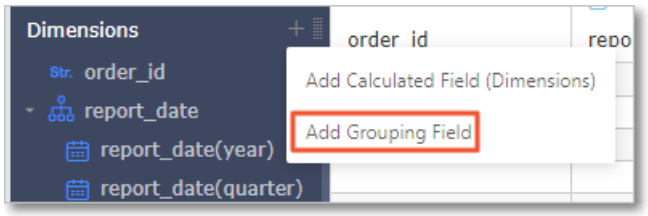
7. Select a data type. For example, if the average profit is a numeric value, you need to select **Number** for Data Type.
8. Click **OK** to add the field.
9. Click **Save** in the upper-right corner to save the dataset.
10. Click **Refresh Preview** to view the new calculated field.



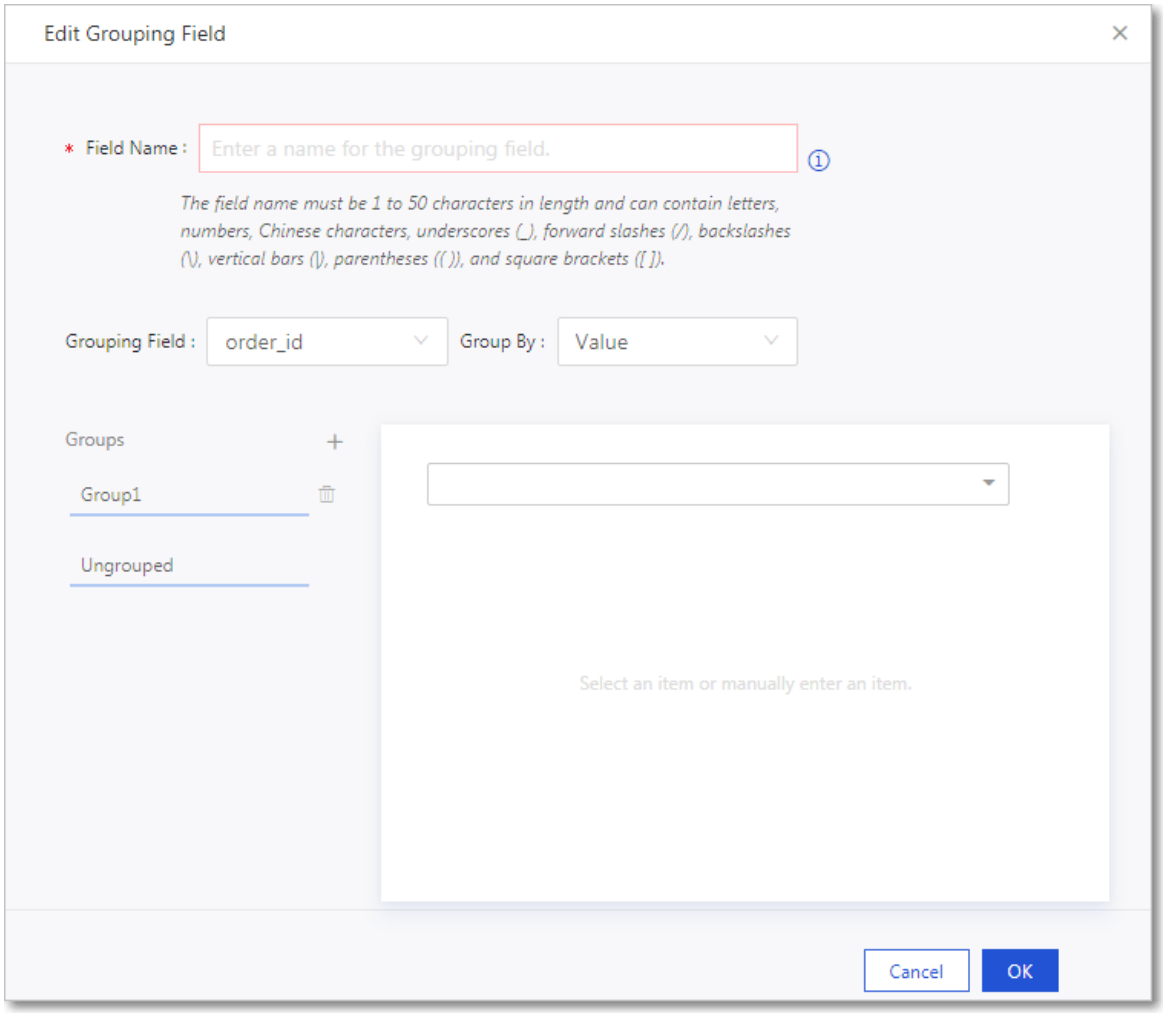
7.3.3.4.7. Add a grouping field

On the dataset edit page, you can use the **Add Grouping Field** feature to group data and store group information.

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane of the Workspace page, click **Datasets**.
4. On the Datasets page, find the dataset to which you want to add a grouping field, and click the Edit icon in the Actions column. On the dataset edit page, choose **+ > Add Grouping Field** next to Dimensions.



5. In the **Edit Grouping Field** dialog box that appears, enter the required information and click **OK**.



6. Click **Save** and then click **Refresh Preview**. The dimension list shows the new grouping field.

7.3.3.5. Rename a dataset

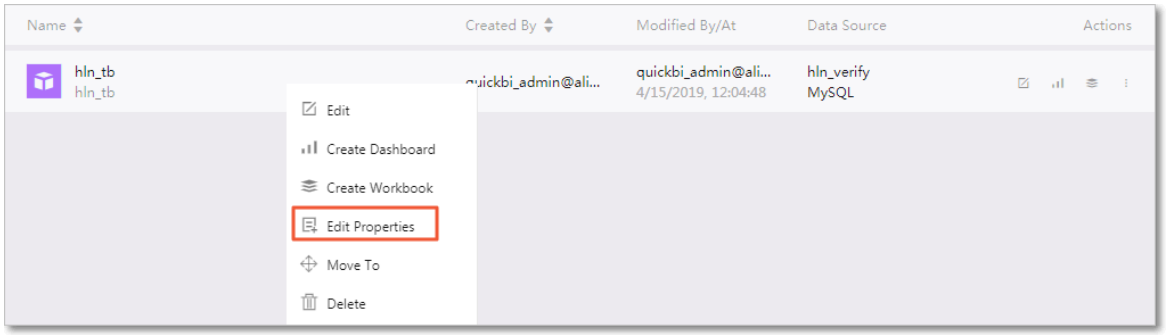
This topic describes how to rename a dataset.

Prerequisites

A dataset is created.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the **Datasets** page, find the dataset that you want to rename. Right-click the dataset or click the **More** icon in the Actions column.
5. Select **Edit Properties**. In the Edit Properties pane, enter a new name for the dataset.



7.3.3.6. Search for a dataset

This topic describes how to search for a dataset.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the **Datasets** page, find the search box.
5. Enter a keyword of the target dataset in the search box and click the icon.

7.3.3.7. Transfer a dataset

This topic describes how to transfer a dataset to another user.

Prerequisites

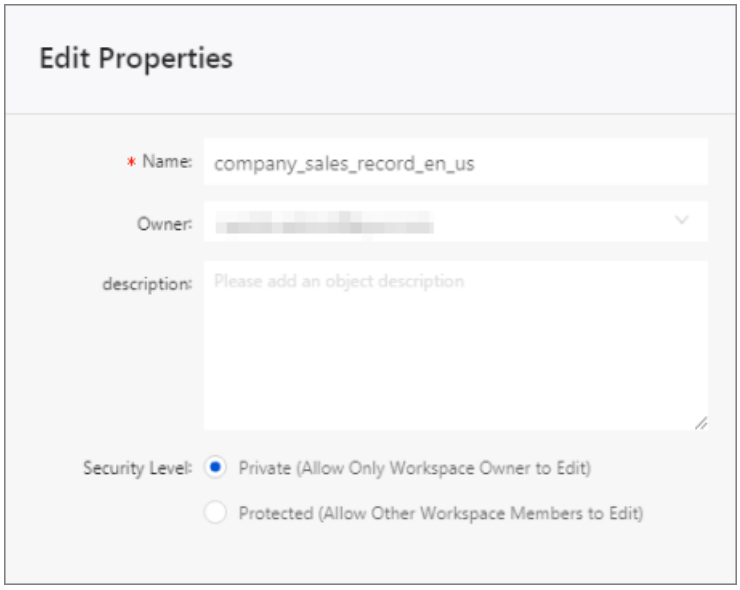
The Quick BI service is purchased.

Context

You can transfer a dataset to another Apsara Stack tenant account or RAM user in the same workspace.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the **Datasets** page, right-click the dataset you want to transfer or click the **More** icon in the Actions column.
5. Select **Edit Properties**.
6. In the **Edit Properties** pane, select a new owner and click **Save**.



7.3.3.8. Copy a dataset from one workspace to another

This topic describes how to copy a dataset from one workspace to another.

Prerequisites

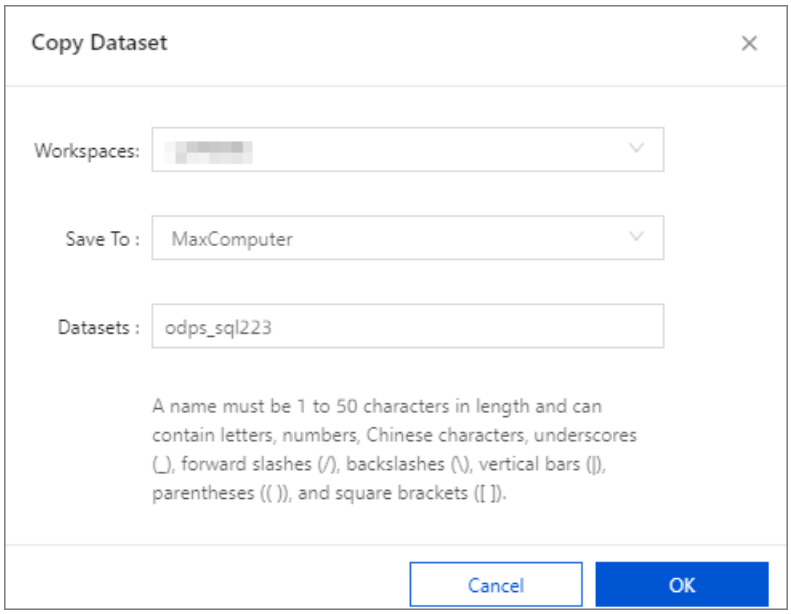
The Quick BI service is purchased.

Context

Only group workspaces support this feature. Only an administrator of two workspaces can copy a dataset from one workspace to the other.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the **Datasets** page, right-click the dataset that you want to copy and select **Copy**.
5. In the **Copy Dataset** dialog box, configure the destination workspace, storage path, and the name of the dataset in the destination workspace.



> **Note** If the destination workspace does not contain the data source based on which the dataset is created, the data source is also copied to the destination workspace.

6. Click **OK**.

7.3.3.9. Create a dataset folder

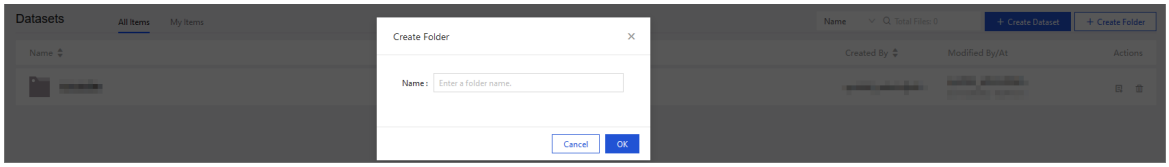
This topic describes how to create a dataset folder on the **Datasets** page.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. In the upper-right corner of the **Datasets** page, click **Create Folder**.
5. In the **Create Folder** dialog box, enter a name for the folder and click **OK**.



7.3.3.10. Rename a dataset folder

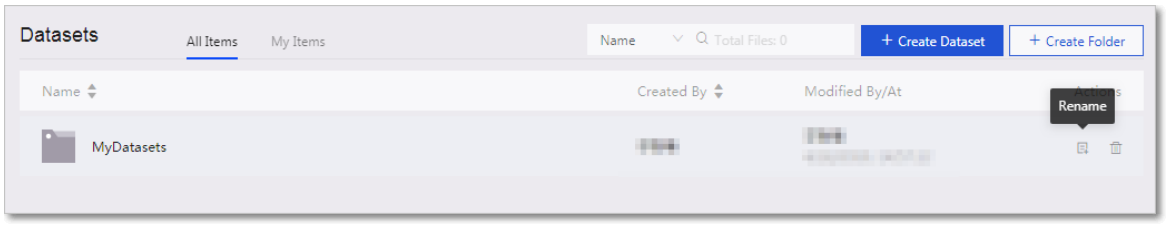
This topic describes how to rename a dataset folder.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the **All Items** tab of the **Datasets** page, find the folder that you want to rename.
5. Right-click the folder and select **Rename**, or click the Rename icon in the Actions column.



6. In the Rename dialog box, enter a new name and click **OK**.

7.3.3.11. Delete a dataset

This topic describes how to delete a dataset and the common issues that may occur during this process.

Prerequisites

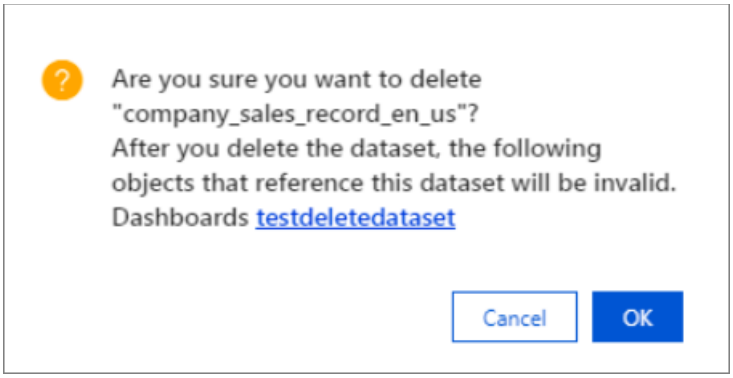
The Quick BI service is purchased.

Context

If workbooks are created based on the dataset, a notification is displayed when you attempt to delete the dataset, as shown in Notification.

After you delete a dataset, an error occurs when you access the dashboard created based on that dataset, as shown in Error message.

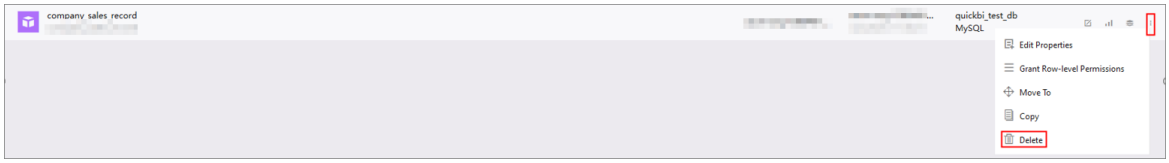
Notification



Error message

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane of the Workspace page, click **Datasets**.
4. On the **Datasets** page, find the dataset you want to delete.
5. Right-click the dataset and select Delete, or click the **More** icon and select **Delete**.



7.3.3.12. Configure row-level permissions

Row-level permissions are granted based on datasets. Quick BI supports two authorization modes: user/user group-based authorization and tag-based authorization.

User/user group-based authorization is suitable for scenarios that involve a small number of members. Tag-based authorization is suitable for scenarios that involve a large number of members. Tag-based authorization allows you to authorize all users at the same time. In scenarios that involve a large number of members, this mode reduces the costs and complexity of row-level permission configurations and facilitates permission management. For information about how to configure row-level permissions, see Manage row-level permissions.

7.4. Dashboards

7.4.1. Dashboard overview

7.4.1.1. Dashboard features

This topic describes the features of a Quick BI dashboard.

- Supports the Filter Bar, Text Area, IFrame, Tab, and Image widgets. You can drag and drop widgets to create pages for various products.

- Provides a wide range of chart components. You can easily create various reports by setting chart elements. A chart can be displayed in either standard or full-screen mode.
- Uses a more flexible tile layout. A dashboard visualizes data. It allows you to filter and query data, use multiple data display modes, and highlight the key fields of data.
- Enables you to drag, drop, and click fields in a dashboard to display data. You can follow the instructions on the pages to analyze data for better user experience.

7.4.1.2. Chart types and scenarios

Different types of data need to be displayed in charts of different types. Currently, Quick BI supports various data charts, such as line charts, vertical bar charts, bubble maps, and funnel charts.

For information about how to create charts, see Create a dashboard.

The following table describes the analysis types and scenarios for each chart type.

Chart types and scenarios

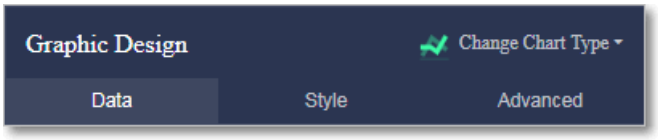
Analysis type	Description	Scenario	Applicable chart
Comparison	Compares values or compares measures by category	Compares the sales or income between different countries or regions.	Vertical bar chart, radar chart, funnel chart, cross table, polar diagram, tornado-leaned funnel chart, and word cloud
Percentage	Displays the proportion of a part to the total, or the proportion of a certain value to the whole.	Displays the sales of the salesperson that has the greatest percentage of total sales.	Pie chart, funnel chart, gauge, and treemap
Relationship	Displays the relationship between values or measures.	Displays the relationship between two measures. This helps you understand the influence the first measure has on the second measure.	Scatter chart, treemap, kanban, hierarchy chart, and flow analysis chart
Trend	Displays data trends, especially trends based on time, such as year, month, or day, or the progress of a data metric or other possible patterns.	Displays trends in sales or revenue for a product over a period of time.	Line chart

Analysis type	Description	Scenario	Applicable chart
Geographic map	Displays the size and distribution of data metrics of a country or region on a map. The datasets must contain geographic data.	Displays the income information about different regions of a country.	Bubble map and colored map

7.4.1.3. Data elements of a chart

This topic describes the data elements of a chart.

The graphic design for each chart has three tabs: **Data**, **Style**, and **Advanced**.



- On the **Data** tab, you can specify the data you want to display in the chart.
- On the **Style** tab, you can set the chart layout and details of the chart.
- On the **Advanced** tab, you can configure the filter interaction feature to dynamically compare and display data.

Each chart has unique core data elements. For example, in a geo map, a latitude field is required. Otherwise, data cannot be displayed.

The following table lists the core data elements of each chart type.

Data elements of different types of charts

Chart type	Required data element	Data element description
Line chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
Stacked line chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
Area chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
Stacked area chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.

Chart type	Required data element	Data element description
100% stacked area chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
Vertical bar chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
Stacked vertical bar chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
100% stacked vertical bar chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
Circular bar	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
Horizontal bar chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
Stacked horizontal bar chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
100% stacked horizontal bar chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
Combination chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
Pie chart	Label and central angle	You can specify only one dimension for labels and only one measure for the central angle.

Chart type	Required data element	Data element description
Bubble map	Geo location and bubble size	You can specify only one dimension for geo locations. The dimension type must be Geo. You can specify one to five measures for the bubble size.
Colored map	Geo location and colorscale	You can specify only one dimension for geo locations. The dimension type must be Geo. You can specify one to five measures for the colorscale.
Geo map	Geo location and colorscale	You can specify only one dimension for geo locations. The dimension type must be Geo. You can specify one to five measures for the colorscale.
Geo bubble map	Geo location and colorscale	You can specify only one dimension for geo locations. The dimension type must be Geo. You can specify one to five measures for the colorscale.
Cross table	Rows and columns	You can specify an unlimited number of dimensions for the rows and an unlimited number of measures for the columns.
Pivot table	Rows and values	You can specify an unlimited number of dimensions for the rows and an unlimited number of measures for the columns.
Gauge	Pointer angle	You can specify only one measure for the pointer angle.
Progress bar	Pointer	You must specify one to five measures for the pointer.
Radar chart	Label and length	You must specify one or two dimensions for labels and at least one measure for the length.

Chart type	Required data element	Data element description
Scatter chart	Color legend, x-axis, and y-axis	You can specify only one dimension for the color legend. The maximum number of dimension values is 1,000. You can specify one to three measures for the x-axis and only one measure for the y-axis.
Bubble chart	x-axis, y-axis, and bubble size	You must specify at least one dimension for the x-axis. The number of dimension values is up to 1,000. You can specify only one measure for the y-axis and only one measure for the bubble size.
Funnel chart	Tier label and tier area	You can specify only one dimension for tier labels and only one measure for tier areas.
Kanban	Label and metric	You can specify only one dimension for labels and one to ten measures for metrics.
Treemap	Label and size	You can specify only one dimension for labels and only one measure for the size.
Polar diagram	Arc radius and label	You can specify only one dimension for the label and only one measure for the arc radius.
Word cloud	Word size and word	You can specify only one dimension for word sizes and only one measure for words.
Tornado-leaned funnel chart	Metrics for measures and dimensions	You can specify one dimension and one measure for data comparison.
Hierarchy chart	Node label and node metric	You must specify at least two dimensions for node labels and at least one measure for node metrics.
Flow analysis chart	Central node, node type, node name, and node indicator	You can specify only one dimension or one measure for each data element.

Chart type	Required data element	Data element description
Waterfall chart	Category axis and value axis	You must specify at least one dimension for the category axis and only one measure for the value axis.
Trend indicator	Date and indicator	You can specify only one dimension for the date and at least one measure for the indicator.
Sankey diagram	Node type and node height	You can specify two to five dimensions for the node type and only one measure for the node height.
Ranking board	Category and indicator	You can specify only one dimension for the category and only one measure for the indicator.
Ticker board	Indicator	You can specify only one dimension for the indicator.

7.4.2. Access a dashboard

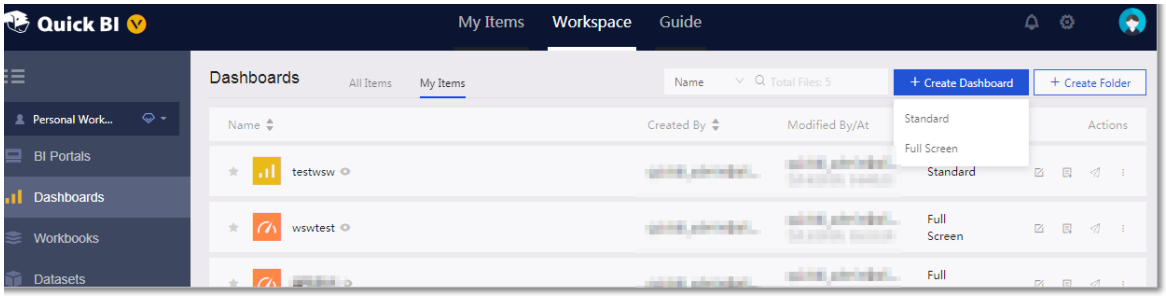
This topic describes how to access a dashboard.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane of the Workspace page, click **Dashboards**.
4. Choose **Create Dashboard** > **Standard** to go to the dashboard.



7.4.3. Areas of a dashboard

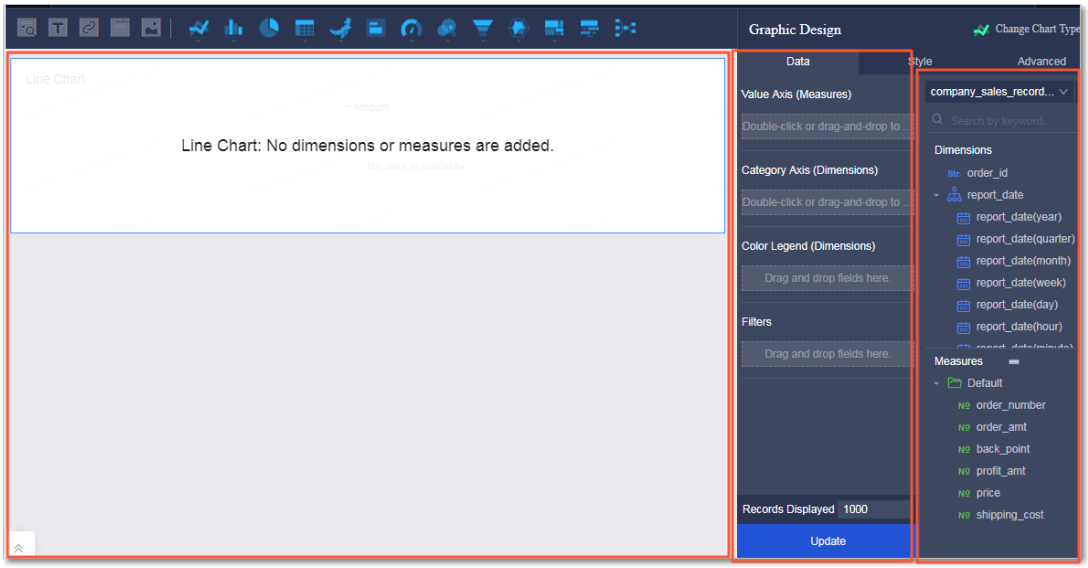
7.4.3.1. Overview

This topic describes the functional areas of a dashboard.

The dashboard edit page contains three areas, as shown in Dashboard.

- Dataset selection area
- Dashboard configuration area
- Dashboard display area

Dashboard



- Dataset selection area: In this area, you can switch the current dataset to another. The fields of each dataset are displayed in the respective Dimensions and Measures lists based on the data types preset in the system. You can select dimensions and measures based on the data elements in the chart.
- In the dashboard configuration area, you can select a chart type, and edit the title, layout, and legend position of a chart. On the Advanced tab, you can associate the current chart with other charts and display analysis results from multiple perspectives. You can also filter data by using filters, or insert a Filter Bar widget to query key data in a chart.
- Dashboard display area: In this area, you can drag charts to adjust their positions and change chart types. For example, you can change a bar chart to a bubble map. The system displays information about missing or error elements. In the dashboard display area, you can save, preview, or create a dashboard. The dashboard provides instructions to help you learn how to create a dashboard.

7.4.3.2. Dataset selection area

7.4.3.2.1. Switch datasets

This topic describes how to switch datasets in a dashboard.

Prerequisites

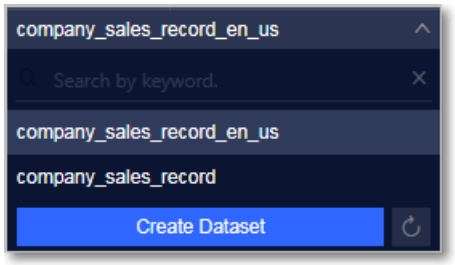
The Quick BI service is purchased.

Context

If you cannot find the required dataset in the drop-down list, go back to the dataset management page and ensure that you created the dataset. For information about how to create a dataset, see Create a dataset.

Procedure

1. Go to the target dashboard.
2. On the Data tab, click the **Switch Datasets** icon.
3. Select the target dataset from the drop-down list that appears.



7.4.3.2.2. Search for a dimension or measure

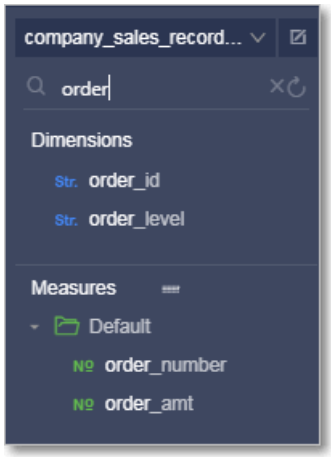
This topic describes how to search for a dimension or measure.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Go to the target dashboard.
2. Enter a keyword of a field, such as **order**, in the search box.
3. Click the **Search** icon.



For information about how to edit dimensions and measures, see Edit a dimension and Edit a measure.

7.4.3.3. Dashboard graphic design area

7.4.3.3.1. Select fields

This topic describes how to select fields from a dataset.

Prerequisites

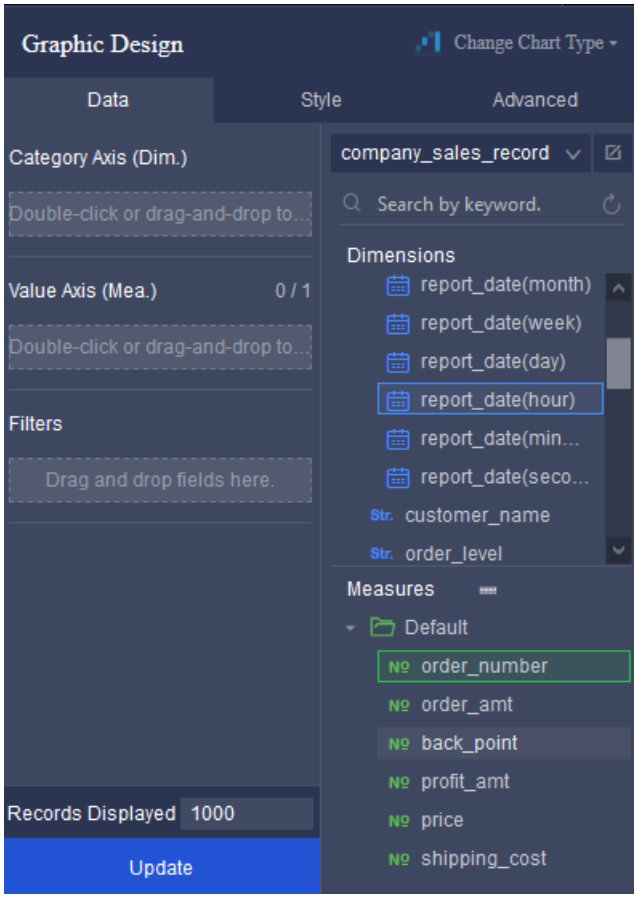
- The Quick BI service is purchased.
- A dataset is selected in the dataset selection area and is edited as required. For information about how to edit a dataset, see Edit a dataset.

Context

Procedure

1. Go to the target dashboard.
2. Select a chart from the toolbar on the top of the dashboard.
3. Click the chart icon. The chart appears in the display area of the dashboard. If you want to change the chart type, click **Change Chart Type** in the Graphic Design area, and select the desired chart type.
4. On the **Data** tab, select the required fields, as shown in Select fields. Double-click a field to add it to the Dimensions or Measures list, or drag the field to the target list.

Select fields



- If you want to delete a field, click the Delete icon next to the field.
- If you want to sort the values of a field, click the ascending or descending icon next to the field.
- You can click the aggregation method icon next to the field and select the method as required. The aggregation methods include SUM, COUNT, MAX, MIN, AVG, COUNT DISTINCT, median, percentile, variance, standard deviation, and compare operations.

5. Click **Update**. The chart is updated.

7.4.3.3.2. Use the color legend

This topic describes how to use the color legend.

Prerequisites

- The Quick BI service is purchased.
- A dataset is selected in the dataset selection area and is edited as required. For information about how to edit a dataset, see Edit a dataset.

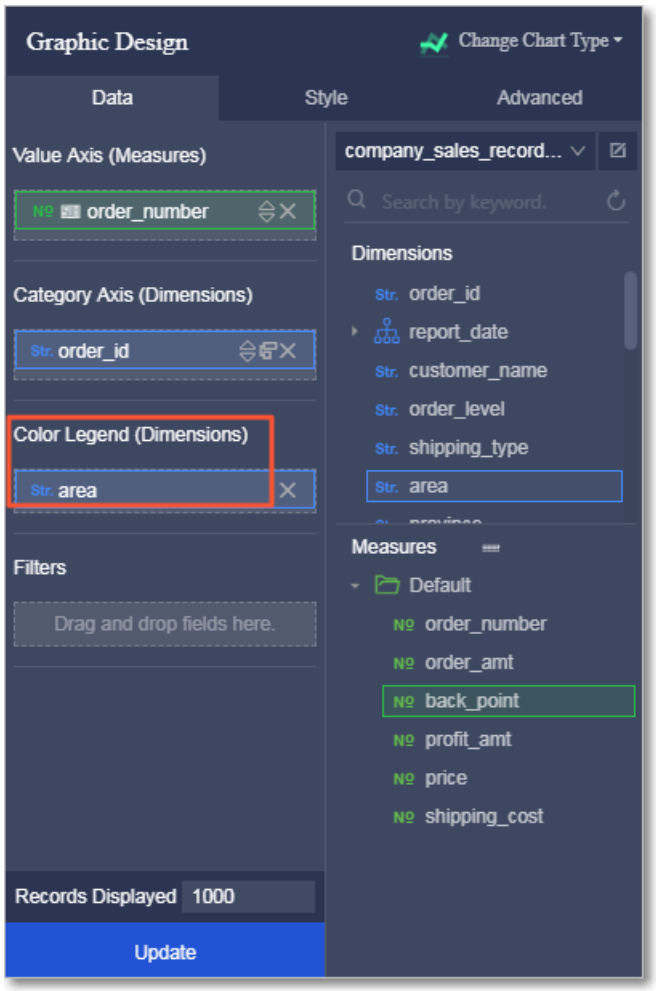
Context

The color legend feature displays the values of a selected field in different colors in a chart.

Only dimensions can be added to the Color Legend field.

Procedure

1. Go to the target dashboard.
2. Drag a dimension, such as product_type, to the **Color Legend (Dimensions)** field.



3. Click **Update**. The values of the field are displayed in different colors in the chart.

4. Change the legend color in the **Series Settings** section on the **Style** tab.

7.4.3.3.3. Sort field data

This topic describes how to sort data on the **Data** tab.

Prerequisites

- The Quick BI service is purchased.
- A dataset is selected in the dataset selection area and is edited as needed. For information about how to edit a dataset, see Edit a dataset.

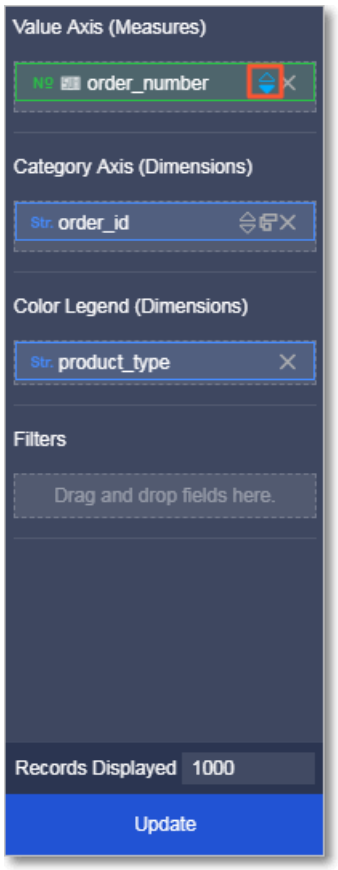
Procedure

1. Go to the target dashboard.

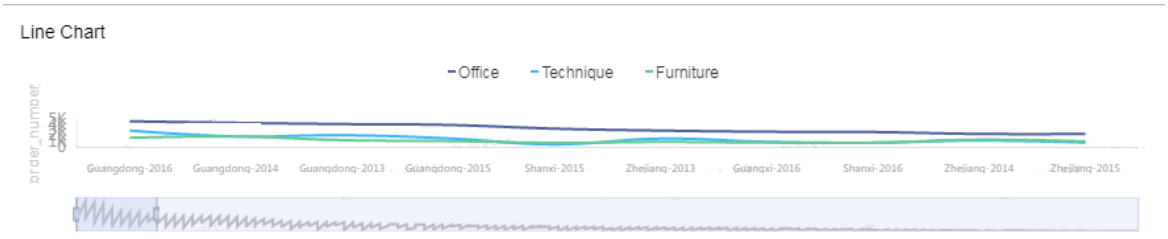
2. Select a field, such as order_number.
3. Click the triangle icon next to the field, as shown in Set the sorting order.

   The upward arrow indicates ascending order, and the downward arrow indicates descending order.

   Set the sorting order



4. After you specify the sorting order, click **Update**.



7.4.3.3.4. Filter by field

This topic describes how to filter data based on specified fields.

Context

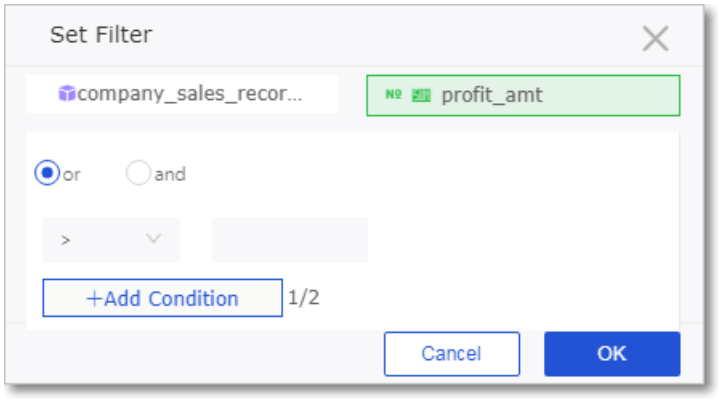
Drag a dimension or measure to the **Filters** area to specify the fields used to filter data.

In the following example, the filed profit_amt is selected.

Procedure

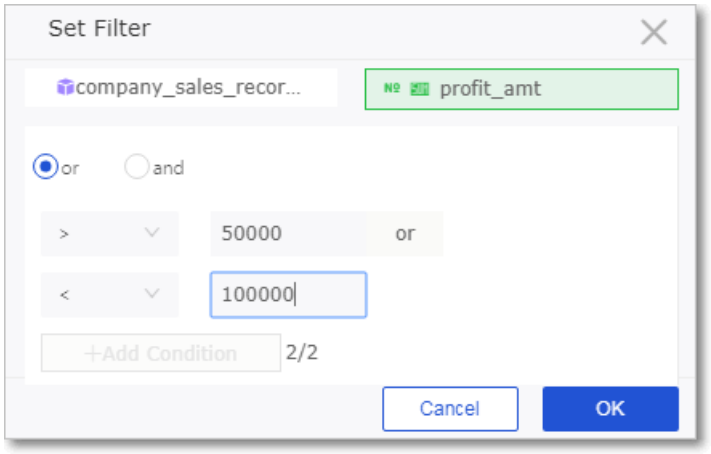
1. Go to the target dashboard.
2. Drag the profit_amt field to the Filters area.
3. Click the **Filter** icon and set the parameters in the Set Filter dialog box, as shown in Set the filter.

   Set the filter



4. Select the filter condition, for example, >, <, or =, as shown in Specify a value range.

   Specify a value range



5. After you set the parameters, click **OK**.
6. Click **Update**. The system then updates the chart based on the parameters of the filter.

7.4.3.3.5. Filter interaction

You can use the filter interaction feature when you have created multiple charts on a dashboard. This topic describes how to use the filter interaction feature.

Context

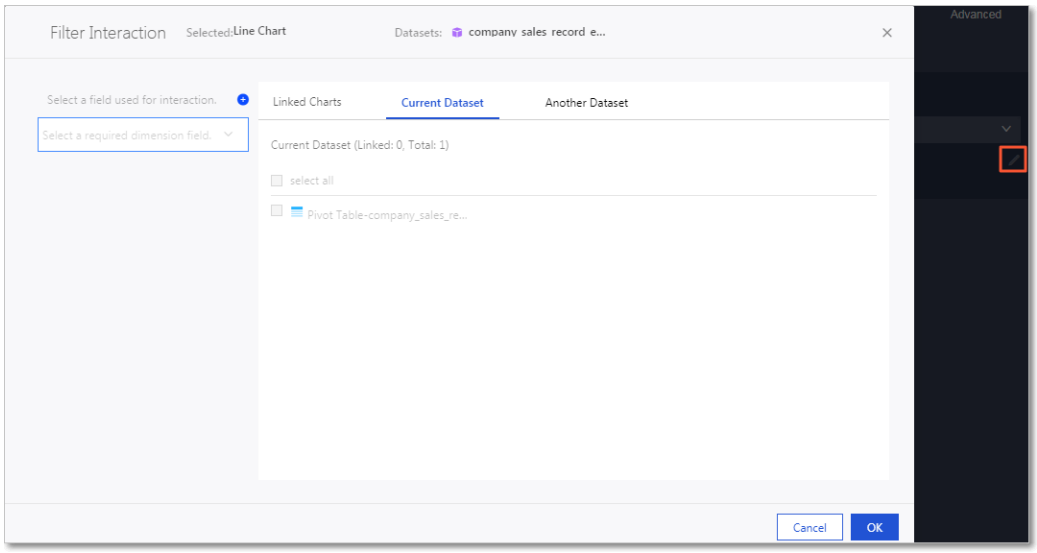
You can configure the filter interaction feature on the **Advanced** tab page.

Before you use this feature, make sure that you have created at least two charts in the current dashboard.

Procedure

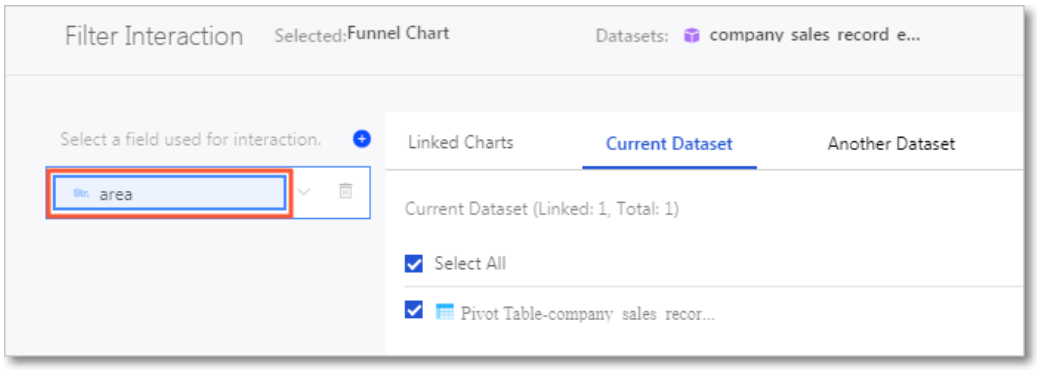
1. Go to the target dashboard.
2. Select a chart, for example, a funnel chart.
3. In the Graphic Design area, click the **Advanced** tab.
4. On the **Advanced** tab page, click the Filter Interaction icon. The system then displays all available charts, as shown in The Advanced tab.

   The Advanced tab



5. Select fields the same as the filter fields from the available charts to associate these charts, as shown in Filter interaction settings.

   Filter interaction settings

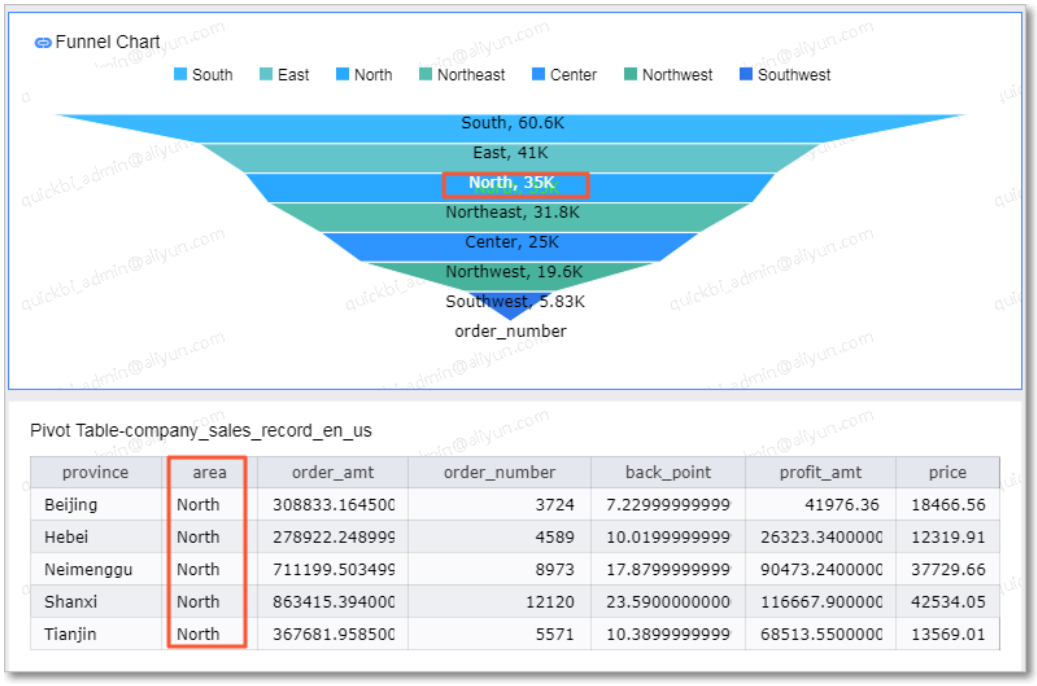


6. In the upper-right corner of the dashboard, click **Preview** to preview the current dashboard.

   Click Preview

7. Click **China North** in the funnel chart, and the associated cross tab chart displays data of China North, as shown in Result.

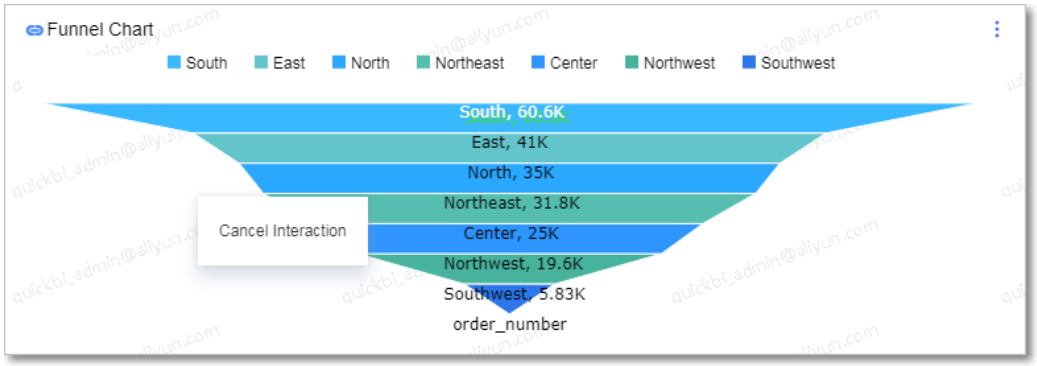
   Result



province	area	order_amt	order_number	back_point	profit_amt	price
Beijing	North	308833.164500	3724	7.22999999999	41976.36	18466.56
Hebei	North	278922.248999	4589	10.0199999999	26323.340000	12319.91
Neimenggu	North	711199.503499	8973	17.8799999999	90473.240000	37729.66
Shanxi	North	863415.394000	12120	23.5900000000	116667.90000	42534.05
Tianjin	North	367681.958500	5571	10.3899999999	68513.550000	13569.01

8. Hover over any blank area in the funnel chart, and click the **Cancel Interaction** notification to disable the filter interaction feature.

   Click the notification



7.4.3.3.6. Metric analysis

This topic describes four methods of analysis: auxiliary line, trendline, prediction, and anomaly detection.

Prerequisites

- The Quick BI service is purchased.
- A dataset is selected in the dataset selection area and is edited as required.
- Go to the target dashboard.

Background

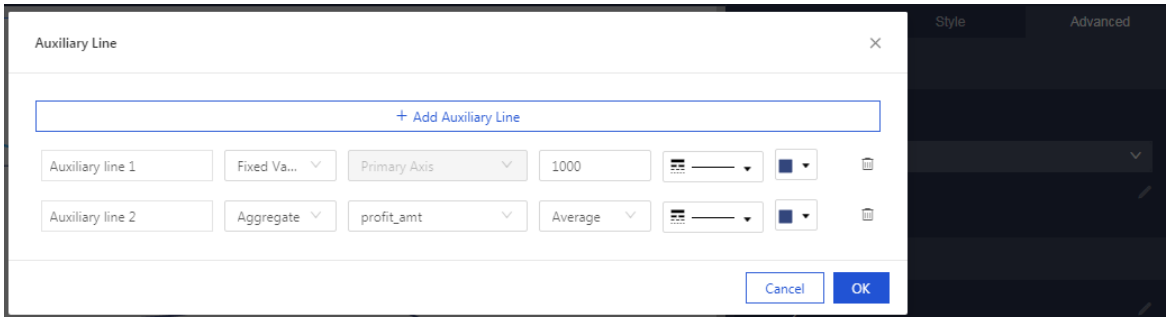
- Metric analysis allows you to analyze data from multiple perspectives. You can use this feature to learn about data trends and anomalies.
- Metric analysis supports four methods of analysis: auxiliary line, trendline, prediction, and

anomaly detection.

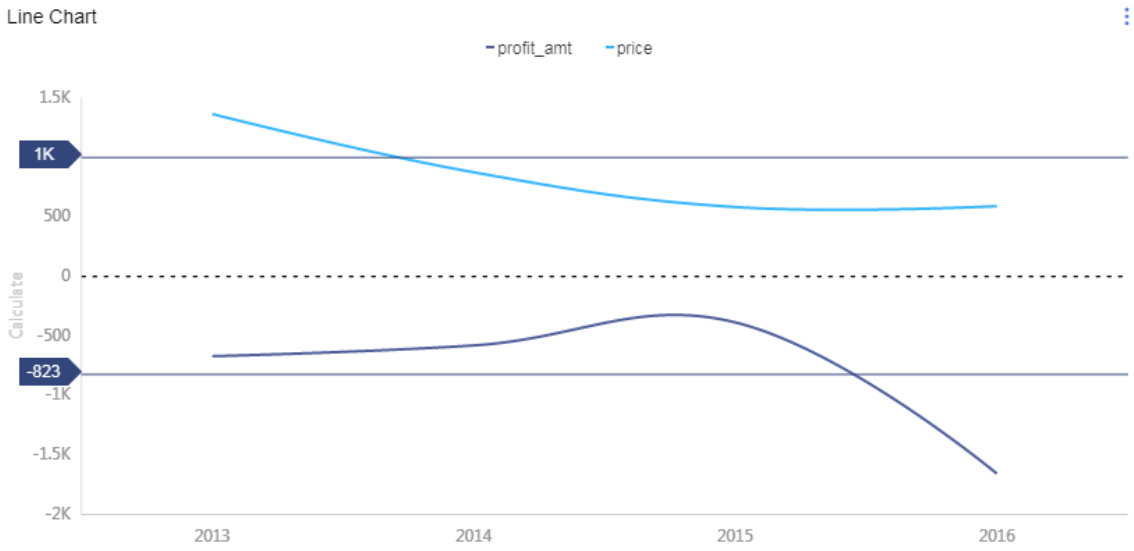
Auxiliary line

You can add an auxiliary line to view the difference between the value of a measure and the value shown by the auxiliary line. The value shown by an auxiliary line is either a fixed value or an aggregate value. Aggregate values includes average, maximum, minimum, and median values.

1. On the **Advanced** tab of the **Graphic Design** page, click next to **Auxiliary line** in the **Metric Analysis** section.
2. In the **Auxiliary Line** dialog box, click Add Auxiliary Line. Select a value type for the auxiliary line you want to create.



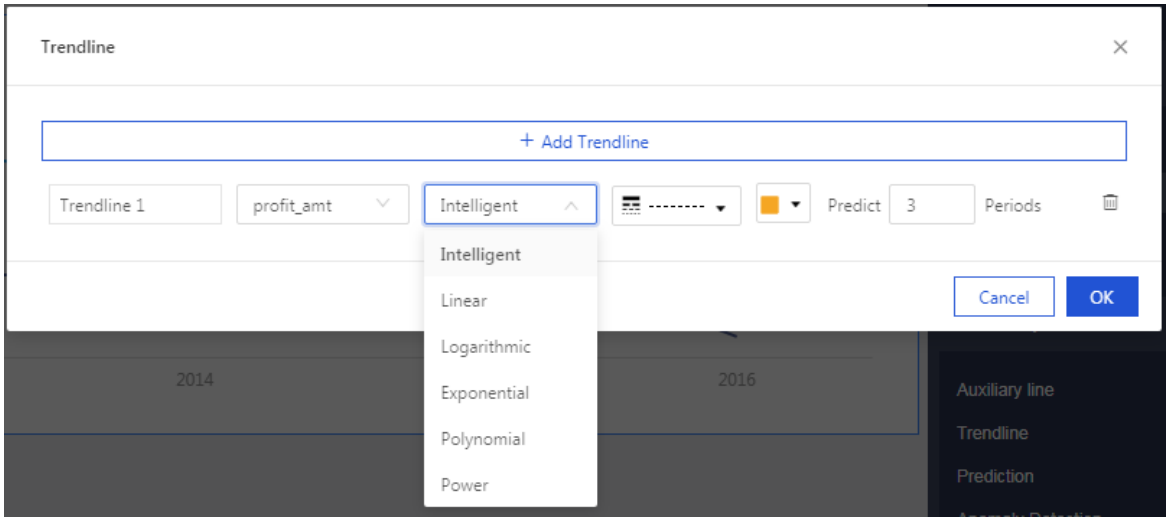
3. Click **OK**. The following figure shows a sample trendline.



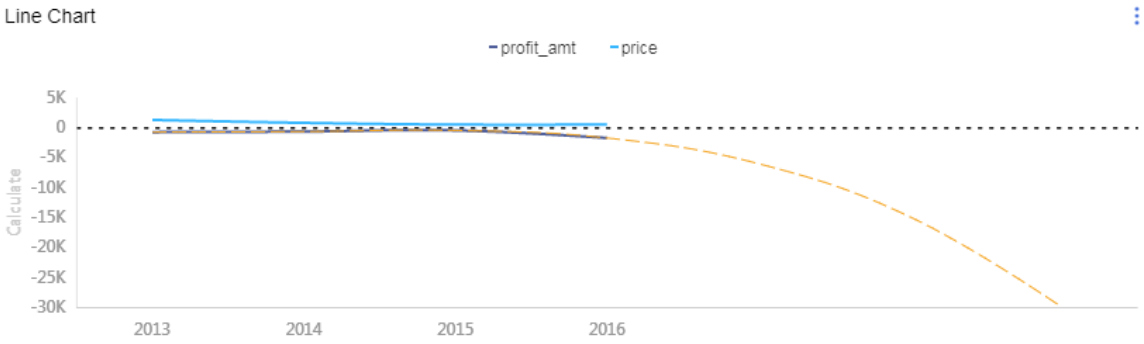
Trendline

A trendline displays data trends. Types of trendlines include Intelligent, Linear, Logarithmic, Exponential, Polynomial, and Power.

1. On the **Advanced** tab of the **Graphic Design** page, click next to **Trendline** in the **Metric Analysis** section.
2. In the **Trendline** dialog box, click Add Trendline. Select a measure, a trendline type, and the number of subsequent periods for which to predict trends.



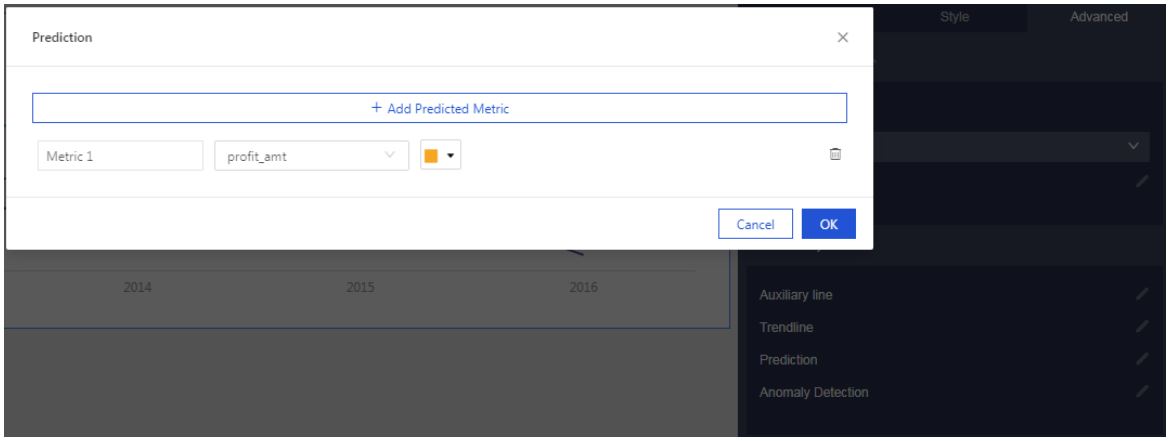
3. Click **OK**. The following figure shows a sample trendline.



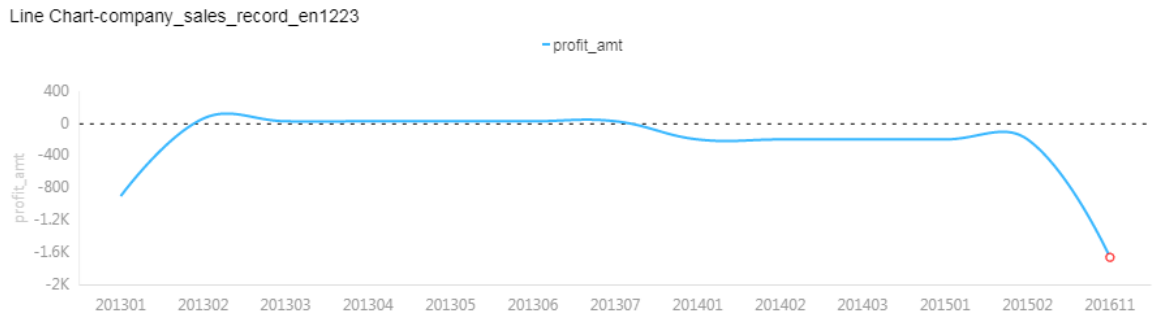
Prediction

You can add a predicted metric to view the trend of current data and predict future trends.

1. On the **Advanced** tab of the **Graphic Design** page, click next to **Prediction** in the **Metric Analysis** section.
2. In the **Prediction** dialog box, click Add Predicted Metric. Select a measure and a color for the line.



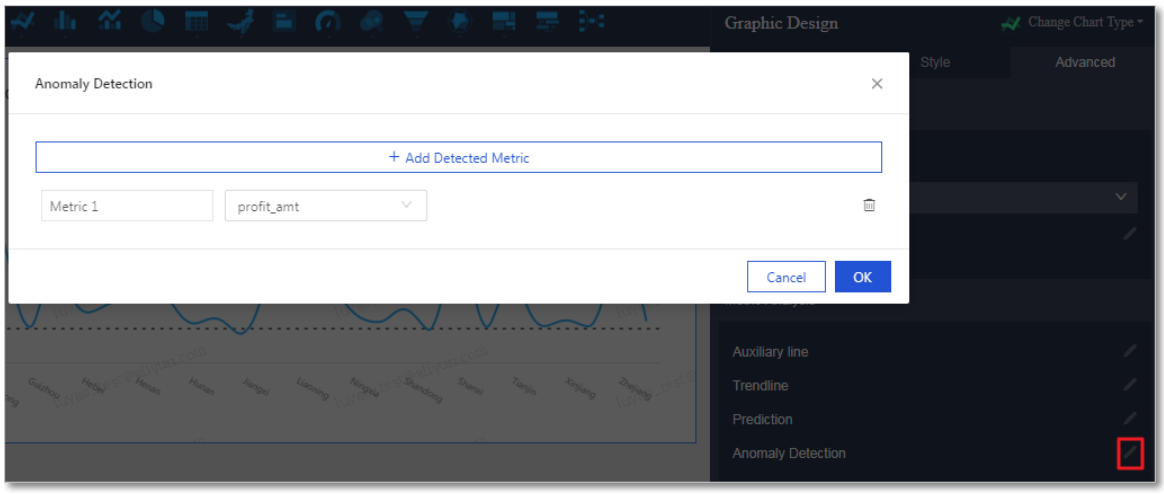
3. Click **OK**. The following figure shows sample prediction results.



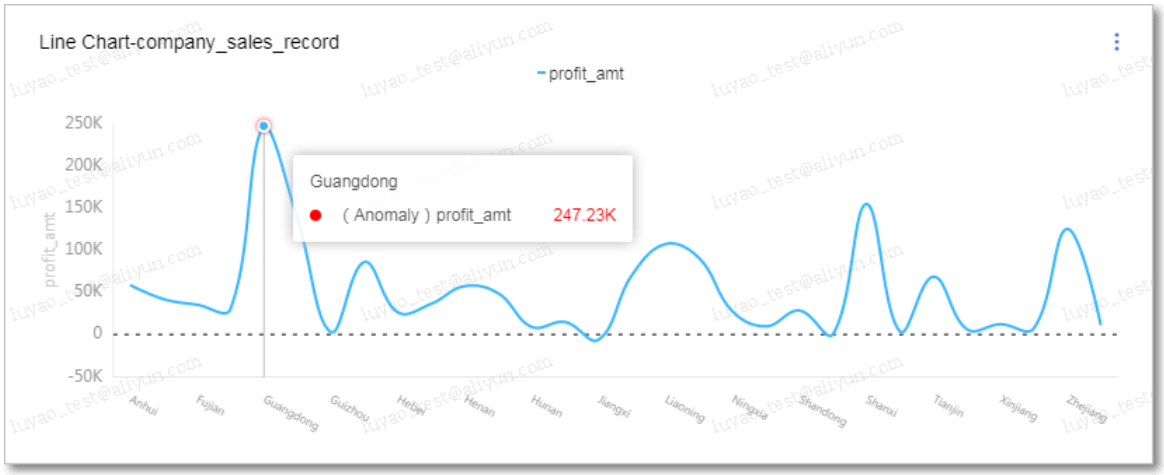
Anomaly Detection

You can add an anomaly detection metric to detect data anomalies.

1. On the **Advanced** tab of the **Graphic Design** page, click next to **Anomaly Detection** in the **Metric Analysis** section.
2. In the **Anomaly Detection** dialog box, click Add Detected Metric. Select a measure.



3. Click **OK**. The following figure shows sample anomaly detection results.



> **Note** In a line chart, anomalies are represented as red dots. In a bar chart, anomalies are represented as red vertical bars.

7.4.3.4. Dashboard display area

7.4.3.4.1. Overview

This topic describes the features of the dashboard display area.

In the display area of a dashboard, you can perform the following operations on one or more charts:

- Adjust chart positions
- View chart data
- Change chart types
- Add to favorites
- Delete a chart

7.4.3.4.2. Toolbar

This topic describes the features of the toolbar.

The toolbar of a dashboard allows you to save, preview, and edit the dashboard, as shown in Dashboard toolbar.

Dashboard toolbar

7.4.3.4.3. Adjust chart positions

Multiple charts may be displayed on the same dashboard. In this case, you can drag the charts to adjust their positions.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Go to the target dashboard.
2. Select a chart or widget.
3. Drag the chart or widget to the desired position.

> **Note** You can drag a chart or widget to anywhere within the display area of the dashboard.

7.4.3.4.4. View chart data

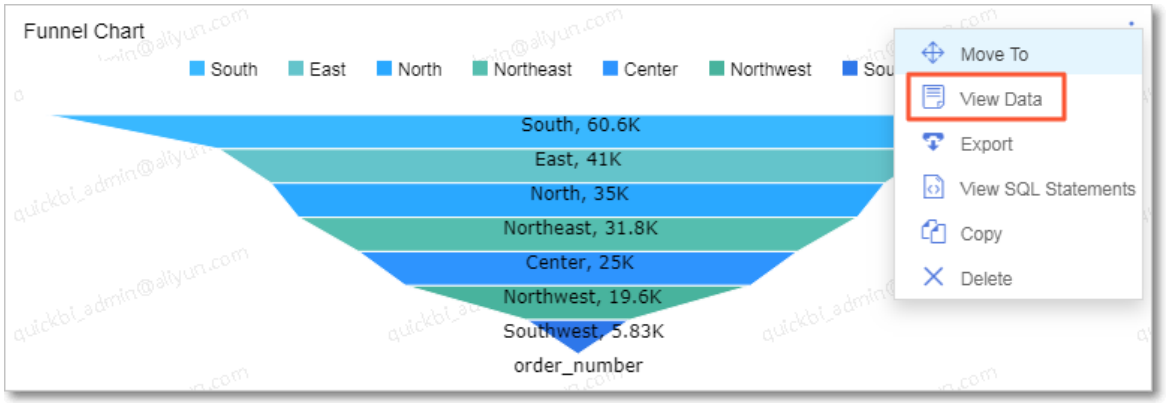
This topic describes how to view chart data.

Prerequisites

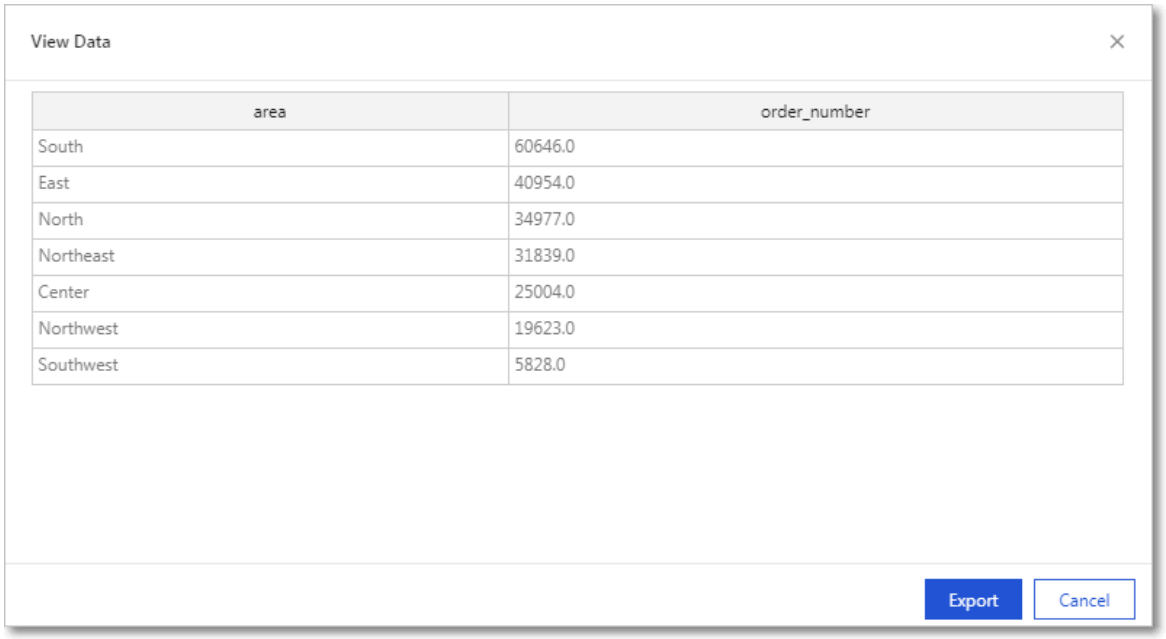
The Quick BI service is purchased.

Procedure

1. Go to the target dashboard.
2. Select a chart, for example, a funnel chart.
3. Click the More icon in the upper-right corner of the chart.
4. Select **View Data** to view data items in the chart.



5. Select **Export** to download data to a local PC.



7.4.3.4.5. Change chart types

You can select different chart types from the toolbar on the top of the dashboard. This topic describes how to change chart types.

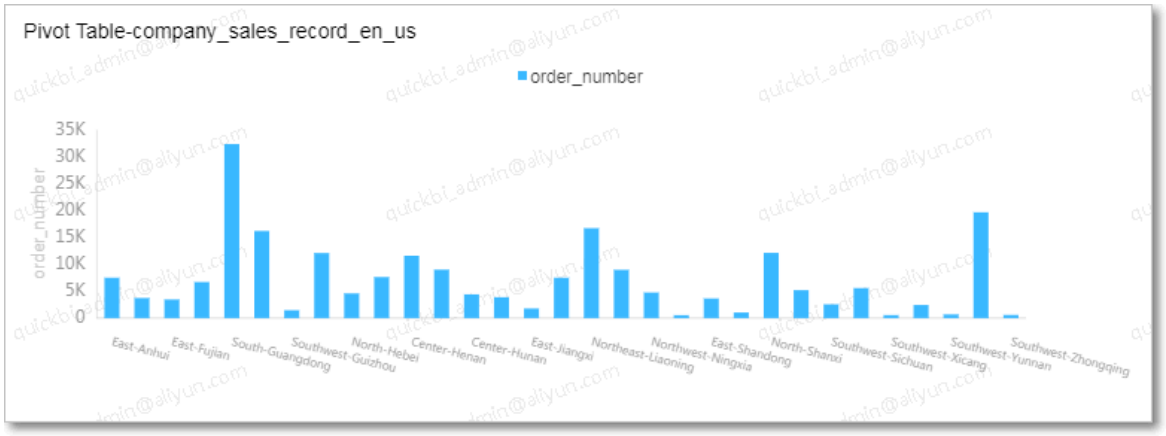
Prerequisites

The Quick BI service is purchased.

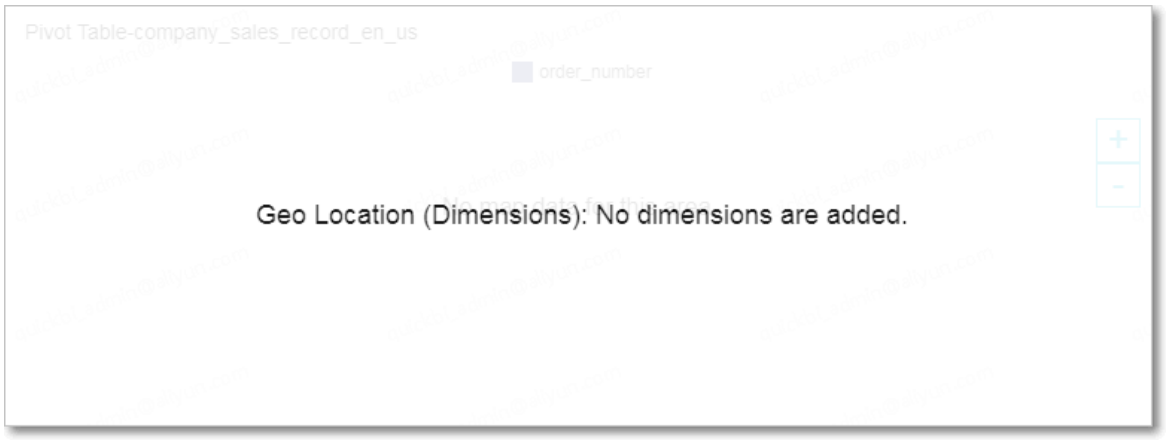
Procedure

1. Go to the target dashboard.
2. Select a chart, such as a cross table.
3. In the Graphic Design area, click **Change Chart Type** and select the required type, such as a vertical bar chart.
4. Click the **Vertical Bar Chart** icon to change the chart type.

   The system then converts the cross table to a vertical bar chart.



If the switch between chart types fails, the elements of the selected chart type do not match those of the current chart type. You need to modify the problematic data fields based on the requirements of the selected chart type.



You can follow the instructions to adjust the dimensions and measures to change the chart type.

7.4.3.4.6. Add to Favorites

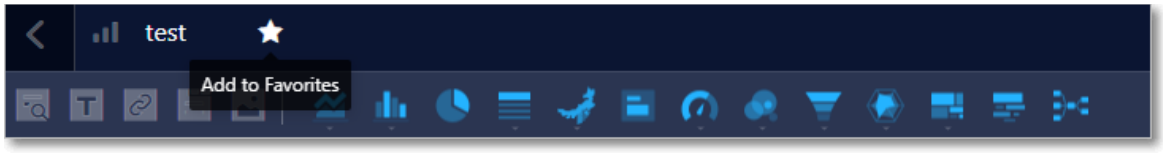
This topic describes how to add a dashboard to the Favorites tab.

Prerequisites

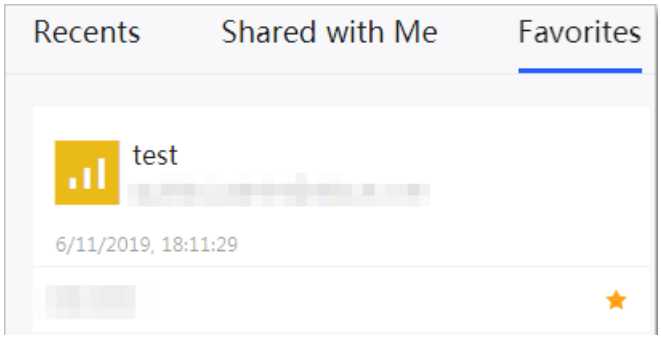
The Quick BI service is purchased.

Procedure

1. Go to the target dashboard.
2. On the top of the dashboard, click the **Add to Favorites** icon.



3. On the Quick BI homepage, you can click the **Favorites** tab to view the dashboards that you have added.



7.4.3.4.7. Delete a chart

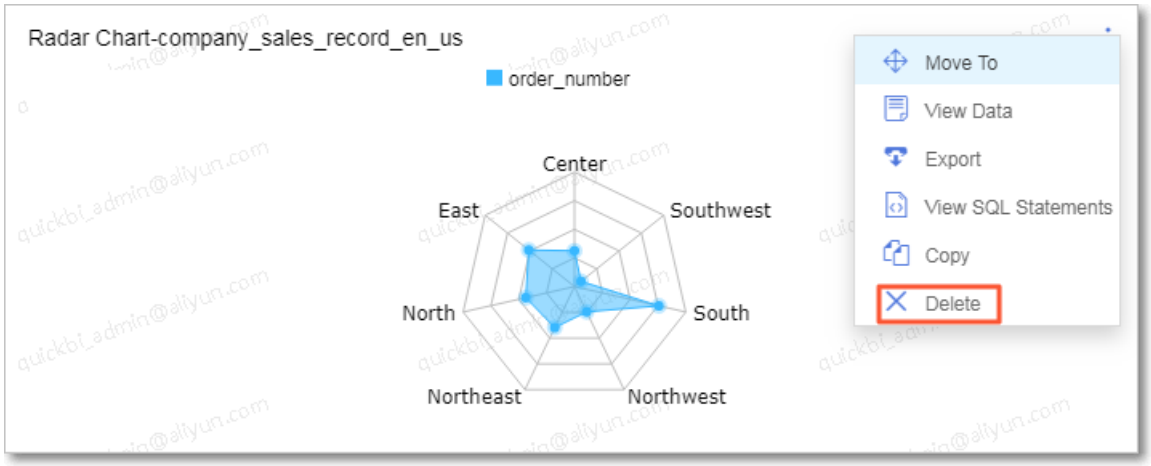
This topic describes how to delete a chart.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Go to the target dashboard.
2. Select a chart, such as a radar chart.
3. Click the **More** icon in the upper-right corner of the chart.
4. Select **Delete**.



7.4.3.4.8. Widgets

7.4.3.4.8.1. Overview

This topic describes the widgets of a dashboard.

The display area of a dashboard provides the following widgets:

- Filter Bar
- Text Area
- IFrame
- Tab
- Image

7.4.3.4.8.2. Filter bar

In a dashboard, you can use the Filter Bar widget to query data in one or more charts.

7.4.3.4.8.3. Expanded filter bar

7.4.3.4.8.4. Compound Query Control

7.4.3.4.8.5. Text Area

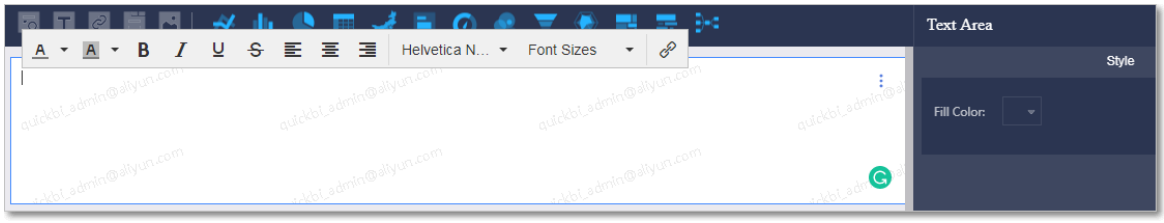
The Text Area widget allows you to enter text into a text area, for example, a title for a chart.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Go to the target dashboard.
2. Click the **Text Area** icon.
3. Enter text in the text box.



7.4.3.4.8.6. IFrame

You can use the IFrame widget to insert web pages to query Internet data or browse web pages or websites related to the data on the current dashboard in real time.

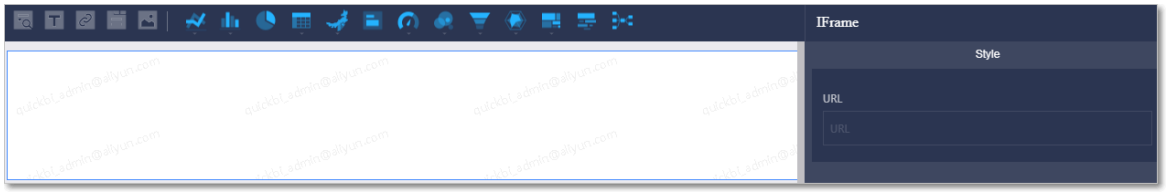
Prerequisites

The Quick BI service is purchased.

Procedure

1. Go to the target dashboard.
2. Click the **IFrame** icon.

3. In the URL input box, enter the address of the web page you want to visit.



> **Note** The web page address must start with https.

If you want to delete the current IFrame widget, click the **More** icon in the upper-right corner of the **IFrame** widget and select **Delete**.

7.4.3.4.8.7. Tab

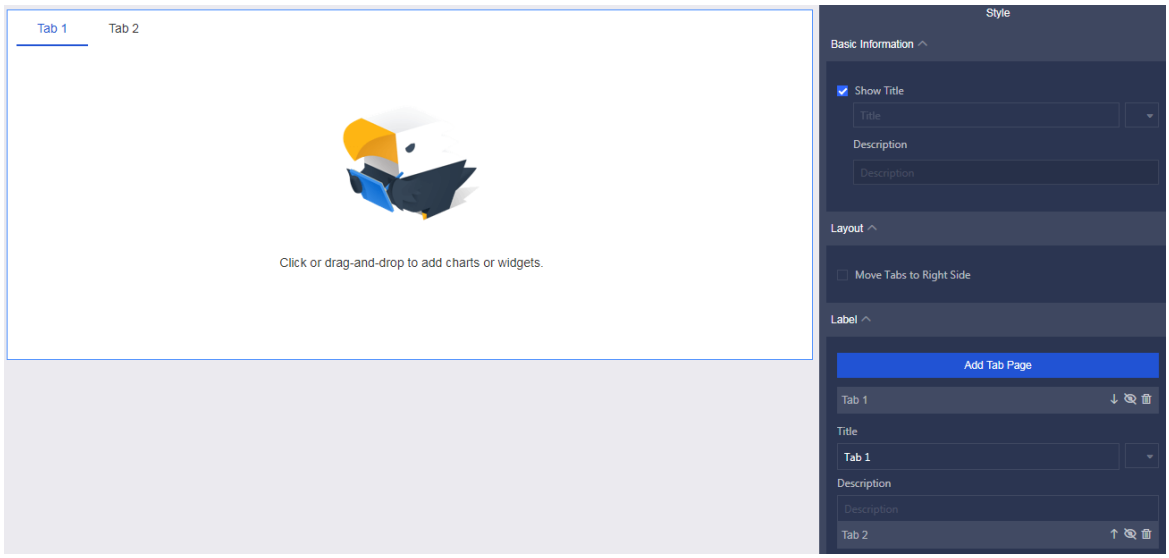
The tab widget enables you to display charts as tabs on a dashboard.

Prerequisites

The Quick BI service is purchased.

Procedure

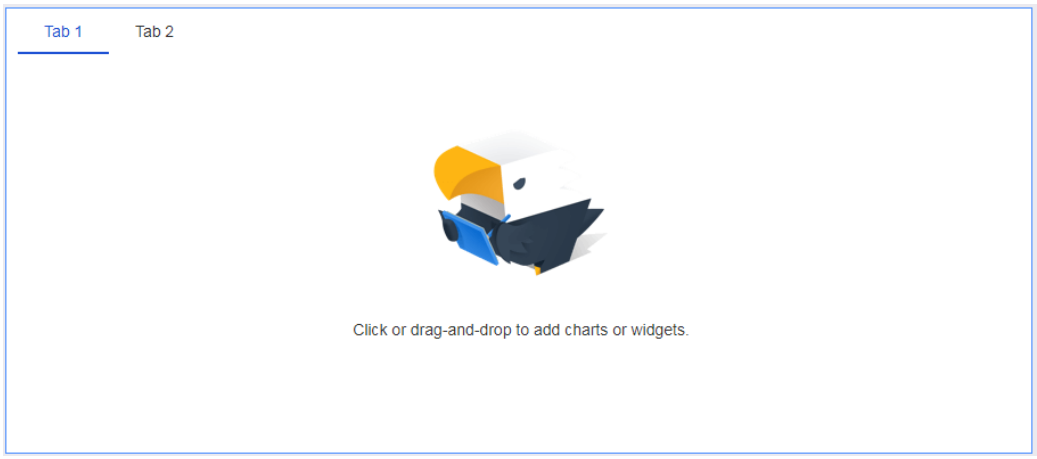
1. Go to the target dashboard.
2. Click the Tab icon.
3. Click the **Style** tab. Click **Add Tab Page** in the **Label** field.



4. Select a tab where you want to add charts, as shown in Tabs.

   Click **Tab 1**. The tab name **Tab 1** becomes blue.

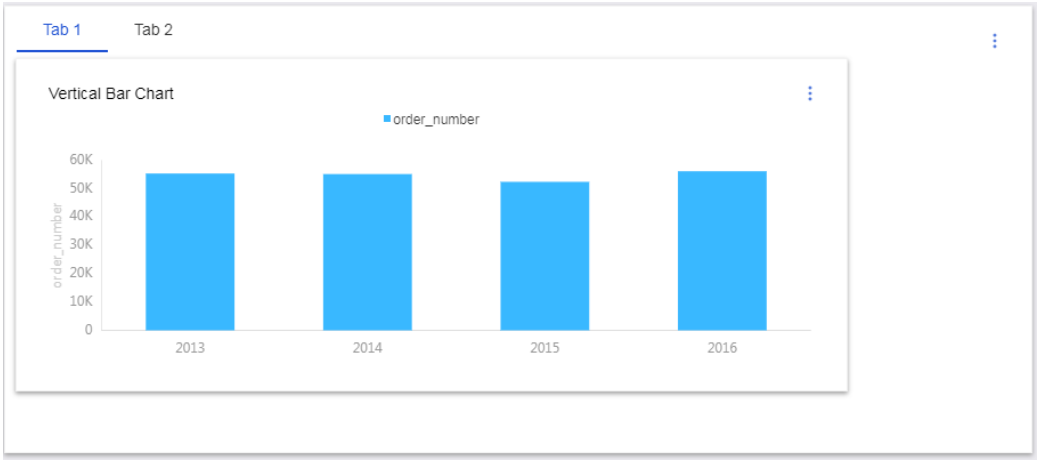
   Tabs



5. Click a chart icon to add a chart to Tab 1.

Add and configure a chart. Sample tab shows the tabs.

Sample tab



If you want to delete the current tab widget, click the **More** icon in the upper-right corner of the tab, and click **Delete**.

7.4.3.4.8.8. Image

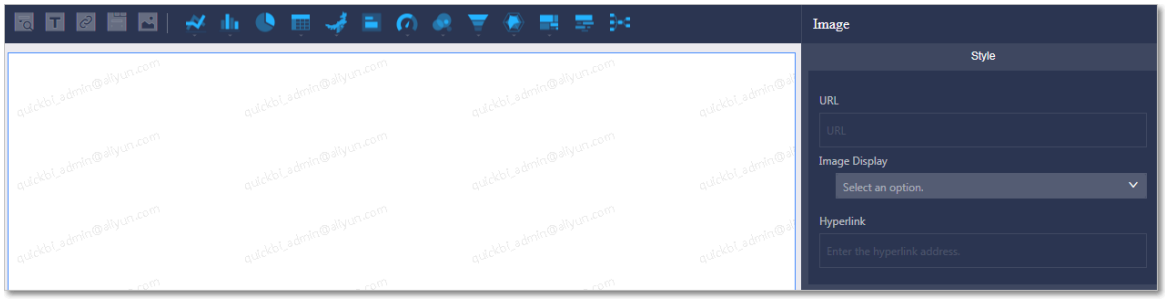
The Image widget allows you to insert images into a dashboard. You can adjust the image position and display effects as needed.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Go to the target dashboard.
2. Click the **Image** icon.
3. In the Style field, enter the URL and hyperlink of the image, and specify **Image Display**.



7.4.4. Create a chart on the dashboard

7.4.4.1. Create a line chart

A line chart shows data change trends and the interactions between multiple groups of data over a period of time. For example, you can use a line chart to analyze the sales volumes of a group of products or multiple groups of products over a period of time to forecast future sales volumes.

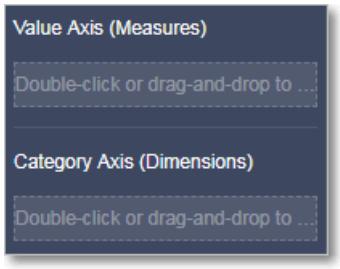
Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A line chart consists of a category axis and a value axis. The category axis is horizontal and determined by dimensions, such as date, province, and product type. The value axis is vertical and determined by measures, such as order quantity and performance metrics.

The system automatically matches dimensions with the category axis and measures with the value axis. You only need to follow the instructions to add fields.



You must specify at least one dimension for the category axis and at least one measure for the value axis. You can specify only one dimension for the color legend.

> Note The color legend is applicable only when the value axis has one measure.

The following example uses the company_sales_record dataset to describe how to use a line chart to demonstrate the order quantity of each type of products in different provinces every year.

Procedure

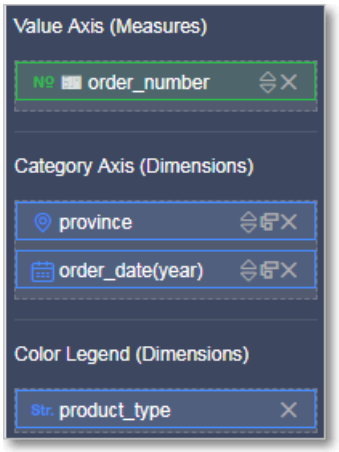
1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Line Chart** icon.
5. Click the **Data** tab, and select required dimensions and measures.

   In the Dimensions list, find and add **order_date(year)** and **province** to the Category Axis (Dim.) field. In the Measures list, find and add **order_number** to the Value Axis (Mea.) field, as shown in Specify fields for the line chart.

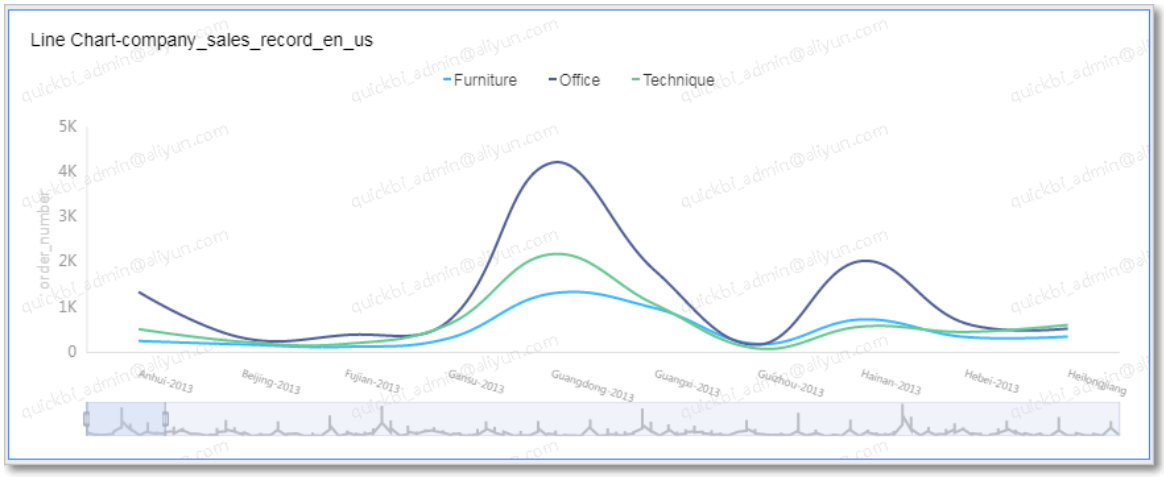
   > Note Ensure that you have converted the dimension type of province from String to Geo.

   For information about how to convert a dimension type, see Edit a dimension.

   Specify fields for the line chart

6. Drag **product_type** to the **Color Legend (Dim.)** field.
7. Click **Update**. The chart is updated.
8. Click the **Style** tab, and change the title, layout, and legend position of the chart.



9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard and click **OK**.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.2. Create an area chart

An area chart shows data change trends at equal intervals with different sizes of area. In addition, you can use an area chart to analyze the interactions between multiple groups of data over a period of time. For example, analyze the sales volumes of a group of products or multiple groups of products over a period of time to forecast future sales volumes.

An area chart consists of a category axis and a value axis. The category axis is horizontal and determined by dimensions, such as date, province, and product type. The value axis is vertical and determined by measures, such as order quantity and performance metrics.

The system automatically matches dimensions with the category axis and measures with the value axis. You only need to follow the instructions to add fields.

Notes

You must specify at least one dimension for the category axis and at least one measure for the value axis.

> **Note** The color legend is applicable only when the value axis has one measure.

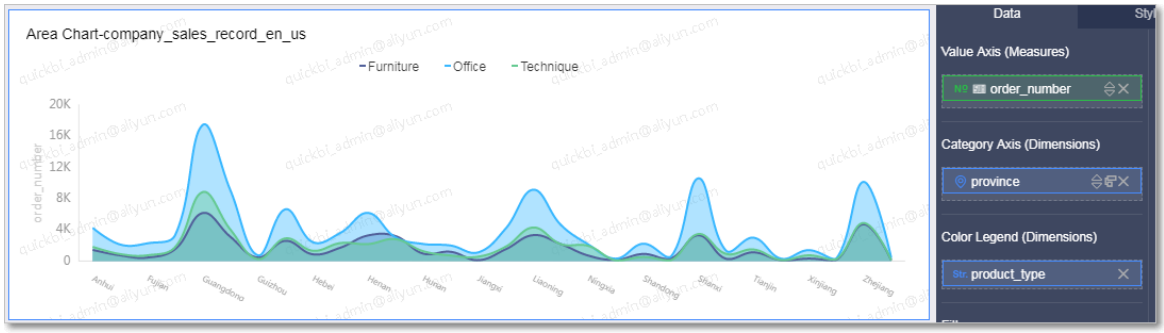
The following example uses the company_sales_record dataset to describe how to use an area chart to demonstrate the order quantity of each type of products in different provinces.

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Area Chart** icon. An area chart appears in the display area of the dashboard.
5. Select required dimensions and measures.

In the Dimensions list, find and add **province** to the Category Axis (Dim.) field. In the Measures list, find and add **order_number** to the Value Axis (Mea.) field.

> **Note** Ensure that you have converted the dimension type of province from String to Geo.

6. Drag **product_type** to the Color Legend (Dim.) field. Click **Update**.
7. Click the **Style** tab, and change the title, layout, legend position, and axis style of the chart. The following figure shows an updated area chart.



> **Note** You can switch to another area chart type, such as stacked area chart, 100% stacked area chart, or stacked line chart as required.

8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard and click **OK**.

If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.3. Create a vertical bar chart

A vertical bar chart demonstrates data changes over a period of time or comparisons between objects. For example, you can use a vertical bar chart to show the traffic flow in different time periods of time at a crossing.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

Similar to a line chart, a vertical bar chart consists of a category axis and a value axis.

This topic uses the following scenarios to describe how to use the filter and the Dual Y-Axis function in a vertical bar chart.

- Scenario 1: Compare the shipping costs for different products in provinces in the East China region.
- Scenario 2: Compare the order quantities and average profits of different products in different provinces.

You must specify at least one dimension, such as **province** or **product_type**, for the category axis. You must specify at least one measure, such as **order_number** or **profit_amt**, for the value axis. You can specify only one dimension for the color legend.

> **Note** The color legend is applicable only when the value axis has one measure.

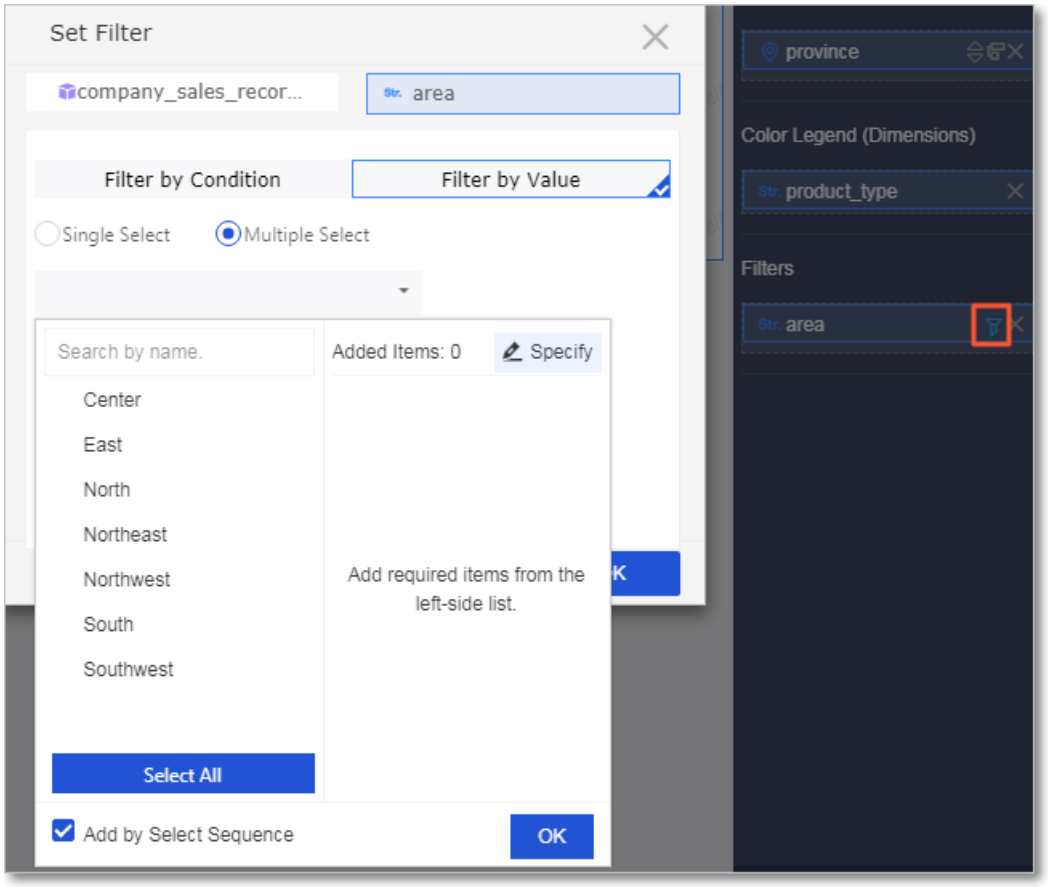
Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Vertical Bar Chart** icon. Scenario 1: The following example uses the company_sales_record dataset to describe how to use a vertical bar chart to compare the shipping costs for different products in provinces in the East China region.
   i. In the Dimensions list, find and add area to the Filters field, as shown in Filters. You can use the filter to filter data of the **East China** region.

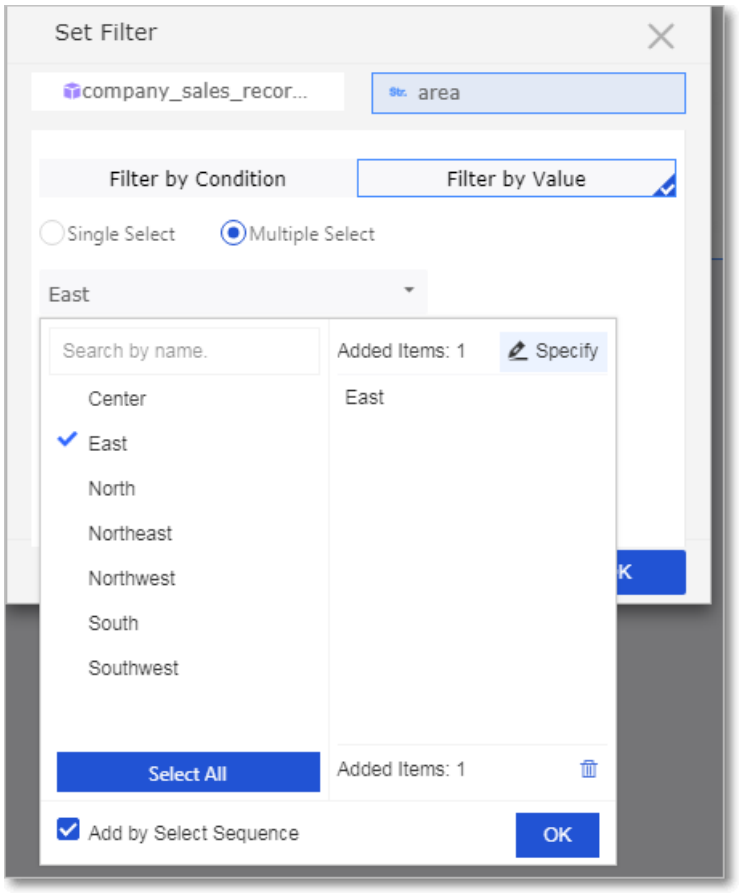
      Filters

      
   ii. Click the **Filter** icon.

iii. In the Set Filter dialog box that appears, select Filter by Value and **Multiple Select**. The system automatically lists all available options.



iv. Select **East** and click **OK**.



v. In the Dimensions list, find and add **province** and **product_type** to the Category Axis (Dim.) field.

vi. In the Measures list, find and add **shipping_cost** to the Value Axis (Measures) field.

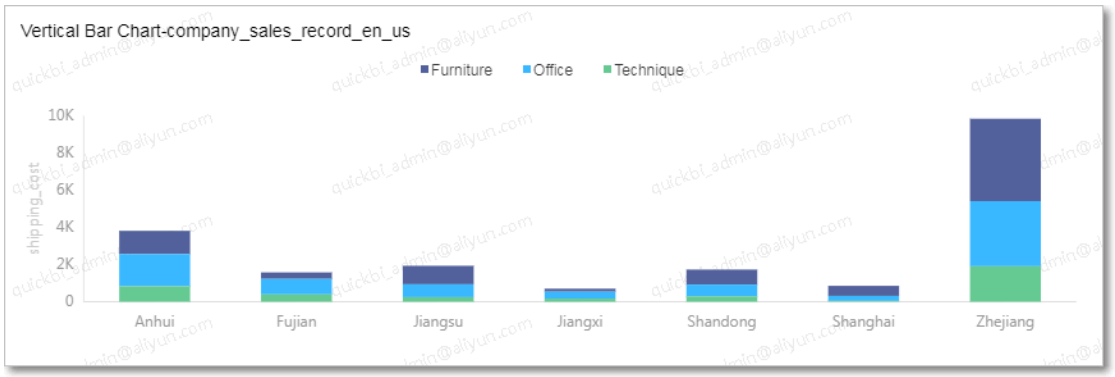
> **Note** Ensure that you have converted the dimension type of province from String to Geo.

For information about how to convert a dimension type, see Edit a dimension.

vii. Drag **product_type** from the Category Axis (Dim.) field to the **Color Legend (Dim.)** field.

viii. Click **Update**. The chart is updated.

ix. Click the **Style** tab and select **Stacked** in the Chart Type section.

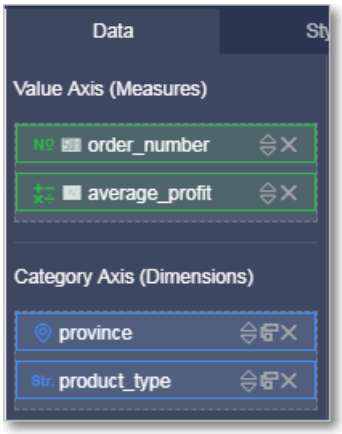


Scenario 2: The following example uses the company_sales_record dataset to describe how to use a vertical bar chart to compare the order quantities and average profits of different products in different provinces.

> **Note**
>
> Data modeling may be required in this scenario. For information about data modeling, see Add a calculated field.

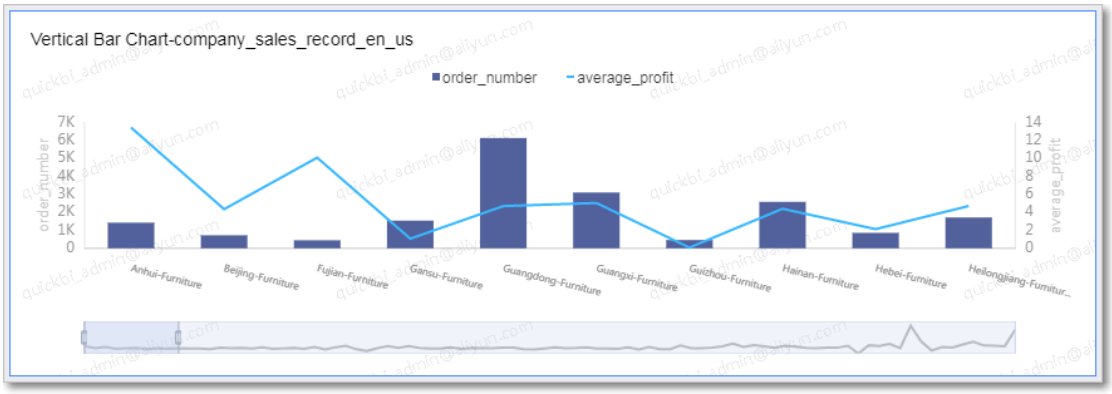
i. Click the **Data** tab and select required dimensions and measures.

In the Dimensions list, find and add **province** and **product_type** to the Category Axis (Dim.) field. In the Measures list, find and add **order_number** and **average_profit** to the Value Axis (Mea.) field.



ii. Click **Update**. The chart is updated.

iii. Click the **Style** tab and select **Dual Y-Axis** in the Chart Type section.



iv. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard and click OK.

7.4.4.4. Create a waterfall chart

A waterfall chart reflects data changes at different time periods or under the impact of different factors. It uses a combination of absolute and relative values and is suitable for business analysis and financial analysis.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

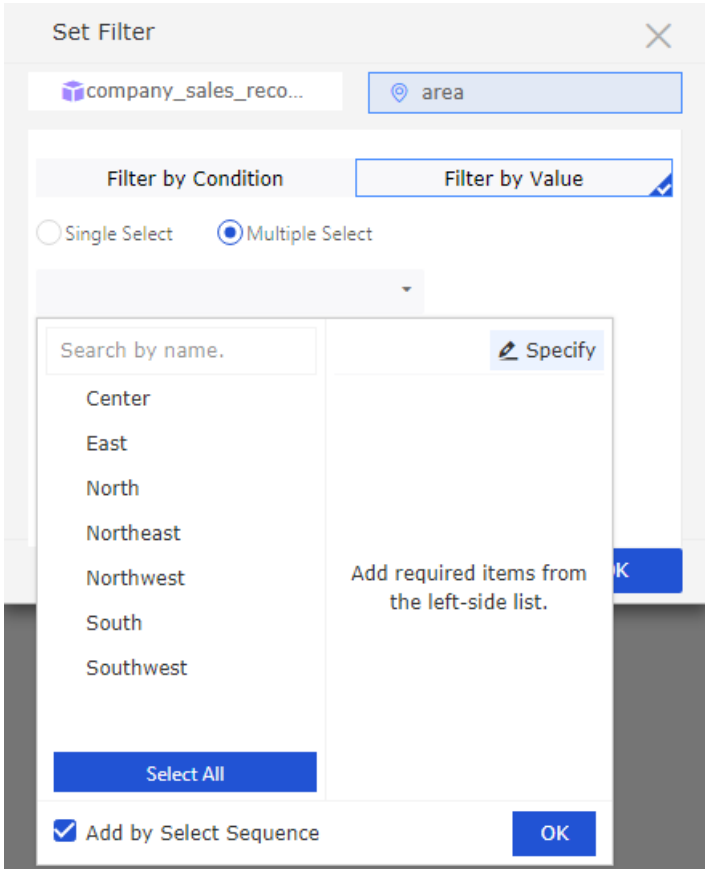
Context

You must specify at least one dimension, such as province or product type, for the category axis. You can specify only one measure, such as order quantity or profit, for the value axis.

The following example uses the *company_sales_record dataset* to describe how to use a waterfall chart to compare the shipping costs in the provinces of East China.

Create a waterfall chart

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **My Items** tab of the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Waterfall Chart** icon.
5. Click the **Data** tab and select the required measure. In the Dimensions list, find and add **province** to the Category Axis (Dim.) field and **area** to the Filters field. In the Measures list, find and add **shipping_cost** to the Value Axis (Mea.) field.
6. Click . In the **Set Filter** dialog box that appears, click the Filter by Value tab and select **North**.



7. Click **Update**. The chart is updated.
8. Click the **Style** tab and set parameters in the **Basic Information**, **Parameter Settings**, **Chart Type**, **Axes**, and **Series Settings** sections.
9. Click Save in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard and click **OK**.

   If you want to delete the chart, click the **More** icon ( ) in the upper-right corner of the chart and select **Delete**.

Configure parameters on the Style tab

You can perform the following steps on the **Style** tab:

1. In the **Basic Information** section, set Show Title and Description, Show Link, and Background. In this example, **Dark Color** is selected for **Background**.

   > **Note** If you want to redirect to a report or an external page, select **Show Link** and specify Link Text and Link Address.

2. In the **Parameter Settings** section, configure Show Initial Value, Show Cumulative Value, and Show Initial Value/Cumulative Value Labels. In this example, Show Initial Value/Cumulative Value Labels is selected.
3. In the **Chart Type** section, configure Show Labels, Show Legend, and Color Settings. In this example, **Show Labels** is selected and the color legend is displayed on the top of the chart.

   > **Note** If multiple measures are specified for the chart, all measure labels are displayed after you select Show Labels. Labels can be displayed in two modes: Smart Display and Full Display. Assume that a chart has many dimension values and the scroll bar is not shown in the chart. In Smart Display mode, only part of labels are displayed. In Full Display mode, all labels are displayed.

4. In the **Axes** section, set Axis Title and Unit. In this example, **Show Scale** is selected on the X-Axis tab.
5. In the **Series Settings** section, set Alias and Data Display Format for a measure. In this example, the default data display format **AutoFit** is used.

After you complete the configurations, the chart is shown in the following figure.

Configure filter interaction

On the **Advanced** tab, you can set Auto Refresh and Filter Interaction. The following example uses a pie chart to describe how to configure filter interaction.

1. Click the **Pie Chart** icon. A pie chart appears in the display area of the dashboard.
2. Specify measures and dimensions.

   > **Note** The measures and dimensions of the pie chart can be different from the waterfall chart.

3. Select the waterfall chart and click the **Advanced** tab.
4. On the **Advanced** tab, click the Edit icon next to Filter Interaction. In the Filter Interaction dialog box that appears, select fields and charts for interaction.
5. Click **OK**.

The following figure shows the chart that appears after the configuration is complete. After you click an area in the waterfall chart, the pie chart displays the data corresponding to the area.

> **Note** The initial value and cumulative value do not support filter interaction.

7.4.4.5. Create a horizontal bar chart

Similar to a vertical bar chart, a horizontal bar chart displays the differences between data of different categories.

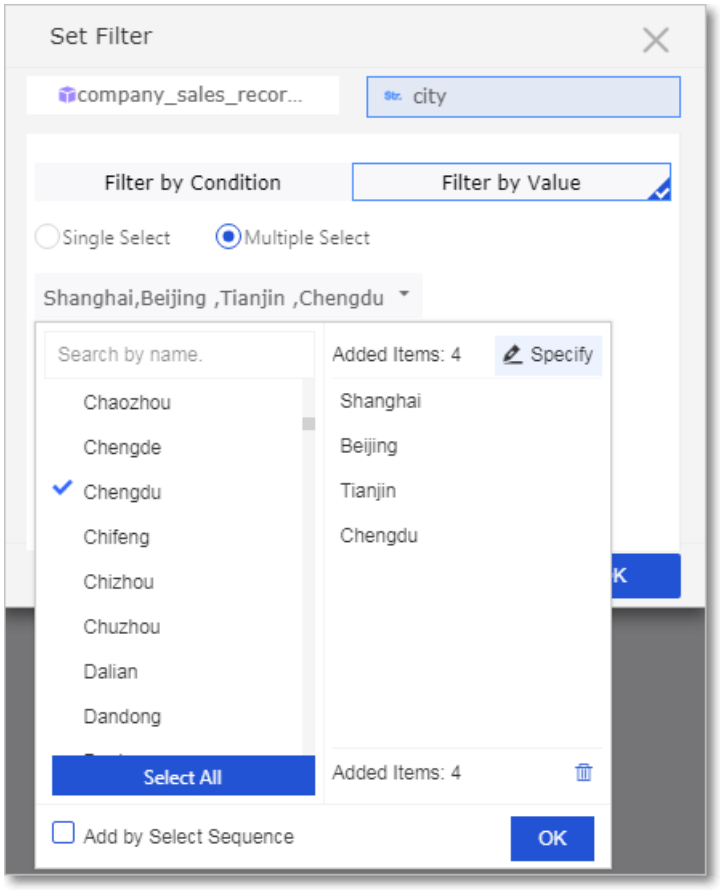
Notes

You must specify at least one dimension, such as province or product type, for the category axis and specify at least one measure, such as order quantity or profit, for the value axis. You can specify only one dimension for the color legend.

> **Note** The color legend is applicable only when the value axis has one measure.

The following example uses the company_sales_record dataset to describe how to use a horizontal bar chart to compare the shipping costs of different products in different municipalities.

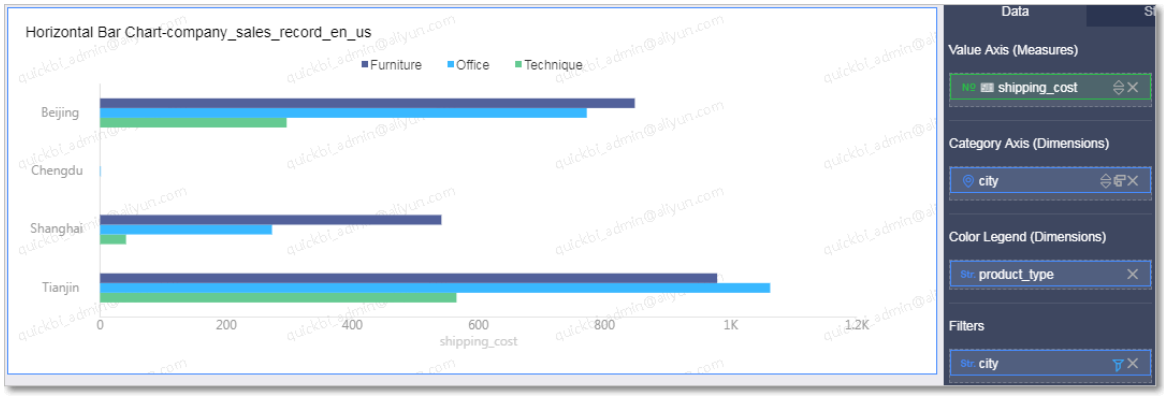
1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Horizontal Bar Chart** icon. A horizontal bar chart appears in the display area of the dashboard.
5. In the Dimensions list, find and add **city** to the Filters field and select four municipalities, as shown in the following figure.



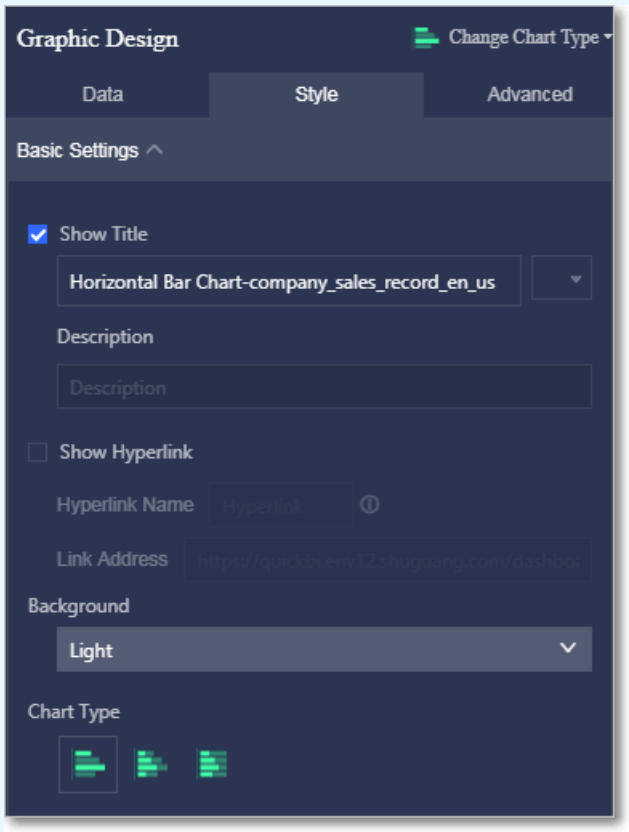
6. In the Dimensions list, find and add **city** to the Category Axis (Dim.) field. In the Measures list, find and add **shipping_cost** to the Value Axis (Mea.) field. In the Dimensions list, find and add **product_type** to the Color Legend (Dim.) field.

> **Note**
>
> - Ensure that you have converted the dimension type of city from String to Geo.
> - The color legend is applicable only when the value axis has one measure.

7. Click **Update**. The chart is updated.



Note You can also switch the current chart to another bar chart type, such as a stacked horizontal bar chart or 100% stacked horizontal bar chart, as shown in the following figure.



8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard and click **OK**.

If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.6. Create a progress bar

Similar to a gauge, a progress bar displays the progress of a specific metric.

A progress bar has a pointer. The pointer is determined by measures, such as order quantity.

Notes

- You can specify one to five measures for the pointer.
- To use a progress bar, you must set the maximum and minimum values in the **Series Settings** section on the **Style** tab.

The following example uses the company_sales_record dataset to describe how to use a progress bar to show order completion.

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the

Create Dashboard icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.

4. On the dashboard edit page, click the Progress Bar icon. A progress bar appears in the display area of the dashboard.
5. Click the **Data** tab and select required measures.

   In the Measures list, find and add **order_number** to the Pointer (Mea.) field. Click the **Style** tab, configure the chart title and color legend position, set an alias for the measure, and set the maximum and minimum values.
6. Click **Update**. The chart is updated.

7. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard and click **OK**.

If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.7. Create a combination chart

A combination chart compares data across multiple categories and magnitudes.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A combination chart provides a dual y-axis to display data in multiple chart types, such as line chart, vertical bar chart, and area chart, in stacked and 100% stacked modes. For example, you can use a combination chart to display the change trends of different projects.

A combination chart consists of a category axis, primary value axis, and secondary value axis.

> **Notice** You can specify at least one dimension for the category axis, such as the order_date(year). You can specify at least one measure each for the primary and secondary value axes, such as order price and profit. You can specify only one dimension for the color legend. The legend is applicable only when the primary or secondary value axis has one measure.

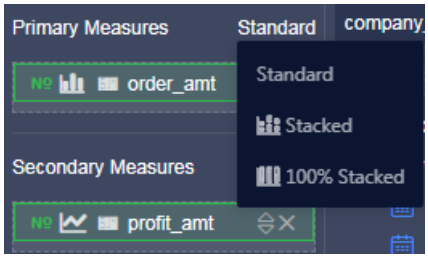
Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the *company_sales_record* dataset, click  in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click  .
5. Click the **Data** tab and select required dimensions and measures.

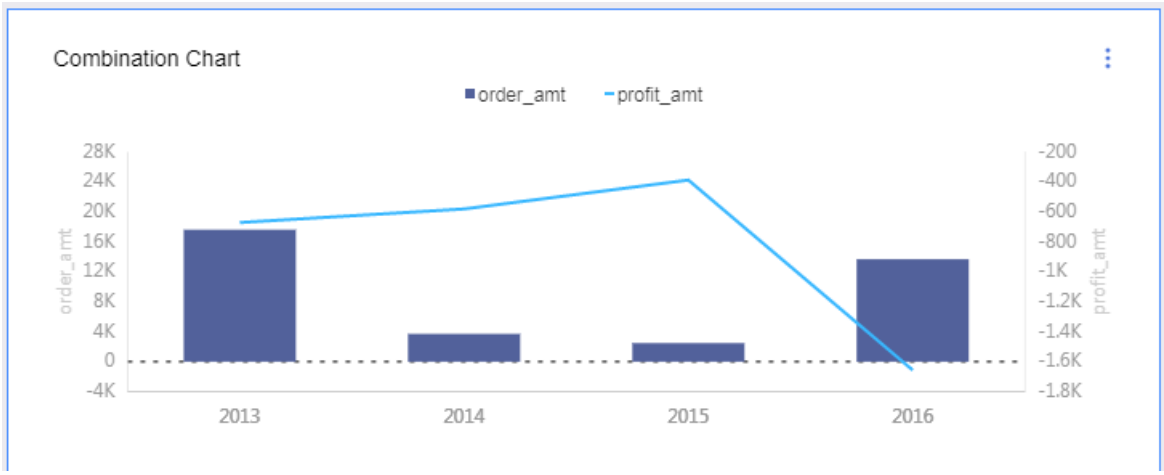
   In the Dimensions list, find and add **order_date (year)** to the Category Axis (Dim.) field. In the Measures list, find and add **order_amt** to the Primary Measures field and **profit_amt** to the Secondary Measures field.

   - In the Primary Measures and Secondary Measures fields, you can click  to switch the chart type to vertical bar chart, line chart, or area chart.

     
   - You can click  to switch the stack mode.

6. Click **Update**. The chart is updated.

7. Click **Save**. The **Save Dashboard** dialog box appears. Set Name and Save To.
8. Click **OK** to save the dashboard.

   If you want to delete the chart, follow these steps:

   i. Click ⋮ in the upper-right corner of the chart.

   ii. Select **Delete**.

7.4.4.8. Create a pie chart

A pie chart shows data of different objects. Each object has a unique color or pattern. A pie chart shows the ratios of multiple values to the total amount. For example, you can use a pie chart to show the ratio of the income tax to the total personal income or the ratio of the sales volume of a car brand to the total sales volume.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A pie chart consists of multiple slices. Slice labels are determined by a dimension, such as area or product type. The central angle of each slice is determined by a measure, such as order quantity, order price, or profit.

You can specify only one dimension for slice labels and only one measure for central angles.

The following example uses the company_sales_record dataset to describe how to use a pie chart to compare the shipping costs in different regions.

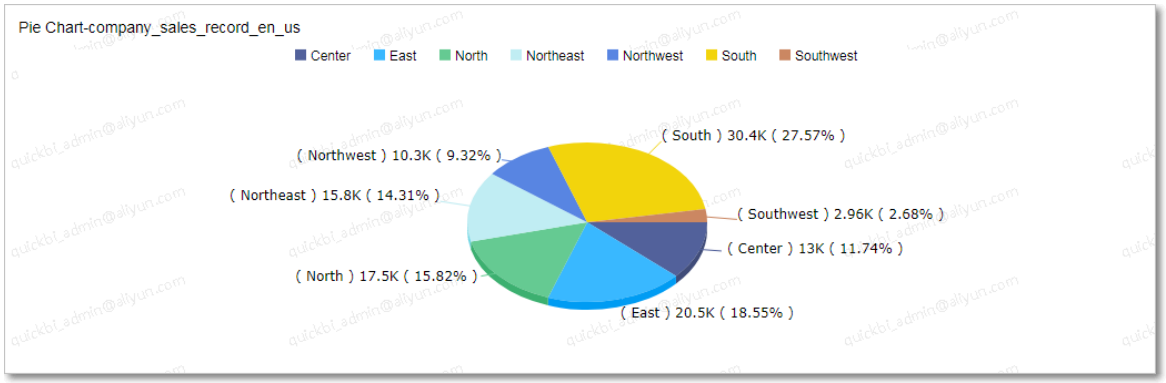
Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click OK.
4. On the dashboard edit page, click the **Pie Chart** icon.
5. Click the **Data** tab and select required dimension and measure.

   In the Dimensions list, find and add area to the Labels (Dim.) field. In the Measures list, find and add shipping_cost to the Central Angle (Measures) field, as shown in Specify fields for the pie chart.

   Specify fields for the pie chart

6. Click **Update**. The chart is updated.
7. Click the **Style** tab. Select **3D** for **Display Mode** and **Name, Percentage** for **Label Style**.



8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.9. Create a bubble map

A bubble map uses a map profile as its background and shows data distribution with bubbles of different sizes. It displays data metrics and their distribution in a country or region. For example, you can use a bubble map to display the volume of tourist arrivals at different destinations, or the average income in different regions.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A bubble map consists of geographic locations and the bubble size. Geographic locations are determined by a dimension, such as province. The bubble size is determined by measures, such as shipping cost and order quantity.

You can specify only one dimension, such as area, province, or city, for geographic locations. The dimension type must be Geo. You can specify one to five measures for the bubble size.

The following example uses the company_sales_record dataset to describe how to use a bubble map to compare the order quantities and average profits in different provinces.

Data modeling may be required for this scenario.

For information about data modeling, see Add a calculated field.

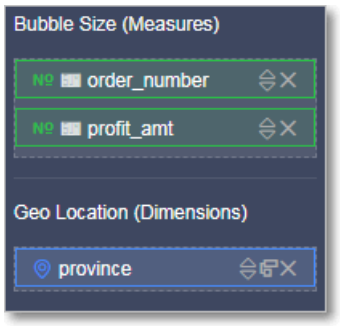
Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. In the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Bubble Map** icon.
5. Click the **Data** tab and select required dimension and measures.

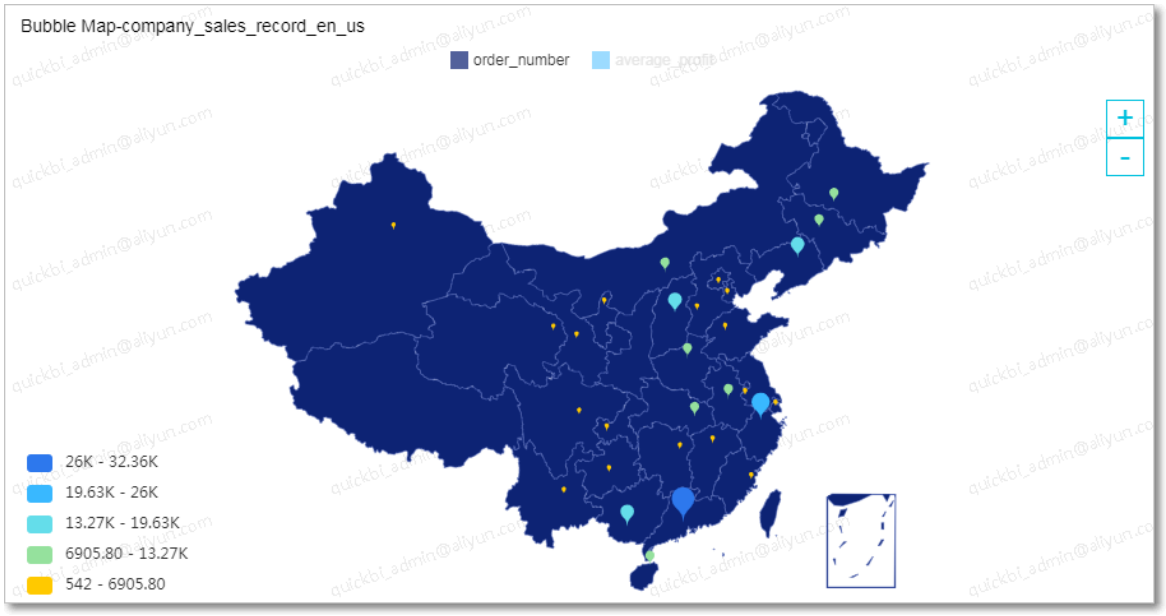
   In the Dimensions list, find and add province to the Geo Location (Dim.) field. In the Measures list, find and add order_number and average_profit to the Bubble Size (Mea.) field, as shown in Specify fields for the bubble map.

   > **Note** Ensure that you have converted the dimension type of province from String to Geo. For information about how to convert a dimension type, see Edit a dimension.

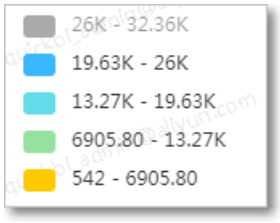
   Specify fields for the bubble map

6. Click **Update**. The chart is updated.
7. Click the **Style** tab, and edit the title and legend position of the chart.



- You can switch between order_number and average_profit to show required data.
- Click a legend to hide its data.



- Click the plus (+) or minus (-) sign to zoom in or zoom out on the map.

8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.10. Create a colored map

Similar to a bubble map, a colored map displays data in a single color at different saturation levels. This visualization is useful to show the distribution of data across areas on a map.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A colored map consists of geographic locations and a colorscale. Geographic locations are determined by a dimension, such as province. The colorscale is determined by measures, such as order price and profit.

You can specify only one dimension for geographic locations. The type of the dimension must be Geo. You can specify one to five measures for the colorscale.

The following example uses the company_sales_record dataset to describe how to use a colored map to compare the shipping costs, order price, and profits in different regions.

Procedure

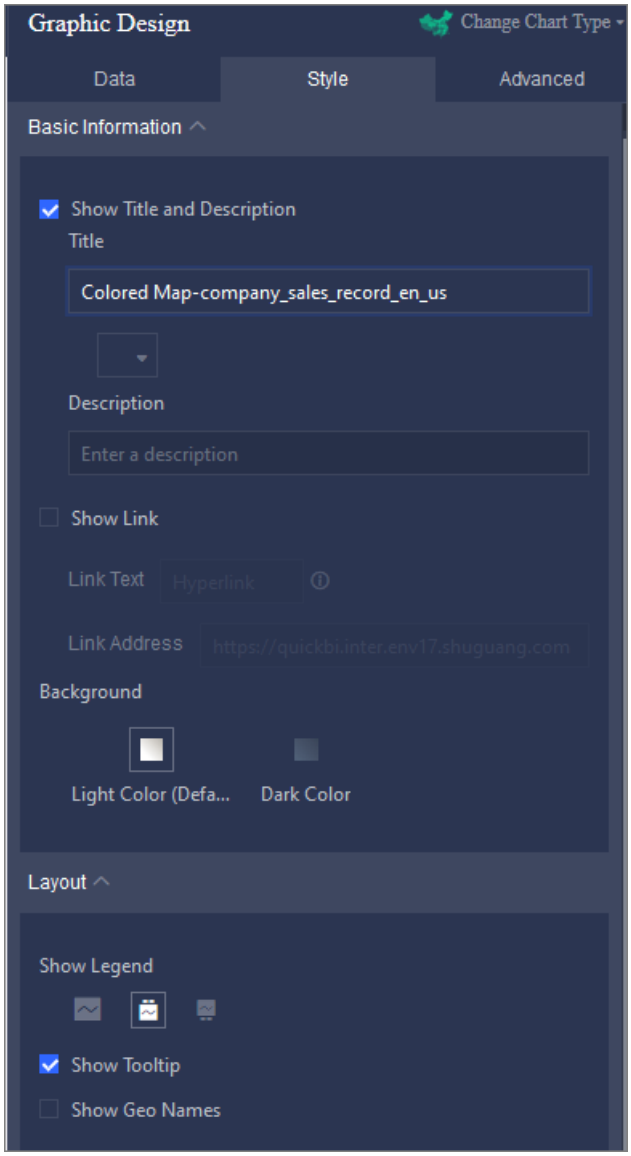
1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click OK.
4. On the dashboard edit page, click the **Colored Map** icon.
5. Click the **Data** tab and select required dimension and measures.

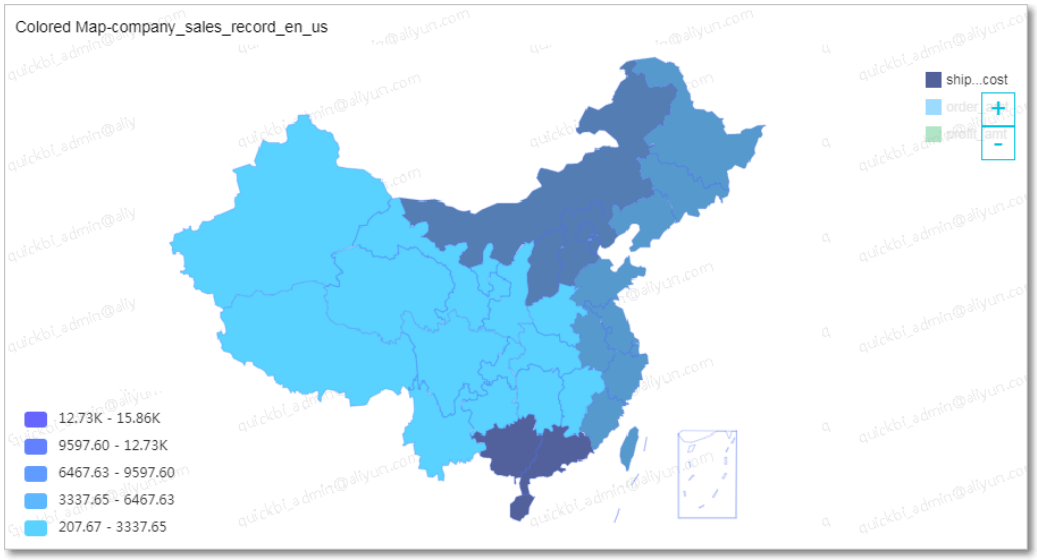
   In the Dimensions list, find and add area to the Geo Location (Dim.) field. In the Measures list, find and add order_amt, profit_amt, and shipping_cost to the Colorscale (Mea.) field.

> **Note** Ensure that you have converted the dimension type of area from String to Geo. For information about how to convert a dimension type, see Edit a dimension.

6. Click **Update**. The chart is updated.
7. Click the **Style** tab, click the **Right** icon for the **Show legend** field in the **Layout** section, as shown in The colored map.

The colored map





You can perform various operations on the map, such as change the title, adjust the position and size, and hide irrelevant data. For more information, see Create a bubble chart.

8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.11. Create a geo bubble map

A geo bubble map uses a map profile as its background and shows data distribution with bubbles of different sizes. It displays data metrics and distribution in a country, region, or city. Compared with bubble maps, geo bubble maps provide more accurate geographic locations.

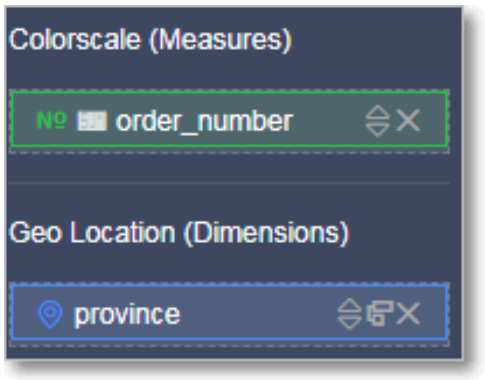
A geo bubble map consists of geographic locations displayed with different saturation levels. Geographic locations are determined by a dimension, such as province. Saturation levels are determined by a measure, such as order quantity. You must specify one dimension and one measure for a geo bubble map. The dimension type must be Geo.

The following example uses the company_sales_record dataset to describes how to use a geo bubble map to compare the order quantities of different provinces in the North China region.

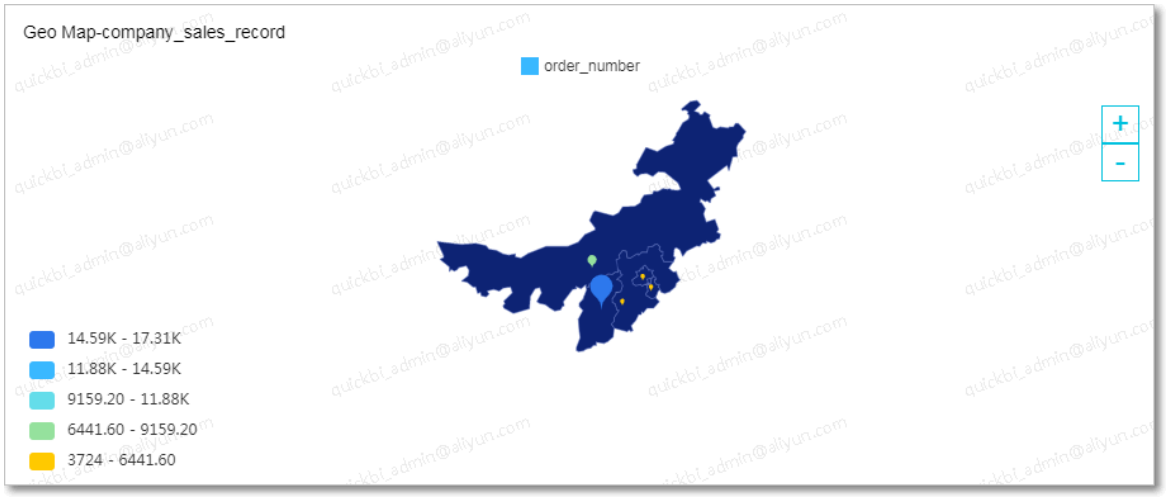
1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets** to go to the Datasets page.
3. Find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column, select Standard in the dialog box that appears, and click OK.
4. Click the Geo Bubble Map icon. A geo bubble map is created in the display area of the dashboard.
5. On the **Data** tab, select the target measure and dimension.

   In the Dimensions list, find and add the **province** dimension to the Location (Dimension) field. In the Measures list, find and add the **order_number** measure to the Color Scale (Measures) field, as shown in the following figure.

> **Note** Ensure that you have converted the dimension type of province from String to Geo.



6. Click **Update**. The chart is updated.
7. On the **Style** tab, change the value ranges and saturation levels, as shown in the following figure.



8. Click **Save** to save the dashboard.

If you want to delete the geo bubble map, click the **More** icon in the upper-right corner of the map and select **Delete**.

7.4.4.12. Create a geo map

A geo map displays data as a single color at different saturation levels. This visualization is useful to show distribution of data across areas on a map. Compared with colored maps, geo maps provide more accurate geographic locations.

A geo map consists of geographic locations displayed in one color with different saturation levels. Geographic locations are determined by a dimension, such as province. Saturation levels are determined by a measure, such as order quantity. You must specify one dimension and one measure for a geo map. The dimension type must be Geo.

The following example uses the company_sales_record dataset to describe how to use a geo map to compare the order quantities of different provinces in the South China region.

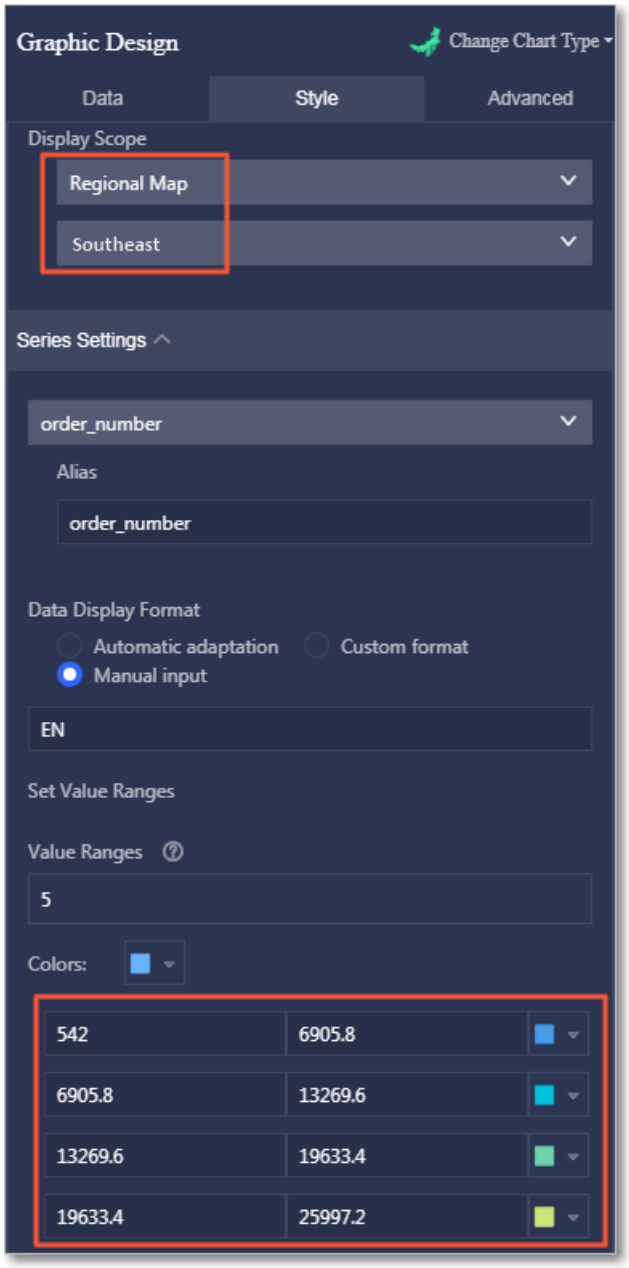
1. Log on to the Quick BI console.

2. In the left-side navigation pane of the **Workspace** tab, click **Datasets** to go to the Datasets page.
3. Find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column, select Standard in the dialog box that appears, and click **OK**.
4. On the dashboard edit page, click the Geo Map icon. A geo map is created in the display area of the dashboard.
5. On the **Data** tab, select the required measures and dimensions.

   In the Dimensions list, find and add the **province** dimension to the Geo Location (Dimensions) field. In the Measures list, find and add the **order_number** measure to the Colorscale (Measures) field, as shown in the following figure:

   > **Note** Ensure that you have converted the dimension type of province from String to Geo.

6. Click **Update**. The chart is updated.
7. On the **Style** tab, change the value ranges and saturation levels.



8. Click **Save** to save the dashboard.

If you want to delete the geo map, click the **More** icon in the upper-right corner of the map and select **Delete**.

7.4.4.13. Create a cross table

A cross table displays the summary of a field and classifies field values into different groups. Aggregate functions used in a cross table include SUM, AVG, COUNT, MAX, and MIN.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A cross table consists of rows and columns. Rows are horizontal and determined by dimensions such as province and product type. Columns are vertical and determined by measures such as order quantity and profit.

There is no limit to the number of dimensions and measures that you can include in a cross table.

The following example uses the company_sales_record dataset to describe how to use a cross table to compare the packaging, shipping costs, order quantities, and average profits of different products in multiple provinces.

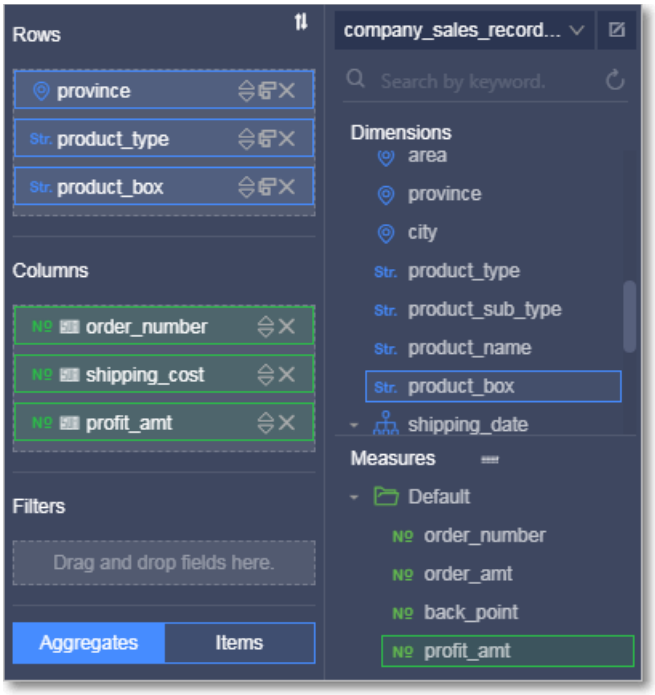
Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Cross Table** icon.
5. Click the **Data** tab and select dimensions and measures.

   In the Dimensions list, find and add province, product_type, and product_box to the Rows field. In the Measures list, find and add order_number, shipping_cost, and profit_amt to the Columns field, as shown in Specify fields for the cross table.

   > **Note** Ensure that you have converted the dimension type of province from String to Geo. For information about how to convert a dimension type, see Edit a dimension.

   Specify fields for the cross table



6. Click **Update**. The chart is updated.
7. Click the **Style** tab and perform the following operations:
   - In the **Basic Settings** section, specify a title and hyperlink for the cross table, as shown in the following figure.

   - In the **Display Settings** section, specify whether to show row numbers, merge cells that belong to the same category, freeze all columns by selecting Auto (Table Head), or freeze specific columns as required. After you configure the parameters, update the table. The following figure shows an updated chart.

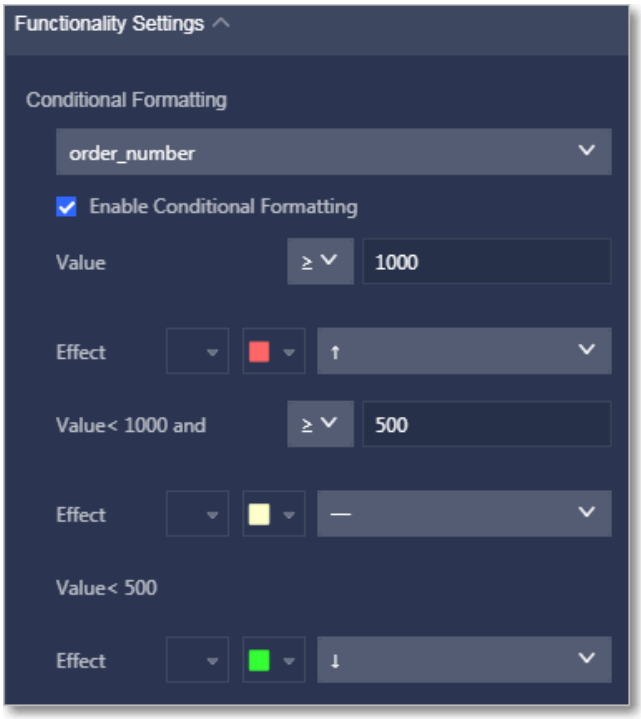
   - In the **Functionality Settings** section, set conditional formatting and sort columns.

     Conditional formatting

- Select the target field and select the **Enable Conditional Formatting** check box to enable conditional formatting. To disable conditional formatting, clear the check box, as shown in the following figure.

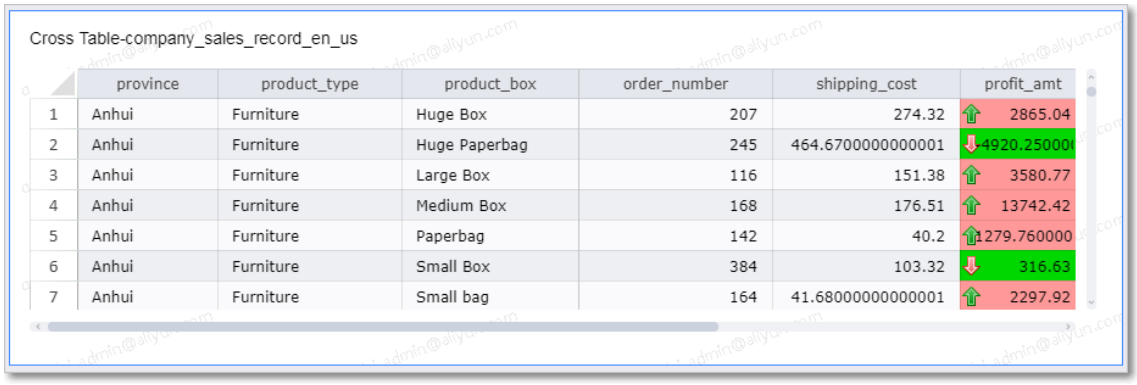
- Click the drop-down icon and select another field, as shown in the following figure.

- Specify a value for the Value parameter, click the Color icons next to the Effect parameter, and select colors to mark the values, as shown in the following figure.



In this example, the **profit_amt** field is selected for conditional formatting. The conditional formatting rules are as follows:

- Cells with values greater than 1000 are highlighted in red and are marked with a green upward arrow.
- Cells with values from 500 to 1000 are highlighted in gray and are marked with an orange hyphen.
- Cells with values less than 500 are highlighted in green and are marked with a red downward arrow.

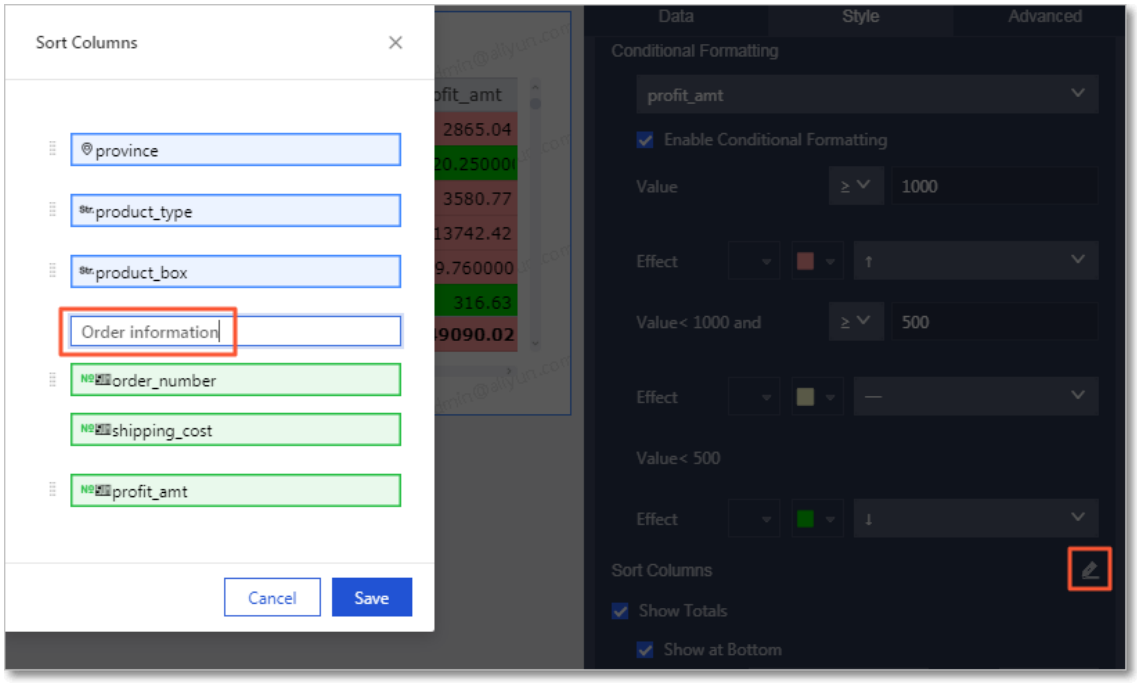


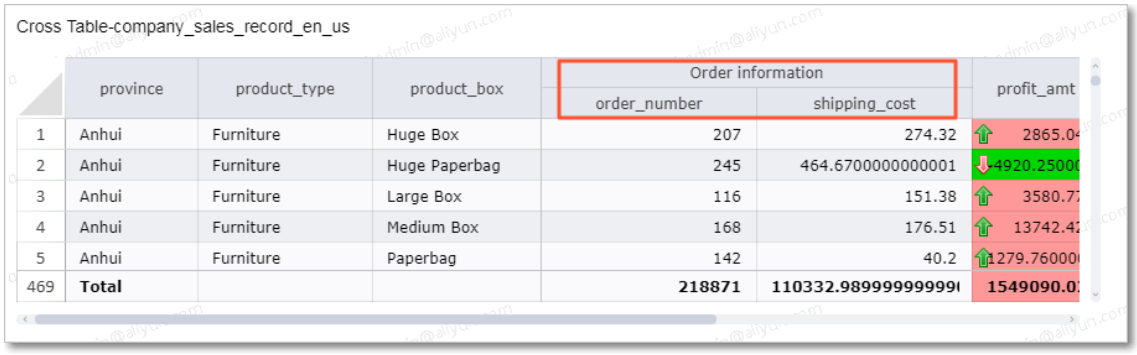
Cross Table-company_sales_record_en_us

	province	product_type	product_box	order_number	shipping_cost	profit_amt
1	Anhui	Furniture	Huge Box	207	274.32	2865.04
2	Anhui	Furniture	Huge Paperbag	245	464.6700000000001	-4920.25000
3	Anhui	Furniture	Large Box	116	151.38	3580.77
4	Anhui	Furniture	Medium Box	168	176.51	13742.42
5	Anhui	Furniture	Paperbag	142	40.2	1279.760000
6	Anhui	Furniture	Small Box	384	103.32	316.63
7	Anhui	Furniture	Small bag	164	41.68000000000001	2297.92

Sort columns

This function allows you to sort columns into different groups. You must name the groups. Otherwise, only the column order is changed.



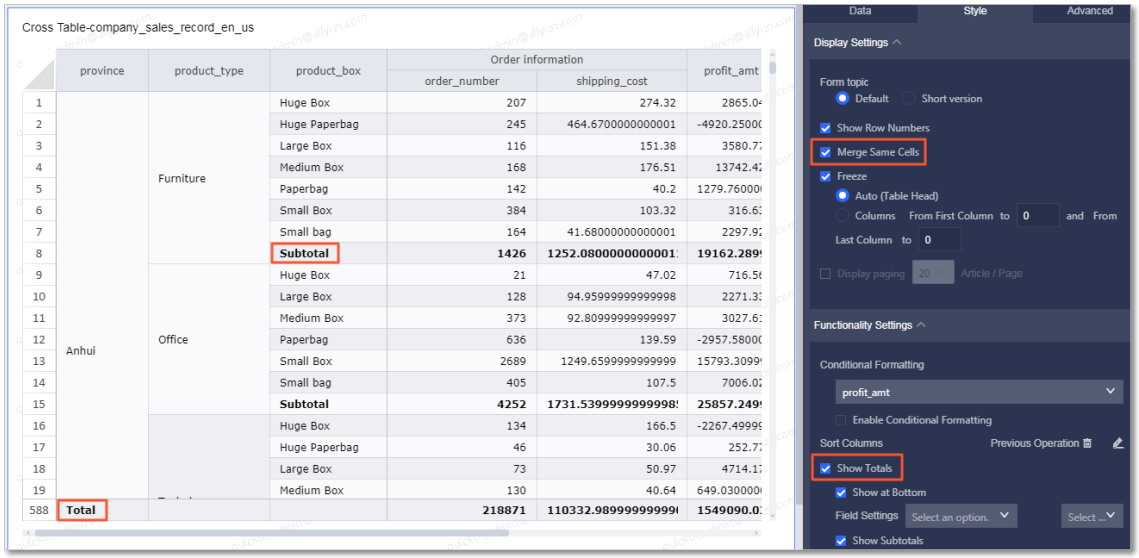


Cross Table-company_sales_record_en_us

	province	product_type	product_box	Order information		profit_amt
				order_number	shipping_cost	
1	Anhui	Furniture	Huge Box	207	274.32	2865.04
2	Anhui	Furniture	Huge Paperbag	245	464.6700000000001	-4920.25000
3	Anhui	Furniture	Large Box	116	151.38	3580.77
4	Anhui	Furniture	Medium Box	168	176.51	13742.42
5	Anhui	Furniture	Paperbag	142	40.2	1279.76000
469	**Total**			**218871**	**110332.98999999999**	**1549090.0**

- Select **Show Totals** to obtain the subtotal or total amount of data items. You can also select an aggregate function, as shown in the following figure.

> **Note** If you want to obtain the subtotal of grouped data items, you must select **Merge Same Cells** in the **Display Settings** section.



- In the **Series Settings** section, rename fields, set the alignment mode, and specify the number of records displayed on a single page.

8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.14. Create a pivot table

A pivot table displays aggregates of variables and allows you to analyze data in a tree structure. One variable defines the values in the header row while the other variable defines the values in the header column. Aggregate functions include SUM, AVG, COUNT, MAX, and MIN.

Similar to a cross table, a pivot table consists of rows and columns. You can specify an unlimited number of dimensions, such as province and product type, to determine rows and an unlimited number of measures, such as order quantity and profit to determine columns.

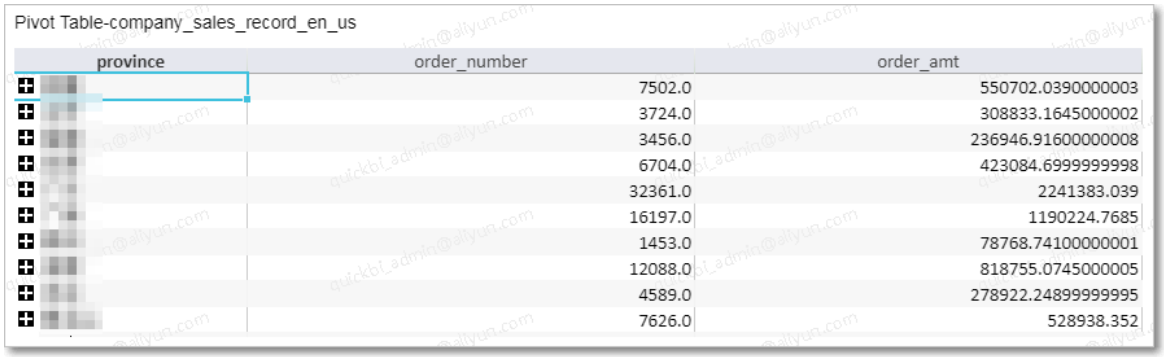
The following example uses the company_sales_record dataset to describe how to use a pivot table to show the packaging, order quantities, and order prices of different products in different provinces.

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click OK.
4. On the dashboard edit page, click the **Pivot Table** icon. A pivot table appears in the display area of the dashboard.
5. Click the **Data** tab and select the required dimensions and measures.

   In the Dimensions list, find and add **province**, **product_type** and **product_box** to the Rows (Dim.) field. In the Measures list, find and add **order_number** and **order_amt** to the Values (Mea.) field.

> **Note** Ensure that you have converted the dimension type of province from String to Geo.

6. Click **Update**. The chart is updated.



7. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.15. Create a gauge

Similar to a dashboard in a car, a gauge shows the range of a specific metric. You can view the progress of the current task or determine whether a metric exceeds its range in a gauge. For example, you can use a gauge to show the inventory status of a commodity, which helps you replenish the inventory in a timely manner.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A gauge consists of the pointer angle and tooltip. The pointer angle and tooltip are determined by a measure, such as profit or discount.

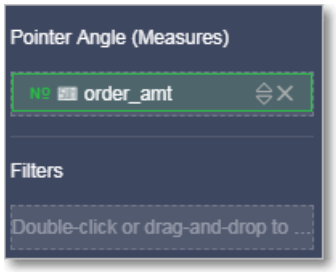
For each gauge, you can specify only one measure for the pointer angle and tooltip.

The following example uses the company_sales_record dataset to describe how to use a gauge to show order prices.

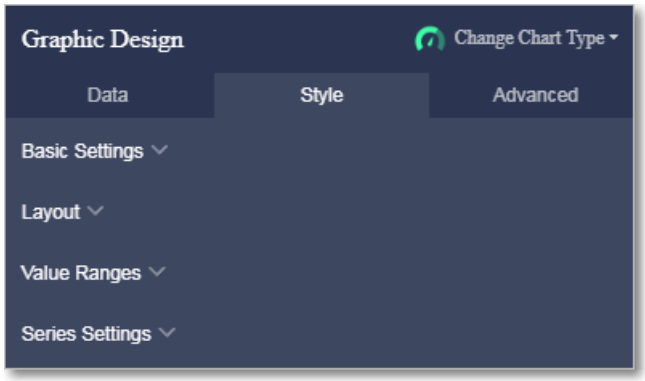
Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Gauge** icon.
5. Click the **Data** tab and select the required measure.

In the Measures list, find and add order_amt to the Pointer Angle (Mea.) or Tooltip (Mea.) field.



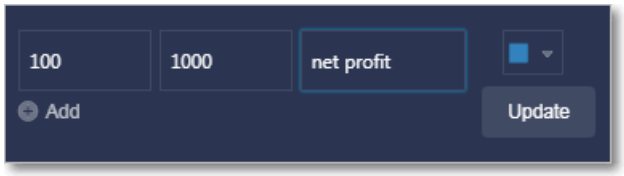
6. Click **Update**. The chart is updated.
7. Click the **Style** tab, and set the title, layout, and show or hide legend and tick marks.



8. Click **Add** in the Value Ranges section, and specify the start value and end value.

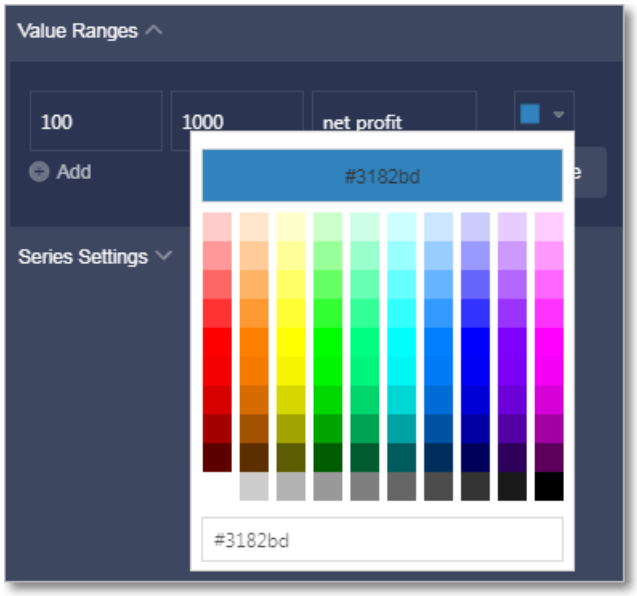
   For example, you can set the start value to 100, the end value to 1000, and the range title to Net Profit, as shown in Set a value range.

   Set a value range



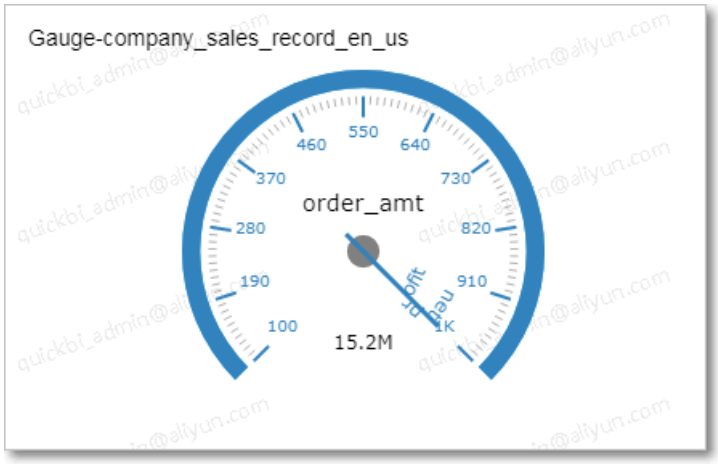
9. Click the Color icon and select a color for the value range, as shown in Change colors for value ranges.

   Change colors for value ranges



10. Click **Update**. The chart is updated, as shown in Gauge.

    Gauge



11. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
12. Click **OK** to save the dashboard.

    If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.16. Create a radar chart

A radar chart shows numbers or ratios obtained from analysis. It allows you to learn about the changes and trends of data metrics. For example, you can use a radar chart to show the sales volumes in different regions.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A radar chart consists of labels and label lengths. Labels are determined by dimensions, such as product type. Label lengths are determined by measures, such as shipping cost.

You can specify one or two dimensions for labels. we recommend that the number of dimension values be greater than or equal to three and less than or equal to 12. You can specify at least one measure for label lengths.

The following example uses the company_sales_record dataset to describe how to use a radar chart to compare the order quantities and order price in different regions.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Radar Chart** icon.
5. Click the **Data** tab and select the required dimensions and measures.

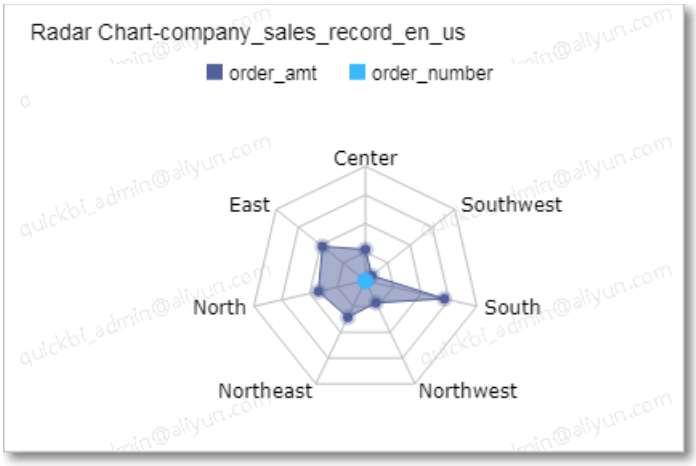
   In the Dimensions list, find and add area to the Labels (Dim.) field. In the Measures list, find and add order_number and order_amt to the Length (Mea.) field, as shown in Specify fields for the radar chart.

   Specify fields for the radar chart

6. Click **Update**. The chart is updated.
7. Click the **Style** tab and change the title, layout, and legend position of the radar chart, as shown in Radar chart.

   Radar chart



8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.17. Create a scatter chart

A scatter chart displays data distribution and aggregation.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A scatter chart consists of x-axes and only one y-axis. You can specify only one dimension, such as product type, for the color legend in a scatter chart. You can specify measures for x-axes and y-axis.

There can be a maximum of 1,000 values in the Dimensions list.

You can specify one to three measures for the x-axes.

You can specify only one measure for the y-axis.

The following example uses the company_sales_record dataset to describe how to use a scatter chart to compare the unit prices and order quantities of different products.

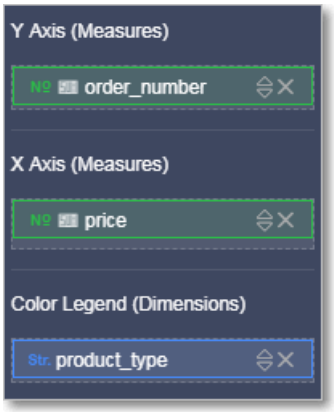
Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click OK.
4. On the dashboard edit page, click the **Scatter Chart** icon.

5. Click the **Data** tab and select the required dimension and measures.

   In the Dimensions list, find and add product_type to the Color Legend (Dim.) field. In the Measures list, find and add price to the X Axis (Mea.) field and order_number to the Y Axis (Mea.) field, as shown in Specify fields for the scatter chart.

   Specify fields for the scatter chart

6. Click **Update**. The chart is updated.
7. Click the **Style** tab and change the title, layout, and legend position of the scatter chart, as shown in Scatter chart.

   Scatter chart

8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.18. Create a bubble chart

A bubble chart displays data distribution and aggregation by placing proportionally sized bubbles in corresponding locations.

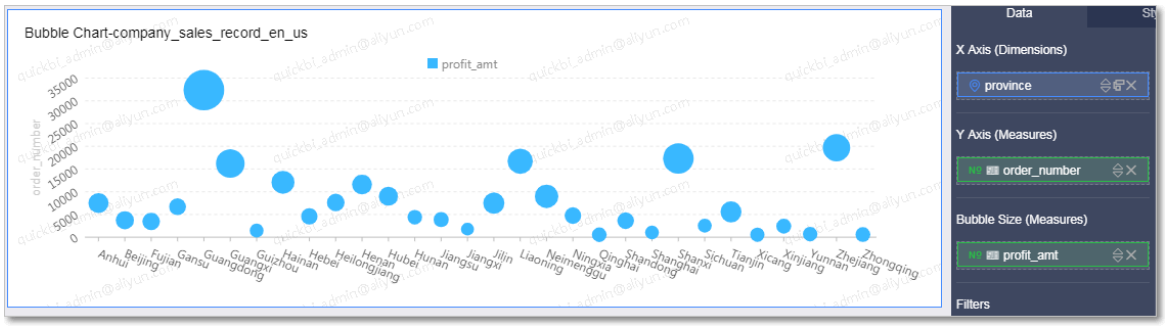
Notes

A bubble chart consists of an x-axis, a y-axis, and bubbles of different sizes. You can specify only one dimension for the x-axis, one measure for the y-axis, and one measure for the bubble size.

The following example uses the company_sales_record dataset to describe how to use a bubble chart to compare the order quantities and profits in different provinces.

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the Bubble Chart icon. A bubble chart appears in the display area of the dashboard.
5. Click the **Data** tab and select the required dimension and measures.

   In the Dimensions list, find and add **province** to the X Axis (Dim.) field. In the Measures list, find and add **order_number** to the Y Axis (Mea.) field and **profit_amt** to the Bubble Size (Mea.) field. Click the **Style** tab and change the title, layout, and legend position of the bubble chart.
6. Click **Update**. The chart is updated.



7. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.

If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.19. Create a funnel chart

A funnel chart is suitable for analyzing standard, long-running, and multi-flow business processes. By comparing business data from different stages, funnel charts allow you to explore and analyze problems. You can also use a funnel chart to show the conversion rates between the stages of a business process, such as the percentage of visitors that become paying customers for a shopping website. Funnel charts are ideal for business process analysis.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A funnel chart consists of tier labels and tier areas. Tier labels are determined by a dimension, such as area. Tier areas are determined by a measure, such as order price.

You can specify only one dimension for tier labels and only one measure for tier areas.

The following example uses the company_sales_record dataset to describe how to use a funnel chart to compare the order price in different regions.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Funnel Chart** icon.
5. Click the **Data** tab and select the required dimension and measure.

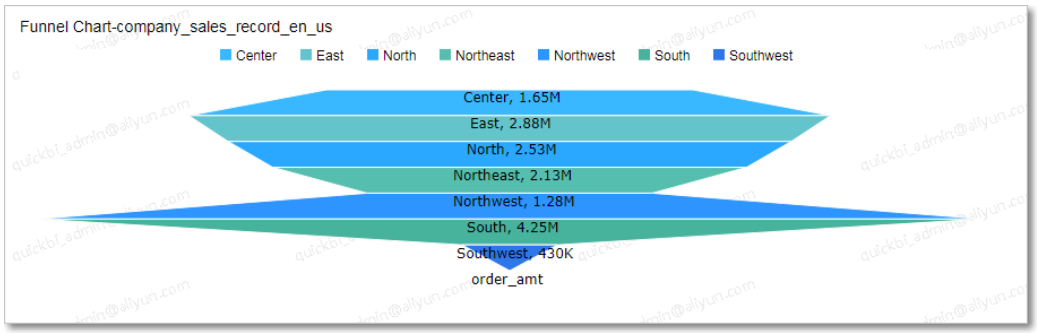
   In the Dimensions list, find and add area to the Tier Labels (Dim.) field. In the Measures list, find and add order_amt to the Tier Area (Mea.) field, as shown in Specify fields for the funnel chart.

   Specify fields for the funnel chart

6. Click **Update**. The chart is updated.
7. Click the **Style** tab and configure the title and legend position of the funnel chart, as shown in Funnel chart.

   Funnel chart

8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.20. Create a kanban

A kanban provides an overview of data such as sales performance. It presents the sales status and management situation, based on which you can quickly formulate solutions, identify issues, and perform troubleshooting.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A kanban consists of metrics and labels. Labels are determined by a dimension, such as area. Metrics are determined by measures, such as order quantity and order price.

You can specify only one dimension for labels and one to ten measures for metrics.

The following example uses the company_sales_record dataset to describe how to use a kanban to compare the order quantities, order price, shipping costs, and profits in different provinces.

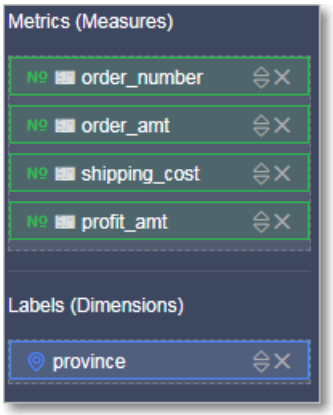
Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Kanban** icon.
5. Click the **Data** tab and select the required dimension and measures.

   In the Dimensions list, find and add province to the Labels (Dim.) field. In the Measures list, find and add order_number, order_amt, shipping_cost, and profit_amt to the Metrics (Mea.) field, as shown in Specify fields for the kanban.

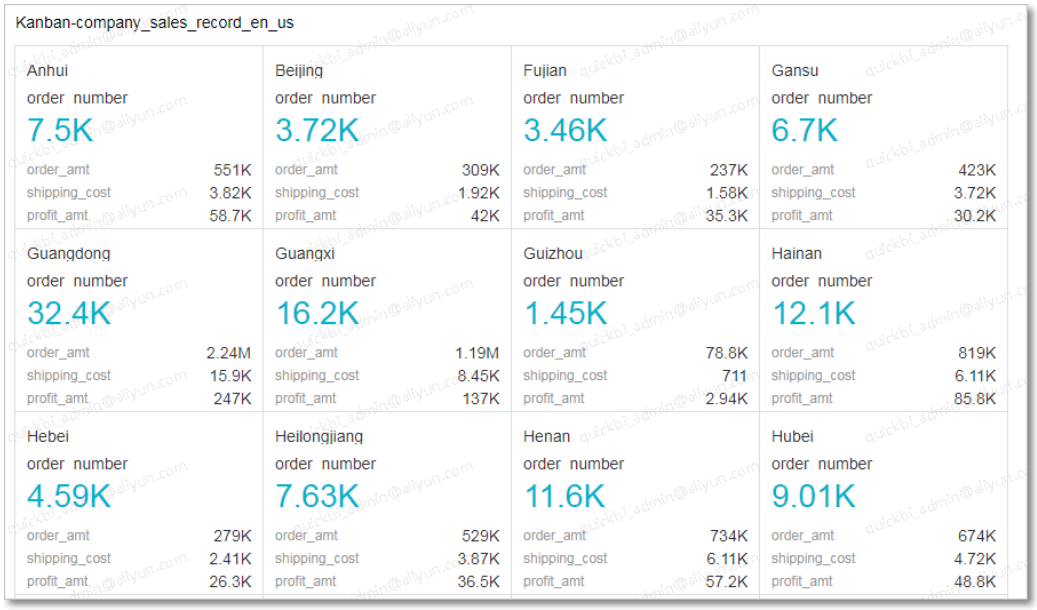
   > **Note** Ensure that you have converted the dimension type of province from String to Geo. For information about how to convert a dimension type, see Edit a dimension.

   Specify fields for the kanban

6. Click **Update**. The chart is updated.
7. Click the **Style** tab, and set the Columns Allowed field to 3, as shown in Kanban.

Kanban



8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.21. Create a trend indicator chart

A trend indicator chart displays multiple indicators over a period of time. By default, the latest data record of each indicator is displayed.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

You can specify only one date dimension for Date (Dimensions) and must specify at least one measure for Indicator (Measures).

The following example uses the company_sales_record dataset to describe how to use a trend indicator chart to compare the order quantities, order price, shipping costs, and profits in different provinces in a specified period of time.

Create a trend indicator chart

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. In the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.

4. On the dashboard edit page, click the **Trend Indicator** icon.
5. In the Dimensions list, find and add order_date(day) to the **Date (Dimensions)** field. In the Measures list, find and add order_number, order_amt, shipping_cost, and profit_amt to the **Indicator (Measures)** field.
6. Click **Update**. The chart is updated.
7. Click the **Style** tab. Configure parameters in the **Basic Information**, **Chart Settings**, **Indicator Settings**, **Functionality Settings**, and **Series Settings** sections.
8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon ( ) in the upper-right corner of the chart and select **Delete**.

Configure parameters on the Style tab

1. In the **Basic Information** section, configure Title, Description, Show Link, and Background.

   > **Note**
   > - This example uses light color as the background color.
   > - If you want to redirect to a report or an external page, select Show Link and specify Link Text and Link Address.

2. In the **Chart Settings** section, select Show Trend by Date, and specify a trend chart style, preview mode, and layout for multiple indicators.
   - If you select Single Choice for Select Preview Mode, the trend chart displays the trend of only one measure indicator. If you select Multiple Choice for Select Preview Mode, the trend chart displays the trend of multiple measure indicators.
   - If you select Displayed in One Line for Layout for Multiple Indicators and the indicators cannot be displayed in one line, you can slide the chart to view all indicators. If you select Displayed in Multiple Lines for Layout for Multiple Indicators, indicators are displayed in multiple lines.
3. In the **Indicator Settings** section, configure Maximum Indicators Each Row. In this example, Maximum Indicators Each Row is set to 4.
4. In the **Functionality Settings** section, configure Enable Indicator Filter and conditional formatting.

   After you select Enable Indicator Filter, an indicator filter icon is displayed in the upper-right corner of the chart. You can click the icon to select the indicators that you want to display.

   Follow these steps to configure conditional formatting:

   i. Select the target measure from the Series drop-down list. Then, select **Enable Indicator Filter** and select icon themes from the drop-down list of the Tag icon.

   ii. Specify the rules for data that you want to mark out, the icon style, and font color.

5. In the **Series Settings** section, set the measure alias, description, prefix and suffix of indicator values, and data display format.
6. On the **Advanced** tab, select Display Secondary Indicator. Select the target measure indicator from the **Select Secondary Indicator** drop-down list, and set the comparison content, display content, and symbol theme.

7.4.4.22. Create a treemap

A treemap compares the proportions of metrics of an object.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A treemap displays labels in different sizes based on the measure. Labels are determined by a dimension, such as packaging. The size of each rectangle label is determined by a measure, such as shipping costs.

You can specify only one dimension for labels and one measure for sizes. The dimension must have a maximum of 12 values.

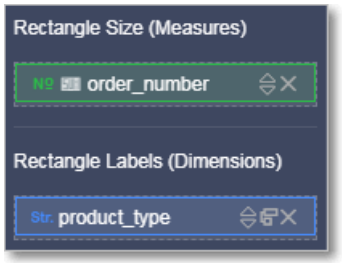
The following example uses the company_sales_record dataset to describe how to use a treemap to compare the order quantities of different products.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. In the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Treemap** icon.
5. Click the **Data** tab and select the required dimension and measures.

   In the Dimensions list, find and add product_type to the Labels (Dim.) field. In the Measures list, find and add order_number to the Size (Mea.) field, as shown in Specify fields for the treemap.

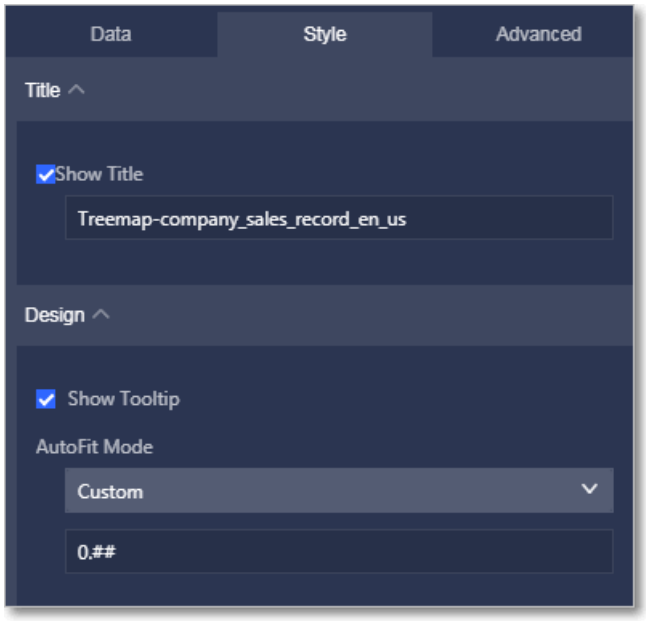
   Specify fields for the treemap

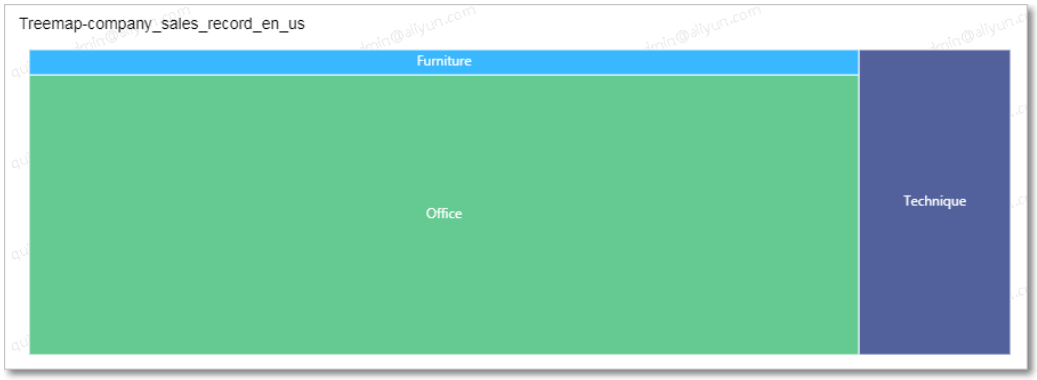
   


6. Click **Update**. The chart is updated.
7. Click the **Style** tab and configure whether to show the title and tooltip of the treemap, as

shown in Treemap.

Treemap





8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.23. Create a polar diagram

A polar diagram displays data changes over a period of time or compares metric values. It is ideal for comparing data of different objects, for example, data across different regions.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

Similar to a pie chart, a polar diagram consists of multiple slices. Slice labels are determined by a dimension, such as area or product type. The arc radius of each slice is determined by a measure, such as order quantity or order price.

You can specify only one dimension for slice labels and only one measure for arc radii.

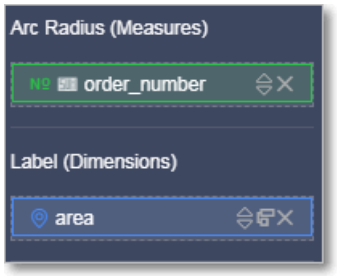
The following example uses the company_sales_record dataset to describe how to use a polar diagram to compare the order quantities in different regions. The number of regions must be greater than or equal to 3 and less than or equal to 12.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Polar Diagram** icon.
5. Click the **Data** tab and select the required dimension and measure.

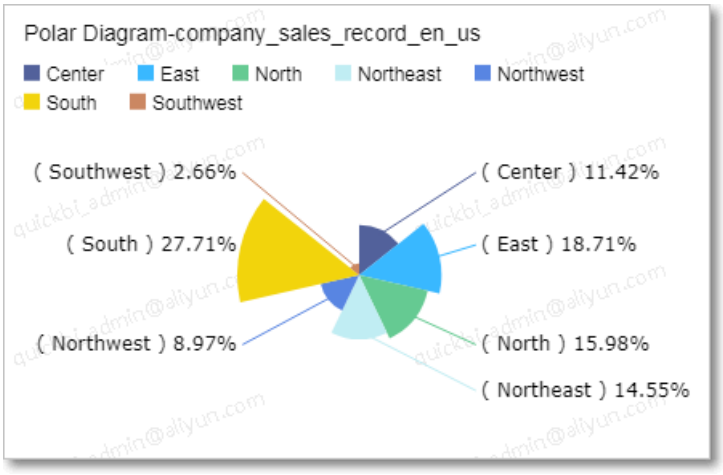
   In the Dimensions list, find and add area to the Label (Dim.) field. In the Measures list, find and add order_number to the Arc Radius (Mea.) field, as shown in Specify fields for the polar diagram.

   Specify fields for the polar diagram

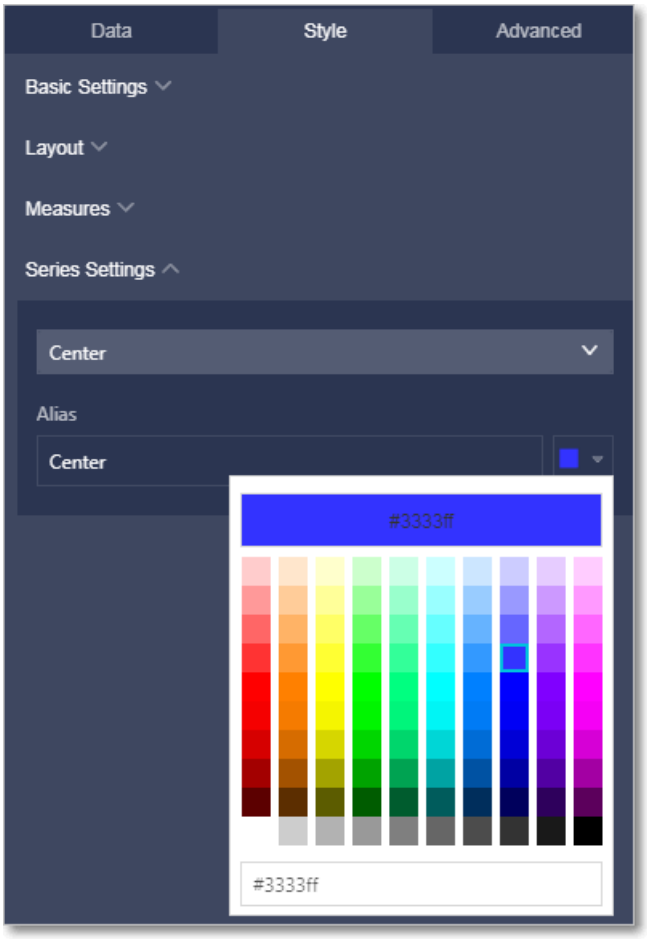
6. Click **Update**. The chart is updated.
7. Click the **Style** tab, change the title of the polar diagram, and specify the legend position, as shown in Polar diagram.

   Polar diagram



8. Click the **Style** tab and change the legend colors in the **Series Settings** section.

   Change legend colors



9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
10. Click **OK** to save the dashboard.

    If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.24. Create a word cloud

A word cloud displays the frequency of words that appear in a dataset. It is ideal for creating user personas and user tags.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A word cloud displays words in different sizes based on their frequency of use. Words are determined by a dimension, such as customer name or product type. The size of each word is determined by a measure, such as profit or unit price.

You can specify only one dimension for words and only one measure for word sizes.

The following example uses the company_sales_record dataset to describe how to use a word cloud to compare the order quantities in different provinces.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Word Cloud** icon.
5. Click the **Data** tab and select the required dimension and measure.

   In the Dimensions list, find and add province to the Word (Dim.) field. In the Measures list, find and add order_number to the Word Size (Mea.) field, as shown in Specify fields for the word cloud.

   > **Note** Ensure that you have converted the dimension type of province from String to Geo. For information about how to convert a dimension type, see Edit a dimension.

   Specify fields for the word cloud

6. Click **Update**. The chart is updated.
7. Click the **Style** tab and change the title of the word cloud, as shown in Word cloud.

   Word cloud

8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.25. Create a tornado-leaned funnel chart

A tornado-leaned funnel chart is the combination of a tornado chart and a funnel chart. A tornado chart compares different metrics between two objects, for example, the income difference and the education level difference between residents in two cities. A funnel chart shows the conversion rates between the stages of business processes, such as the percentage of visitors that become paying customers for a shopping website. Funnel charts are ideal for business process analysis.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A tornado-leaned funnel chart combines the features of a tornado chart and a funnel chart. Assume that you want to compare the percentage of the migrant population, employment rate, and commercial housing transactions in Beijing and Shanghai, and a conversion relationship exists between these metrics. The tornado-leaned funnel chart shows the values of the metrics for the two cities and also the conversion rates between the metrics.

If no conversion relationship exists, the tornado-leaned funnel chart functions the same as a tornado chart. If a conversion relationship exists between metrics and but one comparison subject is defined, the tornado-leaned funnel chart functions the same as a funnel chart.

A tornado-leaned funnel chart consists of comparison subjects and metrics. Comparison subjects are determined by a dimension, such as area or product type. Metrics are determined by measures, such as order quantity and order price.

You can specify only one dimension for the comparison subjects. You must specify at least one measure for metrics.

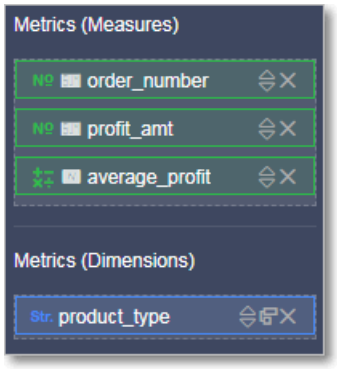
The following example uses the company_sales_record dataset to describe how to use a tornado-leaned funnel chart to compare the order quantities, profits, and average profits of different products.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Tornado-leaned Funnel Chart** icon.
5. Click the **Data** tab and select the required dimension and measures.

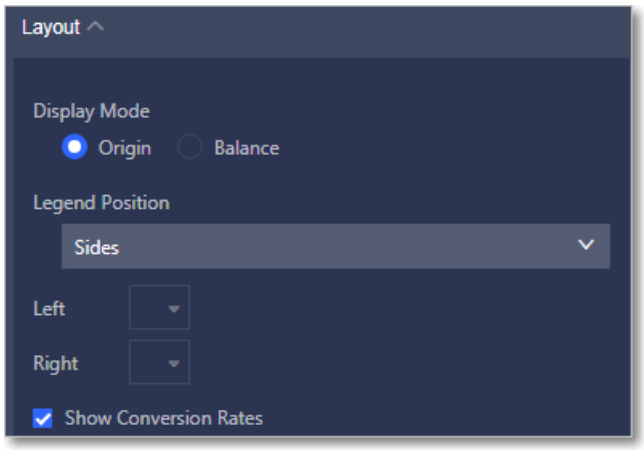
   In the Dimensions list, find and add product_type to the **Metrics (Dim.)** field. In the Measures list, find and add order_number, profit_amt, and average_profit to the **Metrics (Mea.)** field, as shown in Specify fields for the tornado-leaned funnel chart.

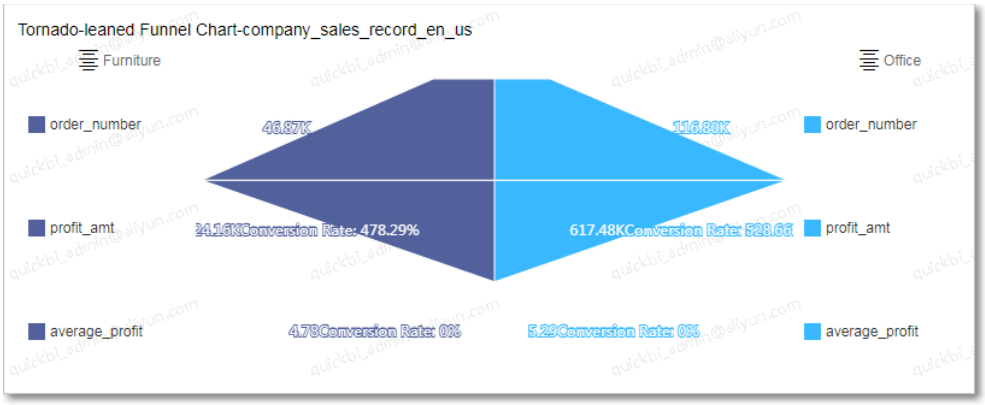
   Specify fields for the tornado-leaned funnel chart

6. Click **Update**. The chart is updated.
7. Click the **Style** tab, change the title, layout, legend position, and background color of the chart, and specify whether to show the conversion rate.
   i. Quick BI provides two layout types for tornado-leaned funnel charts. Select either of them as required.
   ii. In the **Layout** section on the Style tab, change the legend position and background color, and specify whether to show the conversion rate, as shown in Tornado-learned funnel chart.

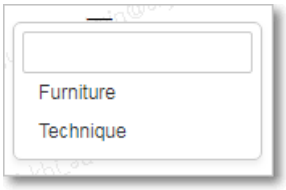
Tornado-learned funnel chart





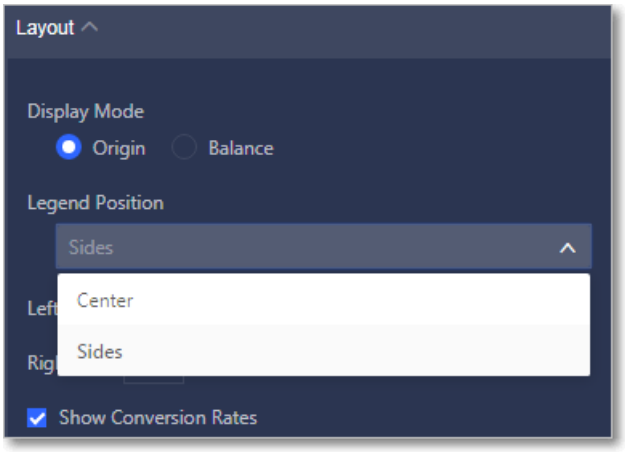
- You can move your pointer over the product type field on the chart to switch to another product, as shown in Switch to another product.

  Switch to another product

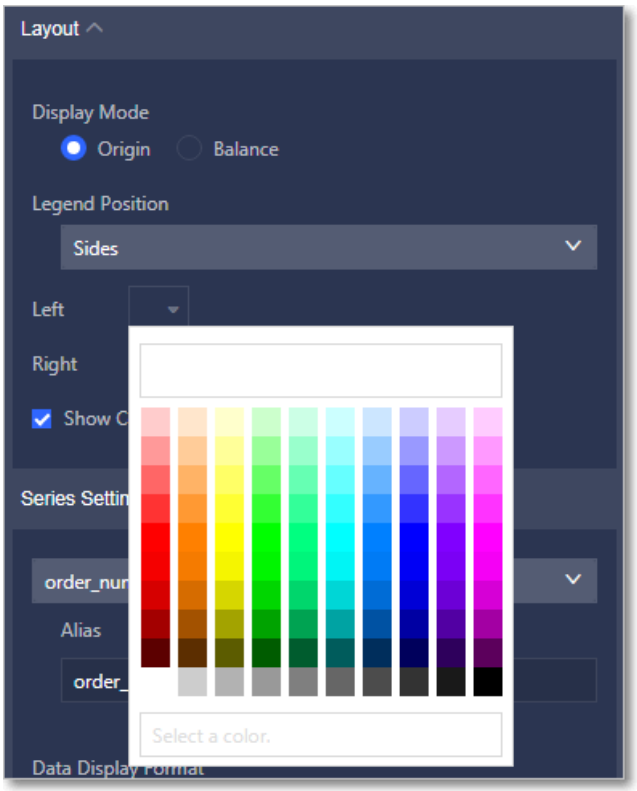
- Change the legend position, as shown in Change the legend position.

  Change the legend position

- Click the Color icon next to Left or Right and select a color from the drop-down list, as shown in Change legend colors.

  Change legend colors

- Hide or show the conversion rate, as shown in Hide or show the conversion rate.

  Hide or show the conversion rate

8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.26. Create a hierarchy chart

A hierarchy chart organizes and displays hierarchical data in a tree structure. It is an implementation of the enumeration method. For example, when you view revenues of cities in a province, the relationships between the province and the cities are displayed in a hierarchical structure. Hierarchy charts are ideal for analyzing data related to organizational structures, such as the staff structure of a company or department structure of a hospital.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A hierarchy chart consists of node metrics and node labels. Node labels are determined by dimensions, such as area and product type. Node metrics are determined by measures, such as order quantity and order price.

This topic uses the following scenarios as examples to describe how to use a hierarchy chart and the filter:

- Scenario 1: Compare the order quantities of different products in the provinces of different regions.
- Scenario 2: View the average profits of different products in different municipalities.

In a hierarchy chart, you must specify at least two dimensions for node labels. Data is displayed clear if these dimensions have a hierarchical relationship. You must specify at least one measure for node metrics.

Scenario 1: Compare the order quantities of different products in the provinces of different regions

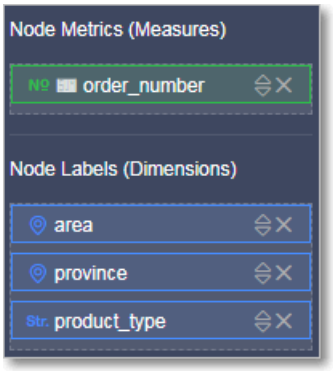
Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click OK.
4. On the dashboard edit page, click the **Hierarchy Chart** icon.
5. Click the **Data** tab and select the required dimensions and measures.

   In the Dimensions list, find and add area, province, and product_type to the Node Labels (Dim.) field. The sequence in which you add these dimensions determines the hierarchical relationship in the chart. In the Measurement list, find and add order_number to the Node Metrics (Mea.) field, as shown in the following figure.

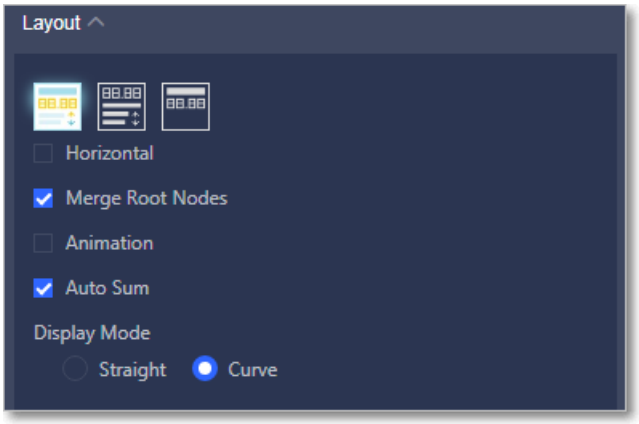
   > **Note** Ensure that you have converted the dimension type of area and province from String to Geo. For information about how to convert a dimension type, see Edit a dimension.

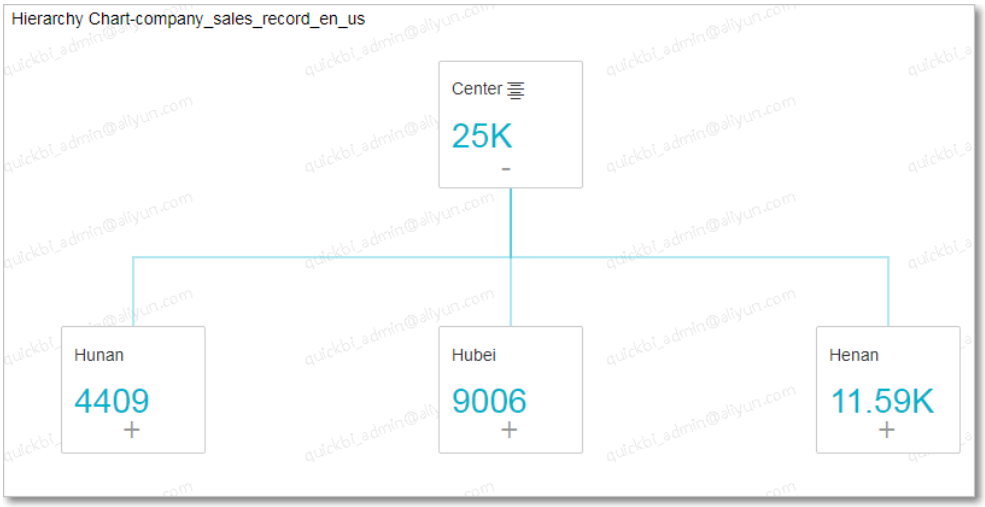
   Specify fields for the hierarchy chart



6. Click **Update**. The chart is updated.
7. Click the **Style** tab and change the title, layout, and design of the chart.
   i. Quick BI provides three layout types for hierarchy charts. You can select a structure and display mode for the chart based on your business needs. The Merge Root Nodes check box is selected by default. In the following example, the **Straight** mode is selected.

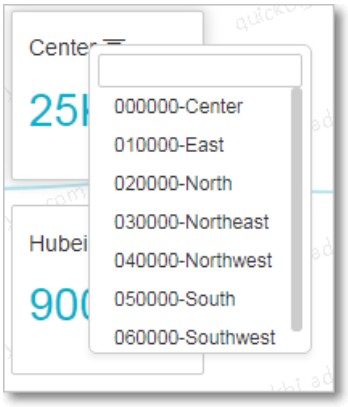
Layout





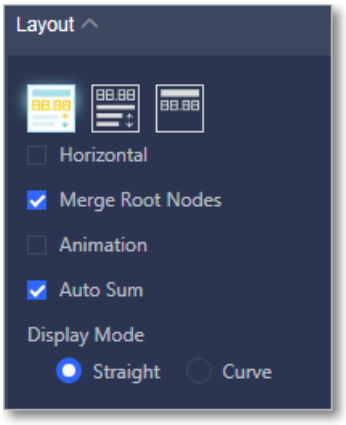
- Move your pointer over the area field in the chart and switch to another region from the drop-down list that appears, as shown in the following figure.

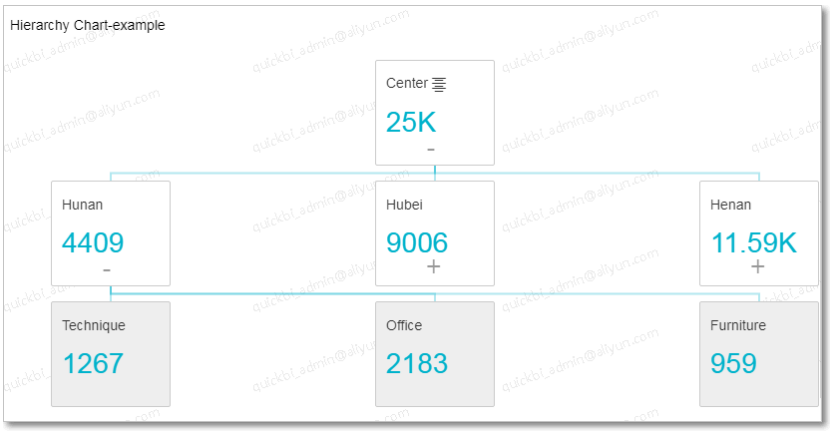
  Switch to another region

- Click the minus sign (-) or plus sign (+) to fold or unfold the child nodes.
- In the Layout section, if you select **Auto Sum**, the chart displays the total amount of each node, as shown in the following figure.

  Auto Sum

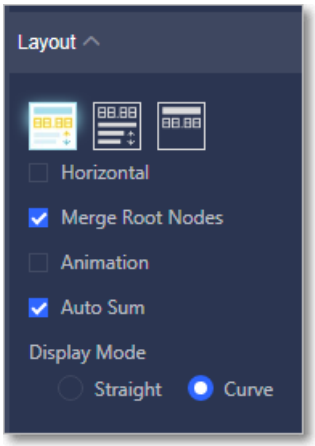
  
  


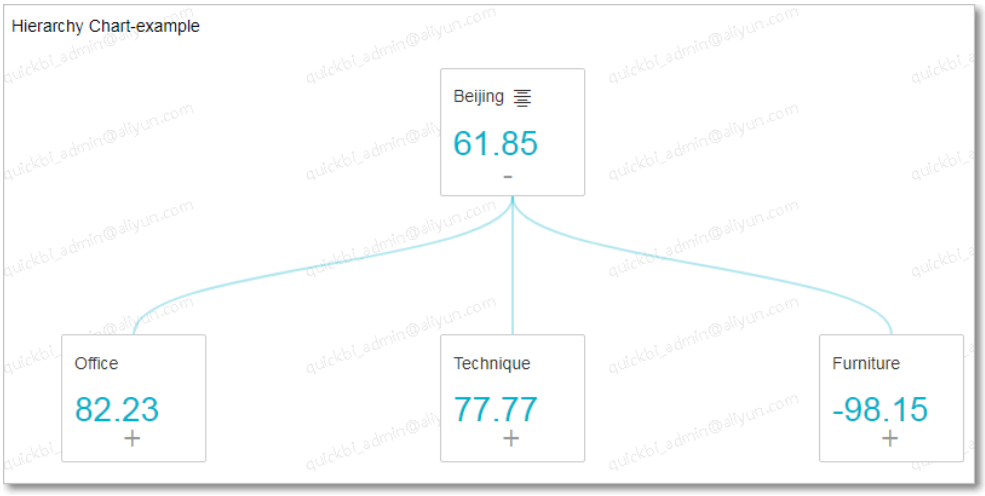


ii. In the Design section, you can configure the Levels field to specify the level of data to be displayed. You can also set a primary path, which is displayed in a different color in the chart. You can select the Show Filter Bar check box to add a toolbar to the chart. This allows you to edit the chart in preview mode or in the dashboard.

In the following example, the Primary Path parameter is set to order_number, the Sort parameter is set to Ascend, the Show Filter Bar check box is selected, and the **Curve** display mode is selected, as shown in the following figure.

Hierarchy chart





8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

   By default, the dashboard is saved to the **My Items** tab on the Dashboards page.

Scenario 2: View the average profits of different products in different municipalities

Context

Data modeling may be required in this scenario. For information about data modeling, see Add a calculated field.

Procedure

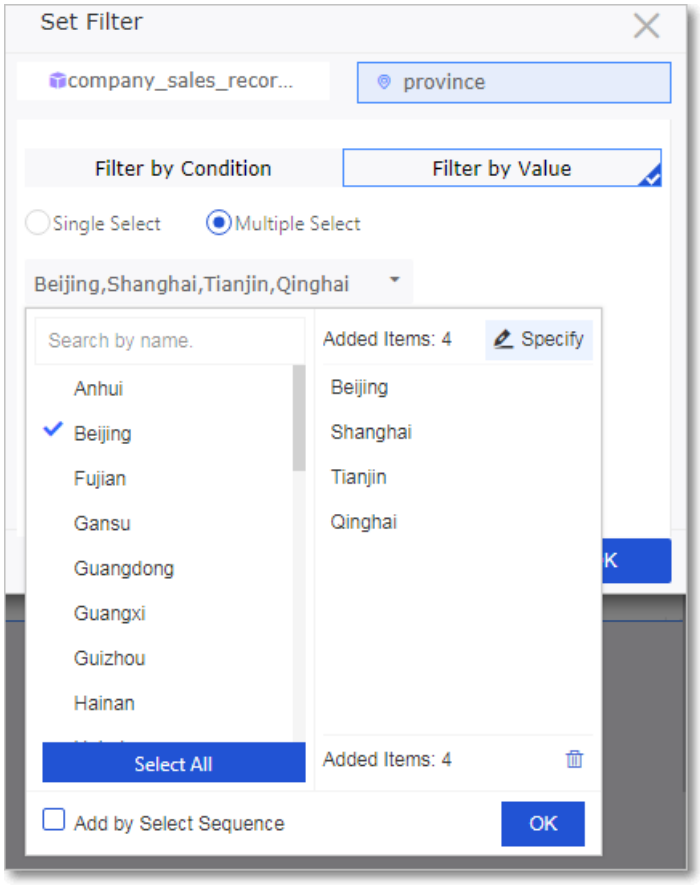
1. In the Dimensions list, find and add province to the Filters field.

   This way, you can filter municipalities.

2. Click the **Filter** icon. In the Set Filter dialog box that appears, select **Filter by Value** and **Multiple Select**, as shown in the following figure.

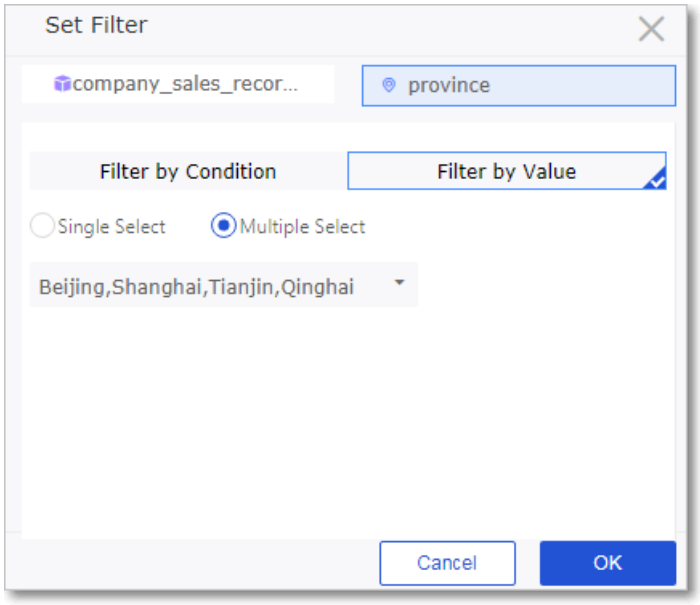
   The system automatically lists all available options of the province field in the drop-down list.

   Filter by Value



3. Select the municipalities or manually enter their names.
4. Click **OK** to set the filter condition, as shown in the following figure.

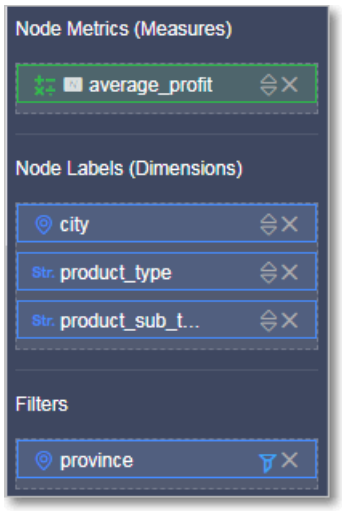
   Set the filter condition



5. In the Dimensions list, find and add city, product_type, and product_sub_type to the Node Labels (Dim.) field, as shown in the following figure.

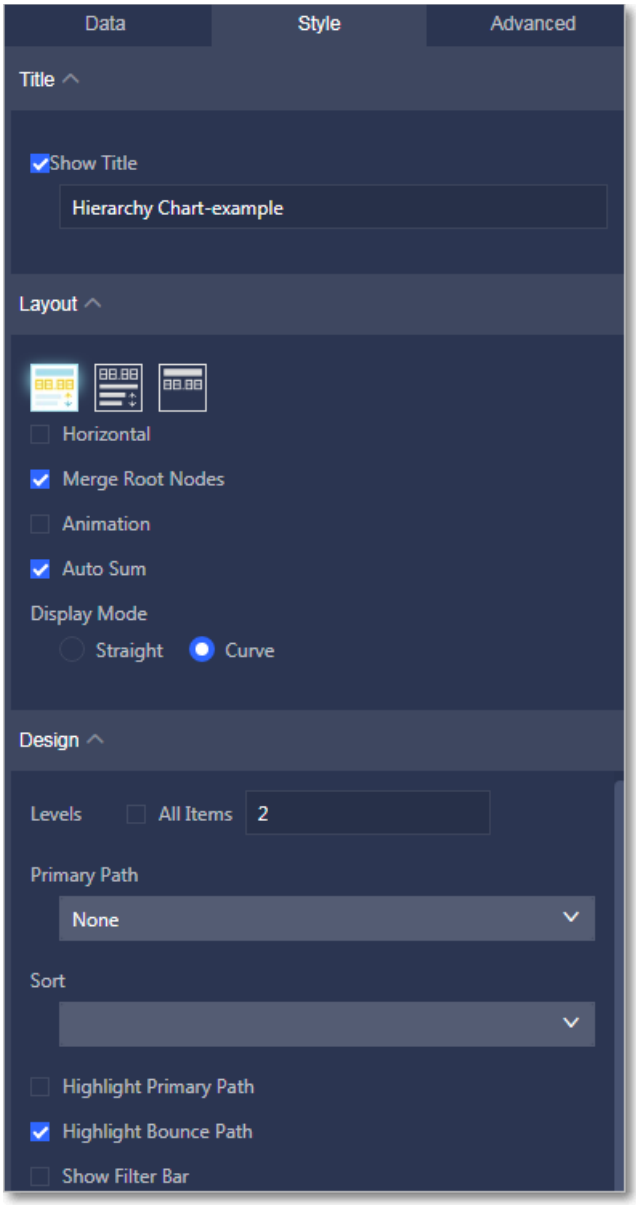
   The sequence in which you add these dimensions determines the hierarchical relationship displayed in the chart. In the Measures list, find and add average_profit to the Node Metrics (Mea.) field.

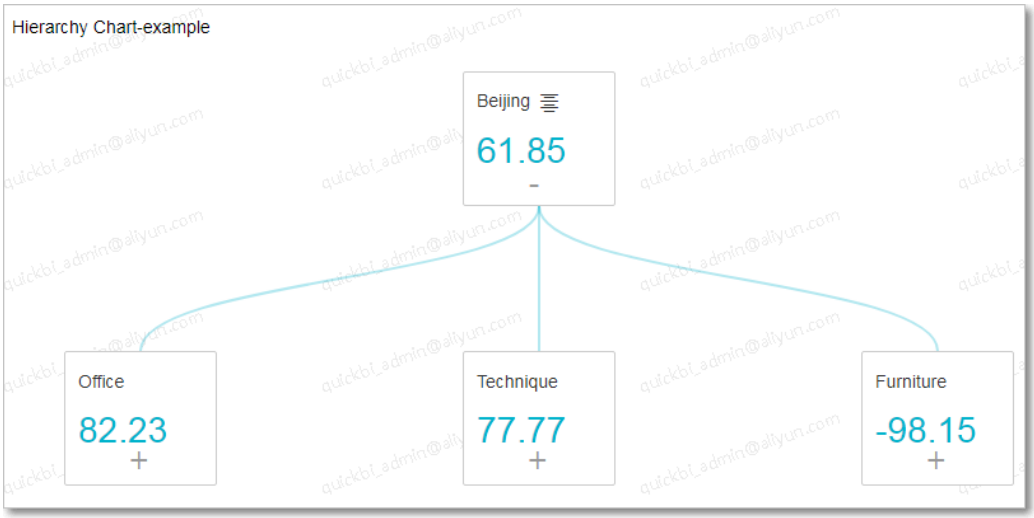
   Specify fields for the hierarchy chart



6. Click **Update**. The chart is updated.
7. Click the **Style** tab and change the title, layout, and design of the chart, as shown in the following figure.

   ## Hierarchy chart





8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a

name for the dashboard.

9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.4.4.27. Create a flow analysis chart

A flow analysis chart shows the data flow among source, central, and destination nodes.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A flow analysis chart supports three-level dimensions, which are used to specify Central Node (Dimensions), Node Type (Dimensions), and Node Name (Dimensions). A measure is used to specify Node Indicator (Measures).

- You can specify only one dimension for each of the Central Node (Dimensions), Node Type (Dimensions), and Node Name (Dimensions) fields. The values of the Node Type (Dimensions) field include **source**, **center**, or **goal**, corresponding to source, central, and destination nodes, respectively. You can specify only one measure for the Node Indicator (Measures) field. After you select a central node, the nodes whose type is source are regarded as source nodes and the nodes whose type is goal are regarded as destination nodes. The ratio is calculated by dividing the number of unique visitors (UVs) of the source nodes by the number of UVs of the central node.
- For more information, see Flow analysis-demo table.

> **Note** The data of nodes whose type is not **source**, **center**, or **goal** is filtered out. If the name for a node is left blank, **Unknown Source** is used as the name when the node type is **source** and **Unknown destination** is used when the node type is **goal**.

Create a flow analysis chart

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the page_source_target_day dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Flow Analysis** icon.
5. Click the **Data** tab and select the required dimensions and measure.

   In the Dimensions list, find and add the required dimensions to the Central Node (Dimensions), Node Type (Dimensions), and Node Name (Dimensions) fields. In the Measures list, find and add the required measure to the Node Indicator (Measures) field.
6. Click **Update**. The chart is updated.
7. Click the **Style** tab and change the title and data display format of the chart.

8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, specify a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

Configure parameters on the Style tab

1. In the **Basic Information** section, configure Title, Description, Show Link, and Background. This example uses a dark color as the background color.

   > **Note** If you want to redirect to a report or an external page, select Show Link and specify Link Text and Link Address.

2. In the **Series Settings** section, configure Alias and Data Display Format for a measure.

7.4.4.28. Create a sankey diagram

A sankey diagram is a flow diagram in which the branch width is proportional to the flow rate. It shows the data flow between two groups of values. It is ideal for visualization analysis of energy, material composition, and finance data.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

You can specify two to five dimensions, such as province and product type, for the node type. You can specify one measure, such as order quantity, at most for the node height.

The following example uses the company_sales_record dataset to describe how to use a sankey diagram to compare the order quantities and order levels of products in different regions.

Create a sankey diagram

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click OK.
4. On the dashboard edit page, click the **Sankey Diagram** icon.
5. Click the **Data** tab and select the required dimensions and measure.

   In the Dimensions list, find and add area and order_level to the **Node Type (Dimensions)** field.

   In the Measures list, find and add order_number to the **Node Height (Measures)** field.
6. Click **Update**. The chart is updated.
7. Click the **Style** tab and modify the basic information, style configuration, and series settings

of the chart.

8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, specify a name for the dashboard.
9. Click **OK** to save the dashboard.

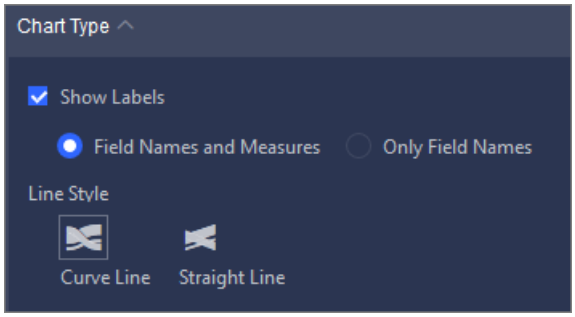
   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

Configure parameters on the Style tab

1. In the **Basic Information** section, you can configure the title, whether to show the link, and the background color. In this example, **Light Color (Default)** is selected for Background.

   > **Note** If you want to redirect to a report or an external page, select **Show Link** and specify Link Text and Link Address.

2. In the **Chart Type** section, configure Show Labels and Line Style.



3. In the **Series Settings** section, configure Alias and Data Display Format for the measure. In this example, **AutoFit** is selected for Data Display Format.

7.4.4.29. Create a ranking board

A ranking board shows the ranking of the Top N objects from a specific measure in descending order. It objectively reflects the strengths of objects of the same category.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

You can specify only one dimension, such as area or product type, for the category, and only one measure, such as order quantity or profit, for indicators. A ranking board shows 20 records by default and can show up to 50 records.

The following example uses the company_sales_record dataset to describe how to use a ranking board to compare the order quantities in different areas.

Create a ranking board

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.

3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click OK.
4. On the dashboard edit page, click the **Ranking Board** icon.
5. Click the **Data** tab and select the required dimension and measure.

   In the Dimensions list, find and add **area** to the **Category (Dimensions)** field.

   In the Measures list, find and add **order_number** to the **Indicator (Measures)** field.
6. Click **Update**. The chart is updated.
7. Click the **Style** tab and modify the basic information, style configuration, and series settings of the chart.
8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, specify a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

Configure parameters on the Style tab

1. In the **Basic Information** section, configure the title, color, and whether to show the link.

   > **Note** If you want to redirect to a report or an external page, select **Show Link** and specify Link Text and Link Address.
2. In the **Style Settings** section, configure Show Column Name, Theme for Top 3 Items, Data Display Format, Value Alignment, and Bar Color.
3. In the **Functionality Settings** section, configure conditional formatting.
   i. Select **Enable conditional formatting**, and select icon themes from the drop-down list of **Tag icon**.
   ii. Specify the rules for data that you want to mark out, the icon style, and font color.
4. In the **Series Settings** section, specify the alias for the measure or dimension, alignment mode, and data display format.

7.4.4.30. Create a ticker board

A ticker board displays KPI data and allows you to customize style settings such as the background color.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

Ticker boards can display only metrics (measures). The following example uses the company_sales_record dataset to describe how to use a ticker board to show order quantities.

Create a ticker board

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click Ok.
4. On the dashboard edit page, click the **Ticker Board** icon.
5. Click the **Data** tab. In the Measures list, find and add **order_number** to the **Indicator (Measures)** field.
6. Click **Update**. The chart is updated.
7. Click the **Style** tab and modify the basic information, style settings, function configuration, and series settings of the chart.
8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, specify a name for the dashboard.
9. Click **OK** to save the dashboard.

   If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

Configure parameters on the Style tab

1. In the **Basic Information** section, specify Show Title and Description, Show Link, and Background.

   You can select Light Color (Default), Color Palette, or Image URL for Background. Quick BI provides six color palettes.

   > **Note** If you want to redirect to a report or an external page, select **Show Link** and specify Link Text and Link Address.

2. In the **Style Settings** section, specify the font colors for data labels and primary indicator values and the indicator position in an indicator block.
3. In the **Functionality Settings** section, configure conditional formatting.
   i. Select **Enable conditional formatting**, and select icon themes from the drop-down list of **Tag icon**.
   ii. Specify the rules for data that you want to mark out, the icon style, and font color.
4. In the **Series Settings** section, specify the measure alias, prefix, suffix, and data display format.

7.4.5. Full Screen mode

This topic describes the basic features of the Full Screen mode.

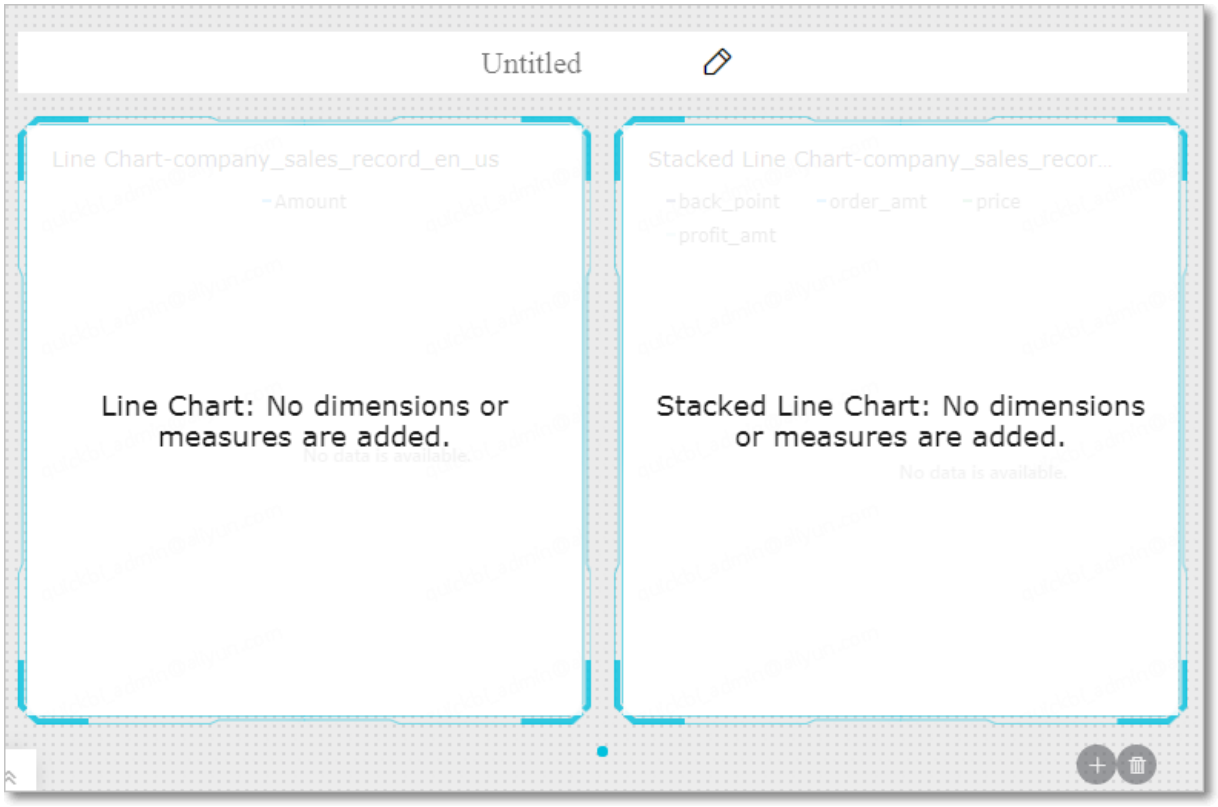
The Full Screen mode allows you to perform the following operations in the display area of a dashboard.

- Adjust chart positions
- Add a subscreen

- View chart data
- Delete a chart
- Change chart types
- Configure page settings

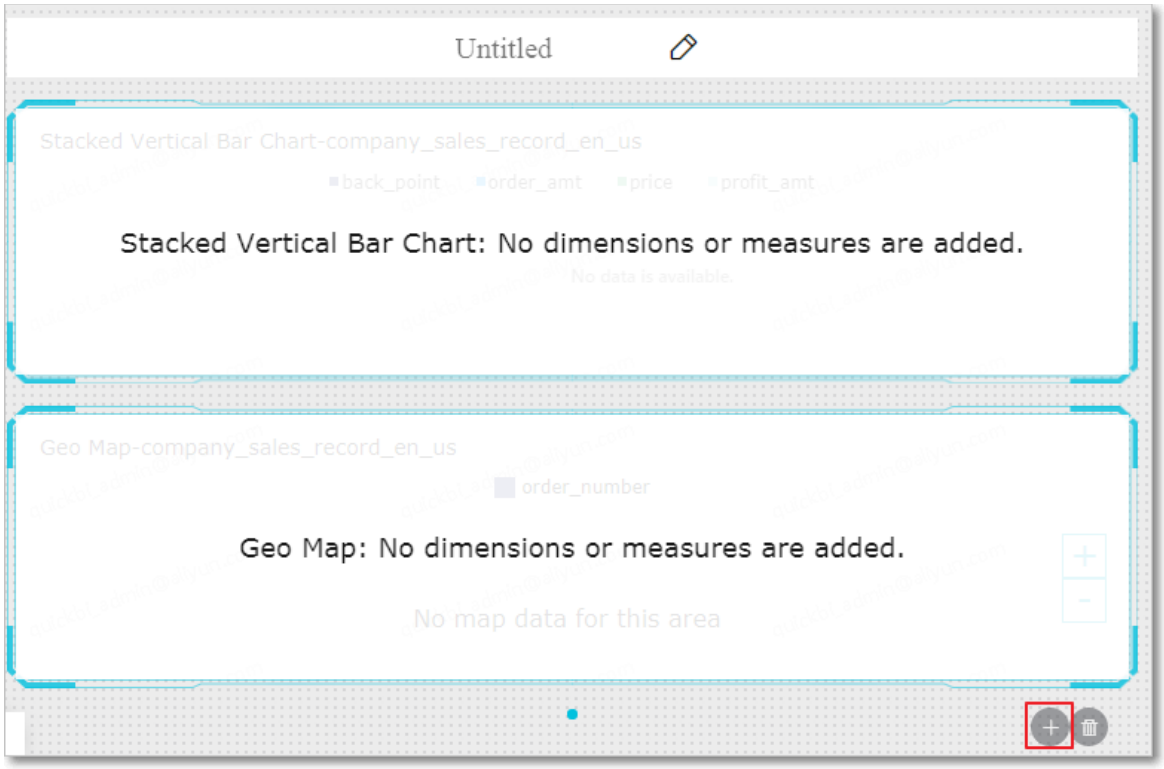
Adjust chart positions

If you create a dashboard by using the Full Screen mode and you have created only one chart, the chart covers the entire display area. If you have created multiple charts, you can click the Move icon (an arrow cross symbol), and drag the chart to the target position.

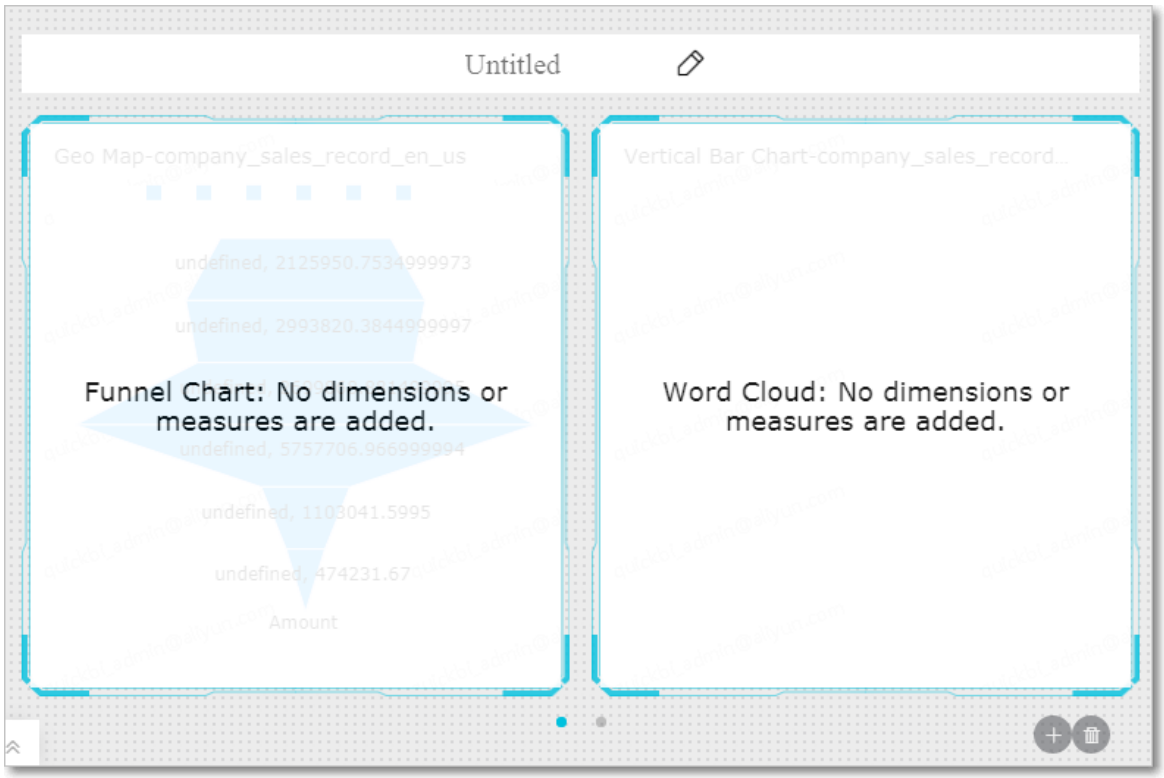


Add a subscreen

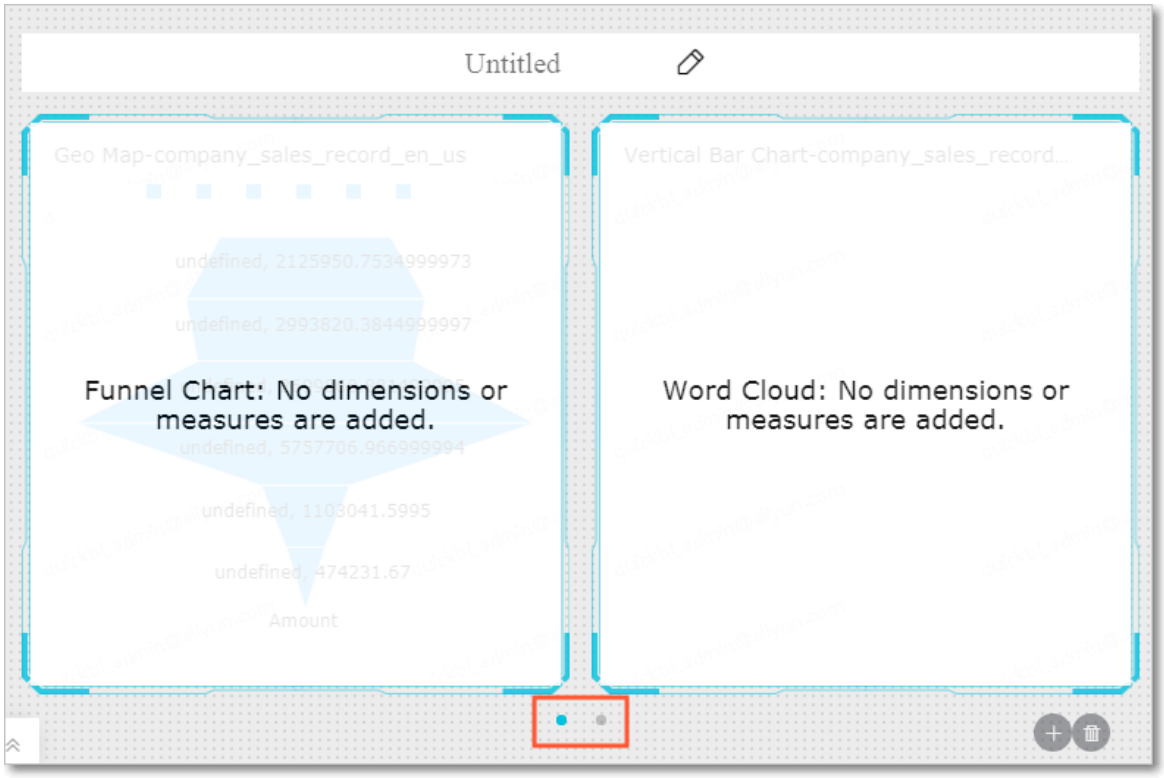
1. Click the plus sign in the lower-right corner.



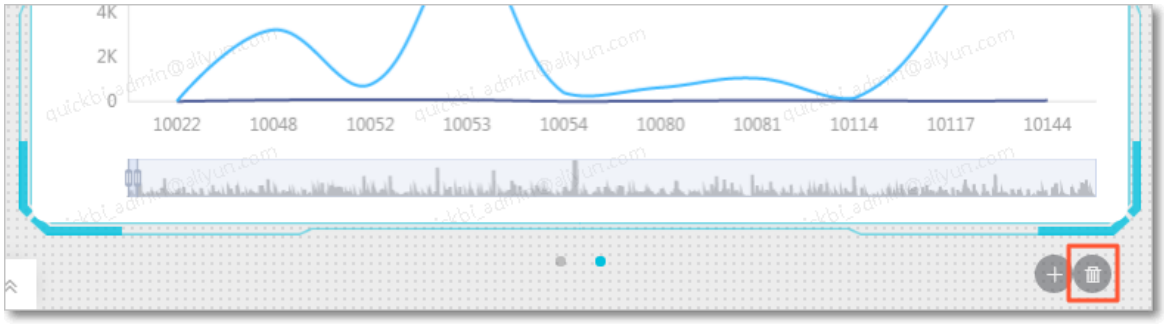
2. Add a chart to the subscreen.



3. Click the **Switch Screen** icon to switch from the current screen to another.



4. Click the **Delete** icon in the lower-right corner to delete a subscreen.



View data, export and view SQL statements, and delete a chart

1. In the target chart, click the More icon in the upper-right corner.
2. Select **View Data** to view chart data.
3. Select **Export** to export the chart data to a local device.
4. Select **View SQL Statements** to view the SQL statements.
5. Select **Delete** to delete the chart.

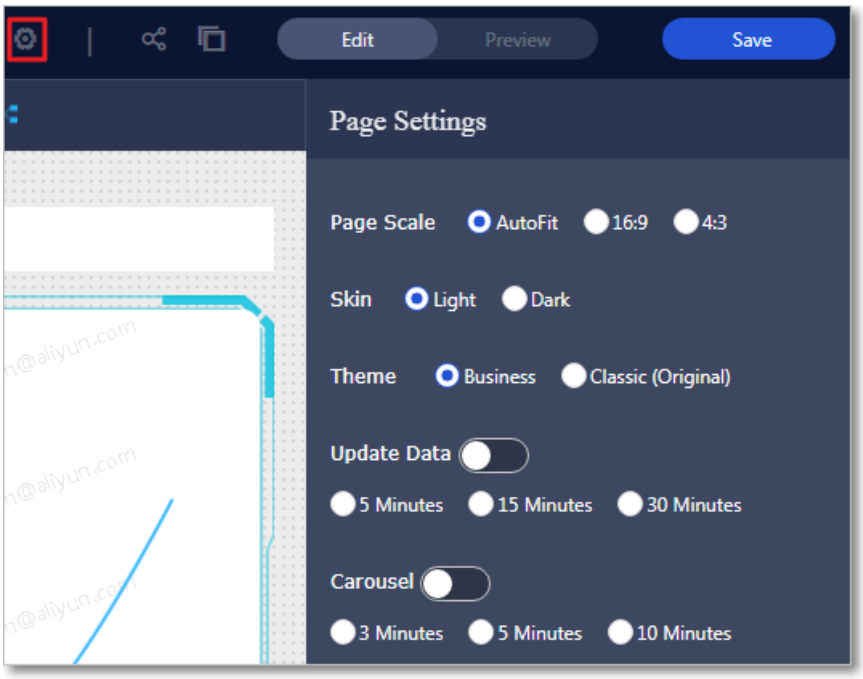
Change chart types

1. Select a chart in the display area of a dashboard.
2. In the Graphic Design area, click **Change Chart Type**.
3. Click the chart type you want.

> **Note**
>
> If the chart type fails to change, the fields of the current chart do not match those of the target chart. You must manually adjust fields before you change the chart type. The system provides instructions to help you adjust fields based on the current and target chart types. To change the chart type, you need to follow the instructions to adjust the dimensions and measures.

Page settings

You can click the **Page settings** icon to set the page scale, skin color, theme, data update interval, and time interval of data carousel.



7.4.6. Search for a dashboard

This topic describes how to search for a specific dashboard.

Prerequisites

- The Quick BI service is purchased.
- One or more dashboards are created.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Dashboards**.
3. Enter a keyword in the search box to search for the target dashboard.

7.4.7. Create a dashboard folder

This topic describes how to create a dashboard folder.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Dashboards**.
3. On the Dashboards page, click **Create Folder** in the upper-right corner.
4. In the **Create Folder** dialog box that appears, specify a name for the folder and click **OK**.

7.4.8. Rename a dashboard folder

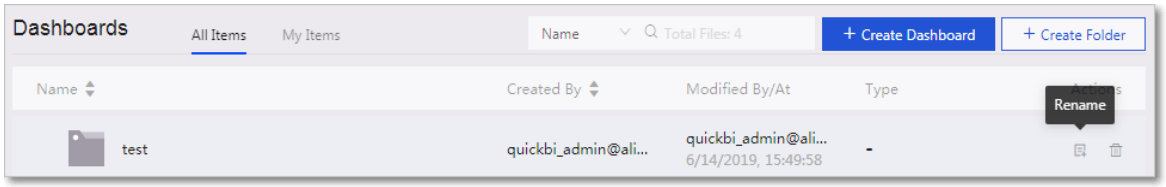
This topic describes how to rename a dashboard folder.

Prerequisites

- The Quick BI service is purchased.
- A dashboard folder is created. For information about how to create a dashboard folder, see Create a dashboard folder.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Dashboards**.
3. On the Dashboards page, find the dashboard folder you want to rename.
4. Click the **Rename** icon in the Actions column.



5. In the dialog box that appears, enter a new folder name and click **OK**.

7.4.9. Share a dashboard

This topic describes how to share a dashboard with other users.

Prerequisites

- The Quick BI service is purchased.
- A dashboard is created.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Dashboards**.
3. On the Dashboards page that appears, right-click the dashboard you want to share with others.

4. Select **Share**.
5. Specify Scope, Permission Type, and Expiration Date in the side pane that appears, as shown in Share a dashboard.

   Share a dashboard

   
   > **Note**
   > - In the Basic Settings section of the right-side Page Settings pane, select **Allow Download**. If you want to download a report, you must set Permission Type to **View and export**.
   > - You can set Scope to All Users, User Groups, or Users.
   > - Users can be authorized in the three scopes at the same time. Users who are authorized in one of these scopes are granted the corresponding permissions.

6. Click **Save**.

7.4.10. Make a dashboard public

After you make a dashboard public, users can access the dashboard by using a shared link.

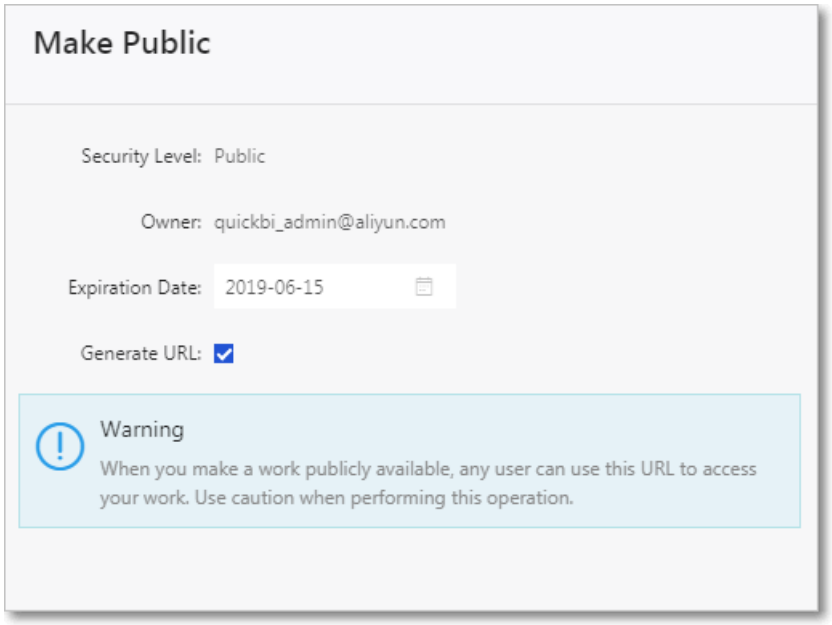
Prerequisites

- The Quick BI service is purchased.
- A dashboard folder is created. For information about how to create a dashboard folder, see Create a dashboard folder.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Dashboards**.
3. On the Dashboards page, right-click the dashboard you want to make public or click the More icon in the Actions column corresponding to the dashboard you want to make public.
4. Select **Make Public**.
5. Set an expiration date and click **Make Public**, as shown in Make a dashboard public.

   Make a dashboard public



7.5. Workbooks

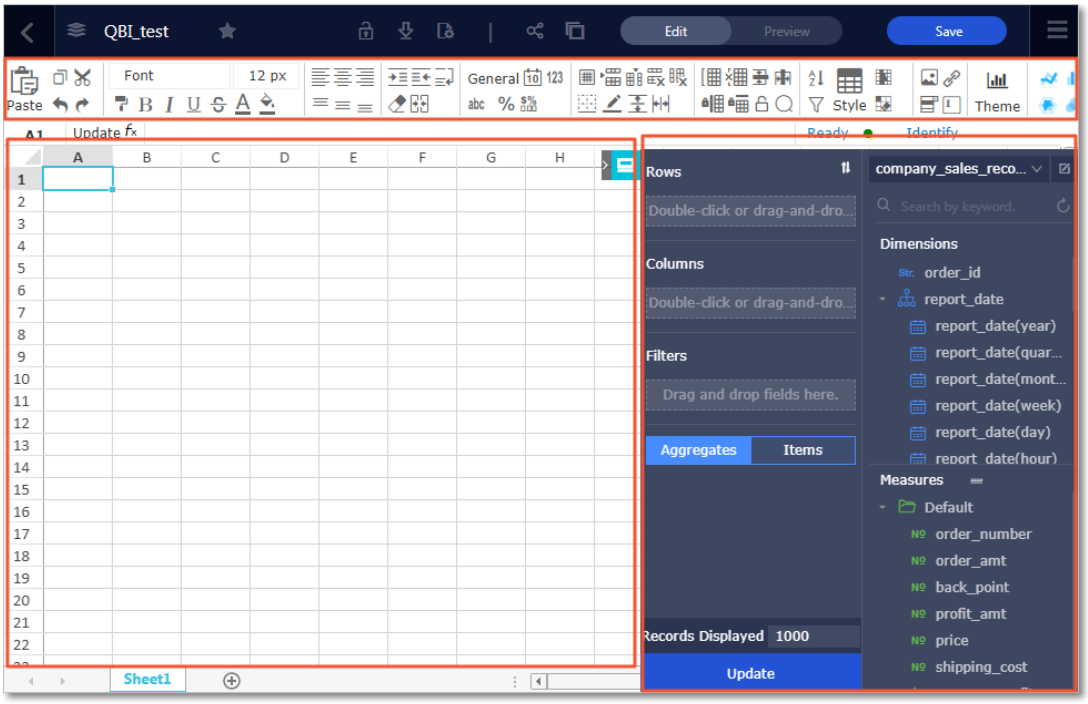
7.5.1. Overview

On the workbook edit page, you can filter and query data in a dataset. You can also visualize data by using different types of charts.

The workbook edit page contains three areas, as shown in Workbook edit page.

- Dataset selection area
- Workbook configuration area
- Workbook display area

Workbook edit page



- Dataset selection area: In this area, you can switch the current dataset to another. The fields of each dataset are displayed in the Dimensions and Measures lists based on the data types preset in the system. You can select dimensions and measures based on the data required by the chart.
- Workbook configuration area: In this area, you can select a chart type, and set the color, font, and data format of cells as needed.
- Workbook display area: In this area, you can reprocess data based on the displayed data in cells and reference data.

7.5.2. Create a workbook

This topic describes how to create a workbook.

Prerequisites

The Quick BI service is purchased.

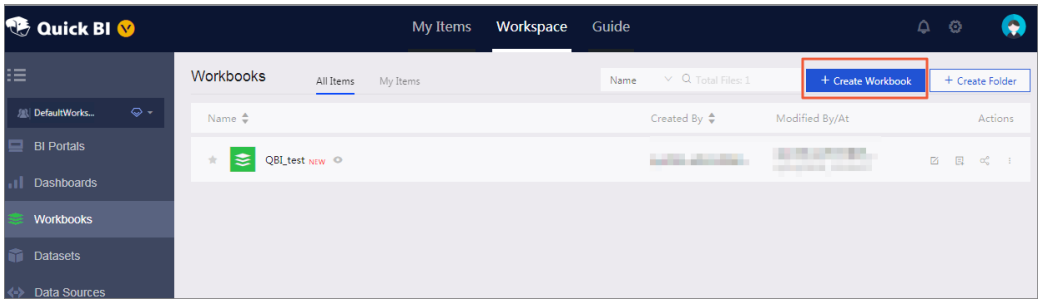
Context

You can create workbooks only in workspaces. Personal workspaces do not support workbooks.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks**.
3. On the **Workbooks** page, click **Create Workbook** to go to the workbook edit page, as shown in Create a workbook.

   Create a workbook



4. Click **Save**. In the Save Workbook dialog box that appears, enter a name for the workbook and set the location where you want to store the workbook, and click **OK**.

7.5.3. Switch to another dataset

This topic describes how to switch from the current dataset to another dataset.

Prerequisites

The Quick BI service is purchased.

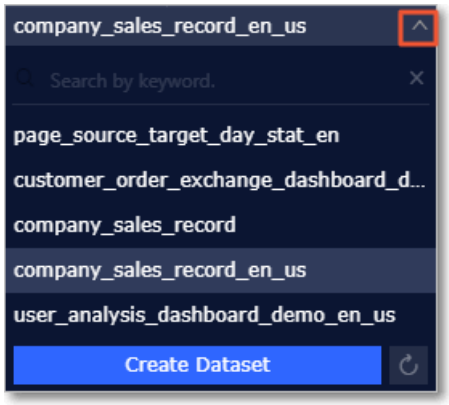
Context

If you cannot find the required dataset, go back to the dataset management page and ensure that the dataset has been created. For information about how to create a dataset, see Create datasets.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. Click the workbook you want to edit.
4. On the workbook edit page, click the drop-down arrow. In the drop-down list, select or search for the dataset you want to switch to, as shown in Switch to another dataset.

Switch to another dataset



7.5.4. Search for a dimension or measure

This topic describes how to search for a specific dimension or measure.

Prerequisites

The Quick BI service is purchased.

Context

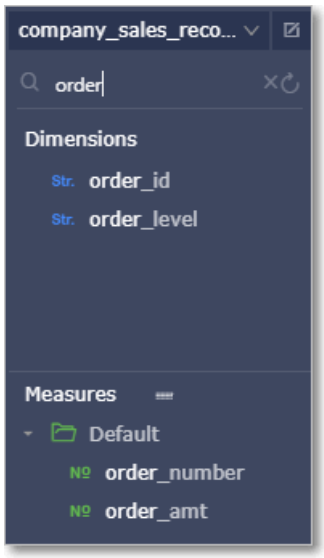
After you select a dataset, the system displays the dimensions in the Dimensions list and measures in the Measures list.

For information about how to edit dimensions and measures, see Edit a dimension and Edit a measure.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. Enter a keyword of the field you want to search in the search box.
4. Click the Search icon to search for the field.

Search for a field



7.5.5. Set the font

You can set a font for a specific text, such as the font size, font color, font style, and background color.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the

Workbooks page.

3. On the Workbooks page, click the workbook that you want to set the font.

   For information about how to create a workbook, see Create a workbook.

4. Click the specific icon to set the font size and style. Set the font style
   - Click the font area.
   - In the drop-down list that appears, select the target font, as shown in Select a font.

     Select a font

   Set the font size
   - Click the font size area.
   - In the drop-down list that appears, select the target font size, as shown in Select a font size.

     Select a font size

7.5.6. Set the alignment mode

You can set the alignment mode to adjust the layout of text.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. On the Workbooks page, click the workbook that you want to set the alignment mode.

   For information about how to create a workbook, see Create a workbook.

4. Click the specific alignment mode icon to adjust the layout of the text, as shown in Alignment modes.

   Alignment modes

7.5.7. Set text and number formats

You can set the format to display texts and numbers in a workbook.

Prerequisites

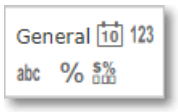
The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. On the Workbooks page, click the workbook for which you want to set the text and number format.

   For information about how to create a workbook, see Create a workbook.
4. Click the specific icon to set the format, as shown in Display formats.

   Display formats

Parameter	Description
General	The General format directly displays numbers the way that you type them.
Date	The Date format displays data in the YYYY-MM-DD format.
Number	The Number format aligns numbers along the right side. It rounds numbers to two decimal places. You can double-click the cell or adjust the column width to show the complete number.
String	The String format aligns strings along the left side. You can double-click the cell or adjust the column width to show the complete string.
Percentage	The Percentage format aligns numbers along the right side. It rounds numbers to two decimal places. You can double-click the cell or adjust the column width to show the complete number.

7.5.8. Set the style, cell, and pane

You can change the style, cell, and pane settings to adjust the gridlines, row heights, and border styles.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.

2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. On the Workbooks page, click the workbook for which you want to change the style, cell, or pane settings.

   For information about how to create a workbook, see Create a workbook.
4. On the workbook edit page, click the specific icons to adjust the layout of the workbook, as shown in Style, cell, and pane settings.

   Style, cell, and pane settings

Parameter	Description
Gridlines	The gridlines are displayed by default. You can click the **Gridlines** icon to hide gridlines.
Borders	You can click the Borders icon to display a top border, bottom border, left border, right border, outside borders, or all borders, or remove all borders.
Border Color	You can specify a color for the borders.
Insert and Delete	You can insert rows and columns into a workbook, or delete rows and columns from a workbook. You can also insert and delete a workbook.
AutoFit Column Width	Double-click the AutoFit Column Width icon. The column width is automatically adjusted.
AutoFit Row Height	Double-click the AutoFit Row Height icon. The row height is automatically adjusted.

7.5.9. Insert images, hyperlinks, and drop-down list boxes

This topic describes how to insert images, hyperlinks, and drop-down list boxes into a workbook.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. On the Workbooks page, click the workbook for which you want to insert images, hyperlinks,

or drop-down list boxes.

For information about how to create a workbook, see Create a workbook.

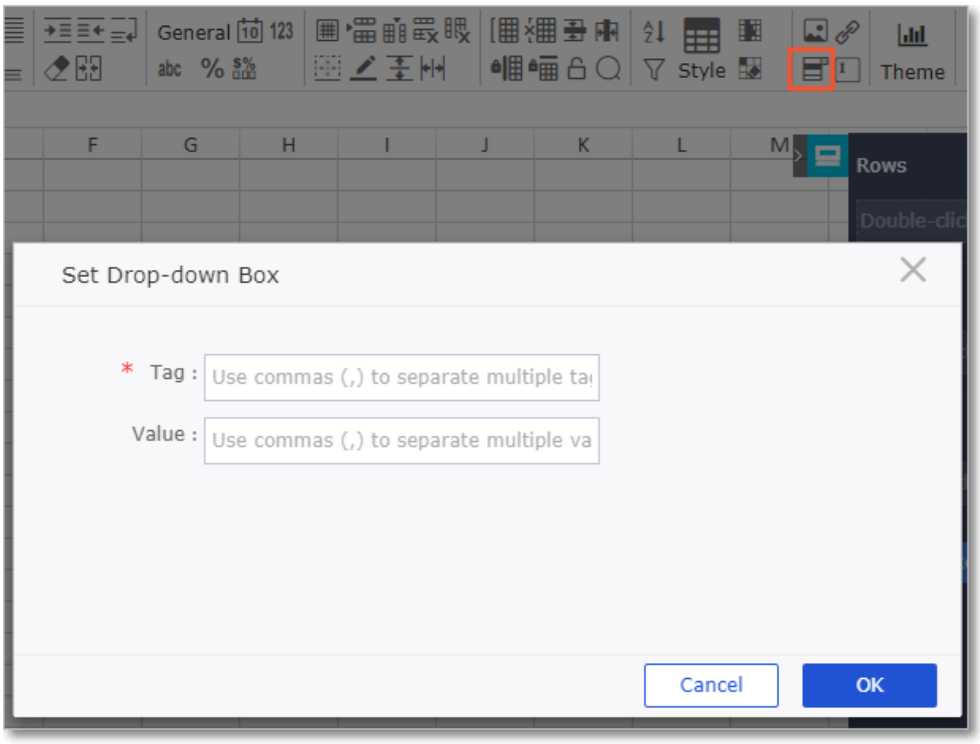
- Insert an image
  - Click the **Upload Image** icon.
  - In the Upload Image dialog box that appears, click **Select File** and select an image to upload.
  - Click **OK** to insert the image.
- Insert a hyperlink
  - Click the **Hyperlink** icon.
  - In the Set Hyperlink dialog box that appears, enter the hyperlink that you want to insert and the text to display, as shown in Insert a hyperlink.

    Insert a hyperlink

  - Click **OK** to insert the hyperlink.
- Insert a drop-down list box
  - Click the **Drop Down** icon.

- In the Set Drop-down Box dialog box that appears, specify tags and values, as shown in Set a drop-down box.

  Set a drop-down box



- Click **OK** to insert the drop-down list box.

7.5.10. Set the workbook style

This topic describes how to set the style for a workbook.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. On the Workbooks page, click the workbook for which you want to set the style.

   For information about how to create a workbook, see Create a workbook.
4. Click the **Style** icon.
5. Select an appropriate table style.

7.5.11. Set conditional formatting

This topic describes how to set conditional formatting, for example, highlight specific numbers or add an upward or downward arrow to indicate an ascending or descending order in a workbook.

Prerequisites

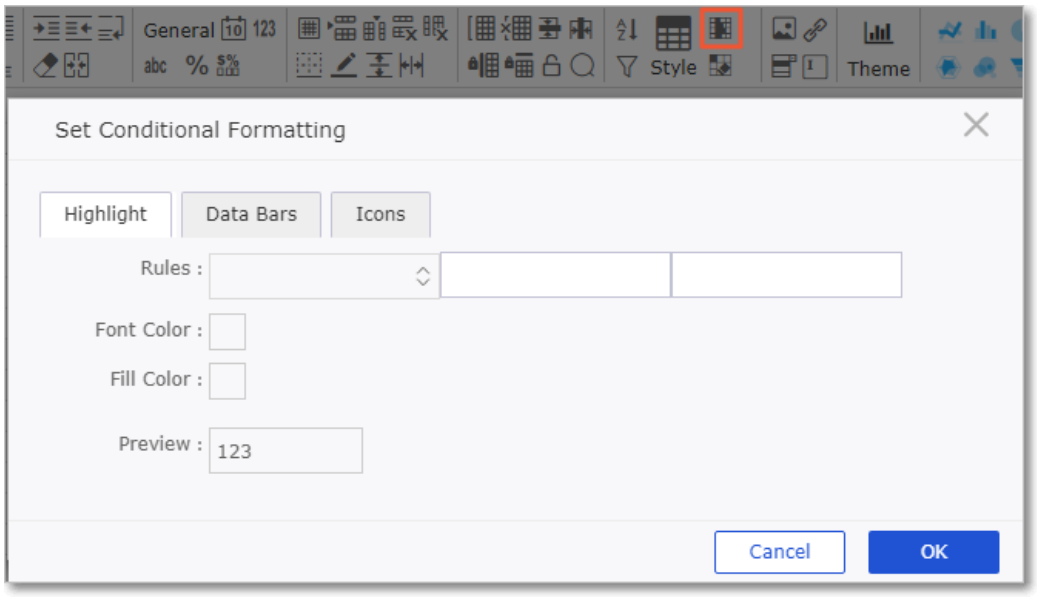
The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. On the Workbooks page, click the workbook for which you want to set conditional formatting.

   For information about how to create a workbook, see Create a workbook.
4. Click the **Set Conditional Formatting** icon.
5. In the Set Conditional Formatting dialog box that appears, click the **Highlight** tab, as shown in Highlight settings.

   Highlight settings

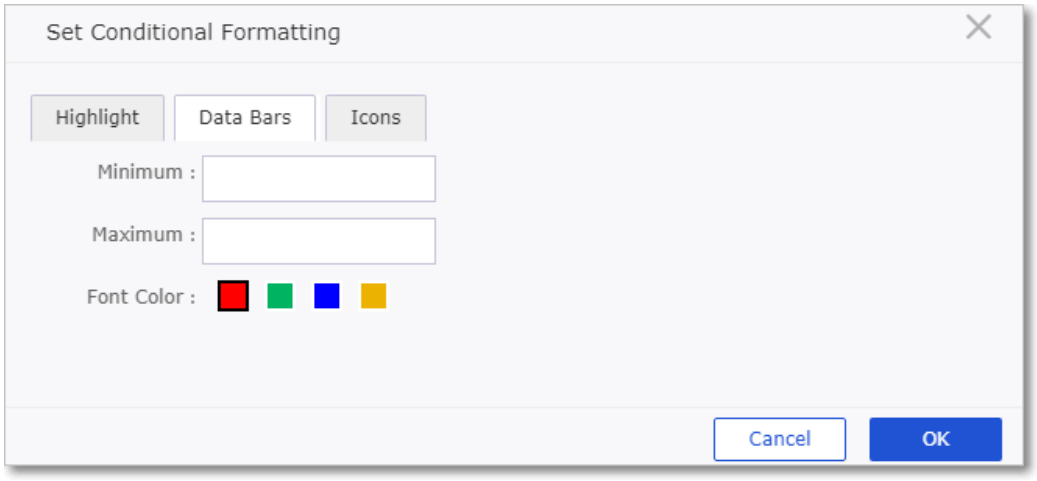


Parameter	Description
Rules	Click the drop-down icon to select a highlighting rule from the drop-down list, and specify a value or value range in the input boxes.
Font Color	Click the Color icon and select a color.
Fill Color	Click the Color icon and select a color.

Parameter	Description
Preview	Displays the highlight effect after you set the colors.

6. Click the **Data Bars** tab, as shown in Data Bars.

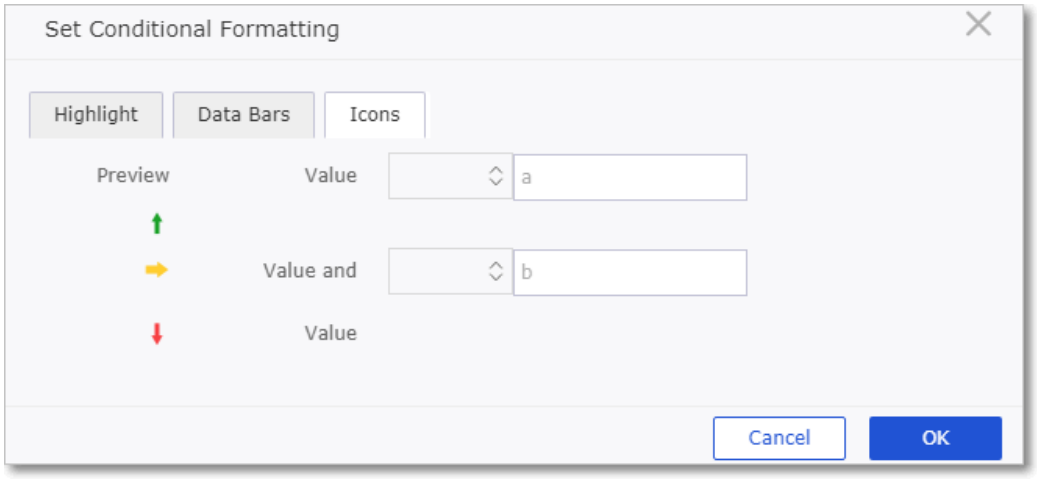
Data Bars



Parameter	Description
Minimum	Enter a value in the input box.
Maximum	Enter a value in the input box.
Font Color	Click the Color icon and select a color.

7. Click the **Icons** tab, as shown in Icons.

Icons



Click the drop-down icon, select a mathematical notation from the drop-down list, and enter a value in the input box. A green, yellow, or red arrow appears next to the values that fit the specific value ranges.

8. After you set the parameters, click **OK**.

7.5.12. Search for a workbook

This topic describes how to search for a specific workbook.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. Enter a keyword in the search box.
4. Click the Search icon to search for the workbook.

7.5.13. Create a workbook folder

This topic describes how to create a workbook folder. Workbook folders help you manage workbooks.

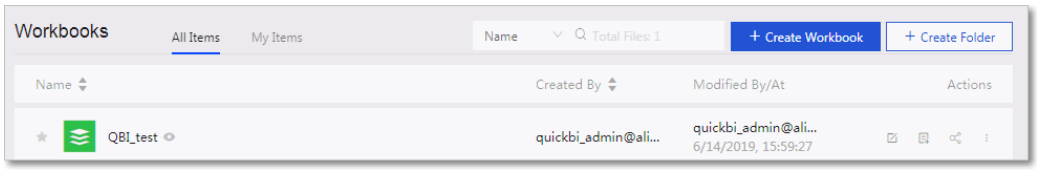
Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. Click **Create Folder**, as shown in Create a folder.

   Create a folder



4. In the Create Folder dialog box that appears, specify a name for the folder and click **OK**.

7.5.14. Rename a workbook folder

This topic describes how to rename a workbook folder.

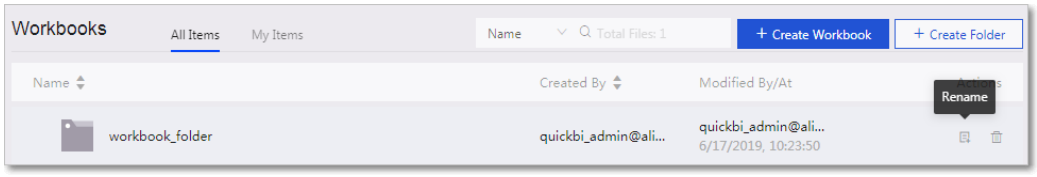
Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. Find the workbook folder you want to rename and click the **Rename** icon in the Actions column, as shown in Rename a workbook folder.

   Rename a workbook folder



4. In the **Rename** dialog box that appears, enter a new folder name and click **OK**.

7.5.15. Share a workbook

This topic describes how to share a workbook with other users.

Prerequisites

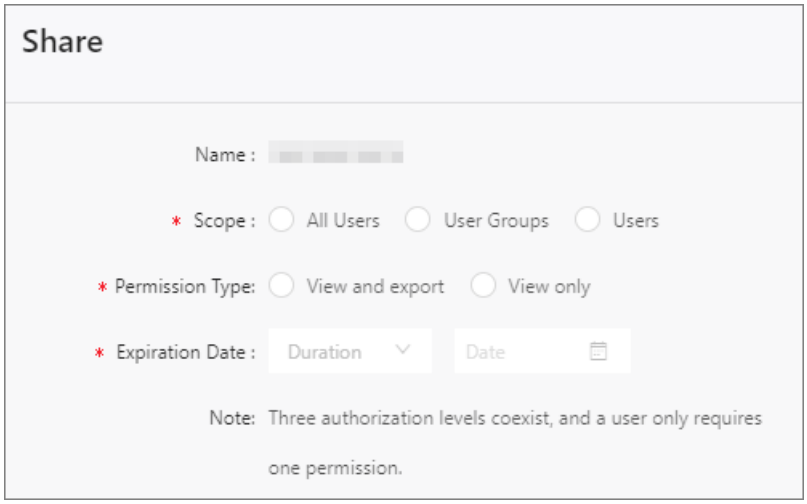
- The Quick BI service is purchased.
- A workbook is created.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. Find the workbook that you want to share with other users.
4. Click the **Share** icon in the Actions column, as shown in Share a workbook.

   Share a workbook

5. Specify Scope, Permission Type, and Expiration Date in the side pane that appears.



> **Note**
> - You can set Scope to All Users, User Groups, or Users.
> - Users can be authorized in the three scopes at the same time. Users who are authorized in one of these scopes are granted the corresponding permissions.

6. Click **Save**.

7.5.16. Make a workbook public

After you create a workbook, you can make it public to allow other users to access the workbook.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. Find the workbook that you want to make public and click the **More** icon in the Actions column.
4. Select **Make Public**.
5. In the Make Public pane that appears, specify an expiration date.
6. Select **Generate URL** and click **Make Public**.

7.6. BI portals

7.6.1. Overview

A BI portal is a collection of dashboards, workbooks, and external links organized with menus. You can create a BI portal to perform complex thematic analysis with navigation panes.

7.6.2. Create a BI portal

This topic describes how to create a BI portal.

Prerequisites

The Quick BI service is purchased.

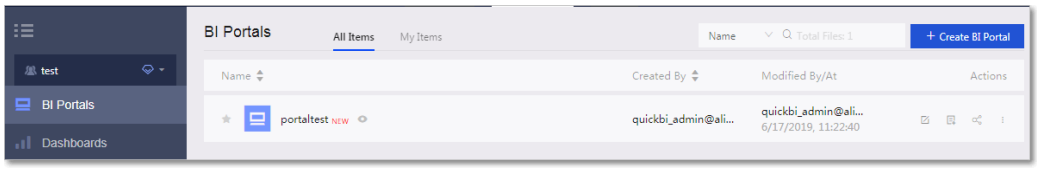
Context

You can create BI portals in workspaces only. Personal workspaces do not support BI portals.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **BI Portals**.
3. On the BI Portals page, click **Create BI Portal** in the upper-right corner, as shown in Create a BI portal.

   Create a BI portal

4. On the Page Settings page, set the parameters and click **Save** in the top navigation bar.

7.6.3. Page settings

This topic describes how to edit a BI portal page, such as the title, layout, logo, and footer.

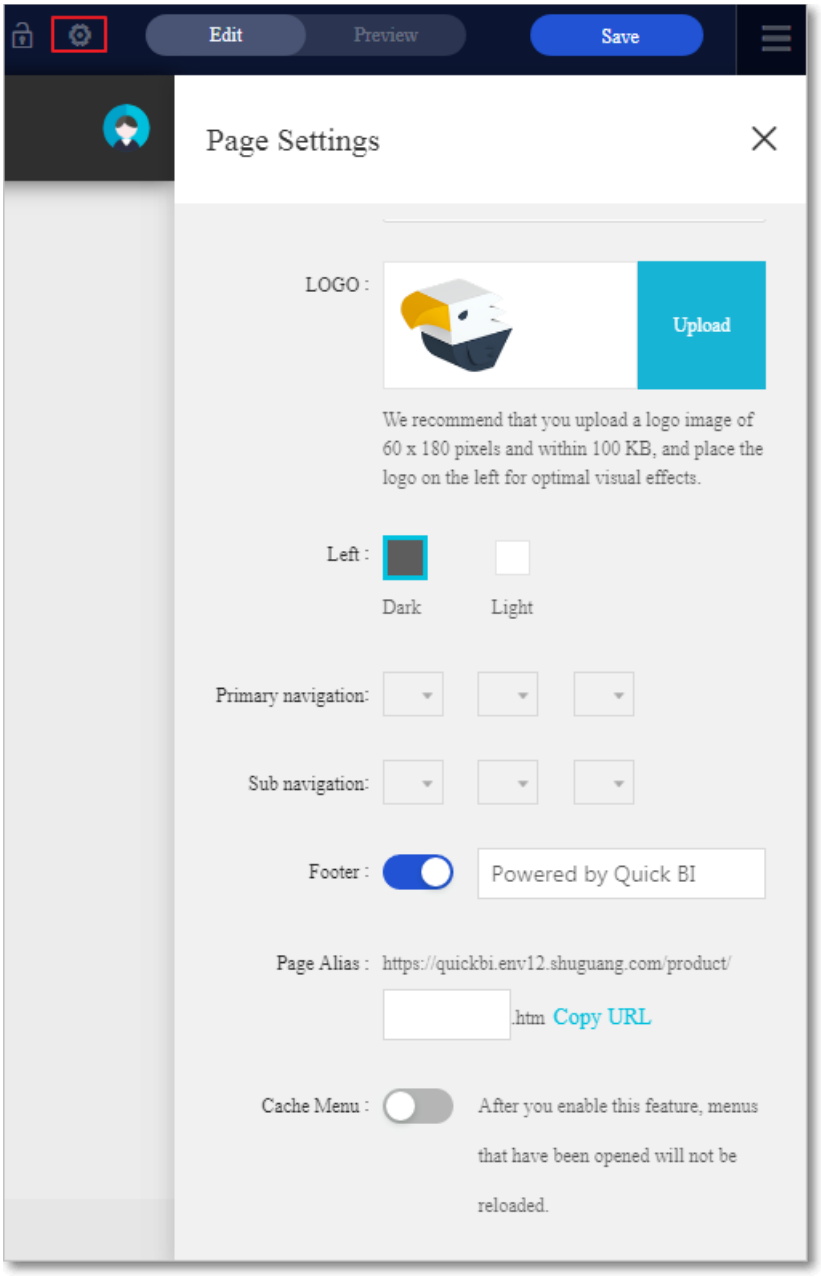
Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **BI Portals**.
3. On the BI Portals page, click a BI portal.

   For information about how to create a BI portal, see Create a BI portal.

4. Click the **Settings** icon in the top navigation bar to edit the BI portal page, as shown in Template settings.

   Template settings



5. Click **Save**.

7.6.4. Menu settings

This topic describes how to edit the menu content, such as menu titles and URLs, on the Menu Settings tab.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **BI Portals**.
3. On the BI Portals page, click a BI portal.

   For information about how to create a BI portal, see Create a BI portal.

4. In the left-side navigation pane, click the target menu, and edit the menu on the right-side **Content** tab, as shown in the following figure.

   Menu settings

   
   - On the **Menu Settings** tab, you can edit menu settings, as shown in the following figure.

     Edit the menu structure

     
   - You can add a dashboard or workbook as a menu.

5. Click **Save**.

7.7. Organization

7.7.1. Overview

An organization typically refers to a small or medium enterprise, public institution, college department, or a department of a large enterprise.

If your organization has a large number of members, requires multiple members to collaborate on data analysis, and has high requirements on data security, Quick BI provides the following features to meet your requirements:

- Different departments have access to different reports.
- Members with different roles have access to different data.

Members in an organization are classified into two types: administrators and common members.

7.7.2. Create an organization

This topic describes how to create an organization.

Prerequisites

Before you create an organization, you must create an Apsara Stack tenant account in the Apsara Stack console. Each Apsara Stack tenant account can be used to create or join in only one organization. Ensure that your Apsara Stack tenant account has neither been used to create an organization nor been added to an organization before.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI** console, or in a workspace, click the **Settings** icon.

3. Click **Organization** in the left-side navigation pane.
4. Select the **Agree** check box and click **Create Organization**.
5. In the **Create Organization** dialog box, enter an organization name.

7.7.3. Modify organization information

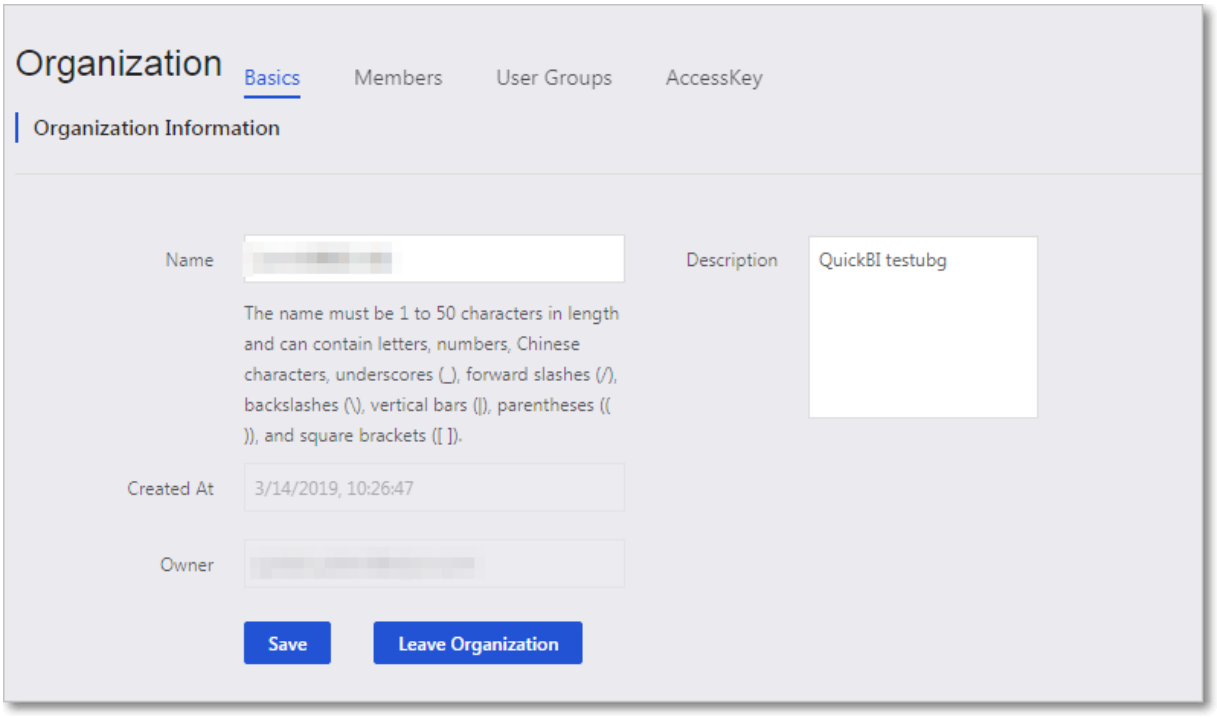
Quick BI allows you to modify the information about an organization as needed.

Prerequisites

The Quick BI service is purchased.

Context

Administrators of an organization have the permissions to modify the information about the organization.



Administrators of an organization have the permissions to add members to the organization to collaborate on tasks.

Administrators of workspaces have the permissions to add members to their workspaces based on the roles and responsibilities of the members. You can create workspaces that correspond to the departments of the organization. For example, if an organization has a sales department and an HR department, administrators can create a workspace for each of the two departments, and then add the employees as members to the corresponding workspaces.

Only administrators of an organization have permissions to manage members in the organization. By default, the creator of an organization is one of the administrators of the organization.

Members in an organization are classified into administrators and common members.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console**, or in a workspace, click the **Settings** icon.
3. On the Organization page, click the **Basics** tab.
4. Modify the organization information and click **Save**.

7.7.4. Leave an organization

Quick BI allows you to leave an organization.

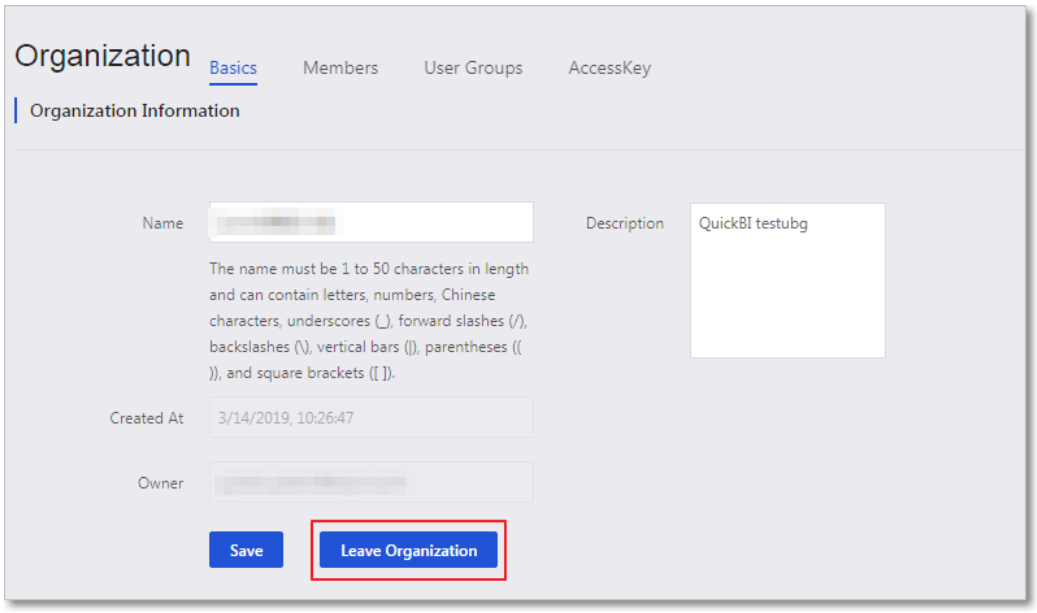
Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console**, or in a workspace, click the **Settings** icon.
3. On the Organization page, click the Basics tab and then click **Leave Organization**, as shown in Leave an organization.

Leave an organization



7.7.5. Add a member to an organization

You can add a member to an organization by **adding an Apsara Stack tenant account** or **adding a RAM user**.

Prerequisites

- The Quick BI service is purchased.
- The Apsara Stack tenant account is obtained.

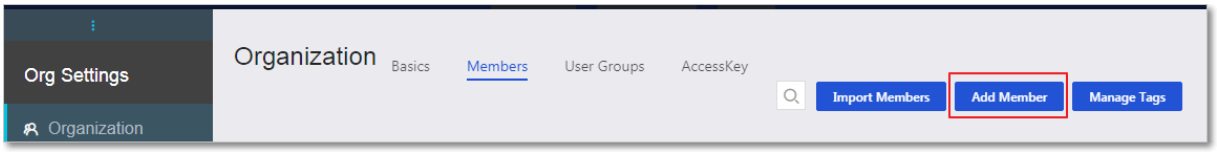
  Each department created in department management in the Apsara Stack console has an Apsara Stack tenant account. The Apsara Stack tenant account of a user can be queried by using the department to which the user belongs.

- The RAM user information is obtained.

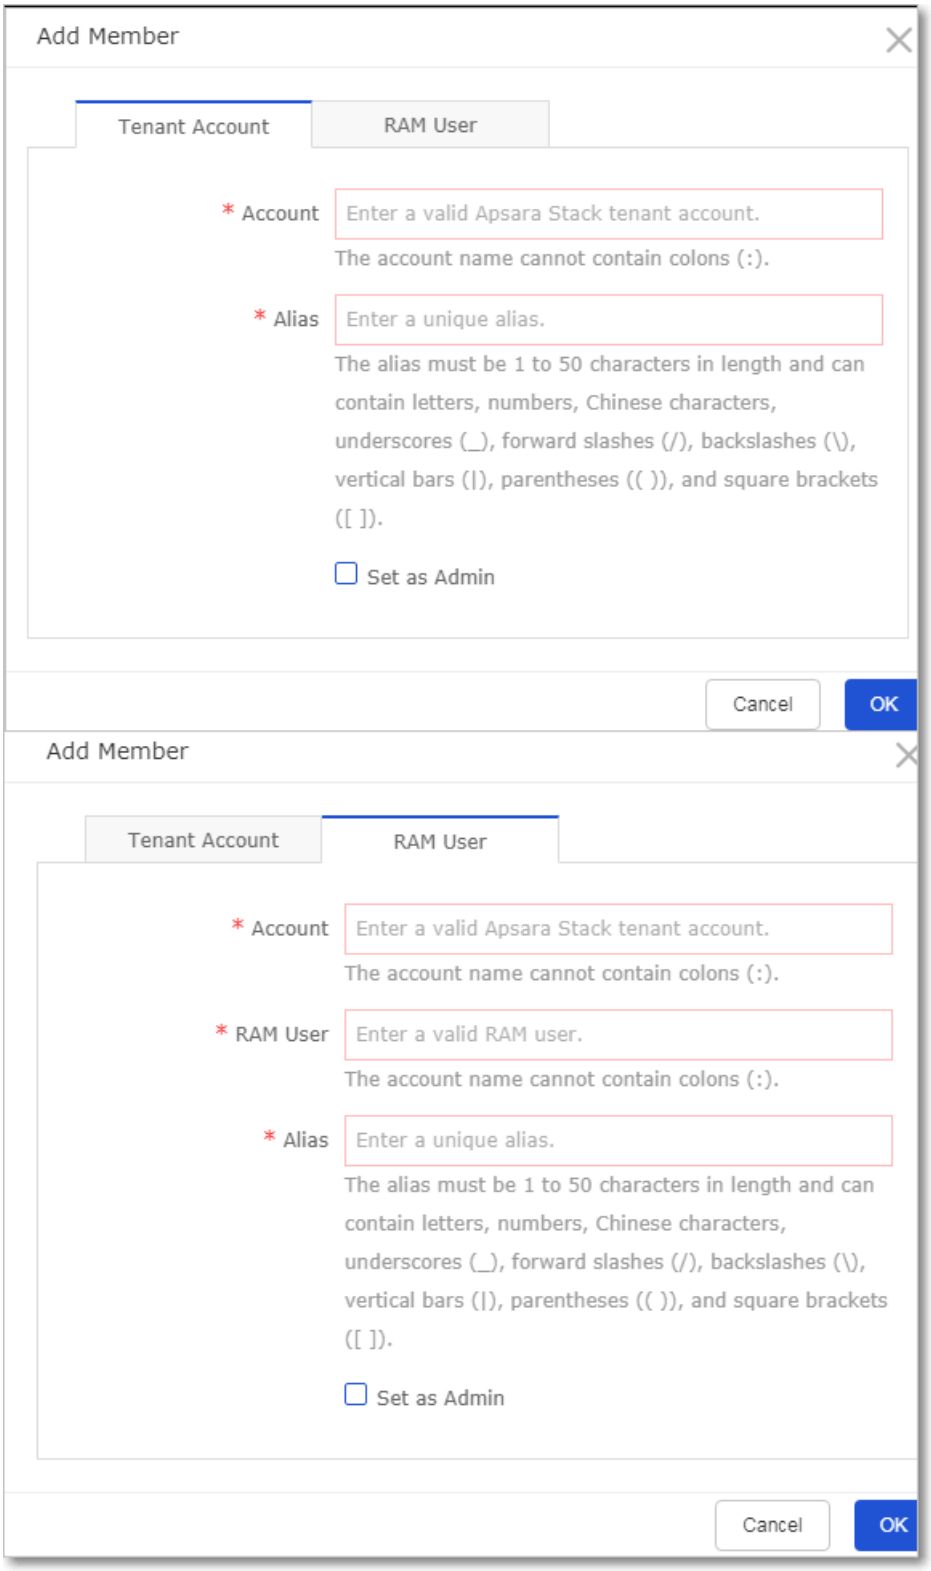
  When you **add a RAM user** in the Quick BI console, you must know both the Apsara Stack tenant account and the RAM user information. The RAM user name is displayed in user management.

Context

Quick BI allows you to add one member at a time or multiple members at the same time to an organization.

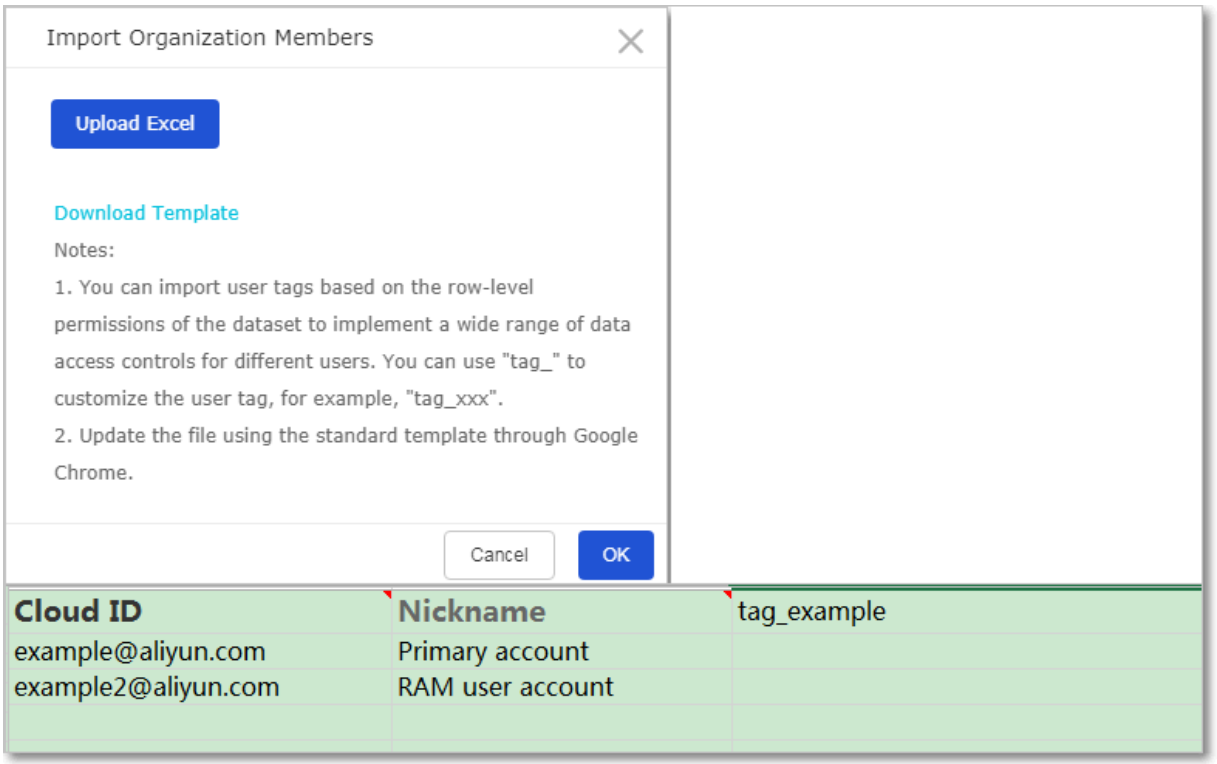


When you add one member at a time, you can add an Apsara Stack tenant account or a RAM user.



Add Member
Tenant Account
RAM User
* Account
Enter a valid Apsara Stack tenant account.
The account name cannot contain colons (:).
* Alias
Enter a unique alias.
The alias must be 1 to 50 characters in length and can contain letters, numbers, Chinese characters, underscores (_), forward slashes (/), backslashes (\), vertical bars (|), parentheses (( )), and square brackets ([ ]).
Set as Admin
Cancel
OK
Add Member
Tenant Account
RAM User
* Account
Enter a valid Apsara Stack tenant account.
The account name cannot contain colons (:).
* RAM User
Enter a valid RAM user.
The account name cannot contain colons (:).
* Alias
Enter a unique alias.
The alias must be 1 to 50 characters in length and can contain letters, numbers, Chinese characters, underscores (_), forward slashes (/), backslashes (\), vertical bars (|), parentheses (( )), and square brackets ([ ]).
Set as Admin
Cancel
OK

To add multiple members at the same time, you need to download a template and enter the Apsara Stack tenant accounts and aliases of the members you want to add into the template. Pay attention to the differences between the Apsara Stack tenant account and the RAM user information. When you add a member by using RAM user information, the format of the user account is Apsara Stack tenant account:RAM user.



Add a member to an organization

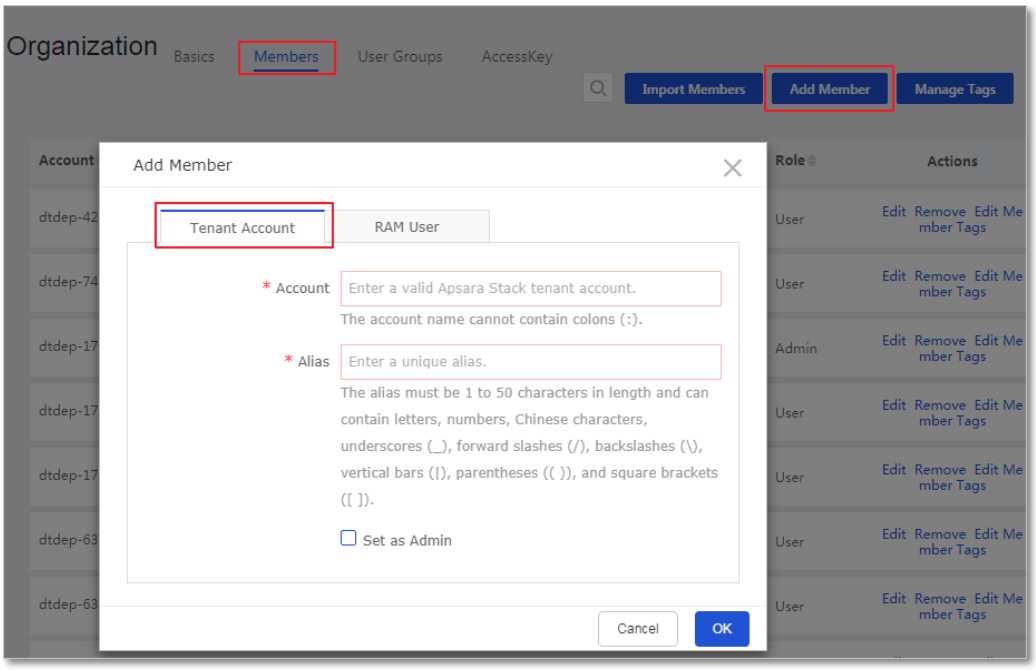
Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI** console, or in a workspace, click the **Settings** icon.
3. On the Organization page, click the **Members** tab.
4. Click **Add Member**.

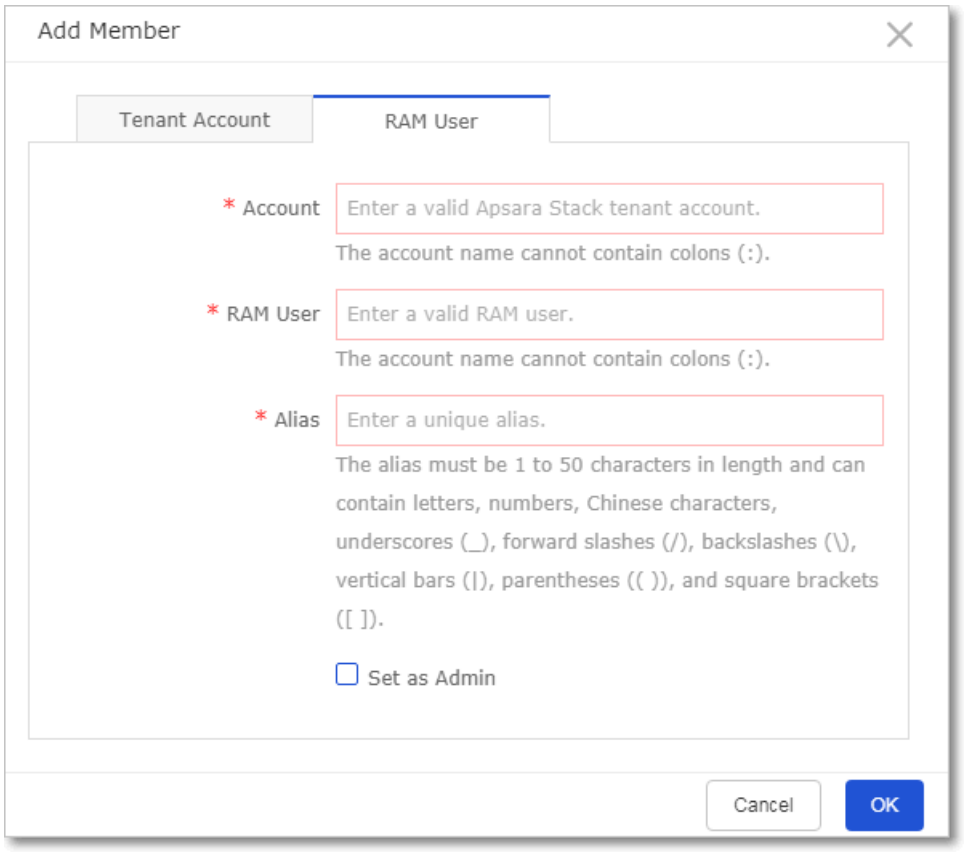
Operation	Procedure
Add an Apsara Stack tenant account	i. In the Add Member dialog box that appears, click the **Tenant Account** tab. ii. Enter the **Apsara Stack tenant account** and **alias**, and select the Set as Admin check box as needed. iii. Click **OK** to add the member.

Operation	Procedure
Add a RAM user	i. In the Add Member dialog box that appears, select **RAM User**. ii. Enter the **Apsara Stack tenant account**, **RAM user**, and **alias**, and select the Set as Admin check box as needed. iii. Click **OK** to add the member. **Note** If the user has been added to another organization, the system prompts an error.

Add an Apsara Stack tenant account



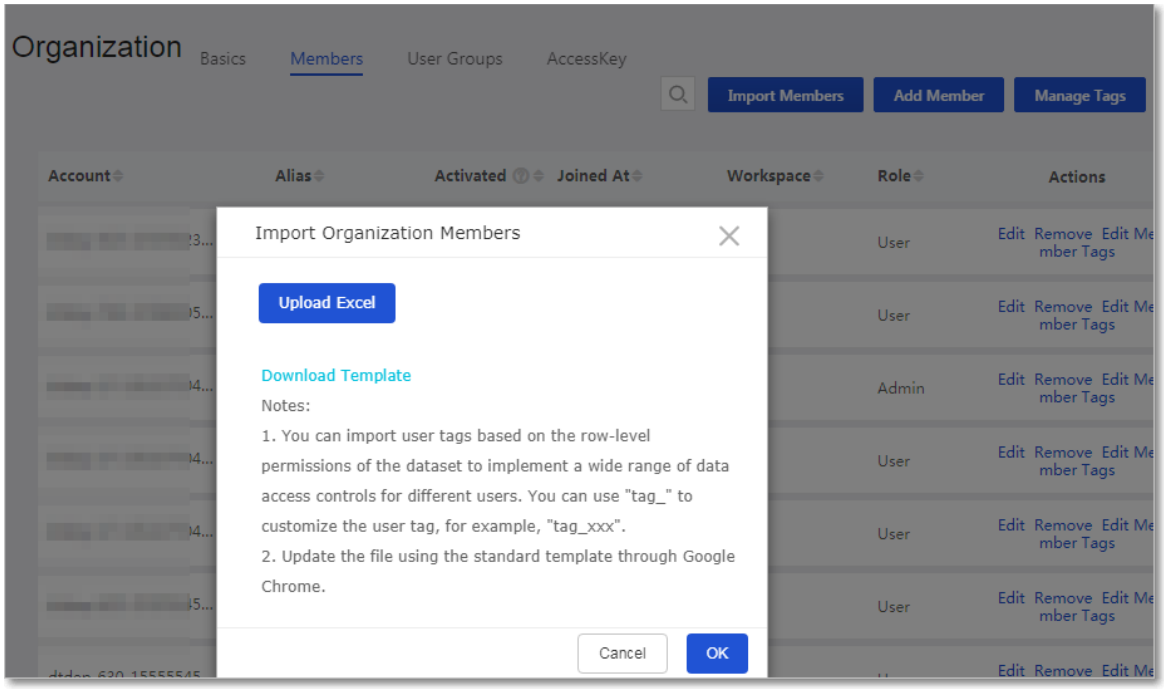
Add a RAM user



Add multiple members at a time

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI** console, or in a workspace, click the **Settings** icon.
3. On the Organization page, click the **Members** tab.
4. On the Organization page, click **Import Members**.
5. In the Import Organization Members dialog box that appears, click **Upload Excel** and select the local file that contains the member list.



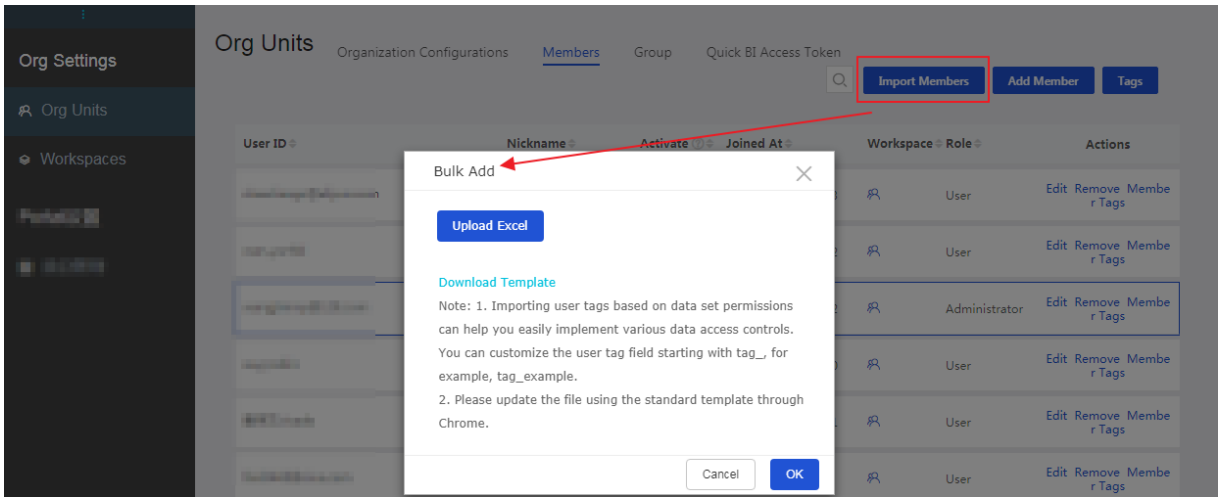
6. Click **OK** to add the members.

7.7.6. Manage member tags

This topic describes how to manage member tags, which are used to configure row-level permissions for datasets.

For information about how to configure row-level permissions, see Set row-level permissions.

You can click the **Import members** icon to add member tags.



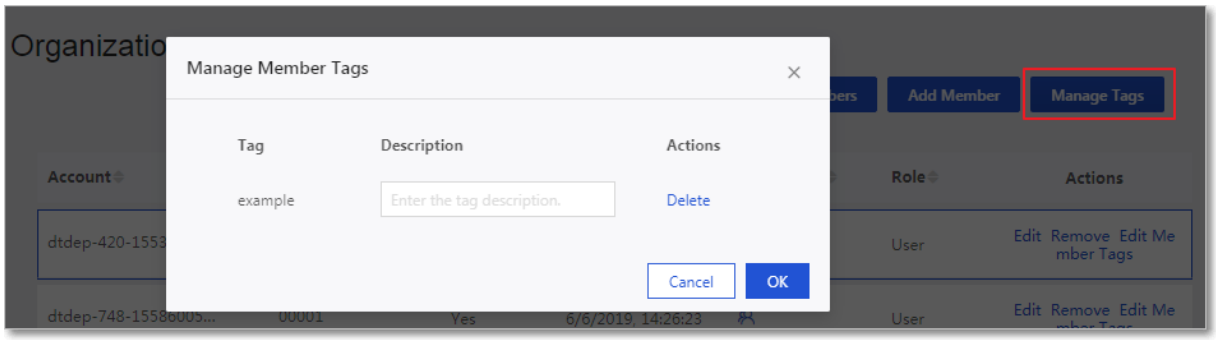
You can click **Download Template** to download the member template. The following figure shows member information.

Account	Nickname	tag_tagArea	tag_tagProvince
example1@aliyun.com	example1	East	Anhui
example2@aliyun.com	example2	East	Anhui

> **Note** If you do not need to set row-level permissions for a member, set the member tag to $ALL_MEMBERS$.

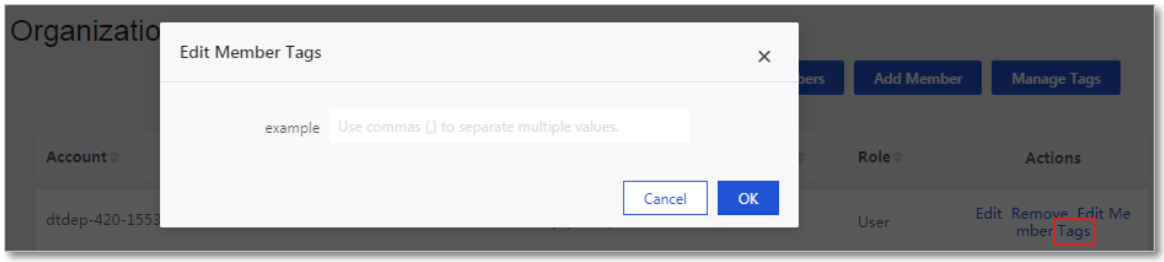
Manage member tags

You can manage tags as shown in the following figure.



Edit a tag

1. Find the member for which you want to set the row-level permissions, and click Edit Member Tags in the Actions column.
2. In the Edit Member Tags dialog box that appears, enter a new tag and click **OK**.



7.7.7. Edit a member

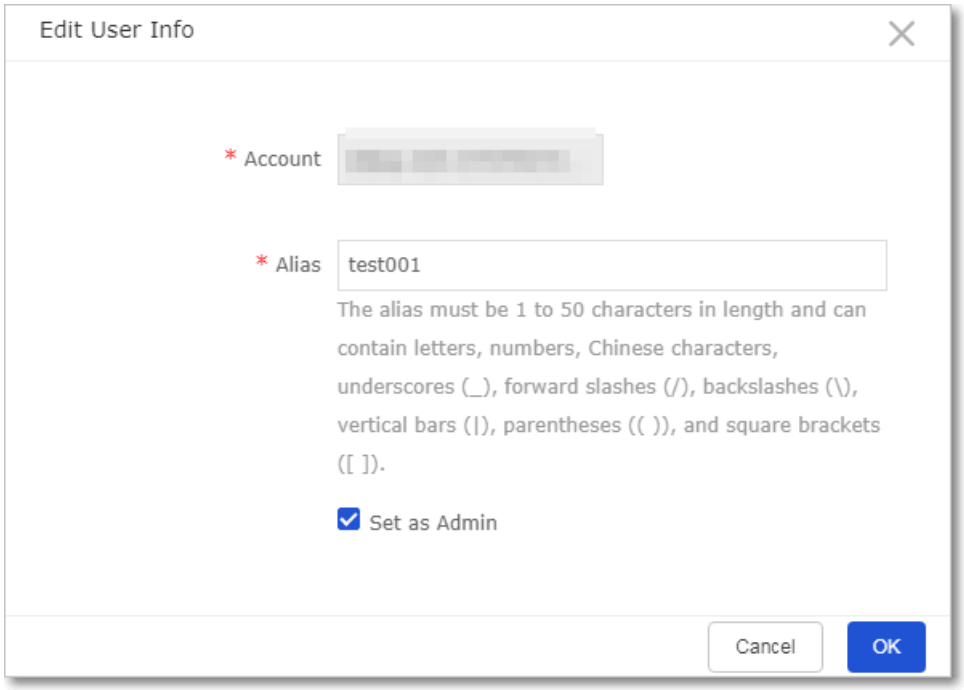
You can set an alias and role for a member in the organization. This makes it easier for you to search for members in the organization.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console** or in a workspace, click the **Settings** icon.
3. On the Organization page, click the **Members** tab.
4. Find the member you want to edit and click **Edit** in the Actions column.
5. Modify the information about the member.



6. Click **OK** to save the changes.

7.7.8. Remove a member

This topic describes how to remove a member from an organization.

Prerequisites

The Quick BI service is purchased.

Context

Only administrators of an organization have the permissions to remove members from the organization. Before you remove a member that has been added to a workspace, you must remove the member from the workspace. Otherwise, you cannot remove the member from the organization.

> **Note** The removal operation is irreversible. If a member that you previously removed is needed, you need to add the member to the organization again. Remove a member with caution.

Procedure

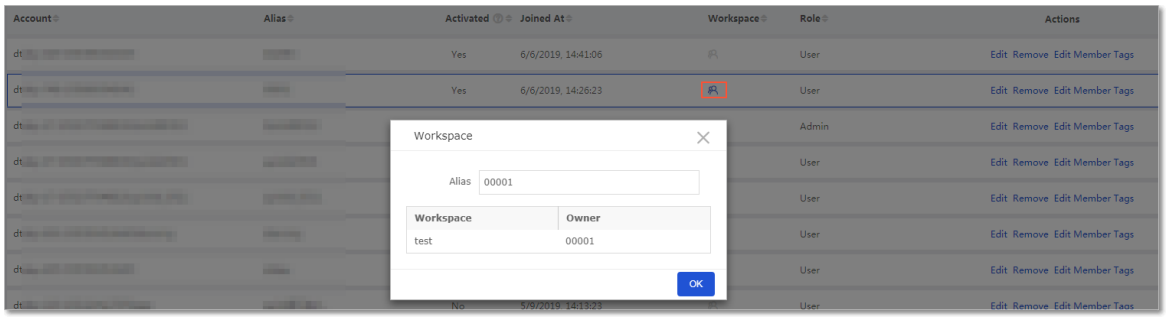
1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console** or in a workspace, click the **Settings** icon.
3. On the Organization page, click the **Members** tab.
4. Find the member you want to remove and click **Remove** in the Actions column.
5. Click **OK** to remove the member.

7.7.9. Query the workspace to which a user belongs

You can query the workspace to which a user belongs.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console** or in a workspace, click the **Settings** icon.
3. On the Organization page, click the **Members** tab.
4. Find the organization member that you want to query and click the **Workspace** icon to view the workspace that the user belongs to.

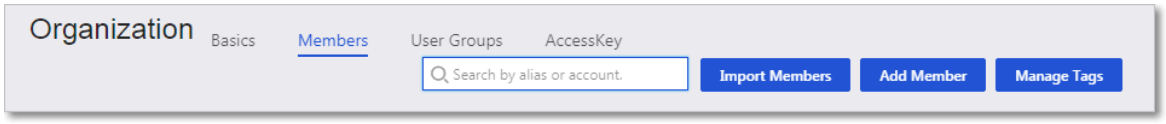


7.7.10. Search for a member of an organization

You can search for a specific member in an organization by its alias or Alibaba Cloud account.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console** or in a workspace, click the **Settings** icon.
3. On the Organization page, click the **Members** tab.
4. Enter the alias or Apsara Stack tenant account of the member you want to search for in the search box, and click the **Search** icon.



7.7.11. Workspaces

7.7.11.1. Overview

A workspace is managed by its administrators. The role of a workspace administrator is assigned to members by the organization administrator that creates the workspace. A workspace administrator can specify other members in the workspace as administrators of the workspace.

A workspace administrator can:

- Create a workspace
- Modify a workspace
- Set a default workspace

7.7.11.2. What is a workspace?

A workspace enables members in the same organization to collaborate on tasks. In a workspace, each member is assigned a role to perform operations such as creating and modifying data sources, datasets, workbooks, dashboards, and BI portals. Data objects are stored in their workspaces. Each workspace has its own data objects.

A workspace has the following properties:

- Name
- Description
- Function permissions: Data objects can be shared and made public by default.
- Preference settings:
  - Use physical field names as dimension and measurement names.
  - Use field annotations as dimension and measurement names.

  Datasets created in this workspace are named based on the new settings. Existing datasets are not affected.

Members of a workspace can be assigned the same role or different roles. The roles in a workspace include:

- Administrator
- Developer
- Analyst
- Viewer

Mapping between roles and permissions

Permissions of a role cannot be changed. If you want to grant specific permissions to a member, you only need to assign the appropriate role to the member. The following tables list the permissions of each role.

- Supported operations on data objects

Supported operations on data objects

Permission	Developer	Analyst	Viewer
Dataset	Yes	No	No
Supported operations on workbooks	Yes	Yes	Yes
Dashboards	Yes	Yes	Yes
BI Portals	Yes	Yes	Yes

- Supported operations on data

Supported operations on data

Permission	Developer	Analyst	Viewer
Create a data source	Yes	No	No
Modify a data source	Developers can modify only data sources created by themselves.	No	No
Delete a data source	Developers can only delete data sources created by themselves.	No	No
Use a data source	Yes	No	No
Create a dataset	Yes	No	No
Modify a dataset	Developers can modify only datasets created by themselves.	No	No
Delete a dataset	Developers can only delete datasets created by themselves.	No	No
Use a dataset	Yes	Yes	No

- Supported operations on workbooks

Supported operations on workbooks

Permission	Developer	Analyst	Viewer
Create a workbook	Yes	Yes	No
Modify a workbook	Developers can modify only workbooks created by themselves.	Analysts can modify only workbooks created by themselves.	No
Delete a workbook	Developers can only delete workbooks created by themselves.	Analysts can only delete workbooks created by themselves.	No
Preview a workbook	Yes	Yes	Yes
Share a workbook	Developers can only share workbooks created by themselves.	Analysts can only share workbooks created by themselves.	No

Permission	Developer	Analyst	Viewer
Reference a workbook	Yes	Yes	No

- Supported operations on dashboards

Supported operations on dashboards

Permission	Developer	Analyst	Viewer
Create a dashboard	Yes	Yes	No
Modify a dashboard	Developers can modify only dashboards created by themselves.	Analysts can modify only dashboards created by themselves.	No
Delete a dashboard	Developers can only delete dashboards created by themselves.	Analysts can only delete dashboards created by themselves.	No
View a dashboard	Yes	Yes	Yes
Share a dashboard	Developers can only share dashboards created by themselves.	Analysts can only share dashboards created by themselves.	No
Reference a dashboard	Yes	Yes	No
Publish a dashboard	Developers can only publish dashboards created by themselves.	Analysts can only publish dashboards created by themselves.	No

- Supported operations on BI portals

Supported operations on BI portals

Permission	Developer	Analyst	Viewer
Create a BI portal	Yes	Yes	No
Modify a BI portal	Developers can modify only BI portals created by themselves.	Analysts can modify only BI portals created by themselves.	No

Permission	Developer	Analyst	Viewer
Delete a BI portal	Developers can only delete BI portals created by themselves.	Analysts can only delete BI portals created by themselves.	No
View a BI portal	Yes	Yes	Yes
Share a BI portal	Developers can only share BI portals created by themselves.	Analysts can only share BI portals created by themselves.	No

7.7.11.3. Differences between a personal workspace and a group workspace

Workspaces of a user are classified into a personal workspace and group workspaces. The personal workspace is automatically created when the user first logs on to the Quick BI console. A group workspace is created for group members to collaborate. Differences between the two types of workspaces are as follows:

- A personal workspace is automatically created when you log on to the Quick BI console for the first time. A group workspace needs to be manually created by an organization administrator.
- You cannot create or delete a personal workspace.
- You cannot add other users to your personal workspace, nor can you collaboratively edit or transfer it.
- A group workspace can be transferred to any member in the group workspace and shared with all members in the organization. A personal workspace can be shared with Apsara Stack tenant accounts.

7.7.12. Create a workspace

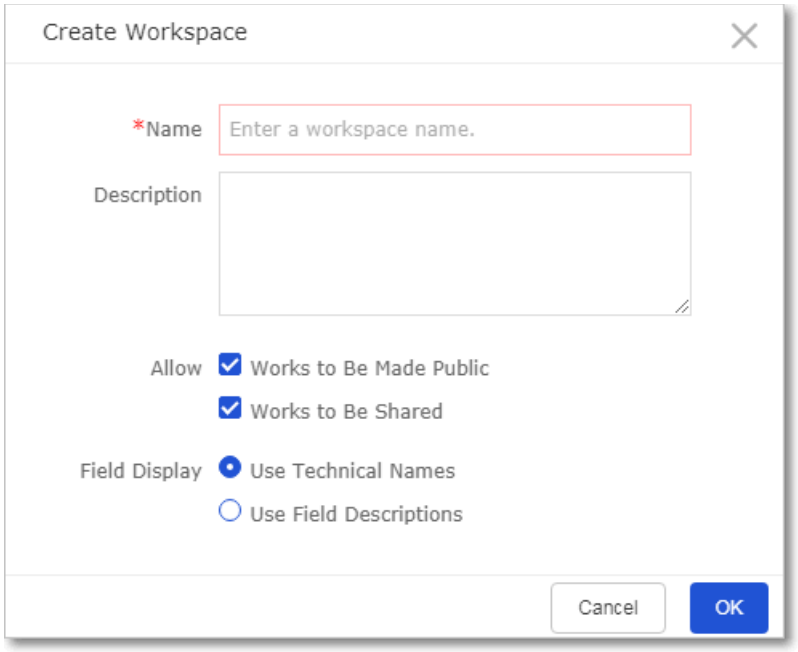
This topic describes how to create a workspace.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console** or in a workspace, click the **Settings** icon.
3. On the Organization page that appears, click **Workspaces** in the left-side navigation pane. Then, click **Create Workspace**.
4. In the Create Workspace dialog box that appears, enter a name for the workspace.



5. Click **OK** to create the workspace.

7.7.13. Modify information about a workspace

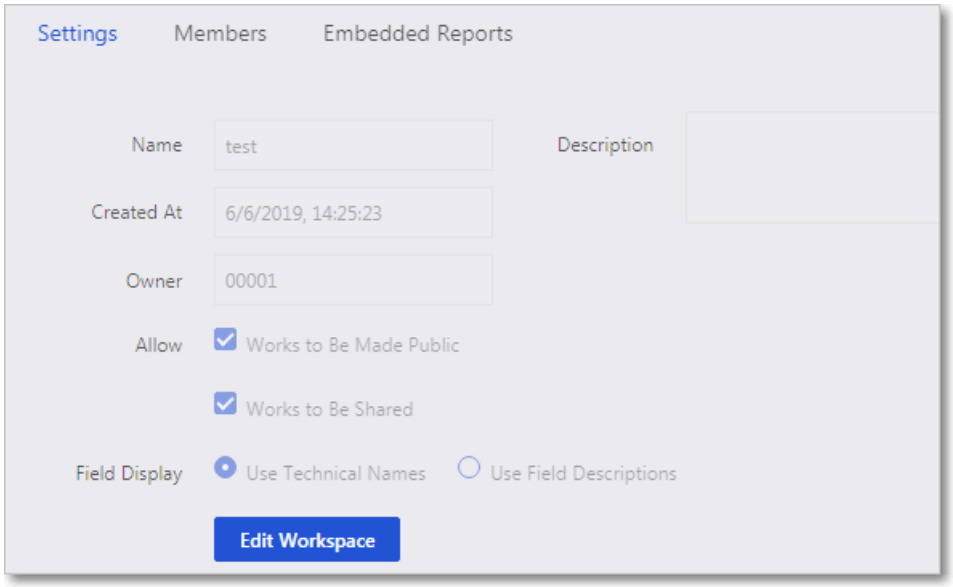
For a personal workspace, only its owner can modify the workspace information. For a group workspace, only its administrators can modify the workspace information.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console** or in a workspace, click the **Settings** icon.
3. In the left-side navigation pane of the Organization page that appears, click **Workspaces**.
4. Click the **Settings** tab.
5. Click **Edit Workspace** and modify the information about the workspace.



6. Click **OK**.

7.7.14. Leave a workspace

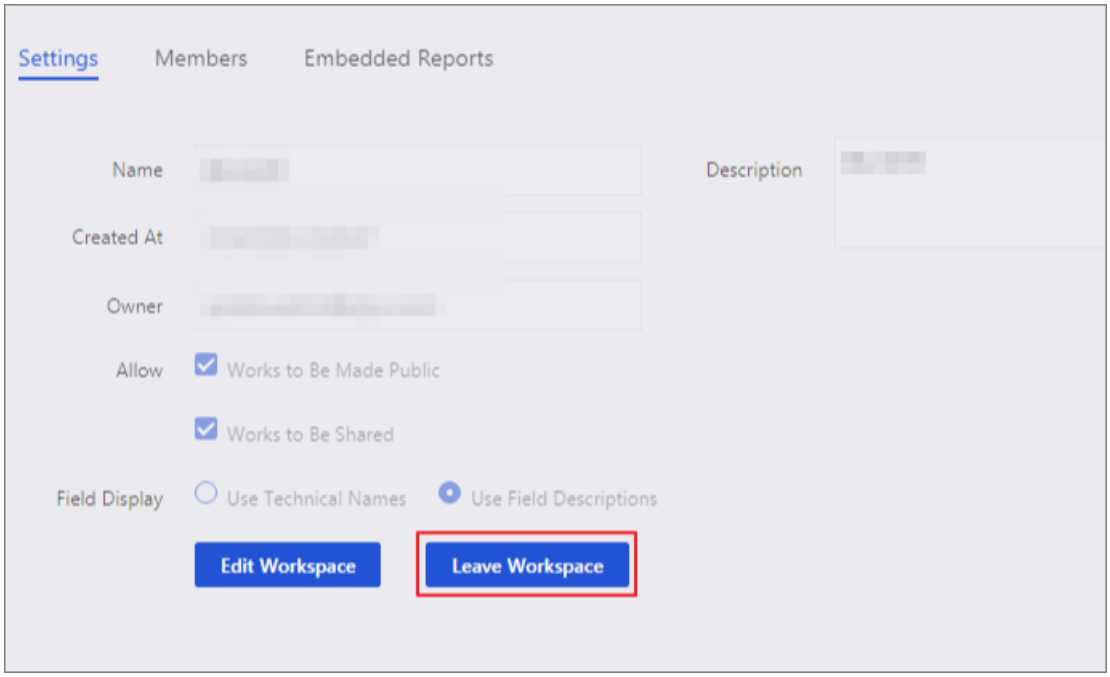
This topic describes how to leave a workspace.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console** or in a workspace, click the **Settings** icon.
3. In the left-side navigation pane of the Organization page that appears, click **Workspaces**.
4. Click the workspace that you want to leave and click the **Settings** tab.
5. Click **Leave Workspace** to leave the current workspace.



7.7.15. Transfer a workspace to another member

This topic describes how to transfer a workspace to another member.

Prerequisites

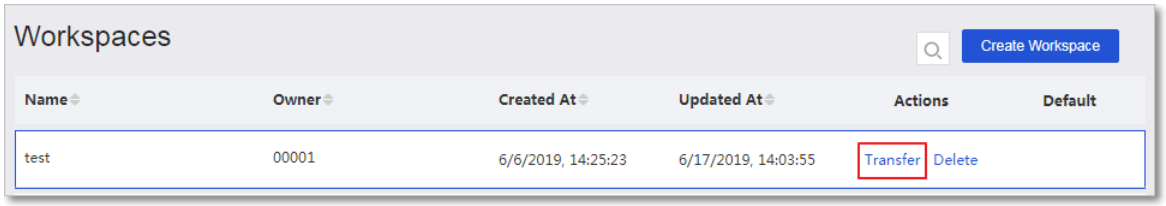
The Quick BI service is purchased.

Context

If you need to remove the owner of a workspace from the organization, you can transfer the workspace to another member. The new owner can be any member in the organization.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console** or in a workspace, click the **Settings** icon.
3. In the left-side navigation pane of the Organization page that appears, click **Workspaces**.
4. Find the workspace that you want to transfer and click **Transfer** in the Actions column.



5. Enter the alias of the new owner and click **OK**.

7.7.16. Delete a workspace

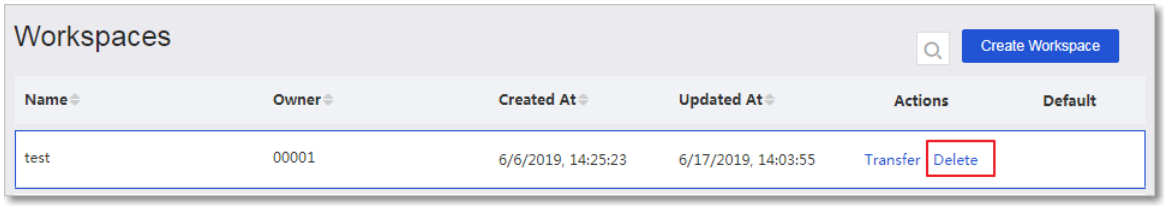
This topic describes how to delete a workspace.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console** or in a workspace, click the **Settings** icon.
3. In the left-side navigation pane of the Organization page that appears, click **Workspaces**.
4. On the Workspaces page, find the workspace that you want to delete and click **Delete** in the Actions column.



7.7.17. Add a member to a workspace

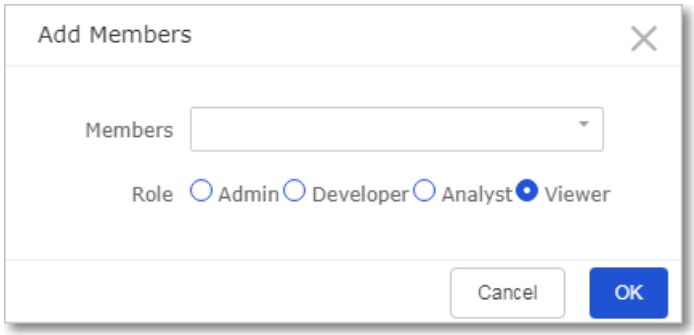
This topic describes how to add a member to a workspace.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console**, or in a workspace, click the **Settings** icon.
3. In the left-side navigation pane of the Organization page that appears, click Workspaces. On the Workspaces page that appears, click the **Members** tab.
4. Click **Add Members**.
5. Enter the account of the member that you want to add and assign a role to the account.



7.7.18. Edit settings of a workspace member

This topic describes how to edit the settings of a workspace member.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console** or in a workspace, click the **Settings** icon.
3. In the left-side navigation pane of the Organization page that appears, click Workspaces. On the Workspaces page that appears, click the **Members** tab.
4. Find the member whose settings you want to edit and click **Edit** in the Actions column.
5. Change the settings of the member and click **OK**.

7.7.19. Search for a member in a workspace

You can search for a member on the **Members** tab.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console**, or in a workspace, click the **Settings** icon.
3. In the left-side navigation pane of the Organization page that appears, click Workspaces.
4. On the Workspaces page that appears, click the **Members** tab. All members in the current workspace are listed on this page.
5. Enter an alias or account in the search box.
6. Click the Search icon to search for the member.

7.7.20. Delete a member from a workspace

This topic describes how to delete a member from a workspace.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. On the homepage of the **Quick BI console**, or in a workspace, click the **Settings** icon.
3. In the left-side navigation pane of the Organization page that appears, click Workspaces. On the Workspaces page that appears, click the **Members** tab.
4. Find the member that you want to delete and click **Delete**.
5. From the Specify a new owner drop-down list, select a member as the new owner.

6. Click OK.

7.8. Permissions

7.8.1. Overview of permissions

You can manage Quick BI permissions at the data object and row levels.

Data object-level permission control

The data objects you can manage in Quick BI include data sources, datasets, dashboards, workbooks, and BI portals. You can manage them in personal workspaces or group workspaces. For information about differences between personal workspaces and group workspaces, see Data objects.

Row-level permission control

You do not need to configure row-level permissions for all fields in a dataset. Configure row-level permissions for specific fields based on your business needs.

> **Note** Only datasets in group workspaces support row-level permission control.

7.8.2. Manage data objects

This topic describes how to manage data objects. Data objects include data sources, datasets, dashboards, workbooks, and BI portals.

The following table lists differences between data object management in a personal workspace and that in a workspace, also referred to as a group workspace.

Item	Workspace (Group workspace)	Personal workspace
Permissions	Data objects can be shared or made public. **Note** Data sources and datasets cannot be shared or made public.	Only the owner of a personal workspace can perform operations on data objects.

Item	Workspace (Group workspace)	Personal workspace
Share data objects	Workbooks, dashboards, and BI portals can be shared. Shared data objects are read-only for other Apsara Stack tenant accounts and RAM users. Other Apsara Stack tenant accounts and RAM users cannot modify, delete or save data objects. • Only the data object owner and the administrators of the workspace have the permissions to share the data object. • If the Works to Be Shared check box is cleared in workspace settings, data objects in the workspace cannot be shared. • Data objects can only be shared with Apsara Stack tenant accounts and RAM users of the same organization. Members can view the data objects in the workspace to which the members belong. Data objects can be shared with users in different workspaces within an organization. Authorized users can view the shared data objects in their own personal workspaces.	Workbooks, dashboards, and BI portals can be shared. Shared data objects are read-only for other Apsara Stack tenant accounts and RAM users. Other Apsara Stack tenant accounts and RAM users cannot modify, delete or save data objects. • Only data object owners have the permissions to share the data objects. • Data objects can only be shared with users of Apsara Stack Quick BI. Authorized users can view shared data objects in their own personal workspaces.
Make data objects public	Everyone can access data objects that have been made public by using URLs. We recommend that you do not make the data objects that contain private business data public.	Everyone can access data objects that have been made public by using URLs. We recommend that you do not make the data objects that contain private business data public.

7.8.3. Manage row-level permissions

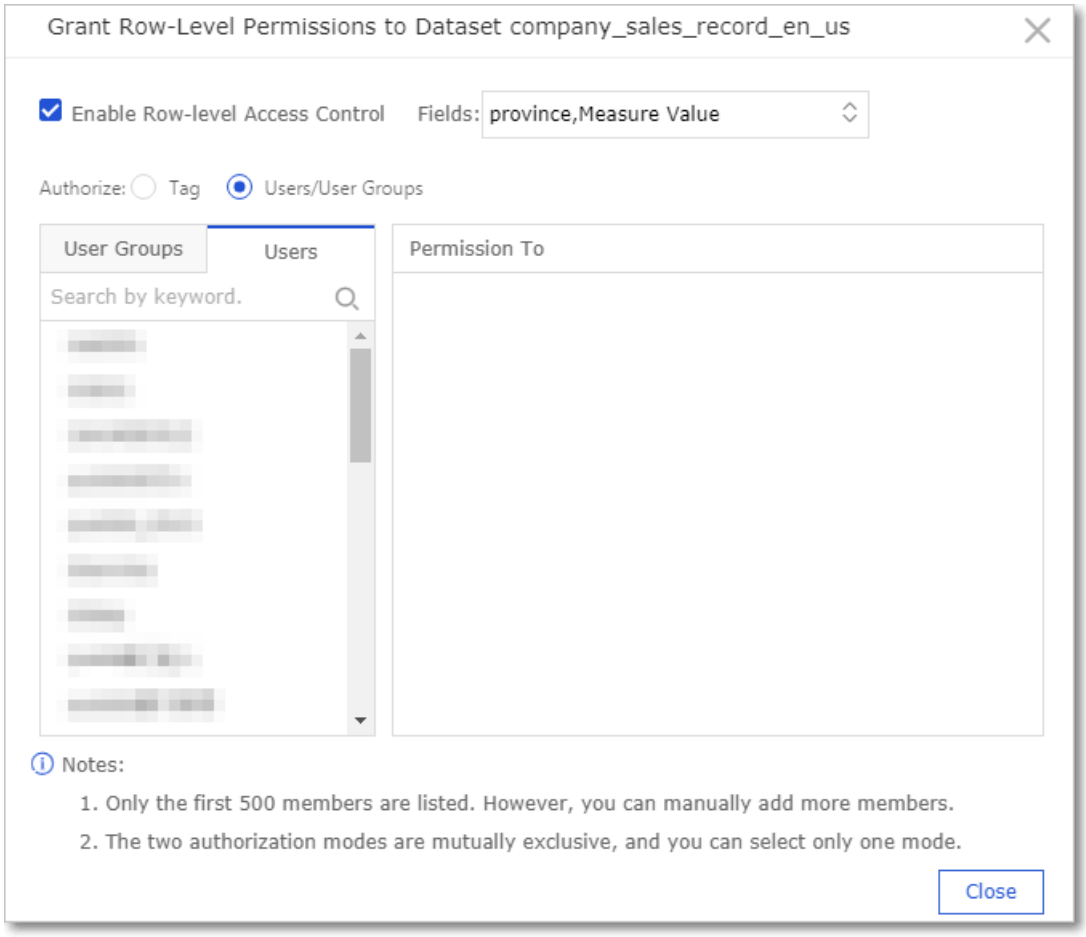
Row-level permissions are managed based on datasets. Quick BI supports the following authorization modes: **user/user group-based authorization** and **tag-based authorization**. **User/user group-based authorization** is ideal for organizations with a small number of members. **Tag-based authorization** is ideal for organizations with a large number of members.

User/user group-based authorization

1. Log on to the Quick BI console
2. Select a workspace. For information about how to create a workspace, see Create a workspace.
3. In the left-side navigation pane of the Workspace page, click **Datasets**.

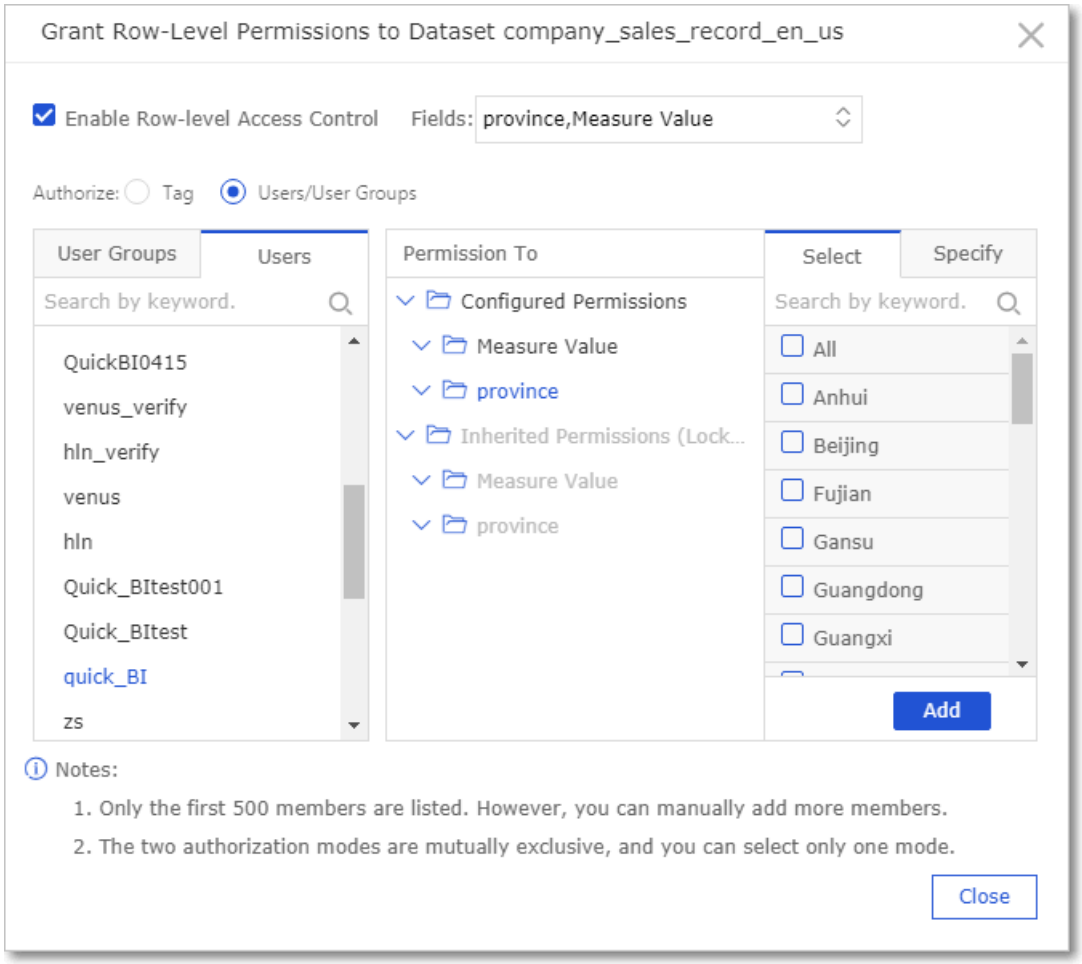
> **Note** Datasets in a personal workspace do not support row-level permission control.

4. Find the target dataset. Click the **More** icon in the Actions column or right-click the dataset.
5. Select **Grant Row-Level Permissions**.
6. On the Grant Row-Level Permissions page, select **Enable Row-level Access Control** and select **Users/User Groups** for Authorize.
7. Click the drop-down arrow of Fields. Select the fields that the authorization is based on, such as province and Measure Value, as shown in the following figure.



The values of the **Measure Value** field are the measures in the dataset. By granting row-level permissions based on the Measure Value field, you can specify the measures available to different users.

8. In the **Permission To** section, click the **province** field. A list of provinces appear.
9. Select a member and choose values of the **province** field to grant permissions to the member, as shown in the following figure.



In this example, the member can view the data of Shanghai and Yunnan.

> **Note** If you grant permissions based on a field of a dataset, you must specify whether all members of the workspace have permissions to access the dataset. Otherwise, when other users attempt to access reports created based on the dataset, the system denies the access requests by default

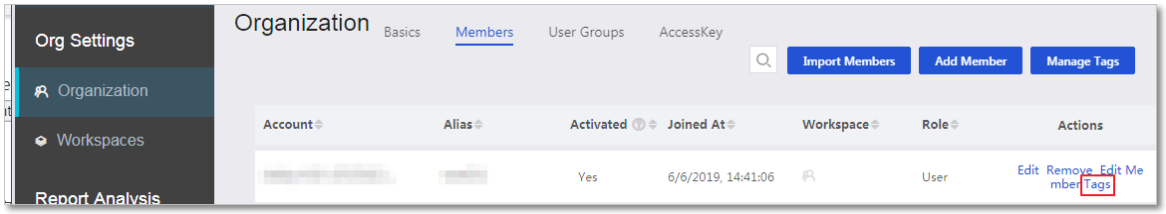
10. Click **Add** to complete the authorization.

Tag-based authentication

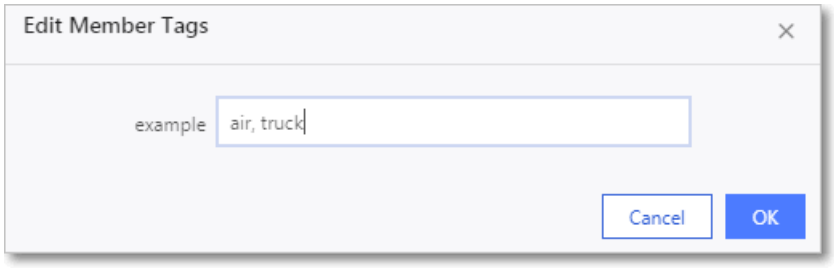
Scenario: Users can only access the data rows in the company_sales_record dataset with shipping_type set to truck and air.

Set member tags

1. In the target workspace, click the **Settings** icon.
2. On the **Settings** page, find the member you want to authorize and click **Edit Member Tags** in the Actions column.



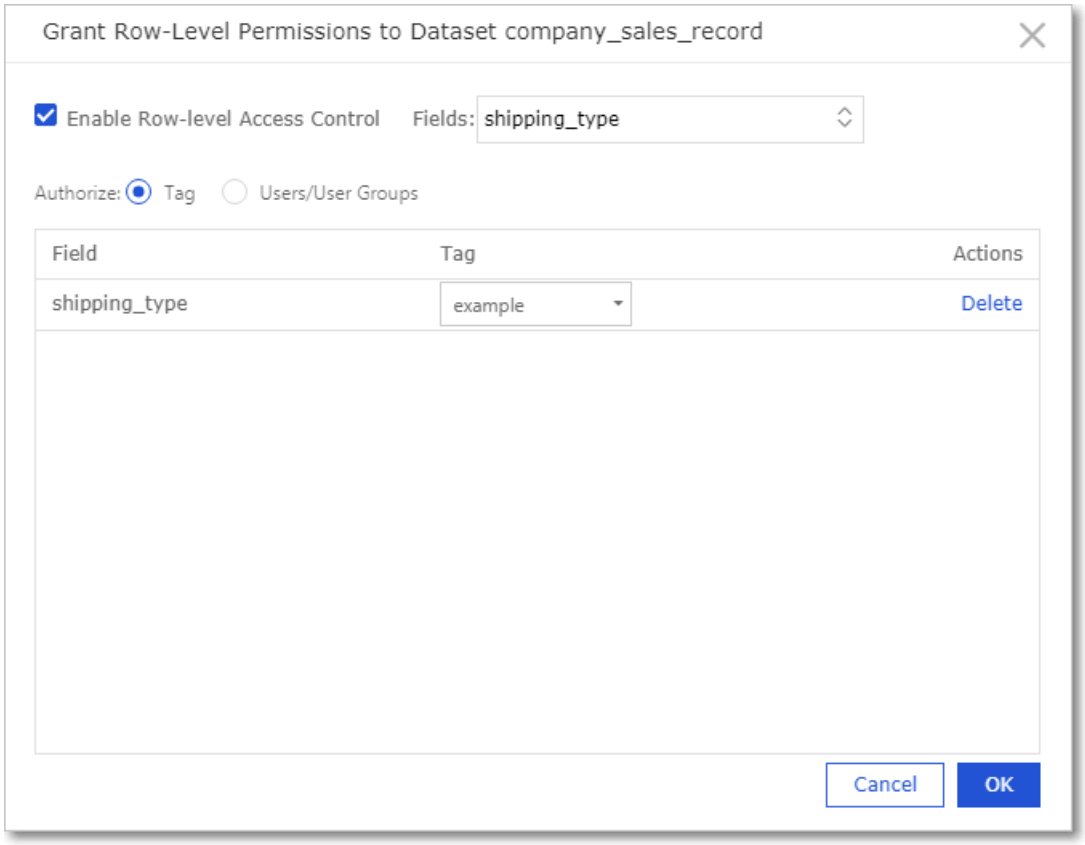
3. In the **Edit Member Tags** dialog box that appears, set the value of the **example** tag to air, truck and click **OK**.



After you set the member tag, you must specify the tag in the Grant Row-Level Permissions dialog box.

Set tag-based authorization

1. Find the company_sales_record dataset. Click the **More** icon in the Actions column or right-click the dataset.
2. Select **Grant Row-level Permissions**.
3. On the Grant Row-Level Permissions page, select **Enable Row-level Access Control** and select **Tag** for Authorize.
4. From the **Fields** drop-down list, select **shipping_type**. Select **example** in the **Tag** column, and click **OK** to complete the settings.



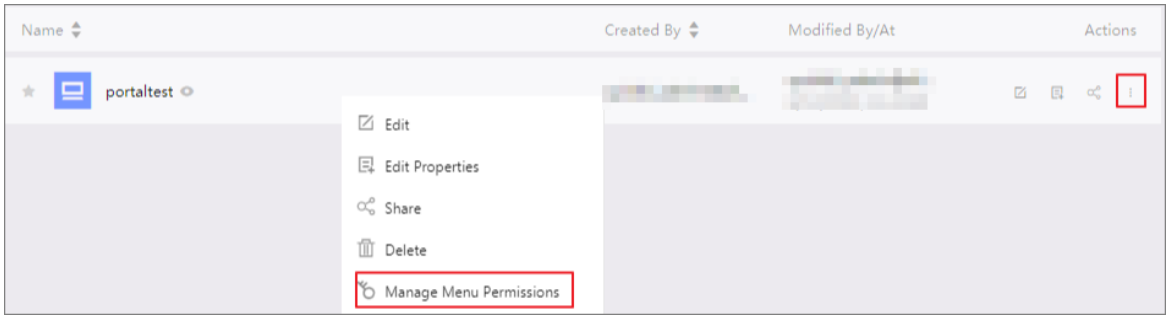
After tag authorization is complete, the user can only access data rows with **shipping_type** set to air or truck.

7.8.4. Configure menu permissions for a BI portal

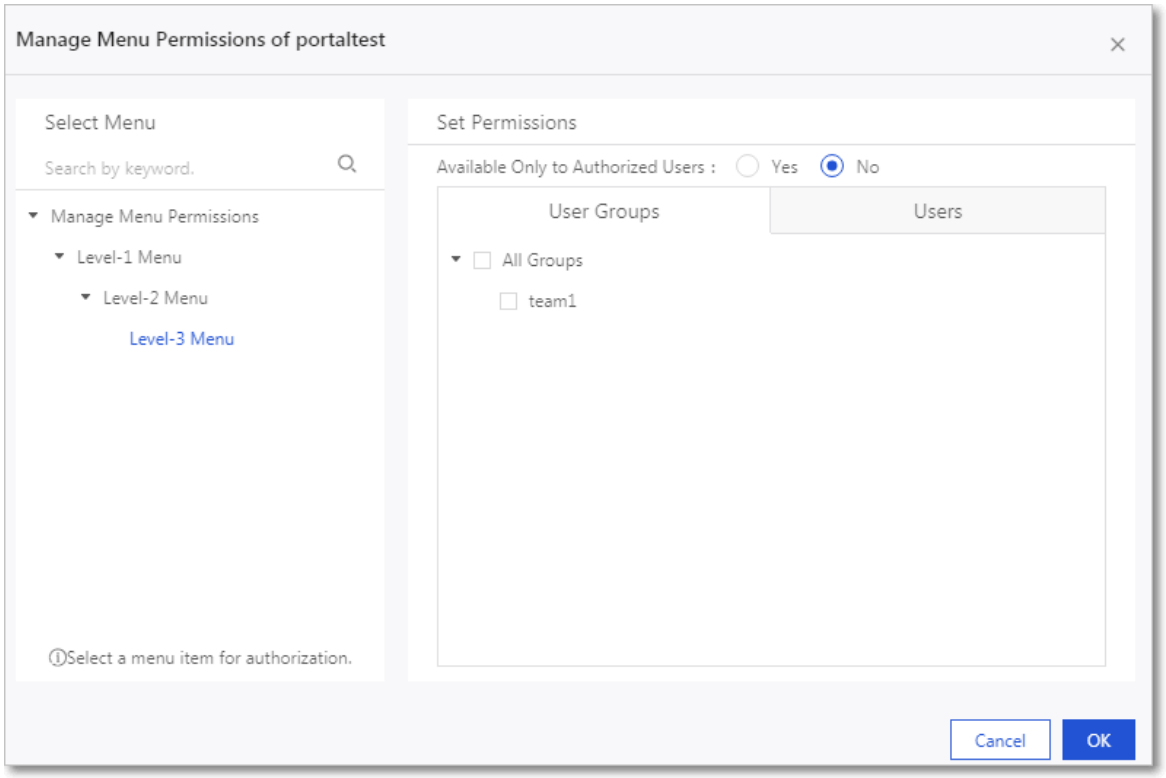
Workspace administrators can configure permissions on viewing BI portal menus in a workspace, also referred to as a group workspace.

The permissions can be granted to user groups or individual users by performing the following steps:

1. Log on to the Quick BI console.
2. Select a workspace. For information about how to create a workspace, see Create a workspace.
3. In the left-side navigation pane of the Workspace page, click **BI Portals**.
4. On the BI Portals page, select the BI portal that you want to configure the menu permissions, click the **More** icon in the Actions column or right-click the BI portal, and select **Manage Menu Permissions**.



5. In the **Manage Menu Permissions** dialog box that appears, select the menu for which you want to manage the permissions, specify whether the menu is available only to authorized users, and select the users or user groups that you want to authorize.



> **Note** The values of **Available Only to Authorized Users** are described as follows:
>
> - Yes: Only authorized users and user groups can access this menu.
> - No: All users and user groups can access this menu.

6. Click **OK**.

7.8.5. Share a data object in a personal workspace

Only the owner of a data object has the permissions to share the data object.

Prerequisites

The Quick BI service is purchased.

Context

In a personal workspace, you can share **workbooks**, **dashboards**, and **BI portals**. Shared data objects are read-only for other Apsara Stack tenant accounts and RAM users. Other Apsara Stack tenant accounts and RAM users do not have the permissions to modify, delete, or save the data objects.

Members with whom a data object is shared can log on to the Quick BI console and view the data object on the **My Items** page.

This topic uses a dashboard as an example to describe how to share data objects in a personal workspace.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the Workspace page, click **Dashboards**.
3. On the Dashboards page, select the dashboard that you want to share with others and click the **Share** icon in the Actions column.
4. Enter the account of the user that you want to share the dashboard with, and specify an expiration date.
5. Click **Save** to share the dashboard.

7.8.6. Share a data object in a workspace

In a workspace, you can share **workbooks**, **dashboards**, and **BI portals**. Shared data objects are read-only for other Apsara Stack tenant accounts and RAM users. Other Apsara Stack tenant accounts and RAM users do not have the permissions to modify, delete, or save the data objects.

Prerequisites

The Quick BI service is purchased.

Context

Only the owner of a data object or administrators of the workspace have the permissions to share the data object. Data objects can only be shared with Apsara Stack tenant accounts and RAM users within the same organization.

If the Works to Be Shared check box is cleared for a workspace, the data objects in the workspace cannot be shared.

This topic takes a dashboard as an example to describe how to share data objects in a workspace.

Procedure

1. Log on to the Quick BI console.
2. Select a workspace.
3. In the left-side navigation pane of the Workspace page, click **Dashboards**.
4. On the Dashboards page, select the dashboard you want to share with others and click the **Share** icon in the Actions column.
5. Enter the alias or account of the user that you want to share the dashboard with, and specify an expiration date.
6. Click **Save** to share the dashboard.

7.8.7. Publish data objects that are stored in a personal workspace

You can publish data objects that are stored in a personal workspace. All Internet users can visit the URLs that point to published data objects. We recommend that you do not publish data objects that include sensitive business data.

Prerequisites

You have purchased Quick BI.

Context

In a personal workspace, you can publish **dashboards** and **workbooks**.

This topic takes a dashboard as an example to describe how to publish data objects in a personal workspace.

Procedure

1. Log on to the Quick BI console.
2. Select a workspace.
3. Click **Dashboards** to go to the Dashboards page.
4. Select the target dashboard and click the **More** icon and select Make Public.
5. Specify an expiration date and click **Make Public**.

   A URL is generated and appears in the Make Public dialog box. You can copy and paste the URL into the address bar of your browser, and then access the dashboard by using the URL.

7.8.8. Make a data object in a workspace public

This topic describes how to make a data object in a workspace, also referred to as a group workspace, public. All Internet users can visit public data objects by using the provided URLs. We recommend that you do not publish data objects that contain sensitive business data.

Prerequisites

The Quick BI service is purchased.

Context

In a workspace, you can make **dashboards** and **workbooks** public.

This topic uses a dashboard as an example to describe how to make data objects in a workspace public.

Procedure

1. Log on to the Quick BI console.
2. Select a workspace.
3. In the left-side navigation pane of the Workspace page, click **Dashboards**.
4. On the Dashboards page, select the dashboard that you want to make public, click the **More** icon in the Actions column, and select Make Public.
5. In the Make Public dialog box, specify an expiration date and click **Make Public**.

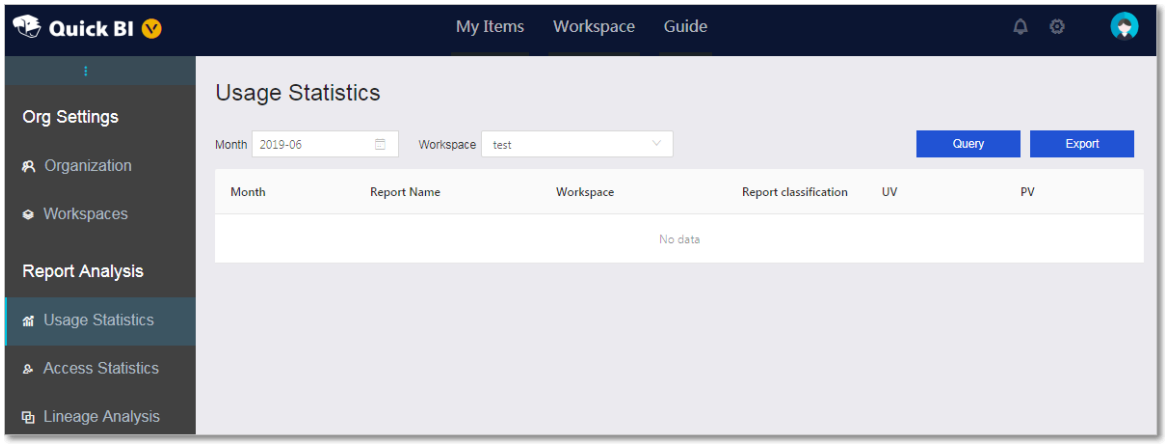
   A URL is generated and appears in the Make Public dialog box. You can copy and paste the URL into the address bar of your browser to access the dashboard.

7.9. Report statistics

7.9.1. Usage statistics

Usage statistics allow you to track the Unique Visitor (UV) and Page View (PV) values of a specific report in a specific month.

1. On the homepage of the Quick BI console, click the **Settings** icon.
2. In the left-side navigation pane, click **Usage Statistics**.
3. On the Usage Statistics page, select a month and workspace and click **Query**.

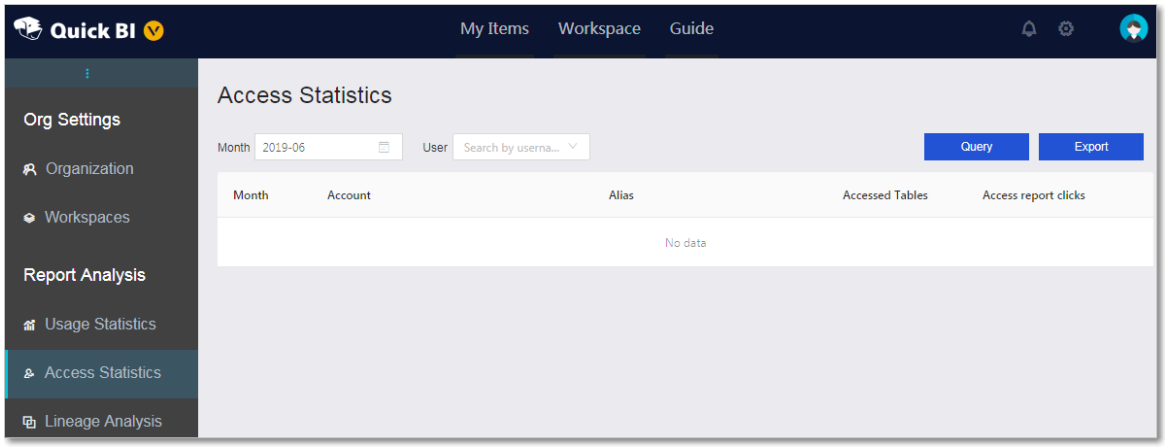


4. Click **Export** to export the statistics data to a local device in an Excel file.

7.9.2. Access statistics

Access statistics allow you to track the number of reports that you have accessed in a specific month and the number of clicks on a specific report.

1. On the homepage of the Quick BI console, click the **Settings** icon.
2. In the left-side navigation pane, click **Access Statistics**.
3. On the Access Statistics page, select a month, enter the member alias, and click **Query**.

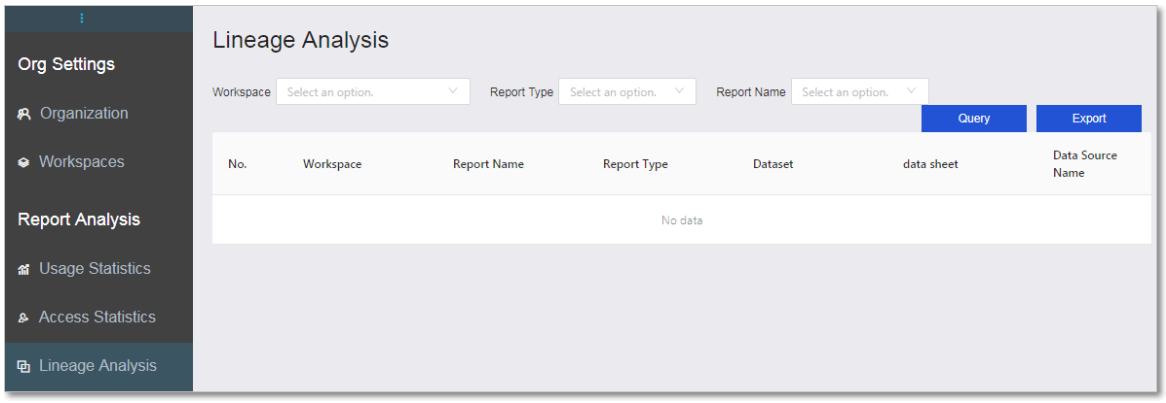


4. Click **Export** to export the statistics data as an Excel file to a local device.

7.9.3. Lineage analysis

Lineage analysis allows you to query information about a specific report, such as the workspace, report type, dataset, chart, and data source name.

1. On the homepage of the Quick BI console, click the **Settings** icon next to the profile picture.
2. In the left-side navigation pane, click **Lineage Analysis**.
3. On the Lineage Analysis page, select the workspace, report type, and report name of the report you want to query, and click **Query**.



4. Click **Export** to export the analysis results as an Excel file to a local device.

8.Graph Analytics

8.1. What is Graph Analytics?

Graph Analytics is a visual analysis platform for relationship networks. Graph Analytics is widely used in Alibaba Group and Ant Financial for risk control including anti-fraud, anti-theft, and anti-money laundering solutions. Graph Analytics provides solutions for multiple industries, including public security protection, taxation, customs, banking, insurance, and the Internet.

Graph Analytics is designed to facilitate multi-source data integration, computing applications, visual analytics, and intelligent businesses. Based on relationship networks, Graph Analytics can visualize the properties of objects and reveal the relationship among objects.

Graph Analytics provides features including relationship networks, search networks, intelligent networks, information cubes, intelligent judgement, collaboration and sharing, and dynamic modeling. It visualizes data and integrates machine computing capabilities with human cognition. This allows you to gain insight into massive data and obtain information and knowledge directly and efficiently.

8.2. Quick Start

8.2.1. Log on to Administration Console of Graph Analytics

Administration Console is the data configuration platform for Graph Analytics. In Administration Console, you can configure data sources, objects, links, events, and other advanced configuration items. Before you use Graph Analytics, you must log on to Administration Console to perform the related configurations.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

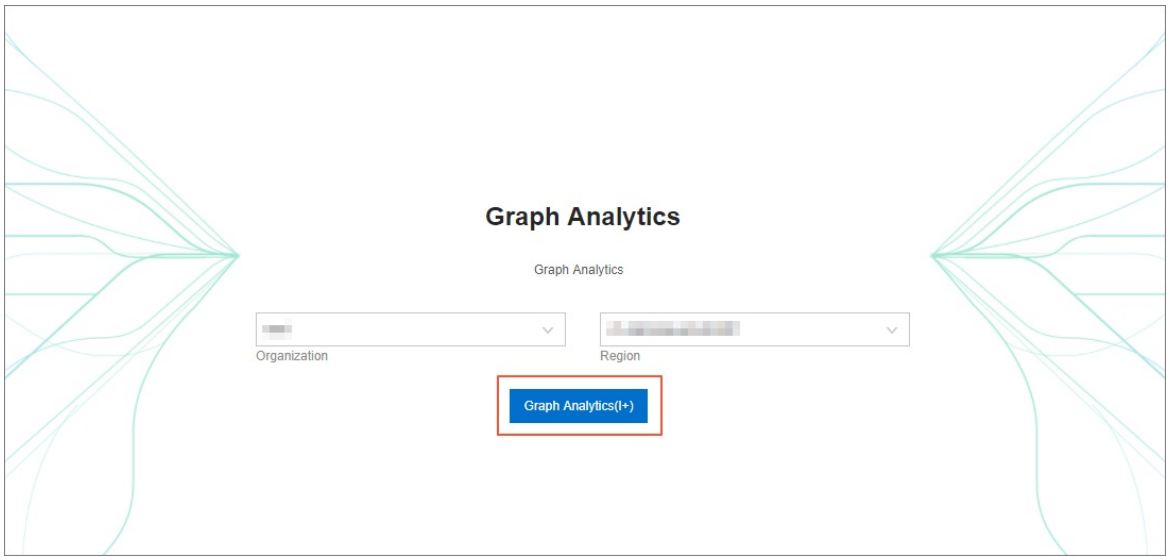
Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password used to log on to the console from the operations administrator.

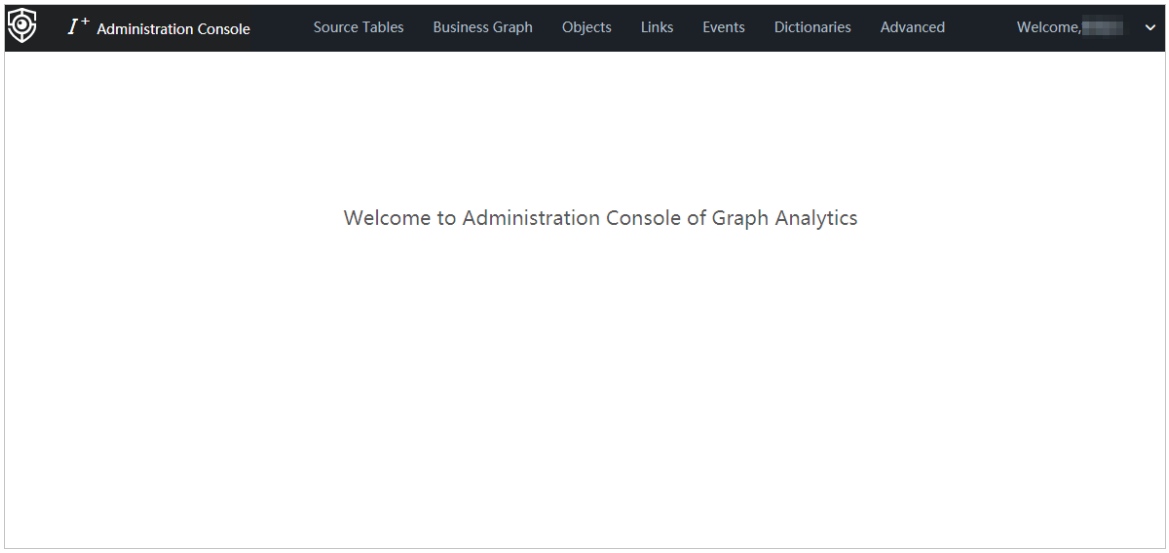
> **Note** When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
>
> - Uppercase or lowercase letters.
> - Digits.
> - Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Product** > **Big Data** > **Graph Analytics**.
5. On the Graph Analytics page that appears, specify **Organization** and **Region**, and click **Graph Analytics(I+)** to redirect to the homepage of Analytics Workbench.



> **Note** You cannot use the root organization for the redirection.

6. Move your pointer over the username in the upper-right corner and select **Administration Console** to redirect to Administration Console of Graph Analytics.



8.2.2. Create data sources

Before you perform a relationship analysis, you must integrate data that you want to analyze, typically databases, into Graph Analytics. These databases will be used as data sources. In Graph Analytics, every data source is unique and can be added only once.

Prerequisites

- You have an account and password for Graph Analytics and are authorized to perform operations on Administration Console of Analytics Workbench.
- You have obtained the IP address, user name, password, port number, and other information of an accessible data source.

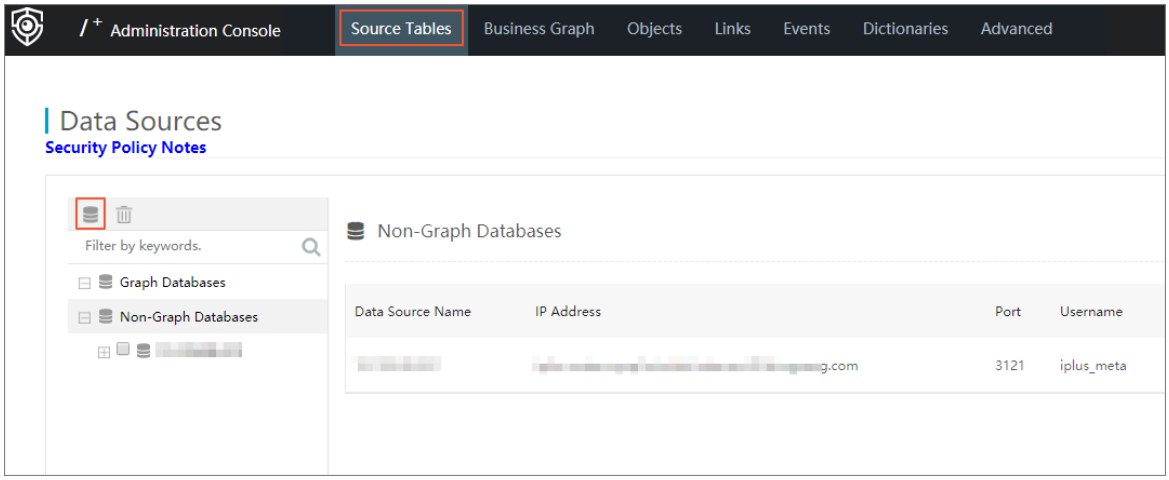
Context

A data source is one of the entries for new objects, links, and events. It is also the only entry for objects, links, and events to map to a data table. Objects, links, and events that are created on the **Object Information**, **Link Information** and **Event Information** pages are logical business objects, links, and events without mappings.

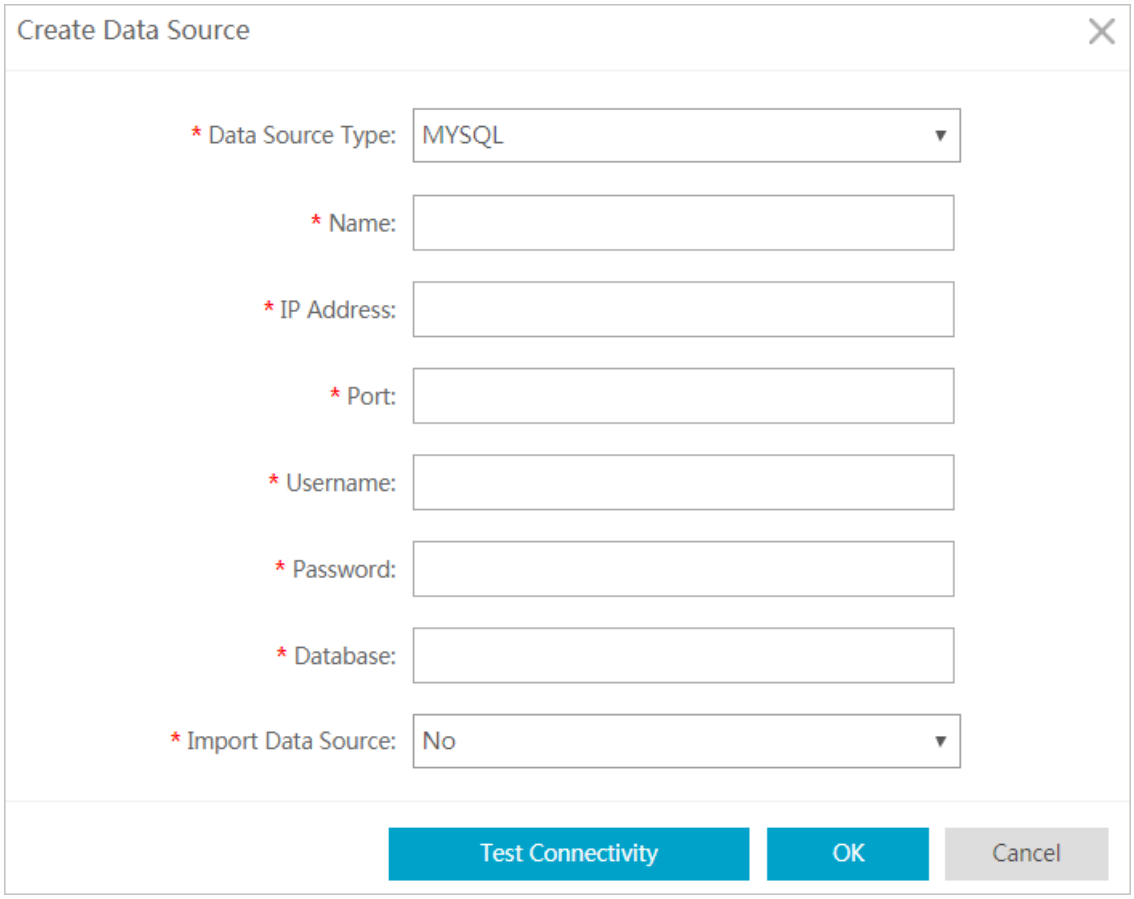
> **Note** Objects, links, and events created for the data source take effect only after you log on again.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Source Tables** to redirect to the **Data Sources** page.



3. On the **Data Sources** page, click the **Create Data Source** icon in the left-side navigation pane. The **Create Data Source** dialog box appears.



4. In the **Create Data Source** dialog box that appears, specify the data source parameters as needed.

Data source parameters

Parameter	Description
Data Source Type	The data source type you want to select. Supported data source types include: **MYSQL**, **ORACLE** , **RDS** , and **GREENPLUM**.

Parameter	Description
Name	The name of the data source. It can be user-defined.
IP Address	The IP address or domain name of the data source.
Port	The port number of the data source.
Group	The department or group to which the data source belongs.
Username and Password	The username and password that are used to connect to the data source.
Database	The name of the database that functions as the data source.
Import Data Source	If Data Source Type is not set to **ORACLE**, you must specify this parameter. You can import data into Analytics Workbench only after you have specified this parameter.

5. After you have configured the preceding parameters, click **Test Connectivity** to check whether the data source can be connected.

   If the data source is connected properly, a message appears, indicating that the test succeeded. If the data source cannot be connected, check whether the information is correct and the data source itself is functioning properly.

6. After the connectivity test is confirmed as successful, click **OK**.

8.2.3. Create OLEP models for tables

After you add a data source, you must create object, link, event, and property (OLEP) models for the tables in the data source as needed. Before you configure OLEP tables, prepare the tables for which you will create OLEP models, the columns of each table, and the business models you want to configure. Referenced tables cannot be deleted.

Prerequisites

You have created an accessible data source.

Context

OLEP models include the following types of mappings: table-to-object mappings, table-to-link mappings, and table-to-event mappings. You can add objects, links, and events when you create OLEP models. After that, you can view and configure these objects, links, and events on the **Object Information**, **Link Information**, and **Event Information** pages, respectively. You can configure these items to reflect your business semantics. An OLEP table serves as a source for configuring objects, first-degree links, and events. A table can be mapped to multiple objects, links, and events.

Procedure

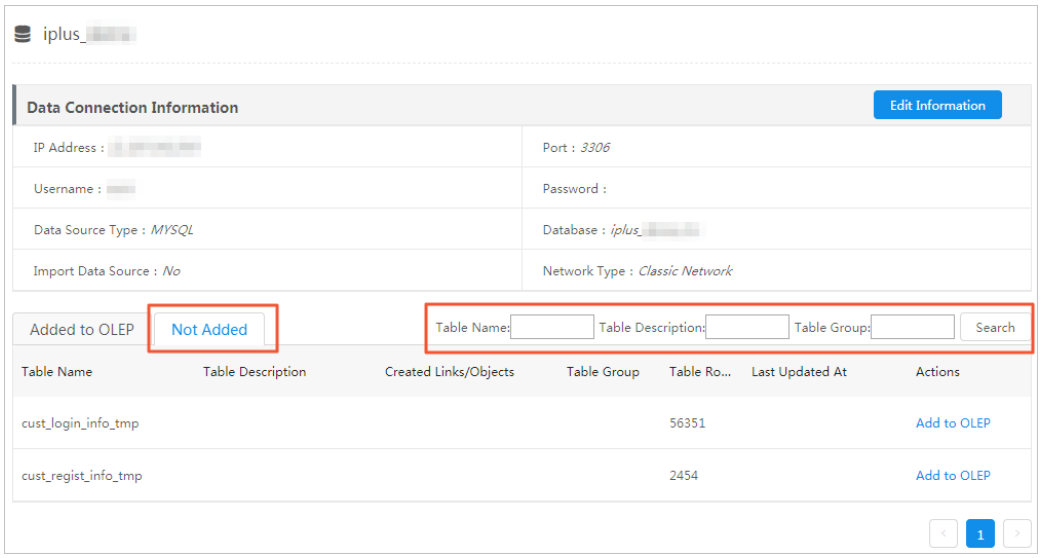
1. Log on to Administration Console of Graph Analytics.
2. Click **Source Tables** in the top navigation bar. The **Data Sources** page appears.
3. Click a data source in the left-side navigation pane. The data source details are displayed

on the right side of the page.

4. Click the **Not Added** tab. All tables that have no OLEP models are displayed.

   You can search for a table quickly and accurately by specifying the Table Name, Table Description, or Table Group parameter.

   Tables that have no OLEP models



5. Select a table, and then click **Add to OLEP** in the Actions column. The **Select OLEP** dialog box appears.

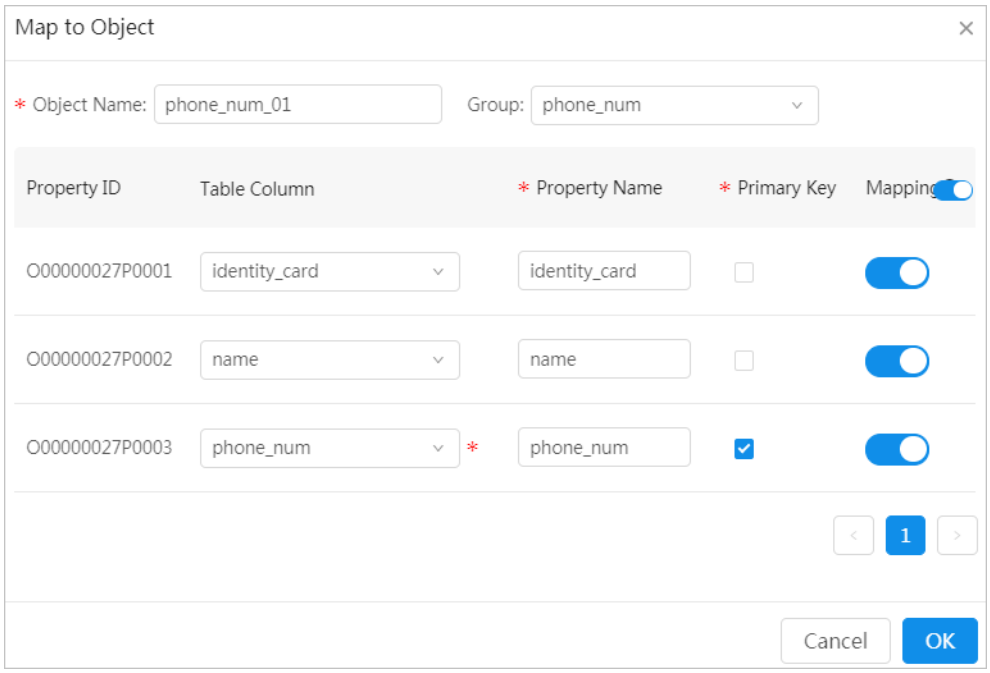
   Select OLEP dialog box

   The **Select OLEP** dialog box contains the **Object**, **Link**, and **Event** tabs which are used to create mappings to objects, links, and events, respectively. For more information about how to create a mapping to an object, link, or event, see Step 6, Step 7, and Step 8.

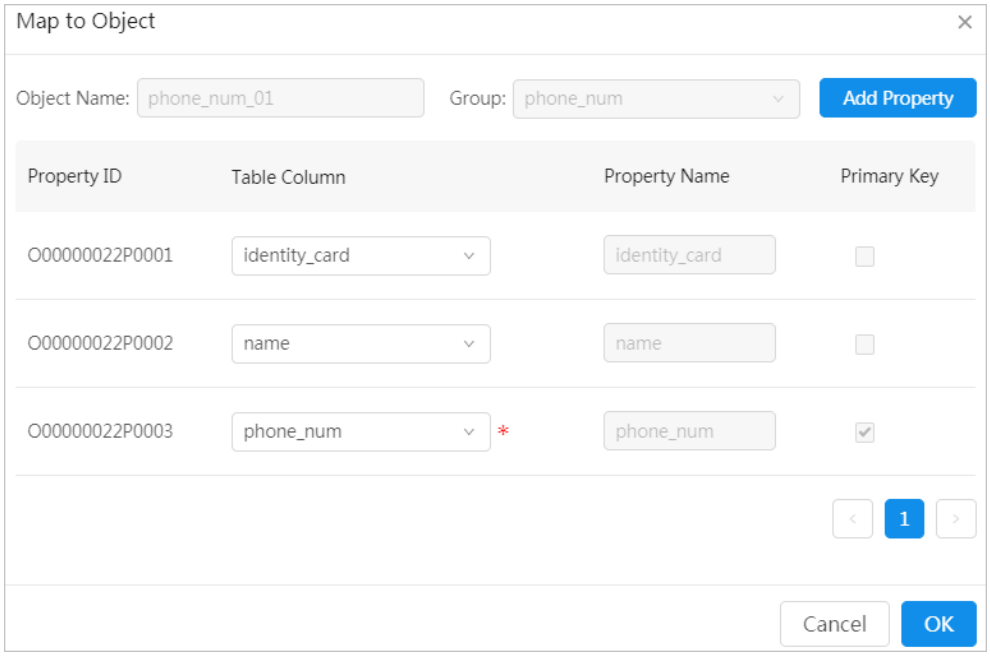
If no existing object groups, link groups, or event groups meet your requirements, click **Create Group** to add an object group, link group, or event group.

6. Map the table to an object.
   i. Select **New Object** or an existing object and then click **OK**. The **Map to Object** dialog box appears.

Map to a newly created object



Map to an existing object



ii. Configure the parameters as needed.

- New object: Configure the parameters based on Parameters used to map the table to a new object.
- Existing object: Create a one-to-one mapping between each **Table Column** and **Property Name** as needed.

  If the number of table columns is greater than the number of existing properties of the object, you can click **Add Property** to add new properties.

Parameters used to map the table to a new object

Field	Description
Object Name	The user-defined object name. It must be unique.
Group	The object group to which the object belongs. All available object groups are displayed in the drop-down list.
Property Name	The name of an object property to which a table column is mapped. By default, the property name is the same as the column name. You can also define the property name as needed. On the Analytics Workbench, property names are displayed instead of the actual table columns that are mapped to the properties.
Mapping	Indicates whether to enable the property mapping.
Primary Key	The property that is used as a primary key. Each primary key uniquely identifies an object. You must configure one or more properties as primary keys for each object. You must enable **Mapping** for primary keys.

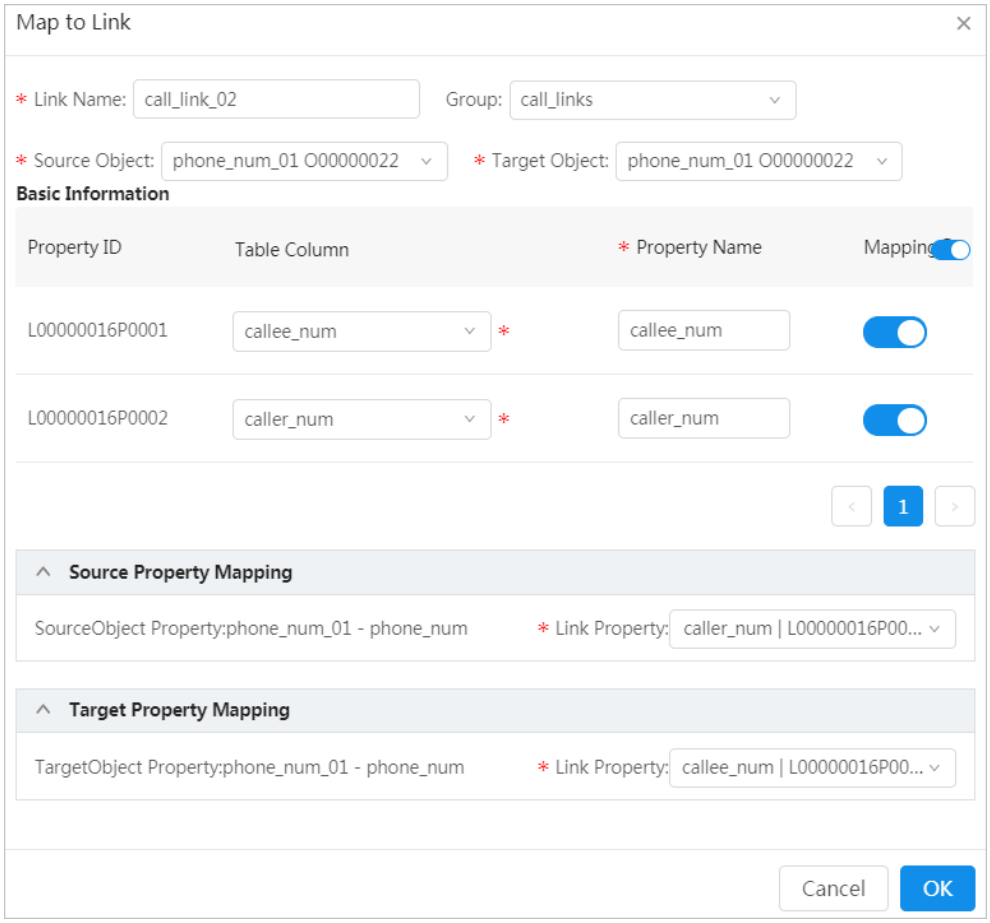
iii. Click **OK**.

7. Map the table to a link.

i. Click the **Link** tab. All first-degree links to which the current table has been mapped are displayed.

ii. Select **New Link** or an existing link and then click **OK**. The **Map to Link** dialog box appears.

Map to a newly created link



Map to an existing link

iii. Configure the parameters as needed.

- New link: Configure the parameters based on Parameters used to map the table to a new link.
- Existing link: Create a one-to-one mapping between each **Table Column** and **Property Name** as needed.

  If the number of table columns is more than the number of existing link properties, you can click **Add Property** to add new link properties.

Parameters used to map the table to a new link

Field	Description
Link Name	The user-defined link name. It must be unique.
Group	The link group to which the link belongs. All available link groups are displayed in the drop-down list.
Source	The source object of the link. You can select an object from the drop-down list. The **Source Property Mapping** parameter is displayed only after you configure the Source Object parameter.
Target	The target object of the link. You can select an object from the drop-down list. The **Target Property Mapping** parameter is displayed only after you configured the Target Object parameter.
Property Name	The name of a link property to which a table column is mapped. By default, the property name is the same as the column name. You can also define the property name as needed. On the Analytics Workbench, the Property Name values are displayed as the table header in **Details** on the **Graph** page.
Switch	Indicates whether to enable the property mapping.
Link Property in Source Property Mapping	The link property to which a primary key property of the source object is mapped.
Link Property in Target Property Mapping	The link property to which a primary key property of the target object is mapped.

iv. Click **OK**.

8. Map the table to an event.

i. Click the **Event** tab. All events to which the current table has been mapped are displayed.

ii. Select **New Event** or an existing event and then click **OK**. The **Map to Event** dialog box appears.

iii. Configure parameters as needed.

- New event: Configure the parameters based on Parameters used to map the table to a new event.
- Existing event: Create a one-to-one mapping between each **Table Column** and **Property Name** as needed.

  If the number of table columns is greater than the number of existing event properties, you can click **Add Property** to add new event properties.

Parameters used to map the table to a new event

Field	Description
Event Definition Name	The user-defined event name. It must be unique.
Group	The event group to which the event belongs. All available event groups are displayed in the drop-down list.
Property Name	The name of an event property to which a table column is mapped. By default, the property name is the same as the column name. You can also define the property name as needed. On the Analytics Workbench, the Property Name values are displayed as the table header in **Details** on the **Graph** page.
Switch	Indicates whether to enable the property mapping.
Primary Key	The property that is used as a primary key. Each primary key uniquely identifies an event. You must configure one or more properties as primary keys for each event. **Switch** must be turned on for the properties that are configured as primary keys.
Map Primary Keys to Correlated Objects	The mappings between the primary keys of correlated objects and the event properties. Two or more correlated objects are required. You can click **Add Mapping** to add more necessary mappings between the primary keys of correlated objects and the event properties. You must enable **Mapping** for the event properties to which the primary keys of the correlated objects are mapped.

iv. Click **OK**.

9. After you create OLEP models for the data tables, click the **Added to OLEP** tab to check the results.

8.2.4. Add OLEP table columns

If a data table has been mapped to an object, link, or event, and the table still has unoccupied columns (columns that are not correlated with any object, link, or event), you can add these columns to the existing mappings as needed.

Prerequisites

A data table has been mapped to an object, link, or event, but the table still has unoccupied columns.

Context

Before you configure the OLEP table columns, sort out the columns for which you will create OLEP models and data types of the columns, especially the time columns.

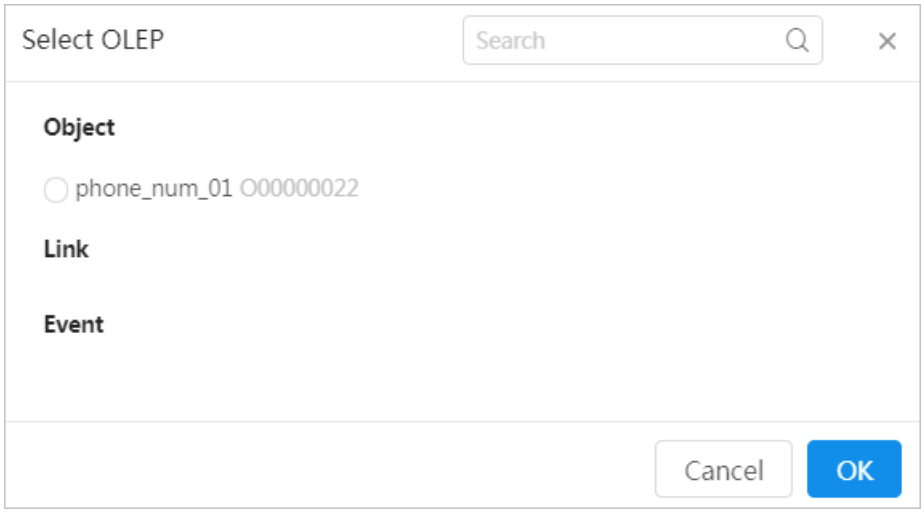
Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click **Source Tables** in the top navigation bar.
3. On the **Data Sources** page, click a data source in the left-side navigation pane, and then click the table to which you want to add the columns.
4. Click the **Columns Not Added** tab in the right-side area. In the **Columns Not Added** tab that appears, click **Add** in the Actions column.

   Columns displayed in the **Columns Not Added** tab are not mapped to any object, link, or event.
5. In the **Select OLEP** dialog box that appears, select the object, link, or event to which the columns map, and then click **OK**.

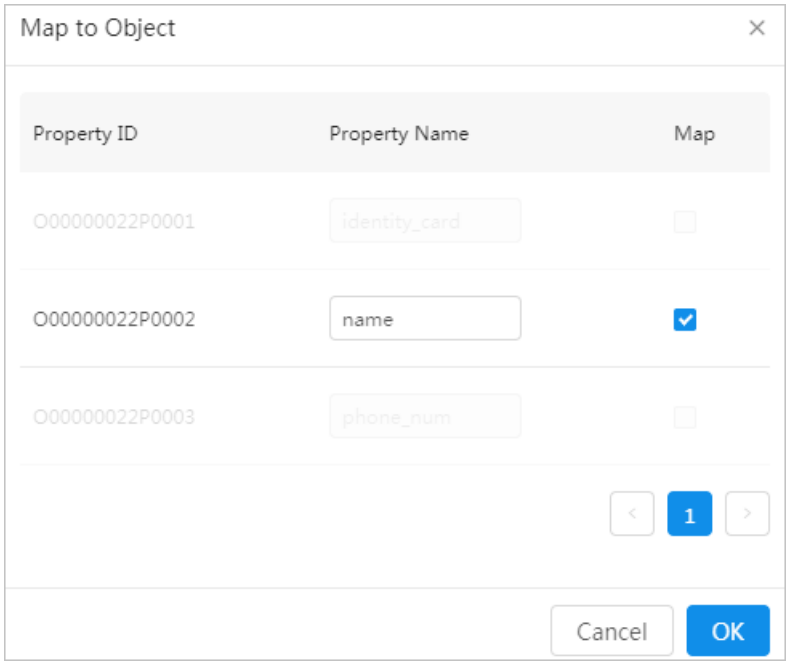
   The **Select OLEP** tab only displays the objects, links, and events that have mapped to the current data table.

   The following example demonstrates how to add columns to an object.

6. In the **Map to Object** dialog box that appears, select the object properties that map to the columns you want to add.

   Object properties that have been mapped to the current data table are dimmed and cannot be operated.



7. After you configure the preceding parameters, click **OK**.

8.2.5. Configure object properties and business parameters

After you add an object, you need to configure the business parameters of the object based on your requirements so that you can view and analyze the object in Analytics Workbench.

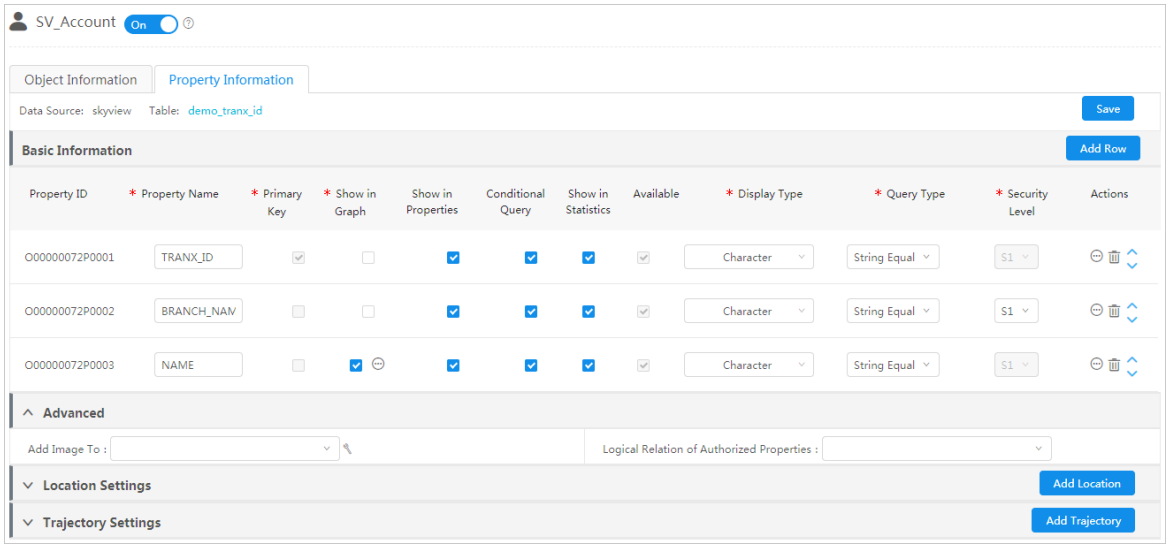
Prerequisites

- You have created a data source. For more information, see Create data sources.
- You have configured mappings between tables and objects, links, or events. For more information, see Create OLEP models for tables.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click **Objects** on the top of the page.
3. In the left-side navigation pane of the **Object Information** page, click the name of the object you want to configure and then click the **Property Information** tab on the right side.

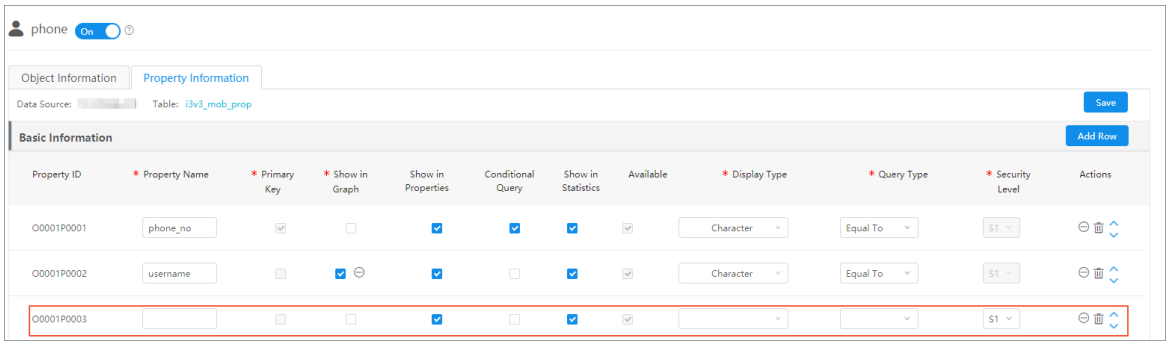
   If this object has been mapped to a physical table in the data source, the **Property Information** tab displays the **Data Source** and **Table** information.



4. Specify parameters in the **Basic Information** section.

   Click **Add Row** to add a property in **Basic information.**

   Parameters in Basic Information describes the parameters in **Basic Information.**



Parameters in Basic Information

Parameter	Description
Property ID	The ID of a property. It is automatically generated.
Property Name	The property name that is displayed on Analytics Workbench. Enter a name that describes your business.
Primary key	You must select one or more primary keys for the properties when you add an object for the first time. After the configuration is complete, you cannot modify or delete the primary keys. If you add a node in Analytics Workbench, you must enter the physical table column mapped by the primary key properties. For example, if the ID card number is the primary key, you need to enter the ID card number when you add an ID card node in Analytics Workbench.

Parameter	Description
Show in Graph	If you select this parameter, **Property Name** of this property will be displayed in **Graph** in Analytics Workbench together with the object node. Otherwise, Property Name will not be displayed. For example, if you select the ID card number, this number will be displayed in **Graph** together with the ID card object. If you select the name property at the same time, the name and the ID card number will be displayed together with the ID card object. If you select this parameter for a specific property, a bubble icon appears next to the option. You can click the bubble icon to specify whether to show the **Property Name** in **Graph**. For example, if you select this parameter for the ID card number, and choose to display **Property Name** in **Graph**, the ID card property displayed in **Graph** will be **ID card number: xxxxxx**.
Show in Properties	If you select this parameter for a property, the property will be displayed on the Details tab and the Property tab in the right-side pane of the Graph page in Analytics Workbench. Otherwise, the property will not be displayed.
Conditional Query:	If you select this parameter for a property, you can query the object based on this property in **Target Object** when you perform an analysis on the **Graph** page.
Show in Statistics	If you select this parameter for a property, the property is displayed on the **Statistics** tab in the right-side pane of the Graph page in Analytics Workbench. If you do not select this parameter, the property is not displayed in Analytics Workbench.
Available	If you select this parameter for a property, the property takes effect and is displayed in Analytics Workbench. This parameter must be selected for primary key properties. If any of the following parameters has been selected for the property: **Primary Key**, **Show in Graph**, **Show in Properties**, **Conditional Query** and **Show in Statistics**, the **Available** parameter will be automatically selected for a property. The **Available** parameter will be automatically cleared if you clear all the preceding parameters.
Display Type	After you configure this parameter, the property is displayed on the Details tab and the Property tab in the right-side pane of the Graph page in Analytics Workbench based on the selected type. **Note** To display a property in the format of **Dictionary**, you need to configure a dictionary first.
Query Type	The data type that is supported in the query condition of a property. If you select **Dictionary** for **Display Type**, you must select **Dictionary Option** for **Query Type**.

Parameter	Description
Security Level	The security level for a property. A user with a security level lower than the value of this parameter cannot view the property.
Search Item Configuration Default Query Condition Settings Authorization Code Derived Field	Click the icon in the Actions column corresponding to a property. Specify the following parameters: ○ Search Item Configuration: Search items are displayed in the drop-down list only after they have been configured in Configure a search item. ○ Default Query Condition Settings: the default condition used for an object query. If other properties are used as conditions for a query, this condition is also used by default. ○ Authorization Code: After the authorization code function is enabled, only the authorized users can access this property. ○ Derived Property: After a property is set as a derived property, it is automatically generated based on other properties. Configure the method in which the field is generated as needed.
Delete	If a property is no longer used, you can click the icon to delete this property.
Sort order	The Move Up and Move Down arrows are used to adjust the order of properties that are displayed in Analytics Workbench.

5. (Optional) If you need to add multiple properties, you can refer to the preceding steps to add more properties.
6. (Optional) Specify parameters in **Advanced**.

   Parameters in Advanced describes the parameters in **Advanced**.

Parameters in Advanced

Parameter	Description
Add Image To	The avatar of the object that is displayed in **Graph**. Select a property of the object, and then specify the URL of the image and the suffix of the image. **Add Image To** allows you to specify a combination of the prefix, the property, and the suffix. The prefix is the URL of the image, and the suffix is the image format.
Logical Relation of Authorized Properties	The logical relationship between the authorization codes of properties in each record: ○ **AND**: The current record is visible to the users who meet all authorization code conditions of the properties in this record. ○ **OR**: The current record is visible to the users who meet any one authorization code condition of the properties in this record.

7. Click **Save**.

8.2.6. Configure link properties and business parameters

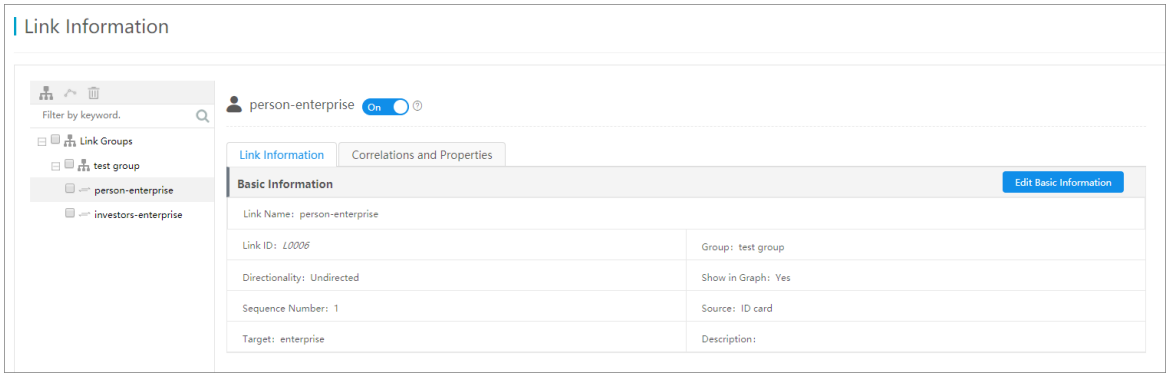
After a first-degree link is added, you need to configure the properties and business parameters of the link based on your business requirements, so that you can view and apply this link in Analytics Workbench. This topic describes how to configure the properties and business parameters of a first-degree link.

Prerequisites

A first-degree link is created. For more information, see Create a first-degree link.

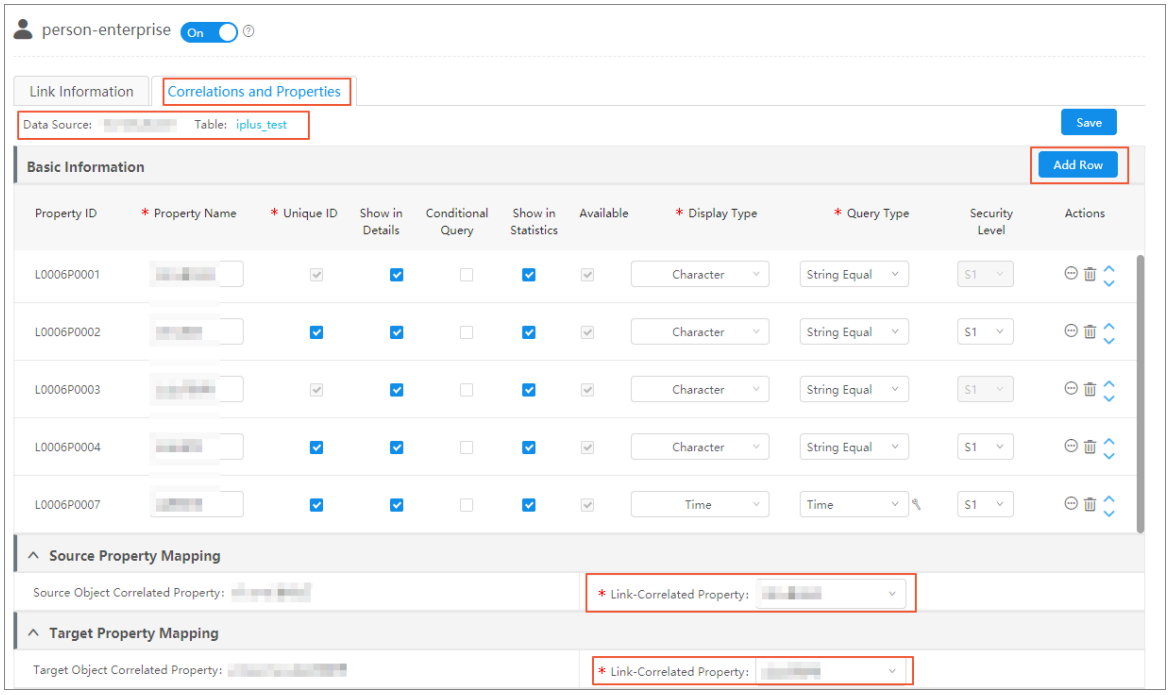
Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Links**.
3. In the left-side navigation pane, click the link group that contains the first-degree link you want to configure, and then click the target link.



4. On the right side of the page, click the **Correlations and Properties** tab.

   On the **Correlations and Properties** tab, if the link is mapped to a data table in the data source, **Data Source** and **Table** are displayed in the property information above the Basic Information section. You can click the table name to redirect to the table page.



5. Configure the parameters in the **Basic Information** section.

   If you need to add a property for a link in the **Basic Information** section, click **Add Row**.

> **Note**
>
> **Link-Correlated Property** in the **Source Property Mapping** section and **Link-Correlated Property** in the **Target Property Mapping** section must be different and both of them must be configured. Therefore, a link must have two or more properties.

Parameters in the Basic Information section describes the parameters in the **Basic Information** section.

Parameters in the Basic Information section

Parameter	Description
Property ID	The ID of a property. It is automatically generated.
Property Name	The name of a property. If you select Available for a property, the name of the property is displayed in Analytics Workbench.
Unique ID	Allows you to define the logical primary key of a data table.
Show in Details	If you select this parameter for a property, the property is displayed on the **Details** tab in Analytics Workbench.
Conditional Query	If you select this parameter for a property, you can query a link based on the link type specified in **Link Type** when you perform analysis on the **Graph** page in Analytics Workbench.

Parameter	Description
Statistics	If you select this parameter for a property, the property is displayed on the **Statistics** tab in the right-side pane of the Graph page in Analytics Workbench. If you do not select this parameter, the property is not displayed in Analytics Workbench.
Available	If you select this parameter for a property, the property takes effect and is displayed in Analytics Workbench. If one of the following parameters is selected for the property, the **Available** option is automatically selected for a property: **Unique ID**, **Show in Details**, **Conditional Query**, and **Show in Statistics**. If all of the preceding parameters are cleared for a property, the **Available** parameter is automatically cleared for the property.
Display Type	After you set the display type, the property is displayed on the **Property** tab in the right-side pane of the Graph page in Analytics Workbench based on the selected type. **Note** If you want to display a property in the **Dictionary** format, configure a dictionary first.
Query Type	The data type that is supported in the query condition of a property. If you select **Dictionary** for **Display Type**, you must select **Dictionary Option** for **Query Type**.
Security Level	The security level for a property. A user with a security level lower than the value of this parameter cannot view the property.
Search Item Configuration **Default Query Condition Settings** **Authorization Code** **Derived Field**	Find the property and click the More icon in the Actions column. Configure the following parameters: ○ Search Item Configuration: Search items are displayed in the drop-down list only after they have been configured in Configure a search item. ○ Default Query Condition Settings: the default condition used for a link query. If other properties are used as conditions for a query, this condition is also used by default. ○ Authorization Code: After the authorization code function is enabled, only authorized users can access this property. ○ Derived Property: After a property is configured as a derived property, it can be generated automatically based on other properties. Configure the method in which the column is generated based on your needs.
Delete	If a property is no longer used, you can click the Delete icon to delete this property.

Parameter	Description
Sort order	The Move Up and Move Down arrows are used to adjust the order of properties that are displayed in Analytics Workbench.

6. Set **Link-Correlated Property** in the **Source Property Mapping** and **Target Property Mapping** sections.

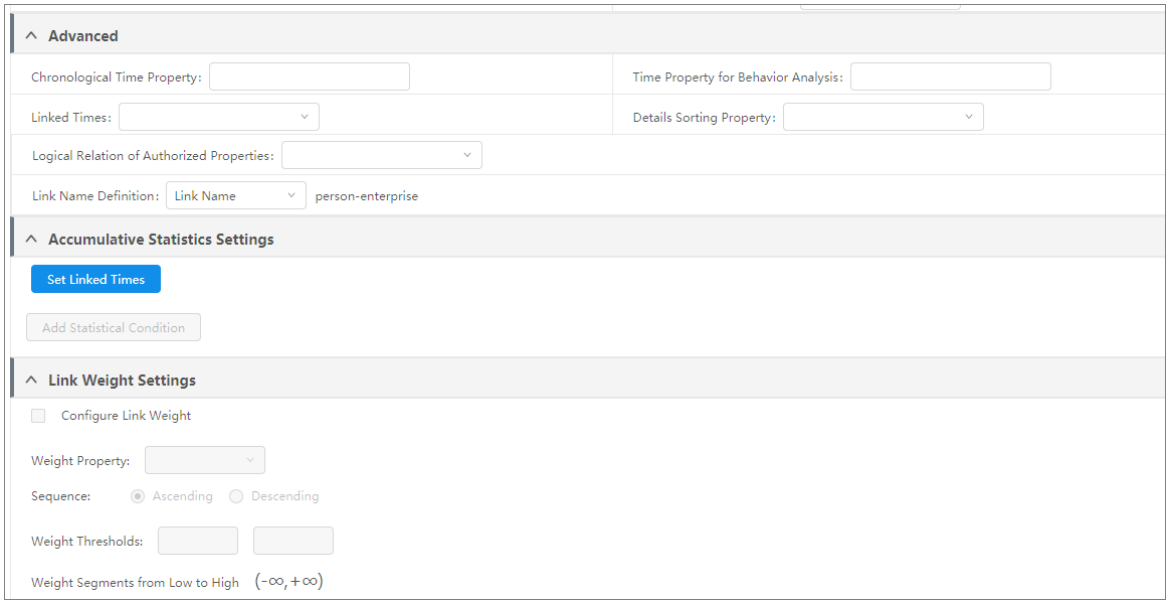
   These configurations are related to Source Object and Target Object of the link.

   Use **Source Property Mapping** as an example. **Source Object Correlated Property** and **Link-Correlated Property** must be mapped to the same column in the same table. The **Source Object Correlated Property** parameter is the primary key property of the source object, which is automatically loaded based on the Source Object parameter. For the **Link-Correlated Property** parameter, you must select the link property that is mapped to the same column in the same table as the Source Object primary key.

   Set **Target Property Mapping** in the same way you set **Source Property Mapping**.

7. (Optional)Configure parameters in the **Advanced**, **Accumulative Statistics Settings**, and **Link Weight Settings** sections based on your requirements.

   For more information about the key parameters, see Key parameters.



Key parameters

Section	Parameter	Description
	Chronological Time Property	The link properties involved in chronological analysis. From the drop-down list, select one or more link properties with the query type of time.
	Time Property for Behavior Analysis	The link properties involved in behavior analysis. From the drop-down list, select one or more link properties with the query type of time.

Section	Parameter	Description
Advanced	Linked Times	The number of the same values that are counted for a specific property in a link. The total number is displayed as the number of link occurrences. The **Linked Times** parameter is used as the default setting to filter link types. Assume that two lines of calls from user A to user C are displayed in the call log. The number of calls from user A to user C is displayed as two in the analysis results.
	Details Sorting Property	The default property by which the returned behavior details are sorted.
Accumulative Statistics Settings	None	Used to perform logical statistics for link properties of which the query type is numeric range. The logical statistics operations include top, equal sign (=), and greater-than-or-equal-to sign (≥). This configuration is suitable for business scenarios where statistics filter is required for link query results. The **Linked Times** parameter is used to filter records in the link query results. You can add statistical conditions to filter the link properties with the query type of numeric range.
Link Weight Settings	None	You can specify a link property with the query type of numeric range and calculate the link weight based on the numeric range specified for the link property.

8. After you modify the parameter configurations, click Save. A message appears, indicating that the modifications are saved.

8.2.7. Configure event properties and business parameters

After you have created an event, you must configure the event properties. Event properties are critical to an event. You can configure event properties, and associate the properties with objects on the Property Information tab.

Prerequisites

You have obtained an account and a password for Graph Analytics and you are granted the required event permissions.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click the **Events** tab in the top navigation bar. The **Event Information** page appears.
3. Click an event in the left-side navigation pane, and click the **Property Information** tab on the right side of the page. The **Property Information** tab appears.

4. Set the required event parameters.

   Click **Add Row** to add a property for a link in **Basic information.**

   The required parameters are displayed in the **Basic Information** and **Set Mappings Between Correlated Objects and Properties** areas. Required event property parameters describes the event parameters.

   > **Note** To save the property information, you must set all the required parameters.

Required event property parameters

Category	Parameter	Description
	Property ID	The ID of a property. It is automatically generated.
	Property Name	The property name that is displayed on Analytics Workbench. We recommend that you enter a name that describes the business type.
	Primary key	Each primary key uniquely identifies an event. A property cannot be deleted after it has been configured as a primary key.
	Show in Graph	**Note** For each event, you must select one or more properties you want to display in the graph. If you select this parameter, the **Property Name** of this property will be displayed in **Graph** in Analytics Workbench together with the object node. Otherwise, the property is not displayed. For example, if this parameter is selected for the ID card property of an event, the ID card number will be displayed in **Graph** with the event. If the name property is also selected, the name and the ID card number will be displayed with the event. If you select this parameter for a specific property, a bubble icon appears next to the option. You can click the bubble icon to specify whether to show the **Property Name** in **Graph**. For example, if you select this parameter for an ID card number, and choose to display the **Property Name** in **Graph**, the ID card property displayed in **Graph** will be **ID card number: xxxxxx**.

Category	Parameter	Description
Basic information	Show in Properties	If you select this parameter for a property, the property will be displayed in the right-side pane on the **Graph** page of Analytics Workbench. To view the property, choose **Properties** > **Event Properties**.
	Element Identifier	The element identifier of a property. Set this parameter based on the actual property.
	Conditional Query	If you select this parameter for a property, the event can be queried based on this property in **Link Type** on the **Graph** page of Analytics Workbench when you perform a relationship analysis.
	Statistics	If you select this parameter for a property, the event will be displayed in the right-side pane on the **Graph** page of Analytics Workbench. To view the property, choose **Statistics** > **Event Distribution**.
	Available	If you select this parameter for a property, the property takes effect and can be displayed on the Graph page of Analytics Workbench. This parameter is selected by default and cannot be changed.
	Display Type	The format in which a property is displayed in the right-side pane of the **Graph** page on Analytics Workbench. Set this parameter as needed.
	Query Type	The data type that is supported in the query condition of a property.
	Security Level	The security level for a property. A user with a security level lower than the value of this parameter cannot view the property.

Category	Parameter	Description
	Search Item Configuration	Click the More icon in the Actions column that corresponds to a property. Configure the following parameters: ○ Search Item Configuration: Search items are displayed in the drop-down list only after they have been configured in Configure a search item. ○ Default Query Condition Settings: The default condition used for a link query. If other properties are used as conditions for a query, this condition is also used by default. ○ Authorization Code: After the authorization code function is enabled, only authorized users can access this property. ○ Derived Property: After a property is set as a derived property, it can be generated automatically based on other properties. Configure the method in which the column is generated based on your needs.
	Default Query Condition Settings	
	Authorization Code	
	Derived Field	
	Delete	If a property is no longer used, you can click the Delete icon to delete this property.
	Sort order	The Move Up and Move Down arrows are used to adjust the order of properties displayed in Analytics Workbench.
Set Mappings Between Correlated Objects and Properties	Add Correlated Object	Adds a mapping between an object and the event. One event must have two or more objects mapped to it. Click **Add Correlated Object** to add a correlated object, and configure the mapping between the event and the primary keys of the object you have added.

5. (Optional)After you have specified the required parameters, you can specify the optional parameters as needed.

   The optional parameters are included in the **Advanced** and **Display Settings** areas. The optional parameters are described in Optional event property parameters.

   > **Note** Location Settings is currently not supported.

Optional event property parameters

Section	Parameter	Description
Advanced	Behavior Property	The properties based on which a behavior analysis is performed.
	Default Details Sorting Property	The property by which the details are sorted.
	Logical Relation of Authorized Properties	The logical relationship between the authorization codes of properties in each record. ○ AND: The current record is visible only to the users who meet all authorization code conditions of the properties in this record. ○ OR: The current record is visible to the users who meet any one authorization code condition of the properties in this record.
Display Settings	Enable Display	Indicates whether to show the event details.
	Group-by Properties	The property based on which events are aggregated. For example, aggregate **Travel Events** into a folder based on the **Train Number** property.

6. After the configurations are complete, click **Save** in the upper-right corner. A success message is displayed after the modifications are saved.

   An event is automatically enabled after its properties are saved.

8.2.8. Log on to Analytics Workbench

Analytics Workbench is a data analysis platform of Graph Analytics. After you configure relevant data in Administration Console of Graph Analytics, you can perform data analysis in Analytics Workbench.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password used to log on to the console from the operations administrator.

> **Note** When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
>
> - Uppercase or lowercase letters.
> - Digits.
> - Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Product** > **Big Data** > **Graph Analytics**.
5. On the Graph Analytics page that appears, specify **Organization** and **Region**, and click **Graph Analytics(I+)** to go to the homepage of Analytics Workbench.

> **Note** You cannot use the root organization for the redirection.

8.2.9. Create an analysis

After you log on to Analytics Workbench, you must create an analysis and add objects as nodes before you perform an analysis.

Prerequisites

- You have obtained an account and a password with the permission to perform graphic operations.
- You have created source tables, objects, links, and events.
- You have obtained data in the tables that have been mapped to the primary keys of the objects you want to analyze. You can query the tables in the database to obtain the data.

Procedure

1. Log on to Analytics Workbench.
2. Click **Create Analysis**. A **Temporary Analysis** tab appears.
3. Click **Add** in the toolbar and then click the blank space, or right-click the blank space and select **Add Node**. Specify parameters in the **Add Node** dialog box that appears.

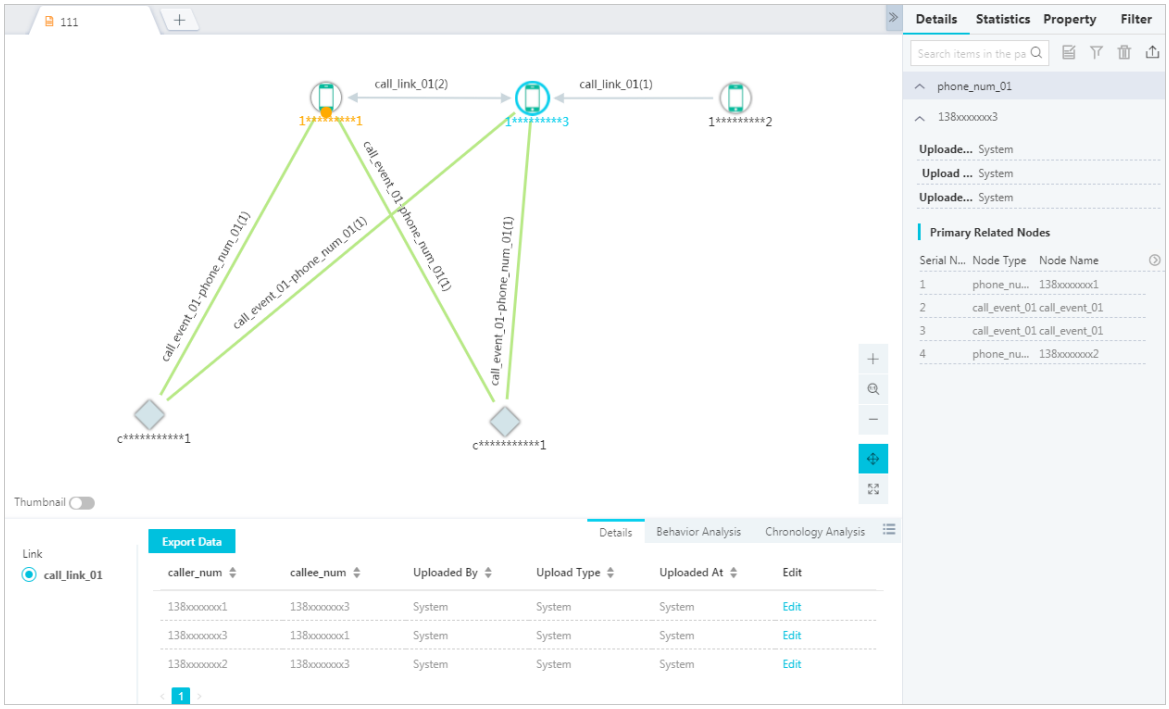
   Parameters to add a node describes the parameters.

Parameters to add a node

Parameter	Description

Parameter	Description
Object type	Displays all created objects. You can select an object as needed. **Note** Graph Analytics allows you to add compound nodes. For example, you can specify two sub-types for object type "person": ID card and passport. The person can be uniquely identified by the ID card or the passport.
Text area	Enter one or more primary key values. Separate multiple primary key values with commas (,).

4. Click **OK**.
5. Right-click a node that has been added, and select **Quick Extension**. The system automatically performs a link analysis based on the configured data sources, objects, links, and events, and displays the analysis results in a graph.



6. Select one or more objects, links, or events. Click **Behavior Chronology** in the lower-right corner to view the information on the **Details**, **Behavior Analysis**, and **Chronology Analysis** tabs.
7. Select one or more objects, links, or events. Click the « icon in the upper-right corner of the right-side pane to view the information on the **Details**, **Statistics**, **Property**, and **Filter** tabs.
8. After the analysis is complete, click **Save** in the upper-right corner. In the **Save Analysis** dialog box, specify **File Name**, select a folder, and then click **OK**. A success message appears after the file has been saved.

   After you have saved the analysis file, if a collaborative analysis is required, you can share

this personal analysis with other members.

9. Click the **Share** icon in the upper-right corner to specify the members you want to share this analysis with.

8.2.10. View analyses

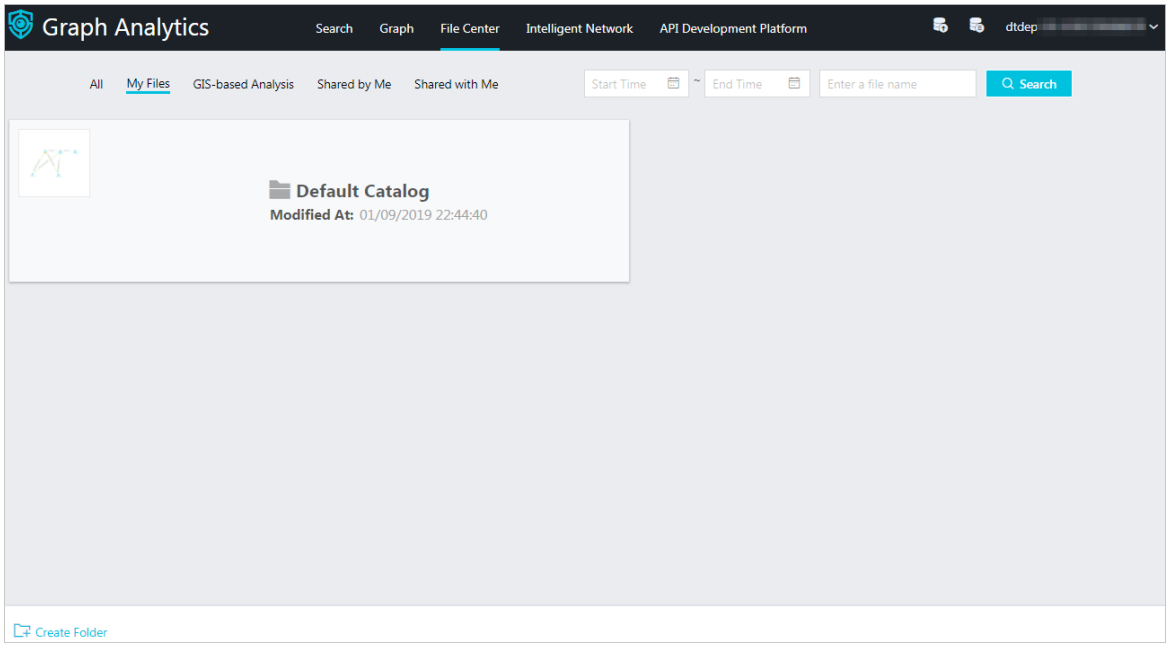
After you close the analysis file or log on to Analytics Workbench again, you can view the existing analyses or shared analyses in **File Center**.

Prerequisites

Make sure that you have obtained an account and a password with the permission to perform graphic operations.

Procedure

1. Log on to Analytics Workbench.
2. Click **File Center** in the top navigation bar. The **File Center** page appears.



3. Click **My Files**, **Shared by Me**, or **Shared with Me** to view the corresponding analysis files.
4. Double-click an analysis to directly open the analysis file on the **Graph** page.

8.3. Source tables

8.3.1. Data sources

8.3.1.1. Create data sources

Before you perform a relationship analysis, you must integrate data that you want to analyze, typically databases, into Graph Analytics. These databases will be used as data sources. In Graph Analytics, every data source is unique and can be added only once.

Prerequisites

- You have an account and password for Graph Analytics and are authorized to perform operations on Administration Console of Analytics Workbench.
- You have obtained the IP address, user name, password, port number, and other information of an accessible data source.

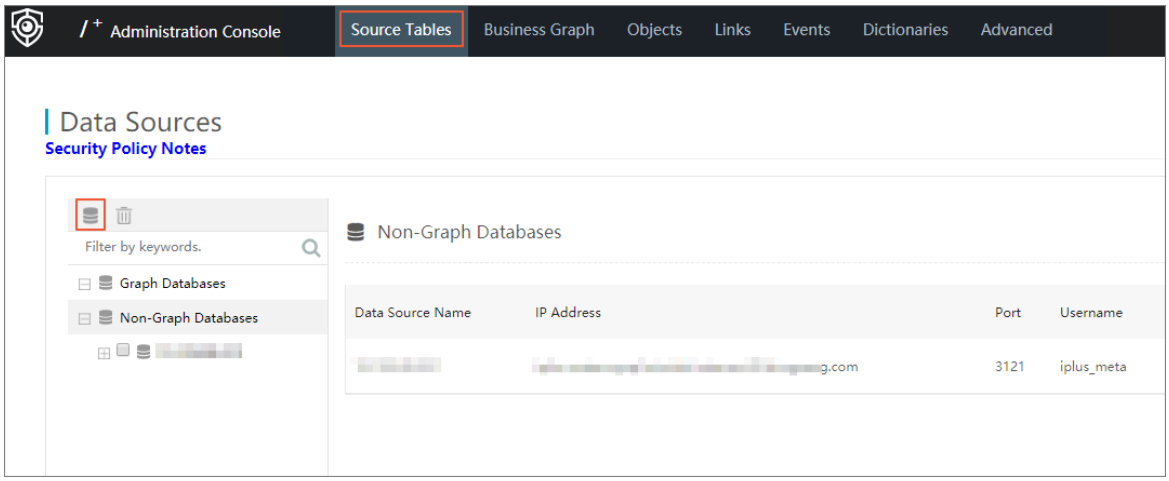
Context

A data source is one of the entries for new objects, links, and events. It is also the only entry for objects, links, and events to map to a data table. Objects, links, and events that are created on the **Object Information**, **Link Information** and **Event Information** pages are logical business objects, links, and events without mappings.

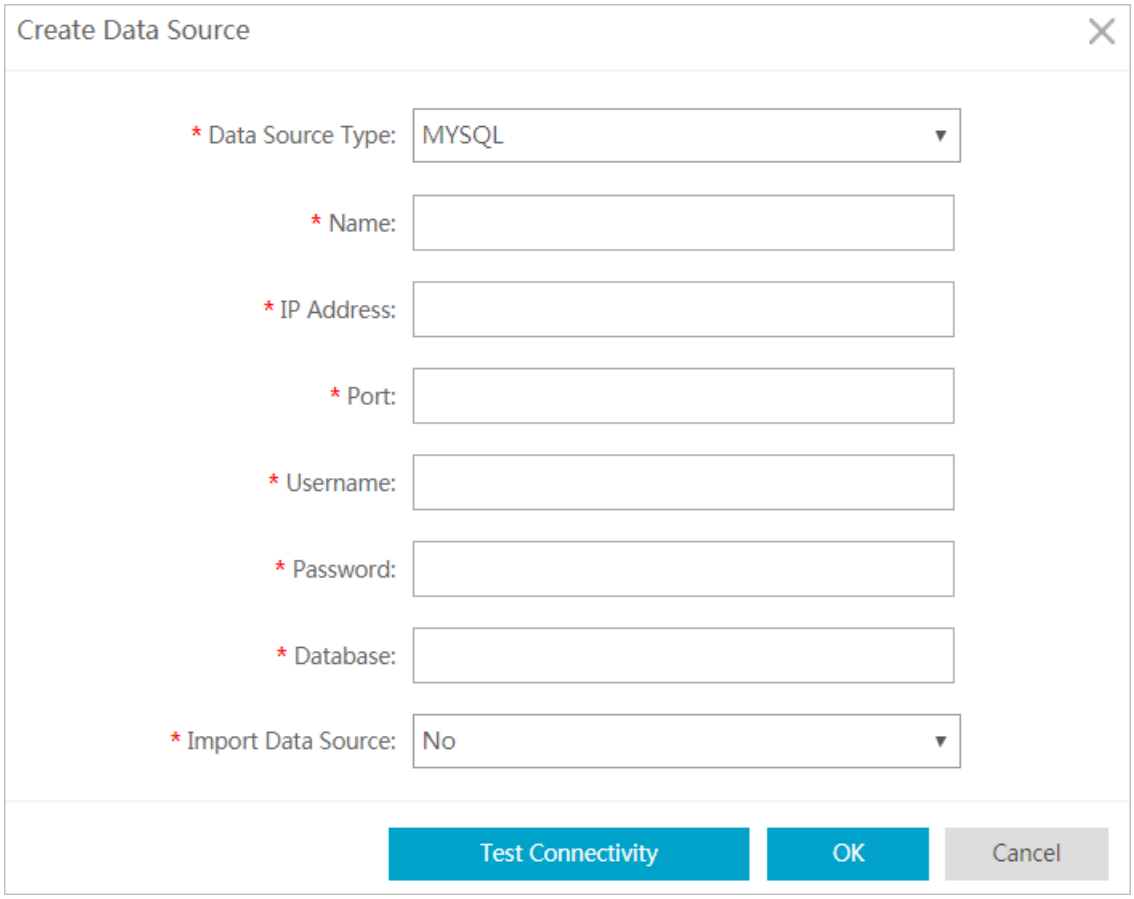
> **Note** Objects, links, and events created for the data source take effect only after you log on again.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Source Tables** to redirect to the **Data Sources** page.



3. On the **Data Sources** page, click the **Create Data Source** icon in the left-side navigation pane. The **Create Data Source** dialog box appears.



4. In the **Create Data Source** dialog box that appears, specify the data source parameters as needed.

Data source parameters

Parameter	Description
Data Source Type	The data source type you want to select. Supported data source types include: **MYSQL**, **ORACLE** , **RDS** , and **GREENPLUM**.
Name	The name of the data source. It can be user-defined.
IP Address	The IP address or domain name of the data source.
Port	The port number of the data source.
Group	The department or group to which the data source belongs.
Username and Password	The username and password that are used to connect to the data source.
Database	The name of the database that functions as the data source.
Import Data Source	If Data Source Type is not set to **ORACLE**, you must specify this parameter. You can import data into Analytics Workbench only after you have specified this parameter.

5. After you have configured the preceding parameters, click **Test Connectivity** to check whether the data source can be connected.

   If the data source is connected properly, a message appears, indicating that the test succeeded. If the data source cannot be connected, check whether the information is correct and the data source itself is functioning properly.

6. After the connectivity test is confirmed as successful, click **OK**.

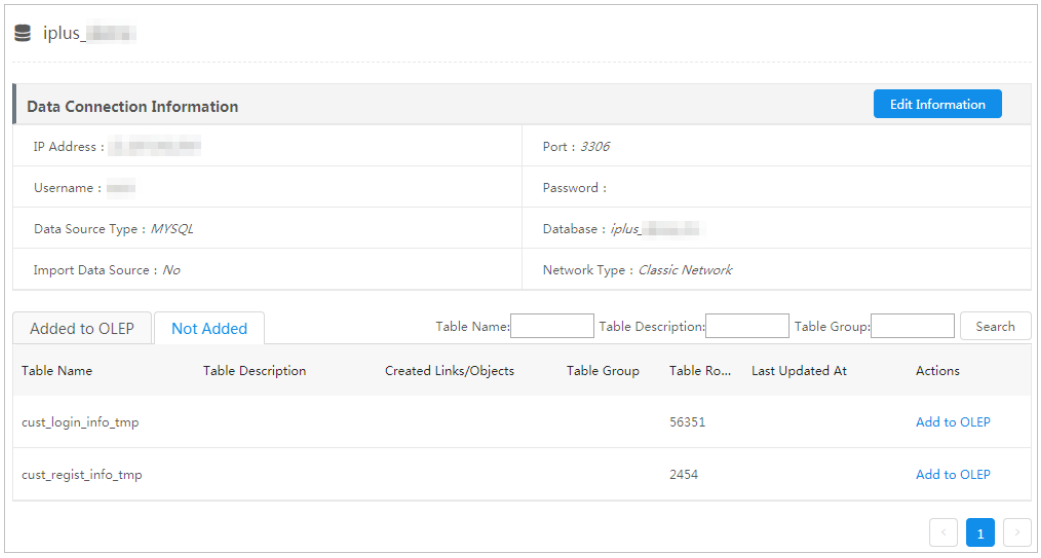
8.3.1.2. View data sources

Graph Analytics allows you to view all data sources in the current environment. This function helps you understand the existing data source information at any time.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click **Source Tables** in the top navigation bar. The **Data Sources** page appears.
3. Select a data source from the left-side navigation pane. The data source details are displayed on the right side of the page, as shown in Data source details.

Data source details



8.3.1.3. Modify a data source

Graph Analytics allows you to modify all data sources in the current environment. This function helps you adjust basic information about data sources at any time if required.

Prerequisites

To modify a data source, you must have the user password that is used to connect to the data source.

Context

You can modify all parameters of a data source except Data Source Type.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click **Source Tables** in the top navigation bar. The **Data Sources** page appears.
3. Click a data source in the left-side navigation pane, and click **Edit Information** in the Data Connection Information section on the right side of the page. Alternatively, click the parent directory of the target data source in the left-side navigation pane, and click **Modify** next to the target data source in the data source list on the right side of the page.
4. In the dialog box that appears, modify the data source parameters as needed, and enter the user **password**.
5. Click **Test Connectivity** to verify the modifications.
6. If the test is successful, click **OK**.

8.3.1.4. Delete a data source

You can delete a data source if it is no longer used.

Prerequisites

All tables in the data source are not correlated with any objects, links, or events. If a data table is correlated with an object, link, or event, remove the association first. For more information, see Remove OLEP tables.

Context

Deleted data sources cannot be recovered. Exercise caution when you delete a data source.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click **Source Tables** in the top navigation bar. The **Data Sources** page appears.
3. Select one or more data sources from the left-side navigation pane, and then click the icon in the top navigation bar.
4. In the Delete Data Sources dialog box that appears, click **OK** to delete the specified data sources.

8.3.2. OLEP tables

8.3.2.1. Create OLEP models for tables

After you add a data source, you must create object, link, event, and property (OLEP) models for the tables in the data source as needed. Before you configure OLEP tables, prepare the tables for which you will create OLEP models, the columns of each table, and the business models to be configured. Referenced tables cannot be deleted.

Prerequisites

You have created an accessible data source.

Context

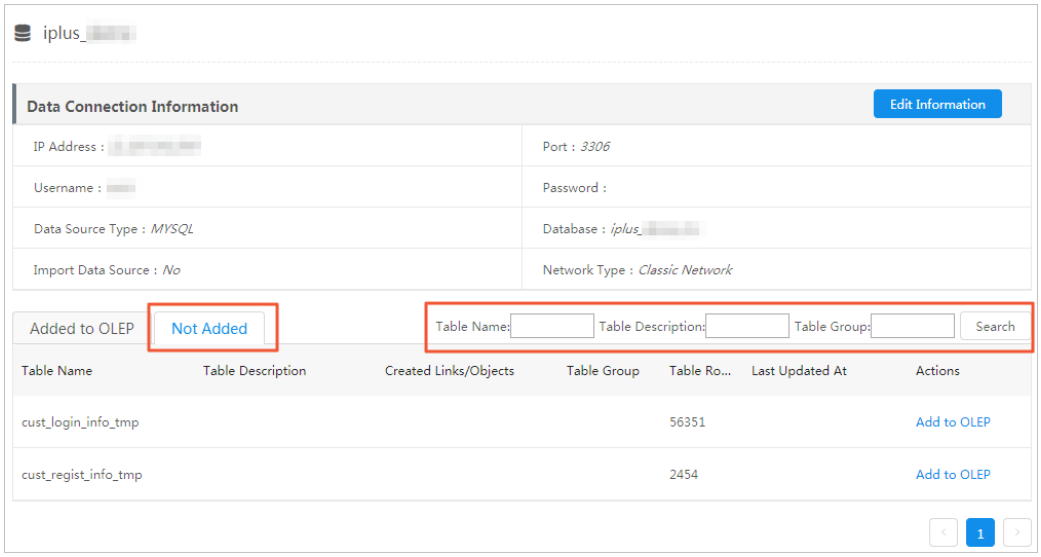
OLEP models include the following three types of mappings: table-to-object mappings, table-to-link mappings, and table-to-event mappings. You can create objects, links, and events when you create OLEP models. Afterward, you can view and configure these objects, links, and events on the **Object Information**, **Link Information**, and **Event Information** pages, respectively. You can configure these items to reflect your business semantics. An OLEP table serves as a source for configuring objects, first-degree links, and events. A table can be mapped to multiple objects, links, and events.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click **Source Tables** in the top navigation bar. The **Data Sources** page appears.
3. Click a data source in the left-side navigation pane. The data source details are displayed on the right side of the page.
4. Click the **Not Added** tab. All tables in the data source that have no OLEP models are displayed.

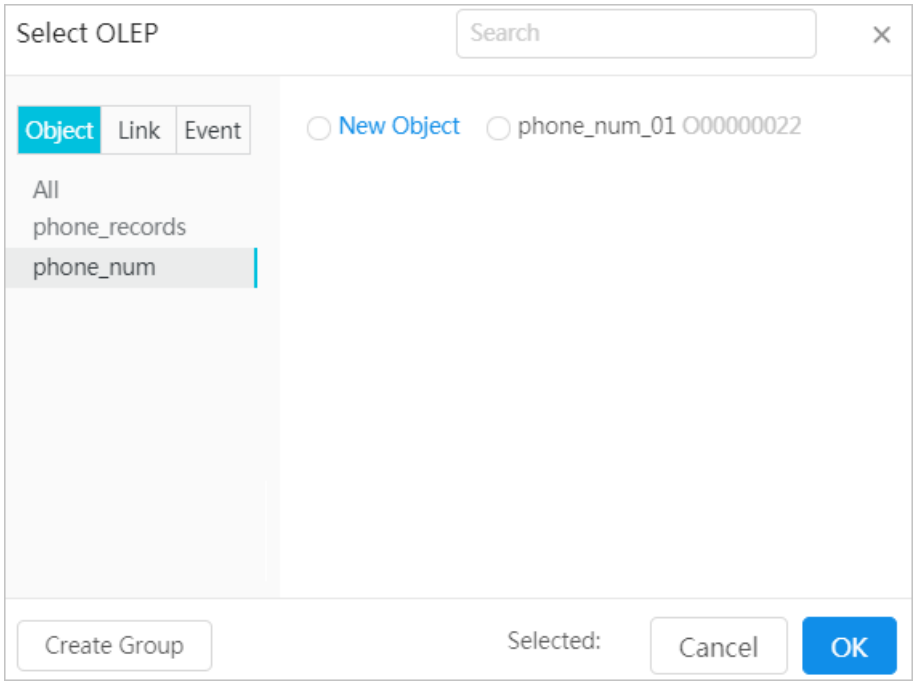
   You can search for a table quickly and accurately by specifying the Table Name, Table Description, or Table Group parameter.

   Tables that have no OLEP models



5. Select a table, and then click **Add to OLEP** in the Actions column. The **Select OLEP** dialog box appears.

   Select OLEP dialog box



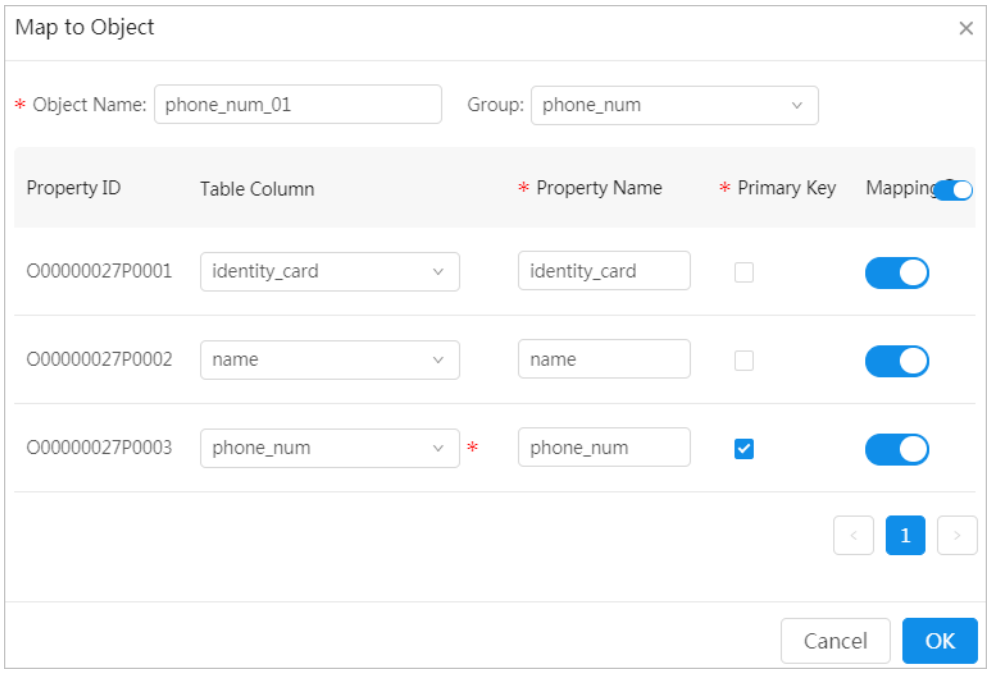
The **Select OLEP** dialog box contains the **Object**, **Link**, and **Event** tabs which are used to create mappings to objects, links, and events, respectively. For more information about how to create a mapping to an object, link, or event, see step 6, step 7, and step 8.

If there are no existing object, link, or event groups that can meet your requirements, click **Create Group** to create a new object, link, or event group.

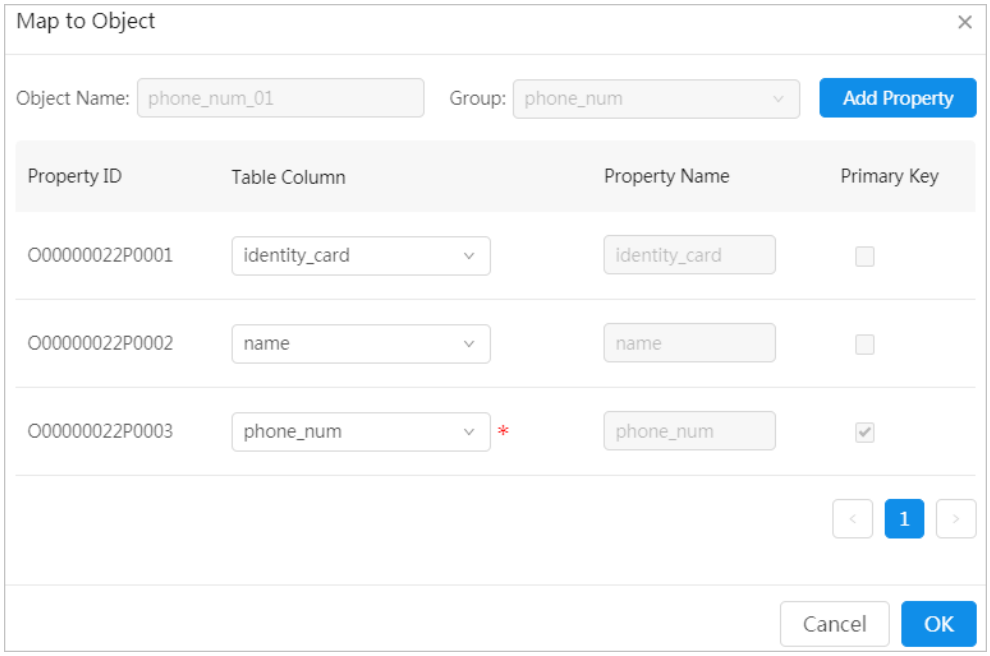
6. Map the table to an object.

i. Select **New Object** or an existing object and then click **OK**. The **Map to Object** dialog box appears.

Map to a newly created object



Map to an existing object



ii. Set the parameters as needed.

- New object: Set parameters based on Parameters used to map the table to a new object.
- Existing object: Create a one-to-one mapping between each **Table Column** and **Property Name** as needed.

  If the number of table columns are more than the number of existing properties of the object, you can click **Add Property** to add new properties.

Parameters used to map the table to a new object

Feature name	Description
Object Name	The user-defined object name. It must be unique.
Group	The object group to which the object belongs. All available object groups are displayed in the drop-down list.
Name	The name of an object property to which a table column is mapped. By default, the property name is the same as the column name. You can also define the property name as needed. On the Analytics Workbench, property names are displayed instead of the actual table columns that are mapped to the properties.
Mapping	Whether to enable the property mapping.
Primary Key	Sets a property as a primary key. Each primary key uniquely identifies an object. You must set one or more properties as primary keys for each object. You must enable **Mapping** for primary keys.

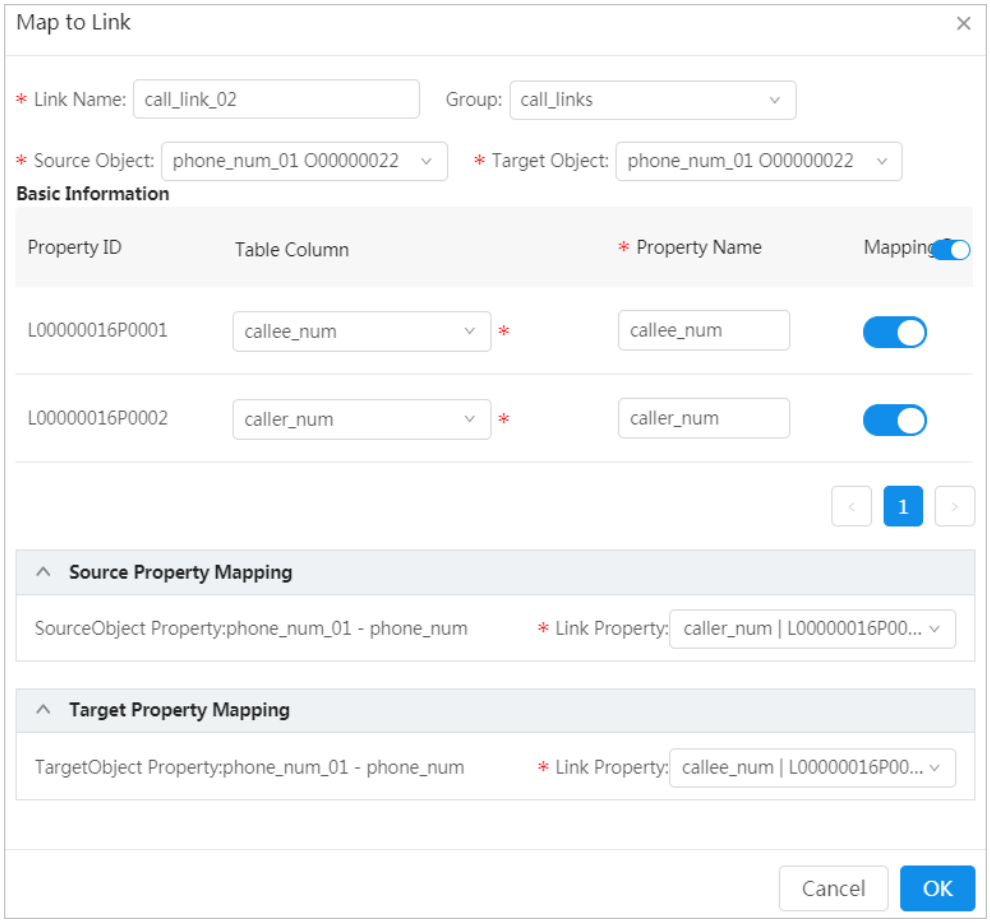
iii. Click **OK**.

7. Map the table to a link.

i. Click the **Link** tab. All first-degree links to which the current table has been mapped are displayed.

ii. Select **New Link** or an existing link and then click **OK**. The **Map to Link** dialog box appears.

Map to a newly created link



Map to an existing link

OK

iii. Set parameters as needed.

- New link: Set parameters based on Parameters used to map the table to a new link.
- Existing link: Create a one-to-one mapping between each **Table Column** and **Property Name** as needed.

  If the number of table columns are more than the number of existing link properties, you can click **Add Property** to add new link properties.

Parameters used to map the table to a new link

Feature name	Description
Link Name	The user-defined link name. It must be unique.
Group	The link group to which the link belongs. All available link groups are displayed in the drop-down list.
Source	The source object of the link. You can select an object from the drop-down list. The **Source Property Mapping** parameter is available only after you set the Source Object parameter.
Target	The target object of the link. You can select an object from the drop-down list. The **Target Property Mapping** parameter is available only after you set the Target Object parameter.
Name	The name of an event property to which a table column is mapped. By default, the property name is the same as the column name. You can also define the property name as needed. On the Analytics Workbench, the Property Name values are displayed as the table header in **Details** on the **Graph** page.
Mapping	Whether to enable the property mapping.
Link Property in Source Property Mapping	The link property to which a primary key property of the source object is mapped.
Link Property in Target Property Mapping	The link property to which a primary key property of the target object is mapped.

iv. Click **OK**.

8. Map the table to an event.

i. Click the **Event** tab. All events to which the current table has been mapped are displayed.

ii. Select **New Event** or an existing event and then click **OK**. The **Map to Event** dialog box appears.

Map to a newly created event

iii. Set parameters as needed.

- New event: Set parameters based on Parameters used to map the table to a new event.
- Existing event: Create a one-to-one mapping between each **Table Column** and **Property Name** as needed.

  If the number of table columns are more than the number of existing event properties, you can click **Add Property** to add new event properties.

Parameters used to map the table to a new event

Feature name	Description
Event Definition Name	The user-defined event name. It must be unique.
Group	The event group to which the event belongs. All available event groups are displayed in the drop-down list.
Name	The name of an event property to which a table column is mapped. By default, the property name is the same as the column name. You can also define the property name as needed. On the Analytics Workbench, the Property Name values are displayed as the table header in **Details** on the **Graph** page.
Switch	Whether to enable the property mapping.
Primary Key	Sets a property as a primary key. Each primary key uniquely identifies an event. You must set one or more properties as primary keys for each event. **Switch** must be turned on for the properties that are set as primary keys.
Map Primary Keys to Correlated Objects	Indicates the mappings between the primary keys of correlated objects and the event properties. At least two correlated objects are required. You can click **Add Mapping** to add more necessary mappings between the primary keys of correlated objects and the event properties. You must enable **Mapping** for the event properties to which the primary keys of the correlated objects are mapped.

iv. Click **OK**.

9. After you have created OLEP models for the table, click the **Added to OLEP** tab to check the results.

8.3.2.2. View an OLEP table

After you have created OLEP models for a table, you can view the created OLEP table.

Prerequisites

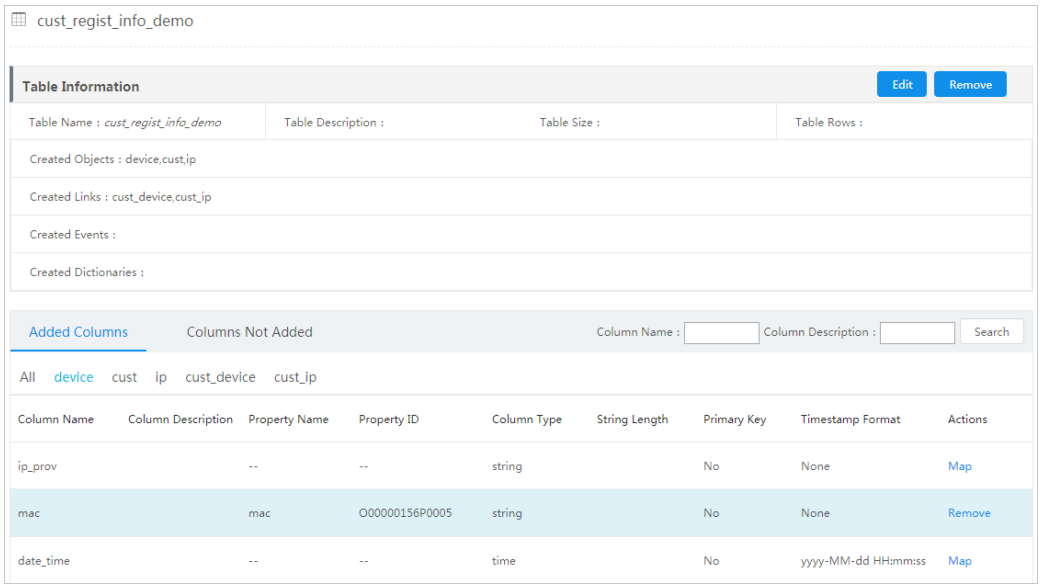
OLEP models have been created for a table.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Select the target table you want to view from the left-side data source list.

   The table information is displayed in the right-side pane, including table basics, dependent objects and links, and table columns, as shown in View tables.

   View tables



8.3.2.3. Edit OLEP tables

After you have created OLEP models for a table, you can still add new object, link, or event mappings to the table. You can also add a description for the table.

Prerequisites

Make sure that OLEP models have been created for a table.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click a table in the left-side navigation pane. The data source details are displayed on the right side of the page.

   Add new object, link, or event mappings to tables.

3. On the **Added to OLEP** tab, select a table, and then click **Add Mapping**. The **Select OLEP** dialog box appears. You can add a new object, link, or event mapping to the table. For more information, see the procedure described in Create OLEP models for tables.

   Modify the table description.

4. You can use one of the following methods to modify the table description.

Method	Operation

Method	Operation
On the **Added to OLEP** page	i. Click the Edit icon  next to the **Table Description** column. You can then modify the **Table Description**. ii. Click **OK** to save the changes. A success message is displayed after the operation is completed.
On the table details page	i. Click a table in the left-side navigation pane. On the right side of the page, click **Edit** in the **Table Information** section. You can then modify the **Table Description**. ii. Click **OK** to save the changes. A success message is displayed after the operation is completed.

8.3.2.4. Remove an OLEP table

If the mapping between a table and an object, link, or event is no longer used, you can remove the mapping.

Prerequisites

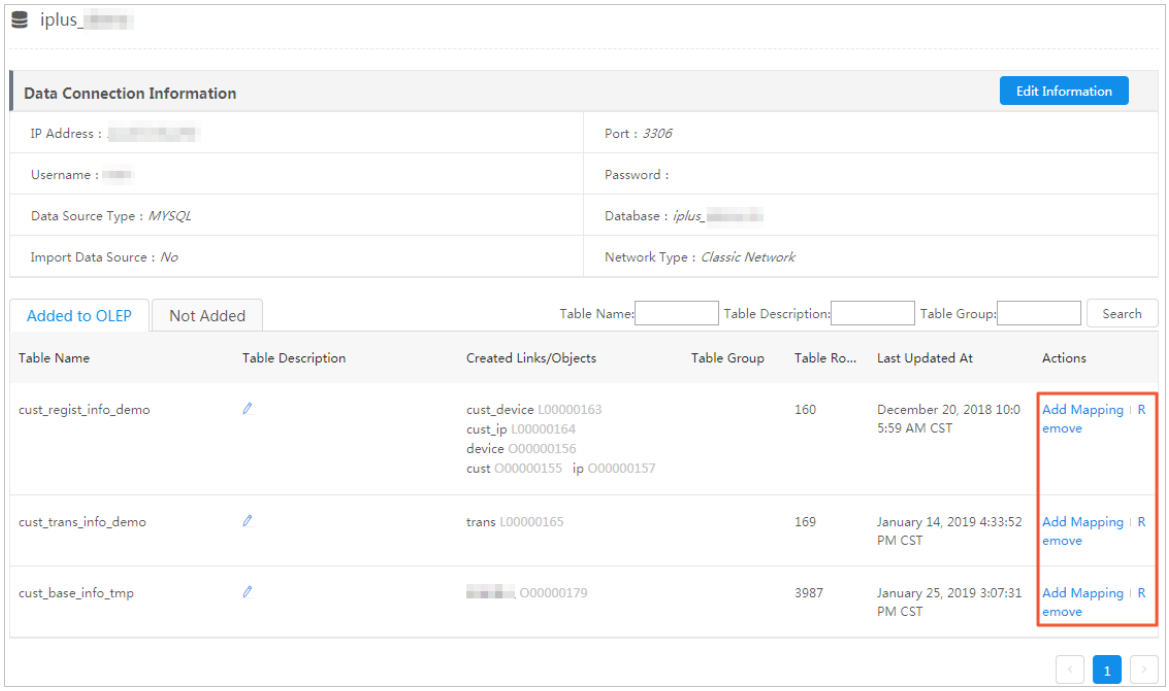
You can access the data source that stores the table.

Context

You only remove the mappings between the tables and objects, links, and events. The objects, links, events, and tables will not be deleted.

Procedure

1. Click the **Source Tables** tab in the top navigation bar. The **Data Sources** page appears.
2. Click a table in the left-side navigation pane. The data source details are displayed in the right-side pane.
3. On the **Added to OLEP** tab, click **Remove** next to a table.



4. In the **Select OLEP** dialog box, select an **Object**, **Link**, or **Event** mapping. You can select only one mapping at a time.
5. Click **OK**.

   If all mappings are removed from a table, the table will be automatically moved from the **Added to OLEP** tab to the **Not Added** tab.

8.3.3. OLEP table columns

8.3.3.1. Add OLEP table columns

If a data table has been mapped to an object, link, or event, and the table still has unoccupied columns (columns that are not correlated with any object, link, or event), you can add these columns to the existing mappings as needed.

Prerequisites

A data table has been mapped to an object, link, or event, but the table still has unoccupied columns.

Context

Before you configure the OLEP table columns, sort out the columns for which you will create OLEP models and data types of the columns, especially the time columns.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click **Source Tables** in the top navigation bar.
3. On the **Data Sources** page, click a data source in the left-side navigation pane, and then click the table to which you want to add the columns.
4. Click the **Columns Not Added** tab in the right-side area. In the **Columns Not Added** tab that

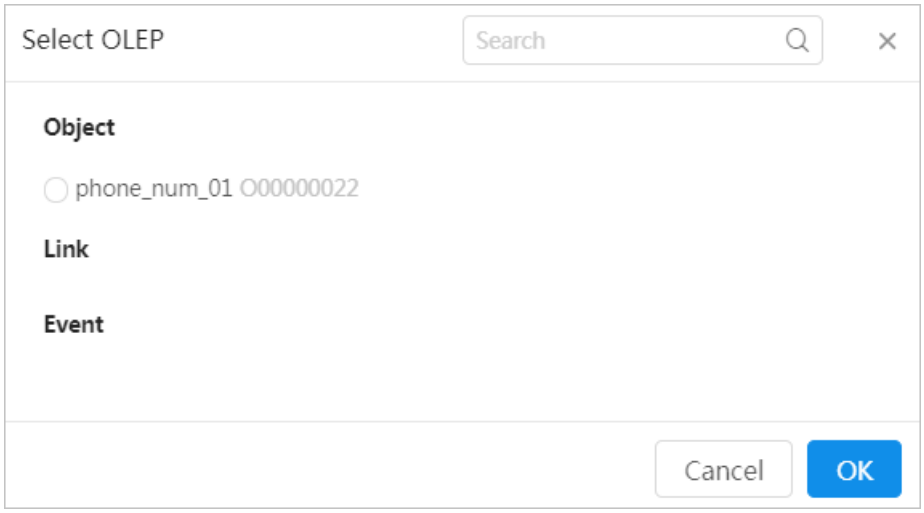
appears, click **Add** in the Actions column.

Columns displayed in the **Columns Not Added** tab are not mapped to any object, link, or event.

5. In the **Select OLEP** dialog box that appears, select the object, link, or event to which the columns map, and then click **OK**.

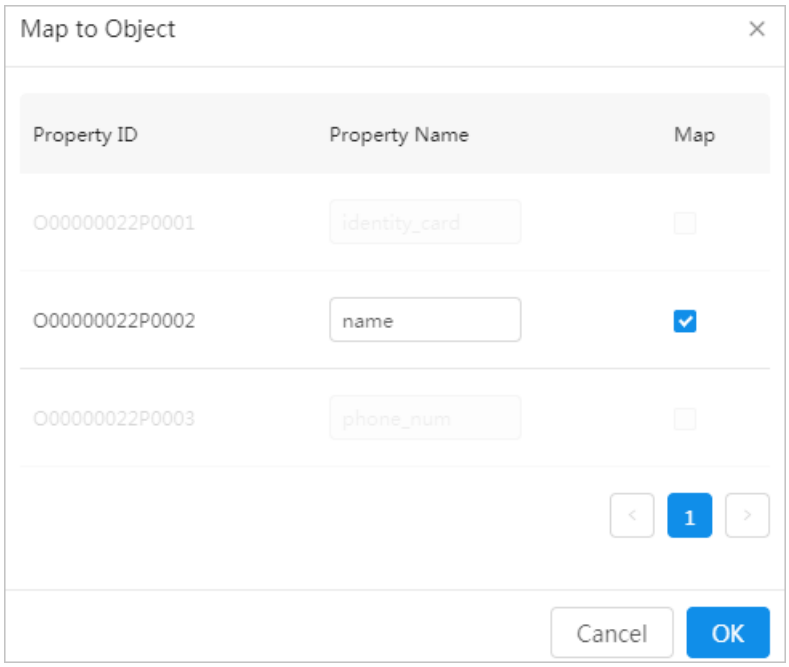
   The **Select OLEP** tab only displays the objects, links, and events that have mapped to the current data table.

   The following example describes how to add columns to an object.



6. In the **Map to Object** dialog box that appears, select the object properties to be mapped to the columns to be added.

   Object properties that have been mapped to the current data table are gray and cannot be operated.



7. After you have configured the preceding parameters, click **OK**.

8.3.3.2. Edit OLEP table columns

After a data table is mapped to objects, links, or events, you can modify the **Column Description** and **Timestamp Format** of added columns.

Prerequisites

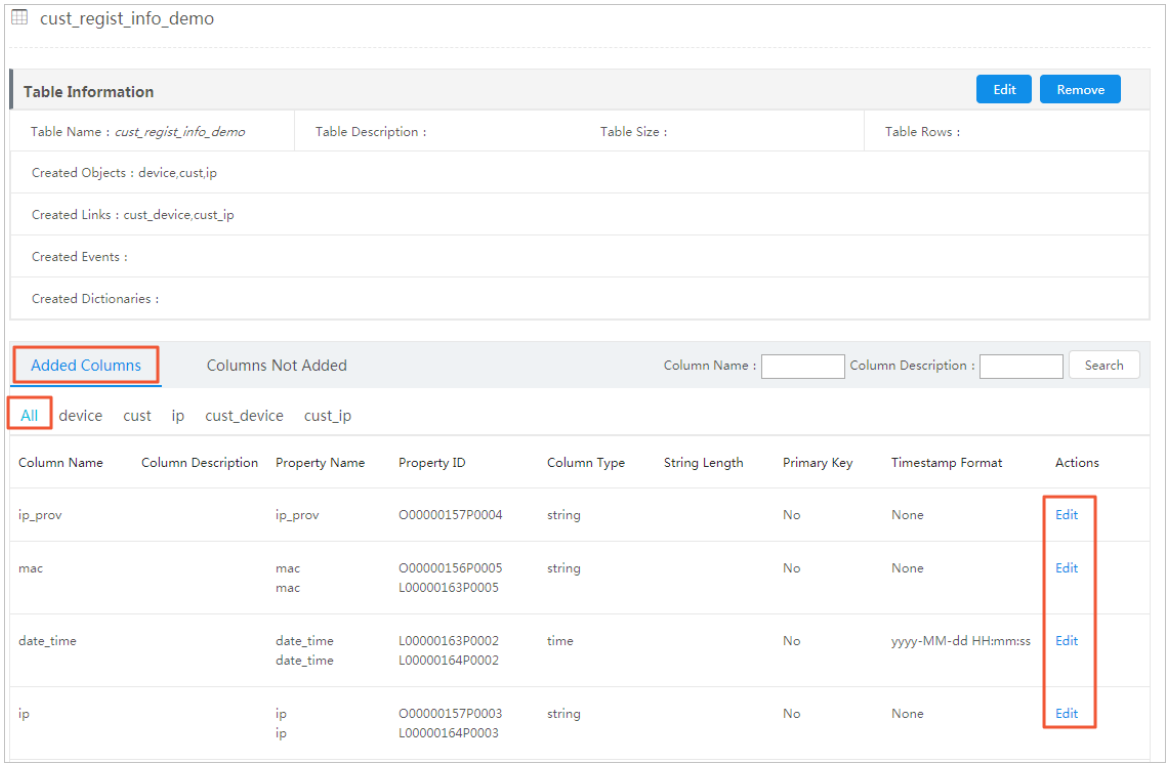
The data table has been mapped to an object, link, or event.

Procedure

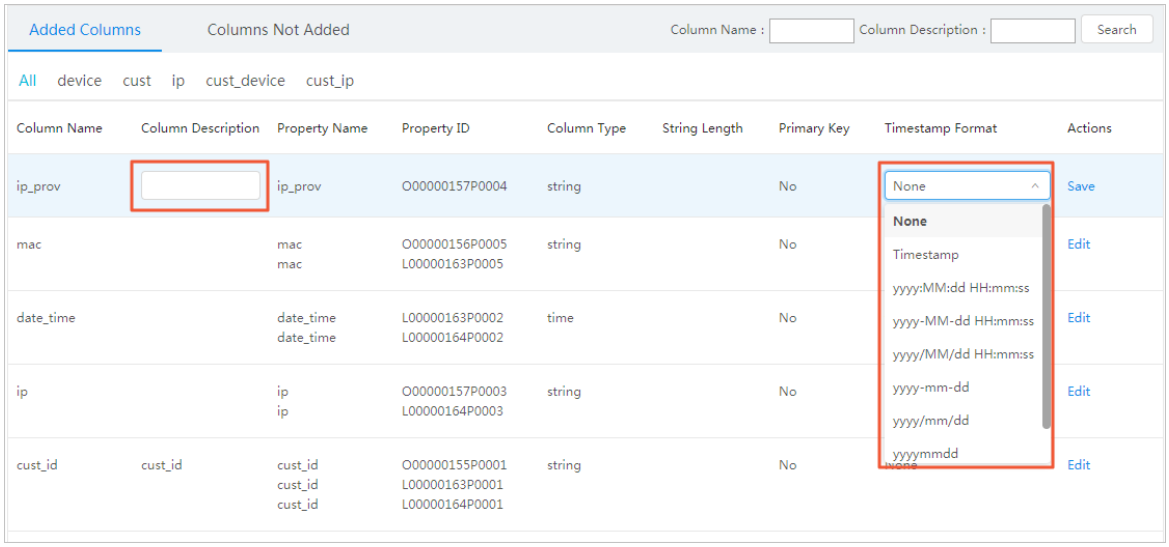
1. Log on to Administration Console of Graph Analytics.
2. Click **Source Tables** in the top navigation bar.
3. On the **Data Sources** page, click a data source in the left-side navigation pane, and then click the table that contains the columns you want to modify.

   After you select the table, the details of the table will be displayed in the right-side **Data Sources** pane.
4. Click the **Added Columns** tab.

   By default, the **Added Columns** tab displays all columns that have been added.



5. On the **All** tab, click **Edit** in the Actions column to modify the **Column Description** and **Timestamp Format** of a column.



The **Timestamp** option in the **Timestamp Format** drop-down list refers to the UNIX timestamp.

6. After you have configured the preceding parameters, click **Save**.

8.3.3.3. Remove OLEP table columns

After you have created OLEP models for a table, you can remove unnecessary OLEP mappings of specific columns in the table.

Prerequisites

OLEP table columns are not referenced.

Context

After a table has been mapped to objects, links, or events, you cannot separately remove the following mappings of a column:

- Table-to-object mappings: The mapping between the column and a primary key property of the object cannot be removed.
- Table-to-link mappings: The mapping between the column and a correlated property of the link cannot be removed.
- Table-to-event mappings: The mapping between the column and a primary key property of the event cannot be removed.

To remove these mappings, remove the OLEP mapping from the table and then add OLEP mappings to the table again. For more information, see Remove OLEP tables and Create OLEP models for tables.

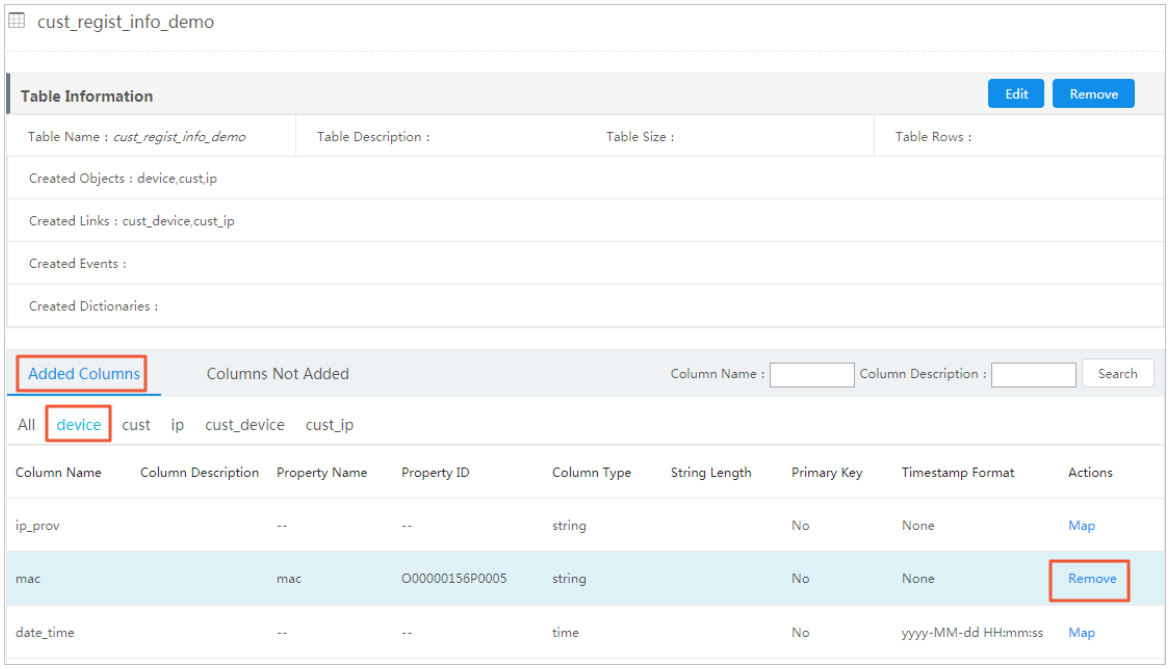
Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click **Source Tables** in the top navigation bar.
3. On the **Data Sources** page, click a data source in the left-side navigation pane, and then click the table that contains the columns you want to remove.
4. On the right side of the **Data Sources** page, click the **Added Columns** tab.

By default, the **Added Columns** tab displays all columns that have been added.

5. On the **Added Columns** tab, click the tab of an object, link, or event that has been mapped to a data table.

   On the selected object, link, or event page, the table columns that have been mapped are highlighted.



6. Select a column, and then click **Remove** to remove the object, link, or event mapping.

   If all mappings of a column are removed, including object, link, and event mappings, the column will be automatically moved to the **Columns Not Added** tab.

8.4. Dictionaries

8.4.1. Create a dictionary

Before you create a dictionary, sort out the columns to be converted from the system data. If a dictionary has been referenced, it cannot be deleted.

Prerequisites

Before you create a dictionary, complete the following tasks:

- Make sure that you have created a data source. For more information, see Create data sources.
- Make sure that you have configured mappings between tables and objects, links, or events. For more information, see Create OLEP models for tables.
- Map table columns to OLEP. For more information, see Add OLEP table columns.

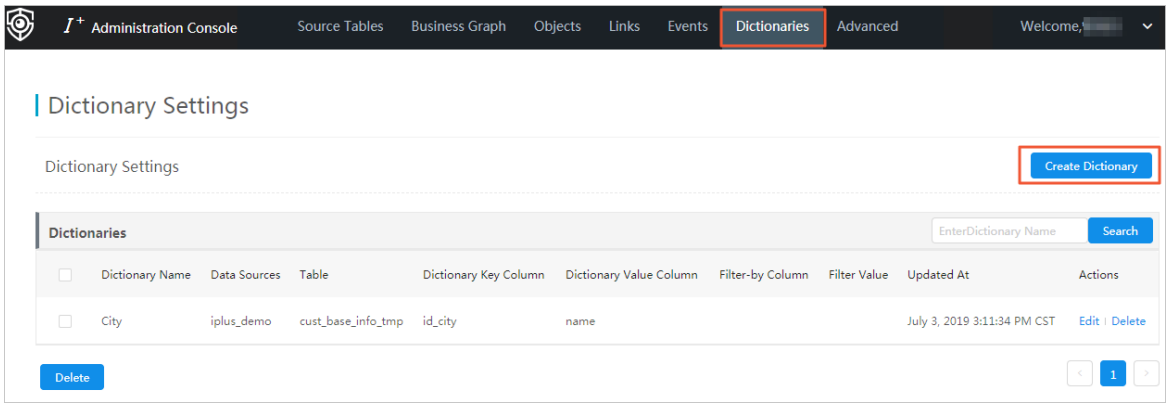
Context

A dictionary is used to map a specific column in the table to a value column and display the value column name in Analytics Workbench instead of the original column name.

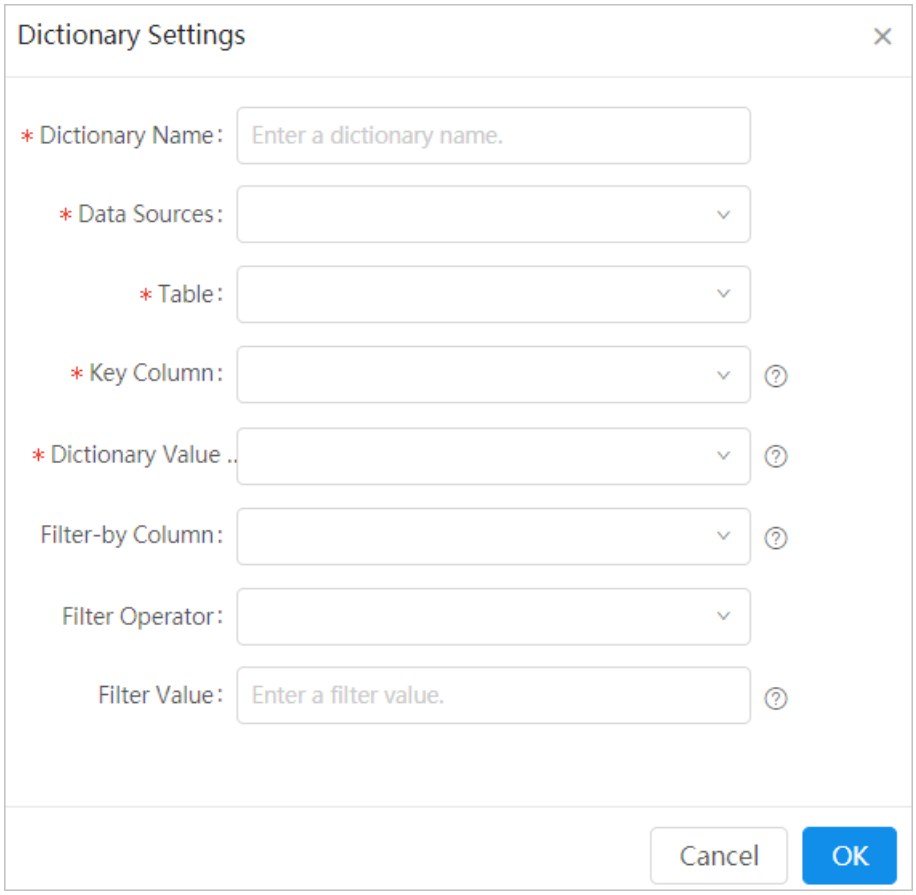
For example, in the **Graph** area of Analytics Workbench, column A (**company code**) is displayed. After column A is escaped to column B (**company name**), the company name corresponding to the code will be displayed in the **Graph** area.

Procedures

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Dictionaries**.



3. On the **Dictionary Settings** page, click **Create Dictionary** in the upper-right corner of the page.



4. In the **Dictionary Settings** dialog box that appears, specify the parameters as needed.

   These parameters are described as follows:

Parameter configurations for adding a dictionary

Parameter	Description
Dictionary Name	The name of the dictionary. The user can customize the name as needed.
Data Sources	The data sources to be referenced.
Table	The table in the data source to be referenced.
Key Column	The column that stores the dictionary code in the selected table.
Dictionary Value Column	The value column corresponding to the converted dictionary.
Filter-by Column	These three parameters are not required and are used to filter dictionary tables based on different conditions. If you specify any of the three parameters, the other two parameters are required.
Filter Operator	
Filter Value	

5. After you have configured the preceding parameters, click **OK**.

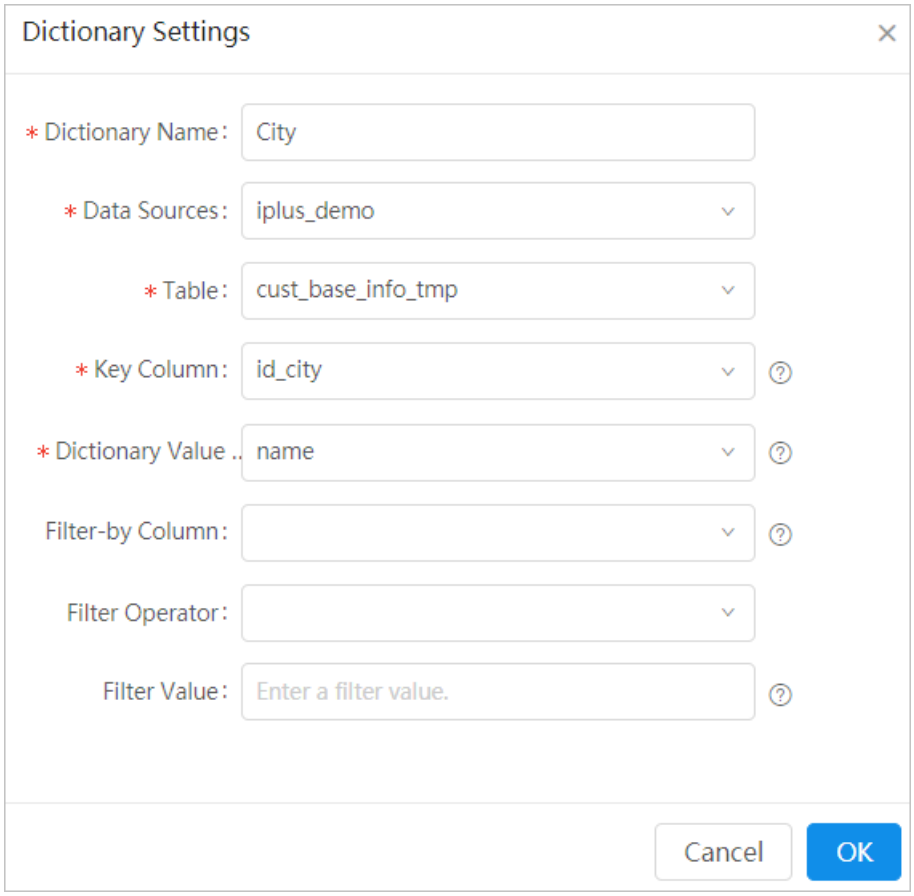
8.4.2. Modify a dictionary

This topic describes how to modify a dictionary in a dictionary list.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Dictionaries**. The Dictionary Settings page appears. All existing dictionaries are displayed.
3. Select a dictionary and then click **Edit**, as shown in Modify a dictionary.

   Modify a dictionary



4. In the dialog box that appears, modify the parameters as needed. For more information about dictionary parameters, see Parameter description.
5. Click **OK**.

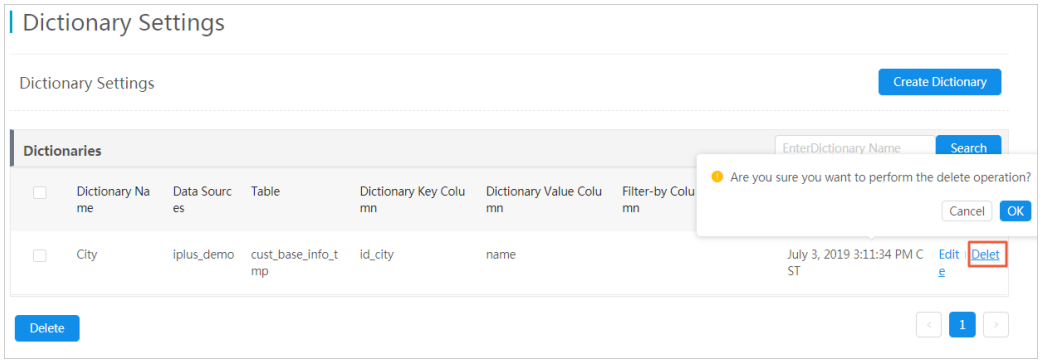
8.4.3. Delete a dictionary

This topic describes how to delete a dictionary. You cannot delete dictionaries that have been referenced.

Delete a dictionary

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Dictionaries**. The Dictionary Settings page appears. All existing dictionaries are displayed.
3. Select a dictionary, and then click **Delete**. A confirm message appears, as shown in Delete a dictionary.

   Delete a dictionary

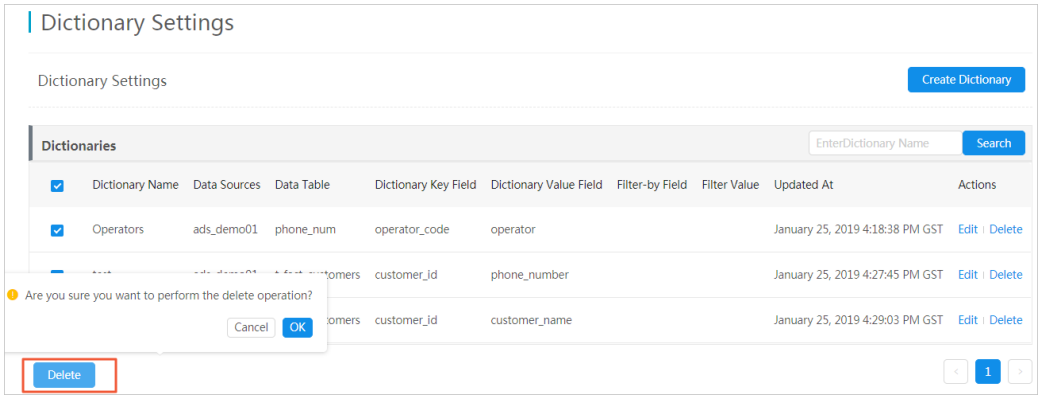


4. Click **OK**.

Delete multiple dictionaries at a time

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Dictionaries**. The Dictionary Settings page appears. All existing dictionaries are displayed.
3. Select one or more dictionaries, and then click **Delete** in the lower-left corner. A confirm message appears, as shown in Delete multiple dictionaries at a time.

   Delete multiple dictionaries at a time



4. Click **OK**.

8.5. Object information

8.5.1. Object groups

8.5.1.1. Create an object group

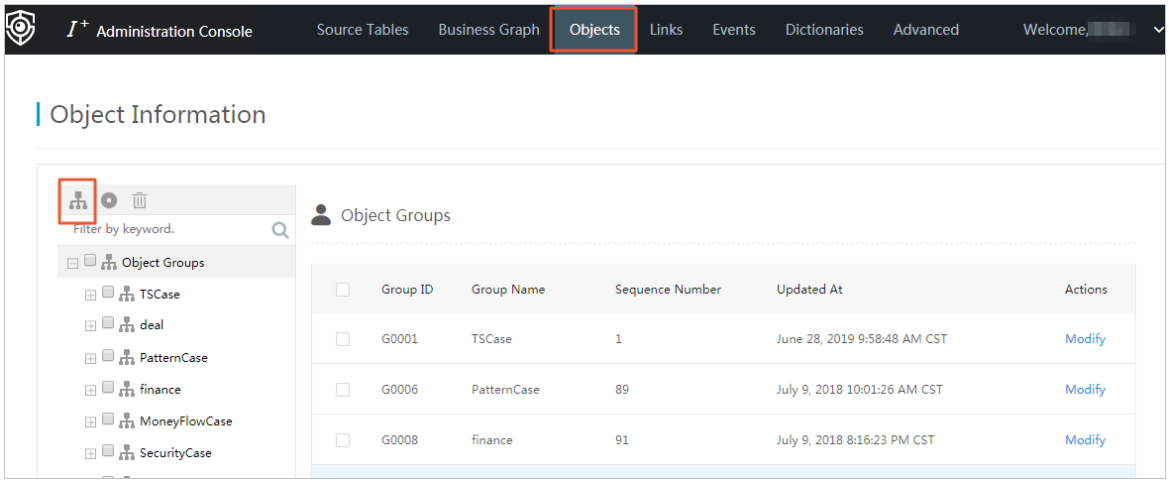
You can use object groups to classify objects, so that you can search for and manage objects with ease. An object must be and can only be included in one object group. You need to create a proper object group before you create an object.

Prerequisites

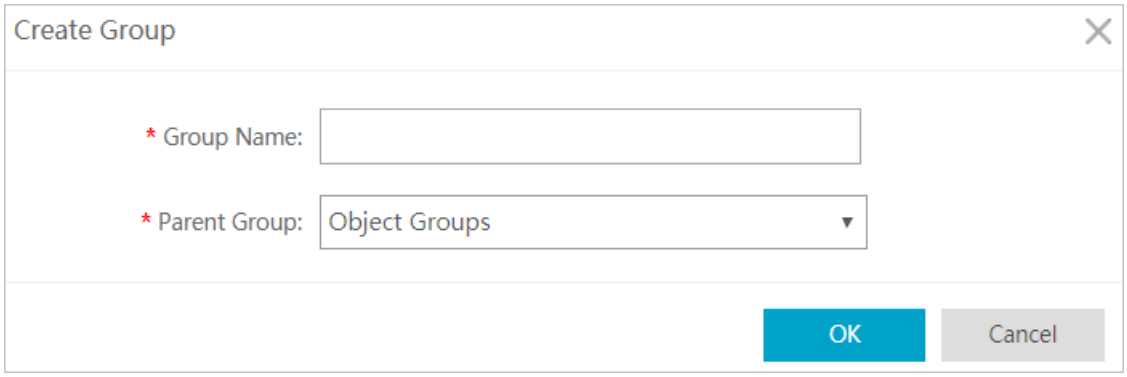
You have an account and password for Graph Analytics and have permissions to perform operations in Administration Console of Graph Analytics.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Objects**.
3. Click the **Create Group** icon to create a group.



4. In the **Create Group** dialog box that appears, specify **Group Name** and **Parent Group**.



5. Click **OK**.

8.5.1.2. View object groups and objects

Graph Analytics allows you to view all object groups in the current environment. This function makes it easy for you to understand the existing object groups and the object information under each group at any time.

Prerequisites

You have an account and password for Graph Analytics and have permissions to perform operations in Administration Console of Graph Analytics.

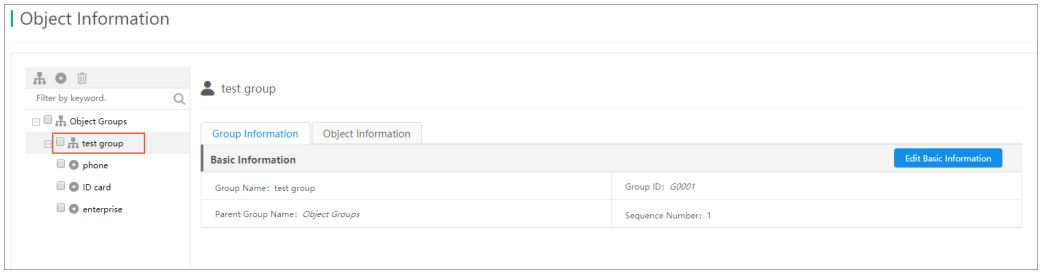
Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Objects**.
3. In the left-side navigation pane of the **Object Information** page, click an object group. The **Group Information** and **Object Information** tabs of the object group are displayed in the

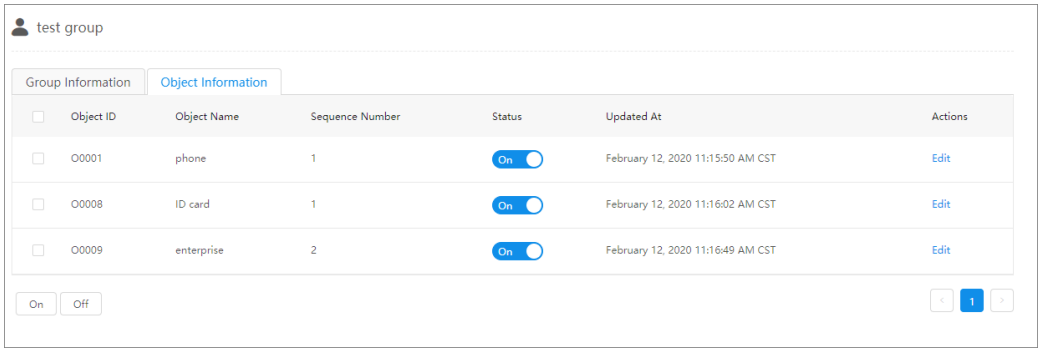
right-side pane.

The left-side navigation pane displays all the object groups in the current environment. You can view the groups one by one.

Group Information



Object Information



4. Click OK.

8.5.1.3. Modify object groups and objects

In Graph Analytics, you can modify the name and sequence number of an object or object group. You can adjust the basic information of an object or object group at any time if required.

Prerequisites

- You have created an object group. For more information about how to create an object group, see Create an object group.
- You have created an object that belongs to this object group. For more information about how to create an object, see Create an object.
- You have deleted the dependency information of an object, including the mapping between the object and a data table if you need to disable this object.

Context

This topic describes the following operations:

- Modify the basic information about an object group
- Modify the basic information about an object
- Disable and enable an object

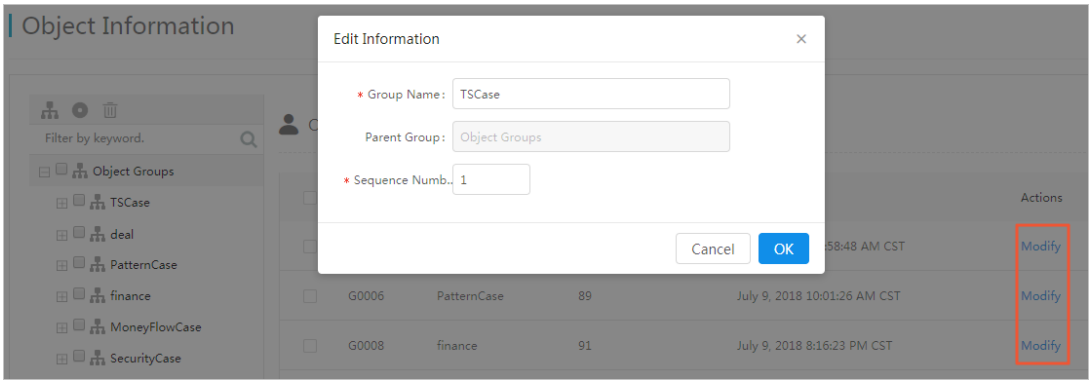
After you have created an object by configuring the object properties, the object is automatically enabled. You can disable an object if it is no longer used for a period of time. You can also enable it again when necessary. You cannot use an object in Analytics Workbench after the object is disabled.

Modify the basic information about an object group

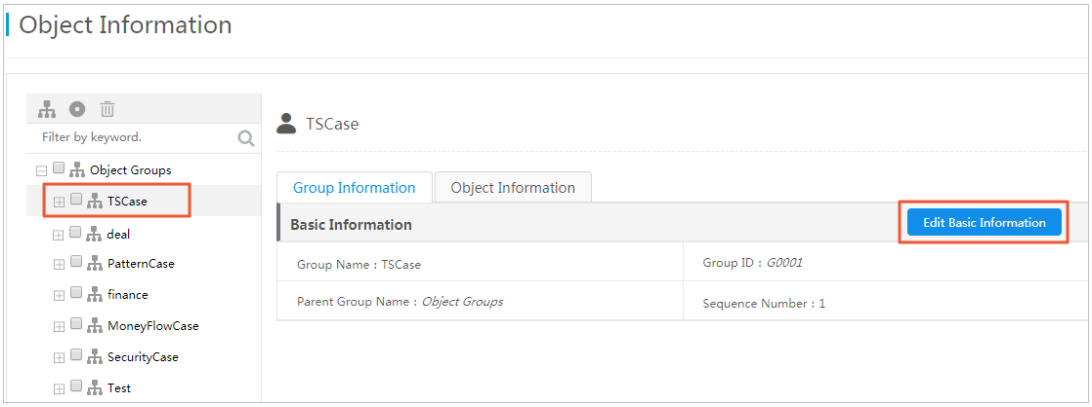
You can modify the basic information about an object group by using one of the following methods:

Method	Procedure
Method 1	1. Log on to Administration Console of Graph Analytics. 2. In the top navigation bar, click **Objects**. 3. In the **Object Groups** area, select an object group and click **Modify** in the Actions column. 4. In the **Edit Information** dialog box that appears, specify **Group Name** and **Sequence Number**, as shown in Edit information. 5. Click **OK**.
Method 2	1. Log on to Administration Console of Graph Analytics. 2. In the top navigation bar, click **Objects**. 3. In the left-side navigation pane, click the object group you want to modify. 4. On the right-side **Group Information** tab, click **Edit Basic Information**. Specify **Group Name** and **Sequence Number**, as shown in Edit information. 5. Click **Save**.

Edit information

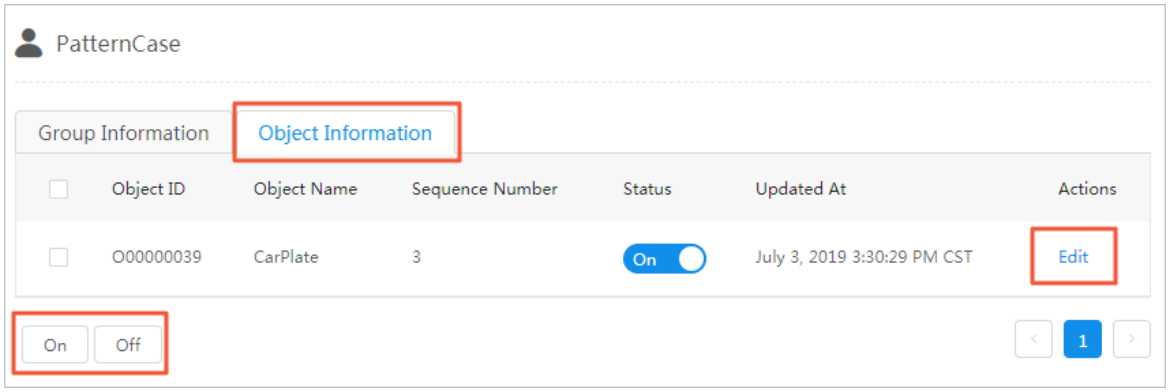


Edit basic information



Modify basic object information

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Objects**.
3. In the left-side navigation pane, click the object group to which the object belongs, and then click the **Object Information** tab on the right side of the page.
4. On the **Object Information** tab, select an object and then click **Edit** in the Actions column.



5. In the **Edit Information** dialog box that appears, reconfigure **Object Name** and **Sequence Number**.
6. Click **OK**.

Disable and enable an object

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Objects**.
3. In the left-side navigation pane, click the object group to which the object belongs, and then click the **Object Information** tab on the right side of the page.
4. You can use the following methods to enable or disable an object on the **Object Information** tab:

Method	Procedure

Method	Procedure
Disable an object	Disable an object: Click the On icon next to the object you want to disable. Disable multiple objects: Select the objects you want to disable and then click **Off** in the lower part of the page. After an object is disabled, the **Status** changes from a highlighted On icon to a dimmed Off icon.
Enable an object	Enable an object: Click the Off icon next to the object you want to enable. Enable multiple objects: Select the objects you want to enable and then click **On**. After the object is enabled, the **Status** changes from a dimmed Off icon to a highlighted On icon.

8.5.1.4. Delete object groups and objects

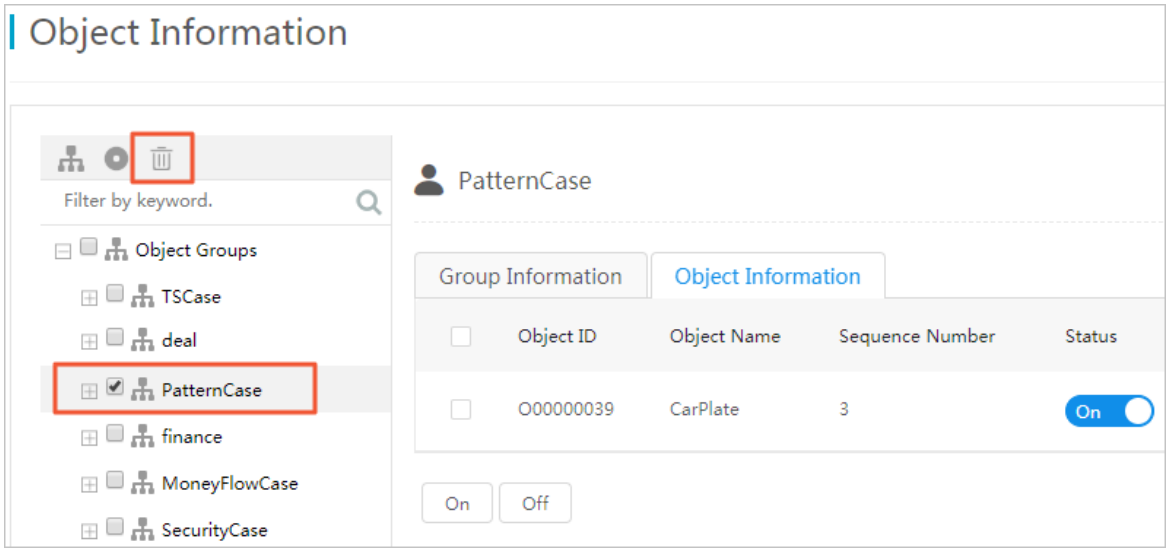
If some objects or object groups are no longer used, you can delete these objects and object groups.

Prerequisites

- The dependency information of an object, for example, the mapping between the object and the physical table, has been deleted before you delete the object.
- All the objects in an object group have been deleted before you delete the object group. Only empty object groups can be deleted.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Objects**.
3. (Optional)If there are still objects in the object group, you must delete these objects first.
   i. In the left-side navigation pane, select all objects in the object group you want to delete, and click the icon in the upper-left corner.
   ii. In the **Delete Object Information** dialog box that appears, click **OK** to clear the object group.
4. In the left-side navigation pane, select the object group you want to delete and then click the icon.



5. In the **Delete Object Information** dialog box that appears, click **OK**.

8.5.2. Objects

8.5.2.1. Create an object

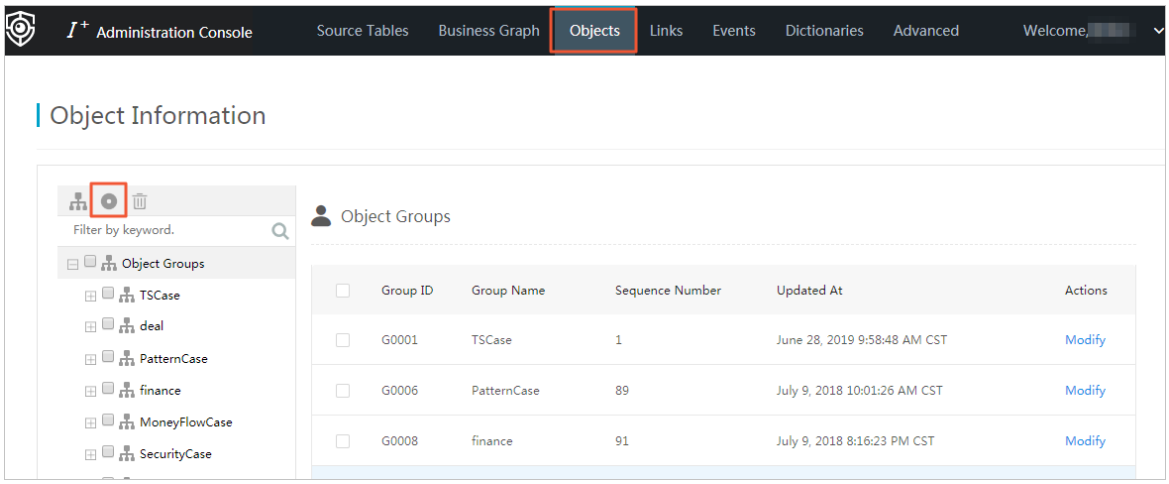
In Graph Analytics, objects are mapped to entities in the real world. Before you perform a relationship analysis on an entity, you must create an object that corresponds to the entity based on the data you have obtained. A complete object contains the basic information, property information, and relevant parameters. This topic describes how to configure the basic information of an object.

Prerequisites

An object group has been created. For more information, see Create an object group.

Procedure

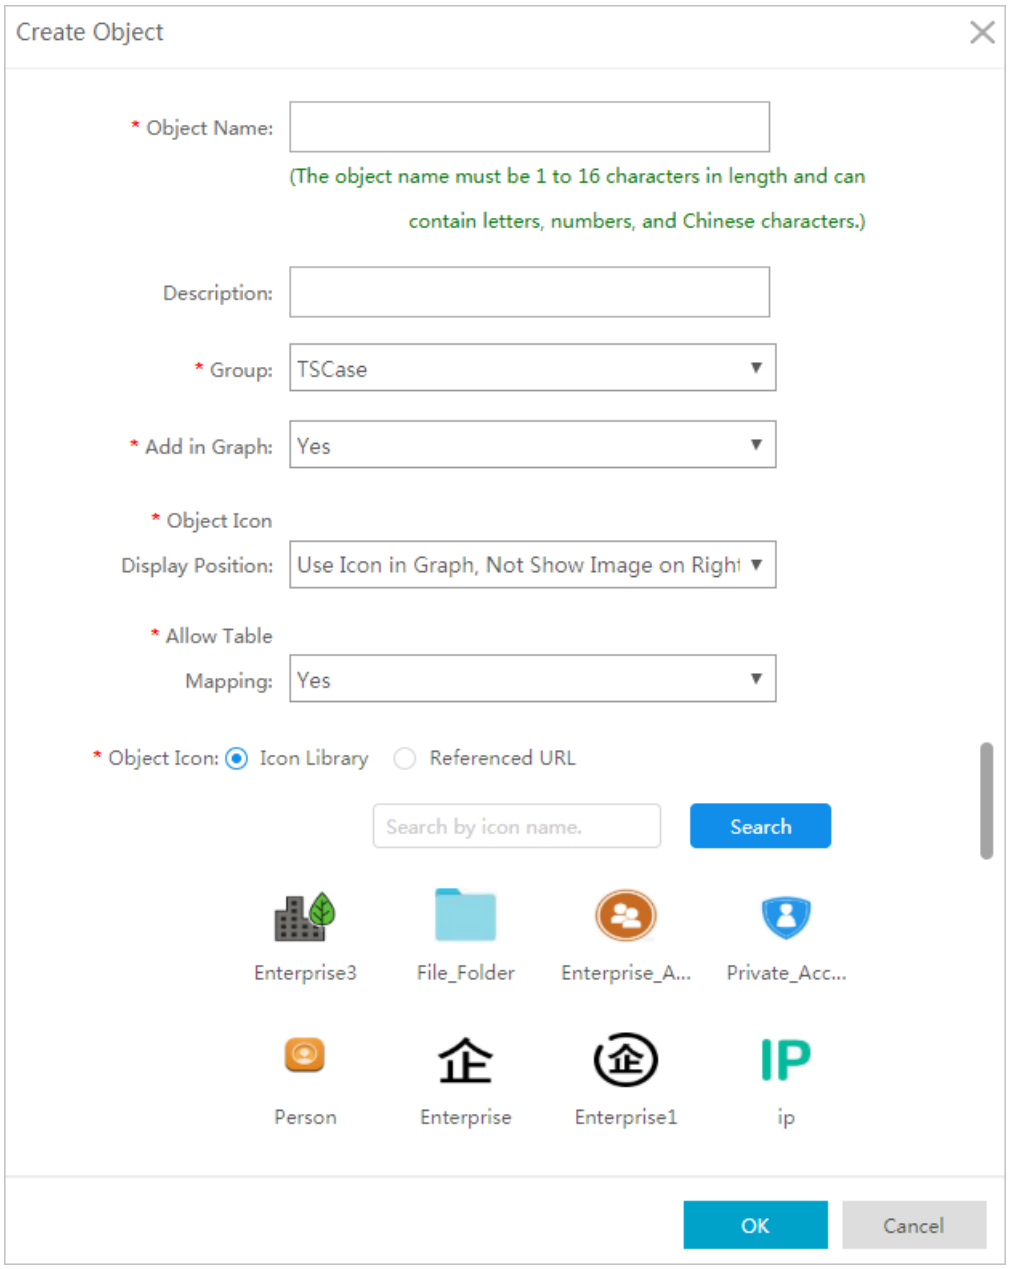
1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Objects**.



3. On the **Object Information** page, click the **Create Object** icon.

4. Configure the object information in the **Create Object** dialog box that appears.

   The parameters are described in Parameters of created objects.



Parameters of created objects

Parameter	Description
Object name	The user-defined object name. It must be unique.
Object Description	The object description that helps you understand the object.
Group	By default, the selected object group in the left-side navigation pane is used. You can also select another group as needed.

Parameter	Description
Add in Graph	Indicates whether you are allowed to manually add an object node to the graph page.
Object Icon Display Position	Valid values: ○ Use Icon in Graph, Not Show Image on Right-side Pane ○ Use Icon in Graph, Show Image on Right-side Pane ○ Use Image in Graph, Not Show Image on Right-side Pane ○ Use Image in Graph, Show Image on Right-side Pane
Allow Table Mapping	By default, this parameter is set to Yes.
Object Icon	Allows you to set the icon of the object. You can select an icon in Icon Library or enter a URL to reference an external icon.

5. Click **OK**.

What's next

1. After you have created an object, you must configure the properties and business parameters based on your business requirements. For more information, see Configure object properties and business parameters.
2. After you have configured the properties and business parameters of an object, you must log on to Analytics Workbench again to use the new object.

8.5.2.2. Configure object properties and business parameters

After you add an object, you need to configure the business parameters of the object based on your requirements so that you can view and analyze the object in Analytics Workbench.

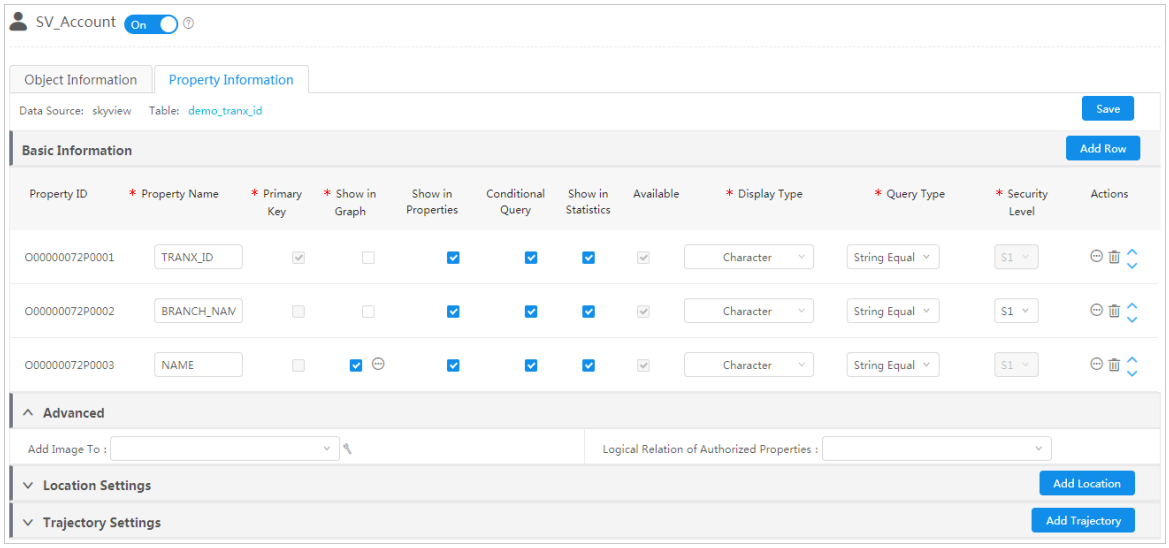
Prerequisites

- You have created a data source. For more information, see Create data sources.
- You have configured mappings between tables and objects, links, or events. For more information, see Create OLEP models for tables.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click **Objects** on the top of the page.
3. In the left-side navigation pane of the **Object Information** page, click the name of the object you want to configure and then click the **Property Information** tab on the right side.

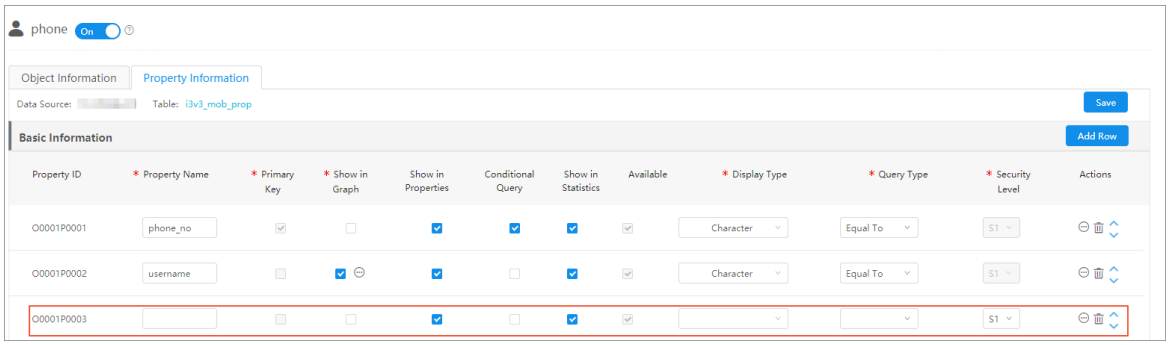
   If this object has been mapped to a physical table in the data source, the **Property Information** tab displays the **Data Source** and **Table** information.



4. Specify parameters in the **Basic Information** section.

   Click **Add Row** to add a property in **Basic information.**

   Parameters in Basic Information describes the parameters in **Basic Information.**



Parameters in Basic Information

Parameter	Description
Property ID	The ID of a property. It is automatically generated.
Property Name	The property name that is displayed on Analytics Workbench. Enter a name that describes your business.
Primary key	You must select one or more primary keys for the properties when you add an object for the first time. After the configuration is complete, you cannot modify or delete the primary keys. If you add a node in Analytics Workbench, you must enter the physical table column mapped by the primary key properties. For example, if the ID card number is the primary key, you need to enter the ID card number when you add an ID card node in Analytics Workbench.

Parameter	Description
Show in Graph	If you select this parameter, **Property Name** of this property will be displayed in **Graph** in Analytics Workbench together with the object node. Otherwise, Property Name will not be displayed. For example, if you select the ID card number, this number will be displayed in **Graph** together with the ID card object. If you select the name property at the same time, the name and the ID card number will be displayed together with the ID card object. If you select this parameter for a specific property, a bubble icon appears next to the option. You can click the bubble icon to specify whether to show the **Property Name** in **Graph**. For example, if you select this parameter for the ID card number, and choose to display **Property Name** in **Graph**, the ID card property displayed in **Graph** will be **ID card number: xxxxxx**.
Show in Properties	If you select this parameter for a property, the property will be displayed on the Details tab and the Property tab in the right-side pane of the Graph page in Analytics Workbench. Otherwise, the property will not be displayed.
Conditional Query:	If you select this parameter for a property, you can query the object based on this property in **Target Object** when you perform an analysis on the **Graph** page.
Show in Statistics	If you select this parameter for a property, the property is displayed on the **Statistics** tab in the right-side pane of the Graph page in Analytics Workbench. If you do not select this parameter, the property is not displayed in Analytics Workbench.
Available	If you select this parameter for a property, the property takes effect and is displayed in Analytics Workbench. This parameter must be selected for primary key properties. If any of the following parameters has been selected for the property: **Primary Key**, **Show in Graph**, **Show in Properties**, **Conditional Query** and **Show in Statistics**, the **Available** parameter will be automatically selected for a property. The **Available** parameter will be automatically cleared if you clear all the preceding parameters.
Display Type	After you configure this parameter, the property is displayed on the Details tab and the Property tab in the right-side pane of the Graph page in Analytics Workbench based on the selected type. **Note** To display a property in the format of **Dictionary**, you need to configure a dictionary first.
Query Type	The data type that is supported in the query condition of a property. If you select **Dictionary** for **Display Type**, you must select **Dictionary Option** for **Query Type**.

Parameter	Description
Security Level	The security level for a property. A user with a security level lower than the value of this parameter cannot view the property.
Search Item Configuration Default Query Condition Settings Authorization Code Derived Field	Click the icon in the Actions column corresponding to a property. Specify the following parameters: ○ Search Item Configuration: Search items are displayed in the drop-down list only after they have been configured in Configure a search item. ○ Default Query Condition Settings: the default condition used for an object query. If other properties are used as conditions for a query, this condition is also used by default. ○ Authorization Code: After the authorization code function is enabled, only the authorized users can access this property. ○ Derived Property: After a property is set as a derived property, it is automatically generated based on other properties. Configure the method in which the field is generated as needed.
Delete	If a property is no longer used, you can click the icon to delete this property.
Sort order	The Move Up and Move Down arrows are used to adjust the order of properties that are displayed in Analytics Workbench.

5. (Optional) If you need to add multiple properties, you can refer to the preceding steps to add more properties.
6. (Optional) Specify parameters in **Advanced**.

   Parameters in Advanced describes the parameters in **Advanced**.

Parameters in Advanced

Parameter	Description
Add Image To	The avatar of the object that is displayed in **Graph**. Select a property of the object, and then specify the URL of the image and the suffix of the image. **Add Image To** allows you to specify a combination of the prefix, the property, and the suffix. The prefix is the URL of the image, and the suffix is the image format.
Logical Relation of Authorized Properties	The logical relationship between the authorization codes of properties in each record: ○ **AND**: The current record is visible to the users who meet all authorization code conditions of the properties in this record. ○ **OR**: The current record is visible to the users who meet any one authorization code condition of the properties in this record.

7. Click Save.

8.5.2.3. Enable and disable an object

After you have created a complete object (configured the object properties), the object is enabled automatically. You can disable an object if it is no longer used for a certain period of time and enable it again when necessary.

Prerequisites

To disable objects, you must first delete the dependency information of these objects, including the mappings between the objects and data tables and the objects referenced by links.

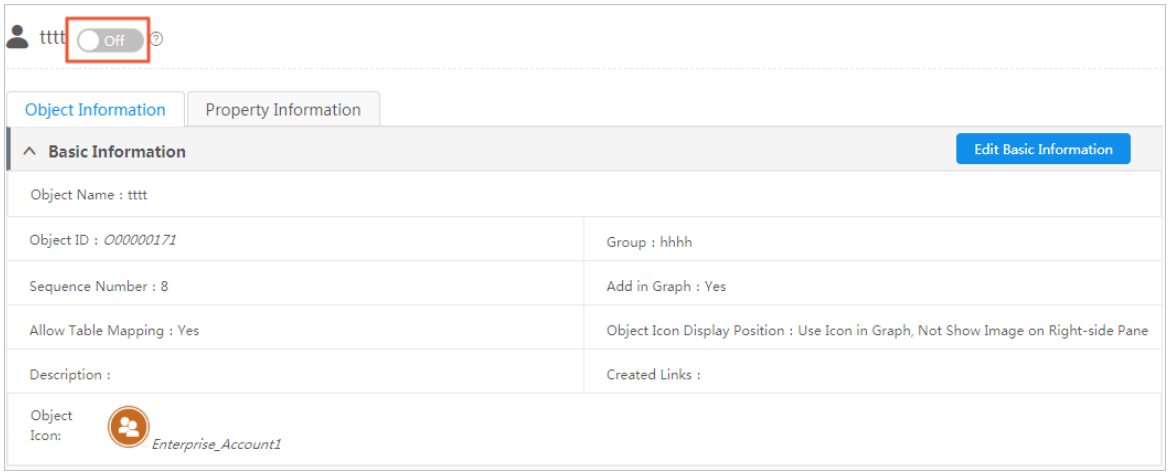
Context

You cannot use an object in Analyitcs Workbench after the object is disabled.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Objects**.
3. In the left-side navigation pane, click the object group to which the object belongs, and then click the object to be enabled or disabled.

   The detailed information of the object is displayed on the right side of the page.



4. Enable or disable an object as follows.

Operation	Procedure
Disable an object	If the current object is enabled, you can click the On icon to disable the object. After the object is disabled, the **Status** changes from a highlighted On icon to a gray Off icon.

Operation	Procedure
Enable an object	If the current object is disabled, you can click the Off icon to enable the object. After the object is enabled, the **Status** changes from a gray Off icon to a highlighted On icon.

8.5.2.4. Modify an object

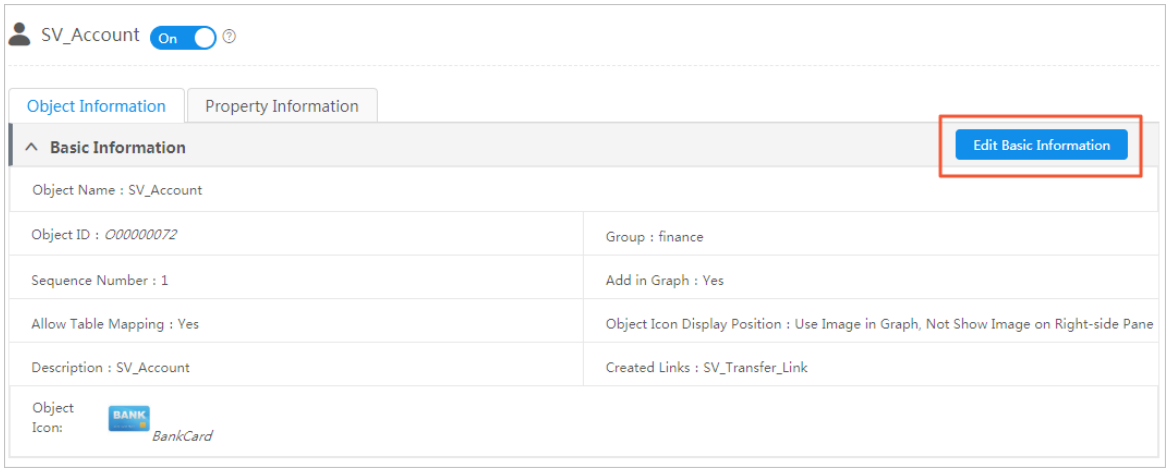
In Graph Analytics, you can modify the basic information of an object at any time, including the object name, object group, and object icon.

Prerequisites

You have created an object. For more information about how to create an object, see Create an object.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Objects**.
3. In the left-side navigation pane, click the object group to which the object belongs, and then click the object to be modified.
4. In right-side area, click **Edit Basic Information**.



5. Modify the object information as needed.

   All parameters can be modified except the **Object ID**.
6. After you have configured the preceding parameters, click **Save**.

8.5.2.5. Delete an object

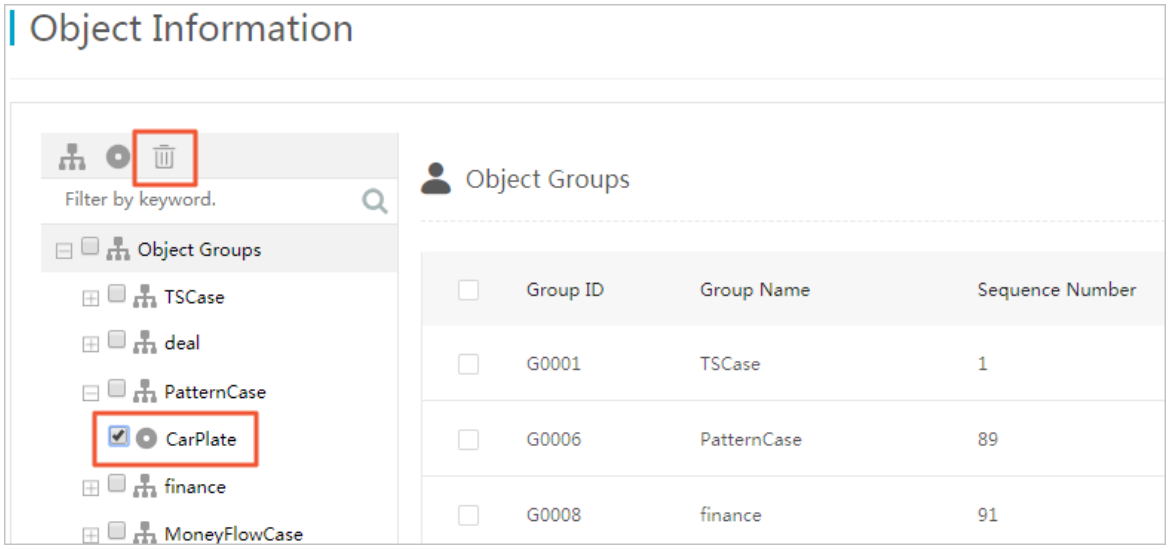
You can delete the objects that are no longer used.

Prerequisites

You have deleted the mappings between the object and the data table. You have deleted links and events that are referenced by the object.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Objects**.
3. In the left-side navigation pane, click the object group to which the object belongs, and select one or more objects to be deleted. You can open multiple object groups and select objects from different groups.



4. Select the objects to be deleted, and click the icon.
5. In the **Delete Object Information** dialog box that appears, click **OK**.

8.6. Link information

8.6.1. Link groups and links

8.6.1.1. Create a link group

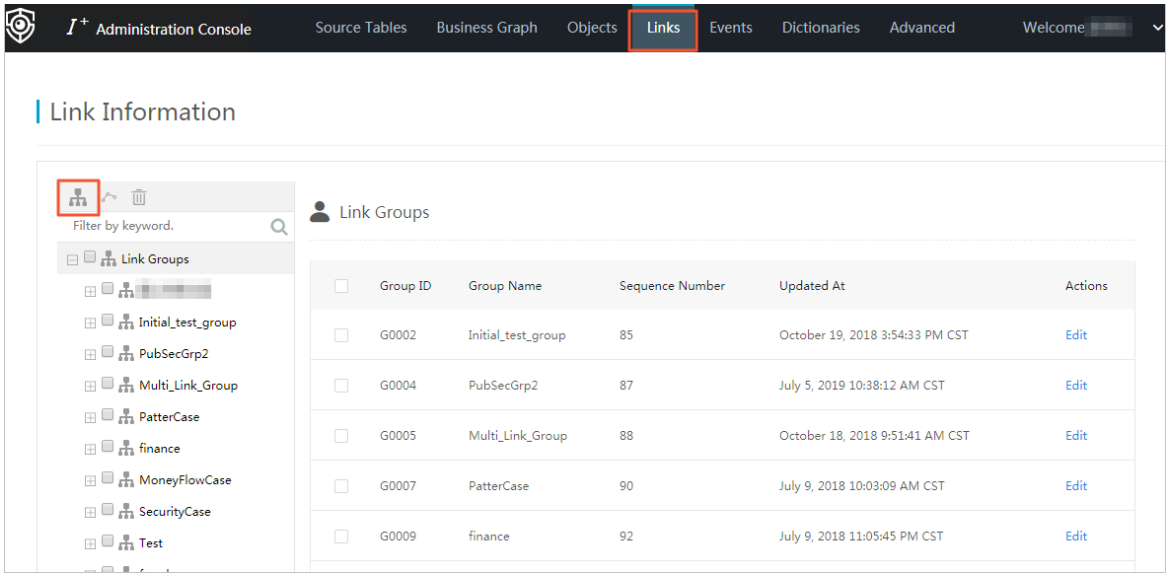
You can use link groups to classify links, so that you can search for and manage links with ease. One link must be and can be included in only one link group. You need to create a proper link group before you create a link.

Prerequisites

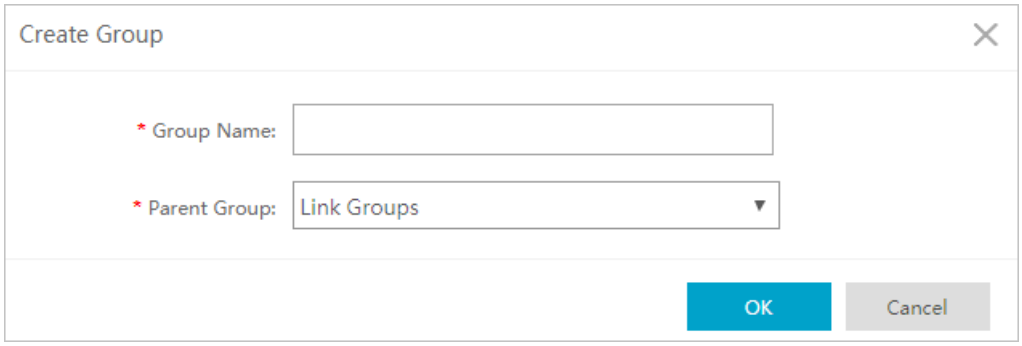
You have an account and password for Graph Analytics and have permissions to perform operations in Administration Console of Graph Analytics.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Links**.



3. On the **Link Information** page, click the **Create Group** icon .
4. In the **Create Group** dialog box that appears, specify **Group Name** and **Parent Group**.



5. Click **OK**.

8.6.1.2. View links and link groups

Graph Analytics allows you to view all link groups in the current environment so that you can understand the existing link groups and the links under each group at any time.

Prerequisites

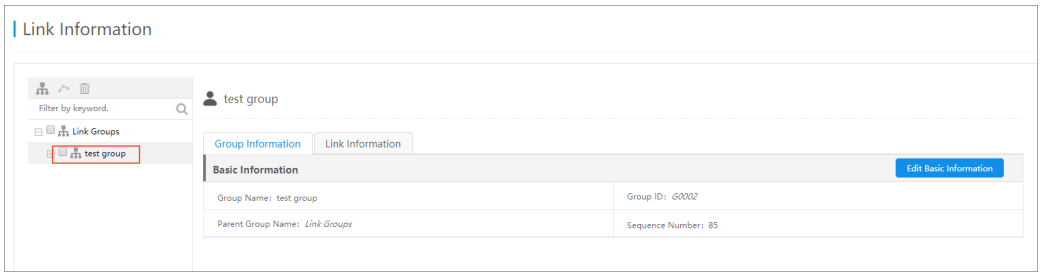
You have an account and password for Graph Analytics and have permissions to perform operations in Administration Console of Graph Analytics.

Procedure

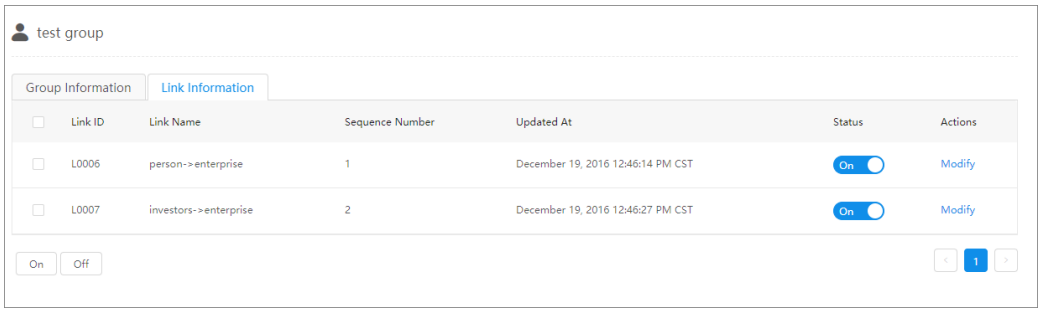
1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Links**.
3. In the left-side navigation pane of the **Link Information** page, click a link group. The **Group Information** and **Link Information** tabs of the link group are displayed on the right side of the page.

   The left-side navigation pane displays all link groups in the current environment. You can view the groups one by one.

Group Information



Link Information



8.6.1.3. Modify a link or link group

In Graph Analytics, you can modify the name and order number of a link or link group. You can adjust the basic information of a link or link group at any time as needed. In Graph Analytics, you can enable or disable a link.

Prerequisites

- You have created a link group. For more information about how to create a link group, see Create a link group.
- You have created a link that belongs to this link group. For more information about how to create a link, see Create a first-degree link, Create a second-degree link, or Create a multi-degree link.
- To disable links, you must first delete the dependency information of these links, including the mappings between the links and data tables.

Context

This topic describes the following operations:

- Modify the basic information about a link group
- Modify the basic information about a link
- Enable or disable a link

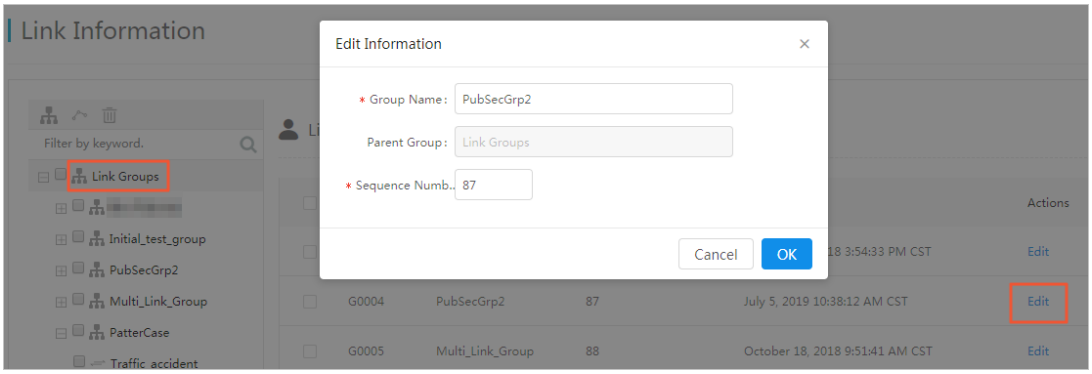
After you create a complete link by configuring the link properties), the link is automatically enabled. You can disable a link if it is no longer used for a period of time and enable it again when necessary. You cannot use a link in Analytics Workbench after the link is disabled.

Modify the basic information about a link group

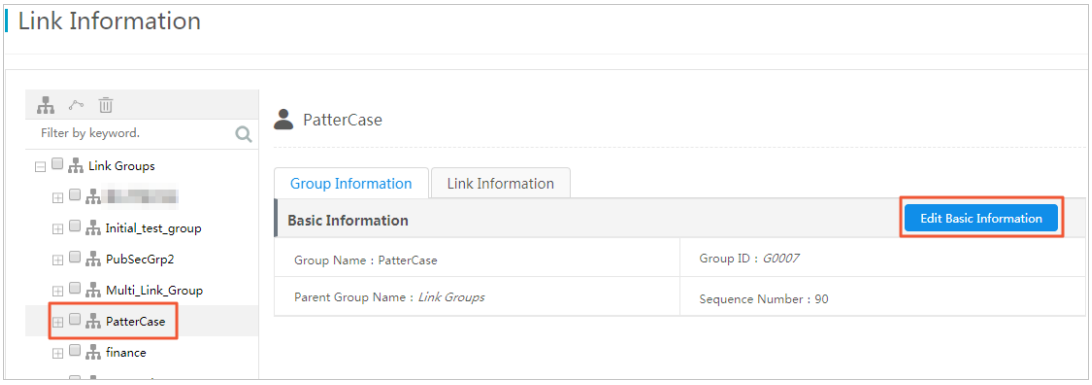
You can modify the basic information of an object group by using one of the following methods:

Configuration method	Procedure
Method 1	1. Log on to Administration Console of Graph Analytics. 2. In the top navigation bar, click **Links**. 3. In the **Link Groups** area that appears, select a link and click **Edit** in the Actions column. 4. In the **Edit Information** dialog box that appears, specify **Group Name** and **Sequence Number**, as shown in Edit the basic information. 5. Click **OK**.
Method 2	1. Log on to Administration Console of Graph Analytics. 2. In the top navigation bar, click **Links**. 3. In the left-side navigation pane, click the link group you want to modify. 4. On the right-side **Group Information** tab, click **Edit Basic Information**. Specify **Group Name** and **Sequence Number**, as shown in Edit the basic information. 5. Click **Save**.

Edit information



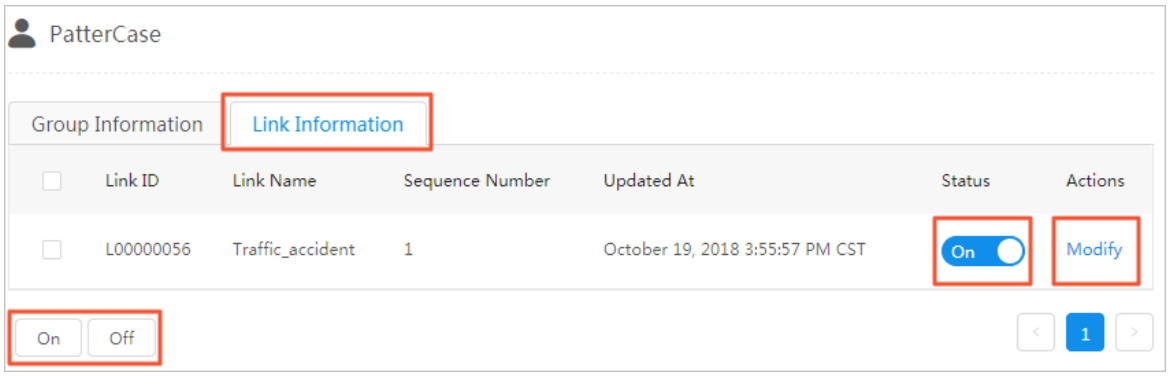
Edit the basic information



Modify the basic information about a link

1. Log on to Administration Console of Graph Analytics.

2. In the top navigation bar, click **Links**.
3. In the left-side navigation pane, click the link group to which the link belongs, and then click the **Link Information** tab.



4. In the **Edit Information** dialog box that appears, specify **Link Name** and **Sequence Number**.
5. Click **OK**.

Enable or disable a link

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Links**.
3. In the left-side navigation pane, click the link group to which the link belongs, and then click the **Link Information** tab on the right side of the page.
4. You can use the following methods to enable or disable a link on the **Link Information** tab.

Configuration method	Procedure
Disable a link	Disable a single link: Click the **On** icon next to the link you want to disable. Disable multiple links: Select the links you want to disable and then click **Off** in the lower part of the page. After the link is disabled, the **Status** changes from a highlighted **On** icon to a dimmed **Off** icon.
Enable a link	Enable a single link: Click the **Off** icon next to the link you want to enable. Enable multiple links: Select the links you want to enable and then click **On**. After the link is enabled, the **Status** changes from a dimmed **Off** icon to a highlighted **On** icon.

8.6.1.4. Delete a link or link group

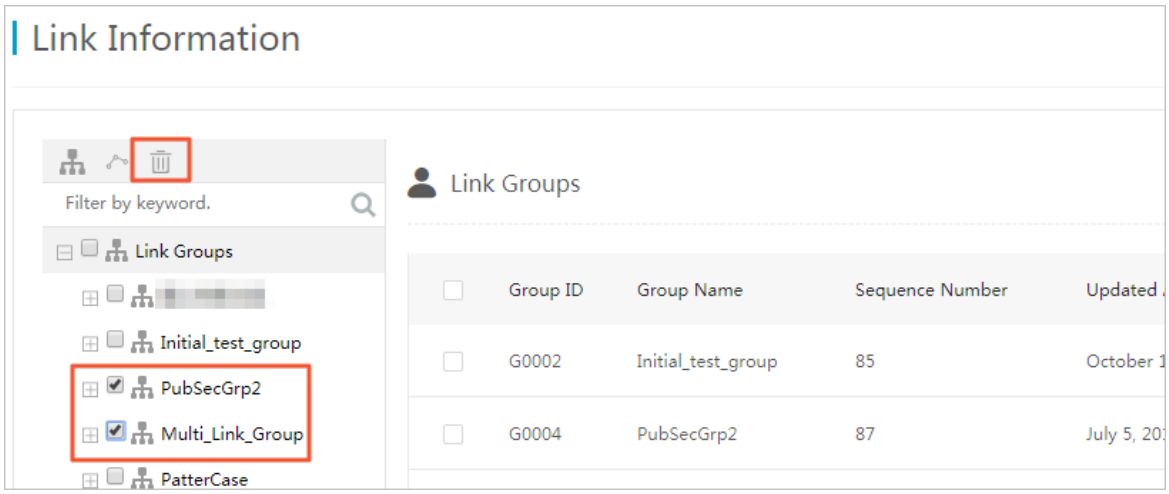
You can delete the links and link groups when they are no longer used.

Prerequisites

- Before you delete a link, you have deleted the dependency information of the link, for example, the mapping between the link and the physical table.
- Before you delete a link group, you have deleted all the links in the group. You can delete only empty link groups.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Links**.
3. (Optional)If there are links in the object group, you must delete these links first.
   i. In the left-side navigation pane, select all links in the link group you want to delete, and click the icon in the upper-left corner.
   ii. In the **Delete Link Information** dialog box that appears, click **OK**.
4. In the left-side navigation pane, select the link groups you want to delete, and then click the icon in the upper-left corner.



5. In the **Delete Link Information** dialog box that appears, click **OK**.

8.6.2. First-degree links

8.6.2.1. Create a first-degree link

A first-degree link reflects the direct relationship between two objects. It is the basis of second-degree links and multiple-degree links. You must create a first-degree link between objects before you perform a link analysis in Graph Analytics. A complete link contains the basic information, property information, and business parameters. This topic describes how to configure the basic information of a link.

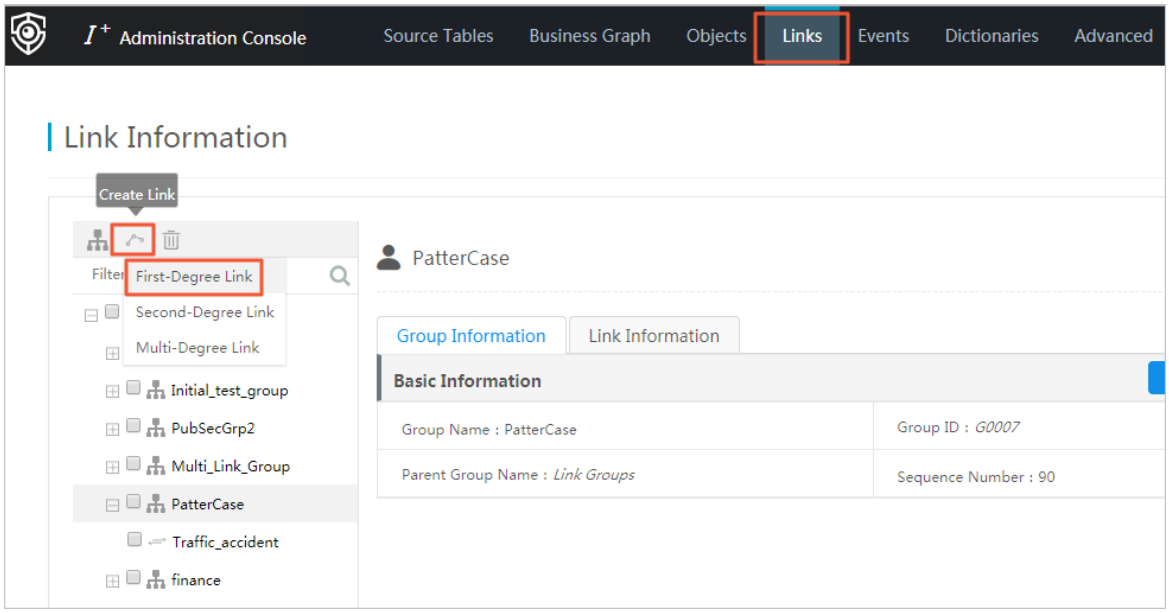
Prerequisites

- You have created and enabled a source object and a target object for the first-degree link. For more information about how to create an object, see Create an object.
- You have created a link group to which the first-degree link belongs. For more information

about how to create a link group, see Create a link group.

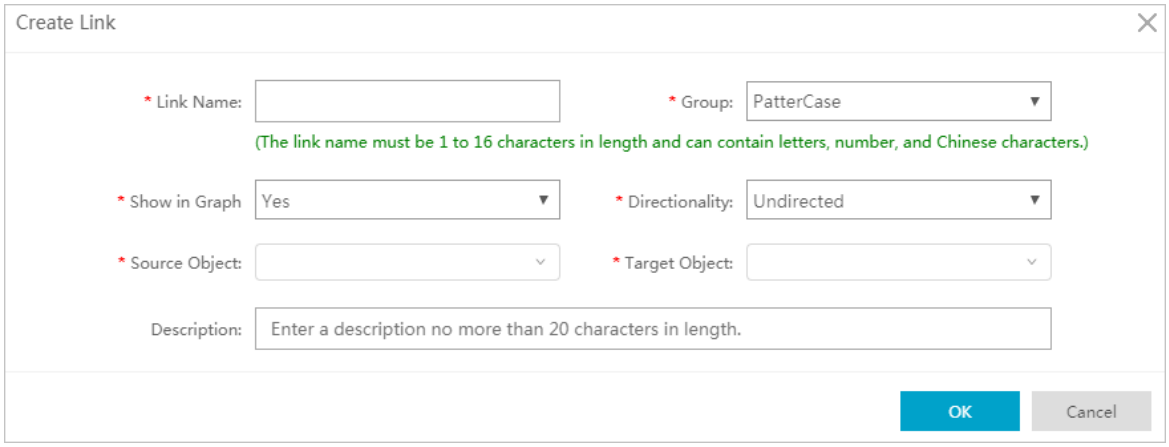
Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Links**.
3. The **Link Information** page appears. Click the **Create Link** icon, and click **First-Degree Link**.



4. In the **Create Link** dialog box that appears, specify the parameters.

   Parameters used to create a first-degree link describes the parameters.



Parameters used to create a first-degree link

Parameter	Description
Link Name	The user-defined link name. It must be unique.
Group	By default, the selected link group in the left-side navigation pane is used. You can also select another link group as needed.

Parameter	Description
Show in Graph	Specifies whether a link is displayed on the **Graph** page. If the value is set to **No**, this link is not displayed on the **Graph** page.
Directionality	Specifies whether the link is directional. For example, if the source object A calls the target object B, a link is established. If this link is set to be directional, it will be displayed on the **Graph** page. The link direction is from A to B (A > B).
Source Object	The source object of the first-degree link. You can select it from the drop-down list.
Target Object	The target object of the first-degree link. You can select it from the drop-down list.
Description	Enter the description of the first-degree link. This makes it easy for you to understand this link.

5. Click **OK**.

What's next

1. After you have created a first-degree link, you must specify the properties and configure the business parameters based on your requirements. For more information, see Configure link properties and business parameters.
2. To use the new link, you must log on to Analytics Workbench again.

8.6.2.2. Configure link properties and business parameters

After you add a first-degree link, you need to configure the properties and business parameters of the link based on your business requirements, so that you can view and apply this link in Analytics Workbench. This topic describes how to configure the properties and business parameters of a first-degree link.

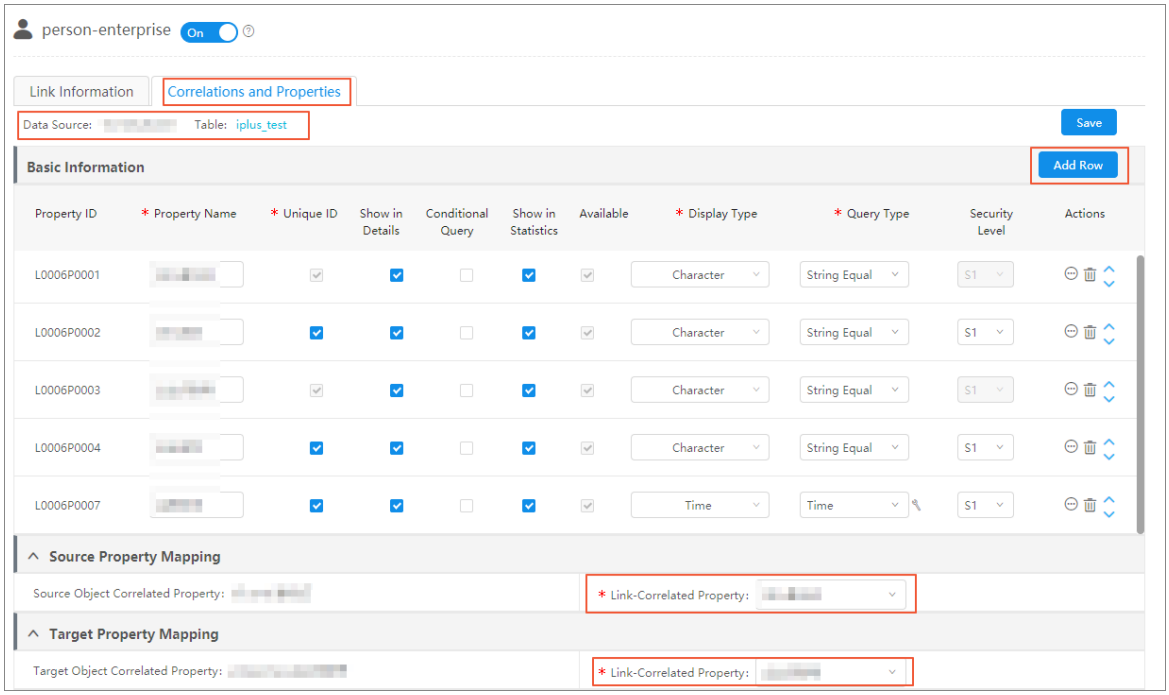
Prerequisites

You have created a first-degree link. For more information about how to create a link, see Create a first-degree link.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click **Links** on the top of the page.
3. In the left-side navigation pane, click the link group that contains the first-degree link to be configured, and then click the link.
4. In the right-side area, click the **Correlations and Properties** tab.

On the **Correlations and Properties** page, if the link has been mapped to a data table in the data source, the property information section will display **Data Source** and **Table**. You can click the table name to go to the table page.



5. Set the basic configurations in the **Basic Information** page.

   Click **Add Row** to add a property for a link in **Basic information**.

> **Note**
>
> **Link-Correlated Property** in **Source Property Mapping** and **Link-Correlated Property** in **Target Property Mapping** are not the same and they are both required to be configured. Therefore, a link must have at least two properties.

The configuration items in **Basic Information** are described in Description of basic configuration items.

Description of basic configuration items

Configuration item	Description
Property ID	The ID of a property. It is automatically generated.
Property Name	The name of the property. If you select Available, the name of the property will be displayed in Analytics Workbench.
Unique ID	Defines the logical primary key of a link table.
Show in Details	If you select this item, the property will be displayed in the **Details** tab in Analytics Workbench.

Configuration item	Description
Conditional Query	If you select this item, when you perform an analysis on the **Graph** page in Analytics Workbench, you can query a link based on the link type in **Link Type**.
Show in Statistics	If you select this item, the property is displayed in **Analytics Workbench > Graph > right-side navigation pane > Statistics**. Otherwise, it is not displayed.
Available	If you select this item, the property takes effect and is displayed in Analytics Workbench. The **Available** parameter is automatically selected for a property if any of the following parameters has been selected for the property: **Unique ID**, **Show in Details**, **Conditional Query**, and **Show in Statistics**. The **Available** parameter is automatically deselected for a property if all of the preceding parameters are deselected for the property.
Display Type	After you set the display type, the property is displayed in **Analytics Workbench > Graph > right-side navigation pane > the Details tab and the Property tab** based on the selected type. Note To display a property in the format of **Dictionary**, you need to configure a dictionary first.
Query Type	The data type that is supported in the query condition of a property. If you select **Dictionary** for **Display Type**, you must select **Dictionary Option** for **Query Type**.
Security Level	The security level for a property. A user with a lower security level cannot view the property.
Search Item Configuration	Associates this property with a search item so that the link can be searched by this property in Analytics Workbench.
Default Query Condition Settings	Specifies the default condition used for a link query. If other properties are used as conditions for the query, this condition is also included by default.
Authorization Code	After the authorization code function has been enabled, only users with the required authorization code can access this property.
Derived Property	Sets a property as a derived property so that it can be generated automatically based on other properties. You can set the derivative method based on your requirements.
Move Up and Move Down arrows	The Move Up arrow and the Move Down arrow can be used to adjust the order of properties that are displayed in Analytics Workbench.

6. You can set **Link-Correlated Property** in **Source Property Mapping** and **Target Property Mapping**.

These two configurations are related with the Source Object and the Target Object of the link.

Take **Source Property Mapping** as an example: **Source Object Correlated Property** and **Link-Correlated Property** must be mapped to the same column in the same table. The **Source Object Correlated Property** parameter is the primary key property of the source object, which is automatically loaded according to the Source Object parameter. For the **Link-Correlated Property** parameter, you must select the link property that is mapped to the same column in the same table as the Source Object primary key.

Set **Target Property Mapping** in the same way you set **Source Property Mapping**.

7. (Optional)Set **Advanced**, **Accumulative Statistics Settings**, and **Link Weight Settings** based on your requirements.

   For more information about the configurations of key parameters, see Parameter configurations.

Parameter configurations

Category	Configuration item	Description
Advanced	**Chronological Time Property**	Specifies the link properties based on which chronological analysis is performed. From the drop-down list, select one or more link properties of which the query type is time.
	Time Property for Behavior Analysis	Specifies the link properties based on which behavior analysis is performed. From the drop-down list, select one or more link properties of which the query type is time.
	Linked Times	Specifies the property of which the number of the same values are counted. The total number is displayed as the number of link occurrences. The **Linked Times** parameter is used as the default setting to filter link types. For example, if there are two limes of A > C calls in the call log, the analysis result displays that the number of A > C calls is two.
	Details Sorting Property	Specifies the property by which the returned behavior details are sorted by default.
Accumulative Statistics Settings	N/A	Used to perform logical statistics for link properties of which the query type is numeric range. The logical statistics operations include top, =, and >=. This configuration applies to business scenarios where statistics filtering is required for link query results. The **Linked Times** parameter is used to filter records in link query results. You can add statistical conditions to filter the link properties of which the query type is numeric range.

Category	Configuration item	Description
Link Weight Settings	N/A	You can specify a link property of which the query type is numeric range and calculate the link weight based on the numeric range specified for the link property.

8. After you have modified the parameters, click Save. A message is displayed, indicating that the modifications have been saved.

8.6.3. Create a second-degree link

A second-degree link reflects the relationship between two objects established by using an intermediary object. Unlike a first-degree link, a second-degree link can be used to explore a more complex relationship network among objects.

Prerequisites

- Related first-degree links have been created for the second-degree link. For more information about how to create a first-degree link, see Create a first-degree link.
- A link group has been created for the second-degree link. For more information about how to create a link group, see Create a link group.

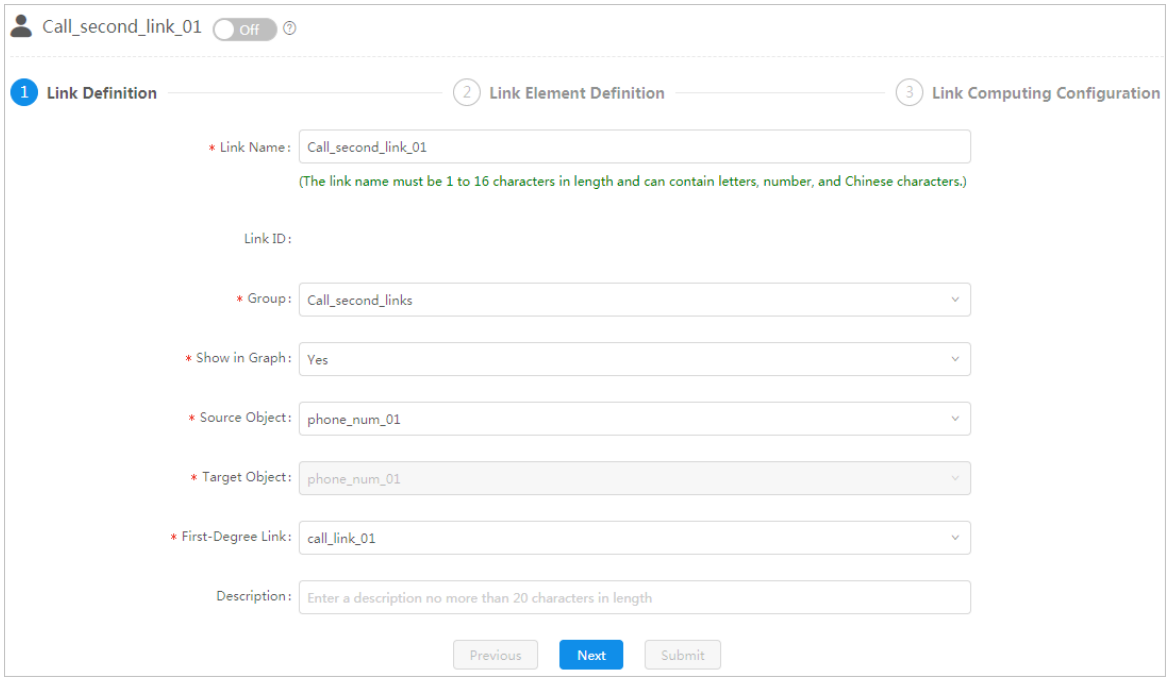
Context

A second-degree link is created based on first-degree links and can be split into two first-degree links. For example, object A has a first-degree link with object C, and object B also has a first-degree link with object C. In this case, you can establish a second-degree link between object A and object B. Typically, people taking the same train or plane or staying in the same hotel have a second-degree link and can be analyzed by using the second-degree link model.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Links**.
3. On the **Link Information** page that appears, click the **Create Link** icon and select **Second-Degree Link**.
4. Configure the parameters on the **Link Definition** page.

   Parameters describes the parameters.

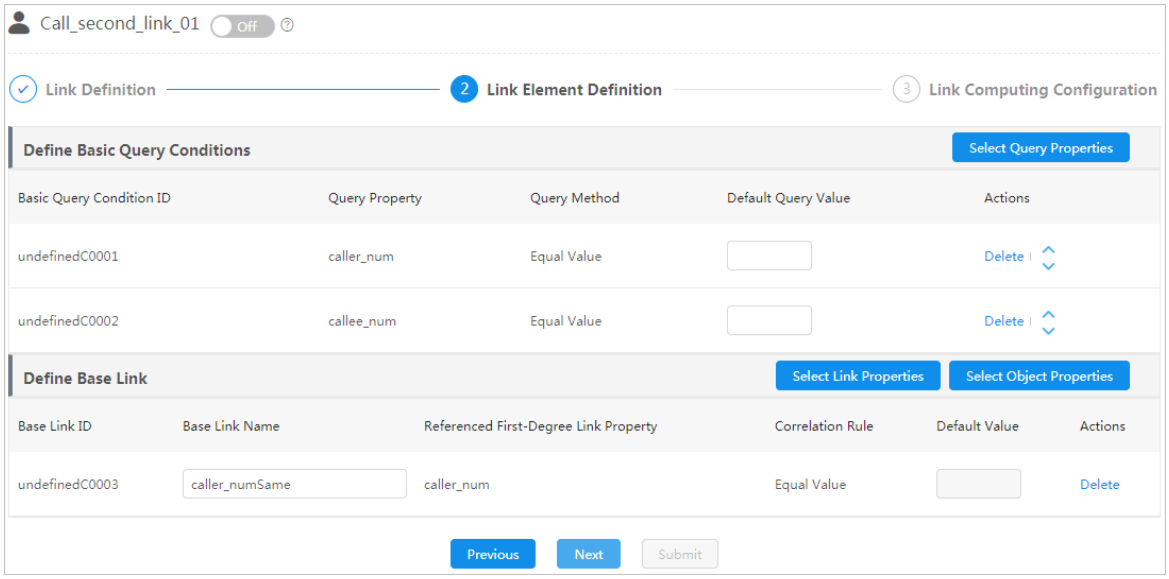


Parameters

Parameter	Description
Link Name	The user-defined link name. It must be unique.
Group	By default, the selected link group in the left-side navigation pane is used. You can also select another link group as needed.
Show in Graph	Indicates whether a link can be displayed on the **Graph** page. If this parameter is set to **No**, this link is not displayed on the **Graph** page.
Source Object	The source object of the second-degree link.
Target Object	The target object of the second-degree link.
First-Degree Link	The first-degree links between the source object and the target object. These links can be used to create a second-degree link.
Description	The description of the second-degree link that helps you understand the link.

5. After you have configured the preceding parameters, click **Next** to configure the parameters in **Link Element Definition**.

   Parameters describes the parameters.

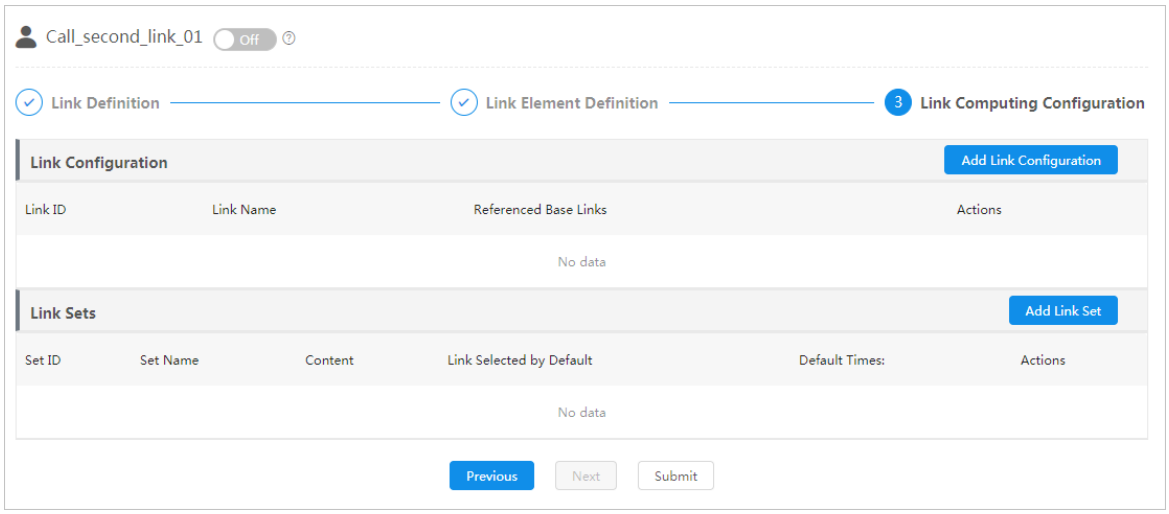


Parameters

Section	Parameter	Description
Define Basic Query Conditions	Select Query Properties	Allows you to define the basic query conditions that can be used to query a link. You can view the conditions in the **Basic Properties** section in the **Link Type** settings when you configure link extension.
Define Basic Link	Select Link Properties and Select Object Properties	Allows you to define the table columns that are needed to perform a query. You can define the alias of a column in **Base Link Name**. The base link can be referenced in **Link Configuration** in the next step. Configure the Correlation Rule. The Default Value will be used when you perform a query in Analytics Workbench.

6. After you have configured these parameters, click **Next** and then configure the parameters in **Link Computing Configuration**.

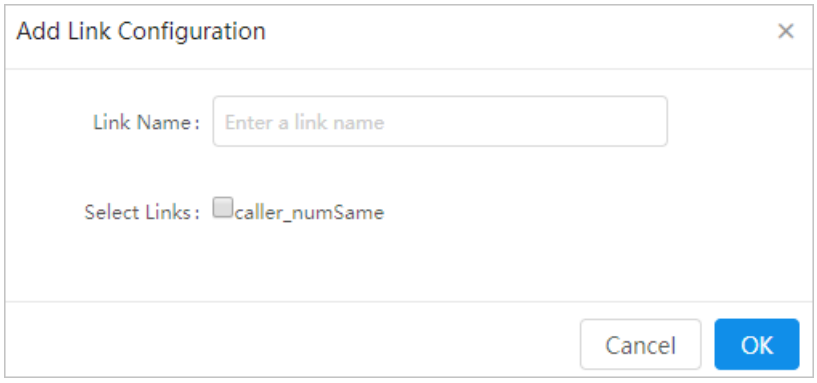
   Parameters describes the parameters.



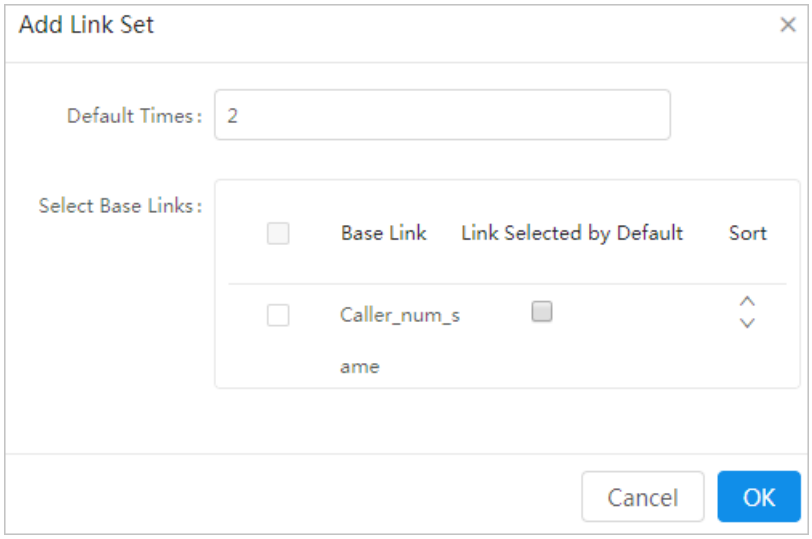
Parameters

Section	Parameter	Description
Link Configuration	**Add Link Configuration**	Allows you to combine multiple first-degree links to form a link that meets multiple conditions. i. Click **Add Link Configuration**, specify **Link Name**, and then select links. ii. Click **OK** to add a link that meets multiple conditions. iii. You can repeat the preceding steps to create more links of the same type as needed.
Link Sets	**Add Link Set**	A link set is a group of links configured in **Link Configuration**. Such link sets define the advanced query conditions for link queries in link analysis. i. Click **Add Link Set** and configure the parameters. Key parameters to add a link set: ■ **Default Times**: the minimum number of occurrences of a link set that can be counted as a query match. The default value is 2. ■ **Base Link**: the links displayed in the Select Base Links area are all the links that have been configured in **Link Configuration**. Each link can be contained in only one link set. ■ **Link Selected by Default**: the default query condition that is displayed on Analytics Workbench. If a link set that contains multiple links is used for a link query, each analysis is performed based on one of the links. By default, **Link Selected by Default** is used. ii. Click **OK**. iii. You can repeat the preceding steps to create more link sets as needed.

Add a link configuration



Add a link set



7. After you have configured the preceding parameters, click **Submit** to create a second-degree link.

8.6.4. Create a multi-degree link

A multi-degree link reflects the relationship between two objects established by using multiple intermediary objects. Compared to a first-degree link or a second-degree link, a multi-degree link can further explore the complex relationship between objects.

Prerequisites

- You have created first-degree links for the multi-degree link. For more information about how to create a first-degree link, see Create a first-degree link.
- You have created second-degree links for the multi-degree link. For more information about how to create a second-degree link, see Create a second-degree link.
- You have created a link group for the multi-degree link. For more information about how to create a link group, see Create a link group.

Context

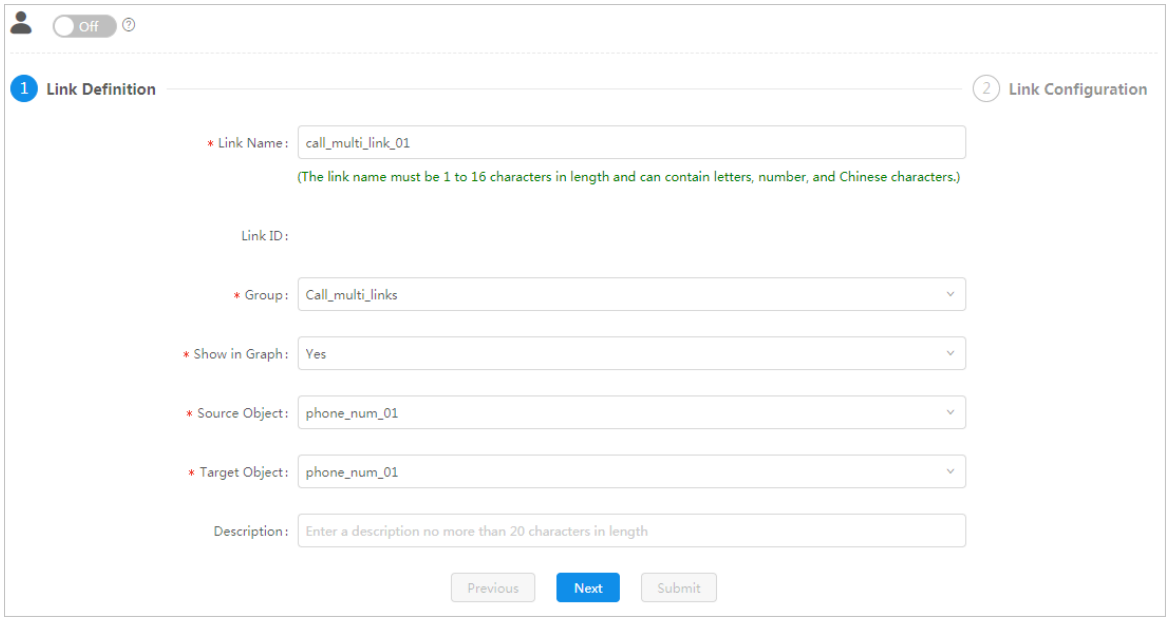
A multi-degree link uses multiple first-degree links and second-degree links to query the relationship between two objects.

For example, if mobile phone A and mobile phone B do not have call or text message records and only have email correspondence records, there are only indirect links between the two mobile phones. In this example, there is no direct relationship between mobile phone A and mobile phone B, so they cannot be directly linked. When mobile phone A sends an email to mobile phone B, an indirect link is established. This indirect link involves three first-level links: the link between mobile phone A and mailbox A, the link between mailbox A and mailbox B, and the link between mobile phone B and mailbox B. You can use mobile phone A to query mobile phone B by using the three links. Indirect links can also be established between two mobile phones that are communicated by using apps such as Facebook and Twitter.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Links**.
3. On the **Link Information** page that appears, click the **Create Link** icon and select **Multi-Degree Link**.
4. Configure the parameters on the **Link Definition** page.

   Link definition parameters describes the parameters.

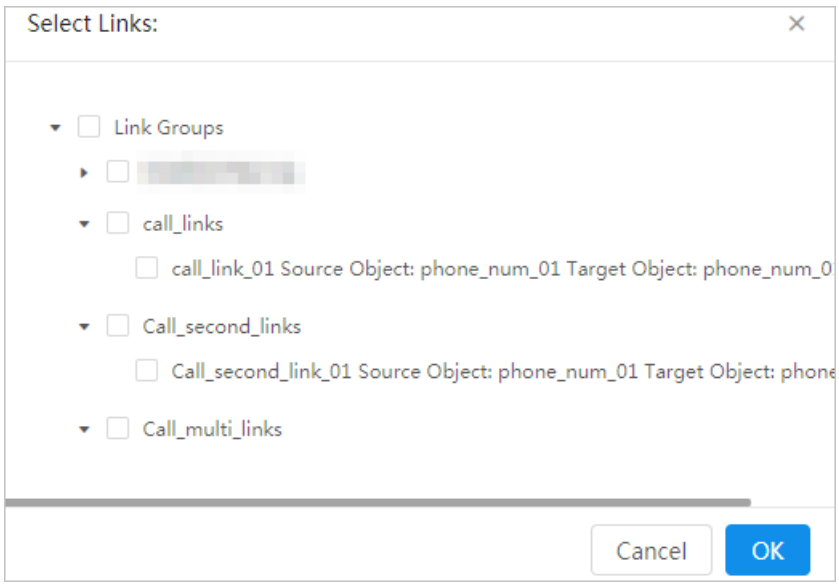


Link definition parameters

Parameter	Description
Link Name	The user-defined link name. It must be unique.
Group	By default, the selected link group in the left-side navigation pane is used. You can also select another link group as needed.
Show in Graph	Specifies whether a link is displayed on the **Graph** page. If the value is set to **No**, this link definition is not displayed on the **Graph** page.
Source Object	The source object of the multi-degree link. You can select it from the drop-down list.

Parameter	Description
Target Object	The target object of the multi-degree link. You can select it from the drop-down list.
Description	The description of the multi-degree link that helps you understand the link.

5. Click **Next**.
6. On the **Link Configuration** page, click **Select Links** in the upper-right corner, and then select the related first-degree links and second-degree links.

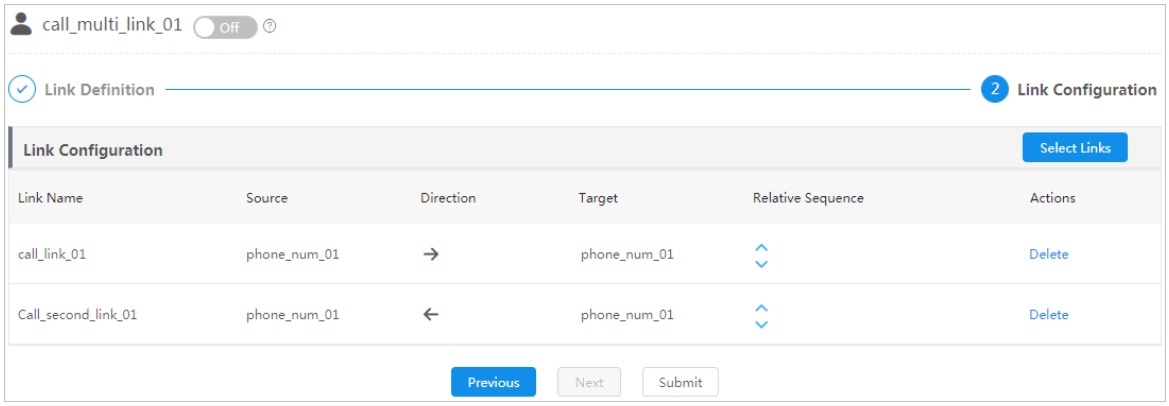


7. After you have configured the preceding parameters, click **OK** to add first-degree links and second-degree links.

   In most cases, you may need to add two first-degree or second-degree links with opposite query directions. For example, if you want to send an email by using your mobile phone, the query direction is from the mobile phone to the email box. If you want to receive an email on your mobile phone, the query direction is from the email box to your mobile phone. Therefore, two first-degree links can be added with opposite query directions.

8. On the **Link Configuration** page, click the right or left arrow in the **Query Direction** column to adjust the query direction.

   The source object and the target object must be correlated with each other by using intermediary objects..



9. After you have configured the preceding parameters, click **Submit** to add a multi-degree link.

8.7. Event information

8.7.1. Event groups

8.7.1.1. Create an event group

You can use event groups to classify events, so that you can easily find and manage events. Any event must be and can only be grouped into one event group. You need to create a proper event group before you create an event.

Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click the **Events** tab in the top navigation bar. The **Event Information** page appears.
3. At the top of the left-side navigation pane, click the **Create Group** icon . The **Create Group** dialog box appears.
4. Enter a **Group Name** as needed, and then select **Event Groups** from the *Parent Group* drop-down list.
5. Click **OK**.

8.7.1.2. View an event group

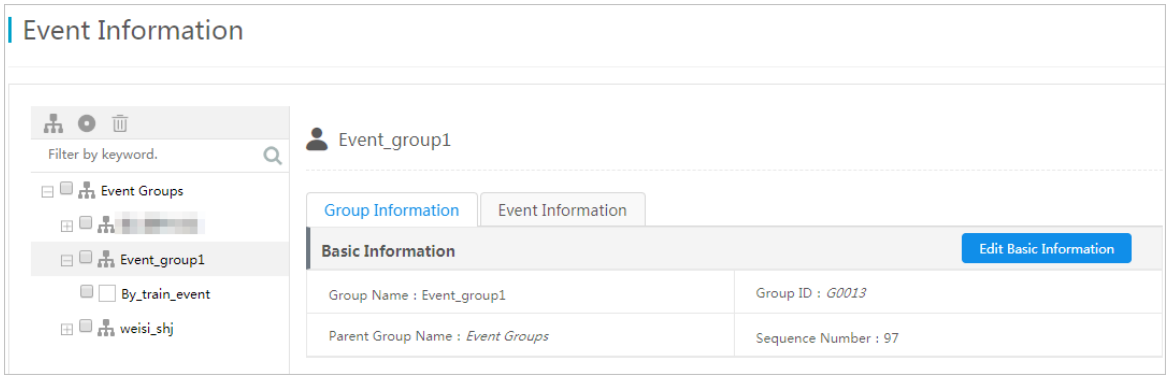
You can view the basic information of an event group and the events in the group in Administration Console.

Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click the **Events** tab in the top navigation bar. The **Event Information** page appears.
3. From the left-side navigation pane, select an event group such as **By Train**. The detailed information about this event group is displayed on the right side of the page.



You can view event group information on the **Group Information** and **Event Information** tabs. The **Group Information** tab displays the basic information about the event group. The **Event Information** tab displays all events in the group.

8.7.1.3. Modify an event group

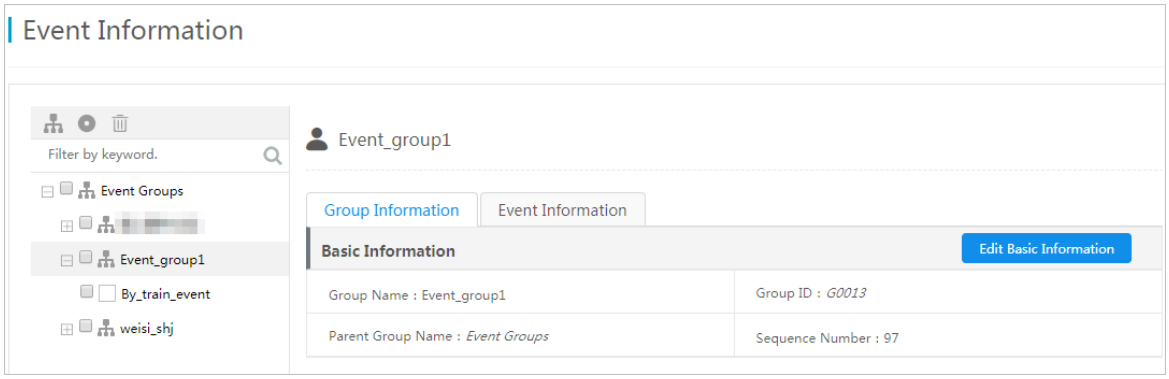
You can modify the basic information of an event group and the events in the group in Administration Console.

Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click the **Events** tab in the top navigation bar. The **Event Information** page appears.
3. From the left-side navigation pane, select an event group such as **By Train**. The detailed information about this event group is displayed on the right side of the page.



4. Click **Edit Basic Information** on the **Group Information** page. You can then modify the **Group Name** and **Sequence Number** of the group.
5. Click **Save**.

8.7.1.4. Delete an event group

If an event group is no longer used, you can first delete all events in the group and then delete the event group.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- You have deleted all events in the event group. For more information about how to delete an event, see Delete an event.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click the **Events** tab in the top navigation bar. The **Event Information** page appears.
3. Select the event groups that you want to delete from the left-side navigation pane, and then click the **Delete** icon on the top of the pane.
4. In the message box that appears, click **OK**.

8.7.2. Events

8.7.2.1. Create an event

Events are used to analyze the behaviors of objects. Event information is used to define the event models in Graph Analytics. A complete event contains basic event information, properties, and relevant parameters. This topic describes how to configure the basic information of an event.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- You have created an event group for the event. For more information about how to create an event group, see Create an event group.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click the **Events** tab in the top navigation bar. The **Event Information** page appears.
3. On the top of the left-side navigation pane, click the **Create Event** icon. Set the parameters in the **Create Event** dialog box. For more information about the parameters and descriptions, see Parameters of created events.

Parameters of created events

Parameter	Configuration method

Parameter	Configuration method
Event Name	The name of the event. Set this parameter as needed. Each event name must be from 1 to 16 characters in length, and can contain letters, digits, and Chinese characters.
Event Description	The description of the event. Set this parameter as needed to help users understand the event.
Group	The event group that the event belongs to. Set this parameter as needed.
Event Icon	The event icon. You can select an icon in **Icon Library**, or enter an accessible URL to reference an external icon.

4. After you set the parameters, click **OK**. A message is displayed, indicating that the event has been created.

What's next

1. After you have created an event, you must configure the properties and business parameters based on your business requirements. For more information, see Configure event property parameters.
2. After you have configured the properties and business parameters of an event, you must log on to Analytics Workbench again to use the new event.

8.7.2.2. Configure event property parameters

After you have created an event, you must configure the event properties. Event properties are critical to an event. You can configure event properties, and correlate the properties to objects on the Property Information tab.

Prerequisites

Make sure that you have obtained an account and a password for Graph Analytics and you have been authorized with the required **Event Permissions**.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click the **Events** tab in the top navigation bar. The **Event Information** page appears.
3. Click an event in the left-side navigation pane, and click the **Property Information** tab on the right side of the page. The **Property Information** tab appears.
4. Set the required event parameters. The required parameters are displayed in the **Basic Information** and **Set Mappings Between Correlated Objects and Properties** areas. The event parameters are described in Required event property parameters.

> **Note** To save the property information, you must set all the required parameters.

Required event property parameters

Area	Parameter	Description
	Property ID	The ID of a property. It is automatically generated.
	Property Name	The property name that is displayed on Analytics Workbench. We recommend that you enter a name that describes the business type.
	Primary Key	Each primary key uniquely identifies an event. A property cannot be deleted after it has been configured as a primary key.
	Show in Graph	Note For each event, you must select at least one property to be displayed in the graph. If you select this parameter, the **Property Name** of this property will be displayed in **Graph** in Analytics Workbench together with the object node. Otherwise, the property is not displayed. For example, if this parameter is selected by the ID card property of an event, the ID card number will be displayed in **Graph** with the event. If the name property is also selected, the name and the ID card number will be displayed with the event. If you select this parameter for a specific property, a bubble icon appears next to the option. You can click the bubble icon to set whether to show the **Property Name** in **Graph**. For example, if you select this parameter for an ID card number, and set to display the **Property Name** in **Graph**, the ID card property displayed in **Graph** will be **ID card number: xxxxxx**.
	Show in Properties	If you select this parameter for a property, the property will be displayed in the right-side pane on the **Graph** page of Analytics Workbench. To view the property, choose **Properties** > **Event Properties**.
	Element Identifier	The element identifier of a property. Set this parameter based on the actual property.
	Conditional Query	If you select this parameter for a property, the event can be queried based on this property in **Link Type** on the **Graph** page of Analytics Workbench when you perform a relationship analysis.

Area	Parameter	Description
Basic Information	Show in Statistics	If you select this parameter for a property, the event will be displayed in the right-side pane on the **Graph** page of Analytics Workbench. To view the property, choose **Statistics** > **Event Distribution**.
	Available	If you select this parameter for a property, the property takes effect and can be displayed on the Graph page of Analytics Workbench. This parameter is selected by default and cannot be changed.
	Display Type	The format in which a property is displayed in the right-side pane of the **Graph** page on Analytics Workbench. Set this parameter as needed.
	Query Type	The data type that is supported in the query condition of a property.
	Security Level	The security level for a property. A user with a lower security level cannot view the property.
	Search Item Configuration	Click the **More** icon in the Actions column corresponding to a property. Set the following four parameters: ○ Search Item Configuration: Search items are displayed in the drop-down list only after they have been configured in Configure a search item. ○ Default Query Condition Settings: The default condition used for a link query. If other properties are used as conditions for a query, this condition is also included by default. ○ Authorization Code: After the authorization code function has been enabled, only authorized users can access this property. ○ Derived Property: After a property is set as a derived property, it can be generated automatically based on other properties. Configure the method in which the column is generated based on your needs.
	Default Query Condition Settings	
	Authorization Code	
	Derived Property	
	Delete	When a property is no longer used, you can click the **Delete** icon to delete this property.

Area	Parameter	Description
Set Mappings Between Correlated Objects and Properties	Add Correlated Object	Adds a mapping between an object and the event. One event must have at least two objects mapped to it. Click **Add Correlated Object** to add a correlated object, and configure the mapping between the event and the primary keys of the object you have added.

5. (Optional)After you have set the required parameters, you can set the optional parameters as needed.

   The optional parameters are included in the **Advanced** and **Display Settings** areas. The optional parameters are described in Optional event property parameters.

   > **Note** **Location Settings** are currently not supported.

Optional event property parameters

Area	Parameter	Description
Advanced	Behavior Property	Defines the properties based on which a behavior analysis is performed.
	Default Details Sorting Property	Defines the property by which the details are sorted.
	Logical Relation of Authorized Properties	The logical relationship between the authorization codes of properties in each record. ○ AND: The current record is visible only to the users who meet all authorization code conditions of the properties in this record. ○ OR: The current record is visible to the users who meet any one authorization code condition of the properties in this record.
Display Settings	Enable Display	Indicates whether to show the event details.
	Group-by Properties	Indicates the property based on which events are aggregated. For example, aggregate **Travel Events** into a folder based on the **Train Number** property.

6. After you have completed the configurations, click **Save** in the upper-right corner. A success message is displayed after the modifications have been saved.

   An event is automatically enabled after its properties have been saved.

8.7.2.3. Enable and disable an event

If you do not need to use a specific event during a specific period, you can disable this event, and this event can be re-enabled.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- To disable some events, you must first delete the dependency information of these events, including the mappings between the events and data tables and the objects referenced by the events.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click the **Events** tab in the top navigation bar. The **Event Information** page appears.
3. You can enable or disable an event by using one of the following methods.

Method	Operation
Operations on the Event Information page	In the left-side navigation pane, select an event to be enabled or disabled, and click the toggle switch to **enable** or **disable** the event.
Operations in Event Groups	i. In the left-side navigation pane, select the event group that contains the event you want to enable or disable. Click the **Event Information** tab to go to the **Event Information** page. ii. Click the toggle switch to **enable** or **disable** the event. You can also select the events to be enabled or disabled, and click the **Off** button or the **On** button at the bottom of the page to disable or enable multiple events at a time.

8.7.2.4. View an event

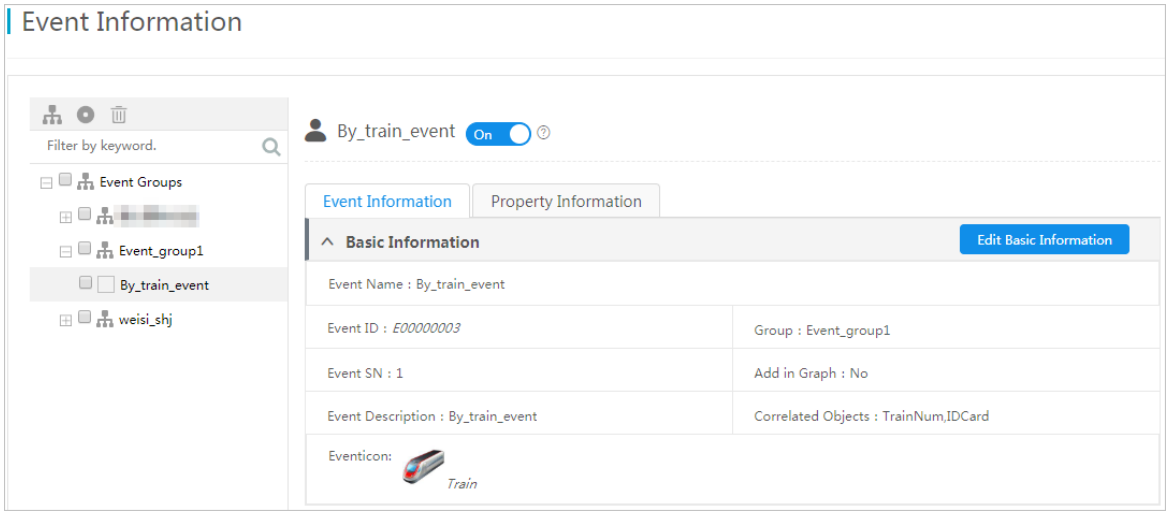
After you have configured an event, you can view the newly created event and all the events that have been created.

Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click the **Events** tab in the top navigation bar. The **Event Information** page appears.
3. In the left-side navigation pane, select an event and view the event details on the right side of the page.



Two tabs are displayed: The **Event Information** tab and the **Property Information** tab. The **Event Information** tab displays the basic information of the event. The **Property Information** tab displays the properties, correlated objects and property mappings, advanced settings, location settings, and display settings.

8.7.2.5. Modify an event

You can modify the basic information of the event you have created based on your needs.

Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click the **Events** tab in the top navigation bar. The **Event Information** page appears.
3. In the left-side navigation pane, select an event to be modified, and click **Edit Basic Information** to modify the parameters based on your requirements. The parameter configurations are described in Modify parameter configurations of events.

Modify parameter configurations of events

Parameter	Description
Event Name, Group, Event Description, and Event Icon	For more information about parameter descriptions, see Create an event.
Event SN	You can change the event sequence number based on your requirements.
Add in Graph	This parameter is not in use. You do not need to configure it.

4. After you have modified the parameters, click **Save**. A message is displayed, indicating that the modifications have been saved.

8.7.2.6. Delete an event

You can delete an event that is no longer used.

Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Click the **Events** tab in the top navigation bar. The **Event Information** page appears.
3. In the left-side navigation pane, select the events to be deleted, and click the **Delete** icon on the top.
4. In the dialog box that appears, click **OK**. A message is displayed, indicating that the selected events have been deleted.

8.8. View the business graph

You can directly view all configured link models on the Business Graph page. Solid lines indicate first-degree links, and dotted lines indicate second-degree or multiple-degree links.

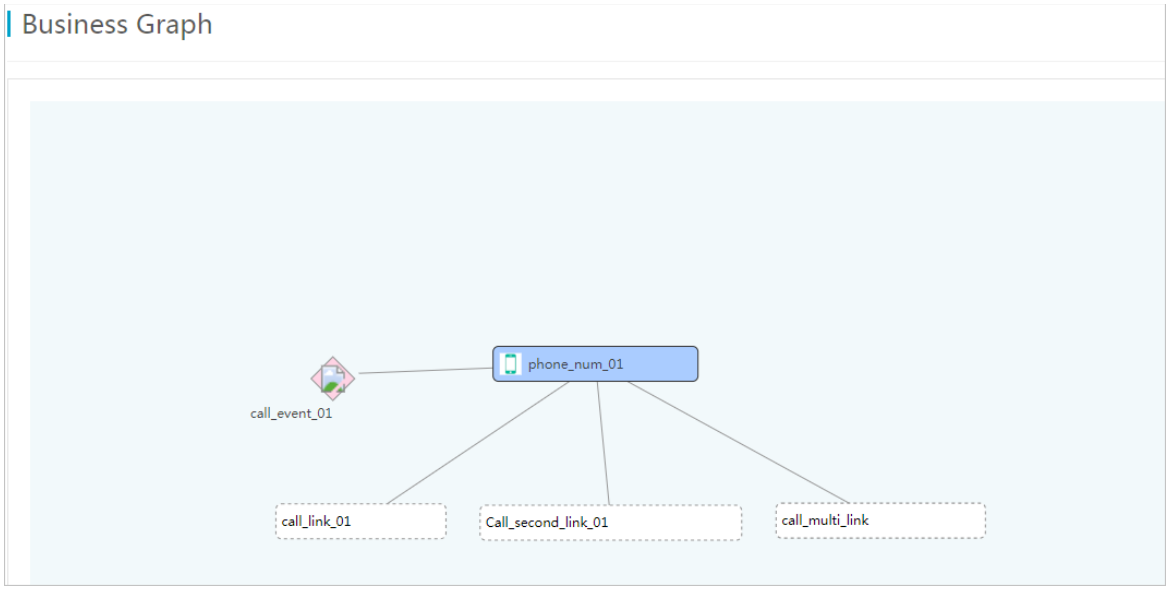
Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Business Graph**.

   On the **Business Graph** page, you can view the created link models between objects, links, and events.



8.9. Advanced configurations

8.9.1. Manage a system model

The Import Models page allows you to configure system models that are used to import data to Analytics Workbench.

Prerequisites

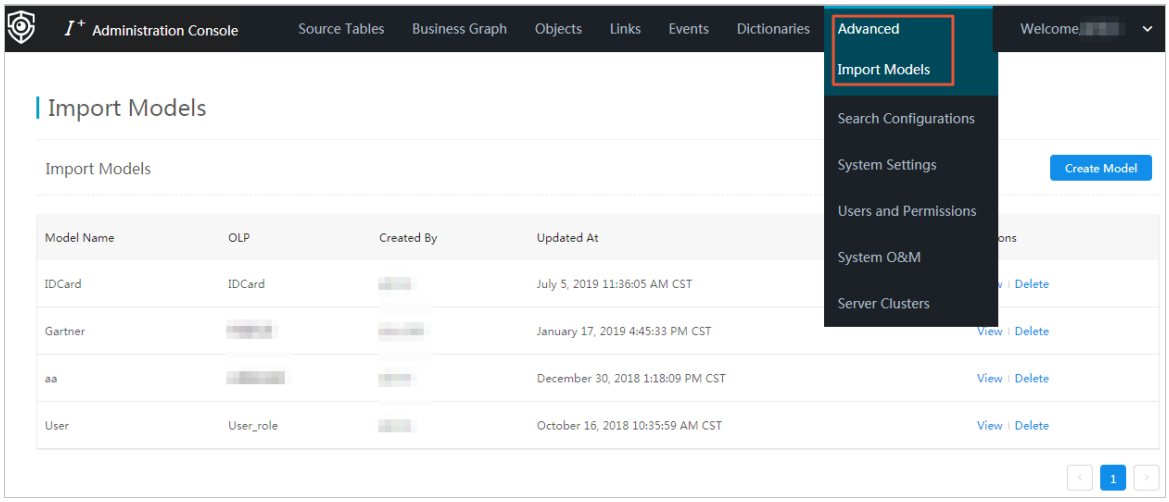
Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Context

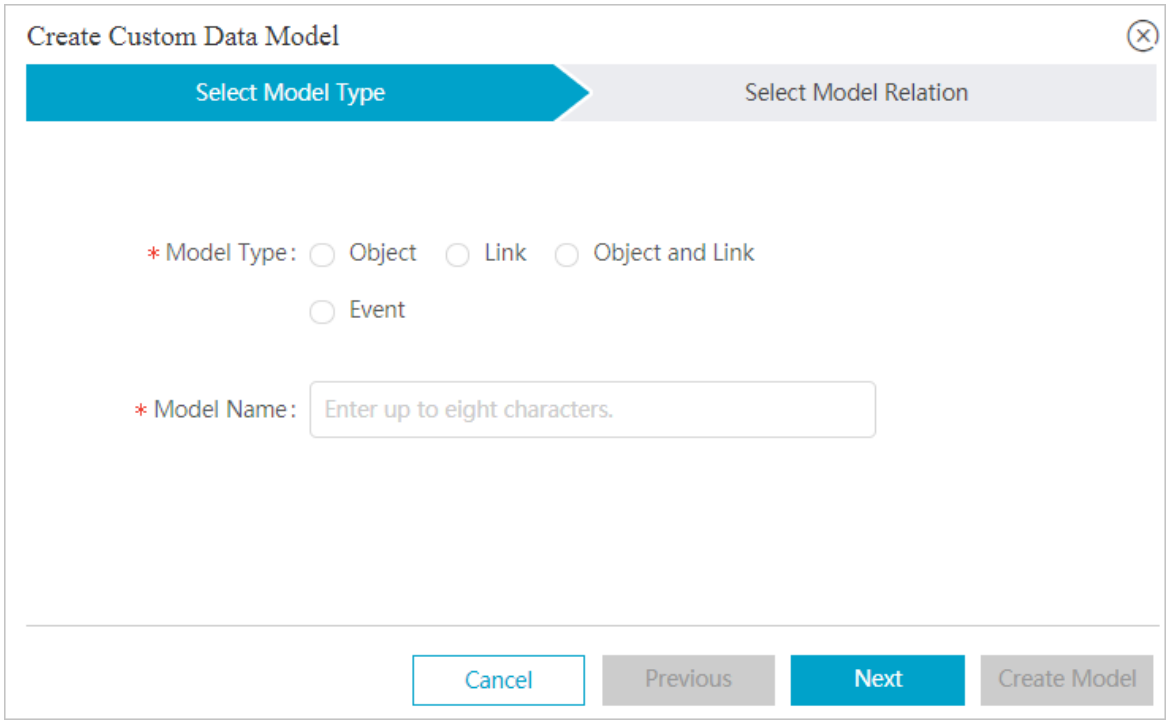
You can create, view, and delete models on the Import Models page. This topic provides examples to help you learn more about these operations.

Create a model

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced** > **Import Models**.

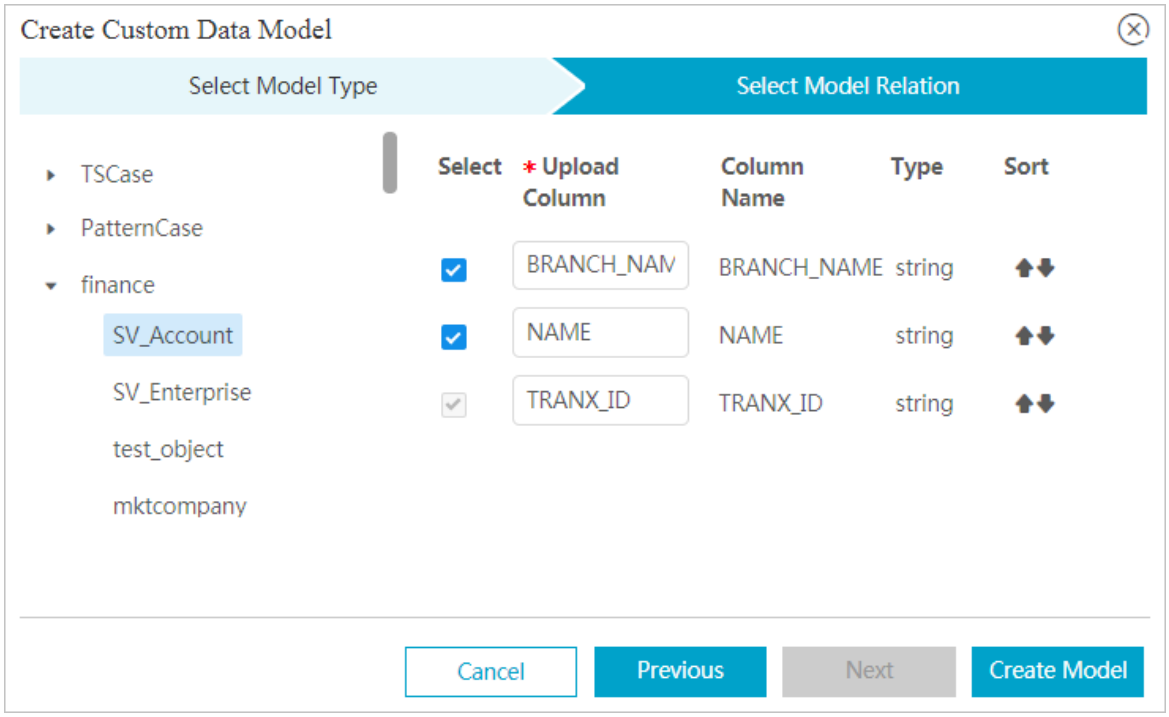


3. On the **Import Models** page, click **Create Model** in the upper-right corner of the page.
4. In the **Create Custom Data Model** dialog box, specify the **Model Type** and the **Model Name**.



5. Click **Next**.
6. Set the model relation in the **Create Custom Data Model** dialog box.

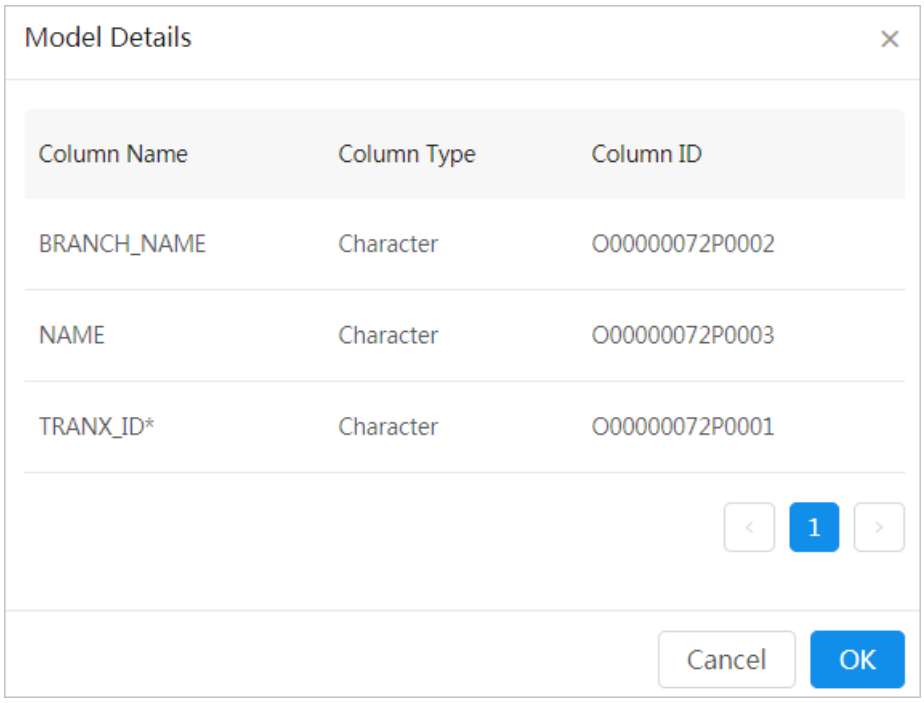
   Select an object, link, or event on the left side, and select the model columns on the right side based on the data to be imported. The columns of the primary key type are selected by default and cannot be operated.



7. After you have configured the preceding parameters, click **Create Model**.

View a model

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced** > **Import Models**.
3. On the **Import Models** page, select a model and click **View** to view the details of the model in the **Model Details** dialog box that appears.



Delete a model

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced** > **Import Models**.
3. On the **Import Models** page, select a model and click **Delete**.
4. In the dialog box that appears, click **OK** to delete the model.

8.9.2. Configure a search item

You can configure search items to set the fields to be searched for in Analytics Workbench. After a search item is configured, it must be correlated with an object, link, or event property to take effect.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- Before you delete a search item, you must first delete the links between the search item and the correlated properties of objects, links, and events.

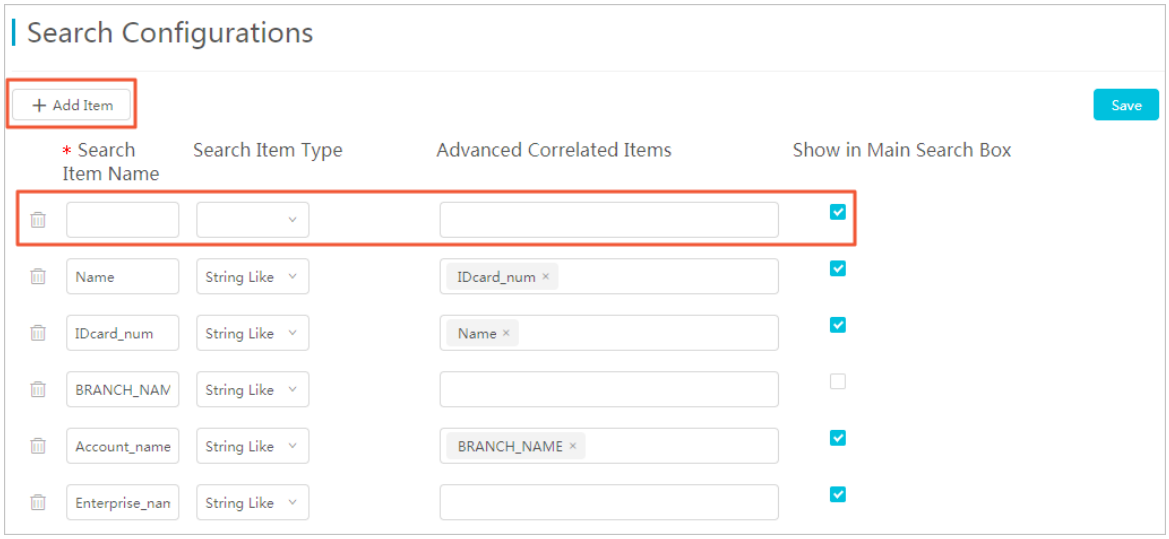
Context

This topic describes how to add, modify, and delete search items, and how to associate search items with the properties of objects, links, or events.

Add a search item

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced** > **Search Configurations**.
3. Click **Add Item** in the upper-left corner of the page that appears.

   The parameters are described in Search item configuration parameters.



Search item configuration parameters

Parameter	Description

Parameter	Description
Search Item Name	**Search Item Name** is customized by the user. We recommend that you set the name according to the properties of the objects, links, or events that need to be correlated. For example, a mobile phone number, an ID number, or a person's name.
Search Item Type	The **Search Item Type** is used to set the data type that is supported by this search item. The **Search Item Type** must be consistent with the **Query Type** of the property of the object, link, or event to be correlated with.
Advanced Correlated Items	**Advanced Correlated Items** are used to group multiple search terms to search for data. You can select multiple configured search terms.
Show in Main Search Box	Sets whether the search item is displayed in the **Search** page of Analytics Workbench.

4. (Optional)Click **Add Item** to add multiple search items as needed.
5. Click **Save**.

After a search item is added, you must correlate the search item to the properties of an object, link, or event. For more information, see Correlate a search item to properties.

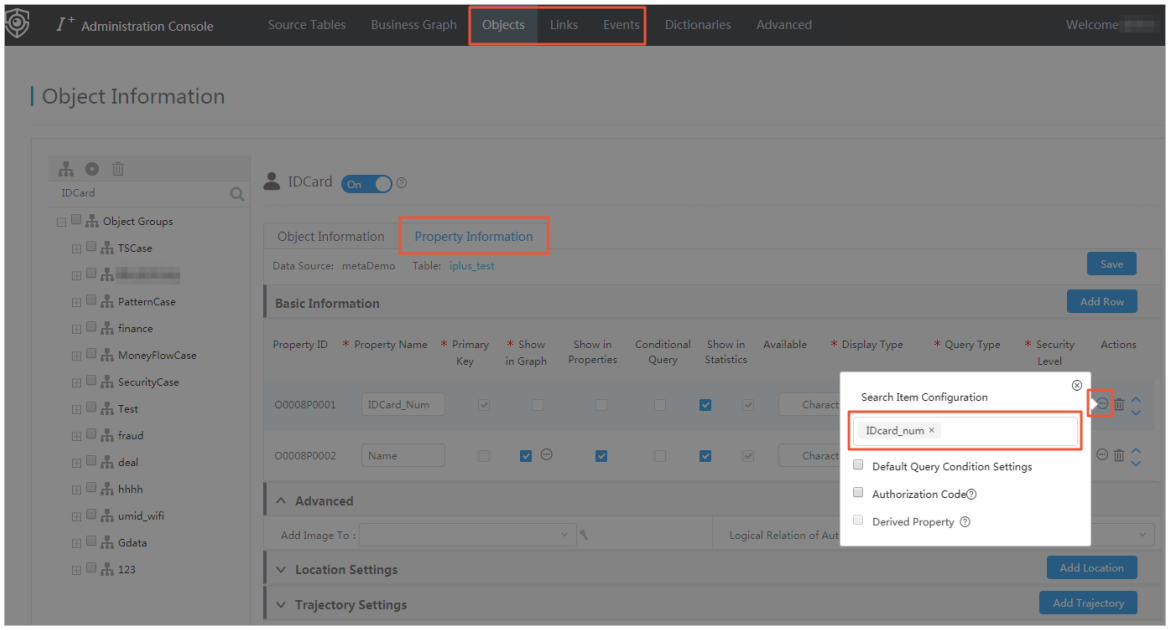
Correlate a search item to properties

The configuration entries are as follows:

- Objects: Administration Console > Objects > selected the object to be correlated to > Property Information > Basic Information > more configurations.
- Links: Administration Console > Links > select the link to be correlated to > Property Information > Basic Information > more configurations.
- Events: Administration Console > Events > select the event to be correlated to > Property Information > Basic Information > more configurations.

This topic describes how to correlate a search item with the properties of an object as an example. You can correlate a search item with the properties of a link or event by using similar methods.

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, click **Objects**.
3. In the left-side navigation pane of the **Object Information** page, click the name of the object to be configured and then click the **Property Information** tab on the right side.
4. In the **Basic Information** area, click the More icon (⊖) next to the property to be correlated, and then select the configured search items in **Search Item Configuration**.



5. After you have configured these parameters, click the icon to close the configuration box.
6. Click **Save** to save the configurations.

Modify a search item

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced** > **Search Configurations**.
3. Modify the parameters of a search item as needed.
4. Click **Save**.

Delete a search item

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced** > **Search Configurations**.
3. Click the icon to delete the corresponding search item.
4. Click **Save**.

8.9.3. System settings

8.9.3.1. Configure components

You can configure the functional components to enable or disable functions in Analytics Workbench and Administration Console and set basic information of Analytics Workbench. When a functional component is disabled, this function will not be displayed in the operation area.

Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Context

The functional component settings take effect globally. Enable or disable components as needed with caution.

Procedure

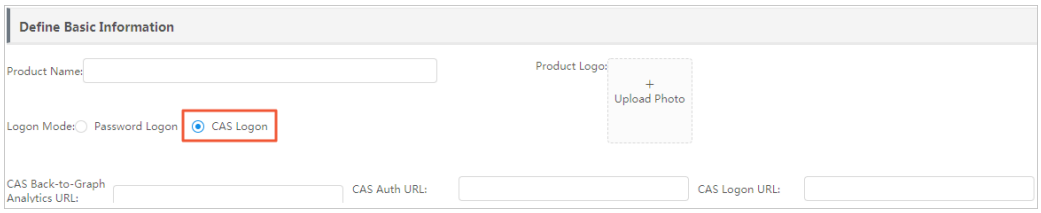
1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced > System Settings > Functional Components**.
3. Define basic information: Set the **Product Name**, **Product Logo**, and **Logon Mode** parameters for Graph Analytics.

> **Note** If you do not set the **Product Name** parameter and the **Product Logo** parameter, the default name and default Logo image are used.

If the CAS (Central Authentication Server) server is deployed in your environment, you can select **CAS logon** as the logon mode, as shown in CAS logon.

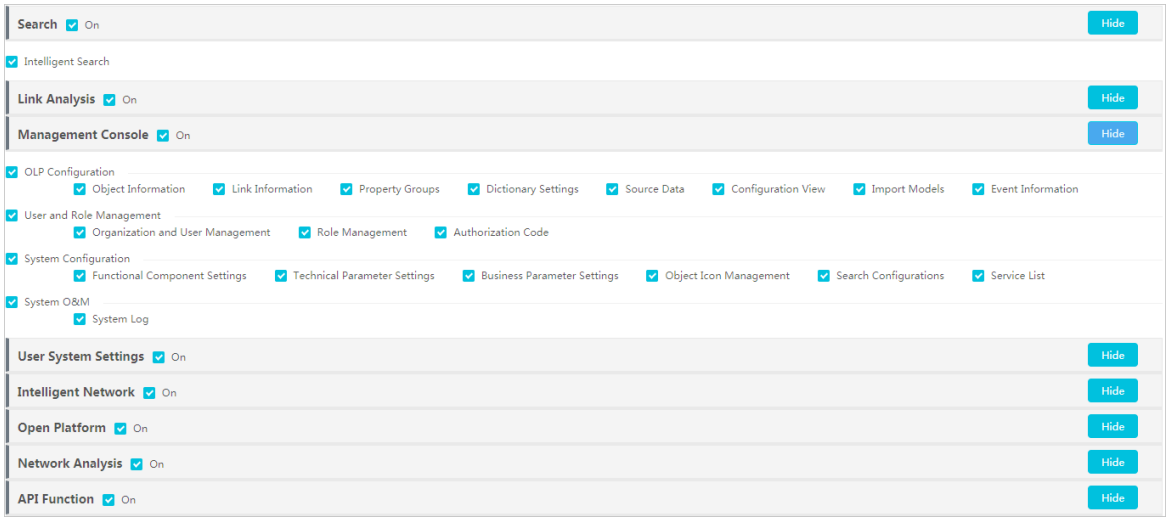
> **Note** CAS is a single sign-on protocol. If you select **CAS logon** as the logon mode, you only need to log on once to access all trusted application systems.

CAS logon



4. Enable and disable functional components: Select the modules to be enabled and cancel the modules to be disabled.

   If you select or clear a parent component, the child components will be automatically selected or cleared.



5. Click **Save**.

8.9.3.2. Technical parameters

8.9.3.2.1. Path analysis settings

In Graph Analytics, you can set the highest link degree of path analysis. Also, you can set whether to calculate only the nodes that are of the same type as the selected nodes.

Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Context

Typically, the default values are used for path analysis settings. Exercise caution when you modify the settings.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced > System Settings > Technical Parameters**.
3. In the **Path Analysis Settings** area, you can set the parameters based on your requirements.

   The parameters are described in Path analysis configuration parameters.

Path analysis configuration parameters

Parameter	Description

Parameter	Description
Current Path Analysis Degree	The highest link degree supported by path analysis. The default value is 2 and the maximum value is 3. If the **Current Path Analysis Degree** parameter is set to *N*, only links of degree *N* or lower degrees will be analyzed. Links of a degree higher than *N* will not be analyzed.
Restrict Node Types in Path Analysis	Valid values: ○ **Yes**: Only nodes of the same type as the selected node are calculated. ○ **No**: All types of nodes are calculated. The default value is **No**.

4. Click **Save** in the upper-right corner.

8.9.3.2.2. Quick extension settings

Graph Analytics, you can set the highest link degree for quick extension.

Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Context

Typically, the default values are used for quick extension settings. Exercise caution when you modify the settings.

> **Note** If the degree is set too high, the running performance of the system will be affected.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced** > **System Settings** > **Technical Parameters**.
3. In the **Quick Extension Settings** area, you can set the **Extension Degree** parameter based on your requirements.

Extended Degree: The highest link degree for quick extension. The default value is 2. If the **Extended Degree** parameter is set to *N*, only links of degree *N* or lower degrees will be analyzed. Links of a degree higher than *N* will not be analyzed.

4. Click **Save** in the upper-right corner.

8.9.3.2.3. Maximum node settings

In Graph Analytics, you can set the maximum number of nodes to be queried at the same time when you perform an analysis.

Prerequisites

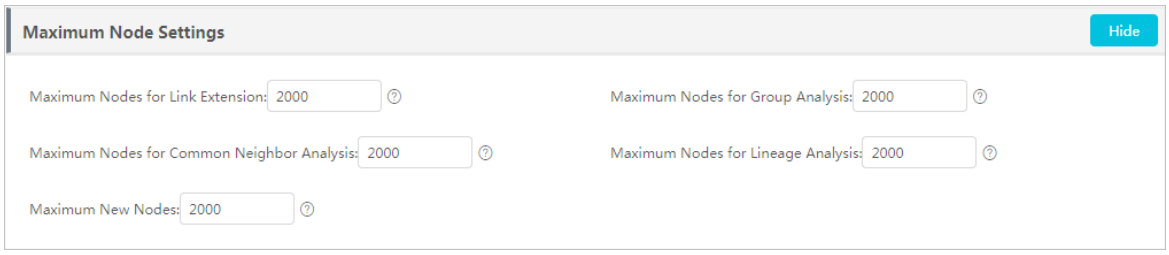
Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Context

Typically, the default value is used for the maximum number of nodes to be queried. Exercise caution when you modify the number of nodes.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced** > **System Settings** > **Technical Parameters**.
3. In the **Maximum Node Settings** area, you can configure the parameters based on your requirements.



4. After you have completed the configurations, click **Save** in the upper-right corner.

8.9.3.3. Business parameters

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Choose **Advanced** > **System Settings** > **Business Parameters** from the top navigation bar. The Business Parameters page appears.

8.9.3.3.1. Add double-click link settings

In Analytics Workbench, you can double-click an object to query the relationship between objects. In Administration Console, you can custom the relationships of an object to be queried when you double-click the object. If no custom configuration is set, all the first-degree relationships of the object are queried by default when you double-click the object.

Prerequisites

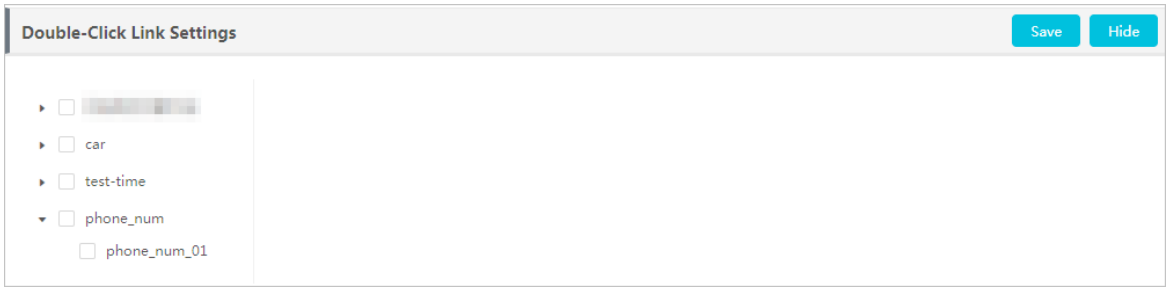
- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- The object has been created and referenced by the link.

Context

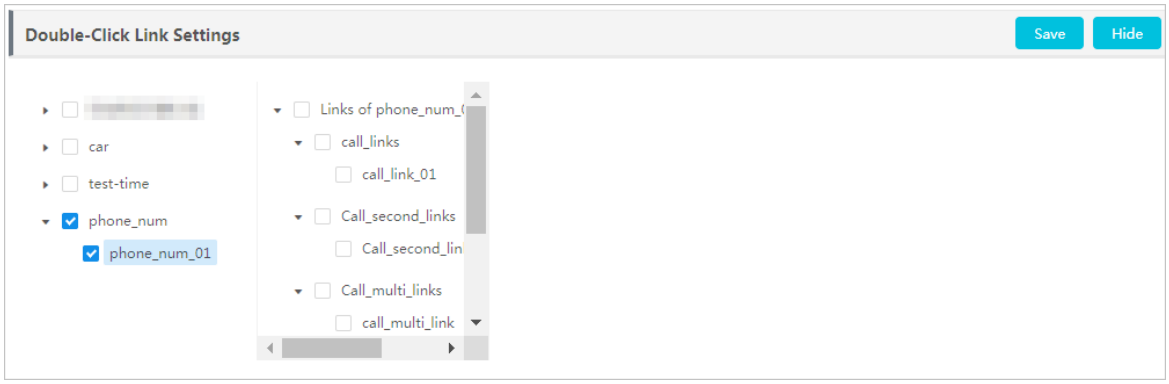
The double-click link settings take effect globally. Exercise caution when you configure the settings.

Procedure

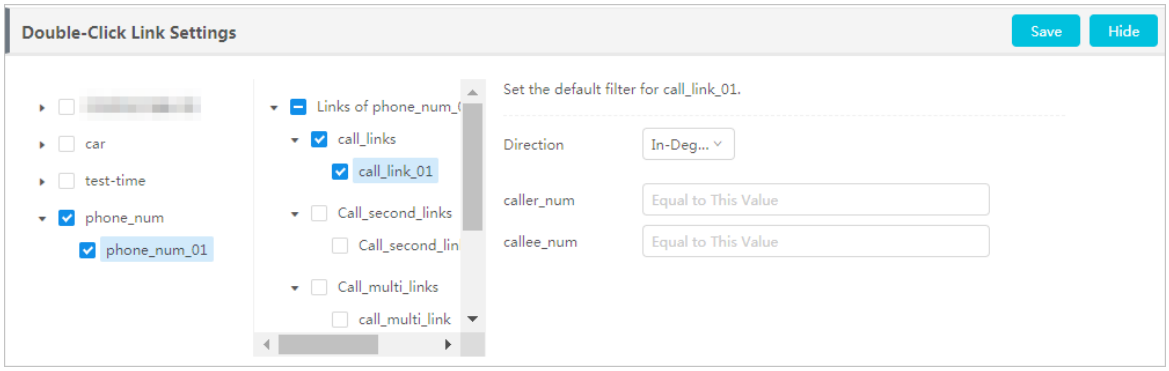
1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced** > **System Settings** > **Business Parameters**.
3. In the **Double-Click Link Settings** area, select the objects to be configured in the left-side list.



4. In the list that is displayed on the right side of the area, select the links to be queried.



5. In the displayed area, set the filter conditions for querying the link.



6. (Optional)If you need to query other links by double-clicking the object, you can continue to select other links and set the filter conditions.
7. Click **Save** to complete the double-click link settings of the object.

8.9.3.3.2. Double-click-disabled object settings

In Analytics Workbench, you can double-click a node to query the relationship network of the node. Administration Console allows you to enable or disable double-clicking on a specified object. By default, double-clicking is supported for all objects.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- You have created an object.

Context

The double-click-disabled object settings take effect globally. Exercise caution when you configure the settings. We recommend that you disable the double-click operations on objects that generate large amounts of data.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced > System Settings > Business Parameters**.
3. In the **Double-Click-Disabled Object Settings** area, click the **Double-Click-Disabled Objects** drop-down list, and select the objects.

4. Click **Save**.

8.9.3.3.3. Object grouping settings

Graph Analytics allows you to set the grouping conditions, so that objects or links of the same type can be grouped automatically when their quantity reaches the threshold value. In a complex graph analytics, we recommend that you set reasonable grouping conditions to keep the analysis graph concise and clear.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- You have created an object.

Context

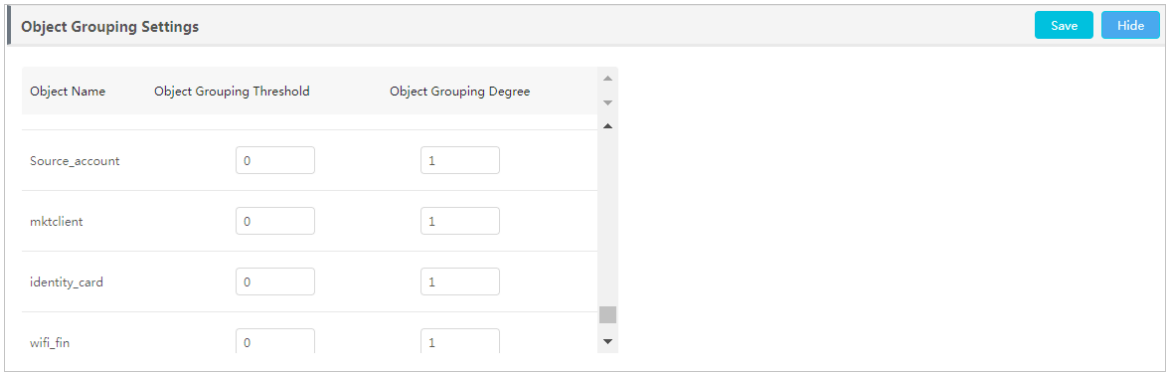
The **Object Grouping Threshold** and **Object Grouping Degree** parameters are described as follows:

- **Object Grouping Threshold**: If the number of object nodes of the same type that are connected to the same node exceeds the threshold, the connected nodes are grouped into one folder.
- **Object Grouping Degree**: If more than one node has the link of the specified degree with the same nodes, these nodes will be grouped into a folder. For example, set **Object Grouping Degree** to 2. If both node A and node B have second-degree links with nodes C and D, node A and node B will be grouped into one folder.

The value of **Object Grouping Threshold** defaults to 0, and the value of **Object Grouping Degree** defaults to 1. The default value indicates that no objects will be grouped automatically.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced** > **System Settings** > **Business Parameters**.
3. In the **Object Grouping Settings** area, specify **Object Grouping Threshold** and **Object Grouping Degree** based on your requirements.



4. Click **Save**.

8.9.3.3.4. Configure lineage analysis

Before you perform a lineage analysis on a specified object node in Analytics Workbench, you need to configure the business parameters for this type of object in Administration Console.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- The object has been created and referenced by a link.

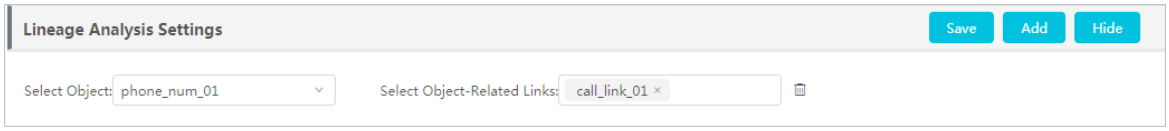
Context

Lineage analysis extends a specific business link to multiple degrees. The specific link typically refers to the lineage link and the same residence number.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced** > **System Settings** > **Business Parameters**.
3. In the **Lineage Analysis Settings** area, click **Add** to add a new setting.

4. Select the object to be analyzed based on your requirements, and then select the object-related link to be analyzed.



5. Click **Save**.

8.9.3.3.5. Intimacy measurement settings

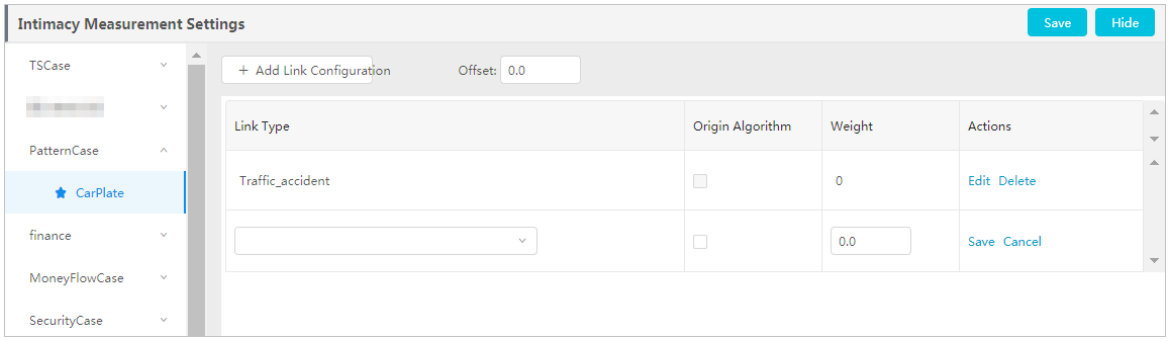
You can set the weight for the relationship between specified objects, so that you can directly view the intimacy between these objects in the analysis result.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- An object has been created and has been referenced by a link.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced** > **System Settings** > **Business Parameters**.
3. On the left side of the **Intimacy Measurement Settings** area, select an object and then click **Add Link Configuration** on the right side of the area.
4. Select a link type in the **Link Type** drop-down list, and then set the intimacy weight and other parameters.



The star icon in front of an object indicates that the object has configured intimacy measurement settings, as shown in **ID Card** in the figure above.

5. After you have configured these parameters, click **Save**.
6. (Optional)To add intimacy measurement settings for another **Link Type**, click **Add Link Configuration**.

   To add intimacy measurement settings for another object, select the object in the left-side navigation pane, and then click **Add Link Configuration**.
7. After you have configured the intimacy measurement settings for all objects, click **Save** on the right side of the **Intimacy Measurement Settings** section.

8.9.3.3.6. Redirect URL settings

When you need to redirect to an external system from Graph Analytics, you can configure the URLs in External System Redirect URL Settings.

8.9.3.4. Object icons

8.9.3.4.1. Upload an object icon

You can upload a local object avatar to the icon library in Graph Analytics.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- Make sure that you have prepared an avatar image in the PNG format. The recommended size is 32px * 32px. We recommend that you limit the size to 320px * 320px.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced** > **System Settings** > **Object Icons**.
3. On the **Object Icons** page, click **Upload Icon**.
4. In the **Upload Icon** dialog box that appears, click the upload area to upload a local icon, and then specify the **Name** column.
5. Click **OK** to upload the object icon.

8.9.3.4.2. Modify an object icon

You can modify the avatar image or the avatar name based on your requirements.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- Make sure that you have prepared an avatar image in the PNG format. The recommended size is 32px * 32px. We recommend that you limit the size to 320px * 320px.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top menu bar, choose **Advanced** > **System Settings** > **Object Icons**.
3. On the **Object Icons** page, move your mouse pointer over the icon, and click the Modify icon ( ).
4. In the **Edit** dialog box that appears, modify **Name** or upload a new avatar image.
5. Click **OK**.

8.9.3.4.3. Delete an object icon

You can delete the object icons that are no longer used.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- Before you delete an object icon, make sure that this icon is not used by another object.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. In the top navigation bar, choose **Advanced** > **System Settings** > **Object Icons**.
3. On the **Object Icons** page, move your mouse pointer over the icon, and click the Delete icon ( ).
4. In the dialog box that appears, click **OK** to delete the object icon.

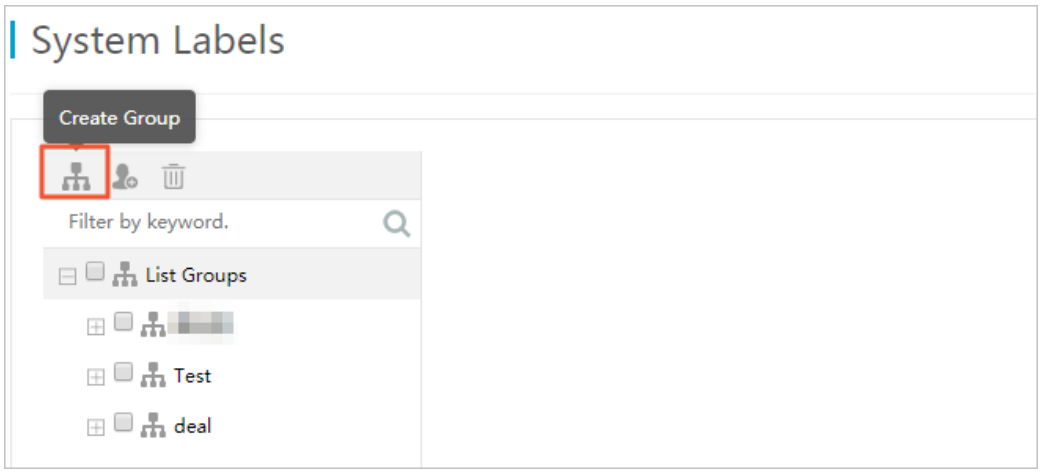
8.9.4. System labels

8.9.4.1. Create a group

Procedure

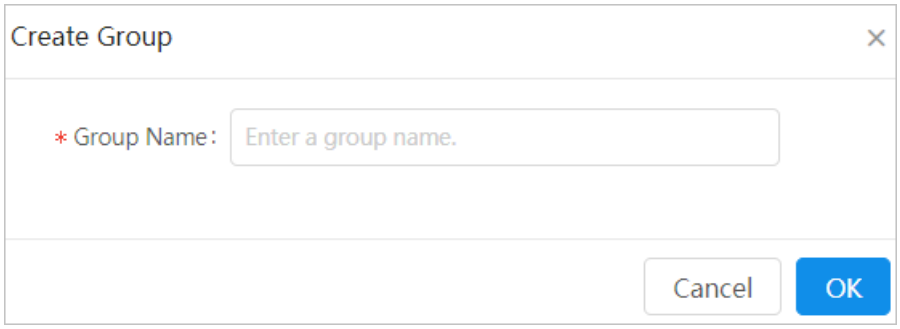
1. Log on to Administration Console of Graph Analytics.
2. Choose **Advanced** > **Users and Permissions** > **System Labels** from the top navigation bar.
3. On the **System Labels** page, click the **Create Group** icon, as shown in Create a group.

   Create a group



4. In the Create Group dialog box that appears, enter a group name, as shown in Enter a group name.

   Enter a group name



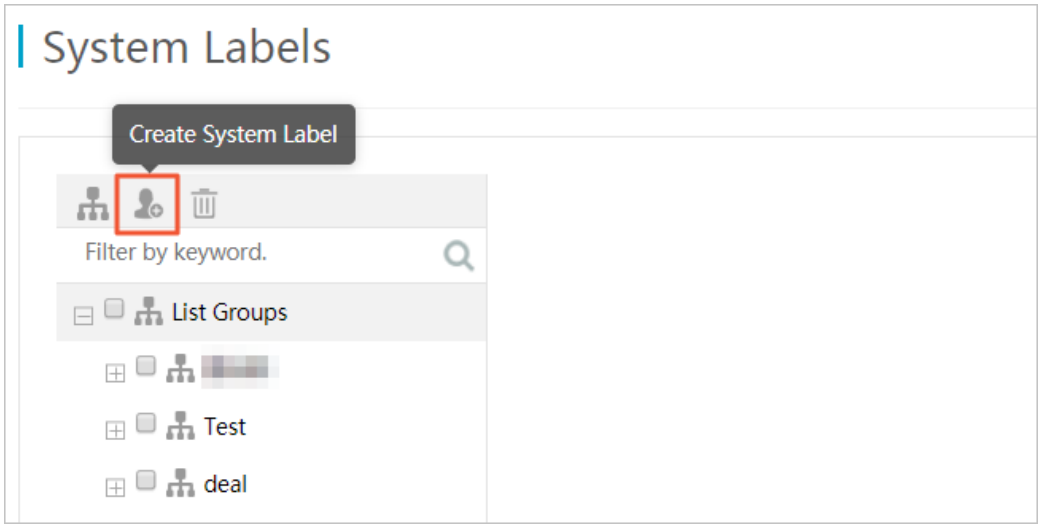
5. Click **OK**.

8.9.4.2. Create a system label

Procedure

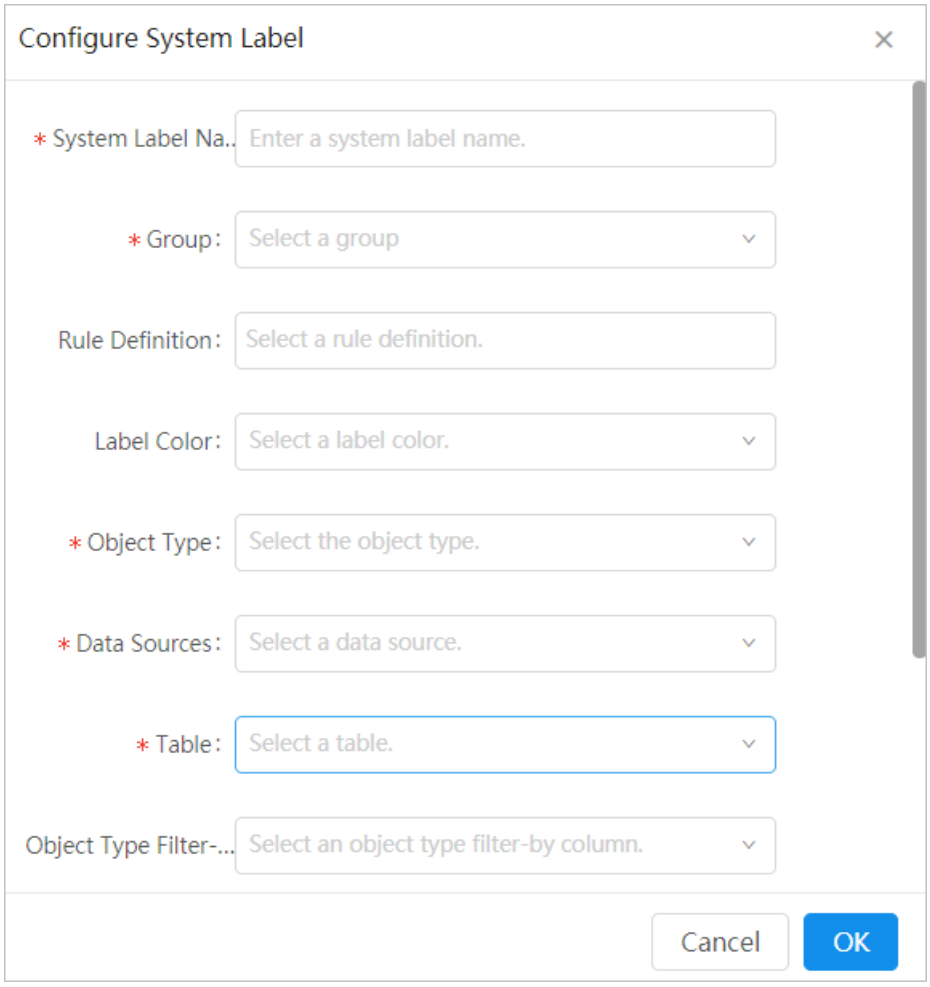
1. Log on to Administration Console of Graph Analytics.
2. Choose **Advanced** > **Users and Permissions** > **System Labels** from the top navigation bar.
3. On the System Labels page, click the **Create System Label** icon, as shown in Create a system label.

   Create a system label



4. In the **Configure System Label** dialog box, configure the required parameters, as shown in Configure a system label.

   Configure a system label



The system label parameters are described as follows:

- System Label Name: the alias of the system label.
- Group: the group to which the system label belongs.
- Rule Definition: The processing rule that is applied when an object matches the system label. Value options include Not Display Object, Not Extend Object, Not Display Properties, Disable Property Statistics, and Disable Behavior Display. If you have selected Not Display Object, the other four options and the Label Color parameter become unavailable.
- Label Color: the display color of the system label.
- Object Type: all available objects are displayed in the drop-down list. Choose an object as needed.

  After you select the object type, a primary key parameter will appear in the dialog box. Select a column corresponding to the primary key property as needed.
- Data Source: the data source where the system label belongs.
- Table: the table where the system label belongs.
- Object Type Filter by Column, Object Type Filter Operator, and Object Type Filter Value: Optional. You can use these parameters to filter system labels. If you have specified any one of these parameters, the other two parameters are required.

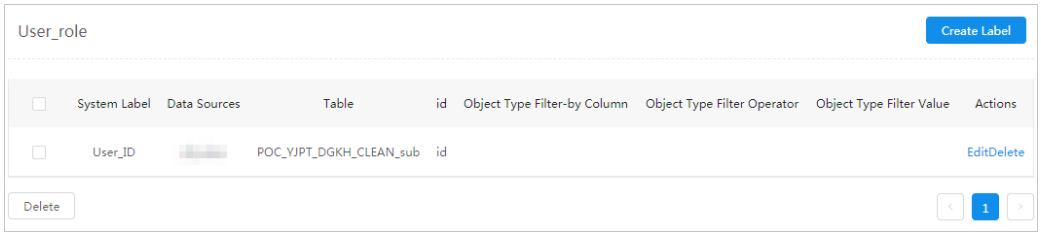
5. Click **OK**.

8.9.4.3. Modify a system label

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Choose **Advanced** > **Users and Permissions** > **System Labels** from the top navigation bar.
3. On the System Labels page, click an object from the left-side navigation pane.
4. In the details area on the right side of the page, select a system label, and click **Edit**, as shown in Modify a system label.

   Modify a system label



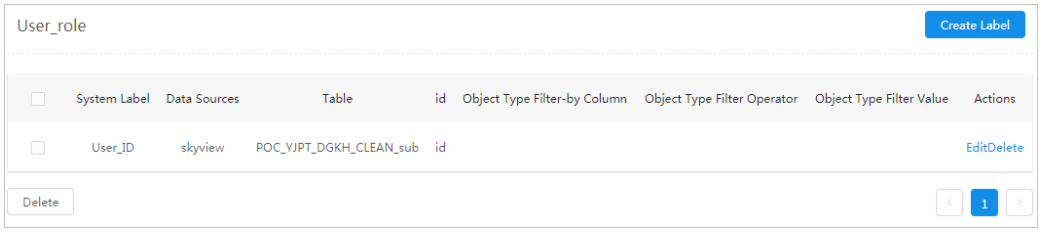
5. Modify the parameters as needed. The object type cannot be modified.
6. Click **OK**.

8.9.4.4. Delete a system label

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Choose **Advanced** > **Users and Permissions** > **System Labels** from the top navigation bar.
3. Click **Delete** next to a system label, or select one or more system labels and then click **Delete** in the lower-left corner, as shown in Delete a system label.

   Delete a system label



8.9.5. System operations and maintenance

8.9.5.1. Audit logs

Procedure

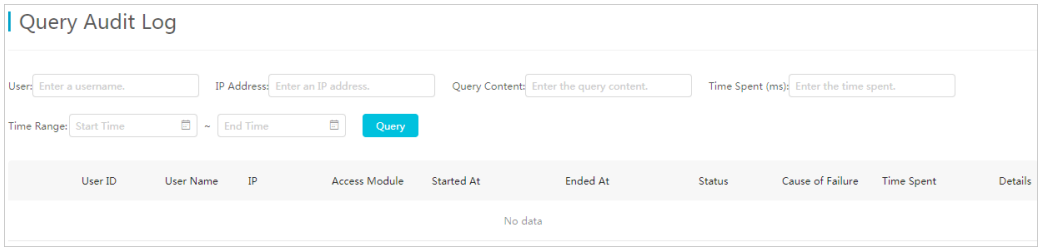
1. Log on to Administration Console of Graph Analytics.
2. Choose **Advanced** > **System O&M** > **Audit Log** from the top navigation bar. The Query Audit

Log page appears.

3. Set the search filters, and then click **Query**, as shown in Log query.

   If you click **Query** without setting any filters, all data will be returned.

   Log query



8.9.6. View server clusters

In Administration Console, you can view the information of all servers in a cluster, including the running status, server exceptions, the number of servers, IP addresses, and port numbers.

Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Procedure

1. Log on to Administration Console of Graph Analytics.
2. Choose **Advanced** > **Server Clusters** to go to the **Server Clusters** page.

   In Administration Console, you can view the information of all servers in a cluster, including the running status, the number of servers and server exceptions, IP addresses, and port numbers.

3. If you have stayed on the current page for too long, you can click **Refresh** to view the latest information.

8.10. Import data

8.10.1. Model list

8.10.1.1. Model overview

A model is a template used to import data to Graph Analytics. You can use models to import individual or small amounts of data to Graph Analytics.

Models include custom models and system models:

- Custom models are directly created by users on Analytics Workbench. Only the creator can view, download, modify, and delete the custom models.
- System models are created by the administrator in Administration Console. All users can view and download system models on Analytics Workbench. However, system models cannot be modified or deleted. To delete a system model, you must log on to Administration Console.

8.10.1.2. View models

In Analytics Workbench, you can view information about the existing data models, including the model type, mapped OLEP, properties, and the property type. This helps you understand the existing models at any time and identify the data model that matches the data to be imported.

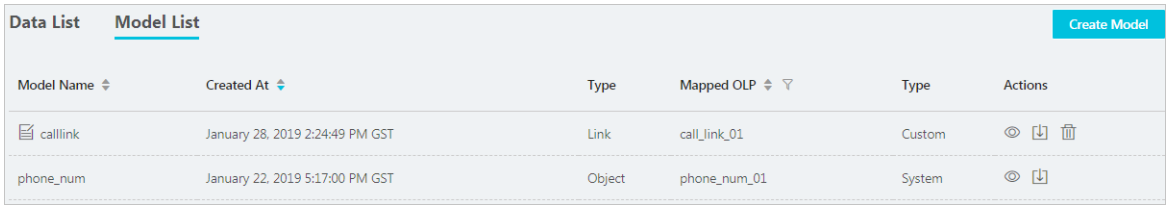
Prerequisites

All users can view the system models. However, to view a custom model, you must have the account and password of the user that created the model.

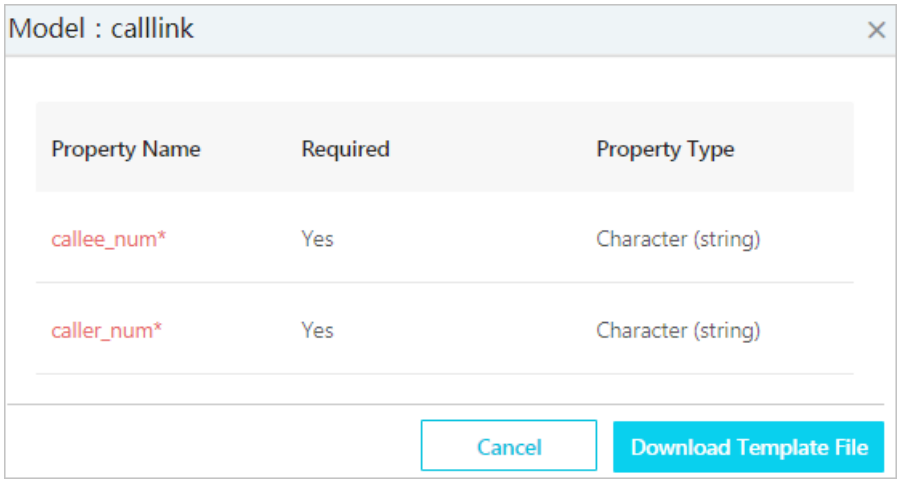
Procedure

1. Log on to Analytics Workbench.
2. Click the icon in the upper-right corner of the page, and click the **Model List** tab. On the **Model List** page, you can view the creation time, model type, and mapped OLEP for all models.

   > **Note** Analytics Workbench supports custom and system models. Custom models are created by users on Analytics Workbench. For more information, see Create models. System models are configured in Administration Console. For more information, see Manage a system model.

3. Click the icon next to the data model that you want to view, and view the property information about the data model in the dialog box that appears.



If the data model meets the requirements for your data import, you can download this model and use this model as a template to sort the data to be imported.

4. (Optional)Click **Download Template File** to download the model file in the XLSX format.

8.10.1.3. Create models

The model list defines a column format for the uploaded file. The columns of the uploaded file will be mapped to the corresponding properties, including the object property, link property, object and link property, and event property. If the existing models cannot meet the requirements of the data to be imported, you must create a data model based on the target data.

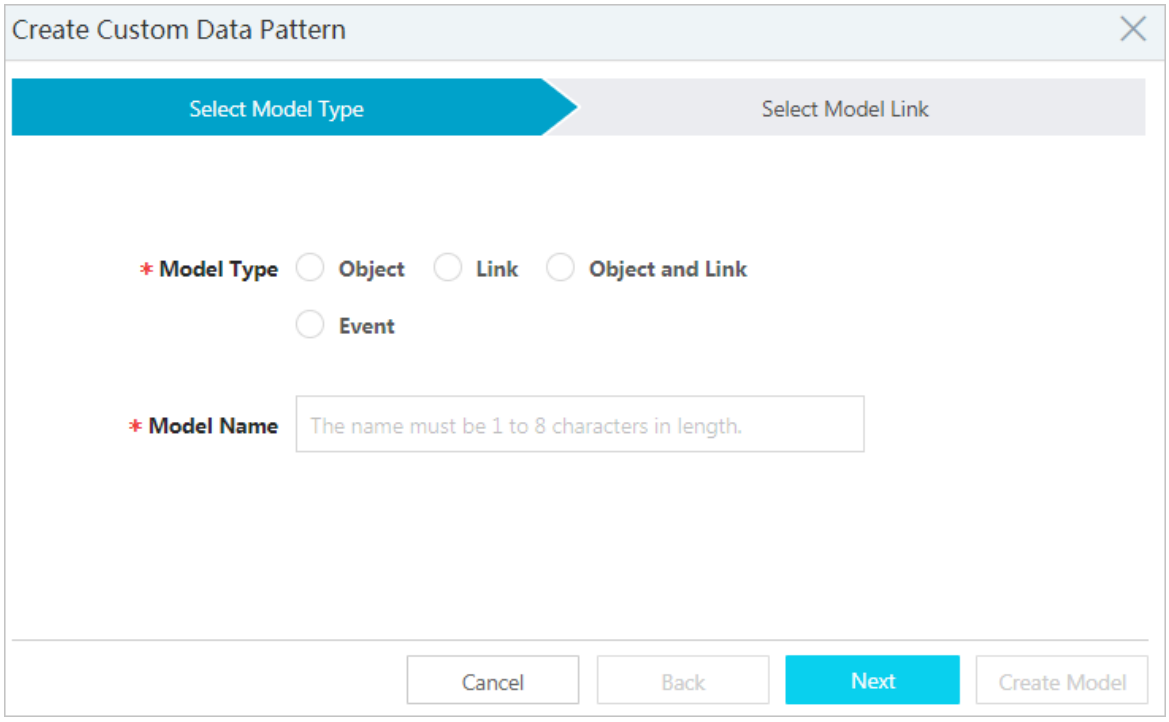
Prerequisites

You have obtained the account and password with the **Import Data** permissions.

Procedure

1. Log on to Analytics Workbench.
2. Click the icon in the upper-right corner of the page, and then click the **Model List** tab. The **Model List** page appears.
3. Click **Create Model** in the upper-right corner of the page, and set the parameters in the **Create Custom Data Model** dialog box that appears.

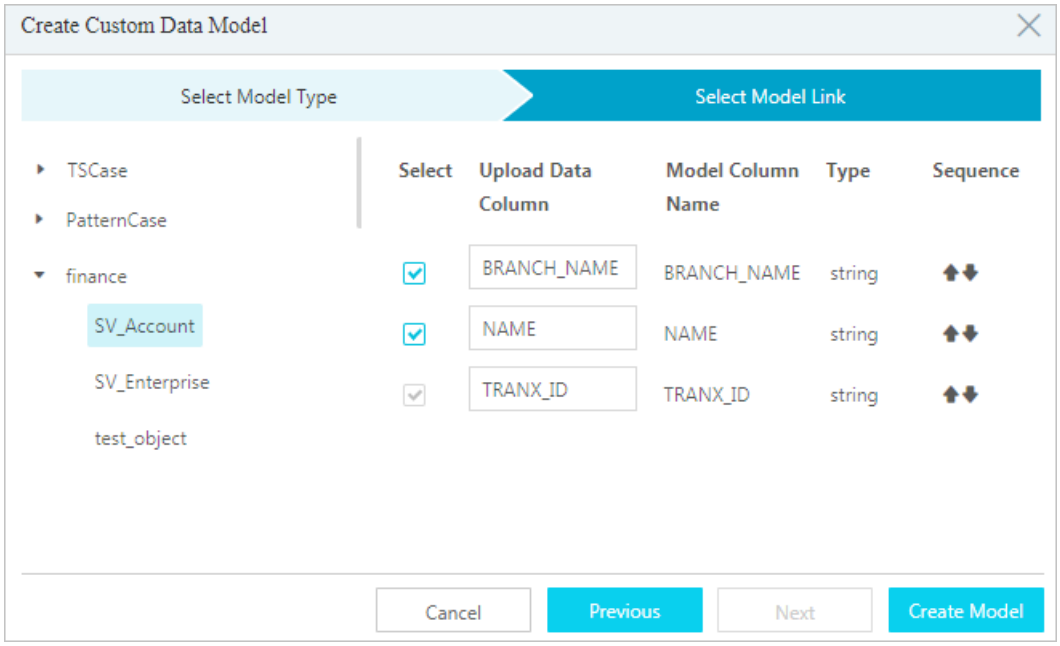
   For more information about the parameter settings, see Parameter configurations.



Parameter configurations

Parameter	Description
Model Type	You can create multiple model types, including **Object**, **Link**, **Object and Link**, and **Event**. Specify a model type as needed.
Model Name	Enter a model name. We recommend that you enter a name that is easy to understand.

4. Click **Next**, select an object, link, or event, select the required columns, and then set the name of **Upload Data Column**.



5. Click **Create Model**. A success message is displayed, indicating that the model has been saved.

8.10.1.4. Modify model names

If a model name is obscure or does not match the model content, you can modify the model name.

Prerequisites

Make sure that you have obtained the account and password of the user that created the model that you want to modify.

> **Note** In Graph Analytics, you can only modify the names of user-defined models. You are not allowed to modify the system models.

Procedure

1. Log on to Analytics Workbench.
2. Click the icon in the upper-right corner of the page, and click the **Model List** tab. The **Model List** page appears.
3. Click the icon in the front of the model that you want to edit, rename the model, and then click **OK**.

8.10.1.5. Download a model

Before you import data, you must download a compatible model, which is an .xlsx file, and use this model as a template to sort the data to be imported.

Prerequisites

You have obtained the account and password with the **Import Data** permissions.

Procedure

1. Log on to Analytics Workbench.
2. Click the icon in the upper-right corner of the page, and click the **Model List** tab. On the **Model List** page, you can view the creation time, model type, and mapped OLEP for all models.
3. Click the icon next to the model that you want to download, and save the model as prompted.

What's next

Use this model as a template to organize the data to be imported, and then import the collected data to Graph Analytics. For more information about the detailed operations, see Import data.

8.10.1.6. Delete a model

You can delete the custom models that are no longer used.

Prerequisites

Make sure that you have obtained the account and password of the user that created the model you want to delete.

> Note Graph Analytics only supports deleting user-defined models. To delete a system model, you need to log on to Administration Console. For more information, see Manage a system model.

Procedure

1. Log on to Analytics Workbench.
2. Click the icon in the upper-right corner of the page, and click the **Model List** tab. On the **Model List** page, you can view the creation time, model type, and mapped OLEP for all models.
3. Click the icon next to the model that you want to delete.

8.10.2. Import data

Analytics Workbench supports importing data in the csv, txt, xls, or xlsx format. You can analyze small amounts of data or individual pieces of data that are missing from the data source.

Prerequisites

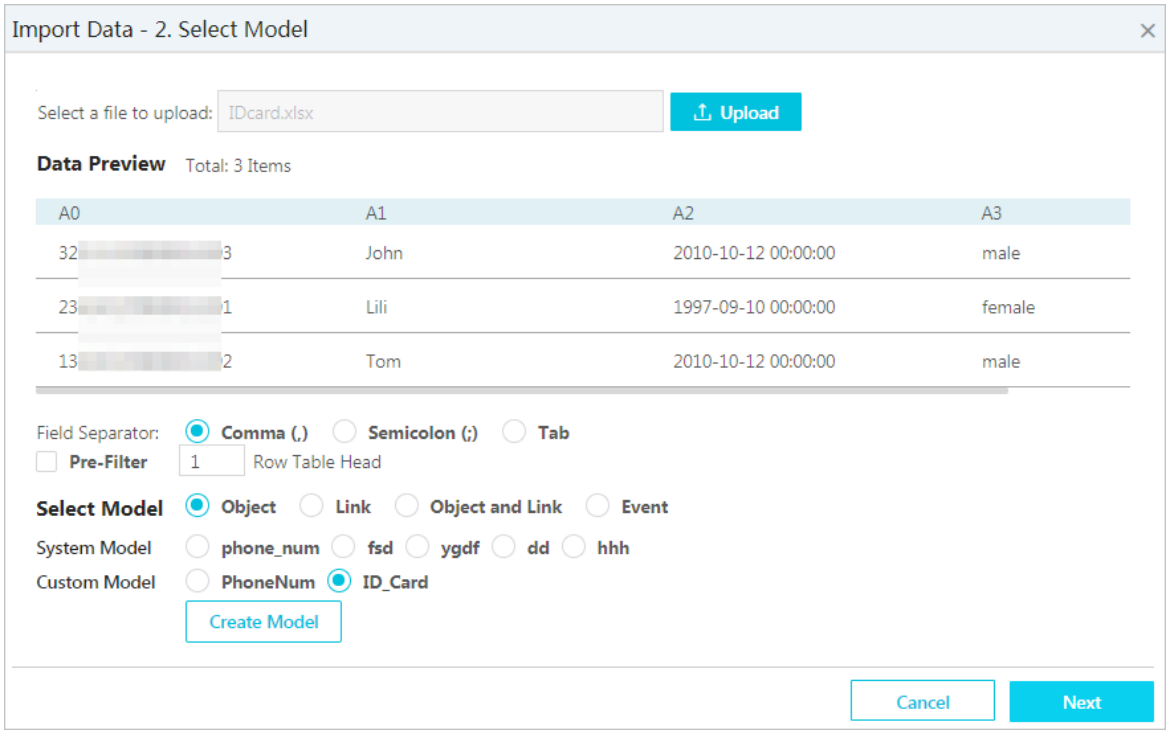
- The import data source is added when you configure the data source Create data sources.
- You have obtained an account and a password with the **Import Data** permissions.
- You have created a model matched to the data to be imported. For more information, see Create models.
- You have organized the data to be imported according to the template file, or sorted the data in the format required by the template, such as the csv, txt, xls, or xlsx format.

Procedure

1. Log on to Analytics Workbench.
2. Click the icon in the upper-right corner. In the dialog box that appears, select the file to be imported.
3. Click **Upload**, and set the read format of the file according to the data content to be imported.

   The parameter configurations are described in Parameter configurations and descriptions.

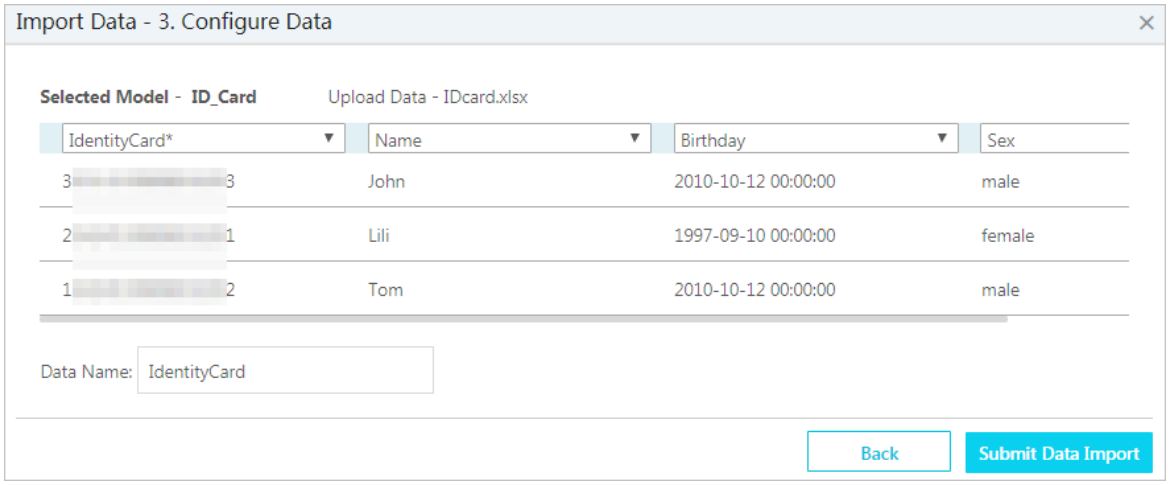
   After the file is imported, you can see the data preview of the file in the dialog box. Only the first 10 lines of the file content and the total number of lines are displayed.



Parameter configurations and descriptions

Parameter	Description
Column Separator	Sets the internal column separator for each line of the content.
Encoding Method	Specifies the character encoding for the file content.
Select Model	After you have selected the model type corresponding to the uploaded data, you can see the currently available system models in the **System Model** tab and custom models in the **Custom Model** tab. If you do not have a model that matches the data to be imported, you can click **Create Model** to create a new model in real time. For more information, see Create models.

4. After you have configured the parameters, click **Next** to set the data name and the mapping relationship between the columns and model properties of the data to be imported.



5. After you have configured the parameters, click **Submit**.

8.10.3. Data list

8.10.3.1. View data

Analytics Workbench allows you to view the imported data at any time, so that you can better understand the data.

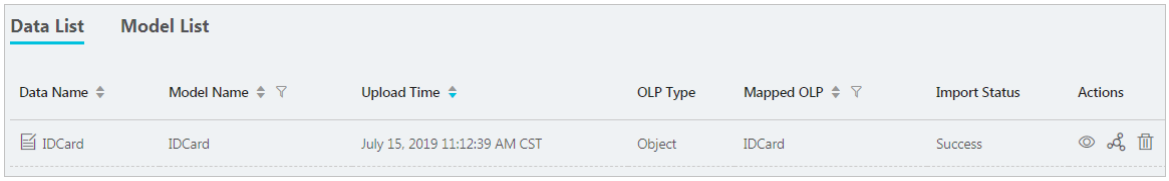
Prerequisites

You have obtained the account and password with the **Import Data** permissions.

Procedure

1. Log on to Analytics Workbench.
2. Click the icon in the upper-right corner of the page to go to the **Data List** tab page. You can view all data that has been imported.

   The Data List page displays information about all imported data, including the data name, model name, upload time, OLEP type, mapped OLEP, and the import status.



3. Click the icon next to a data model that you want to view, and view the property information about this data in the dialog box that appears.

8.10.3.2. Edit a data name

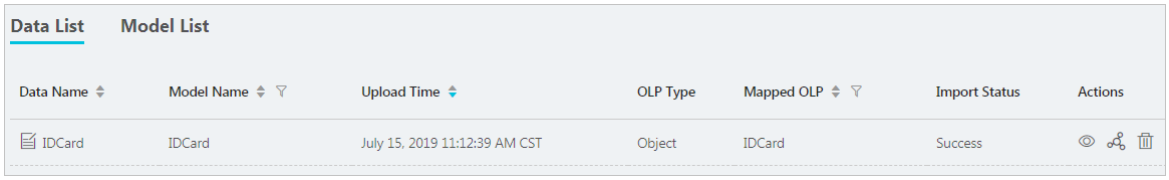
If a data name is obscure or does not match the data content, you can modify the data name.

Prerequisites

You have obtained the account and password with the **Import Data** permissions.

Procedure

1. Log on to Analytics Workbench.
2. Click the icon in the upper-right corner of the page to go to the **Data List** page.



3. Click the icon in front of the data name, rename the data, and then click **OK**.

8.10.3.3. Import data to Graph

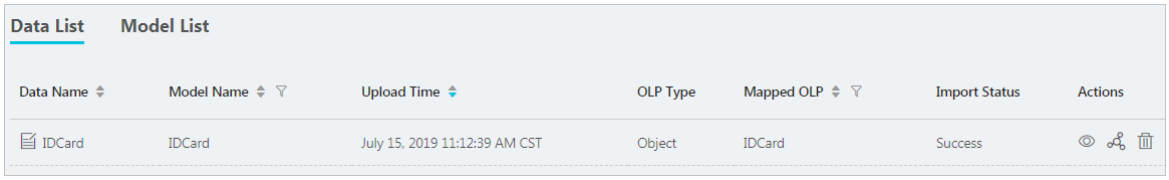
You can use this feature to import a data file to Graph to analyze the data quickly.

Prerequisites

You have obtained the account and password with the **Import Data** permissions.

Procedure

1. Log on to Analytics Workbench.
2. Click the icon in the upper-right corner of the page to go to the **Data List** page.



3. Click the icon next to the specified data file to present the data in Graph.

8.10.3.4. Delete data

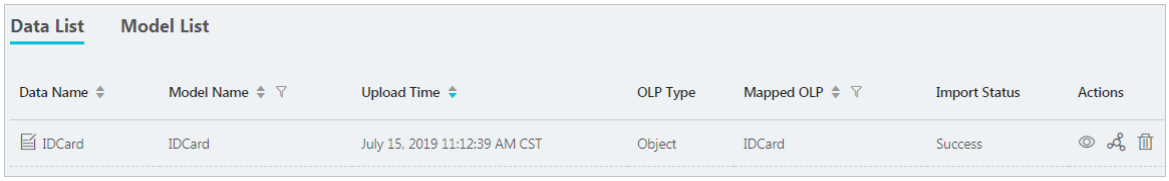
You can delete unnecessary data.

Prerequisites

You have obtained the account and password with the **Import Data** permissions.

Procedure

1. Log on to Analytics Workbench.
2. Click the icon in the upper-right corner of the page to go to the **Data List** page.



3. Click the icon next to the specified data to delete the data from Graph Analytics.

8.11. Search

8.11.1. Search

Search is one of the two key modules of Graph Analytics. Research staffs can use the Search module to find and view different objects, such as mobile phones or identity card information. In this topic, you can learn about the features and the entry of the Search interface.

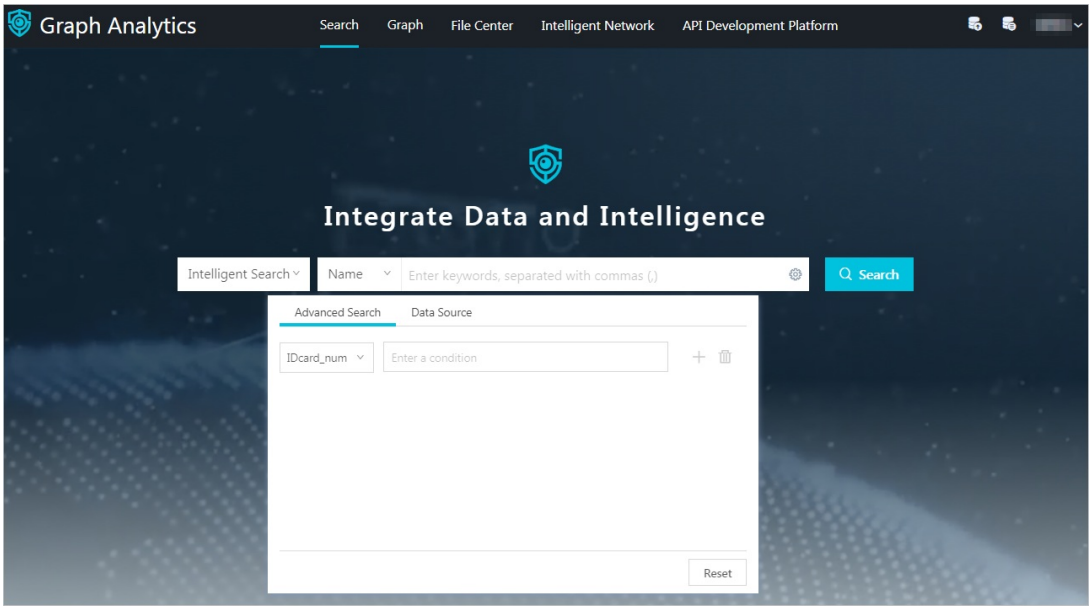
If you have obtained some fuzzy information, you can use the Search module to find objects and link records related to the information. These records can be added as independent object nodes to the relationship analysis, and can be used as a starting point for analysis and decision-making.

In the analysis process, you can expand the information step by step and refine the analysis by keywords, such as name and address. The Search module provides a search tool that allows you to retrieve the object information and locate the target information quickly.

> **Notice** In case of empty search conditions, no results will be returned, and a message Enter at least one condition value. will appear.

The Search module also serves as the entry to the Graph module. You can import the information of retrieved objects to the Graph module for further link extensions and link analyses.

Search



8.11.2. Simple search

You can use this feature to quickly search for objects that contain a certain type of keyword. Fuzzy search is supported.

Prerequisites

A search item has been configured for the target object, and the search item has been associated with the property of the object. For more information, see Configure a search item.

Context

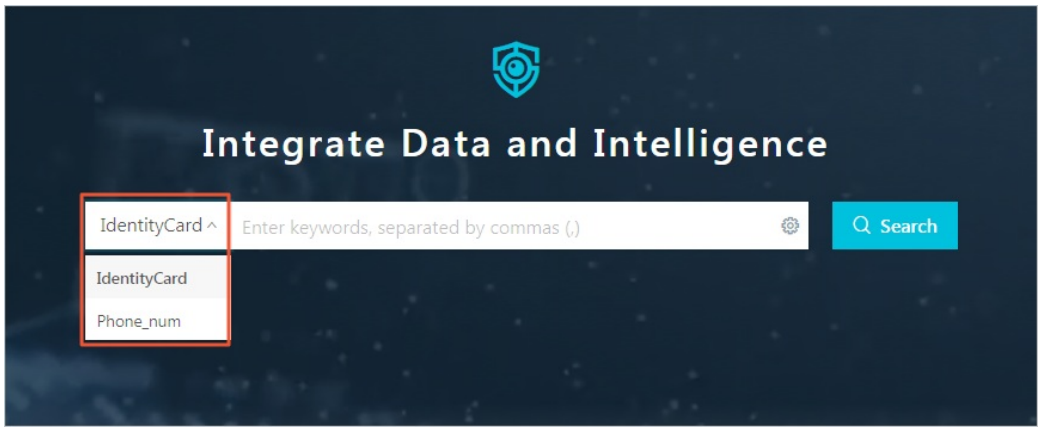
When you perform a simple search, you only need to select a keyword type and enter one or more keywords.

Procedure

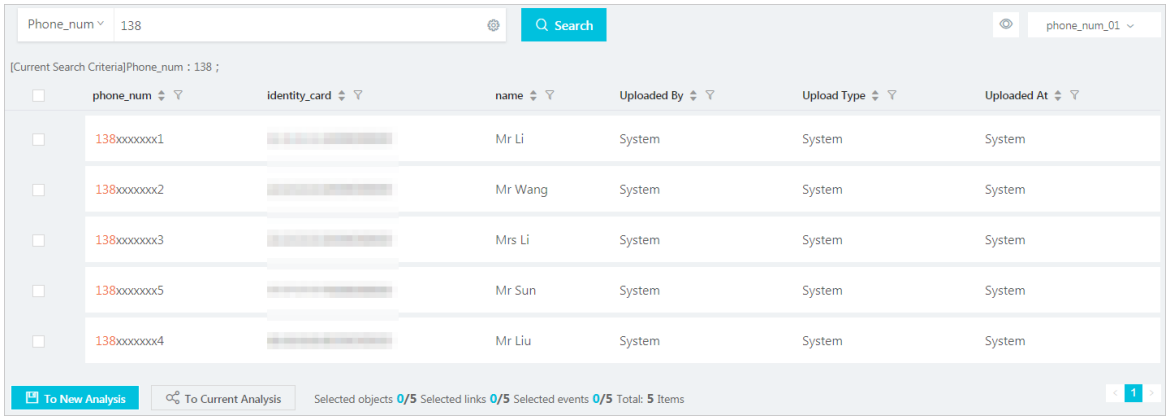
1. Log on to Analytics Workbench.
2. Click **Search** on the top navigation bar to go to the **Search** page.
3. Select a search item in the drop-down list as a keyword type, and enter one or more key words based on the search item you select.

Fuzzy search is supported. For example, if you want to search for objects whose phone number contains 138, you can just enter 138 in the search box.

Search box



4. Click **Search** or press **Enter** to start a search.



8.11.3. Advanced search

Advanced Search supports fuzzy search and multiple search conditions.

Prerequisites

You have configured a search item with an advanced association item for the target object, and the search item has been associated with the property of the object. For more information, see Configure a search item.

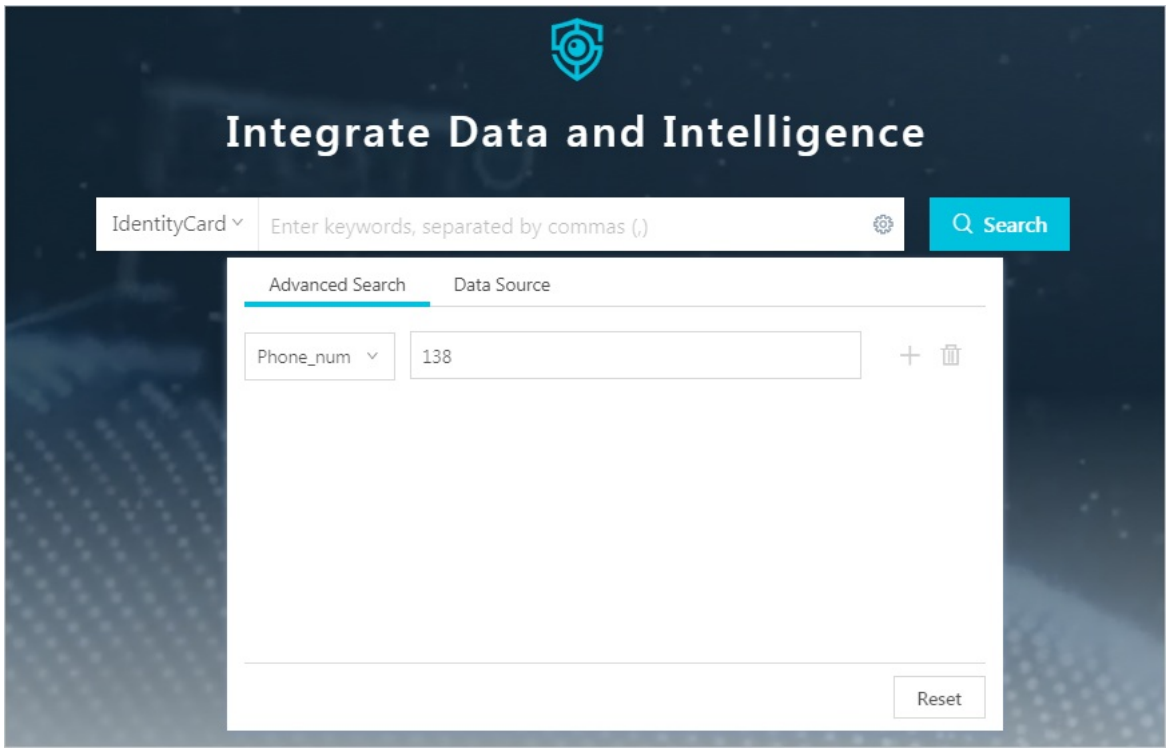
Context

You can specify the search terms in Advanced Search in the same way you perform a simple search. You can specify the advanced correlated items for the selected search terms. This is similar to a combined search based on multiple keyword types. You can also specify the data source items to be searched, which is similar to specifying the search range.

This topic describes a sample search for objects named **liqing344** whose identity card contains **234**.

Procedure

1. Log on to Analytics Workbench.
2. Click **Search** on the top navigation bar to go to the **Search** page.
3. Select a search item in the drop-down list as a keyword type, and enter one or more key words based on the search item you select. In this example, the search item is set to **ID Card** and the keyword is **234**.
4. Click the icon next to the search box to set the condition to perform an advanced search.

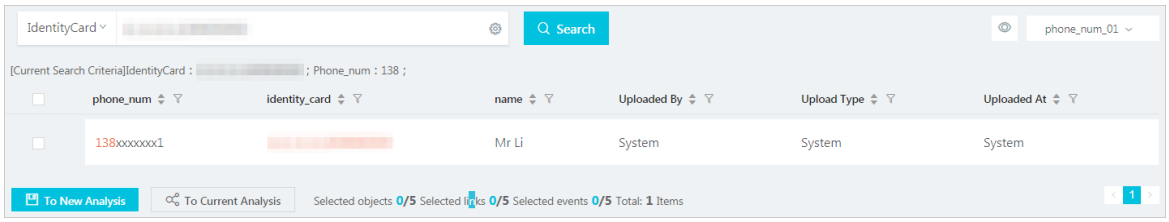


Advanced Search displays the Advanced Correlated Items of the currently selected item. In this case, the **advanced correlated item** is set as **Name**, and the keyword is **liqing344**.

Data Source: The data sources are the objects and links defined in Graph Analytics. Here you only need to select the data sources you want to search.

Reset: You can reset the search condition to the initial status.

5. After you have configured these parameters, click **Search** or press **Enter** to start a search.



8.11.4. View and analyze search results

After you have completed a search, you can view the search results and send the specified content to the graph to perform an analysis.

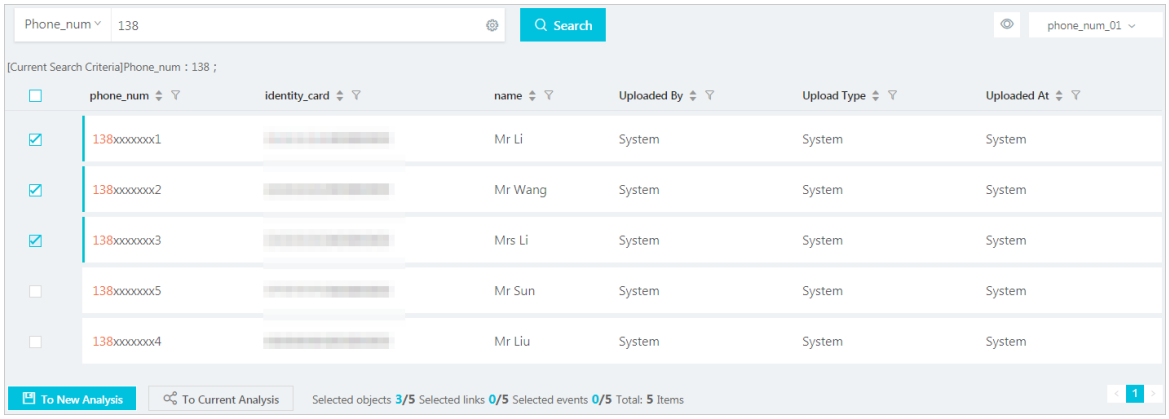
Prerequisites

You have completed a search, and the search results are not empty. For more information, see Simple search or Advanced search.

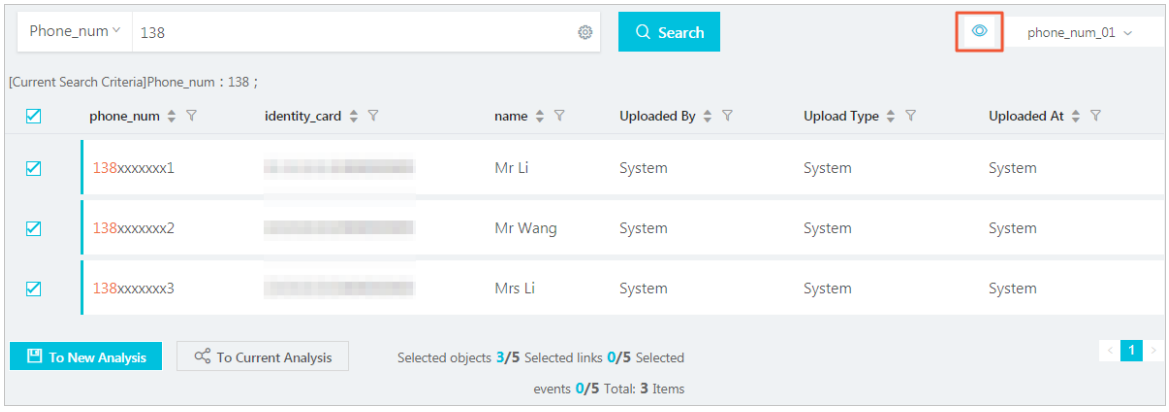
Procedure

1. Log on to Analytics Workbench.
2. Search for objects and view the search results. For more information, see Simple search or Advanced search.

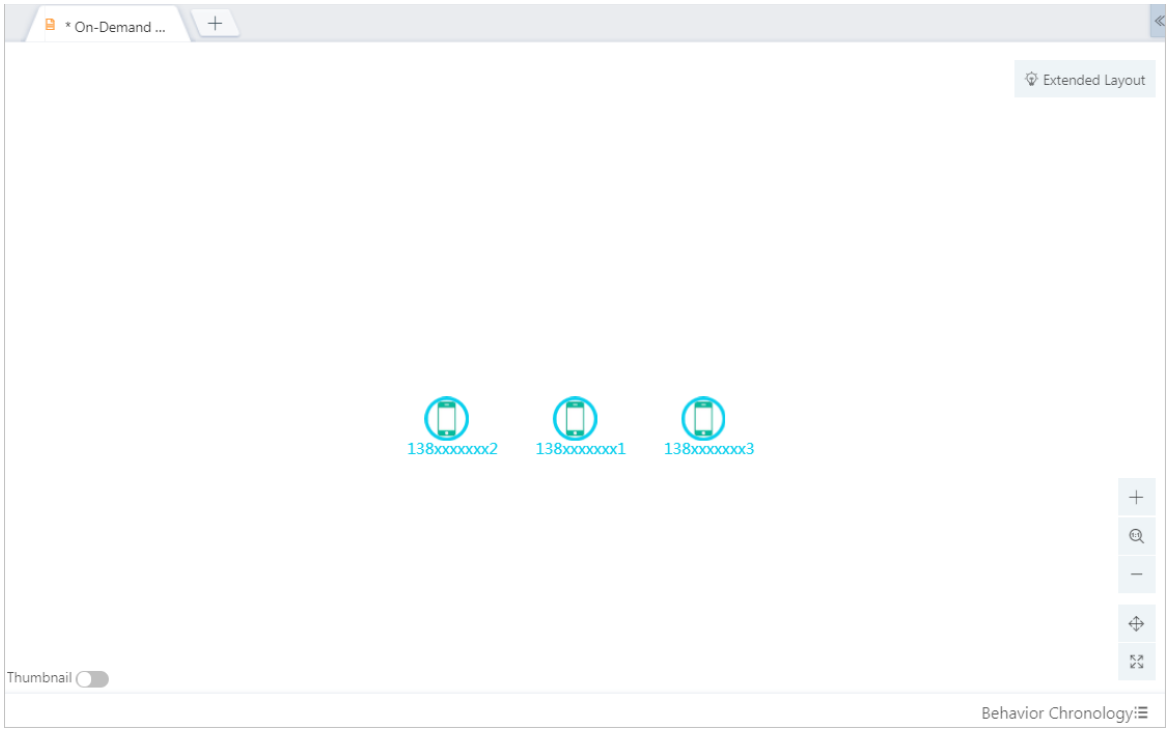
   The search results for this example are as follows:



3. Select part of or all of the search results. A total of 10 records are displayed on the current page. Click the icon in the upper-right corner. The search results only show the information of the selected objects.



4. Click the **To New Analysis** icon in the lower-left corner, or the **To Current Analysis** icon. Send the selected search results to the graph to perform an analysis.



8.12. Graph

8.12.1. Graph

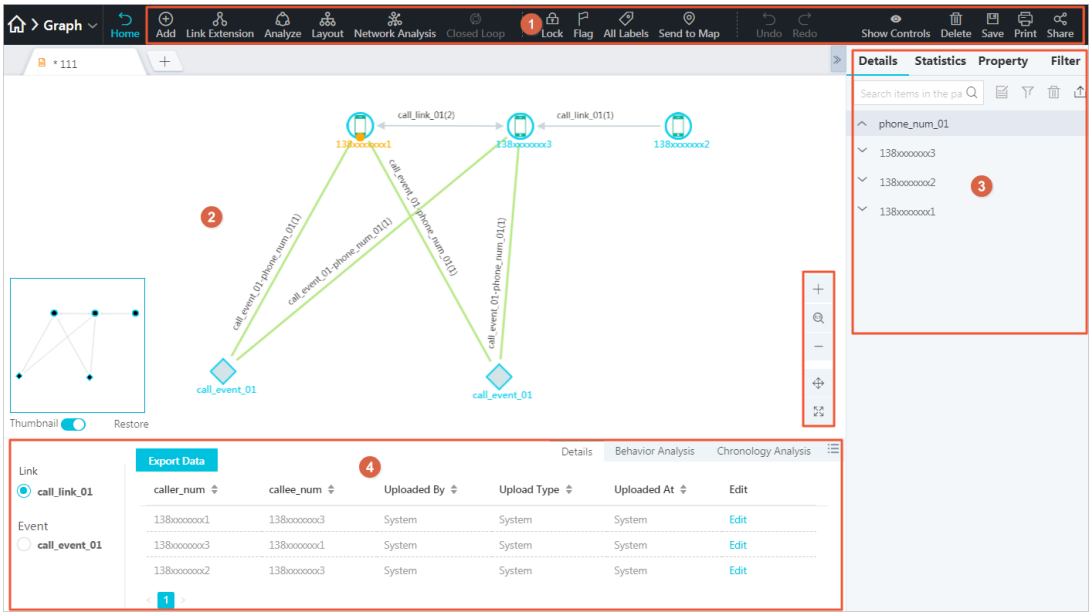
Graph is the operation interface of Analytics Workbench. You can create an analysis and view the analysis results in Graph. In this topic, you can learn about the features, function modules, and other information of Graph.

Graph is the core module of Analytics Workbench. This module covers most of the analysis and decision-making scenarios. The Graph module displays the relationship topologies among all objects. You can perform business computing and interactive graphic operations among multiple objects, and arrange visualized layouts based on your needs.

Meanwhile, user spaces and information cube networks are used as the assisting components to cover a wider range of analysis scenarios.

The **Graph** interface includes the following four areas.

Graph



- Area 1: functions
- Area 2: main graph area
- Area 3: properties and statistics
- Area 4: behavior analysis and chronology analysis

8.12.2. Analysis types

Graph Analytics supports four types of analyses: temporary analysis, common analysis, shared file analysis, and import data analysis.

Temporary analysis

An analysis that has just been created by the user is known as a temporary analysis. Temporary analyses have the same operations and features as other types of analyses, but temporary analyses cannot be shared before they are saved.

Common analysis

After a new analysis is saved and opened again, it is called a common analysis. The common analysis is the most commonly used analysis in Graph Analytics.

Shared file analysis

The analysis of shared files has the following statuses:

- Shared file - initial file

  After a common analysis is shared, it becomes a shared file. Each shared file will generate an initial file that is consistent with the original common analysis.

- Shared file - history analysis (draft)

  After the initial file has been edited by the shared member, a history analysis, also known as draft analysis, will be generated.

- Shared file - merged file

The system automatically merges multiple historical analyses into one analysis. Users can also merge the analyses manually.

Import data analysis

The import data analysis imports data in the **Data List** to the graph area to perform analyses. This type of analysis cannot be saved.

8.12.3. Create analyses

After you log on to Analytics Workbench, you must create an analysis and add the objects to be analyzed as nodes before you analyze the nodes.

Prerequisites

- Make sure that you have obtained an account and a password with the permission to perform graphic operations.
- Make sure that you have created source tables, objects, links, and events.
- Make sure that you have obtained data in the tables that have been mapped to the primary keys of the objects to be analyzed. You can obtain the data by querying the corresponding tables in the database.

Procedure

1. Log on to Analytics Workbench.
2. Click **Create Analysis**. A **Temporary Analysis** tab page appears.
3. Click **Add** in the toolbar and then click the blank space, or right-click the blank space and select **Add Node**. Set the parameters in the **Add Node** dialog box that appears.

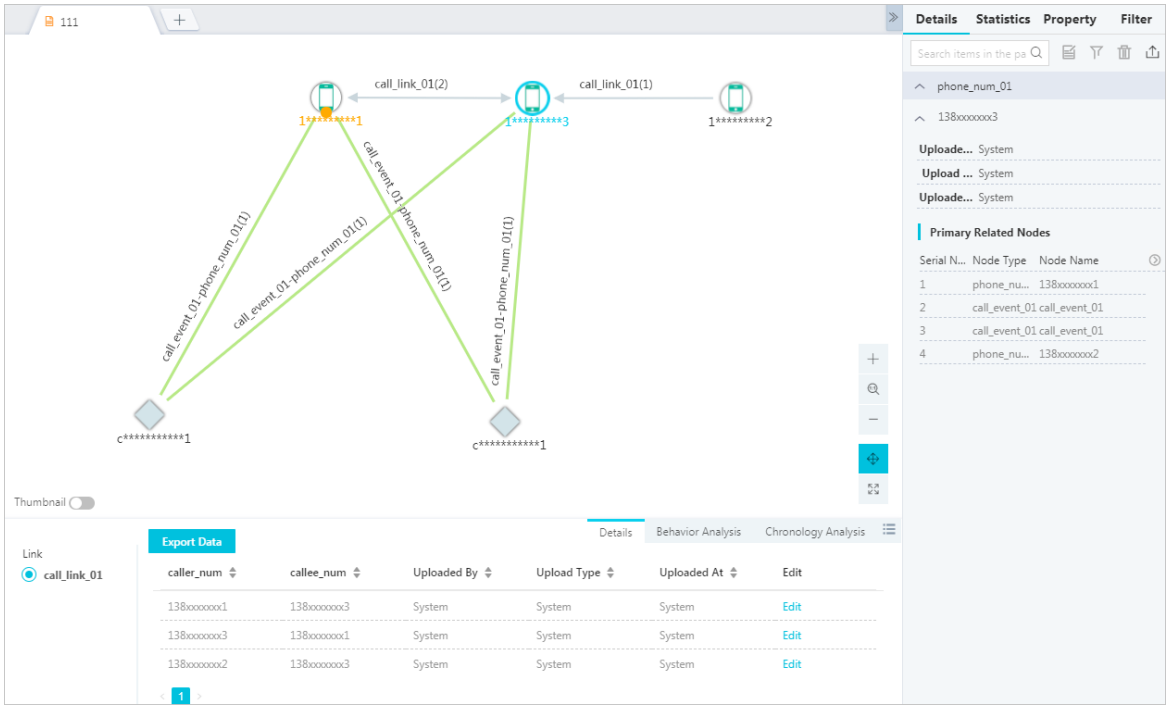
   The parameters are described in Parameters descriptions for adding a node.

Parameters descriptions for adding a node

Parameter	Description
Object type	The drop-down list displays all created objects. Select an object as needed. **Note** Graph Analytics supports adding compound nodes. A compound node is defined by multiple sub-types. For example, you can specify two sub-types for the object type "person": ID card and passport. The person can be uniquely identified by either the ID card or the passport.
Text area	Enter one or more primary key values. Separate multiple primary key values with commas (,).

4. Click **OK**.
5. Right-click a node that has been added, and select **Quick Extension**. The system automatically performs a link analysis based on the configured data sources, objects, links,

and events, and displays the analysis results in a graph.



6. Select one or more objects, links, or events. Click **Behavior Chronology** in the lower-right corner to see the corresponding **Details**, **Behavior Analysis**, and **Chronology Analysis** information.
7. Select one or more objects, links, or events. Click the icon () in the upper-right corner of the right-side pane to see the corresponding information on the **Details**, **Statistics**, **Property** and **Filter** tabs.
8. After the analysis has been completed, click **Save** in the upper-right corner. In the **Save Analysis** dialog box, enter a **File Name** and select a folder, and then click **OK**. A success message is displayed after the file has been saved.

   After you have saved the analysis file, if a collaborative analysis is required, you can share this personal analysis with other members.
9. Click the **Share** icon in the upper-right corner to specify the members you want to share this analysis with.

8.12.4. Add a node

Data analyses are based on nodes. Before you perform a data analysis, you need to add the object to be analyzed as a node.

Prerequisites

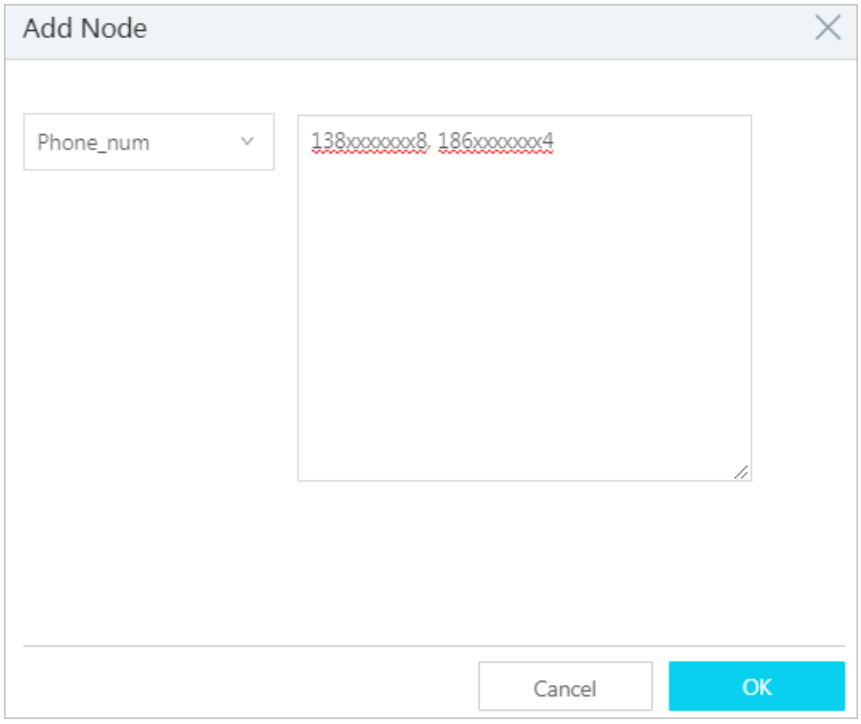
- Make sure that you have obtained an account and a password with the permission to perform graphic operations.
- You have created a source data table, object definitions, link definitions, and event definitions. For more information about these operations, see Data sources and Object information.
- Make sure that you have obtained data in the tables that have been mapped to the primary

keys of the objects to be analyzed. You can obtain the data by querying the corresponding tables in the database.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create a new analysis file.
3. Click **Add Node** and click anywhere in the blank space. Or right-click anywhere on the blank space, select **Add Node**, and then set the parameters in the **Add Node** dialog box.

   The parameters are described in Parameter descriptions.



Parameter descriptions

Parameter	Description
Object Type	Displays all created objects. You can select an object as needed. Note Graph Analytics supports adding compound nodes. For example, you can specify two sub-types for object type "person": ID card and passport. The person can be uniquely identified by either the ID card or the passport.

Parameter	Description
Text Area	Enter one or more primary key values in the data table corresponding to the Object Information. Multiple primary key values must be separated by commas (,).

4. After you have configured the parameters, click **OK**.

   If you want to add only one node, you can click Add Node in the toolbar and click the graph area to place the node. Or, you can right-click anywhere in the blank space and select Add Node in the short-cut menu to place the node. When you add multiple nodes, the nodes are placed in a horizontal line layout or a matrix layout by default. You can configure the layout in **Advanced** > **System Settings** > **Functional Components** > **Relationship Network** > **add multiple node layouts**.

5. Click **Save** in the upper-right corner. In the **Save Analysis** dialog box that appears, enter the **File Name** and select a file directory. Click **OK**. A message is displayed, indicating that you have saved the file.

8.12.5. Delete nodes, links, and events

You can delete the selected content in the current graph area. You can quickly delete the nodes, links, and events.

Prerequisites

Make sure that you have obtained an account and a password with the permission to perform graphic operations.

Context

When you delete object nodes, links and events related to these object nodes are also deleted.

Procedure

1. Log on to Analytics Workbench, and open an existing analysis file, or create a new analysis.
2. You can delete object nodes, links, or events by using the following methods.

Method	Operation
In the toolbar	Select one or more nodes, links, or events in the canvas. Click the **Delete** icon in the toolbar. A message is displayed, indicating that the item has been deleted.
In the right-click menu	Select one or more object nodes, links, or events in the canvas, right-click a selected item, and select **Delete Selected**. A message is displayed, indicating that the item has been deleted.

8.12.6. Link extension

You can use link extension to search for all objects that are related to a specific object. You can discover associated clues and intelligence from large amounts of unrelated information, and turn the information into useful intelligence.

Prerequisites

- An analysis file exists. Add a new analysis as shown in Create analyses.
- A node object exists. Add a new node as shown in Add a node.

Context

Link extension supports the following two modes.

Link extension mode	Description	Reference procedure
Simple mode	Double-click a node to perform a first-degree link analysis on the node. Only the associated information for the first-degree link can be extended.	Step 3
Advanced mode	Filter specific conditions based on business experience to extend the associated information.	Step 4 to Step 7

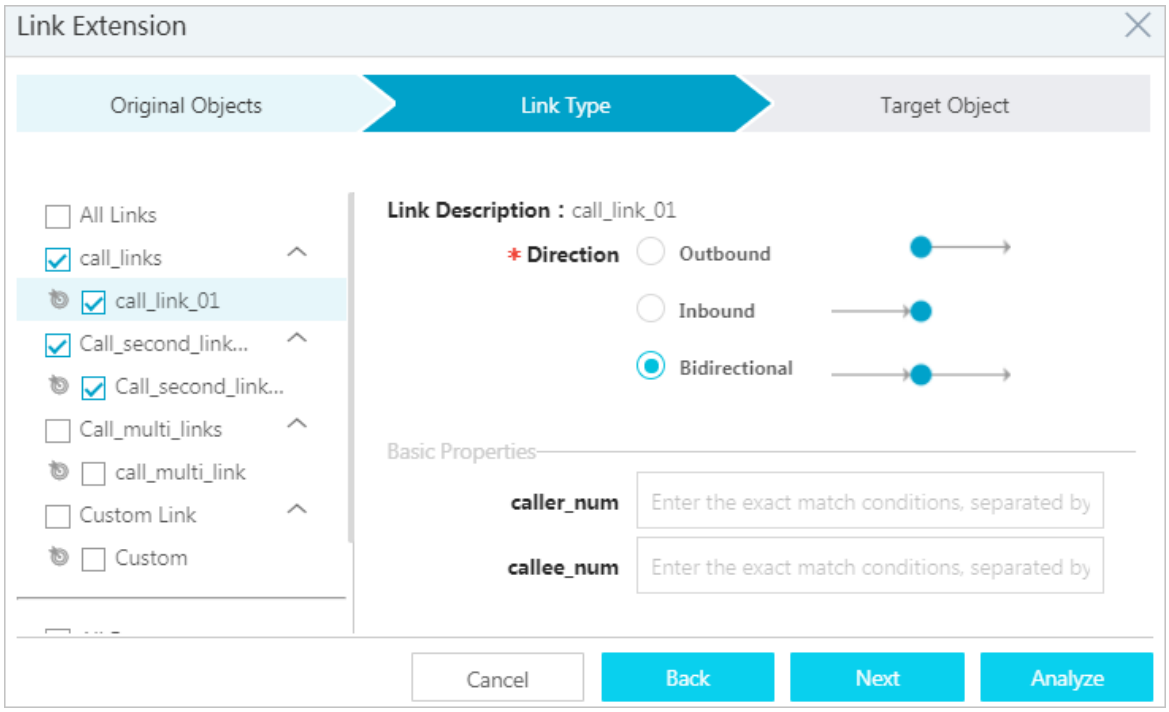
Procedure

1. Log on to Analytics Workbench.
2. Click an existing analysis file to open the file on the Graph page, or click **Create Analysis** to create an analysis file and add nodes.

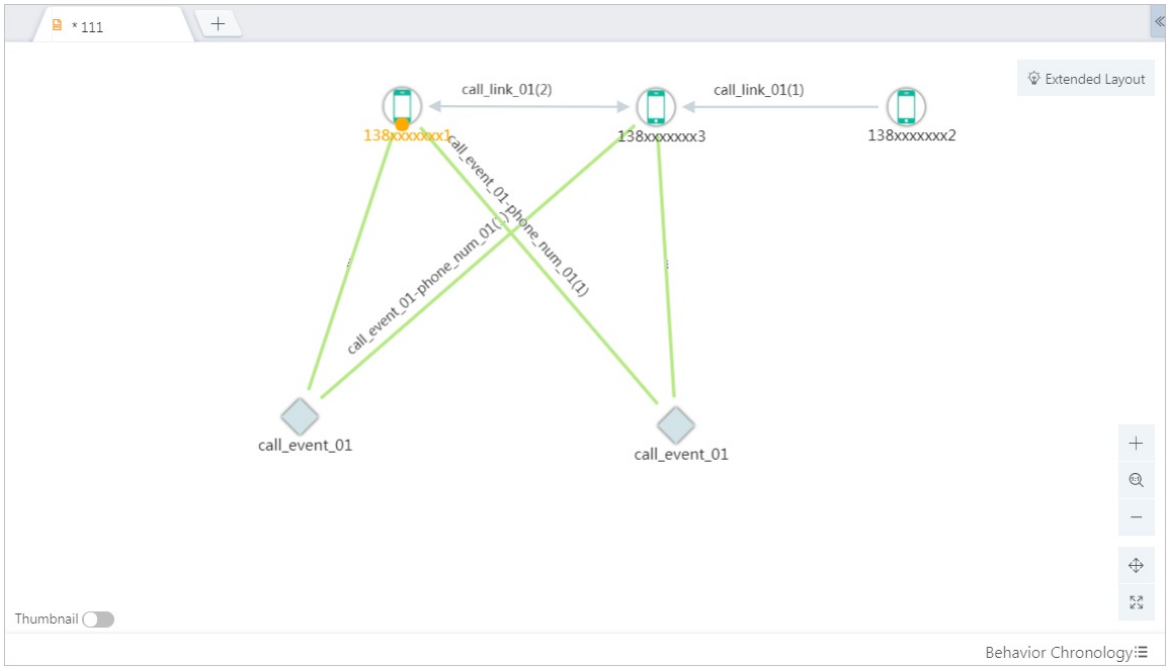
   Perform a simple analysis on a specific node.
3. Double-click a node to perform a first-degree link analysis.

   Perform an advanced analysis on one or more nodes.

4. Select one or more nodes and click the **Link Extension** icon in the toolbar. You can select a maximum of 1,000 nodes. In the **Link Extension** dialog box, select the source objects.
5. Click **Next**, select links and the events, and specify the parameters for the links and events.



6. Click **Next**, and select the target objects.
7. Click **Analyze** to extend the link of the selected nodes.



8.12.7. Graphic operations

8.12.7.1. Move canvases

You can move the entire graph area by moving the canvas to perform comparative analysis.

Prerequisites

Make sure that you have obtained an account and a password with the permission to perform graphic operations.

Procedure

1. Log on to Analytics Workbench, and open an existing analysis file or create a new analysis.
2. You can move the canvas by using the following methods.

> **Note** After you move the canvas, it will take a short time to reproduce the canvas. There will be a short delay. During that time, do not operate the canvas so as to prevent unexpected results.

Method	Operation
In the tool bar	Click the **Enter Move Canvas Mode** icon in the lower-right corner of the graph area and drag the canvas with your mouse.
Space key + mouse	Long press the **Space** key and drag the canvas with your mouse.
Use the scroll wheel	Move the canvas upwards or downwards with the scroll wheel of your mouse.

8.12.7.2. Zoom in and zoom out canvases

Graph Analytics enables you to zoom in and zoom out the content in the graph area to perform a comparative analysis from a full-graph or partial-graph perspective.

Prerequisites

Make sure that you have obtained an account and a password with the permission to perform graphic operations.

Procedure

1. Log on to Analytics Workbench, and open an existing analysis file or create an analysis.
2. You can zoom in or zoom out the canvas in the following methods.

> **Note** After you zoom in or zoom out the canvas, it will take a short time to reproduce the canvas. There will be a short delay. During that time, do not operate the canvas to prevent unexpected results.

Method	Operation
Shift key + mouse pointer	Long press the **Shift** key and zoom in or zoom out the canvas with the scroll wheel of your mouse.

Method	Operation
Interface icons	○ Click the **Zoom In** icon to scale the size of the canvas. ○ Click the **Zoom Out** icon to scale the size of the canvas. ○ Click the **Restore Original Ratio** icon to restore the original ratio of the canvas.

8.12.7.3. Undo and redo operations

Graph Analytics supports undo and redo operations. In case of a mistake, you can quickly restore the graph area to the status prior to the operation.

Prerequisites

Make sure that you have obtained an account and a password with the permission to perform graphic operations.

Background information

The undo and redo functions are described as follows:

- Undo: You can temporarily store the graph area status prior to the operation into the operation history. You can restore a historical version by undoing the operation. A maximum of 20 steps can be undone.
- Redo: After the Undo operation, you can also restore the analysis to a status prior to the undo operation.

The undo and redo operations can be performed to add nodes, add links, save virtual nodes, merge or split nodes. Undo and redo operations are applicable to layout features, link analysis features, and paste operations, and can be used to delete nodes or links.

Procedure

1. Log on to Analytics Workbench, and open an existing analysis file or create a new analysis to perform multiple operations.
2. If you need to go back to a specific status, you can undo the operation by using the following methods.

Method	Description
Undo	In the toolbar, click the **Undo** icon to undo the operation and restore the area to the status prior to the operation. You can perform the undo operation at a maximum of 20 steps.

Method	Description
Redo	In the tool bar, click the **Redo** icon to restore the graph area to the status prior to the undo operation. You can perform the redo operation at a maximum of 20 steps.

8.12.7.4. View thumbnails

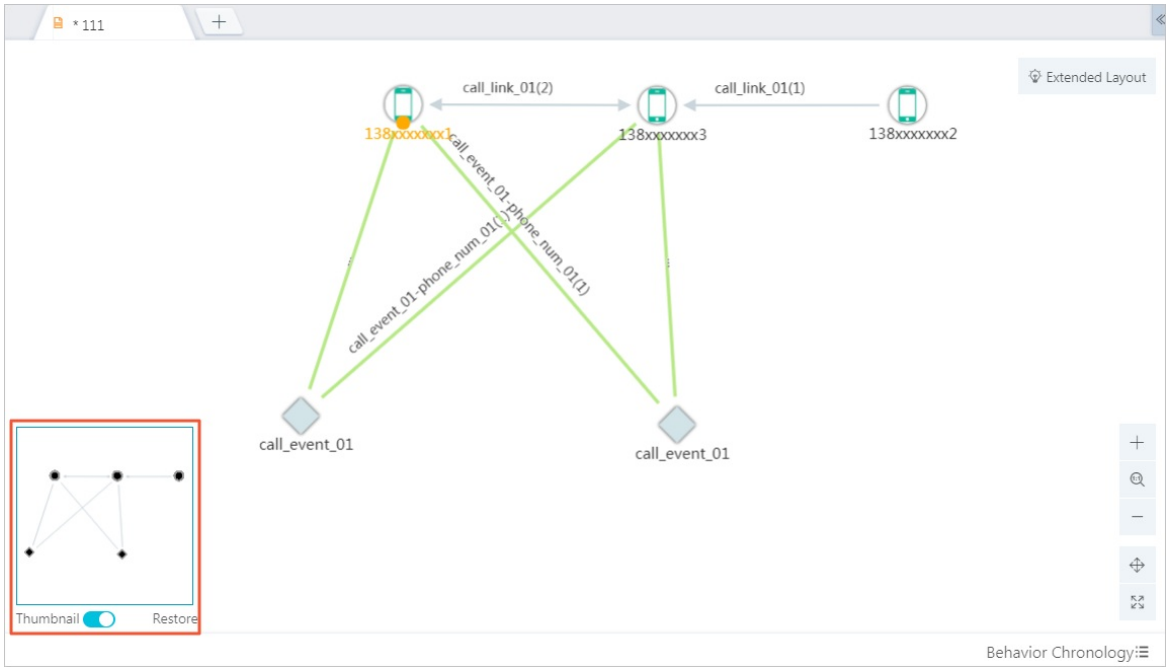
The thumbnail tab is located in the lower-left corner of the graph area. After you click the thumbnail tab, the thumbnail of the current full graph is displayed. The position of the visible area is framed out to help you view the analysis graph easily.

Prerequisites

Make sure that you have obtained an account and a password with the permission to perform graphic operations.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create a new analysis.
3. Click the **Thumbnail** icon in the lower-left corner to open the thumbnail of the current graph area.



4. You can drag the rectangular box in the middle of the thumbnail to drag the corresponding nodes in the canvas.

8.12.7.5. Right-click menu

The right-click menu in the graph area enables you to quickly operate on nodes, links, or events. In this topic, a vertex refers to a node, and an edge refers to a link or an event.

Log on to Analytics Workbench, and open an existing analysis file or create an analysis. The right-click menu varies depending on the position where you click on.

Right-click anywhere on the blank space

Right-click anywhere on the blank space. For more information, see Right-click menu description.

Right-click menu description

Menu option	Description
Add Node	Adds nodes to the graph area. For more information, see Add a node.
Select All Nodes	Selects all nodes in the graph area.
Select All Events	Selects all events in the graph area.
Select All Links	Selects all links in the graph area.
Paste	Pastes the content in the clipboard to the current analysis. This option will be grayed out if no objects or links exist in the clipboard.

Right-click a node or a link

Right-click a vertex or an edge in the graph area. For more information, see Right-click menu description.

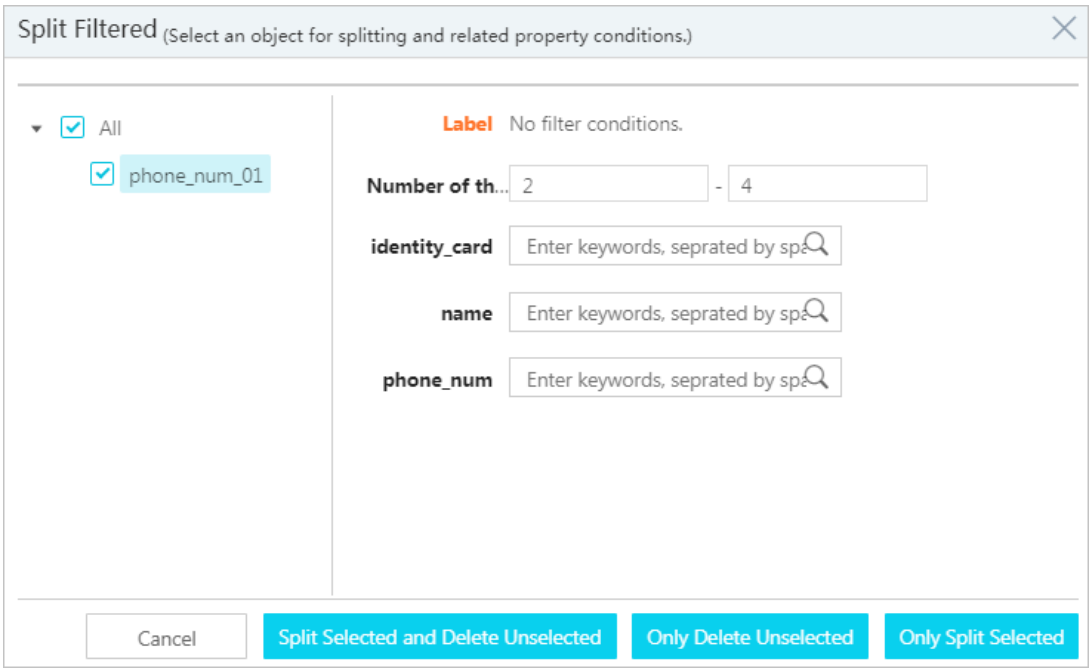
Right-click menu description

Menu option	Description
Add Link	Adds a link for the selected two nodes to establish a relationship network. Graph Analytics supports directed and undirected links. • Directed link: A clearly defined link with specific direction. The link line usually has arrows, as in the case of phone call relationship. • Undirected link: A link with no clear direction. For example: people taking a train.
Add Label	Adds label information to the selected nodes for easy analysis and identification. For more information about labels, see Add user labels.
Delete Selected	Deletes the selected nodes or links from the graph area. For more information, see Delete nodes, links, and events.
Inverse Selection	Selects all nodes other than the currently selected nodes.
Select Correlated Nodes	Selects all nodes that are correlated to the currently selected nodes. This option helps users locate the information for analysis and quickly select the correlated nodes. This option applies only to object nodes.

Menu option	Description
Merge Selected	Merges two or more selected nodes and displays the results. Users can sort, merge, visualize, and simplify the information in the entire graph area. This option applies only to object nodes, and the number of selected nodes must be greater than or equal to 2. Meanwhile, after the Merge Selected option is applied, the object nodes and links in the Selected state in the graph area remain unchanged.
Split Selected	Splits the merged nodes and displays the results. Users can extract information from a merged node for individual analysis. This option applies only to object nodes. Make sure that at least one node in the selected nodes is part of a merged node. Meanwhile, after the Split Selected option is applied, the object nodes and links in the Selected state in the graph area remain unchanged. The split operation filters the label information and property information of merged nodes by type. An UI example is shown in Split Filtered dialog box, and the parameters are described in Filter descriptions. The split options are described in Split options.
Event Chain	Displays all events that occur on a specific object within a specified time range.
Clear Event Chain	Clears all event chains of an object within a specified time range.
Show Event	Shows an event. When an event involves multiple objects, you can use this operation to show the event and view all objects involved in the event.
Hide Event	Hides an event that has been shown.
Quick Extension	Performs a quick extension on the selected nodes, obtains the graphic results of the quick extension, and makes force-directed layouts.
Node Redirect	Redirects to a third-party business system by node type according to the URL configured in Administration Console. **Node Redirect** is a channel that connects Graph Analytics to other products. For example, if the object information can be viewed only by a third-party system, you can click **Node Redirect** to view the information in the third-party system. Configure the redirect URL in Administration Console depending on the specific situation.
Copy	Copies the selected object nodes or link graphs and pastes them to the clipboard. You can copy object nodes and link graphs.

Menu option	Description
Roll Up	If a multi-degree link is established between two objects, multiple intermediary objects are displayed between the two nodes. Select these nodes and click **Roll Up** to hide these intermediary nodes. After the intermediary objects are hidden, a dotted line is displayed between the two objects to represent the multi-degree link. To show these intermediary objects, press **Ctrl** and click on the dotted line.
Save Virtual Node	Persists virtual nodes.
View Selected Node Details	You can view the details of a selected node in the right-side pane.

Split Filtered dialog box

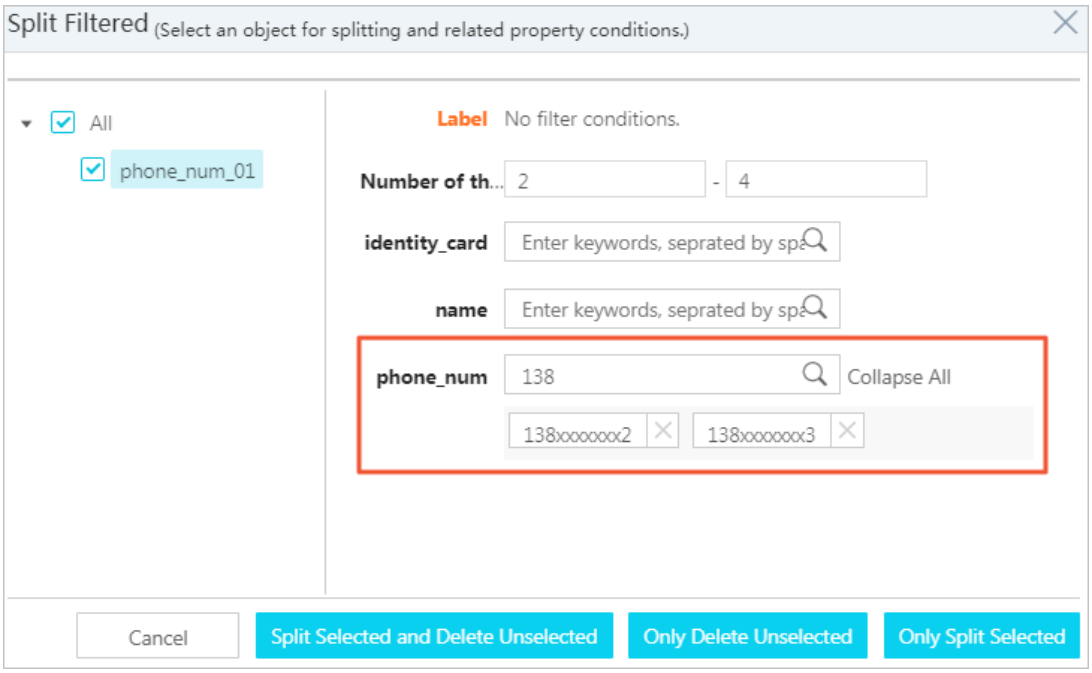


Filter descriptions

Filter	Description
Labels	All labels are enumerated. You can delete some labels as needed.
Time type	Lists the maximum and minimum values of the time property. You can adjust the value range, for example, the departure time.
Value type	Lists the maximum and minimum numerical values. You can adjust the value range, for example, age.
Dictionary type	Like the Label filter, all dictionaries are enumerated. You can delete some dictionaries as needed.

Filter	Description
String	Supports fuzzy searches. As shown in Fuzzy search, search for the mobile phone number containing 189. Each item in the search results can be deleted by clicking the Delete icon next to the item. If no results have been found, the message "No results have been found." is displayed.

Fuzzy search



Split options

Option	Description
Cancel	Cancels the split operation.
Split Selected and Delete Unselected	Splits the nodes that meet the conditions, and deletes the other nodes.
Only Delete Unselected	Retains nodes that meet the conditions in the merged node and deletes the other nodes.
Only Split Selected	Splits nodes that meet the conditions from the merged node, and retains the other nodes in the merged node.

8.12.8. Analyze

8.12.8.1. Group Analysis

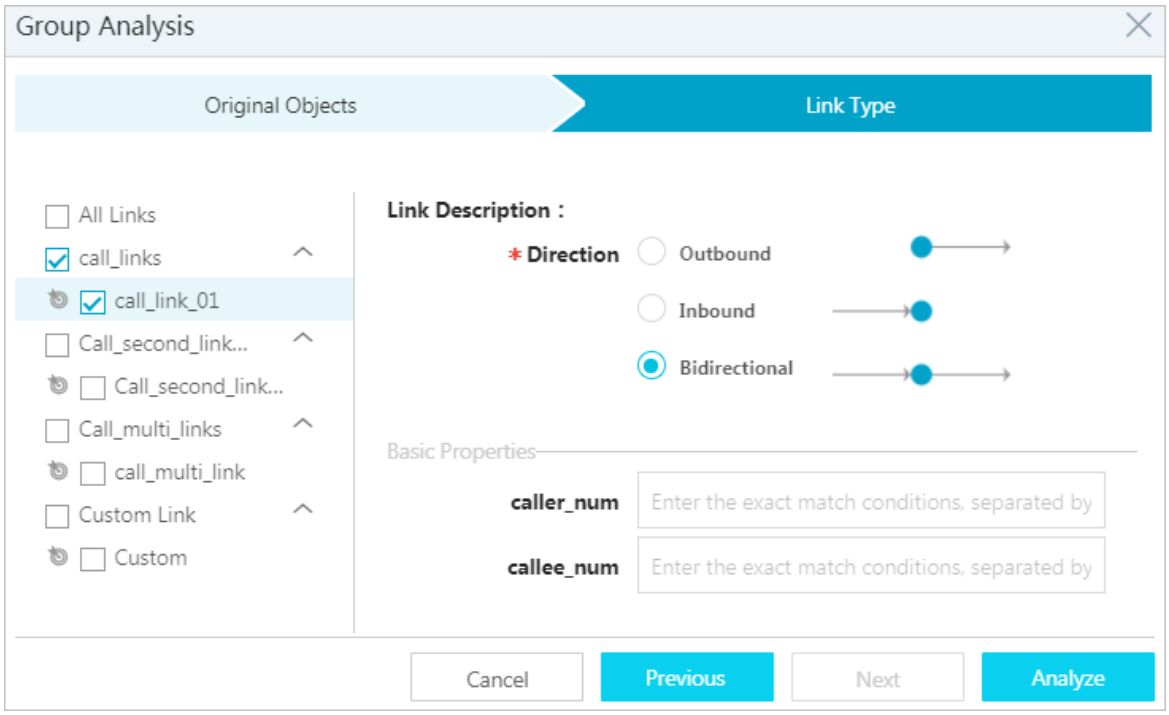
You can use group analysis to perform multiple analyses on the relationships between any two objects in the group.

Prerequisites

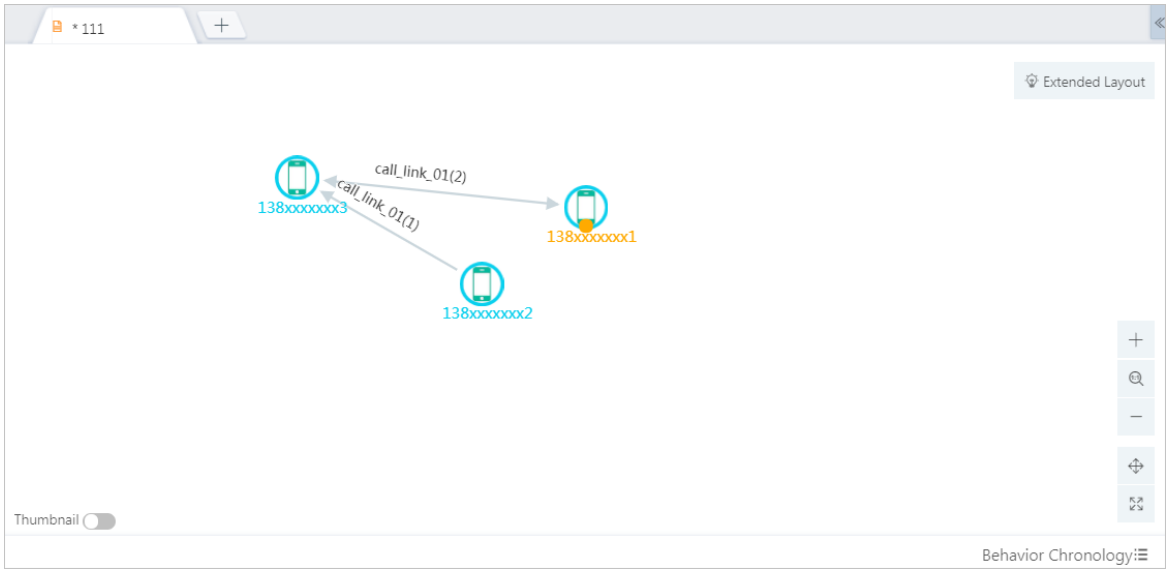
- Make sure that you have obtained an account and a password with the permission to perform graphic operations.
- An analysis file exists. Add a new analysis as shown in Create analyses.
- Two or more node objects already exist. Add a new object node as shown in Add a node.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create a new analysis, and select two or more object nodes in the graph area.
3. Choose **Analyze** > **Group Analysis**. In the **Group Analysis** dialog box that appears, select the start object to be analyzed.
4. Click **Next**, select links, and set conditions for each link based on your needs.



5. Click **Analyze** to complete a group analysis for the selected node.



8.12.8.2. Common neighbor analysis

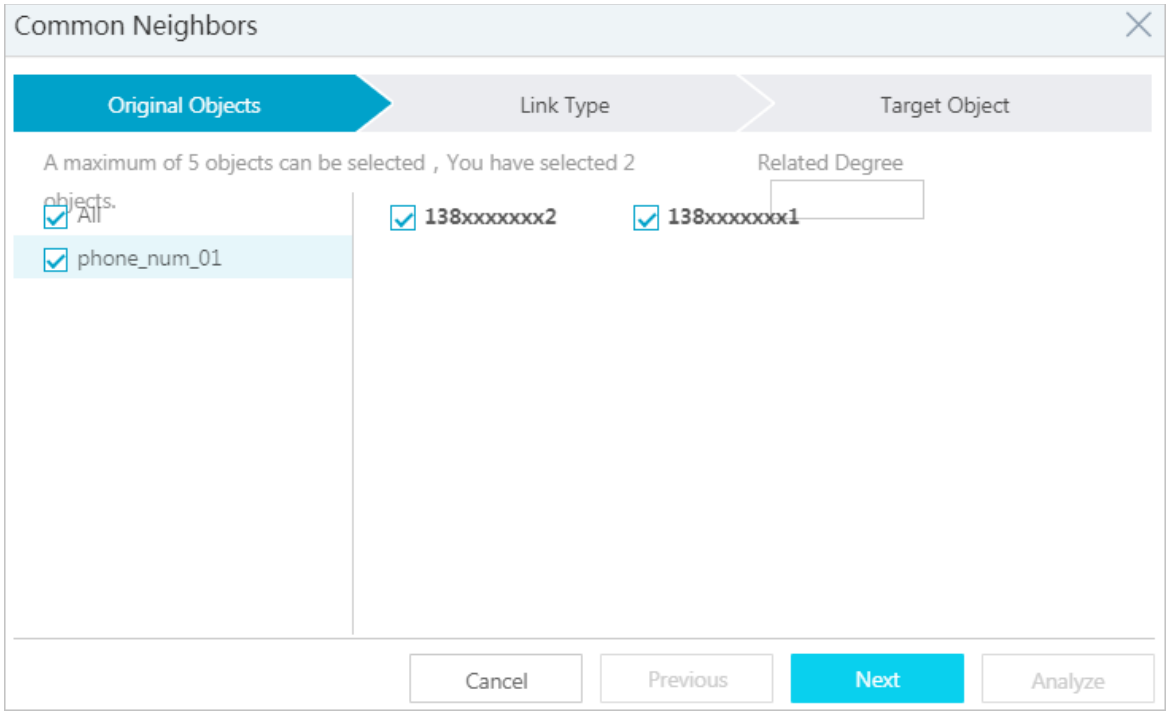
This feature allows you to analyze the commonly associated objects for a group of identical objects or different objects. The correlated degree is set to 2 by default.

Prerequisites

- You have obtained an account and a password with the permission to perform graphic operations.
- An analysis file exists. For more information about how to add an analysis, see Create analyses.
- Two or more node objects already exist. For more information about how to add a node, see Add a node.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create a new analysis, and select two object nodes in the graph area.
3. In the toolbar, choose **Analyze** > **Common Neighbors**. In the **Common Neighbors** dialog box that appears, select the start object to be analyzed.

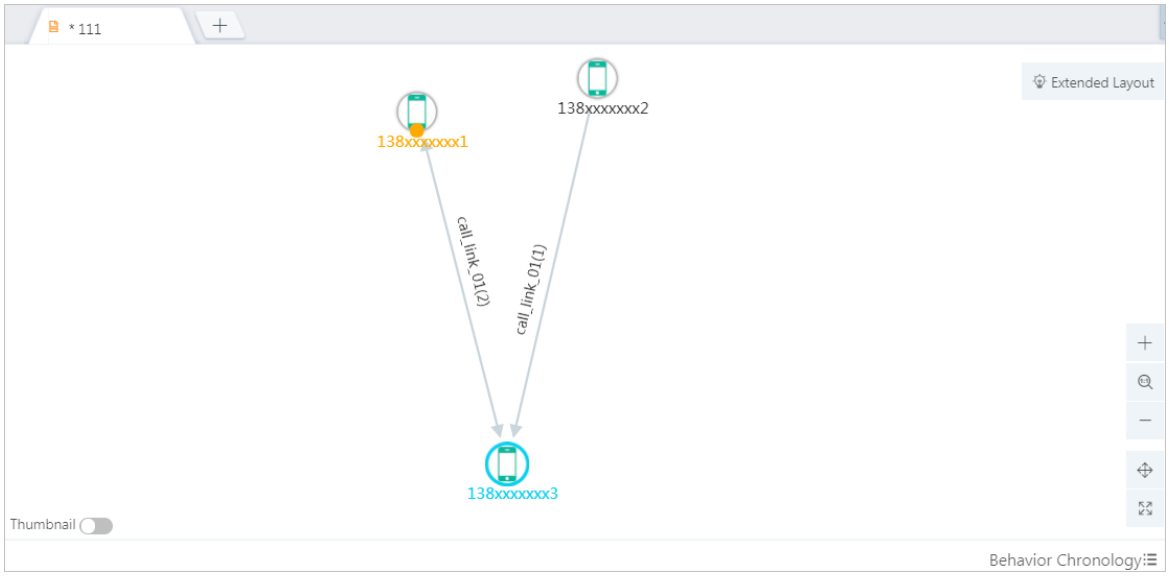


4. Click **Next** to select links and set conditions for each link based on your needs.

   The correlated degree is set to 2 by default.

   You can set the link conditions by time, date, value, enumerated type, string equality, and fuzzy string matching.

5. Click **Analyze** to complete a common neighbor analysis for the target node.



8.12.8.3. Lineage analysis

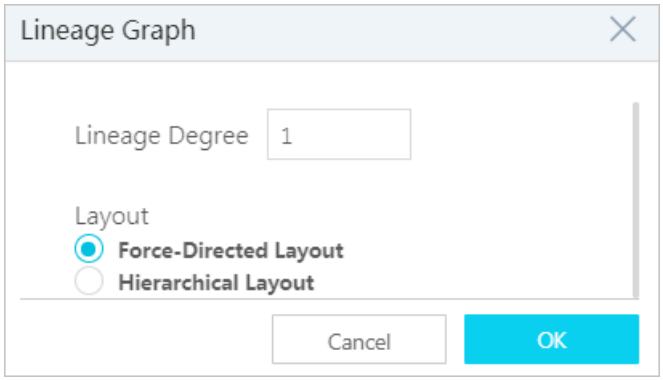
Lineage analysis allows you to search the lineage between certain types of objects based on the lineage configurations in Administration Console.

Prerequisites

- You have obtained an account and a password with the permission to perform graphic operations.
- An analysis file exists. For more information about how to add an analysis, see Create analyses.
- A node object exists. For more information about how to add a node, see Add a node.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create a new analysis, and select one or more nodes in the graph area to perform a lineage analysis.
3. In the toolbar, choose **Analyze** > **Lineage Analysis**. In the dialog box that appears, specify Lineage Degree and Layout.



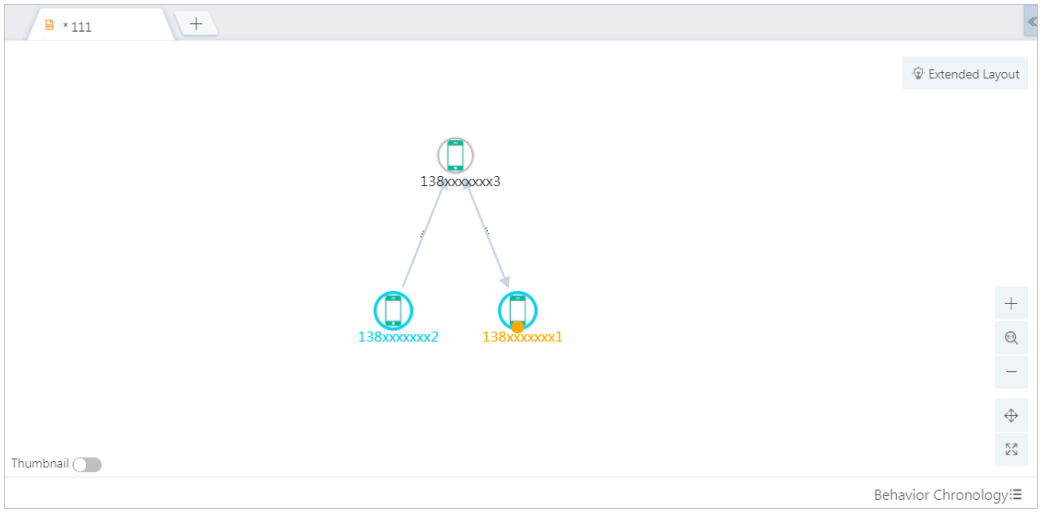
4. Click **OK** to complete the lineage analysis of the target node.

   The Lineage Degree is *1*. The Layout is *Force-Directed Layout*. The result is shown in Analysis results in the force-directed layout.

   Analysis results in the force-directed layout

   Assume that you have set the first-degree link and selected the hierarchical layout. The analysis results are shown in Analysis results in the hierarchical layout.

   Analysis results in the hierarchical layout



8.12.8.4. Path analysis

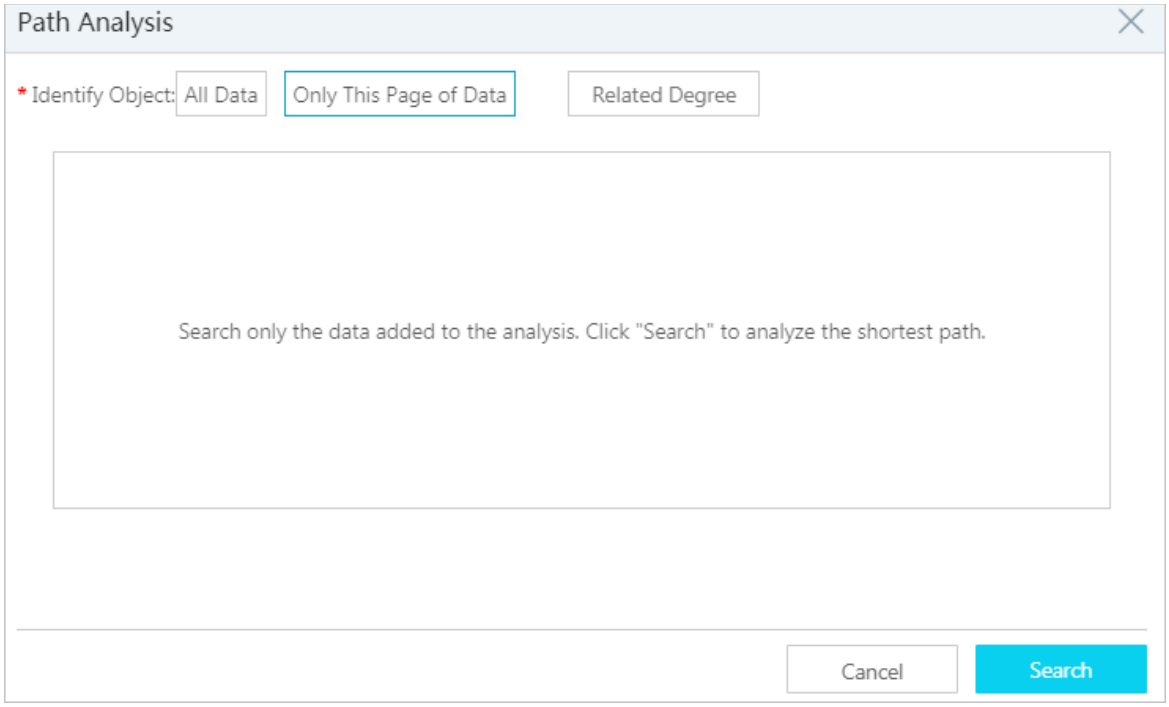
This feature allows you to analyze the link path between two objects.

Prerequisites

- You have obtained an account and a password with the permission to perform graphic operations.
- An analysis file exists. For more information about how to add an analysis, see Create analyses.
- Two or more node objects already exist. For more information about how to add a node, see Add a node.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create a new analysis, and select two object nodes in the graph area.
3. In the toolbar, choose **Analyze** > **Path Analysis**. The **Path Analysis** dialog box appears.



The path analysis supports performing analyses on All Data and Only Data of This Page. For more information about the path analysis, see the following procedure.

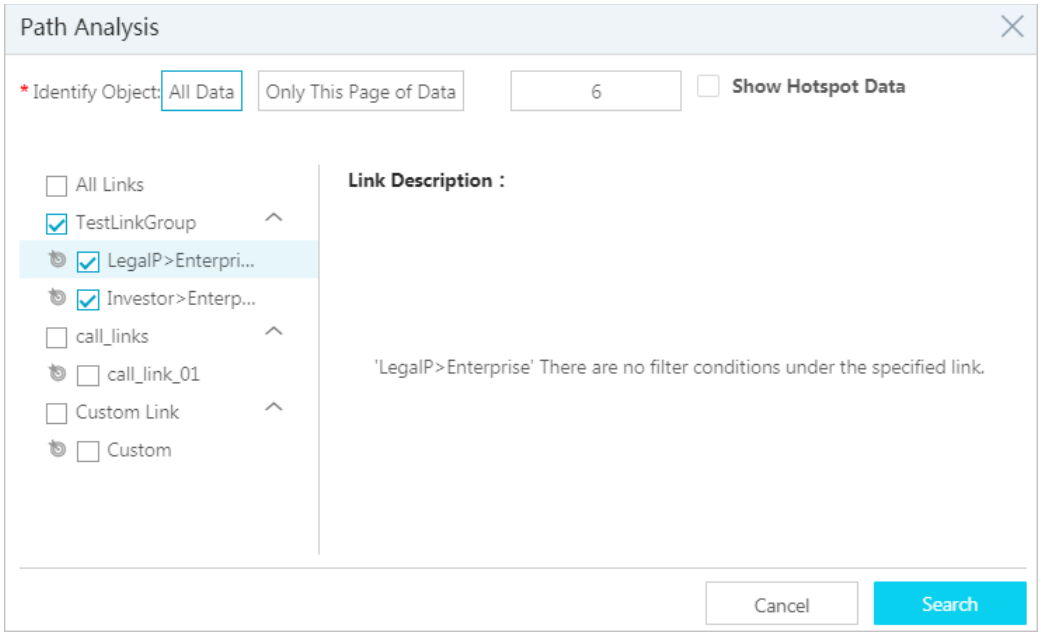
4. Perform path analysis on all data: Select **All Data** to perform a path analysis and specify the relevant parameters.

   All Data: Set the link condition, correlated degree, and whether to show the hotspot data, as shown in Set conditions for the path analysis on all data.

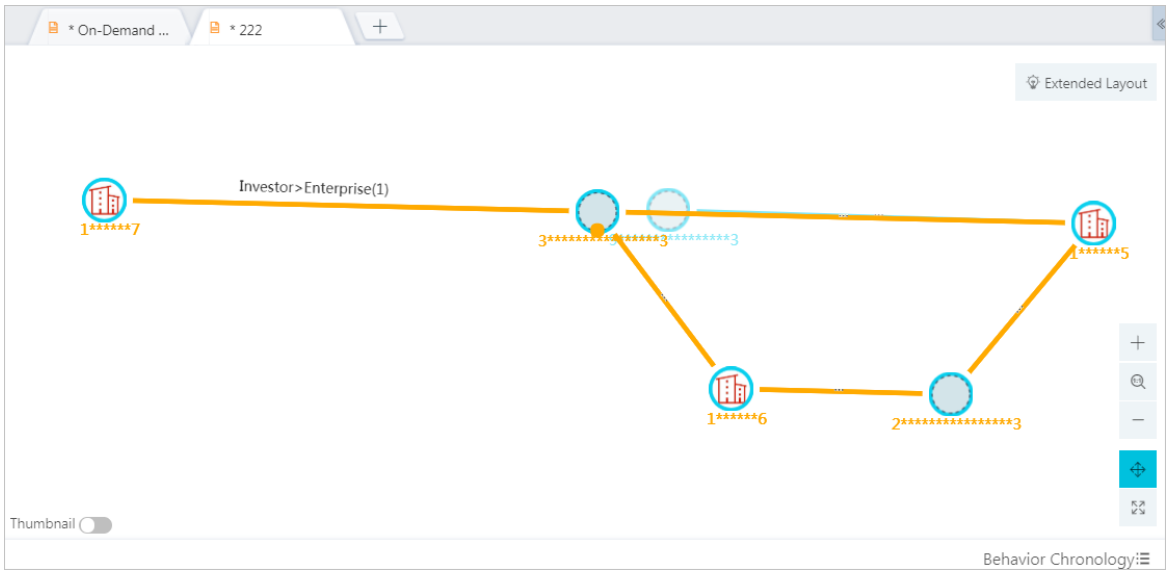
   If you select Show Hotspot Data, the hotspot data is displayed but not extended.

   > **Note** The system administrator monitors the hotspot data and adds a red tab to the hotspot node to inform the users of the hotspot data.

   Set conditions for the path analysis on all data



5. Click **Search** to perform a path analysis on all data.



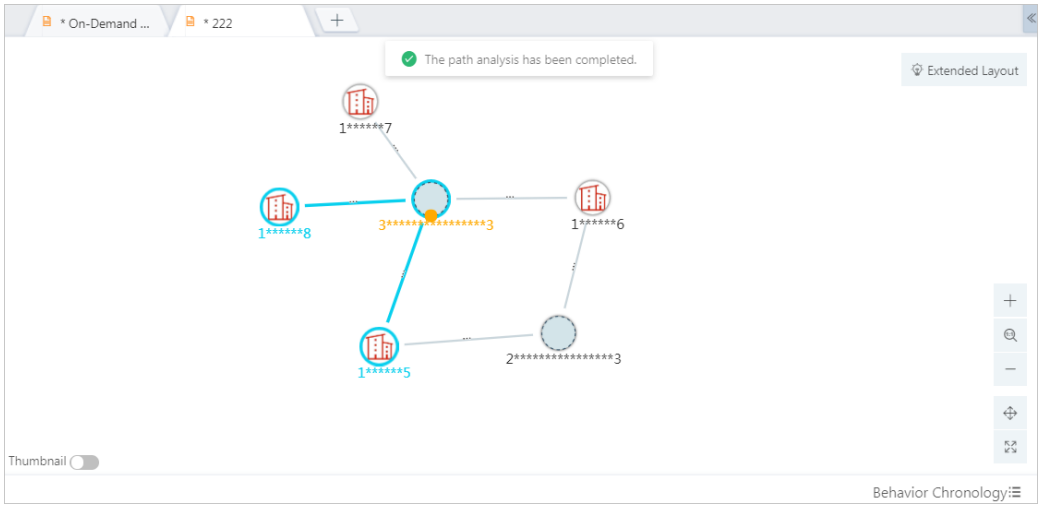
6. Analyze only data of this page: Select **Only Data of This Page** and specify the correlated degree.

   Analyzing only data of this page is to analyze the path between two nodes on the current page. This feature supports analyzing the shortest path and paths with a specified correlated degree.

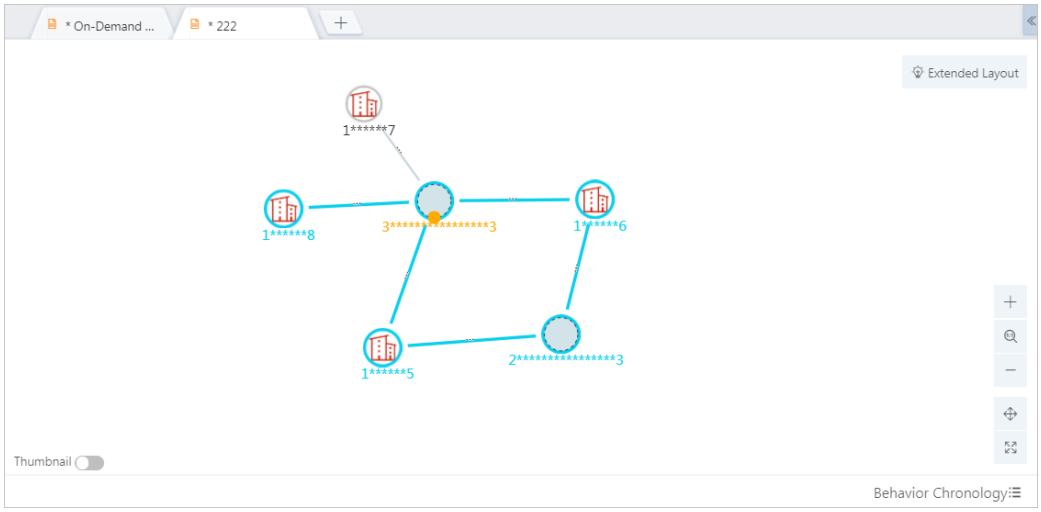
   Correlated Degree: If this parameter is not specified, the shortest path is analyzed by default. If you enter N, all paths with degrees less than or equal to N will be searched. N is specified by Administration Console and cannot be higher than 6.

7. Click **Search** to perform a path analysis on the data of this page.

   Results of shortest path analysis - only data of this page



Results of the path analysis with a specified correlated degree - only data of this page



8.12.8.5. Backbone analysis

Based on the membership network on the current page, the backbone analysis uses smart service algorithms to help you explore the key nodes in a relationship network.

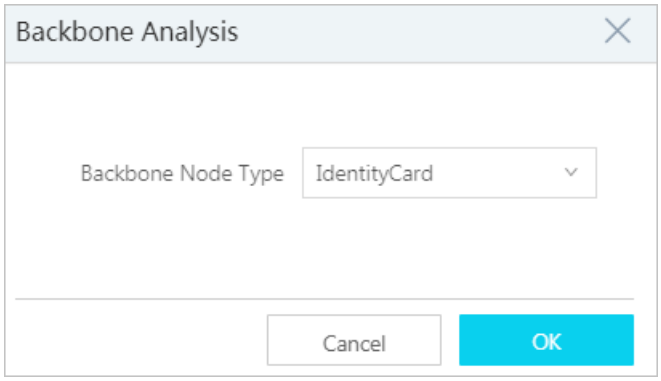
Prerequisites

- You have obtained an account and a password with the permission to perform graphic operations.
- An analysis file exists. For more information about how to add an analysis, see Create analyses.
- An object node already exists. For more information about how to add a node, see Add a node.

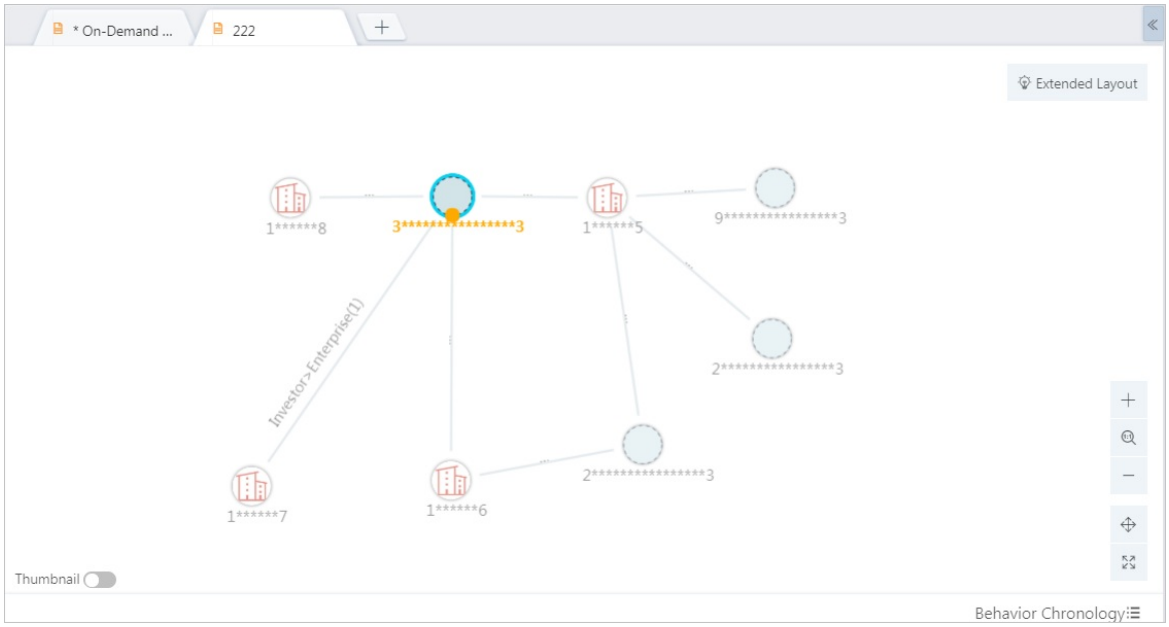
Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create a new analysis, and select an object node in the graph area.

3. In the toolbar, choose **Analyze** > **Backbone Analysis**, and set the Backbone Node Type in the dialog box that appears.



4. Click **OK**, and the key nodes in the graph area are highlighted.



8.12.8.6. Intimacy measurements

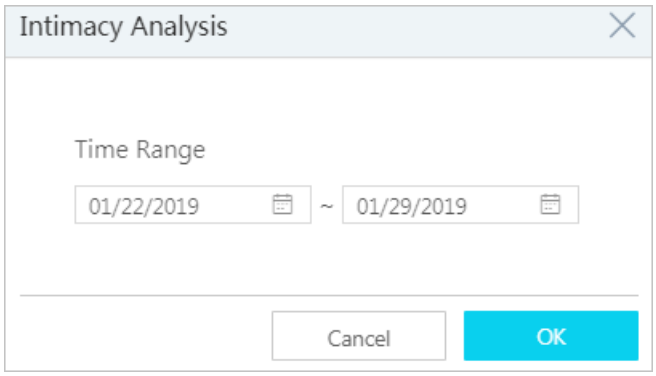
Perform an intimacy measurement to query the intimacy among objects of a specific type based on the intimacy settings configured in Administration Console.

Prerequisites

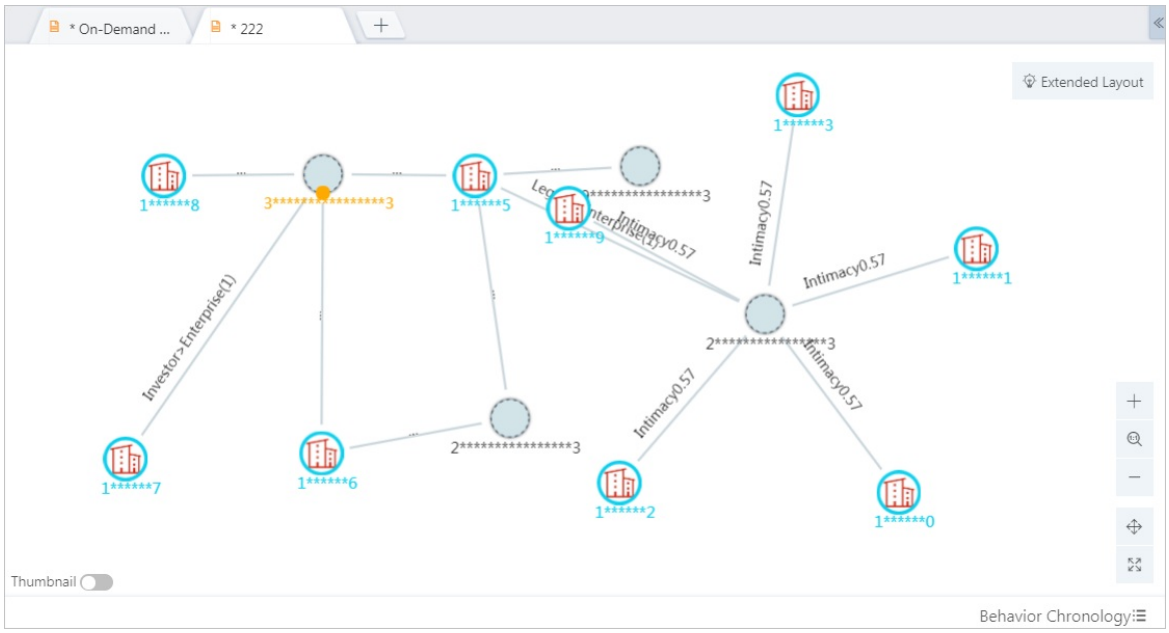
- Make sure that you have obtained an account and a password with the permissions to perform graphic operations and intimacy measurements.
- Make sure that you have configured intimacy settings in Administration Console. For more information, see Intimacy measurement settings.
- An analysis file already exists. For more information about how to create a new analysis, see Create analyses.
- An object node already exists. For more information about how to add a new node, see Add a node.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create an analysis, and select one or more nodes of the same type that have been created in the graph area.
3. Choose **Analyze** > **Intimacy Measurement** from the toolbar. In the **Intimacy Measurement** dialog box, set the time range.



4. Click **OK** to perform an intimacy measurement on the selected nodes.



8.12.9. Lock or unlock nodes

The node locking function keeps the node in a fixed position in the canvas to facilitate your operations.

Prerequisites

Make sure that you have obtained an account and a password with the permission to perform graphic operations.

Context

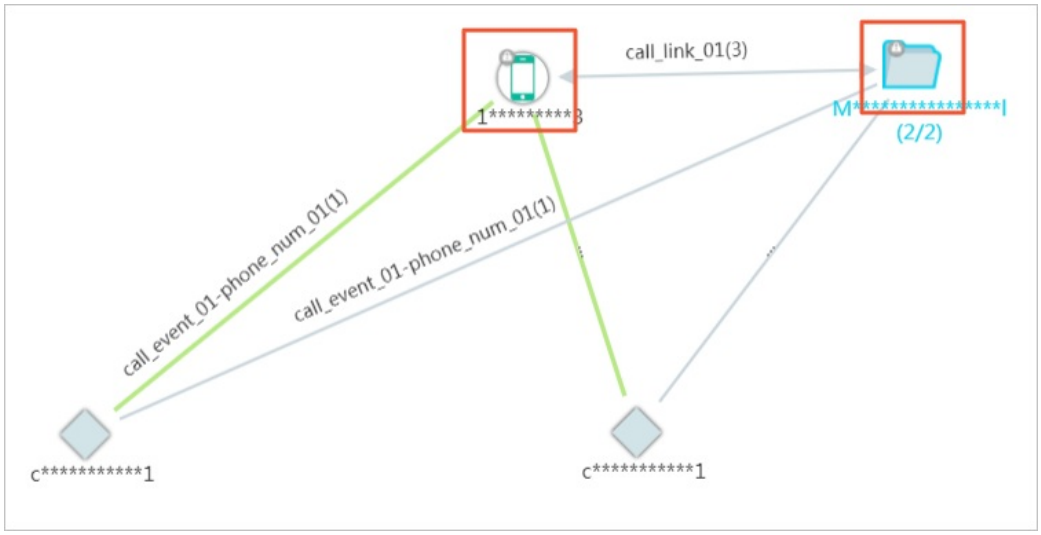
Except for nodes in the **Force-Directed Layout**, nodes in other layouts cannot be dragged. However, when the canvas moves as a whole, the locked nodes will move with the canvas.

Procedure

1. Log on to Analytics Workbench, and open an existing analysis file or create an analysis.
2. You can lock or unlock nodes by using the following methods.

Method	Operation
Lock nodes	In the canvas, select one or more nodes, including merged nodes, and click the **Lock** icon in the toolbar to lock the selected nodes or merged nodes. When a node is locked, you can see a gray lock at the top left of the node, as shown in Lock nodes.
Unlock nodes	In the canvas, select one or more nodes, including merged nodes, and click the **Unlock** icon in the toolbar to unlock the selected nodes or merged nodes. When a node is unlocked, the gray lock at the top left of the node disappears. **Note** If you split a locked merged node, the split nodes are automatically unlocked.

Lock nodes



8.12.10. Network analysis

Network Analysis can be used to analyze node relationships from multiple perspectives, such as location precedence, closeness, and activity frequency.

Prerequisites

You have obtained an account and a password with the permission to perform network analyses.

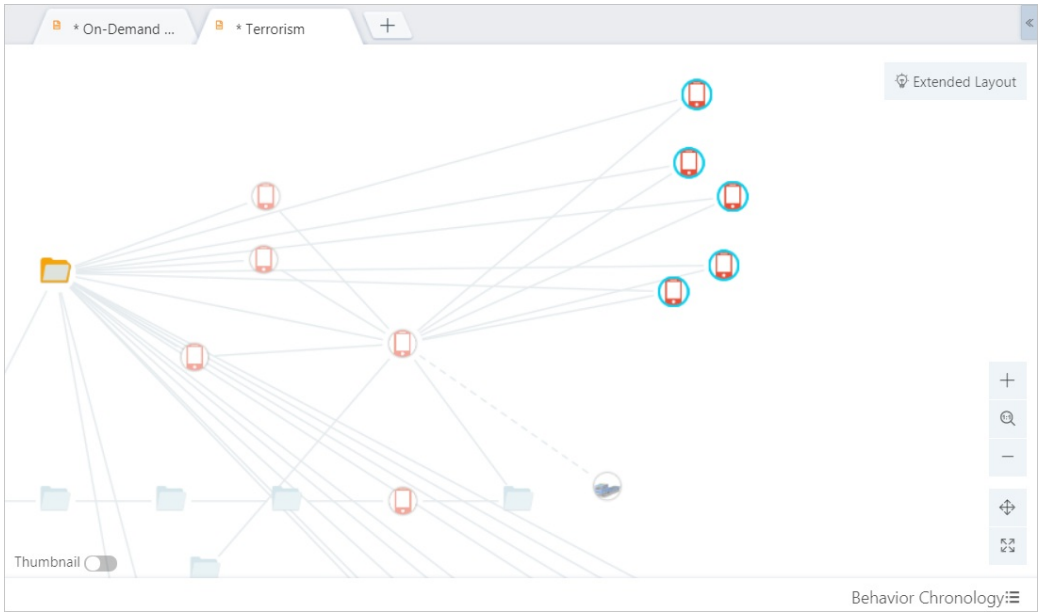
Context

The features of network analysis are described as follows:

- Closeness: Searches the key nodes that are most closely related to other parts of the network and checks the statuses of these nodes.
- Location precedence: Searches the bridging nodes that control the information flow.
- Activity frequency: Searches objects that are more active and more frequently interacted with other objects.
- Data flow direction: Searches the flow of relational data between objects in the network. It is only valid for directed relationships.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create a new analysis, and select one or more object nodes in the graph area.

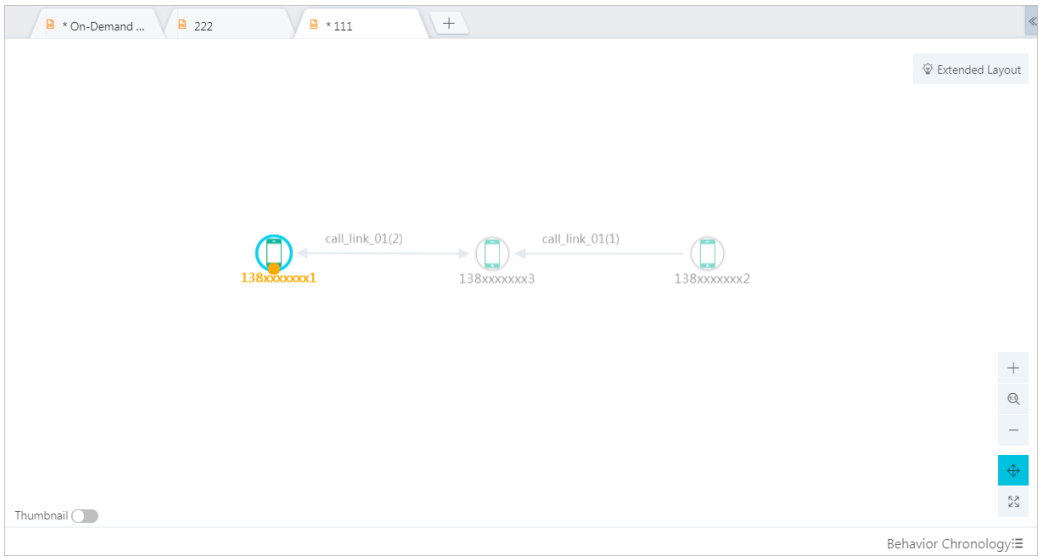


3. Example of location precedence analysis: In the toolbar, choose **Network Analysis** > **Location Precedence**, as shown in Location precedence analysis.

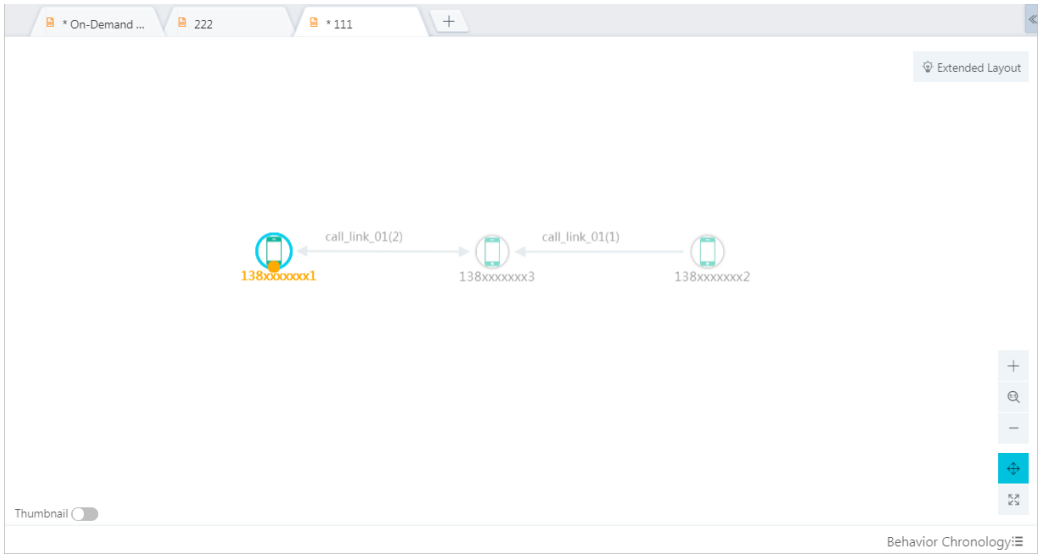
   Location precedence analysis

Other analysis examples are shown in Closeness analysis, Activity frequency analysis, and Data flow direction analysis.

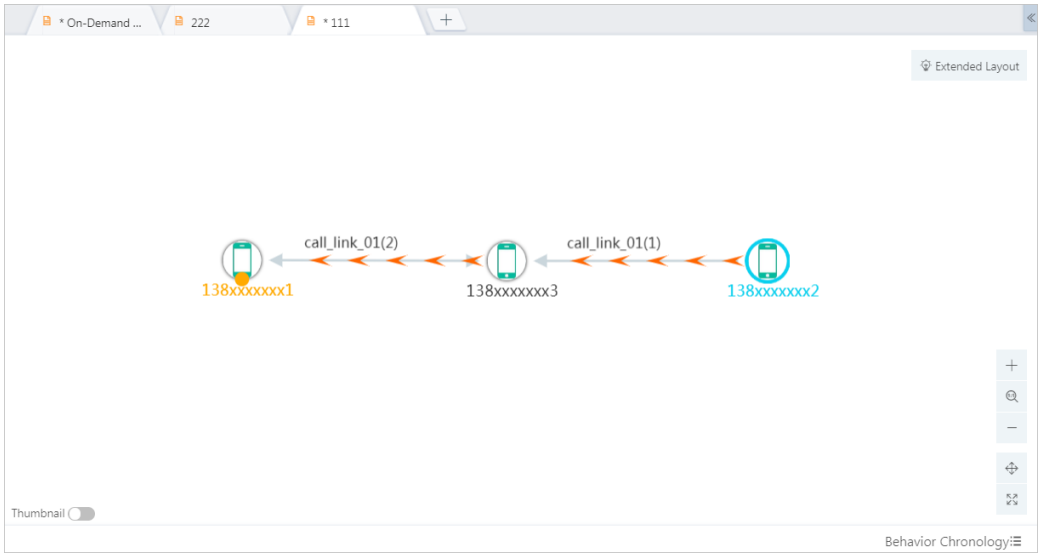
Closeness analysis



Activity frequency analysis



Data flow direction analysis



8.12.11. Closed-loop mining

Closed-loop mining allows you to check one or more nodes for continuous closed-loop links. This feature can be used to analyze cases including cash advance cases.

Prerequisites

- You have obtained the account and password with the permission to perform graphic operations.
- An analysis file already exists. For more information about how to create a analysis, see Create analyses.
- One or more node objects already exist. For more information about how to create a node, see Add a node.

Context

A closed loop refers to a link that starts from a node and ends at the same node. The following closed loops are available: the third-degree closed loops, fourth-degree closed loops, fifth-degree closed loops, and the sixth-degree closed loops.

The following example shows that a credit card cash advance will eventually return to the cashier regardless of the direction of the fund flow. For example, A is the cashier, and both B and C are coordinators. The fund flow is typically A > B > C > A, which forms a closed loop.

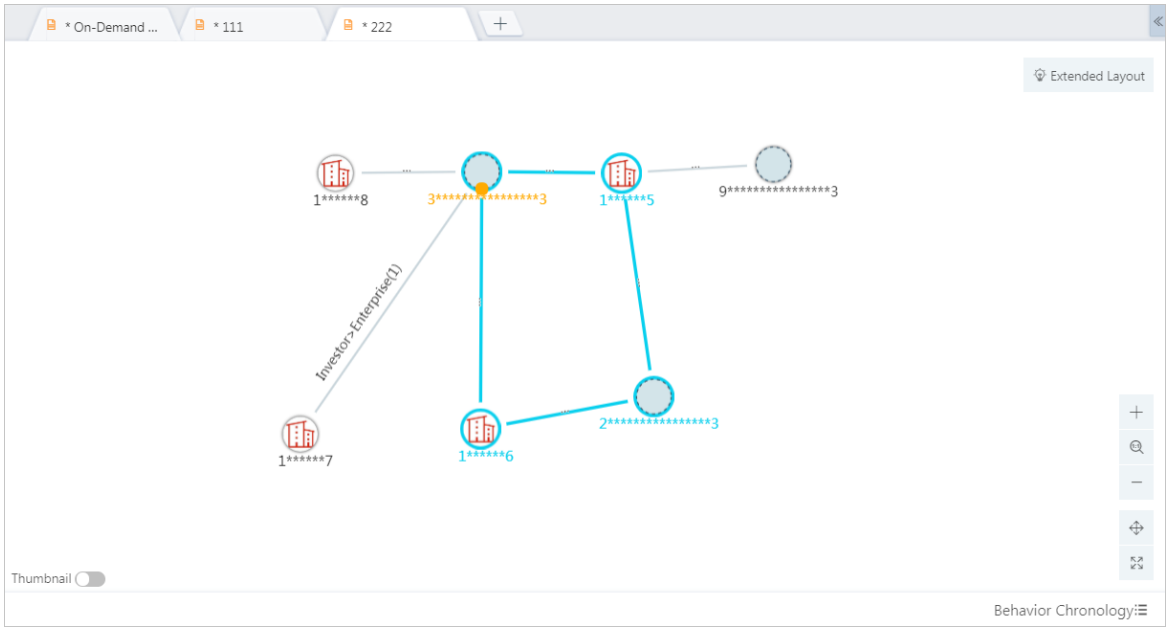
This topic describes loop steps by analyzing the third-degree closed loop of phone calls.

Procedure

1. Log on to Analytics Workbench.
2. Create an analysis and perform related analyses, or open an analysis file that already has analysis results.
3. Select a node in the analysis result, and choose **Closed-Loop > 3-Degree Closed Loop** in the toolbar.
4. In the dialog box that appears, specify **Directionality** and the link, and then click **OK**.

   Directionality has the following options:

   - *Undirected*: Analyzes both directional and undirectional closed-loop links on the specified node.
   - *Directed*: Analyzes only the directional closed-loop links on the specified node.



8.12.12. Layouts

In Graph Analytics, you can easily analyze the content in multiple layouts.

Prerequisites

You have obtained an account and password with **Layout** permissions.

Background

Supported layouts are as follows.

Layout	Description
Matrix Layout	Objects are arranged in a matrix structure to help you sort and organize information during the analysis process.
Circle Layout	Objects are organized and evenly arranged in a circle to display their relationships. This layout helps you sort information and analyze the key nodes during the analysis process.
Horizontal Layout	Objects are arranged along a horizontal line to help you analyze the information from a horizontal perspective.
Vertical Layout	Objects are arranged along a vertical line to help you analyze the information from a vertical perspective.
Force-Directed Layout	The force-directed layout is used to visualize complex networks. All edges are more or less of equal length and there are as few intersecting edges as possible. With nodes and the weights of edges defined in advance, the force-directed layout positions the nodes automatically according to the principle that a higher weight leads to shorter distance. This procedure is convenient for you to tell how close nodes are from each other. This is a global layout where all object nodes and links in the graph area of Graph Analytics are calculated.
Hierarchical Layout	Objects are arranged in a tree structure. The hierarchical layout is used for family trees and the organizational structures of enterprises.

Procedure

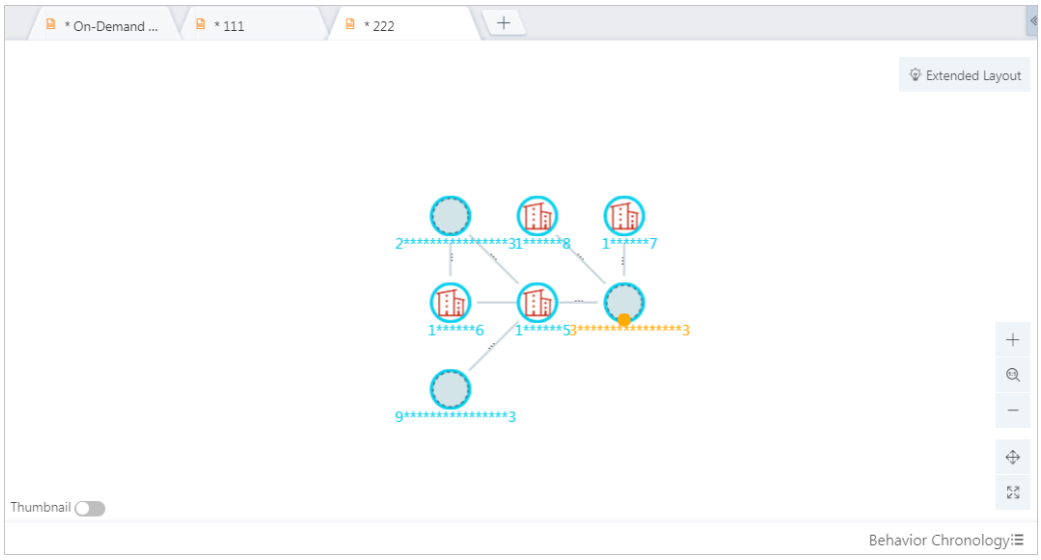
1. Log on to Analytics Workbench.
2. You can create a new analysis and produce the analysis results. Or, you can open an analysis file that already has the analysis results.
3. Take the matrix layout as an example. In the toolbar, choose **Layout** > **Matrix Layout**, as shown in Matrix layout.

   > **Note** We recommend that you choose a suitable layout for your business, so that you can easily view the analysis data.

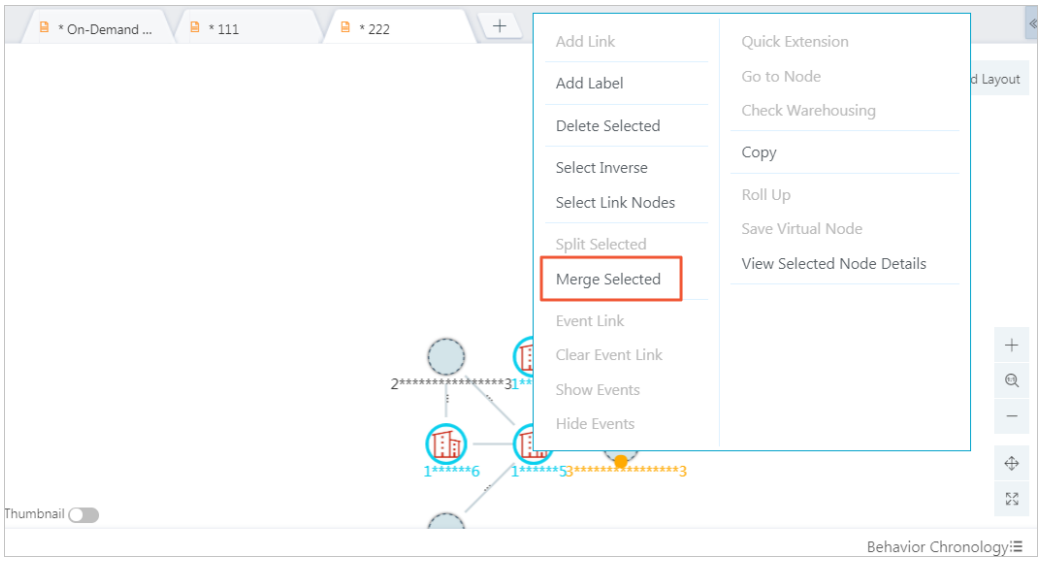
   The matrix layout can be used with the Merge Nodes feature, as shown in Merge nodes. This operation can sort and merge the analysis results when you hand large amounts of information. The merged result is shown in Merged result.

   Other layouts are shown in Circle layout, Horizontal layout, Vertical layout, Force-directed layout, and Hierarchical layout.

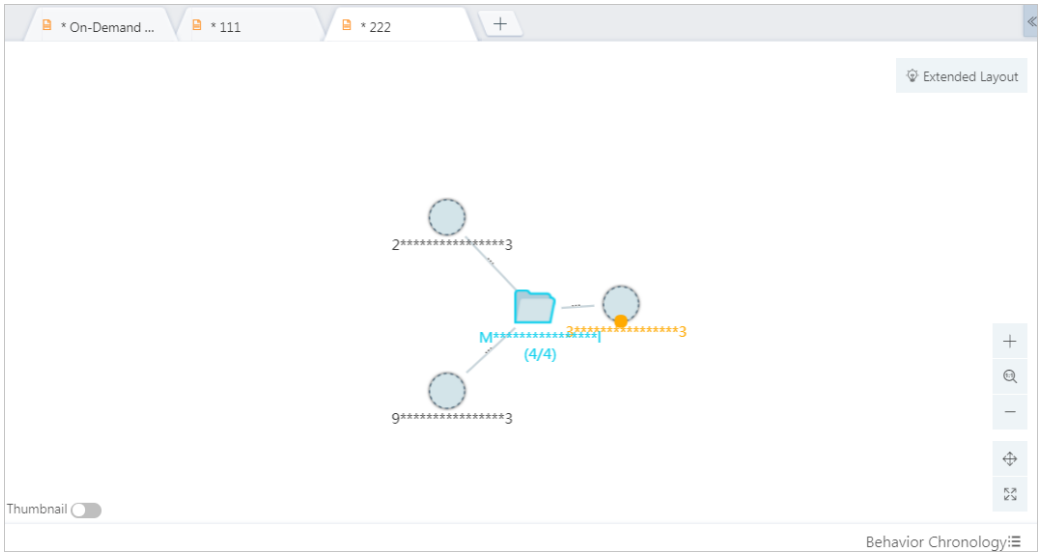
Matrix layout



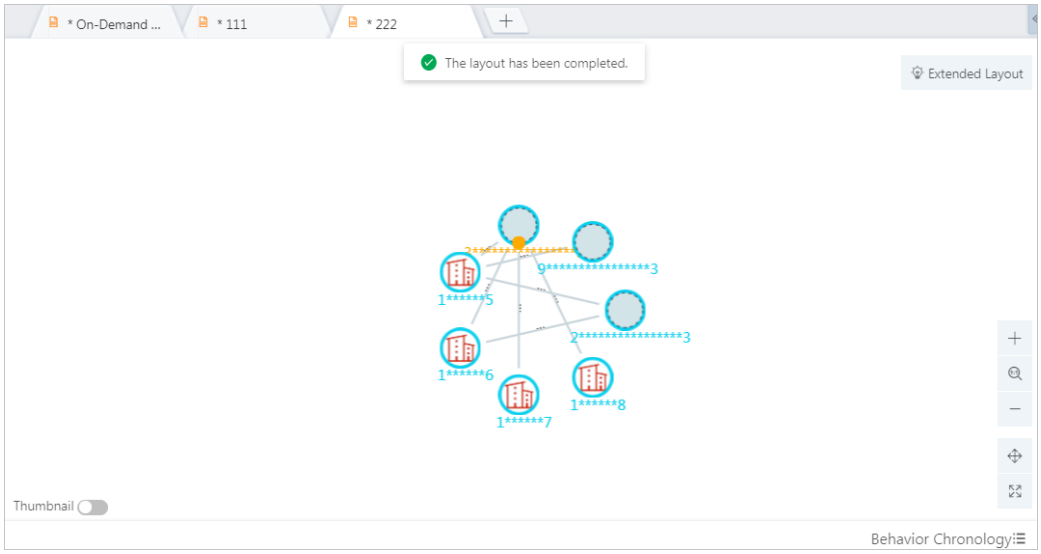
Merge nodes



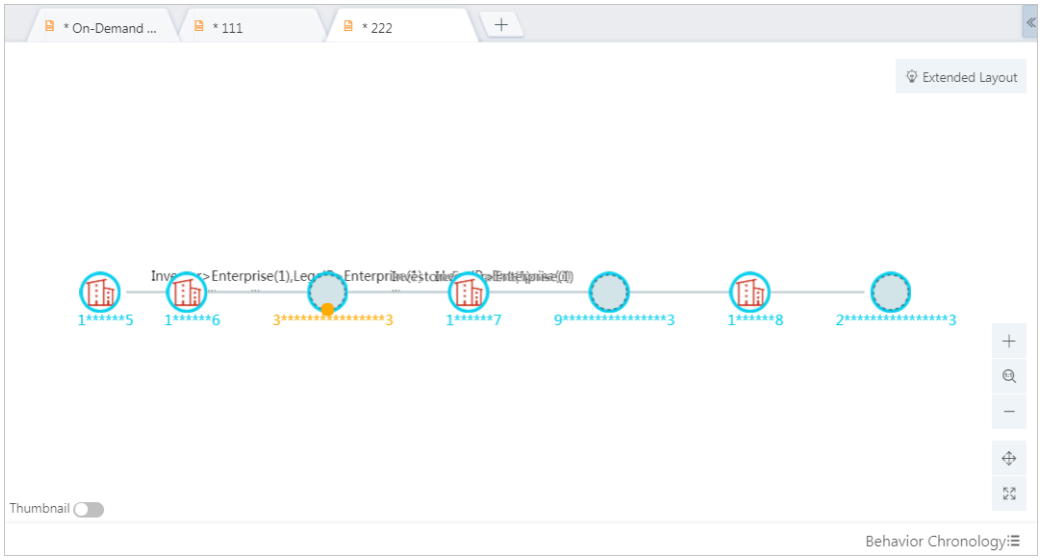
Merged result



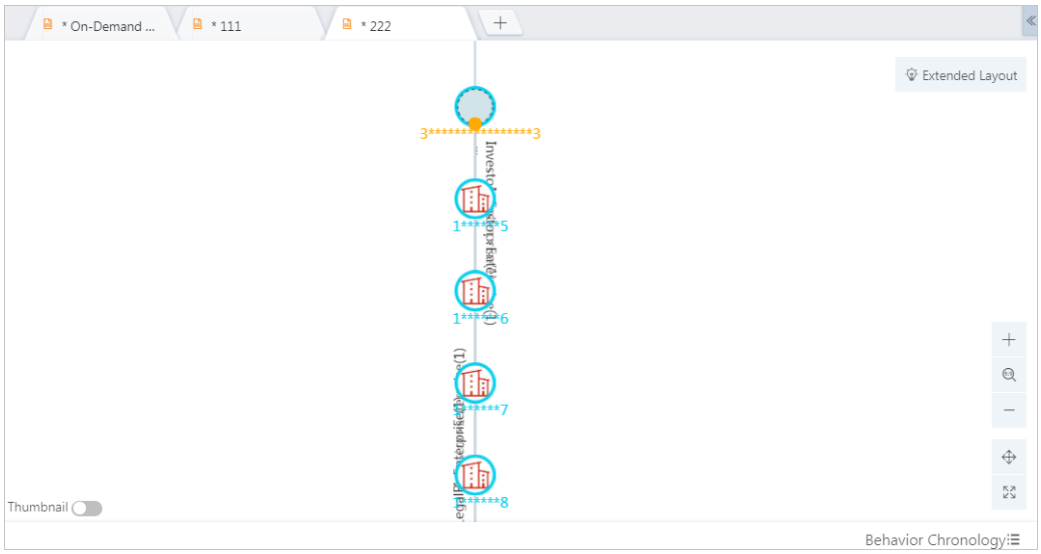
Circle layout



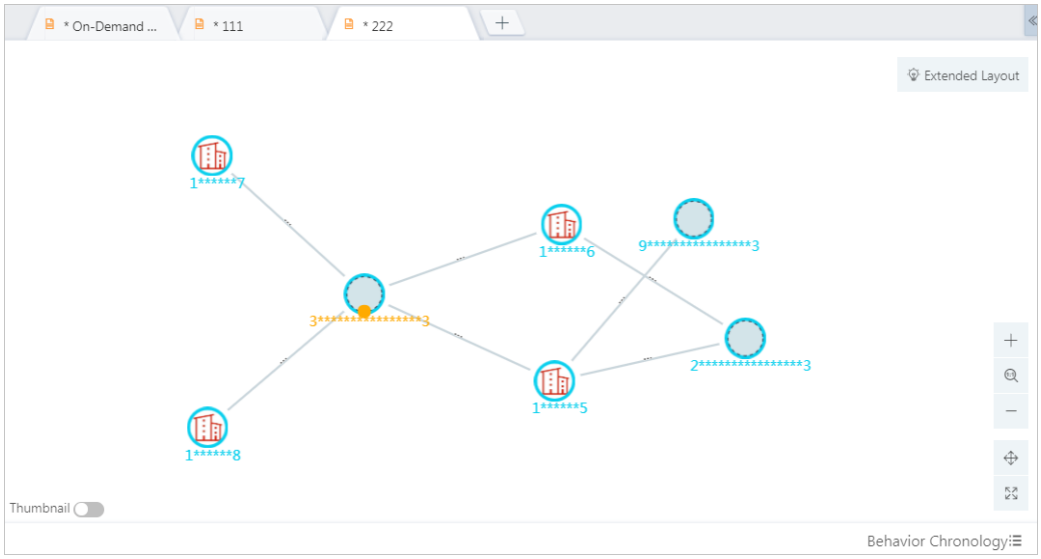
Horizontal layout



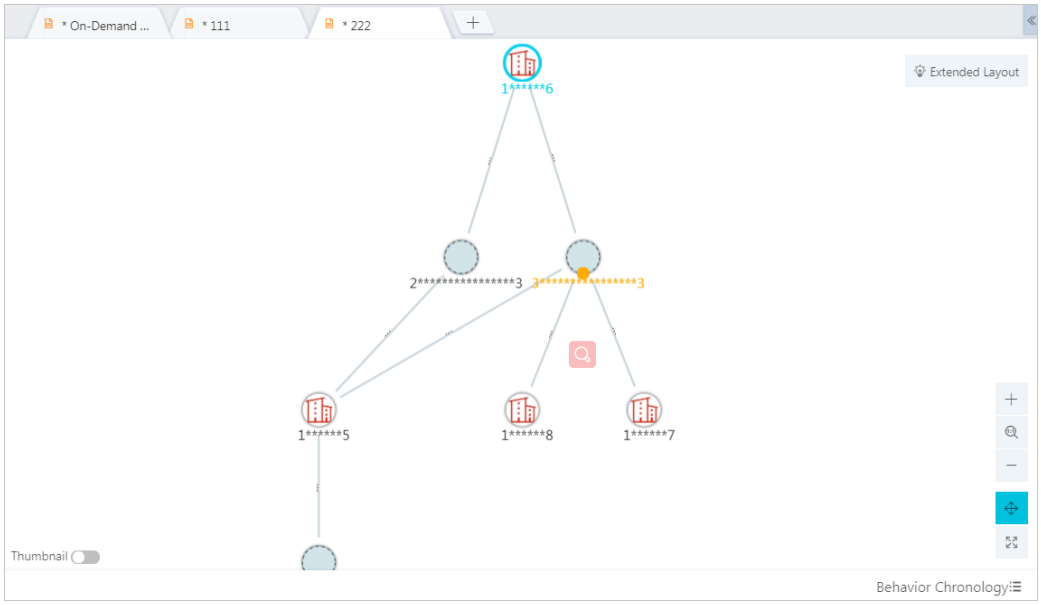
Vertical layout



Force-directed layout



Hierarchical layout



8.12.13. Flag and unflag nodes

When you analyze a large number of object nodes, you can highlight the key object node by adding a small red flag to the node.

Prerequisites

An object node already exists. For more information about how to add a node, see Add a node.

Context

You can perform flag operations on single nodes and merged nodes.

Procedure

1. Log on to Analytics Workbench.
2. Click an existing analysis file to open the file on the Graph page, or click **Create Analysis** to create an analysis file and add nodes.
3. Perform the flag and unflag operations as follows.

Operation	Procedure
Flag	Select the target nodes or merged nodes, and then click **Flag** in the top navigation bar. A red flag is displayed on the selected node or merged node.
Unflag	Select the target nodes or merged nodes, and then click **Unflag** in the top navigation bar. The red flag displayed on the selected node or merged nodes disappears.

8.12.14. Labels

8.12.14.1. Label types

You can use labels to identify the content, category, and other properties of the node, which is easy for you and other users to search and locate nodes. In Graph Analytics, you can add label content to the node objects in the graph area. Labels are divided into system labels and user labels.

You can attach a system label or a user label to each node object.

- **System labels**: labels attached to the node objects by the system based on algorithms.

  The system labels are displayed on the left side of the nodes. You cannot delete or modify the labels or click the Like button on the system label.

- **User labels**: labels attached to objects by the user.

  The user labels are displayed on the right side of the nodes. The user labels with certain permissions can be deleted and liked by corresponding users.

8.12.14.2. User labels

Graph Analytics supports four types of user labels. The visible ranges and operations for labels vary by type.

User label types

- **Public**

  After the analysis is shared, all people can see the label and click the Like button on this label.

- **Only Me**

  This label is visible only to the person who added the label. After the analysis is shared, other people cannot see this label.

- **Only for This Analysis**

  This label is visible only in the current analysis, and the Like button of the label can only be clicked in the current analysis. After a node with this label has been copied to another analysis, this label becomes invisible.

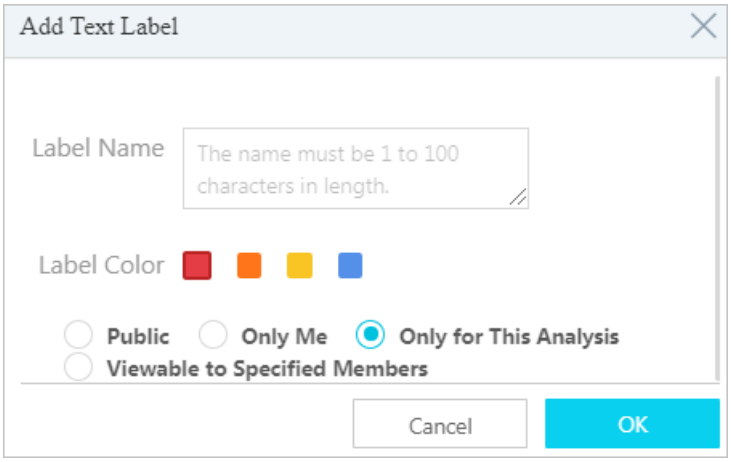
- **Viewable to Specified Members**

  This label can only be seen and liked by the users that are specified when the analysis is shared.

User label colors

You can add user labels of different colors. By default, four colors are provided to differentiate the labels: red, yellow, blue, and green, as shown in User label colors.

User label colors



8.12.14.3. Add user labels

When some nodes are hard to understand, you can classify and describe these nodes by adding labels. This helps you and other users to understand these nodes quickly and easily.

Prerequisites

Make sure that you have obtained an account and a password with the permission to perform graphic operations.

Context

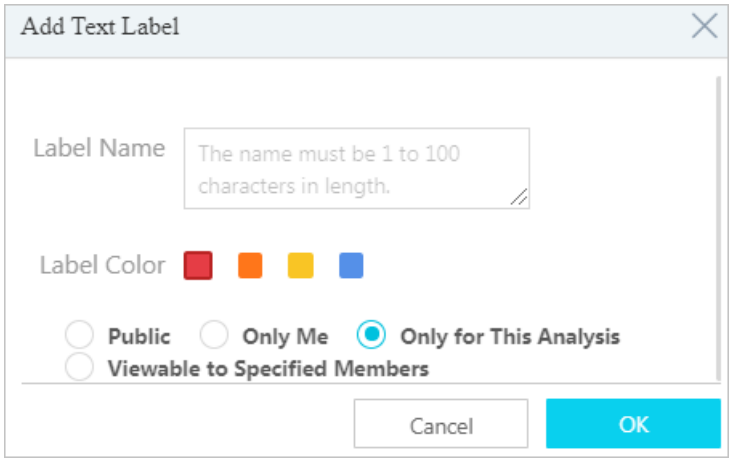
Based on the visible range, labels can be divided into four types: Public, Only Me, Only for This Analysis, and Viewable to Specified Members.

> **Note** You cannot add labels to merged nodes.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create an analysis.
3. You can use one of the following methods to add a label:
   - Select one or more nodes in the graph area, right-click a selected node, and then select **Add Label**. Set the parameters in the dialog box that appears.
   - Select one or more nodes on the **Details** tab of the right-side pane, click the **Text Note** icon in the top of the pane, and then set the parameters in the dialog box that appears.

   The parameters are described in Parameters and descriptions.



Parameters and descriptions

Parameter	Description
Label Name	The note or description of the node, which helps you and other users understand the node. The label name must be from 1 to 20 characters in length.
Label Color	The color of the label displayed in the graph area for easy identification. Four colors are supported: red, orange, yellow, and blue.
Visible range options	◦ **Public**: Users who use the node can see the label and click the Like button of the label. ◦ **Only Me**: The label is visible only to the person who added the label. Other users cannot see the label when they add this node to the graph area. ◦ **Only for This Analysis**: You can see the label and click the Like button of the label only in the current analysis. This label is invisible after this node is added to or appears in another analysis. ◦ **Viewable to Specified Members**: Only the specified users can see the label and click the Like button of the label. When you select **Viewable to Specified Members**, you must specify users as needed.

4. Click **OK**. A success message is displayed after the label has been added.

8.12.14.4. View labels

In Graph Analytics, you can view labels by type and easily analyze the object nodes.

Prerequisites

There are labels visible to you in the current analysis file.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create a new analysis. You can switch the display mode of the labels based on your needs.

Display mode	Operation
All Labels	In the toolbar, click **All Labels**. The system labels of each node and the labels visible to you in the current analysis are displayed in the graph area.
My Labels	In the toolbar, click the label icon and select **My Labels**. All labels created by you for the displayed node are shown in the graph area.
Hide Labels	In the toolbar, click the label icon and select **Hide Labels**. All labels in the graph area are hidden.

8.12.14.5. Click likes and delete likes

When you agree on a label that was added by another user to a node, you can click the Like button for the label.

Prerequisites

- Make sure that you have obtained an account and a password with the permission to perform label-related operations.
- Make sure that other users have added labels that are visible to you.

Context

Only labels that are Public, Only Me, and Viewable to Specified Members can be liked. By default, every label has one like. When the last like of a label is canceled, the label is removed from the node.

After you like a label, the number of likes increases by 1, and the Like button changes to the Undo Like button. After you undo a like, the number of likes decreases by 1.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create an analysis, and add or locate a node that has user labels that are visible to you.
3. Click the label number next to the node, and click a label name. The detailed information about the specified label is displayed.

4. If you agree on the label content, click the Like button . A success message is displayed after the operation is completed.

What's next

If you think that a label you previously liked does not match the node, you can click the Undo Like button to undo the like.

8.12.14.6. Edit user labels

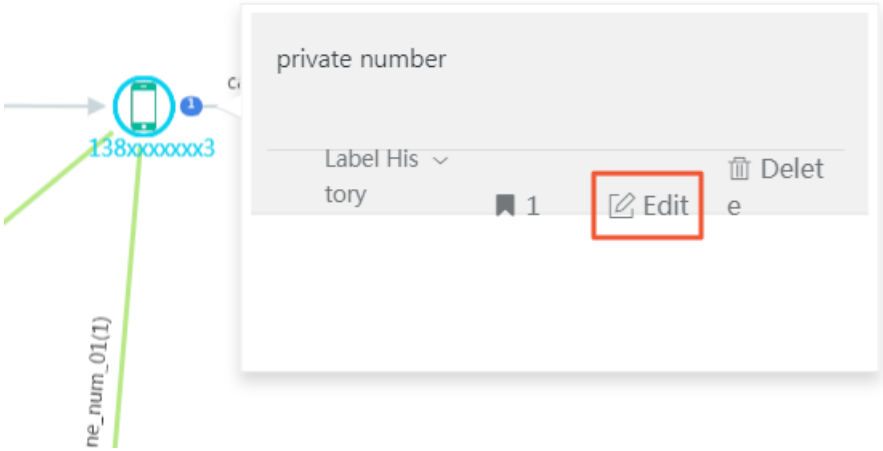
If the name, color, or visible range of a user label is unacceptable, you can edit the user label.

Prerequisites

- You have obtained the account and password with the permission to perform label-related operations.
- Other users have created user labels that are visible to you.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create an analysis, and add or locate a node that has user labels that are visible to you.
3. Click the label number next to the node, click a label name, and view the label details.



4. Click **Edit**, and re-set the parameters in the dialog box that appears.

   For more information about the parameter settings, see Parameters and descriptions in Add user labels.

5. Click **OK**.

8.12.14.7. Delete user labels

You can delete unnecessary user labels.

Prerequisites

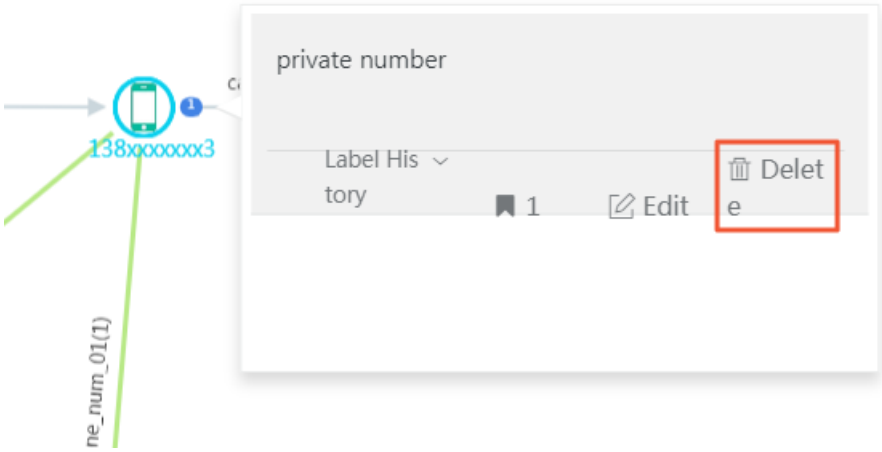
You have obtained the account and password with the permission to perform label-related operations.

Context

If the label is created by you and the number of likes is 1, you can cancel the like, and the number of likes becomes 0. When the number of likes for a label becomes 0, the system automatically deletes this label.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create an analysis, and add or locate a node that has user labels that are visible to you.
3. Click the label number next to the node, and click a label name to view the detailed information about the label.



4. Click the **Delete** icon, and click **OK** in the dialog box that appears. A message is displayed, indicating that the label has been deleted successfully. If the label is created by you and currently has only one like, you can click the delete icon to delete the like, and the number of likes becomes 0. The system will automatically delete this label.

8.12.15. Save analysis

After the analysis is modified, you must save the modifications before you close the analysis. Graph Analytics provides a screenshot analysis function. When an analysis is saved, Graph Analytics generates a global screenshot for the analysis graph and saves the screenshot to the server.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- You have created a new analysis or modified an existing analysis.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis file or create a new analysis.
3. (Optional)Perform multiple operations on an existing analysis or a new analysis in the graph area, such as adding nodes, setting layouts, and performing analyses.
4. The following may occur when you click the **Save** icon in the toolbar.

Operation	Description
Save existing analyses	Saves the analysis content in the graph area by the original name and the original path.
Save new analyses	If you are creating a new analysis, you need to set File Name and Folder of the analysis in the **Save Analysis** dialog box that appears, and click **OK** to save the analysis content in the graph area.

8.12.16. Print graph areas

Analytics Workbench enables you to print the content of an analysis from different perspectives. You can export the content as a paper document, or save the content as a PNG image.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- Make sure that the system has connected to a printing device.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis, or create a new analysis and have the results analyzed.
3. You can print the analysis content or save the analysis content as an image.

Print area	Operation

Print area	Operation
Print the full graph	i. In the toolbar, choose **Print** > **Print Full Graph** . The print settings page appears. ii. Set the print parameters, and then click **Print** to print all the analysis content in the graph area.
Print the visible area	i. In the toolbar, choose **Print** > **Print Visible Area** . The print settings page appears. ii. Set the print parameters, and then click **Print** to print the analysis content in the visible area.
Print the selected subgraph	i. In the toolbar, choose **Print** > **Print Selected** . The print settings page appears. ii. Set the print parameters, and then click **Print** to print the analysis content of the selected nodes in the graph area.
Save the full graph as an image	In the toolbar, choose **Print** > **Save Full Graph as Image** . Save the analysis content as an image in the PNG format.

8.12.17. Share analyses

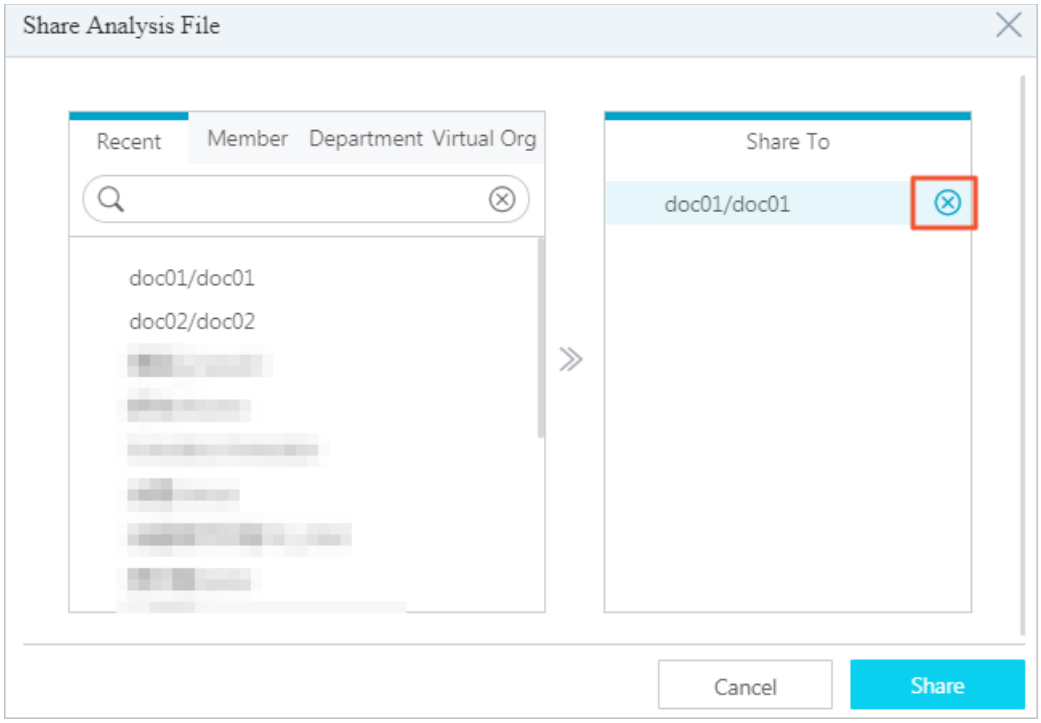
You can use Graph Analytics to share your current analysis with a specific user or group to perform a collaborative analysis. The shared users can view the shared analysis file after they log on to Analytics Workbench.

Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Procedure

1. Log on to Analytics Workbench.
2. Open an existing analysis or create a new analysis.
3. In the toolbar, click the **Share** icon and set the parameters in the dialog box that appears.



You can select the shared members individually by using the search and positioning feature. You can also select the shared members by department.

Members selected for sharing will be displayed in the **Share To** list on the right side. When the mouse pointer is moved over the member, you can see a Delete icon. You can click the icon to delete the current member.

4. After you have specified the shared members, click **Share**, and the system informs you that you have shared the analysis successfully.

What's next

The user you shared files with can choose **File Center** > **Shared with Me** in the top navigation bar to view and operate on the shared analysis files.

After a member receives a shared analysis, the system automatically creates a directory with the same name as the source analysis on the **Shared with Me** page. By default, the directory has two files: the **initial file** and the **automatically merged file**.

8.12.18. Behavior chronology

8.12.18.1. Details

Details are used to display the link and event details of an object.

Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

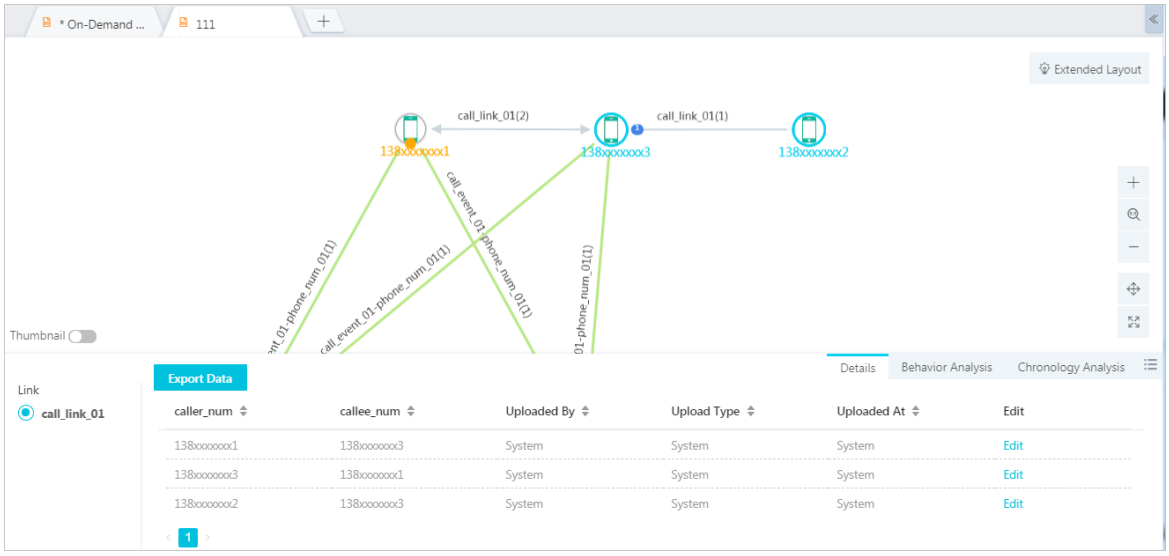
Procedure

1. Log on to Analytics Workbench.

2. Click an analysis file to open the file in the **Graph** area.
3. You can open the **Behavior Chronology** pane by using the following methods.

Method	Procedure
Method 1	Select an object in the **Graph** area, and click **Behavior Chronology** in the lower-right corner. The **Details** area is displayed by default.
Method 2	Select a link in the **Graph** area, and the **Behavior Chronology** pane appears automatically. The **Details** area is displayed by default.

4. On the left side of the **Behavior Chronology** pane, select a link or an event to view its details.



5. (Optional)Click **Export** to export the lists of behavior details for all links to an Excel file.

8.12.18.2. Behavior analysis

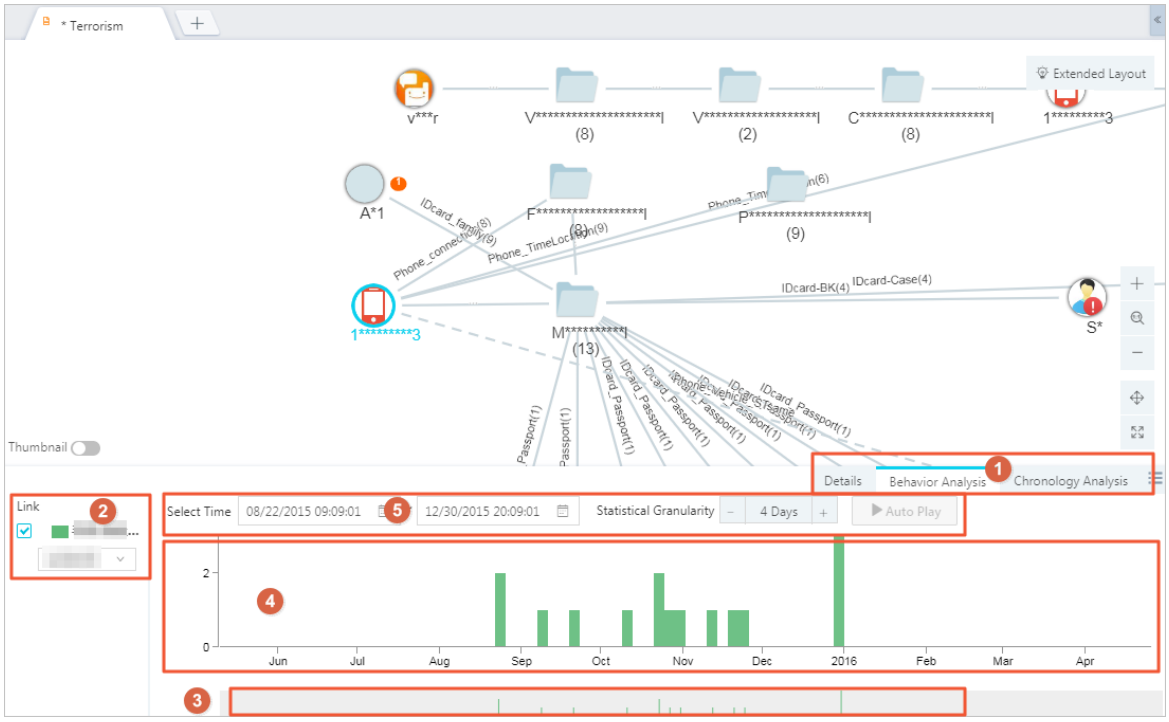
This feature allows you to display and analyze the link data with time properties on the Graph page.

Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

Procedure

1. Log on to Analytics Workbench.
2. Click an analysis file to open the file in the **Graph** area.
3. In the **Graph** area that appears, select an object for the behavior analysis.
4. Click the **Behavior Chronology** icon in the lower-right corner. In the **Behavior Chronology** pane that appears, click the **Behavior Analysis** tab.



The behavior analysis area is described as follows.

Description of the behavior analysis area

Area	Description
Area 1	You can switch to the **Behavior Analysis** tab.
Area 2	You can filter the links to be analyzed.
Area 3	You can filter data using the thumbnail. You can locate the range through the thumbnail at the bottom, and select the middle part to move the thumbnail.
Area 4	Move your mouse pointer to the column chart. Links that occurred at the current time point and the number of times the links have occurred are displayed. Click the column chart. The links and objects correlated to these links will be highlighted in the **Graph** area. Click and hold down the left mouse button and drag to select a time range. All links in the time range and objects correlated to these links will be highlighted in the Graph area.
Area 5	You can set the filter time range and the statistical granularity: ○ Set the start time and the end time for time-based filtering. ○ Click the + icon or the - icon to increase or decrease the statistical granularity.

5. For more information about how to analyze the behaviors of an object in the **Behavior**

Analysis area, see Description of the behavior analysis area.

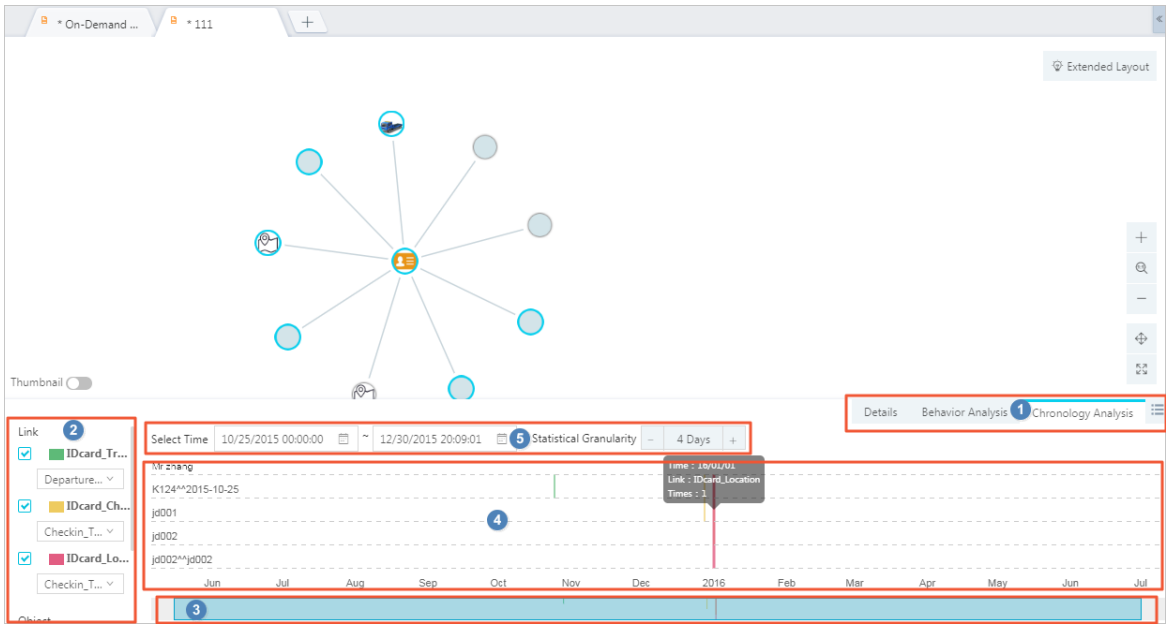
8.12.18.3. Chronology analysis

The chronology analysis shows the details of each event based on time.

Prerequisites

Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

1. Log on to Analytics Workbench.
2. Click an analysis file to open the file in the **Graph** area.
3. In the **Graph** area, select the object and link to perform a chronology analysis.
4. Click the **Behavior Chronology** icon in the lower-right corner. In the **Behavior Chronology** pane that appears, click the **Chronology Analysis** tab.



By default, only five objects can be displayed for an analysis in the chronology analysis area.

The chronology analysis area is described as follows:

Description of the chronology analysis area

Area	Description
Area 1	You can switch to the **Chronology Analysis** tab.
Area 2	You can select a link and an object. You can analyze a maximum of five objects at the same time.
Area 3	You can filter data using the thumbnail. You can locate the range through the thumbnail at the bottom, and select the middle part to move the thumbnail.

Area	Description
Area 4	When you move the mouse pointer to a specific chronology line, the details of the chronology appear. When you click the chronology line, the links and the objects involved in these links will be highlighted in the **Graph** area. Click and hold down the left mouse button and drag to select a time range. All links in the time range and objects correlated to these links will be highlighted in the **Graph** area.
Area 5	You can set the filter time range and the statistical granularity: ○ Set the start time and the end time for time-based filtering. ○ Click the + icon or the - icon to increase or decrease the statistical granularity.

5. For more information about how to analyze the behaviors of an object in the **Behavior Analysis** area, see Description of the chronology analysis area.

8.12.19. Property statistics

8.12.19.1. Details

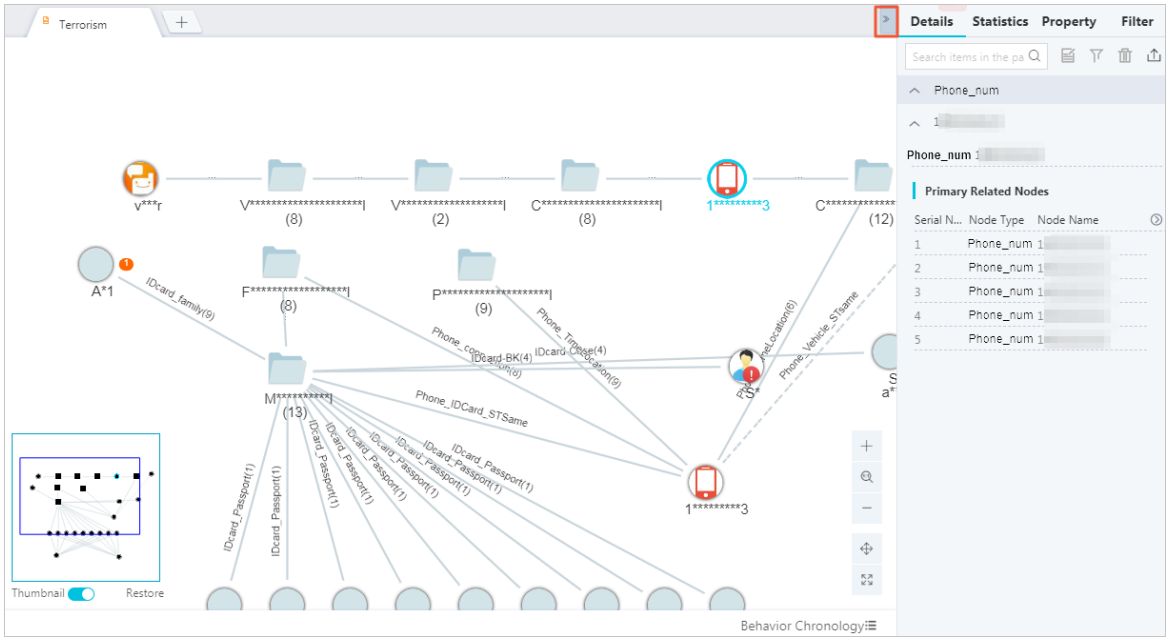
Typically, when you perform an analysis in Graph Analytics, a large number of objects will be involved. You may need to highlight the objects that are important to you. The properties and statistics area displays data with multiple properties. You can highlight the key objects on the Graph page.

Prerequisites

You have obtained an account and a password with the permission to perform network analyses.

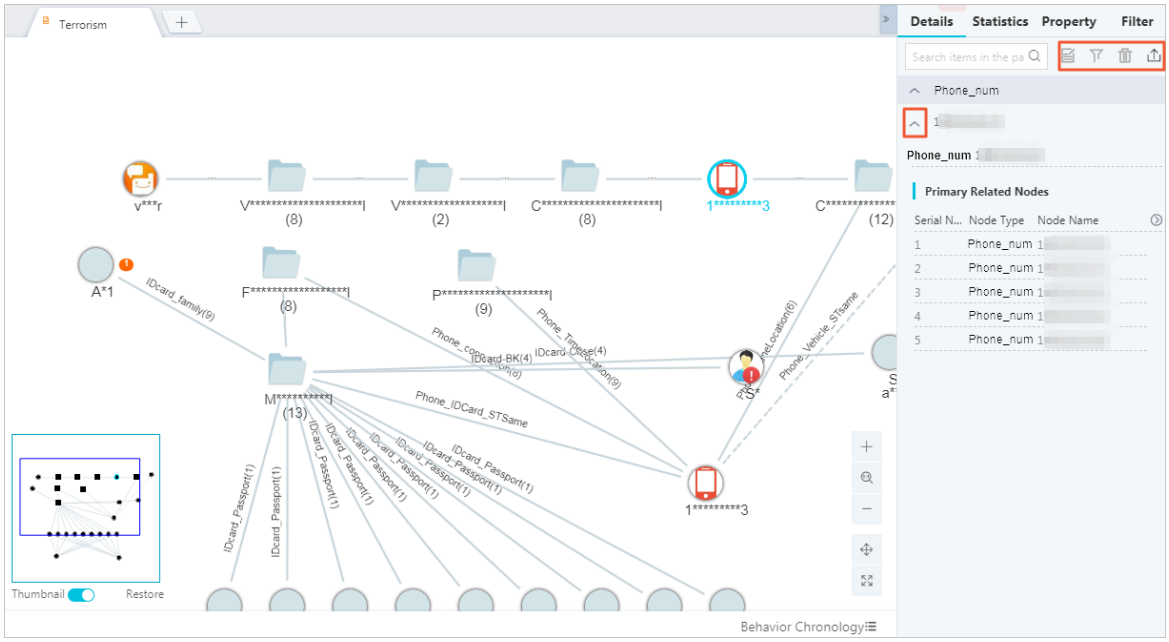
Procedure

1. Log on to Analytics Workbench.
2. Click an analysis file to open the file in the **Graph** area.
3. Select one or more objects or links in the **Graph** area.
4. Click the icon in the right side of the graph area to display the properties and statistics. By default, the **Details** tab is displayed.



The **Details** tab displays the basic information of the selected object, including the object type, object icon or avatar, object ID, object properties, and the correlated nodes.

5. You can perform the following operations in the **Details** tab.



Operation	Procedure
Highlight key objects	When you select objects in the right-side pane, the objects, links, and events in the graph area are masked, except for the selected objects. You can press the **Control** key to select multiple objects.

Operation	Procedure
View object details	When you select nodes or links in the main graph area, the details page on the right side shows all the property information of the selected nodes and links. You can press the **Control** key to select multiple nodes or links. If you select a link in the graph area, the details of the objects involved in the link are displayed.
Add text notes	Add text notes or labels. For more information, see Add user labels.
Select	Select the node in the graph area.
Delete	Delete the selected object in the graph area.
Export	Export the information of the selected object to an Excel file.

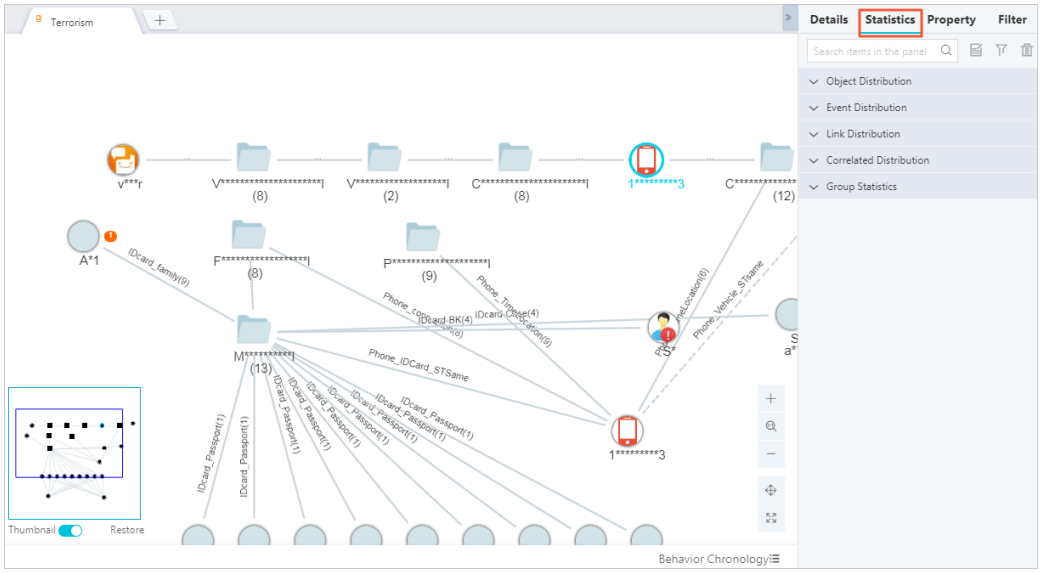
8.12.19.2. Statistics

The Statistics tab displays the statistics of the selected objects or links.

Procedure

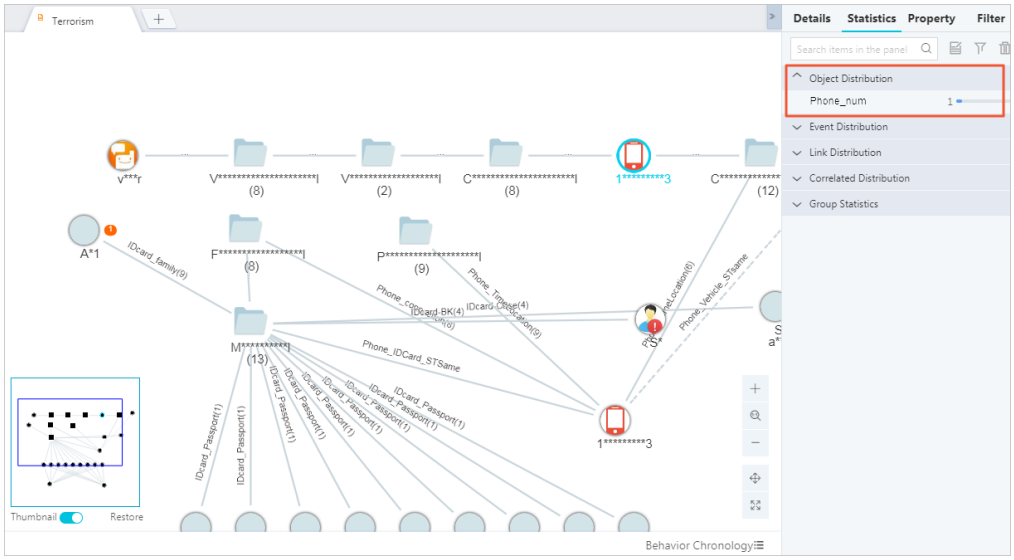
1. Log on to Analytics Workbench.
2. Select one or more nodes or links in the graph area.
3. Click the right arrow in the right side of the graph area to display the properties and statistics.
4. Switch to the **Statistics** tab, as shown in Statistics tab.

   Statistics tab



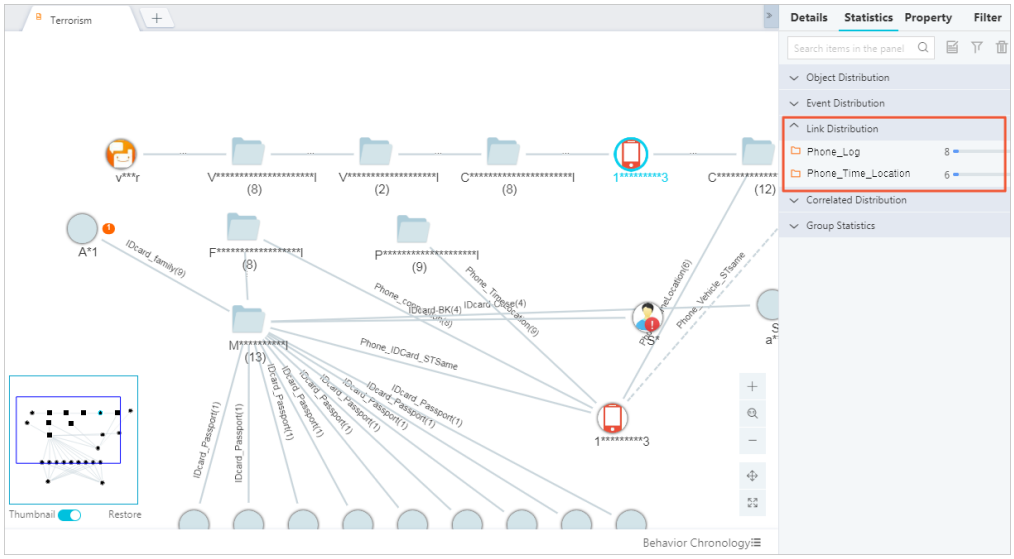
5. Click the up or down arrow to hide or show the properties of the selected object or link.
   - View the object distributions, as shown in Object distributions.

Object distributions



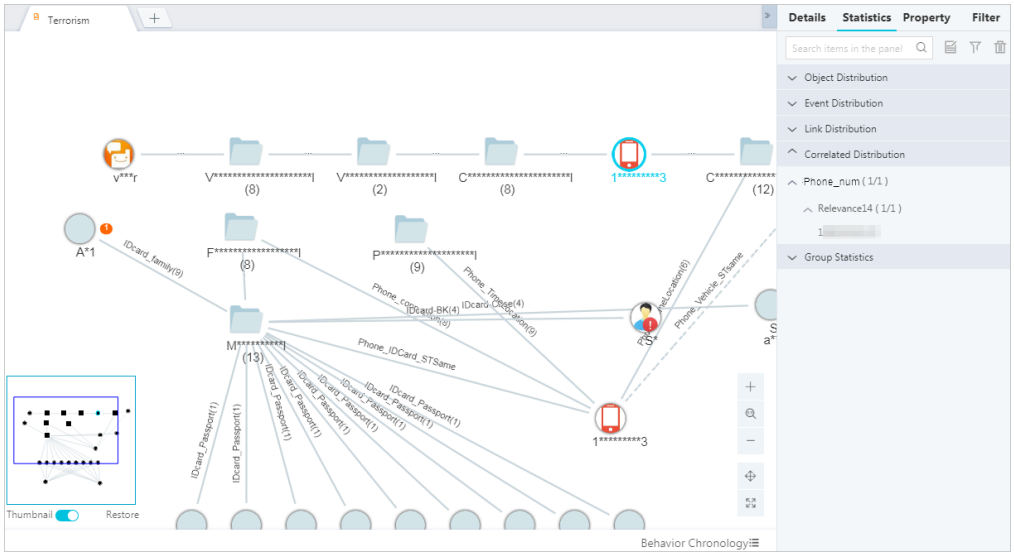
- View the link distributions, as shown in Link distributions.

  Link distributions



- View correlation distributions, as shown in Correlation distributions.

  Correlation distributions



- View the group analysis, as shown in Group analysis.

  Group statistics allows you to analyze group distributions in Graph Analytics. Group statistics is typically used to perform a group analysis. After you enter multiple nodes, Graph Analytics analyzes the interrelations between these nodes, provides the analysis results, and displays the group distribution. A group consists of multiple object nodes, with any two object nodes connected topologically. Nodes within a merged node are connected topologically.

  Group analysis

  - In group statistics, all isolated nodes form a group are called isolated nodes.
  - The list in group statistics displays the number of nodes and the labels of the nodes that have the highest correlated degree in each group, excluding the group of isolated nodes. Group of isolated nodes is displayed at the top of the list, while other groups are listed in a descending order according to the number of nodes contained in the group.

> **Note** Group statistics cover all nodes in Graph Analytics, regardless of your selection of nodes during the analysis process.

On the Statistics page, you can perform the following operations for the selected content:

- Text Note: You can add text notes. For more information, see Add user labels.
- Selected: You can select the node in the graph area.
- Delete: You can delete the selected object in the graph area.

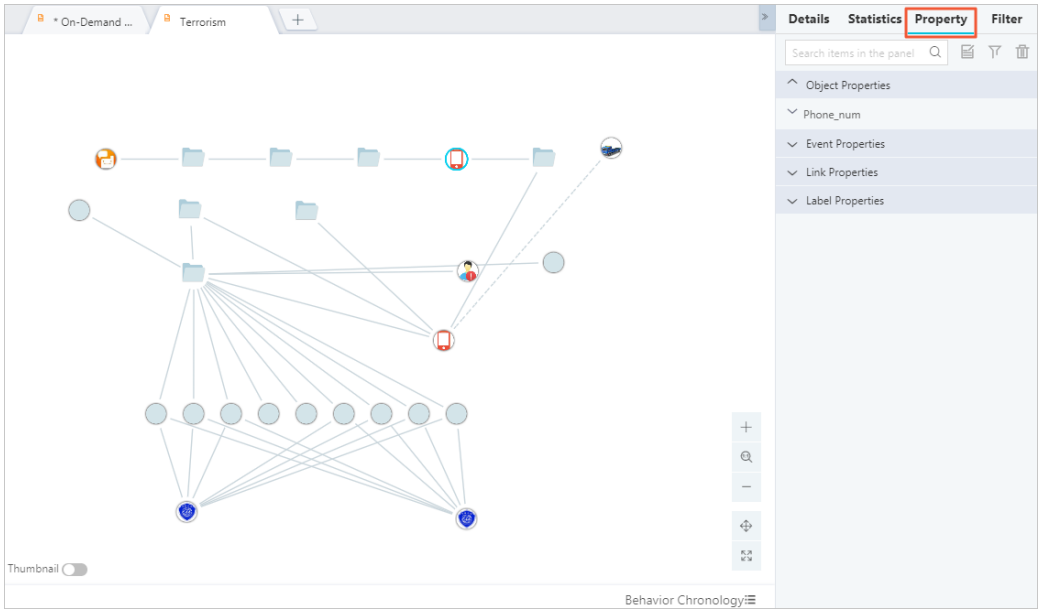
8.12.19.3. Property information

The Property tab in the right-side pane of the Graph page displays the object or link information and the label information of the selected objects or links.

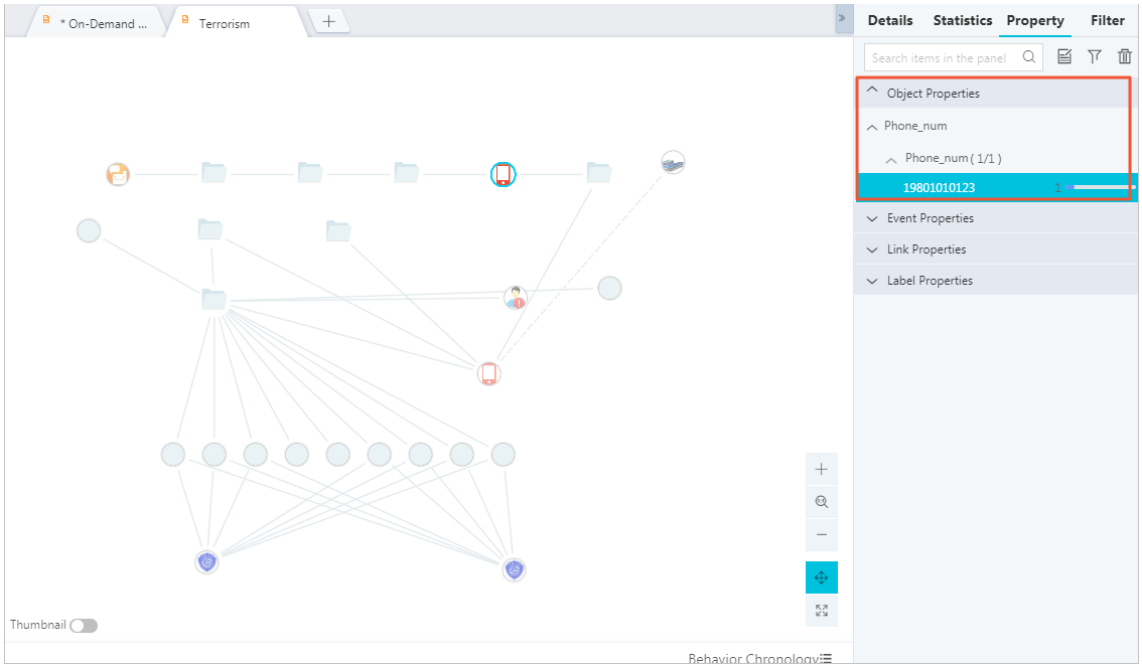
Procedure

1. Log on to Analytics Workbench.
2. Select one or more nodes or links in the graph area.
3. Click the right arrow in the right side of the graph area to display the properties and statistics.
4. Click the **Property** tab. The Property tab appears, as shown in Property tab.

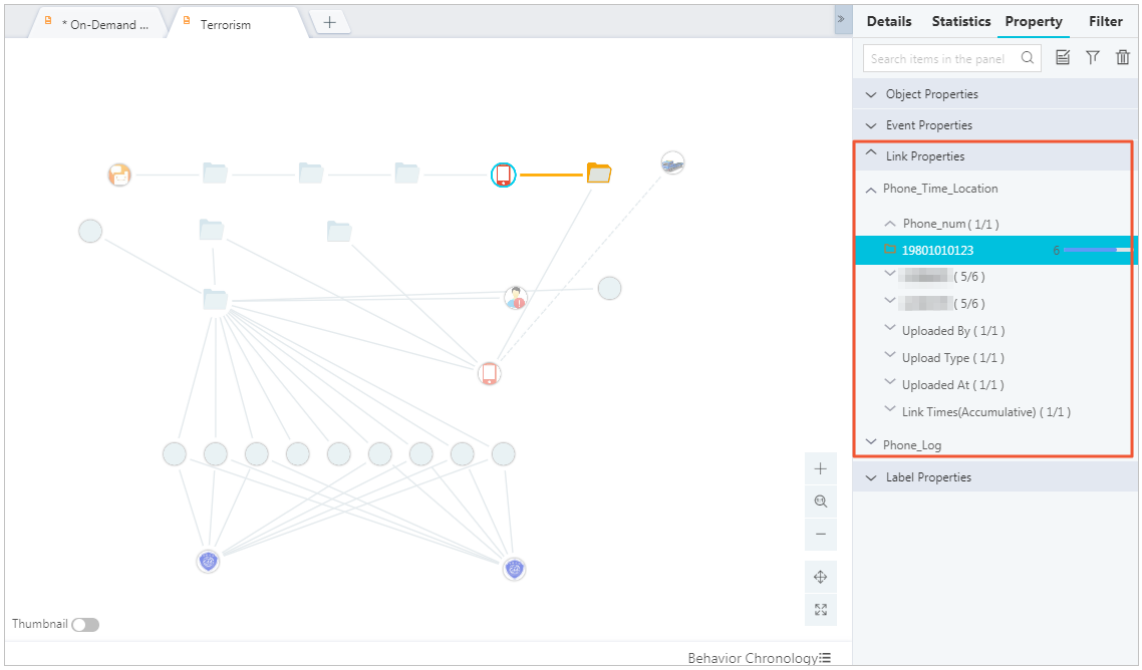
   Property tab



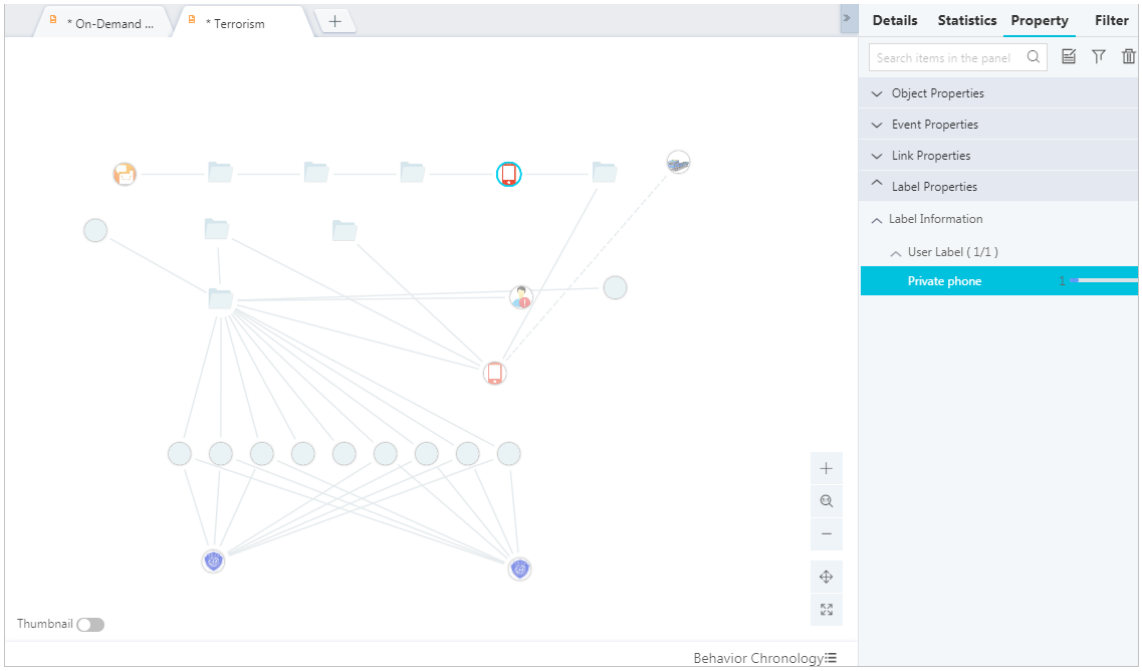
5. Click the up or down arrow to hide or show the properties of the selected object or link.
   - View object properties.



- View event properties.
- View link properties.



- View label properties.



On the Property tab, you can perform the following operations for the selected content:

- Text Note: You can add text notes. For more information, see Add user labels.
- Selected: You can select the node in the graph area.
- Delete: You can delete the selected object in the graph area.

8.12.19.4. Secondary filtering

You can use the secondary filtering feature to filter objects, links, or events in the canvas. In a complex analysis, you can filter out irrelevant objects, links, or events to keep the content simple and concise.

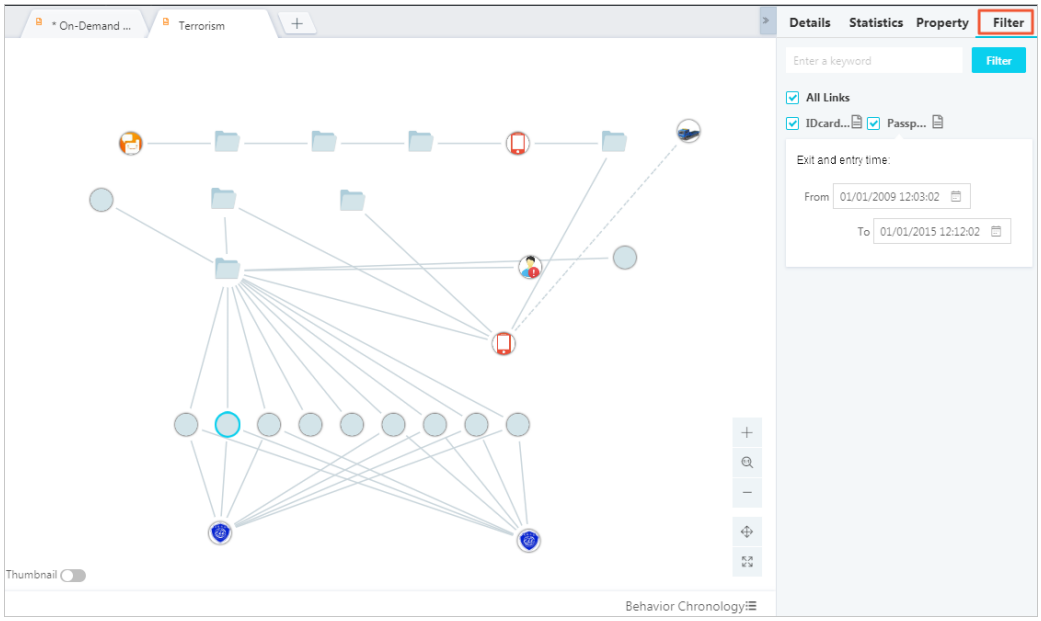
Context

In many service scenarios where data processing is complex, the canvas analysis may become very complex after a few analysis extensions. It is essential to perform secondary filtering before you make further analyses and judgments.

Procedure

1. Log on to Analytics Workbench.
2. Click the arrow-pointing-right icon in the right of the graph area to show the properties and statistics.
3. Click the **Filter** tab, and switch to the **Filter** page, as shown in Entry to the secondary filtering.

   Entry to the secondary filtering



4. Enter a keyword to be filtered.

   Related parameters are described as follows:

   - Time type: maximum and minimum values of the time property. You can adjust the value range, for example, departure time.
   - Numeric type: maximum and minimum numerical values. You can adjust the value range, for example, age.
   - Dictionary type: enumerated values. You can delete some of the enumerated values.
   - Character string: used for searching. Fuzzy search is supported.

8.13. File Center

8.13.1. View and manage all analyses

You can see all the personal analysis files and shared analysis files of the current user. The files are arranged in the order of creation time.

Prerequisites

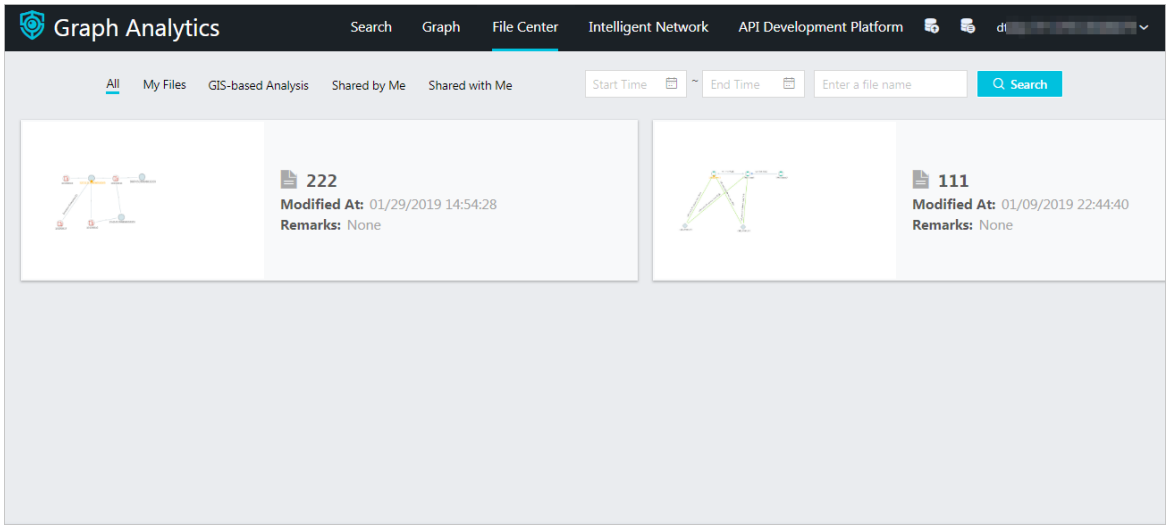
The current user has created and saved analysis files, or has received shared analysis files.

Procedures

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **File Center**, and then click the **All** tab. The **All** tab appears.

   The **All** page displays all the shared files and personal files.

   When you handle a large number of analysis files, you can use the Search feature to find the target files.



3. On the **All** page, you can perform the following operations on each analysis:

Method	Description
Open an analysis file	Double-click an analysis file to open the file in the graph area.
Delete an analysis file	Select an analysis that you created or a shared file that you received, click the **Delete** icon in the lower-left corner, and click **Delete** in the dialog box that appears.
Rename an analysis file	**Note** This operation is only valid for analysis files created by you. Select an analysis, and click the **Rename** icon in the lower-left corner. In the dialog box that appears, enter a new name and click **OK**.
Change sharing permissions	**Note** This operation is only valid for files that have been shared by the current user. Select a shared file, and click the **Change Sharing Permissions** icon in the lower-left corner. In the dialog box that appears, reset the shared members and click **Share**.

8.13.2. View and manage your files

You can view all your personal folders and analysis files in the order of creation time. You can perform operations on the folders and analysis files, such as add, delete, view, and modify.

Prerequisites

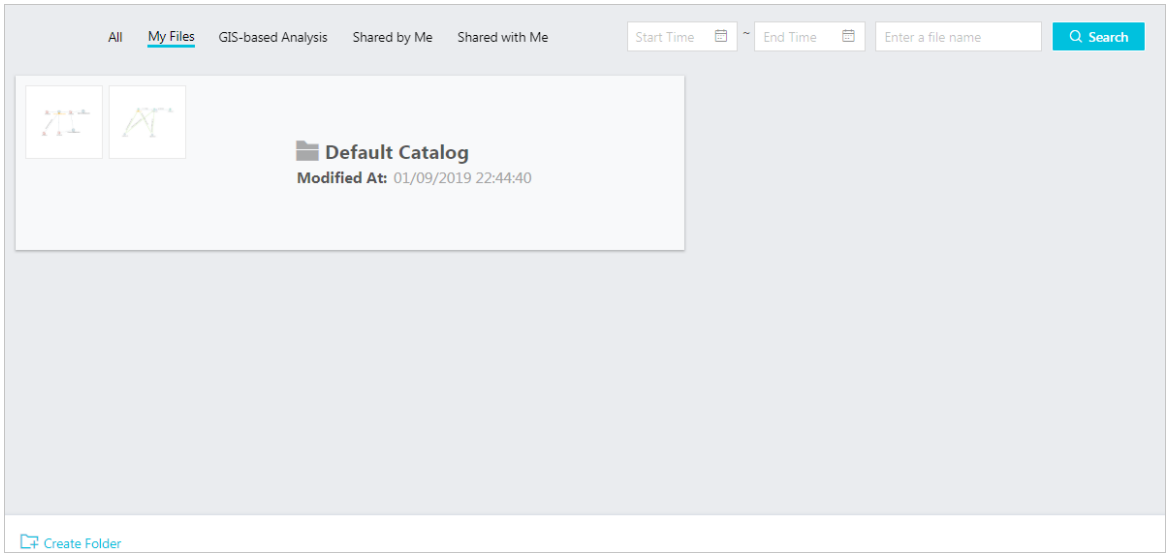
Make sure that you have created and saved an analysis file.

Procedure

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **File Center** and select the **My Files** tab. The **My Files** page appears.

   The **My Files** page displays all folders that contain analysis files that have been saved.

   You can use the Search feature to handle a large number of folders or analysis files.



3. On the **My Files** page, you can perform the following operations.

Operation	Description
Create a folder	Click **Create Folder** in the lower-left corner of the page. In the dialog box that appears, enter a folder name, and then click **OK**.
Rename a folder	Select the folder to be renamed, and click **Rename** in the lower-left corner of the page. In the dialog box that appears, enter a new name, and then click **OK**.
Delete a folder	Select the folder to be deleted, and click **Delete** in the lower-left corner of the page. In the message that appears, click **Delete**.
Rename an analysis file	i. Double-click a folder to open the folder. ii. Select an analysis file to be renamed, and click **Rename** in the lower-left corner of the page. In the dialog box that appears, rename the analysis file, and then click **OK**.
Delete an analysis file	i. Double-click a folder to open the folder. ii. Select an analysis file to be deleted, and click **Delete** in the lower-left corner of the page. In the message that appears, click **Delete**.

Operation	Description
Move an analysis file	i. Double-click a folder to open the folder. ii. Select the analysis file to be moved, and click **Move** in the lower-left corner of the page. In the dialog box that appears, select the target folder, and click **OK**.
Share an analysis file	i. Double-click a folder to open the folder. ii. Select the analysis file to be shared, and click **Share** in the lower-left corner of the page. In the dialog box that appears, select the members you want to share the file with, and click **Share**.

8.13.3. My shared items

8.13.3.1. Overview

Graph Analytics allows you to share personal analyses with others. You can share personal ideas and experiences with other users and combine their intelligence and experiences to achieve collaboration and build a better team.

The initiator and the collaborators are the main roles in the collaboration and sharing process. A collaboration proceeds as follows.

After a member receives a shared analysis, the system automatically creates a directory with the same name as the source analysis on the **Shared with Me** page. By default, the directory has two files: the **initial file** and the **automatically merged file**.

Graph Analytics allows you to manage shared files, including deleting files, renaming files, and managing version history.

> **Note** Only initiators have the permissions to delete and rename shared files.

8.13.3.2. View and manage shared files

The Shared by Me page displays all the files shared by the current user in the order of time when the files were created. You can delete folders and change sharing permissions. You can also merge shared files and delete version files.

Prerequisites

You have shared an analysis file. For more information, see Share analyses.

Context

On the Shared by Me page, you can perform the following operations.

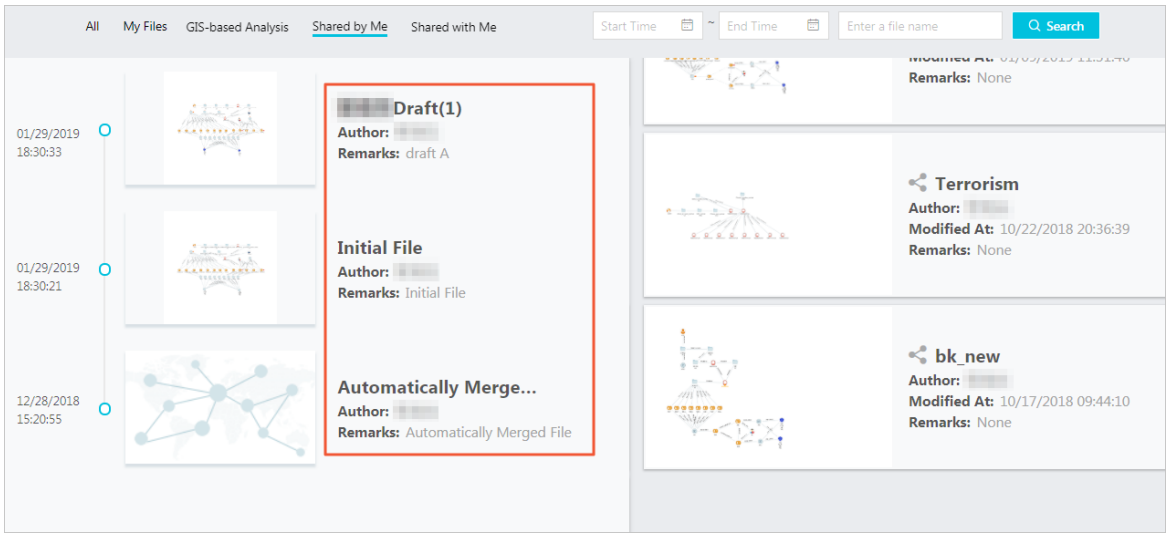
Operation	Description
Delete a shared folder	After the sharer deletes the shared folder, the files will also be deleted from members to which the files are shared.
Modify sharing permissions	After the sharer modifies the sharing permissions, the permissions of the original sharing members are revoked, and the shared files are also deleted.
Delete a shared file	Note You cannot delete the initial file or the automatically merged file that exist by default.
Manually merge files	You can merge multiple published versions in a shared folder to form a new version. Only published file versions can be merged. After the files are merged, a manually merged file is generated. If the published versions are different, use the union of the versions.

Procedure

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **File Center**, and the click the **Shared by Me** tab. The **Shared by Me** page appears.

   The **Shared by Me** page displays all folders that the current user has shared. Each folder is a shared item. It contains multiple draft files, one initial file, one automatically merged file, multiple manually merged files, and multiple published version files.

   When a large number of folders or files are displayed, you can use the search function to query the target.



3. On the **Shared by Me** page, you can perform the following operations.

Operation	Description

Operation	Description
Delete a shared folder	Select a shared folder, click the **Delete** icon in the lower-left corner, and click **Delete** in the dialog box that appears.
Modify sharing permissions	Select a shared folder, and click the **Change Sharing Permissions** icon in the lower-left corner. In the dialog box that appears, reselect the members to whom you want to share the folder, and click **Share**.
Delete a shared file version	i. Double-click the shared folder, and select a file. You can delete draft files, manually merged files, and published version files. ii. Click the **Delete** icon in the lower-left corner, and click **Delete** in the dialog box that appears.
Manually merge files	Select two or more published version files, and click the **Merge Files** icon in the lower-left corner. In the dialog box that appears, enter the description and click **OK**.

8.13.3.3. Edit a shared file

The sharer and shared members can edit shared files, including initial files and automatically merged files. After a file is edited and saved, a draft file will be generated. Only the current user can view the draft.

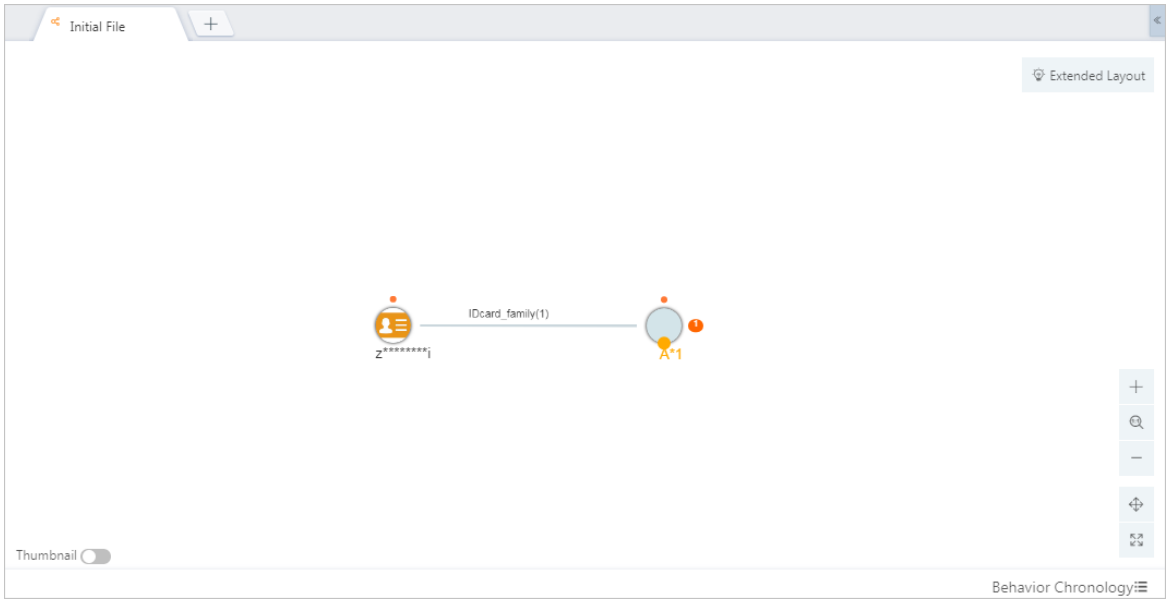
Prerequisites

You have shared an analysis file. For more information, see Share analyses.

Procedure

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **File Center**, and then click the **Shared by Me** tab. The **Shared by Me** page appears.
3. Double-click a shared folder, and then double-click a shared file in the folder, such as the initial file or the automatically merged file, to open the shared file in the graph area.

   Each object node in the initial file has a red dot above it to identify itself as the initial node. Subsequently extended object nodes do not have this red dot.

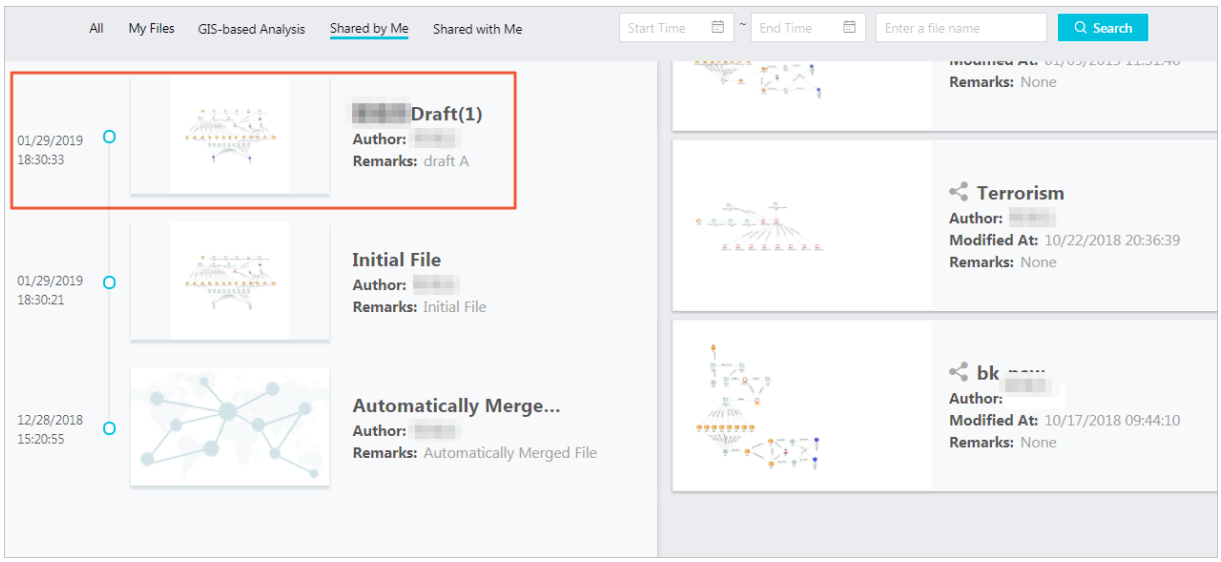


4. Perform analysis or layout operations on the shared file as needed.
5. After the analysis results are shown, click the **Save** icon in the toolbar. In the dialog box that appears, enter the Draft Statement and click **Save**.

   Draft Statement: Enter the draft statement. The statement must be 1 to 200 characters in length.

Result

After a draft of a shared file is saved, the draft file is displayed in the directory of the shared file. However, the draft is visible only to the current user.



- Location: above the **initial file**.
- Name format: username of the current user + draft + (number). For example, test123draft(1).
- Author: the user who saved this draft.
- Description: displayed below the draft file name.
- Time: the time when the draft was created is displayed on the left side of the file.

8.13.3.4. Publish a version

You can edit a shared analysis file and publish a new version. The published analysis file can be viewed by all users with whom the file is shared. However, only the sharer and the publisher can delete the file.

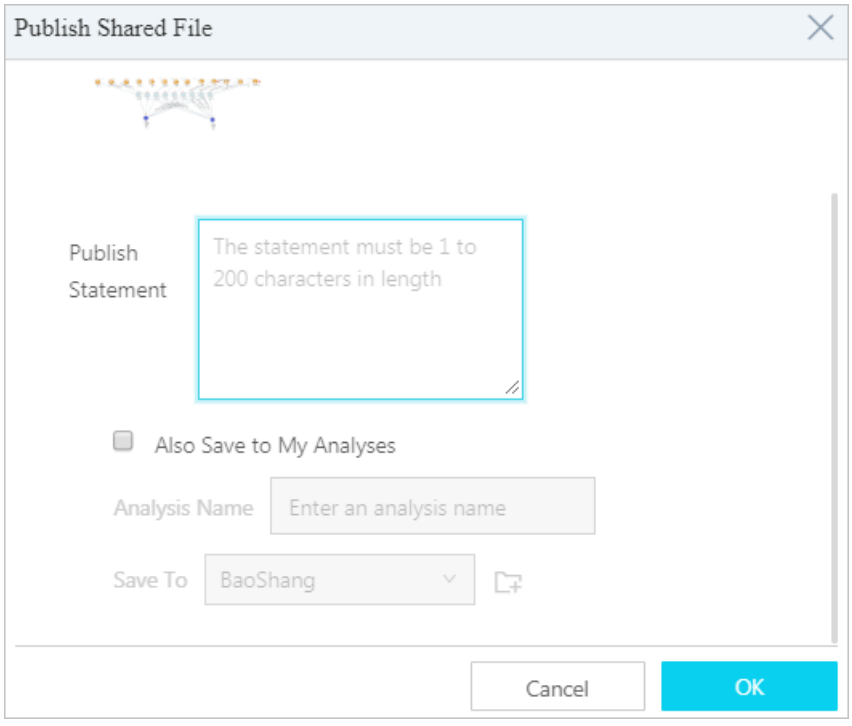
Prerequisites

You have shared an analysis file. For more information, see Share analyses.

Procedure

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **File Center**, and then click the **Shared by Me** tab. The **Shared by Me** page appears.
3. Double-click a shared folder, and double-click a shared file in the folder, such as the initial file or the automatically merged file, to open the shared file in the graph area. Perform analysis or layout operations on the shared file as needed.
4. After the analysis results are shown, click the **Publish** icon in the toolbar and set the parameters in the dialog box that appears.

   The parameters are described in Publish parameters.



Publish parameters

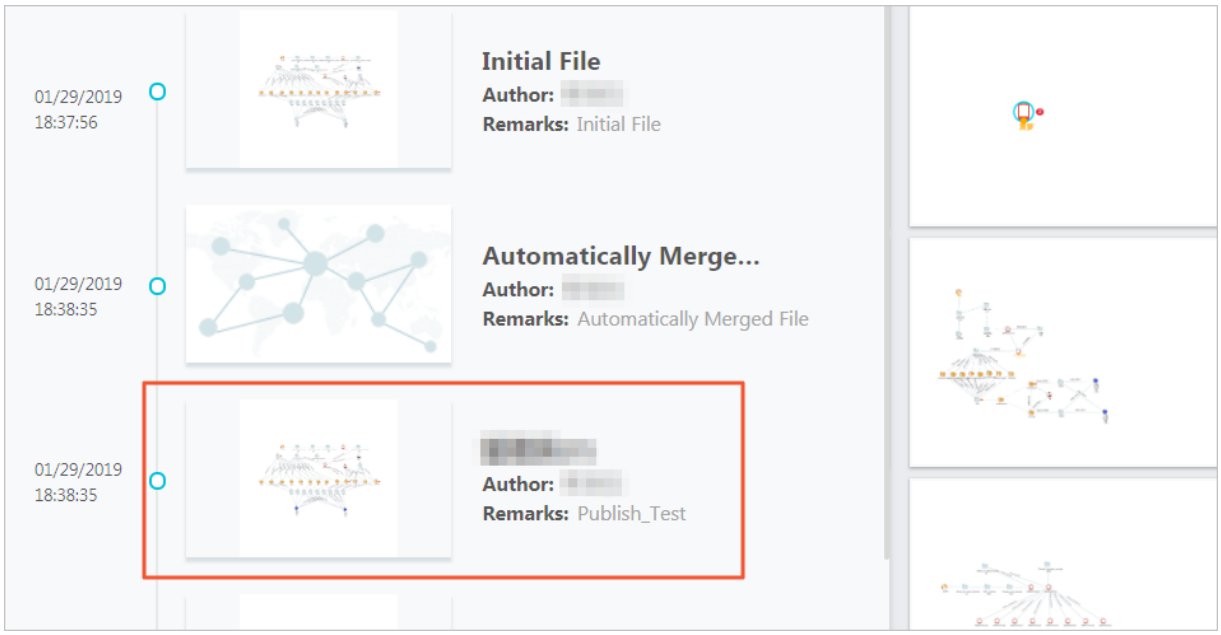
Parameter	Description
Publish Statement	Enter the publish statement. The statement must be 1 to 200 characters in length.

Parameter	Description
Also Save to My Files	After you select this checkbox, the analysis file is displayed on the My Files tab page. You must enter the analysis name and the directory of the analysis file.

5. Click OK.

Result

After a new version of a shared analysis is published, the published version file is displayed in the directory of the shared analysis file.



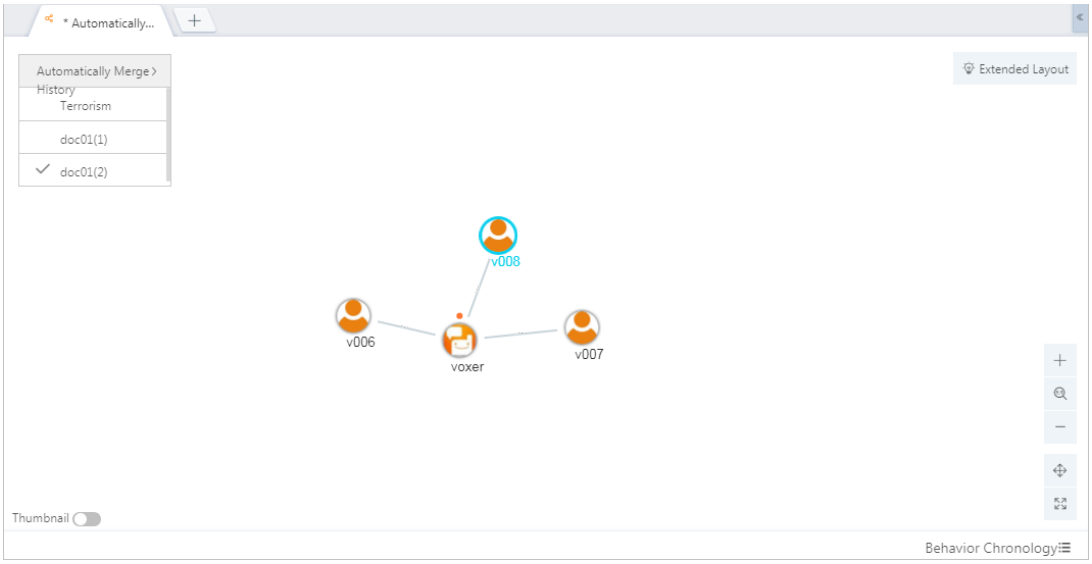
- Location: below the automatically merged file or the manually merged files.
- Name format: username + (version number). For example, test123(1).
- Author: the user who published the file.
- Description: displayed below the file name.
- Time: the time when the file was generated is displayed on the left side of the file.

8.13.3.5. Automatically merge files

When a new version is published, both the shared members and the sharer can use the auto merge feature to merge the new version with the earliest version (the initial file).

After a new version is published, the automatically merged file is updated, as shown in Automatically merge files.

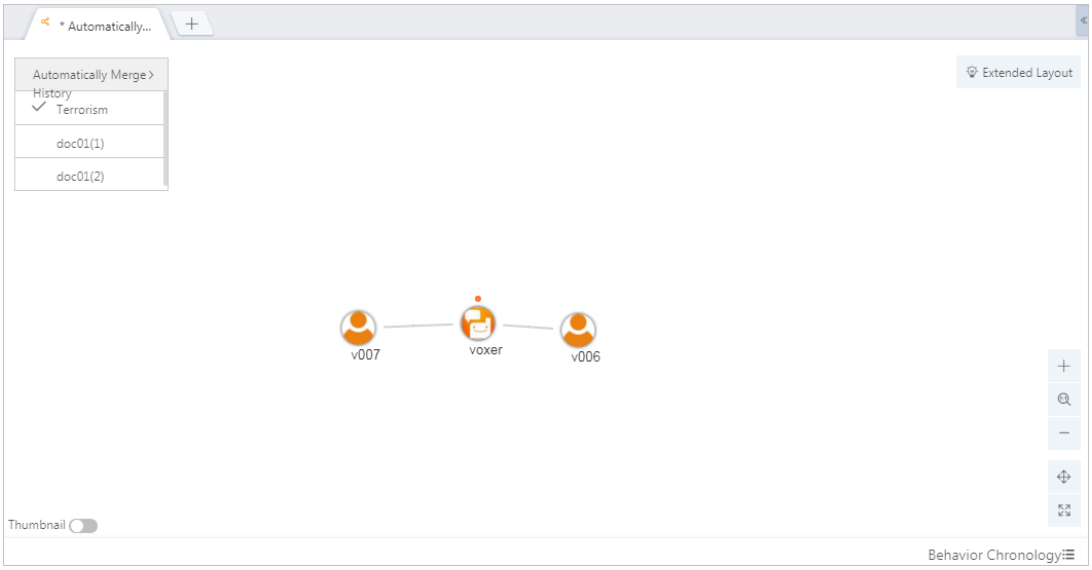
Automatically merge files



The versions are listed in the upper-left corner of the graph area. By default, the file of the latest version is displayed.

You can select an earlier version. Select a version in the **Auto Merge History** list to view the file of an earlier version, as shown in Select an earlier version.

Select an earlier version



8.13.4. View and manage received shared files

You can view and modify the analysis files shared by other users on the Shared with Me page. However, you cannot delete these files.

Prerequisites

You have received a shared file.

Context

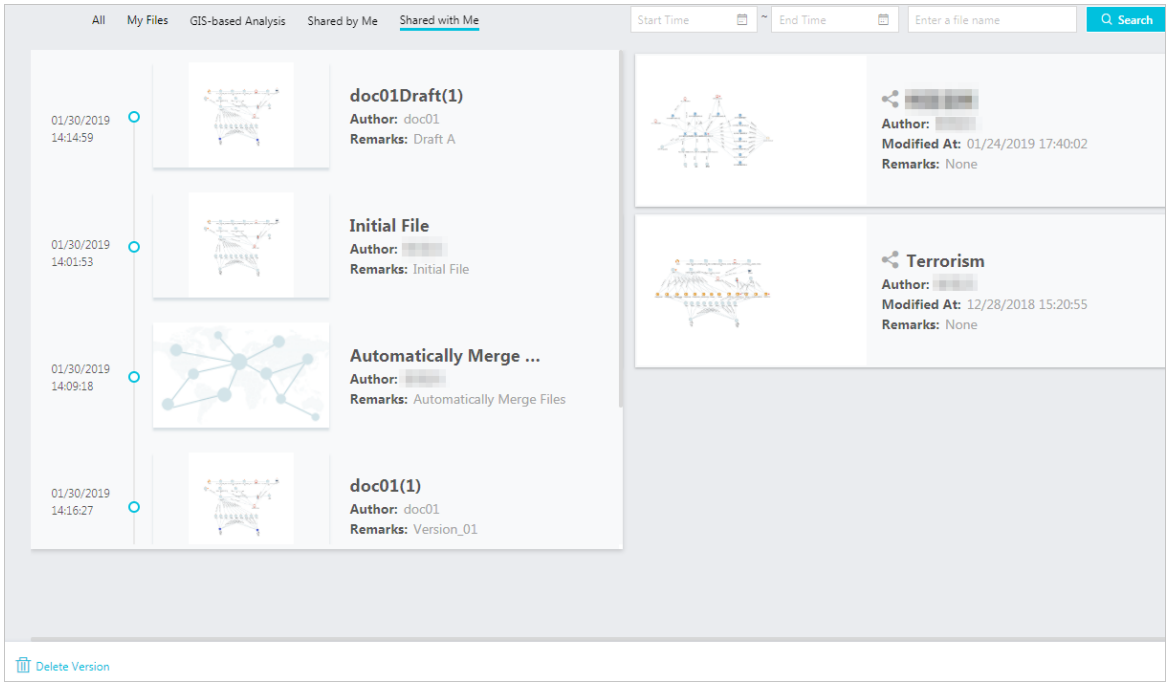
You can edit shared files, delete drafts, and publish new versions on the **Shared with Me** page.

Procedure

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **File Center**, and then click the **Shared with Me** tab. The **Shared with Me** page appears.

   The **Shared with Me** page displays all shared folders received by the current user. Each folder is a shared item. It contains multiple draft files, one initial file, one automatically merged file, multiple manually merged files, and multiple published version files.

   When a large number of folders or files are displayed, you can use the search function to query the target.



3. On the **Shared with Me** page, you can perform the following operations.

Operation	Description
Edit a shared file	Double-click an initial file, an automatically merged file, or a published version file to open the file in the graph area. Edit and save the file, and a draft file is generated.
Delete a draft	Select the draft to be deleted, click the **Delete Version** icon in the lower-left corner, and click **Delete** in the dialog box that appears.
Publish a version	See Publish a version.

8.14. Intelligent Network

8.14.1. Intelligent Network overview

This topic describes related concepts of Intelligent Network and how to use Intelligent Network.

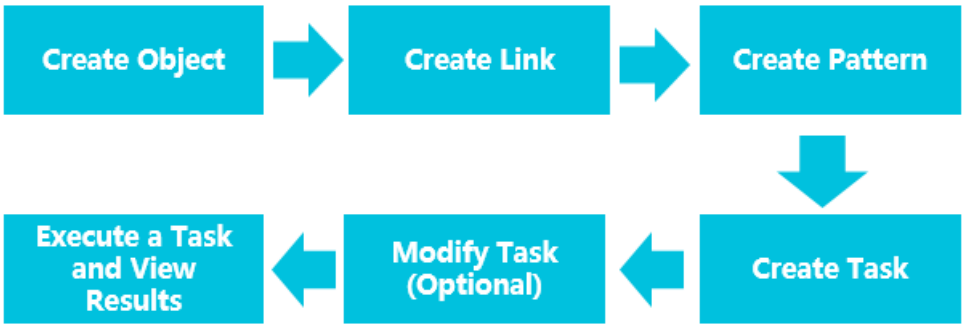
Concepts

Intelligent Network allows you to query subgraphs with the same graph structure as a task specified in a predefined pattern.

Intelligent Network involves the following concepts:

- **Pattern**: the relationship graph structure model that is predefined in Intelligent Network. Patterns are divided into private patterns and public patterns.
  - Private pattern: Only administrators and creators can use private patterns to create private tasks. Private patterns can be set to public patterns, but this is an irreversible operation.
  - Public pattern: All users can use public patterns to create public or private tasks. Public patterns cannot be set to private patterns.
- **Task**: created based on the pattern and used to query data with the same graph structure as the task in the data source. After a task is created based on a pattern, the task has the same settings as the pattern. You can modify the graph structure and filter conditions of the task. Tasks are divided into private tasks and public tasks.
  - Private task: Only administrators and creators can use private tasks. Private tasks created based on public patterns can be set to public tasks, but this is an irreversible operation.
  - Public tasks: All users can use public tasks. Public tasks cannot be set to private tasks.

Procedure to use Intelligent Network



8.14.2. Patterns

8.14.2.1. Create patterns

A pattern is the relationship graph structure model predefined in Intelligent Network. It is the basis of creating a task. Before you use the intelligent network to query a sub-graph, you must use related objects and links to predefine a pattern.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- You have created an object and a first-degree link correlated with the object. For more information about how to create an object and a first-degree link, see Create an object and Create a first-degree link.

Context

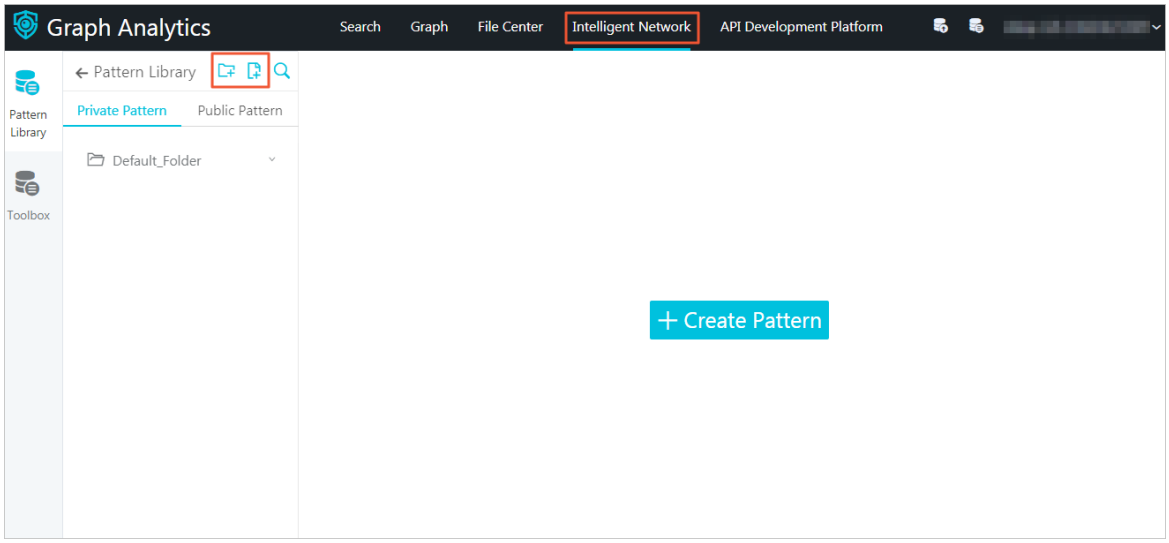
You can set the filter conditions in the **Property** tab and the **Global Conditions** tab based on your requirements.

- **Property** displays the properties of objects and links that can be used as query conditions. The **Conditional Query** properties and properties in **Accumulative Statistics Settings** will be displayed on the Property tab page.
- **Global Conditions** are based on the number and time type properties in a link. Global conditions take effect on the entire pattern. To configure **Global Conditions**, you must name the relevant number or time type properties on the **Property** tab.

The following example shows a transfer pattern (A>B>C>A). The global condition is that the transfer from A to B is made earlier than the transfer from B to C.

Procedure

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **Intelligent Network**.



3. You can create a new folder to save the new pattern separately.
   i. In the **Pattern Library** navigation pane, click the icon (**Create Folder**).
   ii. Specify the **Directory Name** and the pattern type as needed.

   iii. Click **OK**.
4. In the **Pattern Library** navigation pane, click the icon (**Create Pattern**) or **Create Pattern** in

the blank area on the right side.

5. Configure the relationship graph structure model of a pattern.

   If an incorrect operation occurs, you can click the icon (Undo) and the icon (Redo) to quickly restore to a specific state.

   i. For the new pattern **New pattern_xxx**, click the icon in the toolbar, or click **Toolbox** in the left-side navigation pane to open the tool box.

   ii. Drag the objects one by one from the toolbox to the right side of the page to add object nodes to **New mode_xxx**.

   iii. Right-click the object node and select **Change Node Name** to set the name of the object node.

   iv. Move your mouse pointer to the source object. When four cross signs appear around the object, move your mouse pointer to a cross sign and press the left mouse button. Then, drag the mouse pointer to the target object. When four cross signs appear around the target object, release the left mouse button.

   v. In the **Add Link** dialog box that appears, select the link type and specify the link logic.

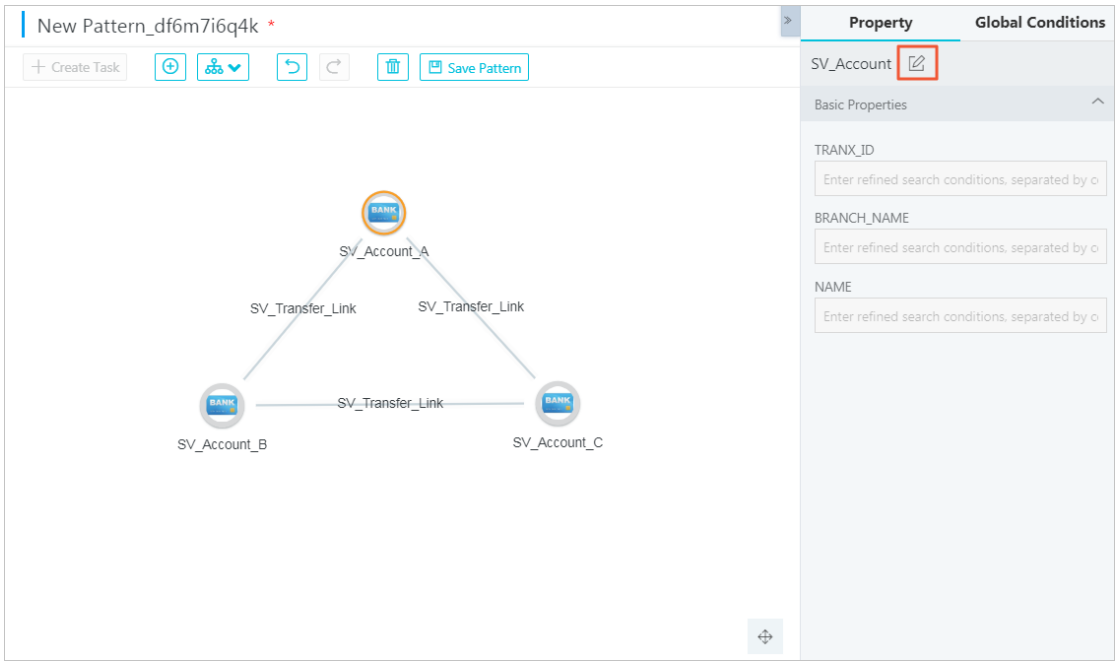
   vi. Click **OK**.

   vii. (Optional)To handle multiple object nodes with complex relationships, you can select the corresponding object node and click the icon to select an appropriate layout.

6. Configure the filter conditions in the **Property** tab.

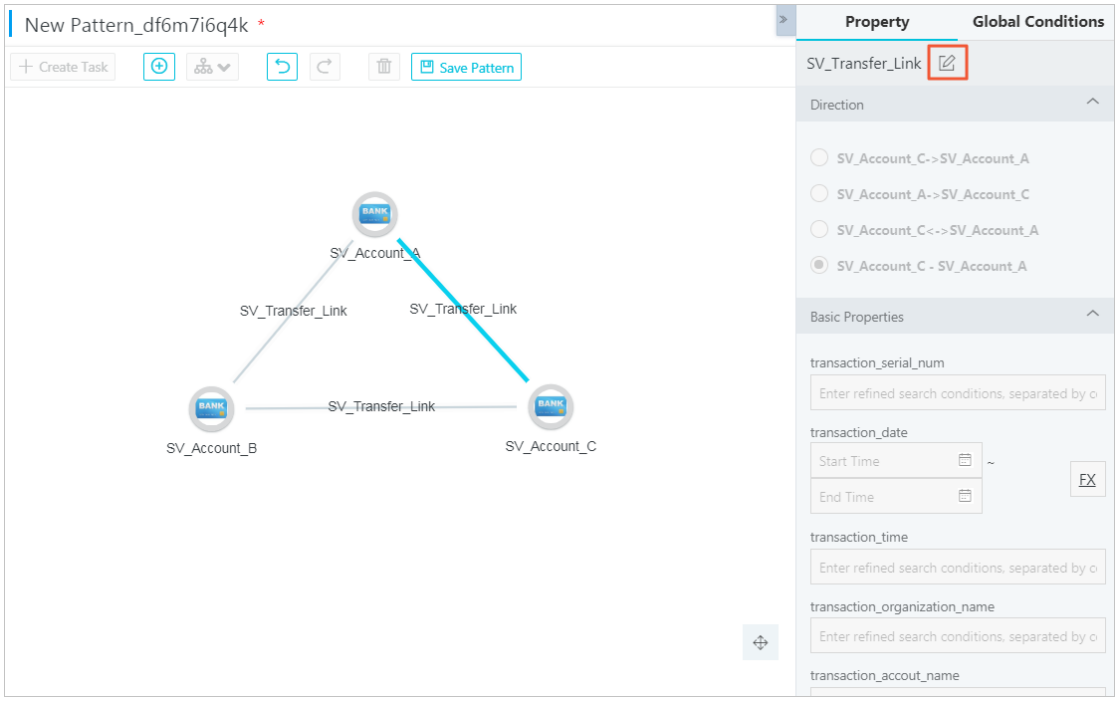
   i. Click the icon in the upper-right corner, and then click **Property**.

ii. Select an object. On the **Property** tab, click the icon to set the filter conditions for the object.



iii. After you have configured the preceding parameters, click the icon to save the **Property** configurations of the object.

iv. Select a link. On the **Property** tab, click the icon to set the filter conditions and direction of the link.



On the **Property** page of a link, properties marked with **FX** are the basis of **Global Conditions**.

v. To set the global conditions based on a property marked with **FX**, click **FX** to name the property.

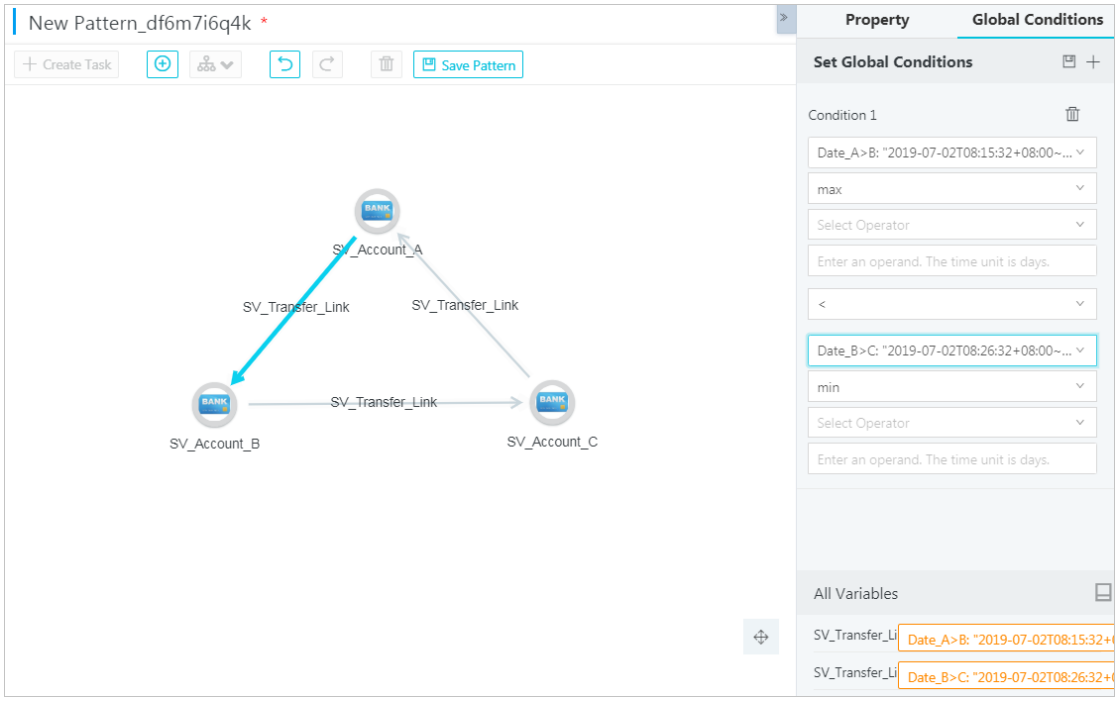
In this example: the **Transaction Date** property of the link between A and B is named as **Date A>B**. The **Transaction Date** property of the link between B and C is named as **Date B>C**.

vi. After you have configured the preceding parameters, click the icon to save the **Property** configurations of the link.

7. Configure filter conditions on the **Global Conditions** tab.

i. Click the icon in the upper-right corner, and then click **Global Conditions**.

ii. If you have not set the global conditions, click **Click here to configure settings**.

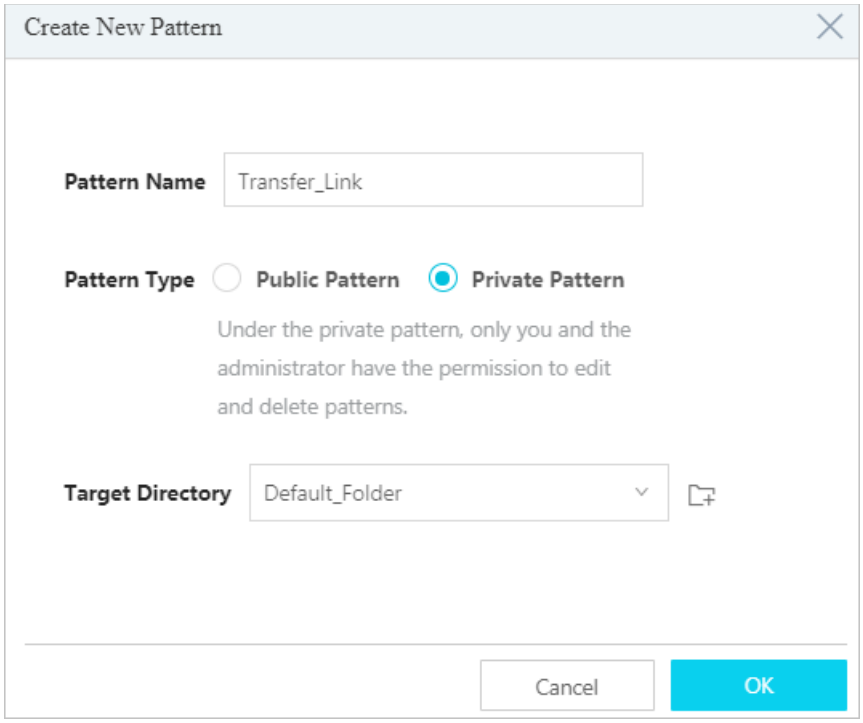


On the **Global Conditions** tab, configure the global conditions based on the link properties that are marked with **FX** in the **Property** tab. The global condition in this example is that the transfer from A to B is made earlier than the transfer from B to C.

iii. After you have configured the preceding parameters, click the icon to save the configurations on the **Global Conditions** tab.

8. Click **Save Pattern**. Set the parameters in the **Create Pattern** dialog box that appears.

If you cannot find a proper folder in **Target Directory**, you can click the icon to create a folder.



9. Click **OK**.

8.14.2.2. View patterns

In Graph Analytics, you can view all the patterns within your permissions and details of each pattern, such as the relationship graph structures and tasks created based on the pattern.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

  > **Note** Only administrators and creators can view the private patterns.

- You have created a pattern. For more information about how to create a pattern, see Create patterns.

Context

You can view the following pattern information:

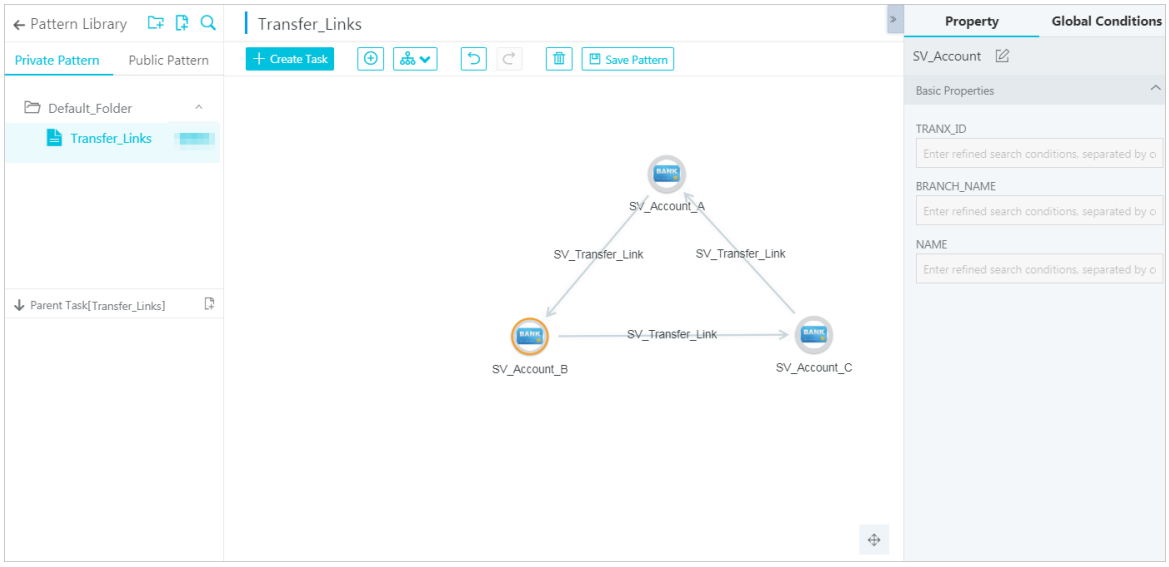
- Relationship graph structures of a pattern
- Tasks created based on a pattern
- Filter conditions of a pattern

Procedure

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **Intelligent Network**.
3. In the **Pattern Library** navigation pane, click **Private Pattern**, and then click a folder to view the private patterns in the folder.Click **Public Pattern**, and then click a folder to view the

private patterns in the folder.

4. Click a pattern to view its details.



Operation	Procedure
View the relationship graph structures	Click a pattern to view the relationship graph structures on the right side of the page.
View tasks created based on a pattern	Click a pattern. All tasks created based on this pattern are displayed under the **Pattern Library** tab.
View the filter conditions of a pattern	In the relationship graph structure, select an object or link, and click the icon in the upper-right corner to display the **Property** tab and the **Global Conditions** tab. You can view the filter conditions of objects or links and the global filter conditions of the pattern.

8.14.2.3. Modify patterns

You can modify a pattern when its relationship graph structure and filter conditions are not suitable for the business scenarios. Modifying a pattern does not affect the tasks that are created based on the pattern.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

  > **Note** Only administrators and creators can modify private patterns.

- You have created a pattern. For more information about how to create a pattern, see Create patterns.

Context

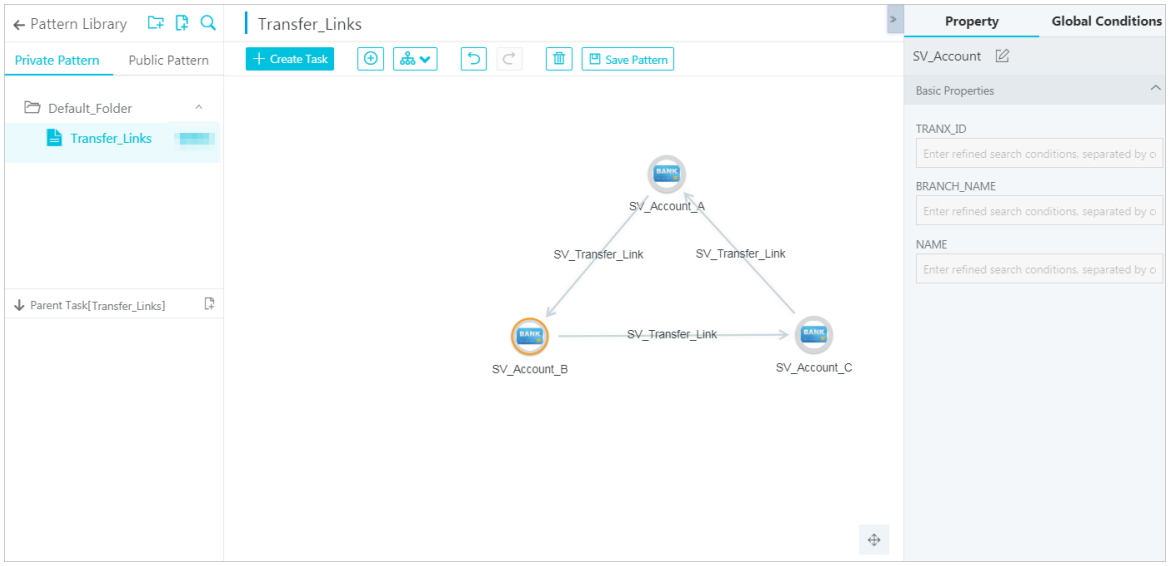
In Graph Analytics, you can modify the following aspects of a pattern:

- Modify the pattern name
- Modify the filter conditions
- Modify the object node name
- Modify the link type
- Add an object node
- Add a link
- Delete an object node
- Delete links

> **Note** After you modify a pattern, the existing tasks that are created based on this pattern are not affected. The modifications will be applied when you create a new task based on the modified pattern.

Procedure

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **Intelligent Network**.
3. In the **Pattern Library** navigation pane, select a pattern in **Private Pattern** or **Public Pattern**.



4. Modify the pattern as needed.

Operation	Procedure
Modify the pattern name	i. In the **Pattern Library** navigation pane, click **Private Pattern** or **Public Pattern** and select a pattern to be modified. Right-click the pattern and select **Rename**. ii. Reset the name, and then press **Enter**. A message is displayed, indicating that the operation is successful.

Operation	Procedure
Modify the filter conditions	Click the icon in the upper-right corner, and set the filter conditions in **Property** and **Global Conditions**. For more information, see Create patterns.
Modify the object node name	i. Right-click the object node to be modified, and select **Change Node Name**. ii. In the dialog box that appears, set the new name of the object node, and then click **OK**.
Modify the link type	i. Right-click the link to be modified, and select **Set Link Type**. ii. In the dialog box that appears, select the link type, specify the link logic, and then click **OK**. You can select multiple link types.
Add an object node	i. Click the icon in the toolbar, or click **Toolbox** on the left side of the page. ii. Drag the objects one by one from the toolbox to the right side of the page to add object nodes. iii. Add a link to a new object node.
Add a link	After you have deleted a link or added a new object node, you need to add a link for the object node. i. Move your mouse pointer to the source object. When four cross signs appear around the object, move your mouse pointer to a cross sign and press the left mouse button. Then, drag the mouse pointer to the target object. When the four cross signs appear around the target object, release the left mouse button. ii. In the **Add Link** dialog box that appears, select the link type and specify the link logic. iii. Click **OK**.

Operation	Procedure
Delete object nodes or links	Note After an object node is deleted, the links related to the object node are also deleted. Method one: i. Select an object node or link, and click the icon in the toolbar. Or, you can press the **Delete** key. You can click-and-drag the mouse to box select multiple object nodes. ii. In the message box that appears, click **Delete Selected**. Method two: Right-click an object node or link, or any of the object nodes in the box selection, and then select **Delete Selected** to directly delete the object node or link.

5. After you have configured the preceding parameters, click **Save Pattern** in the toolbar to save the pattern.

8.14.2.4. Set private patterns to public patterns

In Graph Analytics, you can set private patterns to public patterns, but this is an irreversible operation.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

  Note Only administrators and creators can set private patterns to public patterns.

- You have created a private pattern. For more information about how to create a pattern, see Create patterns.

Procedure

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **Intelligent Network**.
3. In the **Pattern Library** navigation pane, click **Private Pattern**, right-click a private pattern, and then select **Set as Public Pattern**.
4. In the dialog box that appears, configure relevant parameters.

   The parameters are described in Parameter configurations for setting a private pattern to a public pattern.

Parameter configurations for setting a private pattern to a public pattern

Parameter	Description
Publish the dependent task?	Valid values are as follows: ○ **Yes**: Private tasks created based on this private pattern are also set to public tasks. ○ **No**: Private tasks created based on this private pattern remain private tasks. After this private pattern is set to a public pattern, these tasks will be converted to private tasks that are created based on a public pattern. You can manually set these tasks as public tasks when necessary.
Target Directory	Set the target directory in **Public Pattern** to receive the private pattern. When the private pattern is set as a public pattern, it will be moved from the directory in **Private Pattern** to the specified directory in **Public Pattern**.

5. After you have configured the preceding parameters, click **OK**. A message is displayed, indicating that the operation is successful.

8.14.2.5. Delete a pattern

You can delete a pattern that is no longer used. Deleting a pattern does not affect the tasks that are created based on the pattern.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

  > **Note** Only administrators and creators can delete private patterns.

- You have created a pattern. For more information about how to create a pattern, see Create patterns.

Procedure

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **Intelligent Network**.
3. In the **Pattern Library** navigation pane, click **Private Pattern** or **Public Pattern** and select a pattern to be deleted. Right-click the pattern and select **Delete**.
4. In the message box that appears, click **OK**.

8.14.3. Tasks

8.14.3.1. Create a task

A task is created based on a pattern. It can be used to query the data with the same graph structure as the task in the data source.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.
- You have created a pattern. For more information about how to create a pattern, see Create patterns.

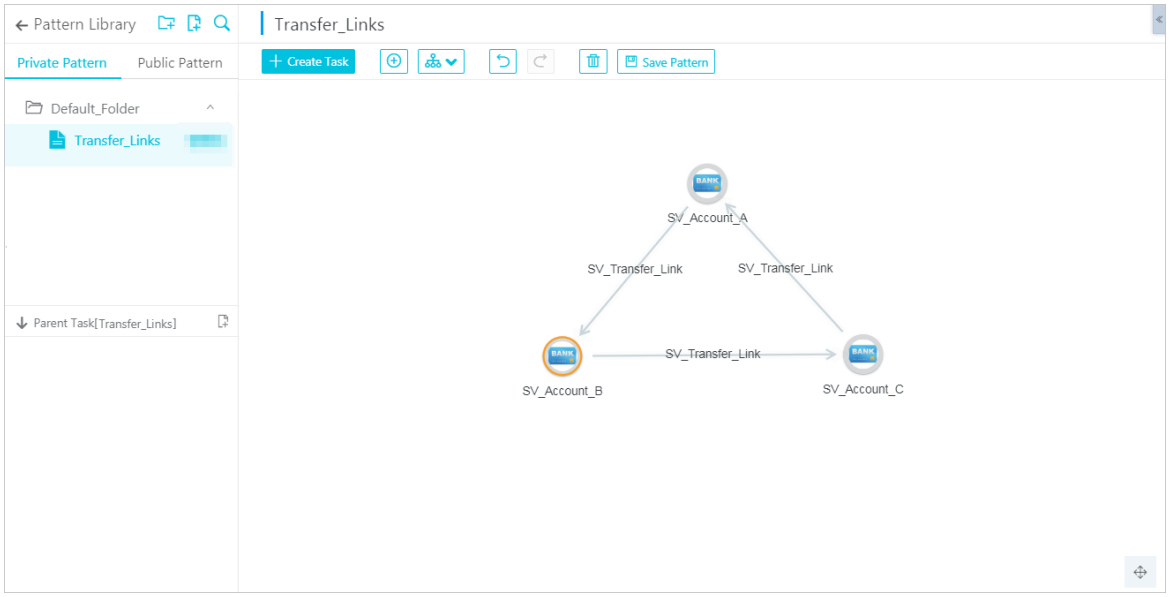
Context

For a task created based on the pattern, the objects, links, and filter conditions of the task are inherited from the pattern by default, which are exactly the same as the pattern. To modify these configurations, see Modify a task.

Procedure

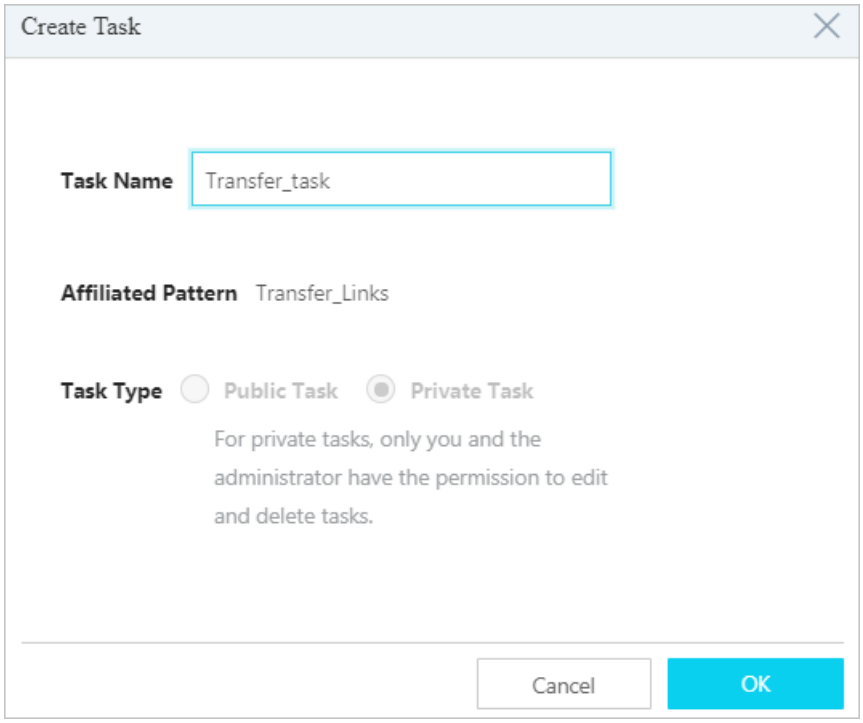
1. Log on to Analytics Workbench.
2. In the top navigation bar, click **Intelligent Network**.
3. In the **Pattern Library** navigation pane, select a pattern in **Private Pattern** or **Public Pattern**. Click **Create Task** on the right side of the page or click the icon (**Create a Task**).

   > **Note** You can only create private tasks based on a private pattern. You can create public tasks or private tasks based on a public pattern.



4. Configure the parameters on the **Create Task** dialog box that appears.

   The parameters are described in Parameter configurations for creating a task.



Parameter configurations for creating a task

Parameter	Description
Task Name	The user-defined task name.
Affiliated Pattern	The pattern that you have selected. It is automatically entered and cannot be modified.
Task Type	When the selected pattern is public, you can set the task type to **Public Task** or **Private Task**. When the selected pattern is private, the default task type is **Private Task** and cannot be modified.

5. Click **OK**.

   After you have configured the preceding parameters, a message appears, indicating that the task has been created. The objects, links, and filter conditions of the task are inherited from the pattern by default, which are exactly the same as the pattern.

8.14.3.2. Check the task

You can view tasks based on patterns. You can select a specific pattern and view all the tasks that are created based on the pattern. You can also view the detailed information about these tasks, such as the relationship graph structures and filter conditions of the tasks.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

  > **Note** Only administrators and creators can view the private tasks.

- You have created a task. For more information about how to create a task, see Create a task.

Context

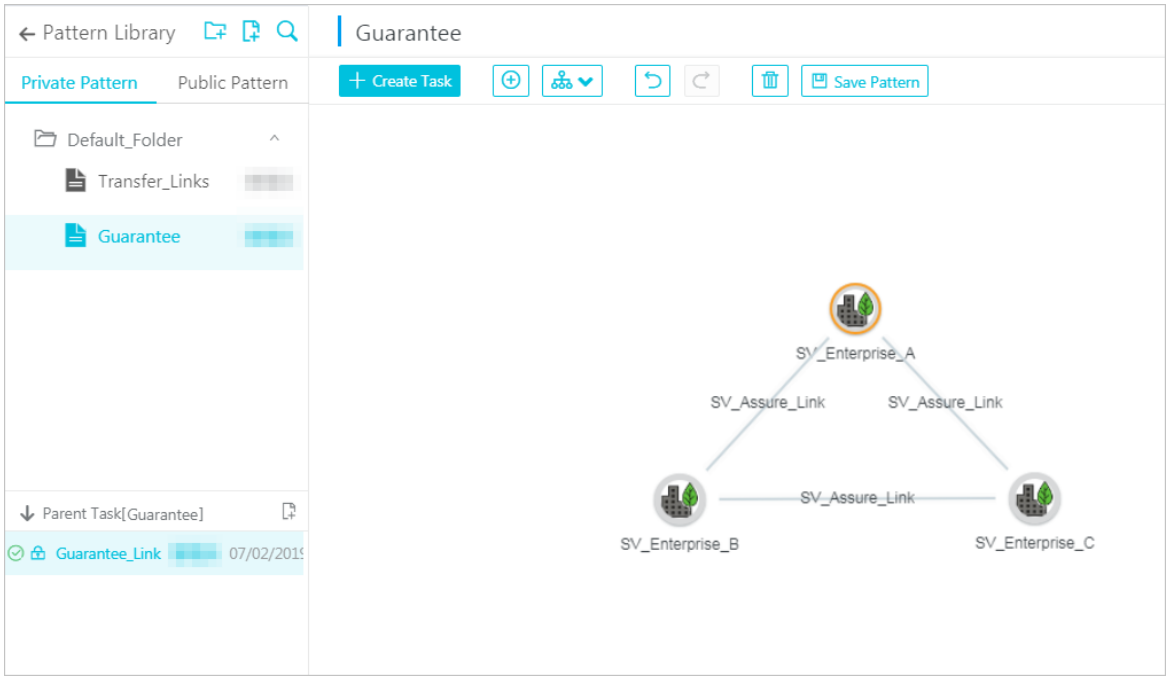
Tasks are divided into public tasks and private tasks. A lock icon is displayed before a private task, but no lock icon is displayed before a public task. A task can have three statuses: executed, not executed, and failed. These three statuses are represented by different icons.

You can view the following task information:

- The task type and task status
- Relationship graph structures of a task
- Filter conditions of a task
- Primary keys of the object in the task

Procedure

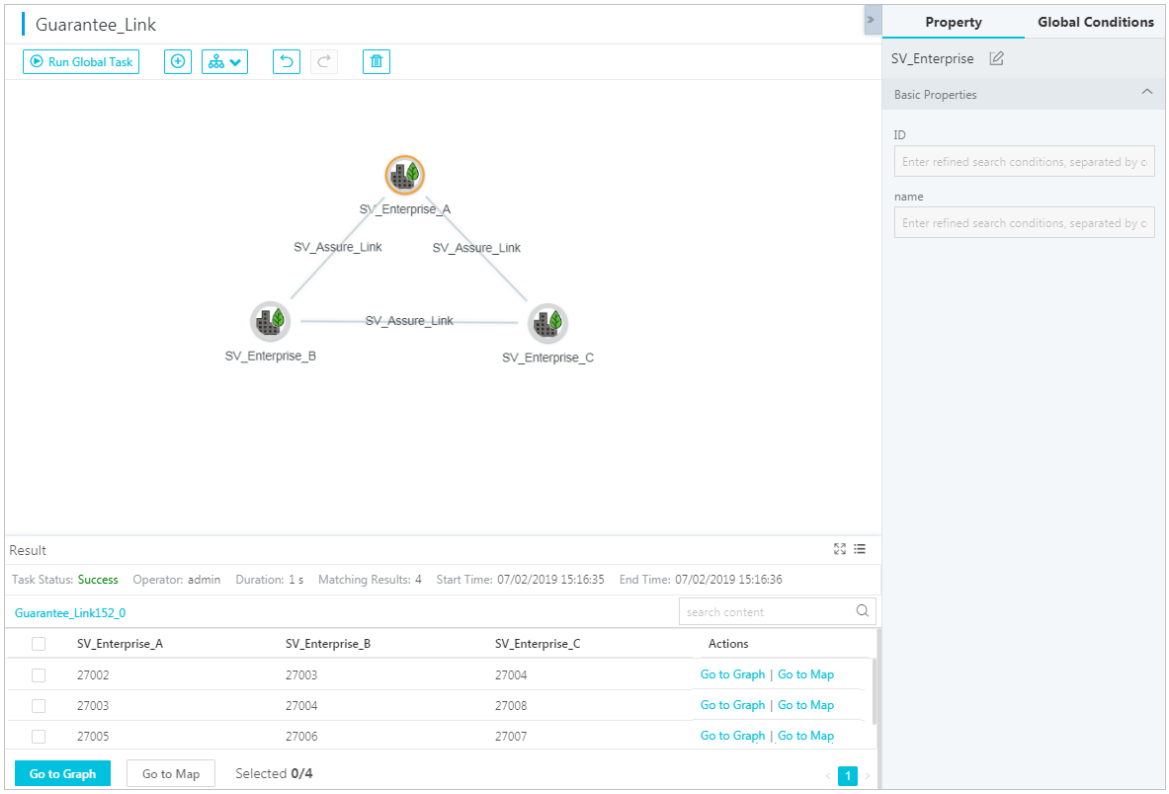
1. Log on to Analytics Workbench.
2. In the top navigation bar, click **Intelligent Network**.
3. In the **Pattern Library** navigation pane, select a pattern in **Private Pattern** or **Public Pattern** and view the tasks that are created based on the pattern.



The task types and statuses are described as follows:

- Tasks are divided into public tasks and private tasks. A lock icon is displayed before a private task, but no lock icon is displayed before a public task.
- A task can have three statuses: executed, not executed, and failed. These three statuses are represented by different icons.

4. Click a task and view the detailed information about the task as follows.



Operation	Procedure
View the relationship graph structures of a task	Click a specific task to view the relationship graph structures on the right side of the page.
View the filter conditions of a task	Select an object or a link, and click the icon in the upper-right corner. The **Property** and **Global Conditions** tabs are displayed. You can view the filter conditions of an object or a link and the global conditions of tasks.
View the primary keys of objects in a task	Right-click an object and select **Set Primary Keys** to view the primary keys that have been set for this object.

8.14.3.3. Modify a task

For a task that is created based on a pattern, the objects, links, and filtering conditions of the task are inherited from the pattern by default, which are exactly the same as the pattern. When some configurations of a task do not match the scenario, you can modify the task accordingly.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

> **Note** Only administrators and creators can modify private tasks.

- You have created a task. For more information about how to create a task, see Create a task.

Context

In Graph Analytics, you can modify the following aspects of a task:

- Modify the filter conditions
- Modify the object node name
- Modify the link type
- Add an object node
- Add a link
- Delete an object node
- Delete a link

Procedure

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **Intelligent Network**.
3. In the **Pattern Library** navigation pane, select a pattern in **Private Pattern** or **Public Pattern**. Select the task to be modified.
4. Modify a task as shown in the following operations.

Operation	Procedure
Modify the filter conditions	You can click the icon in the upper-right corner. You can set the filter conditions for a task in the **Property** and **Global Conditions** tabs that appear. For more information, see Create patterns.
Set the object primary key	i. Right-click the object node to be modified, and select **Set Primary Keys**. ii. In the dialog box that appears, set the primary keys of the object node, and click **OK**. You can set multiple primary keys.
Modify the object node name	i. Right-click the object node to be modified, and select **Change Node Name**. ii. In the dialog box that appears, set the new name of the object node, and then click **OK**.
Modify the link type	i. Right-click the link to be modified, and select **Set Link Type**. ii. In the dialog box that appears, select the link type, specify the link logic, and then click **OK**. You can select multiple link types.

Operation	Procedure
Add an object node	i. Click the icon in the toolbar, or click **Toolbox** on the left side of the page. ii. Drag the objects one by one from the toolbox to the right side of the page to add object nodes. iii. Add a link to a new object node.
Add a link	After you have deleted a link or added a new object node, you need to add a link for the object node. i. Move your mouse pointer to the source object. When four cross signs appear around the object, move your mouse pointer to a cross sign and press the left mouse button. Then, drag the mouse pointer to the target object. When the four cross signs appear around the target object, release the left mouse button. ii. In the **Add Link** dialog box that appears, select the link type and specify the link logic. iii. Click **OK**.
Delete object nodes or links	Note After an object node is deleted, the links related to the object node are also deleted. Method one: i. Select an object node or link, and click the icon in the toolbar. Or, you can press the **Delete** key. You can click-and-drag the mouse to box select multiple object nodes. ii. In the message box that appears, click **Delete Selected**. Method two: Right-click an object node or link, or any of the object nodes in the box selection, and then select **Delete Selected** to directly delete the object node or link.

5. Click **Run Global Task** to save the modification configuration.

Note After a task is modified, you must execute the task again. Otherwise, the modifications cannot be saved.

8.14.3.4. Execute the task and view the result

After the task is created or modified, you can execute the task to query sub-graphs that have the same graph structure as the task. The task execution results are displayed in a list. You can also view the execution results in the graph area.

Prerequisites

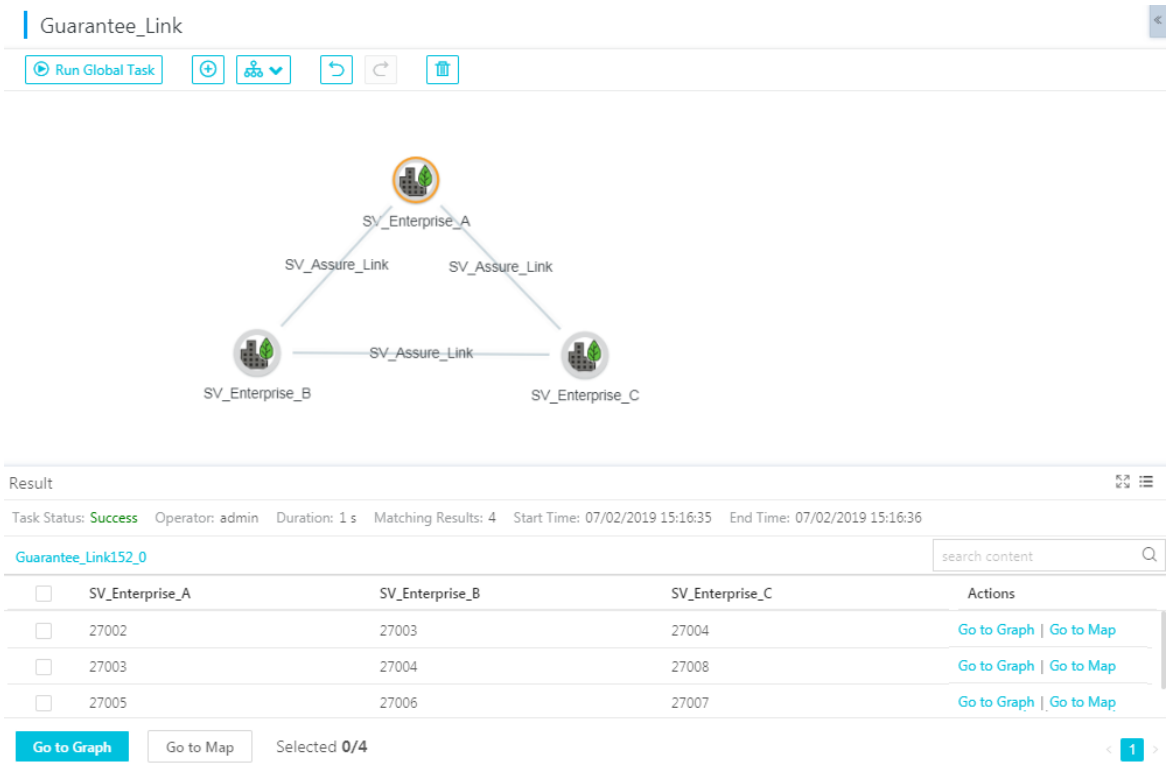
- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

  > **Note** Only administrators and creators can execute private patterns.

- You have created a task. For more information about how to create or modify a task, see Create a task and Modify a task.

Procedure

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **Intelligent Network**.
3. In the **Pattern Library** navigation pane, select a pattern in **Private Pattern** or **Public Pattern**. Select the task to be executed.
4. Click **Run Global Task** in the top toolbar.
5. In the right-side area, click the icon to view the execution results.

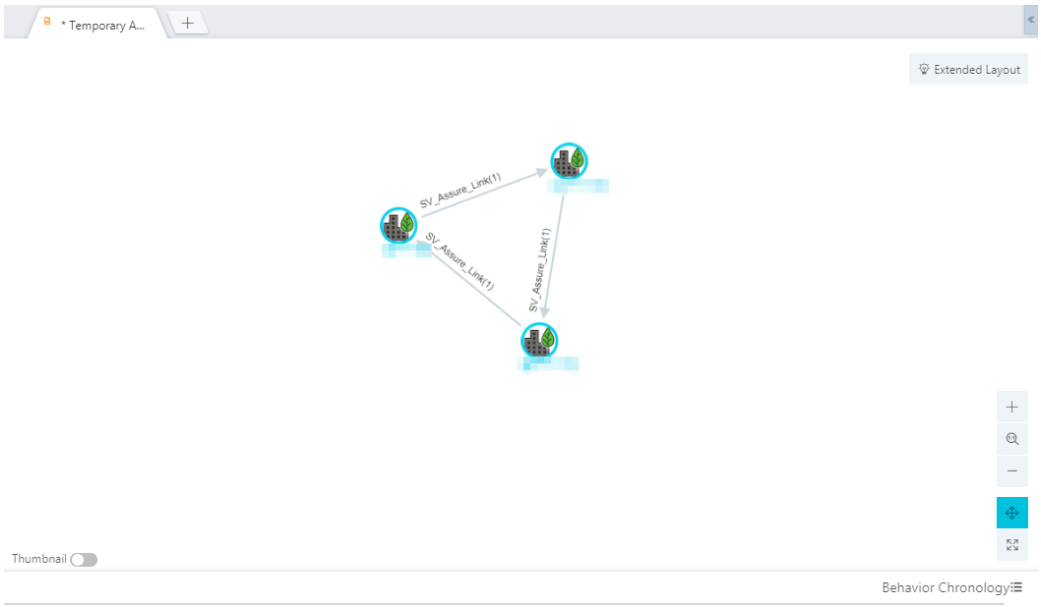


6. View the task execution results in the graph area.

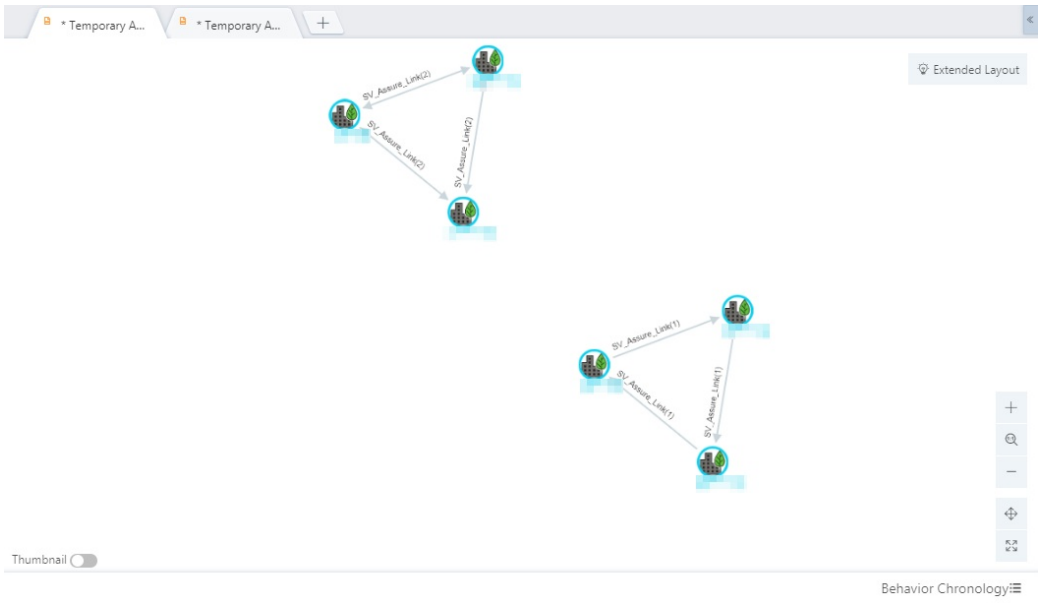
   > **Note** The task result is displayed as a temporary analysis file in the graph area. You can save and share the file and perform other operations. You can also extend the analysis.

Operation	Procedure
View the results of a single task in the graph area	Select a record and click **Go to Graph**. The result is displayed on the graph page, as shown in View the results of a single task in the graph area.
View the results of multiple tasks in the graph area	You can also select multiple records and then click **Go to Graph**.The results are displayed on the graph page, as shown in View the results of multiple tasks in the graph area.

View the results of a single task in the graph area



View the results of multiple tasks in the graph area



8.14.3.5. Set a private task as a public task

Private tasks created based on public patterns can be set to public tasks, but this is an irreversible operation.

Prerequisites

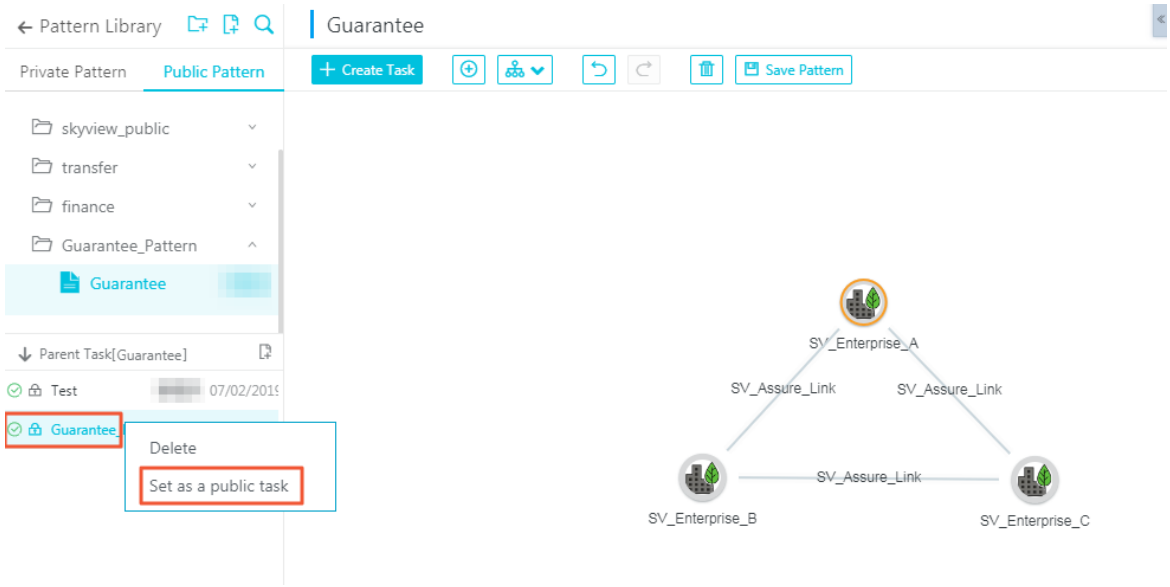
- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

  > **Note** Only administrators and creators can set private patterns to public patterns.

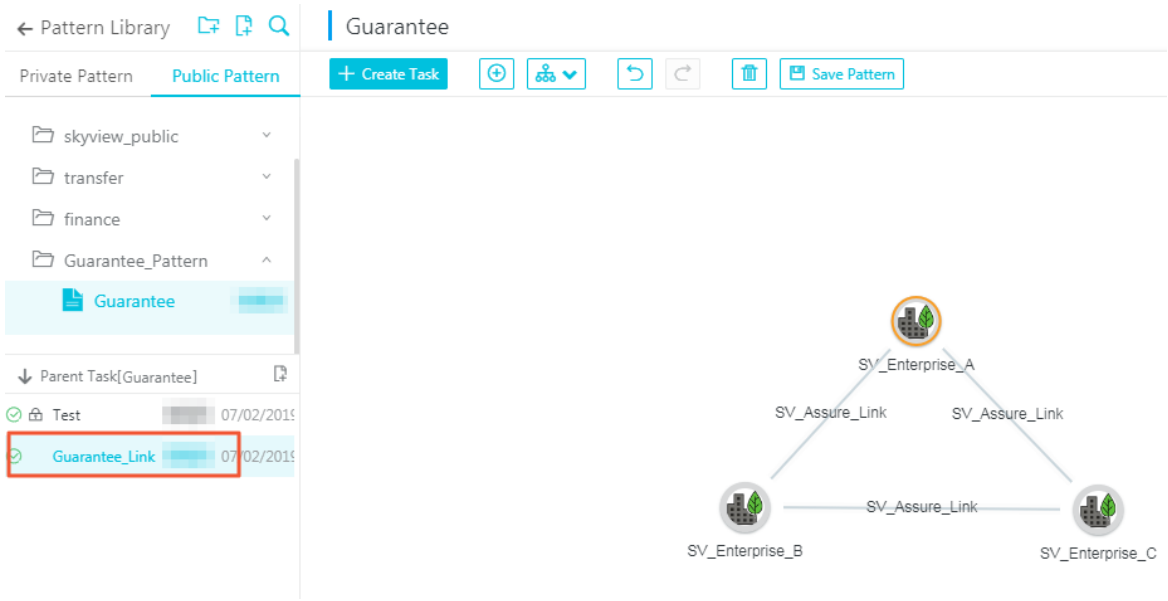
- You have created a private task based on the public pattern. For more information about how to create a pattern, see Create a task.

Procedure

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **Intelligent Network**.
3. In the **Pattern Library** navigation pane, click **Public Pattern** . Right-click a private task that is created based on the pattern, and then select **Set as Public Task**.



After a private task is set to a public task, the lock icon in front of the task disappears. A message is displayed, indicating that the operation is successful.



8.14.3.6. Delete a task

You can delete a task when it is no longer needed.

Prerequisites

- Make sure that you have an account and password for Graph Analytics and are authorized to operate on Analytics Workbench and Administration Console.

  > **Note** Only administrators and creators can delete private patterns.

- You have created a task. For more information about how to create a pattern, see Create a task.

Procedure

1. Log on to Analytics Workbench.
2. In the top navigation bar, click **Intelligent Network**.
3. In the **Pattern Library** navigation pane, select a pattern in **Private Pattern** or **Public Pattern**. Right-click the task to be deleted and then click **Delete**.

   > **Note** Deleted tasks cannot be restored. Exercise caution when you delete a task.

4. In the dialog box that appears, click **OK**.

8.15. Examples

8.15.1. Tax industry case studies

Tax inspectors used Graph Analytics to analyze abnormal information and uncovered a tax cheat group that was related to 13 companies.

Case background

On April 1, 2016, a clerk of an overseas trading platform was routinely checking goods being loaded and unloaded. When the clerk checked “Hangzhou Children's Products Co., Ltd.”, he was told that the goods had been shipped. The company exported goods such as children's products to overseas countries with a total volume of 40 million RMB. Apparently, this was a case of avoiding "loading inspection", and this case attracted the clerk's attention. The clerk used Graph Analytics to analyze the company and found a large-scale tax cheat group related to this company.

Data preparation

> **Note** All the data in this case, including individual people's names, company names, places, and times, is purely fictitious.

Data resources used in this case include:

- Information of the drawer (the manufacturer), the customer (the domestic trader), the remitter, and the overseas trader.
- The relationships between the customer and the drawer, the customer and the remitter, and the customer and the overseas trader are required.

Connect to data sources and configure an OLEP model

Before you perform an analysis, you must connect the data source to Graph Analytics and build an OLEP model based on the data table in the data source.

1. Log on to Administration Console of Graph Analytics. For more information about how to connect the data source to Graph Analytics, see Create data sources.
2. Create objects based on the data table in this case, as shown in Create OLEP models for tables.

   The created objects are as follows.

Objects mapped by the data table

Data table	Object
Drawer information table	○ Drawer: Maps the drawer information. ○ WIFI: Maps the WIFI used by the drawer.
Customer information table	○ Contact phone number: Maps the telephone number of the customer. ○ Customer: Maps the customer information.
Remitter information table	Remitter: Maps the remitter information.
Overseas trader information table	○ Country: Maps the country where the overseas trader is located. ○ Overseas trader: Maps the overseas trader information.

3. Create a first-degree link mapping for the data table in this case, as shown in Create OLEP models for tables.

The first-degree link is created as follows.

Links mapped by the data table

Data table	First-degree link	Source object	Target object
Drawer information table	○ Frequent logon WIFI: The link between the drawer and the frequent logon WIFI can be used to query both the drawer and the WIFI information. ○ Name of the drawer's company: The link between the drawer and the drawer's company can be used to query both the drawer and the company name. ○ Drawer's phone number: The link between the drawer and the drawer's phone number can be used to query both the drawer and the phone number of the drawer.	○ Frequent logon WIFI: The drawer ○ Name of the drawer's company: The drawer	○ Frequent logon WIFI: The WIFI ○ Name of the drawer's company: The name of the company
Customer information table	○ Customer's phone number: The link between the customer and the customer's phone number can be used to query both the telephone number or the user who have used this phone number. ○ Name of the customer's company: The link between the customer and the customer's company can be used to query both the customer or the company of the customer.	○ Customer's phone number: The customer ○ Name of the customer's company: The customer	○ Customer's phone number: The phone number ○ Name of the customer's company: The name of the company
Customer-drawer information table	Invoicing: This link can be used to query both the customer and the drawer.	Drawer	Customer

Data table	First-degree link	Source object	Target object
Customer-remitter information table	Remittance: This link can be used to query both the customer and the remitter.	Remitter	Customer
Customer-overseas trader information table	Purchase: This link can be used to query both the overseas trader and the customer.	Overseas trader	Customer
Overseas trader information table	Country: This link can be used to query both the overseas trader and the country where the overseas trader is located.	Overseas trader	Country

4. For more information about how to configure the business information related to these objects and links, see Configure object properties and business parameters and Configure link properties and business parameters.
5. Create multi-degree links as shown in Create a multi-degree link.

   The multi-degree links created in this case are as follows.

Multi-degree links

Multi-degree link	Base links	Description
The drawer and the customer with the same name.	○ Name of the customer's company. ○ Name of the drawer's company.	Queries the drawer with the same name as the customer.

Analysis process

After you have connected the data source and configured the OLEP model, you can go to Analytics Workbench to analyze cases.

1. Log on to Analytics Workbench.
2. On the **Graph** page, create a new analysis, and add **Hangzhou Children's Products Co., Ltd** as the node to start with.
3. Select the added node, and query the company's information on the right side of the page.

   Results: This company is a manufacturer company instead of a trading company.

   Inferences made by analysts: This company needs a domestic trader to export its goods.
4. Analysts used the link extension feature of Graph Analytics to query the downstream customer of this company, namely the domestic trader.

   Select this company as a node, and click **Link Extension** in the toolbar. Set **Link Type** to**Invoicing** to query the downstream customer of this company.

Results: This company has been the drawer for three trading companies. These three companies are from the medical industry and the apparel industry, but somehow have become the drawee of a manufacturer engaged in children's products.

5. Analysts used the link extension feature to investigate these three customers to find the overseas traders that have built business relationships with these three customers.

   Select these three customers, and click **Link Extension**. Set **Link Type** to **Purchase** to query the overseas traders that have built business relationships with these three customers.

   Results: All these customers have their own overseas trader.

6. Analysts used the link extension feature to search the remitter of these three customers.

   Select these three customers, and click **Link Extension**. Set **Link Type** to **Remitter** , and search for the remitters related to these three customers.

   Results: The analysis results indicate that these three customers receive remittance from the same remitter. In this phase, the relationship network is downward-trend and looks like a symmetrical funnel, which is a typical abnormal pattern.

   Inferences made by analysts: A manufacturer sells products to overseas buyers through three customers, but there is only one remitter. Whether these three overseas traders are in the same area or not, this network pattern is very suspicious.

7. Analysts tried to query the locations of these three overseas traders.

   Select these overseas traders, and click **Link Extension**. Set **Link Type** to **Country** to query the locations of these three overseas traders.

   Results: These three overseas traders are located in different countries.

   Inferences made by analysts: These overseas traders are located in different countries, but the remittance is made by the same remitter. Given that, it is very likely that these three customers and the drawer have committed tax cheating.

8. To obtain more information, analysts viewed the information cubes of these three customers.

   Results: Two of the customers are companies that provide both manufacturing and trading services.

9. Following these clues, analysts queried the manufacturers of these two companies.

   Select these two companies and click **Link Extension**. Set **Link Type** to **Drawer and customer with the same name** to query the manufacturers of these two companies.

   Results: These two companies share the same manufacturer (drawer).

10. Analysts used **Group Analysis** to analyze the relationship between these two companies.

    Select these two nodes and their manufacturers, and choose **Analyze** > **Group Analysis**. Set **Link Type** to **Invoicing** to analyze the relationship between them.

    Results: These two companies issue invoices to each other.

    Judgement made by the analysts: Based on experience, this phenomenon is obviously abnormal.

11. Analysts used **Backbone Analysis** to verify whether this network contains any key members.

    In the toolbar, choose **Analyze** > **Backbone Analysis**. Set the **Backbone Node** to **Customer** to analyze the backbone customers in the current network.

Results: The current relationship network contains two companies as key nodes. These two companies have taken up important positions in the current relationship network.

12. Analysts used the link extension feature to search for the drawers of these two key members.

    Select these two key members, and click **Link Extension**. Set **Link Type** to **Invoicing** to query the drawers of these two key members.

    Results: Analysts found a group of drawers by analyzing one of the key members.

    Inferences made by analysts: This company provides both manufacturing and trading services. It provides trading services for domestic manufacturers from various industries, including the electromechanics industry, electronics industry, moulding industry, and the food industry. This is a suspicious issue of tax cheating.

13. Analysts checked the behavior details of these drawers and the key member.

    Select this key member and the group of drawers. Click **Behavior Chronology**, and then click the **Details** tab. Set **Link** to **Invoicing** to view the invoicing details.

    Results: The proportion of sales and export volumes are both around 10%, which is relatively even.

    Inferences made by analysts: The proportion of orders and exports are too even, which shows obvious human manipulation.

14. Analysts used **Common Neighbors** to check whether these drawers have shared objects, for example, WIFI.

    Select the drawer nodes, and choose **Analyze** > **Common Neighbors**. Set **Link Type** to **WIFI** to check whether the drawers have a shared WIFI.

    Results: These drawers often connect to WIFI using the same MAC address to log on to the trading platform.

    Inferences made by analysts: This is an obvious abnormal phenomenon. It is very likely that these companies are operated by the same group of people.

15. Analysts used **Common Neighbors** to check whether the drawers and the customers have shared phone numbers.

    Select all drawers and customer nodes, and choose **Analyze** > **Common Neighbors**. Set **Link Type** to **Drawer TEL** and **Customer TEL** to check whether the drawer and the customer have a shared contact number.

    Results: A telephone number was shared by different drawers and customers.

    Inferences made by analysts: Based on the abnormal information found in the relationship network, it is very likely that these groups are cheating on tax rebates.

On-the-spot investigation

According to the results returned from the on-the-spot investigation, all these manufacturers and traders are highly suspicious. The department concerned continued to investigate these groups, and uncovered a tax cheat group related with 13 enterprises. This group registered different roles on the trading platform, made fake invoices and transactions internally, and the amount of tax refunds reported to the trade platform reached 100 million RMB.

8.16. FAQ

1. Q: How can I log on to the system for the first time?

   A: Contact the administrator to obtain the account and the initial password to log on to Graph Analytics. To keep your account secure, modify the password as prompted.

2. Q: Why does the system prompt an error message indicating incorrect user name and incorrect password when I was logging on to Graph Analytics?

   A: If you are unable to log on to the system, check whether the account name and the password you entered are correct, and whether the password is entered in half-width characters, in the correct case, or has any space. If the error persists, contact the administrator.

3. Q: What is the default rule for the simple link extension (double-clicking a link to start a link extension)?

   A: To help you analyze the information quickly, the administrator configures common links in Administration Console and synchronizes them to the double-click operation. These common links must be published by the administrator. If you need to add or remove a double-click link extension, contact the administrator.

4. Q: Why does the system prompt "a maximum of five nodes can be selected" when I select all nodes in the graph area to perform the link lookup analysis?

   A: By default, Graph Analytics supports a maximum of five nodes in the link extension analysis. If you need to analyze more than five nodes, contact the administrator, and the administrator will assess the system scale and make adjustments.

5. Q: Why can't I delete a node by pressing Delete on the keyboard?

   A: Currently, you cannot delete a node by pressing Delete on the keyboard. You can right-click the selected node and click **Delete** in the shortcut menu.

6. Q: How many steps can be undone or rolled back?

   A: A maximum of 20 steps can be rolled back or undone.

7. Q: Why does the Path Analysis button turn gray after I select a node?

   A: Path Analysis is available only after two nodes are selected.

8. Q: After I select a node, why do the Group Analysis button and the Common Neighbors button turn gray?

   A: Group Analysis and Common Neighbors are available only after two or more nodes are selected.

9. Q: Can I configure a new link analysis method discovered by myself while using Graph Analytics?

   A: Currently, links are configured by the administrator. If you need to add a new link analysis method, contact the administrator.

10. Q: Why is there no data available after I click Behavior Analysis, Chronology Analysis, and Details?

    Q: You need to select a node in the graph area before performing these analyses or viewing behavior details.

11. Q: Why are statistics displayed on the right side when no node in the graph area is selected?

    A: If no node is selected, statistics on all nodes are collected by default.

12. Q: How to find the nodes that fall out of the scope of the canvas?

    A: You can enable the thumbnail to locate the nodes, and move the nodes that fall out of the canvas to the visible area.

13. Q: Why are all layout buttons become gray and unavailable?

    A: The layout buttons become available only after you select a node in the graph area.

14. Q: After I select all the nodes in the graph area, why does the system give no response after I click Hierarchical Layout?

    A: In the Hierarchical Layout mode, you need to select one node as the starting point to view the hierarchical layout.

15. Q: Besides the drag button in the toolbar, can I use any shortcut operations to move the canvas?

    A: You can press **Space** on the keyboard to move the canvas.

9.Dataphin

9.1. What is Dataphin?

Dataphin is an intelligent engine for building big data platforms. It is designed to meet the requirements of big data development, management, and application across multiple industries. Dataphin combines technologies and methodologies. It provides all-in-one intelligent data development and management services, including data ingestion, data standardization, data modeling, data asset management, and data services.

Dataphin applies to different computing and storage environments. This enables you to use a single console to process data from various data sources. Dataphin allows you to import data, standardize data production, develop data by data modeling, and create a tag system by extracting tags from entities. You can also generate and manage data assets by using your business data and knowledge. Dataphin also provides multiple types of data services such as table query and intelligent voice search.

9.2. Usage notes

This topic describes the notes on using Dataphin.

To use Dataphin, you must have the necessary knowledge and expertise. This document is intended for:

- Application developers
- Analysts
- Data developers
- Technical architects
- System administrators

To ensure stable running of Dataphin, observe the following limits and recommendations.

Operation	Limit and recommendation
Set the computing engine type	Select a computing engine type and configure the cluster where your computing engine resides. For example, specify the endpoint of the cluster. MaxCompute and Hadoop are the available computing engine types. The system uses the selected computing engine type to support data construction in the specified cluster. Select the computing engine type and configure the computing engine settings based on your computing engine cluster.
Create a data source	• We recommend that you configure an AccessKey pair with administrative privileges for data source management. • One physical database can be used only as one data source.

Operation	Limit and recommendation
Create a project	• When the data source type is MaxCompute, the project name must be the same as your MaxCompute project name. • The project name cannot start with `LD_` or `ld_`. If project names start with LD_ or ld_, project names conflict with business unit names. In this case, errors may occur during table query because the system cannot differentiate between a logical table and a physical table. In Dataphin, when you query a logical table, you must prefix the table name with the corresponding business unit name. When you query a physical table, you must prefix the table name with the corresponding project name.
Configure the computing engine	• If a physical database is configured as a computing engine for a project, we recommend that you do not add, delete, or modify data in the database in the consoles of other cloud services. • We recommend that you do not configure computing engines of the same type that reside in different clusters for a project.
Process data	Computing engines can read data only from their own clusters.
Perform data standardization and data modeling	• We recommend that you exercise caution when you name data standardization objects and logical tables. Set names in lowercase for data standardization objects and make sure that the names are valid and easy to read. The names cannot be changed when they have downstream dependencies. • Use abbreviations whenever possible to avoid data production errors. Errors may occur if the length of a field name exceeds the limit that is imposed by the database.
Run an ad hoc query	When you query a logical table, prefix the table name with the corresponding business unit name. When you query a physical table, prefix the table name with the corresponding project name.
Extract the data value	We recommend that you set IDs based on user information to ensure an accurate match between an ID and a user.

9.3. Quick start

9.3.1. Instructions for system administrators

To prepare Dataphin for use, system administrators and deployment engineers must make sure that the environment is ready and required user roles are created.

Procedure

1. Make sure that the following environment and resources are ready:
   - Apsara Infrastructure Management Framework is deployed. The Apsara Stack console is accessible.
   - MaxCompute, Object Storage Service (OSS), DAuth, Server Load Balancer (SLB), Elastic

Compute Service (ECS), three physical machines, and PostgreSQL database resources are available.

> **Note** The PostgreSQL database in your environment must be accessible. This PostgreSQL database can be deployed on an ApsaraDB RDS for PostgreSQL instance or an ECS instance:
>
> - ApsaraDB RDS for PostgreSQL: A 6U model is required for Apsara Stack V3.7.0 and earlier versions. For versions later than V3.7.0, a 7U model is required. We recommend that you do not use miniRDS because it will soon become obsolete.
> - PostgreSQL on ECS: Dataphin provides this configuration in Apsara Stack V3.7.0 and later versions. You can obtain this baseline configuration if you purchase one of these versions. If you purchase a version earlier than V3.7.0, we recommend that you contact the Dataphin team to obtain specific ECS resources and deploy PostgreSQL in a non-standard way.

2. Obtain the following information about the computing engine cluster:
   - MaxCompute endpoint: This information is required when you set the computing engine type.
   - AccessKey ID and AccessKey secret that are used to create the Dataphin_Meta project in MaxCompute: This MaxCompute project is used to compute and store MaxCompute metadata.

   > **Note**
   >
   > After Dataphin and MaxCompute are deployed, a MaxCompute project is created to obtain MaxCompute metadata in the Apsara Stack environment. System administrators and deployment engineers must verify that the Dataphin_Meta project exists and obtain the AccessKey ID and AccessKey secret that are used to create this MaxCompute project. If the Dataphin_Meta project does not exist, contact deployment engineers to create one and grant Dataphin the permission to obtain MaxCompute metadata.

3. Create user roles. After Dataphin is deployed, the account system provides the following three types of user roles in the Apsara Stack environment:
   - O&M super administrator: an independent metadata management tenant of the system. The O&M super administrator can obtain and parse the metadata of your cluster. Each system has only one O&M super administrator. Contact deployment engineers to obtain the username and password of the O&M super administrator.

     > **Note** System administrators must keep the username and password of the O&M super administrator confidential, and exercise caution after logon as the O&M super administrator.

   - Super administrator: a tenant who performs construction operations. For example, the super administrator can manage users and also design and build the architecture of a specific business data system. In the Apsara Stack environment, the role of a department account or Apsara Stack tenant account is the super administrator.
   - Common user: a member of a department. A common user performs development operations, including the detailed design of a specific business data system. In the Apsara

Stack environment, a RAM user can be added under a department account. A RAM user can be added as a tenant member of the super administrator.

> **Note**
>
> Each user can belong to only one tenant. A user from one department cannot be added as a tenant member of another department. We recommend that each Dataphin system be used only for one department, namely, one tenant.

9.3.2. Log on to the Dataphin console

This topic describes how to log on to the Dataphin console in the Apsara Stack Cloud Management (ASCM) console.

Prerequisites

- Before logging on to the ASCM console, make sure that you have obtained the IP address or domain name of the ASCM console from the deployment personnel. The URL used to access the ASCM console is in the following format: https://[IP address or domain name of the ASCM console].
- We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to access the ASCM console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password for logging on to the console from the operations administrator.

   > **Note** When you log on to the ASCM console for the first time, you must change the password of your username as prompted. Due to security concerns, your password must meet the minimum complexity requirements: The password must be 8 to 20 characters in length and must contain at least two of the following character types: uppercase letters, lowercase letters, digits, and special characters such as exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Products** > **Big Data** > **Dataphin**.
5. Select the target organization and region. Then, click **Dataphin**.

9.3.3. Prepare for using Dataphin

This topic describes the preparations that you must complete before you use Dataphin.

Prepare items except data sources

1. Specify the endpoint of the computing engine cluster. For more information, see Set the computing engine type.
2. Create a project and configure the sandbox whitelist. For more information, see Create

projects.

3. Create a data domain named test_dataphin. For more information, see Create a data domain.
4. Create a table named dataphin_test as the destination table of data synchronization. For more information, see Create a destination table for data synchronization. You can execute the following SQL statement to create the destination table:

```
CREATE TABLE IF NOT EXISTS `datax_test` (order_id bigint comment 'Order ID',`area` string comme
nt 'Region',province string comment 'Province',city    string comment 'City',product_type string com
ment 'Type',order_name string comment 'Customer name',report_date datetime comment 'Date',or
der_amt double comment 'Sales amount')PARTITIONED BY (  `ds` STRING);
```

5. Add members to the project. For more information, see Add members. In this tutorial, add two members and set their roles to **Developer** and **Project Administrator**, respectively.

Prepare data sources

In this tutorial, statistics are collected on the total daily sales of office supplies and technical products in each province.

1. Create data sources. In this tutorial, create an ApsaraDB RDS for MySQL instance named dataphin. For more information, see Quick start in *ApsaraDB for RDS User Guide*.
2. Download the company_sales_recrod_copy table to be used in this tutorial.
3. Upload the company_sales_record_copy table to the ApsaraDB RDS for MySQL instance that you create.

9.3.4. Ingest data

This topic uses ApsaraDB RDS for MySQL as an example to describe how to connect a data source to Dataphin.

Prerequisites

A data source and a project are prepared. For more information, see Prepare for using Dataphin.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Planning** in the top navigation bar.
3. On the Planning page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source to be connected to Dataphin. Select **MYSQL**.
Name	The name of the data source. Set the value to dataphin.
Description	The description of the data source.

Parameter	Description
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
JDBC URL	The Java Database Connectivity (JDBC) URL that you can use to connect to the data source. Enter a URL in the format of `jdbc:mysql://RDS ID.mysql.rds.aliyuncs.com:3306/dataphin`. Replace RDS ID with the ID of the ApsaraDB RDS for MySQL instance that you want to connect to Dataphin.
Username	The username that you can use to connect to the data source. Set the value to dataphin.
Password	The password that you set for the dataphin user when you create the ApsaraDB RDS for MySQL instance.

6. Click **Test Connection**.
7. After the data source passes the connectivity test, click **OK**.

9.3.5. Integrate data

This topic describes how to synchronize data from a data source to your project, including the procedure for creating and configuring a sync task.

Prerequisites

A data source is connected to Dataphin. For more information, see Ingest data.

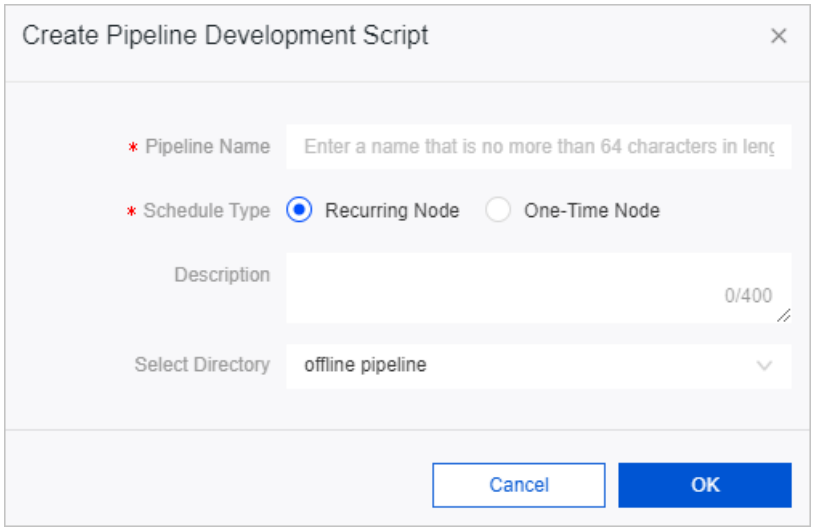
Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. Move the pointer over **Develop** in the top navigation bar and select **Integrated**.
5. Create an offline migration pipeline.

i. On the **Integrated** page, open the **Create Pipeline Development Script** dialog box by using one of the following methods:

- In the Script section, move the pointer over the icon next to Script and select **Offline Single Pipeline**.
- In the left-side navigation pane, move the pointer over the icon next to the project name and select **Offline Single Pipeline**.

ii. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Select **One-Time Node**.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides. Default value: **offline pipeline**.

iii. Click **OK**.

6. Configure the offline migration pipeline.

i. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.

ii. Click the icon before **Input**. Drag the **MySQL** icon to the pipeline canvas on the left.

The MYSQL_1 component appears on the canvas.

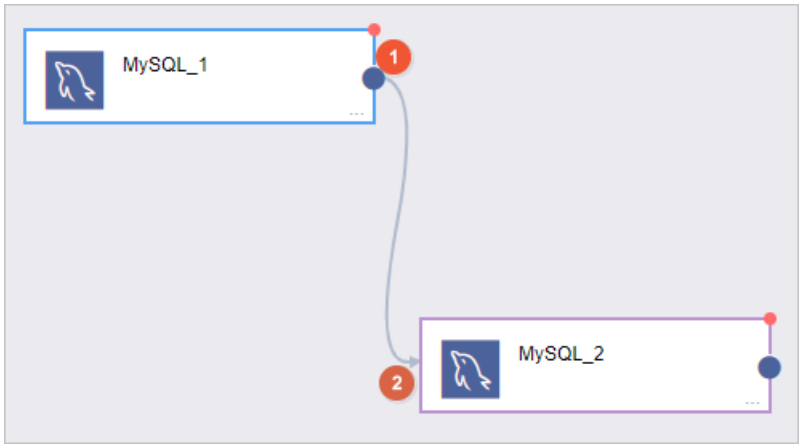
iii. Right-click MYSQL_1 and select **Configure Attributes**. In the MySQL Input Configuration dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ■ The data source is of the MySQL type. ■ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for the permission. For more information, see Data source permissions. You can also click the icon next to **Data Source** to go to the Planning page and connect a data source to Dataphin.
Source Table	The mode for synchronizing data. Select **Single Table**.
Table	The name of the source table. In this example, select company_sales_record_copy.
Split Key	Optional. The shard key of the source table.
Input Filtering	Optional. The filter condition for input fields.
Output Fields	The output fields to be generated based on the input configuration.

iv. Click **OK**.

v. Click the icon before **Output**. Drag the **Maxcompute** icon to the pipeline canvas on the left. The Maxcompute_1 component appears on the canvas.

vi. Drag a directed line from **MySQL_1** to **Maxcompute_1** to establish a relationship between the two components, as shown in the following figure.



vii. Right-click Maxcompute_1 and select **Configure Attributes**. In the Maxcompute Output Configuration dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Data Source	The data source of the component. Select a data source that is bound to your project.
Table	The name of the destination table. In this example, select dataphin_test.
Loading Policy	The policy for writing data to the destination table. Select **Append Data**.
Parse Solution	Optional. The operations before and after data output.
Input Fields	The input fields based on the upstream input.
Output Fields	The output fields to be generated.
Quick Mapping	The GUI element that allows you to specify mappings between the input and output fields. To specify name-based mappings between the input and output fields, perform the following steps: a. Move the pointer over the icon next to **Quick Mapping**. b. Select **Name-based Mapping** from the drop-down list. c. In the **Notification** message, click **OK**.

viii. Click **OK**.

7. In the upper-left corner of the pipeline configuration tab, click **Preview** to check whether the pipeline can be run.
   - If some variables such as bizdate are configured in the components, set relevant parameters as required and click **OK** to preview the running result of the pipeline.
   - If no variable is configured in the components, you can directly preview the running result of the pipeline.
8. In the upper-left corner of the pipeline configuration tab, click **Run** to synchronize data from the data source of the MYSQL_1 component to the data source that is bound to your project.
   - If some variables such as bizdate are configured in the components, set relevant parameters as required and click **OK** to run the pipeline.
   - If no variable is configured in the components, you can directly run the pipeline.
9. Save, submit, and then publish the offline migration pipeline.
   i. Click the icon in the upper-right corner to save the pipeline.

ii. Click the icon in the upper-right corner to submit the pipeline.When you submit the pipeline, Dataphin checks whether you have the following permissions:
   - Read permission on the data source in each input component
   - Write permission on the data source in each output component

iii. (Optional)Publish the pipeline.
   - If the current project is in Dev mode, publish the pipeline to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the pipeline after you submit it.

9.3.6. Define data standardization objects

Based on the methodology of dimensional modeling, you can build a bus matrix, divide data domains, and then define business processes, dimensions, atomic metrics, business filters, statistical periods, and derived metrics. This topic describes how to define data standardization objects.

Sample data

In this tutorial, statistics are collected on the total daily sales of office supplies and technical products in each province. The following table describes the fields that are selected from the company_sales_record_copy table for analysis.

Field	Description
order_id	The order ID.
area	The region.
province	The province.
city	The city.
product_type	The type of the product.
customer_name	The name of the customer.
report_date	The date of the order.
order_amt	The sales amount of the order.

Terms

- Dimension

  A dimension, which serves as the basis of measurement, is composed of a type of business attributes. A dimension can also be called an entity object. When you divide data domains and build a bus matrix, you must define dimensions based on the analysis of business processes. In this example of analyzing the total daily sales of office supplies and technical products in each province in a year, province is used as the dimension for data modeling.

- Business process

A business process refers to a business event of an enterprise, such as order placement, payment, and refund. In most cases, a business process is an indivisible event. This tutorial uses order placement as the business process whose ID is order_pay.

- Atomic metric

  An atomic metric is the measure for a business event. It is an indivisible metric and has a specific business meaning. You must define the `measure and business event` for an atomic metric. For example, the payment amount is an atomic metric, where payment is the event and amount is the measure. In this tutorial, the atomic metric sum(order_amt) is created based on the sum of the measure order_amt.

- Business filter

  A business filter defines the scope of a business. A business filter is unique within a business unit and belongs to only one source logical table. The computing logic of a business filter is defined based on the fields of the source logical table model. This ensures that all metrics are created in a uniform and standardized manner. In this tutorial, `product_type='technical products'` and `product_type='office supplies'` are used as business filters.

- Derived metric

  A derived metric is composed of the `atomic metric, business filter, statistical period, and dimension (statistic granularity)`. A derived metric is an atomic metric that is constrained by the statistical business scope. This tutorial takes the total sales amount of office supplies and technical products of the last day in each province as the derived metric, province as the dimension, order placement as the business process, the total sales amount sum(order_amt) as the atomic metric, technical products and office supplies as business filters, and the last day as the statistical period.

9.3.7. Create data modeling objects

This topic describes how to create data modeling objects.

Prerequisites

- A data source and a project are prepared. For more information, see Prepare for using Dataphin.
- The data source is connected to Dataphin. For more information, see Ingest data.
- Data synchronization is completed. For more information, see Integrate data.
- Data standardization objects are defined. For more information, see Define data standardization objects.

Create a dimension

1. Log on to the Dataphin console.
2. Go to the **Dimensions** section.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.

ii. (Optional)On the Develop page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode. Do not select the **Data_distill** project.You can skip this step if the current project is in **Dev** or **Basic** mode and is not the **Data_distill** project.

iii. In this example, select the project that you create.

iv. On the **Develop** page, click the **Standards and Modeling** tab in the left-side navigation pane.

v. On the Standards and Modeling tab, move the pointer over the left-side navigation submenu and click the icon.

3. In the **Dimensions** section, click the icon in the upper-right corner.

4. On the **Create Dimension** tab, set the parameters as required.

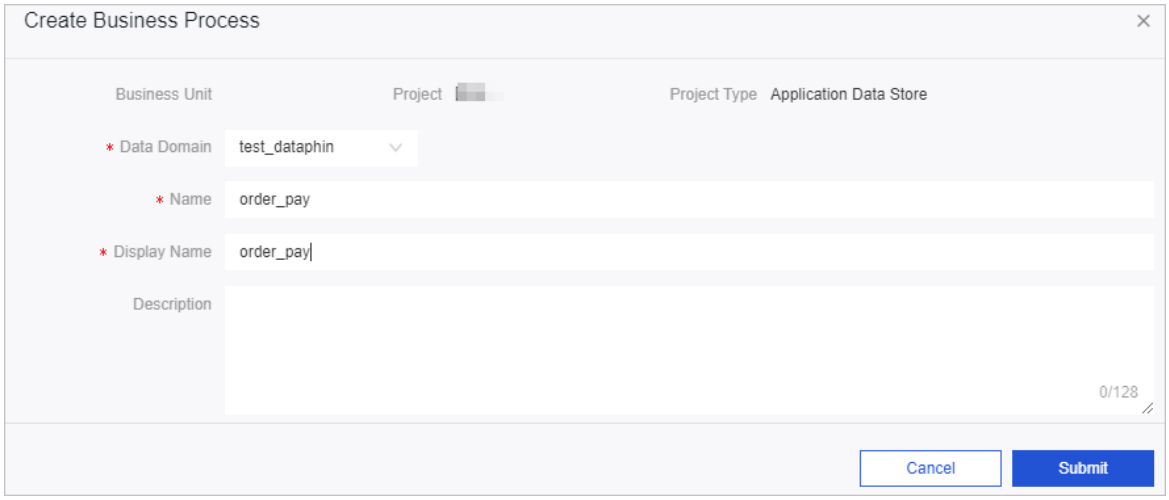
Section	Parameter	Description
Basic Dimension Information	Data Domain	The data domain of the dimension to be created. Select test_dataphin.
	Dimension Name	The name of the dimension. Enter province.
	Dimension Display Name	The display name of the dimension. Enter province.
	Dimension Description	The description of the dimension.
Dimension Logic	Primary Key Name	The name of the primary key. Enter province.
	Primary Key Display Name	The display name of the primary key. Enter province.
	Primary Key Type	The data type of the primary key. Select STRING.

Section	Parameter	Description
	Primary Key Computing Logic	The computing logic of the primary key. Dataphin allows you to define the primary key computing logic of a dimension by writing SQL statements. i. Click **Example** next to **Primary Key Computing Logic** to view an example of SQL statements. Enter the following SQL statement in the SQL editor: `select` `province` `from` `dataphin_test` ii. Click **Code Check** to verify whether the SQL statement that you entered is valid.

5. Save and submit the dimension.
   i. Click the icon in the upper-right corner to save the dimension.
   ii. Click the icon in the upper-right corner to submit the dimension.
6. View the corresponding logical dimension table.
   i. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon.After you create a dimension, Dataphin automatically generates a logical dimension table for the dimension. The name of the generated logical dimension table is the same as the dimension name that you defined.
   ii. In the Logical Dimension Tables section, use the dimension name that you defined to search for the corresponding logical dimension table. Alternatively, search for the logical dimension table dim_province in the data domain test_dataphin.

Create a business process and a logical fact table

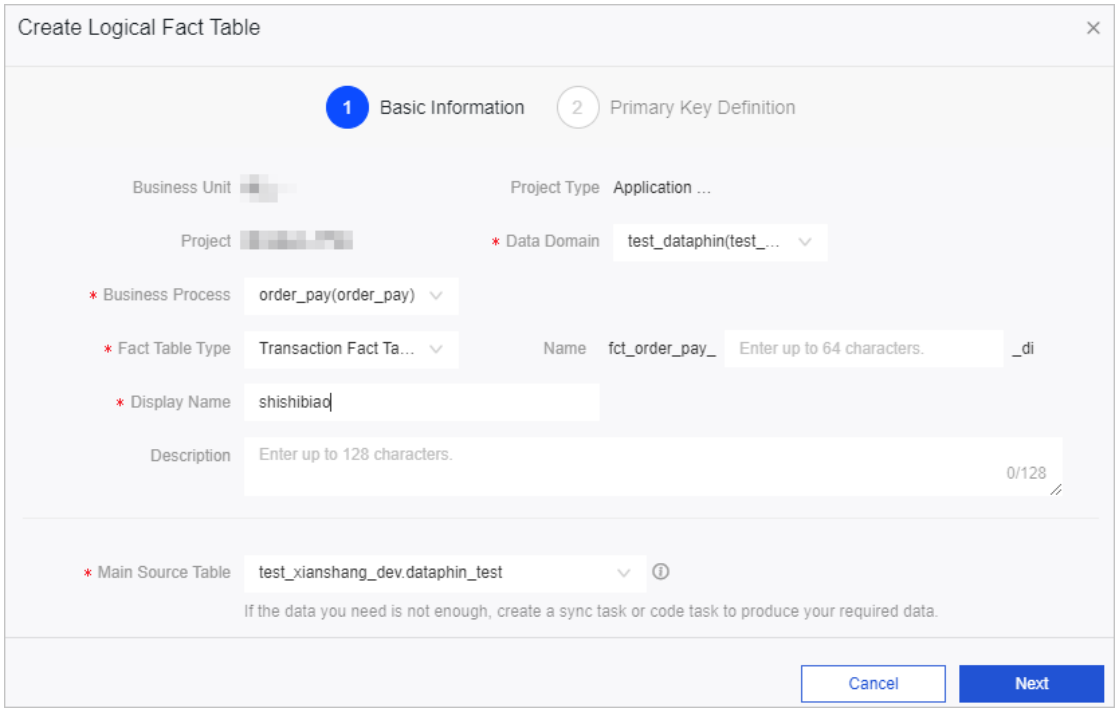
1. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon.
2. In the **Business Processes** section, click the icon in the upper-right corner.
3. In the **Create Business Process** dialog box, set the parameters as required.



Parameter	Description
Data Domain	The data domain of the business process to be created. Select test_dataphin.
Name	The name of the business process. Enter order_pay.
Display Name	The display name of the business process. Enter order_pay.

4. Click **Submit**.
5. In the dialog box that appears, enter your comments.
6. Click **OK**.
7. Create a logical fact table.
   i. Click **order_pay** in the Business Processes section. On the View Attributes tab, you can view the details about the business process.
   ii. Move the pointer over the icon and select **Create Logical Table**.

iii. In the **Create Logical Fact Table** dialog box, set the parameters as required.



Parameter	Description
Business Process	The business process that corresponds to the logical fact table to be created. Select order_pay (order_pay).
Fact Table Type	The type of the logical fact table. Select **Transaction Fact Table**.
Display Name	The display name of the logical fact table. Enter shishibiao.
Main Source Table	The main source table of the logical fact table. Select Project name.dataphin_test. In this example, select test_xianshang_dev.dataphin_test.

iv. Click **Next**.

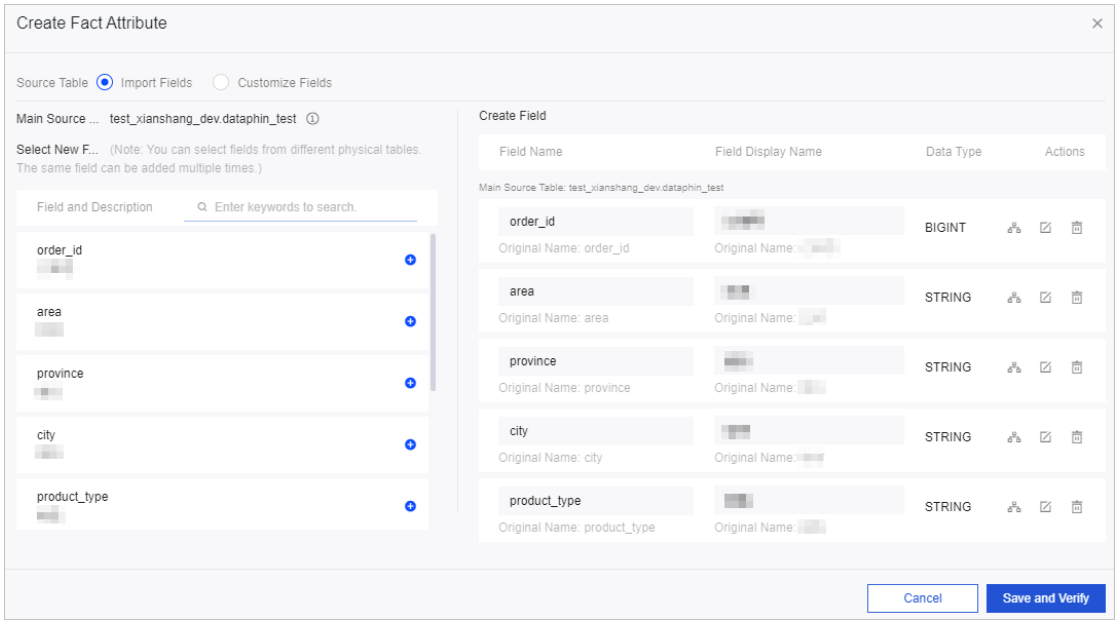
v. In the **Primary Key Definition** step, set the **Set Primary Key** parameter to **No**.

vi. Click **Submit**.

8. Configure the logical fact table.

i. On the configuration tab of the **fac_order_pay_df** logical fact table that appears, click **Add Measure** in the Central Table section.

ii. In the **Create Measure** dialog box, set the parameters as required.

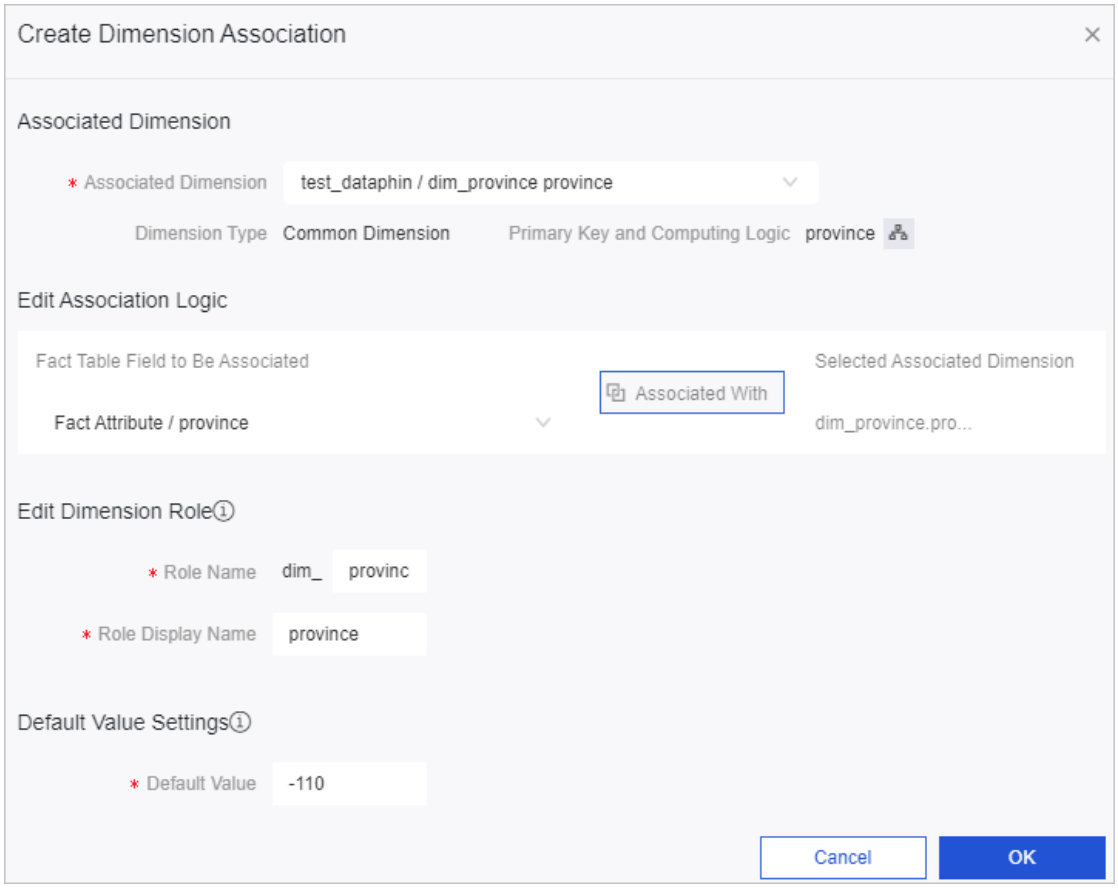


Parameter	Description
Source Table	Specifies whether to import fields from the source table or use SQL statements to reference fields. Select **Import Fields**.
Create Field	The field to be added. Add a field by performing the following steps: a. Click the icon next to a field name in the Select New Fields section. b. Enter a name in the **Field Display Name** field.

iii. Click **Save and Verify**.

iv. On the configuration tab of the fac_order_pay_df logical fact table, click **Create Dimension Association** in the Central Table section.

v. In the **Create Dimension Association** dialog box, set the parameters as required.



- **Associated Dimension**: Select the logical dimension table dim_province in the data domain test_dataphin.
- **Edit Association Logic**: Select province under Measure.
- Use the default values for other parameters.

vi. Click **OK**.

9. Save and submit the logical fact table.

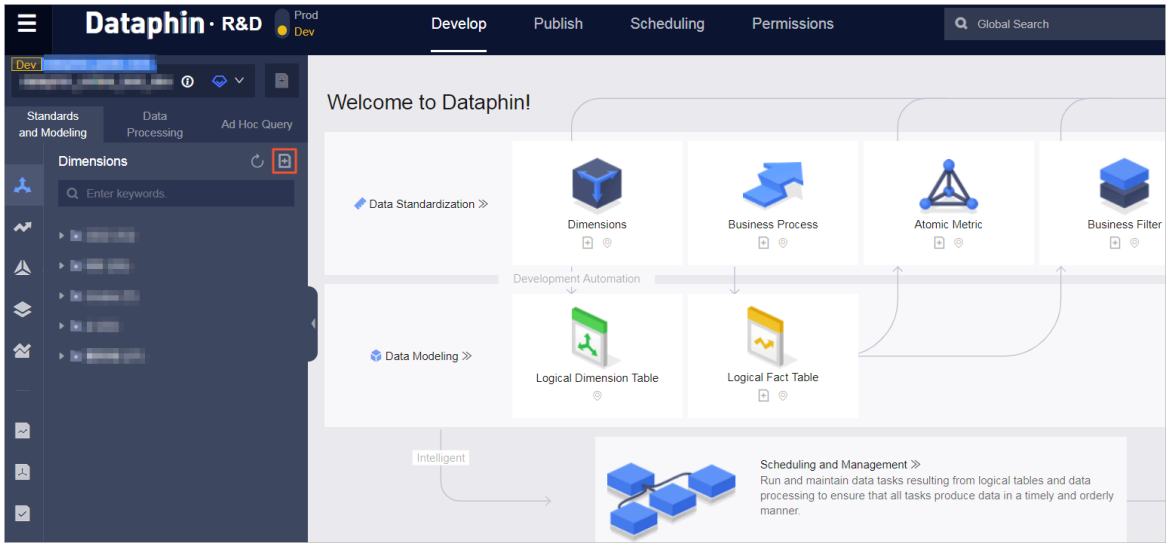
   i. Click the icon in the upper-right corner to save the logical fact table.

   ii. Click the icon in the upper-right corner to submit the logical fact table.

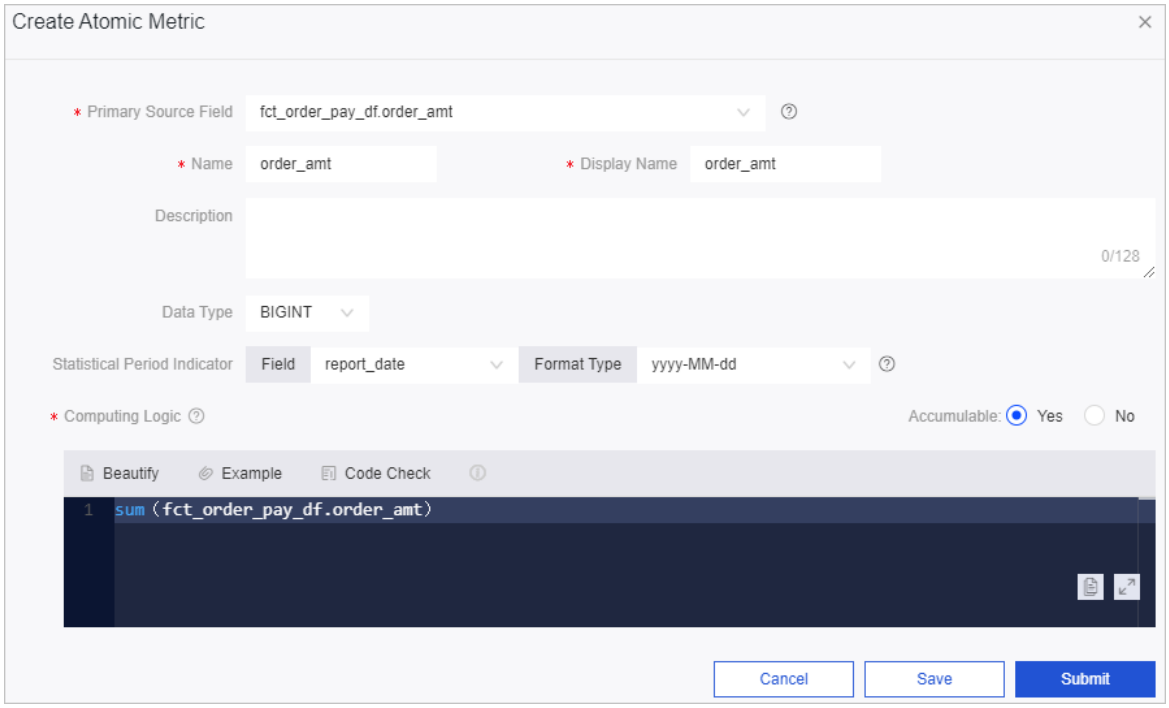
Create an atomic metric

1. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon.

2. In the **Atomic Metrics** section, click the icon in the upper-right corner and select **Create Atomic Metric**.



3. On the **Create Atomic Metric** tab, select fct_order_pay_df from the **Source Table** drop-down list. In the Atomic Metrics section, click **Create Atomic Metric**.
4. In the **Create Atomic Metric** dialog box, set the parameters as required.



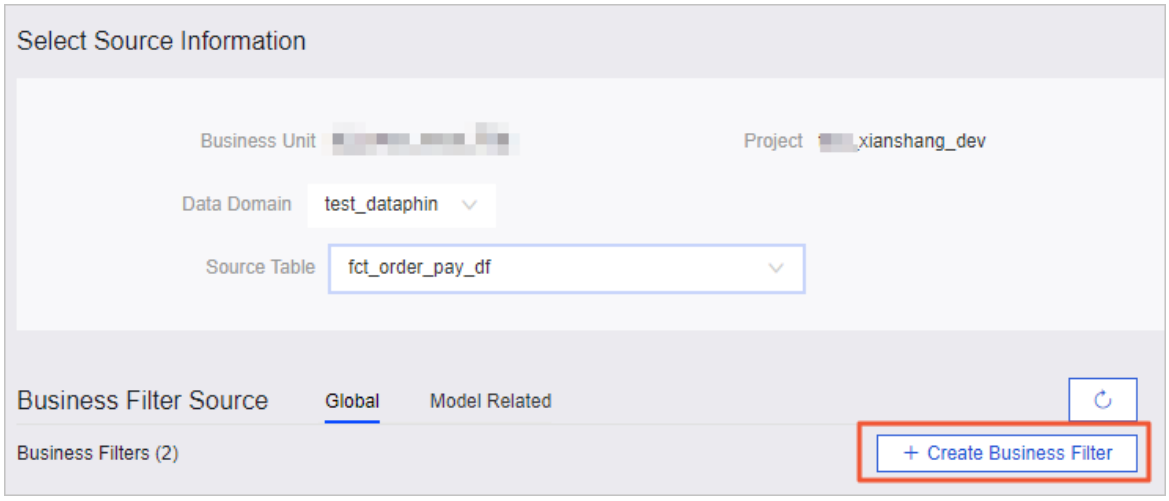
Parameter	Description
Primary Source Field	The source field of the atomic metric to be created. Select fct_order_pay_df.order_amt.
Name	The name of the atomic metric. Enter order_amt.
Display Name	The display name of the atomic metric. Enter order_amt.
Data Type	The data type of the atomic metric. Select BIGINT.

Parameter	Description
Field	The field of the statistical period. Select report_date.
Computing Logic	The computing logic of the atomic metric. Enter `sum(fct_order_pay_df.order_amt)`.

5. Click **Code Check** to verify whether the SQL statement that you entered is valid.
6. After the SQL statement passes the code check, click **Submit**.
7. In the dialog box that appears, enter your comments.
8. Click **OK**.

Create a business filter

1. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon.
2. In the **Business Filters** section, click the icon in the upper-right corner.
3. On the **Create Business Filter** tab, select `fct_order_pay_df` from the **Source Table** drop-down list. In the Business Filter Source section, click **Create Business Filter**.



4. In the **Create Business Filter** dialog box, set the parameters as required.

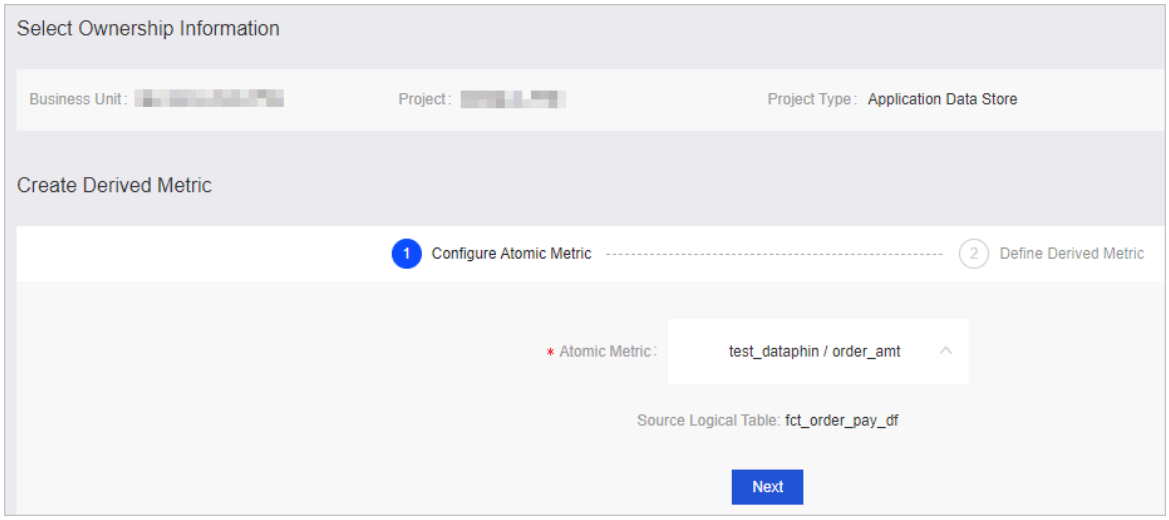
Parameter	Description
Primary Source Field	The source field of the business filter to be created. Select fct_order_pay_df.product_type.
Name	The name of the business filter. Enter product_type_bangongyongpin.
Display Name	The display name of the business filter. Enter product_type_office supplies.

Parameter	Description
Computing Logic	The computing logic of the business filter. Enter `fct_order_pay_df.product_type='office supplies'` .

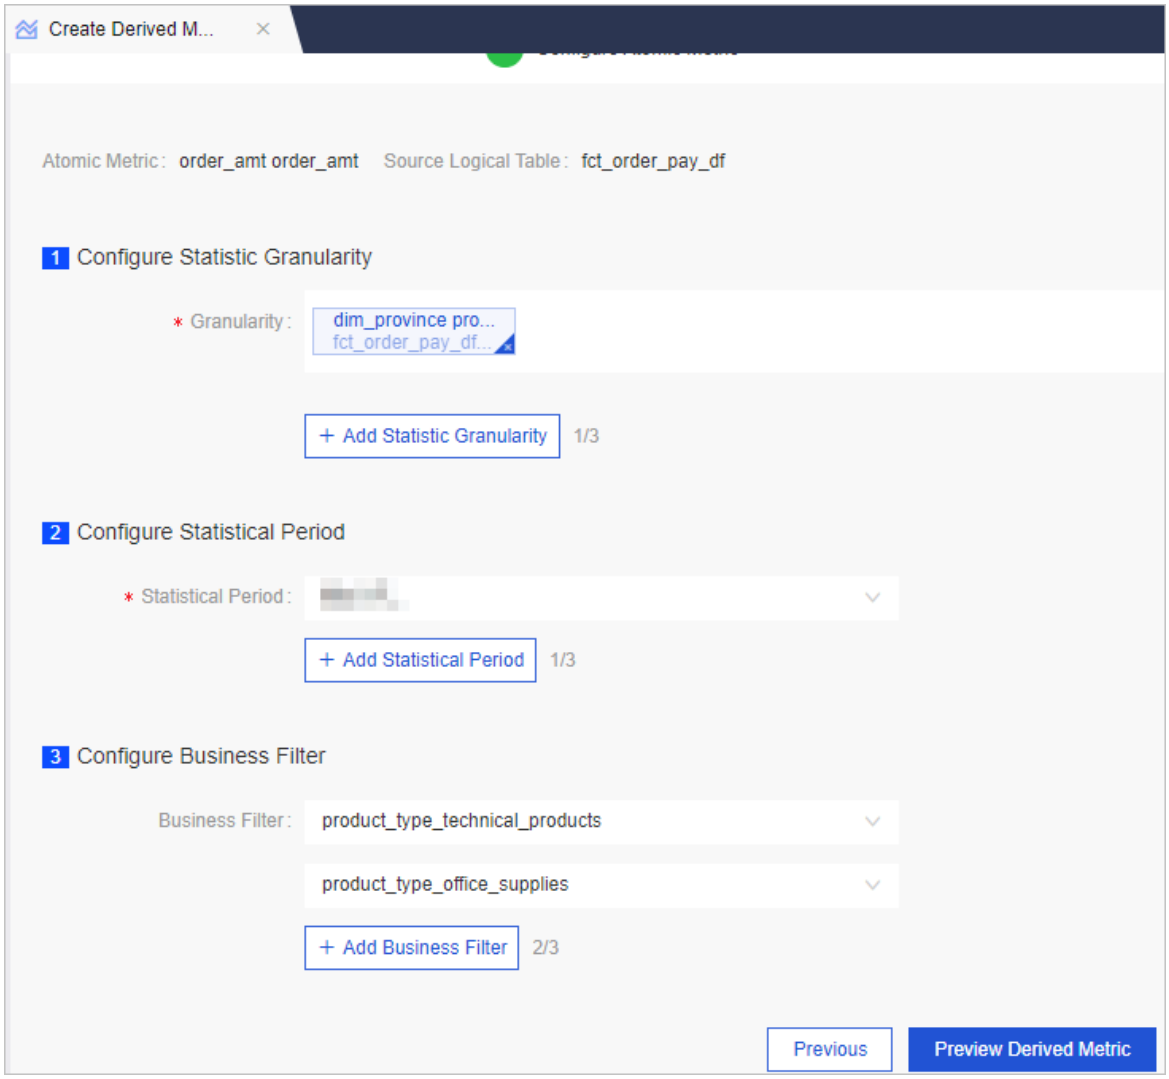
5. Click **Code Check** to verify whether the SQL statement that you entered is valid.
6. After the SQL statement passes the code check, click **Submit**.
7. In the dialog box that appears, enter your comments.
8. Click **OK**.

Create a derived metric

1. On the **Standards and Modeling** tab, move the pointer over the left-side navigation submenu and click the icon.
2. In the **Derived Metrics** section, click the icon in the upper-right corner.
3. On the **Create Derived Metric** tab, select order_amt under test_dataphin from the **Atomic Metric** drop-down list.



4. Click **Next**.
5. In the **Define Derived Metric** step, set the parameters as required.



Parameter	Description
Granularity	The statistic granularity of the derived metric to be created. Select fct_order_pay_df.dim_province under dim_province province.
Statistical Period	The statistical period of the derived metric. Select the last day.
Business Filter	The business filter of the derived metric. Select product_type_office supplies and product_type_technical products.

6. Click **Preview Derived Metric**.
7. In the **Change Derived Metric** section, confirm the parameter settings and click **Submit**.
8. Submit the derived metric.
   i. Click **Submit** to submit the derived metric.
   ii. In the dialog box that appears, enter your comments.
   iii. Click **OK**.

9.3.8. Generate retroactive data

To verify that code and tasks are valid, you can initiate a retroactive data generation task and verify the data. This topic describes how to generate retroactive data for logical table conversion tasks and sync tasks.

Prerequisites

Data modeling objects are created. For more information, see Create data modeling objects.

Context

After you create and submit a dimension, a logical fact table, and a logical aggregate table, Dataphin automatically generates the corresponding logical table conversion tasks, for example, dim_province_core_od001_v1, fct_order_pay_df_od000_v1, and dws_province_od000_v1. You can use the same method to generate retroactive data for these logical table conversion tasks. This topic describes how to generate retroactive data for the logical table conversion task that is generated after you create a dimension, namely, dim_province_core_od001_v1.

Generate retroactive data for a logical table conversion task

1. Log on to the Dataphin console.
2. Go to the **Logical Table Conversion Tasks** tab.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select the project that you create.
   iii. In the top navigation bar, click **Scheduling**.
   iv. In the left-side navigation pane, click the **Global Management** tab.
   v. On the **Global Management** tab, move the pointer over the left-side navigation submenu and click the icon.
   vi. In the **Recurring Tasks** section, click the **Logical Table Conversion Tasks** tab.
3. Click the logical table conversion task dim_province_core_od001_v1.
4. In the directed acyclic graph (DAG), right-click the current node and select **Generate Retroactive Data**.
5. In the **Generate Retroactive Data** dialog box, set the **Data Timestamp** parameter to 2019-10-27~2019-10-27. Set the **Select Downstream Nodes** parameter to **No**.

   > **Note** The system automatically generates a value for the **Instance Name** parameter when you open the **Generate Retroactive Data** dialog box. You can change the value.

6. Click **OK**.
7. View the running result of the retroactive data generation instance.
   i. On the Global Management tab, move the pointer over the left-side navigation submenu and click the icon.

ii. In the Retroactive Data Generation Instances section, click the retroactive data generation instance. In the DAG, right-click the current node and select **View Operations Log**.

iii. In the **Operations Log** pane, view the operational logs of the instance.

Generate retroactive data for a sync task

1. On the **Global Management** tab, move the pointer over the left-side navigation submenu and click the icon.
2. In the **One-time Tasks** section, click the one-time task **dataphin**.
3. On the page that appears, click **Run** in the upper-right corner.
4. In the **Run** dialog box, set the **Data Timestamp** parameter to `2019-10-27`.
5. Click **OK**.
6. View the running result of the one-time instance.
   i. On the Global Management tab, move the pointer over the left-side navigation submenu and click the icon.
   ii. In the **One-time Task Instances** section, click the instance that is generated for the one-time task **dataphin**.
   iii. On the page that appears, click **View Operational Log** in the top navigation bar. On the Operational Log page, view the operational logs of the instance.

9.3.9. Verify data

This topic describes how to use an ad hoc query task to verify that your expected data is generated.

Prerequisites

Retroactive data is generated for the required logical table conversion tasks and sync tasks. For more information about how to generate retroactive data, see Generate retroactive data.

Context

The ad hoc query feature allows you to perform theme-based data query. MaxCompute SQL statements can be executed when MaxCompute is selected as the computing engine type of Dataphin. Dataphin automatically identifies and switches the SQL type based on the computing engine type that you set.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Ad Hoc Query** tab.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the Develop page, click the icon next to the project name in the upper-left corner and select the project that you create.
   iii. On the **Develop** page, click the **Ad Hoc Query** tab in the left-side navigation pane.

3. In the **Ad Hoc Query** section, click the icon next to **Ad Hoc Query**.
4. In the **Create Item** dialog box, set the parameters as required.

Parameter	Description
Name	The name of the ad hoc query task to be created. Enter dim_province.
Description	The description of the ad hoc query task.
Select Directory	The folder where the ad hoc query task resides.

5. Click **OK**.
6. On the **Code Editor** tab of the ad hoc query task, enter `select * from dataphin_test where ds='20191027'`.
7. Save and run the ad hoc query task.
   i. Click the icon in the upper-right corner to save the ad hoc query task.
   ii. Click the Run icon in the upper-right corner to run the ad hoc query task.
8. After the SQL statement is executed, view the running result on the **Result** tab.

	order_id	area	province	city	product_type	customer_name	report_date	order_amt	ds
1	13729				office supplies		2013-01-01 00:00:00	872.48	20191027
2	28774				office supplies		2013-01-01 00:00:00	180.36	20191027
3	37537				technical products		2013-01-02 00:00:00	4083.19	20191027
4	37537				technical products		2013-01-02 00:00:00	4902.38	20191027
5	37537				office supplies		2013-01-02 00:00:00	1239.06	20191027
6	44069				technical products		2013-01-02 00:00:00	137.63	20191027

9.3.10. Publish data

This topic describes how to publish data from the development environment to the production environment for scheduling.

Prerequisites

The data to be published is verified. For more information, see Verify data.

Context

You can publish data only when the data is generated in a project in Dev mode.

- If data is generated in a project in Basic mode, relevant tasks can be scheduled in the production environment after you submit the data.
- If data is generated in a project in Dev mode, you must publish the data to the corresponding project in Prod mode for scheduling after you submit the data. The data to be published may be data standardization and data modeling objects or data processing tasks.

Procedure

1. Log on to the Dataphin console.

2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the Develop page, click the icon next to the project name in the upper-left corner and select the project that you create.
4. In the top navigation bar, click **Publish**.
5. Publish data standardization and data modeling objects.
   i. On the **Objects to Publish** page, click the **Standards and Modeling** tab.
   ii. On the **Standards and Modeling** tab, select the objects that you develop in this tutorial.
   iii. Click **Publish** in the lower part of the page.
   iv. In the **Publish** dialog box, set the **Publishing Name** parameter and click **OK**. You can use the default value of Publishing Name.
6. Publish batch processing tasks.
   i. On the **Objects to Publish** page, click the **Batch Processing** tab.
   ii. On the **Batch Processing** tab, select the sync task that you develop in this tutorial.
   iii. Click the icon in the **Actions** column.
   iv. Alternatively, click **Publish** in the lower part of the page.
   v. In the **Publish** dialog box, set the **Publishing Name** parameter and click **OK**. You can use the default value of Publishing Name.
7. View publishing records.
   i. In the left-side navigation pane, click **Publishing History**. The Publishing History page appears.
   ii. Click the **Standards and Modeling** tab and view publishing records of data standardization and data modeling objects.
   iii. Click the **Batch Processing** tab and view publishing records of data processing tasks.

9.3.11. Verify the scheduling result

This topic describes how to verify that the scheduling result meets your expectations.

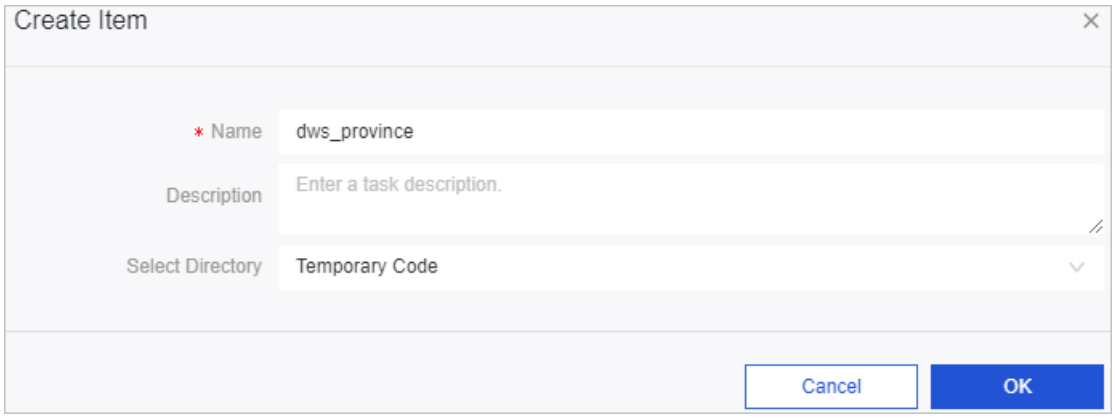
Context

After you publish data to the production environment, relevant tasks will not be run until the next day. You can simulate the task scheduling in the development environment to view the scheduling result.

Procedure

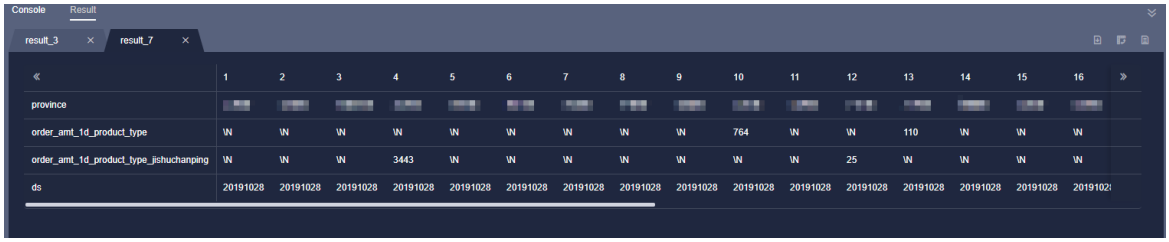
1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. Go to the **Global Management** tab.
   i. On the Develop page, click the icon next to the project name in the upper-left corner and select the project that you create.
   ii. In the top navigation bar, click **Scheduling**. The **Global Management** tab appears.

4. Generate retroactive data for one-time tasks and logical table conversion tasks of logical dimension tables, logical fact tables, and logical aggregate tables. For more information, see Generate retroactive data.
5. Go to the **Ad Hoc Query** tab.
   i. In the top navigation bar, move the pointer over **Develop** and select **Develop**. The **Develop** page appears.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. On the **Develop** page, click the **Ad Hoc Query** tab in the left-side navigation pane.
6. Create an ad hoc query task.
   i. On the **Ad Hoc Query** tab, click the icon.
   ii. In the **Create Item** dialog box, set the parameters as required.



Parameter	Description
Name	The name of the ad hoc query task to be created. Enter dws_province.
Description	The description of the ad hoc query task.
Select Directory	The folder where the ad hoc query task resides.

   iii. Click **OK**.
   iv. On the **Code Editor** tab of the ad hoc query task, enter `select * from dataphin_test where ds='20191027'` .
7. Save and run the ad hoc query task.
   i. Click the icon in the upper-right corner to save the ad hoc query task.
   ii. Click the Run icon in the upper-right corner to run the ad hoc query task.
8. After the SQL statement is executed, view the running result on the **Result** tab.



9.4. Management Center

9.4.1. Initialize metadata

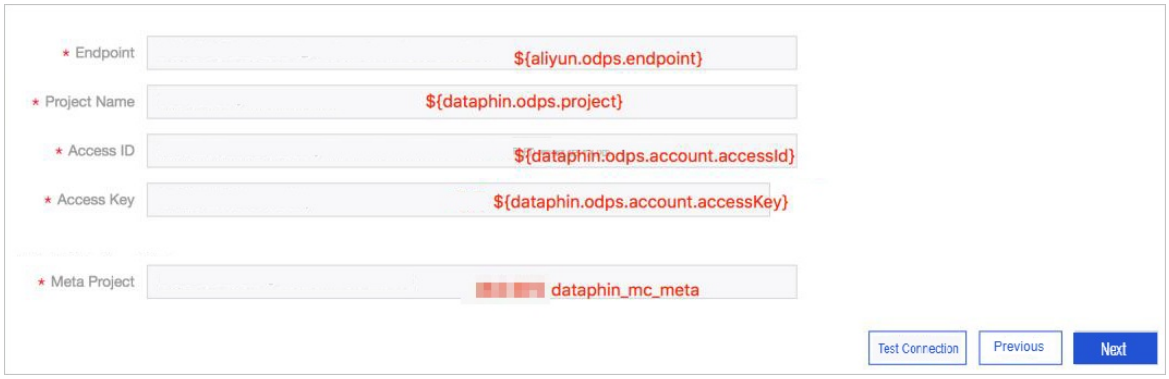
After the compute cluster information is obtained, you can log on to the Dataphin console as the operations and maintenance (O&M) super administrator to configure the metadata warehouse. This topic uses Apsara Stack Dataphin whose computing engine type is MaxCompute as an example.

Procedure

1. Log on to the Dataphin console as the O&M super administrator. For more information about the O&M super administrator account and password, see Instructions for the system administrator.

   > **Note** System administrators must keep the account and password of the O&M super administrator strictly confidential and perform operations with caution after logging on as the O&M super administrator.

2. On the Dataphin homepage, click **Management Center** in the top navigation bar. In the left-side navigation pane, click **Metadata Warehouses Configuration**. On the page that appears, click **Start**.
3. In the Select Computing Engine step, select a computing engine type and click **Next**. In this example, select **MaxCompute v1.1**.
4. In the Parameter Configuration step, set the parameters correctly, as shown in the following figure. Click **Test Connection**. After the test is passed, click **Next**.



5. Perform the subsequent steps as prompted.

> **Note** The subsequent steps, including configuring MaxCompute at the backend, take about 15 minutes. If a message appears to inform you that the subsequent steps are successfully performed, click **Complete**.

9.4.2. Manage members

This topic describes how to add and remove members and configure contact information for members in Dataphin.

Go to the Members Management page

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Management Center** in the top navigation bar.
3. On the **Members Management** page, different roles including members and the super administrator have different permissions:
   - If you are a member, you can view the following information of all members: username, display name, and when a member is added to the system. However, you can only view and edit your own mobile number, email address, and webhook URL.
   - If you are the super administrator, you can perform the following operations:
     - View the following information of all members: username, display name, and when a member is added to the system. You can also click the icon in the **Mobile Phone**, **Mailbox**, and **DingTalk Group Chatbot** columns to view the mobile number, email address, and webhook URL of a member.

       After you view the mobile number, email address, and webhook URL of a member, you can click the icon in the **Mobile Phone**, **Mailbox**, and **DingTalk Group Chatbot** columns to hide corresponding information. You can also edit the mobile number, email address, and webhook URL for all members.
     - Click the icon in the headings of the **Mobile Phone**, **Mailbox**, and **DingTalk Group Chatbot** columns to view the mobile numbers, email addresses, and webhook URLs, if configured, of all members.

       After you view the mobile numbers, email addresses, and webhook URLs of all members, you can click the icon in the headings of the **Mobile Phone**, **Mailbox**, and **DingTalk Group Chatbot** columns to hide corresponding information of all members.

Add members

> **Note** Only the super administrator can add members to Dataphin.

1. On the **Members Management** page, click **Add Members** in the upper-right corner.
2. In the **Add Members** dialog box, click the icon next to the **Username** parameter.
3. Select a RAM user and click **OK**.

You can add multiple RAM users as members at a time. You can enter a keyword in the search box to search for RAM users you want to add.

Configure contact information for members

> **Note** The super administrator can configure contact information for one or more members at a time. Members can configure only their own contact information.

To configure contact information for one or more members at a time, perform the following steps:

- i. On the **Members Management** page, select one or more members and click **Edit Members** in the upper-right corner.
  ii. In the **Modify Contact Information** dialog box, set the parameters as required.

Parameter	Description
Mobile Phone	The mobile number of the member. **Note** Only mobile numbers in mainland China can be added.
Mailbox	The email address of the member.
DingTalk Group Chatbot	The webhook URL of the member. Enter `https://oapi.dingtalk.com/robot/send?access_token=713697da1c2a874bc80518e1872e9627d7e79d3015dd5791a1f03589be76ce3f`.

  iii. Click **OK**.
- i. On the **Members Management** page, find the member for whom you want to configure contact information and click the icon in the **Actions** column.
  ii. In the **Modify Contact Information** dialog box, set the parameters as required.

Parameter	Description
Mobile Phone	The mobile number of the member. **Note** Only mobile numbers in mainland China can be added.
Mailbox	The email address of the member.
DingTalk Group Chatbot	The webhook URL of the member. Enter `https://oapi.dingtalk.com/robot/send?access_token=713697da1c2a874bc80518e1872e9627d7e79d3015dd5791a1f03589be76ce3f`. You can move the pointer over the icon to view how to receive alert notifications by using a DingTalk chatbot.

iii. Click **OK**.

Remove members

> **Note** Only the super administrator can remove members from Dataphin.

To remove one or more members at a time, perform the following steps:

- i. To remove multiple members at a time, select the members and click **Delete** in the upper-right corner.
  ii. In the message that appears, click **OK**.
- i. To remove a single member, find the member and click the icon in the **Actions** column.
  ii. In the message that appears, click **OK**.

> **Note** By default, only RAM users who are added as members can be removed from Dataphin. The super administrator cannot be removed.

Synchronize account information from another account system to Dataphin

If the account information is updated in the RAM user list, you can click **Account System Synchronization** on the **Members Management** page to synchronize the updated account information to Dataphin.

9.4.3. Configure the computing engine settings

This topic describes how to configure the computing engine settings of Dataphin.

Context

Dataphin supports the computing engines for both stream processing and batch processing.

- By default, Dataphin sets **Flink** as the computing engine type for stream computing.
- Dataphin supports **MaxCompute** and **Hadoop-2.6** as the computing engine type for batch computing.

Procedure

1. Log on to the Dataphin console as the super administrator.
2. On the Dataphin homepage, click **Management Center** in the top navigation bar.
3. On the page that appears, click **Computing Engine Configuration** in the left-side navigation pane.
4. On the **Computation Configuration** page, select the computing engine type for batch processing.
5. Set the parameters as required.
   - If you select **MaxCompute** as the computing engine type, you must set the **Endpoint** parameter. Click **Verify**. After the setting passes the verification, click **Submit**.
   - If you select **Hadoop-2.6** as the computing engine type, you must set the **NameNode**

parameter. Click **Verify**. After the setting passes the verification, click **Submit**.

9.4.4. Configure the intelligent data engine

9.4.4.1. Data skew optimization

This topic describes how to use the data skew optimization feature of Dataphin to optimize abnormal tasks during scheduling.

Introduction to the data skew optimization feature

The data skew optimization feature in Dataphin is described as follows:

- After the data skew optimization feature is enabled and the first task is submitted, if the duration and processed data volume of the task exceed the specified duration threshold, multiples of the average duration, and multiples of the average data volume, the intelligent data engine starts the preliminary anomaly detection.
- When the task is running, the intelligent data engine detects data for the task to find hotspot data in associated fields. Based on the detected data, the engine refactors the task code to avoid data skew. In addition, the engine kills the previously running task and uses the optimized code to resubmit the task. This optimizes logical table tasks.
- The intelligent data engine records the detected data skew status and uses it to detect data for the next day. If the engine still detects data skew on the next day, it continues to use the optimized code. If no data skew is detected, the engine uses the code without data skew optimization.
- If a rerun task references data tables and fields that are detected by the intelligent data engine but the engine still detects data skew in a field, the engine optimizes the submitted SQL statements based on the detected data. Then, the engine uses the optimized code to rerun the task. If a rerun task references data tables that are not detected by the intelligent data engine, the engine detects data for the task only when the task exceeds the specified thresholds, and then the engine refactors the code based on the detected data. The intelligent data engine needs to process data skew detected during production in tasks and models that it automatically generates.

If you want to use the data skew optimization feature, you must set YARN parameters for the computing engine, as shown in the following figure.

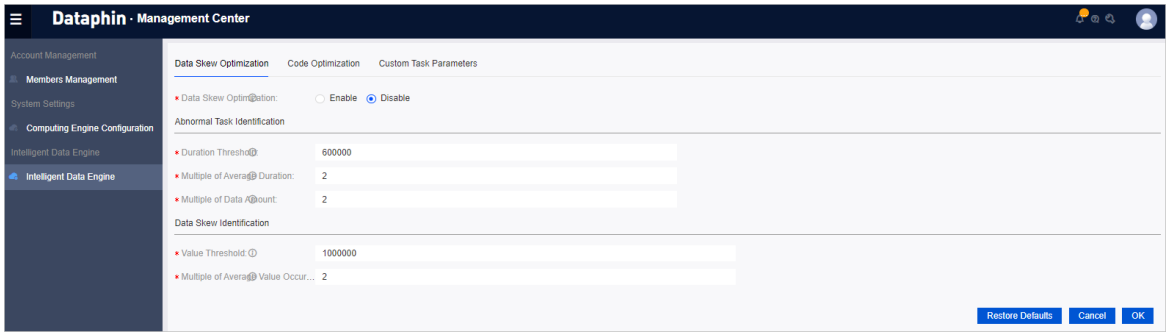
To collect MapReduce logs in real time for data cleansing, you must set YARN parameters. If you do not specify any of the following three parameters, the global switch of the data skew optimization feature is turned off by default for the intelligent data engine.

- MapReduce Log Web Service: the YARN environment variable mapreduce.jobhistory.webapp.address that is used to collect MapReduce logs in real time.
- Yarn Web Service: the YARN environment variable yarn.web-proxy.address that is used to distribute requests for accessing the YARN Resource Manager.
- Yarn Resource Manager: the YARN environment variable yarn.resourcemanager.webapp.address that is used to access the YARN Resource Manager.

Configure the data skew optimization feature

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Management Center** in the top navigation bar.

3. In the left-side navigation pane, click **Intelligent Data Engine**. The Data Skew Optimization tab appears.



4. Set relevant parameters as prompted on the Data Skew Optimization tab. The following table describes the parameters.

Parameter	Description	Example
Data Skew Optimization	Specifies whether to enable the data skew optimization feature for the intelligent data engine.	Enable
Duration Threshold	The duration threshold of an abnormal task. If the duration of a task exceeds this threshold, the intelligent data engine detects data for the task to analyze and identify anomalies. Unit: milliseconds.	600000
Multiple of Average Duration	The multiples of the average duration of all tasks. If the duration of a task is longer than the specified multiples of the average duration of all tasks, the intelligent data engine detects data for the task to analyze and identify anomalies.	2
Multiple of Data Amount	The multiples of the average data volume processed by all tasks. If the data volume processed by a task is greater than the specified multiples of the average data volume processed by all tasks, the intelligent data engine detects data for the task to analyze and identify anomalies.	2
Value Threshold	The threshold of skewed data. If a value in a dataset exceeds this threshold, the value is skewed.	1000000
Multiple of Average Value Occurrences	The multiples of the average occurrences of all values in a dataset. If the occurrences of a value in a dataset are greater than the specified multiples of the average occurrences of all values in the dataset, the value is skewed.	2

5. After the preceding parameters are set, click **OK**. In the dialog box that appears, click **OK**.

The configuration is changed.

On the **Data Skew Optimization** tab, you can also click **Restore Defaults**. In the dialog box that appears, click **OK**. The default configuration is applied.

9.4.4.2. Code optimization

This topic describes how to use the code optimization feature to optimize production code.

Introduction to the code optimization feature

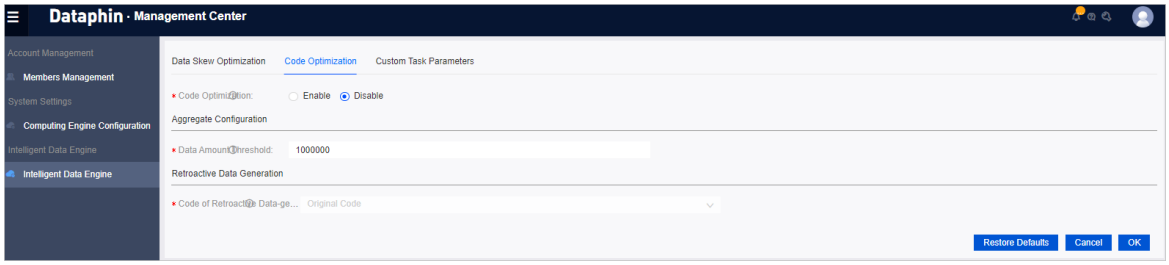
You can enable the code optimization feature to reuse the semantics of SQL statements and optimize production code. Currently, you can optimize only derived metrics. For example, the payment amount of a category on the last day can be accumulated to calculate the payment amount of the category in the last 30 days.

> **Note** The statistical dimensions of derived metrics may change.

The data in an incremental fact table for order payment is associated with products and categories. Based on this fact table, you can calculate the payment amount of each category in the last 30 days. Assume that the category of a product changes from category1 to category2 on a day of the last 30 days. Before code optimization, the payment amount is calculated based on the latest dimensions. In this case, the payment amount of the product in the last 30 days is calculated in category2. After code optimization, the payment amounts of the product in category1 and category2 in the last 30 days are still calculated in respective categories.

Configure the code optimization feature

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Management Center** in the top navigation bar.
3. In the left-side navigation pane, click **Intelligent Data Engine**. On the page that appears, click the **Code Optimization** tab.



4. On the Code Optimization tab that appears, set the following parameters:
   - **Data Amount Threshold**: the threshold of the data volume in a logical table for triggering code optimization. If the data volume of a logical table exceeds this threshold, code optimization is triggered to enable the intelligent data engine to refactor the code and optimize data computing.
   - **Code of Retroactive Data-generated Task**: the code to be run to generate retroactive data for historical tasks before the code is optimized. Code optimization is triggered based on the analysis of derived metrics and logical aggregate tables. To generate retroactive data for historical tasks before the code is optimized, you must select the code to be run. You can select the original code or optimized code. This parameter setting is not yet available.

- **Code Optimization**: specifies whether to enable the code optimization feature. You can select **Enable** or **Disable**.

5. After the preceding parameters are set, click **OK**. In the dialog box that appears, click **OK**. The configuration is changed.

   On the **Code Optimization** tab, you can also click **Restore Defaults**. In the dialog box that appears, click **OK**. The default configuration is applied.

9.4.4.3. Custom task parameters

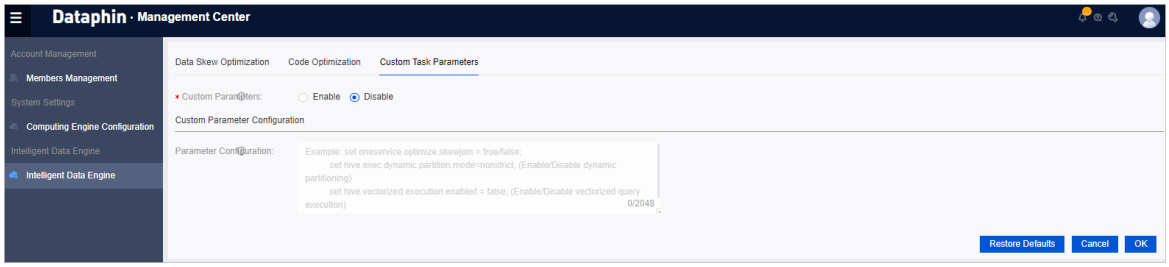
This topic describes how to set custom parameters related to the computing engine to guarantee proper resource allocation.

Introduction to the custom task parameters feature

You can set custom parameters related to the computing engine for logical table tasks to improve the efficiency of computing tasks. By setting these parameters, you can manually control the computing engine to guarantee that varied computing engines used by enterprises can adapt to Dataphin.

Configure the custom task parameters feature

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **Management Center** in the top navigation bar.
3. In the left-side navigation pane, click **Intelligent Data Engine**. On the page that appears, click the **Custom Task Parameters** tab.



4. On the Custom Task Parameters tab that appears, set the following parameters:
   - **Custom Parameters**: specifies whether the custom parameters are valid. After you set custom parameters, you can apply them to the code generation rules of the intelligent data engine to control the resource allocation and operations mechanism for running tasks. For example, you can set the default memory allocated to tasks, set the default priority, and enable or disable MapJoin.
   - **Parameter Configuration**: In this field, set custom parameters based on the actual situation. The parameter settings must be consistent with the features of the computing engine configured in Dataphin. Example:

```
set odps.sql.mapper.cpu=100
set odps.sql.mapper.split.size=256
set odps.sql.reducer.cpu=100
set odps.sql.joiner.cpu=100
```

> **Note** Custom parameter settings take effect based on the priority. Task parameters enjoy the highest priority, whereas global parameters enjoy the lowest priority.

5. After the preceding parameters are set, click **OK**. In the dialog box that appears, click **OK**. The configuration is changed.

   On the **Custom Task Parameters** tab, you can also click **Restore Defaults**. In the dialog box that appears, click **OK**. The default configuration is applied.

9.5. Notifications

9.5.1. View and handle messages

This topic describes how to view and handle messages in Message Center.

View and handle unread messages

1. Log on to the Dataphin console.
2. On the Dataphin homepage, move the pointer over the icon in the top navigation bar and select **Notifications**.In the **Notifications** pane, you can view some messages on the **Messages** tab.
3. In the **Notifications** pane, click **View All** in the lower part.
4. On the page that appears, click **Unread Messages** under **Message Center** in the left-side navigation pane.
5. On the **Unread Messages** page, you can click the **Permission Management**, **Process Control**, and **Data Governance** tabs to view corresponding messages.
6. On the **All** tab, you can mark unread messages as read by using one of the following methods:
   - Find an unread message and click the icon in the **Actions** column.
   - Select multiple unread messages and click **Mark as Read** in the lower part of the page.
   - To mark all unread messages as read, click **Mark All as Read** in the lower part of the page.

View and handle all messages

1. In the left-side navigation pane, click **All Messages** under **Message Center**.
2. On the **All Messages** page, you can click the **Permission Management**, **Process Control**, and **Data Governance** tabs to view corresponding messages, either unread or read.
3. On the **All** tab, you can mark unread messages as read by using one of the following methods:
   - Find an unread message and click the icon in the **Actions** column.
   - Select multiple unread messages and click **Mark as Read** in the lower part of the page.
   - To mark all unread messages as read, click **Mark All as Read** in the lower part of the page.

9.5.2. View and handle tasks

Task Center allows you to manage all process-related tasks in Dataphin. This topic describes how to view and handle tasks in Task Center.

Context

This topic uses the permission application and approval process as an example. This process consists of the following actions:

1. Submit an application.
2. Wait for approval.
3. Approve, reject, or transfer the application, or add an approver.
4. Withdraw the application.

View and handle unprocessed tasks

1. Log on to the Dataphin console.
2. On the Dataphin homepage, move the pointer over the  icon in the top navigation bar and select **Notifications**.In the **Notifications** pane, you can view some tasks on the **Tasks** tab.
3. In the **Notifications** pane, click **View All** in the lower part.The **Unprocessed Tasks** page under **Task Center** appears.
4. On the **Unprocessed Tasks** page, you can view the tasks that need to be handled.You can find unprocessed tasks by using one of the following methods:
   - Click **Permission Approval** next to **Task Type** to filter the tasks that require you to approve permission applications.
   - Enter a keyword of the task name in the search box to search for corresponding unprocessed tasks.
5. On the **Unprocessed Tasks** page, click the name of a task in the **Task Name** column.
6. Handle the unprocessed task.

i. On the page that appears, you can view details of the task. In the **Task Processing** section, set the parameters as required.

Parameter	Description
Approval Result	The approval result of the task. Valid values: ■ **Approve**: approves the application in the task and grants permissions to the applicant. ■ **Reject**: rejects the application in the task and requests the applicant to apply again or modify the application content. ■ **Transfer To**: transfers the task to another person. You can select a person to whom the task is transferred. After you transfer the task, the selected person is responsible for processing the application in the task. ■ **Add Approver**: adds an approver. You can select a person as a new approver. ■ After the new approver approves the application in the task, the task will be transferred back to you. ■ If the new approver rejects the application in the task, the process ends.
Comments	The comments of the approval.

ii. After you set the preceding parameters, click **Submit**.

View processed tasks

1. In the left-side navigation pane, click **Processed Tasks** under **Task Center**.
2. On the **Processed Tasks** page, you can view the processed tasks.You can find processed tasks by using one of the following methods:
   - Set the **Task Type** and **Status** parameters to filter processed tasks.
   - Enter a keyword of the task name in the search box to search for corresponding processed tasks.
3. On the Processed Tasks page, click the name of a task in the **Task Name** column to go to the details page of the task.
4. After you view the task details, click **Cancel** in the lower part of the page.

View tasks that you initiated

1. In the left-side navigation pane, click **Initiated Tasks** under **Task Center**.
2. On the **Initiated Tasks** page, you can view the tasks you initiated.You can find initiated tasks by using one of the following methods:
   - Set the **Task Type** and **Status** parameters to filter corresponding tasks you initiated.
   - Enter a keyword of the task name in the search box to search for corresponding tasks you initiated.
3. On the Initiated Tasks page, click the name of a task in the **Task Name** column to go to the

details page of the task.

4. After you view the task details, click **Cancel** in the lower part of the page.

9.6. Alert Center

9.6.1. Overview

Alert Center is a monitoring and alerting module in Dataphin. It displays alert events, push records, and shift schedules of the Data Quality, Stream Processing, and API Service modules.

Background information

As Dataphin supports more and more features in data collection, data warehouse building, data management, and data application, it also needs to support more complex alert scenarios.

In earlier versions, Dataphin has been able to monitor errors, latency, and timeout exceptions of scheduling tasks and generate alerts when specific conditions are met. However, you can select only a limited number of alert causes to configure alert rules. In this situation, you need a monitoring and alerting center that provides enhanced monitoring capabilities and more monitoring scenarios.

Features

Alert Center provides the following pages:

- **Events**: This page displays alert events of the Stream Processing, Data Quality, and API Service modules.
- **Push Records**: This page displays records about alert messages that Alert Center pushes.
- **Shift Schedules**: This page displays shift schedules that are arranged for alert recipients who need to handle alerts.

Log on to the Dataphin console. On the Dataphin homepage, click the icon in the upper-right corner to go to **Alert Center**.

9.6.2. Terms

This topic describes terms involved in Alert Center, including alert event, push record, shift schedule, and push method.

Term	Description
Alert event	An event generated based on the specific alert object and alert rule.
Push record	A record generated after Alert Center pushes an alert message to the message subscribers.
Shift schedule	A schedule arranged for alert recipients who need to handle alerts.
Push method	A method that Alert Center uses to push an alert message to the message subscribers.

Term	Description
Do-Not-Disturb	A feature that allows you to specify a period during which Alert Center does not push any alert messages to you. For example, if Alert Center repeatedly pushes alert messages of the same alert event to you, you can specify a Do-Not-Disturb period for the alert event.
Service	A module where an alert event was triggered. Currently, alert events may be triggered in Data Quality, Stream Processing, and API Service.

9.6.3. Events

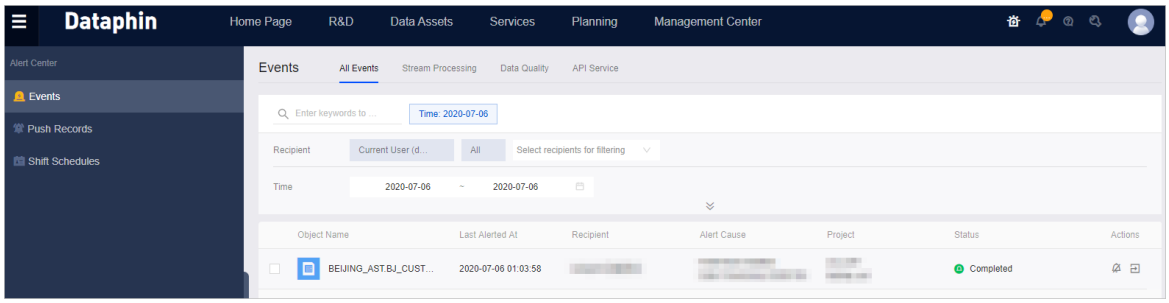
The Events page displays alert events of the Stream Processing, Data Quality, and API Service modules. This topic describes how to view and handle alert events.

Go to the Events page

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click the icon in the upper-right corner to go to Alert Center.

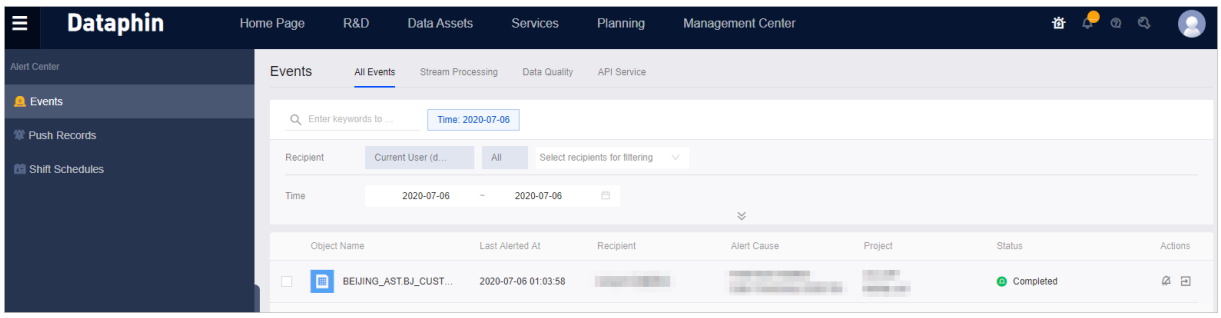
   On the **Events** page, you can click the **Stream Processing**, **Data Quality**, or **API Service** tab to view alert events of the corresponding module.

   To view all alert events of the **Stream Processing**, **Data Quality**, and **API Service** modules, click the **All Events** tab. This topic describes alert events on the **All Events** tab.



View alert events

On the **All Events** tab, you can set the **Recipient**, **Time**, **Status**, **Business Unit**, and **Project** parameters to filter alert events. You can also enter a keyword in the search box to search for alert events.



The **All Events** tab displays the **Object Name**, **Last Alerted At**, **Recipient**, **Alert Cause**, **Project**, and **Status** parameters of each alert event. The **Actions** column of an alert event lists the operations that you can perform on the alert event.

Parameter	Description
Object Name	The name of the object that triggered the alert event. Alert events of each module are named based on the following conventions: • **Stream Processing**: Each alert event is named after the corresponding stream processing task that is published to the production environment, for example, `flink_merge`. • **API Service**: Each alert event is named after the corresponding API operation, for example, `user_info_service`. • **Data Quality**: ○ An alert event that is triggered by a physical table is named in the `{Project name}.{Table name}` format, for example, `v27_ast.ods_user_info`. ○ An alert event that is triggered by a logical table is named in the `{Business unit name}.{Table name}` format, for example, `LD_demo.dws_all`.
Last Alerted At	The time when Alert Center pushed the last alert message for the alert event.
Recipient	The recipient to whom Alert Center pushed alert messages for the alert event. You can configure multiple recipients for an alert event, including: • The owner of the object that triggers the alert event. • Custom users. • Users in a shift schedule.

Parameter	Description
Alert Cause	The cause of the alert event. The cause of an alert event varies based on the module where the alert event may be triggered. • In **Data Quality**, an alert event may be triggered due to the following causes: **Table Rule Violation**, **Field Rule Violation**, and **Custom Rule Violation**. • In **API Service**, an alert event may be triggered due to the following causes: **Unexpected Average Response Time**, **Unexpected Number of Calls**, **Unexpected Error Rate**, and **Unexpected Percentage of Offline Tasks**. • In **Stream Processing**, an alert event may be triggered due to the following causes: **Excessively Long Delay**, **Exceeds Maximum TPS**, **Exceeds Specified Failure Frequency**, and **Exceeds Specified Data Retention Period**.
Project	The project to which the alert event belongs.
Status	The status of the alert event. Valid values: • **Completed**: The alerting process is completed for the alert event. • **Alerting**: The frequent alerting mode is set for the alert event, and the alerting start time has arrived but the end time has not. • **Do-Not-Disturb**: You can change the status of ongoing and completed alert events to **Do-Not-Disturb**. • **Alerting (Silence Period)**: Alert Center does not push alert messages for the alert event because the alert time does not arrive. Assume that API Service requires Alert Center to push alert messages for each alert event at an interval of 5 minutes. After an alert message is pushed, Alert Center does not push alert messages for the same alert event within 5 minutes even if metrics that trigger the alert event are collected every second.
Actions	The operations that you can perform on the alert event. • To handle an alert event, find the alert event and click the  icon in the **Actions** column. For more information, see Handle alert events. • To change the status of an alert event to **Do-Not-Disturb**, find the alert event and click the icon in the **Actions** column. For more information, see Change the status of alert events to Do-Not-Disturb.

View details of an alert event

On the **All Events** tab, click a name in the **Object Name** column. The **Event Details** pane appears.

GUI element	Description
Do-Not-Disturb	Allows you to change the status of the alert event to **Do-Not-Disturb**. For more information, see Change the status of alert events to Do-Not-Disturb.

GUI element	Description
Handle Alert	Allows you to handle the alert event. For more information, see Handle alert events.
Object Type	The type of the object that triggered the alert event. Valid values of the **Object Type** parameter of an alert event vary based on the module where the alert event may be triggered. • In **Data Quality**, valid values are **Logical Table** and **Physical Table**. • In **Stream Processing**, the value is fixed to **Task**. • In **API Service**, the value is fixed to **API**.
Service	The module where the alert event was triggered. Valid values: • **Data Quality** • **Stream Processing** • **API Service**
Alert Cause	The cause of the alert event. For more information, see View alert events.
Push Method	The method that Alert Center used to push alert messages for the alert event. Valid values: • **Cellphone** • **SMS** • **Email** • **DingTalk**
Alert Frequency	The frequency at which Alert Center pushed alert messages for the alert event.
First Alerted At	The time when Alert Center pushed the first alert message for the alert event.
Last Alerted At	The time when Alert Center pushed the last alert message for the alert event.
Alert Recipients	The recipients to whom Alert Center pushed alert messages for the alert event. For more information, see View alert events.
Links	The link to the module where the alert event was triggered and the link to the corresponding operational logs. The links that are provided for an alert event vary based on the module where the alert event may be triggered. • **Data Quality**: The **Go to Quality Check Rules** and **Go to Scheduling Task Instance Log** links are provided. • **Stream Processing**: The **Go to Stream Processing Task Monitoring Rules** link is provided. • **API Service**: The **Go to API Service Monitoring Rules** link is provided.

Handle alert events

1. Go to the module where an alert event was triggered by using one of the following

methods:

- On the **All Events** tab, find the alert event and click the icon in the **Actions** column.
- On the All Events tab, click the name of the object that triggered the alert event. In the **Event Details** pane, click **Handle Alert**.

2. In the module where the alert event was triggered, handle the alert event based on the alert cause.

Change the status of alert events to Do-Not-Disturb

If alert events are in the **Alerting** or **Completed** state, you can change the status to **Do-Not-Disturb**.

1. On the **All Events** tab, open the **Alert Do-Not-Disturb Settings** dialog box by using one of the following methods:
   - Find an alert event and click the icon in the **Actions** column.
   - Select multiple alert events in the **Alerting** or Completed state and click **Do-Not-Disturb** in the lower part of the page.
2. In the **Alert Do-Not-Disturb Settings** dialog box, set the **Duration** parameter to **All Day** and specify the **Specified Duration** parameter as required.
3. Click **OK**.

   The status of one or more alert events changes from **Alerting** or **Completed** to **Do-Not-Disturb**.

9.6.4. Push records

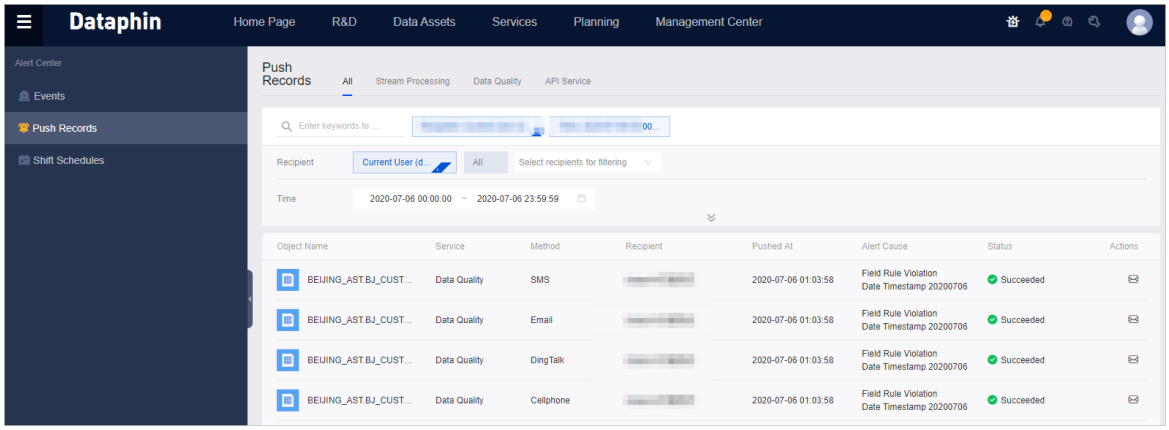
The Push Records page displays records about alert messages that Alert Center pushes. This topic describes how to view push records and the content of alert messages that are pushed.

Go to the Push Records page

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click the icon in the upper-right corner to go to **Alert Center**.
3. In **Alert Center**, click **Push Records** in the left-side navigation pane.

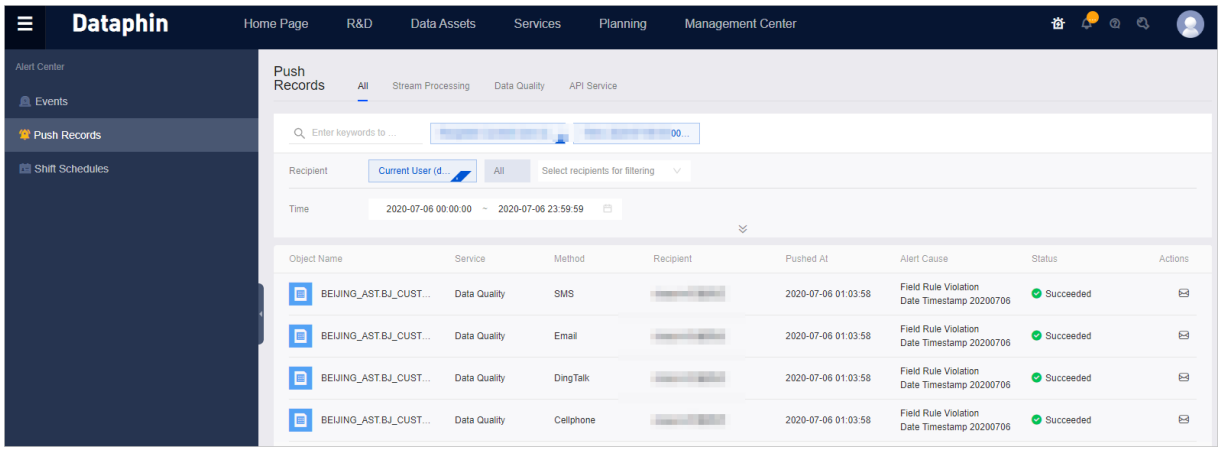
   On the **Push Records** page, click the **Stream Processing**, **Data Quality**, or **API Service** tab to view the push records of the corresponding module.

To view all push records of the **Stream Processing**, **Data Quality**, and **API Service** modules, click the **All** tab. This topic describes push records on the **All** tab.



View push records

On the **All** tab, you can set the **Recipient**, **Time**, **Status**, and **Method** parameters to filter push records. You can also enter a keyword in the search box to search for push records.



The **All** tab displays the **Object Name**, **Service**, **Method**, **Recipient**, **Pushed At**, **Alert Cause**, and **Status** parameters of each push record. The **Actions** column of a push record lists the operations that you can perform on the push record.

Parameter	Description
Object Name	The name of the object that triggered the alert event.
Service	The module where the alert event was triggered. Valid values: • **Data Quality** • **Stream Processing** • **API Service**

Parameter	Description
Method	The method that Alert Center used to push the alert message to the specific recipients. Valid values: • Cellphone • SMS • Email • DingTalk
Recipient	The recipients of the alert message.
Pushed At	The time when the alert message was pushed.
Alert Cause	The cause of the alert event for which the alert message was pushed. The cause of an alert event varies based on the module where the alert event may be triggered. • In **Data Quality**, an alert event may be triggered due to the following causes: **Table Rule Violation**, **Field Rule Violation**, and **Custom Rule Violation**. • In **API Service**, an alert event may be triggered due to the following causes: **Unexpected Average Response Time**, **Unexpected Number of Calls**, **Unexpected Error Rate**, and **Unexpected Percentage of Offline Tasks**. • In **Stream Processing**, an alert event may be triggered due to the following causes: **Excessively Long Delay**, **Exceeds Specified Data Retention Period**, **Exceeds Specified Failure Frequency**, and **Exceeds Maximum TPS**.
Status	The pushing status of the alert message. Valid values: • Sending • Succeeded • Failed
Actions	To view the content of an alert message that was pushed, find the push record and click the icon in the **Actions** column.

View the content of an alert message that was pushed

On the **Push Records** page, find a push record and click the icon in the **Actions** column.

9.6.5. Shift schedules

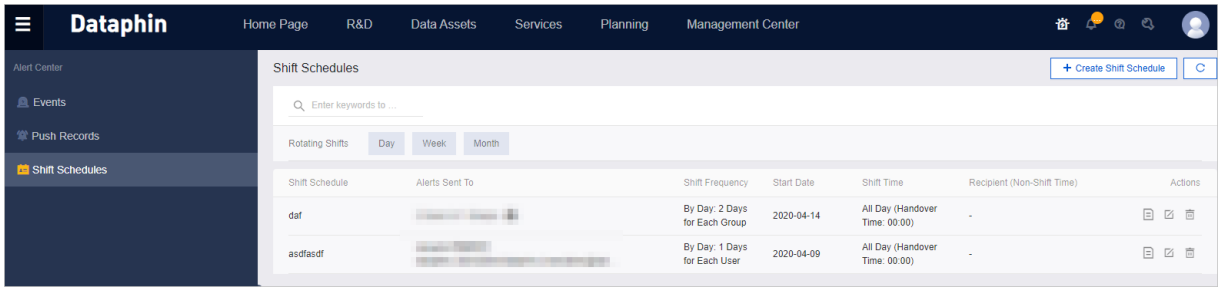
9.6.5.1. Overview

The Shift Schedules page displays shift schedules that are arranged for alert recipients who need to handle alerts.

To go to the **Shift Schedules** page, perform the following steps:

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click the icon in the upper-right corner to go to **Alert Center**.
3. In the left-side navigation pane, click **Shift Schedules**.

On the **Shift Schedules** page, you can set the **Rotating Shifts** parameter to filter shift schedules. You can also enter a keyword in the search box to search for shift schedules.



The **Shift Schedules** page displays the **Shift Schedule**, **Alerts Sent To**, **Shift Frequency**, **Start Date**, **Shift Time**, and **Recipient (Non-Shift Time)** parameters of each shift schedule. The **Actions** column of a shift schedule lists the operations that you can perform on the shift schedule.

Parameter	Description
Shift Schedule	The name of the shift schedule.
Alerts Sent To	The recipients to whom Alert Center pushes alert messages during shifts that are arranged in the shift schedule. • If you set the Alerts Sent To parameter to **Users** when you create a shift schedule, the Alerts Sent To column of the shift schedule displays the specific user accounts. This column displays a maximum of 64 characters for each value. If a value contains more than 64 characters, excess characters are displayed as an ellipsis (...). • If you set the Alerts Sent To parameter to **Groups** when you create a shift schedule, the Alerts Sent To column of the shift schedule displays the number of groups and total number of group members.You can move the pointer over the icon to view group details.
Shift Frequency	The rotating frequency of shifts that are arranged in the shift schedule. For more information, see Create a shift schedule.
Start Date	The start date of shifts that are arranged in the shift schedule. For more information, see Create a shift schedule.
Shift Time	The duration of a shift. For more information, see Create a shift schedule.
Recipient (Non-Shift Time)	The recipient to whom Alert Center pushes alert messages in the non-shift duration of specific alert recipients. For example, the recipient can be the object owner or a specified user.

Parameter	Description
Actions	The operations that you can perform on the shift schedule, including: • View details of the shift schedule. For more information, see View details of a shift schedule. • Modify the shift schedule. For more information, see Modify a shift schedule. • Delete the shift schedule. For more information, see Delete a shift schedule.

9.6.5.2. Create a shift schedule

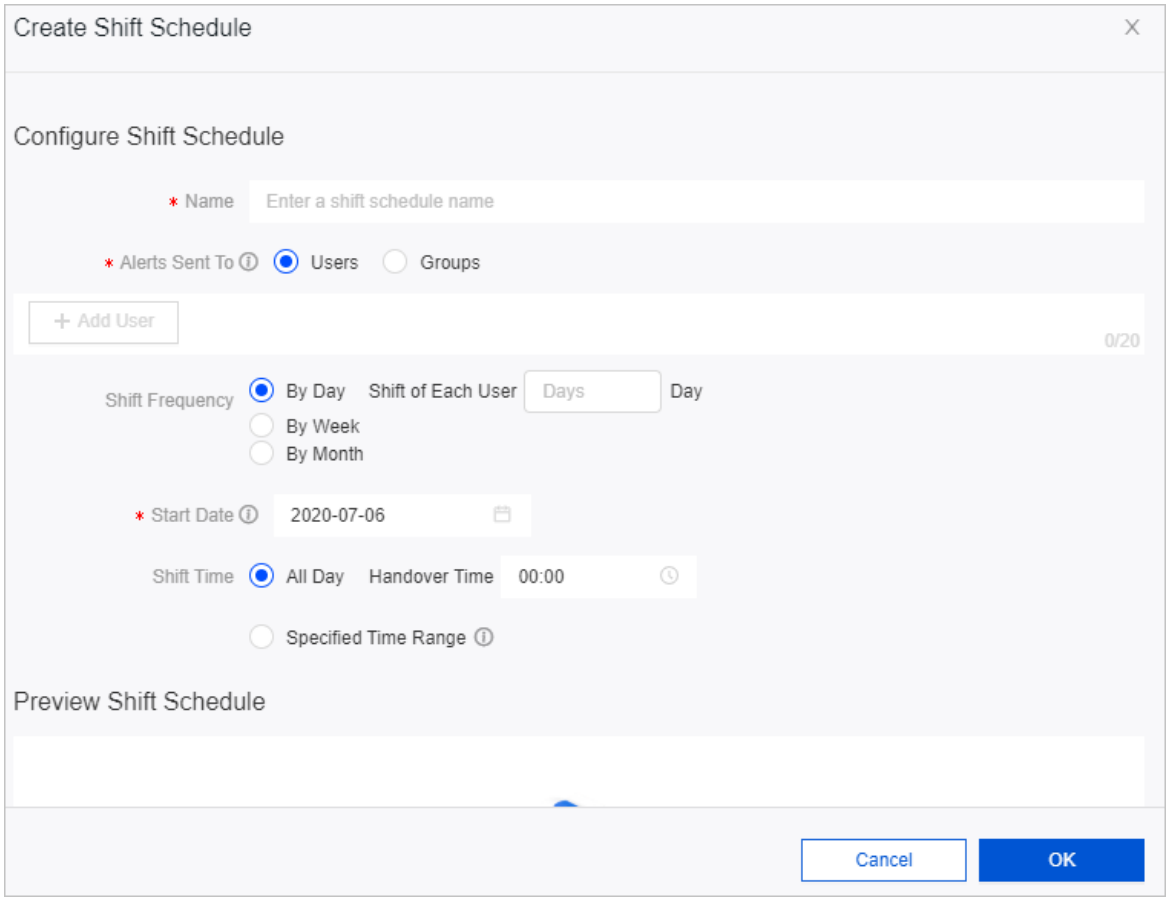
The Shift Schedules page displays shift schedules that are arranged for alert recipients who need to handle alerts. This topic describes how to create a shift schedule.

Context

Only the super administrator and business unit administrators can create a shift schedule.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click the icon in the upper-right corner to go to **Alert Center**.
3. In the left-side navigation pane, click **Shift Schedules**.
4. On the **Shift Schedules** page, click **Create Shift Schedule** in the upper-right corner.
5. In the **Create Shift Schedule** dialog box, set the parameters as required.



Section	Parameter	Description
	Name	The name of the shift schedule.
	Alerts Sent To	The alert recipients for the shift schedule. Valid values: **Users** and **Groups**. ◦ If you select **Users**, click **Add User** to add one or more users as alert recipients. **Note** If the icon appears next to a user to be added as an alert recipient, you must add contact information for the user. For more information, see Manage members. ◦ If you select **Groups**, click **Add User** next to **Group 1** and add alert recipients to the first group. If you want alert recipients in multiple groups to take turns, click **Add Group** to add more groups and add alert recipients to the groups. If an existing group is no longer needed, move the pointer over the group name and click the icon to delete the group.

Section	Parameter	Description
Configure Shift Schedule	Shift Frequency	The rotating frequency of shifts that are arranged in the shift schedule. Valid values: ○ **By Day**: If you select this option, the value in the Shift of Each User or Shift of Each Group field next to this option cannot exceed 366, in units of days. ○ **By Week**: If you select this option, the value in the Shift of Each User or Shift of Each Group field next to this option cannot exceed 53, in units of weeks. ○ **By Month**: If you select this option, the value in the Shift of Each User or Shift of Each Group field next to this option cannot exceed 12, in units of months.
	Start Date	The start date of shifts that are arranged in the shift schedule.
	Shift Time	The duration of a shift. Valid values: **All Day** and **Specified Time Range**. ○ If you select **All Day**, specify the **Handover Time** parameter. ○ If you select **Specified Time Range**, specify a time range and the **Recipient (Non-Shift Time)** parameter. Valid values of the **Recipient (Non-Shift Time)** parameter are **Object Owner** and **Specified User**.
Preview Shift Schedule	Preview	You can click **Preview** to view the configured shift schedule. After you update the shift schedule, you can click **Refresh Preview** to update the preview data of the shift schedule.

6. Click **OK**.

9.6.5.3. View details of a shift schedule

The Shift Schedules page displays shift schedules that are arranged for alert recipients who need to handle alerts. This topic describes how to view details of a shift schedule.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click the icon in the upper-right corner to go to **Alert Center**.
3. In the left-side navigation pane, click **Shift Schedules**.
4. On the **Shift Schedules** page, find the shift schedule whose details you want to view and click the icon in the **Actions** column.

9.6.5.4. Modify a shift schedule

The Shift Schedules page displays shift schedules that are arranged for alert recipients who need to handle alerts. This topic describes how to modify a shift schedule.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click the icon in the upper-right corner to go to **Alert Center**.
3. In the left-side navigation pane, click **Shift Schedules**.
4. On the Shift Schedules page, find the shift schedule that you want to modify and click the icon in the **Actions** column.
5. In the **Change Shift Schedule** dialog box, modify the parameters as needed. For more information, see Create a shift schedule.
6. After you modify the parameters, click **OK**.

9.6.5.5. Delete a shift schedule

The Shift Schedules page displays shift schedules that are arranged for alert recipients who need to handle alerts. This topic describes how to delete a shift schedule.

Context

Limits:

- You cannot delete a shift schedule that is being referenced by the Stream Processing, Data Quality, or API Service module.
- Only the super administrator and business unit administrators can delete a shift schedule.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click the icon in the upper-right corner to go to **Alert Center**.
3. In the left-side navigation pane, click **Shift Schedules**.
4. On the **Shift Schedules** page, find the shift schedule that you want to delete and click the icon in the **Actions** column.
5. In the **Tip** message, click **OK**.

9.7. Data warehouse planning

9.7.1. Overview

Data warehouse planning is a key step in architectural design (during data production). To complete this step, you need to define logical space divisions based on your business characteristics. The logical space divisions include business units, data domains, namespaces, and global objects. Then, create projects based on your development cooperation and management mode. When creating a project, configure project and member settings, and register the required underlying data sources (physical databases).

9.7.2. Business unit management

9.7.2.1. Create business units

As an important part of logical spaces, a business unit defines a data warehouse namespace in Dataphin based on business characteristics. A business unit can contain multiple projects. This topic describes how to create business units in Dev-Prod mode or a business unit in Basic mode.

Prerequisites

Dataphin members are added. For more information, see Manage members.

Context

Only the Apsara Stack tenant account that is assigned the super administrator role can create business units.

Dataphin allows you to create business units in Dev-Prod or Basic mode. The following table describes the two modes.

Mode	Description
Dev-Prod mode	Generates a business unit in Dev mode as the development environment and a business unit in Prod mode as the production environment. The two business units are isolated. This allows you to guarantee data security in the production environment and manage the data production process and production data in a controllable way. We recommend that you select this mode if you are concerned more about management. This mode is applicable to the scenario where you have many developers who have clear responsibilities and you have a large budget for computing and storage.
Basic mode	Generates a business unit in Basic mode as an independent and flexible production environment. In this mode, the data production process is stable and easy-to-use and the production data is controllable. We recommend that you select this mode if you are concerned more about data development efficiency rather than management. This mode is applicable to the scenario where the responsibilities of developers are not clear and you have a limited budget for computing and storage.

Create business units in Dev-Prod mode

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Business Units** in the left-side navigation pane.
4. On the **Business Units** page, click **Create Business Unit** in the upper-right corner.
5. In the **Create Business Unit** dialog box, select Dev-Prod Mode, click Next, and then set the parameters as required.

Parameter	Description
Common Name	The common name of the business units. The common name can be up to 64 characters in length and can contain letters, digits, and underscores (_).
Common Display Name	The common display name of the business units. The common display name can be up to 64 characters in length and can contain letters, digits, underscores (_), and hyphens (-). Note By default, the name of the business unit in Dev mode is suffixed with _dev.
Description	The description of the business units.
Icon	The icon that indicates the category of the business units. Valid values: ○  : E-Commerce ○  : Finance ○  : Cloud Computing ○  : Advertising and Marketing ○  : Logistics ○  : Entertainment ○  : Travel ○  : Health ○  : Socialization and Communications ○  : Food & Drink ○  : Education ○  : Environment

Parameter	Description
Business Unit Administrators	The administrator of the business units. You can specify multiple administrators.

6. Click **OK**.

Create a business unit in Basic mode

1. On the **Business Units** page, click **Create Business Unit** in the upper-right corner.
2. In the **Create Business Unit** dialog box, select Basic Mode, click **Next**, and then set the parameters as required.

Parameter	Description
Name	The name of the business unit. The name can be up to 64 characters in length and can contain letters, digits, and underscores (_).
Display Name	The display name of the business unit. The display name can be up to 64 characters in length and can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the business unit.

Parameter	Description
Icon	The icon that indicates the category of the business unit. Valid values: ○  : E-Commerce ○  : Finance ○  : Cloud Computing ○  : Advertising and Marketing ○  : Logistics ○  : Entertainment ○  : Travel ○  : Health ○  : Socialization and Communications ○  : Food & Drink ○  : Education ○  : Environment
Business Unit Administrators	The administrator of the business unit. You can specify multiple administrators.

3. Click **OK**.

9.7.2.2. Modify a business unit

As an important part of logical spaces, a business unit defines a data warehouse namespace in Dataphin based on business characteristics. A business unit can contain multiple projects. This topic describes how to modify a business unit.

Prerequisites

Business units are created. For more information, see Create business units.

Context

Only the Apsara Stack tenant account that is assigned the super administrator role can modify business units.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Business Units** in the left-side navigation pane.
4. On the **Business Units** page, move the pointer over the business unit that you want to modify and click the icon.
5. In the **Change Business Unit** dialog box, change the parameter values as needed. For more information, see Create business units.
6. Click **OK**.

9.7.2.3. Modify business unit parameters

Business unit parameters include the time-based partitioning parameter and the data timestamp parameter. This topic describes how to modify business unit parameters.

Prerequisites

Business units are created. For more information, see Create business units.

Context

Only the Apsara Stack tenant account that is assigned the super administrator role can modify business unit parameters.

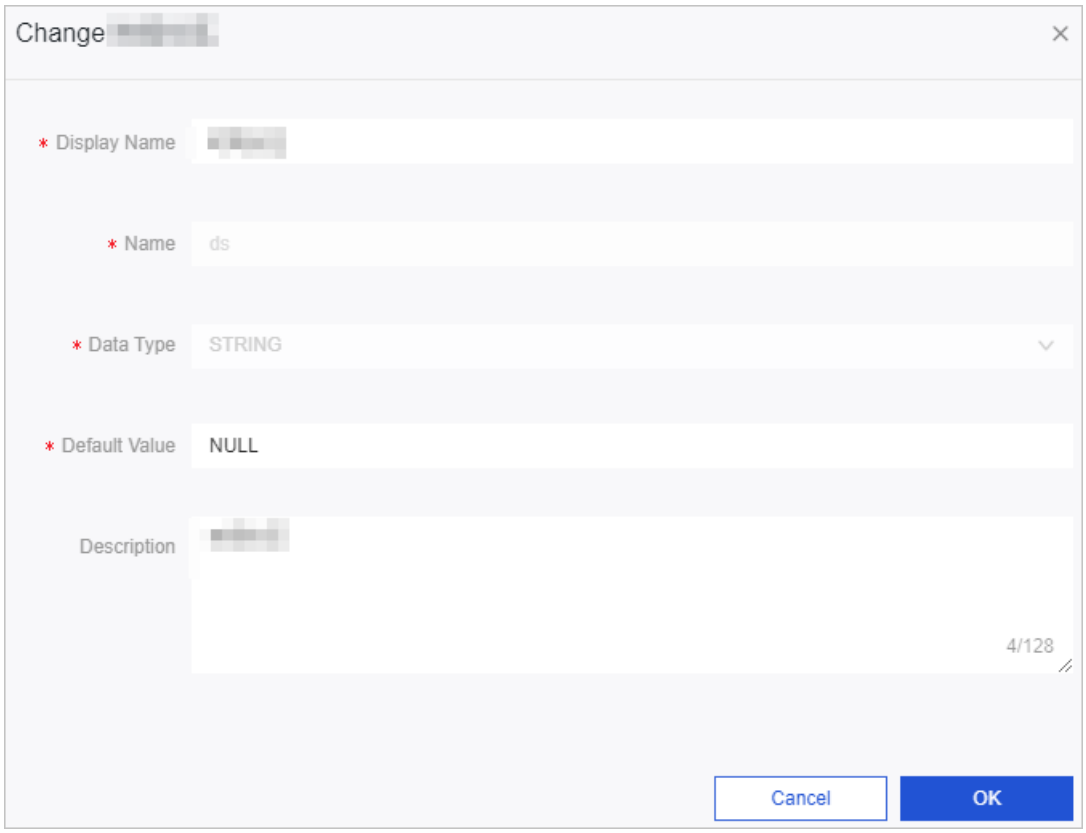
Business unit parameters function as common parameters of a business unit, such as the data type and default value. The following business unit parameters are supported:

- Time-based Partitioning Field: specifies the name, data type, default value, and description of the time-based partitioning parameter.
- Data Timestamp: specifies the name and format of the data timestamp parameter. By default, the data timestamp parameter is named bizdate.

Modify the time-based partitioning parameter

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Business Units** in the left-side navigation pane.

4. On the **Business Units** page, click the business unit for which you want to modify business unit parameters.
5. In the **Business Unit Parameters** section, click the icon next to **Time-based Partitioning Field**.
6. In the **Change Time Partition** dialog box, set the parameters as required.



Parameter	Description
Display Name	The display name of the time-based partitioning parameter. The display name can contain letters, digits, underscores (_), and hyphens (-).
Name	The name of the time-based partitioning parameter. Default value: **ds**. The name can contain letters, digits, and underscores (_).
Date Type	The data type of the time-based partitioning parameter. Valid values: ○ **STRING** ○ **BIGINT** ○ **DOUBLE** ○ **DATETIME**
Default Value	The default value of the time-based partitioning parameter. Enter NULL if you do not specify a default value.
Description	The description of the time-based partitioning parameter.

7. Click **OK**.

Modify the data timestamp parameter

1. On the **Business Units** page, click the business unit for which you want to modify business unit parameters.
2. In the **Business Unit Parameters** section, click the icon next to **Data Timestamp**.
3. In the **Change Data Timestamp** dialog box, click the icon next to **Parameter Value** and select a format for the data timestamp from the drop-down list.
4. Click **OK**.

9.7.2.4. Data domain management

9.7.2.4.1. Create a data domain

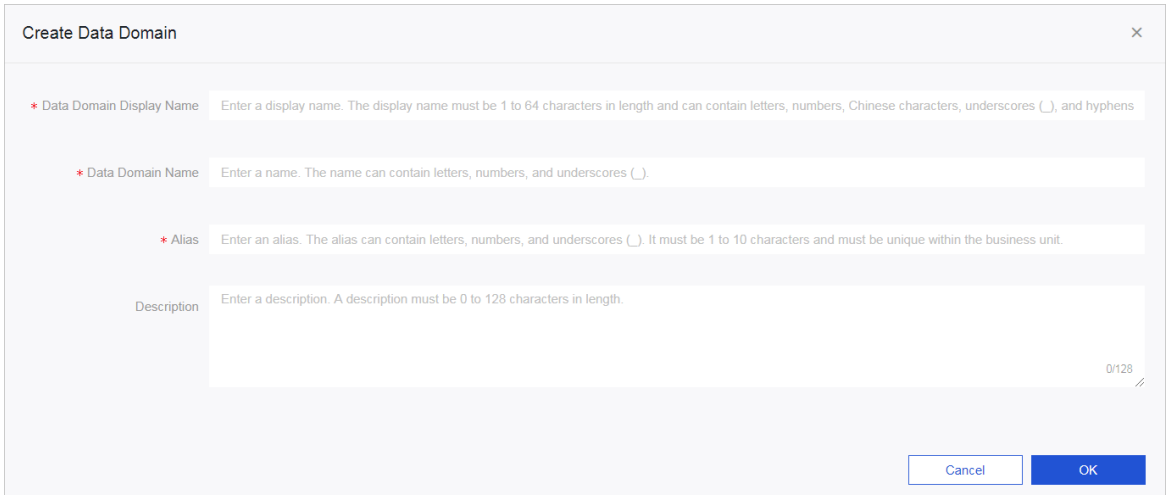
A data domain is used to categorize business concepts in a business unit, such as the commodity domain, transaction domain, and membership domain. This topic describes how to create a data domain.

Context

Only the super administrator and project administrators can create data domains.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Business Units** in the left-side navigation pane.
4. On the **Business Units** page, click the business unit for which you want to create a data domain.
5. In the Data Domain section, Click **Create Data Domain**.
6. In the **Create Data Domain** dialog box, set the parameters as required.



Parameter	Description
Data Domain Display Name	The display name of the data domain.
Data Domain Name	The name of the data domain.
Alias	The alias of the data domain. The alias cannot be the same as the name of the data domain.
Description	The description of the data domain.

7. Click **OK**.

9.7.2.4.2. Modify a data domain

A data domain is used to categorize business concepts in a business unit, such as the commodity domain, transaction domain, and membership domain. This topic describes how to modify a data domain.

Context

If a data domain is referenced, changing its name may result in errors in dependencies. In this case, we recommend that you do not modify the data domain name.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Business Units** in the left-side navigation pane.
4. On the **Business Units** page, click the business unit for which you want to modify a data domain.
5. In the **Data Domain** section, find the data domain that you want to modify and click the icon in the **Actions** column.
6. In the **Change Data Domain** dialog box, change the parameter values as needed. For more information, see Create a data domain.
7. Click **OK**.

9.7.2.4.3. Delete a data domain

A data domain is used to categorize business concepts in a business unit, such as the commodity domain, transaction domain, and membership domain. This topic describes how to delete a data domain.

Context

You cannot delete a data domain if it is referenced.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Business Units** in the left-side navigation pane.
4. On the **Business Units** page, click the business unit for which you want to delete a data domain.
5. In the **Data Domain** section, find the data domain that you want to delete and click the icon in the **Actions** column.
6. In the message that appears, click **OK**.

9.7.2.5. Delete a business unit

As an important part of logical spaces, a business unit defines a data warehouse namespace in Dataphin based on business characteristics. A business unit can contain multiple projects. This topic describes how to delete a business unit.

Prerequisites

Business units are created. For more information, see Create business units.

Context

Limits:

- Only the Apsara Stack tenant account that is assigned the super administrator role can delete business units.
- To delete business units in Dev-Prod mode, make sure that the projects in the business units contain no tasks or objects.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Business Units** in the left-side navigation pane.
4. On the **Business Units** page, move the pointer over the business unit that you want to delete and click the icon.
5. In the **Delete Business Unit** message, click **OK**.

9.7.3. Statistical period management

9.7.3.1. Create a statistical period

Dataphin supports only the common business logic of statistical periods. A statistical period indicates the time range for statistics, for example, the last seven days or the last 30 days. This topic describes how to create a statistical period.

Prerequisites

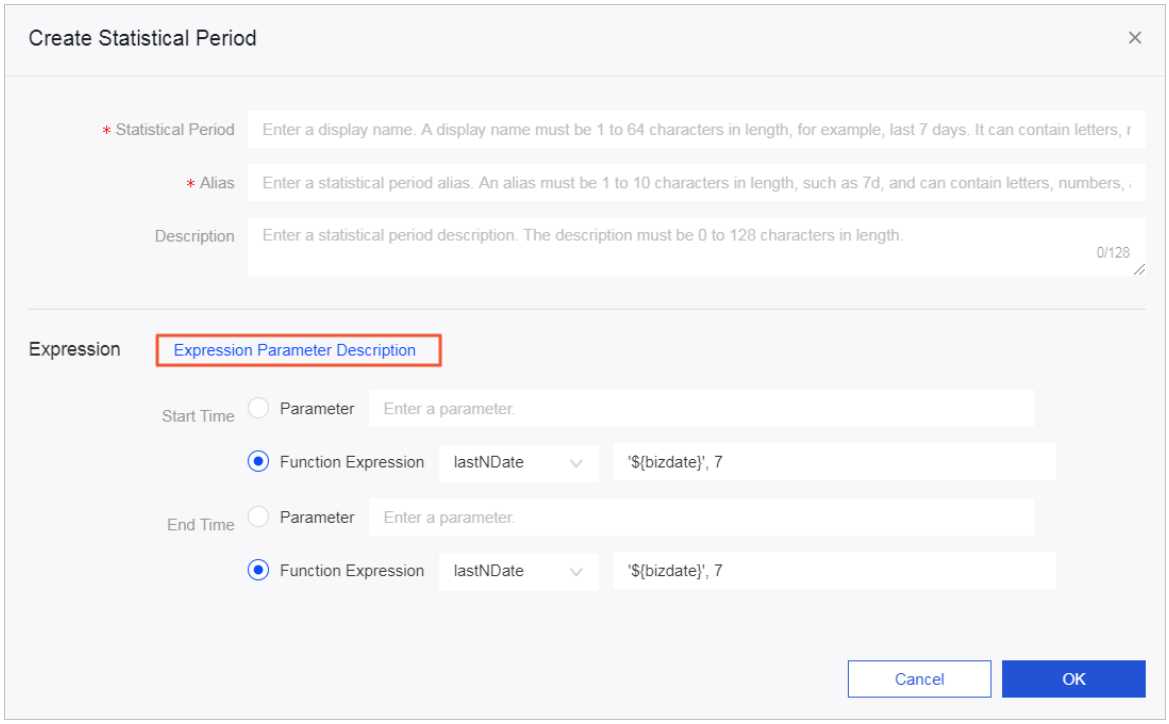
The computing engine type is set. For more information, see Set the computing engine type. After the computing engine type is set, Dataphin automatically initializes the built-in statistical periods.

Context

Only the super administrator and project administrators can create statistical periods.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Common Business Logic** in the left-side navigation pane.
4. On the **Common Business Logic** page, click **Create Statistical Period** in the upper-right corner.
5. In the **Create Statistical Period** dialog box, set the parameters as required.



Parameter	Description
Statistical Period	The display name of the statistical period.
Alias	The alias of the statistical period.
Description	The description of the statistical period.
Expression	The function expressions of the statistical period. You can click **Expression Parameter Description** next to **Expression** to view functions that Dataphin provides.
Start Time	The expression of the start time of the statistical period. You can set the expression of the start time by using one of the following methods: ○ Select **Parameter** and enter a parameter. ○ Select **Function Expression**, click the icon, and then select a function expression.
End Time	The expression of the end time of the statistical period. You can set the expression of the end time by using one of the following methods: ○ Select **Parameter** and enter a parameter. ○ Select **Function Expression**, click the icon, and then select a function expression.

Note You cannot create a duplicate statistical period.

6. Click **OK**.

9.7.3.2. Modify a statistical period

A statistical period indicates the time range for statistics, for example, the last seven days or the last 30 days. This topic describes how to modify a statistical period.

Prerequisites

Statistical periods are created. For more information, see Create a statistical period.

Context

Limits:

- The super administrator and project administrators can modify statistical periods.
- A project administrator cannot modify statistical periods that are created by other administrators. Members who are not administrators can modify only the statistical periods that are created by themselves.

Procedure

1. Log on to the Dataphin console.

2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Common Business Logic** in the left-side navigation pane.
4. On the **Common Business Logic** page, find the statistical period that you want to modify and click the icon in the **Actions** column.
5. In the **Change Statistical Period** dialog box, change the parameter values as needed. For more information, see Create a statistical period.
6. Click **OK**.

9.7.3.3. Delete a statistical period

A statistical period indicates the time range for statistics, for example, the last seven days or the last 30 days. This topic describes how to delete a statistical period.

Prerequisites

Statistical periods are created. For more information, see Create a statistical period.

Context

Limits:

- The super administrator and project administrators can delete statistical periods.
- A project administrator cannot delete statistical periods that are created by other administrators. Members who are not administrators can delete only the statistical periods that are created by themselves.
- If a published derived metric references a statistical period, such as the last 150 days, the statistical period cannot be deleted.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Common Business Logic** in the left-side navigation pane.
4. On the **Common Business Logic** page, find the statistical period that you want to delete and click the icon in the **Actions** column.
5. In the message that appears, click **OK**.

9.7.4. Project management

9.7.4.1. Overview

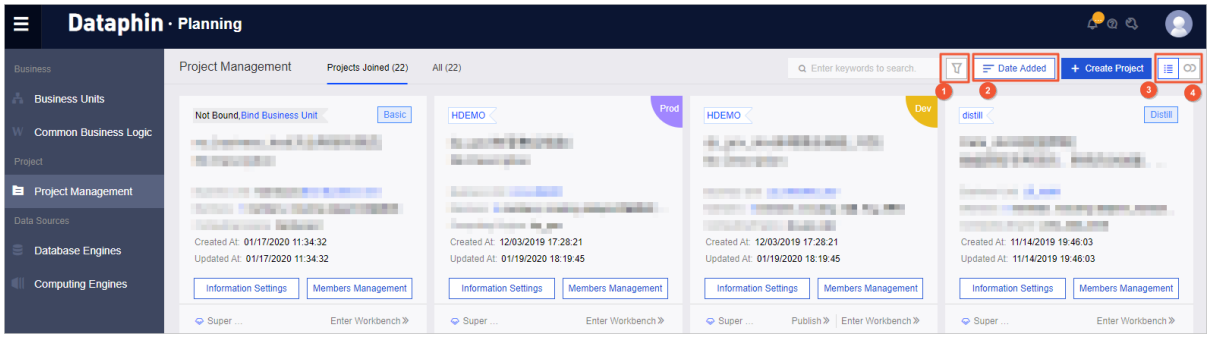
A project is used to isolate physical resources and developers during Data Mid-End construction. A business unit can contain multiple projects. Each Dataphin member can join multiple projects.

> **Note** Before you manage a project, make sure that the computing engine type of Dataphin is set on the Computing Engine Configuration page in Management Center. For more information, see Set the computing engine type.

On the **Project Management** page, you can find the projects that you join on the **Projects Joined** tab and all projects on the **All** tab. You can perform the following operations on the projects that you join:

- Configure project information, manage members, go to the **Publish** page, and go to the **Develop** page.
- In the **Information Settings** dialog box, configure the batch processing computing engine and stream processing computing engine for a project. For more information, see Create a batch processing computing engine and Create a stream processing computing engine. Dataphin supports stream processing and batch processing. You can develop both stream processing tasks and batch processing tasks in the same project. This ensures consistent experience in development and improves the development efficiency.

You can also filter and sort projects and change the display mode of projects on the **Project Management** page, as described in the following table.



No.	Description
1	Click the icon. In the **More Filters** dialog box, set the **Business Units** and **Project Type** parameters. Projects that meet the filter conditions appear.
2	Click the icon and select **Date Added**, **Display Name**, or **Name** to display projects based on the dates when the projects are added in descending order or based on the display names or names in reverse alphabetical order.
3	Click the icon. The projects are listed.
4	Click the icon. The projects are categorized based on the project mode and projects in Dev-Prod mode are paired.

9.7.4.2. Create projects

A project is used to isolate physical resources and developers during Data Mid-End construction. This topic describes how to create projects in Dev-Prod mode or a project in Basic mode.

Prerequisites

Required computing engines are created. For more information, see Create a batch processing computing engine or Create a stream processing computing engine.

Context

Limits:

- Only the super administrator and business unit administrators can create projects.
- A computing engine can be bound to only one project.
- You cannot change the computing engine of a project after they are bound.
- To make sure that tasks can be processed in a project in Prod mode, you must configure the stream processing computing engine or batch processing computing engine for both the project in Prod mode and the corresponding project in Dev mode.

Dataphin allows you to create projects in Dev-Prod or Basic mode. The following table describes the two modes.

Mode	Description
Dev-Prod mode	Generates a project in Dev mode as the development environment and a project in Prod mode as the production environment. The two projects are isolated. This allows you to ensure data security in the production environment and manage the data production process in a controllable way. We recommend that you select this mode if you are concerned more about management. This mode is applicable to the scenario where you have many developers who have clear responsibilities and you have a large budget for computing and storage. Note By default, the name of the project in Dev mode is suffixed with _dev.
Basic mode	Generates a project in Basic mode as an independent and flexible production environment. In this mode, the data production process is stable and easy-to-use and the production data is controllable. We recommend that you select this mode if you are concerned more about data development efficiency rather than management. This mode is applicable to the scenario where the responsibilities of developers are not clear and you have a limited budget for computing and storage.

Create projects in Dev-Prod mode

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Project Management** in the left-side navigation pane.

4. On the **Project Management** page, click **Create Project** in the upper-right corner.
5. In the **Create Project** dialog box, select **Dev-Prod Mode**.
6. Click **Next**.
7. In the **Create Project** dialog box, set the parameters as required.

Section	Parameter	Description
Name Settings	Common Display Name	The common display name of the projects. Note the following naming rules when you set a name: ○ The common display name can contain letters, digits, underscores (_), and hyphens (-). ○ By default, business unit names are prefixed with **LD_**. Therefore, project names cannot have this prefix. This enables Dataphin to distinguish between logical tables and physical tables in data queries. When logical tables and physical tables are referenced, the former is prefixed with the corresponding business unit name, and the latter is prefixed with the corresponding project name. If project names also start with **LD_**, Dataphin cannot distinguish between physical tables and logical tables that are both prefixed with LD_.
	Common Name	The common name of the projects. Note the following naming rules when you set a name: ○ The common name can contain letters, digits, and underscores (_). ○ If the computing engine type is MaxCompute, we recommend that you set **Common Name** to the MaxCompute project name. ○ By default, business unit names are prefixed with **LD_**. Therefore, project names cannot have this prefix. This enables Dataphin to distinguish between logical tables and physical tables in data queries. When logical tables and physical tables are referenced, the former is prefixed with the corresponding business unit name, and the latter is prefixed with the corresponding project name. If project names also start with **LD_**, Dataphin cannot distinguish between physical tables and logical tables that are both prefixed with LD_.
	Business Unit	Optional. The business unit to which the project belongs.

Section	Parameter	Description
Namespace	Project Type	The type of the project. This parameter is used to categorize the tasks and generated data of projects. Default value: Application Data Store. Valid values: ○ **Source Data**: stores raw data of business databases. This layer serves as the source and basis in subsequent data development and is also called the vertical data center. ○ **Common Dimensional Modeling**: extracts themes, standards, and common data from business data. This layer connects the source data layer and application data store layer and is also called the common data center. ○ **Application Data Store**: defines diversified and distinct metrics based on business scenarios.
Project 1: Dev	Batch Processing	The batch processing computing engine. ○ Make sure that the computing engine that you bind to each project is unique. Otherwise, a conflict may occur when data is written to the physical database. ○ Batch processing computing engines are bound to MaxCompute projects. If you have multiple projects, each bound to a batch processing computing engine, make sure that your AccessKey pair has the permissions of the MaxCompute project administrator, including the permission to access data across the MaxCompute projects. If your AccessKey pair does not have the preceding permissions, you must execute the GRANT statement in the authorization code in MaxCompute to grant required permissions to your AccessKey pair. This ensures that you can pass the database authentication when you switch between projects in Dataphin. ○ A batch processing computing engine can be bound to only one project.
	Stream Processing	The stream processing computing engine.
	Name	Optional. The name of the project in Dev mode. Dataphin automatically generates a name based on the specified common name of the project in the format of Common name_dev.
	Display Name	Optional. The display name of the project in Dev mode. Dataphin automatically generates a name based on the specified common display name of the project in the format of Common display name_development.
	Description	The description of the project in Dev mode.

Section	Parameter	Description
Project 2: Prod	Stream Processing	The stream processing computing engine.
	Batch Processing	The batch processing computing engine. For more information, see the description of the batch processing computing engine in Project 1: Dev. Note You must bind different computing engines to the project in Dev mode and the project in Prod mode.
	Stream Processing	The stream processing computing engine.
	Name	Optional. The name of the project in Prod mode. Dataphin automatically generates a name based on the specified common name of the project.
	Display Name	Optional. The display name of the project in Prod mode. Dataphin automatically generates a name based on the specified common display name of the project.
	Description	The description of the project in Prod mode.
Other Settings	Sandbox Whitelist	The IP addresses, domain names, and database endpoints that Shell or Python tasks can access. To configure a sandbox whitelist, perform the following steps: i. Click **Create**. In the fields that appear, enter the IP address, domain name, or database endpoint and the port number. ii. Click the icon to add the IP address, domain name, or database endpoint to the sandbox whitelist. You can find an IP address, a domain name, or a database endpoint and click the icon in the **Actions** column to remove it from the sandbox whitelist.

8. Click **OK**.

Create a project in Basic mode

1. On the **Project Management** page, click **Create Project** in the upper-right corner.
2. In the **Create Project** dialog box, select **Basic Mode**.
3. Click **Next**.
4. In the **Create Project** dialog box, set the parameters as required.

Section	Parameter	Description
Basic Settings	Batch Processing	The batch processing computing engine. ◦ Make sure that the computing engine that you bind to each project is unique. Otherwise, a conflict may occur when data is written to the physical database. ◦ Batch processing computing engines are bound to MaxCompute projects. If you have multiple projects, each bound to a batch processing computing engine, make sure that your AccessKey pair has the permissions of the MaxCompute project administrator, including the permission to access data across the MaxCompute projects. If your AccessKey pair does not have the preceding permissions, you must execute the GRANT statement in the authorization code in MaxCompute to grant required permissions to your AccessKey pair. This ensures that you can pass the database authentication when you switch between projects in Dataphin. ◦ A batch processing computing engine can be bound to only one project.
	Stream Processing	The stream processing computing engine.
	Name	The name of the project. Note the following naming rules when you set a name: ◦ The name can contain letters, digits, and underscores (_). ◦ By default, business unit names are prefixed with LD_. Therefore, project names cannot have this prefix. This enables Dataphin to distinguish between logical tables and physical tables in data queries. When logical tables and physical tables are referenced, the former is prefixed with the corresponding business unit name, and the latter is prefixed with the corresponding project name. If project names also start with LD_, Dataphin cannot distinguish between physical tables and logical tables that are both prefixed with LD_.

Section	Parameter	Description
Namespace	**Display Name**	The display name of the project. Note the following naming rules when you set a name: ○ The display name can contain letters, digits, underscores (_), and hyphens (-). ○ By default, business unit names are prefixed with **LD_**. Therefore, project names cannot have this prefix. This enables Dataphin to distinguish between logical tables and physical tables in data queries. When logical tables and physical tables are referenced, the former is prefixed with the corresponding business unit name, and the latter is prefixed with the corresponding project name. If project names also start with **LD_**, Dataphin cannot distinguish between physical tables and logical tables that are both prefixed with LD_.
	Description	The description of the project in Basic mode.
	Business Unit	Optional. The business unit to which the project belongs.
	Project Type	The type of the project. This parameter is used to categorize the tasks and generated data of projects. Default value: Application Data Store. Valid values: ○ **Source Data**: stores raw data of business databases. This layer serves as the source and basis in subsequent data development and is also called the vertical data center. ○ **Common Dimensional Modeling**: extracts themes, standards, and common data from business data. This layer connects the source data layer and application data store layer and is also called the common data center. ○ **Application Data Store**: defines diversified and distinct metrics based on business scenarios.

Section	Parameter	Description
Other Settings	Sandbox Whitelist	The IP addresses, domain names, and database endpoints that Shell or Python tasks can access. To configure a sandbox whitelist, perform the following steps: i. Click **Create**. In the fields that appear, enter the IP address, domain name, or database endpoint and the port number. ii. Click the icon to add the IP address, domain name, or database endpoint to the sandbox whitelist. You can find an IP address, a domain name, or a database endpoint and click the icon in the **Actions** column to remove it from the sandbox whitelist.

5. Click **OK**.

9.7.4.3. Configure projects

You can configure project information and manage project members. This topic describes how to configure projects in Dev-Prod mode or a project in Basic mode.

Prerequisites

A project in Basic mode is created or projects in Dev-Prod mode are created. For more information, see Create projects.

Context

Limits:

- By default, the super administrator also plays the administrator role in all projects. You cannot delete or change the super administrator role.
- Only project administrators can change the roles of other project members.
- Only the super administrator and project administrators can configure project information.

Configure the information about projects in Dev-Prod mode

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Project Management** in the left-side navigation pane.
4. On the Project Management page, find the project that you want to configure and click **Information Settings**.
5. In the **Information Settings** dialog box, change the parameter values as needed and set the

parameters in the General Feature Control section. For more information, see Create projects.

- If the **Data Result Download** parameter is set to **Yes**, the roles except the guests can download result data.
- If the **Data Result Download** parameter is set to **No**, the result data cannot be downloaded and can only be viewed on the Result tab.

6. Click **OK**.

Configure the information about a project in Basic mode

1. On the **Project Management** page, find the project that you want to configure and click **Information Settings**.
2. In the **Information Settings** dialog box, change the parameter values as needed and set the parameters in the **General Feature Control** section. For more information, see Create projects.
   - If the **Data Result Download** parameter is set to **Yes**, the roles except the guests can download result data.
   - If the **Data Result Download** parameter is set to **No**, the result data cannot be downloaded and can only be viewed on the Result tab.
3. Click **OK**.

Add members

1. On the **Project Management** page, find the project that you want to configure and click **Members Management**.
2. In the **Manage Members** dialog box, click **Add Members**.
3. Add one or more members.
   i. In the **Add Members** dialog box, set the parameters as required.

Parameter	Description
Username	The user to be added as a project member. You can specify multiple users.
Role	The role that you want the selected users to assume.

   ii. Click **OK**.
4. After you set the preceding parameters, click **OK**.

Change the role of a member

1. On the **Project Management** page, find the project that you want to configure and click **Members Management**.
2. In the **Manage Members** dialog box, find the member whose role you want to change and click the icon in the **Role** column.
3. From the drop-down list, select a role.
4. Click **OK**.

Remove a member

1. On the **Project Management** page, find the project that you want to configure and click **Members Management**.
2. Remove a member.
   i. In the **Manage Members** dialog box, find the member you want to remove and click the icon in the **Actions** column.
   ii. In the message that appears, click **OK**.
3. In the Manage Members dialog box, click **OK**.

Remove multiple members at a time

1. On the **Project Management** page, find the project that you want to configure and click **Members Management**.
2. Remove multiple members at a time.
   i. In the **Manage Members** dialog box, select multiple members to be removed.
   ii. Click **Remove** in the lower part of the **Manage Members** dialog box.
   iii. In the message that appears, click **OK**.
3. In the Manage Members dialog box, click **OK**.

9.7.4.4. Delete projects

A project is used to isolate physical resources and developers during Data Mid-End construction. This topic describes how to delete projects.

Prerequisites

A project in Basic mode is created or projects in Dev-Prod mode are created. For more information, see Create projects.

Context

Limits:

- Only the super administrator and project administrators can delete projects.
- Only projects that contain no tasks or objects, such as code tasks or data standardization and data modeling objects, can be deleted.
- To delete projects in Dev-Prod mode, make sure that the project in Dev mode and the project in Prod mode contain no tasks or objects.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the Planning page, click **Project Management** in the left-side navigation pane.

4. In the lower part of the **Project Management** page, click **Enable Batch Deletion**.
5. Select the projects to be deleted. To delete projects in Dev-Prod mode, you can select only the project in Dev mode or the project in Prod mode. The other project is automatically selected.
6. In the lower part of the page, click **Delete**.
7. In the message that appears, click **OK**.

9.7.5. Maintenance and upgrade

9.7.5.1. Important notes for upgrade

This topic describes the important notes for upgrading business units and projects.

If you want to upgrade Dataphin or control Dataphin for data security purposes, you can lock Dataphin by setting Dataphin to work in the maintenance mode.

When the business grows or the publishing process of some data must be controlled, you can upgrade business units or projects from the Basic mode to the Dev-Prod mode. During maintenance and upgrade, data read and write operations are not allowed, but tasks run normally.

Important notes for upgrading business units

- Only the super administrator can upgrade business units.
- You cannot downgrade business units after they are upgraded.
- You cannot upgrade business units whose names are suffixed with _dev.
- You can upgrade only one business unit at a time.
- If you upgrade a business unit in the Basic mode that has no projects, the business unit is upgraded to a business unit in the Prod mode. A corresponding business unit in the Dev mode is created. The two business units share all configurations and resources.
- If you upgrade a business unit in the Basic mode that has projects with data standardization and data modeling objects, the projects are forcibly upgraded to projects in the Prod mode. Corresponding projects in the Dev mode are created.
- If you upgrade a business unit in the Basic mode that has projects without data standardization or data modeling objects, the projects remain in the Basic mode. However, the data standardization and data modeling features of these projects are disabled during and after the upgrade. For example, when you open a logical aggregate table found by global search in these projects, you can only view its information, but cannot perform any operations.

Important notes for upgrading projects

- Only the super administrator can upgrade projects.
- You cannot downgrade projects after they are upgraded.
- You can upgrade one or more projects at a time.
- If you upgrade a project in the Basic mode that is bound to a business unit, the project is upgraded to a project in the Prod mode. A corresponding project in the Dev mode is created. The data standardization and data modeling features are enabled for both projects after the upgrade.
- If you upgrade a project in the Basic mode, Dataphin upgrades the project to a project in the

Prod mode and copies the configuration of the original project in the Basic mode to create a project in the Dev mode. Objects in the draft state in the original project are automatically deleted.

- After a project in the Basic mode is upgraded, you can publish objects in the project in the Dev mode to overwrite the corresponding objects in the developing state in the project in the Prod mode.

9.7.5.2. Maintain and upgrade business units

This topic describes how to maintain and upgrade business units.

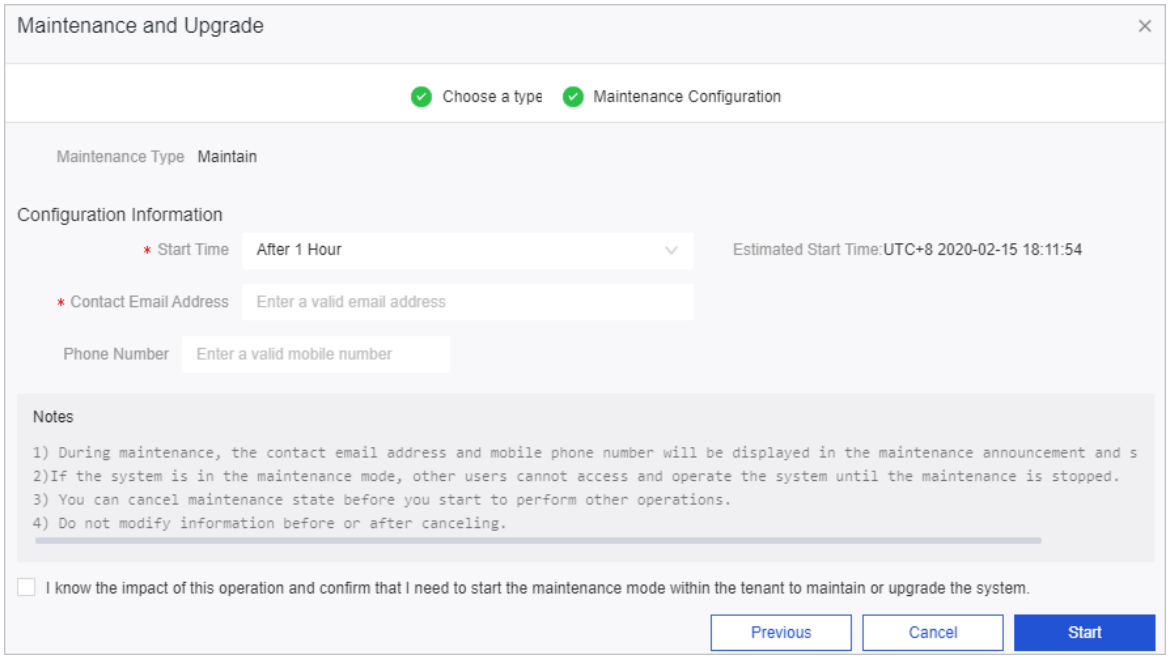
Maintain business units

1. Log on to the Dataphin console.
2. Open the **Maintenance and Upgrade** dialog box by using one of the following methods:
   - a. On the Dataphin homepage, click **Planning** in the top navigation bar.

     You can also click **Intelligent Data Warehouse Planning** in the middle section.

     b. On the **Planning** page, click **Business Units** in the left-side navigation pane.

     c. On the **Business Units** page, click **Maintenance and Upgrade** in the upper-right corner.
   - On the Dataphin homepage, move the pointer over the icon in the upper-right corner and select **Start Maintenance and Upgrade**.
3. In the **Maintenance and Upgrade** dialog box, set the **Choose a type** parameter to **Maintain**. Click **Next**.
4. In the Maintenance Configuration step, set the **Start Time**, **Phone Number**, and **Contact Email Address** parameters, select **I know the impact of this operation and confirm that I need to start the maintenance mode within the tenant to maintain or upgrade the system**, and then click **Start**.



If you want to cancel the maintenance before the maintenance starts, perform the following steps:

i. In the **Maintenance and Upgrade** dialog box, click **Cancel Maintenance**.

ii. In the message that appears, click **OK**.

After the maintenance starts, you cannot perform operations on modules. If you want to stop the ongoing maintenance, perform the following steps as the super administrator:

i. Go to the **Starting Maintenance** page and click **Forcedly Stop Maintenance**.

ii. In the message that appears, click **OK**.

Upgrade business units

1. In the **Maintenance and Upgrade** dialog box, set the **Choose a type** parameter to **Upgrade to Dev-Prod Mode**. Click **Next**.
2. In the Maintenance Configuration step, set the **Start Time**, **Phone Number**, and **Contact Email Address** parameters, select **I know the impact of this operation and confirm that I need to start the maintenance mode within the tenant to maintain or upgrade the system**, and then click **Start**.

   If you want to cancel the upgrade before the upgrade starts, perform the following steps:

   i. In the **Maintenance and Upgrade** dialog box, click **Cancel Maintenance**.

   ii. In the message that appears, click **OK**.

   After the upgrade starts, you cannot perform operations on modules. If you want to stop the ongoing upgrade, perform the following steps as the super administrator:

   i. On the left of the Upgrade Configuration page, click **Stop Maintenance**.

   ii. In the message that appears, click **OK**.
3. After the upgrade is completed, click **Upgraded**.
4. On the page that appears, click **Continue to Upgrade** or **Exit Maintenance Mode**.

9.7.5.3. View maintenance and upgrade logs

This topic describes how to view maintenance and upgrade logs.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, move the pointer over the  icon in the upper-right corner and select **View History**.
3. In the **Operations Log for Maintenance and Upgrades** dialog box, view the operators, operation time, and operations.
4. Click **OK**.

9.7.6. Data source

9.7.6.1. Overview

Data source overview

A data source is a physical data store. You can create data sources to import business data to Dataphin, based on which you can build a Data Mid-End. You can also import existing data to a data source.

Data source types

The following table describes the types of data sources that Dataphin supports.

Category	Data source type
Batch processing	MaxCompute, MySQL, SQL Server, PostgreSQL, Oracle, Hadoop Distributed File System (HDFS), Hive, FTP, Vertica, PolarDB-X, AnalyticDB, Elasticsearch, HBase_1_1_X, HBase_0_9_4, MongoDB, AnalyticDB for MySQL V3.0, AnalyticDB for PostgreSQL, and LogHub
Stream processing	PolarDB-X, DataHub, ApsaraDB for HBase, Log Service, Tablestore, Kafka_9_11, and RocketMQ

Access methods

Dataphin can use different methods to connect to different types of databases.

- Non-ApsaraDB databases accessible from the Internet: After Dataphin is granted the access to a non-ApsaraDB database accessible from the Internet, you can connect Dataphin to the database by using the public IP address or endpoint of the database.
- ApsaraDB databases: If an ApsaraDB database is accessible from the Internet, you can connect Dataphin to the database by using the public IP address of the database after Dataphin is granted the access to the database. If an ApsaraDB database is in a virtual private cloud (VPC), you can connect Dataphin to the database by using the VPC after the IP address of Dataphin is added to the whitelist of the database.
- User-created databases on ECS instances in VPCs: After the IP address of Dataphin is added to the whitelist of a user-created database on an ECS instance in a VPC, you can connect Dataphin to the database by using the VPC.
- Databases in a MaxCompute project: If a database is used in a MaxCompute project, you can connect Dataphin to the database by using the endpoint of the database.

Permissions

- All Dataphin members can create data sources.
- The super administrator can delete and modify all data sources, test the connectivity of all data sources, and change the owners of all data sources.
- Members other than the super administrator can only delete and modify their own data sources, test the connectivity of their own data sources, and change the owner of their own data sources.

9.7.6.2. Create batch processing data sources

9.7.6.2.1. Create a MaxCompute data source

This topic describes how to create a MaxCompute data source.

Prerequisites

- The endpoint that you can use to connect to MaxCompute is obtained.
- The name of a MaxCompute project is obtained.
- The AccessKey ID and AccessKey secret that are used to authenticate the user identity when Dataphin connects to the MaxCompute project are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
   - The **Data Sources** page displays the information about all created data sources, including the name, owner, supported data processing type, creation information, and connection information of each data source.
   - In the upper-right corner of the **Data Sources** page, you can enter a keyword in the search box to search for a specific data source by name.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **MAX_COMPUTE**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ◦ If you want to use the data source only in the production environment, select **Prod**. ◦ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ▪ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ▪ Select **Prod and Dev** and configure the data source for both the production and development environments.
Endpoint	The endpoint that you can use to connect to the MaxCompute project.
Project Name	The name of the MaxCompute project to which the data source is connected.

Parameter	Description
Access ID	The AccessKey ID that is used to authenticate the user identity when Dataphin connects to the MaxCompute project.
Access Key	The AccessKey secret that is used to authenticate the user identity when Dataphin connects to the MaxCompute project.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.2. Create a MySQL data source

This topic describes how to create a MySQL data source.

Prerequisites

- The JDBC URL that you can use to connect to a MySQL database is obtained.
- The username and password that you can use to connect to the MySQL database are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the Planning page, click **Data Sources** in the left-side navigation pane.
   - The **Data Sources** page displays the information about all created data sources, including the name, owner, supported data processing type, creation information, and connection information of each data source.
   - In the upper-right corner of the **Data Sources** page, you can enter a keyword in the search box to search for a specific data source by name.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **MYSQL**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.

Parameter	Description
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
JDBC URL	The JDBC URL that you can use to connect to the MySQL database.
Username	The username that you can use to connect to the MySQL database.
Password	The password that you can use to connect to the MySQL database.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.3. Create an SQL Server data source

This topic describes how to create an SQL Server data source.

Prerequisites

- The JDBC URL that you can use to connect to an SQL Server database is obtained.
- The schema of the SQL Server database is obtained.
- The username and password that you can use to connect to the SQL Server database are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **SQL_SERVER**.

Parameter	Description
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
JDBC URL	The JDBC URL that you can use to connect to the SQL Server database.
Schema	The schema of the SQL Server database.
Username	The username that you can use to connect to the SQL Server database.
Password	The password that you can use to connect to the SQL Server database.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.4. Create a PostgreSQL data source

This topic describes how to create a PostgreSQL data source.

Prerequisites

- The JDBC URL that you can use to connect to a PostgreSQL database is obtained.
- The schema of the PostgreSQL database is obtained.
- The username and password that you can use to connect to the PostgreSQL database are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.

4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **POSTGRE_SQL**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
JDBC URL	The JDBC URL that you can use to connect to the PostgreSQL database.
Schema	The schema of the PostgreSQL database.
Username	The username that you can use to connect to the PostgreSQL database.
Password	The password that you can use to connect to the PostgreSQL database.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.5. Create an Oracle data source

This topic describes how to create an Oracle data source.

Prerequisites

- The JDBC URL that you can use to connect to an Oracle database is obtained.
- The schema of the Oracle database is obtained.
- The username and password that you can use to connect to the Oracle database are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar

- On the Dataphin homepage, click **Planning** in the top navigation bar.
- On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.

3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **ORACLE**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
JDBC URL	The JDBC URL that you can use to connect to the Oracle database.
Schema	The schema of the Oracle database.
Username	The username that you can use to connect to the Oracle database.
Password	The password that you can use to connect to the Oracle database.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.6. Create an HDFS data source

This topic describes how to create an HDFS data source.

Prerequisites

- The JDBC URL that you can use to connect to HDFS is obtained.
- The URL that you can use to connect to an HDFS file system is obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **HDFS**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
DefaultFS	The URL of the HDFS file system, in the format of hdfs://Server IP:Port.
Kerberos	Specifies whether to enable Kerberos authentication. You can select **Enable** or **Disable**. If you select **Enable**, you must also set the following parameters: ○ **KDC Server**: the endpoint of the key distribution center (KDC) server. Separate multiple endpoints with commas (,). ○ **Keytab File**: the keytab file for Kerberos authentication. ○ **Principal**: the Kerberos principal name for Kerberos authentication.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.7. Create an FTP data source

This topic describes how to create an FTP data source.

Prerequisites

- The IP address of an FTP server is obtained.
- The port number of the FTP server is obtained.
- The username and password that you can use to connect to the FTP server are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **FTP**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
Protocol	The protocol that is used to transfer files. You can select **FTP** or **SFTP**. ○ **FTP**: transfers files by using FTP. ○ **SFTP**: transfers files by using SFTP.
Host	The name of the FTP server.
Port	The port number of the FTP server.
Username	The username that you can use to connect to the FTP server.

Parameter	Description
Password	The password that you can use to connect to the FTP server.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.8. Create a Hive data source

This topic describes how to create a Hive data source.

Prerequisites

- The following cluster configurations of Hive are obtained:
  - The hostname of the Hive cluster
  - The IP address of the Hive cluster
  - The port number of the Hive cluster
- The following HDFS configurations of Hive are obtained:
  - The keytab file for Kerberos authentication for HDFS
  - The Kerberos principal name for Kerberos authentication for HDFS
- The following Hive configurations are obtained:
  - The JDBC URL that you can use to connect to Hive
  - The keytab file and the Kerberos principal name for Kerberos authentication for Hive
- The following configurations of the metadatabase are obtained:
  - **JDBC URL**
  - The username that you can use to connect to the metadatabase
  - The password that you can use to connect to the metadatabase

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Section	Parameter	Description
	Type	The type of the data source. Select **HIVE**.

Section	Parameter	Description
Basic information	Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
	Description	The description of the data source.
	Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
Cluster Configuration	NameNode	The location of the current file system root, in the format of Hostname:Port or IP address:Port. Specify the hostname, port number, and IP address of the Hive cluster.
	Kerberos	Specifies whether to enable Kerberos authentication. You can select **Enable** or **Disable**. If you select **Enable**, you must set the **KDC Server** parameter or upload the Kerberos configuration file. The **KDC Server** parameter specifies the endpoint of the KDC server. Separate multiple endpoints with commas (,).
	KRB5 File	The Kerberos configuration file that is used for authentication.
HDFS Configuration	HDFS Keytab File	The keytab file for Kerberos authentication for HDFS.
	HDFS Principal	The Kerberos principal name for Kerberos authentication for HDFS.
Hive Configuration	JDBC URL	The JDBC URL that you can use to connect to Hive.
	Hive Keytab File	The keytab file for Kerberos authentication for Hive.
	Hive Principal	The Kerberos principal name for Kerberos authentication for Hive.

Section	Parameter	Description
Metadatabase Configuration	Database Type	The type of the metadatabase. Valid values: **MySQL** and **PostgreSQL**.
	JDBC URL	The JDBC URL that you can use to connect to the metadatabase.
	Username	The username that you can use to connect to the metadatabase.
	Password	The password that you can use to connect to the metadatabase.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.9. Create an Elasticsearch data source

This topic describes how to create an Elasticsearch data source.

Prerequisites

- The URL that you can use to connect to Elasticsearch is obtained.
- The username and password that you can use to connect to Elasticsearch are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **ELASTIC_SEARCH**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.

Parameter	Description
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
ES URL	The URL that you can use to connect to Elasticsearch.
Username	The username that you can use to connect to Elasticsearch.
Password	The password that you can use to connect to Elasticsearch.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.10. Create a MongoDB data source

This topic describes how to create a MongoDB data source.

Prerequisites

- The JDBC URL that you can use to connect to a MongoDB database is obtained.
- The username and password that you can use to connect to the MongoDB database are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **MONGODB**.

Parameter	Description
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
JDBC URL	The JDBC URL that you can use to connect to the MongoDB database.
Username	The username that you can use to connect to the MongoDB database.
Password	The password that you can use to connect to the MongoDB database.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.11. Create an AnalyticDB data source

This topic describes how to create an AnalyticDB data source.

Prerequisites

- The JDBC URL that you can use to connect to an AnalyticDB database is obtained.
- The username and password that you can use to connect to the AnalyticDB database are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **ANALYTICDB**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
JDBC URL	The JDBC URL that you can use to connect to the AnalyticDB database.
Username	The username that you can use to connect to the AnalyticDB database.
Password	The password that you can use to connect to the AnalyticDB database.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.12. Create a PolarDB-X data source

This topic describes how to create a PolarDB-X data source.

Prerequisites

- The JDBC URL that you can use to connect to a PolarDB-X database is obtained.
- The username and password that you can use to connect to the PolarDB-X database are obtained.

Procedure

1. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
2. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
3. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
4. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **DRDS**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
JDBC URL	The JDBC URL that you can use to connect to the PolarDB-X database.
Username	The username that you can use to connect to the PolarDB-X database.
Password	The password that you can use to connect to the PolarDB-X database.

5. Click **Test Connection** to test the connectivity of the data source.
6. After the data source passes the connectivity test, click **OK**.

9.7.6.2.13. Create a Vertica data source

This topic describes how to create a Vertica data source.

Prerequisites

- The JDBC URL that you can use to connect to a Vertica database is obtained.
- The schema of the Vertica database is obtained.
- The username and password that you can use to connect to the Vertica database are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.

- The **Data Sources** page displays the information about all created data sources, including the name, owner, supported data processing type, creation information, and connection information of each data source.
- In the upper-right corner of the **Data Sources** page, you can enter a keyword in the search box to search for a specific data source by name.

4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **VERTICA**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
JDBC URL	The JDBC URL that you can use to connect to the Vertica database.
Schema	The schema of the Vertica database.
Username	The username that you can use to connect to the Vertica database.
Password	The password that you can use to connect to the Vertica database.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.14. Create an HBase data source

This topic describes how to create an HBase data source.

Prerequisites

- The endpoints of KDC servers are obtained.
- The Kerberos principal name for Kerberos authentication is obtained.
- The keytab file for Kerberos authentication is obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **HBASE_0_9_4** or **HBASE_1_1_X**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
Endpoint	The endpoint that you can use to connect to an HBase database.
Connection Parameters	The parameters that are required to connect to the HBase database. Enter the parameters in the JSON format.
Kerberos	Specifies whether to enable Kerberos authentication. You can select **Enable** or **Disable**. If you select **Enable**, you must also set the following parameters: ○ **KDC Server**: the endpoint of the KDC server. Separate multiple endpoints with commas (,). ○ **Keytab File**: the keytab file for Kerberos authentication. ○ **Principal**: the Kerberos principal name for Kerberos authentication.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.15. Create an AnalyticDB for MySQL V3.0 data source

This topic describes how to create an AnalyticDB for MySQL V3.0 data source.

Prerequisites

- The JDBC URL that you can use to connect to an AnalyticDB for MySQL V3.0 database is obtained.
- The username and password that you can use to connect to the AnalyticDB for MySQL V3.0 database are obtained.
- The ID of the cluster where the AnalyticDB for MySQL V3.0 database resides is obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **ADB_FOR_MYSQL_V3**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ◦ If you want to use the data source only in the production environment, select **Prod**. ◦ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ▪ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ▪ Select **Prod and Dev** and configure the data source for both the production and development environments.
JDBC URL	The JDBC URL that you can use to connect to the AnalyticDB for MySQL V3.0 database.

Parameter	Description
Username	The username that you can use to connect to the AnalyticDB for MySQL V3.0 database.
Password	The password that you can use to connect to the AnalyticDB for MySQL V3.0 database.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.16. Create an AnalyticDB for PostgreSQL data source

This topic describes how to create an AnalyticDB for PostgreSQL data source.

Prerequisites

- The JDBC URL that you can use to connect to an AnalyticDB for PostgreSQL database is obtained.
- The schema of the AnalyticDB for PostgreSQL database is obtained.
- The username and password that you can use to connect to the AnalyticDB for PostgreSQL database are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **ADB_FOR_PG**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.

Parameter	Description
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
JDBC URL	The JDBC URL that you can use to connect to the AnalyticDB for PostgreSQL database.
Schema	The schema of the AnalyticDB for PostgreSQL database.
Username	The username that you can use to connect to the AnalyticDB for PostgreSQL database.
Password	The password that you can use to connect to the AnalyticDB for PostgreSQL database.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.2.17. Create a LogHub data source

This topic describes how to create a LogHub data source.

Prerequisites

- The endpoint that you can use to connect to LogHub is obtained.
- The name of a LogHub project is obtained.
- The AccessKey ID and AccessKey secret that are used to authenticate the user identity when Dataphin connects to the LogHub project are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.

5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **LOG_HUB**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
LogHub Endpoint	The endpoint that you can use to connect to LogHub.
Project	The name of the LogHub project.
Access ID	The AccessKey ID that is used to authenticate the user identity when Dataphin connects to the LogHub project.
Access Key	The AccessKey secret that is used to authenticate the user identity when Dataphin connects to the LogHub project.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.3. Create stream processing data sources

9.7.6.3.1. Create a DataHub data source

This topic describes how to create a DataHub data source.

Prerequisites

- The endpoint that you can use to connect to DataHub is obtained.
- The name of a DataHub project is obtained.
- The AccessKey ID and AccessKey secret that are used to authenticate the user identity when Dataphin connects to the DataHub project are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **DATAHUB**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
Endpoint	The endpoint that you can use to connect to DataHub.
Project Name	The name of the DataHub project.
Access ID	The AccessKey ID that is used to authenticate the user identity when Dataphin connects to the DataHub project.
Access Key	The AccessKey secret that is used to authenticate the user identity when Dataphin connects to the DataHub project.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.3.2. Create a Log Service data source

This topic describes how to create a Log Service data source.

Prerequisites

- The endpoint that you can use to connect to Log Service is obtained.
- The name of a Log Service project is obtained.
- The AccessKey ID and AccessKey secret that are used to authenticate the user identity when Dataphin connects to the Log Service project are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **LOG_SERVICE**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
Endpoint	The endpoint that you can use to connect to Log Service.
Project Name	The name of the Log Service project.
Access ID	The AccessKey ID that is used to authenticate the user identity when Dataphin connects to the Log Service project.
Access Key	The AccessKey secret that is used to authenticate the user identity when Dataphin connects to the Log Service project.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.3.3. Create an ApsaraDB for HBase data source

This topic describes how to create an ApsaraDB for HBase data source.

Prerequisites

- The endpoint that you can use to connect to the quorum servers of ZooKeeper built in ApsaraDB for HBase is obtained.
- The endpoint that you can use to connect to an ApsaraDB for HBase database is obtained.
- The username and password that you can use to connect to the ApsaraDB for HBase database are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **ALIYUN_HBASE**.
Name	The name of the data source.
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.

Parameter	Description
Service type	The edition of ApsaraDB for HBase. Valid values: **STANDARD** and **ENHANCED**. ○ If you set the **Service type** parameter to **STANDARD**, you must also set the **Version** and **zkQuorum** parameters. ○ If you set the **Service type** parameter to **ENHANCED**, you must also set the **endPoint**, **Username**, and **Password** parameters.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.3.4. Create a Kafka data source

This topic describes how to create a Kafka data source.

Prerequisites

The endpoint that you can use to connect to a Kafka cluster is obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **KAFKA_9_11**.
Name	The name of the data source.
Description	The description of the data source.

Parameter	Description
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
Kafka cluster address	The endpoint that you can use to connect to the Kafka cluster.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.3.5. Create a Tablestore data source

This topic describes how to create a Tablestore data source.

Prerequisites

- The endpoint that you can use to connect to a Tablestore instance is obtained.
- The name of the Tablestore instance is obtained.
- The AccessKey ID and AccessKey secret that are used to authenticate the user identity when Dataphin connects to the Tablestore instance are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **TABLE_STORE**.
Name	The name of the data source.
Description	The description of the data source.

Parameter	Description
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
Endpoint	The endpoint that you can use to connect to the Tablestore instance.
Access Id	The AccessKey ID that is used to authenticate the user identity when Dataphin connects to the Tablestore instance.
Access Key	The AccessKey secret that is used to authenticate the user identity when Dataphin connects to the Tablestore instance.
Instance Name	The name of the Tablestore instance.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.3.6. Create a RocketMQ data source

This topic describes how to create a RocketMQ data source.

Prerequisites

- The endpoint that you can use to connect to a RocketMQ instance is obtained.
- The ID of the RocketMQ instance is obtained.
- The AccessKey ID and AccessKey secret that are used to authenticate the user identity when Dataphin connects to the RocketMQ instance are obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the **Data Sources** page, click **Create Data Source** in the upper-right corner.
5. In the **Create Data Source** dialog box, set the parameters as required.

Parameter	Description
Type	The type of the data source. Select **ROCKET_MQ**.
Name	The name of the data source. The name can contain letters, digits, underscores (_), and hyphens (-).
Description	The description of the data source.
Environment	The type of the environment where the data source will be used. ○ If you want to use the data source only in the production environment, select **Prod**. ○ If you want to use the data source in both the production and development environments, create the data source by using one of the following methods: ■ Select **Prod** and configure the data source for the production environment. After that, go to the Data Sources page, find the data source, and then click **Data Source for Dev Environment**. ■ Select **Prod and Dev** and configure the data source for both the production and development environments.
Endpoint	The endpoint that you can use to connect to the RocketMQ instance.
InstanceID	The ID of the RocketMQ instance.
Access ID	The AccessKey ID that is used to authenticate the user identity when Dataphin connects to the RocketMQ instance.
Access Key	The AccessKey secret that is used to authenticate the user identity when Dataphin connects to the RocketMQ instance.

6. Click **Test Connection** to test the connectivity of the data source.
7. After the data source passes the connectivity test, click **OK**.

9.7.6.4. Modify a data source

This topic describes how to modify a data source.

Prerequisites

Data sources are created. For more information, see Create batch processing data sources or Create stream processing data sources.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.

3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. Change the name of a data source.
   i. On the Data Sources page, find the data source that you want to modify and click the icon next to the name of the data source.

   ii. In the field that appears, enter a new name.
5. Modify the connection information about a data source.
   i. Find the data source that you want to modify and click the icon next to **Actions** in the Prod or Dev section.
   ii. In the **Edit Data Source for Prod Environment** or **Edit Data Source for Dev Environment** dialog box, change parameter values as needed. For more information about how to set the parameters, see Create batch processing data sources or Create stream processing data sources.

> **Note** If the data source is bound to a Dataphin project, you cannot change the project name, data source type, or endpoint.

   iii. Click **Test Connection** to test the connectivity of the data source.
   iv. After the data source passes the connectivity test, click **OK**.

9.7.6.5. Test a data source

This topic describes how to test a data source.

Prerequisites

Data sources are created. For more information, see Create batch processing data sources or Create stream processing data sources.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the Data Sources page, find the data source that you want to test and click the icon next to **Actions** in the Prod or Dev section.

9.7.6.6. Change the owner of a data source

This topic describes how to change the owner of a data source.

Prerequisites

Data sources are created. For more information, see Create batch processing data sources or Create stream processing data sources.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. On the Data Sources page, find the data source that you want to change the owner and click the icon next to **Actions** in the Prod or Dev section.
5. In the **Change Owner** dialog box, select the member to whom you want to transfer the ownership of the data source.
6. Click **OK**.

9.7.6.7. Delete a data source

This topic describes how to delete a data source.

Prerequisites

Data sources are created. For more information, see Create batch processing data sources or Create stream processing data sources.

Context

You cannot delete a data source that is bound to a Dataphin project.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Data Sources** in the left-side navigation pane.
4. Delete a data source.
   - On the Data Sources page, find the data source that you want to delete and click the icon numbered 2 or 3 in the preceding figure, next to **Actions** in the Prod or Dev section.
   - On the Data Sources page, click the icon numbered 1 in the preceding figure, next to the name of the data source.
5. In the Delete Data Source message, click **OK**.
   - If you click the icon numbered 2 or 3 in the preceding figure, the data source is deleted from the production or development environment.
   - If you click the icon numbed 1 in the preceding figure, the data source is deleted from both the production and development environments.

9.7.7. Computing engines

9.7.7.1. Overview

A batch processing computing engine provides storage and computing resources for offline computing and a stream processing computing engine provides computing resources for real-time computing.

Usage notes

A stream processing computing engine uses computing resources to process data in queues in real time. A batch processing computing engine can store and then process large amounts of data.

- Before you create a batch processing computing engine, make sure that the computing engine type for batch processing is set on the Computing Engine Configuration page in Management Center.

  > **Note** For more information, see Set the computing engine type.

- By default, Dataphin sets Flink as the computing engine type for stream processing.
- Dataphin supports the MaxCompute computing engine for batch processing and the Flink computing engine for stream processing.
- Before you develop tasks in a Dataphin project, you must bind at least one computing engine to the project. By default, a batch processing computing engine is used to store and then process large amounts of data. You can also use a stream processing computing engine to process data in real time.

- Do not create computing engines based on the same connection information. In addition, we recommend that you do not bind a computing engine to multiple Dataphin projects. Otherwise, a conflict may occur when data is written to the physical database.

Permissions

- Only the super administrator, project administrators, and business unit administrators can create computing engines.
- The super administrator can delete and modify all computing engines, test the connectivity of all computing engines, and change the owners of all computing engines.
- Members other than the super administrator can only delete and modify their own computing engines, test the connectivity of their own computing engines, and change the owner of their own computing engines.

9.7.7.2. Create a batch processing computing engine

This topic describes how to create a batch processing computing engine.

Prerequisites

- The computing engine type for batch processing is set. For more information, see Set the computing engine type.
- The endpoint that you can use to connect to MaxCompute is obtained.
- The name of the MaxCompute project to which the computing engine is connected is obtained.
- The AccessKey ID that is used to authenticate the user identity when Dataphin connects to the MaxCompute project is obtained.
- The AccessKey secret that is used to authenticate the user identity when Dataphin connects to the MaxCompute project is obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Computing Engines** in the left-side navigation pane.
4. On the Computing Engines page, move the pointer over **Create Computing Engine** and select **Batch Processing Computing Engine** in the upper-right corner.
5. In the **Batch Processing Computing Engine** dialog box, set the parameters as required.

Parameter	Description
Computing Engine Type	The type of the computing engine. Default value: MaxCompute. You cannot modify this parameter.
Computing Engine Name	The name of the computing engine.

Parameter	Description
Description	The description of the computing engine.
Endpoint	The endpoint that you can use to connect to MaxCompute. By default, the endpoint is set to the endpoint that is specified on the Computing Engine Configuration page in Management Center. You cannot modify this parameter.
Project Name	The name of the MaxCompute project to which the computing engine is connected.
Access ID	The AccessKey ID that is used to authenticate the user identity when Dataphin connects to the MaxCompute project. Contact the super administrator to obtain the AccessKey ID.
Access Key	The AccessKey secret that is used to authenticate the user identity when Dataphin connects to the MaxCompute project. Contact the super administrator to obtain the AccessKey secret.

> **Note**
>
> - You must specify a MaxCompute project that belongs to the same Apsara Stack tenant account as the current account.
> - To ensure a successful connection to the MaxCompute project, we recommend that you specify the AccessKey ID and AccessKey secret of the MaxCompute project administrator.
> - To ensure normal metadata acquisition, we recommend that you do not change the AccessKey ID and AccessKey secret that are used to connect to the MaxCompute project.
> - After a computing engine is created, you cannot change the computing engine type in Dataphin.

6. Click **Test Connection** to test the connectivity of the computing engine.
7. After the computing engine passes the connectivity test, click **Submit**.

9.7.7.3. Create a stream processing computing engine

This topic describes how to create a stream processing computing engine.

Prerequisites

- The name of the Realtime Compute project to which the computing engine is connected is obtained.
- The AccessKey ID that is used to authenticate the user identity when Dataphin connects to the Realtime Compute project is obtained.
- The AccessKey secret that is used to authenticate the user identity when Dataphin connects to the Realtime Compute project is obtained.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Computing Engines** in the left-side navigation pane.
4. On the Computing Engines page, move the pointer over **Create Computing Engine** and select **Stream Processing Computing Engine** in the upper-right corner.
5. In the **Stream Processing Computing Engine** dialog box, set the parameters as required.

Parameter	Description
Computing Engine Type	The type of the computing engine. Default value: **FLINK**. You cannot modify this parameter.
Computing Engine Name	The name of the computing engine.
Description	The description of the computing engine.
Project Name	The name of the Realtime Compute project to which the computing engine is connected.
Access ID	The AccessKey ID that is used to authenticate the user identity when Dataphin connects to the Realtime Compute project.
Access Key	The AccessKey secret that is used to authenticate the user identity when Dataphin connects to the Realtime Compute project.

> **Note**
>
> - You must specify a Realtime Compute project that belongs to the same Apsara Stack tenant account as the current account.
> - To ensure a successful connection to the Realtime Compute project, we recommend that you specify the AccessKey ID and AccessKey secret of the Realtime Compute project administrator.
> - To ensure normal metadata acquisition, we recommend that you do not change the AccessKey ID and AccessKey secret that are used to connect to the Realtime Compute project.
> - After a computing engine is created, you cannot change the computing engine type in Dataphin.

6. Click **Test Connection** to test the connectivity of the computing engine.
7. After the computing engine passes the connectivity test, click **Submit**.

9.7.7.4. Test a computing engine

This topic describes how to test a computing engine.

Prerequisites

Computing engines are created. For more information, see Create a batch processing computing engine or Create a stream processing computing engine.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Computing Engines** in the left-side navigation pane.
4. On the Computing Engines page, find the computing engine that you want to test and click the icon in the **Actions** column.

9.7.7.5. Modify a computing engine

This topic describes how to modify a computing engine.

Prerequisites

Computing engines are created. For more information, see Create a batch processing computing engine or Create a stream processing computing engine.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Computing Engines** in the left-side navigation pane.
4. On the Computing Engines page, find the computing engine that you want to modify and click the icon in the **Actions** column.
5. In the **Change Data Source (Computing Engine)** dialog box, change the parameter values as needed. For more information, see Create a batch processing computing engine or Create a stream processing computing engine.
6. Click **Test Connection** to test the connectivity of the computing engine.
7. After the computing engine passes the connectivity test, click **Submit**.

9.7.7.6. Change the owner of a computing engine

This topic describes how to change the owner of a computing engine.

Prerequisites

Computing engines are created. For more information, see Create a batch processing computing engine or Create a stream processing computing engine.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Computing Engines** in the left-side navigation pane.
4. On the Computing Engines page, find the computing engine that you want to change the owner and click the icon in the **Actions** column.
5. In the **Change Owner** dialog box, select the member to whom you want to transfer the ownership of the computing engine.
6. Click **OK**.

9.7.7.7. Delete a computing engine

This topic describes how to delete a computing engine.

Prerequisites

Computing engines are created. For more information, see Create a batch processing computing engine or Create a stream processing computing engine.

Procedure

1. Log on to the Dataphin console.
2. Go to the **Planning** page by using one of the following methods:
   - On the Dataphin homepage, click **Planning** in the top navigation bar.
   - On the Dataphin homepage, click **Intelligent Data Warehouse Planning** in the middle section.
3. On the **Planning** page, click **Computing Engines** in the left-side navigation pane.
4. On the Computing Engines page, find the computing engine that you want to delete and click the icon in the **Actions** column.
5. In the message that appears, click **OK**.

9.8. Data ingestion

Data ingestion is achieved through data synchronization. Data synchronization is the process of importing data from a table in the source database to a table in the target database. For example, importing data of table A in a MySQL database to table B in a PostgreSQL database.

1. Go to the R&D workbench. Log on to the Dataphin console. Click **R&D** in the top navigation bar or **Data Ingestion** on the homepage.
2. Go to the data ingestion page. On the R&D page, click **Data Processing**, and then click the

Sync Tasks submenu. You can move the pointer over an icon to expand its corresponding submenu. On the Sync Tasks page, you can create folders, and create, save, and publish sync tasks.

9.8.1. Overview

Dataphin allows you to use the data integration or data synchronization service to import business data from data sources to Dataphin.

If you purchased a Dataphin instance after April 2020, you can use the data integration service to synchronize data, which is simple, efficient, secure, and reliable.

The data integration service allows you to create multiple sync tasks at a time for database migration and can automatically create a destination table for data synchronization to MaxCompute. This improves the data synchronization efficiency.

9.8.2. Data integration

9.8.2.1. Overview

Data integration is a simple, efficient data synchronization service in Dataphin. It provides powerful data preprocessing capabilities and can synchronize data among heterogeneous data sources at a high speed with high stability.

Background information

When big data analytics applies in more and more industries, numerous data integration requirements emerge. For example, people want a platform that can create multiple sync tasks at a time with simple operations, support heterogeneous data sources, preprocess data from data sources, and optimize sync tasks based on fault tolerance, throttling, and concurrency configurations.

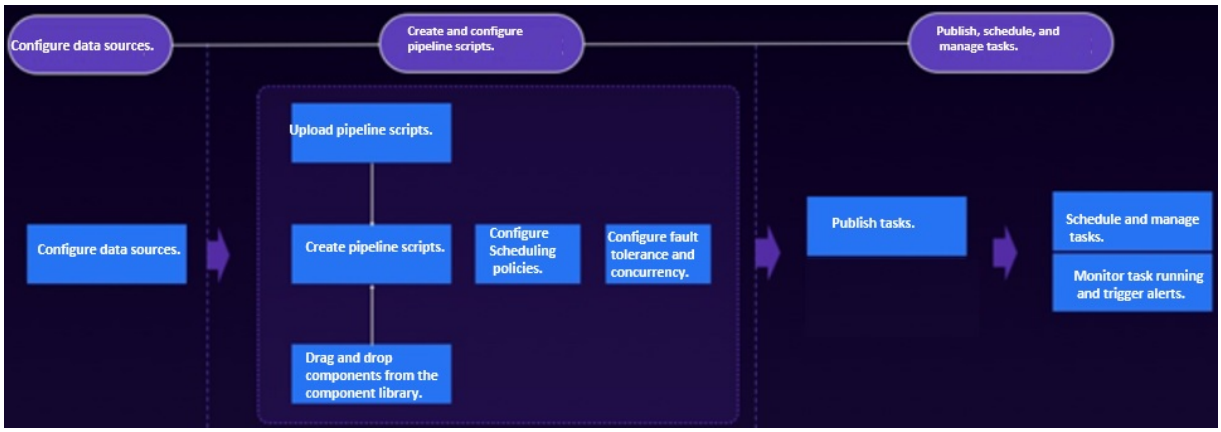
To meet the data integration requirements, Dataphin provides the data integration service with enhanced data integration capabilities. The data integration service is simple, efficient, secure, and reliable and provides the following features:

- Allows you to create multiple sync tasks at a time for database migration and automatically creates a destination table for data synchronization to MaxCompute. This improves the data integration efficiency. For more information, see Create and configure an offline database migration task and Manage Maxcompute output components.
- Provides process and conversion components to preprocess data from data sources, for example, to cleanse, convert, de-identify, compute, merge, distribute, and filter data. For more information, see Create and configure an offline migration pipeline.
- Synchronizes data among heterogeneous data sources at a high speed with high stability. For more information, see Create and configure an offline migration pipeline and Create and configure an offline database migration task.
- Supports projects in Dev-Prod mode and Basic mode.
- Synchronizes logical tables that are created in Dataphin to the destination database.

Features

The data integration service allows you to create pipelines by dragging, configuring, and assembling components. You can also configure pipelines, for example, configure the scheduling policy and pipeline information.

The following figure shows the data integration process in Dataphin.



1. Configure data sources. For more information, see Data sources.
2. Create and configure pipelines for single or multiple sync tasks. For more information, see Create and configure an offline migration pipeline and Create and configure an offline database migration task.
3. Publish tasks. For more information, see Publishing management.
4. Schedule and manage tasks. For more information, see Overview.

9.8.2.2. Manage folders

This topic describes how to create, move, delete, or rename a folder that is used to store pipelines.

Create a folder

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
5. In the Script section, click the icon next to **Script**.
6. In the **Create Folder** dialog box, set the **Name** and **Select Directory** parameters.
7. Click **OK**.You can also perform the following steps to create a subfolder under an existing folder:
   i. Move the pointer over a folder and click the icon.
   ii. In the field that appears, enter a folder name.
   iii. Press the Enter key.

Rename a folder

1. In the Script section of the **Integrated** page, move the pointer over the icon next to the folder that you want to rename and select **Rename**.
2. In the field that appears, enter a new folder name.
3. Press the Enter key.

Move a folder

1. In the Script section of the **Integrated** page, move the pointer over the icon next to the folder that you want to move and select **Move**.
2. In the **Move Folder** dialog box, set the **Select Directory** parameter to the destination directory.
3. Click **OK**.

Delete a folder

In the Script section of the **Integrated** page, move the pointer over the icon next to the folder that you want to delete and select **Delete**.

> **Note** You can delete only the folders that do not contain subfolders or items.

9.8.2.3. Upload a JSON file for creating an offline migration pipeline

You can upload a JSON file to Dataphin to create an offline migration pipeline. This topic describes how to upload a JSON file that is used to create an offline migration pipeline.

Prerequisites

A JSON file is prepared.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
5. In the **Script** section, click the icon next to **Script**.
6. In the **Upload Script for Creating Pipeline** dialog box, set the parameters as required.

Parameter	Description
Upload File	The JSON file to upload.
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ○ **Recurring Node**: a task that is run on a specified schedule. ○ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

7. Click **OK**.
8. (Optional)Configure the scheduling policy.
   - If you set the **Schedule Type** parameter to **Recurring Node**, you must configure the scheduling policy. For more information, see Step 3: Configure the scheduling policy.
   - If you set the **Schedule Type** parameter to **One-Time Node**, you do not need to configure the scheduling policy.
9. Save, submit, and then publish the offline migration pipeline.
   i. Click the icon in the upper-right corner to save the pipeline.
   ii. Click the icon in the upper-right corner to submit the pipeline.
   iii. (Optional)Publish the pipeline.
      - If the current project is in Dev mode, publish the pipeline to the corresponding project in Prod mode. For more information, see Publishing management.
      - If the current project is in Basic mode, you do not need to publish the pipeline after you submit it.

9.8.2.4. Manage offline migration pipelines

9.8.2.4.1. Create and configure an offline migration pipeline

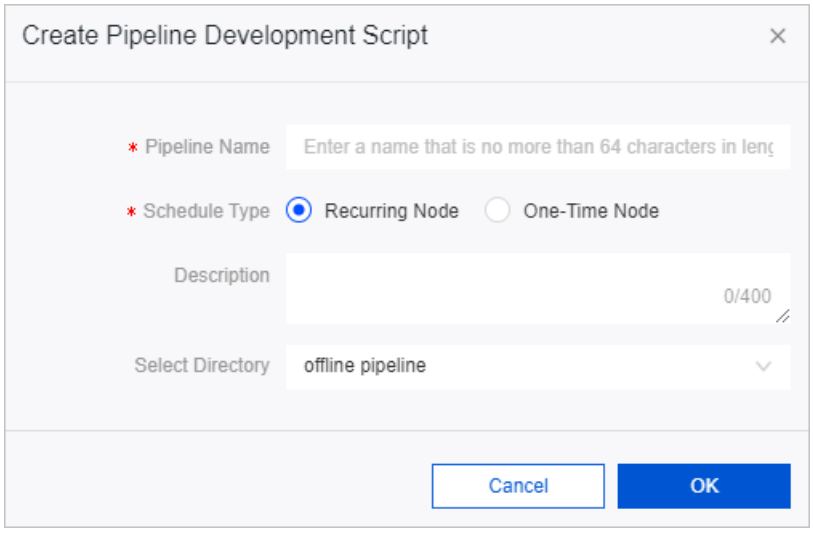
An offline migration pipeline is used to migrate data. This topic describes how to create and configure an offline migration pipeline.

Step 1: Create an offline migration pipeline

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left

corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.

4. Move the pointer over **Develop** in the top navigation bar and select **Integrated**.
5. On the **Integrated** page, open the **Create Pipeline Development Script** dialog box by using one of the following methods:
   - In the Script section, move the pointer over the icon next to Script and select **Offline Single Pipeline**.
   - In the left-side navigation pane, move the pointer over the icon next to the project name and select **Offline Single Pipeline**.
6. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



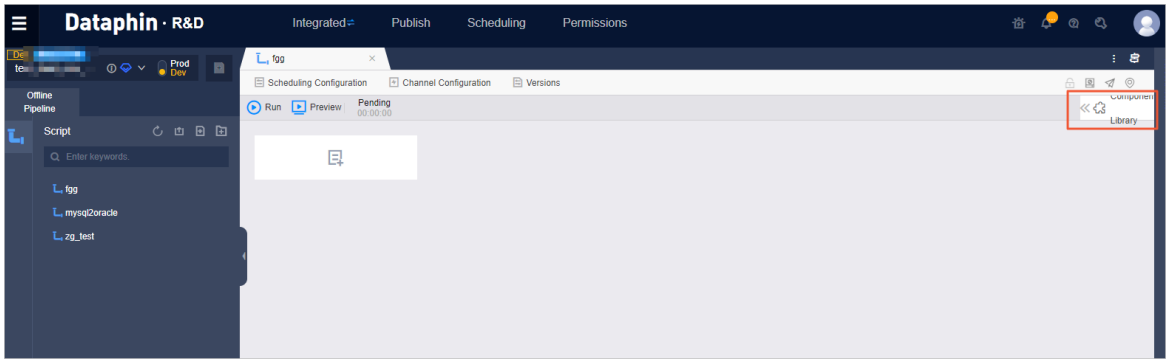
Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ○ **Recurring Node**: a task that is run on a specified schedule. ○ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

7. Click **OK**.

Step 2: Configure components for the offline migration pipeline

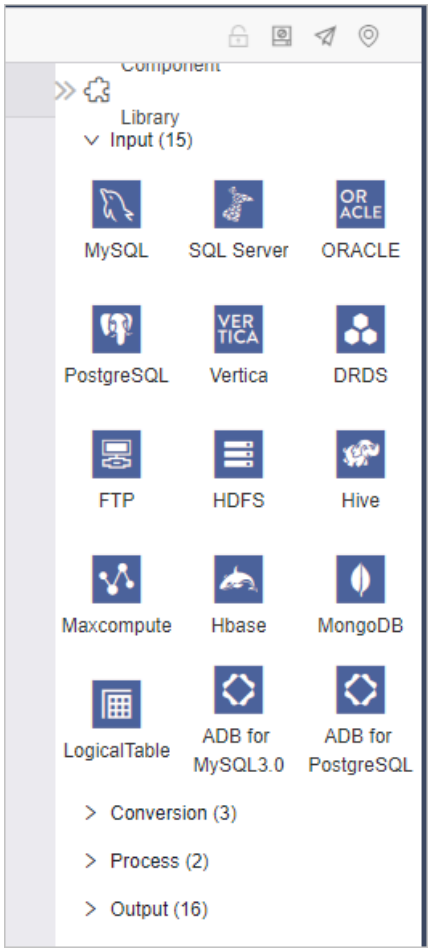
A complete offline migration pipeline is composed of one or more input components, zero or more conversion components, zero or more process components, and one or more output components.

1. Go to the configuration tab of the offline migration pipeline. Click **Component Library** in the upper-right corner. A pane appears and displays the components that Dataphin supports in the **Input**, **Conversion**, **Process**, and **Output** sections.



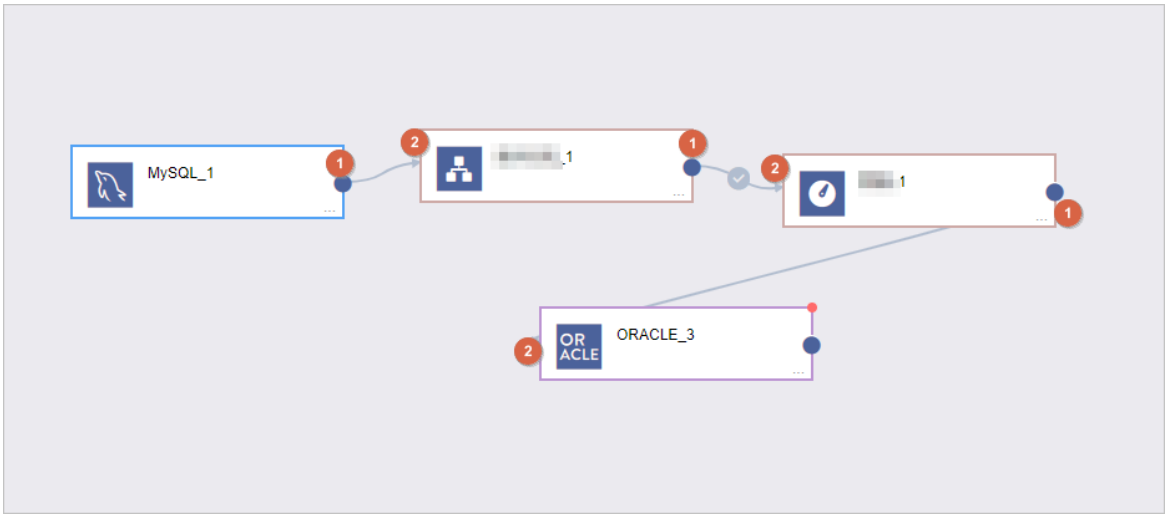
Component type	Component
Input	MySQL, SQL Server, ORACLE, PostgreSQL, Vertica, DRDS, FTP, HDFS, Hive, Maxcompute, Hbase, MongoDB, LogicalTable, ADB for MySQL3.0, and ADB for PostgreSQL
Conversion	Field Selection, Field Computing, and Filtering
Process	Access Limit and Conditional Distribution
Output	MySQL, SQL Server, ORACLE, PostgreSQL, Vertica, DRDS, FTP, HDFS, Hive, Maxcompute, Hbase, MongoDB, ElacticSearch, ADB for MySQL2.0, ADB for MySQL3.0, and ADB for PostgreSQL

2. Select and configure input components based on your business scenario.
   i. Click the > icon before **Input**. Drag a component to the pipeline canvas on the left.
   ii. Right-click the component and select **Configure Attributes**. In the dialog box that appears, configure the component as required. For more information, see Input components. You can also copy or delete the component and select a mode for transmitting data to downstream nodes.



3. (Optional)Select and configure conversion components based on your business scenario.
   i. Click the > icon before **Conversion**. Drag a component to the pipeline canvas on the left.
   ii. Right-click the component and select **Configure Attributes**. In the dialog box that appears, configure the component as required. For more information, see Conversion components. You can also copy or delete the component and select a mode for transmitting data to downstream nodes.
4. (Optional)Select and configure process components based on your business scenario.
   i. Click the > icon before **Process**. Drag a component to the pipeline canvas on the left.
   ii. Right-click the component and select **Configure Attributes**. In the dialog box that appears, configure the component as required. For more information, see Process components. You can also copy or delete the component.
5. Select and configure output components based on your business scenario.
   i. Click the > icon before **Output**. Drag a component to the pipeline canvas on the left.
   ii. Right-click the component and select **Configure Attributes**. In the dialog box that appears, configure the component as required. For more information, see Output components. You can also copy or delete the component.
6. Click and hold Position 1 in an upstream component and drag it to Position 2 in a downstream component to draw a directed line and establish a relationship between the

components.



The following table describes the relationships that you can establish between components.

Component type	Description
Input	Note the following items when you use an input component: ○ An input component does not support upstream nodes. ○ The downstream nodes of an input component can be conversion components, output components, and process components. ○ If you connect an input component to multiple components such as output or conversion components in the downstream, you must select a data transmission mode for the input component.  ■ **Copy**: copies all the data of the upstream node to each downstream node. ■ **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data shares to the downstream nodes in turn. The sum of the data of all the downstream nodes is equal to that of the upstream node.
Output	An output component does not support downstream nodes.

Component type	Description
Process	Note the following items when you use a process component: ○ A process component can be used as any node except the first node and the last node in an offline migration pipeline. ○ If you connect a process component to multiple components such as conversion, output, or process components in the downstream, you must select a data transmission mode for the process component. ○ If you select a Conditional Distribution component as a process component, you must specify the conditions for data distribution when you connect it to downstream nodes.  ■ If you select **Conditioned Result Is true**, the Conditional Distribution component transmits data to downstream nodes only when the specified conditions are met. ■ If you select **Conditioned Result Is false**, the Conditional Distribution component transmits data to downstream nodes only when the specified conditions are not met.
Conversion	If you connect a conversion component to multiple components such as conversion, output, or process components in the downstream, you must select a data transmission mode for the conversion component.

You can perform the preceding steps to configure components for an offline migration pipeline on the pipeline canvas. A pipeline canvas allows you to configure multiple pipelines at the same time. You can also right-click a blank area on the pipeline canvas and perform the operations that are described in the following table.

Operation	Description
Copy	Copy the existing components that you select on the pipeline canvas.
Paste	Paste the copied components on the pipeline canvas.
Delete	Delete the components that you select from the pipeline canvas.
Circle	Select one or more components.
Select All	Select all components on the pipeline canvas.

7. After you configure components for the offline migration pipeline on the pipeline canvas, click the icon in the upper-right corner to save the pipeline. Then, the pipeline enters the **Draft** state.
8. Click the icon before **Pending** in the upper-left corner. If variables such as bizdate are configured in the components, set the parameters as required and click **OK** to run the pipeline.

Step 3: Configure the scheduling policy

1. On the pipeline configuration tab, click **Scheduling Configuration** in the top navigation bar. In the Scheduling Configuration pane, set the parameters as required.
   i. Set the parameters in the **Basic Information** section.Dataphin automatically generates the node name, node ID, node type, and owner. You cannot modify these parameters.

Parameter	Description
Description	The description of the scheduling policy.
Priority	The priority based on which the task corresponding to the offline migration pipeline is scheduled. Valid values: ■ Lowest Priority ■ Low Priority ■ Medium Priority ■ High Priority ■ Highest Priority
Parameters	The specified values for the parameters that are used in the code of the task. Dataphin allows you to specify the parameters that are used in the code of a task. The specified values are used when the task is run. You can click **Parameters and Descriptions** to know how to configure the parameters.

   ii. Set the parameters in the **Scheduling Configuration** section.

Parameter	Description

Parameter	Description
Schedule Mode	The scheduling mode of the task corresponding to the offline migration pipeline. Valid values: ■ **Normal**: runs the task based on the specified recurrence. By default, this option is selected. ■ **Dry-run**: runs the task based on the specified recurrence. However, the scheduling system does not run the task but returns a success response. ■ **Pause Scheduling**: runs the task based on the specified recurrence. However, the scheduling system does not run the task but returns a failure response. You can select this check box if you want to suspend a task and run it later.
Recurrence	The recurrence of the task. Valid values: ■ **Day**: automatically runs the task once per day. When you create a recurring task, the task is set to be run at 00:00 every day by default. You can also click the icon to specify a point in time for the task to be run as needed. ■ **Week**: automatically runs the task at a specified point in time on specified days of each week. You can also click the icon to specify a point in time for the task to be run as needed. On the other days, the scheduling system still generates an instance every day to ensure the proper running of downstream instances. However, the system does not run the instance or consume resources but returns a success response. Assume that you set Recurrence to Week and specify that the task is run every Monday and Tuesday. The scheduling system generates and runs instances every Monday and Tuesday. Every Wednesday, Thursday, Friday, Saturday, and Sunday, the scheduling system generates instances and returns success responses without running the instances. ■ **Month**: automatically runs the task at a specified point in time on specified days of each month. You can also click the icon to specify a point in time for the task to be run as needed. On the other days, the scheduling system still generates an instance every day to ensure the proper running of downstream instances. However, the system does not run the instance or consume resources but returns a success response. Assume that you set Recurrence to Month and specify that the task is run on the seventh day of each month. The scheduling system generates and runs an instance on the seventh day of each month. On the other days, the scheduling system generates instances and returns success responses without running the instances.

Parameter	Description
	■ **Hour**: automatically runs the task at a specified interval during a specified time period or at specified points in time every day. The scheduling system automatically generates instances for the task and runs the instances at the specified interval or points in time. Assume that you set Recurrence to Hour, select Time Period, and set the Start, End, and Interval parameters to 00:00, 23:59, and 1, respectively. The scheduling system automatically generates instances for the task and runs an instance every hour. ■ **Minute**: automatically runs the task at a specified interval during a specified time period every day. You can also click the icon to specify a point in time for the task to be run as needed. Assume that you set Recurrence to Minute and set the Start, End, and Interval parameters to 00:00, 23:59, and 05, respectively. The scheduling system automatically generates instances for the task and runs an instance every 5 minutes.
Depend on Previous Instance	Specifies whether the current task is run after the previous instance of another task or of the current task is run. If you select Depend on Previous Instance, you must further select Current Task or Select Task. ■ If you select **Current Task**, the current task is run after the previous instance of the current task is run. ■ If you select **Select Task**, enter a keyword in the search box that appears to search for and select one or more tasks to depend on.

iii. Set the parameters in the **Dependency** section.

Parameter	Description

Parameter	Description
Upstream Dependency	The upstream nodes on which the current node depends. To specify an upstream node, perform the following steps: a. Click **Create Upstream Dependency**. b. In the **Create Upstream Dependency** dialog box, search for the desired node based on the output name and select the node. **Note** Each node output name is globally unique in Dataphin. c. Click **OK**. To remove a node from the upstream node list, click the icon in the **Actions** column.
Current Node	The output name for the current node. You can set multiple output names for a node to be used for the dependency configuration of other nodes. To set an output name, perform the following steps: a. Click **Add**. b. In the **Add Output Task Nodes for Current Task Node** dialog box, enter an output name. Observe uniform rules when you set each output name for the current node. Generally, set an output name in the format of `Project name. Table name`. This helps other users find this node when they configure the upstream dependency for their nodes. c. Click **OK**. You can also perform the following operations on an existing output name: ■ To delete an output name, click the icon in the **Actions** column. ■ To view the downstream nodes after the current node is submitted or published, click the icon in the **Actions** column.

2. Click **OK**.

Step 4: Configure the channel control policy

1. On the pipeline configuration tab, click **Channel Configuration** in the top navigation bar. In the Channel Configuration pane, set the parameters as required and click **OK**.

Parameter	Description
Error Tolerance Configuration	The maximum number of errors allowed in the offline migration pipeline. After you specify a fault tolerance threshold, one of the following situations may occur when the corresponding task is being run: ○ The task fails if the number of cumulative errors in all components of the offline migration pipeline reaches the specified fault tolerance threshold. ○ The task continues if the number of cumulative errors in all components of the offline migration pipeline falls below the specified fault tolerance threshold.
Global Concurrency Configuration	The maximum number of components that can concurrently transmit data in the entire offline migration pipeline.
JVM Configuration	The Java virtual machine (JVM) parameters.

2. Click the icon in the upper-right corner to save the offline migration pipeline.
3. Click the icon in the upper-right corner to submit the offline migration pipeline.

> **Note** When you submit the pipeline, Dataphin checks whether you have the following permissions:
>
> ○ Read permission on the data source in each input component
>
> ○ Write permission on the data source in each output component

4. (Optional)Publish the offline migration pipeline.
   - If the current project is in Dev mode, publish the pipeline to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the pipeline after you submit it.

9.8.2.4.2. Edit an offline migration pipeline

An offline migration pipeline is used to migrate data. This topic describes how to edit an offline migration pipeline.

Prerequisites

Offline migration pipelines are created. For more information, see Create and configure an offline migration pipeline.

Context

To edit an offline migration pipeline, you must be the creator of the pipeline or the super administrator.

Procedure

1. Log on to the Dataphin console.

2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
5. In the left-side navigation pane, move the pointer over the icon next to the pipeline that you want to edit and select **Change**. The configuration tab of the pipeline appears.
6. (Optional)Steal the lock of the offline migration pipeline.
   - If the pipeline is locked by yourself, you do not need to steal the lock.
   - If the pipeline is locked by another user, click the icon in the upper-right corner of the pipeline configuration tab to steal the lock.
7. On the pipeline configuration tab, configure the pipeline components as required. For more information, see Create and configure an offline migration pipeline.
8. Save and submit the offline migration pipeline.
   i. Click the icon in the upper-right corner of the pipeline configuration tab to save the pipeline.
   ii. Click the icon in the upper-right corner of the pipeline configuration tab to submit the pipeline.When you submit the pipeline, Dataphin checks whether you have the following permissions:
      - Read permission on the data source in each input component
      - Write permission on the data source in each output component
   iii. In the dialog box that appears, enter your comments.
   iv. Click **OK**.
9. (Optional)Publish the offline migration pipeline.
   - If the current project is in Dev mode, publish the pipeline to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the pipeline after you submit it.

9.8.2.4.3. Rename an offline migration pipeline

An offline migration pipeline is used to migrate data. This topic describes how to rename an offline migration pipeline.

Prerequisites

Offline migration pipelines are created. For more information, see Create and configure an offline migration pipeline.

Procedure

1. Log on to the Dataphin console.

2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
5. In the left-side navigation pane, move the pointer over the icon next to the pipeline that you want to rename and select **Rename**.
6. In the field that appears, enter a new name.
7. Press the Enter key.

9.8.2.4.4. Move an offline migration pipeline

An offline migration pipeline is used to migrate data. This topic describes how to move an offline migration pipeline to a specified directory.

Prerequisites

Offline migration pipelines are created. For more information, see Create and configure an offline migration pipeline.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
5. In the left-side navigation pane, move the pointer over the icon next to the pipeline that you want to move and select **Move**.
6. In the **Move File** dialog box, set the Select Directory parameter to the destination directory.
7. Click **OK**.

9.8.2.4.5. View historical version information about an offline migration pipeline and download the script in a version of a pipeline

This topic describes how to view historical version information about an offline migration pipeline and download the script in a version of a pipeline.

Prerequisites

Offline migration pipelines are created. For more information, see Create and configure an offline migration pipeline.

View historical version information about an offline migration pipeline

1. Log on to the Dataphin console.
2. Go to the **Integrated** page.
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
3. In the left-side navigation pane, click the pipeline that you want to view.
4. On the pipeline configuration tab, click **Versions** in the top navigation bar. If the pipeline is locked by another user, you must click the Lock icon in the upper-right corner of the pipeline configuration tab to steal the lock first.
5. In the **Node Version** pane, view the historical versions of the pipeline.
6. Click the icon in the **Actions** column of a version to view the version details.
7. On the **Pipeline Details** page, view the components, scheduling configuration, and fault tolerance configuration in the version.
8. Return to the pipeline configuration tab and click **OK** in the **Node Version** pane.

Download the script in a version of an offline migration pipeline

1. In the left-side navigation pane, click the pipeline that you want to view.
2. On the pipeline configuration tab, click **Versions** in the top navigation bar. If the pipeline is locked by another user, you must click the Lock icon in the upper-right corner of the pipeline configuration tab to steal the lock first.
3. In the **Node Version** pane, find a version and click the icon in the **Actions** column.

9.8.2.4.6. Unpublish and delete an offline migration pipeline

This topic describes how to unpublish, unpublish and delete, and delete offline migration pipelines.

Prerequisites

Offline migration pipelines are created. For more information, see Create and configure an offline migration pipeline.

Context

- Description on the status of an offline migration pipeline:
  - After you create and save a pipeline, it enters the **Draft** state.

- After you create and save a pipeline, it enters the **Draft** state.
  - After you submit a pipeline, it enters the **Submitted** state.
  - After you edit and save a pipeline in the **Submitted** state, it enters the **Developing** state.
  - After you unpublish a pipeline in the **Submitted** state, it enters the **Draft** state.
- Limits on unpublishing offline migration pipelines:
  - You can unpublish only the pipelines in the **Developing** or **Submitted** state.
  - To unpublish a pipeline, you must be the creator of the pipeline or the super administrator.
- Limits on deleting offline migration pipelines:
  - To delete a pipeline, you must be the creator of the pipeline or the super administrator.
  - You can delete only the pipelines in the **Draft** state.
- Limits on unpublishing and deleting offline migration pipelines:
  - You can unpublish and delete only the pipelines in the **Developing** or **Submitted** state.
  - To unpublish and delete a pipeline, you must be the creator of the pipeline or the super administrator.

Unpublish an offline migration pipeline

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
5. In the left-side navigation pane, move the pointer over the icon next to the pipeline that you want to unpublish and select **Unpublish**.
6. In the **Tip** dialog box, enter your comments.
7. Click **OK**.

Unpublish and delete an offline migration pipeline

1. In the left-side navigation pane, move the pointer over the icon next to the pipeline that you want to unpublish and delete and select **Unpublish and Delete**.
2. In the **Tip** dialog box, enter your comments.
3. Click **OK**.

Delete an offline migration pipeline

1. In the left-side navigation pane, move the pointer over the icon next to the pipeline that you want to delete and select **Delete**.
2. In the **Tip** dialog box, enter your comments.
3. Click **OK**.

9.8.2.5. Manage offline database migration tasks

9.8.2.5.1. Create and configure an offline database migration task

Dataphin allows you to manage offline database migration tasks. An offline database migration task consists of multiple offline migration pipelines that can migrate multiple tables from one database to another at a time. This topic describes how to create and configure an offline database migration task.

Context

An offline database migration task allows you to migrate multiple tables from one database to another at a time. This improves the configuration efficiency and reduces costs.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
5. On the **Integrated** page, open the **Create Database Migration** tab by using one of the following methods:
   - In the Script section, move the pointer over the icon next to Script and select **Offline Database Migration**.
   - In the left-side navigation pane, move the pointer over the icon next to the project name and select **Offline Database Migration**.
6. On the **Create Database Migration** tab, set the parameters as required.
   i. Set the parameters in the **Basic Information** section.

Parameter	Description
Script Name	The name of the offline database migration task. The name can be up to 64 characters in length and can contain letters, digits, and underscores (_).
Description	The description of the task.

ii. Set the parameters in the Data Source Configuration section.

Section	Parameter	Description
Synchronization Source	Data Source Type	The type of the data source from which data is read. Valid values: ■ MYSQL ■ ORACLE ■ SQL_SERVER
	Data Source	The name of the data source from which data is read. You can also click Create Data Source in the Data Source drop-down list to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Synchronization Target	Data Source Type	The type of the data source to which data is written. You can set this parameter only to MAX_COMPUTE.
	Data Source	The name of the data source to which data is written. You can also click Create Data Source in the Data Source drop-down list to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.

iii. Set the parameters in the Table Synchronization section.

GUI element	Description
Source Table	The source tables to be migrated.
Target MaxCompute Table	The destination tables to be generated in the specified MaxCompute project. After you select a source table in the Source Table column, a same table name appears in the Target MaxCompute Table column. MaxCompute automatically creates tables based on the table names in the Target MaxCompute Table column.

GUI element	Description
Configure Conversion	The rules for converting table names and field names. By default, the source tables and destination tables use the same names. This button allows you to modify the configuration of the destination tables. To modify the configuration of the destination tables, perform the following steps: a. Click **Configure Conversion**. b. In the **Edit Conversion Rule** dialog box, perform one or more of the following operations as required: ■ In the **Table Name Conversion** section, click **Create Rule** and set conversion rules for the names of the source and destination tables. ■ In the **Field Name Conversion** section, click **Create Rule** and set conversion rules for the field names in the source and destination tables. ■ In the **Table Name Prefix** section, enter a prefix for the names of the destination tables. ■ In the **Data Filtering** section, enter a filter condition for input fields, for example, `gmt_modified>=${bizdate}` . c. Click **Save and Execute**. The configured conversion rules apply to the destination tables that are listed in the **Target MaxCompute Table** column.

iv. Set the parameters in the Synchronization Configuration section.

Parameter	Description
Synchronization Type	The synchronization mode of the task. Valid values: **Everyday, Full** and **Everyday, Incremental**.
Synchronization Concurrency	The synchronization concurrency mode of the task. Valid values: **Everyday, Full** and **Batch Upload**.

7. Click **Generate Pipeline**.View the pipeline generation result.
8. (Optional)Publish the task.
   - If the current project is in Dev mode, publish the task to the corresponding project in Prod mode. For more information, see Publishing management.
   - If the current project is in Basic mode, you do not need to publish the task after you submit it.

9.8.2.5.2. Manage offline migration pipelines

After you create an offline database migration task, multiple offline migration pipelines are accordingly generated. This topic describes how to manage an offline migration pipeline that is generated in an offline database migration task.

Prerequisites

Offline database migration tasks are created. For more information, see Create and configure an offline database migration task.

Context

- To edit an offline migration pipeline, you must be the creator of the pipeline or the super administrator.
- Description on the status of an offline migration pipeline:
  - After you create and save a pipeline, it enters the **Draft** state.
  - After you submit a pipeline, it enters the **Submitted** state.
  - After you edit and save a pipeline in the **Submitted** state, it enters the **Developing** state.
  - After you unpublish a pipeline in the **Submitted** state, it enters the **Draft** state.
- Limits on unpublishing offline migration pipelines:
  - You can unpublish only the pipelines in the **Developing** or **Submitted** state.
  - To unpublish a pipeline, you must be the creator of the pipeline or the super administrator.
- Limits on deleting offline migration pipelines:
  - To delete a pipeline, you must be the creator of the pipeline or the super administrator.
  - You can delete only the pipelines in the **Draft** state.
- Limits on unpublishing and deleting offline migration pipelines:
  - You can unpublish and delete only the pipelines in the **Developing** or **Submitted** state.
  - To unpublish and delete a pipeline, you must be the creator of the pipeline or the super administrator.

Edit an offline migration pipeline

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
5. On the **Integrated** page, find the offline database migration task that you want to manage and click the icon before the icon to show the list of pipelines that are generated in the task.In the left-side navigation pane of the **Integrated** page:
   - The icon indicates a folder where offline migration pipelines reside.
   - The icon indicates an offline database migration task.

- The icon indicates an offline migration pipeline.

6. Move the pointer over the icon next to the pipeline that you want to edit and select **Change**.
7. (Optional)Steal the lock of the offline migration pipeline.
   - If the pipeline is locked by yourself, you do not need to steal the lock.
   - If the pipeline is locked by another user, click the icon in the upper-right corner of the pipeline configuration tab to steal the lock.
8. On the pipeline configuration tab, configure the pipeline components as required. For more information, see Edit an offline migration pipeline.
9. Save, submit, and then publish the offline migration pipeline.
   i. After you edit the pipeline components, click the icon in the upper-right corner of the pipeline configuration tab to save the pipeline.
   ii. Click the icon in the upper-right corner of the pipeline configuration tab to submit the pipeline.When you submit the pipeline, Dataphin checks whether you have the following permissions:
      - Read permission on the data source in each input component
      - Write permission on the data source in each output component
   iii. Optional. If the current project is in Dev mode, publish the offline migration pipeline to the corresponding project in Prod mode. For more information, see Publishing management.
      - After you publish the pipeline to the project in Prod mode, the pipeline can be used for scheduling.
      - If you submit the pipeline in a project in Basic mode, the pipeline can immediately be used for scheduling.

Rename an offline migration pipeline

1. On the **Integrated** page, find the offline database migration task that you want to manage and click the icon before the icon to show the list of pipelines that are generated in the task.
2. In the left-side navigation pane, move the pointer over next to the target pipeline and select **Rename**.
3. In the field that appears, enter a new name.
4. Press Enter.

Move an offline migration pipeline

1. On the **Integrated** page, find the offline database migration task that you want to manage and click the icon before the icon to show the list of pipelines that are generated in the task.
2. In the left-side navigation pane, move the pointer over next to the target pipeline and

select **Move**.

3. In the **Move Folder** dialog box, set the Select Directory parameter to the destination directory.
4. Click **OK**.

View historical version information about an offline migration pipeline

1. On the **Integrated** page, find the offline database migration task that you want to manage and click the icon before the icon to show the list of pipelines that are generated in the task.
2. In the left-side navigation pane, click the target pipeline.
3. On the pipeline configuration tab, click **Versions** in the top navigation bar. If the pipeline is locked by another user, you must click the Lock icon in the upper-right corner of the pipeline configuration tab to steal the lock first.
4. In the **Node Version** pane, view the historical versions of the pipeline.
5. Click in the **Actions** column of a version to view the version details.
6. On the **Pipeline Details** page, view the components, scheduling configuration, and error tolerance configuration in the version.
7. Return to the pipeline configuration tab and click **OK** in the **Node Version** pane.

Download the script in a version of an offline migration pipeline

1. On the **Integrated** page, find the offline database migration task that you want to manage and click the icon before the icon to show the list of pipelines that are generated in the task.
2. Click the pipeline that you want to view.
3. On the pipeline configuration tab, click **Versions** in the top navigation bar. If the pipeline is locked by another user, you must click the Lock icon in the upper-right corner of the pipeline configuration tab to steal the lock first.
4. In the **Node Version** pane, find the target version and click in the **Actions** column.

Unpublish an offline migration pipeline

1. On the **Integrated** page, find the offline database migration task that you want to manage and click the icon before the icon to show the list of pipelines that are generated in the task.
2. In the left-side navigation pane, move the pointer over next to the target pipeline and select **Unpublish**.
3. In the **Tip** dialog box, enter your comments.
4. Click **OK**.

Unpublish and delete an offline migration pipeline

1. On the **Integrated** page, find the offline database migration task that you want to manage

and click the icon before the icon to show the list of pipelines that are generated in the task.

2. Move the pointer over the icon next to the pipeline that you want to unpublish and delete and select **Unpublish and Delete**.
3. In the **Tip** dialog box, enter your comments.
4. Click **OK**.

Delete an offline migration pipeline

1. On the **Integrated** page, find the offline database migration task that you want to manage and click the icon before the icon to show the list of pipelines that are generated in the task.
2. Move the pointer over the icon next to the pipeline that you want to delete and select **Delete**.
3. In the **Tip** dialog box, enter your comments.
4. Click **OK**.

9.8.2.5.3. Rename an offline database migration task

Dataphin allows you to manage offline database migration tasks. An offline database migration task consists of multiple offline migration pipelines that can migrate multiple tables from one database to another at a time. This topic describes how to rename an offline database migration task.

Prerequisites

Offline database migration tasks are created. For more information, see Create and configure an offline database migration task.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
5. In the left-side navigation pane, move the pointer over the icon next to the offline database migration task that you want to rename.
6. Select **Rename**.
7. In the field that appears, enter a new name.
8. Press the Enter key.

9.8.2.5.4. Delete an offline database migration task

Dataphin allows you to manage offline database migration tasks. An offline database migration task consists of multiple offline migration pipelines that can migrate multiple tables from one database to another at a time. This topic describes how to delete an offline database migration task.

Prerequisites

Offline database migration tasks are created. For more information, see Create and configure an offline database migration task.

Context

If you delete an offline database migration task, all the offline migration pipelines that are generated in the task will also be deleted. Proceed with caution.

Procedure

1. Log on to the Dataphin console.
2. On the Dataphin homepage, click **R&D** in the top navigation bar.
3. (Optional)On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
4. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
5. In the left-side navigation pane, move the pointer over the icon next to the offline database migration task that you want to delete.
6. Select **Delete**.

9.8.2.6. Input components

9.8.2.6.1. Manage MySQL input components

This topic describes how to configure, copy, and delete a MySQL input component, and how to select a data sending mode for a MySQL input component.

Context

A MySQL input component is used to import data from a MySQL database. Then, you can write the data to a database, such as another MySQL database, for data consumption.

Configure a MySQL input component

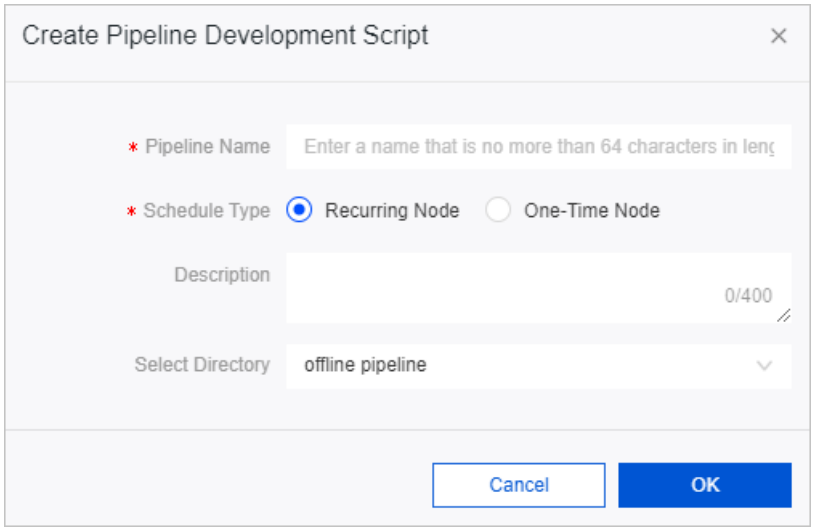
1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.

ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.

iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.

iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the icon before **Input**.
5. Drag a MySQL component to the pipeline canvas on the left.
6. Right-click the MySQL component and select **Configure Attributes**.
7. In the **MySQL Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Data Source	The data source of the component. Select a data source that has been connected to Dataphin. The data source must meet the following requirements: ○ The data source is of the MySQL type. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Source Table	The quantity of source tables. Valid values: **Single Table** and **Multiple Tables**.
Table	The source tables to be migrated. If you set the Source Table parameter to **Multiple Tables**, perform the following steps to add tables: i. Enter an expression in the Table field. Dataphin supports an enumeration expression, a regular-like expression, or a combination of both, for example, `table_[001-100];table_102`. ii. Click the icon. iii. In the **Confirm Match Details** dialog box, select the matching tables. iv. Click **OK**. **Note** The source tables that you select must have the same schema.
Split Key	The shard key of the source table. You can specify a column in the source table as the shard key. We recommend that you use the primary key or an indexed column as the shard key.
Input Filtering	The filter condition for input fields. For example, you can enter `ds=${bizdate}`. The **Input Filtering** parameter is applicable to the following scenarios: ○ Specify a fixed portion of data. ○ Use parameters to filter data.

Parameter	Description
Output Fields	The output fields to be generated based on the input configuration. You can also perform the following operations to manage fields: ○ Click the icon in the **Actions** column to delete a field. ○ Click **Manage Fields**. In the **Manage Fields** dialog box, perform the following operations: ■ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section. ■ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section.

8. Click **OK**.

Copy a MySQL input component

1. Right-click a MySQL input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a MySQL input component

1. Right-click a MySQL input component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for a MySQL input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to downstream nodes.

1. Right-click a MySQL input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are provided:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data shares to the downstream nodes in turn. The sum of the data of all the downstream nodes is equal to that of the upstream node.

9.8.2.6.2. Manage Maxcompute input components

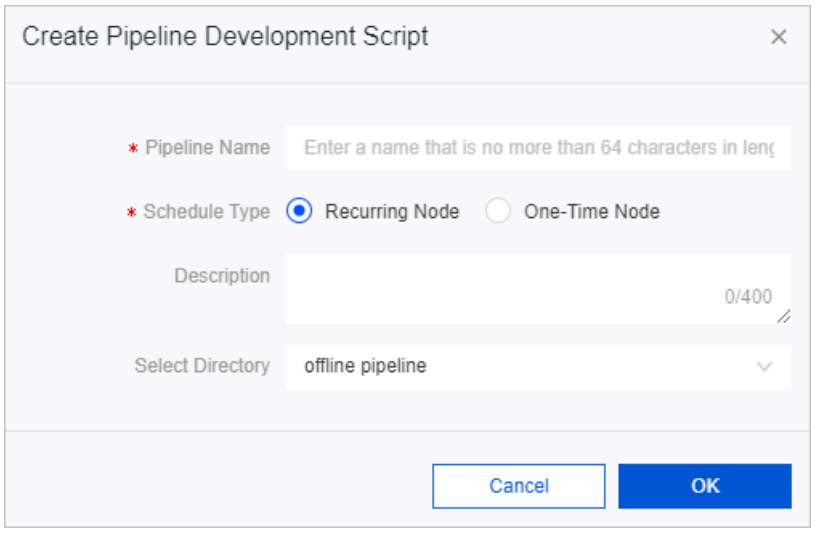
This topic describes how to configure, copy, and delete a Maxcompute input component, and how to select a data sending mode for a Maxcompute input component.

Context

A Maxcompute input component is used to import data from a MaxCompute project. Then, you can write the data to a database, such as a MySQL database, for data consumption.

Configure a Maxcompute input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.
   v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

   vi. Click **OK**.
3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the icon before **Input**.

5. Drag a Maxcompute component to the pipeline canvas on the left.
6. Right-click the Maxcompute component and select **Configure Attributes**.
7. In the **Maxcompute Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.
Data Source	The data source of the component. Select a data source that has been connected to Dataphin. The data source must meet the following requirements: ○ The data source is of the MaxCompute type. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Table	The source table to be migrated. If the table you selected is a partitioned table, enter the partition information, for example, `ds=${bizdate}`.
Output Fields	The output fields to be generated based on the input configuration. You can also perform the following operations to manage fields: ○ Click the icon in the **Actions** column to delete a field. ○ Click **Manage Fields**. In the **Manage Fields** dialog box, perform the following operations: ■ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section. ■ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section.

8. Click **OK**.

Copy a Maxcompute input component

1. Right-click a Maxcompute input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a Maxcompute input component

1. Right-click a Maxcompute input component and select **Delete**.

2. In the message that appears, click **OK**.

Select a data sending mode for a Maxcompute input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to downstream nodes.

1. Right-click a Maxcompute input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are provided:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data shares to the downstream nodes in turn. The sum of the data of all the downstream nodes is equal to that of the upstream node.

9.8.2.6.3. Manage Vertica input components

This topic describes how to configure, copy, and delete a Vertica input component, and how to select a data sending mode for a Vertica input component.

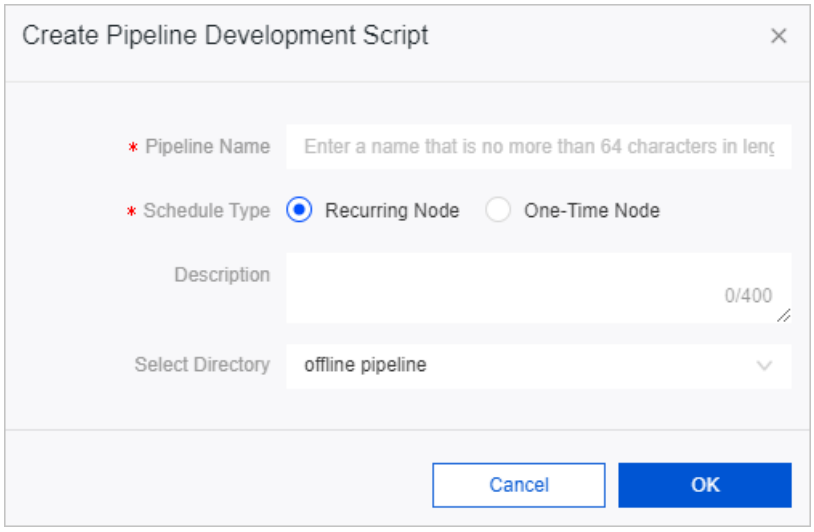
Context

A Vertica input component is used to import data from a Vertica database to Dataphin for integration and reprocessing.

Configure a Vertica input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Input**.
5. Drag a Vertica component to the pipeline canvas on the left.
6. Right-click the Vertica component and select **Configure Attributes**.
7. In the **Vertica Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been connected to Dataphin. The data source must meet the following requirements: ○ The data source is of the Vertica type. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a Vertica data source.
Table	The source table to be migrated.
Split Key	The shard key of the source table. You can specify a column in the source table as the shard key. We recommend that you use the primary key or an indexed column as the shard key.
Input Filtering	The filter condition for input fields. For example, you can enter `ds=${bizdate}`. The **Input Filtering** parameter is applicable to the following scenarios: ○ Specify a fixed portion of data. ○ Use parameters to filter data.
Output Fields	The output fields to be generated based on the input configuration. You can also perform the following operations to manage fields: ○ Click the icon in the **Actions** column to delete a field. ○ Click **Manage Fields**. In the **Manage Fields** dialog box, perform the following operations: ■ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section. ■ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section.

8. Click **OK**.

Copy a Vertica input component

1. Right-click a Vertica input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a Vertica input component

1. Right-click a Vertica input component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for a Vertica input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to downstream nodes.

1. Right-click a Vertica input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are provided:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data shares to the downstream nodes in turn. The sum of the data of all the downstream nodes is equal to that of the upstream node.

9.8.2.6.4. Manage DRDS input components

This topic describes how to configure, copy, and delete a DRDS input component, and how to select a data sending mode for a DRDS input component.

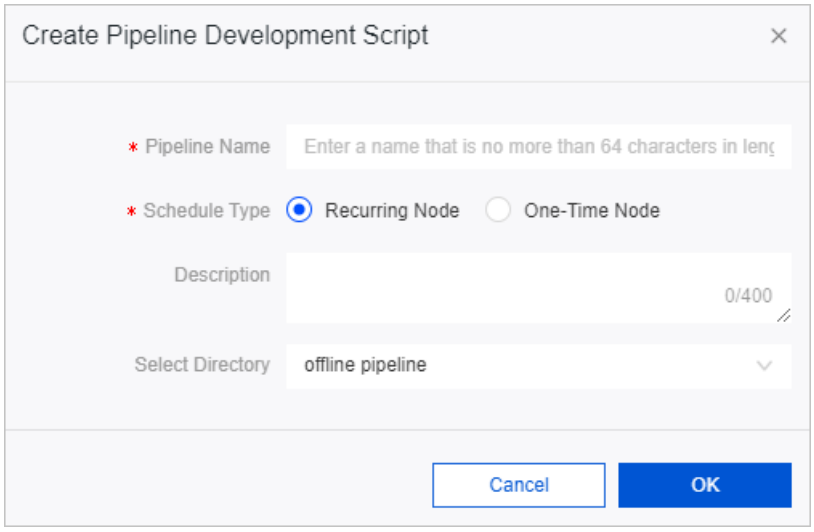
Context

A DRDS input component is used to import data from a PolarDB-X database to Dataphin for integration and reprocessing.

Configure a DRDS input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Input**.
5. Drag a DRDS component to the pipeline canvas on the left.
6. Right-click the DRDS component and select **Configure Attributes**.
7. In the **DRDS Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the PolarDB-X type. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to Data Source to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Table	The source table.
Split Key	The shard key of the source table. You can specify a column in the source table as the shard key. We recommend that you use the primary key or an indexed column as the shard key.
Input Filtering	The filter condition for input fields. For example, you can enter `ds=${bizdate}`. The Input Filtering parameter is applicable to the following scenarios: ○ Specify a fixed portion of data. ○ Use parameters to filter data.
Output Fields	The output fields to be generated based on the input configuration. You can also perform the following operations to manage fields: ○ Click the icon in the Actions column to delete a field. ○ Click Manage Fields. In the Manage Fields dialog box, perform the following operations: ■ Select one or more fields in the Unselected Input Fields section and click the icon to move the fields to the Selected Input Fields section. ■ Select one or more fields in the Selected Input Fields section and click the icon to move the fields to the Unselected Input Fields section.

8. Click OK.

Copy a DRDS input component

1. Right-click a DRDS input component and select Copy.
2. Right-click a blank area on the pipeline canvas and select Paste.

Delete a DRDS input component

1. Right-click a DRDS input component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for a DRDS input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to the downstream nodes.

1. Right-click a DRDS input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.6.5. Manage PostgreSQL input components

This topic describes how to configure, copy, and delete a PostgreSQL input component, and how to select a data sending mode for a PostgreSQL input component.

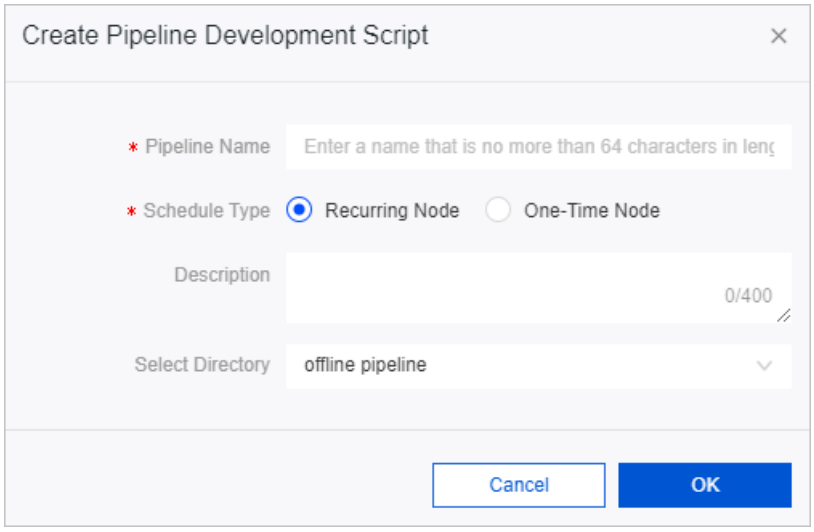
Context

A PostgreSQL input component is used to import data from a PostgreSQL database to Dataphin for integration and reprocessing.

Configure a PostgreSQL input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Input**.
5. Drag a PostgreSQL component to the pipeline canvas on the left.
6. Right-click the PostgreSQL component and select **Configure Attributes**.
7. In the **PostgreSQL Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the PostgreSQL type. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to Data Source to go to the Data Sources page and create a data source. For more information, see Create a PostgreSQL data source.
Source Table	The quantity of source tables. Valid values: Single Table and Multiple Tables. Note If you select Multiple Tables, you must specify multiple source tables that have the same schema.
Table	The one or more source tables. ○ If you set Source Table to Single Table, click the icon and select a source table from the Table drop-down list. ○ If you set Source Table to Multiple Tables, perform the following steps to specify the source tables: a. Enter an expression in the Table field. Dataphin allows you to enter an enumeration expression, a regular-like expression, or a combination of both, for example, `table_[001-100];table_102`. b. Click the icon. c. In the Confirm Match Details dialog box, select the tables that match the expression you entered. d. Click OK.
Split Key	The shard key of the source table. You can specify a column in the source table as the shard key. We recommend that you use the primary key or an indexed column as the shard key. If you specify multiple source tables, you need to specify only one shard key because the source tables have the same schema.

Parameter	Description
Input Filtering	The filter condition for input fields. For example, you can enter `ds=${bizdate}`. The **Input Filtering** parameter is applicable to the following scenarios: ○ Specify a fixed portion of data. ○ Use parameters to filter data.
Output Fields	The output fields to be generated based on the input configuration. You can also perform the following operations to manage fields: ○ Click the icon in the **Actions** column to delete a field. ○ Click **Manage Fields**. In the **Manage Fields** dialog box, view the unselected and selected input fields and perform the following operations: ■ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section. ■ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section.

8. Click **OK**.

Copy a PostgreSQL input component

1. Right-click a PostgreSQL input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete a PostgreSQL input component

1. Right-click a PostgreSQL input component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for a PostgreSQL input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to the downstream nodes.

1. Right-click a PostgreSQL input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.6.6. Manage SQL Server input components

This topic describes how to configure, copy, and delete an SQL Server input component, and how to select a data sending mode for an SQL Server input component.

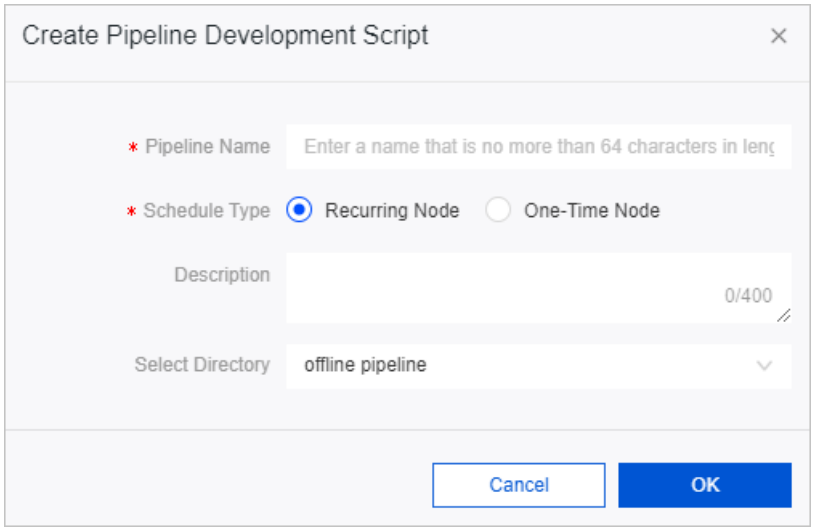
Context

An SQL Server input component is used to import data from an SQL Server database to Dataphin for integration and reprocessing.

Configure an SQL Server input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Input**.
5. Drag an SQL Server component to the pipeline canvas on the left.
6. Right-click the SQL Server component and select **Configure Attributes**.
7. In the **SQL Server Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the SQL Server type. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create a MySQL data source.
Source Table	The quantity of source tables. Valid values: **Single Table** and **Multiple Tables**. **Note** If you select **Multiple Tables**, you must specify multiple source tables that have the same schema.
Table	The one or more source tables. ○ If you set **Source Table** to **Single Table**, click the icon and select a source table from the **Table** drop-down list. ○ If you set **Source Table** to **Multiple Tables**, perform the following steps to specify the source tables: a. Enter an expression in the Table field. Dataphin allows you to enter an enumeration expression, a regular-like expression, or a combination of both, for example, `table_[001-100];table_102`. b. Click the icon. c. In the **Confirm Match Details** dialog box, select the tables that match the expression you entered. d. Click **OK**.
Split Key	The shard key of the source table. You can specify a column in the source table as the shard key. We recommend that you use the primary key or an indexed column as the shard key. If you specify multiple source tables, you need to specify only one shard key because the source tables have the same schema.

Parameter	Description
Input Filtering	The filter condition for input fields. For example, you can enter `ds=${bizdate}`. The **Input Filtering** parameter is applicable to the following scenarios: ○ Specify a fixed portion of data. ○ Use parameters to filter data.
Output Fields	The output fields to be generated based on the input configuration. You can also perform the following operations to manage fields: ○ Click the icon in the **Actions** column to delete a field. ○ Click **Manage Fields**. In the **Manage Fields** dialog box, perform the following operations: ■ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section. ■ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section.

8. Click **OK**.

Copy an SQL Server input component

1. Right-click an SQL Server input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an SQL Server input component

1. Right-click an SQL Server input component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for an SQL Server input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to the downstream nodes.

1. Right-click an SQL Server input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.6.7. Manage ORACLE input components

This topic describes how to configure, copy, and delete an ORACLE input component, and how to select a data sending mode for an ORACLE input component.

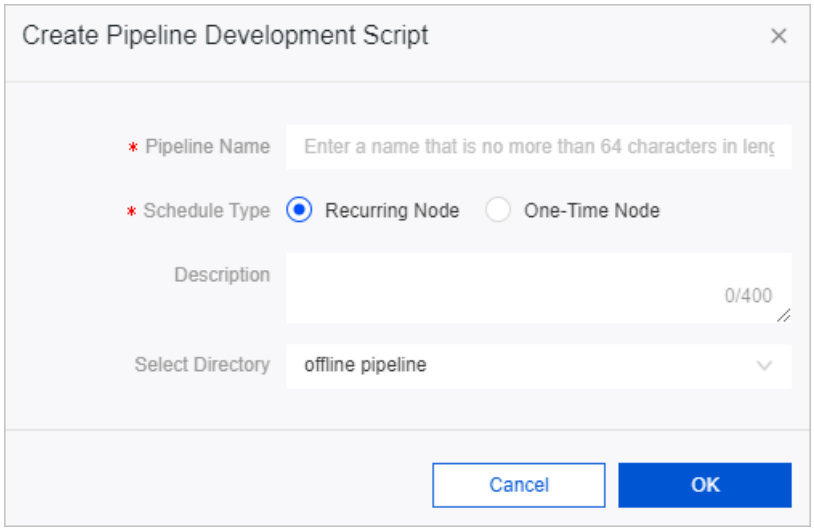
Context

An ORACLE input component is used to import data from an Oracle database to Dataphin for integration and reprocessing.

Configure an ORACLE input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Input**.
5. Drag an Oracle component to the pipeline canvas on the left.
6. Right-click the Oracle component and select **Configure Attributes**.
7. In the **Oracle Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the Oracle type. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create an Oracle data source.
Source Table	The quantity of source tables. Valid values: **Single Table** and **Multiple Tables**. **Note** If you select **Multiple Tables**, you must specify multiple source tables that have the same schema.
Table	The one or more source tables. ○ If you set **Source Table** to **Single Table**, click the icon and select a source table from the **Table** drop-down list. ○ If you set **Source Table** to **Multiple Tables**, perform the following steps to specify the source tables: a. Enter an expression in the Table field. Dataphin allows you to enter an enumeration expression, a regular-like expression, or a combination of both, for example, `table_[001-100];table_102`. b. Click the icon. c. In the **Confirm Match Details** dialog box, select the tables that match the expression you entered. d. Click **OK**.
Split Key	The shard key of the source table. You can specify a column in the source table as the shard key. We recommend that you use the primary key or an indexed column as the shard key. If you specify multiple source tables, you need to specify only one shard key because the source tables have the same schema.
Encoding	The encoding format of the source table. Valid values: **UTF-8**, **GBK**, and **ISO-8859-1**.

Parameter	Description
Input Filtering	The filter condition for input fields. For example, you can enter `ds=${bizdate}`. The **Input Filtering** parameter is applicable to the following scenarios: ○ Specify a fixed portion of data. ○ Use parameters to filter data.
Output Fields	The output fields to be generated based on the input configuration. You can also perform the following operations to manage fields: ○ Click the icon in the **Actions** column to delete a field. ○ Click **Manage Fields**. In the **Manage Fields** dialog box, perform the following operations: ■ Select one or more fields in the **Unselected Input Fields** section and click the icon to move the fields to the **Selected Input Fields** section. ■ Select one or more fields in the **Selected Input Fields** section and click the icon to move the fields to the **Unselected Input Fields** section.

8. Click **OK**.

Copy an ORACLE input component

1. Right-click an ORACLE input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an ORACLE input component

1. Right-click an ORACLE input component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for an ORACLE input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to the downstream nodes.

1. Right-click an ORACLE input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:
   - **Copy**: copies all the data of the upstream node to each downstream node.
   - **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.6.8. Manage FTP input components

This topic describes how to configure, copy, and delete an FTP input component, and how to select a data sending mode for an FTP input component.

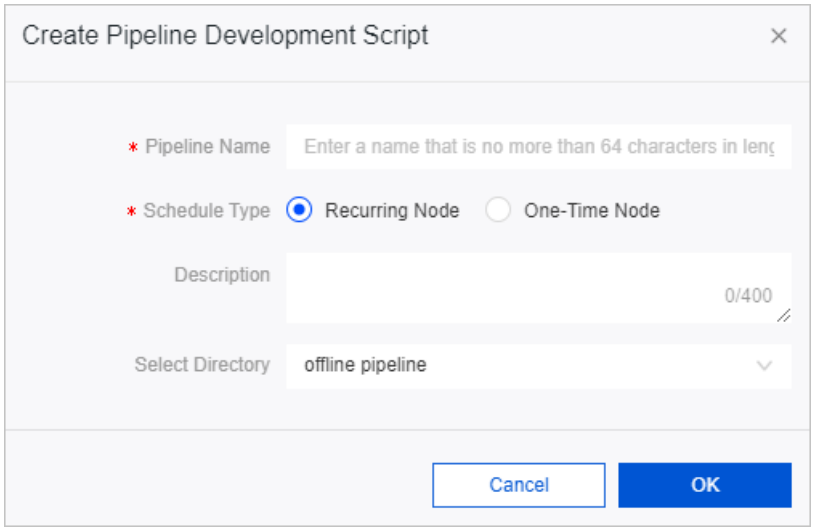
Context

An FTP input component is used to import data from an FTP server to Dataphin for integration and reprocessing.

Configure an FTP input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.



Parameter	Description
Pipeline Name	The name of the offline migration pipeline to be created.
Schedule Type	The scheduling type of the task corresponding to the offline migration pipeline. Valid values: ■ **Recurring Node**: a task that is run on a specified schedule. ■ **One-Time Node**: a task that has no dependencies and is triggered after you click Run.
Description	The description of the offline migration pipeline.
Select Directory	The folder where the offline migration pipeline resides.

vi. Click **OK**.

3. On the configuration tab of the pipeline, click **Component Library** in the upper-right corner.
4. Click the > icon before **Input**.
5. Drag an FTP component to the pipeline canvas on the left.
6. Right-click the FTP component and select **Configure Attributes**.
7. In the **FTP Input Configuration** dialog box, set the parameters as required.

Parameter	Description
Step Name	The name of the component. Enter a name based on the scenario.

Parameter	Description
Data Source	The data source of the component. Select a data source that has been configured in Dataphin. The data source must meet the following requirements: ○ The data source is of the FTP or SFTP type. ○ The account that you use to configure the component has the read-through permission on the data source. If your account does not have the required permission, apply for permissions on the data source. For more information, see Apply for permissions on a data source. You can also click the  icon next to **Data Source** to go to the Data Sources page and create a data source. For more information, see Create an FTP data source.
File Path	The path of the source file.
File Type	The type of the source file. Valid values: **TexT** and **CSV**.
File Encoding	The encoding format of the source file. Valid values: **UTF-8** and **GBK**.
Field Delimiter	The delimiter that is used to separate fields in the source file. If you do not specify this parameter, a comma (,) is used as the field delimiter.
Compression Format	The compression format of the source file. Valid values: ○ **zip** ○ **gzip** ○ **bzip2**
First Line Type	The content type of the first line of the source file. ○ If you select **Data Content**, you must configure output fields by using one of the following methods: ■ Click **Create Output Field**. Set the **Source Serial Number**, **Field**, and **Type** parameters as required. ■ Click **Batch Create**. In the Batch Create in JSON Format dialog box, configure multiple output fields in the JSON format. ○ If you select **Field Name**, the output fields are automatically parsed based on the fields in the first line of the source file.

Parameter	Description
Output Fields	The output fields to be generated. You can create output fields by using one of the following methods: ○ Click **Batch Create**. In the Batch Create in JSON Format dialog box, configure multiple output fields in the JSON format. Example: `[{ "index": 0, "name": "user_id", "type": "String" }, { "index": 1, "name": "user_name", "type": "String" }]` In the example, index, name, and type specify the sequence number, name, and data type of the output field, respectively. ○ Click **Create Output Field**. Set the **Source Serial Number**, **Field**, and **Type** parameters as required. You can also perform the following operations on existing fields: ○ Click the icon in the **Actions** column to edit a field. ○ Click the icon in the **Actions** column to delete a field.

8. Click **OK**.

Copy an FTP input component

1. Right-click an FTP input component and select **Copy**.
2. Right-click a blank area on the pipeline canvas and select **Paste**.

Delete an FTP input component

1. Right-click an FTP input component and select **Delete**.
2. In the message that appears, click **OK**.

Select a data sending mode for an FTP input component

If an input component is connected to multiple components in the downstream, you must select a mode in which the data of the input component is sent to the downstream nodes.

1. Right-click an FTP input component and select **Data Sending Mode**.
2. Select a data sending mode.Two data sending modes are supported:

- **Copy**: copies all the data of the upstream node to each downstream node.
- **Distribute**: divides the data of the upstream node into equal shares based on the number of downstream nodes and distributes the data to the downstream nodes in turn. The total data volume of all the downstream nodes is equal to the data volume of the upstream node.

9.8.2.6.9. Manage HDFS input components

This topic describes how to configure, copy, and delete an HDFS input component, and how to select a data sending mode for an HDFS input component.

Context

An HDFS input component is used to import data from an HDFS to Dataphin for integration and reprocessing.

Configure an HDFS input component

1. Log on to the Dataphin console.
2. Perform the following steps to create an offline migration pipeline:
   i. On the Dataphin homepage, click **R&D** in the top navigation bar.
   ii. On the **Develop** page, click the icon next to the project name in the upper-left corner and select a project in **Dev** or **Basic** mode.You can skip this step if the current project is in **Dev** or **Basic** mode.
   iii. In the top navigation bar, move the pointer over **Develop** and select **Integrated**. The **Integrated** page appears.
   iv. On the **Integrated** page, move the pointer over the icon next to **Script** and select **Offline Single Pipeline**.

v. In the **Create Pipeline Development Script** dialog box, set the parameters as required.
