Legal disclaimer

Alibaba Cloud reminds you to carefully read and fully understand the terms and conditions of this legal disclaimer before you read or use this document. If you have read or used this document, it shall be deemed as your total acceptance of this legal disclaimer.

1. You shall download and obtain this document from the Alibaba Cloud website or other Alibaba Cloud-authorized channels, and use this document for your own legal business activities only. The content of this document is considered confidential information of Alibaba Cloud. You shall strictly abide by the confidentiality obligations. No part of this document shall be disclosed or provided to any third party for use without the prior written consent of Alibaba Cloud.

2. No part of this document shall be excerpted, translated, reproduced, transmitted, or disseminated by any organization, company or individual in any form or by any means without the prior written consent of Alibaba Cloud.

3. The content of this document may be changed because of product version upgrade, adjustment, or other reasons. Alibaba Cloud reserves the right to modify the content of this document without notice and an updated version of this document will be released through Alibaba Cloud-authorized channels from time to time. You should pay attention to the version changes of this document as they occur and download and obtain the most up-to-date version of this document from Alibaba Cloud-authorized channels.

4. This document serves only as a reference guide for your use of Alibaba Cloud products and services. Alibaba Cloud provides this document based on the "status quo", "being defective", and "existing functions" of its products and services. Alibaba Cloud makes every effort to provide relevant operational guidance based on existing technologies. However, Alibaba Cloud hereby makes a clear statement that it in no way guarantees the accuracy, integrity, applicability, and reliability of the content of this document, either explicitly or implicitly. Alibaba Cloud shall not take legal responsibility for any errors or lost profits incurred by any organization, company, or individual arising from download, use, or trust in this document. Alibaba Cloud shall not, under any circumstances, take responsibility for any indirect, consequential, punitive, contingent, special, or punitive damages, including lost profits arising from the use or trust in this document (even if Alibaba Cloud has been notified of the possibility of such a loss).

5. By law, all the contents in Alibaba Cloud documents, including but not limited to pictures, architecture design, page layout, and text description, are intellectual property of Alibaba Cloud and/or its affiliates. This intellectual property includes, but is not limited to, trademark rights, patent rights, copyrights, and trade secrets. No part of this document shall be used, modified, reproduced, publicly transmitted, changed, disseminated, distributed, or published without the prior written consent of Alibaba Cloud and/or its affiliates. The names owned by Alibaba Cloud shall not be used, published, or reproduced for marketing, advertising, promotion, or other purposes without the prior written consent of Alibaba Cloud. The names owned by Alibaba Cloud include, but are not limited to, "Alibaba Cloud", "Aliyun", "HiChina", and other brands of Alibaba Cloud and/or its affiliates, which appear separately or in combination, as well as the auxiliary signs and patterns of the preceding brands, or anything similar to the company names, trade names, trademarks, product or service names, domain names, patterns, logos, marks, signs, or special descriptions that third parties identify as Alibaba Cloud and/or its affiliates.

Document conventions

Style	Description	Example
Danger	A danger notice indicates a situation that will cause major system changes, faults, physical injuries, and other adverse results.	Danger: Resetting will result in the loss of user configuration data.
Warning	A warning notice indicates a situation that may cause major system changes, faults, physical injuries, and other adverse results.	Warning: Restarting will cause business interruption. About 10 minutes are required to restart an instance.
Notice	A caution notice indicates warning information, supplementary instructions, and other content that the user must understand.	Notice: If the weight is set to 0, the server no longer receives new requests.
Note	A note indicates supplemental instructions, best practices, tips, and other content.	Note: You can use Ctrl + A to select all files.
>	Closing angle brackets are used to indicate a multi-level menu cascade.	Click **Settings**> **Network**> **Set network type**.
Bold	Bold formatting is used for buttons , menus, page names, and other UI elements.	Click **OK**.
`Courier font`	Courier font is used for commands	Run the `cd /d C:/window` command to enter the Windows system folder.
Italic	Italic formatting is used for parameters and variables.	`bae log list --instanceid` *Instance_ID*
[] or [a|b]	This format is used for an optional value, where only one item can be selected.	`ipconfig [-all|-t]`
{} or {a|b}	This format is used for a required value, where only one item can be selected.	`switch {active|stand}`

Table of Contents

1.MaxCompute

1.1. What is MaxCompute?

MaxCompute is a data processing platform developed by Alibaba Group to process large volumes of data. MaxCompute provides channels for upload and download, a range of computing and analysis features including SQL and MapReduce, and comprehensive security solutions.

MaxCompute is used to store and compute large volumes of structured data. It provides warehouse solutions for large amounts of data, as well as big data analysis and modeling services.

As data collection techniques are becoming increasingly diverse and comprehensive, industries are amassing larger volumes of data. The scale of data collection has increased from 100 GB to over 1 PB, far exceeding the processing capabilities of traditional software. Analysis tasks for large volumes of data require distributed computing instead of reliance on a single server. However, distributed computing models require skilled data analysts. To use a distributed model, data analysts must understand the business needs and underlying computing model.

MaxCompute is designed to provide an intuitive approach to analyze and process large amounts of data without the need for distributed computing knowledge. MaxCompute is widely implemented within Alibaba's businesses for scenarios such as data warehousing and BI analysis for large Internet enterprises, website log analysis, e-commerce transaction analysis, and exploration of user characteristics and interests.

MaxCompute provides the following features:

- Data channel
  - Tunnel: provides highly-concurrent offline data upload and download services. MaxCompute Tunnel enables you to upload or download a large volume of data to or from MaxCompute. You must use a Java programming API to access MaxCompute Tunnel.
  - DataHub: provides real-time upload and download services. Data uploaded through DataHub is available immediately, while data uploaded through MaxCompute Tunnel is not.
- Computing and analysis
  - SQL: MaxCompute stores data in tables and provides SQL query capabilities. MaxCompute can be used as traditional database software, but it is far more powerful and is capable of processing petabytes of data. MaxCompute SQL does not support transactions, indexes, or operations such as UPDATE and DELETE. The SQL syntax used in MaxCompute is different from that in Oracle and MySQL. SQL statements from other database engines cannot be migrated seamlessly to MaxCompute. MaxCompute SQL responds to queries within a few minutes or seconds, instead of milliseconds. MaxCompute SQL is easy to learn. You can get started with MaxCompute SQL based on your prior experience of database operations, without having a deep understanding of distributed computing.
  - MapReduce: First proposed by Google, MapReduce is a distributed data processing model that has gained extensive attention and been used in a wide range of business scenarios. This document briefly describes the MapReduce model. You must have a basic knowledge of distributed computing and relevant programming experience before using MapReduce. MapReduce provides a Java programming interface.

  - Graph: an iterative graph computing framework provided in MaxCompute. Graph computing jobs use graphs to build models. A graph is a collection of vertices and edges that have values. You can edit and evolve a graph through iteration to obtain the final result. Typical applications include PageRank, single source shortest path (SSSP) algorithm, and K-means clustering algorithm.
  - Unstructured data access and processing (integrated computing scenarios): MaxCompute SQL cannot directly process external data (such as unstructured data from OSS). Data must be imported to MaxCompute tables by using relevant tools before computation. The MaxCompute team introduces the unstructured data processing framework to the MaxCompute system architecture to resolve this problem.

    MaxCompute can process the following data sources by creating external tables:

    - Internal data sources: OSS, Table Store, AnalyticDB, ApsaraDB for RDS, HDFS (Alibaba Cloud), and TDDL.
    - External data sources: HDFS (open source), MongoDB, and Hbase.
  - Unstructured data access and processing (inside MaxCompute): By reading and writing volumes, MaxCompute can store unstructured data, which otherwise must be stored in an external storage system.

- Spark on MaxCompute: a big data analytics engine designed by Alibaba Cloud to provide big data processing capabilities for Alibaba, government agencies, and enterprises. For more information, see Spark on MaxCompute.
- Elasticsearch on MaxCompute: an enterprise-class full-text retrieval system developed by Alibaba Cloud to retrieve large volumes of data. It provides near-real-time (NRT) search performance for government agencies and enterprises. For more information, see Elasticsearch on MaxCompute.
- SDK: a toolkit provided for developers. For more information, see Java SDK.
- Security solution: MaxCompute provides powerful security services to guarantee user data security.

1.2. Usage notes

You can selectively read topics in this document based on your requirements. This topic provides reading suggestions in the document based on user skill level.

Beginners

If you are a beginner, we recommend that you read the following topics:

- What is MaxCompute: The topic provides a general introduction of MaxCompute and its core features. You can obtain general knowledge about MaxCompute.
- Quick start: The topic provides step-by-step examples and instructions on how to perform basic MaxCompute operations, such as installing and configuring the client, creating tables, granting permissions, importing and exporting data, running SQL tasks, running user-defined functions (UDFs), and running MapReduce.
- Basic concepts and common commands: The topic introduces the basic concepts of MaxCompute and common MaxCompute commands. This topic helps familiarize yourself with MaxCompute operations.
- Tools: The topic describes how to download, configure, and use common MaxCompute tools to perform data analysis.

Data analysts

If you are a data analyst, we recommend that you read the following topics:

MaxCompute SQL: The topic describes how to query and analyze large amounts of data stored in MaxCompute. This topic covers the following operations:

- Execute DDL statements CREATE, DROP, and ALERT to manage tables and partitions.
- Execute SELECT statements to select records in a table, and execute WHERE clauses to view the records that meet a specified filtering condition.
- Associate two tables through an EQUIJOIN operation.
- Execute GROUP BY statements to aggregate columns.
- Execute INSERT OVERVIEW or INSERT INTO statements to insert results into another table.
- Use built-in functions and UDFs to complete a variety of computations.
- Use UDTs to reference classes or objects of third-party languages in SQL statements to obtain data or call methods.
- Use UDJs to implement flexible cross-table and multi-table custom operations, and reduce the operations on the underlying details of the distributed system through MapReduce.
- Use the Select Transform feature to simplify the reference of script code.
- Collect table statistics and configure table lifecycles.
- Use regular expressions.

Developers

If you are an experienced developer with basic understanding of distributed computing and need to perform data analysis that cannot be implemented with SQL, we recommend that you read the following topics on advanced MaxCompute functional modules:

- MapReduce is a Java programming model provided by MaxCompute. You can use the API to write MapReduce programs and process MaxCompute data.
- MaxCompute Graph is a processing framework designed that iteratively computes and models graphs. A graph consists of vertices and edges, both of which contain values. MaxCompute Graph iteratively edits and evolves graphs to obtain analysis results.
- Eclipse plugin provides an IDE to help you complete development of MapReduce, UDFs, and Graph.
- Java SDK is a toolkit provided to developers.
- MaxCompute Tunnel allows you to perform batch upload and download operations on offline data to and from MaxCompute.

Project owners or administrators

If you are a project owner or administrator, we recommend that you read the following topics:

Security solution: This topic describes how to authorize users, enable cross-project resource sharing, configure project data protection, and configure authorization policies.

1.3. Preparations

1.3.1. Log on to the ASCM console

This topic describes how to log on to the Apsara Stack Cloud Management (ASCM) console.

Prerequisites

- The IP address or domain name of the ASCM console is obtained from deployment personnel. The URL used to log on to the ASCM console is in the following format: https://IP address or domain name of the ASCM console.
- A browser is available. We recommend that you use Google Chrome.

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press Enter.
2. Enter the correct username and password.

   Obtain the username and password used to log on to the console from the operations administrator.

   > **Note** When you log on to the ASCM console for the first time, you must change the password as prompted. For security purposes, your password must meet the complexity requirements. Specifically, the password must be 8 to 20 characters in length and must contain at least two of the following character types: uppercase letters, lowercase letters, digits, and special characters such as ! @ # $ %

3. Click **Login** to go to the homepage of the ASCM console.

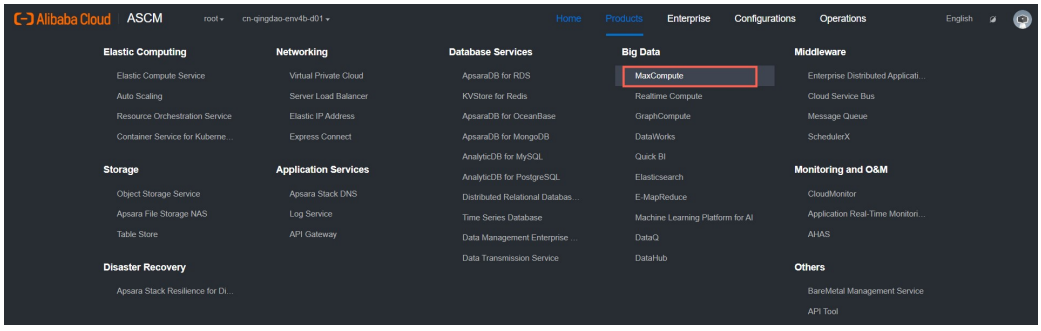
1.3.2. Create an Apsara Stack tenant account

This topic describes how to create an Apsara Stack tenant account.

Procedure

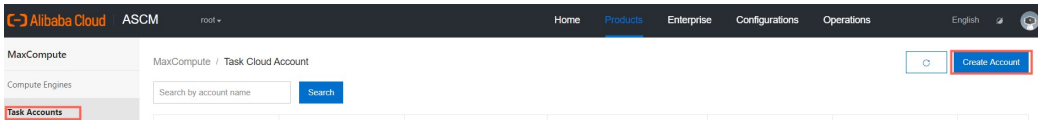
1. Log on to the Apsara Stack Cloud Management (ASCM) console as an administrator.
2. In the top navigation bar, choose **Products** > **Big Data** > **MaxCompute** to go to the **MaxCompute** homepage.

   Go to the MaxCompute homepage



3. In the left-side navigation pane, click **Task Accounts**. In the upper-right corner of the page that appears, click **Create Account**.

   Create an account



4. In the dialog box that appears, specify the required parameters and click **OK**.

Account configurations

Parameter	Description
Name	The name of the Apsara Stack tenant account.
Organization	The organization to which the Apsara Stack tenant account belongs.
Description	The description of the Apsara Stack tenant account. You can leave this parameter empty.

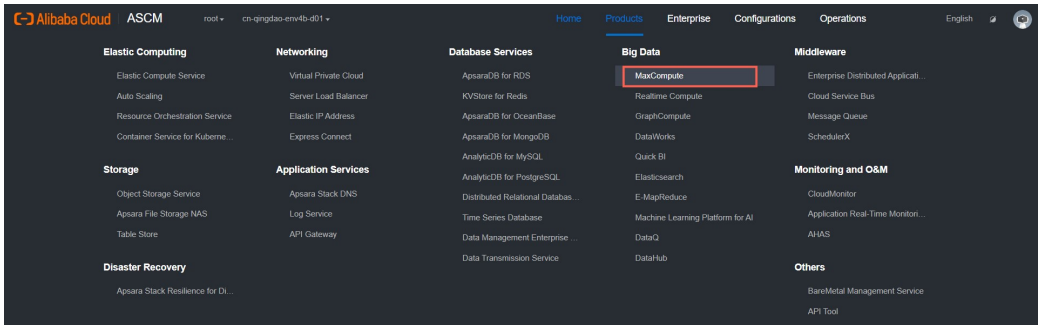
1.3.3. Create a project

This topic describes how to create a MaxCompute project.

Procedure

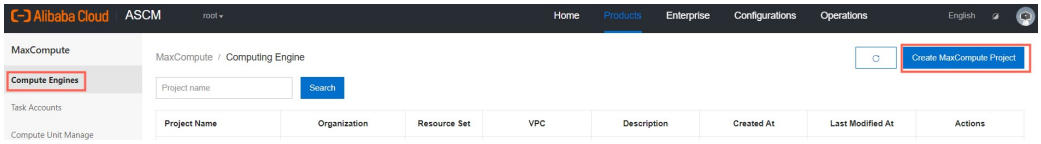
1. Log on to the Apsara Stack Cloud Management (ASCM) console as an administrator.
2. In the top navigation bar, choose **Products** > **Big Data** > **MaxCompute** to go to the **MaxCompute** homepage.

   Go to the MaxCompute homepage



3. In the left-side navigation pane, click **Computing Engines**. In the upper-right corner of the page that appears, click **Create MaxCompute Project**.

   Create a MaxCompute project



4. On the page that appears, specify the required parameters and click **Submit**.

Region configurations

Parameter	Description
Organization	The organization that you select for the project.
Resource Set	The resource set in the selected organization.
Region	The region where the cluster is deployed.
VPC	The Virtual Private Cloud (VPC) in the region. The VPC is used for network isolation.
Cluster	The information about the cluster of the project.
Encryption Settings	No is selected for Encrypt by default. If you select Yes for Encrypt, the available encryption algorithms are AES-CTR, AES-256, and RC4.
Encryption Key	If you select Yes for Encrypt, this parameter is available. The default value is Generate Automatically.

Resource configurations

Parameter	Description
Resource Group	The resource group in the selected cluster. If no resource groups are available, create one.
Apply (GB)	The storage space that is requested for the project. The value cannot be greater than the total capacity of the disk.

Basic configurations

Parameter	Description
MaxCompute Project Name	The name of the project.
Owner Account	The name of the Apsara Stack tenant account that corresponds to the project owner. The value of this parameter depends on the associated organization. You cannot specify this parameter.
Access ID	The AccessKey ID of the Apsara Stack tenant account that corresponds to the project owner. You cannot specify this parameter.

Parameter	Description
Access Key	The AccessKey secret of the Apsara Stack tenant account that corresponds to the project owner. You cannot specify this parameter.
Task Account	Optional. The account of the task.
Access ID	The AccessKey ID of the task account. You cannot specify this parameter.
Access Key	The AccessKey secret of the task account. You cannot specify this parameter.

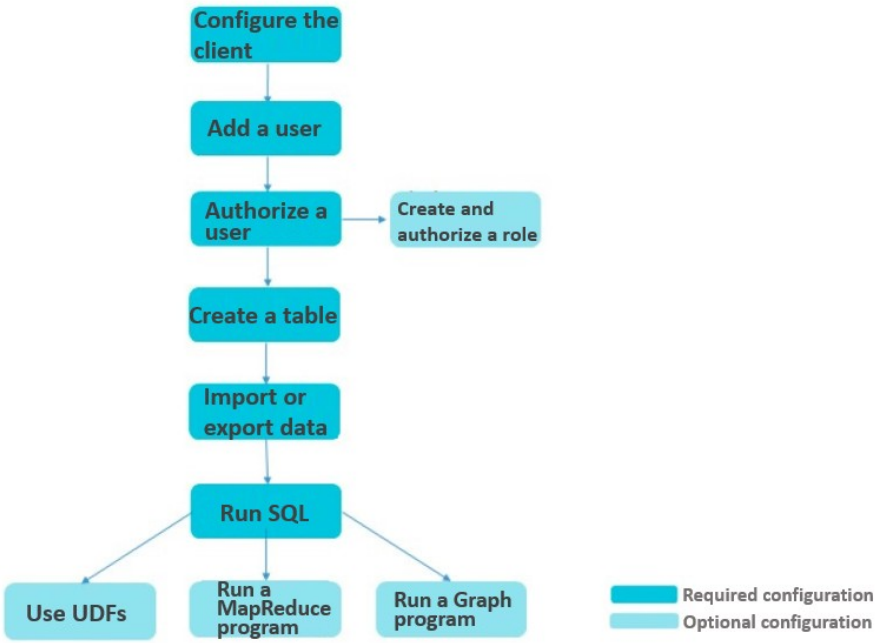
1.4. Quick start

1.4.1. Overview

This topic describes the operation process of MaxCompute. It aims to provide you with step-by-step instructions on basic MaxCompute operations.

MaxCompute operation process shows the procedure.

MaxCompute operation process



1. Configure the client.

   You must install and configure the client to use all the features of MaxCompute.

2. Add a user.

   Except for the project owner, all users must be manually added to a project and granted permissions before they can perform operations on the project.

3. Authorize a user.

   After you add a user, you must authorize the user to perform operations on the project. A user can only perform operations on the project after the user is authorized.

4. (Optional) Create and authorize a role.

   It can be very time-consuming to individually authorize users if a project contains a large number of users. Project administrators can use roles to grant users a specified set of permissions. After you authorize a role, all users assigned this role are granted the same permissions.

5. Create a table.

   After you are added to a project and authorized, you can start to use MaxCompute. Table operations are the most basic operations in MaxCompute.

6. Import or export data.

   You can use the SDK provided by MaxCompute Tunnel to compile your own Java tools and import and export data.

7. Run SQL.

   Only the limits on a few common SQL statements are described here. For more information about how to execute SQL statements, see MaxCompute SQL.

8. Then, you can perform any of the following optional operations:
   - Use UDFs.

     After you install the MaxCompute client, you can try to use UDFs. MaxCompute provides three types of UDFs: UDFs, UDAFs, and UDTFs. These functions are collectively known as UDFs.

   - Run a MapReduce program.

     After you install the MaxCompute client, you can run a MapReduce program.

   - Run a Graph program.

     After you install the MaxCompute client, you can run a Graph program.

1.4.2. Configure the MaxCompute client

The MaxCompute client allows you to access MaxCompute projects and use MaxCompute features. This topic describes how to install, configure, and run the client.

Context

The client is developed in Java. Make sure that you have JRE 1.8 installed on your local PC. In addition, make sure that you have an Apsara Stack tenant account and have obtained the AccessKey ID and AccessKey secret.

> **Note** Before you configure the client, make sure that a project is created and the AccessKey ID and AccessKey secret are obtained.

Procedure

1. Download the client package to your computer.

2. Decompress the package. The package contains the following four folders:

```
bin/
conf/
lib/
plugins/
```

3. Edit the following information in the odps_config.ini file under the conf folder:

```
project_name=my_project
access_id=********************
access_key=**********************
end_point= <Endpoint of MaxCompute>
```

> **Note**
> - Set access_id to the AccessKey ID and access_key to the AccessKey secret of your Apsara Stack tenant account.
> - project_name=my_project specifies the project that you want to access. This is the default project that is accessed each time you log on to the client. If this parameter is not specified, you must run the `use project_name` command to access the project after you log on to the client.
> - Set end_point to the endpoint of MaxCompute. The endpoint varies based on the user account.
> - For more information about the client, see MaxCompute client.

4. After the modification, run the *./bin/odpscmd* program in a Linux system or *./bin/odpscmd.bat* in a Windows system in the bin directory to execute SQL statements. Example:

```
create table tbl1(id bigint);
insert overwrite table tbl1 select count(*) from tbl1;
select 'welcome to MaxCompute!' from tbl1;
```

> **Note** For more information about SQL statements, see MaxCompute SQL.

1.4.3. Add and delete users

Other than the project owner, all other users must be added to a MaxCompute project and granted the corresponding permissions before they can perform any operations on the project. This topic describes how a project owner can add or delete users in a project.

If you are a project owner, we recommend that you read this topic in full. If you are a common user, we recommend that you submit an application to a project owner to join a project, and read the subsequent topics once you are added to the project.

Add users

Run the following command to add a user:

```
ADD USER <full_username>;
```

Run the following command on the client to add a user (bob@aliyun.com) to a project:

```
add user bob@aliyun.com;
```

If you are not sure whether the user is already in the project, run the following command to view the users in the project:

```
LIST USERS;
```

> Note
> - After a user is added to a MaxCompute project, the user must be granted permissions by the project owner. Then, the user can perform operations authorized by the permissions.
> - For more information about authorization, see Grant and view permissions.

Delete users

Run the following command to delete a user:

```
REMOVE USER <full_username>;
```

Run the following command on the client to delete a user from a project:

```
remove user bob@aliyun.com;
```

> Note
> - Before you delete a user, make sure that you have revoked all the permissions of the user. If you delete a user without revoking the permissions of the user, the permissions are retained. If the user is added to the project again, the user will have the permissions that were granted previously.
> - For more information about how to add or delete users, see Manage users in a project.

1.4.4. Grant and view permissions

1.4.4.1. Overview

After you add a user, you need to authorize the user. A user can only perform operations on the project after the user is authorized.

Authorization is a process of granting the permission to perform an operation (such as reading, writing, or viewing), on objects (such as tables, tasks, and resources) in MaxCompute.

This topic is intended for project administrators. If you are a regular MaxCompute user, verify that you have obtained the required permissions. You can quickly skim this topic.

MaxCompute provides two authorization mechanisms, ACL authorization and policy authorization.

1.4.4.2. ACL authorization

This topic describes the commands for ACL authorization and provides examples.

ACL authorization in MaxCompute applies to the following objects: project, table, function, resource, instance, and task. Every object has different operation permissions. For more information, see ACL authorization actions.

Command syntax:

```
GRANT privileges ON project_object TO project_subject
REVOKE privileges ON project_object FROM project_subject
privileges ::= action_item1, action_item2, ...
project_object ::= PROJECT project_name | TABLE schema_name |
INSTANCE inst_name | FUNCTION func_name |
RESOURCE res_name | JOB job_name
project_subject ::= USER full_username | ROLE role_name
```

> **Note** You can skip the ROLE clause in the preceding command. It is described in the topics after this.

Example:

```
grant CreateTable on PROJECT $user_project_name to USER ALIYUN$bob@aliyun.com;
-- Grant bob@aliyun.com the permissions to create tables in the project named $user_project_name.
grant Describe on Table $user_table_name to USER ALIYUN$bob@aliyun.com;
-- Grant bob@aliyun.com the permissions to obtain information (Describe permission) in the table nam
ed $$user_table_name.
grant Execute on Function $user_function_name to USER ALIYUN$bob@aliyun.com;
-- Grant bob@aliyun.com the permissions to run the function named $user_function_name.
```

1.4.4.3. Policy authorization

This topic describes the commands for policy authorization and provides an example.

Policy authorization is a principal-based process. For more information, see Authorization policies.

Command syntax:

```
GET POLICY;
PUT POLICY <policyFile>;
GET POLICY ON ROLE <roleName>;
PUT POLICY <policyFile> ON ROLE <roleName>;
```

Example:

```
{
"Version": "1",
"Statement": [
{
"Effect": "Deny",
"Action": [
"odps:*"
],
"Resource": "acs:odps:*:projects/$user_project_name/tables/*",
 "Condition": {
"StringEquals": {
"odps:TaskType": [
"DT"
]
}
}
},
{
"Effect": "allow ",
 "Action": [
"odps:List",
"odps:Read",
"odps:Describe",
"odps:Select"
],
"Resource": [
 "acs:odps:*:projects/$user_project_name/tables/a",
"acs:odps:*:projects/$user_project_name"
],
"Condition": {
 "StringEquals": {
"odps:TaskType": [
            "SQL"
             ]
       }
  }
}
]
}
```

> **Note** The preceding example disables the Tunnel feature of $user_project_name, and grants a user the permissions to perform list, read, describe, and select operations on the project and table a in the project.

1.4.4.4. View permissions

You can run a command to view user permissions in MaxCompute.

Run the following command to view the permissions of a user:

```
show grants for $user_name;
```

> **Note** For more information about how to view user permissions, see View permissions.

1.4.5. Create and authorize a role

If a project has a large number of users, the authorization process is time-consuming. Project administrators can use roles to categorize users with the same permissions. After you authorize a role, all users assigned with this role are granted the same permissions. This topic describes how to create a role and grant permissions to it.

One user can have multiple roles, and multiple users can have the same role.

Create a role

Run the following command to create a role:

```
CREATE ROLE <roleName>;
```

Example:

```
create role player;
```

Add a user to a role

Run the following command to add a user to a role:

```
GRANT <roleName> TO <full_username>;
```

Example:

```
grant player to bob@aliyun.com;
```

Delete a role

Run the following command to delete a role:

```
DROP ROLE <roleName>;
```

Example:

```
drop role player;
```

> **Note** Before you delete a role, make sure that all users have been removed from the role.

Grant permissions to a role

The command for granting permissions to a role is similar to the command for granting permissions to a user. For more information about how to grant permissions to a user, see Grant and view permissions. For more information about role authorization, see Role management.

1.4.6. Create or delete a table

1.4.6.1. Create a table

This topic describes how to create a table.

Run the following command to create a table:

```
CREATE TABLE [IF NOT EXISTS] table_name
[(col_name data_type [COMMENT col_comment], ...)] [COMMENT table_comment]
[PARTITIONED BY (col_name data_type [COMMENT col_comment], ...)] [LIFECYCLE days]
[AS select_statement]
CREATE TABLE [IF NOT EXISTS] table_name
LIKE existing_table_name
```

Example:

```
create table test1 (key string);
-- Create a non-partitioned table.
create table test2 (key bigint) partitioned by (pt string, ds string);
-- Create a partitioned table.
create table test3 (key boolean) partitioned by (pt string, ds string) lifecycle 100;
-- Create a table with a lifecycle.
create table test4 like test3;
-- Table test3 has the same attributes (such as the field type and partition type) as those of test4, ex
cept for lifecycle.
create table test5 as select * from test2;
-- Create table test5 without replicating the partition and lifecycle information of test2 to it. Only data
of test2 is copied to test5.
```

You can set partitions or lifecycles for MaxCompute tables. For more information about how to create a table, see Create a table. For more information about how to modify partitions, see Add a partition and Delete a partition. For more information about how to modify the lifecycle, see Modify the lifecycle of a table.

1.4.6.2. Obtain table information

This topic describes how to obtain the table information.

Command syntax:

```
desc <table_name>;
```

Example:

```
desc test3;
-- Obtain the information about test3.
desc test4;
-- Obtain the information about test4.
```

1.4.6.3. Delete a table

This topic describes how to delete a table.

Run the following command to delete a table:

```
DROP TABLE [IF EXISTS] table_name;
```

Example:

```
drop table test2;
```

> **Note** For more information, see Delete a table.

1.4.7. Import or export data

You can compile your own Java tools by using the SDK provided by MaxCompute Tunnel to import or export data. For the sample code, see Tunnel SDK examples.

1.4.8. Run SQL

1.4.8.1. Overview

This topic describes the limits to a few common SQL statements only. For more information about how to run SQL statements, see MaxCompute SQL.

Note the following issues when using MaxCompute SQL:

- MaxCompute SQL does not support transactions, indexes, or operations such as UPDATE and DELETE.
- The SQL syntax of MaxCompute is different from that of Oracle or MySQL. You cannot seamlessly migrate SQL statements from other database engines to MaxCompute.
- MaxCompute SQL does not respond to queries in real time. It requires a few minutes to return query results, instead of seconds or milliseconds.

1.4.8.2. SELECT statement

This topic describes limits of the SELECT statement.

The following limits apply to the SELECT statement:

- The key of the GROUP BY statement can be the name of a column in the input table, or the expression composed of input table columns. However, it cannot be the output column of the SELECT statement.

```
select substr(col2, 2) from tbl group by substr(col2, 2);
- Allowed: The key of the GROUP BY statement is an expression of columns in the input table.
select col2 from tbl group by substr(col2, 2);
-- Not allowed: The key of the GROUP BY statement is not included in columns of the SELECT statem
ent.
select substr(col2, 2) as c from tbl group by c;
-- Not allowed: The key of the GROUP BY statement is the alias of a column, or output column of the
SELECT statement.
```

> **Note** For SQL parsing, the GROUP BY operation is conducted before the SELECT operation, which means the GROUP BY statement can only use the column or expression of the input table as the key.

- DISTRIBUTE BY must be added in front of SORT BY.
- The key of ORDER BY/SORT BY/DISTRIBUTE BY must be the output column of SELECT

statement, or the column alias.

```
select col2 as c from tbl order by col2 limit 100
-- Not allowed: The key of the ORDER BY statement is not the output column of the SELECT stateme
nt, or the column alias.
select col2 from tbl order by col2 limit 100;
-- Allowed: If an output column of the SELECT statement does not have an alias, the column name is
used as the alias.
```

> **Note** For SQL parsing, the ORDER BY, SORT BY, and DISTRIBUTE BY operations come after the SELECT operation. Therefore, they can only accept the output columns of the SELECT statement as the key.

For more information about the SELECT statement, see SELECT statement.

1.4.8.3. INSERT statement

This topic describes the limits of the INSERT statement.

The following limits apply to INSERT statements:

- When an INSERT statement is used to insert data into a partition, the partition column cannot be included in the select list.

```
insert overwrite table sale_detail_insert partition (sale_date='2017', region='china') select shop_nam
e, customer_id, total_price, sale_date, region from sale_detail;
-- An error is returned. The sale_date and region columns are partition columns and are not allowed
in a INSERT statement for a static partition.
```

- When an INSERT statement is used to insert a dynamic partition, the dynamic partition column must be included in the select list.

```
insert overwrite table sale_detail_dypart partition (sale_date='2017', region) select shop_name,cust
omer_id,total_price from sale_detail;
-- An error is returned. When a dynamic partition is specified for the insert, the dynamic partition col
umns must be included among the selected columns.
```

For more information about the INSERT statement, see INSERT statement.

1.4.8.4. JOIN statement

This topic describes the limits of JOIN statements.

The following limits apply to JOIN operations:

- MaxCompute SQL supports the following JOIN operations: {LEFT OUTER|RIGHT OUTER|FULL > OUTER|INNER} JOIN.
- MaxCompute SQL supports a maximum of 128 parallel JOIN operations.

For more information about JOIN operations, see JOIN statement.

1.4.8.5. Other limits

This topic describes the other application limits of MaxCompute SQL.

- MaxCompute SQL supports a maximum of 256 concurrent UNION operations.
- MaxCompute SQL supports a maximum of 256 concurrent INSERT OVERWRITE/INTO operations.

1.4.9. Compile and use UDFs

1.4.9.1. Overview

This topic provides examples on how to compile and use MaxCompute UDFs.

MaxCompute provides three types of UDFs: UDFs, UDAFs, and UDTFs. These functions are collectively known as UDFs.

> Note
>
> - UDFs only support Java APIs. To compile a UDF program, you can upload UDF code to your project by adding resources, and run the CREATE FUNCTION statement to create a UDF.
> - This topic provides examples of UDF, UDAF, and UDTF code.

1.4.9.2. UDF example

This topic uses the convert-to-lowercase function as an example to demonstrate the process of creating a UDF. Specifically, follow these steps:

Procedure

1. Write code. To archive function, write a program and compile in terms of MaxCompute UDF frame.

   ```
   package org.alidata.odps.udf.examples; import com.aliyun.odps.udf.UDF;
   public final class Lower extends UDF { public String evaluate(String s) {
   if (s == null) { return null; } return s.toLowerCase();
   }
   }
   ```

   Name the preceding JAR package *my_lower.jar*.

2. Add resources. Specify the referenced UDF code before running UDF. User code must be added to MaxCompute by adding resources. Java UDFs must be compiled into the JAR package and added in MaxCompute as a JAR resource. The UDF framework loads the JAR package automatically and runs UDF.

   Example of the command to add JAR resources:

   ```
   add jar my_lower.jar;
   ```

> **Note** If multiple resources have the same name, rename the JAR package and modify the name of relevant JAR packages in the example command below. You can also use the "f" option to override the existing JAR resources.

3. Register the UDF. When your JAR package is uploaded, MaxCompute does not have any information about this UDF. Therefore, you must register a unique function name in MaxCompute, and specify to which function and under which JAR resources this function name corresponding.

   An example of using commands to register the UDF is as follows:

   ```
   CREATE FUNCTION test_lower AS org.alidata.odps.udf.examples.Lower USING my_lower.jar;
   ```

   Example of the function used in SQL:

   ```
   select test_lower('A') from my_test_table;
   ```

1.4.9.3. UDAF example

This topic provides an example of UDAF code for your reference.

UDAFs are registered in the same way as UDFs and are used in the same way as built-in aggregate functions.

The following UDAF code is for reference only:

```
package org.alidata.odps.udf.examples;
import com.aliyun.odps.io.LongWritable; import com.aliyun.odps.io.Text;
import com.aliyun.odps.io.Writable; import com.aliyun.odps.udf.Aggregator;
import com.aliyun.odps.udf.UDFException;
/**
project: example_project
table: wc_in2
partitions: p2=1,p1=2
columns: colc,colb,cola
*/
public class UDAFExample extends Aggregator {
@Override
public void iterate(Writable arg0, Writable[] arg1) throws UDFException { LongWritable result = (LongW
ritable) arg0;
for (Writable item : arg1) { Text txt = (Text) item;
result.set(result.get() + txt.getLength());
}
}
@Override
public void merge(Writable arg0, Writable arg1) throws UDFException { LongWritable result = (LongWrit
able) arg0;
LongWritable partial = (LongWritable) arg1; result.set(result.get() + partial.get());
}
@Override
public Writable newBuffer() { return new LongWritable(0L);
}
@Override
public Writable terminate(Writable arg0) throws UDFException { return arg0;
}
}
```

1.4.9.4. UDTF example

This topic provides an example of UDTF code for your reference.

UDTFs are registered and used in the similar way to UDFs.

UDTF code example:

```
package org.alidata.odps.udtf.examples;
import com.aliyun.odps.udf.UDTF;
import com.aliyun.odps.udf.UDTFCollector; import com.aliyun.odps.udf.annotation.Resolve; import com.
aliyun.odps.udf.UDFException;
// TODO define input and output types, e.g., "string,string->string,bigint".
@Resolve({"string,bigint->string,bigint"}) public class MyUDTF extends UDTF {
@Override
public void process(Object[] args) throws UDFException { String a = (String) args[0];
Long b = (Long) args[1];
for (String t: a.split("\\s+")) { forward(t, b);
}
}
}
```

1.4.10. Compile and run a MapReduce job

This topic describes how to quickly run a MapReduce program after the MaxCompute client is installed.

Context

A WordCount program is used as an example in this topic.

Before you compile and run a MapReduce program, make sure that the following requirements are met:

- JDK 1.8 has been installed on your host.
- The MaxCompute client has been configured. For more information, see Configure the client.

Procedure

1. Create input and output tables. Example:

   ```
   create table wc_in (key string, value string);
   create table wc_out (key string, cnt bigint);
   ```

   > **Note** For more information about the table creation statement, see Create a table.

2. Use the data transfer tool to upload data. Example:

   ```
   odpscmd -e "tunnel upload kv.txt wc_in"
   ```

3. Compile a MaxCompute program and debug it.
   - MaxCompute provides the Eclipse plug-in to help you quickly develop MapReduce programs and debug them on your local machine.
   - You need to create a MaxCompute project in Eclipse, and then compile a MapReduce program in this project. After successful local debugging, upload the compiled program to

MaxCompute for base testing.

> **Note** If the Java program requires the use of resources, you must use the -resources parameter to specify the resources.

1.4.11. Compile and run a Graph job

You can submit a Graph job in the same way that you would submit a MapReduce job. This topic provides an example of how to submit a Graph job.

Context

This example uses the SSSP algorithm. The operation procedure is as follows:

Procedure

1. Create input and output tables. Example:

```
create table sssp_in (v bigint, es string);
create table sssp_out (v bigint, l bigint);
```

> **Note** For more information about the table creation statement, see Create a table.

2. Use the data transfer tool to upload data. Example:

```
tunnel u -fd " " sssp.txt sssp_in;
```

3. Compile an SSSP.

> **Note** During the Graph development process, you can locally compile and debug SSSP algorithm examples. You only need to package the SSSP code. You do not need to package the SDK into *odps-graph-example-sssp.jar*.

4. Add JAR resources. Example:

```
add jar $LOCAL_JAR_PATH/odps-graph-example-sssp.jar odps-graph-example-sssp.jar
```

> **Note** For more information about how to add resources, see Add resources.

5. Run the SSSP. Example:

```
jar -libjars odps-graph-example-sssp.jar -classpath $LOCAL_JAR_PATH/odps-graph-example-sssp.
jar com.aliyun.odps.graph.examples.SSSP 1 sssp_in sssp_out;
```

> **Note**
>
> The MaxCompute client provides a jar command to run MaxCompute Graph jobs. This command is used in the same way as you would use the jar command in MapReduce. The Graph job execution command outputs the job instance ID, execution progress, and result summary. The command output is as follows:
>
> ID = 20170730160742915gl205u3 2017-07-31 00:18:36 SUCCESS
>
> Summary:

```
Graph Input/Output Total input bytes=211 Total input records=5 Total output bytes=161
Total output records=5 graph_input_[bsp.sssp_in]_bytes=211 graph_input_[bsp.sssp_in]_recor
ds=5 graph_output_[bsp.sssp_out]_bytes=161 graph_output_[bsp.sssp_out]_records=5 Graph

Total edges=14
Total halted vertices=5 Total sent messages=28 Total supersteps=4 Total vertices=5
Total workers=1 Graph Timers
Average superstep time (milliseconds)=7 Load time (milliseconds)=8
Max superstep time (milliseconds) =14 Max time superstep=0
Min superstep time (milliseconds)=5 Min time superstep=2
Setup time (milliseconds)=277 Shutdown time (milliseconds)=20
Total superstep time (milliseconds)=30 Total time (milliseconds)=344
OK
```

1.4.12. View job running information

This topic describes how to use the LogView tool to query job running information.

LogView is a tool used to view and debug tasks after a job is submitted to MaxCompute. You can use LogView to view the following content of a job:

- Running status of tasks
- Running results of tasks
- Details of each task and the progress of each step

After a job is submitted to MaxCompute, a link to LogView is generated. You can open the link in a browser to view the job running information.

```
odps@ test_workshop001>select * from result_test;

ID = 20190917055240226ga6e5mim
Log view:
http://logview.odps.aliyun.com/logview/?h=http://service.cn.maxcomp
m/api&p=test_workshop001&i=20190917055240226ga6e5mim&token=YkxhUzJQ

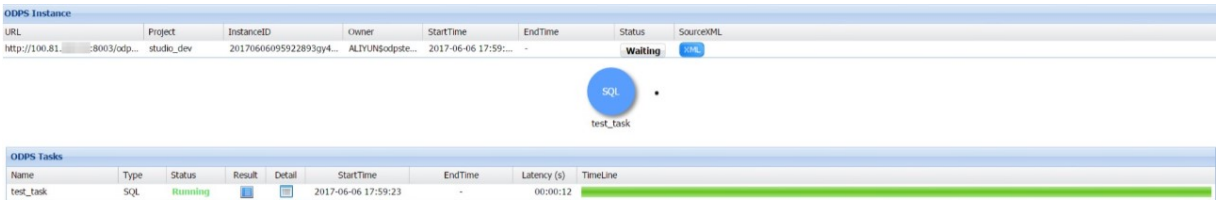
Job Queueing...
Summary:

+------------+------------+
| education  | num        |
+------------+------------+
```

Note The LogView page of each job is valid for seven days.

Features

This section describes components on the LogView Web UI.



The LogView page is composed of two parts:

- Instance information
- Task information

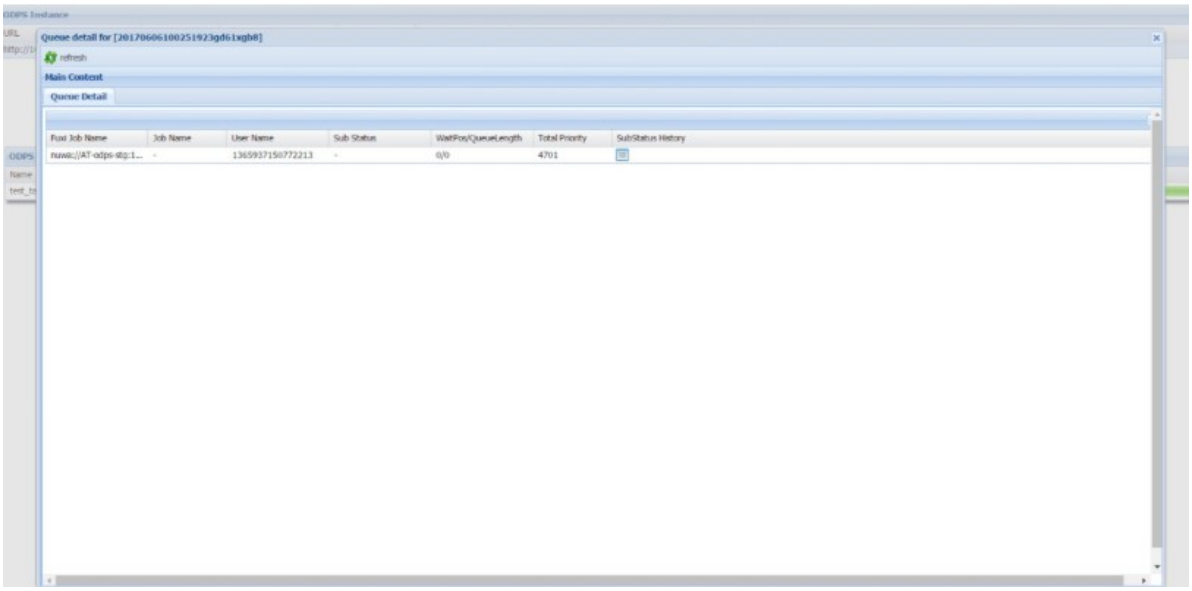
Instance information

The upper pane of the LogView page displays information about the MaxCompute instance corresponding to the SQL tasks that you submit, such as URL, Project, InstanceID, Owner, StartTime, EndTime, and Status.

- If the value of Status is one of the following states, you can click the value to view the queue information:
  - **Waiting**: The job is being processed in MaxCompute and has not been submitted to Job Scheduler.
  - **Waiting List: n**: The job has been submitted to Job Scheduler and is waiting to run in the queue with n-1 other jobs ahead of it.
  - **Running**: The job is running in Job Scheduler.

> **Note** If the value of Status is Terminated, the job has been terminated and has no queue information.

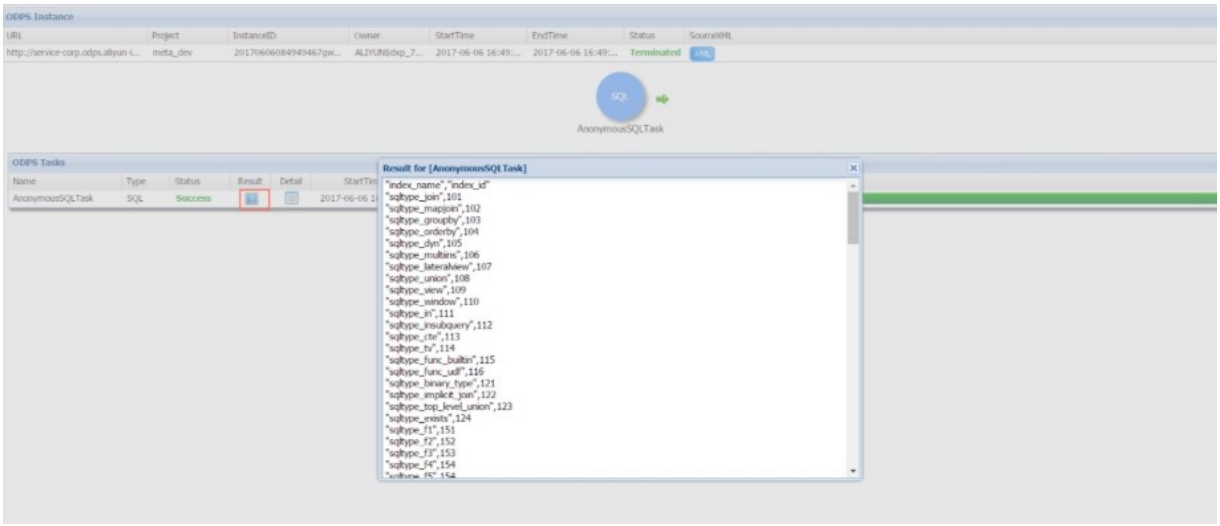
- After you click the value of Status, the following queue information is displayed:
  - **Sub Status**: the current sub-status information.
  - **WaitPos**: the position in the queue. If the value is 0, the job is running. If the value is -, the job has not been submitted to Job Scheduler.
  - **QueueLength**: the total queue length in Job Scheduler.
  - **Total Priority**: the running priority assigned by the system.
  - **SubStatus History**: You can click the icon in this column to view a detailed status history, such as the status code, status description, start time, and duration of a state. This information is unavailable in some versions.



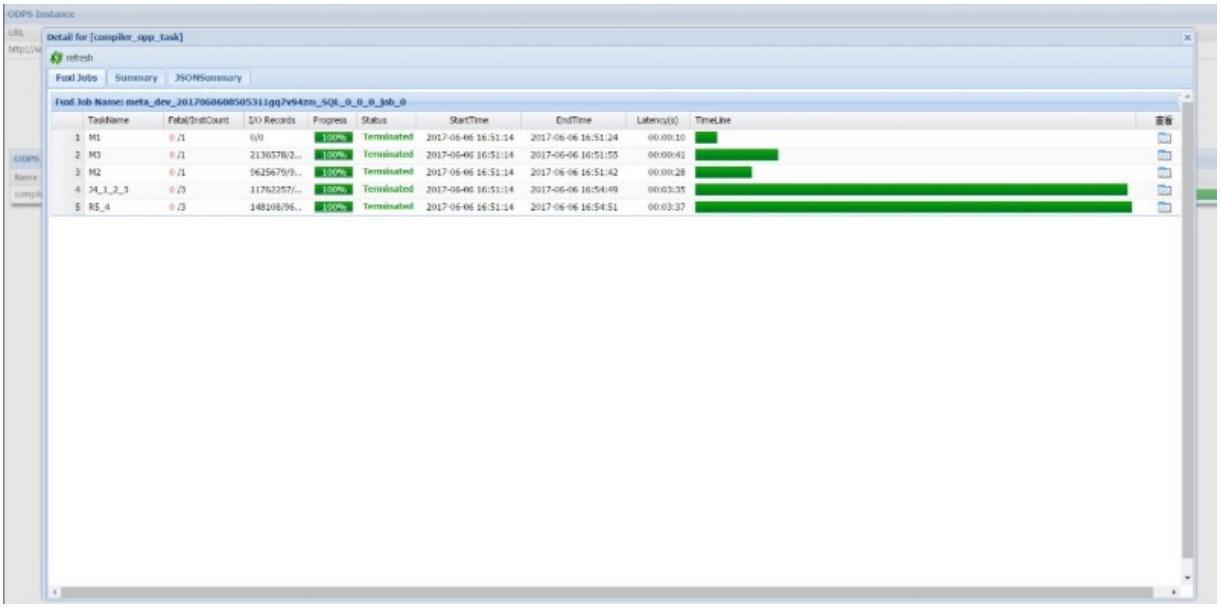
Task information

The lower pane of the LogView page displays the task information corresponding to the instance, such as Name, Type, Status, Result, Detail, StartTime, EndTime, Latency (s), and TimeLine. Like on other pages, latency indicates the total running duration.

Result: You can click the icon in this column to view the task running results after the job is finished. The following figure shows the execution results of a SELECT statement.



Detail: You can click the icon in the **Detail** column to view the task running details regardless of whether the job is running or finished.

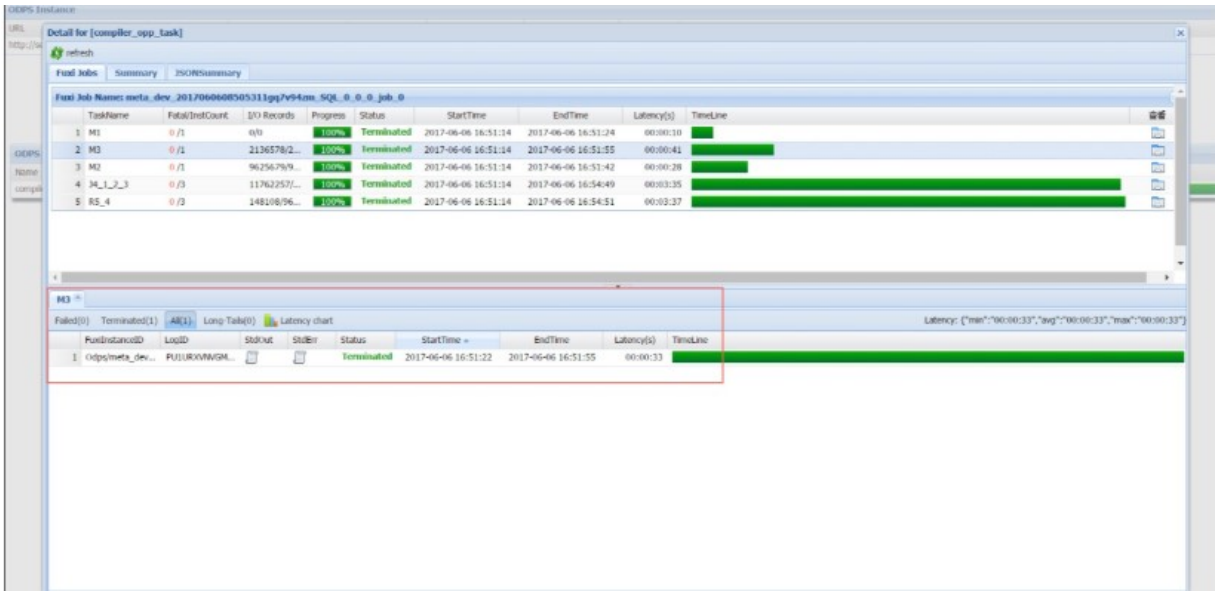


The details about a MaxCompute task are displayed in the detail dialog box. Pay attention to the following points:

- A MaxCompute task consists of one or more Fuxi jobs. For example, if an SQL task that you submit is complex, MaxCompute automatically submits multiple Fuxi jobs to Job Scheduler.
- Each Fuxi job consists of one or more Fuxi tasks. For example, a simple MapReduce task generates two Fuxi tasks: Map Task (M1) and Reduce Task (R2). A complex SQL task may also generate multiple Fuxi tasks.
- The name of a Fuxi task is composed of a letter that indicates the task type and one or more numbers that indicate the task number and its dependencies. For example, in the preceding figure, M1, M2, and M3 are Map tasks, J4_1_2_3 is a Join task that is started after M1, M2, and M3 are finished, and R5_4 is a Reduce task that is started after J4_1_2_3 is finished.
- I/O Records indicates the numbers of input and output records of a Fuxi task.

To view the information about the corresponding instances, you can click the icon in the Show Detail column corresponding to a Fuxi task or double-click the Fuxi task.

> **Note** Each Fuxi task consists of one or more Fuxi instances. As the number of input records of a Fuxi task increases, MaxCompute automatically starts more nodes to help the task process data. Each node corresponds to a Fuxi instance.



In the lower pane of the dialog box, information about the Fuxi instances is displayed in groups. For example, you can click the Failed tab to view the nodes where errors occurred. You can click the icon in the StdOut column to view the standard output information, or click the icon in the StdErr column to view the standard error information.

> **Note** Printed information written in the submitted MaxCompute task is also displayed in the standard output information and standard error information.

Use LogView for troubleshooting

- **Tasks with errors**

  If an error occurs during a task, you can click the icon in the Result column corresponding to the task in the lower pane of the LogView page to view the error information. Alternatively, you can click the icon in the StdErr column corresponding to a Fuxi instance in the detail dialog box to view the error information about the instance.

- **Data skew**

  The long tail of one or more Fuxi instances may slow down the corresponding Fuxi task. The long tail is caused by uneven data distribution in the task. After the task is completed, you can view the running results on the Summary tab of the detail dialog box. The following output provides an example of the running results.

  ```
  output records:
  R2_1_Stg1: 199998999  (min: 22552459, max: 177446540, avg: 99999499)
  ```

  If the difference between the min and max values is large, data skew occurs. For example, if a

specific value appears more often than other values in a column, data skew occurs when you execute a JOIN operation based on this field.

1.5. Basic concepts and common commands

1.5.1. Terms

This topic describes the basic terms of MaxCompute.

Project

A basic organizational unit of MaxCompute. Like a database or schema in a traditional database system, a project is the basic unit of multi-user isolation and access control. A user can have permissions on multiple projects. After security authorization, you can access objects such as tables, resources, functions, and instances in a project from another project.

You can run the Use Project command to access a project. Example:

```
use my_project
-- Access a project named my_project.
```

> **Note** After you run the preceding command, you are navigated to a project named my_project and gain permissions to manage objects in this project. You are then able to manage objects that belong to this project, regardless of which project you are currently in. The Use Project command is provided by the MaxCompute client. For more information, see Common commands.

Table

A data storage unit of MaxCompute. Logically, a table is a two-dimensional structure consisting of rows and columns, in which each row represents a record and each column represents a field of the same data type. One record can contain one or more columns. The column names and types constitute the schema of this table. All data in MaxCompute is stored in tables. Data in table columns can be any of the data types supported by MaxCompute. Tables are the input and output objects of all MaxCompute computing tasks. You can create and delete tables, or import data to tables.

Partitions of a table can be defined to process data more efficiently. You can specify some fields in the table as partition columns. Partitions within a table are similar to directories within a file system. Each value of a partition column is called a partition in MaxCompute. You can group multiple fields of a table to a single partition to create a multi-level partition. Multi-level partitions are similar to multi-level directories. If you specify the name of the partition that you want to access, MaxCompute only scans the specified partition. This improves processing efficiency and reduces cost. For more information, see Column and partition operations.

Data type

Columns of a MaxCompute table must be of a certain data type. MaxCompute supports the following data types:

Basic data types

Type	New in MaxCompute 2.0?	Constant	Description	Value range
TINYINT	Yes	1Y,-127Y	The 8-bit signed integer type.	-128 to 127
SMALLINT	Yes	32767S,-100S	The 16-bit signed integer type.	-32768 to 32767
INT	Yes	1000,-15645787	The 32-bit signed integer type.	-2^{31} to $2^{31}-1$
BIGINT	No	100000000000L,-1L	The 64-bit signed integer type.	$-2^{63}+1$ to $2^{63}-1$
STRING	No	abc, bcd, alibaba, inc	The UTF-8 coded string. The character behaviors of other codes are not defined.	The size of all values in a string column cannot exceed 8 MB.
FLOAT	Yes	None	The 32-bit binary floating point type.	/
BOOLEAN	No	True,False	The Boolean type.	True or False
DOUBLE	No	3.1415926 1E+7	The 64-bit binary floating point type.	$-1.0\ 10^{308}$ to $1.0\ 10^{308}$
DATETIME	No	Datetime '2017-11-11 00:00:00'	The date and time type. The standard system time is UTC+8.	0001-01-01 00:00:00 000 to 9999-12-31 23:59:59 999
DECIMAL	No	3.5BD, 99999999999.9999999BD	The precise numeric type based on the decimal system.	Integer: $-10^{36}+1$ to $10^{36}-1$ Fractional: round to 10^{-18}
VARCHAR	Yes	None	The variable-length type. n specifies the length.	1 to 65535
BINARY	Yes	None	The binary data type.	A single binary column cannot exceed 8 MB.

Type	New in MaxCompute 2.0?	Constant	Description	Value range
TIMESTAMP	Yes	Timestamp '2017-11-11 00:00:00.123456789'	The timestamp type. This type is not time zone specific.	0001-01-01 00:00:00 000000000 to 9999-12-31 23:59:59 999999999

Note that if you want to use the new data types in MaxCompute 2.0, you must first execute the following statement to enable the new data type flag: `set odps.sql.type.system.odps2=true;` (at the session level) or `setproject odps.sql.type.system.odps2=true;` (at the project level). Otherwise, the following error may occur: `xxxx type is not enabled in current mode`. The data types listed in the preceding table can be NULL.

Note Only lowercase letters can be used in the preceding statements.

Notice

Note the following points when you use the new data types in MaxCompute 2.0:

- After you execute the `set odps.sql.type.system.odps2=true;` statement, it results in the following major impacts:
  - The semantics of the INT keyword change. INT in an SQL statement indicates a 32-bit integer.
  - The semantics of an integer constant change. Take the `SELECT 1 + a;` statement as an example.
    - If the new data type flag is not enabled, the integer constant is processed as BIGINT. If the length of the constant exceeds the range for a BIGINT value, the integer constant is processed as DOUBLE.
    - If the new data type flag is enabled, the integer constant is 1 of the 32-bit INT type.
    - Possible compatibility issues: The INT type may lead to inconsistencies in function prototypes during subsequent operations. For example, the actions of peripheral tools and subsequent operations might be changed by new type tables generated after data is written to a disk.
  - Implicit type conversion rules change.

    If the new data type flag is enabled, some implicit types may not be converted. For example, errors may occur or precision may be reduced when the data type is converted from STRING to BIGINT, from STRING to DATETIME, from DOUBLE to BIGINT, from DECIMAL to DOUBLE, or from DECIMAL to BIGINT. In these cases you can use the CAST function to convert the data type.

    Implicit type conversion greatly affects functions and INSERT statements. For example, an INSERT statement can be executed when the new data type flag is disabled, but returns an error when the flag is enabled.

- When the new data type flag is disabled, some operations and built-in functions that use new data types as parameters and response values are ignored. When the new data type flag is enabled, they become valid.
  - Some built-in functions can only be used after the new data type flag is enabled. This includes most functions that use INT type parameters and subsequently suffer from BIGINT overload, such as YEAR, QUARTER, MONTH, DAY, HOUR, MINUTE, SECOND, MILLISECOND, NANOSECOND, DAYOFMONTH, and WEEKOFYEAR. These functions can be implemented by using the DATEPART function.
  - UDF resolution changes.
- The resolution of the BIGINT keyword changes.
- The partition column types change.
  - If the new data type flag is disabled, the partition column type can only be STRING.
  - If the new data type flag is enabled, the partition column type can be STRING, VARCHAR, CHAR, TINYINT, SMALLINT, INT, or BIGINT.
  - If the new data type flag is disabled, partition fields in INSERT operations are processed as STRING.
- The behavior of the LIMIT statement changes.

  Take the `SELECT * FROM t1 UNION ALL SELECT * FROM t2 limit 10;` statement as an example.
  - If the new data type flag is disabled, it is `SELECT * FROM t1 UNION ALL SELECT * FROM ( SELECT * FROM t2 limit 10) t2;` .
  - If the new data type flag is enabled, it is `SELECT * FROM (SELECT * FROM t1 UNION ALL SELECT * FROM t2 ) t limit 10;` .

  Actions of the UNION, INTERSECT, EXCEPT, LIMIT, ORDER BY, DISTRIBUTE BY, SORT BY, and CLUSTER BY statements also change if the new data type flag is enabled.
- The resolution of the IN expression changes.

  Take the a in (1, 2, 3) expression as an example.
  - If the new data type flag is disabled, all the values in the parentheses () must be of the same type.
  - If the new data type flag is enabled, all the values in the parentheses () are implicitly converted to the same type.

- If the value of a constant is greater than the maximum value of INT but less than the maximum value of BIGINT, it is converted to BIGINT. If the constant is greater than the maximum value of BIGINT, it is converted to DOUBLE. If odps.sql.type.system.odps2 is not set to true, MaxCompute retains the conversion and notifies you that the INT data is being processed as the BIGINT type. If odps.sql.type.system.odps2 is not set to true, we recommend that you change these types to BIGINT to prevent confusion.
- VARCHAR constants can be expressed through implicitly converted STRING constants.
- STRING constants can be combined. For example, abc and xyz can be combined as

abcxyz. Different parts can be written in different rows.

- Time values in milliseconds cannot be displayed. You can add `-dfp` in the Tunnel command to specify the time display format in milliseconds.

MaxCompute supports complex data types. The following table lists their definitions and constructors.

Complex data types

Type	Definition	Constructor
Array	array< int >; array< struct< a:int, b:string >>	array(1, 2, 3); array(array(1, 2); array(3, 4))
Map	map< string, string >; map< smallint, array< string>>	map("k1", "v1","k2", "v2"); map(1S, array('a', 'b'), 2S, array('x', 'y'))
Struct	struct< x:int, y:int>; struct< field1:bigint, field2:array< int>, field3:map< int, int>>	named_struct('x', 1, 'y', 2); named_struct('field1', 100L, 'field2', array(1, 2), 'field3', map(1, 100, 2, 200)

If PyODPS is used, you can use the following methods to enable the new data type flag:

- You can execute `o.execute_ SQL ('set ODPS. SQL .type.system.odps2=true;query_ SQL ', hints={" ODPS. SQL .submit.mode": "script"})` to enable the new data type flag.
- You can enable the new data type flag by using DataFrame. For example, use an immediately executed action, such as persist, execute, or to_pandas, by setting the hints parameter. The setting in the following figure is valid only for a single job.

```
from odps.df import DataFrame
users = DataFrame(o.get_table('odps2_test'))
users.persist('copy_test',hints={'odps.sql.type.system.odps2':'true'})
```

- To enable the new data type flag by using DataFrame and have the setting take effect globally, you need to execute `options.sql.use_odps2_extension = True`.

Resource

A concept used in MaxCompute. To accomplish tasks by using user-defined functions (UDFs) or MapReduce, you must use resources.

- MaxCompute SQL UDF: After you write a UDF, you must compile it as a JAR package and upload the package to MaxCompute as a resource. When you run the UDF, MaxCompute automatically downloads the JAR package and obtains the code to run this UDF. JAR packages are a type of

MaxCompute resource. When you upload a JAR package, a resource is created in MaxCompute.

- MaxCompute MapReduce: After you write a MapReduce program, you must compile it as a JAR package and upload the package to MaxCompute as a resource. When you run a MapReduce job, the MapReduce framework automatically downloads the JAR package and obtains the code to run this MapReduce job.

  > Note
  > - There are some limits on how MaxCompute UDFs and MapReduce access resources. For more information, see Limits.
  > - You can also upload tables or text files to MaxCompute as different types of resources. You can read or use these resources when you run UDFs or MapReduce jobs. MaxCompute provides APIs for you to read and use resources. For more information, see the examples for resource use and UDTF instructions.

MaxCompute supports the following resource types:

- File
- Table: tables in MaxCompute.
- JAR: compiled JAR packages.
- Archive: compressed files identified by the resource name extension. Supported file types include .zip, .tgz, .tar.gz, .tar, and .jar.
- Py: Python scripts used by Python UDFs.

> Note For more information about resource operations, see Resource operations.

UDF

MaxCompute provides SQL computing capabilities. You can use the built-in functions in MaxCompute SQL statements to implement certain computing or counting functions. If these built-in functions do not meet your requirements, you can use the Java APIs provided by MaxCompute to develop UDFs. UDFs are classified into user-defined scalar functions (UDSFs), user-defined aggregate functions (UDAFs), and user-defined table-valued functions (UDTFs).

After you write the UDF code, you need to compile the code into a JAR package, upload it to MaxCompute as a resource, and register this UDF in MaxCompute. To use a UDF in MaxCompute, you only need to specify its name and parameters in an SQL statement as you do when you use the built-in functions of MaxCompute.

> Note For more information about UDF operations, see Function operations.

Task

A basic computing unit of MaxCompute. Both SQL and MapReduce features are implemented as tasks. MaxCompute parses most of the tasks that you submit, such as SQL DML statements and MapReduce tasks. MaxCompute generates a task execution plan based on the parsing results.

An execution plan consists of several mutually dependent stages. An execution plan can be logically defined as a directed graph. Vertices of the graph represent stages, and edges of the graph represent dependencies between stages. MaxCompute executes stages based on the dependencies in the graph (execution plan). A stage has multiple processes, also known as workers. The workers in each stage cooperate to complete computations for the stage. Different workers in a stage process different data, but they all use the same execution logic.

A computing task converts to an instance when it is executed. You can perform operations on this instance, such as obtaining status information and killing the instance.

Some MaxCompute tasks, such as SQL DDL statements, are not computing tasks. These tasks only need to read and modify metadata in MaxCompute. MaxCompute does not generate execution plans for these tasks.

> **Notice** MaxCompute does not convert all requests to tasks. For example, project, resource, UDF, and instance operations are not executed as tasks.

Task instance

Some MaxCompute tasks are converted to instances during the execution process. An instance has two stages: Running and Terminated. Instances that are in the Running stage are also in the Running state, while instances that are in the Terminated stage can be in the Success, Failed, or Canceled state. You can query or modify the status of a running task by using the instance ID provided by MaxCompute. Example:

```
status <instance_id>;
-- Query the status of an instance.
kill <instance_id>;
-- Terminate an instance and change its status to Canceled.
```

Resource quota

There are two types of resource quota: storage and computing. The storage quota is the upper limit of storage space configured for a project. If the storage usage approaches the storage quota, an alert is triggered. The computing quota limits the use of memory and CPU resources. The memory and CPUs used to run processes in a project cannot exceed the computing quota.

1.5.2. Common commands

1.5.2.1. Introduction

MaxCompute allows you to perform operations on objects, such as projects, tables, resources, and instances. You can use client commands or the SDK to perform operations on these objects.

This topic describes how to run these commands in the MaxCompute client.

> **Note**
>
> - For more information about how to install and configure the client, see Configure the client.
> - For more information about the SDK, see SDK introduction.

1.5.2.2. Project operations

This topic describes common project commands.

Create or delete a project

MaxCompute does not provide commands for creating or deleting projects. You can configure or operate your projects on the console.

Access a project

Command syntax:

```
use <project_name>;
```

Purpose: It is used to access the specified project. After you enter a project, you can directly operate all objects in the project.

> **Note** If the specified project does not exist or you have not been added to the project, the system returns an exception and exits.

Example:

```
odps@ myproject> use my_project;
-- my_project is a project that you have permission to access.
```

Note

- The preceding command runs in the client.
- All command keywords, project names, table names, and column names in MaxCompute are case-insensitive.
- After you run the command, you can directly access objects in this project. Example:

  Run the following command to access the test_src table in the my_project project (assume test_src exists in my_project):

  ```
  odps@ myproject>select * from test_src;
  ```

  MaxCompute automatically searches for the table from my_project. If this table exists, its data is returned. Otherwise, the system returns an exception and exits.

  If you are in my_project and want to access the test_src table in my_project2, you must specify the project name. Run the following command to access test_src in my_project2:

  ```
  odps@ myproject>select * from my_project2.test_src;
  ```

  Data of test_src in my_project2, not my_project, is returned.

View projects

Command syntax:

```
list projects;
```

Purpose: It is used to display all projects in MaxCompute.

Clear objects from a project

Run the following command to view objects in the recycle bin:

```
show recyclebin;
```

Purpose: It is used to list all objects in the project recycle bin.

Note Only the project owner can run this command.

Run the following command to clear all objects from the project recycle bin:

```
purge all;
```

Purpose: It is used to clear all objects from the project recycle bin to release storage space.

Note Only the project owner can run this command.

Run the following command to clear a table:

```
purge table tblname;
```

Purpose: It is used to clear all objects in a specified table from the recycle bin to release the storage space.

> Note
> - If the specified table exists, the project owner and users who have write permissions on the table can run this command.
> - If the table has been deleted using a DROP command, only the project owner can run this command.

1.5.2.3. Table operations

This topic describes common commands for table operations.

Create a table (CREATE TABLE)

Syntax

```
CREATE TABLE [IF NOT EXISTS] table_name
[(col_name data_type [COMMENT col_comment], ...)] [COMMENT table_comment]
[PARTITIONED BY (col_name data_type [COMMENT col_comment], ...)] [LIFECYCLE days]
[AS select_statement];
CREATE TABLE [IF NOT EXISTS] table_name
LIKE existing_table_name;
```

Description: Creates a table.

Example

```
CREATE TABLE IF NOT EXISTS sale_detail( shop_name STRING,
customer_id STRING, total_price DOUBLE)
PARTITIONED BY (sale_date STRING,region STRING);
-- If a table named sale_detail does not exist, a partitioned table with this name is created.
```

> Note
> - Table names and column names are not case-sensitive.
> - A table name or column name can contain only letters, digits, and underscores (_) and must start with a letter. It cannot exceed 128 bytes in length.
> - A comment must be a valid string within 1,024 bytes. Otherwise, an error is returned.
> - For more information about the command, see Create a table.

Change the owner of a table (CHANGEOWNER)

Syntax

```
ALTER TABLE table_name CHANGEOWNER to new_owner;
```

Description: Changes the owner of a table.

Example

```
ALTER TABLE test1 CHANGEOWNER to 'ALIYUN$xxx@aliyun.com';
-- Change the owner of table test1 to ALIYUN$xxx@aliyun.com.
```

Delete a table (DROP TABLE)

Syntax

```
DROP TABLE [IF EXISTS] table_name;
```

Description: Deletes a table.

> **Note** If a command without the IF EXISTS option is executed and the table does not exist, an exception is returned. If a command with this option is executed, a success is returned regardless of whether the table exists.

Parameters

table_name: the name of the table you want to delete.

Example

```
DROP TABLE sale_detail;
-- If the sale_detail table exists, a success is returned.
DROP TABLE IF EXISTS sale_detail;
-- A success is returned regardless of whether the sale_detail table exists.
```

View table information (DESC)

Syntax

```
DESC <table_name>;
-- View information about a table or view.
DESC extended <table_name>;
-- View information about an external table.
```

Description: Returns the information about a specified table. The returned information includes Owner, Project, CreateTime, LastDDLTime, LastModifiedTime, InternalTable (indicates that the object is a table. The value is always YES), Size (table size in bytes), Native Columns (information about non-partition columns, including field, type, and comment), Partition Columns (information about partition columns, including partition name, type, and comment), and Extended Info (information about the external table, such as StorageHandler and Location).

Parameters

table_name: In the first command, it indicates the name of a table or view. In the second command, it indicates the name of an external table.

Example

```
odps@ project_name>DESC sale_detail;
-- Describe a partitioned table.
+------------------------------------------------------------------------------------+
| Owner: ALIYUN$odpsuser@aliyun.com | Project: test_project |
|TableComment: |
+------------------------------------------------------------------------------------+
|CreateTime: 2017-01-01 17:32:13 |
|LastDDLTime: 2017-01-01 17:57:38 |
|LastModifiedTime: 2017-01-01 18:00:00 |
+------------------------------------------------------------------------------------+
|InternalTable: YES | Size: 0 |
+------------------------------------------------------------------------------------+
|Native Columns: |
+------------------------------------------------------------------------------------+
|Field | Type | Comment |
+------------------------------------------------------------------------------------+
|shop_name | string | |
|customer_id | string | |
|total_price | double | |
+------------------------------------------------------------------------------------+
|Partition Columns: |
+------------------------------------------------------------------------------------+
|sale_date | string | |
|region | string | |
+------------------------------------------------------------------------------------+
```

Note

- The preceding command is executed in the MaxCompute client.
- If the described object is a non-partitioned table, the Partition Columns field is not displayed.
- If the described object is a view, the InternalTable field is replaced with VirtualView whose value is always YES, and the Size field is replaced with ViewText, which defines View, such as select * > from src. For more information about views, see Create a view.

View partition information (DESC)

Syntax

```
desc table_name partition(pt_spec);
```

Description: Views the partition information of a partitioned table.

Example

```
odps@ project_name>desc meta.m_security_users partition (ds='20151010');
+------------------------------------------------------------------------------------+
| PartitionSize: 2109112                                                             |
+------------------------------------------------------------------------------------+
| CreateTime:           2015-10-10 08:48:48                                          |
| LastDDLTime:           2015-10-10 08:48:48                                         |
| LastModifiedTime:       2015-10-11 01:33:35                                        |
+------------------------------------------------------------------------------------+
OK
```

Show tables (SHOW TABLES/SHOW TABLES LIKE)

Syntax

```
SHOW TABLES;
SHOW TABLES like 'chart'
```

Description

- **SHOW TABLES**: shows all tables in the current project.
- **SHOW TABLES like 'chart'**: shows the tables whose name matches chart in the current project. You can use regular expressions in the command to filter tables.

Example

```
odps@ project_name>show tables;
odps@ project_name>show tables like 'ods_brand*';
ALIYUN$odps_user@aliyun.com:table_name
.....
```

Note

- The preceding commands are executed in the MaxCompute client.
- odps_user@aliyun.com indicates the name of the user who creates the table.
- table_name indicates the table name.

Show partitions (SHOW PARTITIONS)

Syntax

```
SHOW PARTITIONS <table_name>;
```

Description: Lists all partitions of a table.

Parameters

table_name: the name of the table that you query. An error is returned if the table does not exist or is a non-partitioned table.

Example

```
SHOW PARTITIONS table_name;
partition_col1=col1_value1/partition_col2=col2_value1
partition_col1=col1_value2/partition_col2=col2_value2
```

Note

- The preceding command is executed in the MaxCompute client.
- partition_col1 and partition_col2 indicate the partition columns of the table.
- col1_value1, col2_value1, col1_value2, and col2_value2 indicate the values in the matching columns.

1.5.2.4. Instance operations

This topic describes common commands for instance operations.

Show instances (SHOW INSTANCES/SHOW P)

Syntax

```
SHOW INSTANCES [FROM startdate TO enddate] [number];
SHOW P [FROM startdate TO enddate] [number];
SHOW INSTANCES [-all];
SHOW P [-all];
SHOW P -p <project name>;
```

Description: Shows information about instances that you have created.

Parameters

- **startdate To enddate**: a period of time. Information about the instances created within the specified period is returned. The dates must be in the format of yyyy-mm-dd. This parameter is optional. If it is not specified, information about instances that you have created in the last three days is returned.
- **number**: the number of instances to be returned. Information about the specified number of instances submitted at the time nearest to the current time is returned in chronological order. If this parameter is not specified, information about all instances that meet the requirements is returned.
- **-all**: Information about instances executed in the current project is returned. By default, a maximum of 50 instances can be returned. You can run the command only when you have the LIST permission on the current project. To return more than 50 instances, you must use the -limit number option. For example, you can run the show p -all -limit 100 command to return information about 100 instances executed in the current project.
- **project name**: the project name. The account that you use must be a member of the project.

Output fields include StartTime (in seconds), RunTime (in seconds), Status (instance status), instanceID, and the SQL statement corresponding to the instance. The following code provides an example of the command output:

```
odps@ $project_name>show p;
StartTime          RunTime  Status   InstanceID              Owner      Query
2015-04-28 13:57:55   1s      Success  20150428xxxxxxxxxxxxxxxxxx   ALIYUN$xxxxx@aliyun-inner.com
select * from tab_pack_priv limit 20;
...    ...    ...    ...    ...    ...
...    ...    ...    ...    ...    ...
```

An instance can be in any of the following states:

- **Running**
- **Success**
- **Waiting**
- **Failed**: The job failed, but data in the target table is not modified.
- **Suspended**
- **Cancelled**

View the status of an instance (STATUS)

Syntax

```
STATUS <instance_id>;
```

Description: Views the status of a specified instance, which can be Success, Failed, Running, or Canceled.

> Note If the instance was not created by you, an exception is returned.

Parameters

instance_id: the unique identifier of an instance. It specifies the instance whose status is queried.

Example

```
odps@ $project_name>status 20131225123xxxxxxxxxxxxxxx;
Success
-- Query the status of the instance whose ID is 20131225123xxxxxxxxxxxxxxx. The query result is Succe
ss.
```

> Note The preceding command is run in the MaxCompute client.

Show running jobs (TOP INSTANCE)

Syntax

```
top instance;
top instance -all;
```

> Note Only the project owner and administrator can use the command.

Description

- top instance: obtains information about running jobs that you submit in the current project. The output fields include InstanceID, Owner, Type, StartTime, Progress, Status, Priority, RuntimeUsage (CPU/MEM), TotalUsage (CPU/MEM), and QueueingInfo (POS/LEN).
- top instance -all: obtains information about all running jobs in the current project. By default, a maximum of 50 jobs are returned. To return more records, use the -limit number option.

Example

```
odps@ $project_name>top instance;
```

> Note The preceding command is run in the MaxCompute client.

Stop an instance (KILL)

Syntax

```
kill <instance_id>;
```

Description: Stops an instance. You can only stop an instance in the Running state. Note that this is an abnormal process. A return from the command only means that the system has received the request. It does not mean that the job has been stopped. Therefore, you must run the STATUS command to view the instance status.

Parameters

instance_id: the unique identifier of an instance. It must be the ID of a running instance. Otherwise, an error is returned.

Example

```
odps@ $project_name>kill 20131225123xxxxxxxxxxxxxxx;
-- Stop the instance whose ID is 20131225123xxxxxxxxxxxxxxx.
```

> **Note** The preceding command is run in the MaxCompute client.

Describe an instance (DESC INSTANCE)

Syntax

```
desc instance <instance_id>;
```

Description: Obtains information about the job corresponding to an instance. The obtained information includes the SQL statement, owner, start time, end time, and status.

Parameters

instance_id: the unique identifier of an instance.

Example

```
odps@ $project_name> desc instance 20150715xxxxxxxxxxxxxxx;
ID                          20150715xxxxxxxxxxxxxxx
Owner                       ALIYUN$XXXXXX@alibaba-inc.com
StartTime                   2015-07-15 18:34:41
EndTime                     2015-07-15 18:34:42
Status                      Terminated
console_select_query_task_1436956481295 Success
Query                       select * from mj_test;
-- Query information about the job corresponding to the instance whose ID is 20150715xxxxxxxxxxxxxxx
xx.
```

> **Note** The preceding command is run in the MaxCompute client.

Obtain task operation log information (WAIT)

Syntax

```
wait instance_id;
```

Description: Obtains task operation log information based on an instance ID. The returned information includes a link to LogView. You can view log details by using the link.

Parameters

instance_id: the unique identifier of an instance.

Example

```
wait 20170925161122379gxxxxxx;
ID = 20170925161122379g3xxxxxx
Log view:
http://logview.odps.aliyun.com/logview/?h=http://service.odps.aliyun.com/api&p=alian&i=2017092516
11223xxxxxxdqp&token=XXXXXXvbiI6IjEifQ==
Job Queueing...
Summary:
resource cost: cpu 0.05 Core * Min, memory 0.05 GB * Min
inputs:
    alian.bank_data: 41187 (588232 bytes)
outputs:

    output records:
        TableSink_REL5213309: 8  (min: 8, max: 8, avg: 8)
-- Query the task operation logs of the instance whose ID is 20170925161122379gxxxxxx.
```

Note The preceding command is run in the MaxCompute client.

1.5.2.5. Resource operations

This topic describes common commands for resource operations.

Add a resource (ADD FILE/ARCHIVE/TABLE/JAR/PY)

Syntax

```
add file <local_file> [as alias] [comment 'cmt'][-f];
add archive <local_file> [as alias] [comment 'cmt'][-f];
add table <table_name> [partition <(spec)>] [as alias] [comment 'cmt'][-f];
add jar <local_file.jar> [comment 'cmt'][-f];
add py <local_file.py> [comment 'cmt'][-f];
```

Description: Adds resources to MaxCompute.

The following table lists parameters in this command.

Parameters

Parameter	Description
file/archive/table/jar/py	Indicates the resource type. For more information about resource types, see Resource in Terms.
local_file	Indicates the path of a local file. The file name is used as the resource name, which uniquely identifies the resource.
table_name	Indicates the name of a table in MaxCompute.
[PARTITION (spec)]	If the resource that is added is a partitioned table, MaxCompute only takes a partition as a resource, as opposed to the whole partitioned table.
alias	Indicates the resource name. If this parameter is not specified, the file name is used as the resource name. JAR and Py resources do not support this parameter.
[comment 'cmt']	Indicates a comment on the resource.
[-f]	If a resource with the same name exists, this operation overwrites the existing resource. If this option is not specified and a resource with the same name exists, the operation fails.

Example

```
odps@ odps_public_dev>add table sale_detail partition (ds='20170602') as sale.res comment 'sale deta
il on 201706 02' -f;
OK: Resource 'sale.res' have been updated.
-- Add a table resource with alias sale.res to MaxCompute.
```

> **Note** The size of each resource file cannot exceed 500 MB. The total size of resources referenced by a single SQL or MapReduce task cannot exceed 2,048 MB.

Delete a resource (DROP RESOURCE)

Syntax

```
DROP RESOURCE <resource_name>;
```

Description: Deletes an existing resource.

Parameters

resource_name: the name of the resource to be deleted. It is specified when the resource is created.

View the resource list (LIST RESOURCES)

Syntax

```
LIST RESOURCES;
```

Description: Lists all resources in the current project.

Example

```
odps@ $project_name>list resources;
Resource Name     Comment     Last Modified Time      Type
1234.txt                  2014-02-27 07:07:56     file
mapred.jar                2014-02-27 07:07:57     jar
```

Download a resource (GET RESOURCE)

Syntax

```
GET RESOURCE <resource_name> <path>;
```

Description: Downloads a resource from MaxCompute to a local device. You can download file, JAR, archive, and Py resources, but not table resources.

Parameters

- **resource_name**: the name of the resource to be downloaded.
- **path**: the local path to save the resource.

Example

```
odps@ $project_name>get resource odps-udf-examples.jar d:\;
OK
```

1.5.2.6. Function operations

This topic describes common commands for function operations.

Register a function (CREATE FUNCTION)

Syntax

```
CREATE FUNCTION <function_name> AS <package_to_class> USING<resource_list>;
```

The following table lists parameters in this command.

Parameters

Parameter	Description
function_name	Indicates the UDF name. This name is used in SQL statements to reference this function.
package_to_class	For a Java UDF, package_to_class indicates a fully qualified class name. It consists of names from the top-level package name all the way to the UDF implementation class name, which are separated with periods (.). For a Python UDF, package_to_class indicates the Python script name and class name, which are separated with periods (.). This name must be enclosed in a pair of single quotation marks (').
resource_list	Indicates the list of resources that the UDF uses. The list must include the resource where the UDF code is located. Ensure that the resource is uploaded to MaxCompute before you register the function. If the user code reads resource files by using the distributed cache API, this list must also include all resource files that are read by the UDF. If the resource list contains multiple resources, separate them with commas (,). The resource list must be enclosed in a pair of single quotation marks ('). If you need to specify the project where the resource is located, use the <project_name>/resources/<resource_name> format.

Example

- Assume that Java UDF class org.alidata.odps.udf.examples.Lower is in my_lower.jar. Execute the following statement to create the my_lower function:

```
CREATE FUNCTION my_lower AS 'org.alidata.odps.udf.examples.Lower'
USING 'my_lower.jar';
```

- Assume that Python UDF class MyLower is in the pyudf_test.py script of the test_project project. Execute the following statement to create the my_lower function:

```
create function my_lower as 'pyudf_test.MyLower'
using 'pyudf_test.py';
```

- Assume that Java UDF class com.aliyun.odps.examples.udf.UDTFResource is in udtfexample1.jar and the function depends on file resource file_resource.txt, table resource table_resource1, and archive resource test_archive.zip. Execute the following statement to create the test_udtf function:

```
create function test_udtf as 'com.aliyun.odps.examples.udf.UDTFResource'
using 'udtfexample1.jar, file_resource.txt, table_resource1,test_archive.zip';
```

> Note
> - Similar to resource file names, function names must be unique.
> - Only the project owner has the permission to use UDFs to overwrite built-in functions. If you use a UDF that overwrites a built-in function, warning information is included in Summary after the SQL statement is executed.

Delete a function (DROP FUNCTION)

Syntax

```
DROP FUNCTION <function_name>;
```

Parameters

function_name: the name of the function you want to delete.

Example

```
DROP FUNCTION test_lower;
```

View the function list (LIST FUNCTIONS)

Syntax

```
LIST FUNCTIONS;
-- View all UDFs in the current project.
LIST FUNCTIONS -p project_name;
-- View all UDFs in a specified project.
```

1.5.2.7. Time zone configuration operations

This topic describes how to use a SET command to configure the time zone of a MaxCompute project.

Time zone configurations

By default, the time zone of a MaxCompute project is UTC+8. The DATETIME, TIMESTAMP, and DATE fields and the related built-in time functions are all calculated based on UTC+8. You can use one of the following methods to configure the time zone:

- **Session level:** Submit the set odps.sql.timezone=<timezoneid>; statement along with a computing statement for execution. Example:

```
set odps.sql.timezone=Asia/Tokyo;
-- Set the time zone to Asia/Tokyo.
select getdate();
-- Query the current time zone.
output:
+------------+
| _c0        |
+------------+
| 2018-10-30 23:49:50 |
+------------+
```

- **Project level:** Execute the setProject odps.sql.timezone=<timezoneid>; statement. Only the project owner has the permission to execute this statement.

> **Notice** After the time zone is set at the project level, it is used in all computing tasks that are time related. The data of existing tasks are also affected. Therefore, set the time zone only when it is absolutely necessary. We recommend that you only set time zones for new projects.

Limits and precautions

- SQL built-in date functions, UDFs, UDTs, UDJs, and the SELECT TRANSFORM statement all support time zone configuration at the project level.
- A time zone must be configured in the format such as Asia/Shanghai, which supports daylight saving time. Do not configure it in the GMT+9 format.
- If the time zone of the SDK differs from that of the project, you must configure the GMT time zone to convert the data type from DATETIME to STRING.
- After you configure the time zone, the output time may be different from the real time when you run the related SQL statements by using DataWorks. For data that is between the years 1900 and 1928, the time difference is 352 seconds. For data that is before the year 1900, the time difference is 9 seconds.
- New versions of MaxCompute, Java SDK, and the related console are provided to ensure that the DATETIME data stored in MaxCompute is correct in multiple time zones. The target Java SDK and console versions have the -oversea suffix. The upgrade may affect the display of the DATETIME data that is before January 1, 1928 in MaxCompute.
- If the local time zone is not UTC+8, we recommend that you upgrade the Java SDK and console to ensure that the SQL-based computing results and data transferred using Tunnel after January 1, 1900 are accurate and consistent. After the upgrade, for the DATETIME data before January 1, 1900, the SQL-based computing results and data transferred using Tunnel may still have a difference of 343 seconds. For the DATETIME data between January 1, 1900 and January 1, 1928 uploaded before the upgrade, the time in the new version is 352 seconds earlier.
- If you do not upgrade the Java SDK and console to the version with the -oversea suffix, the SQL-based computing results and data transferred using Tunnel will have differences. For data before January 1, 1900, the time difference is 9 seconds. For data between January 1, 1900

and January 1, 1928, the time difference is 352 seconds.

> **Note** The time zone of the upgraded Java SDK or console version does not affect the time zone configuration in DataWorks. Therefore, the time zones may vary. You must evaluate the impact on scheduled tasks in DataWorks.

- If you use a third-party client that is connected to MaxCompute by using JDBC, you must set the time zone on the client to ensure the time consistency between the client and the server.
- MapReduce supports time zone configuration.
- Spark supports time zone configuration.
  - If tasks are submitted to the MaxCompute computing cluster, the time zone of the project can be automatically obtained.
  - If tasks are submitted from spark-shell, spark-sql, or pyspark in yarn-client mode, you must configure the spark-defaults.conf parameter of the driver and add the spark.driver.extraJavaOptions -Duser.timezone=America/Los_Angeles statement. The timezone parameter in the preceding statement indicates the time zone to be used.
- PAI supports time zone configuration.
- Graph supports time zone configuration.

1.5.2.8. Tunnel operations

This topic describes common commands for Tunnel operations.

Features

- **UPLOAD**: uploads files or directories (level-1 directories). Data can be uploaded only to a table or a partition of a table. For a partitioned table, you must specify the partition where data is upload.

```
tunnel upload log.txt test_project.test_table/p1="b1",p2="b2";
tunnel upload log.txt test_table --scan=only;
```

- **DOWNLOAD**: downloads a table or partition to a single file. For a partitioned table, specify the partition to be downloaded.

```
tunnel download test_project.test_table/p1="b1",p2="b2" log.txt;
```

- **RESUME**: resumes the transfer of files or directories after a network or Tunnel service error occurs. Dship supports resumable data transfer.

```
tunnel resume;
```

- **SHOW**: displays historical task information.

```
tunnel show history -n 5
tunnel show log
```

- **PURGE**: clears the session directory. Sessions within the past three days are purged by default.

```
tunnel purge 5
```

Use of Tunnel commands

Tunnel commands allows you to obtain help information by using the Help subcommand on the client. Each command and option support short command format:

```
odps@ project_name>tunnel help;
Usage: tunnel <subcommand> [options] [args]
Type 'tunnel help <subcommand>' for help on a specific subcommand.

Available subcommands:
   upload (u)
   download (d)
   resume (r)
   show (s)
   purge (p)
   help (h)
tunnel is a command for uploading data to / downloading data from ODPS.
```

The following table describes parameters in this command.

Parameters

Parameter	Description
upload	Uploads data to MaxCompute tables.
download	Downloads data from MaxCompute tables.
resume	Resumes data upload if a failure occurs. Currently, data download cannot be resumed. Each data upload or download operation is called a session. To resume a session, you must specify the session ID in the RESUME command.
show	Displays historical running information.
purge	Clears the session directory.
help	Provides Tunnel help information.

UPLOAD

Imports data from a local file to a MaxCompute table in append mode. Subcommand syntax:

```
usage: tunnel upload [options] <path> <[project.]table[/partition]>
            upload data from local file
 -bs,-block-size <ARG>            block size in MiB, default 100
 -c,-charset <ARG>                specify file charset, default ignore.
                                  set ignore to download raw data
 -cp,-compress <ARG>              compress, default true
 -dbr,-discard-bad-records <ARG>  specify discard bad records
                                  action(true|false), default false
 -dfp,-date-format-pattern <ARG>  specify date format pattern, default
                                  yyyy-MM-dd HH:mm:ss
 -fd,-field-delimiter <ARG>       specify field delimiter, support
                                  unicode, eg \u0001. default ","
 -h,-header <ARG>                 if local file should have table header,
                                  default false
 -mbr,-max-bad-records <ARG>      max bad records, default 1000
 -ni,-null-indicator <ARG>        specify null indicator string, default
                                  ""(empty string)
 -rd,-record-delimiter <ARG>      specify record delimiter, support
                                  unicode, eg \u0001. default "\n"
 -s,-scan <ARG>                   specify scan file
                                  action(true|false|only), default true
 -sd,-session-dir <ARG>           set session dir, default /D:/console/plugins/dship/
 -te,-tunnel_endpoint <ARG>       tunnel endpoint
   -threads <ARG>                 number of threads, default 1
 -tz,-time-zone <ARG>             time zone, default local timezone:
                                  Asia/Shanghai
Example:
   tunnel upload log.txt test_project.test_table/p1="b1",p2="b2"
```

The following table describes parameters in this command.

Parameters

Parameter	Description
-bs,-block-size	Specifies the size of each data block uploaded using Tunnel. Default value: 100 MiB (1 MiB = 1,024 × 1,024 bytes).
-c,-charset	Specifies the encoding format of local data files. The default value is UTF-8 without timing. The source data is downloaded by default.

Parameter	Description
-cp,-compress	Specifies whether to compress the local file before uploading it to reduce traffic. Compression is enabled by default.
-dbr	Specifies whether to ignore dirty data, such as additional columns, missing columns, and unmatched types of column data. If the value is true, all data that does not comply with table definitions is ignored. If the value is false, an error is returned when dirty data is found, and raw data in the destination table is not contaminated.
-dfp	Specifies the format of DATETIME data. The default format is yyyy-MM-dd HH:mm:ss.
-fd	Specifies the column delimiter used in the local data file. The default delimiter is comma (,).
-h	Specifies whether the data file has a table header. If the value is true, Dship skips the table header and starts uploading data from the second row.
-mbr,-max-bad-records	If more than 1,000 rows of dirty data are uploaded, the upload operation is terminated by default. This parameter allows you to adjust the maximum allowable volume of dirty data.
-ni	Specifies the NULL data identifier. The default value is an empty string ("").
-rd	Specifies the row delimiter in the local data file. The default value is \n in a Linux system or \r\n in a Windows system.
-s	Specifies whether to scan the local data file. The default value is false. If the value is true, data is scanned first, and is imported if the format is correct. If the value is false, data is imported without scanning. If the value is only, data is scanned but not imported.
-sd,-session-dir	Specifies the path of the session directory. The default value is */D:/console/plugins/dship/lib/...*
-te	Specifies the endpoint of Tunnel.
-tz	Specifies the time zone. The default value is Asia/Shanghai.

Example

Create a table:

```
CREATE TABLE IF NOT EXISTS sale_detail(
   shop_name STRING,
   customer_id STRING,
    total_price DOUBLE)
PARTITIONED BY (sale_date STRING,region STRING);
```

Add a partition:

```
alter table sale_detail add partition (sale_date='201705', region='hangzhou');
```

Prepare the data file data.txt with the following content:

```
shop9,97,100
shop10,10,200
shop11,11
```

The third row of this file does not comply with the definitions of the sale_detail table. sale_detail defines three columns, but the third row of this file contains only two columns. Run the following command to import the data:

```
odps@ project_name>tunnel u d:\data.txt    sale_detail/sale_date=201705,region=hangzhou -s false U
pload session:    20170610163922488087 0a002ec60c
Start upload:d:\data.txt
Total bytes:41 Split input to 1 blocks
2017-06-10 16:39:22 upload block: '1'
ERROR: column mismatch -,expected 3 columns, 2 columns found, please check    data or delimiter
```

The data import fails because of the dirty data in data.txt. The session ID and error message are displayed. You can run the following command to verify the upload result:

```
odps@ odpstest_ay52c_ay52> select * from sale_detail where sale_date='201705'; ID = 20170610084135
370gyvc61z5
+-----------+-------------+-------------+-----------+--------+
shop_name | customer_id | total_price | sale_date | region |
+-----------+-------------+-------------+-----------+--------+
+-----------+-------------+-------------+-----------+--------+
```

DOWNLOAD

Subcommand syntax

```
odps@ project_name>tunnel help download
usage: tunnel download [options] <[project.]table[/partition]> <path>
          download data to local file
 -c,-charset <ARG>              specify file charset, default ignore.
                          set ignore to download raw data
 -cp,-compress <ARG>            compress, default true
 -dfp,-date-format-pattern <ARG>   specify date format pattern, default
                          yyyy-MM-dd HH:mm:ss
 -e,-exponential <ARG>          When download double values, use
                          exponential express if necessary.
                          Otherwise at most 20 digits will be
                          reserved. Default false
 -fd,-field-delimiter <ARG>       specify field delimiter, support
                          unicode, eg \u0001. default ","
 -h,-header <ARG>               if local file should have table header,
                          default false
   -limit <ARG>                 specify the number of records to
                          download
 -ni,-null-indicator <ARG>        specify null indicator string, default
                          ""(empty string)
 -rd,-record-delimiter <ARG>      specify record delimiter, support
                          unicode, eg \u0001. default "\n"
 -sd,-session-dir <ARG>         set session dir, defa          /D:/console/plugins/dship/
-te,-tunnel_endpoint <ARG>       tunnel endpoint
   -threads <ARG>               number of threads, default 1
 -tz,-time-zone <ARG>           time zone, default local timezone:Asia/Shanghai
Example:
   tunnel download test_project.test_table/p1="b1",p2="b2" log.txt
```

The following table describes parameters in this command.

Parameters

Parameter	Description
-fd	Specifies the column delimiter used in the local data file. The default delimiter is a comma (,).
-rd	Specifies the row delimiter used in the local data file. The default delimiter is \r\n.
-dfp	Specifies the format of DATETIME data. The default format is yyyy-MM-dd HH:mm:ss.

Parameter	Description
-ni	Specifies the NULL data identifier. The default value is an empty string ("").
-c	Specifies the encoding format of local data files. The default value is UTF-8.

Example

Download data to result.txt:

```
$ ./tunnel download sale_detail/sale_date=201705,region=hangzhou result.txt; Download session: 20
170610165824528387 0a002ed0b9
Total records: 2
2017-06-10 16:58:24 download records: 2
2017-06-10 16:58:24 file size: 30 bytes
OK
```

Open the result.txt file and verify that its content is as follows:

```
shop9,97,100.0
shop10,10,200.0
```

RESUME

Resumes the execution of historical operations. Only data upload can be resumed. Subcommand syntax:

```
usage: tunnel resume [session_id] [--force]
            resume an upload session
 -f,-force   force resume
Example:
   tunnel resume
```

Example

Change the content of the data.txt file to the following items:

```
shop9,97,100
shop10,10,200
```

Resume the data upload:

```
odps@ project_name>tunnel resume 20170610163922488 0870a002ec60c --      force;
start resume
20170610163922488 0870a002ec60c
Upload session: 20170610163922488 0870a002ec60c
Start upload:d:\data.txt
Resume 1 blocks
2017-06-10 16:46:42 upload block: '1'
2017-06-10 16:46:42 upload block complete, blockid=1
upload complete, average > speed is 0 KB/s
OK
```

20170610163922488 0870a002ec60c is the ID of the session that failed to be uploaded. You can run the following command to verify the upload result:

```
odps@ project_name>select * from sale_detail where sale_date='201705';
ID = 20170610084801405g0a741z5
+-----------+-------------+-------------+-----------+--------+
shop_name | customer_id | total_price | sale_date | region |
+-----------+-------------+-------------+-----------+--------+
+-----------+-------------+-------------+-----------+--------+
```

SHOW

Displays historical records. Subcommand syntax:

```
usage: tunnel show history [options]
```

Example

```
odps@ project_name>tunnel show history;
   usage: tunnel show history [options]
          show session information
 -n,-number <ARG>   lines
Example:
   tunnel show history -n 5
   tunnel show log
```

PURGE

Clears the session directory. Sessions within the last three days are purged by default. Subcommand syntax:

```
usage: tunnel purge [n]
        force session history to be purged.([n] days before, default
        3 days)

Example:
  tunnel purge 5
```

1.5.2.9. Other operations

This topic describes common commands for other operations.

ALIAS

The ALIAS command is used to create an alias for a resource. You can read different resources from the MaxCompute MapReduce reference manual or UDF code by creating the same alias for these resources.

Syntax

```
ALIAS <alias>=<real>;
```

Description: Creates an alias for a resource.

Parameters

- **alias**: the alias of a resource.
- **real**: the original name of a resource.

Example

```
ADD TABLE src_part PARTITION (ds='20171208') AS res_20171208;
ADD TABLE src_part PARTITION (ds='20171209') AS res_20171209;
-- Add resources res_20171208 and res_20171209.
ALIAS resName=res_20171208;
jar -resources resName -libjars work.jar -classpath ./work.jar com.company.MainClass args ...;
-- Set the alias of resource res_20171208 to resName and call this resource.
ALIAS resName=res_20171209;
jar -resources resName -libjars work.jar -classpath ./work.jar com.company.MainClass args ...;
-- Set the alias of resource res_20171209 to resName and call this resource.
```

> **Note** In the preceding example, different resource tables are referenced by the same resource alias resName in two jobs. Different data is read with the same code.

SET

Syntax

```
set <KEY>=<VALUE>
```

Description: Configures built-in or user-defined system variables of MaxCompute to affect MaxCompute behavior.

Parameters

- **KEY**: the name of the attribute to be set.
- **VALUE**: the value of the attribute.

MaxCompute SQL and the latest MapReduce version support the following SET commands:

```
set odps.stage.mapper.mem=
-- Set the memory size of each map worker. Unit: MB. Default value: 1024.
set odps.stage.reducer.mem=
-- Set the memory size of each reduce worker. Unit: MB. Default value: 1024.
set odps.stage.joiner.mem=
-- Set the memory size of each join worker. Unit: MB. Default value: 1024.
set odps.stage.mem =
-- Set the memory size of all workers of a specified MaxCompute task. This command has a lower priori
ty than the preceding commands. Unit: MB. This parameter is not specified by default.
set odps.stage.mapper.split.size=
-- Set the input data volume of each map worker (size of each slice in the input file) to indirectly contr
ol the number of workers in each map stage. Unit: MB. Default value: 256.
set odps.stage.reducer.num=
-- Set the number of workers in each reduce stage. This parameter is not specified by default.
set odps.stage.joiner.num=
-- Set the number of workers in each join stage. This parameter is not specified by default.
set odps.stage.num=
-- Set the number of concurrent workers in all stages of a specified MaxCompute task. This command h
as a lower priority than the preceding three commands. This parameter is not specified by default.
```

The earlier MapReduce versions of MaxCompute support the following SET commands:

```
set odps.mapred.map.memory=
-- Set the memory size of each map worker. Unit: MB. Default value: 1024.
set odps.mapred.reduce.memory=
-- Set the memory size of each reduce worker. Unit: MB. Default value: 1024.
setodps.mapred.map.split.size=
-- Set the input data volume of each map worker (size of each slice in the input file) to indirectly contr
ol the number of workers in each map stage. Unit: MB. Default value: 256.
set odps.mapred.reduce.tasks=
-- Set the number of workers in each reduce stage. This parameter is not specified by default.
```

Example

- Adjust the cache size pre-defined for a complex column when data is written to MaxCompute tables to improve write performance.

```
set odps.sql.executionengine.coldata.deep.buffer.size.max=1048576;
```

- Set the input data volume of each map worker to 256 MB.

```
set odps.stage.mapper.split.size=256
```

SETPROJECT

Syntax

```
setproject ["<KEY>=<VALUE>"];
```

Description: Sets project attributes. If < KEY >=< VALUE > is not specified, the current attribute configurations of the project are displayed.

The following table describes project attributes.

Project attributes

Attribute	Permission owner	Description	Value range
odps.table.drop.ignoreonexistent	All users	Indicates whether to report an error when you try to delete a table that does not exist. If the value is true, no error is reported.	true and false
odps.instance.priority.autoadjust	Project owner	Indicates whether to automatically prioritize smaller tasks. If the value is true, this function is enabled.	true and false
odps.instance.priority.level	Project owner	Indicates the priority of a task in a project.	1 to 3 Note The value 1 indicates the highest priority.
odps.security.ip.whitelist	Project owner	Indicates an IP address whitelist for the project.	List of IP addresses separated with commas (,).

Attribute	Permission owner	Description	Value range
odps.table.lifecycle	Project owner	**optional**: The lifecycle clause is optional in a table creation statement. If no lifecycle is set for a table, the table does not expire. **mandatory**: The lifecycle clause is mandatory. **inherit**: If no lifecycle is set for a table, the value of odps.table.lifecycle.value is the lifecycle of this table.	optional, mandatory, inherit
odps.table.lifecycle.value	Project owner	Indicates the default lifecycle.	1 to 37231 Note The default value is 37231.
odps.instance.remain.days	Project owner	Indicates how long the information about an instance is retained. Unit: days.	3 to 30
odps.task.sql.outerjoin.ppd	Project owner	Indicates whether the filter conditions in FULL OUTER JOIN are pushed down.	true and false
odps.function.strictmode	Project owner	Indicates whether to return NULL (false) or report an error (true) when built-in functions have dirty data.	true and false
odps.task.sql.write.str2null	Project owner	Indicates whether to consider empty strings as NULL (true).	true and false

EXPORT project meta

Syntax

```
export <projectname> <local_path>;
```

Description: Exports the meta of a project to a local file. Meta is represented by statements acceptable by odpscmd. The exported meta file can be used to recreate a project.

SHOW FLAGS

Syntax

```
show flags;
```

Description: Displays parameters configured by using the SET command.

> Note This command takes effect only at the project level.

COST SQL

Syntax

```
cost sql <SQL Sentence>;
```

Description: Estimates the measurement information of an SQL statement, including the size of the input data, number of UDFs, and SQL complexity level.

Example

```
odps@ $odps_project >cost sql select distinct project_name, user_name from meta.m_security_users di
stribute by project_name sort by project_name;

ID = 20190715113033121xxxxxxx
Input:65727592 Bytes
UDF:0
Complexity:1.0
```

1.6. MaxCompute SQL

1.6.1. Overview

1.6.1.1. Scenarios

This topic describes the scenarios of MaxCompute SQL.

MaxCompute SQL offline computing is applicable to scenarios where large volumes of data (terabytes) need to be processed, but do not have high real-time requirements. In such scenarios, it takes a relatively long time to prepare and submit each job. MaxCompute SQL is not well-suited for businesses that require to process thousands of transactions per second. MaxCompute SQL online computing provides near real-time (NRT) processing capabilities.

MaxCompute SQL uses the syntax that is similar to SQL syntax. It can be considered as a subset of standard SQL. However, MaxCompute SQL is not equivalent to a database. It does not have common database characteristics, such as transactions, primary key constrains, and indexes. The maximum length of SQL statements currently supported by MaxCompute is 2 MB.

1.6.1.2. Reserved words

Keywords of SQL statements are reserved words in MaxCompute. Do not use reserved words to name tables, columns, or partitions. Otherwise, an error is returned. Reserved words are case-insensitive.

Common reserved words are listed as follows. For a complete list of reserved words, see Reserved words.

```
% & && ( ) * + - . / ; < <= <>
= > >= ? ADD ALL ALTER
AND AS ASC BETWEEN BIGINT BOOLEAN BY
CASE CAST COLUMN COMMENT CREATE DESC DISTINCT
DISTRIBUTE DOUBLE DROP ELSE FALSE FROM FULL
GROUP IF IN INSERT INTO IS JOIN
LEFT LIFECYCLE LIKE LIMIT MAPJOIN NOT NULL
ON OR ORDER OUTER OVERWRITE PARTITION RENAME
REPLACE RIGHT RLIKE SELECT SORT STRING TABLE
THEN TOUCH TRUE UNION VIEW WHEN WHERE
```

1.6.1.3. Partitioned table

Partition columns provide many benefits, such as higher SQL operating efficiency and lower costs. However, too many partitions can cause problems. Using partition columns as filtering conditions in WHERE clauses of SELECT statements can bring greater benefits. Some SQL partition statements run inefficiently. For example, a statement fails when a large volume of data (more than 2,048 MB) is generated in dynamic partitions in a single MaxCompute instance.

It is easy to underestimate the number of partitions generated when multi-level partitions are used. When a huge number of partitions are generated, you must evaluate the original data to determine if there are excessive partitions.

You can create up to six levels of partitions. For some MaxCompute commands, the syntax differs between partitioned and non-partitioned tables. For more information, see DDL statements and DML statements.

For more information about the table creation statement, see Create a table.

1.6.1.4. Type conversion

1.6.1.4.1. Explicit type conversion

Explicit conversion uses CAST to convert a value type to another one. This topic describes explicit type conversion.

The following table lists explicit type conversions supported by MaxCompute SQL.

Explicit type conversion

From/To	Bigint	Double	String	Datetime	Boolean	Decimal
Bigint	-	Y	Y	N	N	Y
Double	Y	-	Y	N	N	Y
String	Y	Y	-	Y	N	Y
Datetime	N	N	Y	-	N	N
Boolean	N	N	N	N	-	N
Decimal	Y	Y	Y	N	N	-

Y indicates that the type can be converted. N indicates that the type cannot be converted.

Note

- When double type values are converted to bigint, the fractional is truncated. For example, cast(1.6 as bigint) = 1.
- When a string that meets double type requirements is converted to bigint, the string is first converted to the double type before it is converted to the bigint type. Hence, the fractional is truncated. For example, cast("1.6" as bigint) = 1.
- When a string that meets bigint type requirements is converted to the double type, one decimal is retained. For example, cast("1" as double) = 1.0.
- To convert a constant string to the decimal type, enclose the constant string within a pair of quotation marks. If the value is not enclosed in quotation marks, it is treated as a double type value. For example, cast("1.234567890123456789" as decimal).
- Unsupported explicit type conversion operations cause an exception.
- If a conversion fails during execution, the system returns an error and exits.
- The datetime data conversion uses the default format yyyy-mm-dd hh:mi:ss. For more information, see Convert data between string and datetime types.
- Some types cannot be explicitly converted, but can be converted using built-in SQL functions. For example, the to_char function can be used to convert boolean type values to the string type. For more information, see TO_CHAR. The to_date function can be used to convert string type values to the datetime type. For more information, see TO_DATE.
- For more information about CAST, see CAST.
- When the values of the decimal type are out of the value range, the cast string to decimal operation may return an error, such as most significant bit overflow or least significant bit overflow truncation.

1.6.1.4.2. Implicit type conversion and its scope

Implicit type conversion is an automatic type conversion performed by MaxCompute based on the context and a predefined set of rules. This topic describes the rules of implicit type conversion.

The following table lists implicit type conversion rules supported by MaxCompute.

Implicit type conversion 1

From/To	BOOLEAN	TINYINT	SMALLINT	INT	BIGINT	FLOAT
BOOLEAN	T	F	F	F	F	F
TINYINT	F	T	T	T	T	T
SMALLINT	F	F	T	T	T	T
INT	F	F	F	T	T	T
BIGINT	F	F	F	F	T	T
FLOAT	F	F	F	F	F	T

From/To	BOOLEAN	TINYINT	SMALLINT	INT	BIGINT	FLOAT
DOUBLE	F	F	F	F	F	F
DECIMAL	F	F	F	F	F	F
STRING	F	F	F	F	F	F
VARCHAR	F	F	F	F	F	F
TIMESTAMP	F	F	F	F	F	F
BINARY	F	F	F	F	F	F

Implicit type conversion 2

From/To	DOUBLE	DECIMAL	STRING	VARCHAR	TIMESTAMP	BINARY
BOOLEAN	F	F	F	F	F	F
TINYINT	T	T	T	T	F	F
SMALLINT	T	T	T	T	F	F
INT	T	T	T	T	F	F
BIGINT	T	T	T	T	F	F
FLOAT	T	T	T	T	F	F
DOUBLE	T	T	T	T	F	F
DECIMAL	F	T	T	T	F	F
STRING	T	T	T	T	F	F
VARCHAR	T	T	T	T	F	F
TIMESTAMP	F	F	T	T	T	F
BINARY	F	F	F	F	F	T

T indicates that the type conversion can be performed, while F indicates that the type conversion cannot be performed.

Note

- An unsupported implicit type conversion will cause an exception.
- If the conversion fails, an error is returned.
- Implicit type conversion is automatically performed by MaxCompute based on context. If the types do not match, we recommend that you perform explicit type conversion using cast.
- The rules of implicit type conversion are applied to different specific scopes. In certain scenarios, only part of the rules will take effect. For more information, see the scope of implicit type conversions.

Implicit type conversion with relational operators

Relational operators include equal to (=), not equal to (<>), less than (<), less than or equal to (<=), greater than (>), greater than or equal to (>=), IS NULL, IS NOT NULL, LIKE, RLIKE, and IN. The implicit conversion rules of LIKE, RLIKE, and IN are different from those of the other relational operators. These three operators are described in a separate section. The rules described in this section do not apply to these three operators. The following table lists implicit conversion rules when different types of data are involved in relational calculations.

Implicit type conversion with relational operators

From/To	BIGINT	DOUBLE	STRING	DATETIME	BOOLEAN	DECIMAL
BIGINT	-	DOUBLE	DOUBLE	N	N	DECIMAL
DOUBLE	DOUBLE	-	DOUBLE	N	N	DECIMAL
STRING	DOUBLE	DOUBLE	-	DATETIME	N	DECIMAL
DATETIME	N	N	DATETIME	-	N	N
BOOLEAN	N	N	N	N	-	N
DECIMAL	DECIMAL	DECIMAL	DECIMAL	N	N	-

Note

- If implicit type conversion is not supported between two values to be compared, the relational operation cannot be completed and an error is returned.
- For more information about relational operators, see Relational operators.

Implicit conversion with special relational operators

Special relational operators are LIKE, RLIKE, and IN.

LIKE and RLIKE are used as follows:

```
source like pattern;
source rlike pattern;
```

Note the following points for the two relational operators in implicit type conversion:

- The source and pattern parameters of LIKE and RLIKE must be of the string type.
- Other types are not supported by this operation and cannot be implicitly converted to the STRING type.
- If the value of source or pattern is NULL, the operation returns NULL.

IN is used as follows:

```
key in (value1, value2,...)
```

The implicit conversion rules of IN are as follows:

- The data types in the value list specified by IN must be consistent.
- If keys and values are compared, the BIGINT, DOUBLE, and STRING types compared are converted to DOUBLE, whereas the DATETIME and STRING types compared are converted to DATETIME. Conversion between other types is not allowed.

Note the following points for the IN operator:

The memory used by the compiler increases with the number of parameters used by the IN operation. An IN operation with 5,000 parameters consumes 17 GB of memory with the GCC compiler. We recommend that you limit the number of parameters to around 1,024. In this case, memory consumption will peak at 1 GB and compilation will only take 39 seconds.

Implicit type conversion with arithmetic operators

Arithmetic operators include plus (+), minus (-), multiplier (*), divider (/), and percent (%). The implicit conversion rules are as follows:

- Only the STRING, BIGINT, DECIMAL, and DOUBLE types can be used in arithmetic operations.
- Before an arithmetic operation, STRING values are implicitly converted to DOUBLE values.
- When an arithmetic operation involves values of both the BIGINT and DOUBLE types, BIGINT values are implicitly converted to DOUBLE values.
- The DATETIME and BOOLEAN types cannot be used in arithmetic operations.

> **Note** For more information about arithmetic operators, see Arithmetic operators.

Implicit conversion with logical operators

Logical operators include AND, OR, and NOT. The implicit conversion rules are as follows:

- Only the BOOLEAN type can be used in logic operations.
- The other types are not supported by logical operations or implicit type conversions.

> **Note** For more information about logical operators, see Logical operators.

1.6.1.4.3. SQL built-in functions

MaxCompute SQL provides a variety of system functions, which can be used to calculate one or more columns of any row and output any type of data.

The implicit conversion rules as follows:

- In a call of a function, if the data type of an input parameter is not consistent with the data type defined in the function, the data type of the input parameter is converted to the function-defined data type.
- The parameters of each built-in SQL function on MaxCompute can have different requirements for implicit type conversion. For more information, see Built-in functions.

1.6.1.4.4. CASE WHEN

This topic describes the implicit conversion rules of CASE WHEN.

The implicit conversion rules of case when are as follows:

- If the returned data types are only bigint and double, they are converted to the double type.
- If data of the string type is also returned, all data types are converted to string. If a data type cannot be converted to string (for example, boolean), an error is returned.
- Conversion between other types is not allowed.

1.6.1.4.5. Partition column

MaxCompute SQL supports partitioned tables. For the definition of partitioned tables, see DDL statements and DML statements. MaxCompute supports partitions of the following types: tinyint, smallint, int, bigint, varchar, and string.

1.6.1.4.6. UNION ALL

The data type, number of column, and column names involved in UNION ALL operation must all be consistent. Otherwise, an error is returned.

1.6.1.4.7. Conversion between string and datetime types

MaxCompute supports conversion between string and datetime types.

The format used in conversion is yyyy-mm-dd hh:mi:ss.ff3.

Value ranges of units

Unit	String (case-insensitive)	Value range
Year	yyyy	0001-9999
Month	mm	01-12
Day	dd	01-28,29,30,31
Hour	hh	00-23
Minute	mi	00-59
Second	ss	00-59
ms	ff3	00-999

> **Note**
>
> - Leading zeros cannot be omitted. For example, 2017-1-9 12:12:12 is an invalid string and cannot be converted into datetime. It must be written as 2017-01-09 12:12:12.
> - Only strings that meet the preceding format requirements can be converted into datetime. For example, cast("2017-12-31 02:34:34" as datetime) converts the "2017-12-31 02:34:34" string into datetime. Similarly, when datetime is converted into strings, the default conversion format is yyyy-mm-dd hh:mi:ss. If you attempt to convert the following examples (or similar strings), the operation will fail and cause an exception.
>
> ```
> cast("2017/12/31 02/34/34" as datetime)
> cast("20171231023434" as datetime)
> cast("2017-12-31 2:34:34" as datetime)
> ```

MaxComppute provides the to_date function, which converts a string type that does not meet the datetime format into datetime type. For more information, see TO_DATE.

1.6.2. Operators

1.6.2.1. Relational operators

This topic describes relational operators in MaxCompute SQL operators.

Relational operators

Operator	Description
A=B	If A or B is NULL, NULL is returned. If A is equal to B, TRUE is returned. Otherwise, FALSE is returned.
A<>B	If A or B is NULL, NULL is returned. If A is not equal to B, TRUE is returned. Otherwise, FALSE is returned.
A<B	If A or B is NULL, NULL is returned. If A is less than B, TRUE is returned. Otherwise, FALSE is returned.
A<=B	If A or B is NULL, NULL is returned. If A is less or equal to B, TRUE is returned. Otherwise, FALSE is returned.
A>B	If A or B is NULL, NULL is returned. If A is greater than B, TRUE is returned. Otherwise, FALSE is returned.
A>=B	If A or B is NULL, NULL is returned. If A is greater than or equal to B, TRUE is returned. Otherwise, FALSE is returned.
A IS NULL	If A is NULL, TRUE is returned. Otherwise, FALSE is returned.
A IS NOT NULL	If A is not NULL, TRUE is returned. Otherwise, FALSE is returned.

Operator	Description
A LIKE B	If A or B is NULL, NULL is returned. A is a string and B is the pattern to be matched. If A matches B, TRUE is returned. Otherwise, FALSE is returned. The percent sign (%) is a wildcard character that matches an arbitrary number of characters. The underscore (_) is a wildcard character that matches a single character. To use these two characters as ordinary characters, use backslashes to escape them: \% and _. 'aaa'like 'a ' = TRUE'aaa' like'a%' = TRUE'aaa'like 'aab' = FALSE'a%b'like 'a\%b' = TRUE'axb'like 'a\%b' = FALSE
A RLIKE B	If A or B is NULL, NULL is returned. A is a string and B is a string constant regular expression. If A matches B, TRUE is returned. Otherwise, FALSE is returned. If B is NULL, the system returns an error and exits.
A IN B	B is a set. If A is NULL, NULL is returned. If A is in B, TRUE is returned. Otherwise, FALSE is returned. If B contains only one element NULL, that is, A IN (NULL), NULL is returned. If B contains NULL, the type of NULL is considered the same as the other elements in B. B must be a constant and have at least one element. All elements must be of the same type.

Double type values have variable precision. We recommend that you do not use the equal sign (=) to compare two double type values. You can subtract between two values of the double type, and then take the absolute value of the result for comparison. When the absolute value is negligible, the two values of the double type are considered equal. For example:

```
abs(0.9999999999 - 1.0000000000) < 0.000000001
-- 0.9999999999 and 1.0000000000 have 10 decimal digits, while 0.000000001 has 9 decimal digits.
-- 0.9999999999 is considered equal to 1.0000000000.
```

Note

- ABS is a built-in function provided by MaxCompute to take the absolute value of its input. For more information, see ABS.
- A value of the double type in MaxCompute can retain 16 valid digits.

1.6.2.2. Arithmetic operators

This topic describes arithmetic operators in MaxCompute SQL operators.

Arithmetic operators

Operator	Description
A + B	If A or B is NULL, NULL is returned. Otherwise, the result of A + B is returned.
A - B	If A or B is NULL, NULL is returned. Otherwise, the result of A - B is returned.
A * B	If A or B is NULL, NULL is returned. Otherwise, the result of A * B is returned.
A / B	If A or B is NULL, NULL is returned. Otherwise, the result of A / B is returned. If both A and B are of the bigint type, the result is of the double type.
A % B	If A or B is NULL, NULL is returned. Otherwise, the result of A % B is returned.
+A	A is returned.
-A	If A is NULL, NULL is returned. Otherwise, -A is returned.

Note

- Only values of the string, bigint, double, and decimal types can be used in arithmetic operations. Values of the datatime and boolean types are not allowed in these operations.
- Before the operation, values of the string type are converted to the double type by implicit type conversion.
- When values of the bigint and double types are involved in an operation, values of the bigint type are converted to the double type by implicit type conversion first. The returned result is a value of the double type.
- When both A and B are of the bigint type, the returned result of A / B is a value of the double type. The returned results of the other arithmetic operations are values of the bigint type.

1.6.2.3. Bitwise operators

This topic describes bitwise operators in MaxCompute SQL operators.

Bitwise operators

Operator	Description
A & B	Returns the bitwise AND result of A and B. For example, 1 & 2 returns 0 and 1 & 3 returns 1. The bitwise AND result of NULL in combination with another value is always NULL. A and B must be of the bigint type.
A | B	Returns the bitwise OR result of A and B. For example, 1 | 2 returns 3 and 1 | 3 returns 3. The bitwise OR result of NULL in combination with another value is always NULL. A and B must be of the bigint type.

Notice Bitwise operators only support bigint type data and do not support implicit type conversion.

1.6.2.4. Logical operators

This topic describes logical operators in MaxCompute SQL operators.

Logical operators

Operator	Description
A and B	TRUE and TRUE = TRUE
	TRUE and FALSE = FALSE
	FALSE and TRUE = FALSE
	FALSE and NULL = FALSE
	FALSE and FALSE = FALSE
	NULL and FALSE = FALSE
	TRUE and NULL = NULL
	NULL and TRUE = NULL
	NULL and NULL = NULL
A or B	TRUE or TRUE = TRUE
	TRUE or FALSE = TRUE
	FALSE or TRUE = TRUE
	FALSE or NULL = NULL
	NULL or FALSE = NULL
	TRUE or NULL = TRUE
	NULL or TRUE = TRUE
	NULL or NULL = NULL
NOT A	If expression A is NULL, NULL is returned.
	If expression A is TRUE, FALSE is returned.
	If expression A is FALSE, TRUE is returned.

> **Note** Only data of the boolean type can be involved in logic operations. These operations do not support implicit type conversion.

1.6.3. DDL statements

1.6.3.1. Table operations

1.6.3.1.1. Create a table (CREATE TABLE)

This topic describes how to execute a DDL statement to create a table.

Syntax

```
create table [if not exists] table_name
[(col_name data_type [DEFAULT value] [comment col_comment], ...)]
[comment table_comment]
[partitioned by (col_name data_type [comment col_comment], ...)]
[STORED AS AliOrc]-- Specify the storage format of the table. You can specify AliORC only for newly cre
ated internal tables.
[lifecycle days]
[as select_statement]
create table [if not exists] table_name like existing_table_name
```

Note

- Table and column names are not case-sensitive.
- If you do not specify the IF NOT EXISTS option and another table with the same name exists, an error is returned. If you specify this option, a message that indicates the operation succeeded is returned. The message is returned regardless of whether an existing table with the same name exists. The message is returned even if the schema of the existing table is different from that of the table you want to create. In addition, the metadata of the existing table does not change.
- A table can contain a maximum of 1,200 column definitions.
- Supported data types are BIGINT, DOUBLE, BOOLEAN, DATETIME, DECIMAL, STRING, ARRAY <T>, and MAP <T1, T2>.

  Note If you need to use the following newly supported data types: TINYINT, SMALLINT, INT, FLOAT, VARCHAR, TIMESTAMP, or BINARY, you must add the `set odps.sql.type.system.odps2=true;` flag before the CREATE TABLE statement. Then, commit them for execution.

- MaxCompute allows you to specify the default value of a column by using DEFAULT value. If the value of a column is not specified in an INSERT operation, the default value is used for this column.
- A table or column name cannot contain special characters. It can contain only lowercase letters, uppercase letters, digits, or underscores (_). A name must start with a letter and can be up to 128 bytes in length.
- The partitioned by option specifies the partition field. The value can only be a string. The name of a partition key column cannot contain double-byte characters. It must start with a letter, either in lowercase or uppercase, followed by letters or digits. The name can be up to 128 bytes in length. The name can contain the following special characters: ! _ : $.# @ and spaces. Other characters, such as \t, \n, and /, are considered undefined characters. After you use partition fields to define partitions for a table, a full table scan is no longer triggered when you add partitions, update partition data, or read partition data. This improves processing efficiency.
- A comment is a valid string that can be up to 1,024 bytes in length.
- The lifecycle option indicates the lifecycle of the table in days. The CREATE TABLE LIKE statement does not replicate the lifecycle attribute from the source table.
- Theoretically, a source table can have up to six levels of partitions. Use as few partitions as possible to avoid extreme table expansion of storage.
- You can configure the maximum number of table partitions for a project. The default maximum number is 60,000.
- STORED AS specifies the storage format of the table. The default value is CFile2. AliORC in C++ is now available. It is developed by the MaxCompute storage team. AliORC is fully compatible with the open source Optimized Row Columnar (ORC). Compared with CFile2, AliORC frees up more than 10% of extra storage space and improves read performance by more than 20%.

Examples

The following example describes how to create a table named sale_detail to store sales records. The sale_date and region columns of the table are used as partition key columns.

```
create table if not exists sale_detail( shop_name string,
customer_id string,
total_price double)
partitioned by (sale_date string,region string);
-- Create a partitioned table named sale_detail.
```

Use the following `create table...as select...` statement to create a table and replicate data to it:

```
create table sale_detail_ctas1 as select * from sale_detail;
```

> **Note** If the sale_detail table contains data, all the data is replicated to sale_detail_ctas1. The sale_detail table is a partitioned table. However, the table created by the `create table...as select...` statement does not replicate the partition attribute of sale_detail. Partition key columns in sale_detail become standard columns in sale_detail_ctas1. Therefore, sale_detail_ctas1 is a non-partitioned table that has five columns.

In the `create table...as select...` statement, if you use constants as column values in the SELECT clause, we recommend that you specify column aliases:

```
create table sale_detail_ctas2 as select shop_name,
customer_id, total_price,
'2017' as sale_date,
'China' as region from sale_detail;
```

> **Note**
>
> If you do not specify column aliases, the fourth and fifth columns of sale_detail_ctas3 created in the following example are automatically named _c3 and _c4.

```
create table sale_detail_ctas3 as select shop_name,
customer_id, total_price, '2017',
'China'
from sale_detail;
```

In this case, to reference sale_detail_ctas3 again, you must enclose _c3 and _c4 in two pairs of grave accents (`). If you execute the select c3, _c4 from sale_detail_ctas3 statement, an error is returned. The column name in a MaxCompute SQL statement cannot start with underscores (_). Therefore, grave accents (`) must be used. We recommend that you use aliases to avoid this issue.

```
select `_c3`, `_c4` from sale_detail_ctas3;
```

To ensure that the destination table has the same schema as the source table, use the following `create table...like` statement:

```
create table sale_detail_like like sale_detail;
```

> **Note** The schema of sale_detail_like is exactly the same as that of sale_detail. Both tables have the same attributes, such as column names, column comments, and table comments, except for the lifecycle. However, data in sale_detail is not replicated to sale_detail_like.

MaxCompute allows you to execute the DESC statement to view table information.

```
desc <table_name>;
desc extended <table_name>;-- View table information and extended information.
```

MaxCompute allows you to use the SHOW CREATE TABLE statement to generate a DDL statement for table creation. This facilitates the SQL-based rebuild of the table schema.

```
SHOW CREATE TABLE <table_name>;
```

1.6.3.1.2. Delete a table

This topic describes how to run a DDL statement to delete a table.

Command syntax:

```
drop table [if exists] table_name;
```

Note If the command is run without the IF EXISTS option and the table does not exist, an exception is returned. With this option, a success is returned regardless of whether the table exists.

Example:

```
create table sale_detail_drop like sale_detail; drop table sale_detail_drop;
-- If the table exists, a success is returned. If not, an exception is returned.
drop table if exists sale_detail_drop2;
-- A success is returned regardless of whether sale_detail_drop2 exists.
```

1.6.3.1.3. Rename a table

This topic describes how to run a DDL statement to rename a table.

Command syntax:

```
alter table table_name rename to new_table_name;
```

Note

- The rename operation only changes the table name, not the table data.
- If the table specified by new_table_name already exists, an error is returned.
- If the table specified by table_name does not exist, an error is returned.

Example:

```
create table sale_detail_rename1 like sale_detail;
alter table sale_detail_rename1 rename to sale_detail_rename2;
```

1.6.3.1.4. Modify the comment of a table

This topic describes how to run a DDL statement to modify the comment of a table.

Command syntax:

```
alter table table_name set comment 'tbl comment';
```

> Note
>
> - table_name must be an existing table.
> - A comment can contain a maximum of 1,024 bytes.

Example:

```
alter table sale_detail set comment 'new coments for table sale_detail';
```

You can run the desc command to view the modified comment in the table. For more information, see Obtain table information.

1.6.3.1.5. Modify the lifecycle of a table

MaxCompute provides the lifecycle management function to release storage space and simplify the data clearance process. This topic describes how to run a DDL statement to modify the lifecycle of a table.

Command syntax:

```
alter table table_name set lifecycle days;
```

> Note
>
> - The days parameter indicates the lifecycle of a table. Unit: days. It must be a positive integer.
> - If the table specified by table_name is a non-partitioned table, and is not modified in the period specified by the days parameter since the last modification date, MaxCompute automatically clears the table (similar to the DROP TABLE operation). In MaxCompute, the LastDataModifiedTime value of a table is updated each time data in the table is modified. MaxCompute determines whether to clear a table based on its LastDataModifiedTime and lifecycle settings.
> - If the table specified by table_name is a partitioned table, MaxCompute determines whether to clear each partition based on the LastDataModifiedTime value. Unlike non-partitioned tables, a partitioned table is not deleted after the last partition is reclaimed.
> - You can configure a lifecycle for tables, but not for partitions.
> - You can specify a lifecycle when creating a table.

Example:

```
create table test_lifecycle(key string) lifecycle 100;
-- Create a table named test_lifecycle with a lifecycle of 100 days.
alter table test_lifecycle set lifecycle 50;
-- Change the lifecycle of the test_lifecycle table to 50 days.
```

1.6.3.1.6. Disable or restore the lifecycle feature

In some cases, if you do not want some partitions to be automatically reclaimed based on the lifecycle feature, you can disable the lifecycle feature for these partitions. This topic describes how to execute DDL statements to disable or restore the lifecycle feature.

Syntax

```
ALTER TABLE table_name partition[partition_spec] ENABLE|DISABLE LIFECYCLE;
```

> **Note**
>
> - TABLE DISABLE LIFECYCLE
>   - It prevents the reclamation of a table and its partitions based on the lifecycle feature. This option has a higher priority than partition_spec enable lifecycle.
>   - The lifecycle settings and the partition_spec enable/disable flag of a table are retained.
>   - You can still modify the lifecycle settings of a table and its partitions.
> - TABLE ENABLE LIFECYCLE
>   - After the lifecycle feature is enabled again, a table and its partitions can be reclaimed based on the lifecycle feature. By default, the lifecycle settings of the current table and its partitions are used.
>   - Before you restore the lifecycle feature for a table and its partitions, you can configure new lifecycles for the table and its partitions. This prevents data from being mistakenly reclaimed due to the use of the previous settings.

Example

```
ALTER TABLE trans PARTITION(dt='20191111') DISABLE LIFECYCLE;
```

1.6.3.1.7. Modify the LastDataModifiedTime value of a table

MaxCompute SQL supports the TOUCH operation, which allows you to modify the LastDataModifiedTime value of a table. This operation changes the LastDataModifiedTime value of a table to the current time. This topic describes how to run a DDL statement to modify the LastDataModifiedTime value of a table.

Command syntax:

```
alter table table_name touch;
```

> **Note**
> - If the specified table_name does not exist, an error is returned.
> - This operation modifies the LastDataModifiedTime value of the table. In this case, MaxCompute considers a change to the table data, and recalculates the lifecycle.

For more information about how to modify the LastDataModifiedTime value of a partition, see Modify the LastDataModifiedTime value of a partition.

1.6.3.1.8. Clear data from a non-partitioned table

This topic describes how to run a DDL statement to clear data from a non-partitioned table.

Command syntax:

```
TRUNCATE TABLE table_name;
```

> **Note** This statement is used to clear data from a specified non-partitioned table. To clear data from a partitioned table, run the `ALTER TABLE table_name DROP PARTITION (partition_spec)` statement.

1.6.3.1.9. Archive table data

This topic describes how to run a DDL statement to archive the data of a table.

If a project does not have enough space, you can use the table archiving feature in MaxCompute to compress data by about 50%. The archiving feature uses a compression algorithm with a higher compression ratio. It saves data as redundant array of independent disks (RAID) files. Data is no longer simply stored in three copies. Instead, six copies and three check blocks are maintained to increase the effective storage ratio from 1:3 to 1:1.5. The archive feature consumes only half of the usual physical space.

However, this feature comes at a price. If a data block or machine is damaged, the time required to restore the data is longer, and the read performance is affected. Therefore, this feature is suitable for compressing cold data for storage. For example, you can store large volumes outdated log data as RAID files for a long time.

Command syntax:

```
ALTER TABLE [table_name] <PARTITION(partition_name='partition_value')> ARCHIVE;
```

Example:

```
alter table my_log partition(ds='20170101') archive;
```

Command output:

```
Summary:
table name: test0128 /pt=a instance count: 1 run time: 21
before merge, file count: 1 file size: 456 file physical size: 1368
after merge, file count: 1 file size: 512 file physical size: 768
```

> **Note**
>
> The output shows the changes in logical size and physical size during the archiving process. In the archiving process, multiple small files are automatically merged. After the archive operation is complete, you can run the `desc extended` command to check whether the data in the partition has been archived, and view the physical space usage:

```
desc extended my_log partition(ds='20170101');
+------------------------------------------------------------------------------------+
PartitionSize: 512 |
+------------------------------------------------------------------------------------+
CreateTime: 2017-01-28 07:05:20 |
LastDDLTime: 2017-01-28 07:05:20 |
LastModifiedTime: 2017-01-28 07:05:21 |
+------------------------------------------------------------------------------------+
```

1.6.3.1.10. Forcibly delete data from a table (partition)

If you need to forcibly and irrecoverably delete data from a table or partition to immediately release storage space, you can perform the deletion operation with the PURGE option. This topic describes how to run a DDL statement to forcibly delete data from a table (partition).

Command syntax:

```
DROP TABLE tblname PURGE;
ALTER TABLE tblname DROP PARTITION(part_spec) PURGE;
```

Example:

```
drop table my_log purge;
alter table my_log drop partition (ds='20170618') purge;
```

1.6.3.2. View-based operation

1.6.3.2.1. Create a view

This topic describes how to run a DDL statement to create a view.

Command syntax:

```
create [or replace] view [if not exists] view_name
[(col_name [comment col_comment], ...)]
[comment view_comment]
[as select_statement]
```

> **Note**
>
> - To create a view, you must have read permissions on the table referenced by the view. Views in MaxCompute are not materialized views. View operations involve accessing data of referenced tables. Note that changes to your permission on the referenced table can result in changes to your permission on the view.
> - A view can contain only one valid SELECT statement.
> - A view can reference other views but cannot reference itself. Circular reference is not supported.
> - You cannot write data to a view. For example, the INSERT INTO and INSERT OVERWRITE operations do not work on views.
> - If the table referenced by a view changes, you may no longer be able to access the view. For example, a view becomes inaccessible after the table it references is deleted. You must maintain the mappings between referenced tables and views properly.
> - If the CREATE VIEW statement is run without the IF NOT EXISTS option and the view already exists, an exception is returned. In this case, you can run the CREATE VIEW or REPLACE VIEW statement to recreate a view. The permissions on the recreated view remain unchanged.

Example:

```
create view if not exists sale_detail_view
(store_name, customer_id, price, sale_date, region)
comment 'a view for table sale_detail'
as select * from sale_detail;
```

1.6.3.2.2. Delete a view

This topic describes how to run a DDL statement to delete a view.

Command syntax:

```
drop view [if exists] view_name;
```

> **Note** If the command is run without the IF EXISTS option and the view does not exist, an error is returned.

Example:

```
drop view if exists sale_detail_view;
```

1.6.3.2.3. Rename a view

This topic describes how to run a DDL statement to rename a view.

Command syntax:

```
alter view view_name rename to new_view_name;
```

> **Note** If a view with the same name already exists, an error is returned.

Example:

```
create view if not exists sale_detail_view
(store_name, customer_id, price, sale_date, region)
comment 'a view for table sale_detail'
as select * from sale_detail;
alter view sale_detail_view rename to market;
```

1.6.3.3. Column and partition operations

1.6.3.3.1. Add a partition (ADD PARTITION)

This topic describes how to use a DDL statement to add a partition.

Syntax

```
alter table table_name add [if not exists] partition partition_spec;-- Add a partition.
alter table table_name add [if not exists] partition partition_spec [PARTITION partition_spec PARTITION
partition_spec...];-- Add multiple partitions at a time.
partition_spec:(partition_col1 = partition_col_value1, partition_col2 = partiton_col_value2, ...)
```

> **Note**
>
> - If you do not specify the IF NOT EXISTS option and another partition with the same name exists, an error is returned.
> - A MaxCompute table can contain a maximum of 60,000 partitions.
> - To add a partition to a table that has multi-level partitions, you must specify all partitioning column values.

Examples

The following examples show how to add partitions to the sale_detail table:

```
alter table sale_detail add if not exists partition (sale_date='201712', region='hangzhou');
-- Add a partition to store the sales records of the China (Hangzhou) region for December 2017.
alter table sale_detail add if not exists partition (sale_date='201712', region='shanghai');
-- Add a partition to store the sales records of the China (Shanghai) region for December 2017.
alter table sale_detail add if not exists partition(sale_date='20171011');
-- Specify only the sale_date partition. An error is returned.
alter table sale_detail add if not exists artition(region='shanghai');
-- Specify only the region partition. An error is returned.
```

1.6.3.3.2. Delete a partition (DROP PARTITION)

This topic describes how to use a DDL statement to delete a partition.

Syntax

```
alter table table_name drop [if exists] PARTITION partition_spec; -- Delete a partition.
alter table table_name drop [if exists] PARTITION partition_spec,PARTITION partition_spec,[PARTITION
partition_spec....] ;-- Delete multiple partitions at a time.
partition_spec:: (partition_col1 = partition_col_value1, partition_col2 = partiton_col_value2, ...)
```

> **Note** If you do not specify the IF EXISTS option and the partition you want to delete does not exist, an error is returned.

Example

Execute the following statement to delete a partition from the sale_detail table:

```
alter table sale_detail drop partition(sale_date='201712',region='hangzhou');
-- The sales records of the China (Hangzhou) region for December 2017 are deleted.
```

1.6.3.3.3. Add a column

This topic describes how to add a column by using a DDL statement.

Command syntax:

```
alter table table_name add columns (col_name1 type1, col_name2 type2...)
```

Note

- A column can only be one of the following types: bigint, double, boolean, datetime, decimal, string, tinyint, smallint, int, float, varchar, binary, timestamp, array, map, or struct.
- You can create up to 1,200 columns in a single table in MaxCompute.

1.6.3.3.4. Change a column name

This topic describes how to run a DDL statement to change a column name.

Command syntax:

```
alter table table_name change column old_col_name rename to new_col_name;
```

Note

- You must specify an existing column for old_col_name.
- You cannot name a column in the table new_col_name.

1.6.3.3.5. Modify the comment of a column or partition

This topic describes how to run a DDL statement to modify the comment of a column or partition.

Command syntax:

```
alter table table_name change column col_name comment 'comment';
```

Note

- The comment cannot exceed 1,024 bytes.
- The data type and position of a column cannot be changed.

1.6.3.3.6. Modify the LastDataModifiedTime value of a partition

MaxCompute SQL supports the TOUCH operation, which allows you to modify the LastDataModifiedTime value of a partition. This operation changes the LastDataModifiedTime value of a partition to the current time. This topic describes how to run a DDL statement to modify the LastDataModifiedTime value of a partition.

Command syntax:

```
alter table table_name touch partition(partition_col='partition_col_value', ...);
```

> Note
>
> - If the specified table_name or partition_col does not exist, an error is returned.
> - If the specified partition_col_value does not exist, an error is returned.
> - This operation modifies the LastDataModifiedTime value of the table. In this case, MaxCompute considers a change to the table or partition value, and recalculates the lifecycle.

For more information about how to modify the LastDataModifiedTime value of a table, see Modify the LastDataModifiedTime value of a table.

1.6.3.3.7. Modify partition values

MaxCompute SQL provides the RENAME operation, which allows you to modify partition values of a table. This topic describes how to run a DDL statement to modify partition values.

Command syntax:

```
ALTER TABLE table_name PARTITION (partition_col1 = partition_col_value1, partition_col2 = partiton_col
_value2, . ..)
RENAME TO PARTITION (partition_col1 = partition_col_newvalue1, partition_col2 = partiton_col_newvalu
e2, ...);
```

> Note
>
> - This command cannot modify the names of partition columns. It can only modify the values of the columns.
> - To modify the values in one or more partitions in the case of multi-level partitions, you must specify values of partitions at each level.

1.6.3.3.8. Merge partitions

MaxCompute allows you to merge multiple partitions in a table into one partition and delete original partitions.

Syntax

```
ALTER TABLE <tableName> MERGE [IF EXISTS] PARTITION(<predicate>) [, PARTITION(<predicate2>) ...] O
VERWRITE PARTITION(<fullPartitionSpec>) [PURGE];
```

> Note
>
> - If you do not specify the IF EXISTS option and the partition you want to merge does not exist, an error is returned.
> - If you specify the IF EXISTS option but no partitions meet the merge conditions, no new partitions are generated.
> - If source data is concurrently modified by operations such as INSERT, RENAME, or DROP when you execute the preceding statement, an error is returned even though you have specified the IF EXISTS option.
> - If the PURGE attribute is specified, merged partitions cannot be restored by using the Kunlunjing.

Limits and troubleshooting

- External tables, shard tables, and tables with extreme storage are not supported. Xlib or Algo tables that depend on the file order are not supported. If you merge partitions of a clustered table, the clustered attribute is removed from the partitions.
- Hash operations are performed by CatalogServer on tables to merge partitions. A capacity limit is imposed on merged partitions. A hard link in the Apsara Distributed File System can have a maximum of seven replicas.
- You can merge a maximum of 4,000 partitions at a time.
- The number of partitions that can wait on CatalogServer to be merged is 10 million.
- If an error that indicates CatalogServer is busy occurs, try again later.
- If a hard link in the Apsara Distributed File System is faulty, purge the recycle bin and then try again.

Example

The following code shows the partitions and data of the tb_test table:

```
odps@ jet_zwz>list partitions tb_test;
ds=20181101/hh=00/mm=00
ds=20181101/hh=00/mm=10
ds=20181101/hh=10/mm=00
ds=20181101/hh=10/mm=10
OK
odps@ jet_zwz>read intpstringstringstring;
+------------+------------+------------+------------+
| value    | ds       | hh       | mm       |
+------------+------------+------------+------------+
| 1        | 20181101   | 00       | 00       |
| 1        | 20181101   | 00       | 10       |
| 1        | 20181101   | 10       | 00       |
| 1        | 20181101   | 10       | 10       |
+------------+------------+------------+------------+
```

Execute the following statement to merge all partitions that meet the hh='00' condition into the ds=20181101/hh=00/mm=00 partition:

```
odps@ jet_zwz>alter table intpstringstringstring merge partition(hh='00') overwrite partition(ds='2018
1101', hh='00', mm='00');
ID = 20190404025755844g80qwa7a
OK
```

Execute the following statement to view the partitions of the table after they are merged:

```
odps@ jet_zwz>list partitions intpstringstringstring;
ds=20181101/hh=00/mm=00
ds=20181101/hh=10/mm=00
ds=20181101/hh=10/mm=10
OK
```

Data in two partitions that meet the hh='00' condition is merged into the ds=20181101/hh=00/mm=00 partition.

```
odps@ jet_zwz>read intpstringstringstring;
+------------+------------+------------+------------+
| value     | ds         | hh         | mm         |
+------------+------------+------------+------------+
| 1         | 20181101   | 00         | 00         |
| 1         | 20181101   | 00         | 00         |
| 1         | 20181101   | 10         | 00         |
| 1         | 20181101   | 10         | 10         |
+------------+------------+------------+------------+
```

When you merge partitions, you can specify multiple predicate conditions. For example, you can execute the following statement to merge all the partitions that remain to the ds=20181101/hh=00/mm=00 partition:

```
odps@ jet_zwz>alter table intpstringstringstring merge if exists partition(ds='20181101', hh='00', mm='
00'), partition(ds='20181101', hh='10', mm='00'),  partition(ds='20181101', hh='10', mm='10') overwrite part
ition(ds='20181101', hh='00', mm='00') purge;
ID = 20190404034632854g431sqzt2
OK
odps@ jet_zwz>show partitions intpstringstringstring;
ds=20181101/hh=00/mm=00
OK
```

1.6.4. DML statements

1.6.4.1. INSERT statement

1.6.4.1.1. Update the data of a table

This topic describes how to run an INSERT statement to update the data of a table.

The INSERT OVERWRITE and INSERT INTO statements are commonly used for data processing in MaxCompute SQL. They are used to save the computing results in the target table for the next computing. The INSERT INTO statement adds data to a table or partition. The INSERT OVERWRITE statement clears the original data before inserting data to a table or partition.

Command syntax:

```
insert overwrite|into table tablename [partition (partcol1=val1, partcol2=val2 ...)] select_statement
from from_statement;
```

> **Note** The INSERT syntax in MaxCompute is different from that in MySQL or Oracle. In MaxCompute, INSERT OVERWRITE or INSERT INTO must be followed by the keyword TABLE, not directly by the table name.

Example:

The following example calculates the sales of different regions in the sale_detail table.

```
create table sale_detail_insert like sale_detail;
alter table sale_detail_insert add partition(sale_date='2017', region='china');
insert overwrite table sale_detail_insert partition (sale_date='2017', region='china') select shop_name,
customer_id, total_price from sale_detail;
```

> **Note** When data is updated using an INSERT operation, the mapping between the source and target tables depends on the column sequence in the SELECT clause, instead of the mapping of column names between both tables.

The following statement is also valid:

```
insert overwrite table sale_detail_insert partition (sale_date='2017', region='china')
select customer_id, shop_name, total_price from sale_detail;
-- When the sale_detail_insert table is created, the column sequence is shop_name string, customer_id
string, and total_price bigint.
-- When data in sale_detail is inserted to sale_detail_insert, the insertion sequence is customer_id, sh
op_name, and total_price.
-- In this case, data in sale_detail.customer_id is inserted into sale_detail_insert.shop_name.
-- Data in sale_detail.shop_name is inserted into sale_detail_insert.customer_id.
```

When data is inserted into a partitioned table, the partition columns cannot appear in the SELECT list.

```
insert overwrite table sale_detail_insert partition (sale_date='2017', region='china') select shop_name,
customer_id, total_price, sale_date, region from sale_detail;
-- An error is returned, because partition columns (sale_date and region) cannot appear in an INSERT s
tatement for a static partition.
```

1.6.4.1.2. Output data to multiple objects

This topic describes how to run the INSERT statement to output data to multiple objects.

MaxCompute SQL allows you to insert data to different result tables or partitions by using one SQL statement.

Command syntax:

```
from from_statement
insert overwrite | into table tablename1 [partition (partcol1=val1, partcol2=val2 ...)] select_statement1
[insert overwrite | into table tablename2 [partition ...] select_statement2]
```

> **Note**
>
> - A SQL statement typically supports up to 256 outputs. A syntax error is returned if more than 256 outputs are specified.
> - In a MULTI INSERT statement, you can specify a target partition in a partitioned table or specify a non-partitioned table only once.
> - The INSERT OVERWRITE and INSERT INTO operations cannot be performed simultaneously on different partitions in a partitioned table. Otherwise, an error is returned.

Example:

```
create table sale_detail_multi like sale_detail;
from sale_detail
insert overwrite table sale_detail_multi partition (sale_date='2016', region='china' ) select shop_name,
customer_id, total_price
insert overwrite table sale_detail_multi partition (sale_date='2017', region='china' ) select shop_name,
customer_id, total_price;
-- A success is returned. Data of the sale_detail table is inserted into the sale records of the China reg
ion in 2016 and 2017 in the sales table.
from sale_detail
insert overwrite table sale_detail_multi partition (sale_date='2017', region='china' ) select shop_name,
customer_id, total_price
insert overwrite table sale_detail_multi partition (sale_date='2017', region='china' ) select shop_name,
customer_id, total_price;
-- An error is returned. The same partition appears more than once.
from sale_detail
insert overwrite table sale_detail_multi partition (sale_date='2016', region='china' )
select shop_name, customer_id, total_price
insert into table sale_detail_multi partition (sale_date='2017', region='china' ) select shop_name, custo
mer_id, total_price;
-- An error is returned. The INSERT OVERWRITE and INSERT INTO operations cannot be performed simul
taneously on different partitions in a partitioned table.
```

1.6.4.1.3. Output data to a dynamic partition

This topic describes how to use the INSERT statement to output data to a dynamic partition.

When you run the INSERT OVERWRITE statement on a partitioned table, you can specify the partition values in the statement. Another flexible method is to specify partition column names instead of setting partition values. In the meantime, specify the partition values in the corresponding columns of a SELECT clause.

Command syntax:

```
insert overwrite table tablename partition (partcol1, partcol2 ...) select_statement from from_stateme
nt;
```

Note

- When you run a SQL dynamic partition statement in a distributed environment, a single process can output up to 512 dynamic partitions. If the number of dynamic partitions exceeds this limit, an exception is returned.
- Currently, a SQL dynamic partition statement can generate up to 2,000 dynamic partitions. If the number of dynamic partitions exceeds this limit, an exception is returned.
- The dynamic partition values cannot be NULL. Otherwise, an exception is returned.
- If a target table has multi-level partitions, you can specify some partitions as static partitions in an INSERT statement. However, the static partitions must be high-level partitions.

Example:

```
create table total_revenues (revenue bigint) partitioned by (region string); insert overwrite table tota
l_revenues partition(region)
select total_price as revenue, region from sale_detail;
```

Note In the preceding example, you do not know which partitions are generated before running the SQL statement. The partitions generated are determined by the value of the region field after the execution of the SELECT statement. This is why the partitions are called dynamic partitions.

Other examples:

```
create table sale_detail_dypart like sale_detail;
insert overwrite table sale_detail_dypart partition (sale_date, region) select * from sale_detail;
-- A success is returned.
insert overwrite table sale_detail_dypart partition (sale_date='2017', region) select shop_name,custom
er_id,total_price,region from sale_detail;
-- A success is returned. The table has multi-level partitions. Specify a primary partition.
insert overwrite table sale_detail_dypart partition (sale_date='2017', region) select shop_name,custom
er_id,total_price from sale_detail;
-- An error is returned. The inserted dynamic partition must be in the SELECT list.
insert overwrite table sales partition (region='china', sale_date) select shop_name,customer_id,total_p
rice,region from sale_detail;
-- An error is returned. You cannot specify only low-level partitions when dynamically inserting high-le
vel partitions.
```

1.6.4.2. SELECT statement

1.6.4.2.1. SELECT

This topic describes how to use the SELECT statement.

Syntax

```
select [all | distinct] select_expr, select_expr, ... from table_reference
[where where_condition] [group by col_list]
[order by order_condition]
[distribute by distribute_condition [sort by sort_condition] ] [limit number]
```

Take note of the following points when you execute the SELECT statement:

- The SELECT statement reads data from a table. You can specify the names of the columns you want to read or use an asterisk (*) to represent all columns.

  Examples

  ```
  select * from sale_detail;
  -- Read data from all columns in the sale_detail table.
  select shop_name from sale_detail;
  -- Read data from the shop_name column in the sale_detail table.
  ```

  > **Note** The SELECT statement can only return a maximum of 1,000 rows of results. However, no such limits are imposed when SELECT is used as a clause. If SELECT is used as a clause, the clause returns all results in response to the query from the upper layer. To obtain more than 1,000 rows of results by using the SELECT statement, you must use Tunnel to download the entire table or a temporary table returned by the SELECT operation. For more information, see MaxCompute Tunnel.

- You can use the WHERE clause to specify filter conditions.

  Examples

  ```
  select * from sale_detail where shop_name like 'hang%';
  ```

  The following table describes filter conditions supported by the WHERE clause.

Filter conditions

Filter condition	Description
>, < , =, >=, <=, <>	/
like, rlike	/
in, not in	If a subquery is added after the IN or NOT IN condition, only one column is returned for the subquery and the number of return values cannot exceed 1,000.

You can specify partitions in the WHERE clause of the SELECT statement to avoid a full table scan.

Examples

```
select sale_detail.* from sale_detail
where sale_detail.sale_date >= '2015' and sale_detail.sale_date <= '2017';
```

> **Notice** To check whether partition pruning takes effect, execute the `EXPLAIN SELECT` statement. A common user-defined function (UDF) or the method that is used to specify partition conditions in a JOIN operation can cause partition pruning to fail to take effect.

UDFs support partition pruning. These UDFs are executed as small jobs and then replaced with the execution results.

You can use one of the following methods:

- Add an annotation to the UDF class when you write a UDF.

  ```
  @com.aliyun.odps.udf.annotation.UdfProperty(isDeterministic=true)
  ```

  > **Notice** com.aliyun.odps.udf.annotation.UdfProperty defines that the version of referenced odps-sdk-udf must be 0.30.x or later in odps-sdk-udf.jar.

- Add the `set odps.sql.udf.ppr.deterministic = true;` flag before SQL statements. Then, all UDFs in the SQL statements are considered deterministic.

  > **Note** This method is used with limits. This method backfills partitions with execution results. A maximum of 1,000 partitions can be backfilled. If an annotation is added to the UDF class, an error that indicates more than 1,000 partitions are backfilled may be returned. If you want to ignore the error, add the `set odps.sql.udf.ppr.to.subquery = false;` flag to disable this feature globally. After this feature is disabled, UDF-based partition pruning becomes invalid.

The WHERE clause in an SQL statement can include the BETWEEN...AND condition. Example:

```
SELECT sale_detail. * FROM sale_detail
WHERE sale_detail.sale_date between '2017' and '2019';
```

> **Note** The number of conditions that can be specified in the WHERE clause cannot exceed 256.

- Nested subqueries are supported in table_reference.

  Examples

  ```
  select * from (select region from sale_detail) t where region = 'shanghai';
  ```

- DISTINCT: If duplicate rows exist, add DISTINCT before the field to remove duplicate values. In this case, only one value is returned. If you use ALL, all duplicate values are returned. If you do not specify the DISTINCT option, the statement returns all duplicate values, same as the result obtained by using the ALL option.

  Examples

  ```
  select distinct region from sale_detail;
  select distinct region, sale_date from sale_detail;
  -- The DISTINCT option applies to multiple columns. The option takes effect on all columns of the SEL
  ECT statement, instead of a single column.
  ```

- GROUP BY: This clause is used to perform group-based queries. In most cases, this clause is used with aggregate functions. If a SELECT statement includes aggregate functions, the key of the GROUP BY clause can be the names of columns in the input table or an expression composed of input table columns. The key cannot be the aliases of the columns in the output table of the SELECT operation.

  > **Note** If the `set hive.groupby.position.alias=true;` flag is added before SQL statements, integer constants in the GROUP BY clause are considered column numbers in a SELECT operation. Example:
  >
  > ```
  > -- The columns in the sale_detail table are in the format of key-value pairs.
  > select region, sum(total_price) from sale_detail group by 1;
  > -- Equivalent to the following statement:
  > select region, sum(total_price) from sale_detail group by region;
  > ```

  Examples

```
select region from sale_detail group by region;
-- The statement is successfully executed because the name of a column in the input table is used a
s the column in the GROUP BY clause.
select sum(total_price) from sale_detail group by region;
-- The statement is successfully executed because the values in the region column are used to grou
p the table and to return the total sales of each group.
select region, sum(total_price) from sale_detail group by region;
-- The statement is successfully executed because the values in the region column are used to grou
p the table and to return the unique region value and the total sales of each group.
select region as r from sale_detail group by r;
-- An error is returned because the alias of the column in the SELECT operation is used as the colum
n in the GROUP BY clause.
select 'China-' + region as r from sale_detail group by 'China-' + region;
-- A complete expression of the column is required.
select region, total_price from sale_detail group by region;
-- An error is returned because all the columns that do not include aggregate functions in the SELEC
T operation must exist in the GROUP BY clause.
select region, total_price from sale_detail group by region, total_price;
-- The statement can be successfully executed.
```

Note The GROUP BY operation is performed before the SELECT operation during the parsing of SQL statements. Therefore, GROUP BY uses only the column names or expressions of the input table as keys. For more information about aggregate functions, see Aggregate functions.

- ORDER BY: This clause is used for global sorting based on specific columns. To sort records in descending order, use the DESC keyword. The ORDER BY clause must be used with the LIMIT clause because records are globally sorted. In an ORDER BY operation, NULL is considered the lowest of all values. This rule is consistent with MySQL, but is different from Oracle. Different from the GROUP BY clause, the columns in the ORDER BY clause must be the aliases of the columns in the SELECT operation. If you want to query a column but the column alias is not specified in the SELECT operation, the column name is used as the column alias.

  Note If the `set hive.orderby.position.alias=true;` flag is added before SQL statements, integer constants in the ORDER BY clause are considered column numbers in a SELECT operation. Example:

  ```
  -- The columns in the sale_detail table are in the format of key-value pairs.
  select region, sum(total_price) from sale_detail order by 2 limit 100;
  -- Equivalent to the following statement:
  select region, sum(total_price) from sale_detail order by sum(total_price) limit 100;
  ```

  Examples

```
select * from sale_detail order by region;
-- An error is returned because the ORDER BY clause is not used with the LIMIT clause.
select * from sale_detail order by region limit 100;
select region as r from sale_detail order by region;
-- An error is returned because the ORDER BY clause is not followed by a column alias.
select region as r from sale_detail order by r;
```

> **Note** The number in the LIMIT clause is a constant that limits the number of output rows. If a SELECT statement is executed without the LIMIT clause, it can return a maximum of 5,000 rows. The screen display limit may vary with projects and can be configured in the console.

The OFFSET clause can be used with the ORDER BY LIMIT clause to skip the number of rows specified by OFFSET.

Examples

```
SELECT * FROM src ORDER BY key LIMIT 20 OFFSET 10;
-- Sort the rows of the src table in ascending order by key, and return the 11th to 30th rows. OFFSET 10 indicates that the first 10 rows are skipped, and LIMIT 20 indicates that a maximum of 20 rows can be returned.
```

- DISTRIBUTE BY: This clause is used to shard data based on hash values of specific columns. The DISTRIBUTE BY clause must be followed by the alias of an output column from the SELECT operation.

  Examples

  ```
  select region from sale_detail distribute by region;
  -- The statement is successfully executed because the column name is used as the column alias.
  select region as r from sale_detail distribute by region;
  -- An error is returned because the DISTRIBUTE BY clause is not followed by a column alias.
  select region as r from sale_detail distribute by r;
  ```

- SORT BY: This clause is used for partial sorting. The DISTRIBUTE BY clause must be placed before the SORT BY clause. In practice, the SORT BY clause is used to partially sort the results of the DISTRIBUTE BY clause. The SORT BY clause must be followed by the alias of an output column from the SELECT operation.

  Examples

  ```
  select region from sale_detail distribute by region sort by region; select region as r from sale_detail sort by region;
  -- An error is returned because the SORT BY clause does not follow a DISTRIBUTE BY clause.
  ```

- The ORDER BY and GROUP BY clauses cannot be used with the DISTRIBUTE BY and SORT BY clauses. The ORDER BY and GROUP BY clauses must be followed by the alias of an output column from the SELECT operation.

> **Note**
>
> - The key of the ORDER BY, SORT BY, or DISTRIBUTE BY clause must be the alias of an output column from the SELECT operation.
> - The SELECT operation is performed before the ORDER BY, SORT BY, and DISTRIBUTE BY clauses during the parsing of SQL statements. Therefore, only the aliases of output columns from the SELECT operation can be used as keys.

1.6.4.2.2. Subquery

This topic describes how to use the SELECT statement for subquery operations.

A common SELECT statement reads data from multiple tables, for example, select column_1, column_2 ... from table_name. The query object can be another SELECT operation, which is a subquery.

Command syntax:

```
select * from (select shop_name from sale_detail) a;
```

> **Notice** A subquery must have an alias.

Example:

```
create table shop as select * from sale_detail;
select a.shop_name, a.customer_id, a.total_price from
(select * from shop) a join sale_detail on a.shop_name = sale_detail.shop_name;
```

> **Note** In a FROM clause, a subquery can be used as a table, which supports a JOIN operation with other tables or subqueries.

1.6.4.3. UNION statements

1.6.4.3.1. UNION ALL

This topic describes how to execute the SELECT statement to perform the UNION ALL operation.

Syntax

```
select_statement union all select_statement
```

> **Note** The UNION ALL clause is used to combine two or more datasets returned from a SELECT operation into one dataset. If duplicate rows exist in the results, all rows that meet the condition are returned, with duplicate rows retained.

MaxCompute SQL does not support the combination of two top-level query results. To combine them, rewrite them into a subquery.

Format example before rewriting

```
select * from sale_detail where region = 'hangzhou'
union all
select * from sale_detail where region = 'shanghai';
```

Format example after rewriting

```
select * from (
select * from sale_detail where region = 'hangzhou' union all
select * from sale_detail where region = 'shanghai') t;
```

The syntax that uses a pair of parentheses to specify the priority of UNION ALL is supported.

Example:

```
SELECT * FROM src UNION ALL (SELECT * FROM src2 UNION ALL SELECT * FROM src3);
-- Execute the UNION ALL clause for the src2 and src3 tables. Then, execute the UNION ALL clause for t
he src table based on the obtained result.
```

> **Notice**
>
> - For a UNION ALL operation, all subqueries must have the same number of columns, column names, and column types. If the column names are inconsistent, use column aliases.
> - In most cases, MaxCompute allows a UNION ALL operation for a maximum of 256 subqueries. If the limit is exceeded, a syntax error is returned.

1.6.4.4. JOIN statement

1.6.4.4.1. JOIN

This topic describes how to use a JOIN statement.

MaxCompute supports multiple JOIN operations in an SQL statement. JOIN does not support Cartesian products (JOIN without an ON clause).

Syntax

```
join_table:
table_reference join table_factor [join_condition]
| table_reference {left outer|right outer|full outer|inner} join table_reference join_condition
table_reference: table_factor
join_table
table_factor: tbl_name [alias]
table_subquery alias
( table_references )
join_condition:
on equality_expression ( and equality_expression )*
```

> **Note** equality_expression indicates an equality expression.

Take note of the following points when you perform a JOIN operation:

- LEFT OUTER JOIN: returns all rows in the left table, such as shop in the following example. The returned rows include the rows that do not match any rows in the right table, such as sale_detail in the following example.

  Example

  ```
  select a.shop_name as ashop, b.shop_name as bshop from shop a left outer join sale_detail b on a.s
  hop_name=b.shop_name;
  -- Both the shop and sale_detail tables have the shop_name column. You must use aliases to disting
  uish the columns in the SELECT operation.
  ```

- RIGHT OUTER JOIN: returns all rows in the right table, such as sale_detail in the following example. The returned rows include the rows that do not match any rows in the left table, such as shop in the following example.

  Example

  ```
  select a.shop_name as ashop, b.shop_name as bshop from shop a right outer join sale_detail b on a.
  shop_name=b.shop_name;
  -- Both the shop and sale_detail tables have the shop_name column. You must use aliases to disting
  uish the columns in the SELECT operation.
  ```

- FULL OUTER JOIN: returns all rows in both the left and right tables.

  Example

  ```
  select a.shop_name as ashop, b.shop_name as bshop from shop a full outer join sale_detail b on a.s
  hop_name=b.shop_name;
  ```

- INNER JOIN: only returns the rows in which two tables can be mapped. The INNER keyword can be omitted.

  Example

```
select a.shop_name from shop a inner join sale_detail b on a.shop_name=b.shop_name; select a.sho
p_name from shop a join sale_detail b on a.shop_name=b.shop_name;
```

- Join condition: You must use equi-joins and combine conditions by using AND. A maximum of 128 JOIN operations are supported in an SQL statement. You can use non-equi joins or combine conditions by using OR in a MAPJOIN operation.

  Example

```
select a.* from shop a full outer join sale_detail b on a.shop_name=b.shop_name full outer join sale_
detail c on a.shop_name=c.shop_name;
-- A maximum of 128 JOIN operations are supported in an SQL statement.
select a.* from shop a join sale_detail b on a.shop_name <> b.shop_name;
-- An error is returned because MaxCompute does not support non-equi joins.
```

- NATURAL JOIN: In a NATURAL JOIN operation, the conditions used to join two tables are automatically determined based on the common fields in the two tables. MaxCompute supports OUTER NATURAL JOIN. You can use the USING clause so that the JOIN operation returns common fields only once.

  Example

```
-- To join the src table that contains the key1, key2, a1, and a2 columns and the src2 table that cont
ains the key1, key2, b1, and b2 columns, execute the following statement:
SELECT * FROM src NATURAL JOIN src2;
-- Both the src and src2 tables include the key1 and key2 fields. In this case, the preceding statemen
t is equivalent to the following statement:
SELECT src.key1 as key1, src.key2 as key2, src.a1, src.a2, src2.b1, src2.b2 FROM src INNER JOIN src2 ON
src.key1 = src2.key1 AND src.key2 = src2.key2;
```

The syntax that uses a pair of parentheses to specify the priorities of JOIN operations is supported.

Example

```
SELECT * FROM src JOIN (src2 JOIN src3 on xxx) ON yyy;
-- The src2 JOIN src3 operation is executed first. Then, the JOIN operation is performed on the src table
based on the result.
```

1.6.4.4.2. MAPJOIN HINT

This topic describes how to use a MAPJOIN statement to join a large table with one or more small tables.

A MAPJOIN operation is faster than common JOIN operations.

When the volume of data is small, MAPJOIN accelerates the execution process by using SQL to load all the specified small tables into the program memory through the JOIN operation.

Example

```
select /* + mapjoin(a) */ a.shop_name, b.customer_id, b.total_price
from shop a join sale_detail b
on a.shop_name = b.shop_name;
```

> **Notice**
>
> Note the following points when you use a MAPJOIN statement:
>
> - The left table of a LEFT OUTER JOIN clause must be a large table.
> - The right table of a RIGHT OUTER JOIN clause must be a large table.
> - Both the left and right tables of an INNER JOIN clause can be large tables.
> - MAPJOIN cannot be used in a FULL OUTER JOIN clause.
> - MAPJOIN supports small tables in subqueries.
> - If you need to reference a small table or a subquery when using MAPJOIN, you must reference the alias of the table or subquery.
> - In MAPJOIN, you can use non-equi joins or combine multiple conditions by using OR.
> - If MAPJOIN is used, the total memory occupied by all the small tables cannot exceed 512 MB. However, you can use the *odps.sql.mapjoin.memory.max* parameter to raise this limit up to 2,048 MB.
>
>   The limit here refers to the original size of data. If you run the desc command to obtain the compressed size, you must multiply it by the compression ratio.

In MaxCompute SQL, you cannot use non-equi joins or the OR logic in the ON condition. However, you can do this in MAPJOIN. Example:

```
select /*+ mapjoin(a) */ a.total_price, b.total_price
from shop a join sale_detail b
on a.total_price < b.total_price or a.total_price + b.total_price < 500;
```

1.6.4.5. EXPLAIN statement

This topic describes the EXPLAIN statement in DML statements of MaxCompute SQL.

MaxCompute SQL provides the EXPLAIN operation, which displays the description of the ultimate execution plan structure of DML statements. An execution plan is the program that is ultimately used to execute SQL semantics.

Command syntax:

```
EXPLAIN <DMLquery>;
```

> **Note**
>
> The execution result of an EXPLAIN statement includes the following:
>
> - Dependencies between all the jobs of this DML statement.
> - Dependencies between all the tasks of each job.
> - All operator dependency structures in a task.

Example:

```
EXPLAIN
SELECT abs(a.key), b.value FROM src a JOIN src1 b ON a.value = b.value;
```

The EXPLAIN statement output includes the following:

- **The first part is the dependency between jobs.**

  Command output:

  ```
  job0 is root job
  ```

  > **Note** Because this query only needs one job (job0), only one line of information is needed.

- **The second part is the dependency between tasks.**

  Command output:

  ```
  In Job job0:
  root Tasks: M1_Stg1, M2_Stg1
  J3_1_2_Stg1 depends on: M1_Stg1, M2_Stg1
  ```

  > **Note**
  >
  > - Job0 contains three tasks, among which M1_Stg1 and M2_Stg1 are executed first, and J3_1_2_Stg1 is executed after the first two tasks are finished.
  > - Naming rules for tasks: MaxCompute provides four task types: MapTask, ReduceTask, JoinTask, and LocalWork. The first letter of a task name indicates the type of the current task (for example, M2Stg1 is a MapTask). The number immediately following the first letter represents the current Task ID, which is unique among all tasks in the current query. The numbers separated by underscores (_) represent the immediate dependencies of the current task. For example, J3_1_2_Stg1 means that the current task (ID 3) is dependent on tasks with ID 1 and ID 2.

- **The third part is the operator structure in the tasks, where each operator string describes the execution semantics of a task.**

  Command output:

```
In Task M1_Stg1:
Data source: yudi_2.src #### "Data source" describes the input content of the current task TS: alia
s: a #### TableScanOperator
RS: order: + #### ReduceSinkOperator keys:
a.value values:
a.key partitions:
a.value
In Task J3_1_2_Stg1:
JOIN: a INNER JOIN b #### JoinOperator
SEL: Abs(UDFToDouble(a._col0)), b._col5 #### SelectOperator FS: output: None #### FileSinkOpera
tor
In Task M2_Stg1:
Data source: yudi_2.src1 TS: alias: b
RS: order: + keys:
b.value values:
b.value partitions:
b.value
```

The meanings of the operators are shown as below.

Operators

Operator	Description
TableScanOperator	Describes the logic of FROM statement blocks in a query statement. The input table name (alias) is displayed in the EXPLAIN results.
SelectOperator	Describes the logic of SELECT statement blocks in a query statement. The columns passed to the next operator, separated by commas, are displayed in the EXPLAIN results. If the result is a reference to a column, it is displayed as < alias >.< column_name >. If the result is an expression, it is displayed as a function, for example, func1(arg1_1, arg1_2, func2(arg2_1, arg2_2)). If the result is a constant, the value is displayed directly.
FilterOperator	Describes the logic of WHERE statement blocks in a query statement. A WHERE condition, which complies with a display rule similar to that of selectOperator, is displayed in the EXPLAIN results.
JoinOperator	Describes the logic of JOIN statement blocks in a query statement. The tables involved in the JOIN operation and the mode of JOIN operation are displayed in the EXPLAIN results.

Operator	Description
GroupByOperator	Describes the logic of the AGGREGATE operation. This structure is displayed if an aggregate function is used in a query. The content of the aggregate function is displayed in the EXPLAIN results.
ReduceSinkOperator	Describes the logic of the data distribution operation between tasks. If the result of the current task is transferred to another task, ReduceSinkOperator must be used to distribute data at the end of the current task. The output sorting method, the distributed keys, values, and columns used to calculate the hash value are displayed in the EXPLAIN results.
FileSinkOperator	Describes the final data storage operation. If there is an INSERT statement block in the query statement, the name of the target table is displayed in the EXPLAIN results.
LimitOperator	Describes the logic of LIMIT statement blocks in a query statement. The limit value is displayed in the EXPLAIN results.
MapjoinOperator	Describes JOIN operations in large tables, similar to JoinOperator.

Note

- If a query is complex and has too many EXPLAIN results, the API restriction is triggered, and incomplete results are displayed. In this case, the query can be split, and the EXPLAIN operation can be performed on each part to show the structure of the job.
- The maximum number of partitions in a query is 10,000. Inputting too many partitions leads to over-length Data source content. To circumvent this limit, you can filter out most partitions by adding a query filter.

1.6.4.6. GROUPING SETS

1.6.4.6.1. Overview

For scenarios where you need to aggregate and analyze data of multiple dimensions, you must execute multiple UNION ALL clauses. For example, you wanted to aggregate column a, aggregate column b, and aggregate columns a and b together. The GROUPING SETS clause is a better choice in such cases.

GROUPING SETS is an extension to the GROUP BY clause in the SELECT statement. You can group results in various ways by using GROUPING SETS without executing multiple SELECT statements. This can produce better execution plans and result in higher performance from the MaxCompute engine.

> **Notice** Many examples in this topic are demonstrated using MaxCompute Studio. We recommend that you install MaxCompute Studio before you proceed with subsequent operations.

1.6.4.6.2. Example

The following example is for your reference.

1. Prepare data.

```
create table requests LIFECYCLE 20 as
select * from values
   (1, 'windows', 'PC', 'Beijing'),
   (2, 'windows', 'PC', 'Shijiazhuang'),
   (3, 'linux', 'Phone', 'Beijing'),
   (4, 'windows', 'PC', 'Beijing'),
   (5, 'ios', 'Phone', 'Shijiazhuang'),
   (6, 'linux', 'PC', 'Beijing'),
   (7, 'windows', 'Phone', 'Shijiazhuang')
as t(id, os, device, city);
```

2. Use GROUPING SETS.

```
SELECT os,device, city ,COUNT(*)
FROM requests
GROUP BY os, device, city GROUPING SETS((os, device), (city), ());
```

A similar output is displayed.

Command output

	os	device	city	_c3
1	ios	Phone	\N	1
2	linux	PC	\N	1
3	linux	Phone	\N	1
4	windows	PC	\N	3
5	windows	Phone	\N	1
6	\N	\N	Beijing	4
7	\N	\N	Shijiazhuang	3
8	\N	\N	\N	7

Note You can also execute multiple SELECT statements to obtain the same result.

```
SELECT NULL, NULL, NULL, COUNT(*)
FROM requests
UNION ALL
SELECT os, device, NULL, COUNT(*)
FROM requests GROUP BY os, device
UNION ALL
SELECT null, null, city, COUNT(*)
FROM requests GROUP BY city;
```

However, the GROUPING SETS method is simpler and more efficient.

Notice Expressions not used in GROUPING SETS use NULL as placeholders. You can execute UNION statements on grouping sets.

1.6.4.6.3. CUBE and ROLLUP

CUBE and ROLLUP are special GROUPING SETS functions. CUBE lists all possible combinations of the specific columns as grouping sets. ROLLUP aggregates data by level to generate grouping sets.

Example

```
GROUP BY CUBE(a, b, c)
-- Equivalent to the following statement:
GROUPING SETS((a,b,c),(a,b),(a,c),(b,c),(a),(b),(c),())

GROUP BY ROLLUP(a, b, c)
-- Equivalent to the following statement:
GROUPING SETS((a,b,c),(a,b),(a), ())

GROUP BY CUBE ( (a, b), (c, d) )
-- Equivalent to the following statement:
GROUPING SETS (
  ( a, b, c, d ),
  ( a, b      ),
  (      c, d ),
  (           )
)

GROUP BY ROLLUP ( a, (b, c), d )
-- Equivalent to the following statement:
```

```
GROUPING SETS (
  ( a, b, c, d ),
  ( a, b, c    ),
  ( a          ),
  (            )
)

GROUP BY a, CUBE (b, c), GROUPING SETS ((d), (e))
-- Equivalent to the following statement:
GROUP BY GROUPING SETS (
  (a, b, c, d), (a, b, c, e),
  (a, b, d),    (a, b, e),
  (a, c, d),    (a, c, e),
  (a, d),       (a, e)
)

GROUP BY grouping sets((b), (c),rollup(a,b,c))
-- Equivalent to the following statement:
GROUP BY GROUPING SETS (
  (b), (c),
  (a,b,c), (a,b), (a), ()
 )
```

1.6.4.6.4. GROUPING and GROUPING_ID

NULL is used as placeholders in grouping sets, but it can also be a value that is manually entered. In the code, however, placeholder NULLs are indistinguishable from value NULLs. The GROUPING function is provided to address this issue.

GROUPING allows you to specify the name of a column as a parameter. If the specified lines are aggregated based on a column whose name is used as a parameter in this function, 0 is returned, indicating that NULL is an entered value. Otherwise, 1 is returned, indicating that NULL is a placeholder.

GROUPING_ID can be used to specify the names of one or more columns as parameters. The GROUPING results in these columns are formed into integers by using BitMap.

Example:

```
SELECT a,b,c ,COUNT(*),
GROUPING(a) ga, GROUPING(b) gb, GROUPING(c) gc, GROUPING_ID(a,b,c) groupingid
FROM VALUES (1,2,3) as t(a,b,c)
GROUP BY CUBE(a,b,c);
```

A similar output is displayed.

Command output

	a	b	c	_c3	ga	gb	gc	groupingid
1	\N	\N	\N	1	1	1	1	7
2	\N	\N	3	1	1	1	0	6
3	\N	2	\N	1	1	0	1	5
4	\N	2	3	1	1	0	0	4
5	1	\N	\N	1	0	1	1	3
6	1	\N	3	1	0	1	0	2
7	1	2	\N	1	0	0	1	1
8	1	2	3	1	0	0	0	0

1.6.4.7. IF statement

MaxCompute SQL supports the IF-ELSE statement.

You can use the IF-ELSE statement to execute SQL scripts with specific conditions. The condition in the IF-ELSE statement can be a standard variable or a scalar subquery that returns only one column value from one row.

The IF statement allows the system to automatically select the execution logic based on the specified conditions. MaxCompute supports the following IF syntax:

```
IF (condition) BEGIN
 statement 1
 statement 2
 ...
END
IF (condition) BEGIN
 statements
END ELSE IF (condition2) BEGIN
 statements
END ELSE BEGIN
 statements
END
```

> **Note** The BEGIN and END conditional clause can be omitted because it contains only one statement, similar to '{ }' in Java.

The IF statement can contain two types of conditions: expressions and scalar subqueries. Both of them are of the BOOLEAN type.

- Expressions: A BOOLEAN-type expression in the IF-ELSE statement determines which branch is executed at the compiling stage. Example:

```
@date := '20190101';
@row TABLE(id STRING); -- Declare the row variable. The type of the row is Table and schema is STR
ING.
IF ( cast(@date as bigint) % 2 == 0 ) BEGIN
@row := SELECT id from src1;
END ELSE BEGIN
@row := SELECT id from src2;
END
INSERT OVERWRITE TABLE dest SELECT * FROM @row;
```

- Scalar subqueries: A BOOLEAN-type scalar subquery in the IF-ELSE statement determines which branch is executed at the running stage. Therefore, you must submit multiple jobs. Example:

```
@i bigint;
@t table(id bigint, value bigint);
IF ((SELECT count(*) FROM src WHERE a = '5') > 1)  BEGIN
@i := 1;
@t := select @i, @i*2;
END ELSE
BEGIN
@i := 2;
@t := select @i, @i*2;
END
select id, value from @t;
```

1.6.5. SELECT TRANSFORM

1.6.5.1. Overview

SELECT TRANSFORM implements features that MaxCompute SQL does not provide. SELECT TRANSFORM allows you to start a specified child process and enter data of a required format into the child process through standard input (stdin). Then, you can parse the standard output (stdout) of the child process to obtain the final output. This process does not require you to compile UDFs.

SELECT TRANSFORM simplifies the reference of script code and supports programming languages such as Java, Python, Shell, and Perl. It is suitable for ad hoc data analysis. MaxCompute Select Transform is fully compatible with Hive syntax, features, and actions, including input/output row format and reader/writer. Most Hive scripts can be added directly to the SELECT TRANSFORM statement. Others can be used after a few changes.

Command syntax:

```
SELECT TRANSFORM(arg1, arg2 ...)
(ROW FORMAT DELIMITED (FIELDS TERMINATED BY field_delimiter (ESCAPED BY character_escape)?)? (LI
NES SEPARATED BY line_separator)? (NULL DEFINED AS null_value)?)?
USING 'unix_command_line'
(RESOURCES 'res_name'  (',' 'res_name') *)?
( AS col1, col2 ...)?
(ROW FORMAT DELIMITED (FIELDS TERMINATED BY field_delimiter (ESCAPED BY character_escape)?)? (LI
NES SEPARATED BY line_separator)? (NULL DEFINED AS null_value)?)?
```

Description:

- SELECT TRANSFORM: The **SELECT TRANSFORM** keyword can be replaced with the **MAP** or **REDUCE** keyword while maintaining the same semantic meaning. However, we recommend that you use**SELECT TRANSFORM** because its syntax is simpler.
- (arg1, arg2 ...): arguments in the TRANSFORM clause. Their format is similar to those of items in the SELECT clause. In the default format, the results of expressions for each argument are combined by using \t after they are implicitly converted into strings. The arguments are then entered into the specified child process.

  > **Note** The default format is configurable. For more information, see **ROW FORMAT**.

- USING: specifies the command used to start a child process. Note the following points about the USING clause.
  - In most MaxCompute SQL statements, the USING clause can only specify resources. However, in the SELECT TRANSFORM statement, the USING clause can specify commands to ensure compatibility with Hive syntax.
  - The format of the USING clause is similar to the syntax of a Shell script. However, a Shell script is not actually expected to start the child process. The child process is created based on the command input. Because of this, a number of Shell functions, such as input and output redirection, pipe, and loop, are unavailable. A Shell script can be used as to start a child process if necessary.
- RESOURCES: specifies the resources that the specified child process can access. You can use one of the following methods to specify resources:
  - Use the RESOURCES clause. Example: `using 'sh foo.sh bar.txt' Resources 'foo.sh','bar.txt'` .
  - Add the `set odps.sql.session.resources=foo.sh,bar.txt;` clause before SQL statements.

    > **Notice** This clause takes effect globally once it is specified. All SELECT TRANSFORM statements will be able to access the resources specified by this clause.

- ROW FORMAT: specifies the input or output format. Two ROW FORMAT clauses are used in the syntax: the first one specifies the input format, and the second one specifies the output format. \t is used to separate columns, \n is used to separate rows, and NULL is represented by \N .

> **Notice**
>
> - For field_delimiter, character_escape, and line_separator, only one character can be accepted. If you specify a string, the first character in the string takes priority over the others.
> - There are a variety of Hive syntaxes to specify formats. MaxCompute supports syntaxes such as inputRecordReader, outputRecordReader, and Serdeinput. To use these formats, you must enable Hive compatibility by adding the `set odps.sql.hive.compatible=true;` clause before SQL statements. If you specify a syntax such as inputRecordReader or outputRecordReader supported by Hive, statements may be executed at lower speeds.

- **AS: specifies output columns.**

> **Note**
>
> - You can specify data types in the AS clause, as in as(col1:bigint, col2:boolean). By default, strings are returned if you do not specify data types, as in as(col1, col2).
> - The output is obtained by parsing the stdout of the child process. If the specified data types do not include STRING, the system implicitly calls the CAST function. Runtime exceptions may occur when the CAST function is called.
> - You cannot specify data types for only some of the columns, as in as(col1, col2:bigint).
> - If you skip the AS clause, the field preceding the first \t in the stdout is a key, and all the following parts are a value. This is equivalent to as(key, value).

1.6.5.2. SELECT TRANSFORM examples

1.6.5.2.1. Call Shell scripts

In this example, a Shell script is used to generate 50 lines of data starting from 1 to 50. The output of the data field is as follows:

```
SELECT  TRANSFORM(script) USING 'sh' AS (data)
FROM   (
       SELECT  'for i in `seq 1 50`; do echo $i; done' AS script
    ) t
;
```

The Shell commands are used as the input of the TRANSFORM clause.

> **Note** In addition to language extensions, SELECT TRANSFORM also provides simple features of AWK, Python, Perl, and Shell to compile scripts in commands. You do not need to compile script files or upload resources separately.

You can upload script files for complex cases, as in the following example Python script call.

1.6.5.2.2. Call Python scripts

This topic provides an example of how to use SELECT TRANSFORM to call Python scripts.

1. Compile a Python script file. In this example, the file name is myplus.py.

```
#! /usr/bin/env python
import sys
line = sys.stdin.readline()
while line:
  token = line.split('\t')
  if (token[0] == '\\N') or (token[1] == '\\N'):
    print '\\N'
  else:
    print int(token[0]) + int(token[1])
  line = sys.stdin.readline()
```

2. Add the Python script file as a resource to MaxCompute.

```
add py ./myplus.py  -f;
```

> **Note** You can also add resources from the DataWorks console.

3. Execute the SELECT TRANSFORM statement to call the resource.

```
Create table testdata(c1 bigint,c2 bigint); -- Create a test table.
insert into Table testdata values (1,4),(2,5),(3,6); -- Insert test data into the test table.
-- Execute the SELECT TRANSFORM statement:
SELECT
TRANSFORM (testdata.c1, testdata.c2)
USING 'python myplus.py'resources 'myplus.py'
AS (result bigint)
FROM testdata;
-- Or
set odps.sql.session.resources=myplus.py;
SELECT
TRANSFORM (testdata.c1, testdata.c2)
USING 'python myplus.py'
AS (result bigint)
FROM testdata;
```

4. A similar output is displayed:

```
+-----+
| cnt |
+-----+
| 5   |
| 7   |
| 9   |
+-----+
```

Python scripts are not subject to any format requirements and do not require a Python framework to be run in MaxCompute. In MaxCompute, Python commands can be used as the input of the TRANSFORM clause. For example, you can call Shell scripts by running Python commands.

```
SELECT TRANSFORM('for i in xrange(1, 50):  print i;') USING 'python' AS (data);
```

1.6.5.2.3. Call Java scripts

Java scripts are called in a similar manner to Python scripts. In this example, you need to compile a Java script file, export it as a JAR package, and then run the add command to add the JAR package as a resource to MaxCompute. The resource will be called by using SELECT TRANSFORM.

1. Compile a Java script file and export it as a JAR package. In this example, the name of the JAR package is Sum.jar.

```
package com.aliyun.odps.test;
import java.util.Scanner;
public class Sum {
 public static void main(String[] args) {
  Scanner sc = new Scanner(System.in);
  while (sc.hasNext()) {
   String s = sc.nextLine();
   String[] tokens = s.split("\t");
   if (tokens.length < 2) {
    throw new RuntimeException("illegal input");
   }
   if (tokens[0].equals("\\N") || tokens[1].equals("\\N")) {
    System.out.println("\\N");
   }
   System.out.println(Long.parseLong(tokens[0]) + Long.parseLong(tokens[1]));
  }
 }
}
```

2. Add the JAR package as a resource to MaxCompute.

```
add jar . /Sum.jar -f;
```

3. Execute the SELECT TRANSFORM statement to call the resource.

```
Create table testdata(c1 bigint,c2 bigint); -- Create a test table.
insert into Table testdata values (1,4),(2,5),(3,6); -- Insert test data into the test table.
-- Execute the SELECT TRANSFORM statement:
SELECT TRANSFORM(testdata.c1, testdata.c2)
  USING 'java -cp Sum.jar com.aliyun.odps.test.Sum' resources 'Sum.jar'
from testdata;
-- Or
set odps.sql.session.resources=Sum.jar;
SELECT TRANSFORM(testdata.c1, testdata.c2)
  USING 'java -cp Sum.jar com.aliyun.odps.test.Sum'
FROM testdata;
```

4. A similar output is displayed:

```
+------+
| cnt |
+------+
| 5   |
| 7   |
| 9   |
+------+
```

You can use the preceding method to run most Java utilities.

Although UDTF frameworks are provided for Java and Python, it is easier to compile code by using SELECT TRANSFORM. SELECT TRANSFORM is a simpler process because it is not subject to any format requirements and can be called offline. The paths for Java and Python offline scripts can be obtained from the JAVA_HOME and PYTHON_HOME environment variables.

1.6.5.2.4. Call scripts of other languages

In addition to language extensions, SELECT TRANSFORM also supports commonly used Unix command and script interpreters, such as AWK and Perl.

An example of calling AWK:

```
SELECT TRANSFORM(*) USING "awk '//{print $2}'" as (data) from testdata;
```

An example of calling Perl:

```
SELECT TRANSFORM (testdata.c1, testdata.c2) USING "perl -e 'while($input = <STDIN>){print $input;}'" F
ROM testdata;
```

> **Notice** PHP and Ruby are not deployed in the MaxCompute cluster and cannot be called.

1.6.5.2.5. Call scripts in series

SELECT TRANSFORM allows you to call scripts in series. For example, you can use DISTRIBUTE BY and SORT BY to pre-process data.

```
SELECT TRANSFORM(key, value) USING 'cmd2' from
(
  SELECT TRANSFORM(*) USINg 'cmd1' from
  (
    SELECt * FROM data distribute by col2 sort by col1
  ) t distribute by key sort by value
) t2;
```

More often, you can use either the map or reduce keywords to produce the same results.

```
@a := select * from data distribute by col2 sort by col1;
@b := map * using 'cmd1' distribute by col1 sort by col2 from @a;
reduce * using 'cmd2' from @b;
```

1.6.5.3. Performance advantages

The performance of SELECT TRANSFORM and UDTF varies depending on the specific scenario. In general, SELECT TRANSFORM performs better. However, UDTF performs better as the volume of data increases. Because the development of transform is easier, SELECT TRANSFORM is more suitable for ad hoc data analysis.

The advantages of UDTFs and SELECT TRANSFORM are listed in the following sections.

Advantages of UDTFs

- Output and input follow specified data types and do not require conversion.
- Processes are not suspended if the operating system pipe is empty or fully occupied. The operating system pipe has a 4 KB buffer.
- Constant parameters do not need to be transmitted.

Advantages of SELECT TRANSFORM

- Supports child and parent processes and can utilize multiple server cores when high CPU usage and low throughput is needed.
- Calls underlying systems to read and write data to be transmitted, giving it a higher performance than Java.
- Supports tools such as AWK and can run native code.

1.6.6. UNION, INTERSECT, and EXCEPT

This topic describes SQL syntax, descriptions and examples of UNOIN ALL, UNION DISTINCT, INTERSECT ALL, INTERSECT DISTINCT, EXCEPT ALL, and EXCEPT DISTINCT.

Syntax:

```
select_statement UNION ALL select_statement;
select_statement UNION [DISTINCT] select_statement;
select_statement INTERSECT ALL select_statement;
select_statement INTERSECT [DISTINCT] select_statement;
select_statement EXCEPT ALL select_statement;
select_statement EXCEPT [DISTINCT] select_statement;
select_statement MINUS ALL select_statement;
select_statement MINUS [DISTINCT] select_statement;
```

Purpose: It is used to return the union of two data sets, the intersection of two data sets, or the complement of the second dataset in the first dataset.

Description:

- UNION: returns the union of two datasets. It combines the two datasets into one dataset.
- INTERSECT: returns the intersection of two datasets. It outputs the records contained in both datasets.
- EXCEPT: returns the complement of the second dataset in the first dataset. It outputs the records that are contained in the first dataset, but not in the second dataset.
- MINUS: equivalent to EXCEPT.

Examples:

- **UNOIN ALL example:**

```
SELECT * FROM VALUES (1, 2), (1, 2), (3, 4) t(a, b)
 UNION ALL
SELECT * FROM VALUES (1, 2), (1, 4) t(a, b);
```

Returned result: two datasets are combined.

```
+------------+------------+
| a          | b          |
+------------+------------+
| 1          | 2          |
| 1          | 4          |
| 1          | 2          |
| 1          | 2          |
| 3          | 4          |
+------------+------------+
```

- **UNION DISTINCT example:**

```
SELECT * FROM VALUES (1, 2), (1, 2), (3, 4) t(a, b)
UNION
SELECT * FROM VALUES (1, 2), (1, 4) t(a, b);
```

Returned result: equivalent to `SELECT DISTINCT * FROM (< the result of UNOIN ALL >) t;` .

```
+------------+------------+
| a       | b       |
+------------+------------+
| 1       | 2       |
| 1       | 4       |
| 3       | 4       |
+------------+------------+
```

- **INTERSECT ALL example:**

```
SELECT * FROM VALUES (1, 2), (1, 2), (3, 4), (5, 6) t(a, b)
INTERSECT ALL
SELECT * FROM VALUES (1, 2), (1, 2), (3, 4), (5, 7) t(a, b);
```

Returned result: deduplication is skipped in INTERSECT ALL. It seems that there is a hidden serial number behind the same row and each row can be displayed separately.

```
+------------+------------+
| a       | b       |
+------------+------------+
| 1       | 2       |
| 1       | 2       |
| 3       | 4       |
+------------+------------+
```

- **INTERSECT DISTINCT example:**

```
SELECT * FROM VALUES (1, 2), (1, 2), (3, 4), (5, 6) t(a, b)
INTERSECT
SELECT * FROM VALUES (1, 2), (1, 2), (3, 4), (5, 7) t(a, b);
```

Returned result: `SELECT DISTINCT * FROM (< the result of INTERSECT ALL >) t;` .

```
+------------+------------+
| a          | b          |
+------------+------------+
| 1          | 2          |
| 3          | 4          |
+------------+------------+
```

- **EXCEPT ALL example:**

```
SELECT * FROM VALUES (1, 2), (1, 2), (3, 4), (3, 4), (5, 6), (7, 8) t(a, b)
EXCEPT ALL
SELECT * FROM VALUES (3, 4), (5, 6), (5, 6), (9, 10) t(a, b);
```

Returned result: deduplication is skipped in EXCEPT ALL. There is a hidden serial number behind the same row and each row can be displayed separately.

```
+------------+------------+
| a          | b          |
+------------+------------+
| 1          | 2          |
| 1          | 2          |
| 3          | 4          |
| 7          | 8          |
+------------+------------+
```

- **EXCEPT DISTINCT example:**

```
SELECT * FROM VALUES (1, 2), (1, 2), (3, 4), (3, 4), (5, 6), (7, 8) t(a, b)
EXCEPT
SELECT * FROM VALUES (3, 4), (5, 6), (5, 6), (9, 10) t(a, b);
```

Returned result: equivalent to `Select distinct * FROM left_branch limit t all select distinct * FROM right_branch;` .

```
+------------+------------+
| a          | b          |
+------------+------------+
| 1          | 2          |
| 7          | 8          |
+------------+------------+
```

Note

- Sorting may be skipped in the preceding operations.
- The left and right branches in the preceding operations must have the same number of columns. In addition, if data types in the left and right branches are not consistent, they may be implicitly converted. Due to compatibility issues, implicit conversion is not carried out between STRING and no-STRING types for the preceding operations.
- Up to 256 branches are allowed in the preceding operations. An error is returned if more branches are used.
- If the UNION statement is followed by the CLUSTER BY, DISTRIBUTE BY, SORT BY, ORDER BY or LIMIT clause and you add `set odps.sql.type.system.odps2=false;`, the SET statement is applicable to the last `select_statement;` of the UNION statement. If you add `set odps.sql.type.system.odps2=true;`, the SET statement is applicable to all select_statements of the UNION statement. Example:

  ```
  set odps.sql.type.system.odps2=true;
  SELECT explode(array(3, 1)) AS (a) UNION ALL SELECT explode(array(0, 4, 2)) AS (a) ORDER BY a LIMIT 3;
  ```

  Returned result:

  ```
  +------+
  | a    |
  +------+
  | 0    |
  | 1    |
  | 2    |
  +------+
  ```

1.6.7. Built-in functions

1.6.7.1. Mathematical functions

1.6.7.1.1. ABS

This topic describes the ABS function.

Function declaration:

```
double abs(double number)
bigint abs(bigint number)
decimal abs(decimal number)
```

Purpose: It is used to return absolute values.

Description:

number: double, bigint or decimal type. When the input is of the bigint type, a value of the bigint type is returned; when the input is of the double type, a value of the double type is returned. If the input is of the string type, it is implicitly converted into a value of the double type before this computation. If the input is of another type, an error is returned.

Returned value: double, bigint, or decimal type, depending on the type of the input. If the input is NULL, NULL is returned.

> **Note** When the input is of the bigint type and is out of the maximum range of the bigint type, the returned value is of the double type. In this case, the precision may be diminished.

Example:

```
abs(null) = null
abs(-1) = 1
abs(-1.2) = 1.2
abs("-2") = 2.0
abs(12232083745629837659238745692 3748) = 1.2232083745629837e32
```

The following example shows the usage of a complete ABS function in SQL. Other built-in functions (except window functions and aggregation functions) are in similar usage to this function and are not shown here.

```
select abs(id) from tbl1;
-- Take the absolute value of the id field in tbl1.
```

1.6.7.1.2. ACOS

Function declaration:

```
double acos(double number)
decimal acos(decimal number)
```

Purpose: It is used to calculate the arccosine of a number.

Description:

number: double or decimal type. Value range: -1 to 1. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned.

Returned value: double or decimal type. Value range: 0 to π. If number is NULL, NULL is returned.

Example:

```
acos("0.87") = 0.5155940062460905
acos(0) = 1.5707963267948966
```

1.6.7.1.3. ASIN

Function declaration:

```
double asin(double number)
decimal asin(DECIMAL number)
```

Purpose: It is used to calculate the arcsine of a number.

Description:

number: double or decimal type. Value range: -1 to 1. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned.

Returned value: double or decimal type. Value range: -π/2 to π/2. If number is NULL, NULL is returned.

Example:

```
asin(1) = 1.5707963267948966
asin(-1) = -1.5707963267948966
```

1.6.7.1.4. ATAN

Function declaration:

```
double atan(double number)
```

Purpose: It is used to calculate the arctangent of a number.

Description:

number: double type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned.

Returned value: double type. Value range: -π/2 to π/2. If number is NULL, NULL is returned.

Example:

```
atan(1) = 0.7853981633974483;
atan(-1) = -0.7853981633974483
```

1.6.7.1.5. CEIL

Command syntax:

```
bigint ceil(double value)
bigint ceil(decimal value)
```

Purpose: It is uesed to return the smallest integer that is equal to or greater than the input value.

Description:

value: double or decimal. If the value is of the string or bigint type, it is implicitly converted to the double type. For all other input types, an error is returned.

Returned value: bigint type. If the input is NULL, NULL is returned.

Example:

```
ceil(1.1) = 2
ceil(-1.1) = -1
```

1.6.7.1.6. CONV

Command syntax:

```
string conv(string input, bigint from_base, bigint to_base)
```

Purpose: It is ued to convert a number from one numeric base number system to another.

Description:

- input: an integer of the string type to be converted. It accepts values of the bigint and double types by means of implicit conversion.
- from_base, to_base: a number system value in decimal form. Value range: 2, 8, 10, and 16. It accepts values of the string and double types by means of implicit conversion.

Returned value: string type. If any input is NULL, NULL is returned. The conversion process runs at a 64-bit precision. An error is returned when overflow occurs. If the input is a negative value (beginning with '-'), an error is returned. If the input is a decimal, it is converted to an integer before hex conversion. The decimal part is left out.

Example:

```
conv('1100', 2, 10) = '12'
conv('1100', 2, 16) = 'c'
conv('ab', 16, 10) = '171'
conv('ab', 16, 16) = 'ab'
```

1.6.7.1.7. COS

Command syntax:

```
double cos(double number)
decimal cos(decimal number)
```

Purpose: It is used to return the cosine of a number. The input must be a radian value.

Description:

number: double or decimal type. If the input is of the string or bigint type, it is implicitly converted to a value of the double type. For all other input types, an error is returned.

Returned value: double or decimal type. If the input is NULL, NULL is returned.

Example:

```
cos(3.1415926/2) = 2.6794896585028633e-8
cos(3.1415926) = -0.9999999999999986
```

1.6.7.1.8. COSH

Command syntax:

```
double cosh(double number)
decimal cosh(decimal number)
```

Purpose: It is used to return the hyperbolic cosine of a number.

Description:

number: double or decimal. If the input is of the string or bigint type, it is implicitly converted to a value of the double type. For all other input types, an error is returned.

Returned value: double or decimal. If the input is NULL, NULL is returned.

1.6.7.1.9. COT

Function declaration:

```
double cot(double number)
decimal cot(decimal number)
```

Purpose: It is used to return the cotangent of a number. The input must be a radian value.

Description:

number: double or decimal. If the input is of the string or bigint type, it is implicitly converted a value of the double type. For all other input types, an error is returned.

Returned value: double or decimal type. If the input is NULL, NULL is returned.

1.6.7.1.10. EXP

Function declaration:

```
double exp(double number)
decimal exp(decimal number)
```

Purpose: It is used to return the exponent value of number.

Description:

number: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned.

Returned value: double or decimal type. If number is NULL, NULL is returned.

1.6.7.1.11. FLOOR

Function declaration:

```
bigint floor(double number)
bigint floor(decimal number)
```

Purpose: It is used to return the round-down integer that is less than or equal to number.

Description:

number: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned.

Returned value: bigint type. If number is NULL, NULL is returned.

Example:

```
floor(1.2) = 1
floor(1.9) = 1
floor(0.1) = 0
floor(-1.2) = -2
floor(-0.1) = -1
floor(0.0) = 0
floor(-0.0) = 0
```

1.6.7.1.12. LN

Function declaration:

```
double ln(double number)
decimal ln(decimal number)
```

Purpose: It is used to return the natural logarithm of a number.

Description:

number: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned.

Returned value: double or decimal type. If the input is NULL, negative, or zero, NULL is returned.

1.6.7.1.13. LOG

Function declaration:

```
double log(double base, double x)
decimal log(decimal base, DECIMAL x)
```

Purpose: It is used to return the logarithm of x to base.

Description:

- base: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned.
- x: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned.

Returned value: logarithm value of the double or decimal type. If either base or x is NULL, negative, or zero, NULL is returned. If base is 1 (which leads to division by zero), NULL is returned.

1.6.7.1.14. POW

Command syntax:

```
double pow(double x, double y)
decimal pow(decimal x, decimal y)
```

Purpose: It is used to return the yth power of x, that is, x^y.

Description:

- x: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned.
- y: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned.

Returned value: double or decimal type. If x or y is NULL, NULL is returned.

1.6.7.1.15. RAND

Command syntax:

```
double rand(bigint seed)
```

Purpose: It is used to return a random number of the double type from 0 to 1 based on the seed.

Description:

Seed: optional, bigint type. It is the seed of a random number, and determines the start value of the random number sequence.

Returned value: double type.

Example:

```
select rand() from dual;
select rand(1) from dual;
```

1.6.7.1.16. ROUND

Function declaration:

```
double round(double number, [bigint decimal_places])
decimal round(decimal number, [bigint decimal_places])
```

Purpose: It is used to return a number rounded to the specified decimal place.

Description:

- number: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. If the input is of another type, an error is returned.
- decimal_place: a constant of the bigint type. It indicates the specified decimal place to which the result is to be rounded off. For all other input types, an error is returned. If it is omitted, the number is rounded to the ones place. The default value is 0.

Returned value: double or decimal type. If number or decimal_places is NULL, NULL is returned.

> **Note** decimal_places can be negative. Negative numbers are counted from the decimal point to left and the decimal part is left out; if the value of decimal_places is greater than the length of the integer part, 0 is returned.

Example:

```
round(125.315) = 125.0
round(125.315, 0) = 125.0
Round (125.315, 1) = 125.3
round(125.315, 2) = 125.32
round(125.315, 3) = 125.315
round(-125.315, 2) = -125.32
round(123.345, -2) = 100.0
round(null) = null
round(123.345, 4) = 123.345
round(123.345, -4) = 0.0
```

1.6.7.1.17. SIN

Function declaration:

```
double sin(double number)
decimal sin(decimal number)
```

Purpose: It is used to return the sine of a number. The input must be a radian value.

Description:

number: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned.

Returned value: double or decimal type. If number is NULL, NULL is returned.

1.6.7.1.18. SINH

Function declaration:

```
double sinh(double number)
decimal sinh(decimal number)
```

Purpose: It is used to return the hyperbolic sine of a number.

Description:

number: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned.

Returned value: double or decimal type. If number is NULL, NULL is returned.

1.6.7.1.19. SQRT

Function declaration:

```
double sqrt(double number)
decimal sqrt(decimal number)
```

Purpose: It is used to return the square root of a number.

Description:

number: double or decimal type. It must be greater than 0. If it is less than 0, an error is returned. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other types of inputs, an error is returned.

Returned value: double or decimal type. If number is NULL, NULL is returned.

1.6.7.1.20. TAN

Function declaration:

```
double tan(double number)
decimal tan(decimal number)
```

Purpose: It is used to return the tangent of a number. The input must be a radian value.

Description:

number: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other types of inputs, an error is returned.

Returned value: double or decimal type. If number is NULL, NULL is returned.

1.6.7.1.21. TANH

Function declaration:

```
double tanh(double number)
decimal tanh(decimal number)
```

Purpose: It is used to return the hyperbolic tangent of a number.

Description:

number: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other types of inputs, an error is returned.

Returned value: double or decimal type. If number is NULL, NULL is returned.

1.6.7.1.22. TRUNC

Function declaration:

```
double trunc(double number[, bigint decimal_places])
decimal trunc(decimal number[, bigint decimal_places])
```

Purpose: It is used to truncate 'number' to the specified decimal place.

Description:

- number: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other types of inputs, an error is returned.
- decimal_places: a constant of the bigint type. It indicates the decimal place to which a number is to be truncated. Numbers of other types are implicitly converted into values of the bigint type. If it is omitted, the result is truncated to the ones place by default.

Returned value: double or decimal type. If number or decimal_places is NULL, NULL is returned.

> **Note**
>
> - The truncated part is supplemented with 0.
> - decimal_places can be negative. Negative numbers are truncated from the decimal point to the left and the decimal part is left out. If the value of decimal_places is greater than the length of the integer part, 0 is returned.

Example:

```
trunc(125.815) = 125.0
trunc(125.815, 0) =125.0
trunc(125.815, 1) = 125.80000000000001
trunc(125.815, 2) = 125.81
trunc(125.815, 3) = 125.815
trunc(-125.815, 2) = -125.81
trunc(125.815, -1) = 120.0
trunc(125.815, -2) = 100.0
trunc(125.815, -3) = 0.0
trunc(123.345, 4) = 123.345
trunc(123.345, -4) = 0.0
```

1.6.7.1.23. Additional mathematical functions

MaxCompute 2.0 provides additional mathematical functions. You must add the following SET statement before SQL statements contained in the UNHEX function:

```
set odps.sql.type.system.odps2=true;
```

> **Note** You must submit and execute the SET statement and the SQL statements of the new functions simultaneously.

The mathematical functions described in subsequent topics are new in MaxCompute 2.0.

1.6.7.1.24. LOG2

Function declaration:

```
Double log2(DOUBLE number)
Double log2(DECIMAL number)
```

Purpose: It is used to return the logarithm of number to base 2.

Description:

number: double or decimal type.

Returned value: double type. If the input is 0 or NULL, NULL is returned.

Example:

```
log2(null) = null
log2(0) = null
log2(8) = 3.0
```

1.6.7.1.25. LOG10

Function declaration:

```
Double log10(Double number)
Double log10(Decimal number)
```

Purpose: It is used to return the logarithm of number to base 10.

Description:

number: double or decimal type.

Returned value: double type. If the input is 0 or NULL, NULL is returned.

Example:

```
log10(null) = null
log10(0) = null
log10(8) = 0.9030899869919435
log10('abc') = null
```

1.6.7.1.26. BIN

Command syntax:

```
string bin(bigint number)
```

Purpose: It is used to return the binary format of a number.

Description:

number: bigint.

Returned value: string type. If the input is 0, 0 is returned. If the input is NULL, NULL is returned.

Example:

```
bin(0) = '0'
bin(null) = 'null'
bin(12) = '1100'
```

1.6.7.1.27. HEX

Function declaration:

```
STRING hex(BIGINT number)
STRING hex(STRING number)
STRING hex(BINARY number)
```

Purpose: It is used to convert an integer or character into hexadecimal format.

Description:

number: If this value is of the bigint type, the hexadecimal format of the number is returned. If this value is of the string type, the hexadecimal value of the string is returned.

Returned value: string type. If the input is 0, 0 is returned. If the input is NULL, NULL is returned.

Example:

```
hex(0) = '0'
hex('abc') = '616263'
hex(17) = '11'
hex('17') = '3137'
hex(null) = 'null'
```

1.6.7.1.28. UNHEX

Function declaration:

```
BINARY unhex(STRING number)
```

Purpose: It is used to return the regular character string represented in the hexadecimal format.

Description:

number: a hexadecimal string.

Returned value: binary type. If the input is 0, a failure is returned. If the input is NULL, NULL is returned.

Example:

```
unhex('616263') = 'abc'
unhex(616263) = 'abc'
```

1.6.7.1.29. RADIANS

Command syntax:

```
double radians(double number)
```

Purpose: It is used to convert degrees into radians.

Description:

number: double type

Returned value: double type. If the input is NULL, NULL is returned.

Example:

```
radians(90) = 1.5707963267948966
radians(0) = 0.0
radians(null) = null
```

1.6.7.1.30. DEGREES

Function declaration:

```
DOUBLE degrees(DOUBLE number)
DOUBLE degrees(DECIMAL number)
```

Purpose: It is used to convert radians into degrees.

Description:

number: double or decimal type.

Returned value: double type. If the input is NULL, NULL is returned.

Example:

```
degrees(1.5707963267948966) = 90.0
degrees(0) = 0.0
degrees(null) = null
```

1.6.7.1.31. SIGN

Function declaration:

```
DOUBLE sign(DOUBLE number)
DOUBLE sign(DECIMAL number)
```

Purpose: It is used to indicate the sign of the input data. 1.0 indicates positive and -1.0 indicates negative. 0.0 indicates 0.

Description:

number: double or decimal type.

Returned value: double type. If the input is 0, 0.0 is returned. If the input is NULL, NULL is returned.

Example:

```
sign(-2.5) = -1.0
sign(2.5) = 1.0
sign(0) = 0.0
sign(null) = null
```

1.6.7.1.32. E

Function declaration:

```
DOUBLE e()
```

Purpose: It is used to return the value of e (Euler's number).

Returned value: double type.

Example:

```
e() = 2.718281828459045
```

1.6.7.1.33. PI

Function declaration:

```
DOUBLE pi()
```

Purpose: It is used to return the value of π.

Returned value: double type.

Example:

```
pi() = 3.141592653589793
```

1.6.7.1.34. FACTORIAL

Function declaration:

```
BIGINT factorial(INT number)
```

Purpose: It is used to return the factorial of number.

Description:

number: int type. Value range: 0 to 20.

Returned value: bigint type. If the input is 0, 1 is returned. If the input is NULL or any value outside the range of 0 to 20, NULL is returned.

Example:

```
factorial(5) = 120 --5! = 5*4*3*2*1 = 120
```

1.6.7.1.35. CBRT

Command syntax:

```
double cbrt(double number)
```

Purpose: It is used to return the cube root of a number.

Description:

number: double type.

Returned value: double type. If the input is NULL, NULL is returned.

Example:

```
cbrt(8) = 2
cbrt(null) = null
```

1.6.7.1.36. SHIFTLEFT

Function declaration:

```
INT shiftleft(TINYINT|SMALLINT|INT number1, INT number2)
BIGINT shiftleft(BIGINT number1, INT number2)
```

Purpose: It is used to shift left a value by a given number of places (<<).

Description:

- number1: an integer of the tinyint, smallint, int, or bigint type.
- number2: an integer of the int type.

Returned value: int or bigint type.

Example:

```
shiftleft(1,2) = 4
-- Shift left the binary value of 1 by two places (1<<2, 0001 changed to 0100)
shiftleft(4,3) = 32
-- Shift left the binary value of 4 by three places (4<<3, 0100 changed to 100000)
```

1.6.7.1.37. SHIFTRIGHT

Function declaration:

```
INT shiftright(TINYINT|SMALLINT|INT number1, INT number2)
BIGINT shiftright(BIGINT number1, INT number2)
```

Purpose: It is used to shift right a value by a given number of places (>>).

Description:

- number1: an integer of the tinyint, smallint, int, or bigint type.

- number2: an integer of the int type.

Returned value: int or bigint type.

Example:

```
shiftright(4,2) = 1
-- Shift right the unsigned binary value of 4 by two places (4>>2, 0100 changed to 0001)
shiftright(32,3) = 4
-- Shift right the unsigned binary value of 32 by two places (32>>3, 100000 changed to 0100)
```

1.6.7.1.38. SHIFTRIGHTUNSIGNED

Function declaration:

```
INT shiftrightunsigned(TINYINT|SMALLINT|INT number1, INT number2)
BIGINT shiftrightunsigned(BIGINT number1, INT number2)
```

Purpose: It is used to shift right an unsigned value by a given number of places (>>>).

Description:

- number1: an integer of the tinyint, smallint, int, or bigint type.
- number2: an integer of the int type.

Returned value: int or bigint type.

Example:

```
shiftrightunsigned(8,2) = 2
-- In this example, shift right the unsigned binary value of 8 (1000 in binary) by two places and return 2
(0010 in binary).
shiftrightunsigned(-14,2) = 1073741820
-- Shift right the unsigned binary value of -14 by two places (-14>>>2, 11111111 11111111 11111111 111
10010 changed to 00111111 11111111 11111111 11111100)
```

1.6.7.2. String processing functions

1.6.7.2.1. CHAR_MATCHCOUNT

Command syntax:

```
bigint char_matchcount(string str1, string str2)
```

Purpose: It is used to return the number of characters in str1 that appear in str2 (repeated characters are not counted).

Description:

str1 and str2: string type. Both must be valid UTF-8 strings. If invalid characters are found during matching, a negative value is returned.

Returned value: bigint type. If any input is NULL, NULL is returned.

Example:

```
char_matchcount('abd', 'aabc') = 2
-- The a and b characters in str1 appear in str2.
```

1.6.7.2.2. CHR

Command syntax:

```
string chr(bigint ascii)
```

Purpose: It is used to convert an ASCII code into the corresponding character.

Description:

ascii: ASCII value of the bigint type. If the input is of the string, double, or decimal type, it is implicitly converted into a value of the bigint type before this computation. If the input is of another type, an error is returned.

Returned value: string type. The parameter value range is from 0 to 255. A value out of range will cause an error. If the input is NULL, NULL is returned.

1.6.7.2.3. CONCAT

Command syntax:

```
string concat(string a, string b...)
```

Purpose: It is used to join input strings into a single string.

Description:

a, b...: string type. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type. For all other input types, an error is returned.

Returned value: string type. If there is no input or if any input is NULL, NULL is returned.

Example:

```
concat('ab', 'c') = 'abc'
concat() = null
concat('a', null, 'b') = null
```

1.6.7.2.4. INSTR

Function declaration:

```
bigint instr(string str1, string str2[, bigint start_position[, bigint nth_appearance]])
```

Purpose: It is used to calculate the position of substring str2 in string str1.

Description:

- str1: string type. It indicates a string to be searched. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. For all other input types, an error is returned.
- str2: string type. It indicates a substring to be searched out. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. For all other input types, an error is returned.
- start_position: bigint type. If it is of another type, an error is returned. It indicates which character in str1 the search will start with. The default start position is the first character, marked as 1.
- nth_appearance: bigint type. If it is greater than 0, it indicates the position where the substring matches the string for the nth_appearance time. If it is of another type or if it is less than or equal to 0, an error is returned.

Returned value: bigint type.

> **Note**
>
> - If str2 is not found in str1, 0 is returned.
> - If any input is NULL, NULL is returned.
> - If str2 is NULL, the matching will always be successful. Therefore, 1 is returned for instr('abc', '').

Example:

```
instr('Tech on the net', 'e') = 2
instr('Tech on the net', 'e', 1, 1) = 2
instr('Tech on the net', 'e', 1, 2) = 11
instr('Tech on the net', 'e', 1, 3) = 14
```

1.6.7.2.5. IS_ENCODING

Function declaration:

```
boolean is_encoding(string str, string from_encoding, string to_encoding)
```

Purpose: It is used to determine whether an input string can be converted from a specified character set (from_encoding) to another character set (to_encoding). It can be used to determine whether the input is garbled. from_encoding is usually set to utf-8, and to_encoding is set to gbk.

Description:

- str: string type. If the input is NULL, NULL is returned. Null is considered to belong to any

character set.

- from_encoding, to_encoding: string type. They indicate the source and the destination character sets respectively. If the input is NULL, NULL is returned.

Returned value: boolean type. If a string is converted successfully, true is returned. Otherwise, false is returned.

Example:

```
is_encoding('test', 'utf-8', 'gbk') = true
is_encoding('test', 'utf-8', 'gbk') = true
-- These two traditional Chinese characters are in GBK stock in China.
is_encoding('test', 'utf-8', 'gb2312') = false
-- The grapheme inventory of 'GB2312' does not contain these two Chinese characters.
```

1.6.7.2.6. KEYVALUE

Function declaration:

```
KEYVALUE(STRING srcStr, STRING split1, STRING split2, STRING key)
KEYVALUE(STRING srcStr, STRING key) //split1 = ";", split2 = ":"
```

Purpose: It is used to split the source string into key-value pairs by split1, separate key-value pairs by split2, and return the value of the corresponding key.

Description:

- srcStr: the source string to be split.
- key: string type. After the source string is split by 'split1' and 'split2', return the corresponding value according to the specification of the 'key' value.
- split1 and split2: strings used as separators. The source string is split by the two separators. If these two parameters are not specified in the expression, split1 is a semicolon (;) and split2 is a colon (:) by default. If a string that has been split by split1 has multiple split2 values, the returned result is undefined.

Returned value: string type.

- If 'split1' or 'split2' is NULL, return NULL.
- If 'scrStr' and 'key' are NULL or if there is no matched 'key', return NULL.
- If multiple 'key-value' matches, return the value corresponding to the first matched key.

Example:

```
keyvalue('0:1\;1:2', 1) = '2'
-- The source string is "0:1\;1:2". Because split1 and split2 are not specified, split1 is a semicolon (;) a
nd split2 is a colon (:) by default. After split1 split, the key-value pair is:
0:1\,1:2
After split2 split, it becomes:
0 1/
1 2
Returns the value(2) of the key corresponding to 1.
keyvalue("\;decreaseStore:1\;xcard:1\;isB2C:1\;tf:21910\;cart:1\;shipping:2\;pf:0\;market:shoes\;in
stPayAmount:0\;", "\;",":","tf") = "21910"
-- The source string is "\;decreaseStore:1\;xcard:1\;isB2C:1\;tf:21910\;cart:1\;shipping:2\;pf:0\;mar
ket:shoes\;instPayAmount:0\;". After the source string is split by split1 "\;", the key-value pairs are a
s follows:
decreaseStore:1, xcard:1, isB2C:1, tf:21910, cart:1, shipping:2, pf:0, market:shoes, instPayAmount:0
 If split2 is ":", after split it becomes:
decreaseStore 1
xcard 1
isB2C 1
tf 21910
cart 1
shipping 2
pf 0
market shoes
instPayAmount 0
For the key parameter whose value is "tf", the returned value of the corresponding value parameter is
21910.
```

1.6.7.2.7. LENGTH

Function declaration:

```
bigint length(string str)
```

Purpose: It is used to return the length of a string.

Description:

str: string type. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. For all other input types, an error is returned.

Returned value: bigint type. If a string is NULL, NULL is returned. If a string is not UTF-8 encoded, -1 is returned.

Example:

```
length('hi! China') = 6
```

1.6.7.2.8. LENGTHB

Function declaration:

```
bigint lengthb(string str)
```

Purpose: It is used to return the length of a string. Unit: byte.

Description:

str: string type. If the input is of the bigint, double, decimal, or datetime type, it is implicitly converted into a value of the string type before this computation. If the input is of another type, an error is returned.

Returned value: bigint type. If the input is NULL, NULL is returned.

Example:

```
lengthb('hi! china') = 10
```

1.6.7.2.9. MD5

Function declaration:

```
string md5(string value)
```

Purpose: It is used to calculate the MD5 value of the input string value.

Description:

value: string type. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. If the input is of another type, an error is returned.

Returned value: string type. If the input is NULL, NULL is returned.

1.6.7.2.10. PARSE_URL

Function declaration:

```
STRING PARSE_URL(STRING url, STRING part[,STRING key])
```

Purpose: It is used to parse a URL and extract information by key.

Description:

- If URL or part is NULL, NULL is returned. If URL is invalid, an error is returned.
- part: string type. It supports HOST, PATH, QUERY, REF, PROTOCOL, AUTHORITY, FILE, and USERINFO, and is case insensitive. If it is none of the preceding values, an error is returned.
- If part is QUERY, the value in query string that corresponds to the key value is extracted.

Otherwise, the parameter key is ignored.

Returned value: string type.

Example:

```
url = file://username:password@example.com:8042/over/there/index.dtb? type=animal&name=narwh
al#nose
parse_url('url', 'HOST') = "example.com"
parse_url('url', 'PATH') = "/over/there/index.dtb"
parse_url('url', 'QUERY') = "type=animal&name=narwhal"
parse_url('url', 'QUERY', 'name') = "narwhal"
parse_url('url', 'REF') = "nose"
parse_url('url', 'PROTOCOL') = "file"
parse_url('url', 'AUTHORITY') = "username:password@example.com:8042"
parse_url('url', 'FILE') = "/over/there/index.dtb? type=animal&name=narwhal"
parse_url('url', 'USERINFO') = "username:password"
```

1.6.7.2.11. REGEXP_EXTRACT

Command syntax:

```
string regexp_extract(string source, string pattern[, bigint occurrence])
```

Purpose: It is used to return part of the source string that matches the regular expression and the occurrence of the matches.

Description:

- source: string type. It indicates a string to be searched.
- pattern: string type. If pattern is NULL or if there is no specified group in pattern, an error is returned.
- occurrence: bigint type. It must be a number that is greater than or equal to 0. Otherwise, an error is returned. The default value is 1 if it is not specified. If it is 0, a substring which meets all pattern requirements is returned.

Returned value: string type. If any input is NULL, NULL is returned.

Example:

```
regexp_extract('foothebar', 'foo(. *?)( bar)', 1) = the
regexp_extract('foothebar', 'foo(. *?)( bar)', 2) = bar
regexp_extract('foothebar', 'foo(. *?)( bar)', 0) = foothebar
regexp_extract('8d99d8', '8d(\\d+)d8') = 99
-- If the regular expression is submitted at the MaxCompute client, two backslashes (\) are needed to be used as the escape character.
regexp_extract('foothebar', 'foothebar')
-- An error is returned because no part is specified in the pattern.
```

1.6.7.2.12. REGEXP_INSTR

Function declaration:

```
bigint regexp_instr(string source, string pattern[,bigint start_position[, bigint nth_occurrence[, bigint return_option]])
```

Purpose: It is used to return the start or end position of the substring that matches the pattern in the source string from start_position for the nth_occurrence time.

Description:

- source: string type. It indicates a string to be searched.
- pattern: a constant of the string type. If pattern is null, an error is returned.
- start_position: a constant of 'bigint' type. It is the start position for the search. When it is not specified, it is 1 by default. If it is of another type or less than or equal to 0, an error is returned.
- nth_occurrence: a constant of the bigint type. When it is not specified, it is 1 by default, indicating the position where a substring matches pattern in search for the first time. If it is of another type or if it is less than or equal to 0, an error is returned.
- return_option: a constant of the bigint type. The value is either 0 or 1. If it is of another type or the value is not supported, an error is returned. 0 indicates that the start position of the matched substring is returned, and 1 indicates that the end position of the matched substring is returned.

Returned value: bigint type. It is the start or end position of the matched substring in source string according to the type specified by return_option. If any input is NULL, NULL is returned.

Example:

```
regexp_instr("i love www.taobao.com", "o[[:alpha:]]{1}", 3, 2) = 14
```

1.6.7.2.13. REGEXP_SUBSTR

Function declaration:

```
string regexp_substr(string source, string pattern[, bigint start_position[, bigint nth_occurrence]])
```

Purpose: It is used to return the string that matches pattern in the source string from position start_position for the nth_occurence time.

Description:

- source: string type. It indicates a string to be searched.
- pattern: a constant of the string type. It indicates a pattern to be matched. If pattern is null, an error is returned.
- start_position: a constant of the bigint type. It must be greater than 0. If it is another type or if it is less than or equal to 0, an error is reported. When it is not specified, it is regarded as 1 by default, so the matching starts from the first character of 'source'.
- nth_occurrence: a constant of the bigint type. It must be greater than 0. If it is another type or is less than or equal to 0, an error is returned. If it is not specified, it is regarded as 1 by default, indicating that the string in the first match is returned.

Returned value: string type. If any input is NULL, NULL is returned. If there is no matching, NULL is returned.

Example:

```
regexp_substr ("I love aliyun very much", "a[[:alpha:]]{5}") = "aliyun"
regexp_substr('I have 2 apples and 100 bucks!', '[[:blank:]][[:alnum:]]*', 1, 1) = " have"
regexp_substr('I have 2 apples and 100 bucks!', '[[:blank:]][[:alnum:]]*', 1, 2) = "2"
```

1.6.7.2.14. REGEXP_COUNT

Command syntax:

```
bigint regexp_count(string source, string pattern[, bigint start_position])
```

Purpose: It is used to return the number of occurrences that a string pattern appears in the source string, starting from start_position.

Description:

- source: string type. It indicates a string to be searched. For all other input types, an error is returned.
- pattern: string type. It indicates a pattern to be matched. If the pattern is NULL or of another type, an error is returned.
- start_position: bigint start_position must be a number that is greater than 0. Otherwise, an error is returned. If start_position is not specified, the default value is 1 which means starting from the first character of the source string.

Returned value: bigint type. If any input is NULL, NULL is returned. If there is no matching, 0 is returned.

Example:

```
regexp_count('abababc', 'a.c') = 1
regexp_count('abcde', '[[:alpha:]]{2}', 3) = 1
```

1.6.7.2.15. SPLIT_PART

Function declaration:

```
string split_part(string str, string delimiter, bigint start[, bigint end])
```

Purpose: It is used to split a string with the specified delimiter, and return the string between the specified start segment and end segment (inclusive).

Description:

- str: string type. It indicates a string to be split. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. If the input is of any other type, an error is returned.
- delimiter: a constant of the string type. It indicates the delimiter used to split a string. It can be a character or a string. If it is neither a character nor a string, an error is returned.
- start: a constant of the bigint type. It must be greater than 0. If it is not a constant or is of a different type, an error is returned. It indicates the start number (starting from 1) of the segment to be returned. If end is not specified, the segment specified by start is returned.
- end: a constant of the bigint type. It must be greater than or equal to the value of start; otherwise, an error is returned. It indicates the end number of the segment to be returned. If it is not a constant or is of a different type, an error is returned. If end is not specified, the last segment is returned.

Returned value: string type. If any input is NULL, NULL is returned. If delimiter is NULL, the original string is returned.

> **Note**
>
> - If delimiter does not exist in str, and start is set to 1, the entire str is returned. If the input is NULL, NULL is returned.
> - If start is set to a value greater than the number of segments (for example, the string has 6 segments but the start value is greater than 6), NULL is returned.
> - If end is set to a value greater than the number of segments, the string between start and the last segment is returned.

Example:

```
split_part('a,b,c,d', ',', 1) = 'a'
split_part('a,b,c,d', ',', 1, 2) = 'a,b'
split_part('a,b,c,d', ',', 10) = ''
```

1.6.7.2.16. REGEXP_REPLACE

Function declaration:

```
string regexp_replace(string source, string pattern, string replace_string[, bigint occurrence])
```

Purpose: It is used to search a source string for substrings that match a given pattern, replace them with the specified replace_string, and return the result.

Description:

- source: string type. It indicates a string to be replaced.
- pattern: a constant of the string type. It indicates a pattern to be matched. If pattern is null, an error is returned.
- replace_string: string type. It is used to replace the matched pattern.
- occurrence: a constant of the bigint type. It must be greater than or equal to 0. This parameter indicates the number of times at which the substring matches the pattern for replacement with replace_string. If the input value is 0, all matched substrings are replaced. If it is of another type or less than 0, an error is returned. It can be omitted. The default value is 0.

Returned value: string type. When the referenced group does not exist, the replace operation is not performed. When the input parameters source, pattern, and occurrence are NULL, NULL is returned. If replace_string is NULL and the pattern is matched, NULL is returned. If replace_string is NULL but the pattern is not matched, the original string is returned.

> **Note** When the referenced group does not exist, the action is not defined.

Example:

```
regexp_replace("123.456.7890", "([[:digit:]]{3})\\.([[:digit:]]{3})\\.([[:digit:]]{4})", "(\\1)\\2-\\3", 0) = "(123
)456-7890"
regexp_replace("abcd", "(.)", "\\1 ", 0) = "a b c d "
regexp_replace("abcd", "(.)", "\\1 ", 1) = "a bcd"
regexp_replace("abcd", "(.)", "\\2", 1) = "abcd"
-- Only a group is defined in pattern and the referenced second group is not existent.
-- Please avoid this. The result to reference nonexistent group is not defined.
regexp_replace("abcd", "(. *)(.)$", "\\2", 0) = "d"
regexp_replace("abcd", "a", "\\1", 0) = "bcd"
-- No group definition is in pattern, so '\1' references a nonexistent group.
-- Try to avoid this. The result of referencing a nonexistent group is not defined.
```

1.6.7.2.17. SUBSTR

Function declaration:

```
string substr(string str, bigint start_position[, bigint length])
```

Purpose: It is used to return a substring of 'length' from 'str' starting from 'start_position'.

Description:

- str: string type. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. For all other types of inputs, an error is returned.

- start_position: bigint type. The start position is 1. If start_position is a negative value, the counting starts from the end to the start of the string and the last character is -1. If the input is of another type, an error is returned.
- length: bigint type. It indicates the length of the substring, which is greater than 0. If it is of another type or less than or equal to 0, an error is returned.

Returned value: string type. If any input is NULL, NULL is returned.

> **Note** If the length is omitted, the substring from start to end is returned.

Example:

```
substr("abc", 2) = "bc"
substr("abc", 2, 1) = "b"
substr("abc",-2,2) = "bc"
substr("abc",-3) = "abc"
```

1.6.7.2.18. TOLOWER

Function declaration:

```
string tolower(string source)
```

Purpose: It is used to convert 'source' into a lowercase string and return the value.

Description:

source: string type. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. For all other input types, an error is returned.

Returned value: string type. If the input is NULL, NULL is returned.

Example:

```
tolower("aBcd") = "abcd"
tolower("Haha Cd") = "haha cd"
```

1.6.7.2.19. TOUPPER

Function declaration:

```
string toupper(string source)
```

Purpose: It is used to convert 'source' into an uppercase string and return the value.

Description:

source: string type. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. For all other types of inputs, an error is returned.

Returned value: string type. If the input is NULL, NULL is returned.

Example:

```
toupper("aBcd") = "ABCD"
toupper("HahaCd") = "HAHACD"
```

1.6.7.2.20. TO_CHAR

Function declaration:

```
string to_char(boolean value)
string to_char(bigint value)
string to_char(double value)
string to_char(decimal value)
```

Purpose: It is used to convert the input of the boolean, bigint, decimal, or double type into a value of the string type.

Description:

value: boolean, bigint, or double type. For all other types of inputs, an error is returned. For more information about the formatted output of data of the datetime type, see Date processing functions — TO_CHAR.

Returned value: string type. If the input is NULL, NULL is returned.

Example:

```
to_char(123) = '123'
to_char(true) = 'TRUE'
to_char(1.23) = '1.23'
to_char(null) = 'null'
```

1.6.7.2.21. TRIM

Function declaration:

```
string trim(string str)
```

Purpose: It is used to remove the spaces from both ends of 'str'.

Description:

str: string type. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. For all other types of inputs, an error is returned.

Returned value: string type. If the input is NULL, NULL is returned.

1.6.7.2.22. LTRIM

Function declaration:

```
string ltrim(string str)
```

Purpose: It is used to remove the left spaces for input string str.

Description:

str: string type. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. For all other input types, an error is returned.

Returned value: string type. If the input is NULL, NULL is returned.

Example:

```
select ltrim(' abc ') from dual;
-- Returned result:
+-----+
| _c0 |
+-----+
| abc  |
+-----+
```

1.6.7.2.23. RTRIM

Function declaration:

```
string rtrim(string str)
```

Purpose: It is used to remove the rightmost spaces from the input string 'str'.

Description:

str: string type. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. For all other input types, an error is returned.

Returned value: string type. If the input is NULL, NULL is returned.

Example:

```
select rtrim('a abc ') from dual;
-- Returned result:
+-----+
| _c0 |
+-----+
| a abc |
+-----+
```

1.6.7.2.24. REVERSE

Function declaration:

```
STRING REVERSE(string str)
```

Purpose: It is used to return a reverse string.

Description:

str: string type. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. For all other input types, an error is returned.

Returned value: string type. If the input is NULL, NULL is returned.

Example:

```
select reverse('abcedfg') from dual;
-- Returned result:
+-----+
| _c0 |
+-----+
| gfdecba |
+-----+
```

1.6.7.2.25. SPACE

Function declaration:

```
STRING SPACE(bigint n)
```

Purpose: It is used to return a string with 'n' consecutive space characters.

Description:

n: bigint type. The length cannot exceed 2 MB. If the input is NULL, an error is returned.

Returned value: string type.

Example:

```
select length(space(10)) from dual;
-- 10 is returned.
select space(400000000000) from dual;
-- An error is returned as the length exceeds 2 MB.
```

1.6.7.2.26. REPEAT

Function declaration:

```
STRING REPEAT(string str, bigint n)
```

Purpose: It is used to return string 'str' that has been repeated n times.

Description:

- str: string type. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. For all other input types, an error is returned.
- n: bigint type. The length cannot exceed 2 MB. If it is NULL, an error is returned.

Returned value: string type.

Example:

```
select repeat('abc',5) from lxw_dual;
-- abcabcabcabcabc is returned.
```

1.6.7.2.27. ASCII

Function declaration:

```
Bigint ASCII(string str)
```

Purpose: It is used to return the ASCII code of the first character of string 'str'.

Description:

str: string type. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. For all other input types, an error is returned.

Returned value: bigint type.

Example:

```
select ascii('abcde') from dual;
-- 97 is returned.
```

1.6.7.2.28. URL_ENCODE

Function declaration:

```
STRING URL_ENCODE(STRING input[, STRING encoding])
```

Purpose: It is used to encode the input string in the application/x-www-form-urlencoded MIME format:

- a-z and A-Z remain unchanged.
- ".", "-", "*", and "_" remain unchanged.
- Spaces are converted into "+".
- The rest of the characters are converted into byte values according to the specified encoding. If encoding is not specified, UTF-8 is used by default. In this case, each byte value is represented in the %xy format, where xy represents the hexadecimal form of the character.

Description:

- input: string type.
- encoding: specifies an encoding format. If it is not specified, UTF-8 is used by default.

Returned value: string type. If the input is NULL, NULL is returned.

Example:

```
url_encode('Example  for url_encode:// (fdsf)') = "%E7%A4%BA%E4%BE%8Bfor+url_encode%3A%2F%2F+
%28fdsf%29"
url_encode('Example for url_encode :// dsf(fasfs)', 'GBK') = "Example+for+url_encode+%3A%2F%2F+dsf
%28fasfs%29"
```

1.6.7.2.29. URL_DECODE

Function declaration:

```
STRING URL_DECODE(STRING input[, STRING encoding])
```

Purpose: It is used to convert an input string from the application/x-www-form-urlencoded MIME format into a normal string. This is the inverse function of URL_ENCODE:

- a-z and A-Z remain unchanged.
- ".", "-", "*", and "_" remain unchanged.
- "+" is converted into a space.
- The %xy formatted sequence is converted into byte values. Consecutive byte values are interpreted as the corresponding strings based on the input encoding.
- Other characters remain unchanged.
- The final returned value of the function is a UTF-8 string.

Description:

- input: string type.

- encoding: specifies an encoding format. If it is not specified, UTF-8 is used by default.

Returned value: string type. If the input is NULL, NULL is returned.

Example:

```
url_decode('%E7%A4%BA%E4%BE%8Bfor+url_encode%3A%2F%2F+%28fdsf%29')= "Example for url_enco
de:// (fdsf)"
url_decode('Exaple+for+url_encode+%3A%2F%2F+dsf%28fasfs%29', 'GBK') = "Exaple for url_encode ://
dsf(fasfs)" ```
```

1.6.7.2.30. Additional string processing functions

MaxCompute 2.0 provides additional string processing functions. You must add the following SET statement before SQL statements contained in the LPAD, RPAD, and TRANSLATE functions:

```
set odps.sql.type.system.odps2=true;
```

> **Note** You must submit and execute the SET statement and the SQL statements of the new functions simultaneously.

The string processing functions described in subsequent topics are new in MaxCompute 2.0.

1.6.7.2.31. CONCAT_WS

Command syntax:

```
string concat_ws(string SEP, string a, string b...)
```

Purpose: It is used to join input strings starting from the second with the first string as the separator.

Description:

- SEP: delimiter of the tring type. If it is not specified, an error is returned.
- a, b...: string type. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type. For all other input types, an error is returned.

Returned value: string type. If there is no input or if any input is NULL, NULL is returned.

Example:

```
concat_ws(':','name','bob') = 'name:bob'
concat_ws(':','avg',null,'34')= 'null'
```

1.6.7.2.32. LPAD

Function declaration:

```
string lpad(string a, int len, string b)
```

Purpose: It is used to pad the left side of string a with string b until the new padded string has len bits.

Description:

- len: int type.
- a, b: string type.

Returned value: string type. If len is less than the number of bits in a, a is truncated from the left to obtain a string with the number of bits specified by len. If len is 0, NULL is returned.

Example:

```
lpad('abcdefgh',10,'12')='12abcdefgh'
lpad('abcdefgh',5,'12')='abcde'
lpad('abcdefgh',0,'12')
-- NULL is returned.
```

1.6.7.2.33. RPAD

Function declaration:

```
string rpad(string a, int len, string b)
```

Purpose: It is used to pad the right side of string 'a' with string 'b' until the new padded string has 'len' places.

Description:

- len: int type.
- a, b: string type.

Returned value: string type. If len is smaller than the number of characters in a, a is truncated from the left to obtain a string with the number of characters specified by len. If len is 0, NULL is returned.

Example:

```
rpad('abcdefgh',10,'12')='abcdefgh12'
rpad('abcdefgh',5,'12')='abcde'
rpad('abcdefgh',0,'12')
-- NULL is returned.
```

1.6.7.2.34. REPLACE

Function declaration:

```
string replace(string a, string OLD, string NEW)
```

Purpose: It is used to replace the part of string a that is exactly the same as string OLD with string NEW, and return string a.

Description:

All parameters are of the string type.

Returned value: string type. If any input is NULL, NULL is returned.

Example:

```
replace('abababab','abab','12') = '12ab'
replace('abababab','cdf','123') = 'abababab'
replace('123abab456ab',null,'abab') = 'null'
```

1.6.7.2.35. SOUNDEX

Function declaration:

```
string soundex(string a)
```

Purpose: It is used to convert an ordinary string into a soundex string.

Description:

All parameters are of the string type.

Returned value: string type. If the input is NULL, NULL is returned.

Example:

```
soundex('hello') = 'H400'
```

1.6.7.2.36. SUBSTRING_INDEX

Function declaration:

```
string substring_index(string a, string SEP, int count))
```

Purpose: It is used to return the substring in 'a' that comes before the 'count' (nth) delimiter ('SEP'). If 'count' is a positive value, it starts from the left of the string. If 'count' is a negative value, it starts from the right of the string.

Description:

- a, SEP: string type.
- count: int type.

Returned value: string type. If the input is NULL, NULL is returned.

Example:

```
substring_index('https://help.aliyun.com', '.', 2) = 'https://help.aliyun'
substring_index('https://help.aliyun.com', '.', -2) = 'aliyun.com'
substring_index('https://help.aliyun.com', null, 2) = 'null'
```

1.6.7.2.37. TRANSLATE

Function declaration:

```
string translate(string|varchar str1, string|varchar str2, string|varchar str3)
```

Purpose: It is used to replace str2 in str1 with str3.

Returned value: STRING type. If any input is NULL, NULL is returned.

Example:

```
translate('MaxComputer','puter','pute')='MaxCompute'
translate('aaa','b','c')='aaa'
translate('MaxComputer','puter',null)=null
```

1.6.7.2.38. JSON_TUPLE

Function declaration:

```
string json_tuple(string json,string key1,string key2,...)
```

Description: This function extracts specific strings from a standard JSON string based on a set of input keys, such as key1 and key2.

Parameters:

- json: a value of the STRING type, which indicates a standard JSON string.
- key: a value of the STRING type, which is used to describe the JSON path. You can enter multiple keys at a time. A key cannot start with a dollar sign ($).

Return value: A value of the STRING type is returned.

Note

- If the json parameter is empty or invalid, NULL is returned.
- If the key parameter is empty or invalid, NULL is returned. If the key parameter does not exist in the JSON string, it is considered invalid.
- If the json parameter is valid and the key parameter exists, the required string is returned.
- This function parses a JSON string the same way as the GET_JSON_OBJECT function for which `set odps.sql.udf.getjsonobj.new=true;` is added. To parse a JSON string multiple times, you must call the GET_JSON_OBJECT function multiple times. However, the JSON_TUPLE function allows you to enter multiple keys at a time and parse the JSON string only once. This improves parsing efficiency.
- JSON_TUPLE is a user-defined table-valued function (UDTF). To select other columns, use JSON_TUPLE with LATERAL VIEW.

Example:

The school table contains the following data:

```
Table: school
+------------+------------+
| Id       | json     |
+------------+------------+
| 1        | {
            "School name": "湖畔大学",
            "Location":"杭州",
            "SchoolRank": "00",
            "Class1":{
              "Student":[{
                "studentId":1,
                "scoreRankIn3Year":[1,2,[3,2,6]]
              }, {
                "studentId":2,
                "scoreRankIn3Year":[2,3,[4,3,1]]
             }]}
           }        |
+------------+------------+
```

Extract JSON objects.

```
SELECT json_tuple(school.json,"SchoolRank","Class1") AS (item0,item1) FROM school;
-- Equivalent to the following statement: SELECT get_json_object(school.json,"$.SchoolRank") item0,ge
t_json_object(school.json,"$.Class1") item1 FROM school;
-- The following result is returned:
+-------+-------+
| item0 | item1 |
+-------+-------+
| 00    | {"Student":[{"studentId":1,"scoreRankIn3Year":[1,2,[3,2,6]]},{"studentId":2,"scoreRankIn3Year":[2
,3,[4,3,1]]}]} |
+-------+-------+
```

Parse JSON data that contains Chinese characters.

```
SELECT json_tuple(school.json,"School name","Location") AS (item0,item1) FROM school;
-- The following result is returned:
+-------+-------+
| item0 | item1 |
+-------+-------+
| 湖畔大学 | 杭州 |
+-------+-------+
```

Parse nested JSON data.

```
SELECT sc.Id, q.item0, q.item1
FROM school sc LATERAL VIEW json_tuple(sc.json,"Class1.Student.[ *].studentId","Class1.Student.[0] .sc
oreRankIn3Year") q AS item0,item1;
-- The following result is returned:
+------------+-------+-------+
| id         | item0 | item1 |
+------------+-------+-------+
| 1          | [1,2] | [1,2,[3,2,6]] |
+------------+-------+-------+
```

Parse JSON data that contains nested arrays.

```
SELECT sc.Id, q.item0, q.item1
FROM school sc LATERAL VIEW json_tuple(sc.json,"Class1.Student[0].scoreRankIn3Year[2]","Class1.Stud
ent[0].scoreRankIn3Year[2][1]") q AS item0,item1;
-- The following result is returned:
+------------+-------+-------+
| id         | item0 | item1 |
+------------+-------+-------+
| 1          | [3,2,6] | 2     |
+------------+-------+-------+
```

1.6.7.3. Date processing functions

1.6.7.3.1. DATEADD

Function declaration:

```
datetime dateadd(datetime date, bigint delta, string datepart)
```

Purpose: It is used to modify date based on delta and datepart.

Description:

- date: This value must be a string type date.If the input is of the string type, it is implicitly converted into a value of the datetime type before this computation. For all other types of inputs, an error is returned.
- delta: bigint type. It indicates the scope of modification. If the input is of the string or double type, it is implicitly converted into a value of the bigint type before this computation. If the input is of another type, an error is returned. If delta is greater than 0, the delta is added to the value. If delta is less than 0, the delta is subtracted from the value.
- datepart: a constant of the string type. This field is set based on the string-datetime conversion convention. yyyy indicates year and mm indicates month. For rules of type conversion, see Conversion between the string type and datetime type. In addition, the extended date format is also supported: year, month or mon, day, and hour. If the parameter value is not a constant or of an unsupported format or another type, an error is returned.

Returned value: datetime type. If any input is NULL, NULL is returned.

Note

- When delta is added to or subtracted from the value, carrying and borrowing are base-10 for year, base-12 for month, base-24 for hour, and base-60 for minute and second. If delta is measured in months, the following calculation is applied: If the month in the datetime value does not cause the day value to become invalid after delta is added, the day value is kept. Otherwise, the day value is adjusted to the last day of the resulting month.
- This field is set based on the string-datetime conversion convention. yyyy indicates the year and mm indicates the month. Unless otherwise specified, all built-in functions related to the datetime type follow this convention. Unless otherwise specified, the datepart of all built-in functions related to the datetime type also supports the extended date format: year, month or mon, day, and hour.

Example:

```
If trans_date = 2017-02-28 00:00:00:
dateadd(trans_date, 1, 'dd') = 2017-03-01 00:00:00
-- Add one day. The result is beyond the last day of February. The actual value is the first day of next month.
dateadd(trans_date, -1, 'dd') = 2017-02-27 00:00:00
-- Subtract one day.
dateadd(trans_date, 20, 'mm') = 2018-10-28 00:00:00
-- 20 months are added. The month overflows, and 1 is added to the year.
trans_date = 2017-02-28 00:00:00, dateadd(transdate, 1, 'mm') = 2017-03-28 00:00:00
trans_date = 2017-01-29 00:00:00, dateadd(transdate, 1, 'mm') = 2017-02-28 00:00:00
-- February has 28 days only, so the last day of the month is returned.
trans_date = 2017-03-30 00:00:00, dateadd(transdate, -1, 'mm') = 2017-02-28 00:00:00
```

The values of trans_date used only serve as examples. The datetime examples in this document use simple formats. In MaxCompute SQL, a constant cannot be of the datetime type. The following syntax is incorrect:

```
select dateadd(2017-03-30 00:00:00, -1, 'mm') from tbl1;
```

If you must use a constant of the datetime type, use the following method:

```
select dateadd(cast("2017-03-30 00:00:00" as datetime), -1, 'mm') from tbl1;
-- The String type constant is converted to datatime type by explicit conversion.
```

1.6.7.3.2. DATEDIFF

Function declaration:

```
bigint datediff(datetime date1, datetime date2, string datepart)
```

Purpose: It is used to calculate the difference between date1 and date2 based on the specified datepart.

Description:

- date1 and date2: minuend and subtrahend of the datetime type respectively. If the input is a string, it is implicitly converted into a value of the datetime type before this computation. For all other input types, an error is returned.
- datapart: A constant of the string type. It supports the extended date format. If datepart is not in the specified format or is of another type, an error is returned.

Returned value: bigint type. If any input is NULL, NULL is returned. If date1 is less than date2, the returned value may be negative.

> **Note** The lower unit part is truncated based on 'datepart' in the computation process and then the result is calcualted.

Example:

```
If start = 2017-12-31 23:59:59 and end = 2018-01-01 00:00:00:
datediff(end, start, 'dd') = 1
datediff(end, start, 'mm') = 1
datediff(end, start, 'yyyy') = 1
datediff(end, start, 'hh') = 1
datediff(end, start, 'mi') = 1
datediff(end, start, 'ss') = 1
datediff('2017-05-31 13:00:00', '2017-05-31 12:30:00', 'ss') = 1800
datediff('2017-05-31 13:00:00', '2017-05-31 12:30:00', 'mi') = 30
```

1.6.7.3.3. DATEPART

Function declaration:

```
bigint datepart(datetime date, string datepart)
```

Purpose: It is used to extract the value of the specified datepart in date.

Description:

- date: datetime type. If the input is a string, it is implicitly converted into a value of the datetime type before this computation. For all other input types, an error is returned.
- datepart: a constant of the string type. It supports the extended date format. If datepart is not in the specified format or is of another type, an error is returned.

Returned value: bigint type. If any input is NULL, NULL is returned.

Example:

```
datepart('2017-06-08 01:10:00', 'yyyy') = 2017
datepart('2017-06-08 01:10:00', 'mm') = 6
```

1.6.7.3.4. DATETRUNC

Function declaration:

```
datetime datetrunc (datetime date,string datepart)
```

Purpose: It is used to return the value of a date after the specified datepart is truncated.

Description:

- date: datetime type. If the input is a string, it is implicitly converted into a value of the datetime type before this computation. For all other input types, an error is returned.
- datepart: a constant of the string type. It supports the extended date format. If datepart is not in the specified format or is of another type, an error is returned.

Returned value: datetime type. If any input is NULL, NULL is returned.

Example:

```
datetrunc('2017-12-07 16:28:46', 'yyyy') = 2017-01-01 00:00:00
datetrunc('2017-12-07 16:28:46', 'month') = 2017-12-01 00:00:00
datetrunc('2017-12-07 16:28:46', 'DD') = 2017-12-07 00:00:00
```

1.6.7.3.5. GETDATE

Function declaration:

```
datetime getdate()
```

Purpose: It is used to obtain the current system time. Use UTC+8 as the standard time of MaxCompute.

Returned value: the current date and time of the datetime type.

> **Note** In a MaxCompute SQL task (executed in a distributed manner), 'getdate' always returns a fixed value. The returned result is any time in MaxCompute. The time returned is precise to the second. In later versions, the time will be precise to the milisecond.

1.6.7.3.6. ISDATE

Function declaration:

```
boolean isdate(string date, string format)
```

Purpose: It is used to determine whether a date string can be converted into a date value based on the corresponding format string. If the conversion can be performed, true is returned. Otherwise, false is returned.

Description:

- date: This value must be a string type date. If the input is of the bigint, decimal, double, or

datetime type, it is implicitly converted into a value of the string type before this computation. For all other input types, an error is returned.

- format: a constant of the string type. The extended date format is not supported. If it is of another type or an unsupported format, an error is returned. If there are redundant format strings appearing in 'format', the date value corresponding to the first format string is used. Other strings are taken as delimiters. If isdate("1234-yyyy", "yyyy-yyyy"), true is returned.

Returned value: boolean type. If any input is NULL, NULL is returned.

1.6.7.3.7. LASTDAY

Function declaration:

```
datetime lastday(datetime date)
```

Purpose: It is used to return the last day of the current month to which the date belongs. The value is accurate to day. The hour, minute, and second part is expressed as 00:00:00.

Description:

date: datetime type. If the input is a string, it is implicitly converted into a value of the datetime type before this computation. For all other input types, an error is returned.

Returned value: datetime type. If the input is NULL, NULL is returned.

1.6.7.3.8. TO_DATE

Function declaration:

```
datetime to_date(string date, string format)
```

Purpose: It is used to convert the 'date' string into a date value.

Description:

- date: string type. It indicates the date value of the string type to be converted. If the input is of the bigint, decimal, double, or datetime type, it is implicitly converted into a value of the string type before this computation. For all other types of inputs or NULL, an error is returned.
- format: a constant of the string type in the date format. For all other types of inputs and non-constant values, an error is returned. It does not support the extended date format. Other characters are ignored as invalid characters in parsing. The format parameter must contain yyyy. Otherwise, an error is returned. If there are redundant format strings in the format, the corresponding date value of the first format string is used, and the rest are processed as separators. For example, to_date('1234-2234', 'yyyy-yyyy') returns '1234-01-01 00:00:00'.

Returned value: datetime type. The format is *yyyy-mm-dd hh:mi:ss*. If any input is NULL, NULL is returned.

Example:

```
to_date('Alibaba2017-12*03', 'Alibabayyyy-mm*dd') = 2017-12-03 00:00:00
to_date('20170718', 'yyyymmdd') = 2017-07-18 00:00:00
to_date('201707182030','yyyymmddhhmi')=2017-07-18 20:30:00
to_date('2017718', 'yyyymmdd')
-- Invalid format. NULL is returned.
to_date('Alibaba2017-12*3', 'Alibabayyyy-mm*dd')
-- Invalid format. NULL is returned.
to_date('2017-24-01', 'yyyy')
-- Invalid format. NULL is returned.
```

1.6.7.3.9. TO_CHAR

Function declaration:

```
string to_char(datetime date, string format)
```

Purpose: It is used to convert a value of the date type into a string based on the specified format.

Description:

- date: date value of the datetime type to be converted. If the input is a string, it is implicitly converted into a value of the datetime type before this computation. For all other types of inputs, an error is returned.
- format: a constant of the string type. If it is not a constant or is of a different type, an error is returned. In format, the date format part is replaced with the corresponding data and other characters are output directly.

Returned value: string type. If any input is NULL, NULL is returned.

Example:

```
to_char('2017-12-03 00:00:00', 'Alibabayyyy-mm*dd') = 'Alibaba2017-12*03'
to_char('2017-07-18 00:00:00', 'yyyymmdd') = '20170718'
to_char('Alibaba 2017-12*3', 'Alibaba yyyy-mm*dd')
-- Null is returned.
to_char('2017-24-01', 'yyyy')
-- Null is returned.
to_char('2017718', 'yyyymmdd')
-- Null is returned.
```

> **Note** For more information about conversion from other types into the string type, see String functions — TO_CHAR.

1.6.7.3.10. UNIX_TIMESTAMP

Function declaration:

```
bigint unix_timestamp(datetime date)
```

Purpose: It is used to convert a date into a datetime value of the integer type in the Unix format.

Description:

date: datetime type. It indicates the date. If the input is a string, it is implicitly converted into a value of the datetime type before this computation. For all other input types, an error is returned.

Returned value: bigint type. It indicates the date value in Unix format. If date is NULL, NULL is returned.

1.6.7.3.11. FROM_UNIXTIME

Function declaration:

```
datetime from_unixtime(bigint unixtime)
```

Purpose: It is used to convert a Unix date value from the BIGINT type to the DATETIME type.

Description:

unixtime: BIGINT type. It is a date value in the Unix format. If the input is of the STRING, DECIMAL, or DOUBLE type, it is implicitly converted into a value of the BIGINT type before computation.

Returned value: DATETIME type. If unixtime is NULL, NULL is returned.

> **Note** In the HIVE-compatible mode (where `set odps.sql.hive.compatible=true;` has been executed), if the input is of the STRING type, a date value of the STRING type is returned.

Example:

```
from_unixtime(123456789) = 1973-11-30 05:33:09;
```

1.6.7.3.12. WEEKDAY

Function declaration:

```
bigint weekday (datetime date)
```

Purpose: It is used to return the day of week for the specified date.

Description:

date: datetime type. If the input is of the string type, it is implicitly converted to a value of the datetime type before this computation. For all other input types, an error is returned.

Returned value: bigint type. If the input is NULL, NULL is returned. Monday is the first day of a week and the returned value is 0. Days are numbered in ascending order starting from 0. If the day is Sunday, the returned value is 6.

1.6.7.3.13. WEEKOFYEAR

Function declaration:

```
bigint weekofyear(datetime date)
```

Purpose: It is used to return the calendar week of the year that the specified date falls in. The system uses Monday as the first day of the week.

> **Note** If a week extends into the next year, the week belongs to the year containing four days or more. If more days fall in the first year, the week is considered as the last week of the first year. If more days fall in the second year, the week is considered as the first week of the second year.

Description:

date: the date of the datetime type. If the input is of the string type, it is implicitly converted to a value of the datetime type before this computation. For all other input types, an error is returned.

Returned value: bigint type. If the input is NULL, NULL is returned.

Example:

```
select weekofyear(to_date("20171229", "yyyymmdd")) from dual;
Returned value:
+------------+
| _c0        |
+------------+
| 1          |
+------------+
-- 20171229 is in year 2017, but the most days of the week are in year 2018. Therefore, the returned val
ue is 1, which indicates the first week of year 2018.
select weekofyear(to_date("20171231", "yyyymmdd")) from dual;
-- 1 is returned.
select weekofyear(to_date("20181229", "yyyymmdd")) from dual;
-- The returned value is 53.
```

1.6.7.3.14. Additional date functions

MaxCompute 2.0 provides additional date functions. You must add the following SET statement before SQL statements contained in the date functions:

```
set odps.sql.type.system.odps2=true;
```

> **Note** You must submit and execute the SET statement and the SQL statements of the new functions simultaneously.

Example:

```
set odps.sql.type.system.odps2=true;
select year('2017-01-01 12:30:00') = 2017 from dual;
```

The date functions described in subsequent topics are new in MaxCompute 2.0.

1.6.7.3.15. YEAR

Function declaration:

```
INT year(string date)
```

Purpose: It is used to return the year of the specified date.

Description:

date: the date of the string type. The date format must include yyyy-mm-dd and have no redundant strings. Otherwise, NULL is returned.

Returned value: int type.

Example:

```
year('2017-01-01 12:30:00') = 2017
year('2017-01-01') = 2017
year('17-01-01') = 17
year(2017-01-01) = null
year('2017/03/09') = null
year(null) = null
```

1.6.7.3.16. QUARTER

Command syntax:

```
int quarter(datetime/timestamp/string date)
```

Purpose: It is used to return the quarter of the input date, ranging from 1 to 4.

Description:

date: datetime, timestamp, or string type. The date format must include yyyy-mm-dd and have no redundant strings. Otherwise, NULL is returned.

Returned value: int type. If the input is NULL, NULL is returned.

Example:

```
quarter('2017-11-12 10:00:00') = 4
quarter('2017-11-12') = 4
```

1.6.7.3.17. MONTH

Function declaration:

```
INT month(string date)
```

Purpose: It is used to return the month of the input date.

Description:

date: This value must be a date of the string type. For all other input types, an error is returned.

Returned value: int type.

Example:

```
month('2017-09-01') = 9
month('20170901') = null
```

1.6.7.3.18. DAY

Function declaration:

```
INT day(string date)
```

Purpose: It is used to return the day of the input date.

Description:

date: This value must be a string type date. For all other input types, an error is returned.

Returned value: int type.

Example:

```
day('2017-09-01') = 1
day('20170901') = null
```

1.6.7.3.19. DAYOFMONTH

Function declaration:

```
INT dayofmonth(date)
```

Purpose: It is used to return the day of the month for the input date.

Description:

date: This value must be a string type date. For all other input types, an error is returned.

Returned value: int type.

Example:

```
dayofmonth('2017-09-01') = 1
dayofmonth('20170901') = null
```

1.6.7.3.20. HOUR

Function declaration:

```
INT hour(string date)
```

Purpose: It is used to return the hour of the input date.

Description:

date: This value must be a string type date. For all other input types, an error is returned.

Returned value: int type.

Example:

```
hour('2017-09-01 12:00:00') = 12
hour('12:00:00') = 12
hour('20170901120000') = null
```

1.6.7.3.21. MINUTE

Function declaration:

```
INT minute(string date)
```

Purpose: It is used to return the minute of the input date.

Description:

date: This value must be a string type date. For all other input types, an error is returned.

Returned value: int type.

Example:

```
minute('2017-09-01 12:30:00') = 30
minute('12:30:00') = 30
minute('20170901120000') = null
```

1.6.7.3.22. SECOND

Function declaration:

```
INT second(string date)
```

Purpose: It is used to return the second of the input date.

Description:

date: This value must be a string type date. For all other input types, an error is returned.

Returned value: int type.

Example:

```
second('2017-09-01 12:30:45') = 45
second('12:30:45') = 45
second('20170901123045') = null
```

1.6.7.3.23. FROM_UTC_TIMESTAMP

Function declaration:

```
timestamp from_utc_timestamp({any primitive type}*, string timezone)
```

Purpose: It is used to convert a UTC timestamp to a timestamp for a specified timezone.

Description:

- {any primitive type}*: the timestamp. The type can be TIMESTAMP, DATETIME, TINYINT, SMALLINT, INT, or BIGIN.
- timezone: Specifies the destination timezone, such as PST.

Returned value: DATETIME type.

Example:

```
select from_utc_timestamp(1501557840,'PST') = '1970-01-18 09:05:57.84'
select from_utc_timestamp('1970-01-30 16:00:00','PST') = '1970-01-30 08:00:00.0'
select from_utc_timestamp('1970-01-30','PST') = '1970-01-29 16:00:00.0'
```

1.6.7.3.24. CURRENT_TIMESTAMP

Function declaration:

```
timestamp current_timestamp()
```

Purpose: The current timestamp is returned as a Timestamp-type value. The value is not fixed.

Returned value: timestamp type.

Example:

```
select current_timestamp() from dual;
-- '2017-08-03 11:50:30.661'is returned.
```

1.6.7.3.25. ADD_MONTHS

Function declaration:

```
string add_months(string startdate, int nummonths)
```

Purpose: It is used to return the date, which is 'nummonths' months later than 'startdate'.

Description:

- startdate: This value must be a string type date. The date format must contain yyyy-mm-dd. Otherwise, NULL is returned.
- num_months: int type.

Returned value: This value must be a string type date. The format is yyyy-mm-dd.

Example:

```
Add_months ('2017-02-14', 3) = '2017-05-14'
add_months('17-2-14',3) = '0017-05-14'
add_months('2017-02-14 21:30:00',3) = '2017-05-14'
add_months('20170214',3) = null
```

1.6.7.3.26. LAST_DAY

Function declaration:

```
string last_day(string date)
```

Purpose: It is used to return the last date of the month.

Description:

date: string type. The format is yyyy-MM-dd HH:mi:ss or yyyy-mm-dd.

Returned value: This value must be a datetime type date. The format is yyyy-mm-dd.

Example:

```
last_day('2017-03-04') = '2017-03-31'
last_day('2017-07-04 11:40:00') = '2017-07-31'
last_day('20170304') = null
```

1.6.7.3.27. NEXT_DAY

Function declaration:

```
string next_day(string startdate, string week)
```

Purpose: It is used to return the next date that is later than startdate and matches the week value. That is, the date of the day specified of the next week.

Description:

- startdate: string type. The format is yyyy-MM-dd HH:mi:ss or yyyy-mm-dd.
- week: string type. The name of a day, or the first 2 or 3 letters of the day, for example, Mo, TUE, or FRIDAY.

Returned value: This value must be a string type date. The format is yyyy-mm-dd.

Example:

```
next_day('2017-08-01','TU') = '2017-08-08'
next_day('2017-08-01 23:34:00','TU') = '2017-08-08'
Next_day ('20170801 ', 'tu') = NULL
```

1.6.7.3.28. MONTHS_BETWEEN

Function declaration:

```
double months_between(datetime/timestamp/string date1, datetime/timestamp/string date2)
```

Purpose: It is used to return the number of months between date1 and date2.

Description:

- date1: datetime, timestamp, or string type. The format is yyyy-MM-dd HH:mi:ss or yyyy-mm-dd.
- date2: datetime, timestamp, or string type. The format is yyyy-MM-dd HH:mi:ss or yyyy-mm-dd.

Returned value: double type.

- If 'date1' is later than 'date2', the returned value is positive. If 'date2' is later than 'date1', the returned value is negative.
- When date1 and date2 correspond to the last days of two months, the returned value is an integer representing the number of months. Otherwise, the formula is (date1 - date2)/31.

Example:

```
months_between('1997-02-28 10:30:00', '1996-10-30') = 3.9495967741935485
months_between('1996-10-30','1997-02-28 10:30:00' ) = -3.9495967741935485
months_between('1996-09-30','1996-12-31') = -3.0
```

1.6.7.3.29. EXTRACT

Function declaration:

```
INT EXTRACT(<datepart> from <timestamp>)
```

Description: This function extracts the part specified by datepart from the time specified by timestamp.

Parameters:

- datepart: a value that can be set to a time unit, such as YEAR, MONTH, DAY, HOUR, or MINUTE
- timestamp: a value of the TIMESTAMP type

Return value: A value of the INT type is returned.

Example:

```
SET odps.sql.type.system.odps2=true;
SELECT  extract(YEAR FROM '2019-05-01 11:21:00') year
       ,extract(MONTH FROM '2019-05-01 11:21:00') month
       ,extract(DAY FROM '2019-05-01 11:21:00') day
       ,extract(HOUR FROM '2019-05-01 11:21:00') hour
       ,extract(MINUTE FROM '2019-05-01 11:21:00') minute;
-- The following result is returned:
+------+-------+------+------+--------+
| year | month | day  | hour | minute |
+------+-------+------+------+--------+
| 2019 | 5     | 1    | 11   | 21     |
+------+-------+------+------+--------+
```

If the time value specified in the SQL statement is invalid or exceeds the specified range, the return value is the remainder obtained by dividing the specified time value by the maximum value in the time range.

Example:

```
SET odps.sql.type.system.odps2=true;
SELECT  extract(HOUR FROM '2019-05-01 31:01:01') hour
       ,extract(MINUTE FROM '2019-05-01 23:61:01') minute;
-- The following result is returned:
+------+-------+
| hour | minute|
+------+-------+
| 7    | 1     |
+------+-------+
-- The maximum value of hour is 24, and the specified time value is 31. The return value is 7 (31/24).
-- The maximum value of minute is 60, and the specified time value is 61. The return value is 1 (61/60).
```

1.6.7.4. Window functions

1.6.7.4.1. Overview

In MaxCompute SQL statements, you can use the window function to analyze and process data flexibly. The window function can only appear in SELECT clauses. It does not support nested Window or aggregation functions. The window function cannot be used with the same-level aggregation functions at the same time.

A MaxCompute SQL statement supports up to five window functions.

Syntax:

```
window_func() over (partition by col1, [col2...]
[order by col1 [asc|desc][, col2[asc|desc]...]] windowing_clause)
```

Description:

- PARTITION BY specifies partition columns. The rows on which the partition column values are the same are considered to be in the same window. A window can contain up to 100 million rows of data (we recommend that the number of rows does not exceed 5 million). Otherwise, an error is returned.
- Use ORDER BY to specify the rule for sorting data in a window.
- You can use ROWS in windowing_clause to specify the partitioning method. There are two methods:
  - rows between x preceding|following and y preceding|following indicates a window range from the xth row preceding or following the current row to the yth row preceding or following the current row.
  - rows x preceding|following indicates a window range from the xth row preceding or following the current row to the current row.

> **Note**
>
> - x and y must be integer constants greater than or equal to 0. Their values range from 0 to 10,000. 0 indicates the current row.
> - You must specify ORDER BY before using ROWS to specify a window range.
> - Not all window functions open windows using the method specified by ROWS. The method is only supported by the following functions: AVG, COUNT, MAX, MIN, STDDEV, and SUM.

1.6.7.4.2. COUNT

Command syntax:

```
bigint count([distinct] expr) over(partition by col1[, col2...]
[order by col1 [asc|desc][, col2[asc|desc]...]] [windowing_clause])
```

Purpose: It is used to return the number of values on the expr column.

Description:

- expr: any type. When it is NULL, this row is not involved in computation. If the distinct keyword is specified, this parameter indicates that only distinct values are counted.
- partition by col1[, col2...]: specifies the partitions used in the computation.
- order by col1 [asc|desc],col2[asc|desc]: The count value of expr in the current window is returned if ORDER BY is not set. The returned results are sorted in the specified order if ORDER BY is specified, and the value is the count value from the start row to the current row in the current window.

Returned value: bigint.

> **Note** If the distinct keyword is specified, ORDER BY cannot be used.

Example:

The user_id column of the bigint type exists in the test_src table.

```
select user_id,count(user_id) over (partition by user_id) as count from test_src;
+---------+------------+
| user_id |  count     |
+---------+------------+
| 1       | 3          |
| 1       | 3          |
| 1       | 3          |
| 2 | 1 |
| 3 | 1 |
+---------+------------+
+---------+------------+
-- If ORDER BY is not specified, the number of values on the user_id column from the current partition i
s returned.
select user_id,count(user_id) over (partition by user_id order by user_id) as count from test_src;
+---------+------------+
| user_id | count      |
+---------+------------+
| 1 | 1 | -- start row of the window
| 1 | 2 | --two records exist from start row to current row. Return 2.
| 1       | 3          |
| 2       | 1          |
| 3       | 1          |
+---------+------------+
-- If ORDER BY is specified, the count value from the start row to the current row from the current parti
tion is returned.
```

1.6.7.4.3. AVG

Function declaration:

```
avg([distinct] expr) over(partition by col1[, col2...]
[order by col1 [asc|desc] [, col2[asc|desc]...]] [windowing_clause])
```

Purpose: It is used to calculate the average value.

Description:

- distinct: If the distinct keyword is specified, this parameter indicates that the average value of distinct values is calculated.
- expr: double type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before computation. If the input is of another type, an error is returned. If the input is NULL, this row is not used in computation. The input cannot be of the boolean type.
- partition by col1[, col2]...: specifies the partitions used in the computation.
- order by col1 [asc|desc], col2[asc|desc]: The count value of expr in the current window is returned if ORDER BY is not set. The returned results are sorted in the specified order if ORDER BY is specified, and the value is the count value from the start row to the current row in the current window.

Returned value: double type.

> **Note** If the distinct keyword is specified, ORDER BY cannot be set.

1.6.7.4.4. MAX

Function declaration:

```
max([distinct] expr) over(partition by col1[, col2...]
[order by col1 [asc|desc][, col2[asc|desc]...]] [windowing_clause])
```

Purpose: It is used to return the maximum value.

Description:

- expr: any types except the boolean type. If the value is NULL, the corresponding row is not involved in the operation. If the distinct keyword is specified, this parameter indicates that the maximum value of the distinct values is taken (whether this parameter is set or not does not affect the result).
- partition by col1[, col2...]: specifies the partitions used in the computation.
- order by col1 [asc|desc], col2[asc|desc]: The maximum value in the current window is returned if ORDER BY is not set. If ORDER BY is set, the returned results are sorted in the specified order, and the values are the maximum values from the start row to the current row in the current window.

Returned value: The type is the same as that of expr.

> Note If the distinct keyword is specified, ORDER BY cannot be set.

1.6.7.4.5. MIN

Function declaration:

```
min([distinct] expr) over(partition by col1[, col2...]
[order by col1 [asc|desc][, col2[asc|desc]...]] [windowing_clause])
```

Purpose: It is used to return the minimum value.

Description:

- expr: any types except the boolean type. If the value is NULL, the corresponding row is not involved in the operation. If the distinct keyword is specified, this parameter indicates that the minimum value of distinct values is taken (whether this parameter is set or not does not affect the result).
- partition by col1[, col2...]: specifies the partitions used in the computation.
- order by col1 [asc|desc], col2[asc|desc]: The minimum value in the current window is returned if ORDER BY is not set. If ORDER BY is set, the returned results are sorted in the specified order, and the returned value is the minimum value in the current window from the start row to the current row.

Returned value: The type is the same as that of expr.

> Note If the distinct keyword is specified, ORDER BY cannot be set.

1.6.7.4.6. MEDIAN

Function declaration:

```
double median(double number) over(partition by col1[, col2...])
decimal median(decimal number) over(partition by col1[,col2...])
```

Purpose: It is used to calculate the median.

Description:

- number: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned. If the input is NULL, NULL is returned.
- partition by col1[, col2...]: specifies the partitions used in the computation.

Returned value: double type.

1.6.7.4.7. STDDEV

Function declaration:

```
double stddev([distinct] expr) over(partition by col1[, col2...] [order by col1 [asc|desc][, col2[asc|desc]...
]] [windowing_clause])
decimal stddev([distinct] expr) over(partition by col1[,col2...] [order by col1 [asc|desc][, col2[asc|desc]...
]] [windowi ng_clause])
```

Purpose: It is used to calculate the population standard deviation.

Description:

- expr: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other types of inputs, an error is returned. If the input value is NULL, then NULL is returned. If the distinct keyword is specified, this parameter indicates that the population standard deviation of distinct values is calculated.
- partition by col1[, col2...]: specifies the partitions used in the computation.
- order by col1 [asc|desc], col2[asc|desc]: The population standard deviation of the current window is returned if ORDER BY is not set. If ORDER BY is set, the returned results are sorted in the specified order, and the values are the population standard deviation of the start row to the current row in the current window.

Returned value: When the input is of the decimal type, a value of the decimal type is returned. Otherwise, a value of the double type is returned.

> **Note** If the distinct keyword is specified, ORDER BY cannot be set.

1.6.7.4.8. STDDEV_SAMP

Function declaration:

```
double stddev_samp([distinct] expr) over(partition by col1[, col2...] [order by col1 [asc|desc][, col2[asc|
desc]...]] [windowing_clause])
decimal stddev_samp([distinct] expr) over(partition by col1[,col2...] [order by col1 [asc|desc][, col2[asc|
desc]...]] [windowing_clause])
```

Purpose: It is used to calculate the sample standard deviation.

Description:

- expr: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other types of inputs, an error is returned. If the input is NULL, NULL is returned. If the distinct keyword is specified, this parameter indicates that the sample standard deviation of distinct values is calculated.
- partition by col1[, col2...]: specifies the partitions used in the computation.
- order by col1 [asc|desc], col2[asc|desc]: The sample standard deviation of the current window is returned if ORDER BY is not set. If ORDER BY is set, the returned results are sorted in the specified order, and the values are the sample standard deviation of the start row to the current row in the current window.

Returned value: When the input is of the decimal type, a value of the decimal type is returned. Otherwise, a value of the double type is returned.

> **Note** If the distinct keyword is specified, ORDER BY cannot be set.

1.6.7.4.9. SUM

Function declaration:

```
sum([distinct] expr) over(partition by col1[, col2...]
[order by col1 [asc|desc][, col2[asc|desc]...]] [windowing_clause])
```

Purpose: It is used calculate the sum.

Description:

- expr: double, decimal, or bigint type. If the input is of the string type, it is implicitly converted into a value of the double type before computation. If the input is of another type, an error is returned. If the value is NULL, this row is not calculated. If the distinct keyword is specified, this parameter indicates that the sum of distinct values is calculated.
- partition by col1[, col2...]: specifies the partitions used in the computation.
- order by col1 [asc|desc], col2[asc|desc]: The sum of the expr value in the current window is returned if ORDER BY is not set. If ORDER BY is set, the returned results are sorted in the order specified. The returned results are the cumulative sum of start row to the current row in the current window.

Returned value: When the input is of the bigint type, a value of the bigint type is returned. When the input is of the double or string type, a value of the double type is returned.

> **Note** If the distinct keyword is specified, ORDER BY cannot be set.

1.6.7.4.10. DENSE_RANK

Function declaration:

```
bigint dense_rank() over(partition by col1[, col2...]
order by col1 [asc|desc][, col2[asc|desc]...])
```

Purpose: It is used to calculate the consecutive ranking of values. The data in the same row of col2 has the same rank.

Description:

- partition by col1[, col2...]: specifies the partitions used in the computation.
- order by col1 [asc|desc], col2[asc|desc]: This parameter specifies the value for deciding the ranking.

Returned value: bigint type.

Example:

The emp table contains the following data:

```
| empno | ename | job | mgr | hiredate| sal| comm | deptno |
7369,SMITH,CLERK,7902,1980-12-17 00:00:00,800,,20
7499,ALLEN,SALESMAN,7698,1981-02-20 00:00:00,1600,300,30
7521,WARD,SALESMAN,7698,1981-02-22 00:00:00,1250,500,30
7566,JONES,MANAGER,7839,1981-04-02 00:00:00,2975,,20
7654,MARTIN,SALESMAN,7698,1981-09-28 00:00:00,1250,1400,30
7698,BLAKE,MANAGER,7839,1981-05-01 00:00:00,2850,,30
7782,CLARK,MANAGER,7839,1981-06-09 00:00:00,2450,,10
7788,SCOTT,ANALYST,7566,1987-04-19 00:00:00,3000,,20
7839,KING,PRESIDENT,,1981-11-17 00:00:00,5000,,10
7844,TURNER,SALESMAN,7698,1981-09-08 00:00:00,1500,0,30
7876,ADAMS,CLERK,7788,1987-05-23 00:00:00,1100,,20
7900,JAMES,CLERK,7698,1981-12-03 00:00:00,950,,30
7902,FORD,ANALYST,7566,1981-12-03 00:00:00,3000,,20
7934,MILLER,CLERK,7782,1982-01-23 00:00:00,1300,,10
7948,JACCKA,CLERK,7782,1981-04-12 00:00:00,5000,,10
7956,WELAN,CLERK,7649,1982-07-20 00:00:00,2450,,10
7956,TEBAGE,CLERK,7748,1982-12-30 00:00:00,1300,,10
```

To obtain their serial number, the employees must be group by their departments and sorted by SAL in descending order.

```
SELECT deptno
      , ename
      , sal
      , DENSE_RANK() OVER (PARTITION BY deptno ORDER BY sal DESC) AS nums
-- DEPTNO (department) is the partition used in the computation, and SAL (salary) is used as basis for sorting returned results.
   FROM emp;
-- Returned result:
+------------+-------+------------+------------+
| deptno     | ename | sal        | nums       |
+------------+-------+------------+------------+
| 10         | JACCKA | 5000.0     | 1          |
| 10 | King | 5000.0 | 1 |
| 10 | CLARK | 2450.0 | 2 |
| 10 | WELAN | 2450.0 | 2 |
| 10 | TEBAGE | 1300.0 | 3 |
10 | Miller | 1300.0 | 3 |
| 20         | SCOTT | 3000.0     | 1          |
| 20 | Ford | 3000.0 | 1 |
| 20 | JONES | 2975.0 | 2 |
| 20 | ADAMS | 1100.0 | 3 |
| 20 | SMITH | 800.0 | 4 |
| 30         | BLAKE | 2850.0     | 1          |
| 30         | ALLEN | 1600.0     | 2          |
| 30         | TURNER | 1500.0     | 3          |
| 30         | MARTIN | 1250.0     | 4          |
| 30 | WARD | 1250.0 | 4 |
| 30 | JAMES | 950.0 | 5 |
+------------+-------+------------+------------+
```

1.6.7.4.11. RANK

Command syntax:

```
bigint rank() over(partition by col1[, col2...] order by col1 [asc|desc][, col2[asc|desc]...])
```

Purpose: It is used to return a ranking value. The ranking of the same row data with col2 drops.

Description:

- partition by col2[, col2..]: specifies the partitions used in the computation.
- order by col1 [asc|desc], col2[asc|desc]: specifies the rule for deciding the ranking.

Returned value: bigint type.

Example:

Table emp contains the following data:

```
| empno | ename | job | mgr | hiredate| sal| comm | deptno |
7369,SMITH,CLERK,7902,1980-12-17 00:00:00,800,,20
7499,ALLEN,SALESMAN,7698,1981-02-20 00:00:00,1600,300,30
7521,WARD,SALESMAN,7698,1981-02-22 00:00:00,1250,500,30
7566,JONES,MANAGER,7839,1981-04-02 00:00:00,2975,,20
7654,MARTIN,SALESMAN,7698,1981-09-28 00:00:00,1250,1400,30
7698,BLAKE,MANAGER,7839,1981-05-01 00:00:00,2850,,30
7782,CLARK,MANAGER,7839,1981-06-09 00:00:00,2450,,10
7788,SCOTT,ANALYST,7566,1987-04-19 00:00:00,3000,,20
7839,KING,PRESIDENT,,1981-11-17 00:00:00,5000,,10
7844,TURNER,SALESMAN,7698,1981-09-08 00:00:00,1500,0,30
7876,ADAMS,CLERK,7788,1987-05-23 00:00:00,1100,,20
7900,JAMES,CLERK,7698,1981-12-03 00:00:00,950,,30
7902,FORD,ANALYST,7566,1981-12-03 00:00:00,3000,,20
7934,MILLER,CLERK,7782,1982-01-23 00:00:00,1300,,10
7948,JACCKA,CLERK,7782,1981-04-12 00:00:00,5000,,10
7956,WELAN,CLERK,7649,1982-07-20 00:00:00,2450,,10
7956,TEBAGE,CLERK,7748,1982-12-30 00:00:00,1300,,10
```

Now group the employees by department. Sort the employees in each group in descending order based on the salary. Each employee obtains a number that represents their position in the group.

```
SELECT deptno
      , ename
      , sal
      , RANK() OVER (PARTITION BY deptno ORDER BY sal DESC) AS nums
-- DEPTNO (department) is the partitioning column. The sal column is sorted to generate the ranking v
alue for each employee.
   FROM emp;
-- Returned result:
+------------+-------+------------+------------+
| deptno     | ename | sal        | nums       |
+------------+-------+------------+------------+
| 10         | JACCKA | 5000.0     | 1          |
| 10         | KING  | 5000.0     | 1          |
| 10         | CLARK | 2450.0     | 3          |
| 10 | WELAN | 2450.0 | 3 |
| 10         | TEBAGE | 1300.0     | 5          |
| 10 | MILLER | 1300.0 | 5 |
| 20         | SCOTT | 3000.0     | 1          |
| 20         | FORD  | 3000.0     | 1          |
| 20         | JONES | 2975.0     | 3          |
| 20         | ADAMS | 1100.0     | 4          |
| 20         | SMITH | 800.0      | 5          |
| 30         | BLAKE | 2850.0     | 1          |
| 30         | ALLEN | 1600.0     | 2          |
| 30         | TURNER | 1500.0     | 3          |
| 30         | MARTIN | 1250.0     | 4          |
| 30         | WARD  | 1250.0     | 4          |
| 30         | JAMES | 950.0      | 6          |
+------------+-------+------------+------------+
```

1.6.7.4.12. LAG

Function declaration:

```
lag(expr, bigint offset, default) over(partition by col1[, col2...] [order by col1 [asc|desc][, col2[asc|desc]
...]])
```

Purpose: It is used to retrieve the value in the row with a negative offset from the current row. For example, if the current row is rn, the value retrieved is from the row rn - offset.

Description:

- expr: any type.
- offset: a constant of the bigint type. If the input is of the string or double type, it is implicitly converted into a value of the bigint type before computation, and the offset is greater than 0.
- default: a constant. It specifies the default value when the offset is out of the valid range. The default value is NULL.
- partition by col1[, col2...]: specifies the partitions used in the computation.
- order by col1 [asc|desc], col2[asc|desc]: indicates the sorting order of the returned results.

Returned value: The type is the same as that of expr.

1.6.7.4.13. LEAD

Function declaration:

```
lead(expr, bigint offset, default) over(partition by col1[, col2...][order by col1 [asc|desc][, col2[asc|desc]
...]])
```

Purpose: It is used to retrieve the value in the row with a positive offset from the current row. For example, if the current row is rn, the value retrieved is from the row rn + offset.

Description:

- expr: any type.
- offset: a constant of the bigint type. If the input is of the string or double type, it is implicitly converted into a value of the bigint type before computation, and the offset is greater than 0.
- default: a constant. It specifies the default value when the offset is out of the valid range.
- partition by col1[, col2...]: specifies the partitions used in the computation.
- order by col1 [asc|desc], > col2[asc|desc]: indicates the sorting order of the returned results.

Returned value: The type is the same as that of expr.

Example:

```
select c_double_a,c_string_b,c_int_a,lead(c_int_a,1) over(partition by c_double_a order by c_string_b) fr
om dual;
select c_string_a,c_time_b,c_double_a,lead(c_double_a,1) over(partition by c_string_a order by c_time_
b) from dual;
select c_string_in_fact_num,c_string_a,c_int_a,lead(c_int_a) over(partition by c_string_in_fact_num ord
er by c_string_a) from dual;
```

1.6.7.4.14. PERCENT_RANK

Function declaration:

```
percent_rank() over(partition by col1[, col2...] order by col1 [asc|desc][, col2[asc|desc]...])
```

Purpose: It is used to return the relative ranking of a row in a group of data.

Description:

- partition by col1[, col2...]: specifies the partitions used in the computation.
- order by col1 [asc|desc], col2[asc|desc]: specifies the value for the ranking.

Returned value: double type. Value range: 0 to 1. The relative ranking is calculated using the following formula: (rank-1)/(number of rows -1).

> **Note** The number of rows in a window cannot exceed 10,000,000.

1.6.7.4.15. ROW_NUMBER

Function declaration:

```
row_number() over(partition by col1[, col2...] order by col1 [asc|desc][, col2[asc|desc]...])
```

Purpose: It is used to calculate the row number, which starts from 1.

Description:

- partition by col1[, col2...]: specifies the partitions used in the computation.
- order by col1 [asc|desc], > col2[asc|desc]: indicates the sorting value of the returned result.

Returned value: bigint type.

Example:

If table emp contains the following data:

```
| Empno | ename | job | Mgr | hiredate | Sal | REM | deptno |
7369, Smith, clerk, maid-12-17 00:00:00, 800, 20
7499, Allen, salesman, maid-02-20 00:00:00, 1600,300, 30
7521, Ward, salesman, maid-02-22 00:00:00, 1250,500, 30
7566, Jones, Manager, fig-04-02 00:00:00, 2975, 20
7654 Martin, salesman, fig-09-28 00:00:00, fig, 30
7698, Blake, Manager, fig-05-01 00:00:00, 2850, 30
7782, Clark, Manager, fig-06-09 00:00:00, 2450, 10
7788, Scott, analyst, fig-04-19 00:00:00, 3000, 20
00:00:00, King, President, 1991-11-17 5000, 7839, 10
7844, Turner, salesman, fig-09-08 00:00:00, 1500,0, 30
7876, Adams, clerk, maid-05-23 00:00:00, 1100, 20
7900 James, clerk, maid-12-03 00:00:00, 950, 30
7902 Ford, analyst, fig-12-03 00:00:00, 3000, 20
7934 Miller, clerk, fig-01-23 00:00:00, 1300, 10
7948, jaccka, clerk, fig-04-12 00:00:00, 5000, 10
7956, welan, clerk, fig-07-20 00:00:00, 2450, 10
7956,TEBAGE,CLERK,7748,1982-12-30 00:00:00,1300,,10
```

Now, all employees need to be grouped by department, and each group must be sorted in descending order according to SAL to obtain the serial number in own group.

```
SELECT deptno
      , ename
      ,sal
      , ROW_NUMBER() OVER (PARTITION BY deptno ORDER BY sal DESC) AS nums
-- DEPTNO (department) is the partition used in the computation, and SAL (salary) is used as basis for sorting results.
   FROM emp;
-- Returned result:
+------------+-------+------------+------------+
| deptno    | ename | sal       | nums      |
+------------+-------+------------+------------+
| 10 | JACCKA | 5000.0 | 1 |
| 10 | KING | 5000.0 | 2 |
| 10 | CLARK | 2450.0 | 3 |
| 10 | WELAN | 2450.0 | 4 |
| 10 | TEBAGE | 1300.0 | 5 |
| 10 | MILLER | 1300.0 | 6 |
| 20 | SCOTT | 3000.0 | 1 |
| 20 | FORD | 3000.0 | 2 |
| 20 | JONES | 2975.0 | 3 |
| 20 | ADAMS | 1100.0 | 4 |
| 20 | SMITH | 800.0 | 5 |
| 30 | BLAKE | 2850.0 | 1 |
| 30 | ALLEN | 1600.0 | 2 |
| 30 | TURNER | 1500.0 | 3 |
| 30 | MARTIN | 1250.0 | 4 |
| 30 | WARD | 1250.0 | 5 |
| 30 | JAMES | 950.0 | 6 |
+------------+-------+------------+------------+
```

1.6.7.4.16. CLUSTER_SAMPLE

Command syntax:

```
boolean cluster_sample(bigint x[, bigint y]) over(partition by col1[, col2..])
```

Purpose: It is used to conduct cluster sampling.

Description:

- x: bigint type. x>=1. If the parameter y is specified, x indicates that a window is divided into x parts. Otherwise, x indicates that x rows of records are extracted from a window (that is, the returned value is true if there are x rows). If x is NULL, NULL is returned.

- y: a constant of the bigint type. y>=1, y<=x. This parameter extracts y records from x parts into which a window is divided (that is, the returned value is true if y records exist). If y is NULL, NULL is returned.
- partition by col1[, col2]: specifies the partitions used in the computation.

Returned value: boolean type.

Example:

The test_tbl table has two columns: key and value. The key column stores the group name of each value. The group names are groupa and groupb. The value column stores the values. The table structure is like this:

```
+------------+--------------------+
| key        | value              |
+------------+--------------------+
| groupa | -1.34764165478145 |
| groupa | 0.740212609046718 |
| groupa | 0.167537127858695 |
| groupa | 0.630314566185241 |
| GroupA | 0.0112401388646925 |
| groupa | 0.199165745875297 |
| groupa | -0.320543343353587 |
| groupa | -0.273930924365012 |
| groupa | 0.386177958942063 |
| groupa | -1.09209976687047 |
| groupb | -1.10847690938643 |
| groupb | -0.725703978381499 |
| groupb | 1.05064697475759 |
| groupb | 0.135751224393789 |
| groupb | 2.13313102040396 |
| groupb | -1.11828960785008 |
| groupb | -0.849235511508911 |
| groupb | 1.27913806620453 |
| groupb | -0.330817716670401 |
| groupb | -0.300156896191195 |
| groupb | 2.4704244205196 |
| groupb | -1.28051882084434 |
+------------+--------------------+
```

Run the following SQL statement to take a sample of 10% of the values in each group:

```
select key, value from (select key, value, cluster_sample(10, 1) over(partition by key) as flag from tbl)
sub where flag = true;
-- Returned result:
+--------+--------------------+
| key    | value              |
+--------+--------------------+
| groupa | -0.273930924365012 |
| groupb | -1.11828960785008  |
+-----+-----------------------
```

1.6.7.4.17. NTILE

Function declaration:

```
BIGINT ntile(BIGINT n) over(partition by col1[, col2...]  [order by col1 [asc|desc] [, col2[asc|desc]...]] [wind
owing_clause]))
```

Purpose: It is used to split grouped data into n slices and return the current slice number. If the slice is uneven, the distribution of the first slice is increased.

Description:

n: BIGINT type.

Returned value: BIGINT type.

Example:

Table emp has the following data:

```
| empno | ename | job | mgr | hiredate| sal| comm | deptno |
7369,SMITH,CLERK,7902,1980-12-17 00:00:00,800,,20
7499,ALLEN,SALESMAN,7698,1981-02-20 00:00:00,1600,300,30
7521,WARD,SALESMAN,7698,1981-02-22 00:00:00,1250,500,30
7566,JONES,MANAGER,7839,1981-04-02 00:00:00,2975,,20
7654,MARTIN,SALESMAN,7698,1981-09-28 00:00:00,1250,1400,30
7698,BLAKE,MANAGER,7839,1981-05-01 00:00:00,2850,,30
7782,CLARK,MANAGER,7839,1981-06-09 00:00:00,2450,,10
7788,SCOTT,ANALYST,7566,1987-04-19 00:00:00,3000,,20
7839,KING,PRESIDENT,,1981-11-17 00:00:00,5000,,10
7844,TURNER,SALESMAN,7698,1981-09-08 00:00:00,1500,0,30
7876,ADAMS,CLERK,7788,1987-05-23 00:00:00,1100,,20
7900,JAMES,CLERK,7698,1981-12-03 00:00:00,950,,30
7902,FORD,ANALYST,7566,1981-12-03 00:00:00,3000,,20
7934,MILLER,CLERK,7782,1982-01-23 00:00:00,1300,,10
7948,JACCKA,CLERK,7782,1981-04-12 00:00:00,5000,,10
7956,WELAN,CLERK,7649,1982-07-20 00:00:00,2450,,10
7956,TEBAGE,CLERK,7748,1982-12-30 00:00:00,1300,,10
```

Group all employees by department, sort each group in descending order by salary, and then obtain sequence numbers of employees in each group.

```
-- Execute the following statement:
select  deptno, ename,sal,NTILE(3) OVER(PARTITION BY deptno ORDER BY sal desc) AS nt3 from emp;
-- Returned result:
+------------+-------+------------+------------+
| deptno     | ename | sal        | nt3        |
+------------+-------+------------+------------+
| 10         | JACCKA | 5000.0     | 1          |

```

1.6.7.4.18. NTH_VALUE

Function declaration:

```
nth_value(expr, bigint n [, boolean skipNulls]) over(partition by col1[, col2...] order by col1 [asc|desc][, c
ol2[asc|desc]...]])
```

Purpose: It is used to return the nth value in partitions used in the computation.

Description:

- expr: required. Any type.
- n: returns the nth value. It starts from 1 and is of the BIGINT type.
- skipNulls: specifies whether to ignore the rows whose values are NULL. This parameter is of the BOOLEAN type. The default value is false.

Returned value: the nth value in partitions used in the computation.

> **Note** If skipNulls is set to true, the nth non-NULL value is returned. If the nth non-NULL value does not exist, NULL is returned.

Example:

```
select a, nth_value(a + 1, 1) over (partition by a order by a) from values (3), (1), (2) as t(a);
-- If n is 1, NTH_VALUE is equivalent to FIRST_VALUE.
-- Returned results:
-- 1  2
-- 2  3
-- 3  4
```

1.6.7.4.19. CUME_DIST

Function declaration:

```
cume_dist() over(partition by col1[, col2...] order by col1 [asc|desc][, col2[asc|desc]...]])
```

Purpose: It is used to return the cumulative distribution. The cumulative distribution is the ratio between the number of rows whose values are less than or equal to the current value of the group and the total number of rows in the group.

Description: None.

> **Note** The order by column specifies values to be compared.

Returned value: the ratio of the number of rows whose values are equal to or less than the current value in the group to the total number of rows in the group.

Example:

Table emp has the following data:

```
| empno | ename | job | mgr | hiredate| sal| comm | deptno |
7369,SMITH,CLERK,7902,1980-12-17 00:00:00,800,,20
7499,ALLEN,SALESMAN,7698,1981-02-20 00:00:00,1600,300,30
7521,WARD,SALESMAN,7698,1981-02-22 00:00:00,1250,500,30
7566,JONES,MANAGER,7839,1981-04-02 00:00:00,2975,,20
7654,MARTIN,SALESMAN,7698,1981-09-28 00:00:00,1250,1400,30
7698,BLAKE,MANAGER,7839,1981-05-01 00:00:00,2850,,30

30	JAMES	950.0	100.0%

1.6.7.4.20. FIRST_VALUE

Function declaration:

```
first_value(expr) over(partition by col1[, col2...] order by col1 [asc|desc][, col2[asc|desc]...]])
```

Purpose: It is used to sort partitions and return the first value in the range from the beginning to the current row.

Description:

expr: required. Any type.

Returned value: the first expr value in partitions used in the computation.

Example:

Table emp has the following data:

```
| empno | ename | job | mgr | hiredate| sal| comm | deptno |
7369,SMITH,CLERK,7902,1980-12-17 00:00:00,800,,20
7499,ALLEN,SALESMAN,7698,1981-02-20 00:00:00,1600,300,30
7521,WARD,SALESMAN,7698,1981-02-22 00:00:00,1250,500,30
7566,JONES,MANAGER,7839,1981-04-02 00:00:00,2975,,20
7654,MARTIN,SALESMAN,7698,1981-09-28 00:00:00,1250,1400,30
7698,BLAKE,MANAGER,7839,1981-05-01 00:00:00,2850,,30
7782,CLARK,MANAGER,7839,1981-06-09 00:00:00,2450,,10
7788,SCOTT,ANALYST,7566,1987-04-19 00:00:00,3000,,20
7839,KING,PRESIDENT,,1981-11-17 00:00:00,5000,,10
7844,TURNER,SALESMAN,7698,1981-09-08 00:00:00,1500,0,30
7876,ADAMS,CLERK,7788,1987-05-23 00:00:00,1100,,20
7900,JAMES,CLERK,7698,1981-12-03 00:00:00,950,,30
7902,FORD,ANALYST,7566,1981-12-03 00:00:00,3000,,20
7934,MILLER,CLERK,7782,1982-01-23 00:00:00,1300,,10
7948,JACCKA,CLERK,7782,1981-04-12 00:00:00,5000,,10
7956,WELAN,CLERK,7649,1982-07-20 00:00:00,2450,,10
7956,TEBAGE,CLERK,7748,1982-12-30 00:00:00,1300,,10
```

Group all employees by department, sort each group in descending order by salary, and then obtain the name of the first employee in each group.

```
SELECT deptno
      , ename
      , sal
      , FIRST_VALUE(ename) OVER(PARTITION BY deptno ORDER BY sal desc) AS first1-- Obtain the name of the first employee in each group after descending sorting by salary.
  FROM emp;
```

Returned result is as follows.

Returned result

deptno	ename	sal	first1
10	JACCKA	5000.0	JACCKA
10	KING	5000.0	JACCKA
10	CLARK	2450.0	JACCKA
10	WELAN	2450.0	JACCKA
10	TEBAGE	1300.0	JACCKA

30	WARD	1250.0	BLAKE
30	JAMES	950.0	BLAKE

1.6.7.4.21. LAST_VALUE

Function declaration:

```
last_value(expr) over(partition by col1[, col2...] order by col1 [asc|desc][, col2[asc|desc]...]])
```

Purpose: It is used to sort partitions and return the last value in the range from the beginning to the current row.

Description:

expr: required. Any type.

Returned value: the last expr value in partitions used in the computation.

Example:

Table emp has the following data:

```
| empno | ename | job | mgr | hiredate| sal| comm | deptno |
7369,SMITH,CLERK,7902,1980-12-17 00:00:00,800,,20
7499,ALLEN,SALESMAN,7698,1981-02-20 00:00:00,1600,300,30
7521,WARD,SALESMAN,7698,1981-02-22 00:00:00,1250,500,30
7566,JONES,MANAGER,7839,1981-04-02 00:00:00,2975,,20
7654,MARTIN,SALESMAN,7698,1981-09-28 00:00:00,1250,1400,30
7698,BLAKE,MANAGER,7839,1981-05-01 00:00:00,2850,,30
7782,CLARK,MANAGER,7839,1981-06-09 00:00:00,2450,,10
7788,SCOTT,ANALYST,7566,1987-04-19 00:00:00,3000,,20
7839,KING,PRESIDENT,,1981-11-17 00:00:00,5000,,10
7844,TURNER,SALESMAN,7698,1981-09-08 00:00:00,1500,0,30
7876,ADAMS,CLERK,7788,1987-05-23 00:00:00,1100,,20
7900,JAMES,CLERK,7698,1981-12-03 00:00:00,950,,30
7902,FORD,ANALYST,7566,1981-12-03 00:00:00,3000,,20
7934,MILLER,CLERK,7782,1982-01-23 00:00:00,1300,,10
7948,JACCKA,CLERK,7782,1981-04-12 00:00:00,5000,,10
7956,WELAN,CLERK,7649,1982-07-20 00:00:00,2450,,10
7956,TEBAGE,CLERK,7748,1982-12-30 00:00:00,1300,,10
```

Group all employees by department, and then obtain the name of the last employee in each group.

```
SELECT deptno
      , ename
      , sal
      , LAST_VALUE(ename) OVER(PARTITION BY deptno  ) AS last1
  FROM emp;
```

The returned result is as follows.

Returned result

deptno	ename	sal	last1
10	TEBAGE	1300.0	WELAN
10	CLARK	2450.0	WELAN
10	KING	5000.0	WELAN
10	MILLER	1300.0	WELAN

30	MARTIN	1250.0	BLAKE
30	BLAKE	2850.0	BLAKE

1.6.7.5. Aggregate functions

1.6.7.5.1. Overview

An aggregate function aggregates multiple input records into an output record. The input is mapped many-to-one to the output. An aggregate function can be used with the GROUP BY clause at the same time.

1.6.7.5.2. COUNT

Command syntax:

```
bigint count([distict|all] value)
```

Purpose: It is used to return the number of records.

Description:

- distinct|all: indicates whether duplicate records are cleared in counting. The default value is all, indicating that records are counted. If it is set to distinct, only records with distinct values are counted.
- value: any type. When it is NULL, this row is not involved in computation. value can be *. When it is set to count(*), the number of all rows is returned.

Returned value: bigint type.

Example:

In the tbla table, the col1 column is of the bigint type.

```
+------+
| COL1 |
+------+
| 1    |
+------+
| 2    |
+------+
| NULL |
+------+
select count(*) from tbla;
-- 3 is returned.
select count(col1) from tbla;
-- The value is 2.
```

Aggregate functions can be used with the GROUP BY statement. For example, table test_src contains two columns: key (string type), and value (double type).

The data in the test_src table:

```
+-----+-------+
| key | value |
+-----+-------+
| a   | 2.0   |
+-----+-------+
| a   | 4.0   |
+-----+-------+
| b   | 1.0   |
+-----+-------+
| b   | 3.0   |
+-----+-------+
select key, count(value) as count from test_src group by key;
-- Run the preceding SQL statement. The output is:
+-----+-------+
| key | count |
+-----+-------+
| a   | 2     |
+-----+-------+
| b   | 2     |
+-----+-------+
```

Aggregate functions perform aggregation on values of the same key. The usage of the following aggregate functions is the same as that of this function and is not described in detail in this document.

1.6.7.5.3. AVG

Function declaration:

```
double avg(double value)
decimal avg(decimal value)
```

Purpose: It is used to calculate the average value.

Description:

value: double type or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned. If the value is NULL, this row is not used for calculation. The input cannot be of the boolean type.

Returned value: If the input is of the decimal type, a value of the decimal type is returned. For all other valid input types, a value of the double type is returned.

Example:

In the tbla table, the value column is of the bigint type.

```
+-------+
| value |
+-------+
| 1     |
| 2     |
| NULL  |
+-------+
select avg(value) as avg from tbla;
+------+
| avg  |
+------+
| 1.5  |
+------+
-- The avg result of this column is as follows: (1 + 2) / 2 = 1.5.
```

1.6.7.5.4. MAX

Function declaration:

```
max(value)
```

Purpose: It is used to return the maximum value.

Description:

value: can be any data type. If the column value is NULL, the corresponding row is not involved in the operation. Values of the boolean type are excluded from the computation.

Returned value: The type is the same as that of value.

Example:

In the tbla table, the col1 column is of the bigint type.

```
+------+
| col1 |
+------+
| 1    |
+------+
| 2    |
+------+
| NULL |
+------+
select max(value) from tbla;
-- 2 is returned.
```

1.6.7.5.5. MIN

Function declaration:

```
MIN(value)
```

Purpose: It is used to return the minimum value.

Description:

value: a column of any data type. If a value in the column is NULL, the corresponding row is not involved in the operation. Boolean types are not allowed in this operation.

Returned value: The type is the same as that of value.

Example:

In the tbla table, the value column is of the bigint type.

```
+------+
| value|
+------+
| 1    |
+------+
| 2    |
+------+
| NULL |
+------+
select min(value) from tbla;
-- 1 is returned.
```

1.6.7.5.6. MEDIAN

Function declaration:

```
double median(double number)
decimal median(decimal number)
```

Purpose: It is used to calculate the median.

Description:

number: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other input types, an error is returned. If the input is NULL, a failure is returned.

Returned value: double or decimal type.

1.6.7.5.7. STDDEV

Function declaration:

```
double stddev(double number)
decimal stddev(decimal number)
```

Purpose: It is used to calculate the population standard deviation.

Description:

number: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other types of inputs, an error is returned. If the input value is NULL, a failure is returned.

Returned value: double or decimal type.

1.6.7.5.8. STDDEV_SAMP

Function declaration:

```
double stddev_samp(double number)
decimal stddev_samp(decimal number)
```

Purpose: It is used to calculate the sample standard deviation.

Description:

number: double or decimal type. If the input is of the string or bigint type, it is implicitly converted into a value of the double type before this computation. For all other types of inputs, an error is returned. If the input is NULL, a failure is returned.

Returned value: double or decimal type.

1.6.7.5.9. SUM

Function declaration:

```
sum(value)
```

Purpose: It is used to calculate the sum.

Description:

value: double, decimal, or bigint type. If the input is of the string type, it is implicitly converted into a value of the double type before computation. If a value in the column is NULL, this row is not used for calculation. Values of the boolean type are excluded from calculation.

Returned value: When the input is of the bigint type, a value of the bigint type is returned. When the input is of the double or string type, a value of the double type is returned.

Example:

In the tbla table, the value column is of the bigint type.

```
+------+
| value|
+------+
| 1    |
+------+
| 2    |
+------+
| NULL |
+------+
select sum(value) from tbla;
-- 3 is returned.
```

1.6.7.5.10. WM_CONCAT

Function declaration:

```
string wm_concat(string separator, string str)
```

Purpose: It is used to use the specified separator as the delimiter to link values in a string.

Description:

- separator: the delimiter, which is a constant of the string type. If it is of another type or is not a constant, an error is returned.
- str: string type. If the input is of the bigint, double, or datetime type, it is implicitly converted to a value of the string type before this computation. For all other input types, an error is returned.

Returned value: string type.

> **Note** If test_src in the select wm_concat(',', name) from > test_src; statement is an empty set, NULL is returned.

1.6.7.5.11. PERCENTILE

Function declaration:

```
DOUBLE percentile(BIGINT col, p)
array<double> percentile(BIGINT col, array(p1 [, p2]...))
```

Purpose: It is used to return the pth percentile of the specified column. p must be between 0 and 1.

> **Notice** You can only calculate true percentiles for integer values.

Description:

- col: BIGINT type.
- p: must be between 0 and 1.

Example:

Column c1 in table test has the following data:

```
+------------+
| c1       |
+------------+
| 8        |
| 9        |
| 10       |
| 11       |
+------------+
```

Calculate the pth percentile of column c1 in table test.

```
-- Execute the following statement:
select percentile(c1,0),percentile(c1,0.3),percentile(c1,0.5),percentile(c1,1) from test;
-- Returned result:
+------------+------------+------------+------------+
| _c0      | _c1      | _c2      | _c3      |
+------------+------------+------------+------------+
| 8.0      | 8.9      | 9.5      | 11.0     |
+------------+------------+------------+------------+
-- Execute the following statement:
select percentile(c1,array(0,0.3,0.5,1))from test;
-- Returned result:
+------+
| _c0  |
+------+
| [8, 8.9, 9.5, 11] |
+------+
```

1.6.7.5.12. Additional aggregate functions

MaxCompute 2.0 provides additional aggregate functions. You must add the following SET statement before SQL statements contained in the aggregate functions:

```
set odps.sql.type.system.odps2=true;
```

> **Note** You must submit and execute the SET statement and the SQL statements of the new functions simultaneously.

The aggregate functions described in subsequent topics are new in MaxCompute 2.0.

1.6.7.5.13. COLLECT_LIST

Command syntax:

```
ARRAY collect_list(col)
```

Purpose: It is used to convert the values on the col column into an array.

Description:

col: a table column of any data type.

Returned value: array type.

1.6.7.5.14. COLLECT_SET

Command syntax:

```
ARRAY collect_set(col)
```

Purpose: It is used to convert the values on the col column with duplicates removed into an array.

Description:

col: a table column of any data type.

Returned value: array type.

1.6.7.5.15. VARIANCE/VAR_POP

Function declaration:

```
DOUBLE variance(col)
DOUBLE var_pop(col)
```

Purpose: It is used to calculate the variance of the specified numeric column.

Description:

col: numeric type column. NULL is returned for other types.

Returned value: DOUBLE type.

Example:

Column c1 in table test has the following data:

```
+------------+
| c1       |
+------------+
| 8        |
| 9        |
| 10       |
| 11       |
+------------+
```

Calculate the variance of column c1 in table test.

```
-- Execute the following statement:
select variance(c1) from test;
-- or
select var_pop(c1) from test;
-- Returned result:
+------------+
| _c0        |
+------------+
| 1.25       |
+------------+
```

1.6.7.5.16. VAR_SAMP

Function declaration:

```
DOUBLE var_samp(col)
```

Purpose: It is used to calculate the sample variance of the specified numeric column.

Description:

col: numeric type column. NULL is returned for other types.

Returned value: DOUBLE type.

Example:

Column c1 in table test has the following data:

```
+------------+
| c1         |
+------------+
| 8          |
| 9          |
| 10         |
| 11         |
+------------+
```

Calculate the variance of column c1 in table test.

```
-- Execute the following statement:
select var_samp(c1) from test;
-- Returned result:
+------------+
| _c0       |
+------------+
| 1.6666666666666667 |
+------------+
```

1.6.7.5.17. COVAR_POP

Function declaration:

```
DOUBLE covar_pop(col1, col2)
```

Purpose: It is used to calculate the population covariance of two specified numeric columns.

Description:

col1 and col2: numeric type columns. NULL is returned for other types.

Example:

Columns c1 and c2 in table test have the following data:

```
+------------+------------+
| c1        | c2        |
+------------+------------+
| 3         | 2         |
| 14        | 5         |
| 50        | 14        |
| 26        | 75        |
+------------+------------+
```

Calculate the population covariance of columns c1 and c2.

```
-- Execute the following statement:
select covar_pop(c1,c2) from test;
-- Returned result:
+------------+
| _c0       |
+------------+
| 123.49999999999997|
+------------+
```

1.6.7.5.18. COVAR_SAMP

Function declaration:

```
DOUBLE covar_samp(col1, col2)
```

Purpose: It is used to calculate the sample covariance of two specified numeric columns.

Description:

col1 and col2: numeric type columns. NULL is returned for other types.

Example:

Columns c1 and c2 in table test have the following data:

```
+------------+------------+
| c1         | c2         |
+------------+------------+
| 3          | 2          |
| 14         | 5          |
| 50         | 14         |
| 26         | 75         |
+------------+------------+
```

Calculate the sample covariance of columns c1 and c2.

```
-- Execute the following statement:
select covar_samp(c1,c2) from test;
-- Returned result:
+------------+
| _c0        |
+------------+
| 164.66666666666663|
+------------+
```

1.6.7.6. Other functions

1.6.7.6.1. ARRAY

Function declaration:

```
array(value1,value2, ...)
```

Purpose: It is used to create an array by using input values.

Description:

value: any type. All the values must be of the same type.

Returned value: ARRAY type.

Example:

```
select array(123,456,789) from dual;
-- Returned result:
[123, 456, 789]
```

1.6.7.6.2. ARRAY_CONTAINS

Function declaration:

```
array_contains(ARRAY<T> a, value v)
```

Purpose: It is used to check whether array a contains value v.

Description:

- a: array type.
- v: The given value v must be of the same type as the data in the array.

Returned value: boolean type.

Example:

```
select array_contains(array('a','b'), 'a') from dual;
-- True is returned.
select array_contains(array(456,789),123) from dual;
-- False is returned.
```

1.6.7.6.3. CAST

Command syntax:

```
cast(expr as <type>)
```

Purpose: It is used to convert an expression of one data type to another. For example, cast ('1' as bigint) converts 1 of the string type to the integer type. If the conversion fails, an error is returned.

Note

- cast(double as bigint) converts a value of the double type into a value of the bigint type.
- cast(string as bigint) converts a value of the string type into a value of the bigint type. If the string is composed of numerals expressed in integer form, it is directly converted into a value of the bigint type. If the string is comprised of numerals expressed in the 'float' or 'exponent' form, it is converted to 'double' type first and then to 'bigint' type.
- For cast(string as datetime) or cast(datetime as > string), the datatime format is yyyy-mm-dd hh:mi:ss by default.

1.6.7.6.4. COALESCE

Command syntax:

```
coalesce(expr1, expr2, ...)
```

Purpose: It is used to return the first non-NULL value in the list. If all values in the list are NULL, NULL is returned.

Description:

expr: a value to be tested. All these values must be of the same type or be NULL. Otherwise, an error is returned.

Returned value: The type is the same as that of the input.

Note At least one parameter is provided. Otherwise, an error is returned.

1.6.7.6.5. DECODE

Function declaration:

```
decode(expression, search, result[, search, result]...[, default])
```

Purpose: It is used to implement the if-then-else conditional branching feature.

Description:

- expression: expression to be compared.
- search: search string to be compared with the expression.
- result: the value returned when the value of search matches the expression.
- default: optional. If no search string matches the expression, the default value is returned. If it is not specified, NULL is returned.

Returned value: The matched search is returned. If there are no matches, the default value is returned. If default is not specified, NULL is returned.

Note

- At least three parameters are specified.
- All results must share the same type or be NULL. Inconsistent data types will cause an error. All values of search and expression must be of the same type. Otherwise, an error is returned.
- If the search option in decode has repeated records and matches the expression, the first search value is returned.

Example:

```
select decode(customer_id,
1, 'Taobao',
2, 'Alipay',
3, 'Aliyun',
NULL, 'N/A',
'Others') as result from sale_detail;
```

The preceding DECODE function implements the feature in the following if-then-else statement:

```
if customer_id = 1 then result := 'Taobao';
elsif customer_id = 2 then result := 'Alipay';
elsif customer_id = 3 then result := 'Aliyun';
...
else
result := 'Others';
end if;
```

Notice The MaxCompute SQL statement returns NULL when calculating NULL = NULL. However, in the DECODE function, values of NULL and NULL are equal. In the preceding example, when the value of customer_id is NULL, the DECODE function returns N/A.

1.6.7.6.6. EXPLODE

Function declaration:

```
explode (var)
```

Purpose: It is used to convert one row of data into multiple rows of UDTF. If var is of the array type, the array stored in the column is converted into multiple rows. If var is of the map type, each key-value pair of the map stored in the column is converted into a row with two columns, with one column for the key and the other for the value.

Description:

var: array < T > type or map < K,V > type.

Returned value: transposed rows.

> **Note**
>
> Limits on the use of UDTFs:
>
> - Only one UDTF is allowed in a SELECT statement, and other columns are not allowed.
> - One select can only have one UDTF and no other columns can appear.

Example:

```
explode(array(null, 'a', 'b', 'c'))  col
```

1.6.7.6.7. GET_IDCARD_AGE

Function declaration:

```
get_idcard_age(idcardno)
```

Purpose: It is used to return the current age based on the ID card number. The current age is the current year minus the birth year on the ID card.

Description:

idcardno: string type, ID number of 15-digit or 18-digit. During the calculation, the validity of the ID card is verified based on the province code and the last check code. If the verification fails, NULL is returned.

Returned value: bigint type. If the input is NULL, NULL is returned. If the difference of the current year minus the birth year is greater than 100, then NULL is returned.

1.6.7.6.8. GET_IDCARD_BIRTHDAY

Function declaration:

```
get_idcard_birthday(idcardno)
```

Purpose: It is used to return the date of birth based on the ID card number.

Description:

idcardno: string type, a 15-digit or 18-digit ID card number. During computation, the validity of the ID card is verified based on the province code and the last check code. If the verification fails, NULL is returned.

Returned value: datetime type. If the input is NULL, NULL is returned.

1.6.7.6.9. GET_IDCARD_SEX

Function declaration:

```
get_idcard_sex(idcardno)
```

Purpose: It is used to return the gender based on the ID card number. The returned value is M (male) or F (female).

Description:

idcardno: string type, a 15-digit or 18-digit ID card number. During computation, the validity of the ID card is verified based on the province code and the last check code. If the verification fails, NULL is returned.

Returned value: string type. If the input is NULL, NULL is returned.

1.6.7.6.10. GREATEST

Function declaration:

```
greatest(var1, var2, ...)
```

Purpose: It is used to return the maximum value among the input values.

Description:

var: bigint, double, datetime, or string type. If all values are NULL, NULL is returned.

Returned value:

- The greatest value in input parameter. If the implicit conversion is not needed, return type is the same as input parameter type.
- NULL is interpreted as the minimum value.
- If the input parameters are of different types, values of the double, bigint, and string types are converted into values of the double type for comparison, and values of the string and datetime types are converted into values of the datetime type for comparison. Implicit conversion of other types is not allowed.

1.6.7.6.11. INDEX

Function declaration:

```
index(var1[var2])
```

Purpose: It is used to return the specified element in a given array, or return the value of the specified key in a given map.

Description:

- var1: array < T > type or map < K,V > type.
- var2: If var1 is of the array < T > type, var2 must be the bigint type must be larger or equal to 0. If var1 is of the map < K,V > type, var2 is of the K type.

Returned value:

- If var1 is of the array < T > type, a value of the T type is returned. If var2 is out of range of array < T > elements, NULL is returned.

- If var1 is of the map < K,V > type, a value of the V type is returned. If no key is var2 in map < K,V >, NULL is returned.

Example:

If var1 is an array, run the following SQL statement:

```
select array('a','b','c')[2] from dual;
-- Returned result:
+-----+
| _c0 |
+-----+
| c   |
+-----+
```

If var1 is of the map type, run the following SQL statement:

```
select str_to_map("test1=1,test2=2")["test1"] from dual;
-- Returned result:
+-----+
| _c0 |
+-----+
| 1   |
+-----+
```

> **Notice**
> - To use the SQL statement, remove the index and run var1[var2] directly. Otherwise, a syntax error is returned.
> - If Var1 is NULL, NULL is returned.

1.6.7.6.12. MAX_PT

Function declaration:

```
max_pt(table_full_name)
```

Purpose: For partitioned tables, it is used to return the maximum values in the first-level partitions that have data files and sort the values in alphabetic order.

Description:

table_full_name: string type. It specifies a table name (project name required, for example, prj.src). You must have the read permission on the table.

Returned value: maximum value in the primary partition.

Example:

Partitioned table tbl has the following partitions with data files: pt='20170901' and pt='20170902'. In the following statement, the returned value of max_pt is '20170902'. The MaxCompute SQL statement reads data from the '20120902' partition.

```
select * from tbl where pt=max_pt('myproject.tbl');
```

Note If a new partition is added by using alter table, but there is no data file in this partition, then this partition is not returned.

1.6.7.6.13. ORDINAL

Function declaration:

```
ordinal(bigint nth, var1, var2, ...)
```

Purpose: It is used to sort the input variables in ascending order, and return the specified nth value.

Description:

- nth: bigint type. It specifies the position at which the value is to be returned. If it is NULL, NULL is returned.
- var: bigint, double, datetime, or string type.

Returned value:

- The value in nth bit. If the implicit conversion is not needed, return type is the same as input parameter type.
- If type conversion is performed, values of the double, bigint, and string types are converted into values of the double type. Values of the string and datetime types are converted into values of the datetime type. Implicit conversion of other types is not allowed.
- NULL is the least value.

Example:

```
ordinal(3, 1, 3, 2, 5, 2, 4, 6) =  2
```

1.6.7.6.14. LEAST

Function declaration:

```
least(var1, var2, ...)
```

Purpose: It is used to returns the minimum value among the input values.

Description:

var: bigint, double, datetime, or string type. If all values are NULL, NULL is returned.

Returned value:

- The least value in input parameter; If the implicit conversion is not needed, return type is the

same as input parameter type.

- If type conversion is performed, values of the double, bigint, and string types are converted into values of the double type. Values of the string and datetime types are converted into values of the datetime type. Implicit conversion of other types is not allowed.
- NULL is interpreted as the minimum value.

1.6.7.6.15. SIZE

Function declaration:

```
size(map<K, V>)
size(array<T>)
```

Purpose: size(map) is used to return the number of key-value pairs in the given map, and size(array) is used to return the number of elements in the given array.

Description:

- map: map type.
- array: array type.

Returned value: int type.

Example:

```
select size(map('a',123,'b',456)) from dual;
-- 2 is returned.
select size(map('a',123,'b',456,'c',789)) from dual;
-- 3 is returned.
select size(array('a','b')) from dual;
-- 2 is returned.
select size(array(123,456,789)) from dual;
-- 3 is returned.
```

1.6.7.6.16. SPLIT

Function declaration:

```
split(str, pat)
```

Purpose: It is used to split a string using the specified separator.

Description:

- str: string type. The string to be separated.
- pat: string type. It indicates the separator and supports regular expressions.

Returned value: array <string >. The returned array contains elements extracted from the string based on the specified separator.

Example:

```
select split("a,b,c",",") from dual;
-- Returned result:
+------+
| _c0 |
+------+
| [a, b, c] |
+------+
```

1.6.7.6.17. STR_TO_MAP

Function declaration:

```
str_to_map(text [, delimiter1 [, delimiter2]])
```

Purpose: It is used to divide 'text' into K-V pairs with 'delimiter1', and to separate each K-V pair with 'delimiter2'.

Description:

ext: string type. It indicates the string to be separated.

delimiter1: string type. It is the delimiter. If it is not specified, the default value ',' is used.

delimiter2: string type. It is the delimiter. If it is not specified, the default value '=' is used.

Returned value: map < string, string >. The elements are the K-V results of the separation of 'text' by the strings 'delimiter1' and 'delimiter2'.

Example:

```
select str_to_map("test1=1,test2=2") from dual;
-- Returned result:
+------------+
| a          |
+------------+
| {Test1: 1, Test2: 2}|
```

1.6.7.6.18. UNIQUE_ID

Function declaration:

```
STRING UNIQUE_ID()
```

Purpose: It is used to return a random but unique ID, for example, 29347a88-1e57-41ae-bb68-a9edbdd94212_1. This function runs more efficiently than UUID.

1.6.7.6.19. UUID

Function declaration:

```
string uuid()
```

Purpose: It returns a random ID, for example, 29347a88-1e57-41ae-bb68-a9edbdd94212.

1.6.7.6.20. SAMPLE

Function declaration:

```
boolean sample(x, y, column_name)
```

Purpose: It is used to sample all values read from the specified column based on the given settings, and filters out the rows that do not meet the sampling condition.

Description:

- x, y: bigint type. It indicates that data is hashed to x portions and the yth portion is taken. y can be omitted. If y is omitted, the first portion is taken and column_name must also be omitted. x and y are constants of the integer type and are greater than 0. If they are of another type or if they are less than or equal to 0, an error is returned. If y is greater than x, an error is returned. If either x or y is NULL, NULL is returned.
- column_name: target column of sampling. column_name can be omitted. If column_name is omitted, random sampling is performed based on values of x and y. It can be of any type, and the column value can be NULL. No implicit conversion is performed. If column_name is the constant NULL, an error is reported.

Returned value: boolean type.

> **Note** To avoid data skew resulting from the NULL value, a uniform hash of x is made for a value of NULL in column_name. If column_name is not added, the output is not necessarily uniform since the data size is smaller. So column_name is suggested to be added to get better output.

Example:

Table tbla contains a column named cola.

```
select * from tbla where sample (4, 1 , cola) = true;
-- The values are hashed to four portions based on cola, and the first portion is used.
select * from tbla where sample (4, 2) = true;
-- The values in each row are randomly hashed to four portions, and the second portion is used.
```

1.6.7.6.21. CASE WHEN expression

MaxCompute provides the following two kinds of CASE WHEN syntax formats:

```
case value
when (_condition1) then result1
when (_condition2) then result2
...
else resultn
end

case
when (_condition1) then result1
when (_condition2) then result2
when (_condition3) then result3
...
else resultn
end
```

CASE WHEN flexibly returns different values based on the calculation result of the expression. Alibaba Cloud StreamCompute supports two types of CASE WHEN expressions:

```
select
case
when shop_name is null then 'default_region'
when shop_name like 'hang%' then 'zj_region'
end as region
From sale_detail;
```

> **Note**
>
> - If there are values of only the bigint and double type in the results, the results are converted into values of the double type.
> - If there is a value of the string type in the results, the results are all converted into values of the string type. If the result of a type cannot be converted (for example, boolean type), an error is returned.
> - Conversion between other types is not allowed.

1.6.7.6.22. IF

Function declaration:

```
if(testCondition, valueTrue, valueFalseOrNull)
```

Purpose: It is used to determine whether 'testCondition' is true. If it is true, valueTrue is returned. If it is not true, valueFalseOrNull is returned.

Description:

testCondition: boolean type. The expression to be determined true or not.

valueTrue: the value returned when expression 'testCondition' is true.

valueFalseOrNull: the value returned when expression 'testCondition' is false. It can be set to NULL.

Returned value: The type is the same as that of valueTrue or valueFalseOrNull.

Example:

```
select if(1=2,100,200) from dual;
-- Returned result:
+------------+
| _c0        |
+------------+
| 200        |
+------------+
```

1.6.7.6.23. Additional functions

MaxCompute 2.0 provides additional functions.

The functions described in the following topics are new in this version.

1.6.7.6.24. MAP

Function declaration:

```
map(K key1, V value1, K key2, V value2, ...)
```

Purpose: It is used to create a map with the given K-V pairs.

Description:

key/value: The types of all keys are the same and must be of one of the basic types. The types of all values are the same and can be of any type.

Returned value: map type.

Example:

```
select map('a',123,'b',456) from dual;
-- Returned result:
{a:123, b:456}
```

1.6.7.6.25. MAP_KEYS

Function declaration:

```
map_keys(map<K, V> )
```

Purpose: It is used to return all keys in the map parameter as an array.

Description:

map: data of the map type.

Returned value: array type. If the input is NULL, NULL is returned.

Example:

```
select map_keys(map('a',123,'b',456)) from dual;
-- Returned result:
[a, b]
```

1.6.7.6.26. MAP_VALUES

Function declaration:

```
map_values(map<K, V>)
```

Purpose: It is used to return all values in the map parameter as an array.

Description:

map: map type.

Returned value: array type. If the input is NULL, NULL is returned.

Example:

```
select map_keys(map('a',123,'b',456)) from dual;
-- Returned result:
[123, 456]
```

1.6.7.6.27. SORT_ARRAY

Function declaration:

```
sort_array(ARRAY<T>)
```

Purpose: It is used to sort a given array.

Description:

ARRAY: array type. The data in the array is of any type.

Returned value: array type.

Example:

```
select sort_array(array('a','c','f','b')),sort_array(array(4,5,7,2,5,8)),sort_array(array('You','Me','He')) from
dual;
-- Returned result:
[a, b, c, f] [2, 4, 5, 5, 7, 8] [him, you, me]
```

1.6.7.6.28. POSEXPLODE

Command syntax:

```
posexplode(ARRAY<T>)
```

Purpose: It is used to explode the given array. Each value is given a row and each row has two columns corresponding to the subscript (starting from 0) and the array element.

Description:

ARRAY: array type. Data in the array can be of any type.

Returned value: table generation function.

Example:

```
select posexplode(array('a','c','f','b')) from dual;
-- Returned result:
+------------+-----+
| pos        | val |
+------------+-----+
| 0          | a   |
| 1          | c   |
| 2          | f   |
| 3          | b   |
+------------+-----+
```

1.6.7.6.29. STRUCT

Function declaration:

```
struct(value1,value2, ...)
```

Purpose: It is used to create a struct using a given value list.

Description:

value: any type.

Returned value: struct type. The field names of the created struct are col1, col2, and so on.

Example:

```
select struct('a',123,'ture',56.90) from dual;
-- Returned result:
{col1:a, col2:123, col3:true, col4:56.9}
```

1.6.7.6.30. NAMED_STRUCT

Function declaration:

```
named_struct(string name1, T1 value1, string name2, T2 value2, ...)
```

Purpose: It is used to create a struct using a given name-value list.

Description:

- value: any type.
- name: field name of the string type.

Returned value: struct type. The field names of the created struct are name1, name2, and so on.

Example:

```
select named_struct('user_id',10001,'user_name','bob','married','F','weight',63.50) from dual;
-- Returned result:
{user_id:10001, user_name:bob, married:F, weight:63.5}
```

1.6.7.6.31. INLINE

Function declaration:

```
inline(ARRAY<STRUCT<f1:T1, f2:T2, ... >>)
```

Purpose: It is used to expand a struct, with each element corresponding to a row, and each struct element in each row corresponding to a column.

Description:

STRUCT: The values in the array can be of any type.

Returned value: table generation function.

Example:

```
select inline(array(named_struct('user_id',10001,'user_name','bob','married','F','weight',63.50))) from du
al;
-- Returned result:
+------------+-----------+---------+------------+
| user_id    | user_name | married | weight     |
+------------+-----------+---------+------------+
| 10001      | bob       | F       | 63.5       |
+------------+-----------+---------+------------+
```

1.6.7.6.32. BETWEEN AND expression

Command syntax:

```
A [NOT] BETWEEN B AND C
```

If A, B, or C is NULL, then the value is NULL. If A is greater than or equal to B, and less than or equal to C, the value is true. Otherwise, the value is false.

Example:

The emp table contains the following data:

```
| empno | ename | job | mgr | hiredate| sal| comm | deptno |
7369,SMITH,CLERK,7902,1980-12-17 00:00:00,800,,20
7499,ALLEN,SALESMAN,7698,1981-02-20 00:00:00,1600,300,30
7521,WARD,SALESMAN,7698,1981-02-22 00:00:00,1250,500,30
7566,JONES,MANAGER,7839,1981-04-02 00:00:00,2975,,20
7654,MARTIN,SALESMAN,7698,1981-09-28 00:00:00,1250,1400,30
7698,BLAKE,MANAGER,7839,1981-05-01 00:00:00,2850,,30
7782,CLARK,MANAGER,7839,1981-06-09 00:00:00,2450,,10
7788,SCOTT,ANALYST,7566,1987-04-19 00:00:00,3000,,20
7839,KING,PRESIDENT,,1981-11-17 00:00:00,5000,,10
7844,TURNER,SALESMAN,7698,1981-09-08 00:00:00,1500,0,30
7876,ADAMS,CLERK,7788,1987-05-23 00:00:00,1100,,20
7900,JAMES,CLERK,7698,1981-12-03 00:00:00,950,,30
7902,FORD,ANALYST,7566,1981-12-03 00:00:00,3000,,20
7934,MILLER,CLERK,7782,1982-01-23 00:00:00,1300,,10
7948,JACCKA,CLERK,7782,1981-04-12 00:00:00,5000,,10
7956,WELAN,CLERK,7649,1982-07-20 00:00:00,2450,,10
7956,TEBAGE,CLERK,7748,1982-12-30 00:00:00,1300,,10
```

Run the following command to query data where sal is greater than or equal to 1,000 and less than or equal to 1,500:

```
select * from emp where sal BETWEEN 1000 and 1500;
-- Returned result:
+-------+-------+-----+------------+------------+------------+------------+------------+
| empno | ename | job | mgr        | hiredate   | sal        | comm       | deptno     |
+-------+-------+-----+------------+------------+------------+------------+------------+
| 7521  | WARD  | SALESMAN | 7698  | 1981-02-22 00:00:00 | 1250.0     | 500.0      | 30  |
| 7654  | MARTIN | SALESMAN | 7698 | 1981-09-28 00:00:00 | 1250.0     | 1400.0     | 30 |
| 7844  | TURNER | SALESMAN | 7698 | 1981-09-08 00:00:00 | 1500.0     | 0.0        | 30 |
| 7876  | ADAMS | CLERK | 7788  | 1987-05-23 00:00:00 | 1100.0     | NULL     | 20   |
| 7934  | MILLER | CLERK | 7782  | 1982-01-23 00:00:00 | 1300.0     | NULL      | 10  |
| 7956  | TEBAGE | CLERK | 7748  | 1982-12-30 00:00:00 | 1300.0     | NULL      | 10  |
+-------+-------+-----+------------+------------+------------+------------+------------+
```

1.6.7.6.33. NVL

Function declaration:

```
nvl(T value, T default_value)
```

Purpose: It is used to return default_value if value is NULL and return value otherwise.

Example:

Table t_data has three columns of c1 string, c2 bigint, and c3 datetime, as well as the following data:

```
+----+------------+------------+
| c1 | c2         | c3         |
+----+------------+------------+
| NULL | 20         | 2017-11-13 05:00:00 |
| ddd | 25         | NULL       |
| bbb | NULL       | 2017-11-12 08:00:00 |
| aaa | 23         | 2017-11-11 00:00:00 |
+----+------------+------------+
```

Use the NVL function to output the NULL values in c1 to 00000, the NULL values in c2 to 0, and the NULL values in c3 to "-".

```
-- Execute the following statement:
SELECT nvl(c1,'00000'),nvl(c2,0) nvl(c3,'-') from nvl_test;
-- Returned result:
+-----+------------+-----+
| _c0 | _c1       | _c2 |
+------------+---------+
| bbb | 0         | 2017-11-12 08:00:00 |
| ddd | 25        | -   |
| 00000 | 20        | 2017-11-13 05:00:00 |
| aaa | 23        | 2017-11-11 00:00:00 |
+-----+------------+-----+
```

1.6.7.6.34. TABLE_EXISTS

Function declaration:

```
boolean table_exists(string table_name)
```

Description: This function checks whether a specific table exists.

Parameters:

table_name: the table name of the STRING type. The value can include the project name, such as my_proj.my_table. If no project name is specified, the name of the current project is used.

Return value: A value of the BOOLEAN type is returned. If the specified table exists, True is returned. Otherwise, False is returned.

Example:

```
-- Used in a SELECT statement.
SELECT IF(table_exists('abd'), col1, col2) FROM src;
-- Used in an IF-ELSE branch statement.
IF (table_exists('abd'))
-- statments
ELSE
-- statments
```

1.6.7.6.35. PARTITION_EXISTS

Function declaration:

```
boolean partition_exists(string table_name, string... partitions)
```

Description: This function checks whether a specific partition exists.

Parameters:

- table_name: the table name of the STRING type. The value can include the project name, such as my_proj.my_table. If no project name is specified, the name of the current project is used.
- partitions: the partition names of the STRING type. Set this parameter to the partitioning column values based on partition key columns in sequence. The number of partition names must be the same as that of partition key columns.

Return value: A value of the BOOLEAN type is returned. If the specified partitions exist, True is returned. Otherwise, False is returned.

Example:

```
CREATE TABLE foo (id BIGINT) PARTITIONED BY (ds STRING, hr STRING);
-- Create a partitioned table named foo.
ALTER TABLE foo ADD PARTITION (ds='20190101', hr='1');
-- Add a partition to foo.
SELECT partition_exists('foo', '20190101', '1');
-- Check whether partitions ds='20190101' and hr='1' exist.
```

1.6.8. UDFs

1.6.8.1. Overview

UDF is short for user defined function. MaxCompute provides a variety of built-in functions. You can also create UDFs based on specific computing requirements. You can use UDFs as using common built-in functions. This topic briefs how to use SQL UDFs. For more information about SQL UDFs, see the official documentation on UDFs.

The following table lists the extended UDFs in MaxCompute.

UDF category

UDF category	Description
UDF	User defined scalar functions are commonly referred to as UDFs. There is a one-to-one mapping between the input and output. Each time a UDF reads a row of data, it writes an output value.
UDTF	User defined table valued functions are commonly referred to as UDTFs. Each time a UDTF is called, it outputs multiple rows of data. UDTFs are the only category that returns multiple fields. A UDF only returns one value each time.
UDAF	User defined aggregation functions are commonly referred to as UDAFs. A UDAF aggregates multiple input records into one output record. There is a many-to-one mapping between input and output. A UDAF can be used together with the GROUP BY clause (SQL) at the same time. For more information about the syntax, see aggregation functions.

Note In general, UDFs refer to all user defined functions: UDFs, UDAFs, and UDTFs. In a narrow sense, UDFs only refer to user defined scalar functions. This term is used interchangeably in this document. You will have to determine the exact meaning based on the context.

1.6.8.2. Types of parameters and returned values

UDFs support the following MaxCompute SQL data types:

- Basic data types: BIGINT, DOUBLE, BOOLEAN, DATETIME, DECIMAL, STRING, TINYINT, SMALLINT, INT, FLOAT, VARCHAR, BINARY, and TIMESTAMP.
- Complex data types: ARRAY, MAP, and STRUCT.

Note In UDFs, you can define the writable attribute of parameters.

The usage of some basic data types (such as TINYINT, SMALLINT, INT, FLOAT, VARCHAR, BINARY, and TIMESTAMP) in Java UDFs is as follows:

- UDAFs and UDTFs use the @Resolve annotation to obtain signatures. Example: `@Resolve("smallint->varchar(10)")`.
- UDFs reflect and analyze the evaluate() method to obtain signatures. In this case, there is a one-to-one mapping between MaxCompute built-in types and Java types.

To use complex data types (ARRAY, MAP, and STRUCT) in Java UDFs, take the following steps:

- UDTFs use the @Resolve annotation to specify signatures. Example: `@Resolve("array<string>,struct<a1:bigint,b1:string>,string->map<string,bigint>,struct<b1:bigint>")`.
- UDFs use the signature of the evaluate() method to map the input and output types. For more information, see the mappings between MaxCompute types and Java types. In the preceding example, ARRAY corresponds to java.util.List, MAP corresponds to java.util.Map, and STRUCT corresponds to com.aliyun.odps.data.Struct.
- UDAFs and UDTFs use the @Resolve annotation to obtain signatures. Example: `@Resolve("smallint->varchar(10)")`.

Notice

- You can use `type,*` to add any number of parameters. Example: @resolve("string,*->array<string>"). Note that you must add a subtype after array.
- The field name and field type of com.aliyun.odps.data.Struct cannot be reflected. Therefore, the @Resolve annotation is required. If you want to use struct in a UDF, you must add the @Resolve annotation to the UDF class. This annotation only affects the overloads of parameters or returned values that contain com.aliyun.odps.data.Struct.
- A class supports only one @Resolve annotation. A UDF that contains struct can only reload parameters or returned values once.

The following table lists the mapping between MaxCompute and Java data types.

Data type mapping

MaxCompute type	Java type
TINYINT	java.lang.Byte
SMALLINT	java.lang.Short
INT	java.lang.Integer
BIGINT	java.lang.Long
FLOAT	java.lang.Float
DOUBLE	java.lang.Double
DECIMAL	java.math.BigDecimal
BOOLEAN	java.lang.Boolean
STRING	java.lang.String
VARCHAR	com.aliyun.odps.data.Varchar
BINARY	com.aliyun.odps.data.Binary
DATETIME	java.util.Date
TIMESTAMP	java.sql.Timestamp
ARRAY	java.util.List
MAP	java.util.Map
STRUCT	com.aliyun.odps.data.Struct

Note

- Java data types and the data types of returned values are objects, and must start with a capitalized letter.
- The NULL value in SQL is represented by a NULL reference in Java. The Java primitive type is not allowed because it cannot represent a NULL value in SQL.
- The ARRAY type in MaxCompute corresponds to a list, not an array, in Java.

The following table compares the API features of two languages.

API feature comparison

Supported language	UDF	UDAF	UDTF	DATETIME type	Read resource file	Read resource table
Python	Yes	Yes	Yes	Yes	Yes	Yes

Supported language	UDF	UDAF	UDTF	DATETIME type	Read resource file	Read resource table
Java	Yes	Yes	Yes	Yes	Yes	Yes

1.6.8.3. UDFs

A UDF must inherit the com.aliyun.odps.udf.UDF class and implement the EVALUATE method. The EVALUATE method must be a non-static public method. The types of parameters and returned values of the EVALUATE method are used as the UDF signatures in SQL. This means that users can implement multiple EVALUATE methods in a UDF. When a UDF is called, the framework matches the correct EVALUATE method based on the parameter type called by the UDF.

Example:

```
package org.alidata.odps.udf.examples;
import com.aliyun.odps.udf.UDF;
public final class Lower extends UDF { public String evaluate(String s) { if (s == null) { return null; } retu
rn s.toLowerCase();
}
}
```

Note You can implement `void setup(ExecutionContext ctx)` and `void close()` to implement UDF initialization and termination code, respectively.

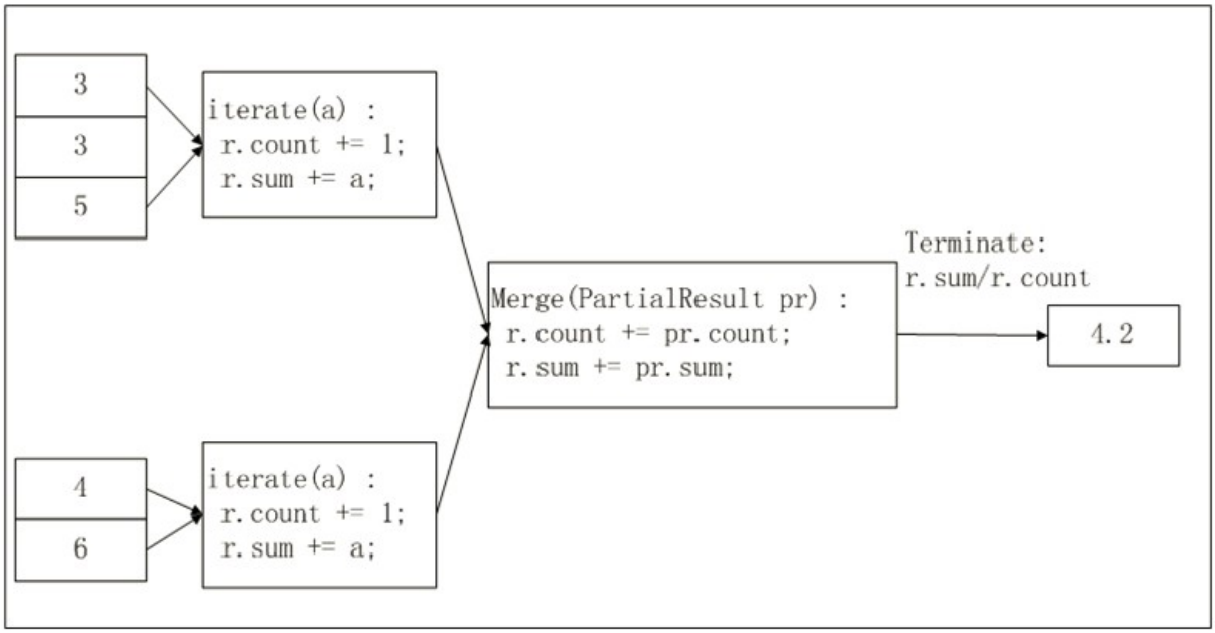
UDFs are used in the same way as built-in functions in MaxCompute SQL. For more information, see Built-in functions.

1.6.8.4. UDAFs

To implement a Java UDAF, you must inherit the com.aliyun.odps.udf.UDAF class and implement the following APIs:

```
public abstract class Aggregator implements ContextFunction {
@Override
public void setup(ExecutionContext ctx) throws UDFException {
}
@Override
public void close() throws UDFException {
}
/**
* Create an aggregate buffer
* @return Writable - Aggregate buffer
*/
abstract public Writable newBuffer();
/**
* @param buffer - Aggregate buffer
* @param args - Parameter specified when SQL calls UDAFs
* @throws UDFException
*/
abstract public void iterate(Writable buffer, Writable[] args) throws UDFException;
/**
* generate final result
* @param buffer
* @return final result of Object UDAF
* @throws UDFException
*/
abstract public Writable terminate(Writable buffer) throws UDFException;
abstract public void merge(Writable buffer, Writable partial) throws UDFException;
}
```

The most important APIs are iterate, merge, and terminate. The primary logic of UDAFs relies on the implementation of these three APIs. In addition, you must implement a custom writable buffer. As an example, the following figure briefly illustrates the implementation logic and computational flow of the avg (average value) MaxCompute UDAF function.



In the preceding figure, the input data is sliced by a certain size (for description of slicing, see MapReduce). The size of each slice is suitable for a worker to complete in an appropriate period of time. You need to manually configure the size of the slices.

The UDAF calculation process is divided into two phases:

- Phase 1: Each Worker counts the number of data rows and the sum of the data in each slice. The user can regard the counted number and sum as an intermediate result.
- Phase 2: The Worker summarizes the information gained from the previous phase within each slice. In the final output, r.sum / r.count is the average of all input data.

The following example shows how to calculate an average by using a UDAF:

```
import java.io.DataInput;
import java.io.DataOutput;
import java.io.IOException;
import com.aliyun.odps.io.DoubleWritable;
import com.aliyun.odps.io.Writable;
import com.aliyun.odps.udf.Aggregator;
import com.aliyun.odps.udf.UDFException;
import com.aliyun.odps.udf.annotation.Resolve;
@Resolve({"double->double"})
public class AggrAvg extends Aggregator {
private static class AvgBuffer implements Writable { private double sum = 0;
private long count = 0;
@Override
public void write(DataOutput out) throws IOException { out.writeDouble(sum);
```

```
out.writeLong(count);
}
@Override
public void readFields(DataInput in) throws IOException { sum = in.readDouble();
count = in.readLong();
}
}
private DoubleWritable ret = new DoubleWritable();
@Override
public Writable newBuffer() { return new AvgBuffer();
}
@Override
public void iterate(Writable buffer, Writable[] args) throws UDFException { DoubleWritable arg = (Doub
leWritable) args[0];
AvgBuffer buf = (AvgBuffer) buffer; if (arg ! = null) {
buf.count += 1; buf.sum += arg.get();
}
}
@Override
public Writable terminate(Writable buffer) throws UDFException { AvgBuffer buf = (AvgBuffer) buffer;
if (buf.count == 0) { ret.set(0);
} else {
ret.set(buf.sum / buf.count);
}
return ret;
}
@Override
public void merge(Writable buffer, Writable partial) throws UDFException { AvgBuffer buf = (AvgBuffer
) buffer;
AvgBuffer p = (AvgBuffer) partial; buf.sum += p.sum;
buf.count += p.count;
}
}
```

Notice

- The SQL syntax used by UDAFs is the same as that used by common built-in aggregate functions. For more information, see Aggregate functions.
- The way to run UDTFs is the same as that to run UDFs. For more information, see Run UDFs.

1.6.8.5. UDTFs

1.6.8.5.1. Overview

Java UDTFs must inherit the com.aliyun.odps.udf.UDTF class. This class requires the implementation of four APIs. The following table lists the definitions of these APIs.

API definitions

API	Description
public void setup(ExecutionContext ctx) throws UDFException	The initialization method to call the user-defined initialization behavior before a UDTF processes the input data. SETUP is called once first in each worker.
public void process(Object[] args) throws UDFException	This method is called by the framework. Each SQL record calls PROCESS once. The parameters of PROCESS are the specified UDTF input parameters in the SQL statement. The input parameters are passed in as Object[], and the results are output by the FORWARD function. You need to call FORWARD in the PROCESS function to determine the output data.
public void close() throws UDFException	The termination method of UDTF. This method is called by the framework for only once after the last record is processed.
public void forward(Object ...o) throws UDFException	You can call the FORWARD method to output data. Each time FORWARD is called, it outputs one record. The record corresponds to the column specified by the UDTF AS clause in the SQL statement.

UDTF example:

```
package org.alidata.odps.udtf.examples;
import com.aliyun.odps.udf.UDTF;
import com.aliyun.odps.udf.UDTFCollector;
import com.aliyun.odps.udf.annotation.Resolve;
import com.aliyun.odps.udf.UDFException;
// TODO define input and output types, e.g., "string,string->string,bigint".
@Resolve({"string,bigint->string,bigint"}) public class MyUDTF extends UDTF {
@Override public void process(Object[] args) throws UDFException { String a = (String) args[0];
Long b = (Long) args[1];
for (String t: a.split("\\s+")) { forward(t, b);
}
}
}
```

The preceding example shows how to create a UDTF in MaxCompute. If this UDTF is named user_udtf, you can run the following SQL statement to call this UDTF:

```
select user_udtf(col0, col1) as (c0, c1) from my_table;
```

The values in my_table col0 and col1 are as follows:

```
+------+------+
| col0 | col1 |
+------+------+
| A B  | 1    |
| C D  | 2    |
+------+------+
```

The result of the SELECT statement is as follows:

```
+----+----+
| c0 | c1 |
+----+----+
| A  | 1  |
| B  | 1  |
| C  | 2  |
| D  | 2  |
+----+----+
```

1.6.8.5.2. UDTF description

Common uses of UDTFs in SQL:

```
select user_udtf(col0, col1) as (c0, c1) from my_table;
select user_udtf(col0, col1) as (c0, c1) from (select * from my_table distribute by col1 sort by col1) t;
```

> **Notice**
>
> The following limits apply to the use of UDTF.
>
> - No other expressions are allowed in a SELECT clause.
>
> ```
> select col0, user_udtf(col0, col1) as (c0, c1) from mytable;
> ```
>
> - UDTFs cannot be nested.
>
> ```
> select user_udtf(mp_udtf(col0,col1)) as (c0,c1)from mytable;
> ```

UDTF examples

The user can use a UDTF to read MaxCompute resources. The following are examples of reading MaxCompute resources by using UDTFs:

1. Write UDTF program. The JAR package (udtfexample1.jar) is exported after compilation.

```
package com.aliyun.odps.examples.udf;
import java.io.BufferedReader;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
import java.util.Iterator;
import com.aliyun.odps.udf.ExecutionContext;
import com.aliyun.odps.udf.UDFException;
import com.aliyun.odps.udf.UDTF;
import com.aliyun.odps.udf.annotation.Resolve;
/**
* project: example_project
* table: wc_in2
* partitions: p2=1,p1=2
* columns: colc,colb
*/
@Resolve({ "string,string->string,bigint,string" }) public class UDTFResource extends UDTF { Execu
tionContext ctx;
long fileResourceLineCount;
long tableResource1RecordCount;
long tableResource2RecordCount;
@Override
public void setup(ExecutionContext ctx) throws UDFException { this.ctx = ctx;
```

```
try {
InputStream in = ctx.readResourceFileAsStream("file_resource.txt");
BufferedReader br = new BufferedReader(new InputStreamReader(in));
String line;
fileResourceLineCount = 0;
while ((line = br.readLine()) ! = null) { fileResourceLineCount++;
}
br.close();
Iterator<Object[]> iterator = ctx.readResourceTable("table_resource1").iterator();
tableResource1RecordCount = 0;
while (iterator.hasNext()) { tableResource1RecordCount++; iterator.next();
}
iterator = ctx.readResourceTable("table_resource2").iterator();
tableResource2RecordCount = 0;
while (iterator.hasNext()) { tableResource2RecordCount++;
iterator.next();
}
} catch (IOException e) { throw new UDFException(e);
}
}
@Override
public void process(Object[] args) throws UDFException { String a = (String) args[0];
long b = args[1] == null ? 0 : ((String) args[1]).length();
forward(a, b, "fileResourceLineCount=" + fileResourceLineCount + "|tableResource1RecordCount="
+ tableResource1RecordCount + "|tableResource2RecordCount=" + tableResource2RecordCount);
}
}
```

2. Add resources to MaxCompute.

```
Add file file_resource.txt;
Add jar udtfexample1.jar;
Add table table_resource1 as table_resource1;
Add table table_resource2 as table_resource2;
```

3. Create UDTF function (mp_udtf) in MaxCompute.

```
create function mp_udtf as com.aliyun.odps.examples.udf.UDTFResource using 'udtfexample1.jar,
file_resource.txt, table_resource1, table_resource2';
```

4. Create resource tables 'table_resource1' and 'table_resource2' in MaxCompute, and insert the corresponding data.
5. Run this UDTF.

```
select mp_udtf("10","20") as (a, b, fileResourceLineCount) from table_resource1;
-- Command output:
+-------+------------+-------+
| a | b     | fileResourceLineCount |
+-------+------------+-------+
| 10 | 2 | fileResourceLineCount=3|tableResource1RecordCount=0|tableResource2RecordCount=0 |
| 10    | 2         | fileResourceLineCount=3|tableResource1RecordCount=0|tableResource2RecordCou
nt=0 |
+-------+------------+-------+
```

Note You can also use the same method to obtain resources. For more information, see MapReduce examples.

UDTF examples — Complex data types

The code in the following example defines a UDF with three overloads. The first overload uses array as the parameter; the second uses map as the parameter; and the third uses struct as the parameter. The third overload uses a struct type as the parameter or returned value, the UDF class must be supplemented with a @Resolve annotation to specify the specific type of struct.

```
@Resolve("struct<a:bigint>,string->string")
public class UdfArray extends UDF {
  public String evaluate(List<String> vals, Long len) {
    return vals.get(len.intValue());
  }
  public String evaluate(Map<String,String> map, String key) {
    return map.get(key);
  }
  public String evaluate(Struct struct, String key) {
    return struct.getFieldValue("a") + key;
  }
}
```

You can import a complex data type in the UDF:

```
create function my_index as 'UdfArray' using 'myjar.jar';
select id, my_index(array('red', 'yellow', 'green'), colorOrdinal) as color_name from colors;
```

1.6.8.6. Python UDFs

1.6.8.6.1. Restricted environment

MaxCompute UDF uses Python V2.7. It executes user codes in a sandbox. The following operations are restricted in the sandbox:

- Read and write local files.
- Start subprocesses.
- Start threads.
- Conduct socket communication.
- Call other systems.

Due to these restrictions, user-uploaded code must all be implemented by Python, as C extension modules are disabled.

In addition, not all modules in the Python standard library are available for use. Modules that involve the preceding features are disabled. Description of available modules in the standard library:

1. All modules implemented purely by Python are available.
2. The following C extension modules are available for use.
   - array
   - audioop
   - binascii
   - _bisect
   - cmath
   - _codecs_cn
   - _codecs_hk
   - _codecs_iso2022
   - _codecs_jp
   - _codecs_kr
   - _codecs_tw
   - _collections
   - cStringIO
   - datetime
   - _functools
   - future_builtins
   - _hashlib
   - _heapq
   - itertools
   - _json
   - _locale
   - _lsprof
   - math
   - _md5
   - _multibytecodec

- operator
- _random
- _sha256
- _sha512
- _sha
- _struct
- strop
- time
- unicodedata
- _weakref
- cPickle

3. Some modules have limited functionality. For example, the sandbox limits the size that user codes can write to the standard output and standard error output. `sys.stdout and sys.stderr` can write up to 20 KB. Any remaining characters are ignored.

1.6.8.6.2. Third-party libraries

Common third-party libraries are installed in the operating environment to supplement the standard library. The supported third-party libraries include NumPy.

> **Warning** The use of third-party libraries is also subject to restrictions. For example, local or remote I/O operations are prohibited. Therefore, the related APIs in the third-party libraries are disabled.

1.6.8.6.3. Types of parameters and returned values

You can run the following command to specify the types of parameters and returned values:

```
@odps.udf.annotate(signature)
```

Python UDFs support the following MaxCompute SQL data types: bigint, string, double, boolean, and datetime. Before you run a SQL statement, you must specify the parameter types and returned value types of all functions. Python is a dynamically-typed language. You need to add decorators to the UDF class to specify the function signature.

The function signature is specified by a string. The syntax is as follows:

```
arg_type_list '->' type_list
arg_type_list: type_list | '*' | ''
type_list: [type_list ','] type
type: 'bigint' | 'string' | 'double' | 'boolean' | 'datetime'
```

Note

- The part to the left of the arrow indicates the type of parameter. The part to the right of the arrow indicates the type of returned value.
- The returned value of a UDTF can contain multiple columns. The returned value of a UDF or UDAF can contain only one column.
- * represents a variable argument. If a variable argument is specified, the UDF, UDTF, or UDAF can match any type of parameter.

Examples of valid signature:

```
'bigint,double->string'
-- The parameter is of the bigint or double type, and the returned value is of the string type.
'bigint,boolean->string,datetime'
-- The UDTF parameter is of the bigint or boolean type, and the returned value is of the string or datet
ime type.
'*->string'
-- Specify a variable argument: The input parameter can be of any type, and the returned value is of t
he string type.
'->double'
-- The parameter is NULL and the returned value is of the double type.
```

If an invalid signature is found during query parsing, an error is returned and the execution is banned. During execution, the UDF parameter with the type specified by the function signature is transferred to the user. The user returned value must be of the type specified by the function signature. Otherwise, an error is returned. The following table shows the mappings between MaxCompute SQL types and Python types.

Mapping

MaxCompute SQL type	Python type
Bigint	int
String	str
Double	float
Boolean	bool
Datetime	int

> **Note**
>
> - A value of the datetime type is passed to user code as the int type. The value is the number of milliseconds that have elapsed since the epoch time. You can use the datetime module in the Python standard library to process the datetime type.
> - NULL corresponds to none in Python.

In addition, the parameter of odps.udf.int(value[, silent=True]) is modified. Parameter silent is added. If silent is true and the value cannot be converted to the int type, none is returned instead of an error.

1.6.8.6.4. UDFs

Implementing a Python UDF is as easy as defining a new-style class and implementing the evaluate method.

Example:

```
from odps.udf import annotate
@annotate("bigint,bigint->bigint")
class myplus (object ):
  def evaluate (self, arg0, arg1 ):
    If none in (arg0, arg1 ):
      return none
    return arg0 + arg1
```

> **Notice** A Python UDF must have its signature specified through annotate.

1.6.8.6.5. UDAFs

Description:

- class odps.udf.BaseUDAF: inherit this class to implement a Python UDAF.
- BaseUDAF.new_buffer(): implement this method and return the median 'buffer' of the aggregate function. Buffer must be mutable object (such as list and dict). The size of the buffer should not increase with the amount of data. The buffer size should not exceed 2 MB after marshal.
- BaseUDAF.iterate(buffer[, args, ...]): This method aggregates args into the median buffer.
- BaseUDAF.merge(buffer, pbuffer): This method aggregates two median buffers; that is, aggregate pbuffer into buffer.
- BaseUDAF.terminate(buffer): This method converts the median 'buffer' into the MaxCompute SQL basic types.

The following example shows how to calculate an average by using a UDAF:

```
#coding:utf-8
from odps.udf import annotate
from odps.udf import BaseUDAF
@annotate('double->double')

class Average(BaseUDAF):
   def new_buffer(self):
      return [0, 0]
   def iterate(self, buffer, number):
      If number is not None:
         buffer[0] += number
         buffer[1] += 1
   def merge(self, buffer, pbuffer):
      buffer [0] + = pbuffer [0]
      buffer [1] + = pbuffer [1]
   def terminate (self, buffer ):
      If buffer [1] = 0:
         return 0.0
      return buffer[0] / buffer[1]
```

1.6.8.6.6. UDTFs

The parameters are described as follows.

Parameters

Parameter	Description
class odps.udf.BaseUDTF	Base class for a Python UDTF. Users inherit this class and implement methods such as PROCESS and CLOSE.
BaseUDTF.init()	Initialization method. To implement this method for an inherited class, you must call the initialization method super(BaseUDTF, self).init() for the base class at the beginning . The INIT method will only be called once during the entire UDTF life cycle; that is, before the first record is processed. When the UDTF needs to save internal states, all states can be initialized in this method.
BaseUDTF.process([args, ...])	The method is called by the MaxCompute SQL framework. The process method is called for each record passed in from SQL. The parameters passed into the process method are the parameters passed into the UDTF in SQL statements.

Parameter	Description
BaseUDTF.forward([args, ...])	The UDTF output method, which is called by user code. Each time FORWARD is called, one record is output. The parameters of FORWARD are the UDTF output parameters specified in SQL statements.
BaseUDTF.close()	The UDTF termination method. This method is called by the MaxCompute SQL framework.This method is called only once, after the last record is processed.

Example:

```
#coding:utf-8
# explode. py
from odps.udf import annotate

from odps.udf import BaseUDTF
@annotate('string -> string')
class Explode(BaseUDTF):
-- Output string as multiple comma-separated records.
  def process(self, arg):
     props = arg.split(',')
      for p in props:
        self.forward(p)
```

Notice A Python UDTF can also specify the parameter type or returned value type without adding 'annotate'. In this case, the function can match any input parameter in SQL. The type of returned value cannot be deduced, but all output parameters will be considered to be of the string type. Therefore, when FORWARD is called, all output values must be converted into values of the string type.

1.6.8.6.7. Reference resources

You can reference file and table resources in Python UDF through the odps.distcache module.

Syntax for referencing file resources:

```
odps.distcache.get_cache_file(resource_name)
```

Note

- Description: returns the content of the specified resource. resource_name is a string that corresponds to the name of an existing resource in the current project. If the resource name is invalid or does not exist, an error is returned.
- Returned value: returns file-like object. After this object is used, the caller must call the CLOSE method to release the resource file that is opened.

Example:

```
from odps.udf import annotate
from odps.distcache import get_cache_file
@annotate('bigint->string')
class DistCacheExample(object):
def __init__(self):
    cache_file = get_cache_file('test_distcache.txt')
    kv = {}
    for line in cache_file:
        line = line.strip()
        if not line:
            continue
        k, v = line.split()
        kv[int(k)] = v
    cache_file.close()
    self.kv = kv
def evaluate(self, arg):
    return self.kv.get(arg)
```

Command syntax:

```
odps.distcache.get_cache_table(resource_name)
```

Note

- Description: returns the content of the specified resource table. resource_name is a string that corresponds to the name of an existing resource table in the current project. If the resource table name is invalid or does not exist, an error is returned.
- Returned value: returns a value of the generator type. The caller traverses the table to obtain the content. Each time the caller traverses the table, a record is obtained in the form of a tuple.

Example:

```
from odps.udf import annotate
from odps.distcache import get_cache_table
@annotate('->string')
class DistCacheTableExample(object):
    def __init__(self):
        self.records = list(get_cache_table('udf_test'))
        self.counter = 0
        self.ln = len(self.records)
    def evaluate(self):
        if self.counter > self.ln - 1:
            return None
        ret = self.records[self.counter]
        self.counter += 1
        return str(ret)
```

1.6.9. UDTs

1.6.9.1. Overview

User-defined types (UDTs) are introduced in MaxCompute 2.0 for the latest version of the SQL engine. UDTs allow you to reference classes or objects of third-party languages in SQL statements to obtain data or call methods.

UDTs are typically applied in the following scenarios:

- **Scenario 1:** MaxCompute does not have built-in functions to complete tasks that can be easily performed using other languages. For example, there are some tasks that can be performed by calling a single built-in Java class. Performing these tasks with user defined functions (UDFs) is complex.
- **Scenario 2:** You need to call a third-party library in SQL statements to implement the corresponding feature. You want to use a feature provided by a third-party library directly in a SQL statement, instead of wrapping the feature inside a UDF.
- **Scenario 3:** SELECT TRANSFORM allows you to include objects and classes in SQL statements to make these SQL statements easier to read and maintain. For some languages, such as Java, the source code can be only executed after it is compiled. You want to reference objects and classes of these languages in SQL statements.

> **Notice**
>
> - UDTs only support Java.
> - All operators use the semantics of MaxCompute SQL.
> - UDTs cannot be used as shuffle keys in the JOIN, GROUP BY, DISTRIBUTE BY, SORT BY, ORDER BY, and CLUSTER BY clauses.
> - DDL statements do not support UDTs. You cannot create tables that contain UDT objects. The final output cannot be UDT types.

1.6.9.2. Feature summary

UDTs allow you to reference classes or objects of third-party languages in SQL statements to obtain data or call methods.

The UDTs supported in MaxCompute are very different from those in other SQL engines.

UDTs supported by other SQL engines are similar to the struct composite type in MaxCompute. UDTs supported by MaxCompute are similar to the CREATE TYPE statement. A UDT contains both fields and methods. Additionally, MaxCompute does not require that you use Data Definition Language (DDL) statements to define type mappings. MaxCompute allows you to reference types directly in SQL statements.

Example:

```
set odps.sql.type.system.odps2=true;
SELECT Integer.MAX_VALUE;
-- A similar output is displayed:
+------------+
| max_value |
+------------+
| 2147483647 |
+------------+
```

The expression in the preceding SELECT statement is similar to a Java expression and executed in the same manner as it would in Java. The expression specifies a UDT in MaxCompute.

You can use UDFs to implement all features provided by UDTs, but with some complexity. If you use a UDF to implement the same feature, you need to follow these steps:

1. Define a UDF class.

   ```
   package com.aliyun.odps.test;
   public class IntegerMaxValue extends com.aliyun.odps.udf.UDF {
   public Integer evaluate() {
    return Integer.MAX_VALUE;
   }
   }
   ```

2. Compile the UDF as a JAR package. Upload the JAR package and create a function.

   ```
   add jar odps-test.jar;
   create function integer_max_value as 'com.aliyun.odps.test.IntegerMaxValue' using 'odps-test.jar'
   ;
   ```

3. Call the function in a SQL statement.

   ```
   select integer_max_value();
   ```

A UDT simplifies this procedure. By using UDTs, you can use features provided by other

languages in SQL statements.

1.6.9.3. Feature description

The example described in the Feature overview topic demonstrates how to use user-defined types (UDTs) to access the static fields of Java classes. UDTs can be used to implement a number of functions. The following example shows a UDT execution procedure and its features.

```
-- Sample data
@table1 := select * from values ('10000000000000000000') as t(x);
@table2 := select * from values (100L) as t(y);
-- Code logic
@a := select new java.math.BigInteger(x) x from @table1;        -- Create an object by using the new m
ethod.
@b := select java.math.BigInteger.valueOf(y) y from @table2;     -- Call a static method.
select /*+mapjoin(b)*/ x.add(y).toString() from @a a join @b b;   -- Call an instance method.
```

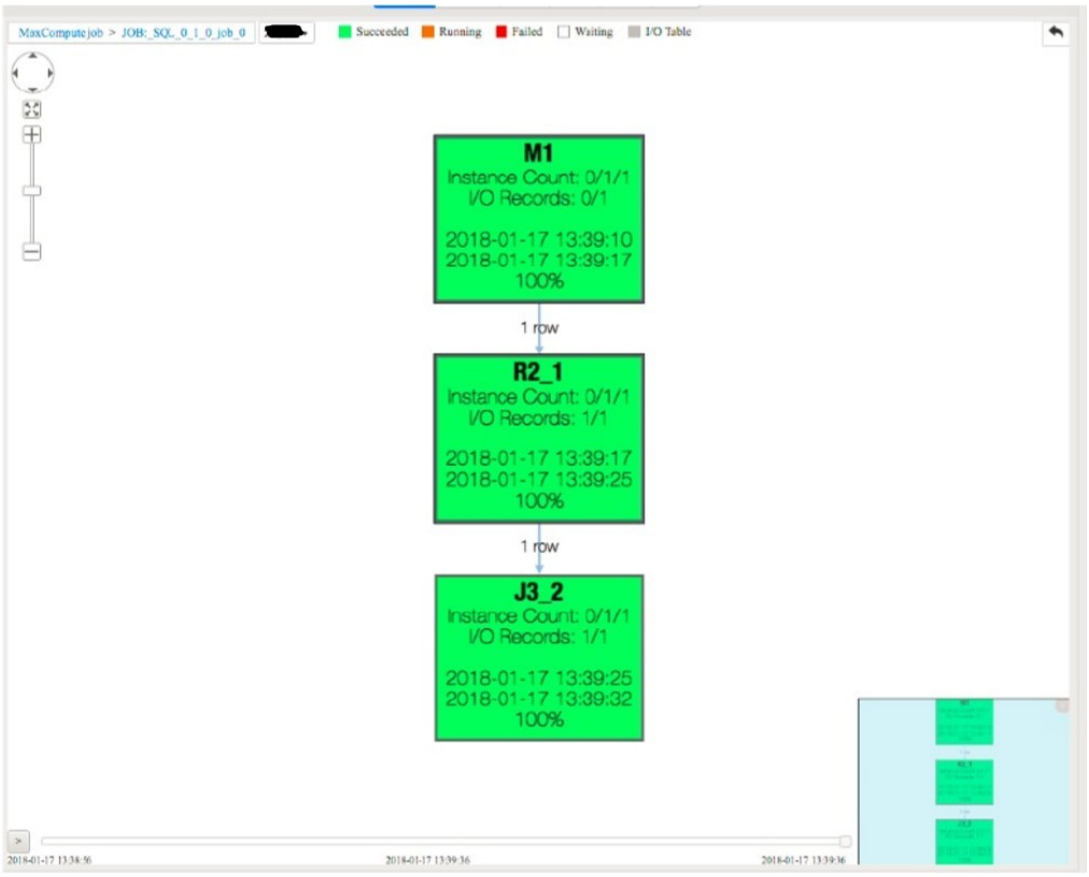
The following result is returned:

```
100000000000000000100
```

> **Note** This example also shows how to use subqueries with UDT columns. User-defined functions (UDFs) cannot be used in such subqueries. Variable a in the x column is of the java.math.BigInteger class, not a built-in class. You can pass UDT data to another operator and then call the required method. You can also use UDT data in data shuffling.

UDT execution

Example



The preceding figure shows the three stages of a UDT: M1, R2, and J3. Only the *new java.math.BigInteger(x)* method is called at the M1 stage. The *java.math.BigInteger.valueOf(y)* and *x.add(y).toString()* methods are called at the J3 stage.

If a JOIN clause is used in MapReduce, data must be reshuffled. As a result, data is processed at multiple stages. Data is processed at different stages or even by different processes or physical machines. The UDT encapsulates these stages and functions as a JVM.

Description

- UDTs support only Java.
- UDTs also allow you to upload JAR packages and directly reference these packages. Some flags are provided for UDTs.

- **set odps.sql.session.resources**: specifies the resource that you want to reference. Separate multiple resources with commas (,). For example, you can set this flag to `foo.sh,bar.txt`. Example:

```
set odps.sql.type.system.odps2=true;
set odps.sql.session.resources=odps-test.jar; -- Specify the JAR package that you want to refere
nce. Before you reference the JAR package, upload the package to your project.
select new com.aliyun.odps.test.IntegerMaxValue().evaluate();
```

> **Notice** This flag is the same as the flag that is used to specify resources in the SELECT TRANSFORM statement. Therefore, this flag affects JAR package uploading in UDTs and resource settings in the SELECT TRANSFORM statement.

- **odps.sql.session.java.imports**: specifies the default Java package. Separate multiple Java packages with commas (,). This flag is similar to the IMPORT statement in Java. You can specify a classpath, such as `java.math.BigInteger`, or use `*`. `Static import` is not supported. Example:

```
set odps.sql.type.system.odps2=true;
set odps.sql.session.resources=odps-test.jar;
set odps.sql.session.java.imports=com.aliyun.odps.test. *;  -- Specify the default Java package.
select new IntegerMaxValue().evaluate();
```

- UDTs allow you to:
  - Create objects by using the new method.
  - Create arrays by using the new method, including ArrayList initialization. Example: `new Integer[] { 1, 2, 3 }`.
  - Call methods, including static methods. You can create objects in the factory method pattern.
  - Access fields, including static fields.

> **Notice**
> - Identifiers in UDTs contain package names, class names, method names, and field names. All identifiers are case-sensitive.
> - UDTs support SQL type conversions, such as cast(1 as java.lang.Object). UDTs do not support Java type conversions, such as (Object)1.
> - Anonymous classes and lambda expressions are not supported.
> - Functions that do not return values cannot be called in UDTs.
>
> > **Note** UDTs are used in expressions. Functions that do not return values cannot be called in expressions.

- All SDK for Java classes can be referenced by UDTs. The JDK runtime environment is JDK 1.8. Later versions may not be supported.

- All operators use the semantic of MaxCompute SQL. The result of `String.valueOf(1) + String.valueOf(2)` is 3. The two strings are implicitly converted to DOUBLE-type values and summed. If you use Java string concatenation to combine the strings, the result is 12.

  You may be confused about the role of the `=` operator. The `=` operator in SQL statements is used as a comparison operator. It is used to compare one expression with another expression. You must call the equals method in Java to compare whether two objects are equivalent. The = operator cannot be used to verify the equivalence of two objects.

- Java data types are mapped to built-in data types. The mapping can be applied to UDTs.
  - You can directly call the method of the Java type to which the built-in type is mapped. Example: `'123'.length()` , `1L.hashCode()` .
  - UDTs can be used in built-in functions and UDFs. For example, in `chr(Long.valueOf('100'))` , `Long.valueOf` returns a value of the `java.lang.Long` type. The CHR built-in function supports the built-in BIGINT type.
  - The data of a Java primitive type is automatically converted to the boxing type and the preceding two rules are applied.

  > **Notice** For some new built-in data types, you must use `set odps.sql.type.system.odps2=true;` to declare these types. Otherwise, an error occurs.

- UDTs completely support Java generics. For example, based on the parameter type, the compiler can determine that the value returned by `java.util.Arrays.asList(new java.math.BigInteger('1'))` is `java.util.List<java.math.BigInteger>` .

  > **Notice** You must specify the type parameter in a constructor function or use java.lang.Object. This is the same as Java. For example, the result of `new java.util.ArrayList(java.util.Arrays.asList('1', '2'))` is of the `java.util.ArrayList<Object>` type. The result of `new java.util.ArrayList<String>(java.util.Arrays.asList('1', '2'))` is of the `java.util.ArrayList<String>` type.

- UDTs do not have a clear definition of **object equality**. This is caused by data reshuffling. The JOIN example shows that objects may be transmitted between different processes or physical machines. During transmission, an object may be referenced as two different objects. For example, an object may be shuffled to two machines and then reshuffled.

  Therefore, when you use UDTs, you must use the equals method instead of the = operator to equate two objects.

  > **Note** Objects in the same row or column are correlated in some way. However, a correlation between objects in different rows or columns cannot be ensured.

- UDTs cannot be used as shuffle keys in clauses, such as JOIN, GROUP BY, DISTRIBUTE BY, SORT BY, ORDER BY, or CLUSTER BY.

UDTs can be used at the stages in expressions, but cannot be used as outputs. For example, you cannot call the `group by new java.math.BigInteger('123')` method. However, you can call the `group by new java.math.BigInteger('123').hashCode()` method. This is because the value returned by hashCode is an int.class type, which can be used as the built-in INT type.

- The following type conversion rules are extended in UDTs:
  - UDT objects can be implicitly converted to the objects of their base classes.
  - UDT objects can be forcibly converted to the objects of their base classes or subclasses.
  - The data type conversion for two objects without inheritance follows native conversion rules.

    > **Notice** The conversion may cause data changes. For example, data of the java.lang.Long type can be forcibly converted to the java.lang.Integer type. This conversion uses the rules that are used to convert the built-in BIGINT type to the INT type. This process may cause data changes or even data precision loss.

- UDT objects cannot be saved or added to tables. DDL statements do not support UDTs. You cannot create tables that contain UDT objects unless the data type is implicitly converted to one of the built-in types. In addition, the output cannot be a UDT. However, you can call the toString() method to convert the data type to the java.lang.String type because the toString() method supports all Java classes. You can use this method to check UDT data during debugging.

  You can also add the `set odps.sql.udt.display.tostring=true;` flag to enable MaxCompute to convert all output UDT data to strings by calling the `java.util.Objects.toString(...)` method for debugging.

  > **Note** This flag is typically used for debugging because it can be applied only to PRINT statements. It cannot be applied to INSERT statements.

  BINARY is a built-in type and supports automatic serialization. You can save the byte[] arrays. The saved byte[] arrays can be deserialized to the BINARY type.

  Some classes may have their own serialization and deserialization methods, such as protobuffer. To save UDTs, you must call serialization and deserialization methods to convert the data type to BINARY.

- You can use UDTs to achieve the feature provided by the SCALAR function. You can use the COLLECT_LIST and EXPLODE built-in functions with UDTs to achieve the features provided by aggregate and table-valued functions.
- UDTs support resource access. You can call the `com.aliyun.odps.udf.impl.UDTExecutionContext.get()` static method to obtain the ExecutionContext object. Then, use the object to access the current execution context and then to access resources, such as files and tables.

1.6.9.4. More examples

1.6.9.4.1. Example of using Java arrays

Example:

```
set odps.sql.type.system.odps2=true;
set odps.sql.udt.display.tostring=true;
select
   new Integer[10],    -- Create an array that contains 10 elements.
   new Integer[] {c1, c2, c3},  -- Create an array that contains three elements by initializing an ArrayList.
   new Integer[][] { new Integer[] {c1, c2}, new Integer[] {c3, c4} },  -- Create a multidimensional array.
   new Integer[] {c1, c2, c3} [2], -- Access the elements in the array using indexes.
   java.util.Arrays.asList(c1, c2, c3);    -- This is another way to create a built-in array. It creates a List<I
nteger>, which can be used as an array<int>.
from values (1,2,3,4) as t(c1, c2, c3, c4);
```

1.6.9.4.2. Example of using JSON

The runtime of UDT carries a GSON dependency (version 2.2.4), which can be directly used in GSON.

Example:

```
set odps.sql.type.system.odps2=true;
set odps.sql.session.java.imports=java.util.*,java,com.google.gson. *; -- To import multiple packages, s
eparate the packages with commas (,).
@a := select new Gson() gson;   -- Create a GSON object.
select
gson.toJson(new ArrayList<Integer>(Arrays.asList(1, 2, 3))), -- Convert an object to a JSON string.
cast(gson.fromJson('["a","b","c"]', List.class) as List<String>) --Deserialize the JSON string. GSON also f
orcibly converts the deserialized result from List<Object> type to List<String> type.
from @a;
```

Compared with built-in function **GET_JSON_OBJECT**, this method is simple and improves efficiency by extracting content from the JSON string and deserializing the string to a supported data type.

In addition to GSON dependencies, MaxCompute runtime also carries other dependencies, including commons-logging (1.1.1), commons-lang (2.5), commons-io (2.4), and protobuf-java (2.4.1).

1.6.9.4.3. Example of using composite types

Built-in types of array and map are mapped to java.util.List and java.util.Map, respectively.

- Java objects in classes calling the java.util.List or java.util.Map API can be used in MaxCompute SQL composite type data processing.
- Array and map type data in MaxCompute can directly call the java.util.List or java.util.Map API.

Example:

```
set odps.sql.type.system.odps2=true;
set odps.sql.session.java.imports=java.util.*;
select
   size(new ArrayList<Integer>()),       -- Call built-in function size to obtain the size of the ArrayList.
   array(1,2,3).size(),                  -- Call the List method for built-in type array.
   sort_array(new ArrayList<Integer>()),  -- Sort the data in the ArrayList.
   al[1],                                -- The Java List method does not support indexing. However, the array type s
upports indexing.
   Objects.toString(a),       -- With this method, you can convert array type to string type data.
   array(1,2,3).subList(1, 2)            -- Get a sublist.
from (select new ArrayList<Integer>(array(1,2,3)) as al, array(1,2,3) as a) t;
```

1.6.9.4.4. Example of aggregation

To achieve aggregation with UDTs, you must first use built-in function COLLECT_SET or COLLECT_LIST to convert the data to the List type and then call the UDT methods to aggregate the data.

The following example shows how to obtain the median from BigInteger data. You cannot directly call the built-in MEDIAN function because the data is java.math.BigInteger type.

```
set odps.sql.session.java.imports=java.math.*;
@test_data := select * from values (1),(2),(3),(5) as t(value);
@a := select collect_list(new BigInteger(value)) values from @test_data;  -- Aggregate the data to a li
st.
@b := select sort_array(values) as values, values.size() cnt from @a;  -- To obtain the median, first sor
t the data.
@c := select if(cnt % 2 == 1, new BigDecimal(values[cnt div 2]), new BigDecimal(values[cnt div 2 - 1].add
(values[cnt div 2])).divide(new BigDecimal(2))) med from @b;
-- Final output.
select med.toString() from @c;
```

You cannot use the COLLECT_LIST function to implement partial aggregation because it aggregates all data. It is more efficient to use the built-in aggregator or UDAF object. We recommend that you use the built-in aggregator. Aggregating all data in a group increases the risk of data skew.

If the logic of the UDAF object is to aggregate all data in a similar manner to built-in function WM_CONCAT, using the COLLECT_LIST function is more efficient than using the UDAF object.

1.6.9.4.5. Example of using table-valued functions

Table-valued functions allow you to input and output multiple rows and columns. To input or output multiple rows and columns, follow these steps:

1. For more information about how to input multiple rows or columns, see the example of using

aggregate functions.

2. To output multiple rows, you can use a UDT to define a Collection type (List or Map), and then call the EXPLODE function to split the collection into multiple rows.
3. A UDT can contain multiple fields. You can retrieve the data from the fields by calling different getter methods. The data is then output in multiple rows.

The following example shows how to split a JSON string and output the result as multiple columns:

```
@a := select '[{"a":"1","b":"2"},{"a":"1","b":"2"}]' str; -- Sample data
@b := select new com.google.gson.Gson().fromJson(str, java.util.List.class) l from @a; -- Deserialize th
e JSON string.
@c := select cast(e as java.util.Map<Object,Object>) m from @b lateral view explode(l) t as e;  -- Call t
he EXPLODE function to split the string.
@d := select m.get('a') as a, m.get('b') as b from @c; -- Output the splitting result in multiple columns.
select a.toString() a, b.toString() b from @d; -- The final output. Columns a and b in variable d are of t
he Object type.
```

1.6.9.5. Feature advantages

UDT has the following features:

- Easy to use. You do not need to define any functions.
- To improve the flexibility of SQL, all JDK supported features can be used directly.
- You can directly reference objects and classes of other languages in SQL statements.
- You can directly reference the libraries of other language and reuse code that you have written in other languages.
- You can create object-oriented features.

1.6.9.6. Performance advantages

UDTs and UDFs use similar execution procedures and provide similar performance. However, UDTs have higher performance in certain scenarios where the compute engine has been greatly improved.

- Deserialization is not required for objects in only one process. Deserialization is required only when the objects are transmitted among processes. This means that UDT do not incur any serialization or deserialization overhead when no data reshuffling is performed, such as calling the join or aggregator function.
- UDTs suffer no performance loss from reflection because the runtime of UDTs is based on Codegen, rather than based on reflection.
- Multiple UDTs can be wrapped into a single function call and executed together. In the following example, a single UDT is being called. UDTs focus on small-granularity data processing. This does not incur additional overhead for the API where multiple functions are called.

  ```
  values[x].add(values[y]).divide(java.math.BigInteger.valueOf(2))
  ```

1.6.9.7. Security advantages

UDTs are restricted in the Java sandbox model similar to UDFs. To perform restricted operations, you must enable sandbox isolation or apply to join the sandbox whitelist.

1.6.10. UDJ

1.6.10.1. Overview

MaxCompute provides multiple JOIN methods natively, including INNER JOIN, RIGHT JOIN, OUTER JOIN, LEFT JOIN, FULL JOIN, SEMIJOIN, and ANTISEMIJOIN methods. You can use these native JOIN methods in most scenarios. However, these methods cannot handle multiple tables.

In most cases, you can build your code framework using UDFs. However, the current UDF, UDTF, and UDAF frameworks only can handle one table at a time. To perform user-defined operations for multiple tables, you have to use native JOIN methods, UDFs, UDTFs, and complex SQL statements. In certain cases when you handle multiple tables, you must use a custom MapReduce framework instead of SQL to complete the required task.

In any situation, these operations require technological expertise and may cause the following problems:

- Calling multiple JOIN methods in SQL statements can lead to computational black box that is complex and difficult to execute with minimal overheads.
- Using MapReduce even make optimal execution of code becomes impossible. Most of the MapReduce code is written in Java. The execution of the MapReduce code is less efficient than the execution of MaxCompute code generated by the LLVM code generator at an optimized native runtime.

With the addition of the MaxCompute 2.0 compute engine, the user defined join (UDJ) API has been added to the user defined function (UDF) framework. This API allows you to handle multiple tables and simplifies operations performed in the underlying MapReduce distributed system.

1.6.10.2. UDJ usage

1.6.10.2.1. Examples

The following example describes how to use UDJ in MaxCompute.

This example uses the payment table and the user_client_log table.

- The payment (user_id string,time datetime,pay_info string) table stores the payment information of a user. Each payment record includes the user ID, payment time, and the payment details.
- The user_client_log (user_id string,time datetime,content string) table stores user client records, including the user ID, operation time, and operation.

Requirements: For each record in the user_client_log table, locate the payment record that has the time closest to the operation time, and join and output the content of both records.

To complete this task by using standard join methods, you would need to join the two tables based on their common user_id fields, and then locate the payment record and operation that most closely match each other's time. The SQL statement may be written as follows:

```
SELECT
  p.user_id,
  p.time,
  merge(p.pay_info, u.content)
FROM
  payment p RIGHT OUTER JOIN user_client_log u
ON p.user_id = u.user_id and abs(p.time - u.time) = min(abs(p.time - u.time))
```

However, when you join two rows in the tables, you must calculate the minimum difference between the p.time and u.time under the same user_id, and the aggregate function cannot be called in the join condition. Because of this, this task cannot be completed by calling the standard JOIN method.

Can we use UDJ to solve this problem? Yes. The following topics describe how to use UDJ to satisfy the preceding requirements.

1.6.10.2.2. Use Java to write the UDJ code

Prerequisites

UDJ is a new feature, so a new SDK is required.

```
<dependency>
  <groupId>com.aliyun.odps</groupId>
  <artifactId>odps-sdk-udf</artifactId>
  <version>0.30.0</version>
  <scope>provided</scope>
</dependency>
```

The SDK contains a new abstract class UDJ. All UDJ features can be implemented through this class.

Sample code

The following sample code is used for reference only.

```
package com.aliyun.odps.udf.example.udj;
import com.aliyun.odps.Column;
import com.aliyun.odps.OdpsType;
import com.aliyun.odps.Yieldable;
import com.aliyun.odps.data.ArrayRecord;
import com.aliyun.odps.data.Record;
import com.aliyun.odps.udf.DataAttributes;
import com.aliyun.odps.udf.ExecutionContext;
import com.aliyun.odps.udf.UDJ;
import com.aliyun.odps.udf.annotation.Resolve;
```

```
import com.aliyun.odps.udf.annotation.Resolve;
import java.util.ArrayList;
import java.util.Iterator;
/** For each record of right table, find the nearest record of left table and
 * merge two records.
 */
@Resolve("->string,bigint,string")
public class PayUserLogMergeJoin extends UDJ {
  private Record outputRecord;
  /** Will be called prior to the data processing phase. User could implement
   * this method to do initialization work.
   */
  @Override
  public void setup(ExecutionContext executionContext, DataAttributes dataAttributes) {
    //
    outputRecord = new ArrayRecord(new Column[]{
      new Column("user_id", OdpsType.STRING),
      new Column("time", OdpsType.BIGINT),
      new Column("content", OdpsType.STRING)
    });
  }
  /** Override this method to implement join logic.
   * @param key Current join key
   * @param left Group of records of left table corresponding to the current key
   * @param right Group of records of right table corresponding to the current key
   * @param output Used to output the result of UDJ
   */
  @Override
  public void join(Record key, Iterator<Record> left, Iterator<Record> right, Yieldable<Record> output)
{
    outputRecord.setString(0, key.getString(0));
    if (! right.hasNext()) {
      // Empty right group, do nothing.
      return;
    } else if (! left.hasNext()) {
      // Empty left group. Output all records of right group without merge.
      while (right.hasNext()) {
        Record logRecord = right.next();
        outputRecord.setBigint(1, logRecord.getDatetime(0).getTime());
        outputRecord.setString(2, logRecord.getString(1));
        output.yield(outputRecord);
```

```
    }
    return;
  }
  ArrayList<Record> pays = new ArrayList<>();
  // The left group of records will be iterated from the start to the end
  // for each record of right group, but the iterator cannot be reset.
  // So we save every records of left to an ArrayList.
  left.forEachRemaining(pay -> pays.add(pay.clone()));
  while (right.hasNext()) {
    Record log = right.next();
    long logTime = log.getDatetime(0).getTime();
    long minDelta = Long.MAX_VALUE;
    Record nearestPay = null;
    // Iterate through all records of left, and find the pay record that has
    // the minimal difference in terms of time.
    for (Record pay: pays) {
      long delta = Math.abs(logTime - pay.getDatetime(0).getTime());
      if (delta < minDelta) {
        minDelta = delta;
        nearestPay = pay;
      }
    }
    // Merge the log record with nearest pay record and output to the result.
    outputRecord.setBigint(1, log.getDatetime(0).getTime());
    outputRecord.setString(2, mergeLog(nearestPay.getString(1), log.getString(1)));
    output.yield(outputRecord);
  }
 }
 String mergeLog(String payInfo, String logContent) {
  return logContent + ", pay " + payInfo;
 }
 @Override
 public void close() {
 }
}
```

Notice In this example, the NULL values in the entries are not processed. To simplify the data processing procedure, assume that no NULL values are contained in the tables.

Each time you call this JOIN method of UDJ, records that match the same key in the two tables are returned. Therefore, UDJ searches all records in the payment table to locate the record with the time closest to each record in the user_client_log table.

Assume that the user only has a few payment records. In this case, you can load the data in the payment table to the memory. Typically, there is sufficient memory to store the user payment data generated each day. What if this assumption is invalid? How can we resolve this issue? This issue will be discussed in **Pre-sorting**.

1.6.10.2.3. Create a UDJ function in MaxCompute

After you have written the UDJ code in Java, upload the code to MaxCompute SQL as a plug-in. You must have registered the code with MaxCompute first.

Assume that the code is compressed into JAR package odps-udj-example.jar. Use the Add JAR command to upload the JAR package to MaxCompute.

```
add jar odps-udj-example.jar;
```

Execute the CREATE FUNCTION statement to create UDJ function *pay_user_log_merge_join*, using JAR package odps-udj-example.jar and Java class *com.aliyun.odps.udf.example.udj.PayUserLogMergeJoin*.

```
create function pay_user_log_merge_join
 as 'com.aliyun.odps.udf.example.udj.PayUserLogMergeJoin'
 using 'odps-udj-example.jar';
```

1.6.10.2.4. Use UDJ in MaxCompute SQL

After you have registered UDJ in the database, UDJ can be used in MaxCompute SQL.

1. Create a sample source table.

   ```
   create table payment (user_id string,time datetime,pay_info string);
   create table user_client_log(user_id string,time datetime,content string);
   ```

2. Create sample data.

   > **Notice** The data in this example is only used for reference. You may need to create different data in actual operations.

```
 -- Create data in the payment table
INSERT OVERWRITE TABLE payment VALUES
('1335656', datetime '2018-02-13 19:54:00', 'PEqMSHyktn'),
('2656199', datetime '2018-02-13 12:21:00', 'pYvotuLDIT'),
('2656199', datetime '2018-02-13 20:50:00', 'PEqMSHyktn'),
('2656199', datetime '2018-02-13 22:30:00', 'gZhvdySOQb'),
('8881237', datetime '2018-02-13 08:30:00', 'pYvotuLDIT'),
('8881237', datetime '2018-02-13 10:32:00', 'KBuMzRpsko'),
('9890100', datetime '2018-02-13 16:01:00', 'gZhvdySOQb'),
('9890100', datetime '2018-02-13 16:26:00', 'MxONdLckwa')
;
-- Create data in the user_client_log table
INSERT OVERWRITE TABLE user_client_log VALUES
('1000235', datetime '2018-02-13 00:25:36', 'click FNOXAibRjkIaQPB'),
('1000235', datetime '2018-02-13 22:30:00', 'click GczrYaxvkiPultZ'),
('1335656', datetime '2018-02-13 18:30:00', 'click MxONdLckpAFUHRS'),
('1335656', datetime '2018-02-13 19:54:00', 'click mKRPGOciFDyzTgM'),
('2656199', datetime '2018-02-13 08:30:00', 'click CZwafHsbJOPNitL'),
('2656199', datetime '2018-02-13 09:14:00', 'click nYHJqIpjevkKToy'),
('2656199', datetime '2018-02-13 21:05:00', 'click gbAfPCwrGXvEjpI'),
('2656199', datetime '2018-02-13 21:08:00', 'click dhpZyWMuGjBOTJP'),
('2656199', datetime '2018-02-13 22:29:00', 'click bAsxnUdDhvfqaBr'),
('2656199', datetime '2018-02-13 22:30:00', 'click XIhZdLaOocQRmrY'),
('4356142', datetime '2018-02-13 18:30:00', 'click DYqShmGbIoWKier'),
('4356142', datetime '2018-02-13 19:54:00', 'click DYqShmGbIoWKier'),
('8881237', datetime '2018-02-13 00:30:00', 'click MpkvilgWSmhUuPn'),
('8881237', datetime '2018-02-13 06:14:00', 'click OkTYNUHMqZzlDyL'),
('8881237', datetime '2018-02-13 10:30:00', 'click OkTYNUHMqZzlDyL'),
('9890100', datetime '2018-02-13 16:01:00', 'click vOTQfBFjcgXisYU'),
('9890100', datetime '2018-02-13 16:20:00', 'click WxaLgOCcVEvhiFJ')
;
```

3. In MaxCompute SQL, use the UDJ function you have created:

```
SELECT r.user_id, from_unixtime(time/1000) as time, content FROM (
SELECT user_id, time as time, pay_info FROM payment
) p JOIN (
SELECT user_id, time as time, content FROM user_client_log
) u
ON p.user_id = u.user_id
USING pay_user_log_merge_join(p.time, p.pay_info, u.time, u.content)
r
AS (user_id, time, content)
;
```

> **Note** The syntax of UDJ is similar to that of the standard JOIN statement. The only difference is that the USING clause is added to UDJ.

Description:

- **pay_user_log_merge_join** is the name of the UDJ function in SQL.
- **(p.time, p.pay_info, u.time, u.content)** are the columns used in these two tables.
- **r** is the alias of the result returned by the UDJ function. You can reference this alias in other SQL statements.
- **(user_id, time, content)** are the columns returned by the UDJ function.

4. Execute this SQL statement. A similar output is displayed:

```
+---------+------------+---------+
| user_id | time       | content |
+---------+------------+---------+
| 1000235 | 2018-02-13 00:25:36 | click FNOXAibRjkIaQPB |
| 1000235 | 2018-02-13 22:30:00 | click GczrYaxvkiPultZ |
| 1335656 | 2018-02-13 18:30:00 | click MxONdLckpAFUHRS, pay PEqMSHyktn |
| 1335656 | 2018-02-13 19:54:00 | click mKRPGOciFDyzTgM, pay PEqMSHyktn |
| 2656199 | 2018-02-13 08:30:00 | click CZwafHsbJOPNitL, pay pYvotuLDIT |
| 2656199 | 2018-02-13 09:14:00 | click nYHJqIpjevkKToy, pay pYvotuLDIT |
| 2656199 | 2018-02-13 21:05:00 | click gbAfPCwrGXvEjpI, pay PEqMSHyktn |
| 2656199 | 2018-02-13 21:08:00 | click dhpZyWMuGjBOTJP, pay PEqMSHyktn |
| 2656199 | 2018-02-13 22:29:00 | click bAsxnUdDhvfqaBr, pay gZhvdySOQb |
| 2656199 | 2018-02-13 22:30:00 | click XIhZdLaOocQRmrY, pay gZhvdySOQb |
| 4356142 | 2018-02-13 18:30:00 | click DYqShmGbIoWKier |
| 4356142 | 2018-02-13 19:54:00 | click DYqShmGbIoWKier |
| 8881237 | 2018-02-13 00:30:00 | click MpkvilgWSmhUuPn, pay pYvotuLDIT |
| 8881237 | 2018-02-13 06:14:00 | click OkTYNUHMqZzlDyL, pay pYvotuLDIT |
| 8881237 | 2018-02-13 10:30:00 | click OkTYNUHMqZzlDyL, pay KBuMzRpsko |
| 9890100 | 2018-02-13 16:01:00 | click vOTQfBFjcgXisYU, pay gZhvdySOQb |
| 9890100 | 2018-02-13 16:20:00 | click WxaLgOCcVEvhiFJ, pay MxONdLckwa |
+---------+------------+---------+
```

As shown in the preceding code, the task that could not be performed by calling native JOIN methods has been completed by using UDJ.

1.6.10.2.5. Pre-sorting

An iterator is used to search all records in the payment table and locate payment records that match the query. To perform this task, you must load all payment records with the same user_id to an ArrayList. This method can be applied when the number of payment records is small. Due to RAM size limits, you must find another method to load the data if a large number of payment records have been generated.

This topic describes how to address this issue using the SORT BY clause. When the size of the payment data is too large to be stored in the memory, it would be easier to address this issue if all data in the table has already been sorted by time. You then only need to compare the first element in these two lists. UDJ code in Java:

```
@Override
public void join(Record key, Iterator<Record> left, Iterator<Record> right, Yieldable<Record> output) {
  outputRecord.setString(0, key.getString(0));
  if (! right.hasNext()) {
    return;
  } else if (! left.hasNext()) {
    while (right.hasNext()) {
```

```
      Record logRecord = right.next();
      outputRecord.setBigint(1, logRecord.getDatetime(0).getTime());
      outputRecord.setString(2, logRecord.getString(1));
      output.yield(outputRecord);
    }
    return;
  }
  long prevDelta = Long.MAX_VALUE;
  Record logRecord = right.next();
  Record payRecord = left.next();
  Record lastPayRecord = payRecord.clone();
  while (true) {
    long delta = logRecord.getDatetime(0).getTime() - payRecord.getDatetime(0).getTime();
    if (left.hasNext() && delta > 0) {
      // The delta of time between two records is decreasing, we can still
      // explore the left group to try to gain a smaller delta.
      lastPayRecord = payRecord.clone();
      prevDelta = delta;
      payRecord = left.next();
    } else {
      // Hit to the point of minimal delta. Check with the last pay record,
      // output the merge result and prepare to process the next record of
      // right group.
      Record nearestPay = Math.abs(delta) < prevDelta ? payRecord : lastPayRecord;
      outputRecord.setBigint(1, logRecord.getDatetime(0).getTime());
      String mergedString = mergeLog(nearestPay.getString(1), logRecord.getString(1));
      outputRecord.setString(2, mergedString);
      output.yield(outputRecord);
      if (right.hasNext()) {
        logRecord = right.next();
        prevDelta = Math.abs(
          logRecord.getDatetime(0).getTime() - lastPayRecord.getDatetime(0).getTime()
        );
      } else {
        break;
      }
    }
  }
}
```

> **Notice** After you have modified the UDJ code, you must update the corresponding JAR package.

When the created UDJ function is used in MaxCompute SQL, you must modify the command as follows:

```
SELECT r.user_id, from_unixtime(time/1000) as time, content FROM (
 SELECT user_id, time as time, pay_info FROM payment
) p JOIN (
 SELECT user_id, time as time, content FROM user_client_log
) u
ON p.user_id = u.user_id
USING pay_user_log_merge_join(p.time, p.pay_info, u.time, u.content)
r
AS (user_id, time, content)
SORT BY p.time, u.time
;
```

In the native SQL language, you must make a few modifications, add a SORT BY clause to the end of the UDJ clause, and then sort the data in both tables by time.

The execution result is the same as the result before the code is modified.

This method uses the SORT BY clause to pre-sort the data. To achieve the same result, only a maximum of three records need to be cached.

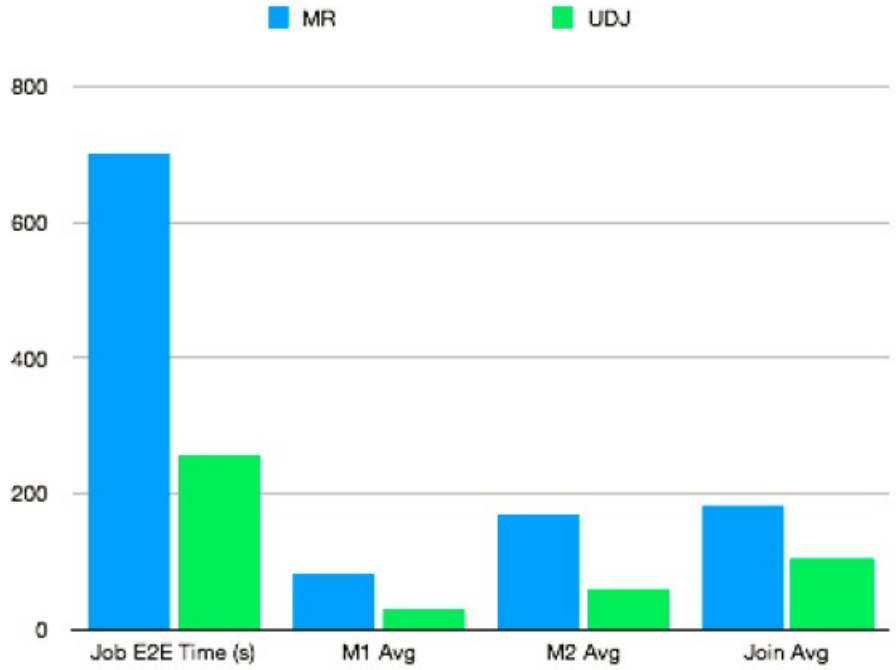
1.6.10.3. Performance advantages

Without UDJ, you must use MapReduce to handle complex cross-table computing tasks in a distributed system.

The following example uses an online MapReduce job to test the UDJ performance. This MapReduce job uses a complex algorithm to join two tables. This example uses UDJ to rewrite the SQL statements of the MapReduce job and checks the execution results.

Under the same programming concurrency, the comparison of performance is as follows.

Performance comparison



As shown in the figure, UDJ helps describe the complex logic of handling multiple tables, and greatly improves the query performance.

> **Note** The code is only executed inside UDJ. The entire logic of the code is executed by the high-performance MaxCompute native runtime.

UDJ optimizes the MaxCompute runtime engine and the data exchange between interfaces. The join logic of UDJ is more efficient than that of the reduce stage.

1.6.11. Parameterized view

MaxCompute supports parameterized views. You can call such views to obtain queried information.

In the traditional views of MaxCompute, complex SQL scripts are encapsulated at the underlying layer. Callers can call views like reading a standard table without the need to understand the underlying implementation mechanism. Traditional views are widely used because they can be used to implement encapsulation and code reuse.

However, you cannot specify parameters for traditional views. If a traditional view is called to read data from an underlying table, you cannot filter data in the underlying table or pass other parameters to the view. This reduces the code reuse rate.

The new SQL engine of MaxCompute V2.0 supports parameterized views and allows you to import any tables or other variables to customize views.

Create a parameterized view

Example

```
--view with parameters
-- param @a -a table parameter
-- param @b -a string parmeter
--returns a table with schema (key string,value string)
create view if not exists pv1(@a table (k string,v bigint), @b string)
as
select srcp.key,srcp.value from srcp join @a on srcp.key=a.k and srcp.p=@b;
```

- The created pv1 view has two parameters, the table and string parameters. The parameter values can be tables or be of a basic data type.
- The parameter values can also be subqueries. Example:

  ```
  select * from view_name( (select 1 fromsrc where a > 0), 1);
  ```

- When you define a view, you can set the type of a parameter value to ANY. Example:

  ```
  create view view_name (@a ANY, @b TABLE (x ANY)) as ...
  ```

- When you define a view, you can use an asterisk (*) to indicate a varying-length column. Example:

  ```
  create view view_name(@a bigint @b TABLE(x bigint, * ANY)) asselect * from @b where x = @a;
  ```

  Note In the table specified by the TABLE parameter, data in the first column is of the BIGINT type. You can execute `SELECT *` to obtain the varying-length part.

Call the created view

Execute the following statement to call the created pv1 view:

```
@a := select * from src where value >0;
--call view with table varable an scalar
@b := select * from pv1(@a,'20170101');
@another_day := '20170102';
--call view with table name and scalar variable
@c := select * from pv1(src2, @another_day);
@d := select * from @c union all select * from @b;
with
t as(select * from src3)
select * from @c
union all
select * from @d
union all
select * from pv1(t,@another_day);
```

Note

- You can use different parameters to call the pv1 view. The value of the table parameter can be a physical table, view, table variable, or table alias in common table expressions (CTEs).
- Common parameters can be variables or constants.

Additional instructions

A parameterized view can contain multiple SQL statements, similar to a script.

```
--view with parameters
-- param @a -a table parameter
-- param @b -a string parmeter
--returns a table with schema (key string,value string)
create view if not exists pv2(@a table (k string,v bigint), @b string) as
BEGIN
@srcp := select * from srcp where p=@b;
@pv2 := select srcp.key,srcp.value from @srcp join @a on srcp.key=a.k;
end;
```

Note

- Content between BEGIN and end is the script of this view.
- The `@pv2 := ...` statement is similar to the RETURN statement in other programming languages. This statement is used to assign a value to an implicit table variable that has the same name as the view.
- Only DML statements can be used in scripts. The INSERT and CREATE TABLE AS statements cannot be included in scripts.
- PRINT statements cannot be included in scripts.

The matching rules for actual and formal view parameters are the same as those specified in a normal programming language. If view parameters can be implicitly converted, these parameters can be matched. For example, the BIGINT value can match the parameters of the DOUBLE type. For table variables, if the schema of Table A can be inserted into Table B, Table A can be used to match the table parameter that has the same schema as Table B.

In some situations, you can declare the return type to make the code easier to read. Example:

```
create view if not exists pv3(@a table (k string,v bigint), @b string)
returns @ret table (x string,y string)
AS
begin
  @srcp := select * from srcp where p=@b;
  @ret := select srcp.key,srcp.value from @srcp join @a on srcp.key=a.k;
end;
```

> **Note** RETURNS @ret TABLE (x string, y string) defines the following information:
>
> - The return type is TABLE (x string, y string), which indicates the type returned to the caller. You can use this parameter to customize the table schema.
> - The response parameter is @ret. A value is assigned to the parameter in the view script.
> - You can regard a view that does not contain the BEGIN and END keywords or that does not return variables as a simplified view.

1.6.12. Geographic functions

1.6.12.1. Usage notes

Before you use geographic functions, understand the following points:

All functions are published in the geospatial project of the DataWorks marketplace. These functions are prefixed with ST_. You can click a function to view and use it without the need to apply for permissions. To use a function, add `geospatial.Project prefix` to the beginning of the function name and commit SQL statements that contain this function with the following flags:

```
set odps.sql.hive.compatible=true;
set odps.sql.udf.java.retain.legacy=false;
set odps.isolation.session.enable=true;
```

1.6.12.2. Constructors

1.6.12.2.1. ST_AsBinary

Function declaration:

```
ST_AsBinary(ST_Geometry)
```

Description: This function returns the well-known binary (WKB) representation of the input geometry.

Example:

```
SELECT ST_AsBinary(ST_Point(1, 2)) FROM onerow;
-- WKB representation of POINT (1 2)
```

1.6.12.2.2. ST_AsGeoJson

Function declaration:

```
ST_AsGeoJson(geometry)
```

Description: This function returns the GeoJSON representation of the input geometry.

Example:

```
SELECT ST_AsGeoJson(ST_Point(1.0, 2.0)) from onerow;
-- {"type":"Point", "coordinates":[1.0, 2.0]}
```

1.6.12.2.3. ST_AsJson

Function declaration:

```
ST_AsJSON(ST_Geometry)
```

Description: This function returns the JSON representation of the input geometry.

Example:

```
SELECT ST_AsJSON(ST_Point(1.0, 2.0)) from onerow;
-- {"x":1.0,"y":2.0}
SELECT ST_AsJSON(ST_SetSRID(ST_Point(1, 1), 4326)) from onerow;
-- {"x":1.0,"y":1.0,"spatialReference":{"wkid":4326}}
```

1.6.12.2.4. ST_AsShape

Function declaration:

```
ST_AsShape(ST_Geometry)
```

Description: This function returns the ESRI shape representation of the input geometry.

Example:

```
SELECT ST_AsShape(ST_Point(1, 2)) FROM onerow;
-- Esri shape representation of POINT (1 2)
```

1.6.12.2.5. ST_AsText

Function declaration:

```
ST_AsText(ST_Geometry)
```

Description: This function returns the well-known text (WKT) representation of the input geometry.

Example:

```
SELECT ST_AsText(ST_Point(1, 2)) FROM onerow;
-- POINT (1 2)
```

1.6.12.2.6. ST_GeomCollection

Function declaration:

```
ST_GeomCollection(wkt)
```

Description: This function constructs a multi-part geometry from the well-known text (WKT) representation based on the Open Geospatial Consortium (OGC).

> **Notice** The ST_GeomCollection function in MaxCompute supports only the multi-part geometry feature, not the collection feature.

Example:

```
SELECT ST_GeomCollection('multipoint ((1 0), (2 3))') FROM src LIMIT 1;
-- Construct a multipoint geometry.
ST_GeomCollection('POINT(1 1), LINESTRING(2 0,3 0)')
-- Not supported.
```

1.6.12.2.7. ST_GeomFromGeoJson

Function declaration:

```
ST_GeomFromGeoJson(json)
```

Description: This function constructs a geometry from the input GeoJSON representation.

Example:

```
SELECT ST_GeomFromGeoJson('{"type":"Point", "coordinates":[1.2, 2.4]}') FROM src LIMIT 1;
-- Construct a point.
SELECT ST_GeomFromGeoJson('{"type":"LineString", "coordinates":[[1,2], [3,4]]}') FROM src LIMIT 1;
-- Construct a linestring.
```

1.6.12.2.8. ST_GeomFromJSON

Function declaration:

```
ST_GeomFromJSON(json)
```

Description: This function constructs a geometry from the input ESRI JSON representation.

Example:

```
SELECT ST_GeomFromJSON('{"x":0.0,"y":0.0}') FROM src LIMIT 1;
-- Construct a point.
```

1.6.12.2.9. ST_GeomFromShape

Function declaration:

```
ST_GeomFromShape(shape)
```

Description: This function constructs a geometry from the input ESRI shape representation.

Example:

```
SELECT ST_GeomFromShape(ST_AsShape(ST_Point(1, 2)));
-- Construct a point.
```

1.6.12.2.10. ST_GeomFromText

Function declaration:

```
ST_GeomFromText(wkt)
```

Description: This function constructs a geometry from the input well-known text (WKT) representation based on the Open Geospatial Consortium (OGC).

Example:

```
SELECT ST_GeomFromText('linestring (1 0, 2 3)') FROM src LIMIT 1;
-- Construct a linestring.
SELECT ST_GeomFromText('multipoint ((1 0), (2 3))') FROM src LIMIT 1;
-- Construct a multipoint geometry.
```

1.6.12.2.11. ST_GeomFromWKB

Function declaration:

```
ST_GeomFromWKB(wkb)
```

Description: This function constructs a geometry from the input well-known binary (WKB) representation based on the Open Geospatial Consortium (OGC).

Example:

```
SELECT ST_GeomFromWKB(ST_AsBinary(ST_GeomFromText('linestring (1 0, 2 3)'))) FROM src LIMIT 1;
-- Construct a linestring.
SELECT ST_GeomFromWKB(ST_AsBinary(ST_GeomFromText('multipoint ((1 0), (2 3))'))) FROM src LIMIT 1
;
-- Construct a multipoint geometry.
```

1.6.12.2.12. ST_GeometryType

Function declaration:

```
ST_GeometryType(geometry)
```

Description: This function returns the type name of the input geometry.

Example:

```
SELECT ST_GeometryType(ST_Point(1.5, 2.5)) FROM src LIMIT 1;
-- ST_Point
SELECT ST_GeometryType(ST_LineString(1.5,2.5, 3.0,2.2)) FROM src LIMIT 1;
-- ST_LineString
SELECT ST_GeometryType(ST_Polygon(2,0, 2,3, 3,0)) FROM src LIMIT 1;
-- ST_Polygon
```

1.6.12.2.13. ST_LineString

Function declaration:

```
ST_LineString(x, y, [x, y]*)
ST_LineString('linestring( ... )')
ST_LineString(array(x+), array(y+))
ST_LineString(array(ST_Point(x,y)+)))
```

Description: This function constructs a two-dimensional line.

Example:

```
SELECT ST_LineString(1, 1, 2, 2, 3, 3) from src LIMIT 1;
SELECT ST_LineString('linestring(1 1, 2 2, 3 3)') from src LIMIT 1;
SELECT ST_LineString(array(1,2,3), array (1,2,3)) from src LIMIT 1;
SELECT ST_LineString(array(ST_Point(1, 1), ST_Point(2,2), ST_Point(3,3))) from src LIMIT 1;
```

1.6.12.2.14. ST_LineFromWKB

Function declaration:

```
ST_LineFromWKB(wkb)
```

Description: This function constructs a two-dimensional line from the input well-known binary (WKB) representation based on the Open Geospatial Consortium (OGC).

Example:

```
SELECT ST_LineFromWKB(ST_AsBinary(ST_GeomFromText('linestring (1 0, 2 3)'))) FROM src LIMIT 1;
-- Construct a two-dimensional line.
```

1.6.12.2.15. ST_MultiLineString

Function declaration:

```
ST_MultiLineString(array(x1, y1, x2, y2, ... ), array(x1, y1, x2, y2, ... ), ... )
ST_MultiLineString('multilinestring( ... )')
```

Description: This function constructs a two-dimensional multilinestring.

Example:

```
SELECT ST_MultiLineString(array(1, 1, 2, 2), array(10, 10, 20, 20)) from src LIMIT 1;
SELECT ST_MultiLineString('multilinestring ((1 1, 2 2), (10 10, 20 20))', 0) from src LIMIT 1;
```

1.6.12.2.16. ST_MLineFromWKB

Function declaration:

```
ST_MLineFromWKB(wkb)
```

Description: This function constructs a two-dimensional multilinestring from the input well-known binary (WKB) representation based on the Open Geospatial Consortium (OGC).

Example:

```
SELECT ST_MLineFromWKB(ST_AsBinary(ST_GeomFromText('multilinestring ((1 0, 2 3), (5 7, 7 5))'))) FRO
M src LIMIT 1;
-- Construct a two-dimensional multilinestring.
```

1.6.12.2.17. ST_MultiPoint

Function declaration:

```
ST_MultiPoint(x1, y1, x2, y2, x3, y3)
ST_MultiPoint('multipoint( ... )')
```

Description: This function constructs a two-dimensional multipoint geometry.

Example:

```
SELECT ST_MultiPoint(1, 1, 2, 2, 3, 3) from src LIMIT 1;
-- Construct a three-point geometry.
SELECT ST_MultiPoint('MULTIPOINT ((10 40), (40 30))') from src LIMIT 1;
-- Construct a two-point geometry.
```

1.6.12.2.18. ST_MPointFromWKB

Function declaration:

```
ST_MPointFromWKB(wkb)
```

Description: This function constructs a two-dimensional multipoint geometry from the input well-known binary (WKB) representation based on the Open Geospatial Consortium (OGC).

Example:

```
SELECT ST_MPointFromWKB(ST_AsBinary(ST_GeomFromText('multipoint ((1 0), (2 3))'))) FROM src LIMIT
1;
-- Construct a two-dimensional multipoint geometry.
```

1.6.12.2.19. ST_MultiPolygon

Function declaration:

```
ST_MultiPolygon(array(x1, y1, x2, y2, ... ), array(x1, y1, x2, y2, ... ), ... )
ST_MultiPolygon('multipolygon ( ... )')
```

Description: This function constructs a two-dimensional multipolygon.

Example:

```
SELECT ST_MultiPolygon(array(1, 1, 1, 2, 2, 2, 2, 1), array(3, 3, 3, 4, 4, 4, 4, 3)) from src LIMIT 1;
SELECT ST_MultiPolygon('multipolygon (((0 0, 0 1, 1 0, 0 0)), ((2 2, 2 3, 3 2, 2 2)))') from src LIMIT 1;
```

1.6.12.2.20. ST_MPolyFromWKB

Function declaration:

```
ST_MPolyFromWKB(wkb)
```

Description: This function constructs a two-dimensional multipolygon from the input well-known binary (WKB) representation based on the Open Geospatial Consortium (OGC).

Example:

```
SELECT ST_MPolyFromWKB(ST_AsBinary(ST_GeomFromText('multipolygon (((0 0, 1 0, 0 1, 0 0)), ((2 2, 1 2,
2 1, 2 2)))'))) FROM src LIMIT 1;
-- Construct a two-dimensional multipolygon.
```

1.6.12.2.21. ST_Point

Function declaration:

```
ST_Point(x, y)
ST_Point('point (x y)')
```

Description: This function constructs a two-dimensional point.

Example:

```
SELECT ST_Point(longitude, latitude) from src LIMIT 1;
SELECT ST_Point('point (0 0)') from src LIMIT 1;
```

1.6.12.2.22. ST_PointFromWKB

Function declaration:

```
ST_PointFromWKB(wkb)
```

Description: This function constructs a two-dimensional point from the input well-known binary (WKB) representation based on the Open Geospatial Consortium (OGC).

Example:

```
SELECT ST_PointFromWKB(ST_AsBinary(ST_GeomFromText('point (1 0)'))) FROM src LIMIT 1;
-- Construct a two-dimensional point.
```

1.6.12.2.23. ST_PointZ

Function declaration:

```
ST_PointZ(x, y, z)
```

Description: This function constructs a three-dimensional point.

Example:

```
SELECT ST_PointZ(longitude, latitude, elevation) from src LIMIT 1;
```

1.6.12.2.24. ST_Polygon

Function declaration:

```
ST_Polygon(x, y, [x, y]*)
ST_Polygon('polygon( ... )')
```

Description: This function constructs a two-dimensional polygon.

Example:

```
SELECT ST_Polygon(1, 1, 1, 4, 4, 4, 4, 1) from src LIMIT 1;
-- Construct a square.
SELECT ST_Polygon('polygon ((1 1, 4 1, 1 4))') from src LIMIT 1;
-- Construct a triangle.
```

1.6.12.2.25. ST_PolyFromWKB

Function declaration:

```
ST_PolyFromWKB(wkb)
```

Description: This function constructs a two-dimensional polygon from the input well-known binary (WKB) representation based on the Open Geospatial Consortium (OGC).

Example:

```
SELECT ST_PolyFromWKB(ST_AsBinary(ST_GeomFromText('polygon ((0 0, 10 0, 0 10, 0 0))'))) FROM src LI
MIT 1;
-- Construct a two-dimensional polygon.
```

1.6.12.2.26. ST_SetSRID

Function declaration:

```
ST_SetSRID(<ST_Geometry>, SRID)
```

Description: This function sets the spatial reference system identifier (SRID) of the input geometry.

Example:

```
SELECT ST_SetSRID(ST_Point(1.5, 2.5), 4326)) FROM src LIMIT 1;
-- Construct a point and set its SRID to 4326.
```

1.6.12.3. Accessors

1.6.12.3.1. ST_Area

Function declaration:

```
ST_Area(ST_Polygon)
```

Description: This function returns the areas of one or more polygons.

Example:

```
SELECT ST_Area(ST_Polygon(1,1, 1,4, 4,4, 4,1)) FROM src LIMIT 1;
-- 9.0
```

1.6.12.3.2. ST_Centroid

Function declaration:

```
ST_Centroid(polygon)
```

Description: This function returns the center point of the minimum bounding rectangle of the input polygon.

Example:

```
SELECT ST_Centroid(ST_GeomFromText('polygon ((0 0, 3 6, 6 0, 0 0))')) FROM src LIMIT 1;
-- POINT(3 3)
SELECT ST_Centroid(ST_GeomFromText('polygon ((0 0, 0 8, 8 0, 0 0))')) FROM src LIMIT 1;
-- POINT(4 4)
```

1.6.12.3.3. ST_CoordDim

Function declaration:

```
ST_CoordDim(geometry)
```

Description: This function returns the coordinate dimension of the input geometry.

Example:

```
SELECT ST_CoordDim(ST_Point(1.5, 2.5)) FROM src LIMIT 1;
-- 2
SELECT ST_CoordDim(ST_PointZ(1.5,2.5, 3) FROM src LIMIT 1;
-- 3
SELECT ST_CoordDim(ST_Point(1.5, 2.5, 3., 4.)) FROM src LIMIT 1;
-- 4
```

1.6.12.3.4. ST_Dimension

Function declaration:

```
ST_Dimension(geometry)
```

Description: This function returns the spatial dimension of the input geometry.

Example:

```
SELECT ST_Dimension(ST_Point(1.5, 2.5)) FROM src LIMIT 1;
-- 0
SELECT ST_Dimension(ST_LineString(1.5,2.5, 3.0,2.2)) FROM src LIMIT 1;
-- 1
SELECT ST_Dimension(ST_Polygon(2,0, 2,3, 3,0)) FROM src LIMIT 1;
-- 2
```

1.6.12.3.5. ST_Distance

Function declaration:

```
ST_Distance(ST_Geometry1, ST_Geometry2)
```

Description: This function returns the distance between a point in geometry1 and a point in geometry2.

Example:

```
SELECT ST_Distance(ST_Point(0.0,0.0), ST_Point(3.0,4.0)) FROM src LIMIT 1;
-- 5.0
```

1.6.12.3.6. ST_GeodesicLengthWGS84

Function declaration:

```
ST_GeodesicLengthWGS84(line)
```

Description: This function returns the distance in meters on a spheroid based on World Geodetic System 1984 (WGS84). The geometry must be in WGS84. Otherwise, this function returns NULL.

Example:

```
SELECT ST_GeodesicLengthWGS84(ST_SetSRID(ST_Linestring(0.0,0.0, 0.3,0.4), 4326)) FROM src LIMIT 1;
-- 55km
SELECT ST_GeodesicLengthWGS84(ST_GeomFromText('MultiLineString((0.0 80.0, 0.3 80.4))', 4326)) FROM src LIMIT 1;
-- 45km
```

1.6.12.3.7. ST_GeometryN

Function declaration:

```
ST_GeometryN(ST_GeometryCollection, n)
```

Description: This function returns the nth geometry in the input geometry collection. n starts from 1.

Example:

```
SELECT ST_GeometryN(ST_GeomFromText('multipoint ((10 40), (40 30), (20 20), (30 10))'), 3) FROM src LIMIT 1;
-- ST_Point(20 20)
SELECT ST_GeometryN(ST_GeomFromText('multilinestring ((2 4, 10 10), (20 20, 7 8))'), 2) FROM src LIMIT 1;
-- ST_Linestring(20 20, 7 8)
```

1.6.12.3.8. ST_Is3D

Function declaration:

```
ST_Is3D(geometry)
```

Description: If the input geometry has Z coordinates, this function returns true. Otherwise, this function returns false.

Example:

```
SELECT ST_Is3D(ST_Polygon(1,1, 1,4, 4,4, 4,1)) FROM src LIMIT 1;
-- false
SELECT ST_Is3D(ST_LineString(0.,0., 3.,4., 0.,4., 0.,0.)) FROM src LIMIT 1;
-- false
SELECT ST_Is3D(ST_Point(3., 4.)) FROM src LIMIT 1;
-- false
SELECT ST_Is3D(ST_PointZ(3., 4., 2)) FROM src LIMIT 1;
-- true
```

1.6.12.3.9. ST_IsClosed

Function declaration:

```
ST_IsClosed(ST_[Multi]LineString)
```

Description: If the input linestring or linestrings are closed, this function returns true.

Example:

```
SELECT ST_IsClosed(ST_LineString(0.,0., 3.,4., 0.,4., 0.,0.)) FROM src LIMIT 1;
-- true
SELECT ST_IsClosed(ST_LineString(0.,0., 3.,4.)) FROM src LIMIT 1;
-- false
```

1.6.12.3.10. ST_IsEmpty

Function declaration:

```
ST_IsEmpty(geometry)
```

Description: If the input geometry is empty, this function returns true.

Example:

```
SELECT ST_IsEmpty(ST_Point(1.5, 2.5)) FROM src LIMIT 1;
-- false
SELECT ST_IsEmpty(ST_GeomFromText('point empty')) FROM src LIMIT 1;
-- true
```

1.6.12.3.11. ST_IsMeasured

Function declaration:

```
ST_IsMeasured(geometry)
```

Description: If the input geometry has M coordinates (measures), this function returns true.

Example:

```
SELECT ST_IsMeasured(ST_Polygon(1,1, 1,4, 4,4, 4,1)) FROM src LIMIT 1;
-- false
SELECT ST_IsMeasured(ST_LineString(0.,0., 3.,4., 0.,4., 0.,0.)) FROM src LIMIT 1;
-- false
SELECT ST_IsMeasured(ST_Point(3., 4.)) FROM src LIMIT 1;
-- false
SELECT ST_IsMeasured(ST_PointM(3., 4., 2)) FROM src LIMIT 1;
-- true
```

1.6.12.3.12. ST_IsSimple

Function declaration:

```
ST_IsSimple(geometry)
```

Description: If the input geometry is simple, this function returns true.

Example:

```
SELECT ST_IsSimple(ST_Point(1.5, 2.5)) FROM src LIMIT 1;
-- true
SELECT ST_IsSimple(ST_LineString(0.,0., 1.,1., 0.,1., 1.,0.)) FROM src LIMIT 1;
-- false
```

1.6.12.3.13. ST_IsRing

Function declaration:

```
ST_IsRing(ST_LineString)
```

Description: If the input linestring is closed or simple, this function returns true.

Example:

```
SELECT ST_IsRing(ST_LineString(0.,0., 3.,4., 0.,4., 0.,0.)) FROM src LIMIT 1;
-- true
SELECT ST_IsRing(ST_LineString(0.,0., 1.,1., 1.,2., 2.,1., 1.,1., 0.,0.)) FROM src LIMIT 1;
-- false
SELECT ST_IsRing(ST_LineString(0.,0., 3.,4.)) FROM src LIMIT 1;
-- false
```

1.6.12.3.14. ST_Length

Function declaration:

```
ST_Length(line)
```

Description: This function returns the length of the input line segment.

Example:

```
SELECT ST_Length(ST_Line(0.0,0.0, 3.0,4.0)) FROM src LIMIT 1;
-- 5.0
```

1.6.12.3.15. ST_M

Function declaration:

```
ST_M(geometry)
```

Description: This function returns the M coordinate of the input geometry.

Example:

```
SELECT ST_M(ST_PointM(3., 4., 2)) FROM src LIMIT 1;
-- 2
```

1.6.12.3.16. ST_MaxM

Function declaration:

```
ST_MaxM(geometry)
```

Description: This function returns the maximum M coordinate of the input geometry.

Example:

```
SELECT ST_MaxM(ST_PointM(1.5, 2.5, 2)) FROM src LIMIT 1;
-- 2
SELECT ST_MaxM(ST_LineString('linestring m (1.5 2.5 2, 3.0 2.2 1)')) FROM src LIMIT 1;
-- 1
```

1.6.12.3.17. ST_MinM

Function declaration:

```
ST_MinM(geometry)
```

Description: This function returns the minimum M coordinate of the input geometry.

Example:

```
SELECT ST_MinM(ST_PointM(1.5, 2.5, 2)) FROM src LIMIT 1;
-- 2
SELECT ST_MinM(ST_LineString('linestring m (1.5 2.5 2, 3.0 2.2 1)')) FROM src LIMIT 1;
-- 1
```

1.6.12.3.18. ST_X

Function declaration:

```
ST_X(point)
```

Description: This function returns the X coordinate of the input point.

Example:

```
SELECT ST_X(ST_Point(1.5, 2.5)) FROM src LIMIT 1;
--  1.5
```

1.6.12.3.19. ST_Y

Function declaration:

```
ST_Y(point)
```

Description: This function returns the Y coordinate of the input point.

Example:

```
SELECT ST_Y(ST_Point(1.5, 2.5)) FROM src LIMIT 1;
--  2.5
```

1.6.12.3.20. ST_Z

Function declaration:

```
ST_Z(point)
```

Description: This function returns the Z coordinate of the input point.

Example:

```
SELECT ST_Z(ST_Point(1.5, 2.5)) FROM src LIMIT 1;
--  1.5
```

1.6.12.3.21. ST_MaxX

Function declaration:

```
ST_MaxX(geometry)
```

Description: This function returns the maximum X coordinate of the input geometry.

Example:

```
SELECT ST_MaxX(ST_Point(1.5, 2.5)) FROM src LIMIT 1;
-- 1.5
SELECT ST_MaxX(ST_LineString(1.5,2.5, 3.0,2.2)) FROM src LIMIT 1;
-- 3.0
```

1.6.12.3.22. ST_MaxY

Function declaration:

```
ST_MaxY(geometry)
```

Description: This function returns the maximum Y coordinate of the input geometry.

Example:

```
SELECT ST_MaxY(ST_Point(1.5, 2.5)) FROM src LIMIT 1;
-- 2.5
SELECT ST_MaxY(ST_LineString(1.5,2.5, 3.0,2.2)) FROM src LIMIT 1;
-- 2.5
```

1.6.12.3.23. ST_MaxZ

Function declaration:

```
ST_MaxZ(geometry)
```

Description: This function returns the maximum Z coordinate of the input geometry.

Example:

```
SELECT ST_MaxZ(ST_PointZ(1.5, 2.5, 2)) FROM src LIMIT 1;
-- 2
SELECT ST_MaxZ(ST_LineString('linestring z (1.5 2.5 2, 3.0 2.2 1)')) FROM src LIMIT 1;
-- 1
```

1.6.12.3.24. ST_MinX

Function declaration:

```
ST_MinX(geometry)
```

Description: This function returns the minimum X coordinate of the input geometry.

Example:

```
SELECT ST_MinX(ST_Point(1.5, 2.5)) FROM src LIMIT 1;
-- 1.5
SELECT ST_MinX(ST_LineString(1.5,2.5, 3.0,2.2)) FROM src LIMIT 1;
-- 3.0
```

1.6.12.3.25. ST_MinY

Function declaration:

```
ST_MinY(geometry)
```

Description: This function returns the minimum Y coordinate of the input geometry.

Example:

```
SELECT ST_MinY(ST_Point(1.5, 2.5)) FROM src LIMIT 1;
-- 2.5
SELECT ST_MinY(ST_LineString(1.5,2.5, 3.0,2.2)) FROM src LIMIT 1;
-- 2.2
```

1.6.12.3.26. ST_MinZ

Function declaration:

```
ST_MinZ(geometry)
```

Description: This function returns the minimum Z coordinate of the input geometry.

Example:

```
SELECT ST_MinZ(ST_PointZ(1.5, 2.5, 2)) FROM src LIMIT 1;
-- 2
SELECT ST_MinZ(ST_LineString('linestring z (1.5 2.5 2, 3.0 2.2 1)')) FROM src LIMIT 1;
-- 1
```

1.6.12.3.27. ST_NumGeometries

Function declaration:

```
ST_NumGeometries(ST_GeometryCollection)
```

Description: This function returns the number of geometries in the input geometry collection.

Example:

```
SELECT ST_NumGeometries(ST_GeomFromText('multipoint ((10 40), (40 30), (20 20), (30 10))')) FROM src
LIMIT 1;
-- 4
SELECT ST_NumGeometries(ST_GeomFromText('multilinestring ((2 4, 10 10), (20 20, 7 8))')) FROM src LIM
IT 1;
-- 2
```

1.6.12.3.28. ST_NumInteriorRing

Function declaration:

```
ST_NumInteriorRing(ST_Polygon)
```

Description: This function returns the number of interior rings of the input polygon.

Example:

```
SELECT ST_NumInteriorRing(ST_Polygon(1,1, 1,4, 4,1)) FROM src LIMIT 1;
-- 0
SELECT ST_NumInteriorRing(ST_Polygon('polygon ((0 0, 8 0, 0 8, 0 0), (1 1, 1 5, 5 1, 1 1))')) FROM src LIMIT
1;
-- 1
```

1.6.12.3.29. ST_NumPoints

Function declaration:

```
ST_NumPoints(geometry)
```

Description: This function returns the number of points in the input geometry.

Example:

```
SELECT ST_NumPoints(ST_Point(1.5, 2.5)) FROM src LIMIT 1;
-- 1
SELECT ST_NumPoints(ST_LineString(1.5,2.5, 3.0,2.2)) FROM src LIMIT 1;
-- 2
SELECT ST_NumPoints(ST_GeomFromText('polygon ((0 0, 10 0, 0 10, 0 0))')) FROM src LIMIT 1;
-- 4
```

1.6.12.3.30. ST_PointN

Function declaration:

```
ST_PointN(ST_Geometry, n)
```

Description: This function returns the nth point of one or more linestrings.

Example:

```
SELECT ST_PointN(ST_LineString(1.5,2.5, 3.0,2.2), 2) FROM src LIMIT 1;
-- POINT(3.0 2.2)
```

1.6.12.3.31. ST_StartPoint

Function declaration:

```
ST_StartPoint(geometry)
```

Description: This function returns the first point of the input linestring.

Example:

```
SELECT ST_StartPoint(ST_LineString(1.5,2.5, 3.0,2.2)) FROM src LIMIT 1;
-- POINT(1.5 2.5)
```

1.6.12.3.32. ST_EndPoint

Function declaration:

```
ST_EndPoint(geometry)
```

Description: This function returns the last point of the input linestring.

Example:

```
SELECT ST_EndPoint(ST_LineString(1.5,2.5, 3.0,2.2)) FROM src LIMIT 1;
-- POINT(3.0 2.0)
```

1.6.12.3.33. ST_SRID

Function declaration:

```
ST_SRID(ST_Geometry)
```

Description: This function returns the spatial reference system identifier (SRID) of the input geometry.

Example:

```
SELECT ST_SRID(ST_Point(1.5, 2.5)) FROM src LIMIT 1
-- Return SRID 0.
```

1.6.12.4. Operations

1.6.12.4.1. ST_Aggr_ConvexHull

Function declaration:

```
ST_Aggr_ConvexHull(ST_Geometry)
```

Description: This function returns a convex hull for input geometries by using aggregation transformation.

Example:

```
SELECT ST_Aggr_ConvexHull(geometry) FROM source;
-- Return the convex hull of input geometries from the data source by using aggregation transformati
on.
```

1.6.12.4.2. ST_Aggr_Intersection

Function declaration:

```
ST_Aggr_Intersection(ST_Geometry)
```

Description: This function returns the intersection of input geometries by using aggregation transformation.

Example:

```
SELECT ST_Aggr_Intersection(geometry) FROM source;
-- Return the intersection of input geometries from the data source by using aggregation transformati
on.
```

1.6.12.4.3. ST_Aggr_Union

Function declaration:

```
ST_Aggr_Union(ST_Geometry)
```

Description: This function returns a union of input geometries by using aggregation transformation.

Example:

```
SELECT ST_Aggr_Union(geometry) FROM source;
-- Return the union of input geometries from the data source by using aggregation transformation.
```

1.6.12.4.4. ST_Bin

Function declaration:

```
ST_Bin(placeholder)
```

Description: This function returns the bin ID of the input point.

1.6.12.4.5. ST_BinEnvelope

Function declaration:

```
ST_BinEnvelope(binsize, point)
```

Description: This function returns the binary envelope for the input point.

Function declaration:

```
ST_BinEnvelope(binsize, binid)
```

Description: This function returns the binary envelope for the input bin ID.

1.6.12.4.6. ST_Boundary

Function declaration:

```
ST_Boundary(ST_Geometry)
```

Description: This function returns the boundary of the input geometry.

Example:

```
SELECT ST_Boundary(ST_LineString(0,1, 1,0))) FROM src LIMIT 1;
-- MULTIPOINT((1 0),(0 1))
SELECT ST_Boundary(ST_Polygon(1,1, 4,1, 1,4)) FROM src LIMIT 1;
-- LINESTRING(1 1, 4 1, 1 4, 1 1)
```

1.6.12.4.7. ST_Buffer

Function declaration:

```
ST_Buffer(geometry, distance)
```

Description: This function returns a geometry that indicates all points whose distance from this geometry to the input geometry is less than or equal to the value of the distance parameter.

1.6.12.4.8. ST_ConvexHull

Function declaration:

```
ST_ConvexHull(ST_Geometry, ST_Geometry, ...)
```

Description: This function returns the convex hull of the input geometry.

Example:

```
SELECT ST_AsText(ST_ConvexHull(ST_Point(0, 0), ST_Point(0, 1), ST_Point(1, 1))) FROM onerow;
-- MULTIPOLYGON (((0 0, 1 1, 0 1, 0 0)))
```

1.6.12.4.9. ST_Difference

Function declaration:

```
ST_Difference(ST_Geometry1, ST_Geometry2)
```

Description: This function returns a geometry that indicates the difference between the input geometries.

Example:

```
SELECT ST_AsText(ST_Difference(ST_MultiPoint(1, 1, 1.5, 1.5, 2, 2), ST_Point(1.5, 1.5))) FROM onerow;
-- MULTIPOINT (1 1, 2 2)
SELECT ST_AsText(ST_Difference(ST_Polygon(0, 0, 0, 10, 10, 10, 10, 0), ST_Polygon(0, 0, 0, 5, 5, 5, 5, 0))) f
rom onerow;
-- MULTIPOLYGON (((10 0, 10 10, 0 10, 0 5, 5 5, 5 0, 10 0)))
```

1.6.12.4.10. ST_Envelope

Function declaration:

```
ST_Envelope(ST_Geometry)
```

Description: This function returns the envelope of the input geometry. If the specified geometry is a point, a horizontal line, or a vertical line, this function returns the common difference or an empty envelope.

Example:

```
SELECT ST_Envelope(ST_LineString(0,0, 2,2)) from src LIMIT 1;
-- POLYGON ((0 0, 2 0, 2 2, 0 2, 0 0))
SELECT ST_Envelope(ST_Polygon(2,0, 2,3, 3,0)) from src LIMIT 1;
-- POLYGON ((2 0, 3 0, 3 3, 2 3, 2 0))
```

1.6.12.4.11. ST_ExteriorRing

Function declaration:

```
ST_ExteriorRing(polygon)
```

Description: This function returns the exterior ring of a polygon as a linestring.

Example:

```
SELECT ST_ExteriorRing(ST_Polygon(1,1, 1,4, 4,1)) FROM src LIMIT 1;
-- LINESTRING(1 1, 4 1, 1 4, 1 1)
SELECT ST_ExteriorRing(ST_Polygon('polygon ((0 0, 8 0, 0 8, 0 0), (1 1, 1 5, 5 1, 1 1))')) FROM src LIMIT 1;
-- LINESTRING (8 0, 0 8, 0 0, 8 0)
```

1.6.12.4.12. ST_InteriorRingN

Function declaration:

```
ST_InteriorRingN(ST_Polygon, n)
```

Description: This function returns the nth interior ring of a polygon as a linestring.

Example:

```
SELECT ST_InteriorRingN(ST_Polygon('polygon ((0 0, 8 0, 0 8, 0 0), (1 1, 1 5, 5 1, 1 1))'), 1) FROM src LIMIT
1;
-- LINESTRING (1 1, 5 1, 1 5, 1 1)
```

1.6.12.4.13. ST_Intersection

Function declaration:

```
ST_Intersection(ST_Geometry1, ST_Geometry2)
```

Description: This function returns a geometry that indicates the intersection of the input geometries. If the input geometries intersect in a lower dimension, ST_Intersection may drop lower-dimension intersections or return a closed linestring.

Example:

```
SELECT ST_AsText(ST_Intersection(ST_Point(1,1), ST_Point(1,1))) FROM onerow;
-- POINT (1 1)
SELECT ST_AsText(ST_Intersection(ST_GeomFromText('linestring(0 2, 0 0, 2 0)'), ST_GeomFromText('lin
estring(0 3, 0 1, 1 0, 3 0)'))) FROM onerow;
-- MULTILINESTRING ((1 0, 2 0), (0 2, 0 1))
SELECT ST_AsText(ST_Intersection(ST_LineString(0,2, 2,3), ST_Polygon(1,1, 4,1, 4,4, 1,4))) FROM onerow
;
-- MULTILINESTRING ((1 2.5, 2 3))
SELECT ST_AsText(ST_Intersection(ST_Polygon(2,0, 2,3, 3,0), ST_Polygon(1,1, 4,1, 4,4, 1,4))) FROM onero
w;
-- MULTIPOLYGON (((2.67 1, 2 3, 2 1, 2.67 1)))
SELECT ST_AsText(ST_Intersection(ST_Polygon(2,0, 3,1, 2,1), ST_Polygon(1,1, 4,1, 4,4, 1,4))) FROM onero
w;
-- MULTIPOLYGON EMPTY or LINESTRING (2 1, 3 1, 2 1)
```

1.6.12.4.14. ST_SymmetricDiff

Function declaration:

```
ST_SymmetricDiff(ST_Geometry1, ST_Geometry2)
```

Description: This function returns a geometry that consists of the symmetric differences of the input geometries.

Example:

```
SELECT ST_AsText(ST_SymmetricDiff(ST_LineString('linestring(0 2, 2 2)'), ST_LineString('linestring(1 2, 3 2)'))) FROM onerow;
-- MULTILINESTRING((0 2, 1 2), (2 2, 3 2))
SELECT ST_AsText(ST_SymmetricDiff(ST_SymmetricDiff(ST_Polygon('polygon((0 0, 2 0, 2 2, 0 2, 0 0))'), ST_Polygon('polygon((1 1, 3 1, 3 3, 1 3, 1 1))'))) from onerow;
-- MULTIPOLYGON (((0 0, 2 0, 2 1, 1 1, 1 2, 0 2, 0 0)), ((3 1, 3 3, 1 3, 1 2, 2 2, 2 1, 3 1)))
```

1.6.12.4.15. ST_Union

Function declaration:

```
ST_Union(ST_Geometry, ST_Geometry, ...)
```

Description: This function returns a geometry that is the union of the input geometries.

Example:

```
SELECT ST_AsText(ST_Union(ST_Polygon(1, 1, 1, 4, 4, 4, 4, 1), ST_Polygon(4, 1, 4, 4, 4, 8, 8, 1))) FROM one row;
-- MULTIPOLYGON (((4 1, 8 1, 4 8, 4 4, 1 4, 1 1, 4 1)))
```

1.6.12.5. Relationship tests

1.6.12.5.1. ST_Contains

Function declaration:

```
BOOLEAN ST_Contains(geometry1, geometry2)
```

Description: If geometry1 contains geometry2, this function returns true. Otherwise, this function returns false.

Example:

```
SELECT ST_Contains(st_polygon(1,1, 1,4, 4,4, 4,1), st_point(2, 3) from src LIMIT 1;
-- true is returned.
SELECT ST_Contains(st_polygon(1,1, 1,4, 4,4, 4,1), st_point(8, 8) from src LIMIT 1;
-- false is returned.
```

1.6.12.5.2. ST_Crosses

Function declaration:

```
BOOLEAN ST_Crosses(geometry1, geometry2)
```

Description: If geometry1 crosses geometry2, this function returns true. Otherwise, this function returns false.

> **Note** Crossing indicates that some points in the two geometries are the same.

Example:

```
SELECT ST_Crosses(st_linestring(0,0, 1,1), st_linestring(1,0, 0,1)) from src LIMIT 1;
-- true is returned.
SELECT ST_Crosses(st_linestring(2,0, 2,3), st_polygon(1,1, 1,4, 4,4, 4,1)) from src LIMIT 1;
-- true is returned.
SELECT ST_Crosses(st_linestring(0,2, 0,1), ST_linestring(2,0, 1,0)) from src LIMIT 1;
-- false is returned.
```

1.6.12.5.3. ST_Disjoint

Function declaration:

```
BOOLEAN ST_Disjoint(geometry1, geometry2)
```

Description: If geometry1 and geometry2 do not intersect, this function returns true. Otherwise, this function returns false.

Example:

```
SELECT ST_Disjoint(ST_LineString(0,0, 0,1), ST_LineString(1,1, 1,0)) from src LIMIT 1;
-- true is returned.
SELECT ST_Disjoint(ST_LineString(0,0, 1,1), ST_LineString(1,0, 0,1)) from src LIMIT 1;
-- false is returned.
```

1.6.12.5.4. ST_EnvIntersects

Function declaration:

```
BOOLEAN ST_EnvIntersects(ST_Geometry1, ST_Geometry2)
```

Description: If the envelopes of geometry1 and geometry2 intersect, this function returns true. Otherwise, this function returns false.

Example:

```
SELECT ST_EnvIntersects(ST_LineString(0,0, 1,1), ST_LineString(1,3, 2,2)) from src LIMIT 1;
-- false is returned.
SELECT ST_EnvIntersects(ST_LineString(0,0, 2,2), ST_LineString(1,0, 3,2)) from src LIMIT 1;
-- true is returned.
```

1.6.12.5.5. ST_Equals

Function declaration:

```
BOOLEAN ST_Equals(geometry1, geometry2)
```

Description: If geometry1 equals geometry2, this function returns true. Otherwise, this function returns false.

Example:

```
SELECT ST_Equals(st_linestring(0,0, 1,1), st_linestring(1,1, 0,0)) from src LIMIT 1;
-- true is returned.
SELECT ST_Equals(st_linestring(0,0, 1,1), st_linestring(1,0, 0,1)) from src LIMIT 1;
-- false is returned.
```

1.6.12.5.6. ST_Intersects

Function declaration:

```
BOOLEAN ST_Intersects(geometry1, geometry2)
```

Description: If geometry1 and geometry2 intersect, this function returns true. Otherwise, this function returns false.

Example:

```
SELECT ST_Intersects(st_linestring(0,0, 1,1), st_linestring(1,1, 0,0)) from src LIMIT 1;
-- true is returned.
SELECT ST_Intersects(st_linestring(0,0, 1,1), st_linestring(1,0, 0,1)) from src LIMIT 1;
-- true is returned.
SELECT ST_Intersects(ST_LineString(2,0, 2,3), ST_Polygon(1,1, 4,1, 4,4, 1,4)) from src LIMIT 1;
-- true is returned.
SELECT ST_Intersects(ST_LineString(8,7, 7,8), ST_Polygon(1,1, 4,1, 4,4, 1,4)) from src LIMIT 1;
-- false is returned.
```

1.6.12.5.7. ST_Overlaps

Function declaration:

```
BOOLEAN ST_Overlaps(geometry1, geometry2)
```

Description: If geometry1 and geometry2 overlap, this function returns true. Otherwise, this function returns false. Overlapping excludes the tangency of the geometries.

Example:

```
SELECT ST_Overlaps(st_polygon(2,0, 2,3, 3,0), st_polygon(1,1, 1,4, 4,4, 4,1)) from src LIMIT 1;
-- true is returned.
SELECT ST_Overlaps(st_polygon(2,0, 2,1, 3,1), ST_Polygon(1,1, 1,4, 4,4, 4,1)) from src LIMIT 1;
-- false is returned.
```

1.6.12.5.8. ST_Relate

Function declaration:

```
BOOLEAN ST_Relate(geometry1, geometry2)
```

Description: If geometry1 has the specified Dimensionally Extended nine-Intersection Model (DE-9IM) relationship with geometry2, this function returns true. Otherwise, this function returns false.

Example:

```
SELECT ST_Relate(st_polygon(2,0, 2,1, 3,1), ST_Polygon(1,1, 1,4, 4,4, 4,1), '****T****') from src LIMIT 1;
-- true is returned.
SELECT ST_Relate(st_polygon(2,0, 2,1, 3,1), ST_Polygon(1,1, 1,4, 4,4, 4,1), 'T********') from src LIMIT 1;
-- false is returned.
SELECT ST_Relate(st_linestring(0,0, 3,3), ST_linestring(1,1, 4,4), 'T********') from src LIMIT 1;
-- true is returned.
SELECT ST_Relate(st_linestring(0,0, 3,3), ST_linestring(1,1, 4,4), '****T****') from src LIMIT 1;
-- false is returned.
```

1.6.12.5.9. ST_Touches

Function declaration:

```
BOOLEAN ST_Touches(geometry1, geometry2)
```

Description: If geometry1 and geometry2 spatially touch and have no similar interior points, this function returns true. Otherwise, this function returns false.

Example:

```
SELECT ST_Touches(st_point(1, 2), st_polygon(1, 1, 1, 4, 4, 4, 4, 1)) from src LIMIT 1;
-- true is returned.
SELECT ST_Touches(st_point(8, 8), st_polygon(1, 1, 1, 4, 4, 4, 4, 1)) from src LIMIT 1;
-- false is returned.
```

1.6.12.5.10. ST_Within

Function declaration:

```
BOOLEAN ST_Within(geometry1, geometry2)
```

Description: If geometry1 is within geometry2, this function returns true. Otherwise, this function returns false.

Example:

```
SELECT ST_Within(st_point(2, 3), st_polygon(1,1, 1,4, 4,4, 4,1)) from src LIMIT 1;
-- true is returned.
SELECT ST_Within(st_point(8, 8), st_polygon(1,1, 1,4, 4,4, 4,1)) from src LIMIT 1;
-- false is returned.
```

1.6.12.6. Geohash index functions

1.6.12.6.1. ST_GeoHash

Function declaration:

```
string ST_GeoHash(st_geometry geometry, integer precision=full_precision)
string ST_GeoHash(double longitude, double latitude, integer precision=full_precision)
```

Description: This function returns the unique Geohash string of the specified point. This function uses a function with the ST_ prefix or the specified longitudes and latitudes as input parameters. If the precision parameter is not specified, the maximum precision is used.

Example:

```
SELECT ST_GeoHash(ST_Point(-102.849854, 36.451113), 8);
SELECT ST_GeoHash(ST_GeomFromText('POINT(-102.849854 36.451113)'));
SELECT ST_GeoHash(-102.849854, 36.451113, 10);
```

1.6.12.6.2. ST_PointFromGeoHash

Function declaration:

```
st_geometry ST_PointFromGeoHash(string geohash, integer precision=full_precision)
```

Description: This function returns a point based on the input Geohash value. If the precision parameter is not specified, the maximum precision is used.

Example:

```
SELECT ST_AsText(ST_PointFromGeoHash('9wqz7eep0eyq'));
SELECT ST_AsText(ST_PointFromGeoHash('9wqz7eep0eyq', 4));
```

1.6.12.6.3. ST_EnvelopeFromGeoHash

Function declaration:

```
st_geometry ST_EnvelopeFromGeoHash(string geohash, integer precision=full_precision)
```

Description: This function returns the envelope of the specified precision based on the input Geohash value. If the precision parameter is not specified, the maximum precision is used.

Example:

```
SELECT ST_AsText(ST_EnvelopeFromGeoHash('9wqz7eep0eyq', 8));
SELECT ST_AsText(ST_EnvelopeFromGeoHash('9wqz7eep0eyq'));
```

1.6.12.6.4. ST_GeoHashNeighbours

Function declaration:

```
list_of_string ST_GeoHashNeighbours(double longitude, double latitude, integer precision)
```

Description: This function is a user-defined table-valued function (UDTF) that generates nine data records. This function returns nine Geohash strings of the current point and its eight neighboring points based on the input longitude, latitude, and precision. These parameters must be specified.

Example:

```
SELECT ST_GeoHashNeighbours(-102.849854, 36.451113, 10);
```

1.6.12.7. S2 mesh functions

1.6.12.7.1. ST_S2CellIdsFromGeom

Function declaration:

```
list_of_string ST_S2CellIdsFromGeom(st_geometry geometry, integer level)
```

Description: This function overwrites the input geometry by using S2 cells at the specified level. Then, it returns the IDs of all S2 cells.

Example:

```
SELECT ST_S2CellIdsFromGeom(ST_Point(-102.849854, 36.451113), 4);
SELECT ST_S2CellIdsFromGeom(ST_LineString('LINESTRING(-71.160281 42.258729,-71.160837 42.259113,-7
1.161144 42.25932)'), 17) as cellid;
```

1.6.12.7.2. ST_S2CellIdsFromText

Function declaration:

```
list_of_string ST_S2CellIdsFromText(string wkt, integer level)
```

Description: This function overwrites the well-known text (WKT) representation of the input geometry by using S2 cells at the specified level. Then, it returns the IDs of all S2 cells.

Example:

```
SELECT ST_S2CellIdsFromText(ST_GeomFromText('POINT(-102.849854 36.451113)'), 4);
SELECT ST_S2CellIdsFromText('LINESTRING(-71.160281 42.258729,-71.160837 42.259113,-71.161144 42.259
32)', 17) as cellid;
```

1.6.12.7.3. ST_S2CellCenterPoint

Function declaration:

```
st_point ST_S2CellCenterPoint(string cellId)
```

Description: This function calculates the center point of the cell specified by the cellId parameter in the input S2 cell.

Example:

```
SELECT ST_S2CellCenterPoint('549015');
SELECT ST_AsText(ST_S2CellCenterPoint('89e37f091'));
```

1.6.12.7.4. ST_S2CellNeighbours

Function declaration:

```
list_of_string ST_S2CellNeighbours(string cellId, integer level)
```

Description: This function calculates the neighboring S2 cells of the cell specified by the cellId parameter at the specified level. Then, it returns the IDs of all neighboring S2 cells.

Example:

```
SELECT ST_S2CellNeighbours('549015', 10);
SELECT ST_S2CellNeighbours('89e37f091', 16) as neighour;
```

1.6.12.8. Geodesic functions

1.6.12.8.1. ST_AreaWGS84

Function declaration:

```
double ST_AreaWGS84(st_geometry geometry)
```

Description: This function returns the approximate geodesic area of the input geometry based on World Geodetic System 1984 (WGS84). This function converts the coordinates of the input geometry from EPSG:4326 to EPSG:3857. Then, it calculates the plane area in square meters.

Example:

```
SELECT ST_AreaWGS84(ST_GeomFromText('POLYGON((743238 2967416,743238 2967450, 743265 2967450, 743265.625 2967416,743238 2967416))'));
```

1.6.12.8.2. ST_DistanceWGS84

Function declaration:

```
double ST_DistanceWGS84(st_geometry geometry1, st_geometry geometry2)
```

Description: This function returns the approximate geodesic distance of the input geometry based on World Geodetic System 1984 (WGS84). This function converts the coordinates of the input geometry from EPSG:4326 to EPSG:3857. Then, it calculates the plane distance in meters.

Example:

```
SELECT ST_DistanceWGS84(ST_GeomFromText('POINT(-72.1235 42.3521)'), ST_GeomFromText('LINESTRING(-72.1260 42.45, -72.123 42.1546)'));
```

1.6.12.8.3. ST_BufferWGS84

Function declaration:

```
st_geometry ST_BufferWGS84(st_geometry geometry, double radius)
```

Description: This function returns the approximate geodesic buffer of the input geometry based on World Geodetic System 1984 (WGS84). This function converts the coordinates of the input geometry from EPSG:4326 to EPSG:3857. Then, it calculates the plane buffer and converts the coordinates back to EPSG:4326.

Example:

```
SELECT ST_AsText(ST_BufferWGS84(ST_GeomFromText('POINT(-72.1235 42.3521)'), 10));
```

1.6.12.8.4. ST_GeodesicDistance

Function declaration:

```
double ST_GeodesicDistance(double lon1, double lat1, double lon2, double lat2, string method = VINCE
NTY)
double ST_GeodesicDistance(st_geometry geo1, st_geometry geo2, string method = VINCENTY)
```

Description: This function calculates the geodesic distance between two points by using the specified method. The supported methods are Vincenty, LawOfCosines, and Haversine. The default value of the method parameter is VINCENTY. The return value is in radians.

Example:

```
SELECT ST_GeodesicDistance(ST_GeomFromText('POINT(152.352298 -24.875975)'), ST_GeomFromText('P
OINT(151.960336 -24.993289)'), 'LawOfCosines');
```

1.6.12.8.5. ST_Distance_Sphere

Function declaration:

```
double ST_Distance_Sphere(st_point geo1, st_point2 geo2)
double ST_Distance_Sphere(double lng1, double lat1, double lng2, double lat2)
```

Description: This function uses the algorithm provided by AMAP to calculate the approximate geodesic distance between the two input points. This function uses ST_Point or the specified longitudes and latitudes as input parameters.

Example:

```
SELECT ST_Distance_Sphere(
        ST_GeomFromText('POINT(116.292078 39.919622)'),
        ST_GeomFromText('POINT(116.286676 39.919593)'));
+------------+
| _c0      |
+------------+
| 460.6965312526471 |
+------------+
```

1.6.12.8.6. ST_Area_Sphere

Function declaration:

```
double ST_Area_Sphere(st_geometry geo)
```

Description: This function uses the algorithm provided by AMAP to calculate the geodesic area of the input geometry. This function uses only ST_Polygon and ST_MultiPolygon as input parameters.

Example:

```
SELECT geospatial.ST_Area_Sphere(geospatial.ST_GeomFromText('POLYGON((116.259097 40.202114,11
6.259024 40.20199,116.258768 40.201662,116.258376 40.201341,116.258031 40.201036,116.257675 40.200734

1.6.12.9. R-tree index functions

1.6.12.9.1. ST_BuildRTreeIndex

Function declaration:

```
RTree ST_BuildRTreeIndex(string uniqueId, string geometryWkt)
```

Description: This function is a user-defined table-valued function (UDAF). It uses the unique ID and well-known text (WKT) string of each geometry as input parameters to create the R-tree index. This function must be used with other R-tree functions.

Example:

```
SELECT geospatial.ST_BuildRTreeIndex(id, shape) AS index FROM poi_sample;
```

1.6.12.9.2. ST_ContainsFromRTree

Function declaration:

```
ST_ContainsFromRTree(string uniqueId, string geometryWkt, RTree rtree)
```

Description: This function is a user-defined table-valued function (UDTF). It uses the unique ID and well-known text (WKT) string of each geometry and the R-tree index that is created by calling ST_BuildRTreeIndex as input parameters. This function returns the IDs of objects that are contained by the geometry from the R-tree index. This function is used to accelerate the ST_Contains query.

1.6.12.9.3. ST_CrossesFromRTree

Function declaration:

```
ST_CrossesFromRTree(string uniqueId, string geometryWkt, RTree rtree)
```

Description: This function is a user-defined table-valued function (UDTF). It uses the unique ID and well-known text (WKT) string of each geometry and the R-tree index that is created by calling ST_BuildRTreeIndex as input parameters. This function returns the IDs of objects that cross the geometry from the R-tree index. This function is used to accelerate the ST_Crosses query.

1.6.12.9.4. ST_EqualsFromRTree

Function declaration:

```
ST_EqualsFromRTree(string uniqueId, string geometryWkt, RTree rtree)
```

Description: This function is a user-defined table-valued function (UDTF). It uses the unique ID and well-known text (WKT) string of each geometry and the R-tree index that is created by calling ST_BuildRTreeIndex as input parameters. This function returns the IDs of objects that equal the geometry from the R-tree index. This function is used to accelerate the ST_Equals query.

1.6.12.9.5. ST_IntersectsFromRTree

Function declaration:

```
ST_IntersectsFromRTree(string uniqueId, string geometryWkt, RTree rtree)
```

Description: This function is a user-defined table-valued function (UDTF). It uses the unique ID and well-known text (WKT) string of each geometry and the R-tree index that is created by calling ST_BuildRTreeIndex as input parameters. This function returns the IDs of objects that intersect with the geometry from the R-tree index. This function is used to accelerate the ST_Intersects query.

1.6.12.9.6. ST_OverlapsFromRTree

Function declaration:

```
ST_OverlapsFromRTree(string uniqueId, string geometryWkt, RTree rtree)
```

Description: This function is a user-defined table-valued function (UDTF). It uses the unique ID and well-known text (WKT) string of each geometry and the R-tree index that is created by calling ST_BuildRTreeIndex as input parameters. This function returns the IDs of objects that overlap with the geometry from the R-tree index. This function is used to accelerate ST_Overlaps query.

1.6.12.9.7. ST_TouchesFromRTree

Function declaration:

```
ST_TouchesFromRTree(string uniqueId, string geometryWkt, RTree rtree)
```

Description: This function is a user-defined table-valued function (UDTF). It uses the unique ID and well-known text (WKT) string of each geometry and the R-tree index that is created by calling ST_BuildRTreeIndex as input parameters. This function returns the IDs of objects that spatially touch the geometry from the R-tree index. This function is used to accelerate the ST_Touches query.

1.6.12.9.8. ST_WithinFromRTree

Function declaration:

```
ST_WithinFromRTree(string uniqueId, string geometryWkt, RTree rtree)
```

Description: This function is a user-defined table-valued function (UDTF). It uses the unique ID and well-known text (WKT) string of each geometry and the R-tree index that is created by calling ST_BuildRTreeIndex as input parameters. This function returns the IDs of objects that include the geometry from the R-tree index. This function is used to accelerate the ST_Within query.

1.6.12.9.9. ST_KNNFromRTree

Function declaration:

```
ST_KNNFromRTree(string uniqueId, string geometryWkt, int k, RTree rtree)
```

Description: This function is a user-defined table-valued function (UDTF). It uses the unique ID and well-known text (WKT) string of each geometry and the R-tree index that is created by calling ST_BuildRTreeIndex as input parameters. This function returns the IDs of k objects that are near to the geometry from the R-tree index.

1.6.12.9.10. Example

This topic provides examples on how to use R-tree index functions.

Example 1

```
-- Query the intersections of line segments in the A table and polygons in the B table.
set odps.sql.allow.cartesian=true;
SELECT a.id as link_id, b.id as shape_id
FROM link_sample_wkt a, poi_sample_wkt b
WHERE geospatial.ST_IsValid(b.shape)
AND geospatial.ST_Intersects(
    geospatial.ST_LineString(a.line),
    geospatial.ST_Multipolygon(b.shape));
Summary:
resource cost: cpu 3.28 Core * Min, memory 5.76 GB * Min
inputs:
  meta_dev.poi_sample_wkt: 1000 (237592 bytes)
  meta_dev.link_sample_wkt: 1000 (105940 bytes)
```

```
outputs:
Job run time: 111.000
+---------+----------+
| link_id | shape_id |
+---------+----------+
| 5121371185457659960 | B000A844XK |
| 5121377123249946651 | B000A85TV4 |
| 5121377166199619654 | B000A844KT |
+---------+----------+
-- After optimization by using the new function:
SELECT /*+mapjoin(i)*/
    geospatial.ST_IntersectsFromRTree(id, line, i.index)
    AS (link_id, shape_id)
FROM link_sample_wkt
JOIN
(
    SELECT geospatial.ST_BuildRTreeIndex(id, shape) AS index
    FROM poi_sample_wkt
    WHERE geospatial.ST_IsValid(shape)
) i;
Summary:
resource cost: cpu 1.03 Core * Min, memory 1.99 GB * Min
inputs:
  meta_dev.poi_sample_wkt: 1000 (237592 bytes)
  meta_dev.link_sample_wkt: 1000 (105940 bytes)
outputs:
Job run time: 41.000
+---------+----------+
| link_id | shape_id |
+---------+----------+
| 5121371185457659960 | B000A844XK |
| 5121377123249946651 | B000A85TV4 |
| 5121377166199619654 | B000A844KT |
+---------+----------+
```

Example 2

```
-- Create an R-tree for all points in a table and use the KNN function to locate the nearest point of eac
h point.
SELECT /*+mapjoin(i)*/
   geospatial.ST_KNNFromRTree(id, point, 1, i.index) AS (id1, id2)
FROM poi_sample_wkt
JOIN
(
   SELECT geospatial.ST_BuildRTreeIndex(id, point) AS index
   FROM poi_sample_wkt
) i;
Summary:
resource cost: cpu 1.17 Core * Min, memory 2.24 GB * Min
inputs:
  meta_dev.poi_sample_wkt: 1000 (237592 bytes)
outputs:
Job run time: 46.000
+-----+-----+
| id1 | id2 |
+-----+-----+
| B000A01B4E | B000A01B4E |
| B000A01C19 | B000A01C19 |
| B000A023A5 | B000A023A5 |
| B000A02F81 | B000A02F81 |
| B000A07BEE | B000A07BEE |
| B000A07E06 | B000A07E06 |
| B000A08863 | B000A08863 |
...
-- The table has 1,000 rows of data. This function returns 1,000 rows of data, which meets your expect
ations.
```

1.6.12.10. Other functions

1.6.12.10.1. ST_IsValid

Function declaration:

```
boolean ST_IsValid(st_geometry geometry)
boolean ST_IsValid(string wkt)
```

Description: This function checks whether the input geometry or well-known text (WKT) string meets the requirements.

Example:

```
SELECT ST_IsValid('POINT(-102.849854 36.451113)');
SELECT ST_IsValid(ST_Point('POINT(-102.849854 36.451113)'));
```

1.6.12.10.2. ST_Transform

Function declaration:

```
st_geometry ST_TransformWGS84(st_geometry geometry)
st_geometry ST_Transform(st_geometry geometry, integer toSRID)
st_geometry ST_Transform(st_geometry geometry, integer fromSRID, integer toSRID)
```

Description: This function converts the coordinates of the input geometry from one spatial reference system to another. The ST_TransformWGS84 function converts the coordinates of the geometry from EPSG:4326 to EPSG:3857. The ST_Transform function converts the geometry from fromSRID to toSRID. If the overload function contains only toSRID, you must call the ST_SetSRID function first.

Example:

```
SELECT ST_AsText(ST_Transform(ST_GeomFromText('POLYGON((743238 2967416,743238 2967450, 74326
5 2967450,743265.625 2967416,743238 2967416))', 2249, 4326));
SELECT ST_AsText(ST_TransformWGS84(ST_GeomFromText('POLYGON((-71.1776848522251 42.39028965
12902,-71.1776843766326 42.3903829478009, -71.1775844305465 42.3903826677917,-71.1775825927231 42.
3902893647987,-71.1776848522251 42.3902896512902))')));
```

1.6.13. SQL Function

User-defined functions (UDFs) in MaxCompute support Java or Python. Some UDFs can be directly implemented by SQL. Therefore, MaxCompute supports SQL functions. This improves the reuse rate of SQL code.

Use SQL functions

Example:

```
FUNCTION ADD(@a BIGINT) AS @a + 1;
SELECT ADD(key), ADD(value) FROM src;
```

Functions as input parameters

Functions can be used as input parameters for SQL functions, including built-in functions, UDFs, and SQL functions.

Example:

```
FUNCTION ADD(@a BIGINT) AS  @a + 1;
FUNCTION OP(@a,  @fun FUNCTION (BIGINT) RETURNS BIGINT) AS  @ fun(@a);
SELECT OP(key, ADD), OP(key, abs) FROM src;
```

Anonymous functions as input parameters

Anonymous functions can be used as input parameters for SQL functions.

Example:

```
FUNCTION OP(@a,  @fun FUNCTION (BIGINT) RETURNS BIGINT) AS   @ fun(@a);
SELECT OP(key, FUNCTION (@a) AS  @a + 1) FROM src;
```

1.6.14. CLONE TABLE

MaxCompute supports the CLONE TABLE statement. You can execute this statement to clone data from one table to another.

Syntax

```
CLONE TABLE <[src_project_name.]src_table_name> [PARTITION(spec), ...]  TO <[dest_project_name.]de
sc_table_name> [IF EXISTS (OVERWRITE | IGNORE)] ;
```

> **Note**
>
> - If the destination table is not created before data is cloned, a table is created by using the CREATE TABLE LIKE statement when you execute the CLONE TABLE statement.
> - If the destination table is created before data is cloned and IF EXISTS OVERWRITE is specified, data in the specified partitions of the destination table is overwritten.
> - If the destination table is created before data is cloned and IF EXISTS IGNORE is specified, existing partitions in the destination table are skipped and data in these partitions is not overwritten.

Limits and troubleshooting

- The schema of a destination table must be compatible with that of the source table.
- The CLONE TABLE statement supports both partitioned and non-partitioned tables. Tables that have special data organization structures are not supported. These tables include clustered tables, shard tables, Xlib or Algo tables, and tables with extreme storage.
- Make sure that the configuration of the cluster for the source table intersects with that for the destination table and the data that you want to process is in the same cluster. If any of the conditions is not met, an error is returned.
- If the destination table already exists before data is cloned, you can clone data from a maximum of 10,000 partitions at a time.
- If the destination table does not exist before data is cloned, the number of partitions that you can clone at a time is not limited, which ensures atomicity.

- If a hard link in the Apsara Distributed File System is faulty, purge the recycle bin and try again.
- The user who submits the command must have the Create Table and Update Table permissions on the target project.

Example

The following code shows the partitions and data of the source tables:

```
odps@ multi>read srcpart_copy;
+------------+------------+------------+------------+
| key      | value     | ds        | hr        |
+------------+------------+------------+------------+
| 1        | ok49      | 2008-04-09 | 11        |
| 1        | ok48      | 2008-04-08 | 12        |
+------------+------------+------------+------------+
odps@ multi>read src_copy;
+------------+------------+
| key      | value     |
+------------+------------+
| 1        | ok        |
+------------+------------+
```

Clone all data from the non-partitioned table.

```
clone table src_copy to src_clone;
odps@ multi>clone table src_copy to src_clone;
ID = 20191023030245544g2540cdv2
OK
odps@ multi>read src_clone;
+------------+------------+
| key      | value     |
+------------+------------+
| 1        | ok        |
+------------+------------+
```

Clone some partitions of the partitioned table.

```
clone table srcpart_copy partition(ds="2008-04-09", hr='11') to srcpart_clone IF EXISTS OVERWRITE;
odps@ multi>clone table srcpart_copy partition(ds="2008-04-09", hr='11') to srcpart_clone IF EXISTS OV
ERWRITE;
ID = 20191023030534986g4540cdv2
OK
odps@ multi>read srcpart_clone;
+------------+------------+------------+------------+
| key      | value     | ds       | hr       |
+------------+------------+------------+------------+
| 1        | ok49      | 2008-04-09 | 11       |
+------------+------------+------------+------------+
```

Clone data from the partitioned table and skip existing partitions in the destination table.

```
clone table srcpart_copy to srcpart_clone IF EXISTS IGNORE;
odps@ multi>clone table srcpart_copy to srcpart_clone IF EXISTS IGNORE;
ID = 20191023030619196g5540cdv2
OK
odps@ multi>read srcpart_clone;
+------------+------------+------------+------------+
| key      | value     | ds       | hr       |
+------------+------------+------------+------------+
| 1        | ok49      | 2008-04-09 | 11       |
| 1        | ok48      | 2008-04-08 | 12       |
+------------+------------+------------+------------+
```

Clone all data from the partitioned table.

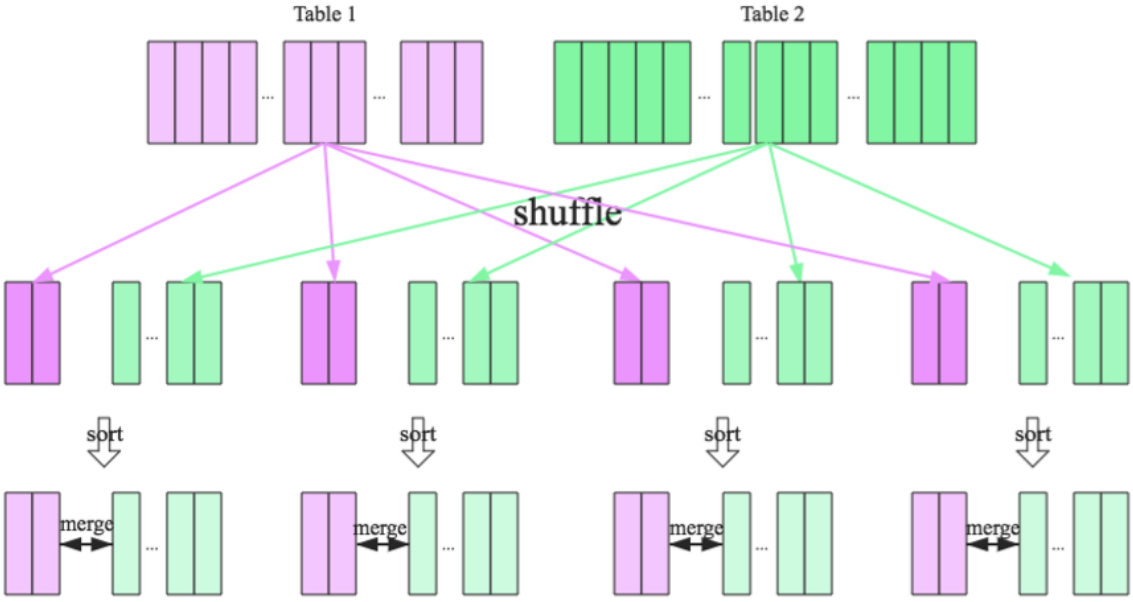
```
clone table srcpart_copy to srcpart_clone2;
odps@ multi>clone table srcpart_copy to srcpart_clone2;
ID = 20191023030825186g6540cdv2
OK
odps@ multi>read srcpart_clone2;
+------------+------------+------------+------------+
| key      | value     | ds       | hr       |
+------------+------------+------------+------------+
| 1        | ok49      | 2008-04-09 | 11       |
| 1        | ok48      | 2008-04-08 | 12       |
+------------+------------+------------+------------+
```

1.6.15. MaxCompute Hash Clustering

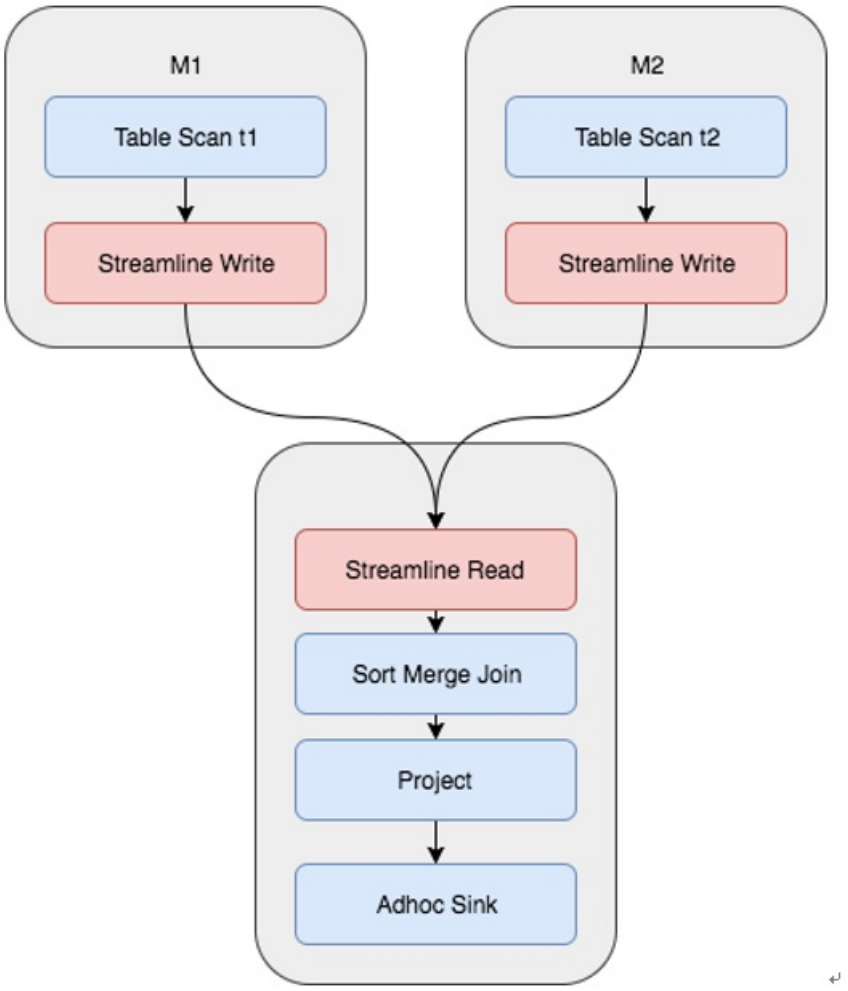
1.6.15.1. Background information

JOIN operations are commonly used for queries in MaxCompute. MaxCompute provides the following implementation methods of JOIN operations:

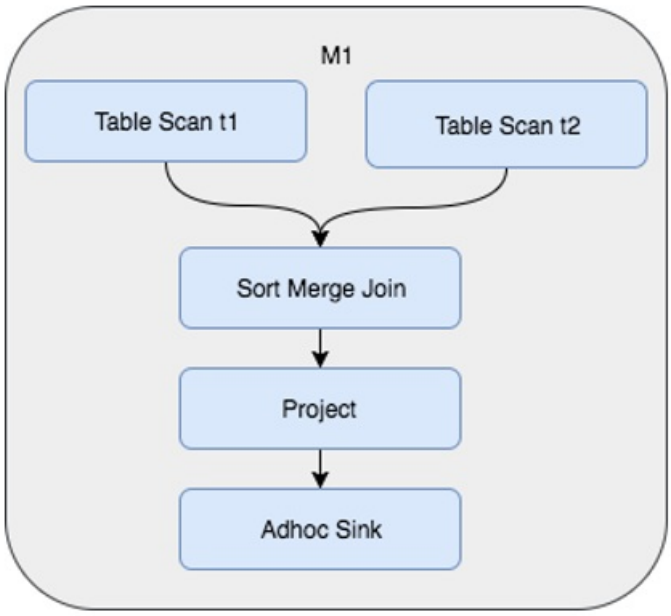
1. **Broadcast hash join**: This method is used when a JOIN operation involves a small table. The small table is broadcasted and transferred to all JoinTask instances. Then, the hash join operation is performed to join the small table with a large table.
2. **Shuffle hash join**: This method is used when a JOIN operation involves large tables that cannot be broadcasted directly. In this case, the hash shuffle operation is performed on two tables based on join keys. The hash results for the same key-value pairs are the same. This ensures that results that have the same key are collected on a JoinTask instance. For each instance, a hash table is created by using a small table, probe operations are performed by using a large table, and then the tables are joined.
3. **Sort merge join**: This method is used when a JOIN operation involves larger tables and the preceding methods cannot be used because the memory is insufficient to create a hash table. In this case, the hash shuffle operation is performed on two tables based on join keys, the obtained values are sorted by using join keys, and then the sorted values are merged.



The **sort merge join** operation is commonly used in MaxCompute because MaxCompute processes huge volumes of data in most cases. This operation generates repeated shuffle and join operations. The physical execution plan of Job Scheduler of the JOIN operation also requires multiple stages, which consumes excessive volumes of resources.



Therefore, MaxCompute allows you to configure the hash shuffle and sort attributes when the data is initially generated in a table. This prevents data from being shuffled and sorted repeatedly in subsequent queries. As a result, the number of stages in the physical execution plan of Job Scheduler of a JOIN operation is reduced. The preceding figure shows that only one stage is required.



MaxCompute Hash Clustering allows you to configure the shuffle and sort attributes of a table when you create the table. As a result, MaxCompute optimizes the execution plan, improves the efficiency, and saves resources based on the existing storage characteristics.

1.6.15.2. Descriptions

1.6.15.2.1. Enable or disable Hash Clustering

The Hash Clustering feature is available and enabled by default. If you want to use clustered indexes, add the following flag:

```
set odps.sql.cfile2.enable.read.write.index.flag=true;
```

After the flag is set to true, the system automatically creates indexes for the sorted hash buckets to improve query efficiency. To use clustered indexes, you must add this flag during table creation and subsequent queries. If you want to use clustered indexes in your project all the time, contact the MaxCompute team.

> **Note** Clustered indexes improve the efficiency of queries (equivalent values or ranges) based on sort keys. However, you can still experience the superior performance provided by Hash Clustering although you do not add this flag.

1.6.15.2.2. Create a hash clustering table

You can use the following statement to create a hash clustering table. You must specify cluster keys or hash keys and the number of hash buckets. The sort operation is optional. However, we recommend that you use the same parameter values as the cluster keys to achieve optimal performance.

```
CREATE TABLE [IF NOT EXISTS] table_name
  [(col_name data_type [comment col_comment], ...)]
  [comment table_comment]
  [PARTITIONED BY (col_name data_type [comment col_comment], ...)]
[CLUSTERED BY (col_name [, col_name, ...]) [SORTED BY (col_name [ASC | DESC] [, col_name [ASC | DESC] ...])] INTO number_of_buckets BUCKETS]
[AS select_statement]
```

You can use the following statement to create a standard table:

```
CREATE TABLE T1 (a string, b string, c bigint) CLUSTERED BY (c) SORTED by (c) INTO 1024 BUCKETS;
```

You can use the following statement to create a partitioned table:

```
CREATE TABLE T1 (a string, b string, c bigint) PARTITIONED BY (dt string) CLUSTERED BY (c) SORTED by (c) INTO 1024 BUCKETS;
```

The following sections detail the CLUSTERED BY, SORTED BY, and INTO number_of_buckets BUCKETS clauses.

CLUSTERED BY

The **CLUSTERED BY** clause specifies hash keys. MaxCompute performs the hash operation on the specified column and distributes data to buckets based on the hash values. To prevent data skew and hot spots, and to concurrently execute statements, we recommend that you specify a column that has large value ranges and a small number of duplicate key-value pairs in CLUSTERED BY. In addition, to optimize the JOIN operation, we recommend that you select commonly used join or aggregation keys. The join and aggregation keys are similar to the primary keys in conventional databases.

SORTED BY

The **SORTED BY** clause specifies how fields are sorted in a bucket. We recommend that you specify the same column in SORTED BY as that in CLUSTERED BY to improve execution efficiency. After you specify the column in SORTED BY, MaxCompute automatically generates indexes and then executes SQL statements faster when you query data based on these indexes.

INTO number_of_buckets BUCKETS

The **INTO number_of_buckets BUCKETS** clause specifies the number of hash buckets, which is required. The number of hash buckets is determined by the volume of data. More buckets indicate higher concurrency, which shortens the job running time. However, if too many buckets exist, excessive small files may be generated. In addition, high concurrency increases CPU time. We recommend that you set the volume of data for each bucket to a value that ranges from 500 MB to 1 GB. If a large table is used, you can adjust the value to a larger value as required.

You can remove the shuffle operation only for tables with the same number of buckets in MaxCompute. In later versions, MaxCompute will support bucket alignment. You will be able to remove the shuffle operation for tables whose numbers of buckets are multiples or factors of each other. To achieve bucket alignment, we recommend that you set the number of buckets to a power of 2, for example, 512, 1,024, and 2,048. The maximum number of buckets is 4,096. If the number of buckets exceeds the value, the performance and resource usage may be affected.

If you want to remove the shuffle and sort operations during a JOIN operation on two tables, the numbers of hash buckets in the tables must be the same. If the numbers that are calculated based on the aforementioned method are inconsistent, we recommend that you use the larger number for the JOIN operation. This guarantees that SQL statements can be executed concurrently in an efficient manner.

If the sizes of two tables greatly differ, you can set the number of buckets for the large table to several times of that for the small table, for example, 256 and 1,024. If automatic hash bucket split and merging are supported, the settings can be optimized by using data features.

1.6.15.2.3. Modify table attributes

For a partitioned table, MaxCompute allows you to execute the ALTER TABLE statement to add the Hash Clustering attribute to a table or remove the Hash Clustering attribute from a table.

```
ALTER TABLE table_name
  [CLUSTERED BY (col_name [, col_name, ...]) [SORTED BY (col_name [ASC | DESC] [, col_name [ASC | DES
C] ...])] INTO number_of_buckets BUCKETS]
ALTER TABLE table_name NOT CLUSTERED;
```

Note the following points when you use the ALTER TABLE statement:

- The ALTER TABLE statement can only modify the Hash Clustering attribute of a partitioned table. The Hash Clustering attribute cannot be modified after it is added to a non-partitioned table.
- The ALTER TABLE statement takes effect only for the new partitions of a table, which include the partitions generated by using the INSERT OVERWRITE statement. New partitions are stored based on the Hash Clustering attribute. The storage formats of existing partitions remain unchanged.
- The ALTER TABLE statement takes effect only for the new partitions of a table. Therefore, you cannot specify a partition in this statement.

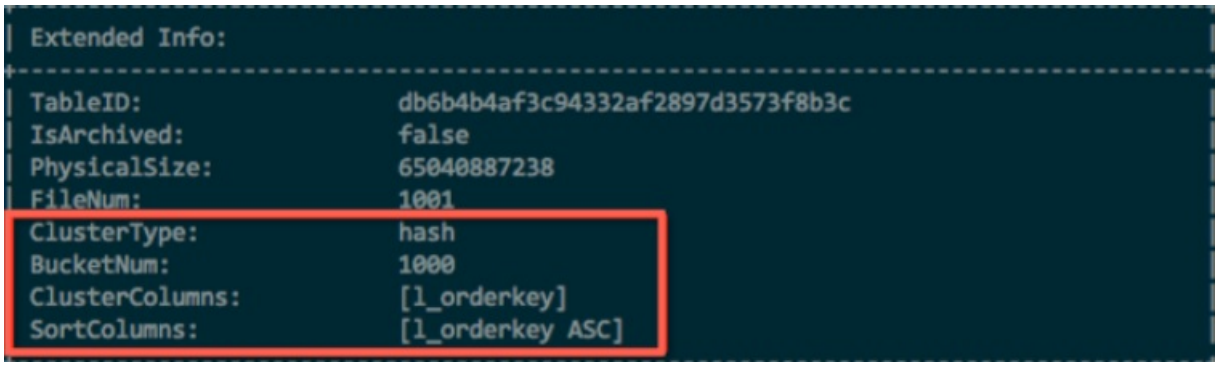
The ALTER TABLE statement is suitable for existing tables. After the Hash Clustering attribute is added, new partitions are stored based on the Hash Clustering attribute.

1.6.15.2.4. View and verify table attributes

After you create a hash clustering table, execute the following statement to view table attributes:

```
DESC EXTENDED table_name;
```

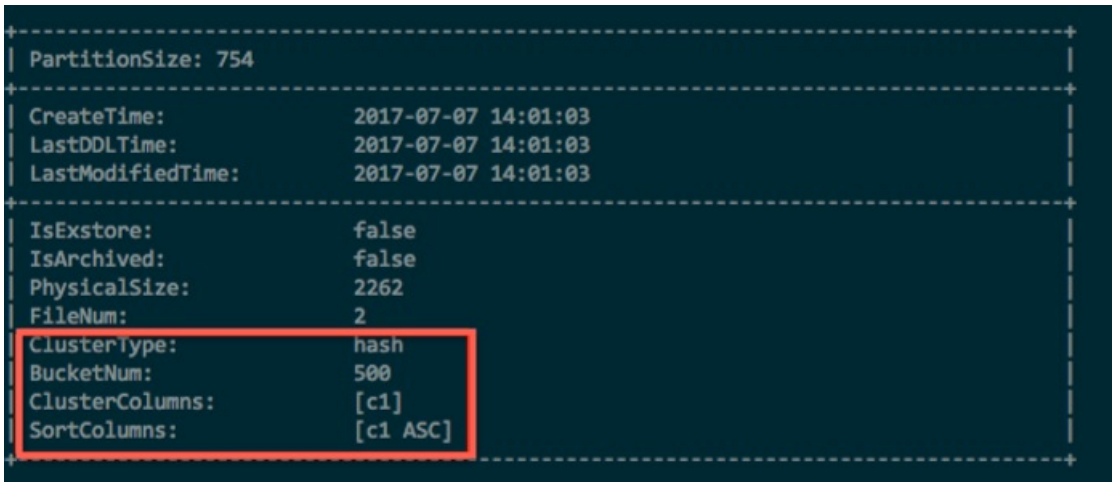
The Hash Clustering attribute is displayed in Extended Info.



You can also execute the following statement to view partition attributes of a partitioned table:

```
DESC EXTENDED table_name partition(pt_spec);
```

The following figure shows the execution result.



1.6.15.3. Benefits

1.6.15.3.1. Bucket pruning and index optimization

The following code provides a syntax sample:

```
CREATE TABLE t1 (id bigint, a string, b string) CLUSTERED BY (id) SORTED BY (id) into 1000 BUCKETS;
...
SELECT t1.a, t1.b, t1.c FROM t1 WHERE t1.id=12345;
```

This syntax indicates a full scan for a standard table. A full scan for a large table consumes a large number of resources. However, if the hash shuffle operation is performed on all id fields and the id fields are sorted, the query is greatly simplified. The sample procedure is as follows:

1. Find the hash bucket that corresponds to 12345. This query is performed in only one bucket, not all 1,000 buckets. This process is called bucket pruning.
2. Data in a bucket is stored based on IDs. MaxCompute automatically creates indexes and uses the INDEX LOOKUP function to locate relevant records.

The simplified procedure not only greatly reduces the number of mappers, but also allows mappers to locate the page where the data is stored by using the INDEX function. Therefore, the volume of loaded data is greatly reduced.

1.6.15.3.2. Aggregation optimization

The following code provides a syntax sample:

```
SELECT department, SUM(salary) FROM employee GROUP BY (department);
```

In most cases, the department column is shuffled and sorted. Then, a stream aggregate operation is performed to collect statistics on the department groups. However, if `CLUSTERED BY (department) SORTED BY (department)` is executed for the table data, the shuffle and sort operations are no longer required.

1.6.15.3.3. Storage optimization

In addition to computation optimization, storage space is greatly saved if tables are shuffled and stored in a sorted manner. MaxCompute uses the column store at the underlying layer. Records with the same or similar key-value pairs are stored together by the sort function, which facilitates encoding and compression. As a result, compression efficiency is improved. In some cases, a sorted table can save 50% more storage space than an unsorted table. Therefore, Hash Clustering is suitable for the storage of tables that have long lifecycles.

For example, take a table with 100 GB of TPC-H line items and multiple data types, such as INT, DOUBLE, and STRING. When Hash Clustering is used, about 10% of the storage space is saved while the volume of data and compression format remain unchanged.

1.6.15.4. ShuffleRemove

- Range clustering tables support the join and aggregate operations. If a join or group key is a range clustering key or its prefix, data redistribution is not required. This mechanism is called ShuffleRemove, which improves execution efficiency.

  Usage: The `odps.optimizer.enable.range.partial.repartitioning` flag controls whether to enable this feature. This feature is disabled by default.

- If you join two hash clustering tables and the numbers of buckets in these tables are different but are multiples or factors of each other, data redistribution is not required. This improves execution efficiency.

  Usage: The `odps.optimizer.enable.hash.partial.repartitioning` flag controls whether to enable this feature. This feature is enabled by default.

- Correlated Shuffle Remove is supported. If data meets distribution requirements but does not meet the sorting requirements, you can add a sort operator to avoid data redistribution.

1.6.15.5. Limits

The limits of Hash Clustering are described as follows:

- The INSERT INTO statement is not supported. You can only execute the INSERT OVERWRITE statement to import data.
- Small files cannot be merged. Data is evenly distributed in buckets when it is split, so no small files are generated. If you merge files, the data distribution is affected. However, you can still use the merge and archive commands to change the storage format of a table file and the format of a RAID file.
- You cannot use Tunnel to upload data to a range-clustered table because data uploaded by using Tunnel is unsorted.

In the future, these limits will be resolved. Stay tuned for updates on the official website.

1.6.16. MaxCompute SQL limits

The following table lists all the limits of MaxCompute SQL statements.

Limits

Item	Maximum value/Limit	Category	Description
Table name length	128 bytes	Length	A table name or column name cannot contain special characters. It can contain only lowercase and uppercase letters, digits, and underscores (_) and must start with a letter.
Comment length	1,024 bytes	Length	A comment can be up to 1,024 bytes in length.
Column definitions in a table	1,200	Quantity	A table can contain a maximum of 1,200 column definitions.

Item	Maximum value/Limit	Category	Description
Partitions in a table	60,000	Quantity	A table can contain a maximum of 60,000 partitions.
Partition levels of a table	6	Quantity	A table can contain a maximum of six levels of partitions.
Statistical definitions of a table	100	Quantity	A table can contain a maximum of 100 statistical definitions.
Statistical definition length of a table	64,000	Length	The length of statistical definitions in a table cannot exceed 64,000.
Screen display	10,000 rows	Quantity	A SELECT statement can generate a maximum of 10,000 rows.
INSERT targets	256	Quantity	A MULTIINS operation can insert a maximum of 256 data tables at a time.
UNION ALL	256 tables	Quantity	A UNION ALL operation can be performed on a maximum of 256 tables.
JOIN sources	128	Quantity	The JOIN operation can be performed on a maximum of 128 source tables.
MAPJOIN memory	512 MB	Quantity	The memory size for all small tables on which the MAPJOIN operation is performed cannot exceed 512 MB.
Window functions	5	Quantity	A SELECT statement can contain a maximum of five window functions.
PTINSUBQ	1,000 rows	Quantity	A PT IN SUBQUERY statement can generate a maximum of 1,000 rows.
Length of an SQL statement	2 MB	Length	The maximum length of an SQL statement is 2 MB.
Conditions of a WHERE clause	256	Quantity	A WHERE clause can contain a maximum of 256 conditions.
Length of a column record	8 MB	Length	The maximum length of a column record in a table is 8 MB.
IN parameters	1,024	Quantity	This item specifies the maximum number of parameters in an IN clause, such as in(1,2,3,...,1024). Excess parameters can slow down the compilation process. We recommend that you use no more than 1,024 parameters, but this is not a fixed upper limit.

Item	Maximum value/Limit	Category	Description
jobconf.json	1 MB	Length	The maximum size of the jobconf.json file is 1 MB. If a table contains a large number of partitions, the size of jobconf.json may exceed 1 MB.
View	Not writable	Operation	A view is not writable and does not support the INSERT operation.
Data type and position of a column	Unmodifiable	Operation	The data type and position of a column are unmodifiable.
Java UDFs	Cannot be abstract or static	Operation	Java UDFs cannot be abstract or static.
Partitions to query	10,000	Quantity	A maximum of 10,000 partitions can be queried.

Notice The preceding MaxCompute SQL limits cannot be modified manually.

1.6.17. Common MaxCompute SQL parameter settings

1.6.17.1. MAP configurations

```
set odps.sql.mapper.cpu=100
```

Purpose: It is used to set the number of CPUs for each instance in a Map task. Default value: 100. Value range: 50 to 800.

```
set odps.sql.mapper.memory=1024
```

Purpose: It is used to set the memory size for each instance in a Map task. Default value: 1024 MB. Value range: 256 MB to 12,288 MB.

```
set odps.sql.mapper.merge.limit.size=64
```

Purpose: It is used to set the maximum size of control files to be merged. Default value: 64 MB. You can set this variable to control the inputs of mappers. Value range: 0 to Integer.MAX_VALUE.

```
set odps.sql.mapper.split.size=256
```

Purpose: It is used to set the maximum data input volume for a map. Default value: 256 MB. You can set this variable to control the inputs of mappers. Value range: 1 to Integer.MAX_VALUE.

1.6.17.2. JOIN configurations

```
set odps.sql.joiner.instances=-1
```

Purpose: It is used to set the number of instances in a JOIN task. Default value: 1. Value range: 0 to 2,000.

```
set odps.sql.joiner.cpu=100
```

Purpose: It is used to set the number of CPUs for each instance in a JOIN task. Default value: 100. Value range: 50 to 800.

```
set odps.sql.joiner.memory=1024
```

Purpose: It is used to set the memory size for each instance in a JOIN task. Default value: 1,024 MB. Value range: 256 MB to 12,288 MB.

1.6.17.3. Reduce configurations

```
set odps.sql.reducer.instances=-1
```

Purpose: It is used to set the number of instances in a Reduce task. Default value: 1. Value range: 0 to 2,000.

```
set odps.sql.reducer.cpu=100
```

Purpose: It is used to set the number of CPUs for each instance in a Reduce task. Default value: 100. Value range: 50 to 800.

```
set odps.sql.reducer.memory=1024
```

Purpose: It is used to set the memory size for each instance in a Reduce task. Default value: 1,024 MB. Value range: 256 to 12,288 MB.

1.6.17.4. UDF configurations

```
set odps.sql.udf.jvm.memory=1024
```

Purpose: It is used to set the maximum memory size for a UDF JVM heap. Default value: 1,024 MB. Value range: 256 to 12,288 MB.

```
set odps.sql.udf.timeout=600
```

Purpose: It is used to set the timeout value of a UDF. Default value: 600 seconds. Value range: 0 to 3,600 seconds.

```
set odps.sql.udf.python.memory=256
```

Purpose: It is used to set the maximum memory size for UDF python. Default value: 256 MB. Value range: 64 to 3,072 MB.

```
set odps.sql.udf.optimize.reuse=true/false
```

Purpose: after start-up, each UDF function expression can only be calculated once, improving performance. The default is true.

```
set odps.sql.udf.strict.mode=false/true
```

Purpose: It is used to control functions regarding whether to return NULL or error if dirty data is encountered. If it is true, an error is returned. If it is false, NULL is returned.

1.6.17.5. MAPJOIN configurations

```
set odps.sql.mapjoin.memory.max=512
```

Purpose: It is used to set the maximum memory of a small table in MAPJOIN. Default vlaue 512 MB. Value range: 128 to 2,048 MB.

```
set odps.sql.reshuffle.dynamicpt=true/false
```

Purpose:

- Some scenarios of dynamic partitioning are time-consuming. Shutting them down can speed up SQL.
- If the dynamic partition value is very small, disabling dynamic partition can avoid data skew.

1.6.17.6. Configure data skew

```
set odps.sql.groupby.skewindata=true/false
```

Effect: enables the group by optimization.

```
set odps.sql.skewjoin=true/false
```

Effect: enables the join optimization. It takes effect only when odps.sql.skewinfo is configured.

```
set odps.sql.skewinfo
```

Purpose: It is used to set detailed information of join optimization. The command syntax is as follows:

```
set odps.sql.skewinfo=skewed_src:(skewed_key)[("skewed_value")]
```

Example:

The following command is used to set a single skewed data value in a single field:

```
set odps.sql.skewinfo=src_skewjoin1:(key)[("0")]
-- Command output: explain select a.key c1, a.value c2, b.key c3, b.value c4 from src a join src_skewjoin
1 b on a.key = b.key;
```

The following command is used to set multiple skewed data values in a single field:

```
set odps.sql.skewinfo=src_skewjoin1:(key)[("0")("1")]
-- Command output: explain select a.key c1, a.value c2, b.key c3, b.value c4 from src a join src_skewjoin
1 b on a.key = b.key;
```

1.6.18. MapReduce-to-SQL conversion for execution

1.6.18.1. Overview

MaxCompute provides a series of Java APIs for MapReduce to process data.

In the current version, MapReduce programs are automatically converted to SQL for execution. After the conversion, you can use the compiler, cost-based optimizer, and vectorized execution engine released with MaxCompute V2.0 to process the MapReduce programs. The new features of the SQL engine can also be used. The features, performance, and stability of the SQL engine are optimized.

Notice

- You do not need to change the original APIs and job logic.
- Only MapReduce jobs of the OpenMR type, which are written with MapReduce APIs, can be converted to SQL.
- This feature can be used for projects and jobs.
- This feature supports views as the input.
- This feature supports external tables as the input.
- This feature supports TemporaryFile reads and writes.
- This feature allows you to read data from and write data to hash clustering tables.
- This feature supports the near-real-time execution of small jobs.

1.6.18.2. Configure local running settings

1. Download the latest MaxCompute client package to your computer and properly configure the client.
2. Configure the execution mode.

   You can configure the execution mode based on your business requirements. The default execution mode is lot. In lot mode, jobs are executed by MapReduce. The new compiler, optimizer, and execution engine are not required.

   You can enable the execution mode by setting the *odps.mr.run.mode* parameter. Valid values: **lot, sql, and hybrid**.

   - Method 1: Enable the execution mode at the project level. When the execution mode is enabled, it affects all jobs. Therefore, the project administrator must apply for and enable the execution mode. Set the *odps.mr.run.mode* parameter to **hybrid** or **sql**. If SQL execution fails in hybrid mode, the job is executed by MapReduce. If SQL execution fails in sql mode, an error is returned.
   - Method 2: Enable the execution mode at the session level. This method is only valid for the current job. To enable the execution mode, use one of the following methods:
     - Add a set flag, such as `set odps.mr.run.mode=hybrid`, before JAR statements.
     - Configure the job parameters. Example:

     ```
     JobConf job = new JobConf();
     job.set("odps.mr.run.mode","hybrid")
     ```

   The execution mode can be enabled at the project level later by MaxCompute O&M personnel.

1.6.18.3. Operation settings in DataWorks

Jobs running in DataWorks are updated by the O&M personnel of MaxCompute and DataWorks. You do not need to update the client manually.

1. Enable the conversion for a single job.

   You can add the SET statement before a MapReduce job or configure the job parameter for it. These methods take effect at the session level and apply only to the current job.

   The following examples demonstrate how to use these methods:

   - Add the SET statement, such as `set odps.mr.run.mode=hybrid`.
   - Configure the job parameter as follows:

   ```
   JobConf job = new JobConf();
   job.set("odps.mr.run.mode","hybrid")
   ```

2. Enable the conversion at the project level by setting *odps.mr.run.mode* for a project.

1.6.18.4. View running details

You can use Logview and MaxCompute Studio to view MapReduce-to-SQL conversion results and running details of SQL jobs.

1. LogView XML.

   Open Logview and click the LOT node in the center of the page. The SQL jobs that are converted from MapReduce jobs are included in the XML information of the node. Example:

```
create temporary function mr2sql_mapper_152955927079392291755 as   'com.aliyun.odps.mapred.br
idge.LotMapperUDTF' using ;
create temporary function mr2sql_reducer_152955927079392291755 as 'com.aliyun.odps.mapred.bri
dge.LotReducerUDTF' using ;
 @sub_query_mapper :=
 SELECT k_id,v_gmt_create,v_gmt_modified,v_product_id,v_admin_seq,v_sku_attr,v_sku_price,v_sku
_stock,v_sku_code,v_sku_image,v_delivery_time,v_sku_bulk_order,v_sku_bulk_discount,v_sku_imag
e_version,v_currency_code
FROM(
SELECT mr2sql_mapper_152955927079392291755(id,gmt_create,gmt_modified,product_id,admin_seq
,sku_attr,sku_price,sku_stock,sku_code,sku_image,delivery_time,sku_bulk_order,sku_bulk_discoun
t,sku_image_version,currency_code ) as (k_id,v_gmt_create,v_gmt_modified,v_product_id,v_admin_
seq,v_sku_attr,v_sku_price,v_sku_stock,v_sku_code,v_sku_image,v_delivery_time,v_sku_bulk_order
,v_sku_bulk_discount,v_sku_image_version,v_currency_code)
FROM ae_antispam.product_sku_tt_inc
WHERE ds = "20180615"  AND hh = "21"
UNION ALL
SELECT mr2sql_mapper_152955927079392291755(id,gmt_create,gmt_modified,product_id,admin_seq
,sku_attr,sku_price,sku_stock,sku_code,sku_image,delivery_time,sku_bulk_order,sku_bulk_discoun
t,sku_image_version,currency_code ) as (k_id,v_gmt_create,v_gmt_modified,v_product_id,v_admin_
seq,v_sku_attr,v_sku_price,v_sku_stock,v_sku_code,v_sku_image,v_delivery_time,v_sku_bulk_order
,v_sku_bulk_discount,v_sku_image_version,v_currency_code)
FROM ae_antispam.product_sku
) open_mr_alias1
 DISTRIBUTE BY k_id SORT BY k_id ASC;
@sub_query_reducer :=
SELECT mr2sql_reducer_152955927079392291755(k_id,v_gmt_create,v_gmt_modified,v_product_id,v_
admin_seq,v_sku_attr,v_sku_price,v_sku_stock,v_sku_code,v_sku_image,v_delivery_time,v_sku_bul
k_order,v_sku_bulk_discount,v_sku_image_version,v_currency_code) as (id,gmt_create,gmt_modifi
ed,product_id,admin_seq,sku_attr,sku_price,sku_stock,sku_code,sku_image,delivery_time,sku_bulk
_order,sku_bulk_discount,sku_image_version,currency_code)
FROM @sub_query_mapper;
FROM @sub_query_reducer
INSERT OVERWRITE TABLE ae_antispam.product_sku
SELECT id,gmt_create,gmt_modified,product_id,admin_seq,sku_attr,sku_price,sku_stock,sku_code,s
ku_image,delivery_time,sku_bulk_order,sku_bulk_discount,sku_image_version,currency_code ;
```

2. LogView detail or summary.

   You can see that the new execution engine is used to execute jobs.

```
Job run mode: fuxi job
 Job run engine: execution engine
```

3. LogView detail or JSON summary.

   The JSON summary information in MapReduce only contains the input and output information of Map and Reduce. However, the JSON summary information in SQL allows you to view details about each stage of SQL execution, such as all execution parameters, logical execution plans, physical execution plans, and execution details. Example:

```
"midlots" :
[
"LogicalTableSink(table=[[odps_flighting.flt_20180621104445_step1_ad_quality_tech_qp_algo_antifake_wordbag_filter_bag_change_result_lv2_20, auctionid,word,match_word(3) {0, 1, 2}]])
OdpsLogicalProject(auctionid=[$0], word=[$1], match_word=[$2])
OdpsLogicalProject(auctionid=[$0], word=[$1], match_word=[$2])
OdpsLogicalProject(auctionid=[$0], word=[$1], match_word=[$2])
OdpsLogicalProject(auctionid=[$2], word=[$3], match_word=[$4])
OdpsLogicalTableFunctionScan(invocation=[[MR2SQL_MAPPER_152955294118813063732($0, $1)]()], rowType=[RecordType(VARCHAR(2147483647) item_id, VARCHAR(2147483647) text, VARCHAR(2147483647) __tf_0_0, VARCHAR(2147483647) __tf_0_1, VARCHAR(2147483647) __tf_0_2)])
OdpsLogicalTableScan(table=[[ad_quality_tech.qp_algo_antifake_wordbag_filter_bag_change_lv2_20, item_id,text(2) {0, 1}]])
]
```

1.6.18.5. Perform operations on the distributed file system

Procedure

1. Specify volume files.

   You can use either of the following methods to specify volume files:

   - Use a utility class to specify the input and output files:

     ```
     com.aliyun. ODPS .mapred.utils.InputUtils.addVolume( new VolumeInfo([project,]inVolume,inPartition, "inLabel"), new JobConf());
     com.aliyun. ODPS .mapred.utils.OutputUtils.addVolume( new VolumeInfo([project,]outVolume, outPartition, "outLabel"), new JobConf());
     ```

     In the preceding commands, project and label are optional, and the current project and default label are used by default. If multiple input and output files are used, labels are used to distinguish the files from each other. Authorization is required before you access the volume files of other projects.

   - Configure parameters to specify the volume and partition of the input and output files. If multiple input or output files are used, separate the parameters with commas (,).

```
set odps.sql.volume.input[/output].desc = [<project>.]<table>.<partition>[:<label>];
```

2. Call the following method by using a context object in the map and reduce steps to write data to the distributed file system or write data stream input and output files:

```
context.getOutputVolumeFileSystem();
```

1.6.19. Analysis of the mapping between SQL input and output fields

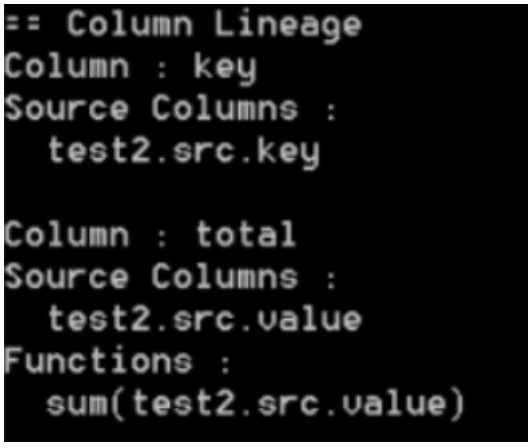
1.6.19.1. Features

MaxCompute SQL provides the feature of analyzing the mapping between SQL input and output fields.

This feature is to calculate the fields in the input and output tables based on field mapping. Example:

```
select key, sum(value) as total from  src group by key;
```

The following result is returned.



Two columns are returned: key and total. The key column corresponds to the src.key column of the input table. The total column corresponds to the src.value column of the input table.

1.6.19.2. Usage notes

This topic describes how to use the feature of analyzing the mapping between input and output fields.

Output format

Field mapping analysis supports human-readable and JSON formats. You can use the `set odps.sql.select.output.format=HumanReadable/json` flag to specify the output format.

SDK-based field mapping analysis

Examples

```
Odps odps = initOdps();
// To perform analysis, use LineageTask.
LineageTask task = new LineageTask("task_name", "select * from dual;");
// Optional. Use the preceding flag to specify the output format.
Map<String, String> settings = new LinkedHashMap<>();
settings.putIfAbsent("odps.sql.select.output.format", "json");
task.setProperty("settings", JSON.toJSONString(settings));
// Submit code to the server for field mapping analysis.
Instance instance = odps.instances().create(task);
System.out.println(instance.getId());
String logView = odps.logview().generateLogView(instance, 72);
System.out.println(logView);
instance.waitForSuccess();
// Obtain the analysis result.
System.out.println(instance.getTaskResults().get("task_name"));
```

odpscmd-based field mapping analysis

Examples

CLI mode: Use the -X parameter for field mapping analysis.

```
./bin/odpscmd.bat -X D:\lineage.q
```

Interactive mode: After you enter the interactive mode of odpscmd, you can use the preceding flag to specify the output format. The usage method is similar to that used to commit SQL jobs.

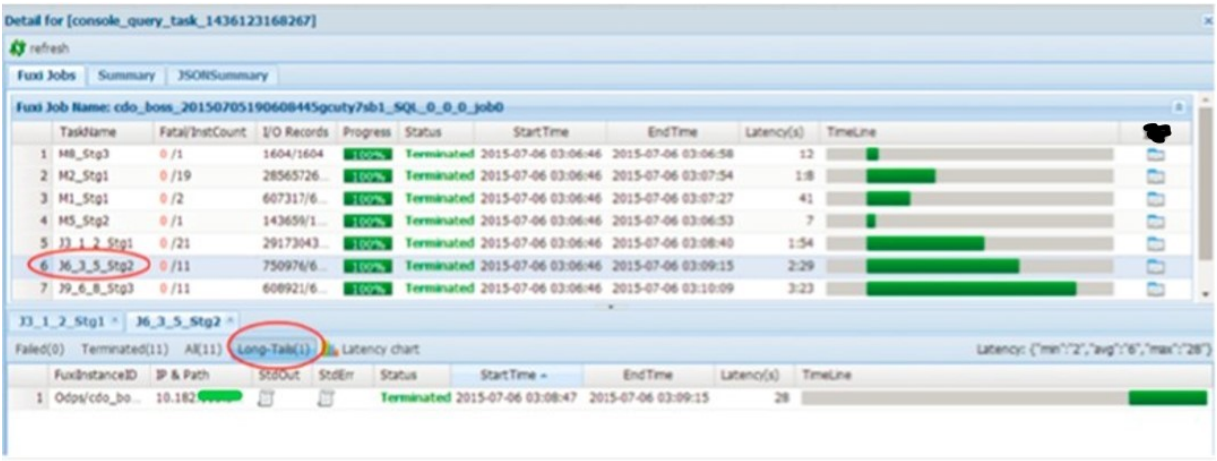
```
odps@ lineage_test>set odps.sql.task.mode=LINEAGE;
OK
odps@ lineage_test>set odps.sql.select.output.format=Humanreadable;
OK
odps@ lineage_test>select * from dual;
== Column Lineage
Column : id
Source Columns :
 test2.dual.id
```

1.6.20. Common MaxCompute SQL errors and solutions

1.6.20.1. Data skew

1.6.20.1.1. Overview

For a running job instance where the min, max, and avg values for the parameters time, input records, and output records are imbalanced (for example, max is much greater than avg), a data skew problem may have occurred. You can check the log view to locate the data skew problem, as shown in the following figure.



The Long Tails tab of each task shows the instance where the data skew occurred. The root cause of data skew is that the amounts of data processed by some instances are much higher than that processed by other instances, causing the running time of these instances to exceed the average time of other instances. As a result, the entire job slows down.

You can reduce the data skew of different SQL data types using different methods.

1.6.20.1.2. GROUP BY skew

Possible cause: The unbalanced distribution of GROUP BY keys causes data skew in the Reduce step.

Solution: Enable the group skew prevention parameter before running SQL statements:

```
set odps.sql.groupby.skewindata=true
```

> **Note** If this parameter is set to true, the system adds random factors to the shuffle hash algorithm and adds a new task to prevent data skew.

1.6.20.1.3. DISTRIBUTE BY skew

Possible cause: Using constants for full-table sorting in DISTRIBUTE BY mode will result in data skew at the Reduce end.

Solution: Avoid the preceding operation.

1.6.20.1.4. JOIN skew

Possible cause: The unbalanced distribution of join on keys (such as a large number of repeated keys in multiple JOIN tables) causes surging Cartesian product data in some JOIN instances, which results in data skew.

Solution: The solutions to different scenarios are as follows:

- If there are small tables on both sides of 'join', perform 'map join' instead of 'join'.
- The skewed key can be dealt with by using individual logic. For example, a large amount of NULL data in keys on both sides of a table results in skew. In this case, you need to filter out the NULL data before performing the JOIN operation or replacing NULL values with random values by using the CASE WHEN clause, and then do JOIN operation.
- If you do not want to change SQL statements, set the following parameters to enable automatic optimization on MaxCompute:

```
set odps.sql.skewinfo=tab1:(col1, col2)[(v1, v2), (v3, v4), ...]
set odps.sql.skewjoin=true;
```

1.6.20.1.5. MULTI-DISTINCT skew

Possible cause: Multiple DISTINCT keywords aggravate the GROUP BY skew problem.

Solution: You can use a two-layer GROUP BY to smooth the skew.

1.6.20.1.6. Data skew caused by misuse of dynamic partitioning

Possible cause: If dynamic partitioning is enabled, and there are K map instances and N target partitions, a number of small files (K * N) may be generated. A large amount of small files can greatly increase the management workload of the file system. Therefore, the following configuration takes effect by default:

```
set odps.sql.reshuffle.dynamicpt=true;
```

It introduces an additional level of ReduceTask to allow one or more reduce instances to write data to the same target partition. This prevents too many small files from being generated. However, dynamic partition shuffle may cause data skew.

Solution: If there are only a few target partitions, the system will not generate many small files. In this case, you can run the following command to disable the preceding function, or disable dynamic partitioning:

```
set odps.sql.reshuffle.dynamicpt=false;
```

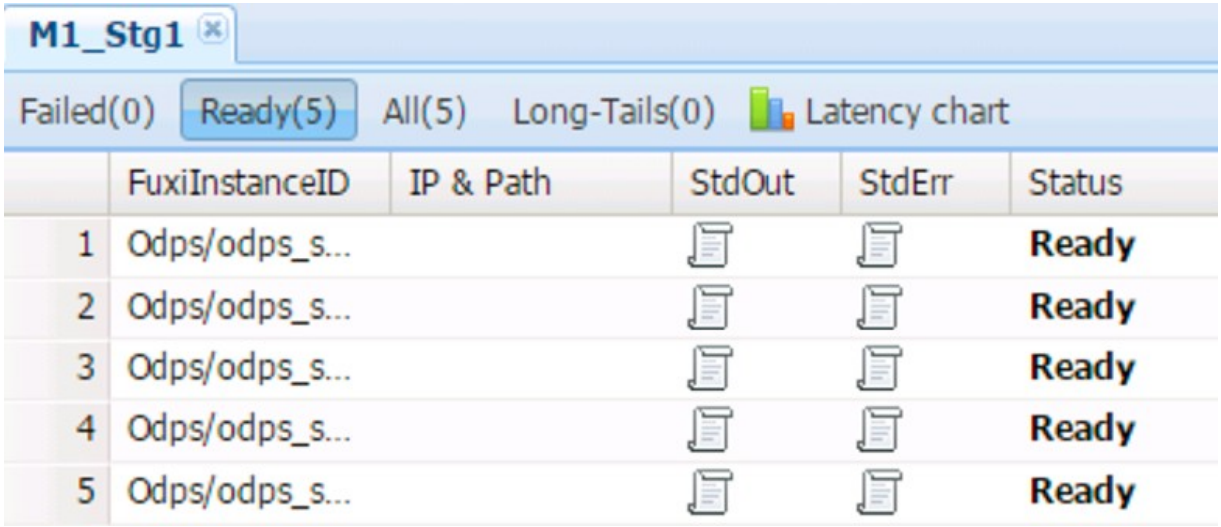
1.6.20.2. Quota and resource usage

Computing resources in MaxCompute may be insufficient sometimes because of improper planning and use of cluster resources.

In general, tasks lacking computing resources have two characteristics, one of which is that the task gets stuck with the output remained at a certain stage. For example, in the following figure, the progress of the M1_Stg1 task has stayed at 0% (because R2_1_Stg1 depends on M1_Stg1, it stays at 0% until M1_Stg1 ends).

```
2016-01-29 13:52:09 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:52:14 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:52:19 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:52:24 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:52:29 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:52:34 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:52:39 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:52:44 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:52:49 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:52:54 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:52:59 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:53:04 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:53:09 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:53:15 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:53:20 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:53:25 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:53:30 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:53:35 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:53:40 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:53:45 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:53:50 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
2016-01-29 13:53:55 M1_Stg1_job0:0/0/5[0%]      R2_1_Stg1_job0:0/0/1[0%]
```

The other characteristic is that the task remains in "Ready" state in the Logview (as shown in the following figure) (a "Ready" task is awaiting allocation of resources; a "Waiting" task is waiting for completion of the dependent task). The "Ready" state indicates that the resources for running these stand-by task instances are insufficient. Once the instances obtain the necessary resources, they resume operating and change to "Running" state.



Each task is split into subtasks based on the execution plan and shown in a DAG, and each subtask invokes multiple instances to execute the computation concurrently. In general, the resources required for invoking an instance are a 1-core CPU and 2 GB of memory. A quota group is assigned to each project for reasonable resource allocation. The quota group determines the maximum amount of resources (CPU and memory) that can be used by all jobs in the project concurrently. Once the resource usage for simultaneously running tasks reaches the limit of the quota group, the tasks are stuck due to insufficient resources.

There are two methods to solve this problem:

- Run the tasks in idle periods.
- Increase the quota group for the project (handled by OAM personnel).

1.6.20.3. MaxCompute storage optimization tips

Partition tables reasonably

MaxCompute supports the concept of partitioning in a table. A partition refers to the specified partition space in the creation of a table; that is, a few fields in the specified table as the partition columns. In most cases, you can consider a partition as a directory in a file system. MaxCompute divides each value of the partition column into a partition (directory). Users can specify multi-level partitions (use multiple fields of the table as partition columns). Multi-level partitions are like multi-level directories. If you specify the name of the partition that you want to access when using the data, then only the corresponding partition are read, avoiding a full table scan. This improves the processing efficiency and reduces costs.

Example of a partitioning statement: `create table src (key string, value bigint) partitioned by (pt string);`. In this example, `select * from src where pt='20160901';` specifies the partitioning format. MaxCompute takes only the data in the "20160901" partition as the input when generating a query plan.

Example of a non-partitioning statement: `select * from src where key = 'MaxCompute';` scans the entire table.

Partitioning is usually based on date or geographical region. You may also set partitions based on your business requirements. Example:

```
create table if not exists sale_detail(
shop_name string,
customer_id string,
total_price double)
partitioned by (sale_date string,region string);
-- Create a two-level partitioned table, in which sale_date is level-1 partition, and region level-2 partiti
on.
```

Set table lifecycle reasonably

Storage space on MaxCompute is precious. You can set the life cycle of a table according to data usage. MaxCompute will delete expired data to save storage space.

Example: Run the `create table test3 (key boolean) partitioned by (pt string, ds string) lifecycle 100;` command to create a table with a lifecycle of 100. If the latest modification time of this table or partition was more than 100 days ago, the table or partition will be deleted.

> **Notice** The lifecycle takes a partition as the smallest unit, so for a partitioned table, if some partitions reach the lifecycle threshold, they will be deleted directly. Partitions that have not reached the lifecycle threshold are not be affected.

Run the `alter table table_name set lifecycle days;` command to modify the lifecycle of an existing table.

Archive cold data

Some data need to be preserved either permanently or for a long period of time, but the frequency of access decreases over time. When the use frequency is very low, you can archive the data. The archive function saves data with RAID. Data is not simply stored as three copies. By using the Cauchy Reed-Solomon algorithm, data is stored as six copies of the original data plus three parity blocks. This improves the effective storage ratio from 1:3 to 1:1.5. In addition, MaxCompute uses the bzip2 algorithm to archive tables with a higher compression ratio than other algorithms. Combining the two algorithms reduces storage usage by more than 70%.

Archiving command format is as below:

```
ALTER TABLE table_name [PARTITION(partition_name='partition_value')] ARCHIVE;
```

Example:

```
alter table my_log partition(ds='20140101') archive;
```

Merge small files

In the reduce calculation or real-time tunnel data collection, a large number of small files are generated. Too many small files may cause the following problems:

- Many instances are occupied because a single instance can process only a small number of files. This results in a waste of resources, affecting the overall execution performance.
- The file system becomes larger, while the use ratio of disk space becomes smaller.

Currently, there are two alternative ways to merge small files: ALTER merge mode and SQL merge mode:

- The ALTER merge mode merges files through 'console' command. The command format is as follows:

  ```
  ALTER TABLE tablename [PARTITION] MERGE SMALLFILES;
  ```

- Set control parameters after SQL execution is complete. Run `odps.task.merge.enabled=true;` to determine whether it is necessary to merge small files. If so, start FuxiJob to merge these files.

1.6.20.4. UDF OOM error

Some jobs will report the OOM error during running. The error message is as follows:

```
FAILED: ODPS-0123144: Fuxi job failed - WorkerRestart errCode:9,errMsg:SigKill(OOM), usually caused by OOM(out of memory)
```

This problem can be solved by setting the UDF runtime parameters:

```
odps.sql.mapper.memory=3072;
set odps.sql.udf.jvm.memory=2048;
set odps.sql.udf.python.memory=1536;
```

1.6.21. Appendix

1.6.21.1. Escape character

String constants in MaxCompute SQL can be enclosed in single or double quotation marks, in double quotation marks enclosed in single quotation marks, or in single quotation marks enclosed in double quotation marks. Otherwise, they must be expressed with an escape character. Examples of correct expressions: "I'm a happy coder!" and 'I\'m a happy coder!'.

In MaxCompute SQL, the backslash (\) is an escape character, which expresses the special character in a string or interprets the character that follows as the character itself. When a string constant is read, if the backslash is followed by three valid octal digits in the range from 001 to 177, the system converts the ASCII values into the corresponding characters. The following table lists the mappings between escape sequences and represented characters.

Escape sequences

Escape sequence	Represented character
\b	Backspace
\t	Tab
\n	Newline
\r	Carriage return
\'	Single quote
\"	Double quote
\ \	Backslash
\;	Semicolon
\Z	Control-Z
\0 or \00	Terminator

Example:

```
select length('a\tb') from dual;
-- The result is 3, indicating that the string contains three characters, with "\t" regarded as one charac
ter. Any character following the escape sequence is interpreted as the character itself.
```

```
select 'a\ab',length('a\ab') from dual;
-- The result is 'aab', with a length of 3. "\a" is interpreted as an ordinary "a".
```

1.6.21.2. LIKE matching

In LIKE matching, "%" indicates matching any number of characters; "_" indicates matching a single character. If the character "%" or "_" needs to be matched, escape conversion is required. "\%" indicates matching "%", and "_" indicates matching "_".

> **Note** For the character set of strings, MaxCompute SQL currently supports the UTF-8 character set. Data that is encoded in a different format may result in incorrect calculations.

1.6.21.3. Regular expressions

MaxCompute SQL adopts the PCRE library for regular expressions. Matching is performed character by character. The supported metacharacters are as follows:

- ^: the beginning of a row
- $: the end of a row
- .: any character
- *: matches zero or multiple times.
- +: matches once or multiple times.
- ?: matches a modifier. If this character follows any one of other delimiters (*, +, ?, {n}, {n,}, or {n,m}), the match is lazy. In the lazy mode, as few strings as possible are matched. In the default greedy mode, as many searched strings as possible are matched zero times or once.
- A|B: A or B
- (abc)*: matches the abc sequence zero or multiple times.
- {n} or {m,n}: the number of matches
- [ab]: matches any character in the brackets.
- [^ab]: ^ represents NOT. This metacharacter matches any character that is neither a nor b.
- \: the escape sequence
- \n: n represents digit 1 to 9. This metacharacter specifies backward reference.
- \d: digit
- \D: non-digit
- [::]: POSIX character set
  - [[:alnum:]]: letter or digit in the range of [a-zA-Z0-9]
  - [[:alpha:]]: letter in the range of [a-zA-Z]
  - [[:ascii:]]: ASCII character in the range of [\x00-\x7F]
  - [[:blank:]]: space and tab in the range of [\t]

- [[:cntrl:]]: control character in the range of [\x00-\x1F\x7F]
- [[:digit:]]: digit in the range of [0-9]
- [[:graph:]]: any character except space in the range of [\x21-\x7E]
- [[:space:]]: space in the range of [\t\r\n\v\f]
- [[:print:]]: [:graph:] and [:space:] in the range of [\x20-\x7E]
- [[:lower:]]: lowercase letter in the range of [a-z]
- [[:punct:]]: punctuation in the range of [][!"#$%&()*+,./:;<=>? @\^_`{|}~-]
- [[:upper:]]: uppercase letter in the range of [A-Z]
- [[:xdigit:]]: hexadecimal character in the range of [A-Fa-f0-9]

The system uses a backslash (\) as the escape character, so a backslash (\) in a regular expression indicates second escape. For example, the string to be matched by the regular expression is "a+b". The plus sign (+) is a special character in regex, and must be escaped to obtain the string "a+b". However, the system needs to escape the first backslash (escape character) before it can be read by regex. Hence, the expression to match "a+b" is "a\\+b".

The following example assumes that there is a table named test_dual:

```
select 'a+b' rlike 'a\\+b' from test_dual;
+------+
_c1 |
+------+
true |
+------+
```

In extreme cases, to match the character "\", which is a special character in the regular engine, the expression must be "\\". The system must perform an escape on the expression, so it is expressed as "\\\".

```
select 'a\\b', 'a\\b' rlike 'a\\\\b' from test_dual;
+-----+------+
_c0 | _c1 |
+-----+------+
a\b | true |
+-----+------+
```

Note

- If a MaxCompute SQL statement contains "a\b", 'a\b' is displayed in the output because MaxCompute escapes the expression.
- If a string contains a tab or tab character, the system reads '\t' and stores it as one character. Therefore, it is a common character in the regular expression mode.

```
select 'a\tb', 'a\tb' rlike 'a\tb' from test_dual;
+---------+------+
_c0 | _c1 |
+---------+------+
a b | true |
+---------+------+
```

1.6.21.4. Reserved words

The following are all reserved words in MaxCompute SQL. Do not use these words to name tables, columns, or partitions. Otherwise, an error is returned. Reserved words are case-insensitive.

```
% & && ( ) * +. / ; < <= <> = > >= ? ADD AFTER ALL ALTER ANALYZE AND ARCHIVE ARRAY AS ASC BEFORE
BETWEEN BIGINT BINARY BLOB BOOLEAN BOTH BUCKET BUCKETS BY CASCADE CASE CAST CFILE CHANGE
CLUSTER CLUSTERED CLUSTERSTATUS COLLECTION COLUMN COLUMNS COMMENT COMPUTE CONCATENA
TE CONTINUE CREATE CROSS CURRENT CURSOR DATA DATABASE DATABASES DATE DATETIME DBPROPER
TIES DEFERRED DELETE DELIMITED DESC DESCRIBE DIRECTORY DISABLE DISTINCT DISTRIBUTE DOUBLE DR
OP ELSE ENABLE END ESCAPED EXCLUSIVE EXISTS EXPLAIN EXPORT EXTENDED EXTERNAL FALSE FETCH FI
ELDS FILEFORMAT FIRST FLOAT FOLLOWING FORMAT FORMATTED FROM FULL FUNCTION FUNCTIONS GRA
NT GROUP HAVING HOLD_DDLTIME IDXPROPERTIES IF IMPORT IN INDEX INDEXES INPATH INPUTDRIVER INP
UTFORMAT INSERT INT INTERSECT INTO IS ITEMS JOIN KEYS LATERAL LEFT LIFECYCLE LIKE LIMIT LINES LO
AD LOCAL LOCATION LOCK LOCKS LONG MAP MAPJOIN MATERIALIZED MINUS MSCK NOT NO_DROP NULL
OF OFFLINE ON OPTION OR ORDER OUT OUTER OUTPUTDRIVER OUTPUTFORMAT OVER OVERWRITE PARTI
TION PARTITIONED PARTITIONPROPERTIES PARTITIONS PERCENT PLUS PRECEDING PRESERVE PROCEDURE
PURGE RANGE RCFILE READ READONLY READS REBUILD RECORDREADER RECORDWRITER REDUCE REGEXP
RENAME REPAIR REPLACE RESTRICT REVOKE RIGHT RLIKE ROW ROWS SCHEMA SCHEMAS SELECT SEMI SEQ
UENCEFILE SERDE SERDEPROPERTIES SET SHARED SHOW SHOW_DATABASE SMALLINT SORT SORTED SSL
STATISTICS STORED STREAMTABLE STRING STRUCT TABLE TABLES TABLESAMPLE TBLPROPERTIES TEMP
ORARY TERMINATED TEXTFILE THEN TIMESTAMP TINYINT TO TOUCH TRANSFORM TRIGGER TRUE UNARCHI
VE UNBOUNDED UNDO UNION UNIONTYPE UNIQUEJOIN UNLOCK UNSIGNED UPDATE USE USING UTC UTC_T
MESTAMP VIEW WHEN WHERE WHILE
```

1.6.21.5. New data type settings

If you want to read a table that includes new data types, you are not required to add the `set setodps.sql.type.system.odps2=true;` flag. However, you must take note of the following points:

- If the flag is not added, the read data is implicitly converted into the original data type for all computations.
- If the flag is not added for integer constants, the BIGINT type is used, and an error message is returned.
- If you write data to a table and the data is in passthrough mode, you can choose not to add the new data type flag. However, if you want to calculate the data, an error is returned because the implicit data type conversion is invalid.

1.7. MaxCompute Tunnel

1.7.1. Overview

MaxCompute provides two types of channels for data uploads and downloads:

- **DataHub**: This channel is used to upload or download data in real time. It includes the OGG, Flume, Logstash, and Fluentd plug-ins.
- **Tunnel**: This channel is used to upload or download large amounts of data at a time. It includes the MaxCompute client, DataWorks, DTS, Sqoop, Kettle plug-in, and MaxCompute Migration Assist (MMA).

DataHub and Tunnel provide their own SDKs. The data upload and download tools derived from these SDKs meet the requirements of the most common scenarios in which data is migrated to the cloud. The tools also enable you to upload or download data in a variety of other scenarios.

Limits

- Limits on Tunnel-based data uploads:
  - You cannot run Tunnel commands to upload or download data of the ARRAY, MAP, or STRUCT types.
  - No limits are specified for the upload speed. The upload speed depends on the network bandwidth and server performance.
  - The number of retries is limited. If the number of retries exceeds the limit, the next block is uploaded. After data is uploaded, you can execute the select count(*) from table_name statement to check whether any data is lost.
  - By default, a project supports a maximum of 2,000 concurrent Tunnel connections.
  - On the server, the lifecycle of a session is 24 hours. A session can be shared among processes and threads on the server, but you must make sure that each block ID is unique.
  - MaxCompute ensures the validity of concurrent writes based on atomicity, consistency, isolation, durability (ACID).
- Limits on DataHub-based data uploads:
  - The size of each field cannot exceed its upper limit.

    > **Note** The size of a string cannot exceed 8 MB.

  - During an upload, multiple data records are packaged.

- Limits on TableTunnel SDK interfaces:
  - A block ID must be greater than or equal to 0 but less than 20,000. The size of the data that you want to upload in a block cannot exceed 100 GB.
  - The lifecycle of a session is 24 hours. If you want to transfer large amounts of data, more than 24 hours are required. In this case, we recommend that you transfer the data in multiple sessions.
  - The lifecycle of an HTTP request that corresponds to a RecordWriter is 120 seconds. If no data flows over an HTTP connection within 120 seconds, the server closes the connection.

1.7.2. Tunnel service connections

DataHub and Tunnel use different endpoints in different network environments. You must also select different endpoints when connecting to the service.

1.7.3. Selection of cloud data migration tools

MaxCompute provides a variety of data upload and download tools, which can be used in different cloud data migration scenarios. This topic describes the selection of data transmission tools in three typical scenarios.

Hadoop data migration

You can use Sqoop and DataWorks to migrate Hadoop data.

- When you use DataWorks, DataX is required.
- When you use Sqoop, a MapReduce job is executed on the original Hadoop cluster for distributed data transmission to MaxCompute.

Synchronization of data in a database

To synchronize data from a database to MaxCompute, you must select a tool based on the database type and synchronization policy.

- Use DataWorks for offline batch synchronization. DataWorks supports a wide range of database types, including MySQL, SQL Server, and PostgreSQL.
- Use the OGG plug-in for real-time synchronization of data in an Oracle database.
- Use DTS for real-time synchronization of data in an ApsaraDB for RDS database.

Log collection

You can use tools such as Flume, Fluentd, and Logstash to collect logs.

1.7.4. Introduction to the tools

MaxCompute supports a wide range of data upload and download tools. The source code for most of the tools can be found and maintained on the open-source community GitHub. You can select the appropriate tools to upload and download data based on the application scenario.

Alibaba Cloud DTplus products

- Data Integration of DataWorks (Tunnel)

Data Integration of DataWorks is a stable, efficient, and scalable data synchronization platform provided by Alibaba Cloud. It is designed to provide full offline and incremental real-time data synchronization, integration, and exchange services for the heterogeneous data storage systems on Alibaba Cloud.

Data synchronization tasks support the following data source types: MaxCompute, ApsaraDB for RDS (MySQL, SQL Server, and PostgreSQL), Oracle, FTP, AnalyticDB (ADS), OSS, ApsaraDB for Memcache, and DRDS.

- MaxCompute client (Tunnel)

  Based on the batch data tunnel SDK, the client provides built-in Tunnel commands for data upload and download.

- DTS (Tunnel)

  Data Transmission (DTS) is an Alibaba Cloud data service that supports data exchange between multiple data sources, such as Relational Database Management System (RDBMS), NoSQL, and Online Analytical Processing (OLAP) databases. It provides data transmission features, such as data migration, real-time data subscription, and real-time data synchronization.

  DTS supports data synchronization from ApsaraDB for RDS and MySQL instances to MaxCompute tables. Other data source types are not supported.

Open-source products

The projects corresponding to each product are open-sourced. You can visit aliyun-maxcompute-data-collectors to view details.

- Sqoop (Tunnel)

  Sqoop 1.4.6 on the community is further developed to provide enhanced MaxCompute support. It can import data from relational databases such as MySQL and data from HDFS or Hive to MaxCompute tables. It can also export data from MaxCompute tables to relational databases such as MySQL.

- Kettle (Tunnel)

  Kettle is an open-source ETL tool that is developed in Java. It can run on Windows, Unix, or Linux. It provides graphic interfaces for you to define data transmission topology by using drag-and-drop components.

- Flume (DataHub)
  - Apache Flume is a distributed and reliable system. It collects large volumes of log data from different data sources and then aggregates and stores the data in a centralized data storage.
  - The DataHub Sink plug-in of Apache Flume allows you to upload log data to DataHub in real time and archive the data in MaxCompute tables.

- Fluentd (DataHub)
  - Fluentd is an open-source software product. It collects logs, such as application logs, system logs, and access logs, from various sources. It allows you to use plug-ins to filter log data and store the data in different data processors, including MySQL, Oracle, MongoDB, Hadoop, and Treasure Data.
  - The DataHub plug-in of Fluentd allows you to upload log data to DataHub in real time and archive the data in MaxCompute tables.

- Logstash (DataHub)
  - Logstash is an open-source log collection and processing framework. The logstash-output-datahub plug-in allows you to import data to DataHub. This tool can be easily configured to collect and transmit data. It can be used together with MaxCompute or StreamCompute to easily create an all-in-one streaming data solution from data collection to analysis.
  - The DataHub plug-in of Logstash allows you to upload log data to DataHub in real time and archive the data in MaxCompute tables.
- OGG (DataHub)

  The DataHub plug-in of OGG allows you to incrementally synchronize data in the Oracle database to DataHub in real time and archive the data in MaxCompute tables.

1.7.5. Tunnel SDK overview

1.7.5.1. Overview

Data upload and download tools provided by MaxCompute are compiled based on the Tunnel SDK. This topic describes the major APIs of the Tunnel SDK.

The usage of the SDK varies according to the version. For specific information, see SDK Java Doc.

Major APIs

API	Description
TableTunnel	An entry class of the MaxCompute Tunnel service.
TableTunnel.UploadSession	A session that uploads data to a MaxCompute table.
TableTunnel.DownloadSession	A session that downloads data from a MaxCompute table.
InstanceTunnel	An entry class of the MaxCompute Tunnel service.
InstanceTunnel.DownloadSession	A session that downloads data from a MaxCompute instance. This session applies only to SQL instances that start with the SELECT keyword and are used to query data.

Note The tunnel endpoint supports automatic routing based on the MaxCompute endpoint settings.

1.7.5.2. TableTunnel

This topic describes the TableTunnel API.

Definition

Definition:

```
public class TableTunnel {
public DownloadSession createDownloadSession(String projectName, String tableName);
public DownloadSession createDownloadSession(String projectName, String tableName, PartitionSpec
partitionSpe c);
public UploadSession createUploadSession(String projectName, String tableName);
public UploadSession createUploadSession(String projectName, String tableName, PartitionSpec partit
ionSpec);
public DownloadSession getDownloadSession(String projectName, String tableName, PartitionSpec pa
rtitionSpec, String id);
public DownloadSession getDownloadSession(String projectName, String tableName, String id);
public UploadSession getUploadSession(String projectName, String tableName, PartitionSpec partition
Spec, String id);
public UploadSession getUploadSession(String projectName, String tableName, String id); public void s
etEndpoint(String endpoint);
}
```

Description:

- **Lifecycle**: the duration from the creation of the TableTunnel instance to the end of the program.
- TableTunnel provides a method to create UploadSession and DownloadSession objects. TableTunnel.UploadSession is used to upload data, and TableTunnel.DownloadSession is used to download data.
- A session refers to the process of uploading or downloading a table or partition. A session consists of one or more HTTP requests to Tunnel RESTful APIs.
- Upload sessions of TableTunnel use the INSERT INTO semantics. Multiple upload sessions of the same table or partition does not affect each other, and the data uploaded in each session is stored in an independent directory.
- In an upload session, each RecordWriter is matched with an HTTP request and is identified by a unique block ID. The block ID is the name of the file corresponding to the RecordWriter.
- If you use the same block ID to enable a RecordWriter multiple times in the same session, the data uploaded by the RecordWriter that calls the close() function last will overwrite all previous data. This feature can be used to retransmit data of a block when data upload fails.

API implementation process

1. The RecordWriter.write() function uploads your data as files to a temporary directory.
2. The RecordWriter.close() function moves the files from the temporary directory to the Data directory.
3. The session.commit() function moves each file in the Data directory to the directory where the corresponding table is located and updates the table metadata. This way, data moved into a table by the current task will be visible to the other MaxCompute tasks such as SQL and MapReduce.

API limits

- The value of a block ID must be greater than or equal to 0 and less than 20000. The size of data to be uploaded in a block cannot exceed 100 GB.
- A session is uniquely identified by its session ID. The lifecycle of a session is 24 hours. If your session times out due to the transfer of large volumes of data, you must transfer your data in multiple sessions.
- The lifecycle of an HTTP request corresponding to a RecordWriter is 120 seconds. If no data flows over an HTTP connection within 120 seconds, the server closes the connection.

  > **Note** HTTP has an 8 KB buffer. When you call the RecordWriter.write() function, your data may be saved to the buffer and no inbound traffic flows over the corresponding HTTP connection. In this case, you can call the TunnelRecordWriter.flush() function to forcibly flush data from the buffer.

- When you use a RecordWriter to write logs to MaxCompute, the RecordWriter may time out due to unexpected traffic fluctuations. Therefore, we recommend that you:
  - Do not use a RecordWriter for each data record. Otherwise, a large number of small files are generated, because each RecordWriter corresponds to a file. This affects the performance of MaxCompute.
- Do not use a RecordWriter to write data until the size of cached code reaches 64 MB.
- The lifecycle of a RecordReader is 300 seconds.

1.7.5.3. InstanceTunnel

This topic describes the InstanceTunnel API.

Definition:

```
public class InstanceTunnel{
 public DownloadSession createDownloadSession(String projectName, String instanceID);
 public DownloadSession createDownloadSession(String projectName, String instanceID, boolean limit
Enabled);
 public DownloadSession getDownloadSession(String projectName, String id);
 }
```

Parameter description:

- **projectName**: the name of a project.
- **instanceID**: the ID of an instance.

Limits: Although InstanceTunnel provides an easy way to obtain instance execution results, it is subject to the following permission limits to ensure data security:

- If the number of records does not exceed 10,000, all users who have the read permission on the specified instance can use InstanceTunnel to download the data. This is also applicable to the scenario of calling a Restful API to query data.
- If the number of records exceeds 10,000, only users who have the permission to read all the source tables from which the specified instance queries data can use InstanceTunnel to download the data.

1.7.5.4. UploadSession

This topic describes the UploadSession interface.

Definition

```
public class UploadSession {
UploadSession(Configuration conf, String projectName, String tableName, String partitionSpec) throws
TunnelException;
UploadSession(Configuration conf, String projectName, String tableName, String partitionSpec, String
uploadId) throws TunnelException;
public void commit(Long[] blocks); public Long[] getBlockList();
public String getId();
public TableSchema getSchema();
public UploadSession.Status getStatus(); public Record newRecord();
public RecordWriter openRecordWriter(long blockId);
public RecordWriter openRecordWriter(long blockId, boolean compress);
}
```

The following section describes the UploadSession interface.

Description

Item	Description
Lifecycle	The lifecycle of an upload instance starts when the instance is created and ends when data is uploaded.
Create a data upload instance	Create a data upload instance by calling a constructor method or by using TableTunnel. • The synchronous request mode is used. • The server creates a session for the data upload instance and generates a unique upload ID. You can run the getId command to obtain the upload ID.
Upload data	• The asynchronous request mode is used. • Call the openRecordWriter method to generate a RecordWriter. The blockId parameter identifies the data to upload and the position of the data in the table. The value of the blockId parameter ranges from 0 to 20000. If the upload fails, you can upload the data again based on the block ID.
View the status of an upload session	• The synchronous request mode is used. • Call the getStatus method to obtain the status of an upload session. • Call the getBlockList method to obtain the block IDs of successful upload sessions. You must check the block IDs of all upload sessions to identify failed upload sessions. Then, upload the data of failed sessions again.

Item	Description
Complete a data upload	• The synchronous request mode is used. • Call the commit(Long[] blocks) method. The blocks parameter indicates the list of the block IDs of successful upload sessions. The server verifies the list. • The verification enhances data accuracy. If the provided list of block IDs is different from the list on the server, an error is reported.
Status	• UNKNOWN: the initial state of a session. • NORMAL: An upload session is created. • CLOSING: The server sets the upload session to the CLOSING state before it calls the COMPLETE method to complete the data upload. • CLOSED: The data upload is complete. The data is moved to the directory of the result table. • EXPIRED: The upload session times out. • CRITICAL: An error occurs.

Notice

- Each block ID in an upload session must be unique. If you use a block ID to open a RecordWriter, write data, and then call the CLOSE and COMMIT methods, you cannot use this block ID to open another RecordWriter.
- The maximum size of a block is 100 GB. Make sure that the volume of data written to each block is greater than 64 MB. Otherwise, computing performance is severely reduced.
- The lifecycle of a session is 24 hours.
- Before you call the openRecordWriter method to write data, we recommend that you prepare data. A network action is triggered every time an openRecordWriter writes 8 KB of data. If no network actions are triggered within 120 consecutive seconds, the server closes the connection and the openRecordWriter becomes unavailable. If this happens, you must open a new openRecordWriter.
- The overwrite mode is added in the COMMIT method. You can use the overwrite mode to submit data. If you use the overwrite mode, the data in this commit overwrites the existing data of a table or partition.

  Notice If multiple sessions are concurrently executed and the overwrite mode is used to submit data, undefined behavior is generated. This may cause data inaccuracy. If you use the overwrite mode to submit data, you must control concurrent commits.

1.7.5.5. DownloadSession

This topic describes the DownloadSession class.

API definition:

```
public class DownloadSession {
DownloadSession(Configuration conf, String projectName, String tableName, String partitionSpec) thr
ows TunnelException
DownloadSession(Configuration conf, String projectName, String tableName, String partitionSpec, Stri
ng downloadId) throws TunnelException
public String getId()
public long getRecordCount() public TableSchema getSchema()
public DownloadSession.Status getStatus()
public RecordReader openRecordReader(long start, long count)
public RecordReader openRecordReader(long start, long count, boolean compress)
}
```

DownloadSession API description.

DownloadSession API

Parameter	Description
Lifecycle	From the creation of the Download instance to the end of the download process.
Purpose	Creates a Download instance by calling a constructor method or using TableTunnel. • Request mode: Synchronous. • The server creates a session for this Download and generates a unique download ID to mark the Download. The console can get data with a get ID. The operation has a high overhead. The server creates indexes for the data files. If many data files exist, the operation takes a long time. Then the server returns the total number of records, and starts concurrent downloads according to the number of records.
Download data	• Request mode: Asynchronous. • Call openRecordReader to generate a RecordReader instance. The Start parameter marks the start position of record for this download. The value of Start is equivalent to or greater than 0. The Count parameter marks the number of records for this download. The value of Count is greater than 0.
View the download process	• Request mode: Synchronous. • Call getStatus to get the download status.
Status	• UNKNOWN: the initial value that is set when the server creates a session. • NORMAL: The download object is successfully created. • CLOSED: The download session is completed. • EXPIRED: The download session times out.

1.7.5.6. TunnelBufferedWriter

This topic describes the TunnelBufferedWriter interface.

The upload process is complex due to limits on block management and connection timeout on the server. The Tunnel SDK provides an enhanced RecordWriter, TunnelBufferWriter, to simplify the upload process.

The TunnelBufferedWriter interface is defined as follows:

```
public class TunnelBufferedWriter implements RecordWriter {
   public TunnelBufferedWriter(TableTunnel.UploadSession session, CompressOption option) throws I
OException;
   public long getTotalBytes();
   public void setBufferSize(long bufferSize);
   public void setRetryStrategy(RetryStrategy strategy);
   public void write(Record r) throws IOException;
   public void close() throws IOException;
}
```

A TunnelBufferedWriter object is described as follows:

- **Lifecycle**: the duration from the time RecordWriter is created to the time the data upload ends.
- **TunnelBufferedWriter instance**: You can call the openBufferedWriter interface of UploadSession to create a TunnelBufferedWriter instance
- **Data upload**: When you call the Write interface, data is first written to the local cache. After the cache is full, the data is submitted to the server in batches to avoid connection timeout. In addition, if the upload fails, the system automatically retries the upload operation.
- **End upload**: Call the Close interface and then call the Commit interface of UploadSession to end the upload process.
- **Buffer control**: You can use the setBufferSize interface to modify the memory occupied by the buffer (in bytes), preferably 64 MB or more to prevent the server from generating too many small files, which may affect performance. The valid range is 1 MB to 1000 MB. The default value is 64 MB, which is recommended in most cases.
- **Retry policy settings**: You have three retry avoidance policies to choose from: EXPONENTIAL_BACKOFF, LINEAR_BACKOFF, and CONSTANT_BACKOFF. For example, the following code segment sets the Write retry count to 6. To avoid unnecessary retries, each retry is performed only after exponentially ascending intervals of 4s, 8s, 16s, 32s, 64s, and 128s by default.

  ```
  RetryStrategy retry
    = new RetryStrategy(6, 4, RetryStrategy.BackoffStrategy.EXPONENTIAL_BACKOFF)
  writer = (TunnelBufferedWriter) uploadSession.openBufferedWriter();
  writer.setRetryStrategy(retry);
  ```

> **Note** We recommend that you do not adjust the preceding settings.

1.7.6. Tunnel SDK example

1.7.6.1. Simple upload example

This topic provides a simple upload example of Tunnel SDK.

Example:

```
import java.io.IOException;
import java.util.Date;
import com.aliyun.odps.Column;
import com.aliyun.odps.Odps;
import com.aliyun.odps.PartitionSpec;
import com.aliyun.odps.TableSchema;
import com.aliyun.odps.account.Account;
import com.aliyun.odps.account.AliyunAccount;
import com.aliyun.odps.data.Record;
import com.aliyun.odps.data.RecordWriter;
import com.aliyun.odps.tunnel.TableTunnel;
import com.aliyun.odps.tunnel.TunnelException;
import com.aliyun.odps.tunnel.TableTunnel.UploadSession;
public class UploadSample {
  private static String accessId = "<your access id>";
  private static String accessKey = "<your access Key>";
  private static String tunnelUrl = "<your tunnel endpoint>";
  private static String odpsUrl = "<your odps endpoint>";
  private static String project = "<your project>";
  private static String table = "<your table name>";
  private static String partition = "<your partition spec>";
  public static void main(String args[]) {
    Account account = new AliyunAccount(accessId, accessKey);
    Odps odps = new Odps(account);
    odps.setEndpoint(odpsUrl);
    odps.setDefaultProject(project);
    try {
      TableTunnel tunnel = new TableTunnel(odps);
      tunnel.setEndpoint(tunnelUrl);
      PartitionSpec partitionSpec = new PartitionSpec(partition);
      UploadSession uploadSession = tunnel.createUploadSession(project,
          table, partitionSpec);
```

```
    System.out.println("Session Status is : "
        + uploadSession.getStatus().toString());
    TableSchema schema = uploadSession.getSchema();
    // After data is prepared, run the Writer command to start writing data. The prepared data is writt
en to a block.
    // Writing a small volume of data to each block can result in a large number of small files.This great
ly reduces computing performance. We strongly recommend that you write at least 64 MB (and up to 10
0 GB) of data to each block.
    // You can estimate the total data volume based on the average data volume and record count. For
example, 64 MB < Average data volume x Record count < 100 GB.
    RecordWriter recordWriter = uploadSession.openRecordWriter(0);
    Record record = uploadSession.newRecord();
    for (int i = 0; i < schema.getColumns().size(); i++) {
      Column column = schema.getColumn(i);
      switch (column.getType()) {
        case BIGINT:
          record.setBigint(i, 1L);
          break;
        case BOOLEAN:
          record.setBoolean(i, true);
          break;
        case DATETIME:
          record.setDatetime(i, new Date());
          break;
        case DOUBLE:
          record.setDouble(i, 0.0);
          break;
        case STRING:
          record.setString(i, "sample");
          break;
        default:
          throw new RuntimeException("Unknown column type: "
              + column.getType());
      }
    }
    for (int i = 0; i < 10; i++) {
      // Write data to the server. A network transmission process is triggered each time 8 KB of data is
written.
      // If no data is transmitted for 120 seconds, the connection times out. The Writer command becom
es unavailable, and you must write data again.
      recordWriter.write(record);
```

```
recordWriter.write(record);
    }
    recordWriter.close();
    uploadSession.commit(new Long[]{0L});
    System.out.println("upload success!");
  } catch (TunnelException e) {
    e.printStackTrace();
  } catch (IOException e) {
    e.printStackTrace();
  }
 }
}
```

1.7.6.2. Simple download example

This topic provides an example for the simple download function of Tunnel SDK.

Example:

```
import java.io.IOException; import java.util.Date;
import com.aliyun.odps.Column; import com.aliyun.odps.Odps;
import com.aliyun.odps.PartitionSpec; import com.aliyun.odps.TableSchema; import com.aliyun.odps.account.Account;
import com.aliyun.odps.account.AliyunAccount; import com.aliyun.odps.data.Record;
import com.aliyun.odps.data.RecordReader; import com.aliyun.odps.tunnel.TableTunnel;
import com.aliyun.odps.tunnel.TableTunnel.DownloadSession; import com.aliyun.odps.tunnel.TunnelException;
public class DownloadSample {
private static String accessId = "<your access id>"; private static String accessKey = "<your access Key>";
private static String tunnelUrl = "<your tunnel endpoint>";
private static String odpsUrl = "<your odps endpoint>";
private static String project = "<your project>"; private static String table = "<your table name>";
private static String partition = "<your partition spec>";
public static void main(String args[]) {
Account account = new AliyunAccount(accessId, accessKey); Odps odps = new Odps(account); odps.setEndpoint(odpsUrl);
odps.setDefaultProject(project);
TableTunnel tunnel = new TableTunnel(odps); tunnel.setEndpoint(tunnelUrl);
PartitionSpec partitionSpec = new PartitionSpec(partition); try {
DownloadSession downloadSession = tunnel.createDownloadSession(project, table, partitionSpec);
System.out.println("Session Status is : "
```

```
+ downloadSession.getStatus().toString());
long count = downloadSession.getRecordCount(); System.out.println("RecordCount is: " + count);
RecordReader recordReader = downloadSession.openRecordReader(0, count);
Record record;
while ((record = recordReader.read()) ! = null) { consumeRecord(record, downloadSession.getSchema(
));
}
recordReader.close();
} catch (TunnelException e) { e.printStackTrace();
} catch (IOException e1) { e1.printStackTrace();
}
}
private static void consumeRecord(Record record, TableSchema schema) { for (int i = 0; i < schema.get
Columns().size(); i++) {
Column column = schema.getColumn(i); String colValue = null;
switch (column.getType()) { case BIGINT: {
Long v = record.getBigint(i);
colValue = v == null ? null : v.toString(); break;
}
case BOOLEAN: {
Boolean v = record.getBoolean(i); colValue = v == null ? null : v.toString(); break;
}
case DATETIME: {
Date v = record.getDatetime(i); colValue = v == null ? null : v.toString(); break;
}
case DOUBLE: {
Double v = record.getDouble(i); colValue = v == null ? null : v.toString(); break;
}
case STRING: {
String v = record.getString(i);
colValue = v == null ? null : v.toString(); break;
}
default:
throw new RuntimeException("Unknown column type: "
+ column.getType());
}
System.out.print(colValue == null ? "null" : colValue); if (i ! = schema.getColumns().size())
System.out.print("\t");
}
System.out.println();
}
```

```
}
```

1.7.6.3. Multithread upload example

This topic provides a multithread upload example of Tunnel SDK.

Example:

```
import java.io.IOException;
import java.util.ArrayList;
import java.util.Date;
import java.util.concurrent.Callable;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;
import com.aliyun.odps.Column;
import com.aliyun.odps.Odps;
import com.aliyun.odps.PartitionSpec;
import com.aliyun.odps.TableSchema;
import com.aliyun.odps.account.Account;
import com.aliyun.odps.account.AliyunAccount;
import com.aliyun.odps.data.Record;
import com.aliyun.odps.data.RecordWriter;
import com.aliyun.odps.tunnel.TableTunnel;
import com.aliyun.odps.tunnel.TunnelException;
import com.aliyun.odps.tunnel.TableTunnel.UploadSession;
class UploadThread implements Callable<Boolean> {
 private long id;
 private RecordWriter recordWriter;
 private Record record;
 private TableSchema tableSchema;
 public UploadThread(long id, RecordWriter recordWriter, Record record, TableSchema tableSchema) {
  this.id = id;
  this.recordWriter = recordWriter;
  this.record = record;
  this.tableSchema = tableSchema;
 }
 @Override
 public Boolean call() {
  for (int i = 0; i < tableSchema.getColumns().size(); i++) {
   Column column = tableSchema.getColumn(i);
   switch (column.getType()) {
    case BIGINT:
```

```
        record.setBigint(i, 1L);
        break;
      case BOOLEAN:
        record.setBoolean(i, true);
        break;
      case DATETIME:
        record.setDatetime(i, new Date());
        break;
      case DOUBLE:
        record.setDouble(i, 0.0);
        break;
      case STRING:
        record.setString(i, "sample");
        break;
      default:
        throw new RuntimeException("Unknown column type: "
            + column.getType());
    }
   }
   try {
    for (int i = 0; i < 10; i++) {
    // Write data to the server. A network transmission process is triggered each time 8 KB of data is w
ritten.
      // If no data is transmitted for 120 seconds, the connection times out. The Writer command becom
es unavailable and you must write data again.
      recordWriter.write(record);
    }
    recordWriter.close();
   } catch (IOException e) {
    e.printStackTrace();
    return false;
   }
   return true;
 }
}
public class UploadThreadSample {
 private static String accessId = "<your access id>";
 private static String accessKey = "<your access Key>";
 private static String tunnelUrl = "<your tunnel endpoint>";
 private static String odpsUrl = "<your odps endpoint>";
```

```
  private static String project = "<your project>";
  private static String table = "<your table name>";
  private static String partition = "<your partition spec>";
  private static int threadNum = 10;:
  public static void main(String args[]) {
    Account account = new AliyunAccount(accessId, accessKey);
    Odps odps = new Odps(account);
    odps.setEndpoint(odpsUrl);
    odps.setDefaultProject(project);

+ ((threadNum - 1) * step));
callers.add(new DownloadThread( threadNum - 1, recordReader, downloadSession.getSchema()));
Long downloadNum = 0L;
List<Future<Long>> recordNum = pool.invokeAll(callers); for (Future<Long> num : recordNum)
downloadNum += num.get(); System.out.println("Record Count is: " + downloadNum); pool.shutdown()
;
} catch (TunnelException e) { e.printStackTrace();
} catch (IOException e) { e.printStackTrace();
} catch (InterruptedException e) { e.printStackTrace();
} catch (ExecutionException e) { e.printStackTrace();
}
}
}
```

1.7.6.5. Example of uploading data by using BufferedWriter

This topic provides an example on how to upload data by using BufferedWriter of the Tunnel SDK.

Example:

```
//Initialize the code of MaxCompute and Tunnel.
RecordWriter writer = null;
TableTunnel.UploadSession uploadSession = tunnel.createUploadSession(projectName, tableName);
try {
  int i = 0;
  //Generate a TunnelBufferedWriter instance.
  writer = uploadSession.openBufferedWriter();
  Record product = uploadSession.newRecord();
  for (String item : items) {
    product.setString("name", item);
    product.setBigint("id", i);
    //Call the Write interface to write data.
    writer.write(product);
    i += 1;
  }
} finally {
  if (writer ! = null) {
    //Disable TunnelBufferedWriter.
    writer.close();
  }
}
//Commit the upload session to end the upload.
uploadSession.commit();
```

1.7.6.6. Example of uploading data by using BufferedWriter in multi-threaded mode

This topic provides an example on how to upload data by using BufferedWriter of the Tunnel SDK in multi-threaded mode.

Example:

```
class UploadThread extends Thread {
  private UploadSession session;
  private static int RECORD_COUNT = 1200;
  public UploadThread(UploadSession session) {
    this.session = session;
  }
  @Override
  public void run() {
    RecordWriter writer = up.openBufferedWriter();
    Record r = up.newRecord();
    for (int i = 0; i < RECORD_COUNT; i++) {
      r.setBigint(0, i);
      writer.write(r);
    }
    writer.close();
  }
};
public class Example {
  public static void main(String args[]) {
    //Initialize the code of MaxCompute and Tunnel.
    TableTunnel.UploadSession uploadSession = tunnel.createUploadSession(projectName, tableName);
    UploadThread t1 = new UploadThread(up);
    UploadThread t2 = new UploadThread(up);
    t1.start();
    t2.start();
    t1.join();
    t2.join();
    uploadSession.commit();
}
```

1.7.6.7. Examples of uploading and downloading complex data

This topic provides examples of uploading and downloading complex data by using the Tunnel SDK.

Upload complex data

Example:

```
RecordWriter recordWriter = uploadSession.openRecordWriter(0);
ArrayRecord record = (ArrayRecord) uploadSession.newRecord();
//Prepare data.
List arrayData = Arrays.asList(1, 2, 3);
Map<String, Long> mapData = new HashMap<String, Long>();
mapData.put("a", 1L);
mapData.put("c", 2L);
List<Object> structData = new ArrayList<Object>();
structData.add("Lily");
structData.add(18);
//Import data to a record.
record.setArray(0, arrayData);
record.setMap(1, mapData);
record.setStruct(2, new SimpleStruct((StructTypeInfo) schema.getColumn(2).getTypeInfo(), structData
));
//Write the record.
recordWriter.write(record);
```

Download complex data

Example:

```
RecordReader recordReader = downloadSession.openRecordReader(0, 1);
//Read a record.
ArrayRecord record1 = (ArrayRecord)recordReader.read();
//Obtain data of the ARRAY type.
List field0 = record1.getArray(0);
List<Long> longField0 = record1.getArray(Long.class, 0);
//Obtain data of the MAP type.
Map field1 = record1.getMap(1);
Map<String, Long> typedField1 = record1.getMap(String.class, Long.class, 1);
//Obtain data of the STRUCT type.
Struct field2 = record1.getStruct(2);
```

Example of upload and download

Example:

```
import java.io.IOException;
import java.util.ArrayList;
import java.util.Arrays;
import java.util.HashMap;
```

```
import java.util.List;
import java.util.Map;
import com.aliyun.odps.Odps;
import com.aliyun.odps.PartitionSpec;
import com.aliyun.odps.TableSchema;
import com.aliyun.odps.account.Account;
import com.aliyun.odps.account.AliyunAccount;
import com.aliyun.odps.data.ArrayRecord;
import com.aliyun.odps.data.RecordReader;
import com.aliyun.odps.data.RecordWriter;
import com.aliyun.odps.data.SimpleStruct;
import com.aliyun.odps.data.Struct;
import com.aliyun.odps.tunnel.TableTunnel;
import com.aliyun.odps.tunnel.TableTunnel.UploadSession;
import com.aliyun.odps.tunnel.TableTunnel.DownloadSession;
import com.aliyun.odps.tunnel.TunnelException;
import com.aliyun.odps.type.StructTypeInfo;
public class TunnelComplexTypeSample {
  private static String accessId = "<your access id>";
  private static String accessKey = "<your access Key>";
  private static String odpsUrl = "<your odps endpoint>";
  private static String project = "<your project>";
  private static String table = "<your table name>";
  //Partitions in a partitioned table, such as "pt=\'1\',ds=\'2\'".
  //If the table is not a partitioned table, you do not need to execute the following statement.
  private static String partition = "<your partition spec>";
  public static void main(String args[]) {
    Account account = new AliyunAccount(accessId, accessKey);
    Odps odps = new Odps(account);
    odps.setEndpoint(odpsUrl);
    odps.setDefaultProject(project);
    try {
      TableTunnel tunnel = new TableTunnel(odps);
      PartitionSpec partitionSpec = new PartitionSpec(partition);
      //---------- Upload data ----------
      //Create an upload session for the table.
      //The table schema is {"col0": ARRAY<BIGINT>, "col1": MAP<STRING, BIGINT>, "col2": STRUCT<name:
STRING,age:BIGINT>}.
      UploadSession uploadSession = tunnel.createUploadSession(project, table, partitionSpec);
      //Obtain the table schema.
      TableSchema schema = uploadSession.getSchema();
```

```
    //Enable the RecordWriter.
    RecordWriter recordWriter = uploadSession.openRecordWriter(0);
    ArrayRecord record = (ArrayRecord) uploadSession.newRecord();
    //Prepare data.
    List arrayData = Arrays.asList(1, 2, 3);
    Map<String, Long> mapData = new HashMap<String, Long>();
    mapData.put("a", 1L);
    mapData.put("c", 2L);
    List<Object> structData = new ArrayList<Object>();
    structData.add("Lily");
    structData.add(18);
    //Import data to a record.
    record.setArray(0, arrayData);
    record.setMap(1, mapData);
    record.setStruct(2, new SimpleStruct((StructTypeInfo) schema.getColumn(2).getTypeInfo(), structD
ata));
    //Write the record.
    recordWriter.write(record);
    //Disable the writer.
    recordWriter.close();
    //Commit the upload session to end the upload.
    uploadSession.commit(new Long[]{0L});
    System.out.println("upload success!") ;
    //---------- Download data ----------
    //Create a download session for the table.
    //The table schema is {"col0": ARRAY<BIGINT>, "col1": MAP<STRING, BIGINT>, "col2": STRUCT<name:
STRING, age:BIGINT>}.
    DownloadSession downloadSession = tunnel.createDownloadSession(project, table, partitionSpec)
;
    schema = downloadSession.getSchema();
    //Enable the record reader. In the example, one record is read.
    RecordReader recordReader = downloadSession.openRecordReader(0, 1);
    //Read a record.
    ArrayRecord record1 = (ArrayRecord)recordReader.read();
    //Obtain data of the ARRAY type.
    List field0 = record1.getArray(0);
    List<Long> longField0 = record1.getArray(Long.class, 0);
    //Obtain data of the MAP type.
    Map field1 = record1.getMap(1);
    Map<String, Long> typedField1 = record1.getMap(String.class, Long.class, 1);
    //Obtain data of the STRUCT type.
```

```
    // Obtain data of the STRUCT type.
    Struct field2 = record1.getStruct(2);
    System.out.println("download success!") ;
   } catch (TunnelException e) {
    e.printStackTrace();
   } catch (IOException e) {
    e.printStackTrace();
   }
  }
}
```

1.7.7. Appendix

1.7.7.1. Tunnel upload/download FAQ

This topic describes frequently asked questions (FAQs) about tunnel upload and download.

What is MaxCompute Tunnel?

Tunnel is data channel of MaxCompute, you are available to upload or download data through Tunnel to or from MaxCompute. You can upload and download only table data (excluding view data) with MaxCompute Tunnel.

Can block IDs be repeated?

Each block ID in an Upload session must be unique. After a block ID is used to start RecordWriter in an upload session, data is written, and the session is closed and committed, this block ID cannot be used to start another RecordWriter. A maximum of 20,000 blocks are supported, with the block IDs ranging from 0 to 19999.

Is there a limit on block size?

The maximum size of a block is 100 GB. We strongly recommend that 64 MB or more data is written into each block. Each block is a file. A file smaller than 64 MB is a small file. Excessive small files will affect the computing performance.

Can a session be shared? Does a session have a life cycle?

Each session has a 24-hour life cycle on the server. It can be used within 24 hours after being created, and can be shared among processes or threads. The block ID of each session must be unique. The procedure for distributed uploading is as follows: **Create a session > Evaluate data volume > Assign blocks (for example, thread 1 uses blocks 0-100 and thread 2 uses blocks 100-200) > Prepare data > Upload data > Commit all blocks with data written.**

How to process write/read timeout or I/O exceptions?

During data uploading, a network action is triggered every time the Writer writes 8 KB data. If no network action is triggered within 120 seconds, the server closes the connection and the Writer becomes unavailable. You have to start a new Writer.

The Reader in data downloading works in a similar way. If no network I/O occurs for a period of time, the connection is closed. We suggest that you run Read without inserting any interfaces from other systems.

Which languages of SDK are available for MaxCompute Tunnel?

MaxCompute Tunnel provides the Java and C++ editions of SDK.

Does MaxCompute Tunnel allow multiple consoles to upload the same table at the same time?

Yes.

Is MaxCompute Tunnel suitable for batch uploading or stream uploading?

MaxCompute Tunnel is more suitable for batch uploading.

Are partitions required for data uploading through MaxCompute Tunnel?

Yes, MaxCompute Tunnel does not automatically build partitions.

What is the relationship between Dship and MaxCompute Tunnel?

Dship is a tool that uploads and downloads data through MaxCompute Tunnel.

Does data uploaded with MaxCompute Tunnel append to the existing file or overwrite the data?

The uploaded data appends to the file.

What is the routing function of MaxCompute Tunnel?

The routing function allows the Tunnel SDK to get the tunnel endpoint by setting MaxCompute. That is, you can run the Tunnel SDK properly by setting the endpoint of MaxCompute.

What is the preferred size of a block when data is uploaded with MaxCompute Tunnel?

The block size depends on factors such as the network situation, real-time performance requirement, data usage, and number of small files in a cluster. If a large volume of data is uploaded continuously, the preferred block size is 64-256 MB. If the data is uploaded in a batch once every day, the block size can be 1 GB.

Why is the timeout error often reported during data downloading with MaxCompute Tunnel?

This may have occurred due to an endpoint error. Check the endpoint configuration. A simple method is to run telnet to check the network connectivity to the endpoint.

Why does the following error occur during data downloading with MaxCompute Tunnel?

```
You have NO privilege 'odps:Select' on {acs:odps:*:projects/XXX/tables/XXX}. project 'XXX' is protecte
d
```

The data protection function has been enabled for the project. Only the project owner has the right to transfer data from one project to another if the project data is protected.

Why does the following error occur during data uploading with MaxCompute Tunnel?

```
ErrorCode=FlowExceeded, ErrorMessage=Your flow quota is exceeded. **
```

The maximum number of concurrent requests is exceeded. By default, MaxCompute Tunnel allows a maximum of 2,000 concurrent upload and download requests (quota). Each request, once it is sent, occupies one quota unit until it ends. Try the following solutions:

- Put the system to sleep, and try again after it awakes.
- Change the concurrency quota to a greater number for the project after obtaining the forecast flow pressure from the administrator.
- Report the problem to the project owner to check and control the top requests occupying a large quota.

1.7.7.2. Common tunnel error codes

This topic describes common tunnel error codes.

Common tunnel error codes are as follows.

Common error codes

Error code	Error	Processing recommendations
NoSuchPartition	The partition does not exist.	Tunnel doesn't create partitions, you need to create partitions and then upload or download.
InvalidProjectTable	Invalid project name or table name.	Check related names.
NoSuchProject	The project does not exist.	Check related names.
NoSuchTable	The table does not exist.	Check related names.
StatusConflict	The session expires or has been committed.	Re-create the session and upload it.
MalformedDataStream	Data format error.	Normally created because network is disconnected, or Schema and Table are different.
InvalidPartitionSpec	Invalid partition information.	Check partition information. An example of a correct value is pt='1',ct='2017'.

Error code	Error	Processing recommendations
InvalidRowRange	Invalid designated row range, normally it exceeds the max. size or it is 0.	Check related parameters.
Unauthorized	Account information error.	Normally it is wrong AccessId or AccessKey, or local device time has a 15-minute gap with server.
DataStoreError	Storage error.	Contact the administrator.
NoPermission	No permission normally because no related permission or IP whitelist has been set.	Check whether permission is correct.
MissingPartitionSpec	Missing partition information, partition table operation must carry partition information.	Add partition information.
TableModified	Data in the table is modified by other tasks while upload or download.	Re-create the session and re-try.
FlowExceeded	Exceed concurrency quota limit.	Check and control volume of concurrency. If it is needed to add concurrency, please contact the project owner or administrator to evaluate flow pressure.
InvalidResourceSpec	Normally because the project, table or partition information is different from the session.	Check related information and re-try.
MethodNotAllowed	Method is not allowed, normally try to export the view.	Exporting the view is not supported currently.
InvalidColumnSpec	Invalid column information.	Normally it is column name error while download designated column.
DataVersionConflict	It is cross-cluster coping.	Re-try later.
InternalServerError	Internal error.	Re-try or contact the administrator.

1.8. MaxCompute MapReduce

1.8.1. Overview

1.8.1.1. MapReduce

MaxCompute provides a MapReduce programming API. You can use the API to write MapReduce programs to process MaxCompute data.

MapReduce is a distributed data processing model initially proposed by Google. It later gained extensive attention in the industry and was widely used in a variety of business scenarios.

A MapReduce program processes data in two stages: the Map stage and the Reduce stage. It executes the Map stage first and then the Reduce stage. Although you can define the processing logics of Map and Reduce, they need to follow the conventions of the MapReduce framework.

The following is a detailed procedure of how MapReduce processes data:

1. Before you formally start Map, ensure that partition is set for input data. The input data is divided into equal-sized blocks, which are partitions. Each partition is processed as the input of a single Map worker so that multiple Map workers can work together.
2. After partitioning, multiple Map Workers start working simultaneously. Each Map Worker reads its respective shard, computes the shard, and works out the result to Reduce.

   > **Note** During data output, each Map worker needs to specify one key for each output data. The key decides the Reduce worker for which the data is targeted. Multiple keys may correspond to a single Reduce worker. Data of the same key is sent to the same Reduce worker, and a single Reduce worker may receive data with different keys.

3. Before entering the Reduce stage, the MapReduce framework will sort the data Key values to make data with the same Key values adjacent. If you specify Combiner, the framework will call Combiner and aggregate data with the same Key.

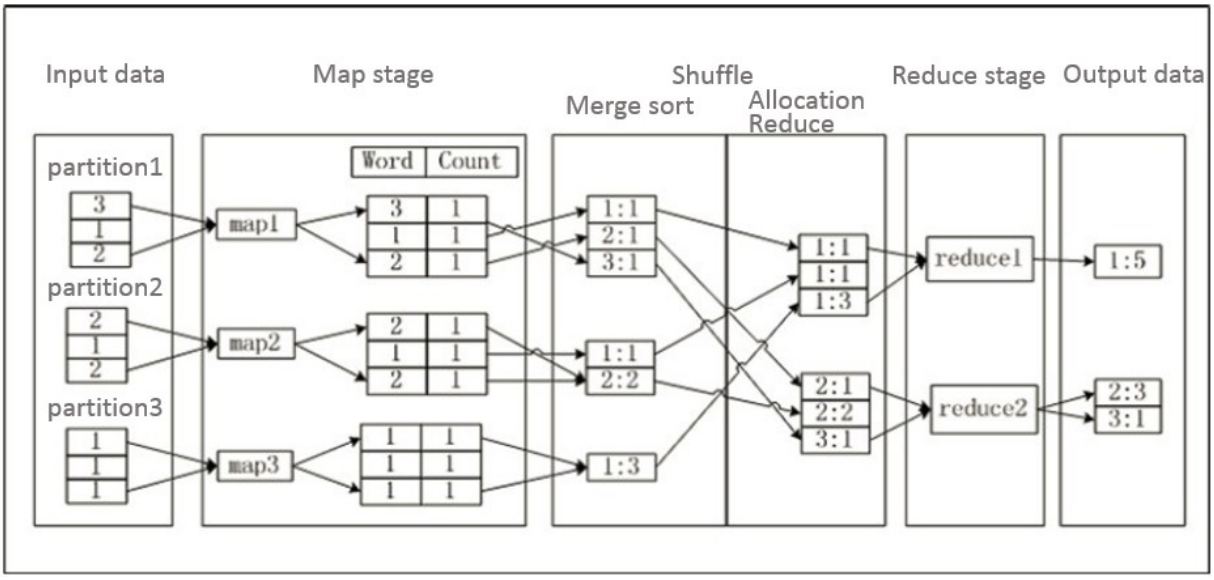
   > **Note** You can customize the Combiner logic. Unlike the typical MapReduce framework protocol, Unlike the typical MapReduce framework protocol, MaxCompute requires the input and output parameters be consistent with those of Reduce. This process is generally called Shuffle.

4. When entering the Reduce stage, data with same Key will be in the same Reduce Worker. A single Reduce Worker may receive data from multiple Map Workers. Each Reduce worker performs the Reduce operation on multiple values with the same key. Finally, the multiple data entries with 1 Key will become 1 Value after the Reduce operation.

> **Note** The preceding section is only a brief introduction to MapReduce. For more details, see related documentation.

The following uses WordCount as an example to explain the related concepts of MaxCompute MapReduce in different stages.

Assume there is a file a.txt, and in each line in the text is a digit. You need to count the number of times each digit appears. Each number is called a Word, and the number of its occurrences is called the Count. To use MaxCompute MapReduce for this purpose, perform the steps shown in the following figure.



1. Partition a.txt data and use data in each partition as input of a single Map worker.
2. For the Map processing input, the Count parameter is set to 1 for each obtained number. The Word|Count pair is output as a Word data key.
3. At the start of the Shuffle stage, the output of each Map worker is sorted by key value (Word value). MapReduce performs the COMBINER operation on the sorted outputs, combining data of the same key (Word value) to form a new Word|Count pair. The process is called combine sorting.
4. Later in the Shuffle stage, data is sent to the Reduce side. The Reduce Worker sorts the received data again depending on Key value.
5. During the Reduce stage, each Reduce Worker uses the same logic as Combiner while processing data, and adds the Count with the same Key value (Word value) to obtain the output result.

> **Note** Because all the MaxCompute data is saved in the table, the input and output of MaxCompute MapReduce can only be a table. Customizing the output format is not permitted, and similar file system APIs are not provided.

1.8.1.2. Extended MapReduce

In a traditional MapReduce model, data must be stored in a distributed file system (such as an HDFS or a MaxCompute table) after each round of MapReduce operations. A typical MapReduce application is composed of multiple MapReduce jobs. Data is written to a disk after each job is completed. Subsequent map tasks usually only read data once to prepare for the following Shuffle stage. This results in redundant I/O operations.

The computing scheduling logic of MaxCompute supports more complicated programming models. In the preceding case, a reduce operation can be followed by the next reduce operation without having a map operation in between. An extended MapReduce model is provided. This model supports any number of reduce operations after map, such as Map-Reduce-Reduce.

Hadoop Chain Mapper and Chain Reducer also support similar serialized map or reduce operations. However, they are essentially different from the extended MapReduce (MR2) model. Chain Mapper and Chain Reducer are based on the traditional MapReduce model. They support one or more mapper operations, not reducer operations, after the original mapper or reduce operation. One benefit is that you can reuse the preceding mapper business logic by splitting a map or reduce operation into multiple mapper stages. This, however, does not change the underlying scheduling or I/O model.

1.8.1.3. Open-source compatibility with MapReduce

MaxCompute offers a set of native MapReduce programming models and interfaces. The inputs and outputs for these interfaces are MaxCompute tables, and the data is organized to be processed in the record format.

However, MaxCompute MapReduce APIs differ from Hadoop MapReduce APIs. Traditionally, to migrate your Hadoop MapReduce jobs to MaxCompute, you need to rewrite the MapReduce code, compile and debug the code by using MaxCompute APIs, compress the final code into a JAR package, and upload the package to the MaxCompute platform. This process is tedious and labor-intensive for development and testing. It was expected that the original Hadoop MapReduce code can be used on the MaxCompute platform with little or no modification at all.

To achieve this purpose, the MaxCompute platform provides a plug-in to adapt Hadoop MapReduce to MaxCompute MapReduce. With this plug-in, Hadoop MapReduce jobs are compatible with MaxCompute at the binary level to a certain extent. You can specify some configurations without modifying the code and then run the original Hadoop MapReduce JAR packages on MaxCompute. Click here to download the plug-in. This plug-in is in the testing stage and does not support custom comparators or key types.

In the following section, a WordCount program is used as an example to introduce the basic usage of this plug-in.

> **Note**
>
> - For more information about open-source compatibility, see Compatibility with Hadoop MapReduce.
> - For more information about the Hadoop MapReduce SDK, see the MapReduce official documentation.
> - The code in the example is for reference only. You need to modify it based on your business needs.

Download the plug-in

Click here to download the plug-in. The package name is openmr_hadoop2openmr-1.0.jar.

> **Note** This JAR package contains the dependencies with Hadoop 2.7.2. To avoid version conflicts, you must not include Hadoop dependencies in the JAR packages of your jobs.

Prepare a JAR package

Compile and export the WordCount JAR package (wordcount_test.jar). The source code of the WordCount program is as follows:

```
package com.aliyun.odps.mapred.example.hadoop;
```

```
import org.apache.hadoop.conf.Configuration;
import org.apache.hadoop.fs.Path;
import org.apache.hadoop.io.IntWritable;
import org.apache.hadoop.io.Text;
import org.apache.hadoop.mapreduce.Job;
import org.apache.hadoop.mapreduce.Mapper;
import org.apache.hadoop.mapreduce.Reducer;
import org.apache.hadoop.mapreduce.lib.input.FileInputFormat;
import org.apache.hadoop.mapreduce.lib.output.FileOutputFormat;
import java.io.IOException;
import java.util.StringTokenizer;
public class WordCount {
  public static class TokenizerMapper
    extends Mapper<Object, Text, Text, IntWritable>{
    private final static IntWritable one = new IntWritable(1);
    private Text word = new Text();
    public void map(Object key, Text value, Context context
    ) throws IOException, InterruptedException {
      StringTokenizer itr = new StringTokenizer(value.toString());
      while (itr.hasMoreTokens()) {
        word.set(itr.nextToken());
        context.write(word, one);
      }
    }
  }
  public static class IntSumReducer
    extends Reducer<Text,IntWritable,Text,IntWritable> {
    private IntWritable result = new IntWritable();
    public void reduce(Text key, Iterable<IntWritable> values,
      Context context
    ) throws IOException, InterruptedException {
      int sum = 0;
      for (IntWritable val : values) {
        sum += val.get();
      }
      result.set(sum);
      context.write(key, result);
    }
  }
  public static void main(String[] args) throws Exception {
```

```
        Configuration conf = new Configuration();
        Job job = Job.getInstance(conf, "word count");
        job.setJarByClass(WordCount.class);
        job.setMapperClass(TokenizerMapper.class);
        job.setCombinerClass(IntSumReducer.class);
        job.setReducerClass(IntSumReducer.class);
        job.setOutputKeyClass(Text.class);
        job.setOutputValueClass(IntWritable.class);
        FileInputFormat.addInputPath(job, new Path(args[0]));
        FileOutputFormat.setOutputPath(job, new Path(args[1]));
        System.exit(job.waitForCompletion(true) ? 0 : 1);
    }
}
```

Prepare test data

1. Create input and output tables.

   ```
   create table if not exists wc_in(line string);
   create table if not exists wc_out(key string, cnt bigint);
   ```

2. Use Tunnel to import data to the input table.

   The following content in the data.txt file needs to be imported:

   ```
   hello maxcompute
   hello mapreduce
   ```

3. You can run the following command on the MaxCompute client to import data from data.txt to wc_in:

   ```
   tunnel upload data.txt wc_in;
   ```

Configure the mapping between HDFS file paths and MaxCompute tables

The configuration file is named wordcount-table-res.conf.

```
{
 "file:/foo": {
  "resolver": {
   "resolver": "com.aliyun.odps.mapred.hadoop2openmr.resolver.TextFileResolver",
   "properties": {
      "text.resolver.columns.combine.enable": "true",
      "text.resolver.seperator": "\t"
   }
  },
  "tableInfos": [
   {
    "tblName": "wc_in",
    "partSpec": {},
    "label": "__default__"
   }
  ],
  "matchMode": "exact"
 },
 "file:/bar": {
  "resolver": {
   "resolver": "com.aliyun.odps.mapred.hadoop2openmr.resolver.BinaryFileResolver",
   "properties": {
      "binary.resolver.input.key.class" : "org.apache.hadoop.io.Text",
      "binary.resolver.input.value.class" : "org.apache.hadoop.io.LongWritable"
   }
  },
  "tableInfos": [
   {
    "tblName": "wc_out",
    "partSpec": {},
    "label": "__default__"
   }
  ],
  "matchMode": "fuzzy"
 }
}
```

The preceding configuration is a JSON file that describes the mapping between HDFS file paths and MaxCompute tables. You need to configure both the input and output. Each HDFS file path matches three configuration items: resolver, tableInfos, and matchMode. The configuration items are described as follows:

- **resolver**: specifies how to process data in files. Currently, the following two built-in resolvers are available: com.aliyun.odps.mapred.hadoop2openmr.resolver.TextFileResolver and com.aliyun.odps.mapred.hadoop2openmr.resolver.BinaryFileResolver. After you specify the resolver name, you must configure properties for the resolver to support data parsing.
  - **TextFileResolver**: regards the input or output as plaintext if the data is of plaintext type. When you configure an input resolver, you must configure the text.resolver.columns.combine.enable and text.resolver.seperator properties. When text.resolver.columns.combine.enable is set to true, all columns in the input table are combined into a single string based on the delimiter specified by text.resolver.seperator. Otherwise, the first two columns in the input table are used as the key and value fields.
  - **BinaryFileResolver**: converts binary data into a data type that is supported by MaxCompute, such as BIGINT, BOOLEAN, and DOUBLE. When you configure an output resolver, you must configure the binary.resolver.input.key.class and binary.resolver.input.value.class properties. binary.resolver.input.key.class defines the key type of the intermediate result, and binary.resolver.input.value.class defines the value type.
- **tableInfos**: specifies the MaxCompute table that corresponds to HDFS. At present, only the tblName parameter is configurable. The partSpec and label parameters must be set to the values the same as those in the preceding example.
- **matchMode**: specifies the path matching mode. It can be set to exact or fuzzy. You can use a regular expression in fuzzy mode to match the HDFS input path.

Submit a job

Use the MaxCompute command line tool odpscmd to submit the job. Run the following command in odpscmd:

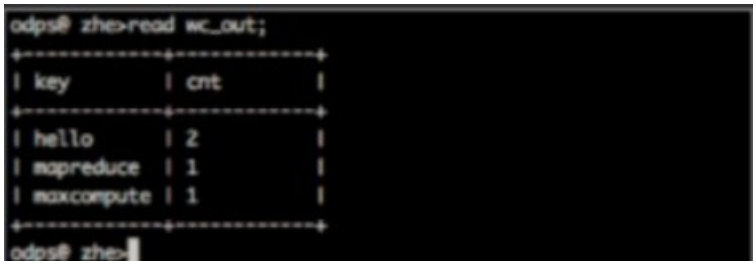
```
jar -DODPS_HADOOPMR_TABLE_RES_CONF=./wordcount-table-res.conf -classpath hadoop2openmr-1.0.j
ar,wordcount_test.jar com.aliyun.odps.mapred.example.hadoop.WordCount /foo/bar;
```

Note

- wordcount-table-res.conf: the mapped configuration file configured with /foo/bar.
- wordcount_test.jar: the JAR package of your Hadoop MapReduce program.
- com.aliyun.odps.mapred.example.hadoop.WordCount: the class name of the job that you want to run.
- /foo/bar: the path on HDFS, which is mapped to wc_in and wc_out in the JSON configuration file.
- After you configure the mapping, you must import the Hadoop HDFS input file to wc_in for MapReduce computing by using the data integration function of DataX or DataWorks, and export the result table wc_out to your HDFS output directory */bar*.
- Before you run the preceding command, make sure that hadoop2openmr-1.0.jar, wordcount_test.jar, and wordcount-table-res.conf have been stored in the current directory of odpscmd. Otherwise, you must make the relevant changes when you specify the configuration and -classpath.

The following figure shows the running process.

After the job running process is complete, you can view the result table wc_out to check whether the job is successful and whether the results meet expectations.



1.8.2. Features

1.8.2.1. Run command

The MaxCompute client provides a jar command for running MapReduce jobs.

Command syntax:

```
Usage: jar [<GENERIC_OPTIONS>] <MAIN_CLASS> [ARGS]
-conf <configuration_file> Specify an application configuration file
-classpath <local_file_list> classpaths used to run mainClass
-D <name>=<value> Property value pair, which will be used to run mainClass
-local Run job in local mode
-resources <resource_name_list> file/table resources used in mapper or reducer, separate by comma
```

The following table describes the parameters.

Parameters

Parameter	Description
-conf <configuration file>	Indicates a JobConf file.
-classpath <local_file_list>	Indicates the classpath for local execution. It specifies the local paths (including relative path and absolute path) of the jar packet where the main function is located.
-D <prop_name>=<prop_value>	Indicates the java attribute of <mainClass> in local execution. You can define multiple attributes.
-local	Indicates that the MapReduce job is run locally. It is mainly used for program debugging.
-resources <resource_name_list>	Declares the resources used by a MapReduce job. Typically, you must specify the name of the resource where the Map or Reduce function is located in resource_name_list. **Notice** If the Map or Reduce function reads from other MaxCompute resources, you must add the names of these resource to resource_name_list. Multiple resources are separated by commas. If you want to use resources in another project, you must append PROJECT_NAME/resources/ before the resource name, such as -resources otherproject/resources/resfile.

Note The preceding optional parameters are included in <GENERIC_OPTIONS>.

You can use the -conf option to specify the JobConf file. This file can affect the settings of JobConf in the SDK. For more information about JobConf, see the introduction of MapReduce core interfaces. The following is an example of a JobConf file.

Example:

```
<configuration>
<property>
<name>import.filename</name>
<value>resource.txt</value>
</property>
</configuration>
```

In the preceding example, the JobConf file is used to define a variable named import.filename. The value of this variable is resource.txt. You can use the JobConf API in MapReduce to obtain the value of this variable. You can also use the JobConf API in the SDK for the same purpose.

Example:

```
jar -resources mapreduce-examples.jar -classpath mapreduce-examples.jar
org.alidata.odps.mr.examples.WordCount wc_in wc_out
add file data/src.txt
jar -resources src.txt,mapreduce-examples.jar -classpath mapreduce-examples.jar org.alidata.odps.mr
.examples.WordCount wc_in wc_out
add file data/a.txt
add table wc_in as test_table add jar work.jar
jar -conf odps-mapred.xml -resources a.txt,test_table,work.jar
-classpath work.jar:otherlib.jar
-D import.filename=resource.txt org.alidata.odps.mr.examples.WordCount args
```

1.8.2.2. Concepts

1.8.2.2.1. MapReduce

Map and Reduce functions support setup and cleanup methods for their corresponding map() and reduce() methods. A setup method is called prior to the Map() or Reduce() method. Each worker calls it once. A cleanup method is called after the Map() or Reduce() method. Each worker calls it once.

> **Note** For more information about the usage example, see Example program.

1.8.2.2.2. Sorting

Columns in the key records output by map can be set as sort columns. Custom comparators are not supported. You can select a few sort columns as group columns. Custom group comparators are not supported. Sort columns are generally used to sort user data, while group columns are used for secondary sorting.

> **Note** For detailed examples, see Secondary sorting source code.

1.8.2.2.3. Partition

MaxCompute supports partition columns and custom partitioners. Partition columns take precedence over custom partitioners. Partitioners are used to allocate Map output data to different Reduce workers based on the partition logic.

1.8.2.2.4. Combiner

The Combiner function combines adjacent records in the Shuffle stage. You can choose to use the Combiner function based on your business logic. The Combiner function is an optimized MapReduce computing framework. The Combiner logic is the same as the Reduce logic. After map outputs data, the framework merges data with the same key value on the map side locally.

1.8.2.2.5. Submit a job

This topic describes how to use the MaxCompute client to run and submit a MapReduce job.

The MaxCompute client provides a JAR command for running MapReduce jobs. Syntax:

```
jar [<GENERIC_OPTIONS>] <MAIN_CLASS> [ARGS];
    -conf <configuration_file>        Specify an application configuration file
    -resources <resource_name_list>    file\table resources used in mapper or reducer, seperate by co
mma
    -classpath <local_file_list>      classpaths used to run mainClass
    -D <name>=<value>                 Property value pair, which will be used to run mainClass
    -l                          Run job in local mode
```

Example:

```
jar -conf \home\admin\myconf -resources a.txt,example.jar -classpath ..\lib\example.jar:.\other_lib.jar
-D java.library.path=.\native;
```

<GENERIC_OPTIONS> includes the following options, which are all optional:

- **-conf <configuration file>**: specifies the JobConf file. This file can affect the settings of JobConf in the SDK.
- **-resources <resource_name_list>**: declares the resources used for running the MapReduce job. You must specify the names of the resources in which the Map or Reduce function is located in resource_name_list.

  > **Note** If the Map or Reduce function reads from other MaxCompute resources, you must add the names of these resources to resource_name_list. Separate multiple resources with commas (,). If you want to use resources in another project, you must append PROJECT/resources/ to the beginning of the resource name, such as -resources otherproject/resources/resfile.

- **-classpath <local_file_list>**: specifies the classpath for local execution. It is used to specify the local paths (including relative and absolute paths) of the JAR package where the main function is located. Package names are separated with default file delimiters of the system. In most cases, semicolons (;) are used in Windows, and commas (,) are used in Linux. If you run a MapReduce job on a cloud server, separate package names with commas (,).

  > **Note** The main function and Map/Reduce function are usually written in the same package. In this case, the -resources and -classpath options both contain information such as mapreduce-examples.jar. However, -resources references the Map or Reduce function and is executed in a distributed environment, while -classpath references the main function and is executed locally with the specified JAR package saved in a local directory.

- **-D <name>=<value>**: specifies the Java attribute of <mainClass> during local execution. You can define multiple attributes.
- **-l** specifies that the MapReduce job is run locally. It is mainly used for program debugging.

The following code is an example of the JobConf file:

```
<configuration>
    <property>
      <name>import.filename</name>
      <value>resource.txt</value>
    </property>
  </configuration>
```

In the preceding example, the JobConf file is used to define a variable named import.filename. The value of this variable is resource.txt. You can use the JobConf API in MapReduce to obtain the value of this variable. You can also use the JobConf API in the SDK for the same purpose.

Example:

```
add jar data\mapreduce-examples.jar;
  jar -resources mapreduce-examples.jar -classpath data\mapreduce-examples.jar
    org.alidata.odps.mr.examples.WordCount wc_in wc_out;
  add file data\src.txt;
  add jar data\mapreduce-examples.jar;
  jar -resources src.txt,mapreduce-examples.jar -classpath data\mapreduce-examples.jar
    org.alidata.odps.mr.examples.WordCount wc_in wc_out;
  add file data\a.txt;
  add table wc_in as test_table;
  add jar data\work.jar;
  jar -conf odps-mapred.xml -resources a.txt,test_table,work.jar
    -classpath data\work.jar:otherlib.jar
    -D import.filename=resource.txt org.alidata.odps.mr.examples.WordCount args;
```

1.8.2.2.6. Input and output

- MaxCompute MapReduce supports the following build-in data types: Bigint, Double, String, Datetime, Boolean, Decimal, Tinyint, Smallint, Int, Float, Varchar, Timestamp, Binary, Array, Map, and Struct. MapReduce does not support custom data types.
- MapReduce supports input from multiple tables with different schemas. You can use the map function to obtain the table information corresponding to the current record.
- MapReduce supports NULL as input, but does not support views as input.
- Reduce can write output to different tables or different partitions of a table. The target tables can have different schemas. Each output is identified by a label. An output is not labeled by default. At least one output is generated.

> Note For examples, see Example programs.

1.8.2.2.7. Read data from resources

You can use the Map or Reduce function to read data from MaxCompute resources. Any Map or Reduce worker loads resources to the memory for you to write code.

> Note For a detailed example, see Resource utilization example.

1.8.2.2.8. Run MapReduce tasks locally

You can specify the -local parameter in the jar command to enable local debugging by simulating the running of a local MapReduce instance. During local running, the client downloads from MaxCompute the metadata and data of the input table, required resources, and the metadata of the output table needed for local debugging. The client saves the data to a local directory named warehouse. When MapReduce running is complete, MapReduce saves the computing results to a file in the warehouse directory. If the input table and required resources are already downloaded to the local warehouse directory, MapReduce directly references the data and files in the warehouse directory the next time it runs, instead of downloading the data again.

A MapReduce instance that is running locally may start multiple map or reduce processes, which run serially rather than concurrently. The simulated running process is different from an actual distributed running process in the following aspects:

- Input table row count: Up to 100 rows of data can be downloaded.
- Resource usage: In a distributed environment, MaxCompute limits the size of referenced resources. For more information, see Application limits. During local running, the size of resources is unlimited.
- Security limits: MaxCompute MapReduce and UDF programs running in a distributed environment are subject to Java sandbox restrictions. There is no such restrictions during local running.

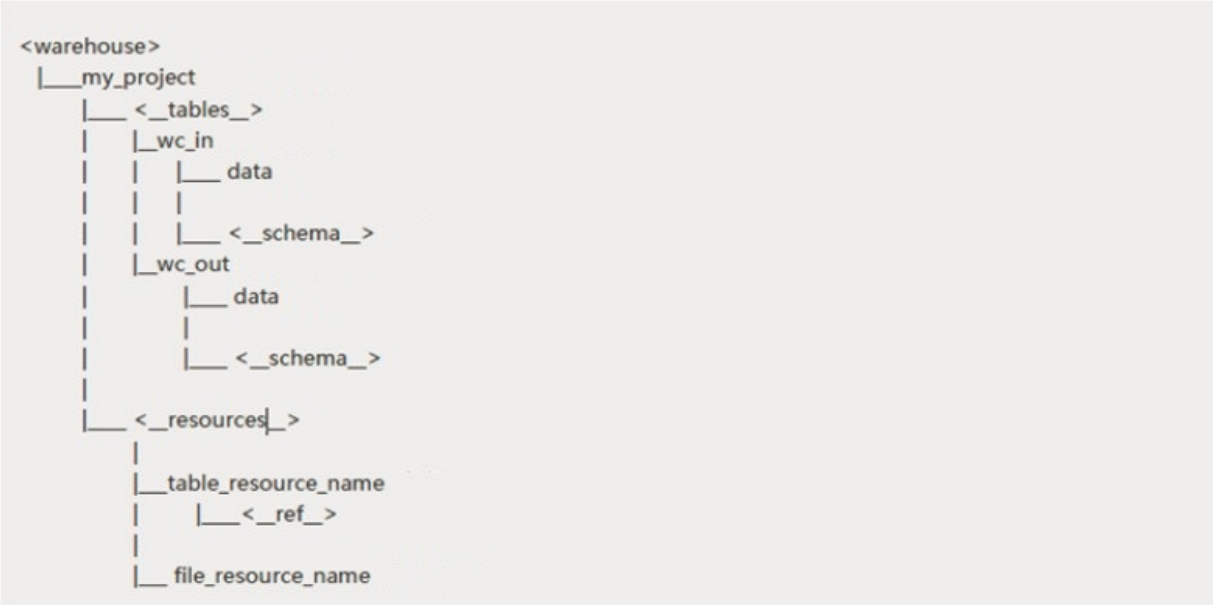
The following is a simple local running example.

Example:

```
odps@my_project> jar -l com.aliyun.odps.mapred.example.WordCount wc_in wc_out;
 Summary:
counters: 10
map-reduce framework combine_input_groups=2 combine_output_records=2 map_input_bytes=4 map_i
nput_records=1 map_output_records=2 map_output_[wc_out]_bytes=0 map_output_[wc_out]_records=0
reduce_input_groups=2 reduce_output_[wc_out]_bytes=8 reduce_output_[wc_out]_records=2
OK
```

> Note For a WordCount example, see WordCount example.

If you run the local debugging command for the first time, a directory named warehouse is created in the current path after the command is complete. The following figure shows the directory structure of warehouse.



Directories of the same level as my_project are projects. wc_in and wc_out are data tables. The table file data that you read or write using the jar command is downloaded to directories of this level. The schema file contains the metadata of a table in the following format:

```
project=local_project_name
table=local_table_name
columns=col1_name:col1_type,col2_name:col2_type
partitions=p1:STRING,p2:BIGINT
-- This field is not required in this example.
```

> **Note** Separate the name and type of a column with a colon (:), and separate columns with commas (,). You need to declare the project name and table name at the top of the schema files as projectname.tablename. Separate the declaration from column definition with a comma (,). The data file stores table data. The number of columns and data values must match the definition in the schema file. Separate columns with commas (,).

Example of wc_in schema file:

```
my_project.wc_in,key:STRING,value:STRING
```

Example of the corresponding data file:

```
0,2
```

> **Note** The client downloads the metadata and part of the data of a table from MaxCompute, and saves the data to the preceding files. The next time you run this example, the client directly uses the data in the wc_in directory, instead of downloading it again. Note that you can download data from MaxCompute only when running MapReduce locally. If you use the Eclipse plugin for local debugging, you cannot download data from MaxCompute.

Example of wc_out schema file:

```
my_project.wc_out,key:STRING,cnt:BIGINT
```

Example of the corresponding data file:

```
0,1
2,1
```

> **Note** The client downloads the metadata of we_out from MaxCompute, and saves the data to the schema file. The data file is generated to store the local running results. You can also compile schema and data files, and save them in the corresponding table directory. Then, when you run MapReduce locally, the client detects these files in the table directory, and will not download data from MaxCompute. The local table directory does not have to correspond to an actual table in MaxCompute.

The following table compares the features of Hadoop MapReduce with MaxCompute MapReduce.

Feature comparison

Feature	Hadoop MapReduce	MaxCompute MapReduce
Task progress report	The map stage calculates the read data volume. The Reduce step monitors the progress of various phases. Based on this information, the overall task progress can be estimated. The client can obtain real-time task progress. Task progress is not controlled by users.	Real-time task progress reporting is supported in a different way.
Statistics	Custom statistics, real-time summary, and real-time updates are supported. Real-time statistics updates are not controlled by users.	Real-time statistics updates are not supported during runtime. Calculation and summary are performed after a task is completed.
File compression	Users have an option to specify compressed storage.	File compression is not supported. Users cannot directly store files.
Speculative execution	/	Speculative execution is enabled by default, and cannot be configured by users.

Feature	Hadoop MapReduce	MaxCompute MapReduce
End of task notification	The server notifies the client of task completion.	No notifications are provided. When using the SDK to submit tasks, users must poll task status constantly until the tasks are completed.

1.8.3. SDK introduction

1.8.3.1. Major API overview

Major APIs

API	Description
MapperBase	User-defined Map functions must inherit this class. It converts the record objects in the input table into key-value pairs, and outputs them to the Reduce stage or directly to the result table by skipping the Reduce stage. The jobs that skip the Reduce stage and directly output calculation results are also called Map-Only jobs.
ReducerBase	User-defined Reduce functions must inherit this class. It reduces a set of values associated with a key.
TaskContext	One of the input parameters of multiple member functions of MapperBase and ReducerBase. It contains the contextual information of task execution.
JobClient	It is used to submit and manage jobs, including the blocking mode (synchronous) and non-blocking mode (asynchronous).
RunningJob	Job runtime objects for tracking running MapReduce job instances.
JobConf	Describes the configuration of a MapReduce task. The JobConf object is generally defined in the main program (main function). Then, JobClient submits the job to MaxCompute.

1.8.3.2. API description

1.8.3.2.1. MapperBase

The following table lists the major function APIs.

Major APIs

API	Description
void cleanup(TaskContext context)	The Map method is called after the map stage ends.
void map(long key, Record record, TaskContext context)	Map method for processing records in the input table.

API	Description
void setup(TaskContext context)	The Map method is called before the map stage begins.

1.8.3.2.2. ReducerBase

The following table lists the major function APIs.

Major APIs

API	Description
void cleanup(TaskContext context)	The Reduce method is called after the reduce stage ends.
void reduce(Record key, Iterator<Record > values, TaskContext context)	Reduce method, processing records in input table.
void setup(TaskContext context)	The Reduce method is called before the reduce stage begins.

1.8.3.2.3. TaskContext

The following table lists the major function APIs.

Major APIs

API	Description
TableInfo[] getOutputTableInfo()	Get output table information.
Record createOutputRecord()	Create record object of default output table.
Record createOutputRecord(String label)	Create record object of given label output table.
Record createMapOutputKeyRecord()	Create record object of Map output Key.
Record createMapOutputValueRecord()	Create record object of Map output Value.
void write(Record record)	Write record to default output for writing data at Reduce end. Can be called multiple times at Reduce end.
void write(Record record, String label)	Write record to given label output for writing data at Reduce end. Can be called multiple times at Reduce end.
void write(Record key, Record value)	Write record to intermediate result for writing data at Map end. Can be called multiple times at Map end.

API	Description
BufferedInputStream readResourceFileAsStream(String resourceName)	Read file type resource.
Iterator<Record > readResourceTable(String resourceName)	Reads table type resources.
Counter getCounter(Enum<? > name)	Get Counter object of given name.
Counter getCounter(String group, String name)	Get Counter object of given group name and name.
void progress()	Report heartbeat information to the MapReduce framework. If the processing time of your method is extended, and you have not called the framework during the current process, call it to avoid a task timeout period. 600 seconds is set as the timeout period by default.

Note TaskContext API has a progress function which prevents it from being forced out due to time-out if a worker runs for a long time. This API sends heartbeats to the framework rather than reporting the Worker progress. The default worker timeout period for MaxCompute MapReduce is 10 minutes (which cannot be modified by the user). If the worker does not send a heartbeat (calling the progress API) in 10 minutes, the framework terminates the worker and the MapReudce task fails. We recommend that you let the worker call the progress API periodically in the Mapper/Reducer function to prevent the framework from terminating the task unexpectedly.

1.8.3.2.4. JobConf

The following table lists the major function APIs.

Major APIs

API	Description
void setResources(String resourceNames)	Declare resources this job uses. Only declared resources are available to be read through TaskContext object while run Mapper/Reducer.
void setMapOutputKeySchema(Column[] schema)	Set attribute of Key output from Mapper to Reducer.
void setMapOutputValueSchema(Column[] schema)	Set attribute of Value output from Mapper to Reducer.
void setOutputKeySortColumns(String[] cols)	Set sorting columns of Key output from Mapper to Reducer.
void setOutputGroupingColumns(String[] cols)	Set Key grouping columns.

API	Description
void setMapperClass(Class<? extends Mapper > > > theClass)	Set Mapper function of job.
void setPartitionColumns(String[] cols)	Set partition columns designated by job. It is all the columns of Mapper output Key by default.
void setReducerClass(Class<? extends Reducer > theClass)	Set the job reducer.
void setCombinerClass(Class<? extends Reducer > theClass)	Set job combiner. When run at Map side, the function is similar to a single Map and local Key value of the local Reduce.
void setSplitSize(long size)	Set input split size, unit: MB, default value: 640.
void setNumReduceTasks(int n)	Set number of Reducer task, it is 1/4 number of Mapper task by default.
void setMemoryForMapTask(int mem)	Set memory size of single Worker in Mapper tasks, unit: MB, default value: 2048.
void setMemoryForReduceTask(int mem)	Set memory size of single Worker in Reduce tasks, unit: MB, default value: 2048.
void setOutputSchema(Column[] schema, String label)	Set output attribute of designated label. While multiplexed output, each output corresponds to 1 label.

Note

- Normally, GroupingColumns is included in KeySortColumns, and KeySortColumns is included in Key.
- At the Map side, the Record output from Mapper calculates Hash value and then, based on the set PartitionColumns, determines which Reducer to distribute to for sorting Records based on KeySortColumns.
- At the Reduce side, after sorting input Records based on KeySortColumns, Records are grouped based on columns designated by GroupingColumns, and are input in traversal sequence. The use of the same Records in columns designated by GroupingColumns as 1 input called by reduce function.

1.8.3.2.5. JobClient

The following table lists the major function APIs.

Major APIs

API	Description

API	Description
static RunningJob runJob(JobConf job)	Use blocking (synchronous) mode to submit MapReduce jobs and return immediately.
static RunningJob submitJob(JobConf job)	Use non-blocking (asynchronous) mode to submit MapReduce jobs and return immediately.

1.8.3.2.6. RunningJob

The following table lists the major function APIs.

Major APIs

API	Description
String getInstanceID()	Get instance ID for checking run log and job management.
boolean isComplete()	Check whether job is complete.
boolean isSuccessful()	Check whether job instance is successful.
void waitForCompletion()	Wait until job instance is complete. It is typically is used for jobs submitted is asynchronous mode.
JobStatus getJobStatus()	Check job instance status.
void killJob()	End the job.
Counters getCounters()	Get Counter information.

1.8.3.2.7. InputUtils

The following table lists the major function APIs.

Major APIs

API	Description
static void addTable(TableInfo table, JobConf conf)	Add table to task input. It can be called more than once. Newly added tables are appended to input queue.
static void setTables(TableInfo [] tables, JobConf conf)	Add tables to task input.

1.8.3.2.8. OutputUtils

The following table lists the major function APIs.

Major APIs

API	Description
static void addTable(TableInfo table, JobConf conf)	Adds a table to the task output. It can be called more than once. Newly added tables are appended to the output queue.
static void setTables(TableInfo [] tables, JobConf conf)	Adds multiple tables to the task output.

1.8.3.2.9. Pipeline

Pipeline is the main class of MR2. A Pipeline can be built with Pipeline.Builder. Major Pipeline APIs are as follows:

```
public Builder addMapper(Class<? extends Mapper> mapper)
public Builder addMapper(Class<? extends Mapper> mapper,Column[] keySchema, Column[] valueSche
ma, String[] sortCols, SortOrder[] order, String[] partCols,Class<? extends Partitioner> theClass, String
[] groupCols)
public Builder addReducer(Class<? extends Reducer> reducer)
public Builder addReducer(Class<? extends Reducer> reducer,Column[] keySchema, Column[] valueSch
ema, String[] sortCols, SortOrder[] order, String[] partCols,Class<? extends Partitioner> theClass, Strin
g[] groupCols)
public setoutputkeyschema builder (Column [] keyschema)
public setoutputvalueschema builder (Column [] valueschema)
public setoutputkeysortcolumns builder (String [] sortcols)
public setoutputkeysortorder builder (Sortorder [] order)
public setpartitioncolumns builder (String [] partcols)
public Builder setPartitionerClass(Class<? extends Partitioner> theClass)
public Builder setOutputGroupingColumns(String[] cols)
```

Example:

```
job job = new job ();
pipeline pipeline = pipeline. builder ()
. Addmapper (maid. Class)
.setOutputKeySchema(
new Column[] { new Column("word", OdpsType.STRING) })
.setOutputValueSchema(
new Column[] { new Column("count", OdpsType.BIGINT) })
. addreducer (Sumreducer. class)
. setoutputkeyschema (
new Column[] { new Column("count", OdpsType.BIGINT) })
.setOutputValueSchema(
new column [] {new column ("word", OdpsType. string),
new column ("count", OdpsType. bigint)})
. addreducer (Identityreducer. class). createPipeline ();
job.setPipeline(pipeline); job.addInput(...)
job.addOutput(...) job.submit();
```

As shown in the preceding example, you can build MapReduce tasks of a Map operation followed by two Reduce operations in the MAIN function. If you are familiar with the basic features of MapReduce, you can use MR2 easily . We also recommend that you learn the basic features of MapReduce before using MR2, namely configuring MapReduce tasks through JobConf. JobConf can only configure MapReduce tasks of a Map operation followed by a single Reduce operation.

1.8.3.3. Compatibility with Hadoop MapReduce

The following table describes whether specific MaxCompute MapReduce interfaces are compatible with Hadoop MapReduce.

Type	Interface	Compatible with Hadoop MapReduce?
Mapper	void map(KEYIN key, VALUEIN value, org.apache.hadoop.mapreduce.Mapper.Context context)	Yes
Mapper	void run(org.apache.hadoop.mapreduce.Mapper.Context context)	Yes
Mapper	void setup(org.apache.hadoop.mapreduce.Mapper.Context context)	Yes

Type	Interface	Compatible with Hadoop MapReduce?
Reducer	void cleanup(org.apache.hadoop.mapreduce.Reducer.Context context)	Yes
Reducer	void reduce(KEYIN key, VALUEIN value, org.apache.hadoop.mapreduce.Reducer.Context context)	Yes
Reducer	void run(org.apache.hadoop.mapreduce.Reducer.Context context)	Yes
Reducer	void setup(org.apache.hadoop.mapreduce.Reducer.Context context)	Yes
Partitioner	int getPartition(KEY key, VALUE value, int numPartitions)	Yes
MapContext (which extends TaskInputOutputContext)	InputSplit getInputSplit()	No. An exception is reported.
ReduceContext	nextKey()	Yes
ReduceContext	getValues()	Yes
TaskInputOutputContext	getCurrentKey()	Yes
TaskInputOutputContext	getCurrentValue()	Yes
TaskInputOutputContext	getOutputCommitter()	No. An exception is reported.
TaskInputOutputContext	nextKeyValue()	Yes
TaskInputOutputContext	write(KEYOUT key, VALUEOUT value)	Yes
TaskAttemptContext	getCounter(Enum<? > counterName)	Yes
TaskAttemptContext	getCounter(String groupName, String counterName)	Yes
TaskAttemptContext	setStatus(String msg)	Empty implementation
TaskAttemptContext	getStatus()	Empty implementation
TaskAttemptContext	getTaskAttemptID()	No. An exception is reported.

Type	Interface	Compatible with Hadoop MapReduce?
TaskAttemptContext	getProgress()	No. An exception is reported.
TaskAttemptContext	progress()	Yes
Job	addArchiveToClassPath(Path archive)	No
Job	addCacheArchive(URI uri)	No
Job	addCacheFile(URI uri)	No
Job	addFileToClassPath(Path file)	No
Job	cleanupProgress()	No
Job	createSymlink()	No. An exception is reported.
Job	failTask(TaskAttemptID taskId)	No
Job	getCompletionPollInterval(Configuration conf)	Empty implementation
Job	getCounters()	Yes
Job	getFinishTime()	Yes
Job	getHistoryUrl()	Yes
Job	getInstance()	Yes
Job	getInstance(Cluster ignored)	Yes
Job	getInstance(Cluster ignored, Configuration conf)	Yes
Job	getInstance(Configuration conf)	Yes
Job	getInstance(Configuration conf, String jobName)	Empty implementation
Job	getInstance(JobStatus status, Configuration conf)	No. An exception is reported.
Job	getJobFile()	No. An exception is reported.
Job	getJobName()	Empty implementation
Job	getJobState()	No. An exception is reported.
Job	getPriority()	No. An exception is reported.

Type	Interface	Compatible with Hadoop MapReduce?
Job	getProgressPollInterval(Configuration conf)	Empty implementation
Job	getReservationId()	No. An exception is reported.
Job	getSchedulingInfo()	No. An exception is reported.
Job	getStartTime()	Yes
Job	getStatus()	No. An exception is reported.
Job	getTaskCompletionEvents(int startFrom)	No. An exception is reported.
Job	getTaskCompletionEvents(int startFrom, int numEvents)	No. An exception is reported.
Job	getTaskDiagnostics(TaskAttemptID taskid)	No. An exception is reported.
Job	getTaskOutputFilter(Configuration conf)	No. An exception is reported.
Job	getTaskReports(TaskType type)	No. An exception is reported.
Job	getTrackingURL()	Yes
Job	isComplete()	Yes
Job	isRetired()	No. An exception is reported.
Job	isSuccessful()	Yes
Job	isUber()	Empty implementation
Job	killJob()	Yes
Job	killTask(TaskAttemptID taskId)	No
Job	mapProgress()	Yes
Job	monitorAndPrintJob()	Yes
Job	reduceProgress()	Yes
Job	setCacheArchives(URI[] archives)	No. An exception is reported.
Job	setCacheFiles(URI[] files)	No. An exception is reported.

Type	Interface	Compatible with Hadoop MapReduce?
Job	setCancelDelegationTokenUponJobCompletion(boolean value)	No. An exception is reported.
Job	setCombinerClass(Class<? extends Reducer> cls)	Yes
Job	setCombinerKeyGroupingComparatorClass(Class<? extends RawComparator> cls)	Yes
Job	setGroupingComparatorClass(Class<? extends RawComparator> cls)	Yes
Job	setInputFormatClass(Class<? extends InputFormat> cls)	Empty implementation
Job	setJar(String jar)	Yes
Job	setJarByClass(Class<? > cls)	Yes
Job	setJobName(String name)	Empty implementation
Job	setJobSetupCleanupNeeded(boolean needed)	Empty implementation
Job	setMapOutputKeyClass(Class<? > theClass)	Yes
Job	setMapOutputValueClass(Class<? > theClass)	Yes
Job	setMapperClass(Class<? extends Mapper> cls)	Yes
Job	setMapSpeculativeExecution(boolean speculativeExecution)	Empty implementation
Job	setMaxMapAttempts(int n)	Empty implementation
Job	setMaxReduceAttempts(int n)	Empty implementation
Job	setNumReduceTasks(int tasks)	Yes
Job	setOutputFormatClass(Class<? extends OutputFormat> cls)	No. An exception is reported.
Job	setOutputKeyClass(Class<? > theClass)	Yes

Type	Interface	Compatible with Hadoop MapReduce?
Job	setOutputValueClass(Class<? > theClass)	Yes
Job	setPartitionerClass(Class<? extends Partitioner> cls)	Yes
Job	setPriority(JobPriority priority)	No. An exception is reported.
Job	setProfileEnabled(boolean newValue)	Empty implementation
Job	setProfileParams(String value)	Empty implementation
Job	setProfileTaskRange(boolean isMap, String newValue)	Empty implementation
Job	setReducerClass(Class<? extends Reducer> cls)	Yes
Job	setReduceSpeculativeExecution(boolean speculativeExecution)	Empty implementation
Job	setReservationId(ReservationId reservationId)	No. An exception is reported.
Job	setSortComparatorClass(Class <? extends RawComparator> cls)	No. An exception is reported.
Job	setSpeculativeExecution(boolean speculativeExecution)	Yes
Job	setTaskOutputFilter(Configuration conf, org.apache.hadoop.mapreduce.Job.TaskStatusFilter newValue)	No. An exception is reported.
Job	setupProgress()	No. An exception is reported.
Job	setUser(String user)	Empty implementation
Job	setWorkingDirectory(Path dir)	Empty implementation
Job	submit()	Yes
Job	toString()	No. An exception is reported.
Job	waitForCompletion(boolean verbose)	Yes

Type	Interface	Compatible with Hadoop MapReduce?
Task Execution & Environment	mapreduce.map.java.opts	Empty implementation
Task Execution & Environment	mapreduce.reduce.java.opts	Empty implementation
Task Execution & Environment	mapreduce.map.memory.mb	Empty implementation
Task Execution & Environment	mapreduce.reduce.memory.mb	Empty implementation
Task Execution & Environment	mapreduce.task.io.sort.mb	Empty implementation
Task Execution & Environment	mapreduce.map.sort.spill.percent	Empty implementation
Task Execution & Environment	mapreduce.task.io.soft.factor	Empty implementation
Task Execution & Environment	mapreduce.reduce.merge.inmem.thresholds	Empty implementation
Task Execution & Environment	mapreduce.reduce.shuffle.merge.percent	Empty implementation
Task Execution & Environment	mapreduce.reduce.shuffle.input.buffer.percent	Empty implementation
Task Execution & Environment	mapreduce.reduce.input.buffer.percent	Empty implementation
Task Execution & Environment	mapreduce.job.id	Empty implementation
Task Execution & Environment	mapreduce.job.jar	Empty implementation
Task Execution & Environment	mapreduce.job.local.dir	Empty implementation
Task Execution & Environment	mapreduce.task.id	Empty implementation
Task Execution & Environment	mapreduce.task.attempt.id	Empty implementation
Task Execution & Environment	mapreduce.task.is.map	Empty implementation
Task Execution & Environment	mapreduce.task.partition	Empty implementation
Task Execution & Environment	mapreduce.map.input.file	Empty implementation
Task Execution & Environment	mapreduce.map.input.start	Empty implementation
Task Execution & Environment	mapreduce.map.input.length	Empty implementation
Task Execution & Environment	mapreduce.task.output.dir	Empty implementation

Type	Interface	Compatible with Hadoop MapReduce?
JobClient	cancelDelegationToken(Token <DelegationTokenIdentifier> token)	No. An exception is reported.

org.apache.hadoop.mapreduce.lib.db	N/A	No. An exception is reported.

1.8.4. Data types

MapReduce supports the following data types: bigint, double, string, datetime, boolean, decimal, tinyint, smallint, int, float, varchar, timestamp, binary, array, map, and struct. The following table lists the mappings between MaxCompute data types and Java types.

Data type mapping

MaxCompute type	Java type
Tinyint	java.lang.Byte
Smallint	java.lang.Short
Int	java.lang.Integer
Bigint	java.lang.Long
Float	java.lang.Float
Double	java.lang.Double
Decimal	java.math.BigDecimal
Boolean	java.lang.Boolean
String	java.lang.String
Varchar	com.aliyun.odps.data.Varchar
Binary	com.aliyun.odps.data.Binary
Datetime	java.util.Date
Timestamp	java.sql.Timestamp
Array	java.util.List

MaxCompute type	Java type
Map	java.util.Map
Struct	com.aliyun.odps.data.Struct

1.8.5. Limits

The following limits apply to MapReduce:

- A Map or Reduce worker consumes 2,048 MB memory by default. The value range is 256 MB to 12 GB.
- Each task can reference up to 256 resources. Each partitioned table is considered as one unit.
- Each task can have up to 1,024 inputs and up to 256 outputs.
- Each task can have up to 64 custom counters.
- The number of Map instances in a job is calculated by the framework based on the split size. If no input table is specified, you can use odps.stage.mapper.num to set the number of Map instances. The number is in the range of 1 to 100,000.
- The default number of Reduce instances in a job is 1/4 of the number of Map instances. You can set this number in the range of 0 to 2,000. The following situation may occur: Reduce instances process much more data than Map instances, which results in a slow Reduce stage. Furthermore, a maximum of 2,000 Reduce instances can be created.
- Each Map or Reduce instance can retry three times after failure. Exceptions that do not allow retries can cause a job to fail.
- For local jobs, the number of Map or Reduce workers cannot exceed 100, while the number of downloads for an input is 100 by default.
- Each Map or Reduce worker can read a resource a maximum of 64 times.
- A task can reference a maximum of 2 GB resources.
- The framework determines the number of Map instances based on the split size.
- The length of string columns in MaxCompute tables cannot exceed 8 MB.
- If no data access operations or heartbeat packets are sent through context.progress(), the default timeout period of a Map or Reduce worker is 600s.

1.8.6. Sample programs

1.8.6.1. WordCount example

Example:

```
package com.aliyun.odps.mapred.open.example;
import java.io.IOException; import java.util.Iterator;
import com.aliyun.odps.data.Record;
import com.aliyun.odps.data.TableInfo;
import com.aliyun.odps.mapred.JobClient;
import com.aliyun.odps.mapred.MapperBase;
import com.aliyun.odps.mapred.ReducerBase;
import com.aliyun.odps.mapred.TaskContext;
```

```
import com.aliyun.odps.mapred.TaskContext;
import com.aliyun.odps.mapred.conf.JobConf;
import com.aliyun.odps.mapred.utils.InputUtils;
import com.aliyun.odps.mapred.utils.OutputUtils;
import com.aliyun.odps.mapred.utils.SchemaUtils;
public class WordCount {
public static class TokenizerMapper extends MapperBase {
private Record word;
private Record one;
@Override
public void setup(TaskContext context) throws IOException {
word = context.createMapOutputKeyRecord();
one = context.createMapOutputValueRecord();
one.set(new Object[] { 1L });
System.out.println("TaskID:" + context.getTaskID().toString());
}
@Override
public void map(long recordNum, Record record, TaskContext context) throws IOException {
for (int i = 0; i < record.getColumnCount(); i++) {
word.set(new Object[] { record.get(i).toString() });
context.write(word, one);
}
}
}
/**
*A combiner class that combines map output by sum them.
**/
public static class SumCombiner extends ReducerBase {
private Record count;
@Override
public void setup(TaskContext context) throws IOException {
count = context.createMapOutputValueRecord();
}
@Override
public void reduce(Record key, Iterator<Record> values, TaskContext context)
throws IOException {
long c = 0;
while (values.hasNext()) {
Record val = values.next();
c += (Long) val.get(0);
}
```

```
count.set(0, c);
context.write(key, count);
}
}
/**
* A reducer class that just emits the sum of the input values.
**/
public static class SumReducer extends ReducerBase {
private Record result = null;
@Override
public void setup(TaskContext context) throws IOException { result = context.createOutputRecord();
}
@Override
public void reduce(Record key, Iterator<Record> values, TaskContext context)
throws IOException {
long count = 0;
while (values.hasNext()) {
Record val = values.next();
count += (Long) val.get(0);
}
result.set(0, key.get(0));
result.set(1, count);
context.write(result);
}
}
public static void main(String[] args)
throws Exception {
if (args.length ! = 2) {
System.err.println("Usage: WordCount <in_table> <out_table>");
System.exit(2);
}
JobConf job = new JobConf();
job.setMapperClass(TokenizerMapper.class);
job.setCombinerClass(SumCombiner.class);
job.setReducerClass(SumReducer.class);
job.setMapOutputKeySchema(SchemaUtils.fromString("word:string"));
job.setMapOutputValueSchema(SchemaUtils.fromString("count:bigint"));
InputUtils.addTable(TableInfo.builder().tableName(args[0]).build(), job);
OutputUtils.addTable(TableInfo.builder().tableName(args[1]).build(), job);
JobClient.runJob(job);
}
```

```
}
```

1.8.6.2. MapOnly example

For MapOnly jobs, Map directly sends < Key, Value > pairs to tables on MaxCompute. You only need to specify output tables. You do not need to specify the key-value metadata for map output.

Example:

```
package com.aliyun.odps.mapred.open.example;
import java.io.IOException;
import com.aliyun.odps.data.Record;
import com.aliyun.odps.mapred.JobClient;
import com.aliyun.odps.mapred.MapperBase;
import com.aliyun.odps.mapred.conf.JobConf;
import com.aliyun.odps.mapred.utils.SchemaUtils;
import com.aliyun.odps.mapred.utils.InputUtils;
import com.aliyun.odps.mapred.utils.OutputUtils;
import com.aliyun.odps.data.TableInfo;
public class MapOnly {
public static class MapperClass extends MapperBase {
@Override
public void setup(TaskContext context)
throws IOException {
boolean is = context.getJobConf().getBoolean("option.mapper.setup", false);
if (is) {
Record result = context.createOutputRecord();
result.set(0, "setup");
result.set(1, 1L); context.write(result);
}
}
@Override
public void map(long key, Record record, TaskContext context) throws IOException {
boolean is = context.getJobConf().getBoolean("option.mapper.map", false);
if (is) {
Record result = context.createOutputRecord();
result.set(0, record.get(0));
result.set(1, 1L); context.write(result);
}
}
@Override
```

```
public void cleanup(TaskContext context) throws IOException {
boolean is = context.getJobConf().getBoolean("option.mapper.cleanup", false);
if (is) {
Record result = context.createOutputRecord();
result.set(0, "cleanup");
result.set(1, 1L); context.write(result);
}
}
}
public static void main(String[] args) throws Exception {
if (args.length ! = 2 && args.length ! = 3) {
System.err.println("Usage: OnlyMapper <in_table> <out_table> [setup|map|cleanup]");
System.exit(2);
}
JobConf job = new JobConf();
job.setMapperClass(MapperClass.class);
job.setNumReduceTasks(0);
InputUtils.addTable(TableInfo.builder().tableName(args[0]).build(), job);
OutputUtils.addTable(TableInfo.builder().tableName(args[1]).build(), job);
if (args.length == 3) {
String options = new String(args[2]);
if (options.contains("setup")) {
job.setBoolean("option.mapper.setup", true);
}
if (options.contains("map")) {
job.setBoolean("option.mapper.map", true);
}
if (options.contains("cleanup")) {
job.setBoolean("option.mapper.cleanup", true);
}
}
JobClient.runJob(job);
}
}
```

1.8.6.3. Example: Input and output data to multiple objects

MaxCompute jobs can read data from multiple input tables, and write data to multiple output tables. All input tables for a job must have the same schema (number and type of columns). The output tables for a job can have different schemas (number and type of columns).

Example:

```
package com.aliyun.odps.mapred.open.example;
import java.io.IOException; import java.util.Iterator;
import java.util.LinkedHashMap;
import com.aliyun.odps.data.Record;
import com.aliyun.odps.data.TableInfo;
import com.aliyun.odps.mapred.JobClient;
import com.aliyun.odps.mapred.MapperBase;
import com.aliyun.odps.mapred.ReducerBase;
import com.aliyun.odps.mapred.TaskContext;
import com.aliyun.odps.mapred.conf.JobConf;
import com.aliyun.odps.mapred.utils.InputUtils;
import com.aliyun.odps.mapred.utils.OutputUtils;
import com.aliyun.odps.mapred.utils.SchemaUtils;
/**
*Multi input & output example.
*
*To run: jar -resources odps-mapred-example-0.12.0.jar com.aliyun.odps.mapred.open.example.Multipl
eInOut
*mr_src,mr_src1,mr_srcpart|pt=1,mr_srcpart|pt=2/ds=2
*mr_multiinout_out1,mr_multiinout_out2|a=1/b=1|out1,mr_multiinout_out2|a=2/b=2|out2;
*
**/
public class MultipleInOut {
public static class TokenizerMapper extends MapperBase {
private Record word;
private Record one;
@Override
public void setup(TaskContext context) throws IOException {
word = context.createMapOutputKeyRecord();
one = context.createMapOutputValueRecord();
one.set(new Object[] { 1L });
}

OutputUtils.addTable(TableInfo.builder().tableName(args[1]).build(), job);
JobClient.runJob(job); System.exit(0);
}
}
```

1.8.6.6. Resource usage example

Example:

```
package com.aliyun.odps.mapred.open.example;
import java.io.BufferedInputStream;
import java.io.FileNotFoundException;
import java.io.IOException;
import com.aliyun.odps.data.Record;
import com.aliyun.odps.data.TableInfo;
import com.aliyun.odps.mapred.JobClient;
import com.aliyun.odps.mapred.MapperBase;
import com.aliyun.odps.mapred.TaskContext;
import com.aliyun.odps.mapred.conf.JobConf;
import com.aliyun.odps.mapred.utils.InputUtils;
import com.aliyun.odps.mapred.utils.OutputUtils;
import com.aliyun.odps.mapred.utils.SchemaUtils;
/**
* Upload
*
* Import data from text file into table
*
* To run: jar -resources > odps-mapred-example-0.12.0.jar,mr_join_src1.txt
* com.aliyun.odps.mapred.open.example.Upload mr_join_src1.txt > mr_join_src1;
```

```
* com.aliyun.odps.mapred.open.example.Upload mr_join_src1.txt > mr_join_src1;
*
**/
public class Upload {
public static class UploadMapper extends MapperBase {
@Override
public void setup(TaskContext context) throws IOException { Record record = context.createOutputRec
ord();
StringBuilder importdata = new StringBuilder();
BufferedInputStream bufferedInput = null;
try {
byte[] buffer = new byte[1024]; int bytesRead = 0;
String filename = context.getJobConf().get("import.filename");
bufferedInput = context.readResourceFileAsStream(filename);
while ((bytesRead = bufferedInput.read(buffer)) ! = -1) {
String chunk = new String(buffer, 0, bytesRead);
importdata.append(chunk);
}
String lines[] = importdata.toString().split("\n"); for (int i = 0; i < lines.length; i++) {
String[] ss = lines[i].split(",");
record.set(0, Long.parseLong(ss[0].trim()));
record.set(1, ss[1].trim()); context.write(record);
}
} catch (FileNotFoundException ex) { throw new IOException(ex);
} catch (IOException ex) { throw new IOException(ex);
} finally {
}
}
@Override
public void map(long recordNum, Record record, TaskContext context) throws IOException {
}
}
public static void main(String[] args) throws Exception { if (args.length ! = 2) {
System.err.println("Usage: Upload <import_txt> <out_table>");
System.exit(2);
}
JobConf job = new JobConf();
job.setMapperClass(UploadMapper.class);
job.set("import.filename", args[0]);
job.setNumReduceTasks(0);
job.setMapOutputKeySchema(SchemaUtils.fromString("key:bigint"));
```

```
job.setMapOutputValueSchema(SchemaUtils.fromString("value:string"));
InputUtils.addTable(TableInfo.builder().tableName("mr_empty").build(), job);
OutputUtils.addTable(TableInfo.builder().tableName(args[1]).build(), job);
JobClient.runJob(job);
}
}
```

> **Note**
>
> You can use the following methods to configure JobConf:
>
> - Use the JobConf API in the SDK. This method has the highest priority.
> - Use the -conf parameter in a jar command to specify a new JobConf file. This method has the lowest priority. For how to use -Conf, refer to the relevant command.

1.8.6.7. Example for using counters

Three counters are defined in this example: map_outputs, reduce_outputs, and global_counts. You can use the setup, map, reduce and cleanup APIs of the Map or Reduce function to obtain and operate custom counters.

Example:

```
package com.aliyun.odps.mapred.open.example;
import java.io.IOException; import java.util.Iterator;
import com.aliyun.odps.counter.Counter;
import com.aliyun.odps.counter.Counters;
import com.aliyun.odps.data.Record;
import com.aliyun.odps.mapred.JobClient;
import com.aliyun.odps.mapred.MapperBase;
import com.aliyun.odps.mapred.ReducerBase;
import com.aliyun.odps.mapred.RunningJob;
import com.aliyun.odps.mapred.conf.JobConf;
import com.aliyun.odps.mapred.utils.SchemaUtils;
import com.aliyun.odps.mapred.utils.InputUtils;
import com.aliyun.odps.mapred.utils.OutputUtils;
import com.aliyun.odps.data.TableInfo;
/**
* User Defined Counters
*
* To run: jar -resources odps-mapred-example-0.12.0.jar
* com.aliyun.odps.mapred.open.example.UserDefinedCounters mr_src > mr_testcounters_out;
*
**/
```

```
public class UserDefinedCounters {
enum MyCounter {
TOTAL_TASKS, MAP_TASKS, REDUCE_TASKS
}
public static class TokenizerMapper extends MapperBase {
private Record word;
private Record one;
@Override
public void setup(TaskContext context) throws IOException { super.setup(context);
Counter map_tasks = context.getCounter(MyCounter.MAP_TASKS);
Counter total_tasks = context.getCounter(MyCounter.TOTAL_TASKS);
map_tasks.increment(1);
total_tasks.increment(1);
word = context.createMapOutputKeyRecord();
one = context.createMapOutputValueRecord();
one.set(new Object[] { 1L });
}
@Override
public void map(long recordNum, Record record, TaskContext context) throws IOException {
for (int i = 0;
i < record.getColumnCount();
i++) {
word.set(new Object[] { record.get(i).toString() });
context.write(word, one);
}
}
}
public static class SumReducer extends ReducerBase {
private Record result = null;
@Override
public void setup(TaskContext context) throws IOException { result = context.createOutputRecord();
Counter reduce_tasks = context.getCounter(MyCounter.REDUCE_TASKS);
Counter total_tasks = context.getCounter(MyCounter.TOTAL_TASKS);
reduce_tasks.increment(1);
total_tasks.increment(1);
}
@Override
public void reduce(Record key, Iterator<Record> values, TaskContext context) throws IOException {
long count = 0;
while (values.hasNext()) {
Record val = values.next();
```

```
count += (Long) val.get(0);
}
result.set(0, key.get(0));
result.set(1, count);
context.write(result);
}
}
public static void main(String[] args) throws Exception { if (args.length ! = 2) {
System.err.println("Usage: TestUserDefinedCounters <in_table> <out_table>");
System.exit(2);
}
JobConf job = new JobConf();
job.setMapperClass(TokenizerMapper.class);
job.setReducerClass(SumReducer.class);
job.setMapOutputKeySchema(SchemaUtils.fromString("word:string"));
job.setMapOutputValueSchema(SchemaUtils.fromString("count:bigint"));
InputUtils.addTable(TableInfo.builder().tableName(args[0]).build(), job);
OutputUtils.addTable(TableInfo.builder().tableName(args[1]).build(), job);
RunningJob rJob = JobClient.runJob(job);
Counters counters = rJob.getCounters();
long m = counters.findCounter(MyCounter.MAP_TASKS).getValue();
long r = counters.findCounter(MyCounter.REDUCE_TASKS).getValue();
long total = counters.findCounter(MyCounter.TOTAL_TASKS).getValue();
System.exit(0);
}
}
```

1.8.6.8. grep example

Example:

```

 // sort by
// decreasing
// freq
@SuppressWarnings("unused")
RunningJob rjSort = JobClient.runJob(sortJob);
}
}
```

1.8.6.9. JOIN example

The MaxCompute MapReduce framework does not support the JOIN logic. However, you can use custom Map and Reduce functions to complete JOIN operations. This requires extra work.

Table mr_join_src1(key bigint, value string) must be joined with mr_join_src2(key bigint, value string). The output table is mr_join_out(key bigint, value1 string, value2 string), where value1 indicates the value of mr_join_src1 and value2 indicates the value of mr_join_src2.

Example:

```
package com.aliyun.odps.mapred.open.example;
import java.io.IOException;
Import java. util. arraylist;
import java.util.Iterator;
import java.util.List;
import com.aliyun.odps.counter.Counter;
import com.aliyun.odps.data.Record;
import com.aliyun.odps.data.TableInfo;
import com.aliyun.odps.mapred.JobClient;
import com.aliyun.odps.mapred.MapperBase;
import com.aliyun.odps.mapred.ReducerBase;
import com.aliyun.odps.mapred.TaskContext;
import com.aliyun.odps.mapred.conf.JobConf;
import com.aliyun.odps.mapred.utils.InputUtils;
import com.aliyun.odps.mapred.utils.OutputUtils;
import com.aliyun.odps.mapred.utils.SchemaUtils;
/**
```

```
* Join
*
* To run: jar -resources odps-mapred-example-0.12.0.jar
* com.aliyun.odps.mapred.open.example.Join mr_join_src11 > mr_join_src22 mr_join_out;
*
**/
public class Join {
public static class JoinMapper extends MapperBase {
private Record mapkey;
private Record mapvalue;
@Override
public void setup(TaskContext context) throws IOException {
mapkey = context.createMapOutputKeyRecord();
mapvalue = context.createMapOutputValueRecord();
}
@Override
public void map(long key, Record record, TaskContext context) throws IOException {
/* Determine the source table of the record based on the value field. This is the user code logic. If the
source table of the record cannot be determined based on the value field, you can add a field in the in
put table. The tag generated based on the value field is used in connection operations in the Reduce s
tage. */
long tag = 1;
String val = record.get(1).toString();
if (val.startsWith("valb_")) {

}
/**
* Implement the identity function, mapping record's first two columns > to
* outputs.
**/
public static class IdentityMapper extends MapperBase {
private Record key;
private Record value;
@Override
public void setup(TaskContext context) throws IOException {
key = context.createMapOutputKeyRecord();
value = context.createMapOutputValueRecord();
}
@Override
public void map(long recordNum, Record record, TaskContext context) throws IOException {
Key.set (new object [] {(long) record.get (0 )});
value.set(new Object[] { (Long) record.get(1) });
context.write(key, value);
}
}
/**
* The main driver for sort program. Invoke this method to submit the
```

```
* map/reduce job.
*
* @throws IOException
* When there is communication problems with the job tracker.
**/
public static void main(String[] args) throws Exception {
JobConf jobConf = new JobConf();
jobConf.setMapperClass(IdentityMapper.class);
jobConf.setReducerClass(IdentityReducer.class);
jobConf.setNumReduceTasks(1);
Jobconf.setmapoutputkeyschema schemautils schemeiutils.fromstring ("key: bigint "));
jobConf.setMapOutputValueSchema(SchemaUtils.fromString("value:bigint"));
InputUtils.addTable(TableInfo.builder().tableName(args[0]).build(), jobConf);
OutputUtils.addTable(TableInfo.builder().tableName(args[1]).build(), jobConf);
Date startTime = new Date(); System.out.println("Job started: " + startTime);
JobClient.runJob(jobConf);
Date end_time = new Date(); System.out.println("Job ended: " + end_time); System.out.println("The jo
b took " + (end_time.getTime() - startTime.getTime()) / 1000 + " seconds.") ;
}
}
```

1.8.6.13. Example of using partitioned table as an input

The following examples use partitions as an input.

Example 1:

```
public static void main(String[] args) throws Exception {
JobConf job = new JobConf();
...
LinkedHashMap<String, String> input = new LinkedHashMap<String, String>();
input.put("pt", "123456");
InputUtils.addTable(TableInfo.builder().tableName("input_table").partSpec(input).build(), job);
LinkedHashMap<String, String> output = new LinkedHashMap<String, String>(); output.put("ds", "6543
21");
OutputUtils.addTable(TableInfo.builder().tableName("output_table").partSpec(output).build(), job);
JobClient.runJob(job);
}
```

Example 2:

```
package com.aliyun.odps.mapred.open.example;
...
public static void main(String[] args) throws Exception {
if (args.length ! = 2) {
System.err.println("Usage: WordCount <in_table> <out_table>");
System.exit(2);
}
JobConf job = new JobConf();
job.setMapperClass(TokenizerMapper.class);
job.setCombinerClass(SumCombiner.class);
job.setReducerClass(SumReducer.class);
job.setMapOutputKeySchema(SchemaUtils.fromString("word:string"));
job.setMapOutputValueSchema(SchemaUtils.fromString("count:bigint"));
Account account = new AliyunAccount("my_access_id", "my_access_key");
Odps odps = new Odps(account);
odps.setEndpoint("odps_endpoint_url");
odps.setDefaultProject("my_project");
Table table = odps.tables().get(tblname);
TableInfoBuilder builder = TableInfo.builder().tableName(tblname);
for (Partition p : table.getPartitions()) { if (applicable(p)) {
LinkedHashMap<String, String> partSpec = new LinkedHashMap<String, String>();
for (String key : p.getPartitionSpec().keys()) {
partSpec.put(key, p.getPartitionSpec().get(key));
}
InputUtils.addTable(builder.partSpec(partSpec).build(), conf);
}
}
OutputUtils.addTable(TableInfo.builder().tableName(args[1]).build(), job);
JobClient.runJob(job);
}
```

Note In the preceding example, the MaxCompute SDK and MapReduce SDK are used together to allow MapReduce tasks to read data from partitions. The preceding code cannot be compiled for execution. It is just an example of the main function. In the preceding example, the applicable function is the user logic that determines whether the partitions can be used as an input of the MapReduce job.

1.8.6.14. Pipeline example

Example:

```
package com.aliyun.odps.mapred.example;
import java.io.IOException;
import java.util.Iterator;
import com.aliyun.odps.Column;

new Column[] { new Column("count", OdpsType.BIGINT) })
.setOutputKeySortColumns(new String[] { "word" })
.setPartitionColumns(new String[] { "word" })
.setOutputGroupingColumns(new String[] { "word" })
```

```
.addReducer(SumReducer.class)
.setOutputKeySchema(
new Column[] { new Column("count", OdpsType.BIGINT) })
.setOutputValueSchema(
new Column[] { new Column("word", OdpsType.STRING)})
.addReducer(IdentityReducer.class).createPipeline();
job. setpipeline (pipeline);
job.addInput(TableInfo.builder().tableName(args[0]).build());
job.addOutput(TableInfo.builder().tableName(args[1]).build());
job.submit(); job.waitForCompletion();
System.exit(job.isSuccessful() == true ? 0 : 1);
}
}
```

1.9. MaxCompute Graph

1.9.1. Graph overview

1.9.1.1. Graph overview

MaxCompute Graph is a processing framework designed for iterative graph computing. Graph computing jobs use graphs to build models. Graphs are composed of vertices and edges with values. MaxCompute Graph supports the following operations to edit a graph:

- Editing the value of vertex or edge.
- Adding/deleting vertex.
- Adding/deleting edge.

> **Note** When editing the vertex or edge, you must maintain the relationship between the two items.

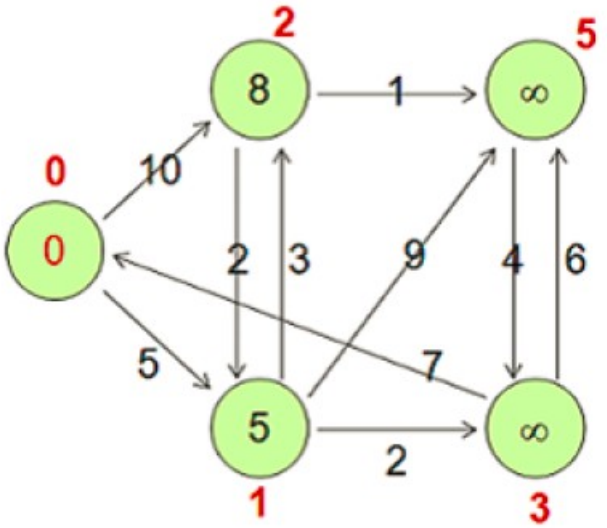
After performing iterative graph editing and evolution, you can get the final result. Typical applications include PageRank, SSSP algorithm, and K-Means algorithm. Furthermore, you can use the Java SDK provided by MaxCompute Graph to compile computing programs.

1.9.1.2. Graph data structure

MaxCompute Graph processes directed graphs, or digraphs, that consist of a vertex and an edge. MaxCompute stores data in two-dimensional tables, so you must convert graph data into two-dimensional tables and store them in MaxCompute. To perform graph analysis, you must use a custom GraphLoader to convert two-dimensional table data to vertexes and edges in the MaxCompute Graph engine. You can then determine how to break down and analyze your graph data based on your business requirements. In the following chapter, the examples provided use different tabular expressions to represent the data structure of a graph.

The vertex structure can be expressed as < ID, Value, Halted, Edges >, indicating respectively the vertex identifier, the value, the state (Halted, meaning whether to stop iteration), and the edge set (Edges, indicating lists of all edges starting from the vertex). The edge structure can be described as < DestVertexID, Value >, indicating respectively the destination vertex (DestVertexID) and value (Value). The following figure shows Graph data structure.

Graph data structure



The preceding figure involves the following vertexes.

Graph data structure

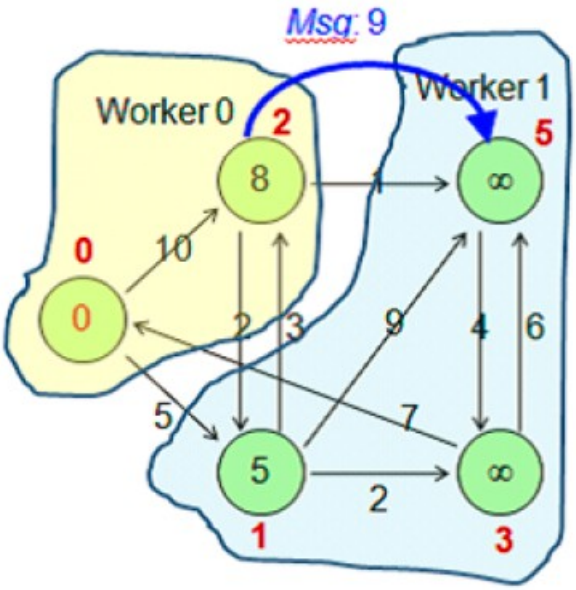
Vertex	<ID, Value, Halted, Edges>
v0	<0, 0, false, [<1, 5 >, <2, 10 >] >
v1	<1, 5, false, [<2, 3>, <3, 2>, <5, 9>]>
v2	<2, 8, false, [<1, 2>, <5, 1 >]>
v3	<3, Long.MAX_VALUE, false, [<0, 7>, <5, 6>]>
v5	<5, Long.MAX_VALUE, false, [<3, 4 >]>

1.9.1.3. Graph logic

1.9.1.3.1. Load graph

- Graph load: The framework calls the custom GraphLoader to parse the records in the input table into vertices or edges.
- Partitioning: The framework calls the custom Partitioner to partition vertices (default partition logic: the hash value of the vertex ID modulo the number of workers). Then, the framework distributes the partitions to the corresponding workers.

Load graph



Based on the preceding figure, if there are two workers, v0 and v2 are distributed to Worker0, because the result of the ID modulo 2 (total number of workers) is 0. v1, v3, and v5 are distributed to Worker1, because the result of the ID modulo 2 is 1.

1.9.1.3.2. Iterative computation

An iteration is a superstep. During a superstep, all vertices not in the halted state (Halted value is false) or vertices that receive messages (vertices in the halted state automatically wake up when receiving a message) are traversed. The compute method (ComputeContext context, Iterable messages) of these vertices is called.

In a custom compute method (ComputeContext context, Iterable messages):

- The messages sent by the previous superstep to the current vertex are processed.
- The graph is edited as required:
  - The values of vertices or edges are modified.
  - Messages are sent to some vertices.
  - Vertices or edges are added or deleted.
- The aggregator aggregates information to obtain global information.
- The current vertex is set to the halted or non-halted state.
- During each iteration, the framework automatically sends messages to the corresponding workers asynchronously. The messages are processed in the next superstep.

1.9.1.3.3. End of iteration

An iteration ends if any of the following conditions is satisfied.

- All vertices are in the halted state (Halted value is true), and no new messages are generated.
- The maximum number of iterations is reached.
- The terminate method of an aggregator returns true.

Example:

```
// 1. Load
for each record in input_table { GraphLoader.load();
}
// 2. Setup
WorkerComputer.setup();
for each aggr in aggregators { aggr.createStartupValue();
}
for each v in vertices { v.setup();
}
// 3. Superstep
for (step = 0; step < max; step ++) { for each aggr in aggregators { aggr.createInitialValue();
}
for each v in vertices { v.compute();
}
}
// 4. Cleanup
for each v in vertices { v.cleanup();
}
WorkerComputer.cleanup();
```

1.9.1.4. Aggregator overview

Aggregator is a common feature in MaxCompute Graph jobs and is especially suited for solving machine learning issues. In MaxCompute Graph, Aggregator is used to summarize and process global information.

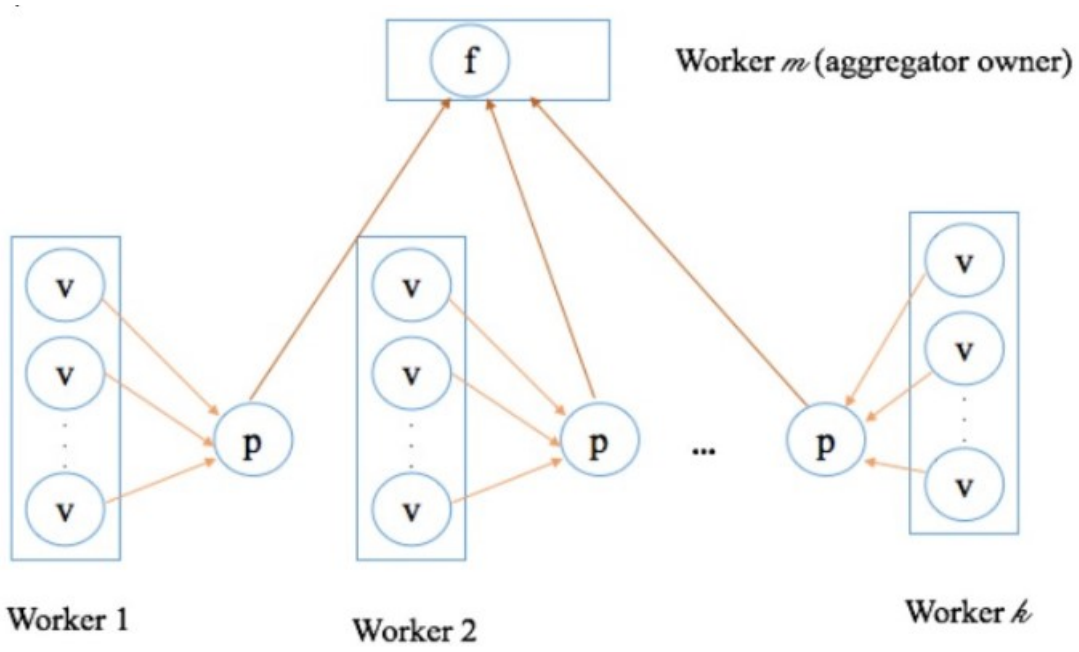
This topic describes the implementation mechanism and related API operations of Aggregator and uses Kmeans Clustering as an example to demonstrate how to use Aggregator.

Implementation mechanism

The logic of Aggregator is divided into two parts:

- One part is implemented on all Workers in distributed mode.
- The other part is only implemented on the Worker where Aggregator Owner is located in single vertex mode.

Initial values are created and partially aggregated on each Worker, and then the partial aggregation results of all Workers are sent to the Worker where Aggregator Owner is located. This Worker then aggregates the received partial aggregation objects into a global aggregation result and determines whether to end the iteration. The global aggregation result is distributed to all Workers in the next superstep for iteration.



API operations

Aggregator provides five API operations. The following parts describe when to call these API operations and for what purposes.

- **createStartupValue(context)**

  This API operation is performed once on all Workers before all supersteps start. It is used to initialize AggregatorValue. In the first superstep iteration (superstep 0), WorkerContext.getLastAggregatedValue() or ComputeContext.getLastAggregatedValue() is called to obtain the initialized AggregatorValue object.

- **createInitialValue(context)**

  This API operation is performed once on all Workers when each superstep starts. It is used to initialize AggregatorValue for the current iteration. Generally, WorkerContext.getLastAggregatedValue() is called to obtain the result of the previous iteration, and then partial initialization is implemented.

- **aggregate(value, item)**

  This API operation is also performed on all Workers. It is triggered by an explicit call to ComputeContext#aggregate(item), while the preceding two API operations are automatically called by the framework.

This API operation is used to implement partial aggregation. The first parameter value indicates the aggregation result of the Worker in the current superstep. The initial value is the object returned by createInitialValue. The second parameter is passed in when ComputeContext#aggregate(item) is called by using user code. In this API operation, item is typically used to update value for aggregation. After all the aggregate operations are performed, the obtained value is the partial aggregation result of the Worker. The result is then sent by the framework to the Worker where Aggregator Owner is located.

- **merge(value, partial)**

  This API operation is performed on the Worker where Aggregator Owner is located. It is used to merge partial aggregation results of Workers to obtain the global aggregation object. Similar to aggregate, value in this API operation indicates the aggregated results, while partial indicates objects to be aggregated. partial is used to update value.

  Assume that there are three Workers w0, w1, and w2, and the corresponding partial aggregation results are p0, p1, and p2. If p1, p0, and p2 are sent to the Worker where Aggregator Owner is located in sequence, the following merge operations are performed:

  i. merge(p1, p0) is executed first to aggregate p1 and p0 as p1.
  ii. Then, merge(p1, p2) is executed to aggregate p1 and p2 as p1. p1 is the global aggregation result in this superstep.

  Therefore, when only one Worker exists, the merge method is not required. In this case, merge() is not called.

- **terminate(context, value)**

  After the Worker where Aggregator Owner is located executes merge(), the framework calls terminate(context, value) to perform the final processing. The second parameter value indicates the global aggregation result obtained by calling merge(). The global aggregation result can be further modified in this API operation. After terminate() is executed, the framework distributes the global aggregation object to all Workers for the next superstep.

  If true is returned for terminate(), iteration is ended for the entire job. Otherwise, the iteration continues. In machine learning scenarios, jobs end generally when true is returned after convergence.

Kmeans Clustering example

This section uses typical Kmeans Clustering as an example to demonstrate how to use Aggregator.

> **Note** If you need the complete code, see Kmeans. In this section, the code is resolved and is for reference only.

- GraphLoader

  GraphLoader is used to load an input table and convert it to vertices or edges of a graph. In this example, each row of data in the input table is a sample, each sample constructs a vertex, and vertex values are used to store samples.

  A Writable class KmeansValue is defined as the value type of a vertex.

```
public static class KmeansValue implements Writable {
   DenseVector sample;
   public KmeansValue() {
   }
   public KmeansValue(DenseVector v) {
      this.sample = v;
   }
   @Override
      public void write(DataOutput out) throws IOException {
      wirteForDenseVector(out, sample);
   }
   @Override
      public void readFields(DataInput in) throws IOException {
      sample = readFieldsForDenseVector(in);
   }
}
```

A DenseVector object is encapsulated in KmeansValue to store a sample. The DenseVector type stems from matrix-toolkits-java. wirteForDenseVector() and readFieldsForDenseVector() are used for serialization and deserialization. For more information, see the complete code.

Custom KmeansReader code:

```
public static class KmeansReader extends
   GraphLoader<LongWritable, KmeansValue, NullWritable, NullWritable> {
   @Override
      public void load(
      LongWritable recordNum,
      WritableRecord record,
      MutationContext<LongWritable, KmeansValue, NullWritable, NullWritable> context)
      throws IOException {
      KmeansVertex v = new KmeansVertex();
      v.setId(recordNum);
      int n = record.size();
      DenseVector dv = new DenseVector(n);
      for (int i = 0; i < n; i++) {
         dv.set(i, ((DoubleWritable)record.get(i)).get());
      }
      v.setValue(new KmeansValue(dv));
      context.addVertexRequest(v);
   }
}
```

In KmeansReader, a vertex is created when each row of data (a record) is read. recordNum is used as the vertex ID, and the record content is converted to a DenseVector object and encapsulated in VertexValue.

- Vertex

  Custom KmeansVertex code:

```
public static class KmeansVertex extends
   Vertex<LongWritable, KmeansValue, NullWritable, NullWritable> {
   @Override
      public void compute(
      ComputeContext<LongWritable, KmeansValue, NullWritable, NullWritable> context,
      Iterable<NullWritable> messages) throws IOException {
      context.aggregate(getValue());
   }
}
```

  The logic of the preceding code is to implement partial aggregation for samples maintained for each iteration. For more information about the logic, see the implementation of Aggregator in the following section.

- Aggregator

  The main logic of Kmeans is concentrated on Aggregator. Custom KmeansAggrValue is used to maintain the content you want to aggregate and distribute.

```
public static class KmeansAggrValue implements Writable {
   DenseMatrix centroids;
   DenseMatrix sums; // used to recalculate new centroids
   DenseVector counts; // used to recalculate new centroids
   @Override
      public void write(DataOutput out) throws IOException {
      wirteForDenseDenseMatrix(out, centroids);
      wirteForDenseDenseMatrix(out, sums);
      wirteForDenseVector(out, counts);
   }
   @Override
      public void readFields(DataInput in) throws IOException {
      centroids = readFieldsForDenseMatrix(in);
      sums = readFieldsForDenseMatrix(in);
      counts = readFieldsForDenseVector(in);
   }
}
```

  In the preceding code, three objects are maintained in KmeansAggrValue:

- **centroids**: indicates the existing K centers. If the sample is m-dimensional, centroids is a matrix of K × m.
- **sums**: indicates a matrix of the same size as centroids. Each element records the sum of a specific dimension of the sample closest to a specific center. For example, sums(i,j) indicates the sum of dimension j of the sample closest to center i.
- **counts** is a K-dimensional vector. It records the number of samples closest to each center. counts is used with sums to calculate a new center, which is the main content to be aggregated.

KmeansAggregator is a custom Aggregator implementation class. The implementation is described below in order of the preceding API operations:

i. Implementation of **createStartupValue()**

```
public static class KmeansAggregator extends Aggregator<KmeansAggrValue> {
   public KmeansAggrValue createStartupValue(WorkerContext context) throws IOException {
      KmeansAggrValue av = new KmeansAggrValue();
      byte[] centers = context.readCacheFile("centers");
      String lines[] = new String(centers).split("\n");
      int rows = lines.length;
      int cols = lines[0].split(",").length; // assumption rows >= 1
      av.centroids = new DenseMatrix(rows, cols);
      av.sums = new DenseMatrix(rows, cols);
      av.sums.zero();
      av.counts = new DenseVector(rows);
      av.counts.zero();
      for (int i = 0; i < lines.length; i++) {
         String[] ss = lines[i].split(",");
         for (int j = 0; j < ss.length; j++) {
            av.centroids.set(i, j, Double.valueOf(ss[j]));
         }
      }
      return av;
   }
```

This method initializes a KmeansAggrValue object, reads the initial center from the resource file centers, and assigns a value to centroids. The initial values of sums and counts are 0.

ii. Implementation of **createInitialValue()**

```
@Override
public KmeansAggrValue createInitialValue(WorkerContext context)
    throws IOException {
    KmeansAggrValue av = (KmeansAggrValue)context.getLastAggregatedValue(0);
    // reset for next iteration
    av.sums.zero();
    av.counts.zero();
    return av;
}
```

This method first obtains KmeansAggrValue of the previous iteration, and then clears the values of sums and counts. Only the centroids value of the previous iteration is retained.

iii. Implementation of **aggregate()**

```
@Override
public void aggregate(KmeansAggrValue value, Object item)
    throws IOException {
    DenseVector sample = ((KmeansValue)item).sample;
    // find the nearest centroid
    int min = findNearestCentroid(value.centroids, sample);
    // update sum and count
    for (int i = 0; i < sample.size(); i ++) {
        value.sums.add(min, i, sample.get(i));
    }
    value.counts.add(min, 1.0d);
}
```

This method calls findNearestCentroid() to find the index of the center closest to the sample item, uses sums to add up all dimensions, and increments the value of counts by 1.

The preceding three methods are executed on all Workers to implement partial aggregation. The global aggregation operations performed on the Worker where Aggregator Owner is located are described as follows:

i. Implementation of **merge()**

```
@Override
public void merge(KmeansAggrValue value, KmeansAggrValue partial)
    throws IOException {
    value.sums.add(partial.sums);
    value.counts.add(partial.counts);
}
```

In the preceding example, the implementation logic of merge is to sum up the values of sums and counts aggregated by each Worker.

ii. Implementation of terminate()

```
@Override
public boolean terminate(WorkerContext context, KmeansAggrValue value)
    throws IOException {
    // Calculate the new means to be the centroids (original sums)
    DenseMatrix newCentriods = calculateNewCentroids(value.sums, value.counts, value.centroi
ds);
    // print old centroids and new centroids for debugging
    System.out.println("\nsuperstep: " + context.getSuperstep() +
                    "\nold centriod:\n" + value.centroids + " new centriod:\n" + newCentriods);
    boolean converged = isConverged(newCentriods, value.centroids, 0.05d);
    System.out.println("superstep: " + context.getSuperstep() + "/"
                    + (context.getMaxIteration() - 1) + " converged: " + converged);
    if (converged || context.getSuperstep() == context.getMaxIteration() - 1) {
        // converged or reach max iteration, output centriods
        for (int i = 0; i < newCentriods.numRows(); i++) {
            Writable[] centriod = new Writable[newCentriods.numColumns()];
            for (int j = 0; j < newCentriods.numColumns(); j++) {
                centriod[j] = new DoubleWritable(newCentriods.get(i, j));
            }
            context.write(centriod);
        }
        // true means to terminate iteration
        return true;
    }
    // update centriods
    value.centroids.set(newCentriods);
    // false means to continue iteration
    return false;
}
```

In the preceding example, terminate() calls calculateNewCentroids() based on sums and counts to calculate the average value and obtain a new center. isConverged() is then called to determine whether the center is converged based on the Euclidean distance between the new and old centers. If the number of convergences or iterations reaches the upper limit, the new center is generated, and true is returned to end the iteration. Otherwise, the center is updated, and false is returned to continue the iteration.

iii. main method

The main method is used to construct GraphJob, configure related settings, and submit a job.

```
public static void main(String[] args) throws IOException {
    if (args.length < 2)
        printUsage();
    GraphJob job = new GraphJob();
    job.setGraphLoaderClass(KmeansReader.class);
    job.setRuntimePartitioning(false);
    job.setVertexClass(KmeansVertex.class);
    job.setAggregatorClass(KmeansAggregator.class);
    job.addInput(TableInfo.builder().tableName(args[0]).build());
    job.addOutput(TableInfo.builder().tableName(args[1]).build());
    // default max iteration is 30
    job.setMaxIteration(30);
    if (args.length >= 3)
        job.setMaxIteration(Integer.parseInt(args[2]));
    long start = System.currentTimeMillis();
    job.run();
    System.out.println("Job Finished in "
                    + (System.currentTimeMillis() - start) / 1000.0 + " seconds");
}
```

> **Note** If job.setRuntimePartitioning(false) is set to false, data loaded by each Worker is not partitioned based on Partitioner. Data is maintained by the Worker that loads it.

Summary

The basic steps of Aggregator are as follows:

1. When each Worker starts, it executes createStartupValue to create AggregatorValue.
2. Before each iteration starts, each Worker executes createInitialValue to initialize AggregatorValue for the iteration.
3. In an iteration, each vertex uses context.aggregate() to call aggregate() to implement partial iteration in the Worker.
4. Each Worker sends the partial iteration result to the Worker where Aggregator Owner is located.
5. The Worker where Aggregator Owner is located executes merge multiple times to implement global aggregation.
6. The Worker where Aggregator Owner is located executes terminate to process the global aggregation result and determines whether to end the iteration.

1.9.2. Graph feature overview

1.9.2.1. Run a job

The MaxCompute client provides a jar command for running MaxCompute Graph jobs. This command is used in the same way as the jar command in MapReduce.

Command syntax:

```
Usage: jar [<GENERIC_OPTIONS>] <MAIN_CLASS> [ARGS]
-conf <configuration_file> Specify an application configuration file
-classpath <local_file_list> classpaths used to run mainClass
-D <name>=<value> Property value pair, which will be used to run mainClass
-local Run job in local mode
-resources <resource_name_list> file/table resources used in graph, seperate by comma
```

The following table describes the parameters.

Parameters

Parameter	Description
-conf <configuration file>	Indicates a JobConf file.
-classpath <local_file_list>	Indicates the classpath for local execution. It specifies the local paths (including relative path and absolute path) of the JAR package where the main function is located.
-D <prop_name>=<prop_value>	Indicates the Java attribute of <mainClass> in local execution. You can define multiple attributes.
-local	Runs the MapReduce job locally, mainly for program debugging.
-resources <resource_name_list>	Declares the resources used for running the Graph job. You typically need to specify the name of the resource where the Graph job is located in resource_name_list. **Notice** If you read other MaxCompute resources while running the Graph job, you also need to add those resource names to resource_name_list. Multiple resources must be separated by commas (,). If you need to use resources of another project, add the prefix PROJECT_NAME/resources/, for example, -resources otherproject/resources/resfile.

Note The preceding optional parameters are included in <GENERIC_OPTIONS>.

You can directly run the main function in the Graph job to submit the job to MaxCompute, instead of submitting the job through the MaxCompute client. Take the PageRank algorithm as an example.

Example:

```
public static void main(String[] args) throws IOException {
if (args.length < 2)
printUsage();
GraphJob job = new GraphJob();
job.setGraphLoaderClass(PageRankVertexReader.class);
job.setVertexClass(PageRankVertex.class);
job.addInput(TableInfo.builder().tableName(args[0]).build());
job.addOutput(TableInfo.builder().tableName(args[1]).build());
// Add the resources used in the job to cache resource. These resources correspond to those specifie
d by -resources and libjars in the jar command.
job.addCacheResource("mapreduce-examples.jar");
// Add the used JAR file and other files to the class cache resource. These resources correspond to th
ose specified by -libjars in the jar command.
job.addCacheResourceToClassPath("mapreduce-examples.jar");
// Set the configuration item corresponding to odps_config.ini in the client. Replace it with the actual o
ne in your configuration file.
Account account = new AliyunAccount(accessId, accessKey);
Odps odps = new Odps(account);
odps.setDefaultProject(project);
odps.setEndpoint(endpoint);
SessionState.get().setOdps(odps);
SessionState.get().setLocalRun(false); // default max iteration is 30
job.setMaxIteration(30);
if (args.length >= 3)
job.setMaxIteration(Integer.parseInt(args[2]));
long startTime = System.currentTimeMillis(); job.run();
System.out.println("Job Finished in "
+ (System.currentTimeMillis() - startTime) / 1000.0 + " seconds");
}
```

1.9.2.2. Input and output

The input and output of MaxCompute Graph jobs must be tables. You cannot customize the input or output format.

Job input definition:

```
GraphJob job = new GraphJob();
job.addInput(TableInfo.builder().tableName("tblname").build());
// Tables are used as input.
job.addInput(TableInfo.builder().tableName("tblname").partSpec("pt1=a/pt2=b").build());
// Partitions are used as input.
job.addInput(TableInfo.builder().tableName("tblname").partSpec("pt1=a/pt2=b").build(), new String[]{"
col2", "col0 "});
// Read only col2 and col0 of the input table. Use record.get(0) to obtain col2 in the load() method of G
raphLoader. Both are read in the same sequence.
```

Note

- Multiple inputs are supported.
- Partition filtering is not supported. For more application limits, see Application limits.
- For more information about job input definition, see the addInput method description in GraphJob.
- The framework reads records from the input table and transfers the records to the user-defined GraphLoader to load graph data.

Job output definition:

```
GraphJob job = new GraphJob();
job.addOutput(TableInfo.builder().tableName("table_name").partSpec("pt1=a/pt2=b").build());
// If the output table is a partitioned table, the last level of partitions must be provided.
job.addOutput(TableInfo.builder().tableName("table_name").partSpec("pt1=a/pt2=b").lable("output1")
.build(), true);
// True indicates that the code will overwrite partitions specified in tableinfo, which is similar to the IN
SERT OVERWRITE operation. False is similar to the INSERT INTO operation.
```

Note

- Multiple outputs are supported, and each output is identified by a label.
- A Graph job can use the Write method of WorkContext to write data to an output table during runtime. Multiple outputs must be labeled.
- For more information about job output definition, see the addOutput method description in GraphJob.

1.9.2.3. Read data from resources

1.9.2.3.1. Add resource in Graph program

In addition to the jar command, the following two methods of GraphJob can be used to specify the resources read by Graph:

```
void addCacheResources(String resourceNames)
void addCacheResourcesToClassPath(String resourceNames)
```

1.9.2.3.2. Use resources in Graph

In Graph, you can use the following methods of the corresponding context object WorkerContext to read resources:

```
public byte[] readCacheFile(String resourceName) throws IOException;
public Iterable<byte[]> readCacheArchive(String resourceName) throws IOException;
public Iterable<byte[]> readCacheArchive(String resourceName, String relativePath)throws IOExceptio
n;
public Iterable<WritableRecord> readResourceTable(String resourceName);
public BufferedInputStream readCacheFileAsStream(String resourceName) throws IOException;
public Iterable<BufferedInputStream> readCacheArchiveAsStream(String resourceName) throws IOExc
eption;
public Iterable<BufferedInputStream> readCacheArchiveAsStream(String resourceName, String relativ
ePath) throws IOException;
```

Note

- Normally, resources are read in the setup of WorkerComputer, saved in WorkerValue, and obtained through getWorkerValue.
- The preceding stream API is recommended while reading and processing to reduce memory consumption.
- For more information about limits, see Application limits.

1.9.3. Graph SDK introduction

Major APIs

API	Description
GraphJob	GraphJob is inherited from JobConf to define, submit, and manage a MaxCompute Graph job.
Vertex	Vertex is an abstract of a graph and has the following attributes: id, value, halted, and edges. It is implemented through the setVertexClass API in GraphJob.
Edge	Edge is an abstract of a graph and has the following attributes: destVertexId and value. The graph data structure is maintained by an adjacency list. The outgoing edges of a vertex are stored in its edges attribute.
GraphLoader	GraphLoader is used to load graphs. It is set through the setGraphLoaderClass API in GraphJob.

API	Description
VertexResolver	VertexResolver is used to customize the collision processing logic of the revising graph topology. It provides this logic through the setLoadingVertexResolverClass and setComputingVertexResolverClass APIs in GraphJob for graph loading and iteration computing.
Partitioner	Partitioner is used to partition graphs for partition computing. It is set through the setPartitionerClass API in GraphJob. By default, the HashPartitioner is used to first obtain the Vertex ID Hash value, and then to model the number of Workers.
WorkerComputer	WorkerComputer allows customized logic to be executed while Worker starts and exits. WorkerComputer is set through the setWorkerComputerClass API in GraphJob.
Aggregator	Allows you to define one or multiple Aggregators through the setAggregatorClass(Class ...) API in Aggregator.
Combiner	You can set Combiner through the setCombinerClass API in Combiner.
Counters	In the job operating logic, counters can be taken and counted through the WorkerContext API, and the framework will automatically summarize them.
WorkerContext	Context objects encapsulate the functions provided by the framework, such as revising the topology of graphs, sending messages, writing results, reading resources, and so on.

1.9.4. Development and debugging

1.9.4.1. Development procedure

MaxCompute does not provide plug-ins for Graph development. Instead, you can develop MaxCompute Graph programs in Eclipse. The recommended development procedure is as follows:

1. Write Graph code and perform local debugging to test basic functions.
2. Perform cluster debugging to verify results.

1.9.4.2. Development example

Context

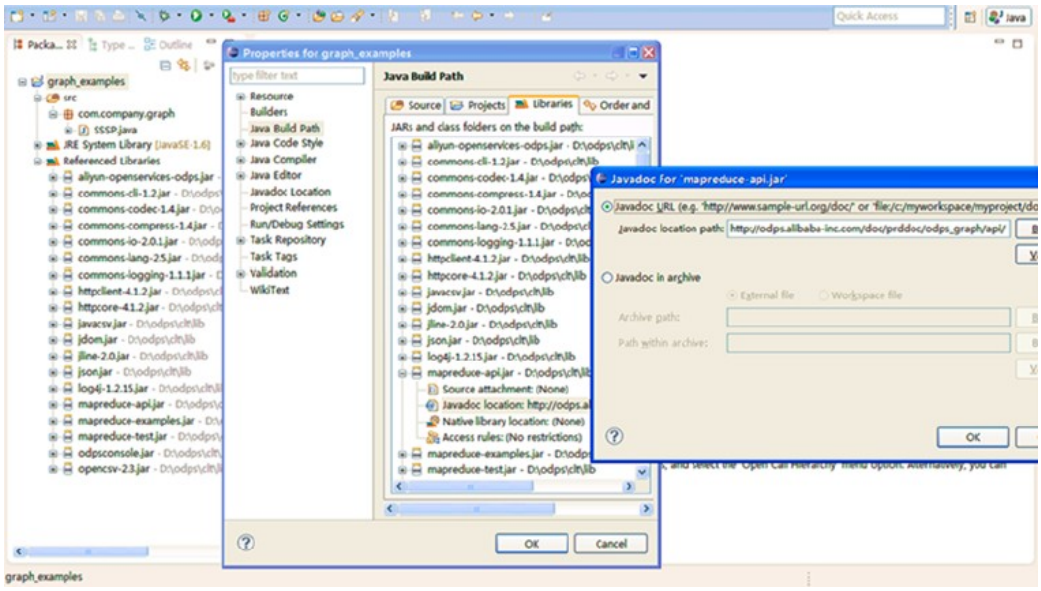
This topic uses the SSSP algorithm as an example to describe how to use Eclipse to develop and debug a Graph program. The development procedure is as follows:

Procedure

1. Create a Java project.

   In this example, the project is graph_examples. Add the JAR package in the lib directory of the MaxCompute client to Build Path of the Eclipse project. The following figure shows a configured Eclipse project.

Create a Java project



2. Develop a MaxCompute Graph program.

   In the actual development process, you can copy a sample program (such as SSSP) and then modify it as required. In this example, only the package path is changed to *package com.aliyun.odps.graph.example*.

3. Compile and build the package. In an Eclipse environment, right-click the source code directory (the src directory in the figure) and choose **Export** > **Java** > **JAR file** to generate a JAR package. Select the path for storing the target JAR package, such as *D:\odps\clt\odps-graph-example-sssp.jar*.

4. Use the MaxCompute client to run SSSP. For more information, see Compile and run a Graph job.

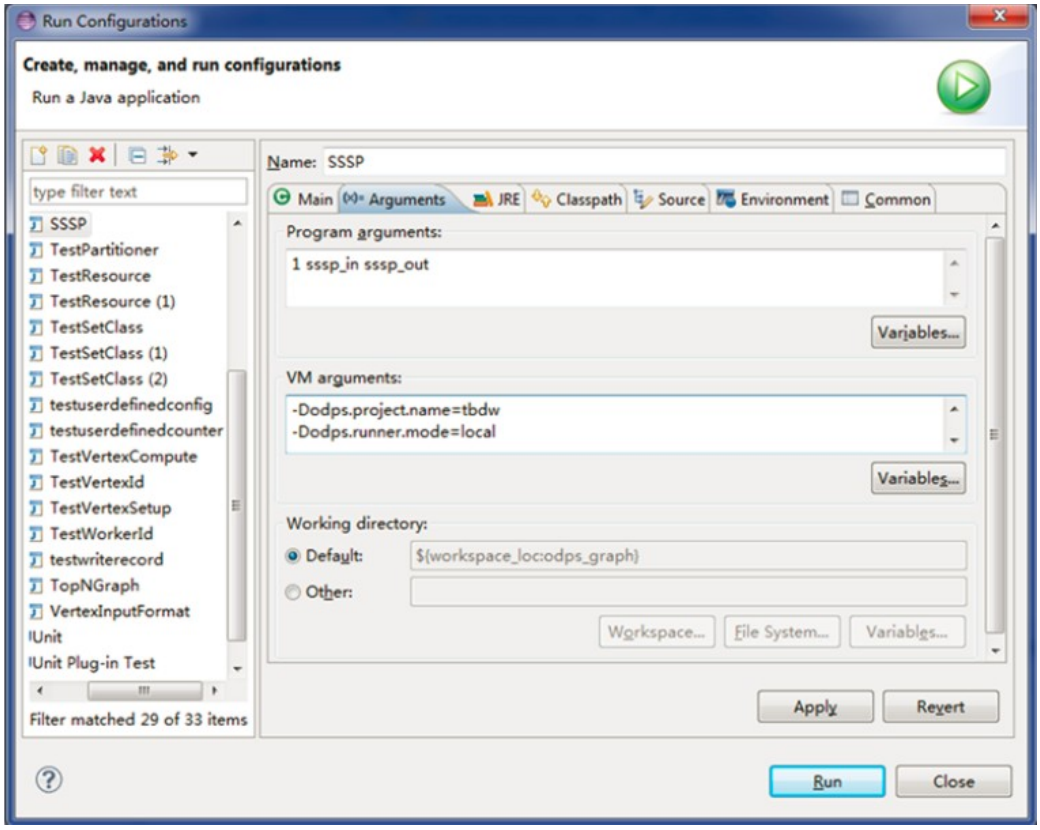
1.9.4.3. Local debugging

MaxCompute Graph supports the local debugging mode. You can use Eclipse for breakpoint debugging. The breakpoint debugging procedure is as follows:

Procedure

1. Select an Eclipse project. Right-click the Graph job main program file (the file that contains the main function), and configure its execution arguments, as shown in the following figure.

   Local debugging



2. On the **Arguments** tab page, set the following arguments as the input parameters of the main program:
   - Program arguments: 1 sssp_in sssp_out.
   - VM arguments: Dodps.runner.mode=local, Dodps.project.name=<project.name>, Dodps.end.point=<end.point>, Dodps.access.id=<access.id>, and Dodps.access.key=<access.key>.
   - For the local mode (odps.end.point not specified), you need to create the sssp_in and sssp_out tables in the warehouse, and add the following data to sssp_in:

```
1,"2:2,3:1,4:4"
2,"1:2,3:2,4:1"
3,"1:1,2:2,5:1"
4,"1:4,2:1,5:1"
5,"3:1,4:1"
```

   > **Note** For more information about the warehouse, see Run MapReduce tasks locally.

3. Click **Run** to run SSSP on the local machine.

   Refer to conf/odps_config.ini in the MaxCompute client for the settings of common parameters. The other parameters are described as follows:
   - odps.runner.mode: The value is local. It is required for the local debugging feature.
   - odps.project.name: specifies the current project, which is required.

- odps.end.point: specifies the current MaxCompute service address, which is optional. If this parameter is not specified, SSSP only reads metadata and data from the tables or resources in the warehouse. If the data does not exist, an error is returned. If this parameter is specified, SSSP first reads data from the warehouse. If the data does not exist, it reads data from the remote MaxCompute service.
- odps.access.id: specifies the AccessKey ID for accessing the MaxCompute service. It is valid only if odps.end.point is specified.
- odps.access.key: specifies the AccessKey secret for accessing the MaxCompute service. It is effective only if odps.end.point is specified.
- odps.cache.resources: specifies the resource list to be used. This parameter is the same as -resources of the jar command.
- odps.local.warehouse: specifies the local warehouse path. It is ./warehouse by default.

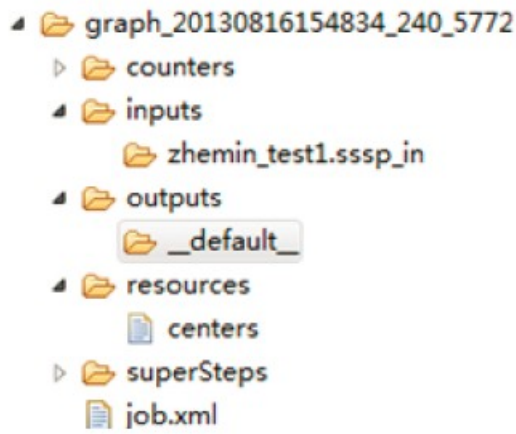
The output is as follows:

```
Counters: 3
com.aliyun.odps.graph.local.COUNTER
TASK_INPUT_BYTE=211
TASK_INPUT_RECORD=5
TASK_OUTPUT_BYTE=161
TASK_OUTPUT_RECORD=5
graph task finish
```

Notice In the preceding examples, the local warehouse must contain the sssp_in and sssp_out tables. For more information about sssp_in and sssp_out, see Compile and run Graph.

1.9.4.4. Temporary directory for local jobs

Each time MaxCompute Graph runs a local debugging job, it creates a temporary directory in the Eclipse project directory, as shown in the following figure.



The temporary directory for a local Graph job contains the following directories and files:

- counters: stores the counter information that is generated during the running of the job.

- inputs: stores the input data of the job. Graph first reads data from the local warehouse. If no data is found, Graph uses the MaxCompute SDK to read data from the server (if odps.end.point is configured). An input operation reads 10 records by default. You can use the Dodps.mapred.local.record.limit parameter to modify the number of records read during each input operation. Up to 10,000 records can be read each time.
- outputs: stores the output data of the job. If there is an output table in the local warehouse, the results in outputs will overwrite data in that table after the job is executed.
- resources: stores the resources used by the job. Similarly, Graph first reads data from the local warehouse. If no data is found, Graph uses the MaxCompute SDK to read data from the server (if odps.end.point is configured).
- job.xml: stores job configurations.
- superstep: stores persistent message information from each iteration.

> **Notice** If you need to output detailed logs during local debugging, place the log4j configuration file named log4j.properties_odps_graph_cluster_debug in the src directory.

1.9.4.5. Cluster debugging

After you perform local debugging, you can perform the following steps to submit a job for cluster testing:

1. Configure the MaxCompute client.
2. Run the `add jar /path/work.jar -f;` command to update the JAR package.
3. Run a JAR command to execute the job and check the operation log and command output.

> **Notice** For more information about running a Graph job in a cluster, see Compile and run a Graph job.

1.9.4.6. Performance optimization

1.9.4.6.1. Configure job parameters

The following table lists the GraphJob configuration parameters that affect job performance.

GraphJob configuration parameters

Parameter	Description
setSplitSize(long)	Indicates the split size in MB. The value must be greater than 0. Default value: 64.
setNumWorkers(int)	Indicates the number of job workers. Value range: 1 to 1,000. Default value: 1. The number of workers is determined by the number of input bytes and split size.
setWorkerCPU(int)	Indicates the CPU resources for a map job. 100 resources are equivalent to one CPU core. Value range: 50 to 800. Default value: 200.

Parameter	Description
setWorkerMemory(int)	Indicates the memory resources in MB for a map job. Value range: 256M to 12G. Default value: 4,096.
setMaxIteration(int)	Indicates the maximum number of iterations. Default value: -1. If the value is equal to or smaller than 0, the job is not terminated after the maximum number of iterations.
setJobPriority(int)	Indicates the job priority. Value range: 0 to 9. Default value: 9. A greater value indicates a lower priority.

Recommendations:

1. Use setNumWorkers to increase the number of workers.
2. Use setSplitSize to reduce the split size and increase the data loading speed.
3. Use setWorkerCPU or setWorkerMemory to increase the CPU or memory resources for workers.
4. Use setMaxIteration to set the maximum number of iterations. For applications that do not require precise results, you can reduce the number of iterations to accelerate the iterating process.

Use setNumWorkers and setSplitSize together to accelerate data loading. If setNumWorkers is workerNum, setSplitSize is splitSize, and the total number of input bytes is inputSize, splitNum equals inputSize divided by splitSize. The relationship between workerNum and splitNum is as follows:

1. If splitNum is equal to workerNum, each worker loads one split.
2. If splitNum is greater than workerNum, each worker loads one or more splits.
3. If splitNum is smaller than workerNum, each worker loads zero or one split.

Therefore, you can adjust workerNum and splitSize to obtain a suitable loading speed. In the first two cases, data loading is faster. In the iteration phase, you only need to adjust workerNum. If you set runtime partitioning to false, we recommend that you either use setSplitSize to adjust the number of workers, or ensure the conditions in the first two cases are met. In the third case, the number of vertices in some of the workers is 0. In this case, you can use set odps.graph.split.size=<m>; set odps.graph.worker.num=<n>; before the JAR command, which achieves the same effect as setNumWorkers and setSplitSize.

Another common performance problem is data skew. As indicated by the counters, some workers process much more vertices or edges than others.

Data skew usually occurs when the number of vertices, edges, or messages corresponding to certain keys is far greater than that corresponding to other keys. These keys are distributed for processing by a small number of workers, resulting in long execution time of these workers. You can use the following methods to resolve this issue:

- Use Combiner to aggregate the messages of vertices corresponding to the keys, to reduce the number of generated messages.
- Improve the business logic.

1.9.4.6.2. Use Combiner

Developers can set Combiner to reduce the memory and network traffic consumed by message storage, and reduce job execution time. For more information, see the Combiner description in Graph SDK overview.

1.9.4.6.3. Reduce data input

If a disk stores large volumes of data, reading data from the disk may prolong the processing time. You can reduce the number of bytes to be read to increase the overall throughput and improve job performance. You can use either of the following methods:

- Reduce data input: For some decision-making applications, processing sampled data only affects the precision of the results, not the overall accuracy. In this case, you can sample specific data to the input table for further processing.
- Avoid reading unnecessary fields: The TableInfo class provided in the MaxCompute Graph framework can read specific columns (sent through a column name array), instead of the entire table or partition. This effectively reduces the amount of input data and improves job performance.

1.9.4.6.4. JAR packages

The following JAR packages are loaded on the JVM that runs Graph programs by default. You do not need to manually upload these resources, or use -libjars to specify them in a command.

- commons-codec-1.3.jar
- commons-io-2.0.1.jar
- commons-lang-2.5.jar
- commons-logging-1.0.4.jar
- commons-logging-api-1.0.4.jar
- guava-14.0.jar
- json.jar

> **Notice** In CLASSPATH of the running JVM, the preceding JAR packages are loaded before your JAR package. This may cause version conflicts. For example, your program calls a certain class function of commons-codec-1.5.jar, but the function is not included in the current MaxCompute packages. In this case, you can choose to call a similar function in version 1.3 or wait until MaxCompute is upgraded to the required version.

1.9.5. Application limits

- Each job can reference up to 256 resources. Each table or archive is considered as one unit.
- The total resource size referenced by a job cannot exceed 512 MB.
- Each job can have up to 1,024 inputs (the number of input tables cannot exceed 64). Each job can have up to 256 outputs.
- Labels specified for multiple outputs cannot be null or empty strings. The label length cannot

exceed 256, and the label can contain only upper-case letters (A to Z), lower-case letters (a to z), digits (0 to 9), underlines (_), pound signs (#), periods (.), and hyphens (-).

- The number of custom counters in a job cannot exceed 64. The counter group name and counter name cannot contain pound signs (#), and the total length of both names cannot exceed 100.
- The number of workers for each job is calculated by the framework. The maximum number of workers is 1,000. An error is returned when the number of workers exceeds this value.
- Each worker consumes 200 units of CPU resources by default. The range of resources consumed is 50 to 800.
- Each worker consumes 4,096 MB memory by default. The range of memory consumed is 256 MB to 12 GB.
- Each worker can read from a single resource up to 64 times.
- The split size is 64 MB by default, but can be defined by the user. The split size must be greater than 0, and the maximum value is in the range of 20 to 9223372036854775807.
- GraphLoader/Vertex/Aggregator in MaxCompute Graph are restricted by Java Sandbox (however, the main program of a Graph job is not subject to this restriction) while they run in a cluster. For more information, see Java sandbox restrictions.

1.9.6. Sample programs

1.9.6.1. SSSP

Dijkstra's algorithm is a typical algorithm for calculating the Single Source Shortest Path (SSSP) in a directed graph.

Shortest path: For a weighted directed graph G = (V, E), many paths are available from source vertex s to sink vertex v. The path with the smallest sum of edge weights is called the shortest path from s to v. The algorithm is implemented as follows:

- Initialization: The distance from s to s is 0 (d[s] = 0), and the distance from u to s is infinite (d[u] = ∞).
- Iteration: If an edge from u to v exists, the shortest distance from s to v is updated to d[v] = min(d[v], d[u] + weight(u, v)). The iteration ends until the distance from all vertices to s does not change.

> **Note** The implementation process determines that the algorithm is applicable to the MaxCompute Graph program. Each vertex maintains the current shortest distance to the source vertex. If the value changes, a message containing the new value and the edge weight is sent to the adjacent vertices. In the next iteration, the adjacent vertices update the current shortest distance based on the received message. The iteration ends when the current shortest distance values of all vertices do not change.

Example:

```
import java.io.IOException;
import com.aliyun.odps.io.WritableRecord;
import com.aliyun.odps.graph.Combiner;
import com.aliyun.odps.graph.ComputeContext;
import com.aliyun.odps.graph.Edge;
```

```
import com.aliyun.odps.graph.GraphJob;
import com.aliyun.odps.graph.GraphLoader;
import com.aliyun.odps.graph.MutationContext;
import com.aliyun.odps.graph.Vertex;
import com.aliyun.odps.graph.WorkerContext;
import com.aliyun.odps.io.LongWritable;
import com.aliyun.odps.data.TableInfo;

System.out.println("Job Finished in " + (System.currentTimeMillis() - startTime) / 1000.0 + " seconds");
}
}
```

1.9.6.2. PageRank

PageRank is an algorithm for Web page ranking. For more information, see PageRank. The input of the algorithm is a digraph G, where Vertex represents pages. If there is a link between page A to page B, there is an Edge linking A and B. Basic principles of the algorithm are as follows:

- Initialization: Vertex value means rank value of PageRank (double type). Initially, the value of all Vertices is 1/TotalNumVertices.
- Iteration formula: PageRank(i)=0.15/TotalNumVertices+0.85*sum. Sum indicates the sum of PageRank(j)/out_degree(j). (j indicates all vertices pointing to vertex i.)

Note The PageRank algorithm is best suited to be run on MaxCompute Graph as each j point maintains its PageRank value and sends PageRank(j)/out_degree(j) to its adjacent vertex (to vote it) per iteration. Upon the next iteration, each vertex re-calculates the PageRank value using the iteration formula.

Example:

```
import java.io.IOException;
import org.apache.log4j.Logger;
import com.aliyun.odps.io.WritableRecord;
import com.aliyun.odps.graph.ComputeContext;
import com.aliyun.odps.graph.GraphJob;

System.out.println("Job Finished in "
+ (System.currentTimeMillis() - startTime) / 1000.0 + " seconds");
}
}
```

1.9.6.3. K-means clustering

K-means clustering is a basic macro-clustering algorithm. Basic principles of the K-means clustering algorithm are as follows: Clustering is performed around k points in space, and the closest vertices are classified. The values of the clustering centers are successively updated through iterations until the optimal clustering result is obtained.

Assuming the sample set is divided into k sets or categories, the steps in the algorithm are as follows:

- Select initial center of k classes.
- In the ith iteration, select any sample, solve its path to k center, and then classify the sample into the class of shortest path to center.
- Use the mean method to update the center value of the class.
- For all k clustering centers, if the value remains unchanged or is less than a certain threshold after iteration of the first two steps, the iteration ends. Otherwise, the iteration continues.

Example:

```
import java.io.DataInput; import java.io.DataOutput;
import java.io.IOException;
importorg.apache.log4j.Logger;
import com.aliyun.odps.io.WritableRecord;
import com.aliyun.odps.graph.Aggregator;
import com.aliyun.odps.graph.ComputeContext;
```

```
import com.aliyun.odps.graph.GraphJob;

```

1.9.6.4. BiPartiteMatching

In a bipartite graph, all vertices can be divided into two sets, to which the two vertices of each edge respectively belong. For a bipartite graph G, M is its subgraph. If any two edges of M's edge set are not attached to the same vertex, then M is a match. The bipartite graph matching is usually used for information matching in scenarios with clear supply and demand relationships (such as online dating websites).

The procedure is as follows:

- Start from the first vertex on the left, select unmatched vertex to search for augmented path.
- If it goes through an unmatched vertex, the search is successful.
- Update path information, match number of Edge +1, and stop searching.
- If no augmented path is found, it does not search again from the specific vertex.

Example:

```
import java.io.DataInput;
import java.io.DataOutput;
import java.io.IOException;
import java.util.Random;
import com.aliyun.odps.data.TableInfo;
import com.aliyun.odps.graph.ComputeContext;
import com.aliyun.odps.graph.GraphJob;
import com.aliyun.odps.graph.MutationContext;
import com.aliyun.odps.graph.WorkerContext;
```

```
import com.aliyun.odps.graph.Vertex;
import com.aliyun.odps.graph.GraphLoader;

1.9.6.5. Strongly-connected component

A directed graph is called a strongly-connected graph if every vertex is reachable from every other vertex. A strongly-connected sub-graph with a large number of vertices in a directed graph is called a strongly-connected component. This algorithm example is based on the parallel coloring algorithm.

Each vertex contains the following two parts:

- colorID: stores the color of the vertex (v) during forward traversal. At the end of computing, the vertices with the same colorID belong to one strongly-connected component.
- transposeNeighbors: stores neighbor IDs of v in the transpose graph of the input graph.

The algorithm is implemented as follows:

- Transpose graph formation: contains two supersteps. In the first superstep, each vertex sends a message with its ID to all its outgoing neighbors. These IDs are stored in transposeNeighbors in the second superstep.
- Triming: contains one superstep. Each vertex with only one incoming or outgoing edge sets its colorID to its own ID, and becomes inactive. Subsequent messages sent to these vertexes are ignored.
- Forward traversal: contains two subphases (supersteps): Start and Rest. In the Start phase, each vertex sets its colorID to its own ID, and sends the ID to outgoing neighbors. In the Rest phase, each vertex uses the maximum colorID it received to update its own colorID, and propagates the colorID until the colorIDs converge. When the colorIDs converge, the master process sets the phase to backward traversal.
- Backward traversal: contains two subphases, Start and Rest. In the Start phase, each vertex whose ID equals its colorID propagates its ID to the vertices in transposeNeighbors and sets its

status as inactive. Subsequent messages sent to these vertexes are ignored. In each of the Rest phase supersteps, each vertex receives a message matching its colorID, propagates its colorID in the transpose graph, and sets its status as inactive. If there are still active vertices after this step, the process goes back to the trimming phase.

Example:

```

/**
* Definition from Wikipedia:
* In the mathematical theory of directed graphs, a graph is said
* to be strongly connected if every vertex is reachable from every
* other vertex. The strongly connected components of an arbitrary
* directed graph form a partition into subgraphs that are themselves
* strongly connected.
*
* Algorithms with four phases as follows.
* 1. Transpose Graph Formation: Requires two supersteps. In the first
* superstep, each vertex sends a message with its ID to all its > outgoing
* neighbors, which in the second superstep are stored > in transposeNeighbors.
*
* 2. Trimming: Takes one superstep. Every vertex with only in-coming or
* only outgoing edges (or neither) sets its colorID to its own ID and
* becomes inactive. Messages subsequently sent to the vertex > are ignored.
*
* 3. Forward-Traversal: There are two sub phases: Start and Rest. In the
```

```
* Start phase, each vertex sets its colorID to its own ID and > propagates
* its ID to its outgoing neighbors. In the Rest phase, vertices update
* their own colorIDs with the minimum colorID they have seen, and > propagate
* their colorIDs, if updated, until the colorIDs converge.
* Set the phase to Backward-Traversal when the colorIDs converge.
*
* 4. Backward-Traversal: We again break the phase into Start and Rest.
* In Start, every vertex whose ID equals its colorID propagates its ID > to
* the vertices in transposeNeighbors and sets itself inactive. > Messages
* subsequently sent to the vertex are ignored. In each of the Rest > phase supersteps,
* each vertex receiving a message that matches its colorID: (1) > propagates
* its colorID in the transpose graph; (2) sets itself inactive. > Messages
* subsequently sent to the vertex are ignored. Set the phase back to Trimming
* if not all vertex are inactive.

1.9.6.6. Connected component

Two vertices are connected if a path exists between them. Undirected graph G is called a connected graph if every two vertices in the graph are connected. Otherwise, G is called an unconnected graph. A connected sub-graph with a large number of vertices is called a connected component. This algorithm calculates connected component members of each vertex, and outputs the connected component of the vertex value that includes the smallest vertex ID. The smallest vertex ID is propagated along edges to all vertices of the connected component.

Example:

```
import java.io.IOException;
import com.aliyun.odps.data.TableInfo;
import com.aliyun.odps.graph.ComputeContext;
import com.aliyun.odps.graph.GraphJob;
import com.aliyun.odps.graph.GraphLoader;

}
```

1.9.6.7. Topological sorting

For a directed edge (u,v), all vertex sequences satisfying u < v are called topological sequences. Topological sorting is an algorithm that is used to calculate the topological sequence of a directed graph.

The algorithm is implemented as follows:

- A vertex without incoming edges in the graph is found and output.
- The output vertex and all its outgoing edges are deleted.
- The preceding steps are repeated until all vertices are output.

Example:

```
import java.io.IOException;
import org.apache.commons.logging.Log;
import org.apache.commons.logging.LogFactory;
import com.aliyun.odps.data.TableInfo;
import com.aliyun.odps.graph.Aggregator;
import com.aliyun.odps.graph.Combiner;
import com.aliyun.odps.graph.ComputeContext;
```

```

1.9.6.8. Linear regression

In statistics, linear regression is a statistical analysis method used to determine the dependency between two or more variables. compared with the classification algorithm that predicts discrete data, the regression algorithm can predict continuous value-type data. The linear regression algorithm defines the loss function as the sum of the least square errors of a sample set. It solves the weight vector by minimizing the loss function.

A common solution is the gradient descent method. It is implemented as follows:

- Initialize the weight vector to provide the descent speed and iterations (or iteration convergence condition).
- Calculate the least square error for each sample.
- Calculate the sum of the least square error, and update the weight based on the descent speed.
- Repeat iterations until convergence occurs.

Example:

```
import java.io.DataInput;
import java.io.DataOutput;
import java.io.IOException;
import com.aliyun.odps.data.TableInfo;
import com.aliyun.odps.graph.Aggregator;
import com.aliyun.odps.graph.ComputeContext;
import com.aliyun.odps.graph.GraphJob;
import com.aliyun.odps.graph.MutationContext;
import com.aliyun.odps.graph.WorkerContext;
import com.aliyun.odps.graph.Vertex;
import com.aliyun.odps.graph.GraphLoader;
import com.aliyun.odps.io.DoubleWritable;
import com.aliyun.odps.io.LongWritable;
import com.aliyun.odps.io.NullWritable;
import com.aliyun.odps.io.Tuple;
import com.aliyun.odps.io.Writable;
import com.aliyun.odps.io.WritableRecord;

1.9.6.9. Count triangles

This algorithm is used to calculate the number of triangles passing through each vertex. The algorithm is implemented as follows:

- Each vertex sends its ID to all outgoing neighbors.
- Each vertex stores information about incoming and outgoing neighbors, and sends this information to outgoing neighbors.

- Each vertex calculates the number of endpoint intersections for each edge, calculates the sum, and outputs the results to a table.
- The number of triangles is the sum of the output results in the table divided by 3.

Example:

```
import java.io.IOException;
import com.aliyun.odps.data.TableInfo;
import com.aliyun.odps.graph.ComputeContext;
import com.aliyun.odps.graph.Edge;
import com.aliyun.odps.graph.GraphJob;
import com.aliyun.odps.graph.GraphLoader;
import com.aliyun.odps.graph.MutationContext;
import com.aliyun.odps.graph.Vertex;
import com.aliyun.odps.graph.WorkerContext;
import com.aliyun.odps.io.LongWritable;
import com.aliyun.odps.io.NullWritable;
import com.aliyun.odps.io.Tuple;
import com.aliyun.odps.io.Writable;
import com.aliyun.odps.io.WritableRecord;
/**
* Compute the number of triangles passing through each vertex.
*
* The algorithm can be computed in three supersteps:
* I. Each vertex sends a message with its ID to all its outgoing
* neighbors.
* II. The incoming neighbors and outgoing neighbors are stored and
* send to outgoing neighbors.
* III. For each edge compute the intersection of the sets at destination
* vertex and sum them, then output to table.
*
* The triangle count is the sum of output table and divide by three > since
* each triangle is counted three times.
*
**/

1.9.6.10. GraphLoader

The following example describes how to compile a graph job program to load data of different types. It mainly covers how GraphLoader and VertexResolver are used together to build the graph.

Example:

```
import java.io.IOException;
import com.aliyun.odps.conf.Configuration;
import com.aliyun.odps.data.TableInfo;
```

```
import com.aliyun.odps.data.TableInfo;
import com.aliyun.odps.graph.ComputeContext;
import com.aliyun.odps.graph.GraphJob;
import com.aliyun.odps.graph.GraphLoader;
import com.aliyun.odps.graph.Vertex;
import com.aliyun.odps.graph.VertexResolver;
import com.aliyun.odps.graph.MutationContext;
import com.aliyun.odps.graph.VertexChanges;
import com.aliyun.odps.graph.Edge;
import com.aliyun.odps.io.LongWritable;
import com.aliyun.odps.io.WritableComparable;
import com.aliyun.odps.io.WritableRecord;
/**
* A MaxCompute Graph job uses MaxCompute tables as the input. Assume that a job has two input tabl
es, one storing vertices and the other storing edges.
* The format of the table storing vertices is as follows:
* +------------------------+
* VertexID | VertexValue |
* +------------------------+
* | id0| 9|
* +------------------------+
* | id1| 7|
* +------------------------+
* | id2| 8|
* +------------------------+
*
* The format of the table storing edges is as follows:
* +-----------------------------------+
* VertexID | DestVertexID| EdgeValue|
* +-----------------------------------+
* | id0| id1| 1|
* +-----------------------------------+
* | id0| id2| 2|
* +-----------------------------------+
* | id2| id1| 3|
* +-----------------------------------+
*
* The two preceding tables show that id0 has two outgoing edges pointing to id1 and id2. id2 has an o
utgoing edge pointing to id1, and id1 has no outgoing edges.
*
* For data of this type, in GraphLoader::load(LongWritable, Record, MutationContext), > MutationCont
```

```
ext#addVertexRequest(Vertex) can be used to add vertices to the graph, while link MutationContext#
addEdgeRequest(WritableComparable,Edge) can be used to add edges to the graph. In link VertexRes
olver#resolve(WritableComparable, Vertex, VertexChanges, boolean), vertices and edges added in the
load() method are combined to a vertex object, which is used as the returned value and added to the
graph for participating in computation.
*
**/

1.10. Java SDK

MaxCompute provides Java SDK with a variety of APIs to support development on MaxCompute. For more inforamtion about the APIs, see *MaxCompute Developer Guide*.

1.11. PyODPS

1.11.1. Overview

Although you can implement most MaxCompute development by executing SQL statements, you need to use Python in complex business scenarios and custom UDF scenarios.

PyODPS is the Python SDK of MaxCompute. It provides simple and convenient Python programming interfaces, basic operations on MaxCompute objects, and the DataFrame framework. It allows you to easily analyze data on MaxCompute.

1.11.2. Quick start

This topic describes how to use a PyODPS node in DataWorks for development. The following procedure is for reference only.

1. Create a PyODPS node.
   i. Create a business flow.

      Right-click **Business Flow** below **Data Analytics** and choose **Create Workflow** from the shortcut menu.

   ii. Create a node.

      Right-click **Data Analytics** and choose **Create Data Analytics Node > PyODPS**.
2. Edit the PyODPS node.
   i. Write the program code.

      The following code is for reference only:

```
import time              # Similar to Java, module import is required before an additional SDK is
called.
import datetime          # In this example, only the print function is used.
import base64
import hashlib
import httplib
import json
import sys
import csv
from odps import ODPS      # To call an SDK related to MaxCompute, you must import this mo
dule.
def main():
   print"Hello World"      # Provide the output in the log file.
if __name__ == "__main__":   # The main entry of the program.
   main()
```

ii. Run the code.

After you edit the code, click the Run icon. You can view the running results in the **Runtime Log** section.

The first code snippet is completed. The main entry of the code is determined based on `if __name__ == "__main__"`. This statement takes effect only when the preceding script is run directly (name = main). It does not take effect when it is referenced as a module by other code files (name = Python file name).

1.11.3. Installation instructions

If you can access the Internet, we recommend that you use the Python package installer PIP to install PyODPS. For more information, see PIP installation instructions. If you want to speed up the download, we recommend that you use Alibaba Cloud images.

Prerequisites

Before you install PyOPDS, make sure that the following requirements are met:

- The Setuptools version is 3.0 or later.
- The Requests version is 2.4.0 or later.

Installation commands for reference:

```
pip install setuptools>=3.0
pip install requests>=2.4.0
```

Installation suggestions

We recommend that you install the following tools to speed up Tunnel upload:

- Greenlet. Recommended version: 0.4.10 or later.
- Cython. Recommended version: 0.19.0 or later.

Installation commands for reference:

```
pip install greenlet>=0.4.10  # Optional. It accelerates Tunnel upload.
pip install cython>=0.19.0  # Optional. It is not recommended if you use a Windows operating system.
```

> **Note** If you use a Windows operating system, make sure that you have installed Visual C++ and Cython of correct versions. Otherwise, you cannot speed up Tunnel upload.

Installation procedure

Run the following command to install PyODPS:

```
pip install pyodps
```

Run the following command to check whether the installation is complete:

```
python -c "from odps import ODPS"
```

If the Python version is not the default, you can run the following command to switch to the default version after you have installed PIP:

```
/home/tops/bin/python2.7 -m pip install setuptools>=3.0  # Replace the version of Setuptools with the actual version.
```

1.11.4. Platform instructions

1.11.4.1. Overview

PyODPS can be called as a data development node on a data development platform such as DataWorks. The platform provides a PyODPS running environment and supports scheduling and execution. You do not need to manually create a MaxCompute object. To migrate from a platform to a locally deployed PyODPS environment, see the instructions in the next topic.

1.11.4.2. Use local PyODPS

If you need to debug PyODPS locally or the resources on the platform where PyODPS is deployed cannot meet your requirements, you can deploy a local PyODPS environment.

You must install PyODPS first. For information about how to install it, see Installation instructions.

After you have installed PyODPS, you must manually create the MaxCompute object that was previously created on the platform. Then, execute the following statement on the platform to generate a statement template required by the MaxCompute object and manually modify the code:

```
print("\nfrom odps import ODPS\no = ODPS(%r, '<access-key>', %r, '<endpoint>')\n" % (o.account.access_id, o.project))
```

> **Note** You need to replace **access-key** and **endpoint** with valid values. For information about how to obtain the values, see the corresponding topics in *MaxCompute Developer Guide*.

Then, place the modified code at the beginning of all code.

1.11.4.3. Use PyODPS in DataWorks

Create a workflow node

Set Node Type to PYODPS.

MaxCompute entry

The PyODPS node in DataWorks contains a global variable odps or o, which is the MaxCompute entry. You do not need to manually define the MaxCompute entry.

```
print(o.exist_table('pyodps_iris'))
```

Execute SQL statements

For more information, see SQL.

> **Note** By default, InstanceTunnel is disabled in DataWorks, and instance.open_reader is executed by using the Result interface. In this case, a maximum of 10,000 data records can be read. After InstanceTunnel is enabled, you can execute reader.count to obtain the number of data records. If you need to obtain all data iteratively, you must disable the limit on the data volume.

You can execute the following statements to enable InstanceTunnel and disable the limit:

```
options.tunnel.use_instance_tunnel = True
options.tunnel.limit_instance_tunnel = False  # Disable the limit on the data volume.

with instance.open_reader() as reader:
    # Use InstanceTunnel to read all data.
```

You can also add `tunnel=True` and `limit=False` to open_reader to enable InstanceTunnel and disable the limit on the data volume for the current open_reader operation.

```
with instance.open_reader(tunnel=True, limit=False) as reader:
# The current open_reader operation is executed by using InstanceTunnel and all data can be read.
```

> **Note** If you do not enable InstanceTunnel, the format of the obtained data may be incorrect.

DataFrame

- Execute DataFrame.

  To execute DataFrame in DataWorks, you must explicitly call automatically executed methods, such as execute and head.

  ```
  from odps.df import DataFrame
  iris = DataFrame(o.get_table('pyodps_iris'))
  for record in iris[iris.sepal_width < 3].execute():  # Call an automatically executed method to proces
  s each record.
  ```

  To call an automatically executed method for data display, set `options.interactive` to True.

```
from odps import options
from odps.df import DataFrame
options.interactive = True  # Set options.interactive to True at the beginning of the code.
iris = DataFrame(o.get_table('pyodps_iris'))
print(iris.sepal_width.sum())  # The method is executed immediately when the system displays infor
mation.
```

- Display details.

  To display details, you must set `options.verbose`. By default, this parameter is set to True in DataWorks. The system displays details such as the LogView URL while running.

Obtain scheduling parameters.

Different from SQL nodes in DataWorks, a PyODPS node does not replace strings such as **${param_name}** in the code. Instead, it adds a dict parameter named `args` to the global variable. You can obtain the scheduling parameters in dict. This way, the Python code is not affected. For example, if you set `ds=${yyyymmdd}` under **Schedule** > **Parameter** in DataWorks, you can run the following commands to obtain the parameter value:

```
print('ds=' + args['ds'])
ds=yyyymmdd
```

> **Note** You can run the following command to obtain the partition named ds=${yyyymmdd}:
>
> ```
> o.get_table('table_name').get_partition('ds=' + args['ds'])
> ```

Limits on functions

Functions may be limited in the following aspects due to the lack of packages such as matplotlib:

- The use of the plot function of DataFrame is affected.
- User defined functions (UDFs) of DataFrame can be executed only after they are submitted to MaxCompute. As required by the Python sandbox, you can only use pure Python libraries and the NumPy library to execute UDFs. Other third-party libraries such as pandas cannot be used.
- However, you can use the NumPy and pandas libraries pre-installed in DataWorks to execute non-UDFs. You are not allowed to use other third-party libraries that contain binary code.

For compatibility reasons, `options.tunnel.use_instance_tunnel` is set to **False** in DataWorks by default. If you want to enable `InstanceTunnel` globally, you must set this parameter to **True**.

For implementation reasons, the Python atexit package is not supported. You need to use the try-finally structure to implement related functions.

Limits on usage

- The Python version of a PyODPS node is 2.7.
- Locally processed data obtained by a PyODPS node cannot exceed 50 MB, and the memory space occupied by the node cannot exceed 1 GB. Otherwise, the system stops tasks in the node. Do not write unnecessary Python data processing code in PyODPS tasks.
- Writing and debugging code in DataWorks is inefficient. We recommend that you install an IDE locally to write code.
- To prevent excess pressure on the gateway of DataWorks, the memory usage and CPU utilization are limited when PyODPS is used in DataWorks. The limits are managed by DataWorks. If the system displays **Got killed**, the memory usage exceeds the limit and the system stops the related processes. Therefore, we do not recommend you perform local data operations. However, the limits on the memory usage and CPU utilization do not apply to SQL and DataFrame tasks (except to_pandas) that are initiated by PyODPS.

1.11.5. Basic operations

1.11.5.1. Overview

PyODPS provides basic operations for MaxCompute objects. You can use Python-compliant programming methods to perform operations on MaxCompute.

1.11.5.2. Projects

You can use the `get_project` method of a MaxCompute object to obtain a project.

```
project = o.get_project('my_project')  # Obtain a specific project.
project = o.get_project()              # Obtain the default project.
```

If the my_project parameter is not specified, the default project is obtained.

You can use the `exist_project` method to check whether a project exists.

1.11.5.3. Tables

Basic operations

You can call `list_tables` for a MaxCompute object to list all tables in a project.

```
for table in o.list_tables():
# Process each table.
```

You can call `exist_table` to check whether a table exists and call `get_table` to obtain the table.

```
t = o.get_table('dual')
t.schema
odps.Schema {
  c_int_a             bigint
  c_int_b             bigint
  c_double_a          double
  c_double_b          double
  c_string_a          string
  c_string_b          string
  c_bool_a            boolean
  c_bool_b            boolean
  c_datetime_a        datetime
  c_datetime_b        datetime
}
t.lifecycle
-1
print(t.creation_time)
2014-05-15 14:58:43
t.is_virtual_view
False
t.size
1408
t.comment
'Dual Table Comment'
t.schema.columns
[<column c_int_a, type bigint>,
 <column c_int_b, type bigint>,
 <column c_double_a, type double>,
 <column c_double_b, type double>,
 <column c_string_a, type string>,
 <column c_string_b, type string>,
 <column c_bool_a, type boolean>,
 <column c_bool_b, type boolean>,
 <column c_datetime_a, type datetime>,
 <column c_datetime_b, type datetime>]
t.schema['c_int_a']
<column c_int_a, type bigint>
t.schema['c_int_a'].comment
'Comment of column c_int_a'
```

You can obtain a table from another project by specifying the project parameter.

```
t = o.get_table('dual', project='other_project')
```

Create a table schema

You can initialize a table in two ways:

- Initialize a table based on table columns and available partitions.

```
from odps.models import Schema, Column, Partition
columns = [Column(name='num', type='bigint', comment='the column'),
           Column(name='num2', type='double', comment='the column2')]
partitions = [Partition(name='pt', type='string', comment='the partition')]
schema = Schema(columns=columns, partitions=partitions)
schema.columns
[<column num, type bigint>,
 <column num2, type double>,
 <partition pt, type string>]
schema.partitions
[<partition pt, type string>]
schema.names  # Obtain the names of non-partition fields.
['num', 'num2']
schema.types  # Obtain the types of non-partition fields.
[bigint, double]
```

- Initialize a table by calling `Schema.from_lists`. This method is easier to call, but you cannot directly set the comments of columns and partitions.

```
schema = Schema.from_lists(['num', 'num2'], ['bigint', 'double'], ['pt'], ['string'])
schema.columns
[<column num, type bigint>,
 <column num2, type double>,
 <partition pt, type string>]
```

Create a table

You can use a table schema to create a table.

```
table = o.create_table('my_new_table', schema)
table = o.create_table('my_new_table', schema, if_not_exists=True)  #The table is created only if no ta
ble with the same name exists.
table = o.create_table('my_new_table', schema, lifecycle=7)  # Set the lifecycle.
```

You can also use a comma-connected string in the "field name, field type" format to create a table. This method is easier.

```
table = o.create_table('my_new_table', 'num bigint, num2 double', if_not_exists=True)
# To create a partitioned table, you can pass in (table field list, partition field list).
table = o.create_table('my_new_table', ('num bigint, num2 double', 'pt string'), if_not_exists=True)
```

By default, when you create a table, you can only use the BIGINT, DOUBLE, DECIMAL, STRING, DATETIME, BOOLEAN, MAP, and ARRAY data types. If you need to use other data types, such as TINYINT and STRUCT, you can set `options.sql.use_odps2_extension` to True. Example:

```
from odps import options
options.sql.use_odps2_extension = True
table = o.create_table('my_new_table', 'cat smallint, content struct<title:varchar(100), body string>')
```

Synchronize table updates

After another program updates a table, such as its schema, you can call the `reload` method to synchronize the update.

```
table.reload()
```

Record

A record refers to a single row in a table. You can call new_record for the table object to create a record.

```
t = o.get_table('mytable')
r = t.new_record(['val0', 'val1'])  # The number of values must be equal to the number of fields in the ta
ble schema.
r2 = t.new_record()  # You can leave the value empty.
r2[0] = 'val0' # Set a value based on an offset.
r2['field1'] = 'val1'  # Set a value based on a field name.
r2.field1 = 'val1'  # Set a value based on an attribute.

print(record[0])  # Obtain the value at position 0.
print(record['c_double_a'])  # Obtain a value based on a field.
print(record.c_double_a)  # Obtain a value based on an attribute.
print(record[0: 3])  # Perform slicing operations.
print(record[0, 2, 3])  # Obtain values at multiple positions.
print(record['c_int_a', 'c_double_a'])  # Obtain values based on multiple fields.
```

Obtain table data

You can obtain table data in three ways:

- Call `head` to retrieve up to the first 10,000 data records in a table. Example:

```
t = odps.get_table('dual')
for record in t.head(3):
    print(record[0])  # Obtain the value at position 0.
    print(record['c_double_a'])  # Obtain a value based on a field.
    print(record[0: 3])  # Perform slicing operations.
    print(record[0, 2, 3])  # Obtain values at multiple positions.
    print(record['c_int_a', 'c_double_a'])  # Obtain values based on multiple fields.
```

- Use `open_reader` for a table object to open a reader and read the table data. You can open the reader with or without a WITH clause.

```
# Open the reader with a WITH clause:
 with t.open_reader(partition='pt=test') as reader:
    count = reader.count
    for record in reader[5:10]  # You can execute this line multiple times until all records are read. Th
e number of records is specified by count. You can change it to parallel-operation code.
        # Process a record.

# Open the reader without a WITH clause:
 reader = t.open_reader(partition='pt=test')
 count = reader.count
 for record in reader[5:10]  # You can execute this line multiple times until all records are read. The
number of records is specified by count. You can change it to parallel-operation code.
    # Process a record.
```

- Use the `read_table` method for a MaxCompute object to obtain table data. Example:

```
for record in o.read_table('test_table', partition='pt=test'):
# Process a record.
```

Write data to a table.

Similar to `open_reader`, you can use `open_writer` for a table object to open a writer and write data to a table. Example:

```
 # Open the writer with a WITH clause:
 with t.open_writer(partition='pt=test') as writer:
records = [[111, 'aaa', True],              # A list can be used.
        [222, 'bbb', False],
        [333, 'ccc', True],
        [444, 'Chinese', False]]
writer.write(records)  # records can be iterable objects.

with t.open_writer(partition='pt1=test1,pt2=test2') as writer: #Write data in multi-level partitioning m
ode.

records = [t.new_record([111, 'aaa', True]),   # Record objects can be used.
         t.new_record([222, 'bbb', False]),
         t.new_record([333, 'ccc', True]),
         t.new_record([444, 'Chinese', False])]
writer.write(records)

with t.open_writer(partition='pt=test', blocks=[0, 1]) as writer:  # Two blocks are enabled.
    writer.write(0, gen_records(block=0))
    writer.write(1, gen_records(block=1))  # The two write operations can be performed in parallel base
d on the multithreading technique. Each block is independent.

 # Open the writer without a WITH clause:
 writer = t.open_writer(partition='pt=test', blocks=[0, 1])
 writer.write(0, gen_records(block=0))
 writer.write(1, gen_records(block=1))
 writer.close()  # You must close the writer. Otherwise, the written data may be incomplete.
```

If the specified partition does not exist, use the create_partition parameter to create a partition. Example:

```
with t.open_writer(partition='pt=test', create_partition=True) as writer:
   records = [[111, 'aaa', True],              # A list can be used.
           [222, 'bbb', False],
           [333, 'ccc', True],
           [444, 'Chinese', False]]
   writer.write(records)  # records can be iterable objects.
```

You can also use the `write_table` method for a MaxCompute object to write data. Example:

```
records = [[111, 'aaa', True],          # A list can be used.
           [222, 'bbb', False],
           [333, 'ccc', True],
           [444, 'Chinese', False]]
o.write_table('test_table', records, partition='pt=test', create_partition=True)
```

> **Note**
>
> - Each time you call write_table, MaxCompute generates a file on the server. This operation is time-consuming. If too many files are generated, the efficiency of subsequent queries will be reduced. Therefore, we recommend that you write multiple records at a time or provide a Generator object when you use the write_table method.
> - When you use `write_table`, new data will be appended to existing data. PyODPS does not provide options to overwrite existing data. You need to manually remove the data that you want to overwrite. For a non-partitioned table, you must call `table.truncate()`. For a partitioned table, you need to delete partitions first.

Delete a table

```
o.delete_table('my_table_name', if_exists=True)  # Delete a table if the table exists.
t.drop()  # The drop function can be directly executed if a table object exists.
```

Create a DataFrame object

PyODPS provides a DataFrame framework, which allows you to conveniently query and manage MaxCompute data. You can use `to_df` to convert a table to a DataFrame object.

```
table = o.get_table('my_table_name')
df = table.to_df()
```

Table partitions

- Basic operations

  Check whether a table is partitioned:

  ```
  if table.schema.partitions:
      print('Table %s is partitioned.' % table.name)
  ```

  Iterate over all the partitions in a table:

```
for partition in table.partitions:
    print(partition.name)
for partition in table.iterate_partitions(spec='pt=test'):
# Iterate over subpartitions.
```

Check whether a specific partition exists:

```
table.exist_partition('pt=test,sub=2019')
```

Obtain a specific partition:

```
partition = table.get_partition('pt=test')
 print(partition.creation_time)
2019-09-18 22:22:27
 partition.size
0
```

- Create a partition.

```
t.create_partition('pt=test', if_not_exists=True)  # Create the partition if it does not exist.
```

- Delete a partition.

```
t.delete_partition('pt=test', if_exists=True)  # Delete the partition if it exists.
partition.drop()  # Use the drop method to delete the partition object if it exists.
```

Data upload and download channels

MaxCompute Tunnel is the data channel of MaxCompute. You can use it to upload data to or download data from MaxCompute.

> **Note** We recommend that you use the write and read interfaces of tables instead of the Tunnel interface. In a Cython environment, PyODPS compiles C programs during installation to accelerate the Tunnel upload and download.

- Upload example:

```
from odps.tunnel import TableTunnel

table = o.get_table('my_table')

tunnel = TableTunnel(odps)
upload_session = tunnel.create_upload_session(table.name, partition_spec='pt=test')

with upload_session.open_record_writer(0) as writer:
    record = table.new_record()
    record[0] = 'test1'
    record[1] = 'id1'
    writer.write(record)

    record = table.new_record(['test2', 'id2'])
    writer.write(record)

upload_session.commit([0])
```

- Download example:

```
from odps.tunnel import TableTunnel

tunnel = TableTunnel(odps)
download_session = tunnel.create_download_session('my_table', partition_spec='pt=test')

with download_session.open_record_reader(0, download_session.count) as reader:
    for record in reader:
# Process each record.
```

> **Note** PyODPS currently does not allow you to upload external tables.

1.11.5.4. SQL

PyODPS supports MaxCompute SQL queries and provides methods to read execution results.

You can use the `execute_sql` and `run_sql` methods to create task instances.

> **Note** The commands that are executable in the MaxCompute console may not be executed as SQL statements in MaxCompute. Use other methods to execute non-DDL/DML statements. For example, use the `run_security_query` method to execute GRANT/REVOKE statements, and use the `run_xflow` or `execute_xflow` method to execute PAI commands.

Execute SQL statements

```
o.execute_sql('select * from dual')  # Run the SQL statement in synchronous mode. Blocking continues until execution of the SQL statement is completed.
instance = o.run_sql('select * from dual')  # Run the SQL statement in asynchronous mode.
print(instance.get_logview_address())  # Obtain the LogView address.
instance.wait_for_success()  # Blocking continues until execution of the SQL statement is completed.
```

Configure runtime parameters

You can configure runtime parameters by setting the `hints` parameter. The type of this parameter is DICT.

```
o.execute_sql('select * from pyodps_iris', hints={'odps.sql.mapper.split.size': 16})
```

If you set the `sql.settings` parameter globally, you need to configure runtime parameters each time you execute the statement.

```
from odps import options
options.sql.settings = {'odps.sql.mapper.split.size': 16}
o.execute_sql('select * from pyodps_iris')  # The hints parameter is automatically set based on global s ettings.
```

Obtain SQL query results

You can directly call the `open_reader` method to obtain SQL query results. In the following example, structured data is returned.

```
with o.execute_sql('select * from dual').open_reader() as reader:
    for record in reader:
    # Process each record.
```

When the `DESC` command is executed, you can use `reader.raw` to obtain the raw SQL query results.

```
with o.execute_sql('desc dual').open_reader() as reader:
print(reader.raw)
```

If `options.tunnel.use_instance_tunnel` is set to True when you use `open_reader`, PyODPS calls Instance Tunnel by default. Otherwise, PyODPS calls the old Result interface. However, if you are using an earlier version of MaxCompute or an error occurs when PyODPS calls Instance Tunnel, PyODPS generates an alert and automatically downgrades the call object to the old Result interface. You can identify the cause of the downgrade based on the alert information. If the result of Instance Tunnel does not meet your expectation, set this option to False. When you call `open_reader`, you can specify a Result interface by setting the tunnel parameter.

```
# Call Instance Tunnel.
with o.execute_sql('select * from dual').open_reader(tunnel=True) as reader:
    for record in reader:
    # Process each record.
# Call the Result interface.
with o.execute_sql('select * from dual').open_reader(tunnel=False) as reader:
    for record in reader:
    # Process each record.
```

By default, PyODPS does not limit the amount of data that can be read from an instance. For protected projects, the amount of data that can be downloaded by using Tunnel is limited. If `options.tunnel.limit_instance_tunnel` is not set, the limit is automatically enabled. The number of data entries that can be downloaded is limited based on project configurations. Generally, a maximum of 10,000 data entries can be downloaded. You can add a limit option to the `open_reader` method or set `options.tunnel.limit_instance_tunnel` to True to manually limit the amount.

If your MaxCompute version only supports the old Result interface and you need to read all data, you can export the SQL query results to another table and then use the table read interface to read data. This may be limited by project security settings.

In PyODPS V0.7.7.1 and later, you can use `open_reader` to call Instance Tunnel to obtain all data.

```
instance = o.execute_sql('select * from movielens_ratings limit 20000')
with instance.open_reader() as reader:
    print(reader.count)
     # for record in reader: Traverse the 20,000 data records. In this example, only 10 data records are o
btained based on data slicing.
    for record in reader[:10]:
        print(record)
```

Set alias

During runtime, if the resource referenced by a UDF changes dynamically, you can use the old resource name as the alias of the current resource. This way, you do not need to delete the UDF or create a UDF.

```
from odps.models import Schema
myfunc = '''\
from odps.udf import annotate
from odps.distcache import get_cache_file

@annotate('bigint->bigint')
class Example(object):
    def __init__(self):
        self.n = int(get_cache_file('test_alias_res1').read())

    def evaluate(self, arg):
        return arg + self.n
'''
res1 = o.create_resource('test_alias_res1', 'file', file_obj='1')
o.create_resource('test_alias.py', 'py', file_obj=myfunc)
o.create_function('test_alias_func',
                  class_type='test_alias.Example',
                  resources=['test_alias.py', 'test_alias_res1'])

table = o.create_table(
    'test_table',
    schema=Schema.from_lists(['size'], ['bigint']),
    if_not_exists=True
)

data = [[1, ], ]
# Write a row of data that contains only one value: 1.
o.write_table(table, 0, [table.new_record(it) for it in data])

with o.execute_sql(
    'select test_alias_func(size) from test_table').open_reader() as reader:
    print(reader[0][0])
res2 = o.create_resource('test_alias_res2', 'file', file_obj='2')
# Use the name of the resource whose content is 1 as the alias of the resource whose content is 2. Yo
u do not need to modify the UDF or resource.
with o.execute_sql(
    'select test_alias_func(size) from test_table',
    aliases={'test_alias_res1': 'test_alias_res2'}).open_reader() as reader:
    print(reader[0][0])
```

Execute SQL statements in an interactive environment

In IPython and Jupyter, SQL plug-ins can be used to execute SQL statements and parameterized queries are supported.

Set biz_id

Occasionally, when an SQL statement is executed, biz_id must be submitted. Otherwise, an error occurs. In this case, you can set biz_id in the global options to troubleshoot the error.

```
from odps import options
options.biz_id = 'my_biz_id'
o.execute_sql('select * from pyodps_iris')
```

1.11.5.5. Task instances

Tasks, such as SQL tasks, are the basic computing unit of MaxCompute.

Basic operations

Tasks are implemented as MaxCompute instances. You can call `list_instances` to obtain all instances in a project, `exist_instance` to check whether an instance exists, and `get_instance` to obtain an instance.

```
for instance in o.list_instances():
    print(instance.id)
    o.exist_instance('my_instance_id')
```

You can call the `stop` method for an instance or call `stop_instance` at the MaxCompute entry to stop an instance.

Obtain the LogView address of a task

You can call `get_logview_address` to obtain the LogView address of an SQL task.

```
# Obtain the LogView address based on an existing instance object.
instance = o.run_sql('desc pyodps_iris')
print(instance.get_logview_address())
# Obtain the LogView address based on an instance ID.
instance = o.get_instance('20160426055209459g9k5pvyi2')
print(instance.get_logview_address())
```

For an XFlow task, you must enumerate its subtasks and then obtain the LogView address of each subtask.

```
instance = o.run_xflow('AppendID', 'algo_public', {'inputTableName': 'input_table', 'outputTableName': 'o
utput_table'})
for sub_inst_name, sub_inst in o.get_xflow_sub_instances(instance).items():
    print('%s: %s' % (sub_inst_name, sub_inst.get_logview_address()))
```

Obtain the status of a task instance

An instance can be in the **Running**, **Suspended**, or **Terminated** state. You can obtain the status from the status attribute. You can call the `is_terminated` method to check whether the execution of the current instance is completed and call the `is_successful` method to check whether the execution is successful. If the task is running or fails, False is returned for both methods.

```
instance = o.get_instance('2016042605520945g9k5pvyi2')
instance.status
<Status.TERMINATED: 'Terminated'>
    from odps.models import Instance
    instance.status == Instance.Status.TERMINATED
    True
    instance.status.value
    'Terminated'
```

You can call the `wait_for_completion` method to ask the system to return the status until the instance execution is completed. The `wait_for_success` method functions similarly. The difference is that if the execution fails, an exception is reported.

Subtask operations

A running instance may contain one or more subtasks, which are called Tasks. Note that Task here does not refer to the basic computing unit of MaxCompute.

You can call the `get_task_names` method to obtain the names of all Tasks.

```
instance.get_task_names()
['SQLDropTableTask']
```

After obtaining a Task name, you can call `get_task_result` to obtain the execution result of the Task. You can also call `get_task_results` to obtain the execution result of each Task in the form of a dictionary.

```
instance = o.execute_sql('select * from pyodps_iris limit 1')
instance.get_task_names()
['AnonymousSQLTask']
instance.get_task_result('AnonymousSQLTask')
'"sepallength","sepalwidth","petallength","petalwidth","name"\n5.1,3.5,1.4,0.2,"Iris-setosa"\n'
instance.get_task_results()
OrderedDict([('AnonymousSQLTask', "sepallength","sepalwidth","petallength","petalwidth","name"\n5.
1,3.5,1.4,0.2,"Iris-setosa"\n')])
```

You can call `get_task_progress` to obtain the current running progress of a Task when the task instance is running.

```
while not instance.is_terminated():
    for task_name in instance.get_task_names():
        print(instance.id, instance.get_task_progress(task_name).get_stage_progress_formatted_string()
)
        time.sleep(10)
20190519101349613gzbzufck2 2019-05-19 18:14:03 M1_Stg1_job0:0/1/1[100%]
```

1.11.5.6. Resources

PyODPS mainly supports file and table resources.

Resources commonly apply to UDFs and MapReduce on MaxCompute.

You can call `list_resources` to list all resources, `exist_resource` to check whether a resource exists, and `delete_resource` to delete a resource. You can also call the `drop` method to delete a resource.

File resources

Files of basic file types and the .py, .jar, and .archive types are supported.

- Create a file resource

  You can create a file resource by specifying a resource name, a file type, and a file-like or string object. Example:

  ```
  resource = odps.create_resource('test_file_resource', 'file', file_obj=open('/to/path/file')) # Use a fil
  e-like object.
  resource = odps.create_resource('test_py_resource', 'py', file_obj='import this') # Use a string object
  .
  ```

- Read and modify a file resource

You can call the `open` method for a file resource or call `open_resource` at the MaxCompute entry to open a file resource. The opened object is a file-like object. Similar to the `open` method built in Python, file resources also support various opening modes. Example:

```
with resource.open('r') as fp:  # Open the file in read mode.
  content = fp.read()  # Read all content.
  fp.seek(0)  # Return to the beginning of the resource.
  lines = fp.readlines()  # Read multiple lines.
  fp.write('Hello World') # Error. Data cannot be written into a file in read mode.

with odps.open_resource('test_file_resource', mode='r+') as fp:  # Open the file in read/write mode.
  fp.read()
  fp.tell()  # Current position
  fp.seek(10)
  fp.truncate()  # Truncate the file to the specified length.
  fp.writelines(['Hello\n', 'World\n'])  # Write multiple lines into the file.
  fp.write('Hello World')
  fp.flush()  # Manually calling the method will submit the update to MaxCompute.
```

PyODPS supports the following opening modes:

- r: read mode. The file can be opened but data cannot be written into it.
- w: write mode. Data can be written into the file, but data in it cannot be read. Note that the file content is cleared first if the file is opened in write mode.
- a: append mode. Data can be added to the end of the file.
- r+: read/write mode. You can read and write data from and to the file.
- w+: This mode is similar to r+, but the file content is cleared first.
- a+: This mode is similar to r+, but data can only be written to the end of the file.

In PyODPS, file resources can be opened in binary mode. For example, some compressed files must be opened in binary mode. **rb** indicates that a file is opened in binary read mode, and **r+b** indicates that a file is opened in binary read/write mode.

Table resources

- Create a table resource

```
o.create_resource('test_table_resource', 'table', table_name='my_table', partition='pt=test')
```

- Update a table resource

```
table_resource = o.get_resource('test_table_resource')
table_resource.update(partition='pt=test2', project_name='my_project2')
```

- Obtain a table and a partition

```
table_resource = o.get_resource('test_table_resource')
table = table_resource.table
print(table.name)
partition = table_resource.partition
print(partition.spec)
```

- Read and write data

```
table_resource = o.get_resource('test_table_resource')
with table_resource.open_writer() as writer:
    writer.write([0, 'aaaa'])
    writer.write([1, 'bbbbb'])
    with table_resource.open_reader() as reader:
        for rec in reader:
            print(rec)
```

1.11.5.7. Functions

You can create UDFs and use them in MaxCompute SQL.

Basic operations

You can call `list_functions` of a MaxCompute object to obtain all functions in the project. You can call `exist_function` to check whether a function exists and call `get_function` to obtain a function.

Create a function

```
# Reference resources in the current project.
resource = o.get_resource('my_udf.py')
function = o.create_function('test_function', class_type='my_udf.Test', resources=[resource])
# Reference resources in another project.
resource2 = o.get_resource('my_udf.py', project='another_project')
function2 = o.create_function('test_function2', class_type='my_udf.Test', resources=[resource2])
```

Delete a function

```
o.delete_function('test_function')
function.drop()  # Call the drop method if the function exists.
```

Update a function

You can call the `update` method to update a function.

```
function = o.get_function('test_function')
new_resource = o.get_resource('my_udf2.py')
function.class_type = 'my_udf2.Test'
function.resources = [new_resource, ]
function.update()  # Update the function.
```

1.11.6. DataFrame

PyODPS provides an interface similar to pandas called PyODPS DataFrame. This interface operates on MaxCompute tables and makes full use of the capabilities of MaxCompute. You can also change the data source from MaxCompute tables to pandas DataFrame, so that the same code can be executed on pandas.

This topic describes how to create and perform operations on DataFrame objects and how to use DataFrame to process data. For the complete DataFrame document, see DataFrame.

DataFrame object operations

The following example demonstrates how to create a DataFrame object. It is for reference only.

> **Note** The data used in the example is downloaded from movielens 100K. You can download the data as needed.

Assume that the following three tables already exist: pyodps_ml_100k_movies (movie-related data), pyodps_ml_100k_users (user-related data), and pyodps_ml_100k_ratings (rating-related data).

1. If no MaxCompute object is provided in the runtime environment, you must create an object.

   ```
   from odps import ODPS
   o = ODPS('**your-access-id**', '**your-secret-access-key**',
           project='**your-project**', endpoint='**your-end-point**')
   ```

2. You only need to import a Table object to create a DataFrame object.

   ```
   from odps.df import DataFrame
   users = DataFrame(o.get_table('pyodps_ml_100k_users'))
   ```

3. You can use the dtypes attribute to view the fields of DataFrame and the types of these fields.

```
users.dtypes
odps.Schema {
 user_id          int64
 age              int64
 sex              string
 occupation       string
 zip_code         string
}
```

4. You can use the `head` method to obtain the first N data records for quick data preview. Example:

```
users.head(10)
   user_id  age  sex    occupation  zip_code
0        1   24    M    technician     85711
1        2   53    F         other     94043
2        3   23    M        writer     32067
3        4   24    M    technician     43537
4        5   33    F         other     15213
5        6   42    M     executive     98101
6        7   57    M  administrator     91344
7        8   36    M  administrator     05201
8        9   29    M       student     01002
9       10   53    M        lawyer     90703
```

5. You can add a filter on the fields if you do not want to view all of them.
   - Example:

```
users[['user_id', 'age']].head(5)
   user_id  age
0        1   24
1        2   53
2        3   23
3        4   24
4        5   33
```

   - You can also exclude several fields. Example:

```
users.exclude('zip_code', 'age').head(5)
  user_id  sex  occupation
0       1    M  technician
1       2    F       other
2       3    M      writer
3       4    M  technician
4       5    F       other
```

- When you exclude some fields, you may want to obtain new columns through computation. For example, add the sex_bool attribute and set it to True if sex is M. Otherwise, set it to False.

```
users.select(users.exclude('zip_code', 'sex'), sex_bool=users.sex == 'M').head(5)
  user_id  age  occupation  sex_bool
0       1   24  technician      True
1       2   53       other     False
2       3   23      writer      True
3       4   24  technician      True
4       5   33       other     False
```

6. Obtain the numbers of male and female users.

```
users.groupby(users.sex).agg(count=users.count())
  sex  count
0   F    273
1   M    670
```

7. To divide users by occupation, obtain the first 10 occupations that have the largest population, and sort the occupations in descending order of population.

```
df = users.groupby('occupation').agg(count=users['occupation'].count())
df.sort(df['count'], ascending=False)[:10]
     occupation  count
0       student    196
1         other    105
2      educator     95
3  administrator     79
4      engineer     67
5    programmer     66
6     librarian     51
7        writer     45
8     executive     32
9     scientist     31
```

Alternatively, you can use the `value_counts` method. Note that the number of records returned by this method is limited by `options.df.odps.sort.limit`.

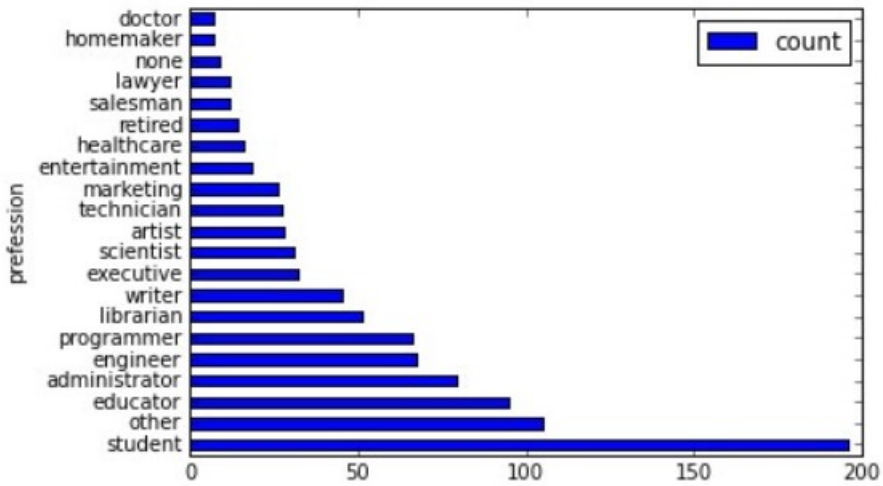
```
users.occupation.value_counts()[:10]
    occupation  count
0      student    196
1        other    105
2     educator     95
3 administrator     79
4     engineer     67
5   programmer     66
6    librarian     51
7       writer     45
8    executive     32
9    scientist     31
```

8. Show data in a more intuitive graph.

```
%matplotlib inline
```

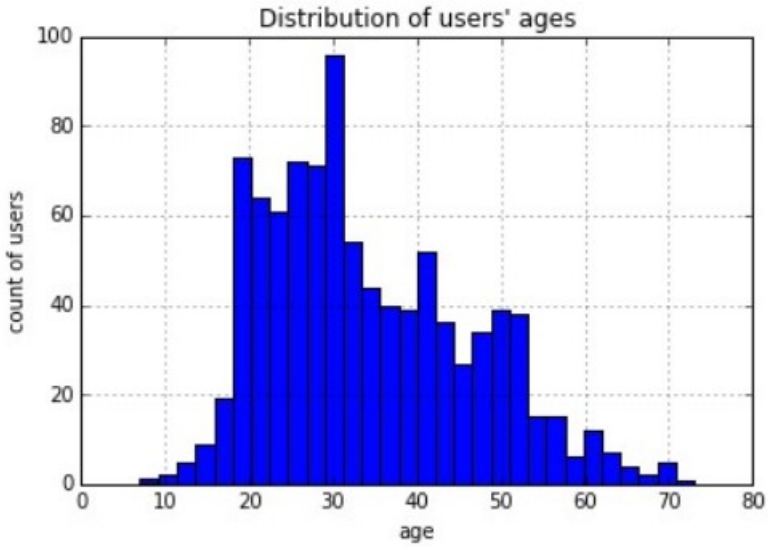
9. Use a horizontal column chart to visualize data.

```
users['occupation'].value_counts().plot(kind='barh', x='occupation', ylabel='prefession')
<matplotlib.axes._subplots.AxesSubplot at 0x10653cfd0>
```



10. Divide users into 30 groups by age and view the histogram of age distribution.

```
users.age.hist(bins=30, title="Distribution of users' ages", xlabel='age', ylabel='count of users')
<matplotlib.axes._subplots.AxesSubplot at 0x10667a510>
```



11. Use `join` to join the three tables and save them as a new table.

```
movies = DataFrame(o.get_table('pyodps_ml_100k_movies'))
ratings = DataFrame(o.get_table('pyodps_ml_100k_ratings'))

o.delete_table('pyodps_ml_100k_lens', if_exists=True)
lens = movies.join(ratings).join(users).persist('pyodps_ml_100k_lens')

lens.dtypes
odps.Schema {
  movie_id                int64
  title                   string
  release_date            string
  video_release_date      string
  imdb_url                string
  user_id                 int64
  rating                  int64
  unix_timestamp          int64
  age                     int64
  sex                     string
  occupation              string
  zip_code                string
}
```

12. Divide users aged 0 to 80 into eight age groups.

```
labels = ['0-9', '10-19', '20-29', '30-39', '40-49', '50-59', '60-69', '70-79']
cut_lens = lens[lens, lens.age.cut(range(0, 81, 10), right=False, labels=labels).rename('age_group'
)]
```

13. View the first 10 data records of a single age in a group.

```
cut_lens['age_group', 'age'].distinct()[:10]
  age_group  age
0     0-9    7
1    10-19   10
2    10-19   11
3    10-19   13
4    10-19   14
5    10-19   15
6    10-19   16
7    10-19   17
8    10-19   18
9    10-19   19
```

14. View the total rating and average rating of users in each age group.

```
cut_lens.groupby('age_group').agg(cut_lens.rating.count().rename('total_rating'), cut_lens.rating.
mean().rename('avg_rating'))
    age_group  avg_rating  total_rating
0     0-9  3.767442       43
1    10-19  3.486126     8181
2    20-29  3.467333    39535
3    30-39  3.554444    25696
4    40-49  3.591772    15021
5    50-59  3.635800     8704
6    60-69  3.648875     2623
7    70-79  3.649746      197
```

DataFrame data processing

The following example demonstrates how to process DataFrame data. It is for reference only.

> **Note** The data used in the example is downloaded from Iris dataset. You can download the data as needed.

1. Create a test data table.

   Use the table management feature of DataWorks to create a table, and then click **DDL mode**.

   Enter the CREATE TABLE statement and submit the table. Example:

```
CREATE TABLE `pyodps_iris` (
    `sepallength` double COMMENT 'sepallength(cm)',
    `sepalwidth` double COMMENT 'sepalwidth(cm)',
    `petallength` double COMMENT 'petallength(cm)',
    `petalwidth` double COMMENT 'petalwidth(cm)',
    `name` string COMMENT 'name'
) ;
```

2. Upload test data.

   Click the **Import** icon.

   Enter the table name and upload the downloaded dataset.

   Select **By Location** and click Import.

3. Create a PyODPS node to store and run code.
4. Enter the code and click the Run icon. You can view the result in the **Runtime Log** section in the lower pane.

   Code details:

```
from odps.df import DataFrame
from odps.df import output
iris = DataFrame(o.get_table('pyodps_iris')) #Create the DataFrame object iris from the MaxCompu
te table.
print iris.head(10)
print iris.sepallength.head(5) # Display part of the iris content.

# Use a user defined function to calculate the sum of two columns of iris.
print iris.apply(lambda row: row.sepallength + row.sepalwidth, axis=1, reduce=True, types='float')
.rename('sepaladd').head(3)

# Specify the output name and type of the function.
@output(['iris_add', 'iris_sub'], ['float', 'float'])
def handle(row):
# Use the yield keyword to return multiple rows of results.
    yield row.sepallength - row.sepalwidth,row.sepallength + row.sepalwidth
    yield row.petallength - row.petalwidth,row.petallength + row.petalwidth
# Display the results of the first five rows. axis=1 indicates that the axis of the column extends h
orizontally.
print iris.apply(handle,axis=1).head(5)
```

1.11.7. User experience enhancement

1.11.7.1. Command line

PyODPS provides an enhanced command line tool.

You can perform the following steps to configure and call the tool:

1. Import the PyODPS enhancement tool:

```
from odps.inter import setup, enter, teardown
```

2. Configure your account:

```
setup('**your-access_id**', '**your-access-key**', '**your-project**', endpoint='**your-endpoint**')
```

> **Note**
> - If you do not specify the room parameter, the default room is used.
> - After you have configured an account, you do not need to enter the account information again upon the next logon.

3. You can then call the enter method to create a Room object in any Python interactive interface.

```
room = enter()
o = room.odps
o.get_table('dual')
odps.Table
 name: odps_test_sqltask_finance.`dual`
 schema:
  c_int_a             : bigint
  c_int_b             : bigint
  c_double_a          : double
  c_double_b          : double
  c_string_a          : string
  c_string_b          : string
  c_bool_a            : boolean
  c_bool_b            : boolean
  c_datetime_a        : datetime
  c_datetime_b        : datetime
```

> **Note** The MaxCompute object is not automatically updated when you change the setup of the room. You need to call `enter()` again to retrieve the new Room object.

After you have configured an account and called objects, you can store, retrieve, or delete objects in the room or delete the entire room.

- You can store commonly used MaxCompute tables or resources in the room. Example:

```
room.store('stored-table', o.get_table('dual'), desc='Simple stored table example')
```

- You can call the `display` method to display the stored objects as a table. Example:

```
room.display()
```

default name	desc
stored-table	Simple stored table example
iris	Iris dataset

- You can use `room['stored-table']` or `room.iris` to retrieve the stored objects. Example:

```
room['stored-table']
odps.Table
 name: odps_test_sqltask_finance.`dual`
 schema:
   c_int_a             : bigint
   c_int_b             : bigint
   c_double_a          : double
   c_double_b          : double
   c_string_a          : string
   c_string_b          : string
   c_bool_a            : boolean
   c_bool_b            : boolean
   c_datetime_a        : datetime
   c_datetime_b        : datetime
```

- You can call the `drop` method to delete objects in the room.

```
room.drop('stored-table')
room.display()
default name       desc
iris       Iris dataset
```

- You can call `teardown()` to delete a room. When no parameter is specified, the default room is deleted.

```
teardown()
```

1.11.7.2. IPython

PyODPS provides the IPython plug-in to facilitate MaxCompute operations.

IPython enhancement

Some commands are provided for command line enhancement.

- You can run the following code to load the plug-in:

```
%load_ext odps
%enter
```

Result:

```
<odps.inter.Room at 0x11341df10>
```

- In this case, the global `o` and `odps` variables can be retrieved. You can run the `o.get_table` or `odps.get_table` command to call a table.

```
o.get_table('dual')
odps.get_table('dual')
```

Result:

```
odps.Table
  name: odps_test_sqltask_finance.`dual`
  schema:
    c_int_a             : bigint
    c_int_b             : bigint
    c_double_a          : double
    c_double_b          : double
    c_string_a          : string
    c_string_b          : string
    c_bool_a            : boolean
    c_bool_b            : boolean
    c_datetime_a        : datetime
    c_datetime_b        : datetime
```

- Run the following command to display the stored objects as a table:

```
%stores
```

Result:

default name	desc
iris	Iris dataset

Object name completion

PyODPS enhances the code completion feature that is provided by IPython. When you write statements such as o.get_xxx, the object name is automatically completed. In the following examples, <tab> is used to denote pressing the Tab key. When you enter the statement and encounter <tab>, press the Tab key.

- Use the Tab key to complete the object name:

```
o.get_table(<tab>
```

- You can enter the first few characters of an object name and press the Tab key to complete it:

```
o.get_table('tabl<tab>
```

  IPython auto-completes the table name that starts with tabl.

- This feature can also complete the names of objects in different projects. The syntax is as follows:

```
o.get_table(project='project_name', name='tabl<tab>
o.get_table('tabl<tab>', project='project_name')
```

- If multiple matching objects exist, IPython provides a list. `options.completion_size` specifies the maximum number of objects in the list. The default value is 10.

SQL statements

PyODPS provides a SQL plug-in to execute MaxCompute SQL statements.

- You can use `%sql` to execute a single-line SQL statement. Example:

```
In [*]: %sql select * from pyodps_iris limit 5
|==========================================|  1 /  1  (100.00%)       3s
Out[*]:
   sepallength  sepalwidth  petallength  petalwidth       name
0          5.1         3.5          1.4         0.2  Iris-setosa
1          4.9         3.0          1.4         0.2  Iris-setosa
2          4.7         3.2          1.3         0.2  Iris-setosa
3          4.6         3.1          1.5         0.2  Iris-setosa
4          5.0         3.6          1.4         0.2  Iris-setosa
```

- You can use `%%sql` to execute a multiple-line SQL statement. Example:

```
In [*]: %%sql
  ....: select * from pyodps_iris
  ....: where sepallength < 5
  ....: limit 5
  ....:
|==========================================|  1 /  1  (100.00%)       15s
Out[*]:
  sepallength  sepalwidth  petallength  petalwidth       name
0         4.9         3.0          1.4         0.2  Iris-setosa
1         4.7         3.2          1.3         0.2  Iris-setosa
2         4.6         3.1          1.5         0.2  Iris-setosa
3         4.6         3.4          1.4         0.3  Iris-setosa
4         4.4         2.9          1.4         0.2  Iris-setosa
```

- To execute parameterized SQL statements, you can use `:parameter` to specify the parameter. Example:

```
In [1]: %load_ext odps

In [2]: mytable = 'dual'

In [3]: %sql select * from :mytable
|==========================================|  1 /  1  (100.00%)       2s
Out[3]:
  c_int_a  c_int_b  c_double_a  c_double_b  c_string_a  c_string_b c_bool_a  \
0       0       0       -1203           0           0       -1203     True

  c_bool_b       c_datetime_a       c_datetime_b
0    False  2012-03-30 23:59:58  2012-03-30 23:59:59
```

- For SQL runtime parameters, you can use `%set` to set a global parameter or use SET within a SQLCell to set a local parameter. The following example sets a local parameter, which does not affect the global setting.

```
In [*]: %%sql
        set odps.sql.mapper.split.size = 16;
        select * from pyodps_iris;
```

- The following example sets a global parameter. Global settings apply to all subsequent SQL statements.

```
In [*]: %set odps.sql.mapper.split.size = 16
```

Upload pandas DataFrame to MaxCompute tables

PyODPS provides the following command to upload pandas DataFrame objects to MaxCompute tables:

You only need to use the `%persist` command. The first parameter df is the variable name. The second parameterpyodps_pandas_df is the MaxCompute table name.

```
import pandas as pd
import numpy as np
df = pd.DataFrame(np.arange(9).reshape(3, 3), columns=list('abc'))
%persist df pyodps_pandas_df
```

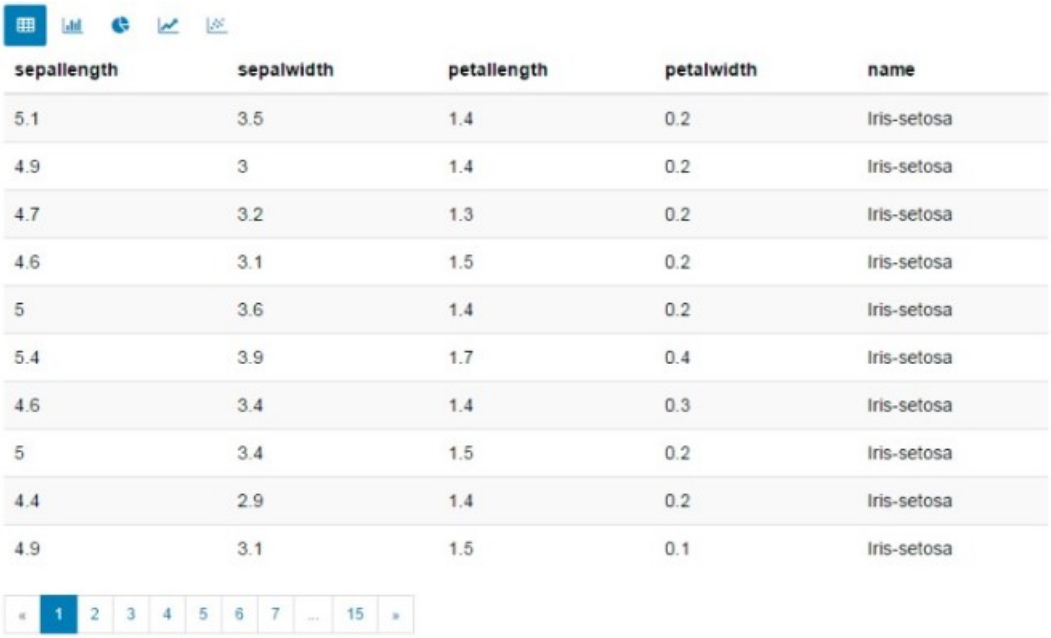
1.11.7.3. Jupyter Notebook

PyODPS enhances the result exploration and progress display features of Jupyter Notebook.

Result exploration

PyODPS provides a data exploration feature in Jupyter Notebook for SQLCell and DataFrame. You can use interactive data exploration tools to browse local data and create graphs.

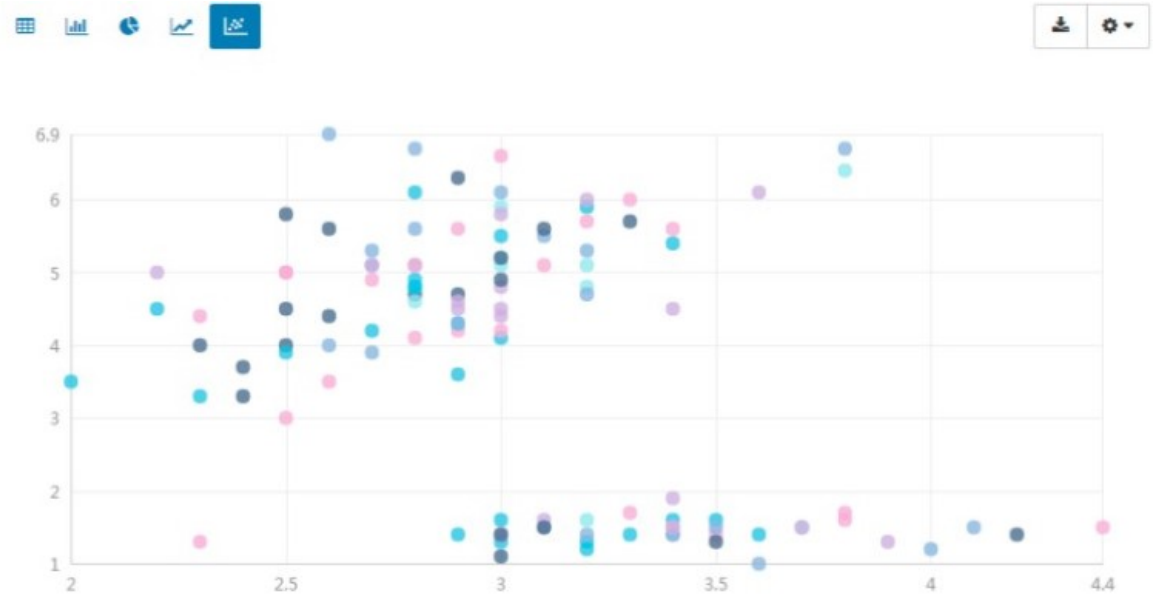
1. If the execution result is a DataFrame object, PyODPS reads the result and displays it in a paged table. You can click a page number or the Previous or Next button to browse the data.



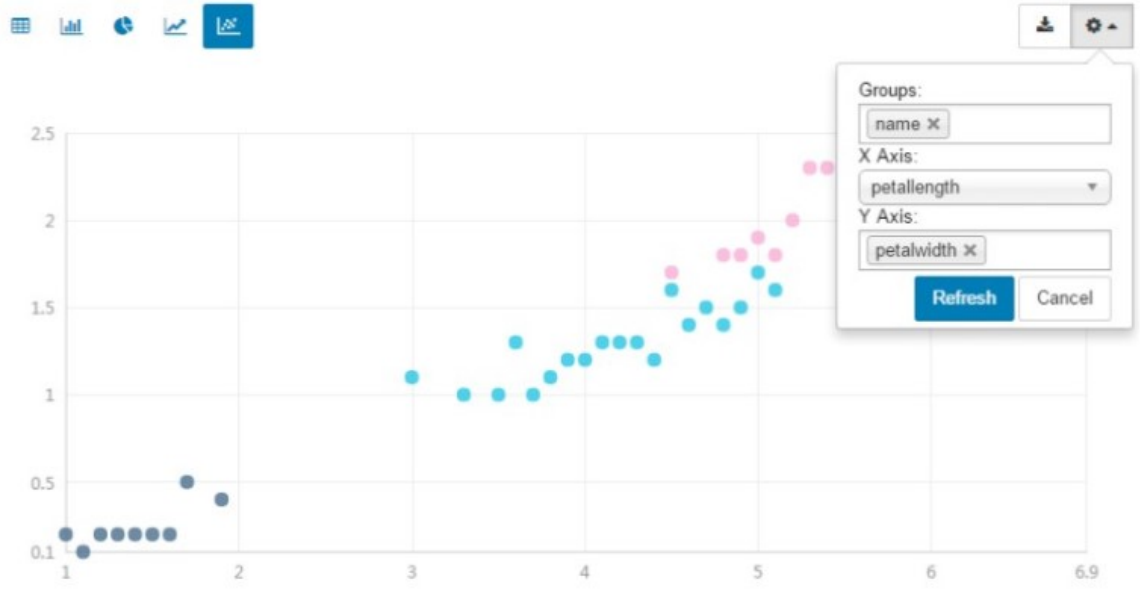
sepallength	sepalwidth	petallength	petalwidth	name
5.1	3.5	1.4	0.2	Iris-setosa
4.9	3	1.4	0.2	Iris-setosa
4.7	3.2	1.3	0.2	Iris-setosa
4.6	3.1	1.5	0.2	Iris-setosa
5	3.6	1.4	0.2	Iris-setosa
5.4	3.9	1.7	0.4	Iris-setosa
4.6	3.4	1.4	0.3	Iris-setosa
5	3.4	1.5	0.2	Iris-setosa
4.4	2.9	1.4	0.2	Iris-setosa
4.9	3.1	1.5	0.1	Iris-setosa

« 1 2 3 4 5 6 7 ... 15 »

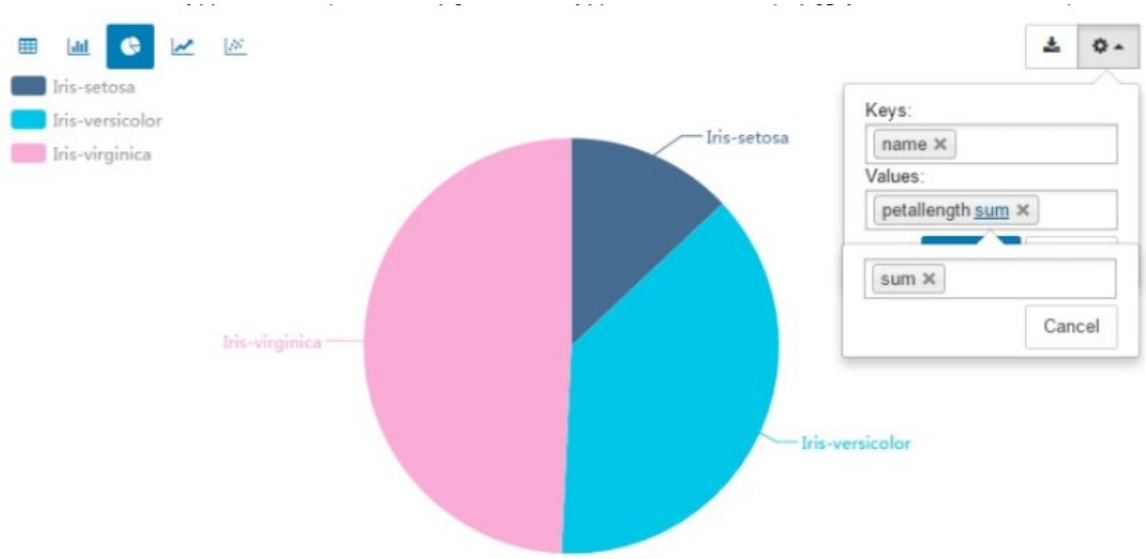
2. You can select other display modes on the top of the table to display the result in a column chart, pie chart, line chart, or scatter chart. The following figure shows a scatter chart created based on the default fields, which are the first three fields.



3. You can click the settings icon in the upper-right corner of a graph to modify the settings. For example, set Groups to **name**, X Axis to **petallength**, and Y Axis to **petalwidth**. The result is shown in the following graph. The **petallength-petalwidth** setting displays the data in a manner that is easy to understand.



For bar charts and pie charts, you can select an aggregate function for the value fields. The default aggregate function for column charts is `sum`, and that for pie charts is `count`. You can click the function name next to the value field name to select another function. For line charts, ensure that the values on the x-axis are not null. Otherwise, the graph may not display correctly.



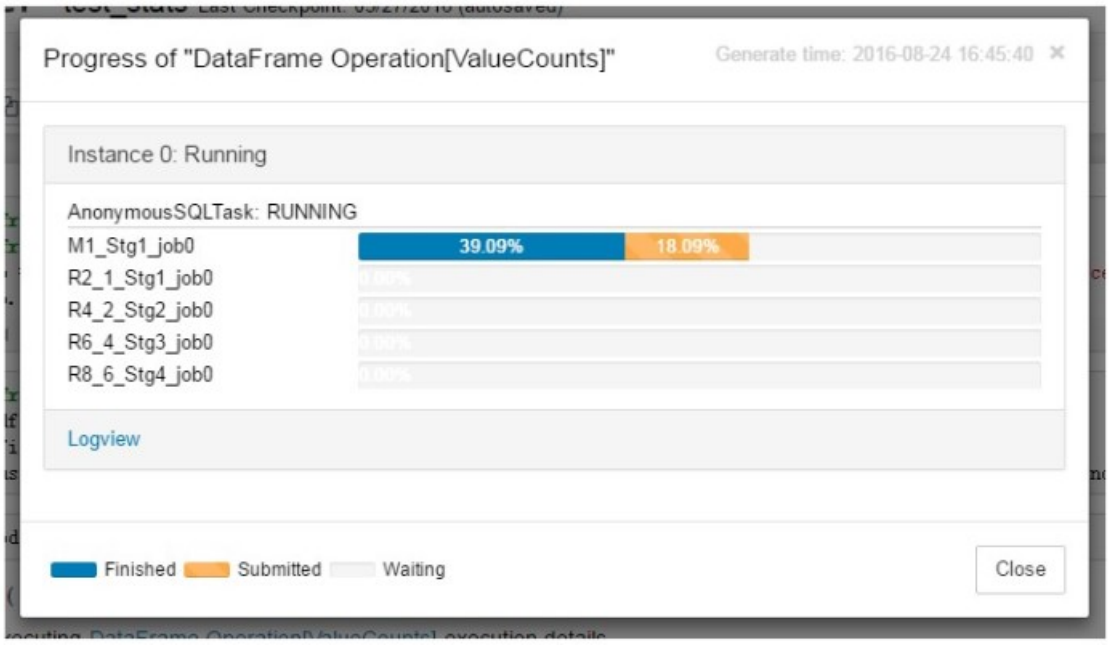
4. After you finish drawing the graph, click the **Download** icon to save it.

> **Note** Before you use this feature, ensure that you have installed pandas and ipywidgets.

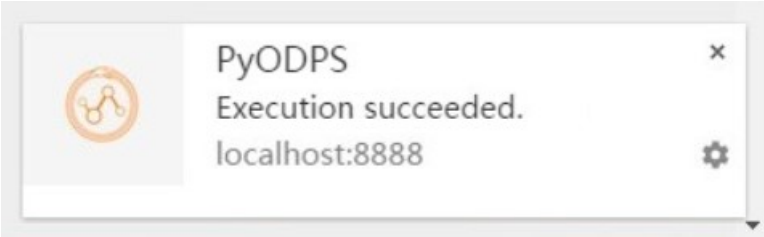
Progress display

The execution of large jobs takes extended periods of time. PyODPS provides progress bars to show the execution progress. When DataFrame jobs, machine learning jobs, or SQL statements that start with `%sql` are executed in Jupyter Notebook, a list of these jobs and their overall progress are displayed.

When you click a job name, a dialog box that displays the progress of each task in the job appears.



After the execution has been completed, a message that indicates whether the job is successful appears.



1.11.8. Configuration

PyODPS provides a series of configuration options. You can obtain them by using `odps.options`. Example:

```
from odps import options
# Set the lifecycle option, which specifies the lifecycle of all output tables.
options.lifecycle = 30
# Set the tunnel.string_as_binary option to True to use bytes instead of unicode to download data of t
he STRING type.
options.tunnel.string_as_binary = True
# When you execute PyODPS DataFrame on MaxCompute, you can refer to the following configuration
to set the limit to a relatively large value during a sort operation.
options.df.odps.sort.limit = 100000000
```

General configuration

Option	Description	Default value
end_point	The endpoint of MaxCompute.	None
default_project	The default project.	None
log_view_host	The hostname of LogView.	None
log_view_hours	The retention time of LogView (unit: hours).	24
local_timezone	The time zone used. True indicates local time, and False indicates UTC. The time zone of pytz can also be used.	None
lifecycle	The lifecycle of all tables.	None
temp_lifecycle	The lifecycle of temporary tables.	1
biz_id	The user ID.	None
verbose	Specifies whether to display logs.	False
verbose_log	The log receiver.	None
chunk_size	The size of the write buffer.	1496
retry_times	The number of request retries.	4
pool_connections	The number of cached connections in the connection pool.	10
pool_maxsize	The maximum capacity of the connection pool.	10
connect_timeout	The connection timeout period (unit: seconds).	5
read_timeout	The read timeout period (unit: seconds).	120
api_proxy	The API proxy server.	None
data_proxy	The data proxy server.	None
completion_size	The limit on the number of object completion listing items.	10
notebook_repr_widget	Specifies whether to use interactive graphs.	True

Option	Description	Default value
sql.settings	MaxCompute SQL runs global hints.	None
sql.use_odps2_extension	Specifies whether to enable MaxCompute 2.0 language extension.	False

Data upload and download configuration

Option	Description	Default value
tunnel.endpoint	The endpoint of Tunnel.	None
tunnel.use_instance_tunnel	Specifies whether to use Instance Tunnel to obtain execution results.	True
tunnel.limit_instance_tunnel	Specifies whether to limit the number of data records obtained by using Instance Tunnel.	None
tunnel.string_as_binary	Specifies whether to use bytes instead of unicode for data of the STRING type.	False

DataFrame configuration

Option	Description	Default value
interactive	Specifies whether DataFrame is used in an interactive environment.	Depends on the detection value.
df.analyze	Specifies whether to enable non-MaxCompute built-in functions.	True
df.optimize	Specifies whether to enable full DataFrame optimization.	True
df.optimizes.pp	Specifies whether to enable DataFrame predicate push optimization.	True
df.optimizes.cp	Specifies whether to enable DataFrame column pruning optimization.	True
df.optimizes.tunnel	Specifies whether to enable DataFrame tunnel optimization.	True

Option	Description	Default value
df.quote	Specifies whether to use `` to mark fields and table names in the backend of MaxCompute SQL.	True
df.libraries	The third-party library (resource name) that is used by DataFrame.	None
df.supersede_libraries	Specifies whether to use the self-uploaded NumPy to replace the version in the service.	False
df.odps.sort.limit	The default limit on the number of items added during a sort operation of DataFrame.	10000

Machine learning configuration

Option	Description	Default value
ml.xflow_settings	The XFlow execution configuration.	None
ml.xflow_project	The default XFlow project name.	algo_public
ml.use_model_transfer	Specifies whether to use ModelTransfer to obtain the model PMML.	False
ml.model_volume	The name of the volume used by ModelTransfer.	pyodps_volume

1.11.9. API overview

Links to PyODPS API documentation are provided below. You can see the parameter description and example of each function:

- Definitions
- DataFrame Reference

1.11.10. FAQ

How do I view the current PyODPS version?

Run the following commands:

```
import odps
print(odps.__version__)
```

How do I troubleshoot the "Project not found" error?

This problem is generally caused by incorrect endpoint configurations. You must check the configurations and rectify the problem. You also need to check whether the position of the MaxCompute object parameter is correct.

How do I manually specify a Tunnel endpoint?

You can create your MaxCompute object with the tunnel_endpoint parameter specified, as shown in the following code. Replace the content enclosed with asterisks (*) with actual parameter values and remove the asterisks (*).

```
from odps import ODPS
o = ODPS('**your-access-id**', '**your-secret-access-key**', '**your-default-project**',
        endpoint='**your-end-point**', tunnel_endpoint='**your-tunnel-endpoint**')
```

How do I troubleshoot the "project is protected" error reported while data is being read?

The project security policy does not allow you to read data from tables. To retrieve all the data, you can use the following solutions:

- Contact the project owner to add exception rules.
- Use DataWorks or other masking tools to mask the data and then export the data to an unprotected project before reading it.

To retrieve part of the data, you can use the following solutions:

- Use `o.execute_sql('select * from <table_name>').open_reader()` .
- Use `o.get_table('<table_name>').to_df()` in DataFrame.

I can only retrieve a maximum of 10,000 data records by executing SQL command open_reader. How do I retrieve more than 10,000 data records?

Use `create table as select ...` to save the SQL result to a table, and then use `table.open_reader` to read data.

How do I troubleshoot the "ODPSError: ODPS entrance should be provided" error reported when I upload pandas DataFrame to MaxCompute?

This error is reported because the global MaxCompute object cannot be found. Use one of the following methods to resolve this problem:

- If you use the room mechanism `%enter` , configure the global MaxCompute object.

- Call the `to_global` method for the MaxCompute object.
- Use the following MaxCompute parameter:

```
DataFrame(pd_df).persist('your_table', odps=odps)
```

How do I use max_pt in DataFrame?

Use the `odps.df.func` module to call built-in functions of MaxCompute. Example:

```
from odps.df import func
df = o.get_table('your_table').to_df()
df[df.ds == func.max_pt('your_project.your_table')]  # ds is a partition column.
```

How do I troubleshoot the "table lifecycle is not specified in mandatory mode" error reported when I use DataFrame to write data to a table?

Your project requires that every table be created with a lifecycle. Therefore, you must make the following configuration every time you run your own code:

```
from odps import options
options.lifecycle = 7  # You can also set this parameter to your expected lifecycle in days.
```

How do I traverse each row of data in PyODPS DataFrame?

PyODPS DataFrame currently does not support this feature. PyODPS DataFrame focuses on handling large volumes of data. Traversing data is inefficient.

We recommend that you use the apply or map_reduce method of DataFrame to parallelize your serial traverse operations.

If you confirm that data traversing is necessary in your scenario and that the cost is acceptable, you can use the `to_pandas` method to convert your DataFrame to pandas DataFrame, or you can store DataFrame as a table and use `read_table` or Tunnel to read data.

1.12. Java sandbox limits

MaxCompute MapReduce and UDF programs in distributed environments are run in Java sandboxes. The main programs of MapReduce are not subject to these limits.

The limits include:

- Local files cannot be accessed directly, and can only be accessed through APIs provided by MaxCompute MapReduce or Graph. You can access the resources specified by the resources option, such as files, JAR packages, and resource tables. You can use System.out and System.err to export logs and run the log command on the MaxCompute console to view log information.
- Direct access to the distributed file system is not allowed. You can only use MaxCompute MapReduce to Graph to access records of tables.
- JNI calls are not allowed.

- Java threads cannot be created, and Linux commands cannot be executed by sub-threads.
- Network access, including the operation of getting the local IP address, is prohibited.
- Java reflection restriction: The suppressAccessChecks permission is prohibited, so you cannot set a private attribute or method accessible to read private attributes or call private methods.

  Specifically, an access denied error is returned when you perform any of the preceding operations.

  Methods for accessing local files:

  java.io.File:

```
public boolean delete()
public void deleteOnExit()
public boolean exists()
public boolean canRead()
public boolean isFile()
public boolean isDirectory()
public boolean isHidden()
public long lastModified()
public long length()
public String[] list()
public String[] list(FilenameFilter filter)
public File[] listFiles()
public File[] listFiles(FilenameFilter filter)
public File[] listFiles(FileFilter filter)
public boolean canWrite()
public boolean createNewFile()
public static File createTempFile(String prefix, String suffix)
public static File createTempFile(String prefix, String suffix,File directory)
public boolean mkdir()
public boolean mkdirs()
public boolean renameTo(File dest)
public boolean setLastModified(long time)
public boolean setReadOnly()
java.io.RandomAccessFile:
RandomAccessFile(String name, String mode)
RandomAccessFile(File file, String mode)
java.io.FileInputStream:
FileInputStream(FileDescriptor fdObj)
FileInputStream(String name) FileInputStream(File file)
java.io.FileOutputStream:
FileOutputStream(FileDescriptor fdObj)
FileOutputStream(File file)
```

```
FileOutputStream(String name)
FileOutputStream(String name, boolean append)
java.lang.Class:
public ProtectionDomain getProtectionDomain()
java.lang.ClassLoader:
ClassLoader ()
ClassLoader(ClassLoader parent)
java. lang. Runtime:
public Process exec(String command)
public Process exec(String command, String envp[])
public Process exec(String cmdarray[])
public Process exec(String cmdarray[], String envp[])
public void exit(int status)
public static void runFinalizersOnExit(boolean value)
public void addShutdownHook(Thread hook)
public boolean removeShutdownHook(Thread hook)
public void load(String lib)
public void loadLibrary(String lib)
java.lang.System:
public static void exit(int status)
public static void runFinalizersOnExit(boolean value)
public static void load(String filename)
public static void loadLibrary( String libname)
public static Properties getProperties()
public static void setProperties(Properties props)
public static String getProperty(String key)
// Only some keys are accessible.
public static String getProperty(String key, String def)
// Only some keys are accessible.
public static String setProperty(String key, String value)
public static void setIn(InputStream in)
public static void setOut(PrintStream out)
public static void setErr(PrintStream err)
public static synchronized void setSecurityManager(SecurityManager s)
```

List of keys allowed by System.getProperty:

```
java.version
java.vendor
java.vendor.url
java.class.version
os.name os.version
```

os.arch

```

1.13. Volume lifecycle management

1.13.1. Overview

In the previous version of MaxCompute, a partition in a volume does not have a lifecycle and can exist forever. You have to manage the lifecycle of a volume. In some cases, user management of volume lifecycle may cause a problem. For example, if the account used to delete a partition is different from the account used to create the partition, the delete operation fails. The new feature of volume lifecycle management can solve this problem.

For more information about simple volume lifecycle management operations, see *Volume lifecycle operations* .

1.13.2. Volume lifecycle operations

Create a volume with a specified lifecycle

Example:

```
odps@ your_project>fs -mkv test_volume -lifecycle 7 "this is a test volume";
OK
```

Modify the lifecycle of a volume

Example:

```
odps@ your_project>fs -alter test_volume -lifecycle 3;
OK
```

View the lifecycle of a volume

Example:

```
odps@ your_project>fs -meta test_volume;
Comment: "this is a test volume"
Length: 0
File number: 0
Lifecycle: 3
OK
```

1.14. Spark on MaxCompute

1.14.1. Overview

Spark on MaxCompute is a solution developed by Alibaba Cloud to enable the seamless use of Spark on the MaxCompute platform. It supplements a wide variety of features to MaxCompute.

Spark on MaxCompute provides a native Spark user experience and offers native Spark components and APIs. Spark on MaxCompute can access MaxCompute data sources and enhance security for multi-tenant scenarios. Spark on MaxCompute can also act as a management platform to share resources, storage, and user systems between jobs and ensure high performance at a low cost. Spark can work with MaxCompute to create better and more efficient data processing solutions. Community Spark applications can run in **Spark on MaxCompute**.

Spark on MaxCompute has an independent data development node in DataWorks and supports data development in DataWorks.

1.14.2. Project resources

Before you use **Spark on MaxCompute**, you may need to pay attention to or download the following project resources:

- **Spark on MaxCompute** release package: Download the latest release package at Spark on MaxCompute.
- **Spark on MaxCompute** plugin: This is an open-source program. Download the plugin at Aliyun Cupid SDK.

After you prepare the preceding project resources, you need to complete environment configuration. Then, you can run related GitHub demos.

1.14.3. Environment settings

1.14.3.1. Decompress the Spark on MaxCompute release package

Download the latest version of the **Spark on MaxCompute** release package and decompress it. The structure of the decompressed folder is as follows:

```
.
|-- R
|-- RELEASE
|-- __spark_libs__.zip
|-- bin
|-- conf
|-- cupid
|-- derby.log
|-- examples
|-- jars
|-- logs
|-- metastore_db
|-- python
|-- sbin
|-- yarn
```

1.14.3.2. Set environment variables

Set required environment variables.

> Note The main environment variables are JAVA_HOME and SPARK_HOME.

Set JAVA_HOME

```
export JAVA_HOME=/path/to/jdk
export CLASSPATH=.:$JAVA_HOME/lib/dt.jar:$JAVA_HOME/lib/tools.jar
export PATH=$JAVA_HOME/bin:$PATH
```

Set SPARK_HOME

```
export SPARK_HOME=/path/to/spark_extracted_package
export PATH=$SPARK_HOME/bin:$PATH
```

If you use SparkR, install R in the */home/admin/R* directory. Then, run the following command to set the path:

```
export PATH=/home/admin/R/bin/:$PATH
```

If you use PySpark, install Python 2.7. Then, run the following command to set the path:

```
export PATH=/path/to/python/bin/:$PATH
```

1.14.3.3. Configure Spark-defaults.conf

The *$SPARK_HOME/conf* directory contains a file named spark-defaults.conf. Before you submit a Spark task to MaxCompute, you must configure your MaxCompute account in this file.

The following content is the default configuration in the file. You only need to enter your account information in the blanks.

```
# OdpsAccount Info Setting
spark.hadoop.odps.project.name=
spark.hadoop.odps.access.id=
spark.hadoop.odps.access.key=
spark.hadoop.odps.end.point=
#spark.hadoop.odps.moye.trackurl.host=
#spark.hadoop.odps.cupid.webproxy.endpoint=
spark.sql.catalogImplementation=odps

# spark-shell Setting
spark.driver.extraJavaOptions -Dscala.repl.reader=com.aliyun.odps.spark_repl.OdpsInteractiveReader
-Dscala.usejavacp=true

# SparkR Setting
# odps.cupid.spark.r.archive=/path/to/R-PreCompile-Package.zip

# Cupid Longtime Job
# spark.hadoop.odps.cupid.engine.running.type=longtime
# spark.hadoop.odps.cupid.job.capability.duration.hours=8640
# spark.hadoop.odps.moye.trackurl.dutation=8640

# spark.r.command=/home/admin/R/bin/Rscript
# spark.hadoop.odps.cupid.disk.driver.enable=false
spark.hadoop.odps.cupid.bearer.token.enable=false
spark.hadoop.odps.exec.dynamic.partition.mode=nonstrict
```

1.14.4. Quick start

This topic describes how to use **Spark on MaxCompute**.

1. Download the Spark package from Spark on MaxCompute and decompress the package.
2. Set environment variables.

```
export SPARK_HOME=/path/to/spark-2.1.0-private-cloud-v3.1.0
export JAVA_HOME=/path/to/java/
```

3. Set spark-defaults.conf.

```
cp $SPARK_HOME/conf/spark-defaults.conf.template $SPARK_HOME/conf/spark-defaults.conf
```

Edit $SPARK_HOME/conf/spark-defaults.conf by filling information in the blanks.

```
# OdpsAccount Info Setting
spark.hadoop.odps.project.name=
spark.hadoop.odps.access.id=
spark.hadoop.odps.access.key=
spark.hadoop.odps.end.point=
#spark.hadoop.odps.moye.trackurl.host=
#spark.hadoop.odps.cupid.webproxy.endpoint=
spark.sql.catalogImplementation=odps

# spark-shell Setting
spark.driver.extraJavaOptions -Dscala.repl.reader=com.aliyun.odps.spark_repl.OdpsInteractiveRe
ader -Dscala.usejavacp=true

# SparkR Setting
# odps.cupid.spark.r.archive=/path/to/R-PreCompile-Package.zip

# Cupid Longtime Job
# spark.hadoop.odps.cupid.engine.running.type=longtime
# spark.hadoop.odps.cupid.job.capability.duration.hours=8640
# spark.hadoop.odps.moye.trackurl.dutation=8640

# spark.r.command=/home/admin/R/bin/Rscript
# spark.hadoop.odps.cupid.disk.driver.enable=false
spark.hadoop.odps.cupid.bearer.token.enable=false
spark.hadoop.odps.exec.dynamic.partition.mode=nonstrict
```

4. Prepare spark-example.

```
git clone https://github.com/aliyun/aliyun-cupid-sdk.git
cd aliyun-cupid-sdk
mvn -T 1C clean install -DskipTests
```

5. Run SparkPi.

```
cd $SPARK_HOME
bin/spark-submit --master yarn-cluster --class com.aliyun.odps.spark.examples.SparkPi /path/to/
aliyun-cupid-sdk/examples/spark-examples/target/spark-examples_2.11-1.0.0-SNAPSHOT-shade
d.jar
```

If you see the following output, your operation is successful. Other logs may be included in the output.

```
18/02/09 15:52:28 INFO Client: Application report for application_1518162700322_1635034099 (state: FIN

1.14.5. Demo

This topic provides a demo on how to use Spark.

The demo is as follows:

1. Modify the configuration file.

   Decompress the Spark package, go to the *conf* directory, and modify the following configuration items in the configuration file spark-defaults.conf:

   ```
   spark.hadoop.odps.project.name=xxxx
   spark.hadoop.odps.access.id=xxxx
   spark.hadoop.odps.access.key=xxxx
   spark.hadoop.odps.end.point=http://service.xxxx.xxxx.xxxxx.qd-inc.com:80/api
   spark.hadoop.odps.cupid.distributedcache.mincopy=3
   spark.hadoop.odps.cupid.distributedcache.maxcopy=3
   spark.hadoop.odps.cupid.proxy.domain.name=jobview.xxxx.xxxx.xxxx.com
   spark.hadoop.odps.cupid.history.server.address=10.xx.xx.xx:18080
   ```

> **Note**
>
> - You can obtain the first four configuration items from the web_component.conf file in the */cloud/app/odps-service-console/CupidFrontendServer#/cupid_web_proxy/current/conf.local/* directory.
> - spark.hadoop.odps.cupid.proxy.domain.name: specifies the domain name of odps_jobview_server_dns. Remove sparkui at the beginning of the domain name.
> - spark.hadoop.odps.cupid.history.server.address: specifies the IP address of the AG machine. Add the port number 18080 to the end of the IP address.

2. Start the program.

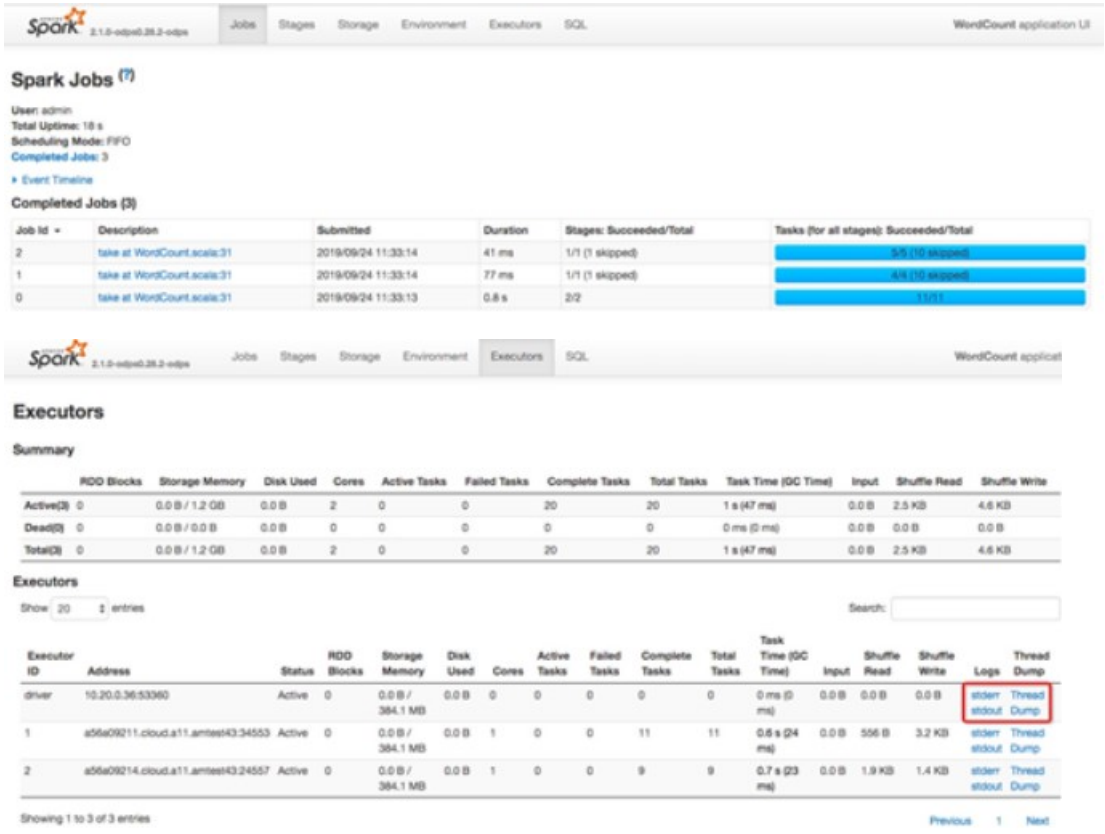
   Go to the directory where the Spark package is decompressed and run the following commands:

```
bin/spark-submit
--class com.aliyun.odps.spark.examples.WordCount --master yarn-cluster
examples/spark-examples-2.0.0-SNAPSHOT-shaded.jar
```

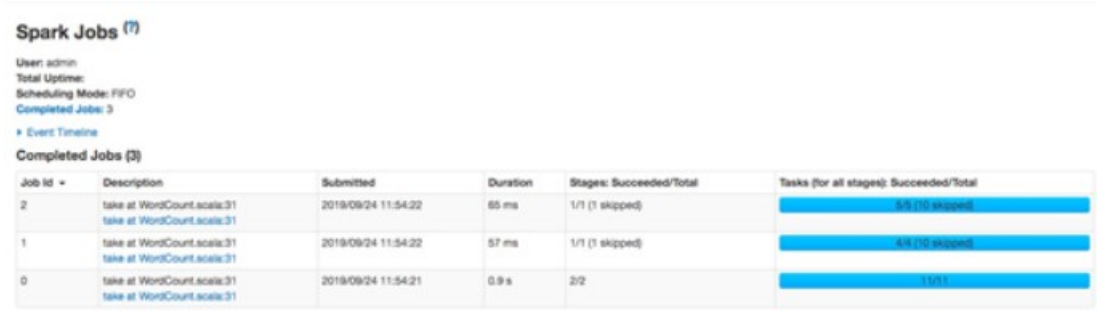
3. Access the link in the command output.

   LogView

SparkUI



Spark History



1.14.6. Common cases

1.14.6.1. WordCount example

Spark runs simple WordCount.

> **Note**
>
> You must download the GitHub project and compile the project before running the corresponding demos.
>
> ```
> git clone https://github.com/aliyun/aliyun-cupid-sdk.git
> -- Download a GitHub project.
> cd aliyun-cupid-sdk
> mvn -T 1C clean install -DskipTests
> -- Compile the GitHub project.
> ```
>
> After you complete the preceding steps, JAR packages are created. These JAR packages will be used to run the demos in this and the subsequent topics.

The following is the code for this example:

```
package com.aliyun.odps.spark.examples

import org.apache.spark.sql.SparkSession

object WordCount {
  def main(args: Array[String]) {
    val spark = SparkSession
      .builder()
      .appName("WordCount")
      .getOrCreate()
    val sc = spark.sparkContext
    try {
      sc.parallelize(1 to 100, 10).map(word => (word, 1)).reduceByKey(_ + _, 10).take(100).foreach(println
)
    } finally {
      sc.stop()
    }
  }
}
```

Run the following command to submit the job:

```
bin/spark-submit \
--master yarn-cluster \
--class com.aliyun.odps.spark.examples.WordCount \
/path/to/aliyun-cupid-sdk/examples/spark-examples/target/spark-examples_2.11-1.0.0-
SNAPSHOT-shaded.jar
```

1.14.6.2. OSS access example

Spark can access OSS data.

Example:

```
package com.aliyun.odps.spark.examples.oss

import org.apache.spark.sql.SparkSession

object SparkUnstructuredDataCompute {
 def main(args: Array[String]) {
   val spark = SparkSession
     .builder()
     .appName("SparkUnstructuredDataCompute")
     .config("spark.hadoop.fs.oss.accessKeyId", "***")
     .config("spark.hadoop.fs.oss.accessKeySecret", "***")
     .config("spark.hadoop.fs.oss.endpoint", "oss-cn-hangzhou-zmf.aliyuncs.com")
     .getOrCreate()

   val sc = spark.sparkContext
   try {
     val pathIn = "oss://bucket/inputdata/"
     val inputData = sc.textFile(pathIn, 5)
     val cnt = inputData.count
     println(s"count: $cnt")
   } finally {
     sc.stop()
   }
 }
}
```

Run the following command to submit the job:

```
./bin/spark-submit
--jars cupid/hadoop-aliyun-package-3.0.0-alpha2-odps-jar-with-dependencies.jar
--class com.aliyun.odps.spark.examples.oss.SparkUnstructuredDataCompute
/path/to/aliyun-cupid-sdk/examples/spark-examples/target/spark-examples_2.11-1.0.0-SNAPSHOT-shaded.jar
```

1.14.6.3. MaxCompute table read/write example

Read/write a MaxCompute table and convert it to Spark RDD.

> **Notice** The project or table specified in the demo must exist or be changed to the specific project or table.

Example:

```
package com.aliyun.odps.spark.examples

import com.aliyun.odps.data.Record
import com.aliyun.odps.{ PartitionSpec, TableSchema}
import org.apache.spark.odps.OdpsOps
import org.apache.spark.sql.SparkSession
import scala.util.Random

object OdpsTableReadWrite {
 def main(args: Array[String]) {

   val spark = SparkSession
    .builder()
    .appName("OdpsTableReadWrite")
    .getOrCreate()

   val sc = spark.sparkContext
   val projectName = sc.getConf.get("odps.project.name")

   try {
    val odpsOps = new OdpsOps(sc)

    // read from normal table via rdd api
    val rdd_0 = odpsOps.readTable(
     projectName,
     "cupid_wordcount",
     (r: Record, schema: TableSchema) => (r.getString(0), r.getString(1))
```

```
    )

    //read from single partition column table via rdd api
    val rdd_1 = odpsOps.readTable(
      projectName,
      "dftest_single_parted",
      Array("pt=20160101"),
      (r: Record, schema: TableSchema) => (r.getString(0), r.getString(1), r.getString("pt"))
    )

    // read from multi partition column table via rdd api
    val rdd_2 = odpsOps.readTable(
      projectName,
      "dftest_parted",
      Array("pt=20160101,hour=12"),
      (r: Record, schema: TableSchema) => (r.getString(0), r.getString(1), r.getString("pt"), r.getString(3
))
    )

    // read with multi partitionSpec definition via rdd api
    val rdd_3 = odpsOps.readTable(
      projectName,
      "cupid_partition_table1",
      Array("pt1=part1,pt2=part1", "pt1=part1,pt2=part2", "pt1=part2,pt2=part3"),
      (r: Record, schema: TableSchema) => (r.getString(0), r.getString(1), r.getString("pt1"), r.getString(
"pt2"))
    )

    // save rdd into normal table
    val transfer_0 = (v: Tuple2[String, String], record: Record, schema: TableSchema) => {
      record.set("id", v._1)
      record.set(1, v._2)
    }
    odpsOps.saveToTable(projectName, "cupid_wordcount_empty", rdd_0, transfer_0, true)

    // save rdd into partition table with single partition spec
    val transfer_1 = (v: Tuple2[String, String], record: Record, schema: TableSchema) => {
      record.set("id", v._1)
      record.set("value", v._2)
    }
    odpsOps.saveToTable(projectName, "cupid_partition_table1", "pt1=test,pt2=dev", rdd_0, transfer_1
```

```
    odpsOps.saveToTable(projectName, "cupid_partition_table1", "pt1=test,pt2=dev", rdd_0, transfer_1
, true)

    // dynamic save rdd into partition table with multiple partition spec
    val transfer_2 = (v: Tuple2[String, String], record: Record, part: PartitionSpec, schema: TableSchem
a) => {
      record.set("id", v._1)
      record.set("value", v._2)

      val pt1_value = if (new Random().nextInt(10) % 2 == 0) "even" else "odd"
      val pt2_value = if (new Random().nextInt(10) % 2 == 0) "even" else "odd"
      part.set("pt1", pt1_value)
      part.set("pt2", pt2_value)
    }
    odpsOps.saveToTableForMultiPartition(projectName, "cupid_partition_table1", rdd_0, transfer_2, tr
ue)
   } catch {
    case ex: Exception => {
      throw ex
    }
   } finally {
    sc.stop
   }
 }
}
```

Run the following command to submit the job:

```
bin/spark-submit \
--master yarn-cluster \
--class com.aliyun.odps.spark.examples.OdpsTableReadWrite \
/path/to/aliyun-cupid-sdk/examples/spark-examples/target/spark-examples_2.11-1.0.0-SNAPSHOT-s
haded.jar
```

You can use either of the following methods to adjust the MaxCompute table read concurrency:

- Modify the spark.hadoop.odps.input.split.size parameter. A larger value results in a smaller number of Map tasks. The default value is 256 MB.
- Set numPartition in OdpsOps.readTable. The value determines the number of Map tasks. The number is calculated based on spark.hadoop.odps.input.split.size.

1.14.6.4. MaxCompute Table Spark-SQL example

Use sqlContext to read/write a MaxCompute table.

> **Notice**
>
> - The project or table specified in the demo must exist or be changed to the specific project or table.
> - Spark-defaults.conf must contain the setting *spark.sql.catalogImplementation = odps*.

Example:

```
package com.aliyun.odps.spark.examples

import org.apache.spark.sql.SparkSession

object OdpsTableReadWriteViaSQL {

 def main(args: Array[String]) {

  // please make sure spark.sql.catalogImplementation=odps in spark-defaults.conf
  // to enable odps catalog
  val spark = SparkSession
   .builder()
   .appName("OdpsTableReadWriteViaSQL")
   .getOrCreate()

  val projectName = spark.sparkContext.getConf.get("odps.project.name")
  val tableName = "cupid_wordcount"

  // get a ODPS table as a DataFrame
  val df = spark.table(tableName)
  println(s"df.count: ${df.count()}")

  // Just do some query
  spark.sql(s"select * from $tableName limit 10").show(10, 200)
  spark.sql(s"select id, count(id) from $tableName group by id").show(10, 200)

  // any table exists under project could be use
  // productRevenue
  spark.sql(
   """
    |SELECT product,
    |     category,
    |     revenue
```

```
      |FROM
      |  (SELECT product,
      |          category,
      |          revenue,
      |          dense_rank() OVER (PARTITION BY category
      |                             ORDER BY revenue DESC) AS rank
      |   FROM productRevenue) tmp
      |WHERE rank <= 2
    """.stripMargin).show(10, 200)

    spark.stop()
  }
}
```

Run the following command to submit the job:

```
bin/spark-submit \
--master yarn-cluster \
--class com.aliyun.odps.spark.examples.OdpsTableReadWrite \
/path/to/aliyun-cupid-sdk/examples/spark-examples/target/spark-examples_2.11-1.0.0-SNAPSHOT-s
haded.jar
```

1.14.6.5. MaxCompute self-developed Console mode example

For safety reasons, machines in MaxCompute can not be directly connected. Therefore, the yarn-clientmode in native Spark cannot be used. To enable interaction, the MaxCompute team developed a proprietary client mode.

Example:

```
package com.aliyun.odps.spark.examples

import com.aliyun.odps.cupid.client.spark.client.CupidSparkClientRunner

object SparkClientNormalFT {
  def main(args: Array[String]) {
    val cupidSparkClient = CupidSparkClientRunner.getReadyCupidSparkClient()
    val jarPath = args(0) //client-jobexamples jar path
    val sparkClientNormalApp = new SparkClientNormalApp(cupidSparkClient)
    sparkClientNormalApp.runNormalJob(jarPath)
    cupidSparkClient.stopRemoteDriver()
  }
}
```

Run the following command to submit the job:

```
java -cp \
/path/to/aliyun-cupid-sdk/examples/spark-examples/target/spark-examples_2.11-1.0.0-SNAPSHOT-shaded.jar:$SPARK_HOME/jars/* \
com.aliyun.odps.spark.examples.SparkClientNormalFT /path/to/aliyun-cupid-sdk/examples/client-jobexamples/target/client-jobexamples_2.11-1.0.0-SNAPSHOT.jar
```

1.14.6.6. MaxCompute Table PySpark example

Use PySpark to read/write MaxCompute tables.

Example:

```
from odps.odps_sdk import OdpsOps
from pyspark import SparkContext, SparkConf
from pyspark.sql import SQLContext, DataFrame

if __name__ == '__main__':
    conf = SparkConf().setAppName("odps_pyspark")
    sc = SparkContext(conf=conf)
    sql_context = SQLContext(sc)

    project_name = "cupid_testa1"
    in_table_name = "cupid_wordcount"
    out_table_name = "cupid_wordcount_py"

    normal_df = OdpsOps.read_odps_table(sql_context, project_name, in_table_name)

    for i in normal_df.sample(False, 0.01).collect():
        print i
    print "Read normal odps table finished"

    OdpsOps.write_odps_table(sql_context, normal_df.sample(False, 0.001), project_name, out_table_na
me)
    print "Write normal odps table finished"
```

Run the following command to submit the job:

```
spark-submit \
--master yarn-cluster \
--jars /path/to/aliyun-cupid-sdk/external/cupid-datasource/target/cupid-datasource_2.11-1.0.0-SNAP
SHOT.jar \
--py-files /path/to/aliyun-cupid-sdk/examples/spark-examples/src/main/python/odps.zip \
/path/to/aliyun-cupid-sdk/examples/spark-examples/src/main/python/odps_table_rw.py
```

1.14.6.7. Mllib example

We recommend that you use OSS for read/write operations in the Mllib model.

Example:

```
package com.aliyun.odps.spark.examples.mllib

import org.apache.spark.mllib.clustering.KMeans._
import org.apache.spark.mllib.clustering.{ KMeans, KMeansModel}
```

```
import org.apache.spark.mllib.linalg.Vectors
import org.apache.spark.sql.SparkSession

object KmeansModelSaveToOss {
 val modelOssDir = "oss://bucket/kmeans-model"

 def main(args: Array[String]) {

  //1. train and save the model
  val spark = SparkSession
   .builder()
   .appName("KmeansModelSaveToOss")
   .config("spark.hadoop.fs.oss.accessKeyId", "***")
   .config("spark.hadoop.fs.oss.accessKeySecret", "***")
   .config("spark.hadoop.fs.oss.endpoint", "***")
   .getOrCreate()

  val sc = spark.sparkContext
  val points = Seq(
   Vectors.dense(0.0, 0.0),
   Vectors.dense(0.0, 0.1),
   Vectors.dense(0.1, 0.0),
   Vectors.dense(9.0, 0.0),
   Vectors.dense(9.0, 0.2),
   Vectors.dense(9.2, 0.0)
  )
  val rdd = sc.parallelize(points, 3)
  val initMode = K_MEANS_PARALLEL
  val model = KMeans.train(rdd, k = 2, maxIterations = 2, runs = 1, initMode)
  val predictResult1 = rdd.map(feature => "cluster id: " + model.predict(feature) + " feature:" + featur
e.toArray.mkString(",")).collect
  println("modelOssDir=" + modelOssDir)
  model.save(sc, modelOssDir)

  //2. predict from the oss model
  val modelLoadOss = KMeansModel.load(sc, modelOssDir)
  val predictResult2 = rdd.map(feature => "cluster id: " + modelLoadOss.predict(feature) + " feature:"
+ feature.toArray.mkString(",")).collect
  assert(predictResult1.size == predictResult2.size)
  predictResult2.foreach(result2 => assert(predictResult1.contains(result2)))
 }
```

```
}
```

Run the following command to submit the job:

```
./bin/spark-submit
--jars cupid/hadoop-aliyun-package-3.0.0-alpha2-odps-jar-with-dependencies.jar
--class com.aliyun.odps.spark.examples.mllib.KmeansModelSaveToOss
/path/to/aliyun-cupid-sdk/examples/spark-examples/target/spark-examples_2.11-1.0.0-SNAPSHOT-shaded.jar
```

1.14.6.8. PySpark interactive execution example

PySpark can only run on a host that can be directly connected to a computing cluster.

Install Python 2.7 and set the following path:

```
export PATH=/path/to/python/bin/:$PATH
```

Start command:

```
bin/pyspark --master yarn-client
```

Interactive execution:

```
df=spark.sql("select * from spark_user_data")
df.show()
```

1.14.6.9. Spark-shell interactive execution example (read tables)

Spark-shell can only run on a host that can be directly connected to a computing cluster.

Start command:

```
bin/spark-shell --master yarn
```

Interactive execution:

```
sc.parallelize(0 to 100, 2).collect
sql("show tables").show
sql("select * from spark_user_data").show(200,100)
```

1.14.6.10. Spark-shell interactive execution example (MLlib and OSS read/write)

Spark-shell can only run on a host that can be directly connected to a computing cluster.

Add the following configuration to conf/spark-defaults.conf:

```
spark.hadoop.fs.oss.accessKeyId=***
spark.hadoop.fs.oss.accessKeySecret=***
spark.hadoop.fs.oss.endpoint=***
```

Start command:

```
bin/spark-shell --master yarn --jars cupid/hadoop-aliyun-package-3.0.0-alpha2-odps-jar-with-dependencies.jar
```

Interactive execution:

```
import org.apache.spark.mllib.clustering.KMeans._
import org.apache.spark.mllib.clustering.{ KMeans, KMeansModel}
import org.apache.spark.mllib.linalg.Vectors
val modelOssDir = "oss://your_bucket/kmeans-model"
val points = Seq(
    Vectors.dense(0.0, 0.0),
    Vectors.dense(0.0, 0.1),
    Vectors.dense(0.1, 0.0),
    Vectors.dense(9.0, 0.0),
    Vectors.dense(9.0, 0.2),
    Vectors.dense(9.2, 0.0)
  )
val rdd = sc.parallelize(points, 3)
val initMode = K_MEANS_PARALLEL
val model = KMeans.train(rdd, k = 2, maxIterations = 2, runs = 1, initMode)
val predictResult1 = rdd.map(feature => "cluster id: " + model.predict(feature) + " feature:" + feature.toArray.mkString(",")).collect
println("modelOssDir=" + modelOssDir)
model.save(sc, modelOssDir)
val modelLoadOss = KMeansModel.load(sc, modelOssDir)
val predictResult2 = rdd.map(feature => "cluster id: " + modelLoadOss.predict(feature) + " feature:" + feature.toArray.mkString(",")).collect
assert(predictResult1.size == predictResult2.size)
predictResult2.foreach(result2 => assert(predictResult1.contains(result2)))
```

1.14.6.11. SparkR interactive execution example

SparkR can only be run on a host which can directly connect to a computing cluster. In addition, you must install R in the */home/admin/R* directory and set the path:

```
export PATH=/home/admin/R/bin/:$PATH
```

Start command:

```
bin/sparkR --master yarn -—archives . /R/R.zip
```

Interactive execution:

```
df <- as.DataFrame(faithful)
df
head(select(df, df$eruptions))
head(select(df, "eruptions"))
head(filter(df, df$waiting < 50))

results <- sql("FROM spark_user_data SELECT *")
head(results)
```

1.14.6.12. GraphX-PageRank example

Spark on MaxCompute supports native GraphX.

Example:

```
package com.aliyun.odps.spark.examples.graphx

import org.apache.spark.{ SparkConf, SparkContext}
import org.apache.spark.graphx._
import org.apache.spark.rdd.RDD

object PageRank {
 def main(args: Array[String]): Unit = {
  val conf = new SparkConf().setAppName("pagerank")
  val sc = new SparkContext(conf)

  // construct vertices
  val users: RDD[(VertexId, Array[String])] = sc.parallelize(List(
   "1,BarackObama,Barack Obama",
   "2,ladygaga,Goddess of Love",
   "3,jeresig,John Resig",
```

```
    "4,justinbieber,Justin Bieber",
    "6,matei_zaharia,Matei Zaharia",
    "7,odersky,Martin Odersky",
    "8,anonsys"
  ).map(line => line.split(",")).map(parts => (parts.head.toLong, parts.tail))

  // construct edges
  val followers: RDD[Edge[Double]] = sc.parallelize(Array(
    Edge(2L,1L,1.0),
    Edge(4L,1L,1.0),
    Edge(1L,2L,1.0),
    Edge(6L,3L,1.0),
    Edge(7L,3L,1.0),
    Edge(7L,6L,1.0),
    Edge(6L,7L,1.0),
    Edge(3L,7L,1.0)
  ))

  // construct graph
  val followerGraph: Graph[Array[String], Double] = Graph(users, followers)

  // restrict the graph to users with usernames and names
  val subgraph = followerGraph.subgraph(vpred = (vid, attr) => attr.size == 2)

  // compute PageRank
  val pageRankGraph = subgraph.pageRank(0.001)

  // get attributes of the top pagerank users
  val userInfoWithPageRank = subgraph.outerJoinVertices(pageRankGraph.vertices) {
    case (uid, attrList, Some(pr)) => (pr, attrList.toList)
    case (uid, attrList, None) => (0.0, attrList.toList)
  }

  println(userInfoWithPageRank.vertices.top(5)(Ordering.by(_. _2. _1)).mkString("\n"))
 }
}
```

Run the following command to submit the job:

```
bin/spark-submit \
--master yarn-cluster \
--class com.aliyun.odps.spark.examples.graphx.PageRank \
/path/to/aliyun-cupid-sdk/examples/spark-examples/target/spark-examples_2.11-1.0.0-SNAPSHOT-shaded.jar
```

1.14.6.13. Spark Streaming - NetworkWordCount example

Spark on MaxCompute supports native Spark Streaming. To use NetworkWordCount, you need to install Netcat on your local host, and then run the following command:

```
$ nc -lk 9999
```

The input on the console then becomes the input of Spark Streaming.

Example:

```
package com.aliyun.odps.spark.examples.streaming

import org.apache.spark.SparkConf
import org.apache.spark.examples.streaming.StreamingExamples
import org.apache.spark.storage.StorageLevel
import org.apache.spark.streaming.{ Seconds, StreamingContext}

object NetworkWordCount {
 def main(args: Array[String]) {
   if (args.length < 2) {
    System.err.println("Usage: NetworkWordCount <hostname> <port>")
    System.exit(1)
   }

   StreamingExamples.setStreamingLogLevels()

   // Create the context with a 1 second batch size
   val sparkConf = new SparkConf().setAppName("NetworkWordCount")
   val ssc = new StreamingContext(sparkConf, Seconds(1))

   // Create a socket stream on target ip:port and count the
   // words in input stream of \n delimited text (eg. generated by 'nc')
   // Note that no duplication in storage level only for running locally.
   // Replication necessary in distributed scenario for fault tolerance.
   val lines = ssc.socketTextStream(args(0), args(1).toInt, StorageLevel.MEMORY_AND_DISK_SER)
   val words = lines.flatMap(_.split(" "))
   val wordCounts = words.map(x => (x, 1)).reduceByKey(_ + _)
   wordCounts.print()
   ssc.start()
   ssc.awaitTermination()
 }
}
```

Run the following command to submit the job:

```
bin/spark-submit \
--master local[4] \
--class com.aliyun.odps.spark.examples.streaming.NetworkWordCount \
/path/to/aliyun-cupid-sdk/examples/spark-examples/target/spark-examples_2.11-1.0.0-SNAPSHOT-s
haded.jar localhost 9999
```

1.14.7. Maven dependencies

The GitHub project mentioned earlier can be used as your quick start template. For custom development, use the following pom.xml file.

Use Spark community edition 2.3.0 and ensure that the scope is provided.

```
<dependency>
  <groupId>org.apache.spark</groupId>
  <artifactId>spark-core_2.11</artifactId>
  <version>2.3.0</version>
  <scope>provided</scope>
</dependency>
```

The MaxCompute plugin has been released to the Maven warehouse. Add the following dependencies:

```
<dependency>
   <groupId>com.aliyun.odps</groupId>
   <artifactId>cupid-core_2.11</artifactId>
   <version>1.0.0</version>
   <scope>provided</scope>
</dependency>

<dependency>
   <groupId>com.aliyun.odps</groupId>
   <artifactId>cupid-client_2.11</artifactId>
   <version>1.0.0</version>
</dependency>

<dependency>
   <groupId>com.aliyun.odps</groupId>
   <artifactId>cupid-datasource_2.11</artifactId>
   <version>1.0.0</version>
</dependency>
```

The file list in the Maven warehouse is as follows:

- The core code of the Cupid platform encapsulates the Cupid task submission API and the parent-child process read/write table API.

```
<dependency>
    <groupId>com.aliyun.odps</groupId>
    <artifactId>cupid-core_2.11</artifactId>
    <version>1.0.0</version>
</dependency>
```

- The datasource encapsulates the spark-related MaxCompute table read/write API.

```
<dependency>
    <groupId>com.aliyun.odps</groupId>
    <artifactId>cupid-datasource_2.11</artifactId>
    <version>1.0.0</version>
```

- The SDK encapsulates the Cupid client mode.

```
<dependency>
    <groupId>com.aliyun.odps</groupId>
    <artifactId>cupid-client_2.11</artifactId>
    <version>1.0.0</version>
</dependency>
```

1.14.8. Special notes

1.14.8.1. Running modes

Spark on MaxCompute supports three running modes: Local, Cluster, and DataWorks.

Local mode

The Local mode is used to facilitate code debugging for applications. In Local mode, you can use **Spark on MaxCompute** the same way as native Spark in the community. Additionally, you can use Tunnel to read and write data from and to MaxCompute tables.

In this mode, you can use either an IDE or the command line to run Spark on MaxCompute. If you use this mode, you must add the `spark.master=local[N]` configuration. N indicates the CPU resources required to implement this mode.

To use Tunnel to read and write data from and to tables in Local mode, you must add the Tunnel configuration item to Spark-defaults.conf. Enter the endpoint based on the region and network environment where the MaxCompute project is located.

The following code provides an example on how to use the command line to run Spark on MaxCompute in this mode:

```
1.bin/spark-submit --master local[4] \
--class com.aliyun.odps.spark.examples.SparkPi \
${path to aliyun-cupid-sdk}/spark/spark-2.x/spark-examples/target/spark-examples_2.11-version-shaded.jar
```

Cluster mode

In Cluster mode, you need to specify the Main method as the entry point of a custom application. The Spark job ends when Main succeeds or fails. This mode is suited for offline jobs. You can use Spark on MaxCompute in this mode together with DataWorks to schedule jobs.

The following code provides an example on how to use the command line to run Spark on MaxCompute in this mode:

```
1.bin/spark-submit --master yarn-cluster \
-class SparkPi \
${ProjectRoot}/spark/spark-2.x/spark-examples/target/spark-examples_2.11-version-shaded.jar
```

DataWorks mode

You can run offline jobs of **Spark on MaxCompute** (in Cluster mode) in DataWorks to integrate and schedule the other types of nodes.

The following procedure is for reference only.

1. Upload the resources in the DataWorks business flow and click **Submit**.
2. In the created business flow, select **ODPS Spark** from **Data Analytics**.
3. Double-click the Spark node and define the Spark job.

   Select a Spark version, a development language, and a resource file. The resource file is the JAR file uploaded and published in the business flow.

   You can specify configuration items, such as the number of executors and memory size, for the job to be submitted.

   You also need to set `spark.hadoop.odps.cupid.webproxy.endpoint` to the endpoint of the region where the project is located, for example, http://service.cn.maxcompute.aliyun-inc.com/api.
4. You can manually run the Spark node to view the task operation log and obtain the URLs of LogView and JobView from the log for further analysis and diagnosis.
5. After you have defined the Spark job, you can orchestrate and schedule services of different types in the business flow.

1.14.8.2. Streaming tasks

MaxCompute also supports Spark Streaming. To support long-running tasks, add the following special configurations to spark-defaults.conf.

Compared with offline jobs, streaming jobs have additional configurations, which take effect immediately after they are completed in spark-defaults.conf.

```
spark.hadoop.odps.cupid.engine.running.type=longtime
-- Set the type to longtime so that the job will not be reclaimed.
spark.hadoop.odps.cupid.job.capability.duration.hours=25920
-- Set the duration.
spark.yarn.maxAppAttempts=10
-- Set the maximum number of retries for a failover.
spark.streaming.receiver.writeAheadLog.enable=true
-- Determine whether to enable the writeAheadLog mode. This mode prevents data loss but lowers th
e efficiency.
```

1.14.8.3. Job diagnosis

After you submit a job, you need to check the job log to determine whether the job is submitted and executed properly. MaxCompute provides LogView and Spark Web UI for you to diagnose jobs.

Submit a job in Spark-submit mode. Logs are also generated when you use DataWorks to execute Spark tasks. Example:

```
cd $SPARK_HOME
bin/spark-submit --master yarn-cluster --class  SparkPi /tmp/spark-2.x-demo/target/AliSpark-2.x-quic
kstart-1.0-SNAPSHOT-shaded.jar
```

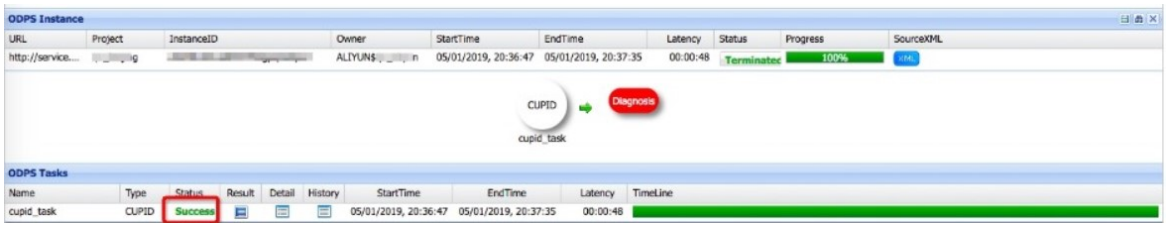
After the job is submitted, MaxCompute creates an instance and displays the LogView URL of the instance in the log.

```
19/01/05 20:36:47 INFO YarnClientImplUtil: logview url: http://logview.odps.aliyun.com/logview/?h=htt
p://service.cn.maxcompute.aliyun.com/api&p=qn_beijing&i=xxx&token=xxx
Success criterion: <If the following output is displayed, the operation succeeded. Other logs may be in
cluded in the output.>
19/01/05 20:37:34 INFO Client:
  client token: N/A
  diagnostics: N/A
  ApplicationMaster host: 11.220.xxx.xxx
  ApplicationMaster RPC port: 30002
  queue: queue
  start time: 1546691807945
  final status: SUCCEEDED
  tracking URL: http://jobview.odps.aliyun.com/proxyview/jobview/?h=http://service.cn.maxcompute.
aliyun-inc.com/api&p=project_name&i=xxx&t=spark&id=application_xxx&metaname=xxx&token=xxx
```

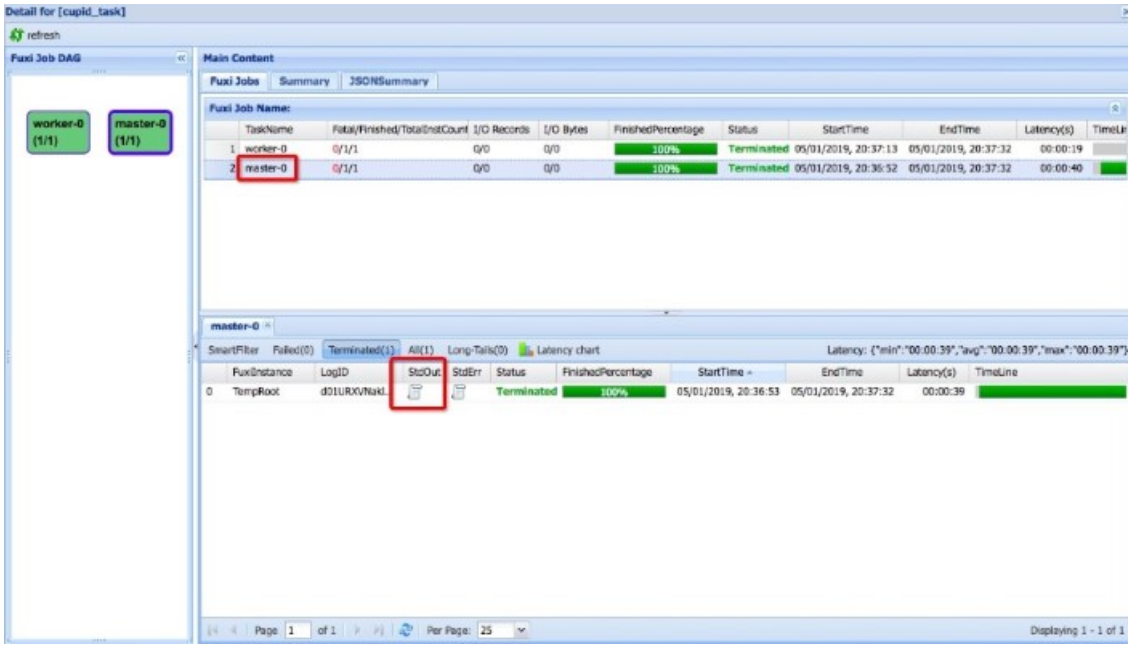
Use LogView to diagnose a job

Example:

1. View basic execution information about the task of the CUPID type in a browser based on the LogView URL.



2. Click the progress bar of the task whose **TaskName** is master-0. In the lower pane, click **All** and find TempRoot in the **FuxiInstance** column.



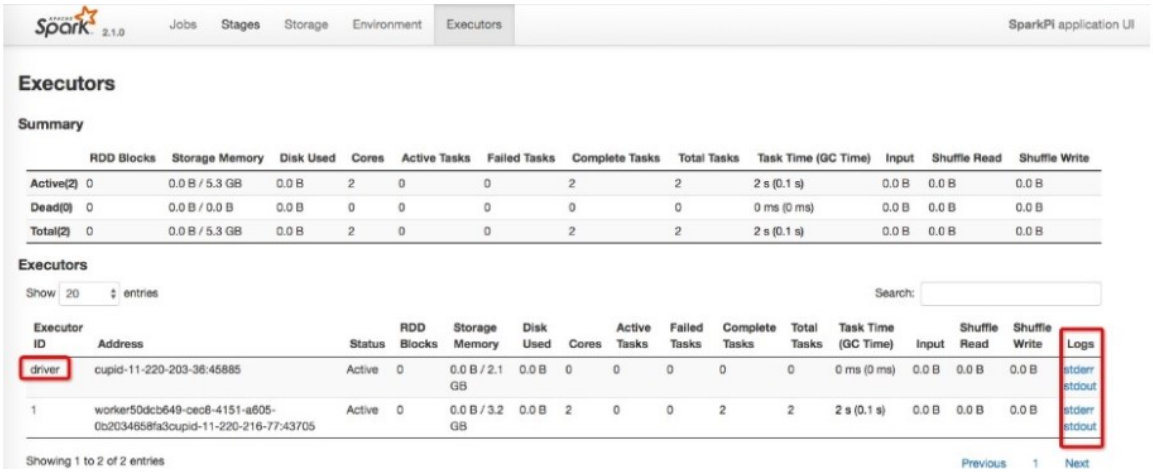
3. Click the icon in the **StdOut** column corresponding to TempRoot to view the output of SparkPi.

Use Spark Web UI to diagnose a job

The tracking URL in the log indicates that your job is submitted to the MaxCompute cluster. This URL is crucial because it is the URL of both Spark Web UI and History Server.

Example:

1. Access the URL in a browser to track the running status of your Spark job.



2. Click **stdout** in the Logs column corresponding to driver to view the output of the Spark job.

1.14.9. APIs supported by Spark

1.14.9.1. Spark Shell

Run the following commands to start the application.

```
$cd $SPARK_HOME
-- Access the spark directory.
<b>Start command</b>: <codeblock>bin/spark-shell --master yarn</codeblock>
-- Select a running mode and start the application.
```

Example:

```
sc.parallelize(0 to 100, 2).collect
sql("show tables").show
sql("select * from spark_user_data").show(200,100)
```

1.14.9.2. Spark R

Run the following commands to start the application:

```
$mkdir -p /home/admin/R && unzip . /R/R.zip -d /home/admin/R/
-- Create directory R and decompress R.zip in the directory.
$export PATH=/home/admin/R/bin/:$PATH
-- Set environment variables.
$bin/sparkR --master yarn --archives . /R/R.zip
-- Select a running mode and start the application.
```

Example:

```
df <- as.DataFrame(faithful)
df
head(select(df, df$eruptions))
head(select(df, "eruptions"))
head(filter(df, df$waiting < 50))
results <- sql("FROM spark_user_data SELECT *")
head(results)
```

1.14.9.3. Spark SQL

Run the following commands to start the application:

```
$cd $SPARK_HOME
-- Access the spark directory.
$bin/spark-sql --master yarn
-- Select a running mode and start the application.
```

Example:

```
show tables;
select * from spark_user_data limit 3;;
quit;
```

1.14.9.4. Spark JDBC

Run the following commands to start an application:

```
$sbin/stop-thriftserver.sh
-- Stop a thread.
$sbin/start-thriftserver.sh
-- Restart a thread.
$bin/beeline
-- Start an application.
```

Example:

```
! connect jdbc:hive2://localhost:10000/odps_smoke_test
show tables;
select * from mr_input limit 3;
! quit
```

1.14.10. Spark dynamic resource allocation

Background

Spark provides a large number of configuration items to implement a wide array of semantics. You can use the default values for most configuration items, but there are some items require manual configurations. Of these items, **spark.executor.instances** is the most complicated.

A value that is too small will cause operations to run slowly or fail, while a value that is too large will waste resources.

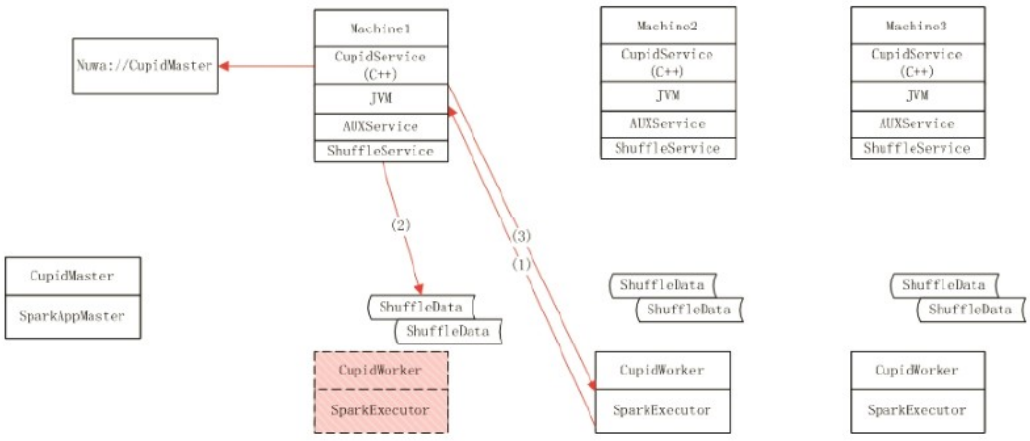
Even the optimal value based on full understanding of the data and logic is not reliable. For complex jobs, the number of executors required at different stages is different and different resources are required during the job execution process. Fixed configurations of resources will cause a waste. When long tail latency occurs, idle resources will be occupied by other executors even for simple jobs.

Solution

The best solution is to allocate resources as needed. Dynamic Resource Allocation (DRA) is such a solution. The CupidService developed by the Cupid team supports native DRA. Its implementation process is as shown in the following figure.

> **Note** For more information about the community native DRA and related configurations, see **Dynamic Resource Allocation** in **Job Scheduling** and **Dynamic Allocation** in **Spark Configuration**.

Implementation process



Enable DRA

You must add the following settings to enable DRA. You do not need to modify the code.

```
spark.hadoop.odps.cupid.shuffleservice.enable=true  // Required, the flag at the Cupid end.
spark.hadoop.odps.cupid.disk.driver.enable=true  // Required, the dependent item.
spark.dynamicAllocation.enabled=true // Required, the flag at the Spark end.
spark.shuffle.service.enabled=true // Required, the dependent item.
spark.shuffle.service.port=7338 // Required, the shuffle service port.
spark.authenticate=true // Required, authentication.
spark.dynamicAllocation.maxExecutors=128 // Optional, the maximum number of executors.
spark.dynamicAllocation.minExecutors=1 // Optional, the minimum number of executors.
spark.dynamicAllocation.initialExecutors=1 // Optional, the initial number of executors.
spark.dynamicAllocation.executorIdleTimeout=60s // Optional, the waiting period before idle executor
s are released.
```

When DRA is enabled, **spark.executor.instances** is optional and equivalent to `spark.dynamicAllocation.initialExecutors`.

1.14.11. FAQ

This topic describes the frequently asked questions about **Spark on MaxCompute**.

How do I migrate open-source Spark code to Spark on MaxCompute?

The migration method depends on whether the job needs to access MaxCompute tables or OSS:

- If the job does not need to access MaxCompute tables or OSS:

  Run the JAR package directly. Note that you must set the dependency on Spark or Hadoop to provided.

- If the job needs to access MaxCompute tables:

  Configure the related dependencies and re-package the application.

- If the job needs to access OSS:

  Configure the related dependencies and re-package the application.

How do I use Spark to access services in a VPC?

Currently, Spark does not allow access to services in a VPC. If you need to access a service in a VPC, submit a ticket to contact the MaxCompute team.

How do I troubleshoot the error indicating the ID and key provided by spark-defaults.conf are incorrect?

Error:

```
Stack:
com.aliyun.odps.OdpsException: ODPS-0410042:
Invalid signature value - User signature dose not match
```

Check whether the ID and key provided by spark-defaults.conf are consistent with the **AccessKey ID** and **AccessKey secret** obtained from the Apsara Stack console.

How do I troubleshoot the error indicating that I do not have permissions?

Error:

```
Stack:
com.aliyun.odps.OdpsException: ODPS-0420095:
Access Denied - Authorization Failed [4019], You have NO privilege 'odps:CreateResource' on {acs:odp
s:*:projects/*}
```

Contact the project owner to grant you the permissions to read and create resources.

How do I troubleshoot the error indicating that the project does not support Spark tasks?

Error:

```
Exception in thread "main" org.apache.hadoop.yarn.exceptions.YarnException: com.aliyun.odps.OdpsE
xception: ODPS-0420095: Access Denied - The task is not in release range: CUPID
```

Check whether the **Spark on MaxCompute** service is provided in the region where the project is located. Check whether the configuration of Spark-defaults.conf is consistent with the requirements in the service documentation. If the Spark on MaxCompute service is provided in the region and the configuration of Spark-defaults.conf is correct, submit a ticket.

How do I handle the "No space left on device" error reported while a task is running?

Error:

```
No space left on device
```

Spark uses online storage to replace local storage. Shuffled data and overflow data of BlockManager are all stored online. Therefore, you must check the setting of the online storage space. The online storage space is specified by the `spark.hadoop.odps.cupid.disk.driver.device_size` parameter. The default space is 20 GB and the maximum space is 100 GB. If this error persists after you adjust the capacity to 100 GB, further analysis is needed.

The most common cause is data skew. During the shuffle and cache processes, data is centrally distributed in some blocks. In this case, you can decrease the number of concurrent tasks in each executor (spark.executor.cores) or increase the number of executors (spark.executor.instances).

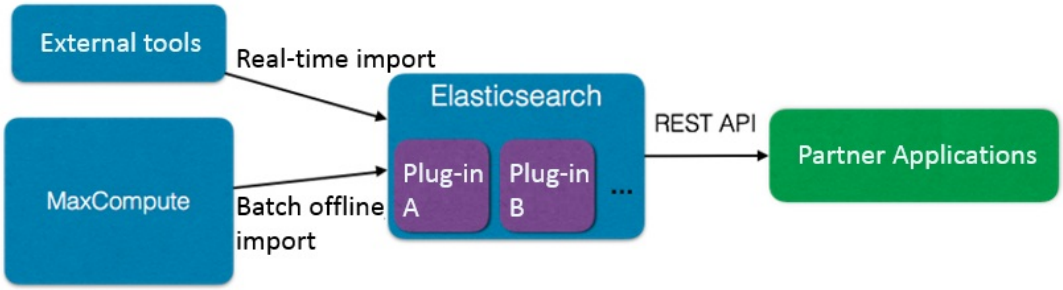
1.15. Elasticsearch on Maxcompute

1.15.1. Overview

Elasticsearch on MaxCompute is an enterprise-class full-text retrieval system developed by Alibaba Cloud for retrieving large volumes of data. It provides near-real-time (NRT) search performance for government agencies and enterprises. **Elasticsearch on MaxCompute** provides elastic full-text retrieval and supports native Elasticsearch APIs. Based on the APIs, it supports data import from heterogeneous data sources as well as cluster and service OAM. Based on the centralized scheduling and management capabilities of MaxCompute, Elasticsearch provides more efficient core services for retrieving large volumes of data.**Elasticsearch on MaxCompute** can also work with plugins available from the Elasticsearch open source community to provide a range of retrieval features.

You can import data to Elasticsearch on MaxCompute using external tools in real time or use MaxCompute to import offline data in batches. After indexing imported data, Elasticsearch on MaxCompute provides the retrieval service through the RESTful API. The following figure shows the usage of Elasticsearch on MaxCompute.

Elasticsearch on MaxCompute usage



1.15.2. Workflow

1.15.2.1. Overview

Elasticsearch on MaxCompute is based on the open source Elasticsearch. It can run the Elasticsearch service on MaxCompute clusters.

In the MaxCompute client, you can start and manage your Elasticsearch service as needed, including the number of nodes, disk space, memory size, and custom settings. The resources consumed by the Elasticsearch service are counted towards your MaxCompute instance quota.

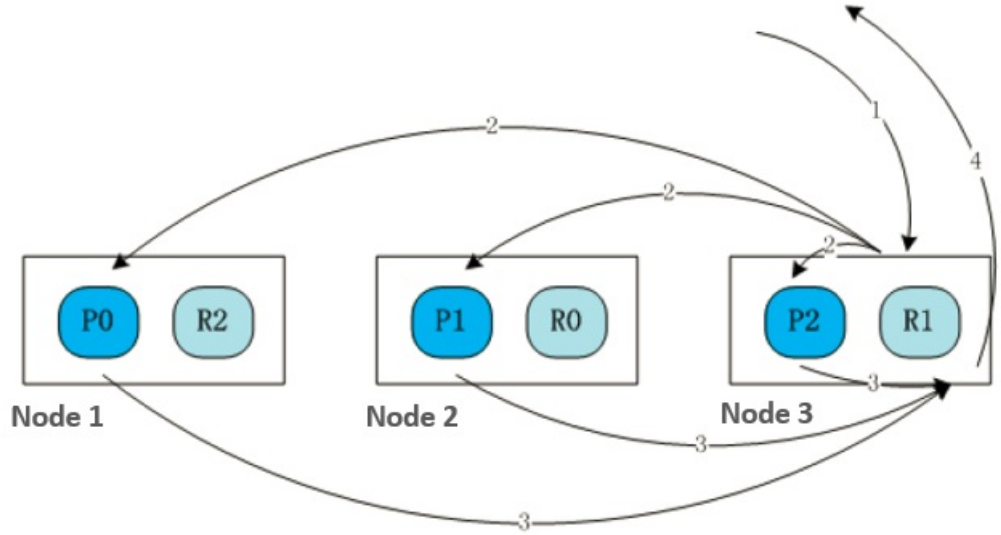
For the process of starting Elasticsearch, see the workflow chart in Typical practice of Elasticsearch.

The following topics describe the workflows of **Elasticsearch on MaxCompute** features.

1.15.2.2. Distributed retrieval workflow

The following figure shows the distributed retrieval workflow:

Distributed retrieval workflow



Each cluster consists of three nodes, as shown in the preceding figure. The index has three shards: P0, P1, and P2, which are distributed across three nodes. The shards work in 1:1 backup mode, so there are three replicas: R0, R1, and R2. The retrieval process is as follows:

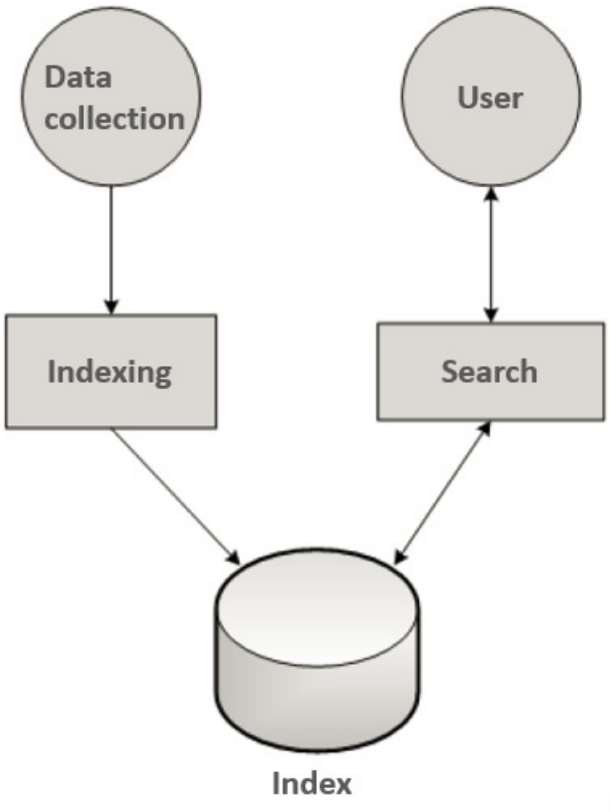
1. A user sends a retrieval request to node 3.
2. After receiving the request, node 3 sends a retrieval request (2) to P0, P1, and P2 based on the recorded index shard information.
3. The nodes where P0, P1, and P2 are located search for the requested information in the specified shards. Each node sends a retrieval result message (3) to node 3.
4. Node 3 combines the retrieval results from the other nodes, and returns a result to the user in an acknowledgment message (4).

Because multiple nodes perform data retrieval at the same time, the retrieval speed is improved. The performance of distributed retrieval increases with the number of nodes.

1.15.2.3. Full-text retrieval process

The following figure shows the full-text retrieval process.

Full-text retrieval process



The process is as follows:

1. The data collection module collects structured and unstructured data, converts the data into the field + value format, and submits the data to the index module.
2. The index module receives the data in the field + value format, performs segmentation and creates inverted indexes based on the predefined indexing method, and saves the indexes. The field type, indexing method, and segmentation rule are configured on the retrieval management page.
3. The search module receives and processes user requests. It parses the requests to obtain indexes, fields, and query statements. Then, the search module finds matching records from the inverted indexes.
4. The search module returns data that satisfies the user requirements, such as the sorting rule and quantity.

1.15.2.4. Authentication process

The authentication process is as follows:

1. **You try to log on to the Elasticsearch on MaxCompute** retrieval management or O&M platform. You are redirected to the authentication module. If you pass the authentication, you can access the platform. Otherwise, you are denied access to the platform.
2. The administrator can use the MaxCompute client to add Elasticsearch users and configure permissions for the users.
3. When you try to access the index library through an API, the system implements authentication. You can search for or operate data in the index library only after passing the authentication.

1.15.3. Quick start

Before you start an Elasticsearch cluster, make sure that you have determined the following information:

- **Node planning**: Determine the number of nodes that are required for each role in an Elasticsearch cluster. By default, an Elasticsearch cluster has two roles, master and data. Each role is deployed on three nodes. You can add nodes to the cluster at any time.
- **Resource planning**: Determine the vCPU, memory, and disk space resources that are required for each node. The resources configured for each node cannot be changed. By default, 8 GiB of memory and 20 GiB of disk space are allocated to each node.

  > **Note** Only 50% of the memory allocated to a data node is used for the JVM heap.

- **Elasticsearch configuration**: Determine the running configurations of nodes in an Elasticsearch cluster, such as the queue size of bulk requests, and support for cross-domain HTTP requests.

After you determine the preceding information, you can start your Elasticsearch cluster in the MaxCompute client.

The following example shows how to quickly start a small Elasticsearch cluster based on the default configurations. The name of the Elasticsearch cluster is es_first_cluster.

1. Download the MaxCompute client that supports Elasticsearch. Configure the AccessKey pair, project, and endpoint.
2. Start the client (odpscmd) and run the following command:

   ```
   server create es_first_cluster type elasticsearch_mdu;
   ```

   Wait for several minutes. If OK is returned, the Elasticsearch cluster is active. You must create an Elasticsearch user to access the cluster.
3. In odpscmd, create an Elasticsearch user with the permission of all_access.

   ```
   server execute es_first_cluster create user admin with password 123456|all_access;
   ```

   If OK is returned, the Elasticsearch user is created.
4. Access the started Elasticsearch cluster. Assume that the prj1 MaxCompute project is used to access the Elasticsearch cluster. Run the following command to return information about the Elasticsearch cluster:

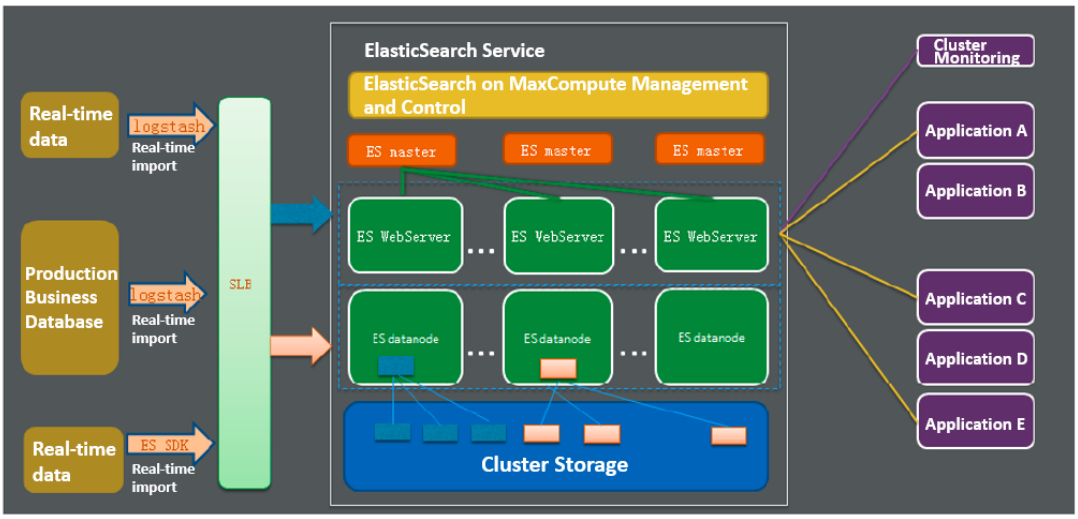
   ```
   curl -u admin:123456 http://search.aliyun.com:9200/prj1.es_first_cluster
   ```

> **Note** To delete the Elasticsearch cluster, run the `server delete es_first_cluster` command. If you run this command, the Elasticsearch cluster is **permanently deleted**, and data cannot be recovered.

1.15.4. Support for Elasticsearch applications

1.15.4.1. ElasticSearch typical practice

Typical practice



Elasticsearch on MaxCompute allows you to start a set of Elasticsearch services on MaxCompute clusters by submitting a job. The project does not modify the native Elasticsearch code. **Elasticsearch on MaxCompute** works in the same way as the native Elasticsearch cluster.

1.15.4.2. Elasticsearch on MaxCompute support for VPC

Alibaba Cloud Elasticsearch on MaxCompute is an enterprise-class full-text retrieval system for retrieving massive amounts of data. To comply with data isolation and security requirements, **Elasticsearch on MaxCompute** provides support for Virtual Private Cloud (VPC) networks so that you can apply access policies at VPC level. (Elasticsearch VPC limits).

Elasticsearch on MaxCompute supports VPC networks in the following model:

- Classic networks, VPC, and the Internet are isolated from each other. Users can access only the endpoints and virtual IP addresses (VIPs) on their networks.
- Projects without a whitelist of VPC IDs and IP addresses are accessible for users from valid domains over the three types of networks. A domain is valid only if its access request is acknowledged.
- When an ElasticSearch service instance is started in a MaxCompute project, they share the same VPCLIST, which is a whitelist of VPCs.
- Starting an ElasticSearch service instance occupies all resources by default. You must scale up the MaxCompute instance or scale down the ElasticSearch service instance if you start more ElasticSearch service instances.

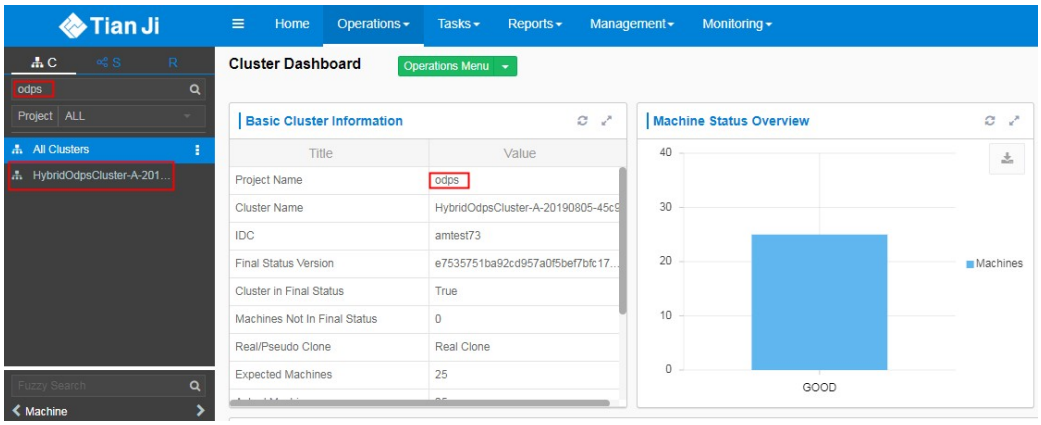
Here is a specific use example. Starting one ElasticSearch service instance for each project is taken as the default practice when a MaxCompute VPC is deployed. You can start your Elasticsearch instances for your projects, apply for domain names and VIPs, and perform VPC health check in the Elasticsearch frontend.

1.15.5. Special notes

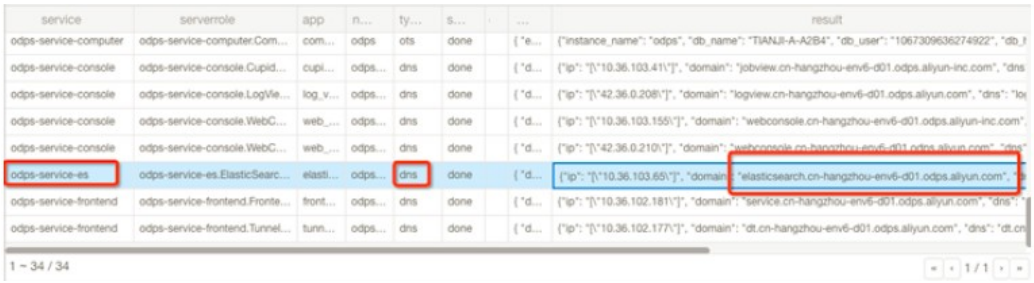
1.15.5.1. Find the Elasticsearch service domain name

1. Log on to the Apsara Infrastructure Management Framework console. Choose Operations >

Cluster Operations from the top navigation bar. In the left-side navigation pane, click the C tab and search for ODPS.



2. Navigate to the MaxCompute cluster resource usage page.
3. Find the Elasticsearch service domain name.



1.15.5.2. Import table data from MaxCompute to Elasticsearch

Before you can use **Elasticsearch on MaxCompute** to search for MaxCompute table data, you must import table data from MaxCompute to Elasticsearch clusters. MaxCompute MapReduce is designed to carry out the task of exporting data from MaxCompute to Elasticsearch. You can import data to Elasticsearch through simple configurations.

By utilizing the distributed dispatching capability of MaxCompute, you can easily control the concurrency. Besides, you can add the MapReduce job to the scheduled tasks on D2.

The data import process is as follows:

1. Download the JAR package of the MapReduce job.
2. Run the following command to add the JAR package to the MaxCompute resource files in the MaxCompute console:

```
add jar /PATH/TO/elasticsearch_output-1.0.0.jar
```

3. Create configuration file es_mr.conf in the following format for the MapReduce job:

```
<configuration>
 <property>
    <name>key1</name>
    <value>value1</value>
 </property>
 <property>
    <name>key2</name>
    <value>value2</value>
 </property>
</configuration>
```

4. Submit the MapReduce job in the MaxCompute console. Example:

```
jar -conf es_mr.conf -classpath /PATH/TO/elasticsearch_output-1.0.0.jar
      -resources elasticsearch_output-1.0.0.jar -Dworker_num=5
com.aliyun.odps.export.elasticsearch.mr.EsOutputJob <TABLE_NAME> [PARTITION_SPEC];
-- Five workers run concurrently to export data from <TABLE_NAME> [PARTITION_SPEC] to the Elas
ticsearch cluster.
```

The following table describes the parameters in the es_mr.conf file.

Parameters

Parameter	Example	Required	Default value	Description
es.resource	my_index/my_type	Yes	-	Index and type in the target Elasticsearch for imported data.
es.nodes	-	Yes	-	Elasticsearch endpoint.
es.nodes.client.only	true	No	false	Send data to client-only nodes only.
es.col.field.mapping	odps_col1:es_field1,odps_col3:es_field2	Yes	-	Mapping between the MaxCompute columns to be imported and the Elasticsearch fields.
es.batch.size.bytes	1 MB	No	1 MB	Batch data transfer size.
es.batch.size.entries	1000	No	1000	Number of data entries transferred each time.
es.net.http.auth.user	admin	No	-	Elasticsearch username.

Parameter	Example	Required	Default value	Description
es.net.http.auth.pass	123456	No	-	Elasticsearch password.
es.mapping.routing	field_routing	No	-	Routing field name, in the <CONSTANT> format for a constant.
es.mapping.id	field_id	No	-	id field of a document.

1.16. Flink on MaxCompute

In the current MaxCompute version, Flink on MaxCompute is only for trial use. The following demo describes only the trial features. For more information about new features, see later versions.

Demo:

1. Modify the configuration file.

   Decompress the Flink package, go to the configuration file directory *conf*, and make the following modifications to the flink-conf.yaml file:

   ```
   project_name: xxxx
   access_id: xxxx
   access_key: xxxx
   end_point: xxxx
   odps.cupid.distributedcache.mincopy: 1
   odps.cupid.proxy.domain.name:xxxx
   #odps.task.major.version:
   cupid_v2
   ```

   > **Note**
   > - The first four configuration items can be obtained from the odps_config.ini file under the */home/admin/odps/odps_tools/clt/conf/* directory.
   > - odps.cupid.proxy.domain.name specifies the domain name of odps_jobview_server_dns. The value is the domain name without sparkui.

2. Start the program.

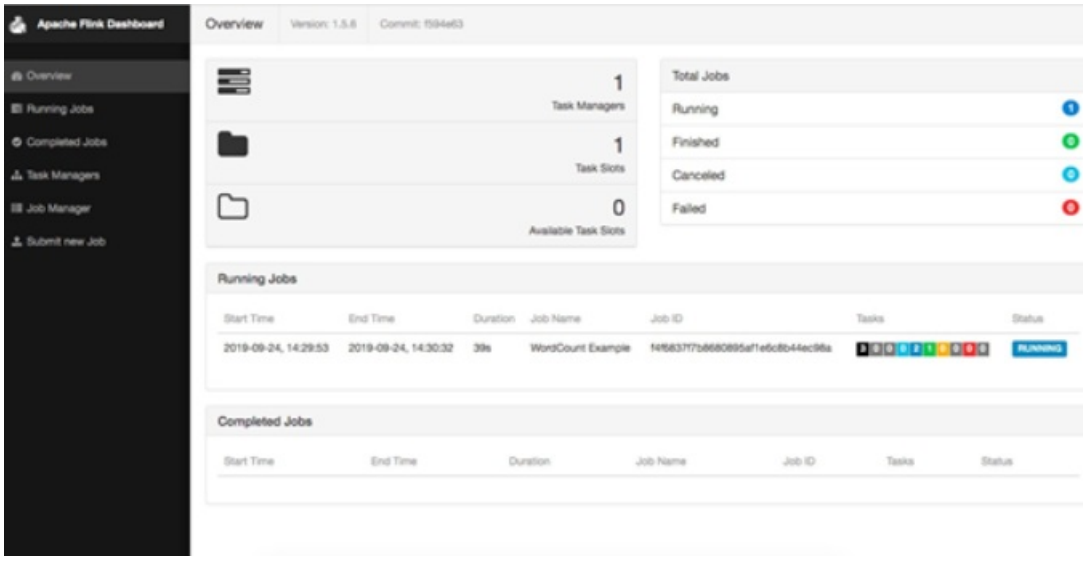
   Save flink-java-project-0.1.jar to the decompressed directory of Flink and run the following commands:

```
/bin/flink
run -c org.apache.flink.odps.WordCount -m yarn-cluster -yn 1
flink-java-project-0.1.jar --projectName odps_smoke_test --inputTable wc_in
--outputTable wc_out --sleepTime 100
```

3. Log on to Logview and Flink.

   Logview

   Flink



Note MaxCompute is compatible with Flink in terms of the following aspects:

- Group windows of Flink: The TUMBLE, HOP, and SESSION built-in functions are supported.
- Flink UDFs, UDAFs, and UDTFs: MaxCompute supports UDFs that run in Flink. You can use the `odps.sql.enable.flink.udf` flag to enable this feature.
- SQL syntax in Flink: The || operator is supported to connect strings. extract(dateunit from datetime) and substring(str from startIndex to endIndex) are supported.
- Flink HistoryServer: You can use Flink HistoryServer to view information about completed tasks.

1.17. Non-structured data access and processing (integrated computing scenarios)

1.17.1. Overview

MaxCompute SQL cannot directly process external data, such as non-structured data from Object Storage Service (OSS). This type of data must be imported to MaxCompute tables by using the relevant tools, which involves complex operations. The MaxCompute team introduced the non-structured data processing framework to the MaxCompute system architecture to simplify the processing of external data.

You can execute a DDL statement to create an external table in MaxCompute and associate the table with external data sources. This table can then act as an interface between MaxCompute and external data sources. External tables can be accessed like standard MaxCompute tables. You can fully use the computing capabilities of MaxCompute SQL to process external data.

MaxCompute allows you to create external tables to process data from the following data sources:

- Internal data sources: OSS, Tablestore, AnalyticDB, ApsaraDB for RDS, Alibaba Cloud HDFS, and TDDL
- External data sources: open source HDFS, MongoDB, and HBase

The subsequent topics describe various data sources.

> **Note** MaxCompute V2.0 supports multiple new data types. To use the new data types, you must add `set odps.sql.type.system.odps2=true;` before the SQL statement and commit them to enable the new data types. For ease of reading, sample code in subsequent topics uses new data types by default.

1.17.2. Internal data sources

1.17.2.1. OSS data source

1.17.2.1.1. Preface

As the core computing component of the Alibaba Cloud big data platform, MaxCompute provides powerful computing capabilities. It can schedule large amounts of nodes for parallel computing, and effectively manage failover and retry mechanisms in distributed computing. MaxCompute SQL implements different data processing logics through simple semantics. It is widely used within and outside Alibaba Group. It allows interoperability among different data sources and is significant for the integrated data ecology of Alibaba Cloud.

The following examples show how to access and process OSS unstructured data in MaxCompute.

1.17.2.1.2. Use the built-in extractor to read OSS data

1.17.2.1.2.1. Overview

You can use the MaxCompute built-in extractor to easily read OSS data in the specified format. You only need to create an external table as the source table for data query. For example, a CSV file is stored in OSS. The endpoint is oss-cn-shanghai-internal.aliyuncs.com, the bucket is oss-odps-test, and the file path is */demo/SampleData/CSV/AmbulanceData/vehicle.csv*. The following topics provide operation examples.

1.17.2.1.2.2. Create an external table

Execute the following statement to create an external table:

```
CREATE EXTERNAL TABLE IF NOT EXISTS ambulance_data_csv_external
(
vehicleId bigint,
recordId bigint,
patientId bigint,
calls bigint,
locationLatitute double,
locationLongtitue double,
recordTime string,
direction string
)
STORED BY 'com.aliyun.odps.CsvStorageHandler'
LOCATION 'oss://<*your-id*>:<*your-secret-key*>@oss-cn-shanghai-internal.aliyuncs.com/oss-odps-test/Demo/SampleData/CSV/AmbulanceData/';
```

Note

- com.aliyun.odps.CsvStorageHandler is a built-in storage handler that is used to process CSV files. It defines how to read and write CSV files. You only need to specify this parameter. The logic is implemented by the system. To read and write TSV files, use com.aliyun.odps.TsvStorageHandler.
- LOCATION specifies an OSS directory. The system reads all files in the directory by default.
- An external table contains only related OSS directories. If you delete this table, the data in the directory specified by LOCATION is not deleted.

1.17.2.1.2.3. Query an external table

After an external table is created, you can use it the same way that you use a standard table.

The following content is included in the */demo/SampleData/CSV/AmbulanceData/vehicle.csv* file:

```
1,1,51,1,46.81006,-92.08174,9/14/2017 0:00,S
1,2,13,1,46.81006,-92.08174,9/14/2017 0:00,NE
1,3,48,1,46.81006,-92.08174,9/14/2017 0:00,NE
1,4,30,1,46.81006,-92.08174,9/14/2017 0:00,W
1,5,47,1,46.81006,-92.08174,9/14/2017 0:00,S
1,6,9,1,46.81006,-92.08174,9/14/2017 0:00,S
1,7,53,1,46.81006,-92.08174,9/14/2017 0:00,N
1,8,63,1,46.81006,-92.08174,9/14/2017 0:00,SW
1,9,4,1,46.81006,-92.08174,9/14/2017 0:00,NE
1,10,31,1,46.81006,-92.08174,9/14/2017 0:00,N
```

Execute the following statement to submit a job, which calls a built-in CSV extractor to read data from OSS:

```
SELECT recordId, patientId, direction
FROM ambulance_data_csv_external
WHERE patientId > 25;
```

> **Note**
>
> - An external table can only be managed by using MaxCompute SQL, not MaxCompute MapReduce.
> - To obtain data over HTTPS at the underlying layer, add the `set odps.sql.unstructured.data.oss.use.https=true;` flag before an SQL statement. Then, commit them for execution.

The following result is returned:

```
+------------+------------+-----------+
| recordId | patientId | direction |
+------------+------------+-----------+
| 1 | 51 | S |
| 3 | 48 | NE |
| 4 | 30 | W |
| 5 | 47 | S |
| 7 | 53 | N |
| 8 | 63 | SW |
| 10 | 31 | N |
+------------+------------+-----------+
```

> **Note** The system provides built-in CsvStorageHandler, TsvStorageHandler, and TextStorageHandler.

1.17.2.1.2.4. MSCK REPAIR TABLE

The **MSCK REPAIR TABLE** statement can be used to add partitions to external tables. Syntax:

```
MSCK [REPAIR] TABLE external_table_name [ADD PARTITIONS];
```

To add partitions, perform the following steps:

1. Import data to Object Storage Service (OSS). The storage path must be in the following format: `oss://xxx/table-location/ptname1=ptvalue1/ptname2=ptvalue2/xxx` .
2. Create an external table and specify the structures of the ptname1 and ptname2 partitions.
3. Execute the `msck repair table external_table_name [add partitions]` statement. MaxCompute SQL automatically parses the OSS directory structure, identifies partitions, and adds partitions to the external table.

Sample code:

```
CREATE EXTERNAL TABLE orc_pt_v0
(
name string
)
partitioned by (pt bigint)
STORED AS textfile
location 'oss://xxx/odps-ext-reg-perf/orc-pt-v0';msck repair table orc_pt_v0 add partitions;
-- In this case, the MSCK statement is equivalent to the following three statements:
alter table orc_pt_v0 add partition (pt=1);
alter table orc_pt_v0 add partition (pt=10);
alter table orc_pt_v0 add partition (pt=100);
```

1.17.2.1.3. Custom extractors

1.17.2.1.3.1. Overview

If OSS data is in a complicated format that cannot be processed by the built-in extractor, you must customize an extractor to read data from OSS files. For example, a text file is stored in OSS. The file is not in the CSV format and the columns of records are separated by vertical bars (|). The file path is */demo/SampleData/CustomTxt/AmbulanceData/vehicle.csv*. The following topics provide operation examples.

1.17.2.1.3.2. Define StorageHandler

You can customize the data parsing logic. StorageHandler is the unified entrance of your custom logic. You can specify the types of custom extractors and outputers. StorageHandler provides only a simple definition. For example, you can implement SpeicalTextStorageHandler:

```
package com.aliyun.odps.udf.example.text;
public class SpeicalTextStorageHandler extends OdpsStorageHandler {
@Override
public Class&lt;? extends Extractor&gt; getExtractorClass() {
return TextExtractor.class;
}
@Override
public Class&lt;? extends Outputer> getOutputerClass() {
return TextOutputer.class;
}
}
```

> **Note** Note that TextStorageHandler that is built in MaxCompute can process the data format in the preceding example (text separated by vertical bars (|)). This example is provided only to show you how to use the SDK to customize a StorageHandler (especially extractor) for processing uncommonly structured data.

1.17.2.1.3.3. Define an extractor

In the following example, TextExtractor is used to extract records from a text file, where the delimiter is imported as a parameter. TextExtractor can be used for all text files of the similar format.

```
/**
* Text extractor that extract schematized records from formatted plain-
text(csv, tsv etc.)
**/
public class TextExtractor extends Extractor {
private InputStreamSet inputs;
private String columnDelimiter;
private DataAttributes attributes;
private BufferedReader currentReader;
private boolean firstRead = true;
public TextExtractor() {
// Default to ",", this can be overwritten if a specific delimiter is
provided (via DataAttributes)
this.columnDelimiter = ",";
}
// No particular usage for execution context in this example
```

```
@Override
public void setup(ExecutionContext ctx, InputStreamSet inputs,
DataAttributes attributes) {
this.inputs = inputs;
-- inputs specifies an InputStreamSet. An InputStream is returned each time next() is called. This Input
Stream can read all the content of an OSS file.
this.attributes = attributes;
// Check if "delimiter" attribute is supplied via SQL query
String columnDelimiter = this.attributes.getValueByKey("delimiter");
-- The delimiter can be used as a parameter in DDL statements.
if ( columnDelimiter ! = null)
{
this.columnDelimiter = columnDelimiter;
}
// note: more properties can be inited from attributes if needed
}
@Override
public Record extract() throws IOException {
String line = readNextLine();
if (line == null) {
return null;
-- If NULL is returned, all records in the table have been read.
}
return textLineToRecord(line);
-- textLineToRecord splits a row into multiple columns using the delimiter. For the implementation proc
ess, see Complete TextExtractor implementation.
-- extractor() returns a record that is extracted from OSS data.
}
@Override
public void close(){
// no-op
}
}
```

1.17.2.1.3.4. Compile and package code

You can compile and package Java code, and run the following command to upload it to MaxCompute. The procedure is the same as that for a normal Java UDF.

add jar odps-udf-example.jar;

1.17.2.1.3.5. Create an external table

After you upload a JAR package, you need to run the following command to create an external table. This command is similar to the one that you run before using a built-in extractor. The difference is that this command uses a custom StorageHandler.

```
CREATE EXTERNAL TABLE IF NOT EXISTS ambulance_data_txt_external
(
vehicleId int,
recordId int,
patientId int,
calls int,
locationLatitute double,
locationLongtitue double,
recordTime string,
direction string
)
STORED BY 'com.aliyun.odps.udf.example.text.SpeicalTextStorageHandler'
-- STORED BY specifies the class name of a custom StorageHandler.
WITH SERDEPROPERTIES('delimiter'='|')
-- SERDEPROPERITES can be used to specify parameters. These parameters are transferred to an extra
ctor through DataAttributes.
LOCATION 'oss://<*your-id*>:<*your-secret-key*>@oss-cn-shanghai-internal.aliyuncs.com/oss-odps-t
est/Demo/SampleData/CustomTxt/AmbulanceData/'
USING 'odps-udf-example.jar';
-- Specify the JAR package where the class definition is located.
```

1.17.2.1.3.6. Query an external table

The content of */demo/SampleData/CustomTxt/AmbulanceData/vehicle.csv* is as follows:

```
1|1|51|1|46.81006|-92.08174|9/14/2017 0:00|S
1|2|13|1|46.81006|-92.08174|9/14/2017 0:00|NE
1|3|48|1|46.81006|-92.08174|9/14/2017 0:00|NE
1|4|30|1|46.81006|-92.08174|9/14/2017 0:00|W
1|5|47|1|46.81006|-92.08174|9/14/2017 0:00|S
1|6|9|1|46.81006|-92.08174|9/14/2017 0:00|S
1|7|53|1|46.81006|-92.08174|9/14/2017 0:00|N
1|8|63|1|46.81006|-92.08174|9/14/2017 0:00|SW
1|9|4|1|46.81006|-92.08174|9/14/2017 0:00|NE
1|10|31|1|46.81006|-92.08174|9/14/2017 0:00|N
```

Run the following command to submit a job, which calls a custom extractor to read data from OSS:

```
SELECT recordId, patientId, direction
FROM ambulance_data_txt_external
WHERE patientId > 25;
```

Command output:

```
+------------+------------+-----------+
| recordId | patientId | direction |
+------------+------------+-----------+
| 1 | 51 | S |
| 3 | 48 | NE |
| 4 | 30 | W |
| 5 | 47 | S |
| 7 | 53 | N |
| 8 | 63 | SW |
| 10 | 31 | N |
+------------+------------+-----------+
```

1.17.2.1.4. Advanced usage

1.17.2.1.4.1. Use a custom extractor to read external unstructured data

The preceding topic describes how to use built-in and custom extractors to process text files such as .csv files that are stored in OSS. This topic describes how to use UDF extractors to process non-text files in OSS.

The following example shows how to process audio files (.wav files) in OSS.

1. Customize the SpeechSentenceSnrExtractor main logic. Use the SETUP API to read parameters, initialize the parameters, and import the audio processing model (by using the resource function).

```
public SpeechSentenceSnrExtractor(){
this.utteranceLabels = new HashMap&lt;String, UtteranceLabel&gt;();
}
@Override
public void setup(ExecutionContext ctx, InputStreamSet inputs,
DataAttributes attributes){
this.inputs = inputs;
this.attributes = attributes;
this.mlfFileName = this.attributes.getValueByKey(MLF_FILE_ATTRIBUTE_KEY);
```

```
this.mlfFileName = this.attributes.getValueByKey(MLF_FILE_ATTRIBUTE_KEY);
String sampleRateInKHzStr =
this.attributes.getValueByKey(SPEECH_SAMPLE_RATE_KEY);
this.sampleRateInKHz = Double.parseDouble(sampleRateInKHzStr);
try {
// read the speech model file from resource and load the model into
memory
BufferedInputStream inputStream =
ctx.readResourceFileAsStream(mlfFileName);
loadMlfLabelsFromResource(inputStream);
inputStream.close();
} catch (IOException e) {
throw new RuntimeException("reading model from mlf failed with exception
" + e.getMessage());
}
}
@Override
public Record extract() throws IOException {
SourceInputStream inputStream = inputs.next();
if (inputStream == null){
return null;
}
// process one wav file to extract one output record [snr, id]
String fileName = inputStream.getFileName();
fileName = fileName.substring(fileName.lastIndexOf('/') + 1);
logger.info("Processing wav file " + fileName);
// infer id from speech file name
String id = fileName.substring(0, fileName.lastIndexOf('.'));
// read speech file into memory buffer
long fileSize = inputStream.getFileSize();
byte[] buffer = new byte[(int)fileSize];
int readSize = inputStream.readToEnd(buffer);
inputStream.close();
// compute the avg sentence snr from speech file
double snr = computeSnr(id, buffer, readSize);
// construct output record [snr, id]
Column[] outputColumns = this.attributes.getRecordColumns();
ArrayRecord record = new ArrayRecord(outputColumns);
record.setDouble(0, snr);
record.setString(1, id);
return record;
```

```
}
private void loadMlfLabelsFromResource(BufferedInputStream fileInputStream)
throws IOException {
// loading MLF label from resource, skipped here
}
// compute the snr of the speech sentence, assuming the input buffer
contains the entire content of a wav file
private double computeSnr(String id, byte[] buffer, int validBufferLen){
// computing the snr value for the wav file (supplied as byte buffer
array), skipped here
}
```

> **Note** The Extractor() API implements the reading and processing logic of audio files. It calculates the signal-to-noise ratio (SNR) of the read data based on the audio processing model and writes the result to a record in [snr, id] format.

2. Run the following commands to create an external table:

```
CREATE EXTERNAL TABLE IF NOT EXISTS speech_sentence_snr_external
(
sentence_snr double,
id string
)
STORED BY 'com.aliyun.odps.udf.example.speech.SpeechStorageHandler'
WITH SERDEPROPERTIES (
'mlfFileName'='sm_random_5_utterance.text.label' ,
'speechSampleRateInKHz' = '16'
)
LOCATION 'oss://<*your-id*>:<*your-secret-key*>@oss-cn-shanghai-internal.aliyuncs.com/oss-od
ps-test/dev/SpeechSentenceTest/'
USING 'odps-udf-example.jar,sm_random_5_utterance.text.label';
```

3. Run the following commands to read data from OSS:

```
SELECT sentence_snr, id
FROM speech_sentence_snr_external
WHERE sentence_snr > 10.0;
```

4. The command output is as follows:

```
------------------------------------------------------------
| sentence_snr | id |
------------------------------------------------------------
| 34.4703 | J310209090013_H02_K03_042 |
------------------------------------------------------------
| 31.3905 | tsh148_seg_2_3013_3_6_48_80bd359827e24dd7_0 |
------------------------------------------------------------
| 35.4774 | tsh148_seg_3013_1_31_11_9d7c87aef9f3e559_0 |
------------------------------------------------------------
| 16.0462 | tsh148_seg_3013_2_29_49_f4cb0990a6b4060c_0 |
------------------------------------------------------------
| 14.5568 | tsh_148_3013_5_13_47_3d5008d792408f81_0 |
------------------------------------------------------------
```

Note By using the UDF extractor, you can run SQL statements to process multiple audio files in OSS in a distributed manner. Similarly, you can use the large-scale computation capabilities of MaxCompute to process unstructured data such as images and videos.

1.17.2.1.5. Data partitions

1.17.2.1.5.1. Overview

In the preceding topic, LOCATION is used to specify an OSS directory, which is associated with an external table. MaxCompute reads all data in the directory, including all files in the subdirectories. When there is a large volume of data in the directory, a full-text scan will cause extra I/O operations and processing time. There are two solutions:

- Reducing the data volume: You need to properly plan data storage addresses. Create multiple external tables for data from different parts, with the LOCATION of each external table pointing to a subset of data.
- Partitioning data: The external table, like an internal table, supports partitioning. You can create partitions to facilitate data management.

The following topics describe the partition feature of external tables.

1.17.2.1.5.2. Standard organization method and path format of partition data in OSS

Unlike the data in internal tables, data stored in external storage (such as OSS) cannot be managed in MaxCompute. If you need to use the partitioned table feature of MaxCompute, make sure that the data file paths in OSS are in the following format:

```
partitionKey1=value1\partitionKey2=value2\...
```

Example:

1. Your daily log files are stored in OSS, and you want to access some of the data from MaxCompute on a daily basis. If the log files are in the CVS format or a similar custom format, you can execute the following statement to create a partitioned external table:

```
CREATE EXTERNAL TABLE log_table_external (
click STRING,
ip STRING,
url STRING,
)
PARTITIONED BY (
year STRING,
month STRING,
day STRING
)
STORED BY 'com.aliyun.odps.CsvStorageHandler'
LOCATION 'oss://<ak_id>:<ak_key>@oss-cn-shanghai-internal.aliyuncs.com/oss-odps-test/log_d
ata/';
```

> **Note** In the preceding example, the PARTITIONED BY clause is used to specify a partitioned external table. The partition keys are year, month, and day.

2. For the partitions to take effect, you must specify the OSS storage directory in the format shown in the preceding example. An example of a valid directory layout is as follows:

```
osscmd ls oss://oss-odps-test/log_data/
2017-09-14 08:03:35 128MB Standard oss://oss-odps-
test/log_data/year=2017/month=06/day=01/logfile
2017-09-14 08:04:12 127MB Standard oss://oss-odps-
test/log_data/year=2017/month=06/day=01/logfile. 1
2017-09-14 08:05:02 118MB Standard oss://oss-odps-
test/log_data/year=2017/month=06/day=02/logfile
2017-09-14 08:06:45 123MB Standard oss://oss-odps-
test/log_data/year=2017/month=07/day=10/logfile
2017-09-14 08:07:11 115MB Standard oss://oss-odps-
test/log_data/year=2017/month=08/day=08/logfile
...
```

> **Note** If you have uploaded offline data to OSS by using osscmd or other OSS tools, you can define the data path format. To ensure the partitioned external table feature operates normally, we recommend that the path where data is stored to is in the format specified in the previous example.

3. Then, you can execute the ALTER TABLE ADD PARTITION statement to import the partition information to MaxCompute. An example of the DDL statement is as follows:

```
ALTER TABLE log_table_external ADD PARTITION (year = '2017', month = '06', day = '01')
ALTER TABLE log_table_external ADD PARTITION (year = '2017', month = '06', day = '02')
ALTER TABLE log_table_external ADD PARTITION (year = '2017', month = '07', day = '10')
ALTER TABLE log_table_external ADD PARTITION (year = '2017', month = '08', day = '08')
...
```

4. When the data is ready and the partition information has been imported to MaxCompute, you can execute SQL statements to operate the partitions in the external table in OSS.
   - Execute the following statement to count the number of unique IP addresses in the log dated June 1, 2017:

     ```
     SELECT count(distinct(ip)) FROM log_table_external
     WHERE year = '2017' AND month = '06' AND day = '01';
     ```

     Note In the log_table_external directory that corresponds to an external table, only files in the *log_data/year=2017/month=06/day=01* subdirectory (logfile and To prevents unnecessary I/O operations, a full scan of the *log_data/* directory is not performed.

   - Similarly, you can execute the following statement to analyze data for the second half of 2017:

     ```
     SELECT count(distinct(ip)) FROM log_table_external
     WHERE year = '2017' AND month > '06';
     ```

     Note In this case, only the logs for the second half of 2017 stored in OSS are accessed.

1.17.2.1.5.3. Custom path of partition data in OSS

If you have historical data stored in OSS paths that are not in the partitionKey1=value1\partitionKey2=value2\... format, you can still access the data by using the MaxCompute partition feature. MaxCompute provides a way to import partitions through a custom path.

Example:

1. The data path only contains partition values (without partition keys). An example of the path layout is as follows:

```
osscmd ls oss://oss-odps-test/log_data_customized/
2017-09-14 08:03:35 128MB Standard oss://oss-odps-
test/log_data_customized/2017/06/01/logfile
2017-09-14 08:04:12 127MB Standard oss://oss-odps-
test/log_data_customized/2017/06/01/logfile. 1
2017-09-14 08:05:02 118MB Standard oss://oss-odps-
test/log_data_customized/2017/06/02/logfile
2017-09-14 08:06:45 123MB Standard oss://oss-odps-
test/log_data_customized/2017/07/10/logfile
2017-09-14 08:07:11 115MB Standard oss://oss-odps-
test/log_data_customized/2017/08/08/logfile
...
```

2. You can run the following statement to bind subdirectories to different partitions:

```
ALTER TABLE log_table_external ADD PARTITION (year = '2017', month = '06', day = '01')
LOCATION 'oss://<ak_id>:<ak_key>@oss-cn-shanghai-internal.aliyuncs.com/oss-odps-test/log_d
ata_customized/2017/06/01/';
```

> **Note** The ADD PARTITION and LOCATION clauses are specified in the preceding example to bind the partitions to data paths. Even if the data storage path is not in the partitionKey1=value1\partitionKey2=value2\... format, you can still access the partition data in the subdirectory.

1.17.2.1.5.4. Access fully-customized non-partitioned data subsets

In certain situations, you might need to access a file subset in an OSS path, but files in this subset do not have any obvious regularity in terms of directory layout. The unstructured data processing framework of MaxCompute is able to handle this situation, but will not be discussed in this topic.

If you require advanced operations such as this, contact the MaxCompute technical team for support.

1.17.2.1.6. Output OSS data

1.17.2.1.6.1. Create an external table

To write data to OSS, you need to run the CREATE EXTERNAL TABLE statement to create an external table first. The process is the same as that of reading data from OSS. After the external table is created, you can run MaxCompute SQL statements such as INSERT INTO and INSERT OVERWRITE to write data to OSS. In the following example, the built-in TsvStorageHandler is used.

```
DROP TABLE IF EXISTS tpch_lineitem_tsv_external;
CREATE EXTERNAL TABLE IF NOT EXISTS tpch_lineitem_tsv_external
(
orderkey BIGINT,
suppkey BIGINT,
discount DOUBLE,
tax DOUBLE,
shipdate STRING,
linestatus STRING,
shipmode STRING,
comment STRING
)
STORED BY 'com.aliyun.odps.TsvStorageHandler'
LOCATION 'oss://<AK_id>:<AK_secret>@oss-cn-hangzhou-zmf.aliyuncs.com/oss-odps-test/tsv_output
_folder/';
```

Note

The preceding DDL statement creates an external table named tpch_lineitem_tsv_external, and associates two external data dimensions with this external table.

- Data storage medium: LOCATION associates an OSS address with the external table. This address will be used to read or write data from or to the external table.
- Data storage format: StorageHandler is used to define the data access mode. In this example, MaxCompute built-in com.aliyun.odps.TsvStorageHandler is used to read or write data from or to TSV files. You can also use the MaxCompute SDK to define StorageHandlers.

1.17.2.1.6.2. Write data to a TSV text file by using an INSERT statement on an external table

After you associate a file in OSS with an external table, you can run a standard SQL INSERT OVERWRITE/INSERT INTO statement on the external table to write data to the OSS file. The source data can be either data stored in a MaxCompute internal table or external data that is imported to MaxCompute through an external table.

> **Note**
>
> - MaxCompute internal table: You can run an INSERT statement on an external table to write data from a MaxCompute internal table to an external storage medium.
> - External data imported to MaxCompute through an external table: You can import external data to MaxCompute through an external table, use the data for computations, and then export the results to an external address or storage medium. For example, import Table Store data to MaxCompute and then export the data to OSS.

The following example assumes that you have a MaxCompute internal table named tpch_lineitem and want to export some of the data to OSS in the TSV format. After you create an external table, run the following INSERT OVERWRITE statements to export data:

```
INSERT OVERWRITE TABLE tpch_lineitem_tsv_external
SELECT l_orderkey, l_suppkey, l_discount, l_tax, l_shipdate, l_linestatus,
l_shipmode, l_comment
FROM tpch_lineitem
WHERE l_discount = 0.07 and l_tax = 0.01;
```

The preceding example selects eight columns from the rows in tcph_lineitem table that satisfy the conditions l_discount = 0.07 and l_tax = 0.01 and writes it to tpch_lineitem_tsv_external in OSS in the TSV format. After this operation is complete, you can view the corresponding TSV data file in OSS.

> **Notice**
>
> Data exported from MaxCompute to OSS is stored in a special file structure.
>
> - When you run INSERT INTO/OVERWRITE statements on an OSS address, all data is exported to the .odps folder at the specified LOCATION.
> - The .meta file in the .odps folder is an extra macro data file written by MaxCompute to record valid data in the current folder. Typically, if the INSERT operation is successful, all the data in the current folder is valid. You are only required to parse the macro data if a job fails.
> - If a job fails or is terminated, perform the INSERT OVERWRITE operation again until it is complete. This prevents parsing of the .meta file.
> - If you need to parse the .meta file, contact Alibaba Cloud technical team for support.

The number of files that are generated during MaxCompute built-in TSV/CSV processing is equal to the number of concurrent SQL stages. You can use the flexible semantics and configurations of MaxCompute to limit the number of generated files. In the preceding example, if you need to force a TSV file to be generated, you can append DISTRIBUTE BY l_discount to the INSERT OVERWRITE operation. Then, a reduce stage with only one reducer is added at last so that only one TSV file is output.

1.17.2.1.6.3. Write data to an unstructured file by using an INSERT statement on an external table

MaxCompute also provides Outputer APIs for data output. You can use the APIs to write user data to a custom unstructured data file through OutputStream. Further details are not covered in this topic.

If you have this requirement, contact the MaxCompute technical team for support.

1.17.2.1.6.4. Migrate data between different storage media with MaxCompute

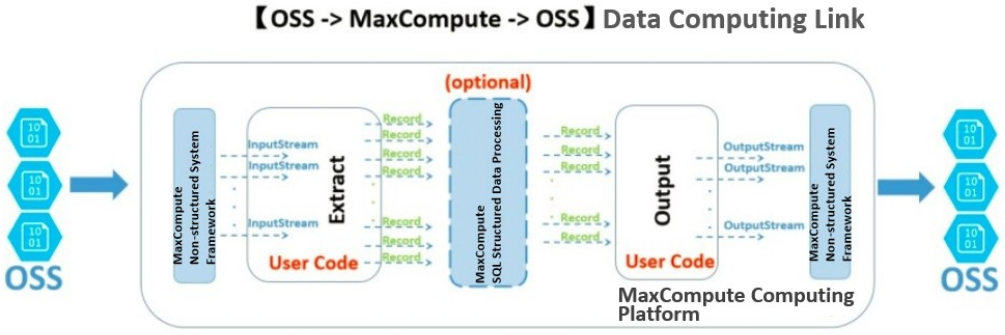
External tables act as an interface between MaxCompute and external storage media. External tables can be used to read or write data from or to various external storage media such as OSS and Table Store. Based on the external table feature, various data computing and storage links can be established. For example,

1. MaxCompute reads the OSS data associated with External Table A, and performs complicated computations. MaxCompute then outputs the results to the OSS address associated with External Table B.
2. MaxCompute reads the Table Store data associated with External Table A, and performs complicated computations. MaxCompute then outputs the results to the OSS address associated with External Table B.

> **Note** The preceding examples and data sources are scenarios with MaxCompute tables. The only difference is that the SELECT statement originates from an external table instead of a MaxCompute table.

Example:

By using MaxCompute as a central computing platform, you can import data from an OSS instance, and export that data to a different OSS instance (in a different location, or a different OSS account), as shown in the following figure.



From a data flow and processing logic standpoint, the unstructured data processing framework can be considered as a coupled data ingress and egress at both ends of the MaxCompute platform.

1. The external data (from an OSS instance) is converted based on the unstructured

framework, and provided to the UDF API in the form of a Java InputStream class. The UDF extract logic is only required to read, parse, transform, and compute the data from the InputStream class, and return the data in the Record format used by MaxCompute.

2. Part of the returned records are used in the SQL logical operations on MaxCompute. These operations utilize the powerful SQL computation engine built into MaxCompute, and may generate new records.
3. The computed records are transferred to the UDF Output logic for further computation. Finally, the required information is extracted from the records, output through OutputStream, and written to the OSS instance.

> **Notice** You can perform any combination of the preceding steps based on your needs.

1.17.2.1.7. STS mode authorization for OSS

When you create an external table, the Location-based OSS access account supports plaintext input of the AccessKey ID and AccessKey secret, but the account information may be exposed. To prevent the leakage of account information, MaxCompute provides a more secure way to access OSS.

MaxCompute combines RAM and Security Token Service (STS) of Alibaba Cloud to resolve security issues of accounts. You can grant permissions in two ways:

- If the owners of MaxCompute and OSS use the same Alibaba Cloud account, you can authorize access to OSS with one click in the RAM console.
- Custom authorization is supported.
  i. You can log on to the RAM console and authorize access to OSS.

     Create a role named AliyunODPSDefaultRole or AliyunODPSRoleForOtherUser and set the policy content as follows:

```
-- If the owners of MaxCompute and OSS use the same account:
{
"Statement": [
{
 "Action": "sts:AssumeRole",
 "Effect": "Allow",
 "Principal": {
   "Service": [
     "odps.aliyuncs.com"
   ]
 }
}
],
"Version": "1"
}
-- If the owners of MaxCompute and OSS use different accounts:
{
"Statement": [
{
 "Action": "sts:AssumeRole",
 "Effect": "Allow",
 "Principal": {
   "Service": [
     "ID of the Alibaba Cloud account used by the owner of MaxCompute@odps.aliyuncs.com"
   ]
 }
}
],
"Version": "1"
}
```

ii. Set the AliyunODPSRolePolicy permission, which is the necessary permission for the role to access OSS.

```
{
"Version": "1",
"Statement": [
{
 "Action": [
   "oss:ListBuckets",
   "oss:GetObject",
   "oss:ListObjects",
   "oss:PutObject",
   "oss:DeleteObject",
   "oss:AbortMultipartUpload",
   "oss:ListParts"
 ],
 "Resource": "*",
 "Effect": "Allow"
}
]
}
--You can also add other permissions as required.
```

iii. Grant the AliyunODPSRolePolicy permission to the role.

> **Note** After authorization is complete, view the role details to obtain the RAM information of this role. You need to specify the RAM information when you create an OSS external table later.

1.17.2.2. Table Store data source

1.17.2.2.1. Preface

As the core computing component of the Alibaba Cloud big data platform, MaxCompute meets most distributed computing requirements within and outside Alibaba Group. As the entry of distributed data processing, MaxCompute SQL provides powerful support for quick processing and storage of large volumes (exabytes) of offline data. With the continuous expansion of big data business, many new data usage scenarios emerge. To adapt to the new scenarios, the MaxCompute computing framework is constantly evolving. Its powerful computation capabilities, originally designed to process internal data in special formats, have expanded to process external data sources in various formats. This topic describes in detail how to import data from Table Store to MaxCompute, implementing seamless interoperability between data sources.

Compared with traditional databases, NoSQL KV Store supports flexible schema, scalability and real-time response for applications such as online service. Alibaba Cloud Table Store is a large-scale NoSQL data storage service based on the Apsara system. It supports storage and real-time access of massive KV data. Table Store is widely used by all business units in Alibaba Group and the Alibaba Cloud ecosystem. In particular, Table Store features, such as row-level real-time update and override writing, are a supplement to the append-only operation of MaxCompute tables. As a storage-oriented service, Table Store does not provide sufficient computing capabilities to process large amounts of data concurrently. This makes it important to enable data interoperability between MaxCompute and Table Store.

The following examples show how to access and process Table Store data in MaxCompute.

1.17.2.2.2. MaxCompute reads and computes data in Table Store

1.17.2.2.2.1. Prerequisites and assumptions

This document assumes that you have basic knowledge of Table Store operations. If you are not familiar with Table Store or KV tables, we recommend that you first familiarize yourself with the basic concepts of Table Store (such as primary keys, partition keys, and attribute columns) before reading this topic.

1.17.2.2.2.2. Create an external table

External tables can act as interfaces between MaxCompute and Table Store: You can run a DDL statement (CREATE EXTERNAL TABLE) to import a table description in Table Store to the MaxCompute meta system. Then, you can process data in the Table Store table in the same way you process data in a MaxCompute table.

Example:

```
DROP TABLE IF EXISTS ots_table_external;
CREATE EXTERNAL TABLE IF NOT EXISTS ots_table_external
(
odps_orderkey bigint,
odps_orderdate string,
odps_custkey bigint,
odps_orderstatus string,
odps_totalprice double
)
STORED BY 'com.aliyun.odps.TableStoreStorageHandler'
-- com.aliyun.odps.TableStoreStorageHandler is a MaxCompute built-in StorageHandler for processing Table Store data. It defines the interaction between MaxCompute and Table Store. The relevant logic is implemented by MaxCompute.
WITH SERDEPROPERTIES (
-- SERDEPROPERITES is an API that provides parameter options. Two options must be specified for TableStoreStorageHandler: tablestore.columns.mapping and tablestore.table.name.
'tablestore.columns.mapping'=':o_orderkey, :o_orderdate, o_custkey,
o_orderstatus,o_totalprice',
-- tablestore.columns.mapping: This option is required. It describes the columns of Table Store tables that are accessed by MaxCompute, including primary key and attribute columns. Column names starting with a colon (:) are primary key columns in Table Store tables. In this example, :o_orderkey and :o_orderdate are primary key columns. The other column names specified are attribute columns. Table Store supports up to four primary keys of the bigint or string type. The first primary key is the partition key. When you specify a mapping, you must provide all primary key columns of the specified Table Store table. You do not have to specify all the attribute columns, only those accessed by MaxCompute.
'tablestore.table.name'='ots_tpch_orders'
-- tablestore.table.name: This option is required. It describes the names of Table Store tables that are accessed by MaxCompute. If you specify an invalid (nonexistent) Table Store table name, an error is returned and MaxCompute does not create a Table Store table with this name.
)
LOCATION 'tablestore://<*your AK id*>:<*your AK secret key*>@odps-ots-dev.cn-
hangzhou.ots.aliyuncs.com';
-- The LOCATION clause specifies the Table Store information, including the instance name and endpoint.
```

Note The preceding example maps a Table Store table to a MaxCompute external table. The subsequent operations on the Table Store table can be performed through the external table.

1.17.2.2.2.3. Access Table Store data through an external table

After you follow the preceding example to create an external table, Table Store data is imported to MaxCompute. Then, you can access Table Store data by using MaxCompute SQL statements.

Example:

```
SELECT odps_orderkey, odps_orderdate, SUM(odps_totalprice) AS totalprice
FROM ots_table_external
WHERE odps_orderkey > 5000 AND odps_orderdate >20170725 AND odps_orderdate <20170910
GROUP BY odps_orderkey, odps_orderdate
HAVING totalprice> 2000;
```

> **Note** This example uses common MaxCompute SQL statements. Table Store access details are processed internally by MaxCompute.

If you need to use a copy of data for multiple computations, you can import the data from Table Store to a MaxCompute table (internal). This is more efficient than reading the data from Table Store every time.

Example:

```
CREATE TABLE internal_orders AS
SELECT odps_orderkey, odps_orderdate, odps_custkey, odps_totalprice
FROM ots_table_external
WHERE odps_orderkey > 5000 ;
```

> **Note** internal_orders is a common MaxCompute table that has all the features of a MaxCompute internal table. These features include efficient compressed column storage and complete meta. This table is stored in MaxCompute, so it can be accessed faster than an external table in Table Store. This feature is particularly suitable for hot data that is used for multiple computations.

1.17.2.2.3. Export data from MaxCompute to Tablestore

Data interaction between MaxCompute and Tablestore includes importing data from Tablestore to MaxCompute for batch processing and exporting data processing results from MaxCompute to Tablestore. Tablestore features, such as real-time update and single-row overwriting, allow you to quickly upload offline computing results to online applications. The INSERT OVERWRITE statement is used to export data processing results from MaxCompute to Tablestore.

> **Note** MaxCompute does not create external tables in Tablestore. Before you export data to a table in Tablestore, make sure that the table exists in Tablestore. Otherwise, an error is reported.

Assume that a user creates the ots_table_external table in MaxCompute to access data of the ots_tpch_orders table in Tablestore. A data record named internal_orders is stored in MaxCompute. To process the internal_orders data record and write the processing result to Tablestore, execute the INSERT OVERWRITE TABLE statement. Example:

```
INSERT OVERWRITE TABLE ots_table_external
SELECT odps_orderkey, odps_orderdate, odps_custkey, CONCAT(odps_custkey,
'SHIPPED'), CEIL(odps_totalprice)
FROM internal_orders;
```

> **Note**
> - Tablestore is a NoSQL data storage service that stores data in the format of key-value pairs. Data outputs from MaxCompute affect only the rows that contain the primary keys of the Tablestore table. In addition, only the attribute columns specified when you create the table are updated. The columns that are not included in the external table are not modified.
> - When you execute the INSERT OVERWRITE statement on the external table, MaxCompute writes 200 data records in each batch by default. You can adjust a batch size to limit the total batch size to 4 MB.

1.17.2.3. AnalyticDB data source

1.17.2.3.1. Overview

AnalyticDB updates or processes data. If both the data processed by AnalyticDB and the data in MaxCompute are used for computation, the data from AnalyticDB must be synchronized with the data from MaxCompute. To accomplish this, you can create an external table to access the AnalyticDB data.

The following example shows how MaxCompute accesses and processes AnalyticDB data.

1.17.2.3.2. Write data to AnalyticDB

1.17.2.3.2.1. Create an external table

Run the following command to create an external table:

```
set odps.sql.hive.compatible=true;
drop table if exists ads_table_external;
 CREATE EXTERNAL TABLE if not exists ads_table_external
 (
   c_int int ,
  c_tinyint tinyint ,
  c_boolean boolean ,
  c_smallint smallint ,
  c_biging bigint ,
  c_double double ,
  c_float float ,
  --c_time datetime ,
  c_date date ,
  c_timestamp datetime ,
  c_string string
 )
 STORED BY 'com.aliyun.odps.jdbc.JdbcStorageHandler'
 location 'jdbc:mysql:host:port/databasename? useSSL=false&user=${user}&password=${password}&
table=${tablename}'
 TBLPROPERTIES(
   'mcfed.mapreduce.jdbc.input.orderby'='c_int'
   )
;
```

> **Note** The preceding command is for reference only.

1.17.2.3.2.2. Write and query data

After an external table is created, you can use it in the same way you would use a MaxCompute table. You can execute the **INSERT OVERWRITE | INTO** and **SELECT** statements to write data and query whether the write operation is successful respectively. For more information about the statements, see *DML statements* in *MaxCompute SQL*.

1.17.2.3.3. Read data from AnalyticDB

Run the following commands to read data from AnalyticDB:

```
set odps.sql.hive.compatible=true;
drop table if exists ads_read_external;
 CREATE EXTERNAL TABLE if not exists ads_read_external
 (
   c_int int ,
  c_tinyint tinyint ,
  c_boolean boolean ,
  c_smallint smallint ,
  c_biging bigint ,
  c_double double ,
  c_float float ,
  --c_time datetime ,
  c_date date ,
  c_timestamp datetime ,
  c_string string
 )
 STORED BY 'com.aliyun.odps.jdbc.JdbcStorageHandler'
 location 'jdbc:mysql:host:port/databasename? useSSL=false&user=${user}&password=${password}&
table=${tablename}'
 TBLPROPERTIES(
   'mcfed.mapreduce.jdbc.input.orderby'='c_int'
   )
;
-- Create an external table.
select * from ads_read;
-- Query and read data.
```

Note The preceding commands are for reference only.

1.17.2.4. RDS data source

1.17.2.4.1. Overview

RDS updates or processes data. If both the data processed by RDS and the data in MaxCompute is used in computation, the data in RDS must be synchronized to MaxCompute. In this case, you can access the data in RDS by creating an external table.

The following examples show how MaxCompute accesses and processes RDS data.

Note When you create an external table, the corresponding table may not exist in RDS. However, when you perform the SELECT or INSERT operation on external tables, you must create the corresponding tables in RDS first.

1.17.2.4.2. Write data to RDS

1.17.2.4.2.1. Create an external table

Run the following command to create an external table:

```
set odps.sql.hive.compatible=true;
drop table if exists rds_table_external;
 CREATE EXTERNAL TABLE if not exists rds_table_external
 (
   id bigint,
   name string,
   age tinyint
 )
 STORED BY 'com.aliyun.odps.jdbc.JdbcStorageHandler'
 location 'jdbc:mysql:host:port/databasename? useSSL=false&user=${user}&password=${password}&
table=${tablename}'
 TBLPROPERTIES(
   'mcfed.mapreduce.jdbc.input.orderby'='c_int'
   )
;
```

> **Note** The preceding command is for reference only.

1.17.2.4.2.2. Write and query data

After an external table is created, you can use it in the same way you use a MaxCompute table. You can execute the **INSERT OVERWRITE | INTO** and **SELECT** statements respectively to write data and query whether the write operation is successful. For more information about the INSERT OVERWRITE | INTO and SELECT statements, see *DML statements* in *MaxCompute SQL*.

1.17.2.4.3. Read data from RDS

Run the following commands to read data from RDS:

```
set odps.sql.hive.compatible=true;
drop table if exists rds_read_external;
 CREATE EXTERNAL TABLE if not exists rds_read_external
 (
   id int,
   name string,
   age int
 )
 STORED BY 'com.aliyun.odps.jdbc.JdbcStorageHandler'
 location 'jdbc:mysql:host:port/databasename? useSSL=false&user=${user}&password=${password}&
table=${tablename}'
 TBLPROPERTIES(
   'mcfed.mapreduce.jdbc.input.orderby'='c_int'
   )
;
-- Create an external table.
select * from rds_read;
-- Query and read data.
```

> **Note** The preceding commands are for reference only.

1.17.2.5. HDFS data source (Alibaba Cloud)

1.17.2.5.1. Overview

Alibaba Cloud Hadoop Distributed File System (HDFS) is a distributed file system designed for Alibaba Cloud computing resources such as ECS and Container Service.

HDFS allows you to manage and access data in the same way as its open-source counterpart. HDFS features such as unlimited capacity, performance scale-out, single namespace, multi-tenancy, high reliability, and high availability, can be used without the need to modify existing big data analysis applications.

MaxCompute can interact with HDFS to jointly compute external tables.

HDFS supports multiple file formats, such as **text file**, **sequence file**, **RC file**, **Parquet**, and **AVRO**. The following example use **text file** to show how MaxCompute accesses and processes HDFS data.

1.17.2.5.2. Data processing for common tables

1.17.2.5.2.1. Write data to HDFS

1.17.2.5.2.2. Read data from HDFS

Run the following command to read data from HDFS after you upload the textfile file to HDFS:

```
set odps.sql.hive.compatible=true;
drop table if exists textfile_external_read;
CREATE external TABLE if not exists textfile_external_read
(
 c_int int ,
 c_tinyint tinyint ,
 c_boolean boolean ,
 c_smallint smallint ,
 c_biging bigint ,
 c_double double ,
 c_float float ,
 c_date date ,
 c_timestamp datetime ,
 c_string string
)
 ROW FORMAT SERDE 'org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe'
 WITH SERDEPROPERTIES ('field.delim'=',')
 STORED AS textfile
 location "mcfed:dfs://host:port/user/textfile"
-- host must be set as MountPointId.
-- /user/textfile is the file path. Replace it with the actual file path.
 TBLPROPERTIES(
   "mcfed.fs.dfs.impl"="com.alibaba.dfs.DistributedFileSystem"
);
-- Create an external table.
select * from textfile_external_read;
select count(*) from textfile_external_read;
select a.c_int,a.c_boolean,a.c_string,b.value from textfile_external_read a join dfstest b on a.c_int=b.id
;
-- Query and read data.
```

> **Note** The preceding command is for reference only.

1.17.2.5.3. Data processing for partitioned tables

Run the following commands to create an external table and process its data:

```
set odps.sql.hive.compatible=true;
drop table if exists textfile_partition;
CREATE external TABLE if not exists textfile_partition
(
 id string,
 name string
)
 partitioned by (date string)
 ROW FORMAT SERDE 'org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe'
 WITH SERDEPROPERTIES ('field.delim'=',')
 STORED AS textfile
 location "mcfed:dfs://host:port/user/partition/textfile/"
-- host must be set as MountPointId.
-- user/partition/textfile/ is the file path. Replace it with the actual file path.
 TBLPROPERTIES(
   "mcfed.fs.dfs.impl"="com.alibaba.dfs.DistributedFileSystem"
);
-- Create an external table.
alter table textfile_partition add partition (date='20190218');
alter table textfile_partition add partition (date='20190219');
-- Add partitions.
insert into table textfile_partition partition(date='20190218')select '1','cd' from (select count(*) from tex
tfile_partition)a;
insert into table textfile_partition partition(date='20190219')select '2','gh' from (select count(*) from te
xtfile_partition)a;
-- Write data to HDFS.
select * from textfile_partition;
select count(*) from textfile_partition;
select a.id,a.name,b.value from textfile_partition a join dfstest b on a.id=b.id;
-- Query and read data.
```

Note The preceding commands are for reference only.

1.17.2.6. TDDL data source

1.17.2.6.1. Overview

By encapsulating MySQL, TDDL provides features such as data partitioning, read/write splitting, and failover. In most cases, TDDL can be directly used to access MySQL databases. TDDL also provides Corona connection mode. Corona is a MySQL proxy that follows the standard MySQL protocol and can use JDBC to establish a connection.

MaxCompute can access MySQL databases of TDDL. Built-in StorageHandlers encapsulate native APIs provided by Hadoop such as org, Apache, Hadoop, MapReduce, lib, and db. MySQL JDBC is used for underlying data communication.

The following topics describe how MaxCompute accesses and processes TDDL data.

> **Notice** Among create, read, update, and delete (CRUD) operations, only the following operations are supported:
>
> - MaxCompute reads data from the external table created for a MySQL database.
> - MaxCompute writes data to the external table in the append mode.

1.17.2.6.2. Prerequisites

Because many features are disabled in the MaxCompute 2.0 by default, you must manually configure the following settings:

```
set odps.sql.hive.compatible=true;
-- You must configure this item for all DDL and DML statements to be used on TDDL external tables.
```

```
set odps.sql.udf.java.retain.legacy=false;
-- You must configure this item for all DDL and DML statements to be used on TDDL external tables.
```

```
set odps.sql.jdbc.splits.num=3;
-- Set the number of splits that MaxCompute reads from the MySQL database. Maximum value: 256. De
fault value: 1. You must configure this item for the SELECT operation on TDDL external tables.
```

```
set odps.sql.jdbc.reducer.num=3;
-- Set the number of concurrent instances that MaxCompute writes to the MySQL database. Maximum
value: 256. Default value: 64. If the number of concurrent instances in the generated execution plan is
smaller than this value, no changes are made. You must configure this item for the INSERT operation o
n TDDL external tables.
```

```
set odps.sql.hive.compatible=true;
-- Use an open-source community API to obtain and parse MySQL data types. You must configure this i
tem for all DDL and DML statements to be used on TDDL external tables.
```

```
set odps.sql.type.system.odps2=true;
-- You must configure this item if new data types TINYINT, SMALLINT, INT, FLOAT, VARCHAR, TIMESTAM
P, and BINARY are involved in SQL operations such as CREATE, SELECT, and INSERT.
```

1.17.2.6.3. Create a TDDL external table

1.17.2.6.3.1. Syntax

External tables can act as interfaces between MaxCompute and databases. The method used to process MySQL unstructured data in TDDL is similar to the method to access and process OSS unstructured data. First, you must execute the CREATE EXTERNAL TABLE statement to create an external table. The syntax is as follows:

```
-- Remember to add the corresponding SET statement.
DROP TABLE [IF EXISTS] <external_table_name>;
CREATE EXTERNAL TABLE [IF NOT EXISTS] <external_table_name>
(<column schemas>)
STORED BY 'com.aliyun.odps.jdbc.JdbcStorageHandler'
location 'jdbc:mysql://path_format'
TBLPROPERTIES(
  ...
);
```

Description:

- **column schema**: supports the following data types.

Data type mapping

MySQL type	MaxCompute type
TINYINT (unsigned)	TINYINT
SMALLINT (unsigned)	SMALLINT
INT (unsigned)	INT
BIGINT (unsigned)	BIGINT
BOOLEAN	BOOLEAN
FLOAT	FLOAT
DOUBLE	DOUBLE
VARCHAR	VARCHAR
TEXT	STRING
DATE	DATE
DATETIME	DATETIME

MySQL type	MaxCompute type
DECIMAL	DECIMAL (x, y) (The default precision is (10, 0). An error is returned when overflow occurs.)

Notice Because unsigned data types are not supported in MaxCompute, loss of precision may occur if unsigned types are specified.

- `setproject odps.sql.udf.strict.mode=true;` (strict mode, which is the default mode).
  - When reading external tables: MaxCompute can read the data if unsigned data is converted to signed data without loss of precision. A RuntimeException ("value out of range") error is reported if loss of precision occurs during data type conversion.
  - When writing external tables: MaxCompute does not check data types. You can specify the SQL mode to let MySQL produce desired data check actions. For more information about SQL mode settings and data check actions, see Server SQL Modes.
- `setproject odps.sql.udf.strict.mode=false;` (non-strict mode)
  - When reading external tables: MaxCompute can read unsigned data that has been converted to signed data without loss of precision. NULL is obtained if loss of precision occurs during data type conversion.
  - When writing external tables: MaxCompute does not check data types. You can specify the SQL mode to let MySQL produce desired data check actions.

- **STORED BY:** Only built-in StorageHandlers are supported. TDDL table field types must be within the range of supported data types in **column schema**.
- **LOCATION:** Three LOCATION formats are supported.

  1. Access a MySQL database through a JDBC connection string.

  ```
  jdbc:mysql://<user>:<password>@<host>/<databaseName>? useSSL=false&table=<tableName>
  ```

  user and password are the username and password of the JDBC connection string. host is the network address of the MySQL database. databaseName is the name of the MySQL database. tableName is the name of the MySQL table corresponding to the external table.

  2. Access the MySQL database of TDDL through Corona.

  ```
  jdbc:mysql://<user>:<password>@<host>/<databaseName>? useSSL=false&table=<tableName>
  ```

  3. Access the MySQL database of TDDL through an application name.

  ```
  jdbc:mysql://dummy_host? table=<tableName>
  ```

  tableName is the name of the MySQL table corresponding to the external table. You must specify `odps.federation.jdbc.tddl.appname` in the TBLPROPERTIES clause.

> **Notice**
>
> In the first location format, MaxCompute interacts with the database through JDBC. You must enter your username and password as plaintext data, which makes this location format less secure than others. Although usernames and passwords will be hidden when LogView or DESC EXTENDED TABLE is used in MaxCompute, we recommend that you use a separate DDL statement to create an external table before using the external table.
>
> For example, a project member with higher permissions can create an external table in MaxCompute. Other project members can then directly use the external table. This prevents project members with lower permissions from using the plaintext username and password, and prevents the plaintext password from being contained in SQL scripts.

- **TBLPROPERTIES**: includes the following items.
  - **odps.federation.jdbc.condition**: specifies the filter when MaxCompute reads data from a MySQL database. The difference between `odps.federation.jdbc.condition` and `select * from text_test_jdbc_write_external where condition` :

    Suppose the MySQL table contains 100 rows of data and you want to filter the data such that you obtain 10 rows. When you execute `odps.federation.jdbc.condition` , the MySQL table is filtered and MaxCompute only reads 10 rows from the external table. When you execute `select * from text_test_jdbc_write_external where condition` , MaxCompute reads 100 rows from the MySQL table, and then obtains 10 rows.
  - **odps.federation.jdbc.colmapping**: specified column name mapping. Example:

```
-- mysql schema:  mysqlId int
 -- MaxCompute create table
 CREATE EXTERNAL TABLE if not exists table_external
 (
 odpsId1 int,
 odpsId2 int
 )
 STORED BY ...
 location ...
 TBLPROPERTIES('odps.federation.jdbc.colmapping'='odpsId1:mysqlId, odpsId2:mysqlId');
```

  - **odps.federation.jdbc.insert.type**: specifies the insertion type when data is written into the MySQL database. The following data insertion types are supported: simpleInsert, insertOnDuplicateKeyUpdate, and replaceInto. By default, the insertion type is simpleInsert if this parameter is not specified.

    The INSERT statement executed in MaxCompute is parsed into the following SQL statements to update the database:

```
insert into sqlTable xxx values xxx;
 insert into sqlTable xxx values xxx on duplicate key update col1=values(col1), col2=values(col2);
 replace into sqlTable xxx values xxx;
```

- **odps.federation.jdbc.tddl.app.access.key**: the AccessKey ID for the authorized application.
- **odps.federation.jdbc.tddl.app.secret.key**: the AccessKey Secret for the authorized application.
- **odps.federation.jdbc.tddl.appname**: the application name of TDDL. Note that if you specify this value, MaxCompute uses the application name to access the MySQL database in TDDL SDK mode.

1.17.2.6.3.2. Example

The following example shows how to use the application name to access the MySQL database of TDDL. In this example, the application name is ODPS_TDDL_TEST_APP and the table name is odps_federation_localrun_write.

Example:

```
-- Remember to add the corresponding SET statement.
drop table if exists text_test_jdbc_external;
CREATE EXTERNAL TABLE if not exists text_test_jdbc_external
(
 colmapping tinyint, --c_tinyint tinyint,
 c_smallint smallint,
 c_int int,
 c_bigint bigint,
 c_utinyint tinyint,
 c_usmallint smallint,
 c_uint int,
 c_ubigint bigint,
 c_boolean tinyint,
 --c_float float,  -- in tddl, not recommend float and double type as it may lost precision
 --c_double double,
 c_string string,
 c_datetime datetime,
 c_decimal decimal
)
STORED BY 'com.aliyun.odps.jdbc.JdbcStorageHandler'
location 'jdbc:mysql://dummy_host? table=odps_federation_localrun_write'
TBLPROPERTIES(
'odps.federation.jdbc.insert.type'='simpleInsert',
'odps.federation.jdbc.condition'='c_boolean = 1 and c_int is not null and c_utinyint=127',
'odps.federation.jdbc.colmapping'='colmapping:c_tinyint',
'odps.federation.jdbc.tddl.appname'='ODPS_TDDL_TEST_APP',
'odps.federation.jdbc.tddl.app.access.key'='your tddl app access key',
'odps.federation.jdbc.tddl.app.secret.key'='your tddl app secret key');
```

1.17.2.6.4. Read data from an external table

For complex operations such as GROUP JOIN, we recommend that you import data from external table to MaxCompute tables before performing operations. This improves the efficiency of data computation. The following example shows how to import data from an associated MySQL external table to MaxCompute.

Create a MaxCompute table

Example:

```
CREATE TABLE if not exists text_test_jdbc_max_compute
(
 c_tinyint tinyint,
 c_smallint smallint,
 c_int int,
 c_bigint bigint,
 c_utinyint tinyint,
 c_usmallint smallint,
 c_uint int,
 c_ubigint bigint,
 c_boolean tinyint,
 --c_float float,
 --c_double double,
 c_string string,
 c_datetime datetime,
 c_decimal decimal
);
```

Import data to a MaxCompute table

Example:

```
-- Remember to add the SET statement.
insert OVERWRITE TABLE text_test_jdbc_odps select * from text_test_jdbc_read_external;
```

Relationship between creating an external table and importing data to a MaxCompute table

When you create an external table, only a data channel is established between MaxCompute and MySQL. MaxCompute does not store any MySQL data. If external table data is lost from the MySQL database, it will not be available in MaxCompute.

When data is imported to a MaxCompute table, the data is actually stored in the MySQL database. If imported data is lost from the MySQL database, it can be retrieved from the MaxCompute table.

1.17.2.6.5. Write data to an external table in the append mode

The column names and data types of the external table must be consistent with those of the database to ensure that the correct data is written to the eternal table. For more information about data check actions when loss of precision occurs during data type conversion, see the column schema parameter of Syntax.

An example of the command used is as follows:

```
-- Remember to add the SET statement.
insert INTO TABLE  text_test_jdbc_external select * from text_test_jdbc_max_compute;
```

> **Note** For MySQL external tables, **insert INTO** mysql-external-table uses the same syntax as **insert OVERWRITE** mysql-external-table. No matter which statement is executed, data is appended to the table and you can use `ODPS. federation. jdbc. insert. type` to specify the data insertion type. For more information, see the **TBLPROPERTIES** parameter in Syntax. However, the preceding syntax notes are not applicable to MaxCompute tables.

1.17.3. External data sources

1.17.3.1. HDFS data source (open-source)

1.17.3.1.1. Overview

HDFS is the most widely used storage service in the open-source community. Most customers use HDFS at the underlying layer of their self-developed big data systems.

MaxCompute uses external tables to access HDFS data to facilitate data migration, interact with self-developed customer systems, and reduce the efforts and costs of customers.

HDFS supports multiple file formats, such as **text file**, **sequence file**, **RC file**, **Parquet**, and **AVRO**. The following example use **text file** to show how MaxCompute accesses and processes HDFS data.

1.17.3.1.2. Write data to HDFS

1.17.3.1.2.1. Create an external table

Run the following command to create an external table after the testfile script has been compiled:

```
set odps.sql.hive.compatible=true;
drop table if exists textfiletest;
 CREATE EXTERNAL TABLE if not exists textfiletest
 (
  c_int int ,
  c_tinyint tinyint ,
  c_boolean boolean ,
  c_smallint smallint ,
  c_biging bigint ,
  c_double double ,
  c_float float ,
  --c_time datetime ,
  c_date date ,
  c_timestamp datetime ,
  c_string string
 )
 STORED as TEXTFILE
 location 'hdfs://host:port/user/wbyy/';
-- File path /user/wbyy/ is for reference only. Replace it with the path to actually be accessed.
```

> **Note** The preceding command is for reference only.

1.17.3.1.2.2. Write and query data

After an external table is created, you can use it in the same way you would use a MaxCompute table. You can execute the **INSERT OVERWRITE | INTO** and **SELECT** statements to write data and check whether the write operation is successful respectively. For more information about the statements, see *DML statements* in *MaxCompute SQL*.

1.17.3.1.3. Read data from HDFS

Run the following command to read data from HDFS after you compile the testfile script:

```
set odps.sql.hive.compatible=true;
drop table if exists testfile_read;
 CREATE EXTERNAL TABLE if not exists testfile_read
 (
  c_int int ,
  c_tinyint tinyint ,
  c_boolean boolean ,
  c_smallint smallint ,
  c_biging bigint ,
  c_double double ,
  c_float float ,
  --c_time datetime ,
  c_date date ,
  c_timestamp datetime ,
  c_string string
 )
 STORED as TEXTFILE
 location 'hdfs://host:port/user/wbyy/';
-- File path /user/wbyy/ is for reference only. Replace it with the path to actually be accessed.
-- Create an external table.
select * from testfile_read;
-- Query and read data.
```

> **Note** The preceding command is for reference only.

1.17.3.2. MongoDB data source

1.17.3.2.1. Overview

ApsaraDB for MongoDB is a stable, reliable, and auto-scaling database service that is fully compatible with MongoDB protocols. MongoDB offers a full range of database solutions, such as disaster recovery, backup, restoration, monitoring, and alerting.

MaxCompute can interact with MongoDB for joint computation after you create external tables.

The following examples show how MaxCompute accesses and processes MongoDB data.

1.17.3.2.2. Prerequisites

You must first deploy MongoDB before creating an external table and processing MongoDB data.

1. Run the following command to enable the MongoDB service:

   ```
   bin/mongod --dbpath=./db
   ```

2. Run the following command to start the MongoDB client:

```
bin/mongo --host=${host}
```

3. Run the following command to create a database:

```
use mongodb
```

4. Run the following command to create a username and password:

```
db.createUser({user: '${user}', pwd: '${password}', roles: [{role:'readWrite',db:'mongodb'}]})
```

5. Run the following command to check whether the operation is successful. A response of 1 indicates a successful operation.

```
db.auth('${user}', '${password}')
```

1.17.3.2.3. Write data to MongoDB

1.17.3.2.3.1. Create an external table

Run the following command to create a collection in MongoDB:

```
db.createCollection("${tablename}", { capped : true, autoIndexId : true, size : 6142800, max : 10000 } )
-- The values of the size and max parameters are for reference only. Replace them with the values to actually be used.
```

After the collection has been created, run the following command to create an external table:

```
set odps.sql.hive.compatible=true;
drop table if exists mongo_table_external;
CREATE external TABLE if not exists mongo_table_external
   (
    id string,
    name string
   )
   STORED BY 'com.mongodb.hadoop.hive.MongoStorageHandler'
   location "mcfed:mongodb://${user}:${password}@host:port/mongodb.${tablename}"
   TBLPROPERTIES(
      "mcfed.mongo.input.split_size"="2",
-- input.split_size value is for reference only. Replace them with the values to actually be used.
      "mcfed.location"="mongodb://${user}:${password}@host:port/mongodb.${tablename}",
      "mcfed.mongo.input.uri"="mongodb://${user}:${password}@host:port/mongodb.${tablename}",
      "mcfed.mongo.output.uri"="mongodb://${user}:${password}@host:port/mongodb.${tablename}"
);
```

> **Note** The preceding commands are for reference only.

1.17.3.2.3.2. Write and query data

After an external table is created, you can use it in the same way that you would use a MaxCompute table. You can execute the **INSERT OVERWRITE | INTO** and **SELECT** statements to write data and check whether the write operation is successful respectively. For more information about the statements, see *DML statements* in *MaxCompute SQL*.

1.17.3.2.4. Read data from MongoDB

Run the following command to read data from MongoDB after a row of data has been inserted into a created collection:

```
set odps.sql.hive.compatible=true;
drop table if exists mongo_read_external;
CREATE external TABLE if not mongo_read_external
  (
   id string,
   name string
  )
  STORED BY 'com.mongodb.hadoop.hive.MongoStorageHandler'
  location "mcfed:mongodb://${user}:${password}@host:port/mongodb.${tablename}"
  TBLPROPERTIES(
     "mcfed.mongo.input.split_size"="2",
-- The value of the input.split_size parameter is for reference only. Replace it with the value to actuall
y be used.
     "mcfed.location"="mongodb://${user}:${password}@host:port/mongodb.${tablename}",
     "mcfed.mongo.input.uri"="mongodb://${user}:${password}@host:port/mongodb.${tablename}"
);
-- Create an external table.
select * from mongo_external;
-- Query and read data.
```

> **Note** The preceding command is for reference only.

1.17.3.3. HBase data source

1.17.3.3.1. Overview

ApsaraDB for HBase is a distributed database based on Hadoop. It can store PBs of data and be used in scenarios requiring high-throughput random read/writes.

MaxCompute can interact with HBase for joint computation after you create external tables.

The following examples show how MaxCompute accesses and processes HBase data.

1.17.3.3.2. Write data to HBase

1.17.3.3.2.1. Create an external table

Run the following command to create an external table:

```
set odps.sql.hive.compatible=true;
drop table if exists hbase_table_external;
CREATE EXTERNAL TABLE if not exists hbase_table_external
(
id string,
cfa string
)
STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
WITH SERDEPROPERTIES ('mcfed.hbase.table.name'='${table.name}','mcfed.hbase.columns.mapping':key,cf:a')
-- cf is the column family in the HBase table.
location 'hbase://host:port'
TBLPROPERTIES('hbase.table.name'='${table.name}','hbase.columns.mapping':key,cf:a', 'mcfed.zookeeper.session.timeout'='30', 'mcfed.hbase.client.retries.number'='1', "mcfed.hbase.zookeeper.quorum"="${host}", "mcfed.hbase.zookeeper.property.clientPort"="${port}");
-- The values of the zookeeper.session.timeout and hbase.client.retries.number parameters are for reference only. Replace them with the values to actually be used.
```

> **Note** The preceding command is for reference only.

1.17.3.3.2.2. Write and query data

After an external table is created, you can use it in the same way that you would use a MaxCompute table. You can execute the **INSERT OVERWRITE | INTO** and **SELECT** statements to write data and check whether the write operation is successful respectively. For more information about the statements, see *DML statements* in *MaxCompute SQL*.

1.17.3.3.3. Read data from HBase

Run the following commands to read data from HBase after you have created a table in the HBase client and inserted data into it:

```
set odps.sql.hive.compatible=true;
drop table if exists hbase_read_external;
CREATE EXTERNAL TABLE if not exists hbase_read_external
(
id string,
name string,
a string
)
STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
WITH SERDEPROPERTIES ('mcfed.hbase.table.name'='${table.name}','mcfed.hbase.columns.mapping'=':key,f1:name,f1:a')
-- f1 is the column family in the HBase table.
location 'hbase://host:port'
TBLPROPERTIES('hbase.table.name'='${table.name}','hbase.columns.mapping'=':key,f1:name,f1:a', 'mcfed.zookeeper.session.timeout'='30', 'mcfed.hbase.client.retries.number'='1', "mcfed.hbase.zookeeper.quorum"="${host}", "mcfed.hbase.zookeeper.property.clientPort"="${port}");
-- The values of the zookeeper.session.timeout and hbase.client.retries.number parameters are for reference only. Replace them with the values to actually be used.
-- Create an external table.
select * from hbase_read_external;
select count(*) from hbase_read_external;
select a.id,a.name from hbase_read_external a join hbase_test b on a.id=b.id;
-- Query and read data.
```

> **Note** The preceding commands are for reference only.

1.18. Unstructured data access and processing (inside MaxCompute)

1.18.1. Overview

MaxCompute has the following problems when processing unstructured data: MaxCompute stores data as volumes and must export generated unstructured data to an external system for processing.

To alleviate these problems, MaxCompute uses external tables to enable connections between MaxCompute and various data types. MaxCompute uses external tables to read and write data volumes as well as process unstructured data from external sources such as OSS.

The following topics describe how MaxCompute accesses and processes volume unstructured data through external tables.

1.18.2. Create a volume external table

1.18.2.1. Syntax

You must execute the CREATE EXTERNAL TABLE statement to create an external table.

```
DROP TABLE [IF EXISTS] <external_table_name>;
CREATE EXTERNAL TABLE [IF NOT EXISTS] <external_table_name>
(<column schemas>)
[PARTITIONED BY (partition column schemas)]
STORED BY '<StorageHandler>'
[WITH SERDEPROPERTIES (
                'name'='value'
                )]
LOCATION 'volume://...'
[USING '<Resourcename>']
;
```

Description:

- **STORED BY**: Two built-in StorageHandlers `com.aliyun.odps.CsvStorageHandler` and `com.aliyun.odps.TsvStorageHandler` are supported. They can be used to read and write CSV files where the column delimiter is a comma and the row delimiter is `\n` or TSV files where the column delimiter is `\t` and the row delimiter is `\n`). If the built-in StorageHandlers cannot be used for some reason, you can build a custom StorageHandler.
- **WITH SERDEPROPERTIES**: specifies table attributes such as delimiters for a custom StorageHandler.
- **LOCATION**: the location format of the table.

  Format:

  ```
  volume://[project_name]/volume_name/partition_value
  ```

  Example:

  ```
  volume://test_project/volume_data/20190102
  ```

  project_name is optional. If **project_name** is not specified, the current project is used to obtain volume data after the DML SQL statement is executed. In the preceding example, if the current project is myproject, you can use the following location format:

  ```
  volume:///volume_data/20190102
  ```

> **Notice**
>
> - The location of a non-partitioned table must point to a volume partition, instead of the volume itself.
> - The location of a partitioned table must point to the volume itself.
> - The volume path cannot contain an equal sign (=) and does not support the default standard partition path *ds=2017071* that is used when a partition is created. The partition path must be customized. The custom partition path can be any path supported by the volume. For example, if the partition path is 20190102, the path combined with volume path can be *volume://test_project/volume_data/20190102*.

- **USING**: specifies the StorageHandler resource. To use a custom StorageHandler, you must first export the custom StorageHandler as a JAR package and then add it to MaxCompute as a JAR resource.

1.18.2.2. Use the built-in StorageHandler to create an external table

You can use the built-in StorageHandler to create a partitioned or non-partitioned table.

Create a non-partitioned table

Example:

```
DROP TABLE IF EXISTS volume_ext;
CREATE EXTERNAL TABLE volume_ext
(
key string,
value string
)
STORED BY 'com.aliyun.odps.CsvStorageHandler'--The built-in StorageHandler.
LOCATION 'volume://test_project/volume_data/20190102'
;
```

Create a partitioned table

Example:

```
DROP TABLE IF EXISTS volume_ext_pt;
CREATE EXTERNAL TABLE volume_ext_pt
(
key string,
value string
)
PARTITIONED BY (ds string)
STORED BY 'com.aliyun.odps.CsvStorageHandler'--The built-in StorageHandler.
LOCATION 'volume://test_project/volume_data'
;
ALTER TABLE volume_ext_pt DROP IF EXISTS PARTITION (ds="20190102");
ALTER TABLE volume_ext_pt ADD PARTITION (ds="20190102") LOCATION "volume://test_project/volume
_data/20190102";
```

1.18.2.3. Use a custom StorageHandler to create a table

When the built-in StorageHandlers are unable to meet the requirements of your business, you can customize a StorageHandler through Java and specify some attributes of the Volume external table which you want to process data through.

The following example shows how to use a custom StorageHandler to create an external table.

Assume that the data type is TEXT and the column delimiter is "|". You can perform the following steps to create an external table:

1. Use MaxCompute Studio or MaxCompute Eclipse development plug-in to customize various Java classes.
2. Export the JAR package. In this example, the package name is **odps-volume-example.jar**.
3. Run the following command to add the JAR package to MaxCompute as a resource:

   ```
   add jar odps-volume-example.jar -f;
   ```

4. Run the following commands to create an external table:

```
DROP TABLE IF EXISTS volume_ext;
CREATE EXTERNAL TABLE volume_ext
(
key string,
value string
)
STORED BY 'com.aliyun.odps.udf.example.text.TextStorageHandler'
WITH SERDEPROPERTIES (
                'delimiter'='|'
                )
LOCATION 'volume://myproject/volume_data/20190102'
USING 'odps-volume-example.jar'
  ;
```

Note After the external table is created, you can operate the volume data through the external table.

1.18.3. Access a volume external table

Volume external tables can be accessed in the same way that you would access a MaxCompute table. Example:

```
select key,value from volume_ext_pt where ds="20190102";
```

1.19. Multi-region cluster deployment on MaxCompute

1.19.1. Overview

MaxCompute supports multi-region cluster deployment.

The control clusters is deployed in a centralize manner and configures resources as well as manages compute tasks. The Compute cluster is deployed independently for each region and handles project creation and compute task delegation.

1.19.2. Characteristics of multi-region deployment

This topic describes the characteristics of multi-region deployment.

The multi-region deployment on MaxCompute has the following features:

- One MaxCompute service instance can manage multiple clusters that are located in different cities.
- Cross-cluster data interaction is implemented within the MaxCompute service, and cross-cluster data replication and synchronization are managed based on the actual configuration.

- Metadata is stored in a centralized manner. Therefore, the infrastructure requirements, such as network connections between different data centers, are relatively high.
- A unified account system is required.
- Big data application development systems, such as DataWorks, are used in all regions and clusters.
- You must change the mode of the current MaxCompute cluster to cross-cluster for multi-region deployment.

  > **Note** The conditions and limits on changing the cluster mode are as follows:
  >
  > - The network bandwidth must be sufficient for multi-region data synchronization and link redundancy.
  > - The central-region control cluster has a relatively high latency for basic services such as DNS and TableStore. We recommend that you deploy basic services in the same data center to keep the network latency within 5 ms.
  > - The network latency between the central-region control cluster and computing clusters in other regions must must be kept within 20 ms.
  > - Clocks must be synchronized between clusters in different cities and between machines in the same cluster.
  > - The network bandwidth must be sufficient for data replication among clusters.
  > - DNS is required.
  > - In order for cross-cluster servers to communicate on the same network, the clusters must have similar network bandwidth conditions, such as GE or 10GE.

- The operations, maintenance, deployment, and upgrade for multi-region deployment are different from those for a single cluster deployment. Multi-region deployment requires higher onsite operations and maintenance capabilities.

1.19.3. Instructions on multi-region deployment

This topic describes multi-region deployment.

The instructions to implement multi-region deployment are as follows:

- Computing tasks on MaxCompute are implemented in a cluster based on data distribution within the service. Cross-cluster replication and direct reads are performed based on the cluster configuration and distribution of data.
- Data replication and synchronization can be performed between different clusters by table or partition based on the actual cluster configuration.
- You must plan the relationship between the MaxCompute project and the cluster at the business layer. You can select one or multiple clusters for a single project.

  > **Note** If you select multiple clusters for a project, data replication is carried out among these clusters.

- If the project contains business that cannot implement cross-cluster computing, you can distribute data to different clusters and divide the computing tasks based on their distribution.

> Note Cross-cluster data replication and management requires management policies.

- The bandwidth between clusters in different remote data centers must be sufficient for data replication or read-only operations.
- Replication and read-only operations across clusters in MaxCompute involving large amounts of data will consume all of the bandwidth between the two clusters, as the two data centers share bandwidth.
- A cluster failure in the primary data center will affect the entire service because the primary data center stores information such as metadata and accounts.
- When the secondary data center fails, the project where data is stored on the cluster and the O&M of services are affected.

> Note If project data is independently stored in the primary data center, the failure of the secondary data center will not affect computing tasks of the project.

- In general scenarios, data is partitioned and replicated based on business characteristics, and computing tasks are performed based on data types in different clusters. The combined results of different MaxCompute tasks are applied.

1.19.4. Multi-region deployment examples

1.19.4.1. Synchronize table data among multiple clusters

This topic provides an example on how to synchronize table data among multiple clusters in multi-region deployment scenarios.

Prerequisites

- When you create a project in the AdminConsole, you have selected two clusters and set one as the default cluster. The following figure shows an example.

> Note
> - In this example, the project is multiregion, and AT-MDU-TEST and AT-5KN are selected for it, with AT-MDU-TEST as the default cluster.
> - The URL of Apsara Stack MaxCompute AdminConsole is **http://{odps_ag}:9090**, which is port 9090 of MaxCompute AG.
> - The operation entry to create the project is **MaxCompute Configuration > Project Management > Create Project**.

- You have configured cross-cluster replication for the project. The following example demonstrates how to configure it.
  i. Choose **MaxCompute Configuration > Global Cross-cluster Replication Configuration** to go to the **Global Cross-cluster Replication Configuration** page.
  ii. In the Add Item part of the **InfoBetweenClusters** section, set key to **AT-5KN#AT-MDU-TEST**, set both availableBandwith and totalBandwith to **2000**, and click **add**.
  iii. Choose **MaxCompute Configuration > Project Management**. Find multiregion and click **Cross-cluster Replication Configuration**.

iv. In the dialog box that appears, configure the parameters, as shown in the following figure.

v. Click **Save** and then click **Start Replication**.

Procedure

Example:

1. In the AG of the default cluster AT-MDU-TEST, construct an upload tunnel data file in the directory of the same level as console, such as `echo "testtest" > uploaddata`.
2. Go to the console command line and run the following commands to create a table and insert data into the table:

```
use multiregion;
create table t1 (s string);
tunnel upload uploaddata t1;
```

3. Run the following command to check whether the data is inserted into the table:

```
select * from t1;
```

4. In the AG of AT-MDU-TEST, view the Apsara Distributed File System directory for this table. Run the following command to check whether data exists in the directory:

```
pu ls product/aliyun/odps/multiregion/data/t1
```

5. In the AG of AT-5KN, view the Apsara Distributed File System directory for this table. Run the following command to check whether data exists in the directory:

```
pu ls /apsara/odps/mdutesting/multiregion/data/t1
```

6. If data is displayed after you perform both steps 4 and 5, the cross-cluster data synchronization operation is successful.

1.19.4.2. Query the status of data synchronization between primary and secondary clusters

This topic provides an example on how to query the status of data synchronization between the primary and secondary clusters in multi-region deployment scenarios.

Prerequisites

- When you create a project in the AdminConsole, you have selected two clusters and set one as the default cluster. The following figure shows an example.

> **Note**
>
> - In this example, the project is multiregion, and AT-MDU-TEST and AT-5KN are selected for it, with AT-MDU-TEST as the default cluster.
> - The URL of Apsara Stack MaxCompute AdminConsole is **http://{odps_ag}:9090**, which is port 9090 of MaxCompute AG.
> - The operation entry to create the project is **MaxCompute Configuration > Project Management > Create Project**.

- You have configured cross-cluster replication for the project. The following example demonstrates how to configure it.
  i. Choose **MaxCompute Configuration > Global Cross-cluster Replication Configuration** to go to the **Global Cross-cluster Replication Configuration** page.
  ii. In the Add Item part of the **InfoBetweenClusters** section, set key to **AT-5KN#AT-MDU-TEST**, set both availableBandwith and totalBandwith to **2000**, and click **add**.
  iii. Choose **MaxCompute Configuration > Project Management**. Find multiregion and click **Cross-cluster Replication Configuration**.
  iv. In the dialog box that appears, configure the parameters, as shown in the following figure.
  v. Click **Save** and then click **Start Replication**.

Procedure

Example:

1. Compile the bodychecksync configuration file, which is used to send admintask.

```
<Instance>
 <Job>
  <Comment>
  </Comment>
  <Priority>1</Priority>
  <Tasks>
   <Admin>
   <Name>task_1</Name>
   <Comment>test</Comment>
   <Config>
    <Property>
     <Name>PROJECT</Name>
     <Value>multiregion</Value>
    </Property>
    <Property>
     <Name>CLUSTER</Name>
     <Value>AT-MDU-TEST</Value>
    </Property>
   </Config>
   <Command>GET_UNREPLICATED_OBJECTS</Command>
   </Admin>
  </Tasks>
  <DAG>
   <Comment/>
   <RunMode>Sequence</RunMode>
  </DAG>
 </Job>
</Instance>
```

2. Compile the header.

```
content-type: application/xml
```

3. Run the following command to send admintask:

```
CLTrelease/bin/odpscmd -e "http post  /projects/admin_task_project/instances -header=header -
content=bodychecksync;"
```

4. Run the following command to check the instance execution results:

```
CLTrelease/bin/odpscmd  --project=admin_task_project -e "wait 20180711050550317gnege3ms2;"
```

5. Access the LogView URL generated in step 4 in a browser.
6. On the page that appears, click **Detail**. The status of data synchronization between the

primary and secondary clusters is displayed.

1.19.4.3. Cross-region direct read

This topic provides examples of cross-region direct read operations in multi-region deployment scenarios.

Cross-region direct read can be implemented with or without cross-cluster access.

> **Note** When cross-cluster access is not configured and the data volume is large, cross-region direct read takes a long period of time.

Direct read when cross-cluster access is not configured

Example:

1. In the AdminConsole, create two projects: testmdu and testcross5kn.

   > **Note**
   > - In this example, AT-MDU-TEST and AT-5KN are selected for testmdu, with AT-MDU-TEST as the default cluster. AT-5KN is selected for testcross5kn and serves as the default cluster.
   > - The URL of Apsara Stack MaxCompute AdminConsole is **http://{odps_ag}:9090**, which is port 9090 of MaxCompute AG.
   > - The operation entry to create the projects is **MaxCompute Configuration > Project Management > Create Project**.

2. Create tables for testmdu and testcross5kn.

   ```
   create table testrep(s string );
   create table tablecross5kn (s string );
   ```

3. Construct some data for tables testrep and tablecross5kn.
4. Run the following commands to read the table data in testmdu directly from testcross5kn:

   ```
   use testcross5kn;
   select * from testmdu.testrep;
   ```

   > **Note** If the specified data is returned, the cross-region direct read operation is successful.

Direct read when cross-cluster access is configured

Example:

1. In the AdminConsole, create two projects: testmdu and testcross5kn.

> **Note**
>
> - In this example, AT-MDU-TEST and AT-5KN are selected for testmdu, with AT-MDU-TEST as the default cluster. AT-5KN is selected for testcross5kn and serves as the default cluster.
> - The URL of Apsara Stack MaxCompute AdminConsole is http://{odps_ag}:9090, which is port 9090 of MaxCompute AG.
> - The operation entry to create the projects is **MaxCompute Configuration** > **Project Management** > **Create Project**.

2. Create tables for testmdu and testcross5kn.

```
create table testrep(s string );
create table tablecross5kn (s string );
```

3. Construct some data for tables testrep and tablecross5kn.
4. Configure cross-cluster replication for testmdu.

> **Note** Choose **MaxCompute Configuration** > **Project Management**. Find testmdu and click **Cross-cluster Replication Configuration**.

5. Run the following commands to read the table data in testmdu directly from testcross5kn:

```
use testcross5kn;
select * from testmdu.testrep;
```

> **Note** If the specified data is returned, the cross-region direct read operation is successful.

1.19.4.4. Cross-region JOIN

This topic provides an example of cross-region JOIN in multi-region deployment scenarios.

Example:

1. In the AdminConsole, create two projects: crosssregion and crossregion02.

> **Note**
>
> - In this example, AT-MDU-TEST and AT-70N are selected for crosssregion, with AT-MDU-TEST as the default cluster. AT-70N is selected for crossregion02 and serves as the default cluster.
> - The URL of Apsara Stack MaxCompute AdminConsole is http://{odps_ag}:9090, which is port 9090 of MaxCompute AG.
> - The operation entry to create the projects is **MaxCompute Configuration** > **Project Management** > **Create Project**.

2. Configure cross-cluster replication for crosssregion.

> Note Choose MaxCompute Configuration > Project Management. Find crosssregion and click Cross-cluster Replication Configuration.

3. Create a table named business for crosssregion.

```
create table business(bid bigint,name string,phone string,address string,region string);
```

4. Construct some data for the table.
5. Run the following command to import data into the table:

```
tunnel upload business business;
```

6. Create a table named product for crossregion02.

```
create table if not exists product(pid bigint,name string,type string,color string,bid bigint);
```

7. Construct some data for the table.
8. Run the following command to import data into the table:

```
tunnel upload product product;
```

9. Run the following command in the console to obtain specific data from the preceding two tables:

```
select pro.pid,pro.name,pro.type,pro.color,bus.name,bus.phone from crossregion02.product pro joi
n crosssregion.business bus on pro.bid=bus.bid where bus.region='Shanghai';
```

> Note If the specified data is returned, the cross-region JOIN operation is successful.

1.20. Security solution

1.20.1. Target users

This User Guide is intended for all owners and administrators of MaxCompute projects, and users interested in the MaxCompute multi-tenant data security system. The MaxCompute multi-tenant data security system includes:

- User authentication
- User and authorization management of projects
- Cross-project resource sharing
- Project protection

1.20.2. Quick start

Add a user and grant permissions to the user

Scenario: Jack is the administrator of the prj1 project. A new team member Alice, who already has an Alibaba Cloud account (alice@aliyun.com), applies to join the project. Alice applies for the following permissions: viewing table lists, submitting jobs, and creating tables.

The admin performs the following operations to add Alice to the project:

```
use prj1
add user aliyun$alice@aliyun.com;
-- Add a user.
grant List, CreateTable, CreateInstance on project prj1 to user aliyun$alice@aliyun.com
-- Grant permissions to the user.
```

Add a user and grant permissions to the user using an ACL

Scenario: Jack is the administrator of prj1. Three new members Alice, Bob, and Charlie join in as data reviewers. They require the following permissions: viewing table lists, submitting jobs, and reading the table userprofile.

The project administrator can use object-based ACL authorization in this scenario.

The operations are as follows:

```
use prj1
add user aliyun$alice@aliyun.com
-- Add a user.
add user aliyun$bob@aliyun.com
add user aliyun$charlie@aliyun.com
create role tableviewer
-- Create a role.
grant List, CreateInstance on project prj1 to role tableviewer; --Grant permissions to the role
-- Grant permissions to the role.
grant Describe, Select on table userprofile to role tableviewer
grant tableviewer to aliyun$alice@aliyun.com
-- Grant the tableviewer role to a user.
grant tableviewer to aliyun$bob@aliyun.com
grant tableviewer to aliyun$charlie@aliyun.com
```

Package and share resources

Scenario: Jack is the administrator of prj1. John is the administrator of prj2. Due to business requirements, Jack wants to share some resources of prj1 (such as datamining.jar and sampletable) to John's prj2. A user in prj2 (Bob) requires access to these resources. The prj2 administrator can configure an ACL or policy to automatically authorize prj2 users to access these resources, without the intervention of Jack.

The operations are as follows:

1. Prj1 administrator Jack creates a resource package in prj1.

```
use prj1
create package datamining
-- Create a package.
add resource datamining.jar to package datamining
-- Add resources to the package.
add table sampletable to package datamining
-- Add the table to the package.
allow project prj2 to install package datamining
-- Share the package to prj2.
```

2. Prj2 administrator Bob installs the package in prj2.

```
use prj2
install package prj1.datamining
-- Install the package.
describe package prj1.datamining
-- View the resource list of the package.
```

3. Configure automatic authorization for Bob on the package.

```
use prj2
grant Read on package prj1.datamining to user aliyun$bob@aliyun.com
-- Use an ACL to allow Bob to use the package.
```

> **Note** For more information about cross-project resource sharing, see Cross-project resource sharing.

Configure project protection

Scenario: Jack is the administrator of project prj1. This project contains sensitive data such as user IDs and shopping records. The project also stores many data mining algorithms to which the organization holds intellectual property rights. Jack wants to protect the sensitive data and algorithms in the project. He wants the data to be accessible only to users in the project. The data must not be able to flow out of the project.

The operations are as follows:

```
use prj1
set ProjectProtection=true
-- Enable project protection.
```

When project protection is enabled, data in the project can flow only within the project. Data cannot flow out. In some cases, for example, a user (Alice) requires to export data tables for business purposes. This operation is approved by the project administrator. MaxCompute provides two methods to export data from a protected project.

Method 1: Create an exception policy. For more information, see Data export methods when project protection is enabled.

1. Create a policy file. Create a policy file named */tmp/exception_policy.txt*. It only allows Alice to export t1 from prj1 using a SQL task. The policy is defined as follows:

```
{
"Version": "1",
"Statement": [{
"Effect":"Allow",
"Principal":"ALIYUN$alice@aliyun.com",
"Action":["odps:Describe","odps:Select"],
"Resource":"acs:odps:*:projects/prj1/tables/t1",
"Condition":{
"StringEquals": { "odps:TaskType":"SQL"
}
}
}]
```

2. Configure the exception policy.

```
use prj1
-- Enable project protection and configure an exception policy.
set ProjectProtection=true with exception /tmp/exception_policy.txt
```

> **Note** When you configure the exception policy, ensure that the principal cannot update the data resources or recreate an object with the same name (using DROP TABLE and CREATE TABLE). This prevents data leakage due to time-of-check to time-of-use (TOC2TOU).

Method 2: Configure trusted projects. Configure prj2 as a trusted project of prj1 to enable data flow from prj1 to prj2. For more information, see Data export methods when project protection is enabled.

```
use prj1
        add trustedproject prj2
```

> **Note** In MaxCompute, package-based resource sharing and project protection are mutually independent mechanisms that take effect at the same time, but their functions are mutually restrictive.

In MaxCompute, resource sharing has a higher priority than project protection. This means, if an object in a protected project is shared with other projects through the package mechanism, cross-project access to this object is not subject to the project protection rules.

1.20.3. User authentication

The main purpose of user authentication is to verify the identity of a request sender. Authentication typically includes:

- Verifying the true identity of a message sender
- Checking whether the message was tampered with before it is received.

1.20.4. Project user and authorization management

1.20.4.1. Overview

Projects are the foundation of the MaxCompute multi-tenant system and the basic units of data management and computing. When you create a project, you are automatically the project owner. All objects in the project, such as tables, instances, resources, and UDFs, belong to you. Objects in the project can only be accessed by the owner and users that are authorized by the owner.

This topic describes users, roles, and authorization management of projects. For example, Alice is the owner of test_project, and another user from Alice's project team requests to access the resources in test_project. Alice can use the methods described in this topic to perform user and authorization management. If a user that wants access to Alice's project is not from her project team, Alice can implement cross-project sharing. For more information, see Cross-project resource sharing.

1.20.4.2. User management

Add a user

If Alice (the project owner) decides to authorize another user, she must add the user to this project. Only users in a project can be authorized.

Run the following command to add a user:

```
add user <full_username>
-- Add a user to a project.
```

Remove a user

When a user leaves the project team, Alice needs to remove the user from the project. After a user is removed from the project, the user no longer has any access permissions on project resources.

Run the following command to remove a user from a project:

```
remove user <full_username>
-- Remove a user from a project.
```

Note

- After a user is removed, the user no longer has any access permissions on project resources.
- Before you remove a user who has been assigned a role, you must first revoke the role. For information about roles, see Role management.
- After a user is removed, the ACL authorization related to the user is retained. However, the policy authorization at the role level is revoked, and the policy authorization at the project level is retained. If the user is added to the project again, the previous ACL authorization of the user is re-activated.
- MaxCompute does not support complete removal of a user and the relevant authorization data.

1.20.4.3. Role management

A role is a collection of access permissions. A role can be used to assign the same permissions to a group of users. Role-based authorization can greatly simplify the authorization process and reduce authorization management costs. When granting permissions to users, you should consider using role-based authorization.

An admin role is automatically created when a project is created. This role is granted permissions to access all objects of the project, manage users and roles, and authorize users and roles. Compared with the project owner, the admin role cannot assign another user with the admin role, configure security rules for a project, or change the authentication model of the project. Permissions of the admin role cannot be modified.

The role management commands are as follows:

```
create role <rolename>
-- Create a role.
drop role <rolename>
-- Delete a role.
grant <rolename> to <username>
-- Assign a role to a user.
revoke <rolename> from <username>
-- Revoke the role of a user.
```

Note When you delete a role, MaxCompute checks whether there are users assigned with this role. If the role is assigned to users, the role fails to be deleted. To delete the role, you must revoke this role from all users.

1.20.4.4. ACL authorization actions

Authorization usually involves three elements: subject, object, and action. In MaxCompute, a subject is the user, there are various types of objects in a project, and actions are performed on objects. Different types of objects support different actions.

MaxCompute projects support the following object types and actions:

Object types and actions

Object	Action	Description
Project	Read	Check the information about the project itself (not including any objects of the project), such as CreateTime.
Project	Write	Update the information of the project itself (not including any objects of the project), such as Comments.
Project	List	View a list of all types of objects in the project.
Project	CreateTable	Create a table in the project.
Project	CreateInstance	Create an instance in the project.
Project	CreateFunction	Create a function in the project.
Project	CreateResource	Create resource in the project.
Project	CreateJob	Create a job in the project.
Project	CreateVolume	Create a volume in the project.
Project	All	All the permissions above.
Table	Describe	Read the metadata of the table.
Table	Select	Read the information of the table.
Table	Alter	Alter the metadata of the table; add or drop partitions.
Table	Update	Override or add data to the table.
Table	Drop	Drop the table.
Table	All	All the preceding permissions.
Function	Read	Read and execute permissions.
Function	Write	Update.
Function	Delete	Delete.
Function	All	All the preceding permissions.
Resource, instance, job, volume	Read	Read permissions.
Resource, instance, job, volume	Write	Update permissions.

Object	Action	Description
Resource, instance, job, volume	Delete	Delete permissions.
Resource, instance, job, volume	All	All the preceding permissions.

Note In the preceding permissions, the CreateTable action of project objects, as well as the Select, Alter, Update, and Drop actions of table objects, must be used together with the CreateInstance action of project objects. Before using the preceding permissions to complete actions, you must assign the CreateInstance permission.

After adding users or creating roles, these users or roles should be authorized. The ACL authorization mechanism of MaxCompute is object-based. Authorization data (the access control list, or ACL) is considered as a sub-resource of an object). Therefore, ACL authorization can be performed only when the objects exist. When the objects are deleted, authorized permission data is automatically deleted.

The ACL of MaxCompute supports authorization using commands like SQL92-defined GRANT/REVOKE commands. Use the corresponding authorization commands to authorize existing project objects or revoke their authorization.

Command syntax:

```
grant actions on object to subject
revoke actions on object from subject
actions ::= action_item1, action_item2, ...
object ::= project project_name | table schema_name | instance inst_name | function func_name | resou
rce res_name
subject ::= user full_username | role role_name
```

Note

The ACL authorization commands of MaxCompute do not support the [WITH GRANT OPTION] parameter. That is, when user A authorizes user B to access an object, user B cannot authorize user C to access the same object. Therefore, all authorization actions must be completed by users with at least one of the following identities:

- Project owner
- Users with the admin role in the project
- Object creators in the project

ACL authorization example:

Scenario: Users alice@aliyun.com and bob@aliyun.com are new members of test_project. In test_project, they must submit jobs, create data tables, and view existing objects of the project. The administrator then takes the following authorization actions:

```
use test_project
-- Open a project.
security
add user aliyun$alice@aliyun.com
-- Add a user.
add user aliyun$bob@aliyun.com
-- Add a user.
create role worker
-- Create a role.
grant worker TO aliyun$alice@aliyun.com
-- Assign a role.
grant worker TO aliyun$bob@aliyun.com
-- Assign a role.
grant CreateInstance, CreateResource, CreateFunction, CreateTable, List ON PROJECT test_project TO
ROLE worke r
-- Authorize a role.
```

1.20.4.5. View permissions

MaxCompute allows you to view permissions in different dimensions. For example, you can view permissions of a specified user, permissions of a specified role, or the authorization list of a specified object.

View the permissions of a user

```
show grants
-- View the access permissions of the current user.
show grants for <username>
-- View the access permissions of a specified user. Only project owners and administrators can view th
e access permissions of a specified user.
```

View the permissions of a role

```
describe role <rolename>
-- View the access permissions granted to a specified role.
```

View the authorization list of an object

```
show acl for <objectName> [on type <objectType>]
-- View the authorization list of a specified object.
```

> **Note** If [on type <objectType>] is not specified, the default type is table.

MaxCompute uses characters A, C, D, and G to indicate the permissions of users or roles. The characters are described as follows:

- A: allow. Access is allowed.
- D: deny. Access is denied.
- C: condition. This is a conditional authorization. This character appears only in the policy authorization system. For more information, see Condition block structure.
- G: grant. You can grant permissions to this object.

Example:

```
odps@test_project> show grants for aliyun$odpstest1@aliyun.com
[roles]
dev
Authorization Type: ACL
[role/dev]
A projects/test_project/tables/t1: Select [user/odpstest1@aliyun.com]
A projects/test_project: CreateTable | CreateInstance | CreateFunction | List
A projects/test_project/tables/t1: Describe | Select
Authorization Type: Policy
[role/dev]
AC projects/test_project/tables/test_*: Describe
DC projects/test_project/tables/alifinance_*: Select [user/odpstest1@aliyun.com]
A projects/test_project: Create* | List
AC projects/test_project/tables/alipay_*: Describe | Select
Authorization Type: ObjectCreator
AG projects/test_project/tables/t6: All
AG projects/test_project/tables/t7: All
```

1.20.5. Cross-project resource sharing

1.20.5.1. Overview

You are the owner or administrator (admin role) of a project, and someone requests to access resources of your project. If the applicant is a member of your project team, we recommend that you use the user and authorization management features for your project. For more information, see User and authorization management of projects. If the applicant is not a member of your project team, you can use the package-based resource sharing feature described in this topic.

A package is used to share data and resources across projects. It can be used to implement cross-project user authorization. The following scenario describes a problem that can only be resolved effectively with the package mechanism.

Members of the Alifinance project need to access Alipay project data. The Alipay project administrator adds Alifinance project users to the Alipay project, and then grants the new users common permissions. For security concerns, the Alipay project administrator does not want to authorize every user of the Alifinance project team. A mechanism is required to allow the Alifinance project administrator to control access to the authorized objects.

By using the package feature, the Alipay project administrator can package the objects that the Alifinance team needs to access, and then allow the package to be installed in the Alifinance project. After installing the package, the Alifinance project administrator can decide whether to grant permissions on the package to users in the Alifinance project.

A package involves two subjects: package creator and package user. The package creator provides resources. The package creator packages the resources to be shared and the corresponding access permissions, and provides the package receiver with the permissions to install and use the package. The package user consumes the resources. After installing the package published by the package creator, the package user can directly access the resources.

The following topics describe the operations that can be performed by a package creator and package user.

1.20.5.2. Package usage

1.20.5.2.1. Operations for package creators

Create a package

Run the following commands to create a package:

```
create package <pkgname>
```

Delete a package

Run the following commands to drop a package:

```
delete package <pkgname>
```

Add a resource to be shared to the package

Run the following commands to add a resource to the package:

```
add project_object to package package_name [with privileges <privileges>]
remove project_object from package package_name
project_object ::= table table_name | instance inst_name | function func_name | resource res_name
privileges ::= action_item1, action_item2, ...
```

Note

- The types of supported objects exclude projects, so you cannot use a package to create objects in other projects.
- In addition to the objects, the operation permissions on the objects are also added to the package. When not passed [with privileges Privileges] When you specify an action permission, the default is read-only, that is, read/describe/select. An object (resource) and its permissions are considered as a whole. You can delete resources in a package. The permissions are revoked when resources are deleted.

Allow other projects to use a package

Run the following commands to allow other projects to use a package:

```
allow project <prjname> to install package <pkgname> [using label <number>]
```

Revoke the permission for other projects to use a package

Run the following commands to revoke another project's permission to use package:

```
disallow project <prjname> to install package <pkgname>
```

View the list of packages already created and installed

Run the following commands to view the list of packages already created and installed:

```
show packages
```

View details of a package

Run the following commands to view details of a package:

```
describe package <pkgname>
```

1.20.5.2.2. Operations for package users

The installed package is a type of independent object in MaxCompute. To access resources in a package (other projects' resources shared with you), you must have the permission to read the package. If you do not have read permissions, submit an application to the project owner or admin for the permissions. The project owner or admin can grant the permissions by using ACL authorization or policy authorization.

For example, the following ACL authorization rule allows user odps_test@aliyun.com to access resources in a package:

```
use prj2 security
install package prj1.testpkg
grant read on package prj1.testpackage to user aliyun$odps_test@aliyun.com
```

The following policy authorization rule allows any user in prj2 to access resources in a package:

```
use prj2
install package prj1.testpkg
put policy /tmp/policy.txt
```

The contents of /tmp/policy.txt are as follow:

```
{
"Version": "1", "Statement": [{
"Effect":"Allow",
"Principal":"*",
"Action":"odps:Read", "Resource":"acs:odps:*:projects/prj2/packages/prj1.testpkg"
}]
}
```

Install a package

Run the following commands to install a package:

```
install package <pkgname>;
```

> **Note** The pkgName of a package to be installed must be in the format of <projectName>.<packageName>.

Uninstall package

Run the following commands to uninstall a package:

```
uninstall package <pkgname>;
```

> **Note** The pkgName of a package to be uninstalled must be in the format of <projectName>.<packageName>.

View packages

Run the following commands to view packages:

```
show packages
-- View the list of packages already created and installed.
describe package <pkgname>
-- View details of a package.
```

1.20.6. Project protection

1.20.6.1. Overview

Some enterprises (such as financial institutions and military enterprises) have high data security requirements. For example, their employees can only perform their jobs in the workplace, and are not allowed to take work materials out of the office. All USB ports on office computers are disabled. These measures aim to prevent leakage of sensitive data.

For example, you are a MaxCompute project administrator in charge of a project with sensitive data. The data must not be shared to other projects. You are required to perform the following configurations to prohibit all operations that could result in data outflow.

1.20.6.2. Data protection

MaxCompute provides a project protection mechanism that prohibits operations that introduce data leakage risks. You can simply configure your project as follows to enable project protection:

```
set security.ProjectProtection=true
-- Enable project protection. This rule allows inbound data flows, but prohibits outbound data flows.
```

After project protection is enabled, the data flow of the project is controlled. Data can flow in, but cannot flow out.

Project protection is disabled by default (ProjectProtection = false). If you have access permissions on multiple projects, you can use any cross-project data access to migrate data between projects. If a project stores highly-sensitive data, the administrator must configure a project protection mechanism.

1.20.6.3. Data export methods when project protection is enabled

After you enable project protection, you may soon encounter this situation: A user (Alice) submits a request to export the data of a table from the project. It is verified that this table contains no sensitive data. MaxCompute provides two methods to export data after project protection is enabled.

Configure an exception policy

The project owner can run the following command to attach an exception policy when enabling project protection:

```
SET ProjectProtection=true WITH EXCEPTION <policyFile>
```

> **Note** This policy mechanism is different from the policy-based authorization mechanism (though the command syntax is the same). This policy describes exceptions of the project protection mechanism. All access requests matching the policy are not subject to the project protection rules.

Example:

The following policy allows the user Alice@aliyun.com to export data out of the alipay project when performing the SELECT operation on the alipay.table_test table in a SQL task:

```
{
"Version": "1", "Statement": [{
"Effect":"Allow", "Principal":"ALIYUN$Alice@aliyun.com",
"Action":["odps:Select"],
"Resource":"acs:odps:*:projects/alipay/tables/table_test",
"Condition":{
"StringEquals": { "odps:TaskType":["DT", "SQL"]
}
}
}]
}
```

Note

- The preceding exception policy does not grant any permissions. If Alice does not have the SELECT permission on alipay.table_test, the preceding exception policy does not allow Alice to export data. Project protection specifies data flow control, not access control. Data flow control is effective only when a user can access the target data.
- Data leakage due to TOC2TOU (also known as the race condition problem) arises in the following situation:
  i. [TOC stage] User A submits an application to the project owner to export table t1. The project owner verifies that t1 does not contain sensitive data. The project owner configures an exception policy, which allows user A to export t1.
  ii. A malicious user changes the content of t1 by writing sensitive data to it.
  iii. [TOU stage] User A exports t1. The t1 exported by the user is not the same t1 that was authorized by the project owner.

  Suggestions on TOC2TOU prevention: For a table that a user applies to export, the project owner must make sure that no other user (including admins) can update the table or create a table with the same name (using DROP TABLE and CREAT TABLE). In the preceding TOC2TOU scenario, we recommend that the project owner create a snapshot of t1 in step 1. Then, create an exception policy for the user to use this snapshot. Do not grant the admin role to any users.

Configure a trusted project

If the current project is protected, and the target project is a trusted project of the current project, data flows to the target project are not subject to the project protection rules. If each project in a group is mutually configured as trusted projects, the group is considered a trusted project group. Data can flow freely within the group, but cannot flow out.

Run the following command to manage trusted projects:

```
ist trustedprojects
-- Show all trusted projects of the current project.
add trustedproject <projectname>
-- Add a trusted project of the current project.
remove trustedproject <projectname>
-- Remove a trusted project of the current project.
```

1.20.6.4. Resource sharing and data protection

In MaxCompute, package-based resource sharing and project protection are mutually independent mechanisms that take effect at the same time, but their functions are mutually restrictive.

In MaxCompute, resource sharing takes precedence over project protection. If a data object is shared to users in other projects through resource sharing, the project protection rules will not apply to this data object.

To prevent data outflow from the project, after you enable project protection (ProjectProtection=true), you must verify the following points:

- Make sure that no trusted projects are added. If one is added, evaluate possible risks.
- Make sure that no exception policies are configured. If one is configured, evaluate possible risks, especially risks due to TOC2TOU.
- Check whether package data sharing is not in use. If package data sharing is in use, make sure that the package contains no sensitive data.

1.20.7. Project security configuration

MaxCompute is a multi-tenant data processing platform. Different tenants may have different data security requirements. MaxCompute provides project-level security configuration to satisfy data security requirements of different tenants. Project owners can customize their external accounts and authentication models as required.

MaxCompute supports multiple orthogonal authorization mechanisms, such as ACL-based authorization, policy-based authorization, and implicit authorization (for example, an object creator is automatically authorized to access the object). However, not all users require these security mechanisms. You can configure an authentication model that best suits your business demands and usage habits.

```
show SecurityConfiguration
-- View the security configuration of the project.
set security.CheckPermissionUsingACL=true/false
-- Enable or disable ACL-based authorization. Default value: true.
set security.CheckPermissionUsingPolicy=true/false
-- Enable or disable policy-based authorization. Default value: true.
set security.ObjectCreatorHasAccessPermission=true/false
-- Allow or disallow an object creator to be granted the object access permission by default. Default v
alue: true.
set security.ObjectCreatorHasGrantPermission=true/false
-- Allow or disallow an object creator to be granted the authorization permission by default. Default v
alue: true.
set security.LabelSecurity=true/false
-- Enable or disable the label security policy.
set security.ProjectProtection=true/false
-- Enable or disable project protection to allow or prohibit data transfer from the project.
```

1.20.8. Authorization policies

1.20.8.1. Policy overview

Policy authorization is a principal-based authorization. Permission data authorized by policy (that is, access policy) is considered as a type of sub-resource of the authorization subject. Policy authorization can be performed only if the subject exists. When a subject is deleted, their authorization data is deleted automatically. Policy authorization uses an access policy language customized for MaxCompute to allow or deny subjects access to project objects.

Policy authorization is a new authorization mechanism mainly used to handle complicated authorization scenarios that ACL authorization struggles to deal with, such as:

- Authorize a group of objects, such as all functions and all tables starting with taobao, at a time.
- For authorizations with restrictive conditions, such as one that takes effect only in a specified period, one that takes effect only if the requester initiates the request from a specified IP addresses, or one that allows the user to use SQL only (disallowing other tasks) to access a table.

The command format of policy authorization is as follows:

```
GET POLICY;
-- Read the project policy.
PUT POLICY <policyFile>;
-- Set (overwrite) the project policy.
GET POLICY ON ROLE <roleName>;
-- Read the policy of a role in the project.
PUT POLICY <policyFile> ON ROLE <roleName>;
-- Set (overwrite) the policy of a role in the project.
```

> **Note** MaxCompute currently supports project policies and role policies. A project policy applies to all users of the project, while a role policy applies only to users to whom the role is assigned. You must specify a principal (user) for project policies, but you cannot specify a principal for role policies, because the role will be assigned to users.

An example of project policy authorization is as follows:

Scenario: Authorized user alice@aliyun.com can only submit a request before 23:59:59 2017-11-11 from an IP address in the subnet 10.32.180.0-23, and can only perform the CreateInstance, CreateTable, and List operations in test_project. No tables in test_project can be dropped.

The policy is as follows:

```
{
"Version": "1", "Statement": [{
"Effect":"Allow", "Principal":"ALIYUN$alice@aliyun.com",
"Action":["odps:CreateTable","odps:CreateInstance","odps:List"],
"Resource":"acs:odps:*:projects/test_project",
"Condition":{ "DateLessThan": {
"acs:CurrentTime":"2017-11-11T23:59:59Z"
},
"IpAddress": { "acs:SourceIp":"10.32.180.0/23"
}
}
},
{
"Effect":"Deny", "Principal":"ALIYUN$alice@aliyun.com", "Action":"odps:Drop", "Resource":"acs:odps:
*:projects/test_project/tables/*"
}]
}
```json
```
```

```json
{
"Version": "1", "Statement": [{
"Effect":"Allow", "Principal":"ALIYUN$alice@aliyun.com",
"Action":["odps:CreateTable","odps:CreateInstance","odps:List"],
"Resource":"acs:odps:*:projects/test_project",
"Condition":{ "DateLessThan": {
"acs:CurrentTime":"2017-11-11T23:59:59Z"
},
"IpAddress": { "acs:SourceIp":"10.32.180.0/23"
}
}
},
{
"Effect":"Deny", "Principal":"ALIYUN$alice@aliyun.com",
"Action":"odps:Drop",
"Resource":"acs:odps:*:projects/test_project/tables/*"
}]
}
```

```
{
"Version": "1", "Statement": [{
"Effect":"Allow", "Principal":"ALIYUN$alice@aliyun.com",
"Action":["odps:CreateTable","odps:CreateInstance","odps:List"],
"Resource":"acs:odps:*:projects/test_project",
"Condition":{ "DateLessThan": {
"acs:CurrentTime":"2017-11-11T23:59:59Z"
},
"IpAddress": { "acs:SourceIp":"10.32.180.0/23"
}
}
},
{
"Effect":"Deny", "Principal":"ALIYUN$alice@aliyun.com",
"Action":"odps:Drop",
"Resource":"acs:odps:*:projects/test_project/tables/*"
}]
}
```

Note

- Currently, only role policies and project policies are supported, and user policies are not.
- Every policy only supports one policy file. Since put policies override existing policies, you must follow the sequence below to modify a policy:
  i. Get Policy.
  ii. Merge policy statements.
  iii. Put policies.

1.20.8.2. Policy-related terms

Permission is a basic concept of access control. When a requester wants to take an action on a resource, the action may be allowed or denied, based on the permission settings. A statement refers to the formal description of a single permission, and policy refers to a set of statements.

An access policy comprises the following access control elements: principal, action, resource, access restriction, and effect. These elements are briefly described below.

Principal

A principal of an object is a user or group to which permissions are assigned in an access policy. For example, the access policy allows Michael to perform the CreateObject action on the resource SampleBucket before December 31, 2017. Michael is the principal of the object.

Action

An action is an activity that the principal has permission to perform. For example, the access policy allows Michael to perform the CreateObject action on the resource SampleBucket before December 31, 2017. Therefore, CreateObject is an action of the access policy.

Resource

Resource is the object a principal requests access to. For example, the access policy allows Michael to perform the CreateObject action on the resource SampleBucket before December 31, 2017. SampleBucket is a resource of the access policy.

Access restriction

Access restriction is the prerequisite for the permission to take effect. For example, the access policy allows Michael to perform the CreateObject action on resource SampleBucket before December 31, 2017. The access restriction is before December 31, 2017.

Effect

Authorization effect has two options: Allow (action) or deny (action). In general, deny actions are generally more efficient and are checked first during permission checks.

Notice The deny action and revoking pemission are completely different concepts. The latter usually revokes permissions for both allow action and deny action. For example, a traditional database supports the revoke and revoke deny actions.

1.20.8.3. Access policy structure

1.20.8.3.1. Overview

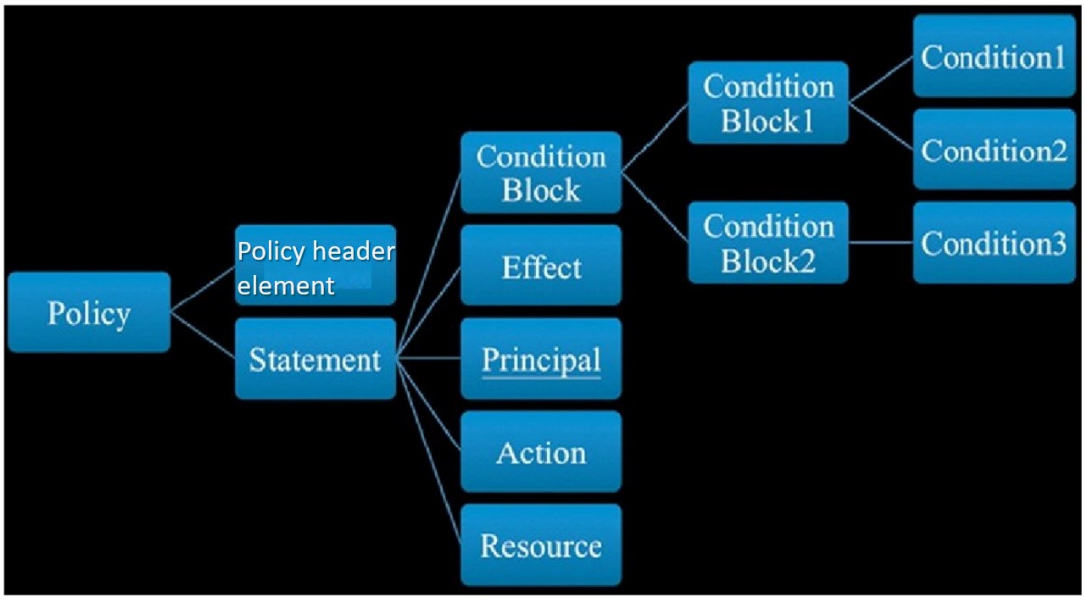
The following figure shows the structure of an access policy. A policy consists of the following parts:

- An optional policy header
- One or more statements

The policy header is optional and includes the policy version. The policy body is a set of statements.

The following figure shows the structure of a policy.

Policy structure



1.20.8.3.2. Authorization statement structure

An authorization statement includes the following entries:

- Effect: indicates the permission type of this statement. The value can be either Allow or Deny.
- Principal: If a policy is bound to a user or role in the authorization process, such as the role policy of MaxCompute, you cannot appoint a principal. If a policy is bound to a project or objects of the project in the authorization process, such as the project policy of MaxCompute, you must specify a principal.
- Action: indicates the authorization operation. It can be one or more operation names, and supports the asterisk (*) and question mark (?) wildcard characters. The asterisk (*) matches any number of characters, and the question mark (?) matches a single character. For example, Action = * indicates all operations.
- Resource: indicates the authorization object. It can be one or more object names, and supports the asterisk (*) and question mark (?) wildcard characters. The asterisk (*) matches any number of characters, and the question mark (?) matches a single character. For example, Resource = * indicates all objects.
- Condition block: indicates the conditions that must be met for the permission described by this

authorization statement to take effect. See the next topic for the structure of the condition block.

1.20.8.3.3. Conditional block structure

A condition block consists of one or more condition clauses. A condition clause consists of an action type, keyword, and condition value. The action types and keywords will be described in detail in the subsequent sections.

Whether a condition block is satisfied is determined as follows:

- A conditional keyword can correspond to one or more values. If the conditional keyword value is equal to one of the corresponding values, the condition is satisfied.
- A condition clause of a conditional operation type is satisfied if all conditional keywords in the clause are satisfied.
- A condition block is satisfied only if all of its condition clauses are satisfied.

1.20.8.3.4. Conditional action type

The following action types are supported: string, number, date, Boolean, and IP address. The methods supported by each conditional operation type are as follows:

String:

```
StringEquals
StringNotEquals
StringEqualsIgnoreCase
StringNotEqualsIgnoreCase
StringLike
StringNotLike
```

Numeric:

```
NumericEquals
NumericEquals
NumericLessThan
NumericLessThanEquals
NumericGreaterThan
NumericGreaterThanEquals
```

Date and time:

```
DateEquals
DateNotEquals
DateLessThan
DateLessThanEquals
DateGreaterThan
DateGreaterThanEquals
```

Boolean:

```
Bool
```

IP address:

```
IpAddress NotIpAddress
```

1.20.8.3.5. Conditional keywords

MaxCompute supports the conditional keywords reserved by Alibaba Cloud Service (ACS). The following table describes these conditional keywords.

Conditional keywords

Conditional keywords reserved by ACS	Type	Description
acs:CurrentTime	Date and time	The time when the Web server receives a request. It is based on the ISO 8601 standard, for example, 2017-11-11T23:59:59Z.
acs:SecureTransport	Boolean	Whether the request is sent over a secure channel, such as an HTTPS channel.
acs:SourceIp	IP address	The IP address of the client that sent the request.
acs:UserAgent	String	The UserAgent of the client that sent the request.
acs:Referer	String	The HTTP referer that sent the request.

Note acs:SourceIp refers to the remote_ip of the HTTP connection, not the (leftmost) client IP address in the x-forwarded-for HTTP header field. For example, if 10.230.205.105 is a LAN IP address, acs:SourceIp is the egress gateway IP address of this LAN. If the network egress uses a proxy server, acs:SourceIp is the IP address of the proxy server. If the request traverses across multiple proxy servers, acs:SourceIp is the IP address of the final proxy server. The value of acs:SourceIp may vary depending on the rules configured on the proxy server.

1.20.8.4. Access policy norm

1.20.8.4.1. Principal naming convention

The principal is the request sender. Currently, only an Alibaba Cloud account, domain account, or Taobao account is accepted as a principal. A cloud account can be represented by ID or DisplayName.

Example:

```
"Principal": "43274"
"Principal": "ALIYUN$bob@aliyun.com"
"Principal": ["ALIYUN$bob@aliyun.com","ALIYUN$jack@aliyun.com", "TAOBAO$alice"]
```

1.20.8.4.2. Resource naming convention

The following naming conventions are used for MaxCompute resources.

```
acs:<service-name>:<namespace>:<relative-id>
```

The parameters are described as follows.

Parameters

Name	Description
acs	Retained resource header.
service-name	The name of an open cloud service, such as MaxCompute, OSS, and TableStore.
namespace	Naming space, used for resource isolation. If a cloud account ID is used for resource isolation, the value can be the cloud account ID. If this option is not supported, use the asterisk (*) wildcard character instead.
relative-id	Indicates the service-related resource. Its meaning depends on specific services. This part of the format description supports a tree structure similar to the file path. Using MaxCompute as an example, the format of relative-id is: `projects/<project_name>/<object_type>/<object_name>`

Some MaxCompute resource naming examples.

Naming examples

Item	Description

Item	Description
*	All objects in the project.
projects/prj1/tables/t1	Table t1 of Project prj1.
projects/prj1/instances/*	All instances of Project prj1.
projects/prj1/tables/*	All tables of Project prj1.
projects/prj1/tables/taobao*	All tables of Project prj1 whose names start with "taobao".

1.20.8.4.3. Action naming

Action naming conventions are as follows:

```
<service-name>:<action-name>
```

Description:

- service-name: name of an open cloud service, for example, maxcompute, oss, and table store.
- action-name: name of service-related action APIs.

The following table lists MaxCompute action naming examples.

MaxCompute action naming examples

Naming example	Description
*	All actions.
odps:*	All MaxCompute actions.
odps:CreateTable	The CreateTable action of MaxCompute.
odps:Create*	All MaxCompute actions whose names start with "Create".

1.20.8.4.4. Condition keys naming

The naming format for condition keys retained by the open cloud service is:

```
acs:<condition-key>
```

Description:

condition-key: ACS reservs 5 types of condition keys, which are accessible for all open services. They are: acs:CurrentTime, acs:SecureTransport, acs:SourceIp, acs:UserAgent, acs:Referer.

The naming format for condition keys related to the specific service is:

```
<service-name>:<condition-key>
```

Description:

Condition-key: service-defined condition key.

1.20.8.4.5. Access policy example

Policy example:

```
{
"Version": "1",
"Statement": [{
"Effect":"Allow",
"Principal":"ALIYUN$alice@aliyun.com",
"Action":["odps:CreateTable","odps:CreateInstance","odps:List"],
"Resource":"acs:odps:*:projects/prj1",
"Condition":{ "DateLessThan": {
"acs:CurrentTime":"2017-11-11T23:59:59Z"
},
"IpAddress": { "acs:SourceIp":"10.32.180.0/23"
}
}
},
{
"Effect":"Deny", "Principal":"ALIYUN$alice@aliyun.com",
"Action":"odps:Drop",
"Resource":"acs:odps:*:projects/prj1/tables/*"
}]
}
```

Note The authorized user (alice@aliyun.com) can only submit a request from subnet 10.32.180.0/23 before 2017-11-11T23:59:59Z. The user can only perform the CreateInstance, CreateTable, and List operations on the prj1 project. The user cannot delete tables from prj1.

1.20.8.5. Differences between policy authorization and ACL authorization

ACL authorization:

- Use ACL authorization to grant or revoke permissions when both the grantee (such as a user or role) and the object (such as a table) exist. Like the security feature of Oracle authorization, this avoids the security risk out of dropping and recreating an object with the same name.
- When dropping an object, all authorizations related to the object are automatically revoked.
- It only supports allow (whitelist) authorization, and does not support deny (blacklist)

authorization.

- Use the classic Grant/Revoke commands for authorization. The command is simple and not prone to mistakes. Conditional authorization is not supported.
- This method is suitable for simple scenarios where condition or deny is not needed for authorization, and only the existing objects need to be authorized.

Policy authorization:

- Use policy authorization to grant or revoke permissions when the grantee or object is not available. The Object parameter supports wildcard "". For example, *projects/tbproj/tables/taobao* matches all tables whose names start with taobao in project tbproj. Like the features of MySQL authorization, policy authorization allows a non-existent object to be authorized, so the authorizer must consider the security risks of dropping and recreating an object with the same name.
- When dropping an object, the policy authorization related to this object is not deleted.
- Both allow (whitelist) authorization and deny (blacklist) authorization are supported. If allow and deny conflict, the deny action takes priority.
- Conditional authorization is supported. The authorizer can enforce 20 conditions on allow or deny authorization. For example, these conditions can be used to limit access to IP addresses within a subnet, and allow access before 23:59:59 on November 11, 2017.
- This method is suitable for relatively complicated scenarios where conditional authorization and deny action are needed and non-existent objects need to be authorized.
- Using policy authorization is more complicated than ACL authorization, but provides more flexibility.

1.20.8.6. Application limits

Application limits

Item	Limit	Description
ACCESS_POLICY_SIZE_LIMIT	32 KB	The maximum size of AccessPolicy.
USER_NUMBER_LIMIT_IN_ON E_PROJECT	1,000	The maximum number of users in a project.
ROLE_NUMBER_LIMIT_IN_ON E_PROJECT	500	The maximum number of roles in a project.
ROLE_NAME_LENGTH_LIMIT	64	The maximum number of characters in a role name.
SECURITY_COMMENT_SIZE_L IMIT	1 KB	The maximum size of a security comment.
PACKAGE_NAME_LENGTH_LI MIT	128	The maximum number of characters in a package name.
ALLOW_PROJECT_NUMBER_LIMIT_IN_ONE_P ACKAGE	1024	The maximum number of projects installed in a package.

Item	Limit	Description
RESOURCE_NUMBER_LIMIT_IN_ONE_PACKAGE	256	The maximum number of resources in a package.
PACKAGE_NUMBER_LIMIT_IN_ONE_PROJECT	512	The maximum number of packages that can be created in a project.
INSTALLED_PACKAGE_NUMBER_LIMIT_IN_ONE_PROJECT	64	The maximum number of packages that can be installed in a project.

1.20.9. Collection of security statements

1.20.9.1. Project security configuration

Authentication

Authorization configuration statements

Statement	Description
show SecurityConfiguration	Displays the project security configuration.
set CheckPermissionUsingACL=true/false	Enables or disables ACL-based authorization.
set CheckPermissionUsingPolicy=true/fal se	Enables or disables policy-based authorization.
set ObjectCreatorHasAccessPermission=true/false	Allows or disallows an object creator to be granted the object access permission by default.
set ObjectCreatorHasGrantPermission=true/false	Allows or disallows an object creator to be granted the ACL-based authorization permission by default.

Data protection

Data protection statements

Statement	Description
set ProjectProtection=false	Disables project protection.
set ProjectProtection=true [with exception <policy>]	Enables project protection.
list TrustedProjects	Displays the list of trusted projects.
add TrustedProject <projectName>	Adds a project to trusted projects.

Statement	Description
remove trustedproject <projectname>;	Removes a project from trusted projects.

1.20.9.2. Project permission management

User management

User management statements

Statement	Description
list users	Lists all added users.
add user <username>	Adds a user.
remove user <username>	Removes a user.

Role management

Role management statements

Statement	Description
list roles	Lists all created roles.
create role <rolename>	Creates a role.
drop role <rolename>	Deletes a role.
grant <rolelist> to <username>	Revokes roles from a user.
revoke <rolelist> from <username>	Grants one or more roles to a user.

ACL-based authorization

ACL-based authorization statements

Statement	Description
grant <privList> on <objType> <objName> to user <username>	Authorizes a user.
grant <privList> on <objType> <objName> to role <rolename>	Authorizes a role.
revoke <privList> on <objType> <objName> from user <username>	Revokes permissions from a user.

Statement	Description
revoke <privList> on <objType> <objName> from role <rolename>	Revokes permissions from a role.

Policy-based authorization

Policy-based authorization statements

Statement	Description
get policy	Displays policy settings at the project level.
put policy <policyFile>	Configures a policy at the project level.
get policy on role <roleName>	Displays the policy settings of a role.
put policy <policyFile> on role <roleName>	Configures a policy for a role.

Permission review

Permission review statements

Statement	Description
whoami	Displays information about the current user.
show grants [for <username>] [on type <objectType>]	Displays permissions and roles of a user.
show acl for <objectName> [on type <objectType>]	Displays the authorization information of an object.
describe role <roleName>	Displays the authorization and assignment information of a role.

1.20.9.3. Package-based resource sharing

Resource sharing

Resource sharing statements

Statement	Description
create package <pkgName>	Creates a package.
delete package <pkgName>	Deletes a package.
add <objType> <objName> to package<pkgName> [with privileges privs]	Adds resources that need to be shared to a package.

Statement	Description
remove <objType> <objName> from package <pkgName>	Removes shared resources from a package.
allow project <prjName> to install package <pkgName> [using label <num>]	Allows a project to use a user package.
disallow project <prjName> to install package <pkgName>	Disables a project from using a user package.

Resource use

Resource use statements

Statement	Description
install package <pkgName>	Installs a package.
uninstall package <pkgName>	Uninstalls a package.

Package viewing

Package viewing statements

Statement	Description
show packages	Lists all created and installed packages.
describe package <pkgName>	Views details of a package.

1.21. Frequently-used tools

1.21.1. MaxCompute console

1.21.1.1. Usage notes

This topic provides usage notes for the MaxCompute client.

> **Notice**
>
> - Do not rely on the output data of the client in any development or planning processes, as the data format may change. The client output format may not be forward compatible. The command syntax and behavior vary according to versions.
> - The MaxCompute client is a Java program. It requires JRE to run. You need to download and install JRE 1.8 to use the MaxCompute client.

For more information about how to configure and use the client, see Quick start.

1.21.1.2. Install the client

This topic describes how to install the MaxCompute client.

1. Download the client package to your client computer.
2. Decompress the client package to a folder, where you can see the following folders:

```
bin/
conf/
lib/
plugins/
```

3. Edit the following parameters in the odps_config.ini file in the conf folder:

```
project_name=
access_id=**********
access_key=**********
end_point= <MaxCompute service address>
```

> **Note**
> - Set access_id and access_key to the AccessKey ID and AccessKey Secret of your cloud account.
> - If you frequently use a project, enter the project name after project_name=. Then, you do not need to run the `use project_name;` command each time you log on to the client.

4. After the modifications, run the odps file in the bin directory (*./bin/odpscmd* in a Linux system or *./bin/odpscmd.bat* in a Windows system). Then, you are ready to run SQL statements. An example is as follows:

```
create table tbl1(id bigint);
insert overwrite table tbl1 select count(*) from tbl1;
select 'welcome to MaxCompute!' from tbl1;
```

1.21.1.3. Configuration description

This topic describes some configurations and corresponding parameters of the MaxCompute client.

Help

Run the following command to view the help information about the client:

```
odps@ >./bin/odpscmd -h;
```

> **Note** You can also enter `h;` or `help;` (case insensitive) in the interaction mode.

Startup parameters

Run the following command to specify a number of startup parameters:

```
Usage: odpscmd [OPTION]...
where options include:
  --help (-h)for help
  --project= use project
  --endpoint= set endpoint
  -u  -p  user name and password
  -k  will skip beginning queries and start from specified position
  -r  set retry times
  -f <"file_path;"> execute command in file
  -e <"command;[command;]..."> execute command, include sql command
  -C will display job counters
```

Example: (-f is used as an example)

1. Prepare a local script file named script.txt. The file is stored in D:/. Its contents are as follows:

   ```
   DROP TABLE IF EXISTS test_table_mj;
   CREATE TABLE test_table_mj (id string, name string);
   DROP TABLE test_table_mj;
   ```

2. Run the following command:

   ```
   odpscmd\bin>odpscmd -f d:/script.txt;
   ```

3. The command output is as follows:

```

Interactive mode

Directly run the client, and you will enter the interaction mode. The following information is displayed:

```
[admin: ~]$odpscmd
Aliyun ODPS Command Line Tool
Version 1.0
@Copyright 2012 Alibaba Cloud Computing Co., Ltd. All rights reserved.
XXX@ XXX> INSERT OVERWRITE TABLE DUAL SELECT * FROM DUAL;
```

> **Note** The first XXX indicates the identifier of MaxCompute, and the second XXX indicates the project to which you belong. Enter a command at the cursor (terminated by a semicolon), and press Enter to run it.

Command output

The output of a SQL statement is in either HumanReadable (default) or MachineReadable format. If you use the -M parameter when running odpscmd, the output format is CSV.

> **Note** This function currently applies only to SELECT and READ statements, and takes effect when reading data.

Continue run

When you run odpscmd in -e or -f mode and want to start with an intermediate statement among a few statements, you can use the -k parameter. This parameter indicates that the execution starts from the specified statement while the preceding statements are skipped. If the parameter value is equal to or smaller than 0, execution starts from the first statement. A statement terminated by a semi-colon is considered a valid statement. At runtime, the process indicates the specific statement that is running successfully or fails.

For example, the */tmp/dual.sql* file includes the following three SQL statements:

```
drop table dual;
create table dual (dummy string);
insert overwrite table dual select count(*) from dual;
```

You can run the following command to ignore the first two statements:

```
odpscmd-k 3 -f dual.sql
```

Obtain information about the current logon user

Run the following command to obtain the cloud account of the current logon user and the endpoint that is used:

```
whoami
```

Example:

```
odps@ hiveut>whoami; Name: odpstest@aliyun.com ID: 1090142773636588 End_Point: <MaxCompute s
ervice address> Project: lijunsecuritytest
```

Exit

Command syntax:

```
odps@ > quit;
```

or

```
q;
```

Configure a job priority

Command syntax:

```
Admin@ > ./bin/odpscmd --instance-priority=<PRIORITY>;
```

Configuration file: odps_config.ini

```
instance_priority=<PRIORITY>
```

> **Notice**
>
> - The value range of <PRIORITY > is 0-9, where 0 indicates the highest priority and 9 the lowest priority.
> - The priority setting in the configuration file applies to all instances submitted in CLT.
> - The priority value is 9 by default.

DryRun mode

In the DryRun mode, MaxCompute parses a SQL statement to check if the syntax is correct and generates an execution plan. MaxCompute does not submit a distributed job. Command syntax:

```
./bin/odpscmd -y
```

SQL reliability

If an exception is returned during the execution of SQL statements such as INSERT or CREATE TABLE AS, the client tries to automatically recover data and metadata to the pre-execution state based on known information.

- Data that is overwritten by INSERT OVERWRITE during QUERY execution is recovered from the temporary backup directory to the original directory.
- Data that is generated by INSERT INTO during QUERY execution is removed.
- Tables created during QUERY execution and dynamically generated partition information are removed.

If MaxCompute fails to recover data, it returns a specific error code. The error code alerts you that further attempts can make some data unrecoverable. The error code is as follows:

```
ODPS-
0110999: Critical! Internal error happened in commit operation and rollback failed, possible breach of a
tomicity
```

1.21.2. Eclipse development plugin

1.21.2.1. Install Eclipse

This topic describes how to install the Eclipse plug-in.

Context

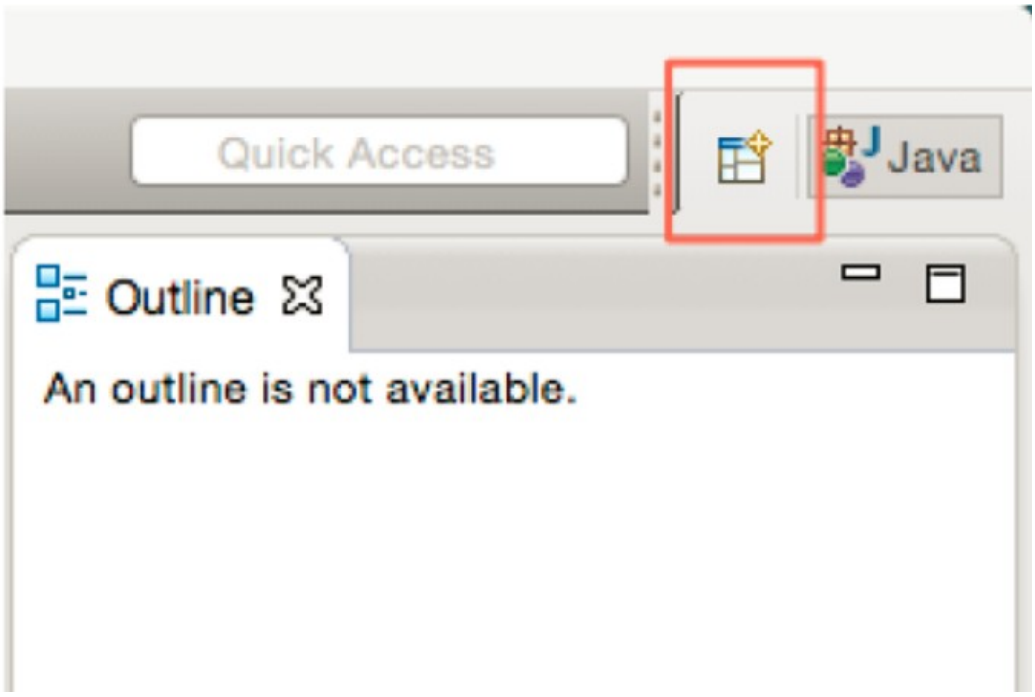
MaxCompute provides the Eclipse plug-in to help you easily use the Java SDKs for MapReduce and UDFs in your development work. This plug-in can simulate the running process of MapReduce or UDFs. It provides local debugging methods and simple template generation features. You can download the software package from Eclipse.

> **Note** Unlike the local running mode of MapReduce, the Eclipse plug-in cannot synchronize data with MaxCompute. You need to manually copy the required data to the warehouse directory of Eclipse.

Procedure

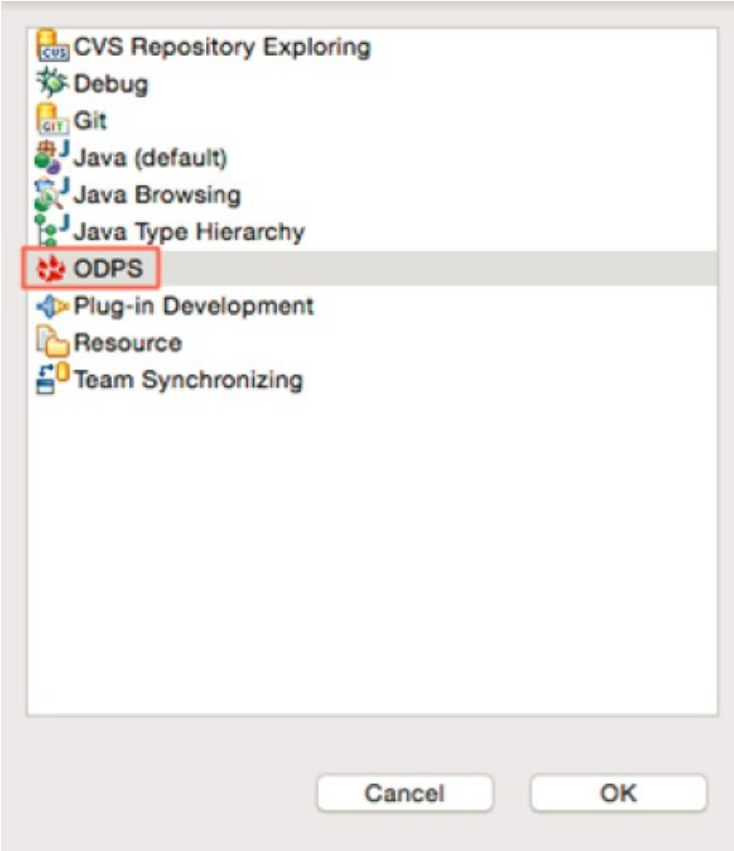
1. Decompress the Eclipse package to obtain the following JAR file: *odps-eclipse-plugin-bundle-0.15.0.jar*
2. Place the JAR file in the plugins folder under the Eclipse installation directory.
3. Start Eclipse and click the Open Perspective icon in the upper-right corner, as shown in the following figure.

   Eclipse installation 1

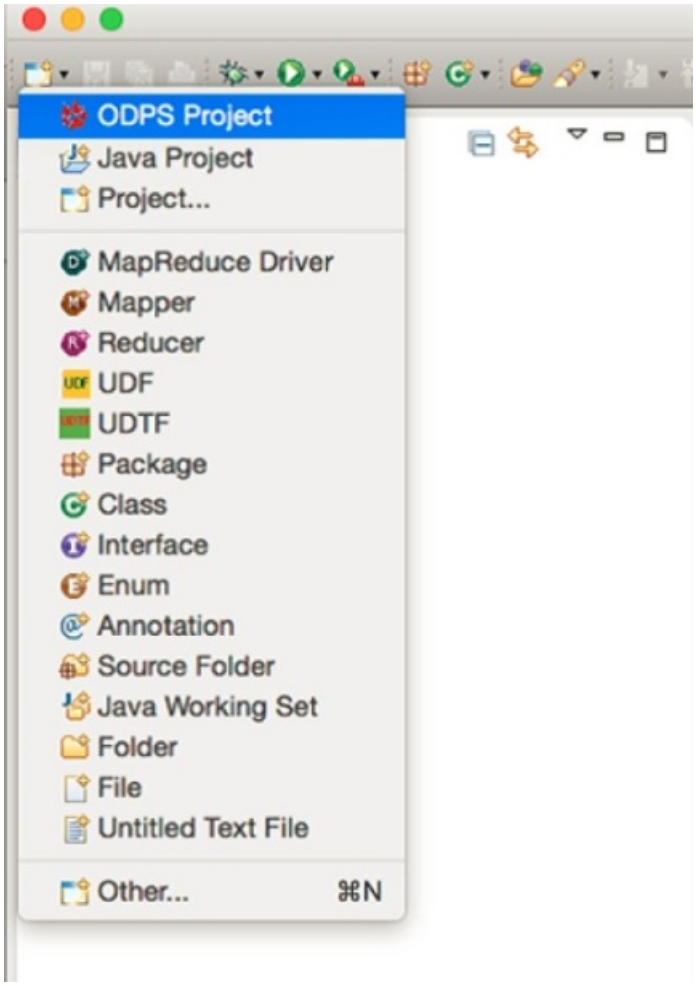
4. Click **ODPS** in the dialog box that appears, as shown in the following figure.

   Eclipse installation 2



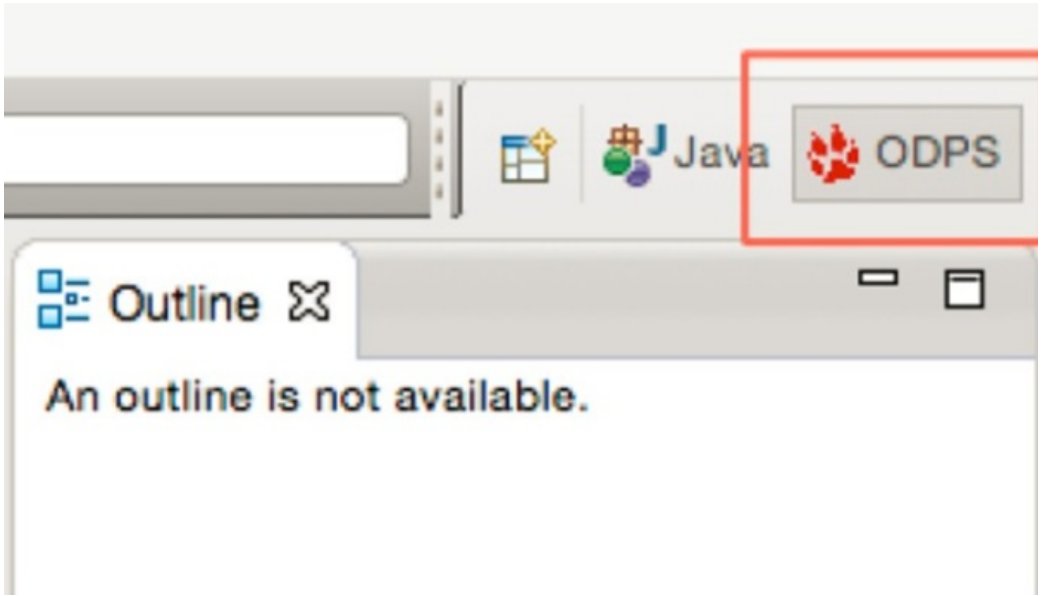
5. After you click **ODPS**, a navigation pane appears, as shown in the following figure.

   Eclipse installation 3



6. Click **ODPS Project** in the navigation pane and then click **OK**. The ODPS icon is displayed in the upper-right corner, as shown in the following figure. The icon indicates that the plug-in has taken effect.

Eclipse installation 4



1.21.2.2. Create a project

1.21.2.2.1. Method 1

This topic describes the first method to create a project in the Eclipse development plugin.

Procedure

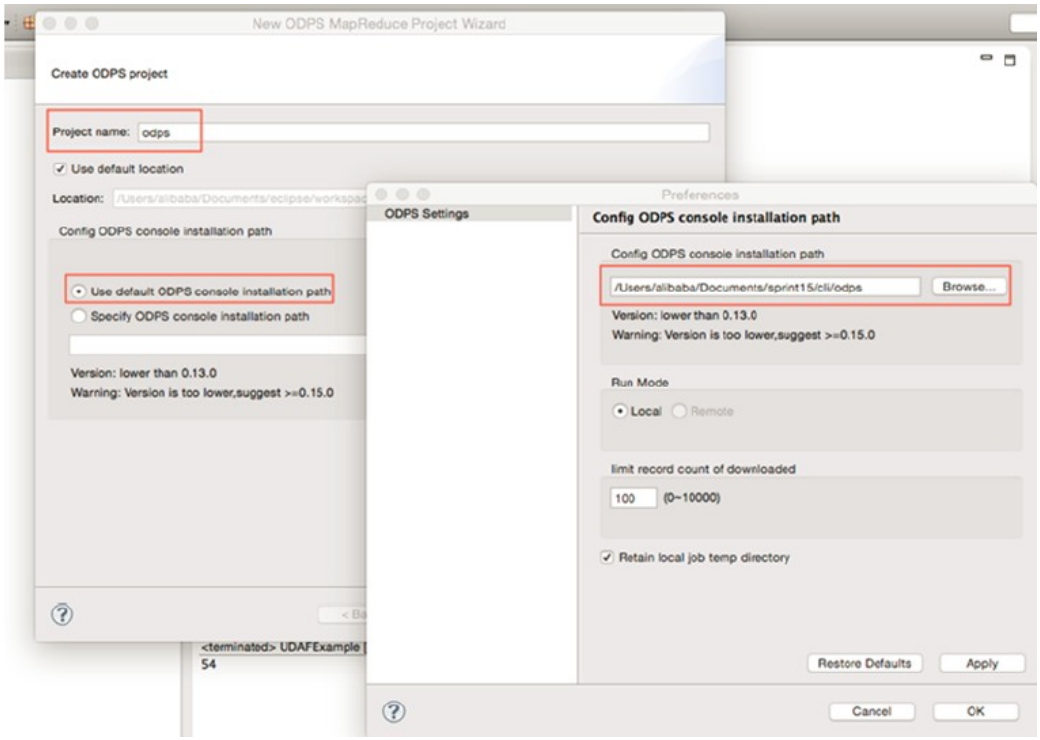
1. Start Eclipse. Choose **File** > **New** > **Project** > **ODPS** > **ODPS Project** in the upper-left corner to create a project, as shown in the following figure.

   Step 1

   
   > **Note** In this example, the project name is ODPS.

2. After the ODPS project is created, a dialog box is displayed, as shown in the following figure. Set Project name, select the path of the MaxCompute client, and then click **Finish**.

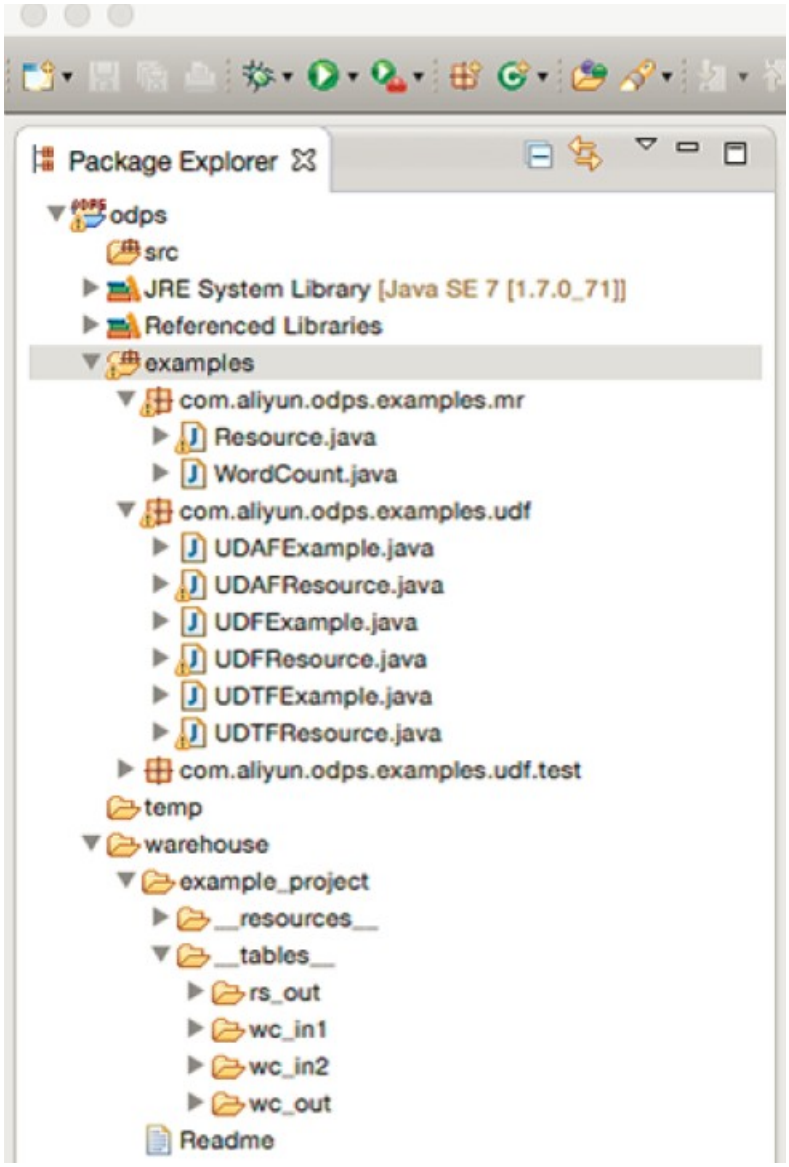
   Step 2



> **Note** The client must be installed in advance.

3. After creating a project, you can see the directory structure on the left-side Package Explorer pane, as shown in the following figure.

   Step 3



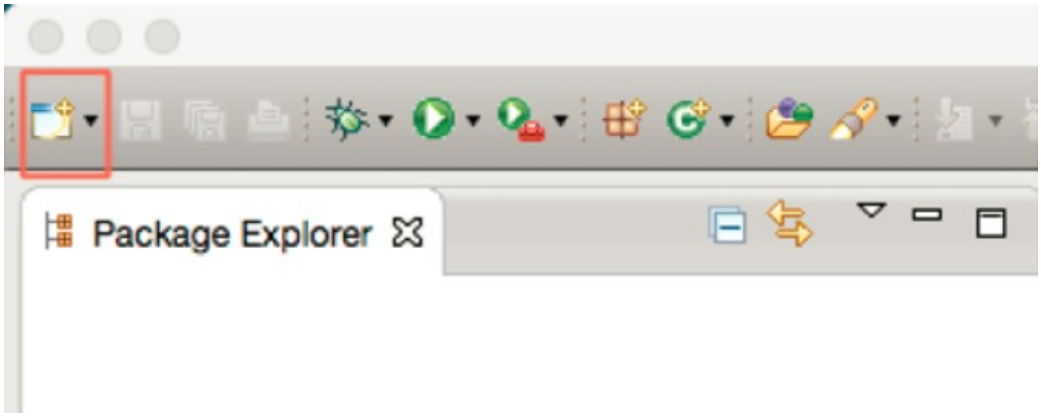
1.21.2.2.2. Method 2

This topic describes the second method to create a project in the Eclipse development plugin.

Procedure

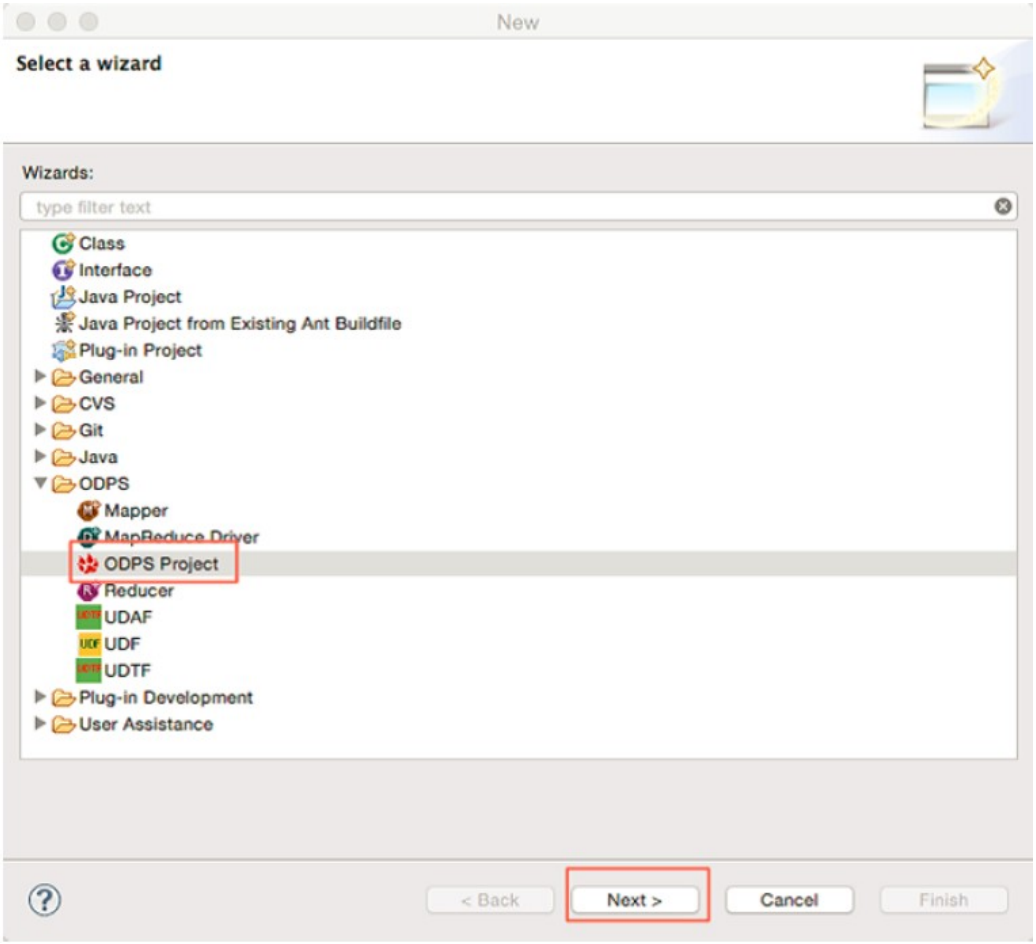
1. Start Eclipse. Click **New** in the upper-left corner, as shown in the following figure.

   Step 1



2. In the dialog box that appears, select **ODPS Project** and click **Next**, as shown in the following figure.

   Step 2



> **Note** In this example, the project name is ODPS.

3. The subsequent steps are the same as those in method 1. After installing the Eclipse plugin, you can use it to compile MapReduce or UDF programs.

> **Note** For a MapReduce running example, see MapReduce running example. For a UDF development and running example, see UDF development and running example.

1.21.2.3. MapReduce running example

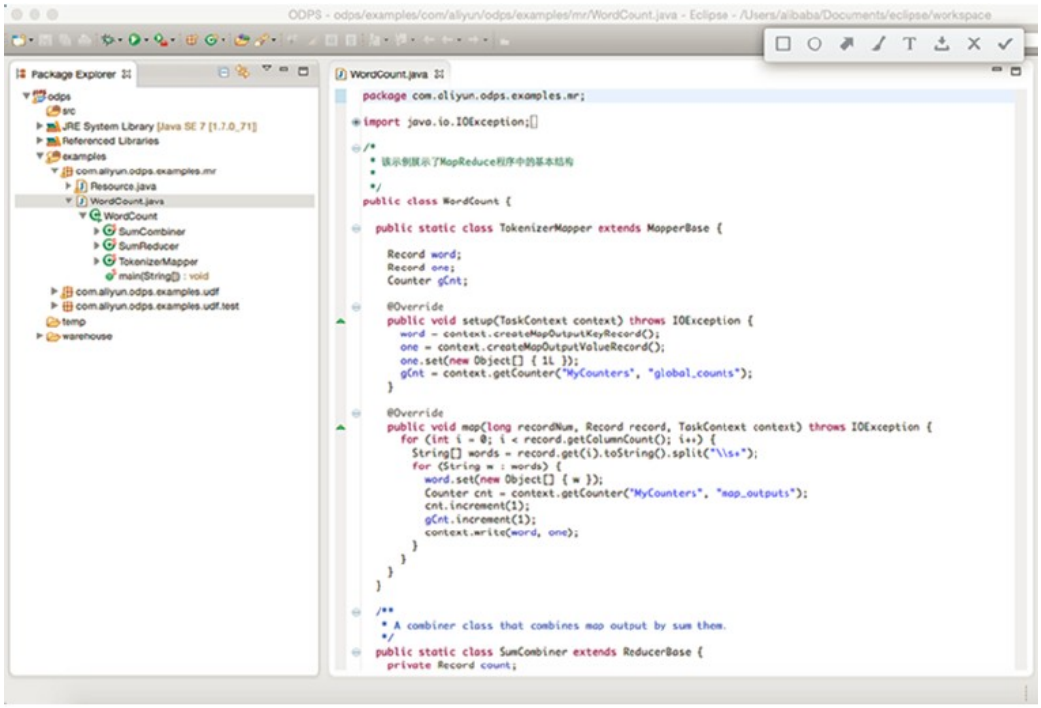
1.21.2.3.1. Quickly run a WordCount example

This topic describes how to use MapReduce to quickly run a WordCount example in the Eclipse plugin.

Procedure

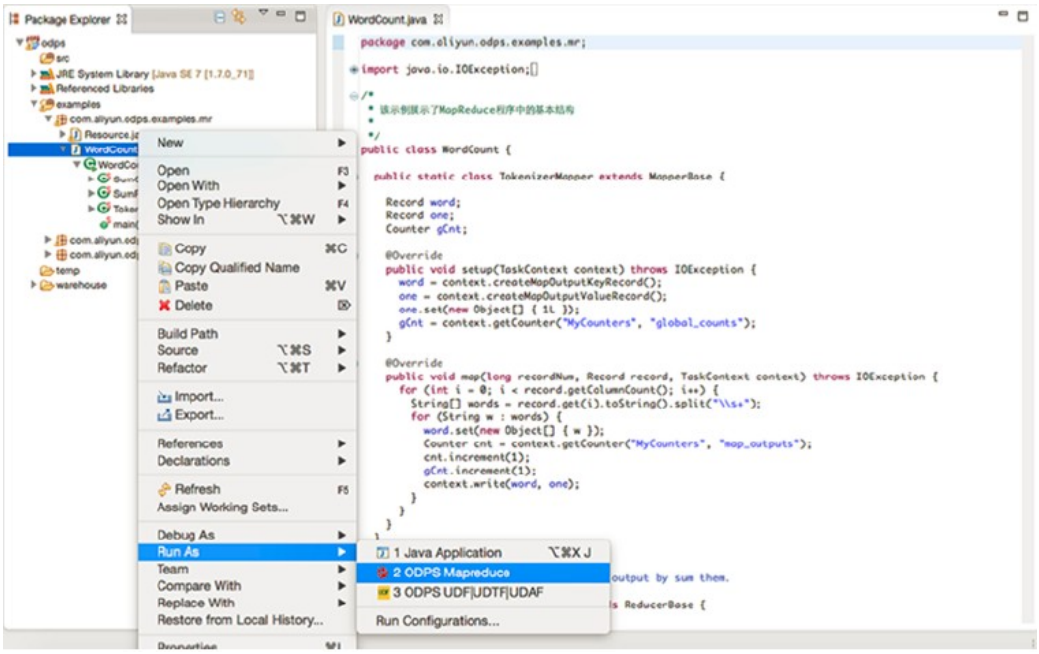
1. Select a WordCount example in MaxCompute, as shown in the following figure.

   WordCount example

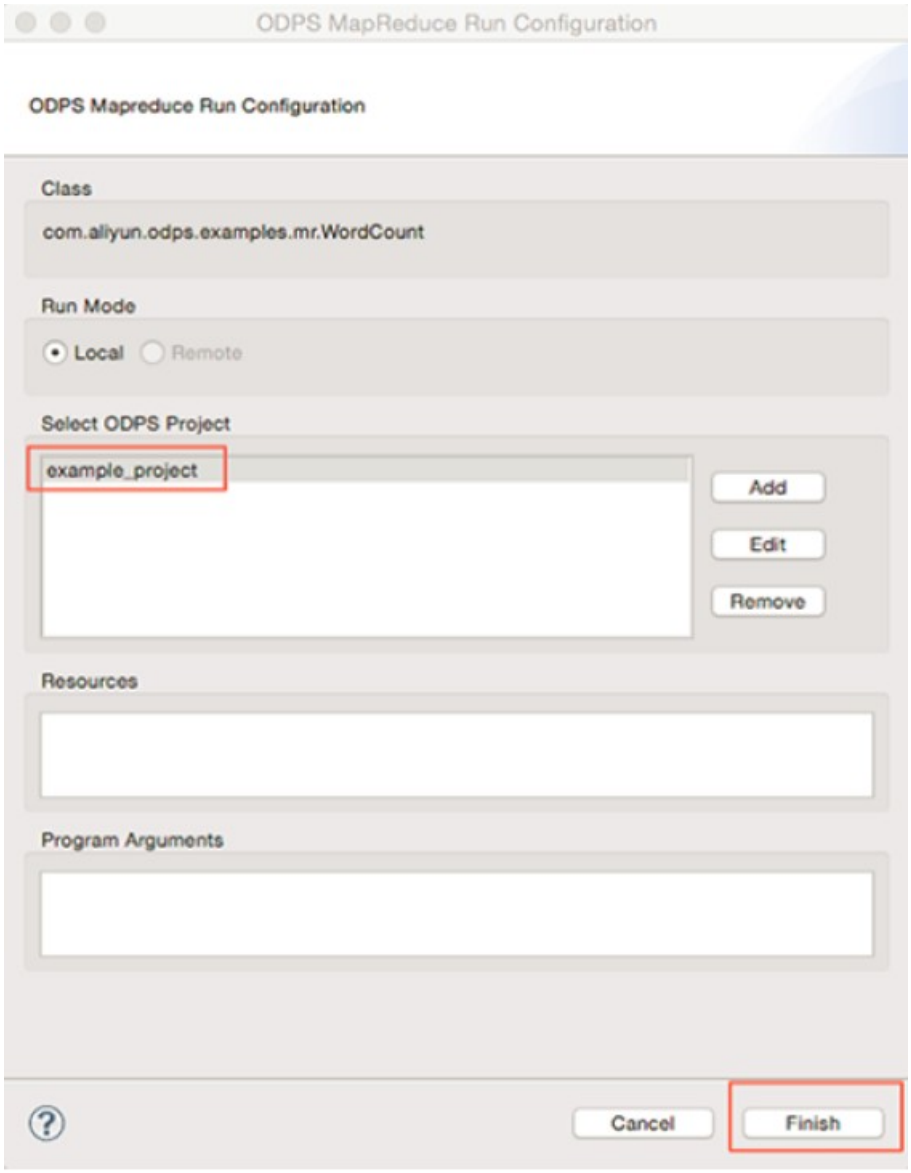
2. Right-click **WordCount.java** and choose **Run AsODPS MapReduce** from the shortcut menu, as shown in the following figure.

   Run the WordCount example



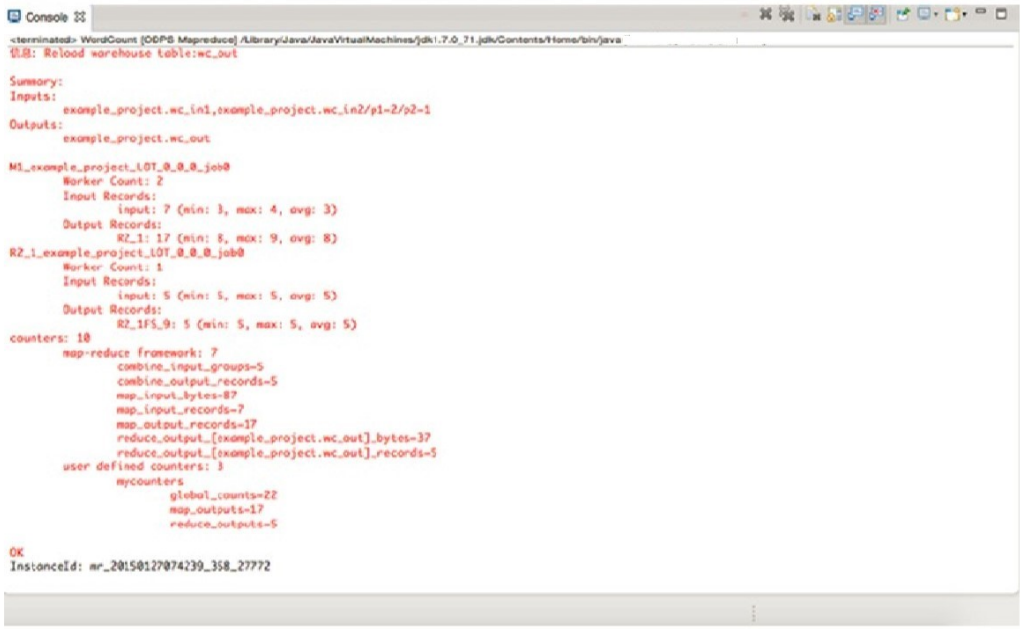
3. In the dialog box that appears, select **example_project** and click **OK**, as shown in the following figure.

   Run the WordCount example



4. The results of the operation are displayed after the operation is executed, as shown in the following figure.

   Execution result of the WordCount example



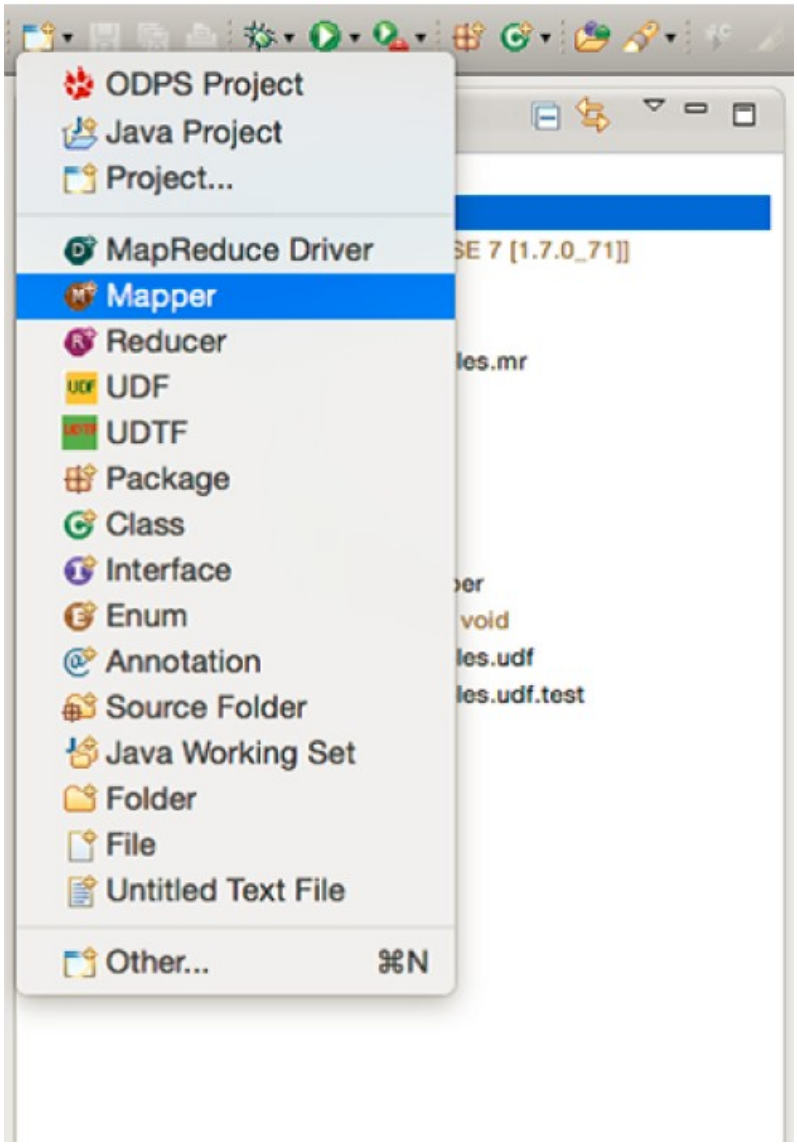
1.21.2.3.2. Run a custom MapReduce program

This topic provides an example on how to run a custom MapReduce program in the Eclipse plugin.

Procedure

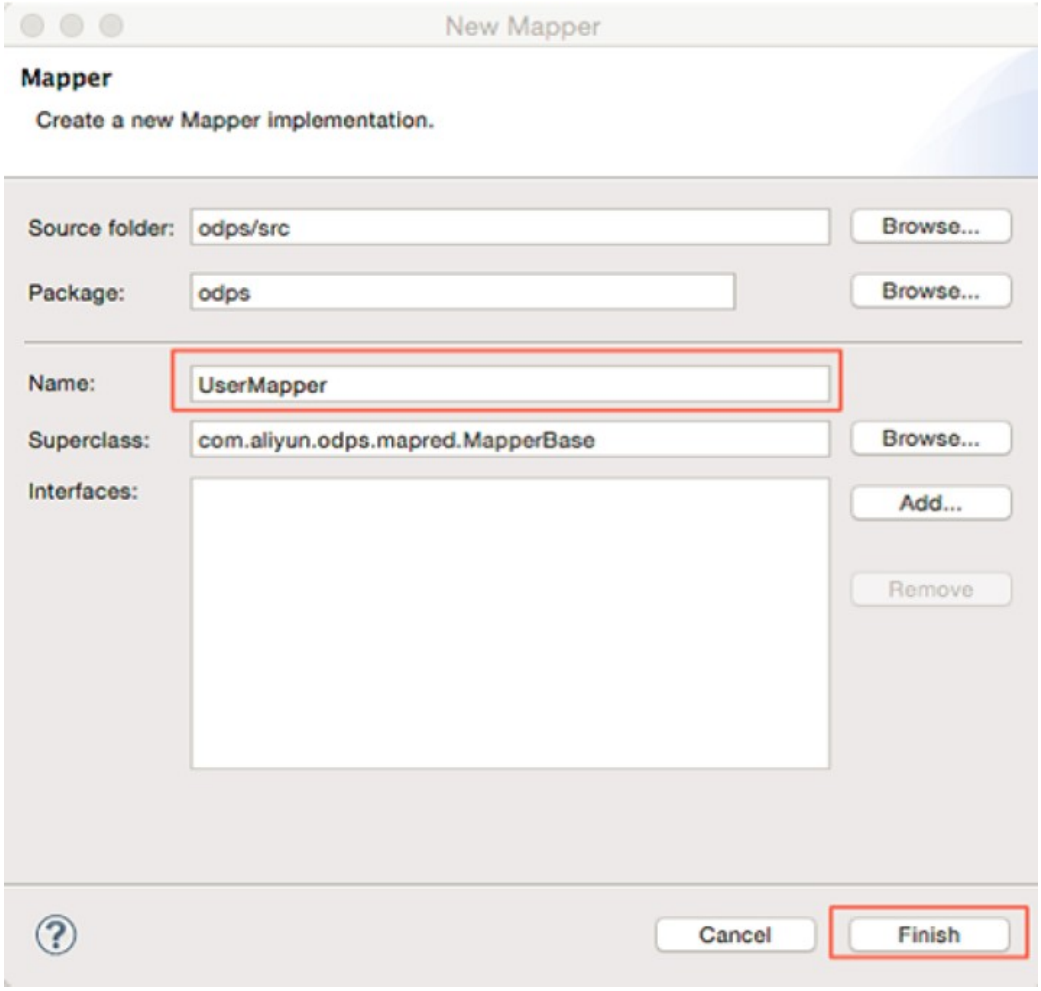
1. In Eclipse, right-click the **src** directory, and choose **New** > **Mapper** from the shortcut menu, as shown in the following figure.

   Step 1



2. Select Mapper. A dialog box is displayed, as shown in the following figure. Enter the name of the Mapper class, and click Finish.

   Step 2

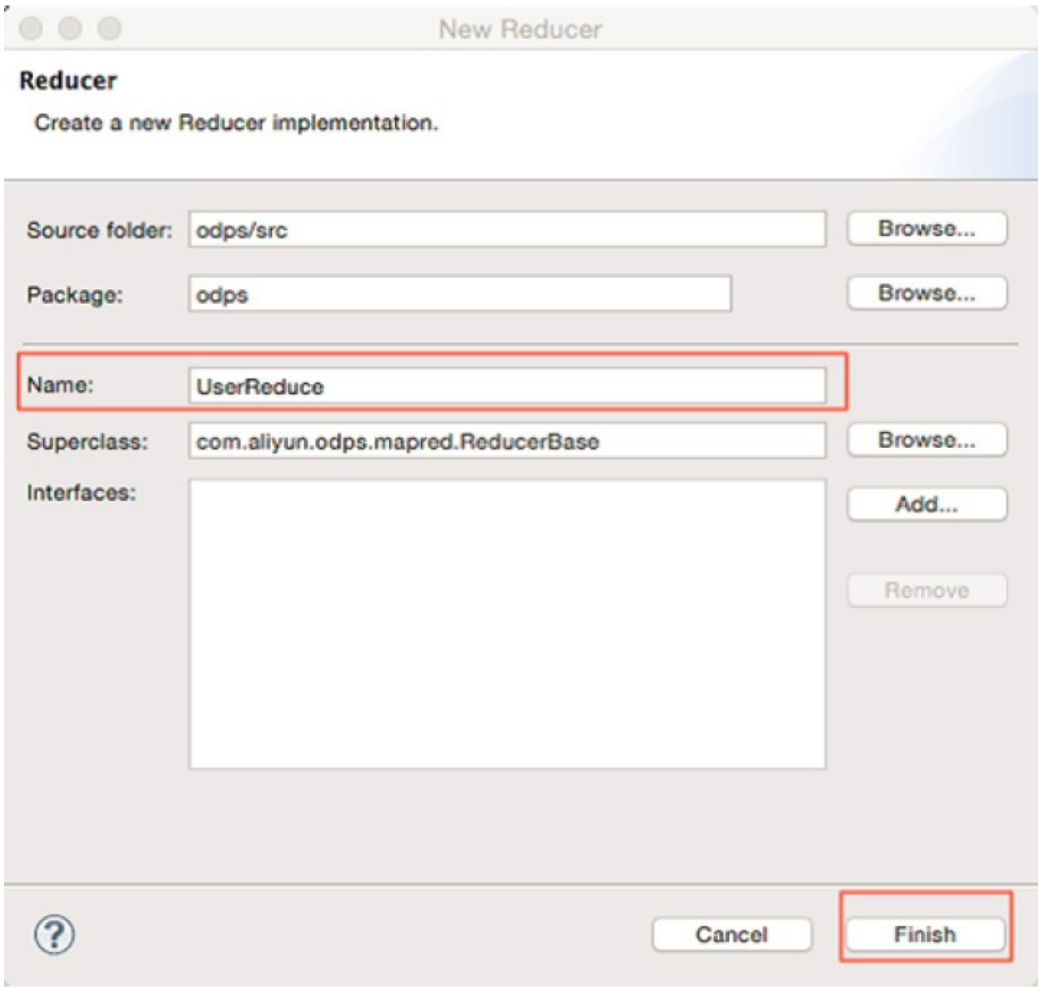


3. On the left-side Package Explorer, the UserReducer.java file is generated in the src directory. The file contains a Mapper class template. The package name is odps by default. The template content is as follows.

```
package odps;
import java.io.IOException;
import com.aliyun.odps.counter.Counter; import com.aliyun.odps.data.Record;
import com.aliyun.odps.mapred.MapperBase;
public class UserMapper extends MapperBase {
Record word; Record one; Counter gCnt;
@Override
public void setup(TaskContext context) throws IOException {
word = context.createMapOutputKeyRecord(); one = context.createMapOutputValueRecord(); one
.set(new Object[] { 1L });
gCnt = context.getCounter("MyCounters", "global_counts");
}
@Override
public void map(long recordNum, Record record, TaskContext context) throws IOException {
for (int i = 0; i < record.getColumnCount(); i++) { String[] words = record.get(i).toString().split("\\s
+"); for (String w : words) {
word.set(new Object[] { w });
Counter cnt = context.getCounter("MyCounters", "map_outputs"); cnt.increment(1);
gCnt.increment(1); context.write(word, one);
}
}
}
@Override
public void cleanup(TaskContext context) throws IOException {
}
}
```

4. In Eclipse, right-click the **src** directory, and choose **New** > **Reduce** from the shortcut menu, as shown in the following figure.

   Reducer



5. In the dialog box that appears, enter the name of the Reduce class and click Finish.

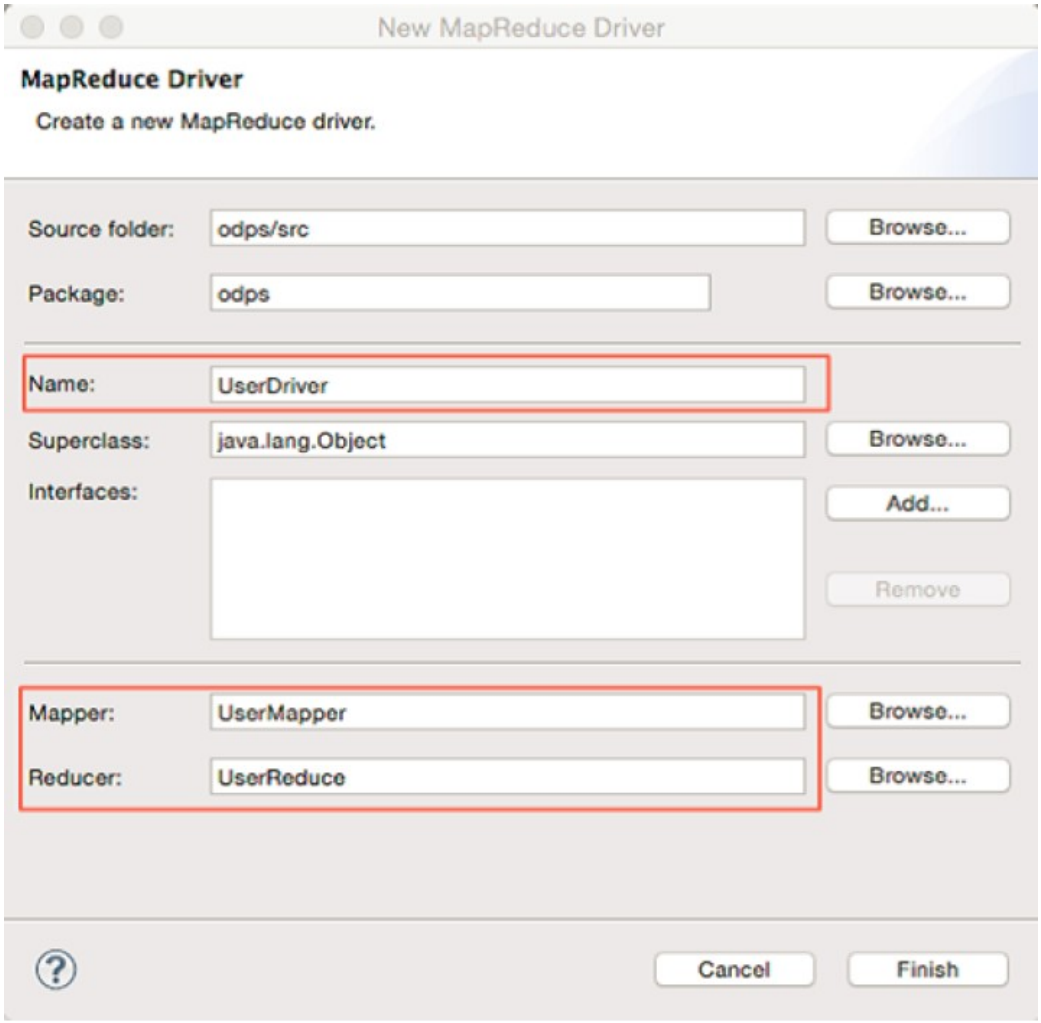
   > **Note** This example uses UserReducer.

6. On the left-side Package Explorer, the UserReducer.java file is generated in the src directory. The file contains a Reduce class template. The package name is odps by default. The template content is as follows:

```
package odps;
import java.io.IOException;
import java.util.Iterator;
import com.aliyun.odps.counter.Counter;
import com.aliyun.odps.data.Record;
import com.aliyun.odps.mapred.ReducerBase;
public class UserReducer extends ReducerBase {
private Record result; Counter gCnt;
@Override
public void setup(TaskContext context) throws IOException { result = context.createOutputRecord
();
gCnt = context.getCounter("MyCounters", "global_counts");
}
@Override
public void reduce(Record key, Iterator<Record> values, TaskContext context) throws IOException
{
long count = 0;
while (values.hasNext()) { Record val = values.next(); count += (Long) val.get(0);
}
result.set(0, key.get(0)); result.set(1, count);
Counter cnt = context.getCounter("MyCounters", "reduce_outputs"); cnt.increment(1);
gCnt.increment(1);
context.write(result);
}
@Override
public void cleanup(TaskContext context) throws IOException {
}
}
```

7. In Eclipse, right-click the **src** directory, and choose **New** > **MapReduce Driver** from the shortcut menu.
8. A dialog box is displayed, as shown in the following figure. Set Name, Mapper, and Reducer, and then click Finish.

   MapReduce Driver

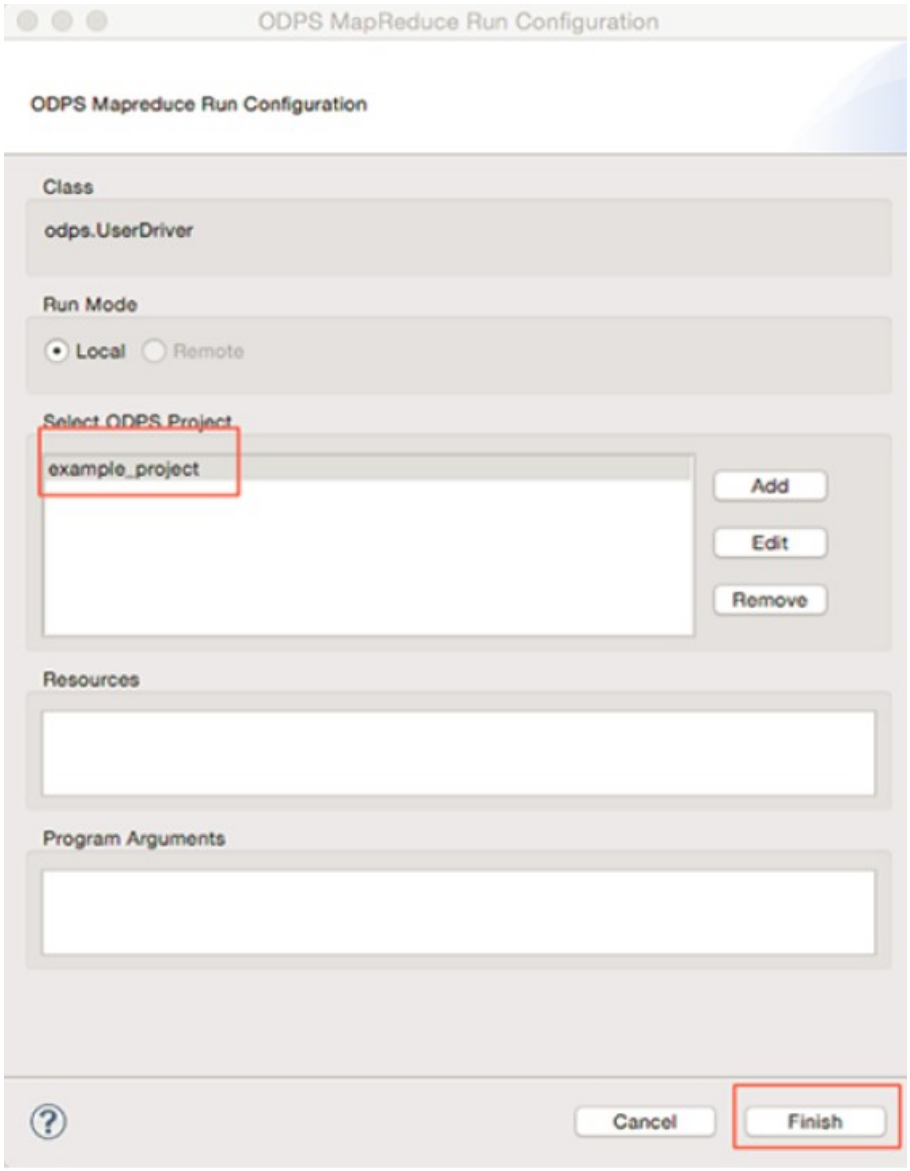


9. On the left-side Package Explorer, the MyDriver.java file is generated in the src directory. The file contains a MapReduce Driver template. The package name is odps by default. The template content is as follows:

```
package odps;
import com.aliyun.odps.OdpsException;
import com.aliyun.odps.data.TableInfo;
import com.aliyun.odps.examples.mr.WordCount.SumCombiner;
import com.aliyun.odps.examples.mr.WordCount.SumReducer;
import com.aliyun.odps.examples.mr.WordCount.TokenizerMapper;
import com.aliyun.odps.mapred.JobClient;
import com.aliyun.odps.mapred.RunningJob;
import com.aliyun.odps.mapred.conf.JobConf;
import com.aliyun.odps.mapred.utils.InputUtils;
import com.aliyun.odps.mapred.utils.OutputUtils;
import com.aliyun.odps.mapred.utils.SchemaUtils;
public class UserDriver {
public static void main(String[] args) throws OdpsException { JobConf job = new JobConf();
job.setMapperClass(TokenizerMapper.class);
job.setCombinerClass(SumCombiner.class);
job.setReducerClass(SumReducer.class);
job.setMapOutputKeySchema(SchemaUtils.fromString("word:string"));
job.setMapOutputValueSchema(SchemaUtils.fromString("count:bigint"));
InputUtils.addTable(
TableInfo.builder().tableName("wc_in1").cols(new String[] { "col2", "col3" }).build(), job);
InputUtils.addTable(TableInfo.builder().tableName("wc_in2").partSpec("p1=2/p2=1").build(), job);
OutputUtils.addTable(TableInfo.builder().tableName("wc_out").build(), job);
RunningJob rj = JobClient.runJob(job); rj.waitForCompletion();
}
}
```

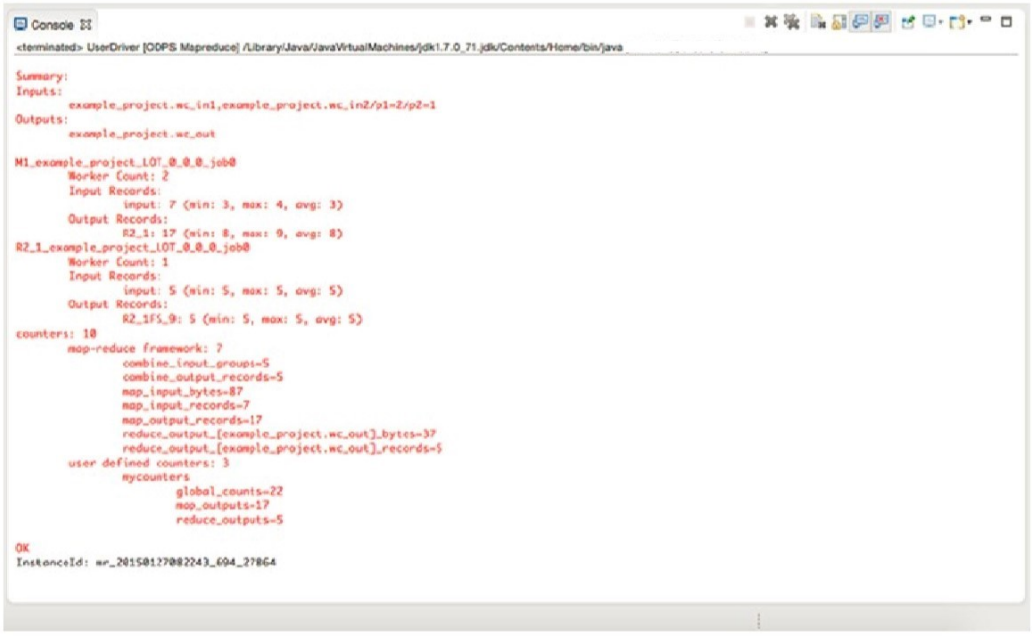
10. Run the MapReduce program. Right-click UserDriver.java and choose **Run As > ODPS MapReduce** from the shortcut menu. In the dialog box that appears, click **OK**. A dialog box is displayed, as shown in the following figure.

    ODPS MapReduce Run Configuration



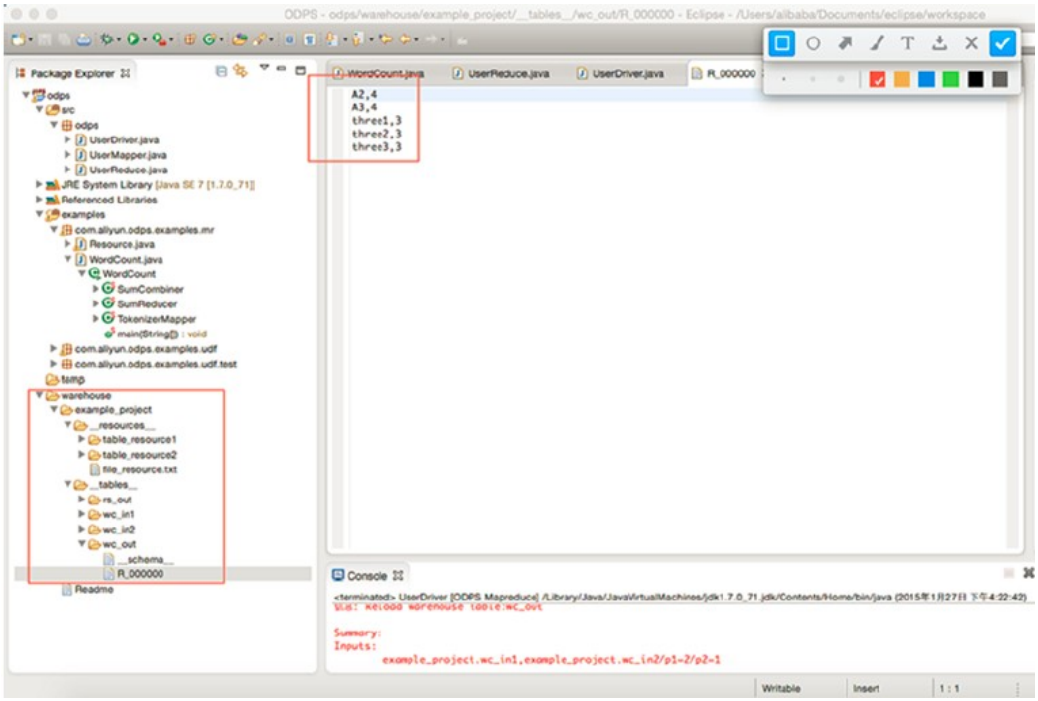
11. Select example_project as the MaxCompute project. Click **Finish** to start running the MapReduce program locally. If the output is as shown in the following figure, the local running is successful.

    Console



12. The execution result is stored in the warehouse directory. Refresh the ODPS project, as shown in the following figure.

    Output

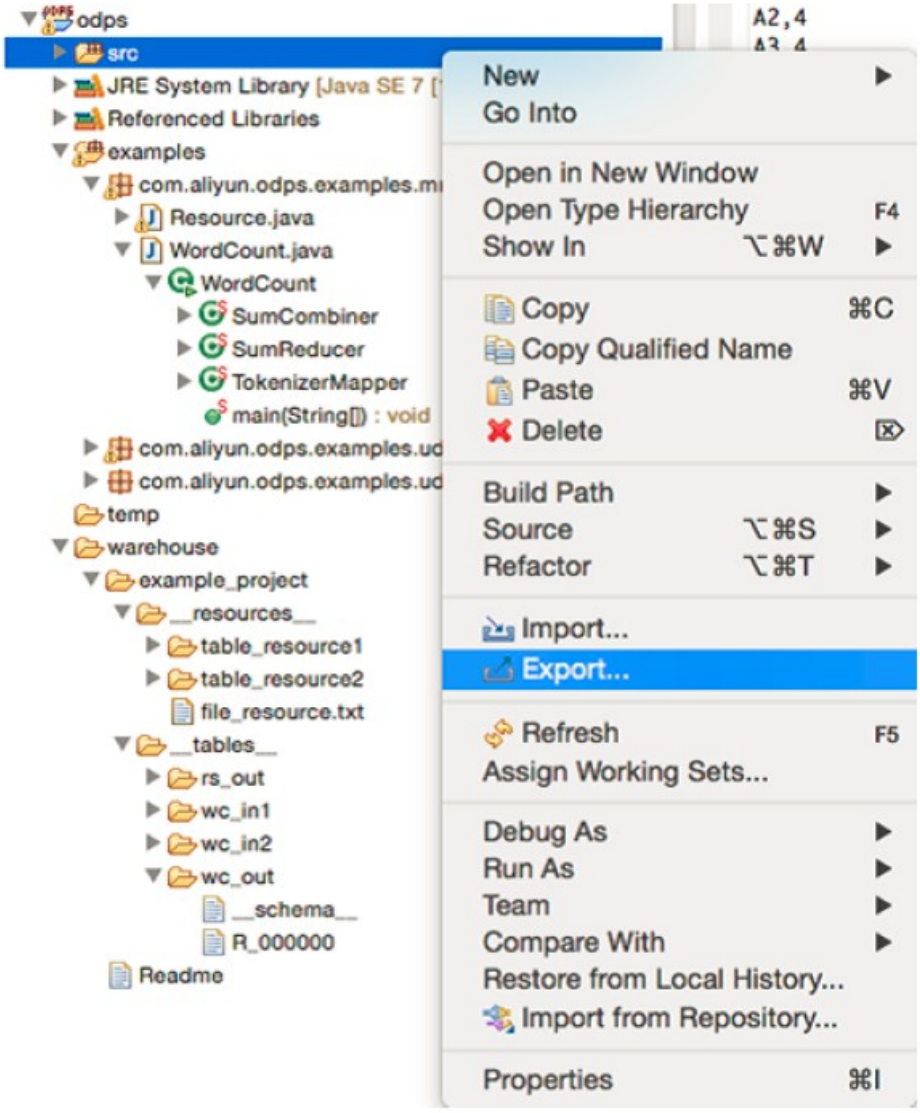


> **Note** wc_out is the output directory, and R_000000 is the result file. After confirming that the result is correct through local debugging, you can use the export function of Eclipse to package the MapReduce program for subsequent use in the distributed environment.

13. The export procedure is as follows:

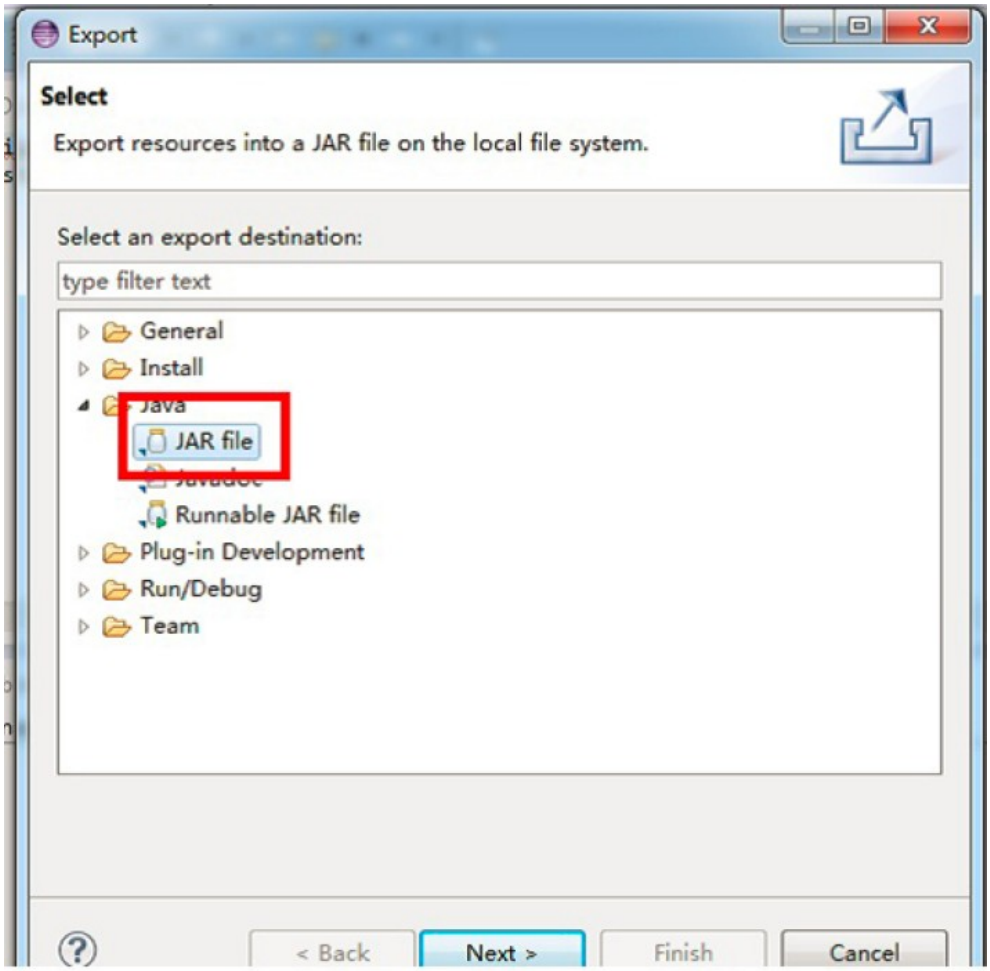
i. Right-click the src directory and select **Export** from the shortcut menu, as shown in the following figure.

Step 1



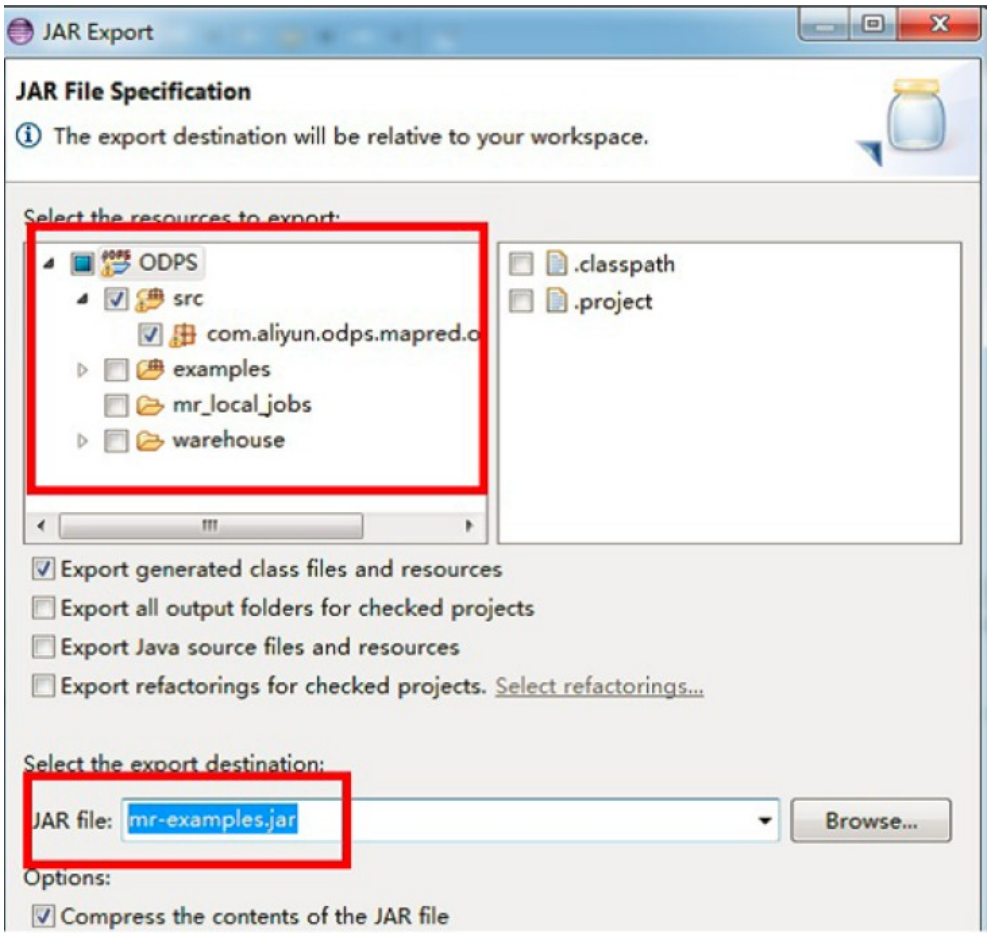
ii. Select JAR file as the export destination, as shown in the following figure.

Step 2



iii. You only need to export the package (com.aliyun.odps.mapred.open.example) in the src directory. Set JAR file to mr- examples.jar, as shown in the following figure.

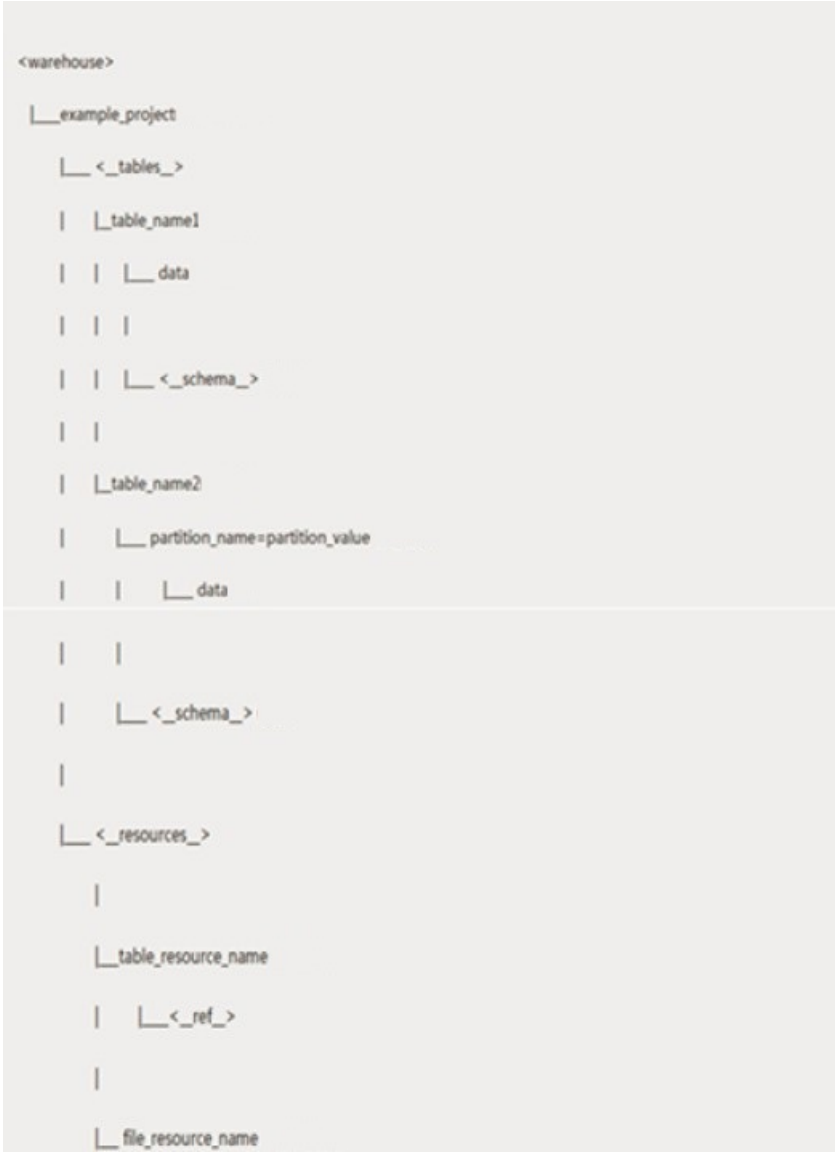
Step 3



> **Note** In this example, the program package is named mr-examples.jar. You can name the package based on your actual requirements.

iv. Click OK. The export process is complete.

14. If you want to create a new project locally, you can create a new subdirectory (at the same level as example_project) under warehouse. The following figure shows the directory structure.



An example of the schema file:

Non-partitioned table:

```
project=project_name table=table_name
columns=col1:BIGINT,col2:DOUBLE,col3:BOOLEAN,col4:DATETIME,col5:STRING
-- Partitioned table: project=project_name table=table_name
columns=col1:BIGINT,col2:DOUBLE,col3:BOOLEAN,col4:DATETIME,col5:STRING partitions=col1:BIGIN
T,col2:DOUBLE,col3:BOOLEAN,col4:DATETIME,col5:STRING
-- Note that the following data formats are supported: bigint, double, boolean, datetime, and stri
ng. These formats correspond to the following Java data types: long, double, boolean, java.util.Da
te, and java.lang.String.
```

An example of the data file:

```
1,1.1,true,2015-06-04 11:22:42 896,hello world
\N,\N,\N,\N,\N
-- Note that the time is in milliseconds. For all time formats, \N is used to represent NULL.
```

> **Note**
>
> - Run the MapReduce program locally. The warehouse directory is checked for data tables or resources by default. If the tables or resources do not exist, data of the server is downloaded to the warehouse directory. Then the program runs locally.
> - After running MapReduce, refresh the warehouse directory to view the generated result.

1.21.2.4. UDF development and running example

1.21.2.4.1. Local debug UDF programs

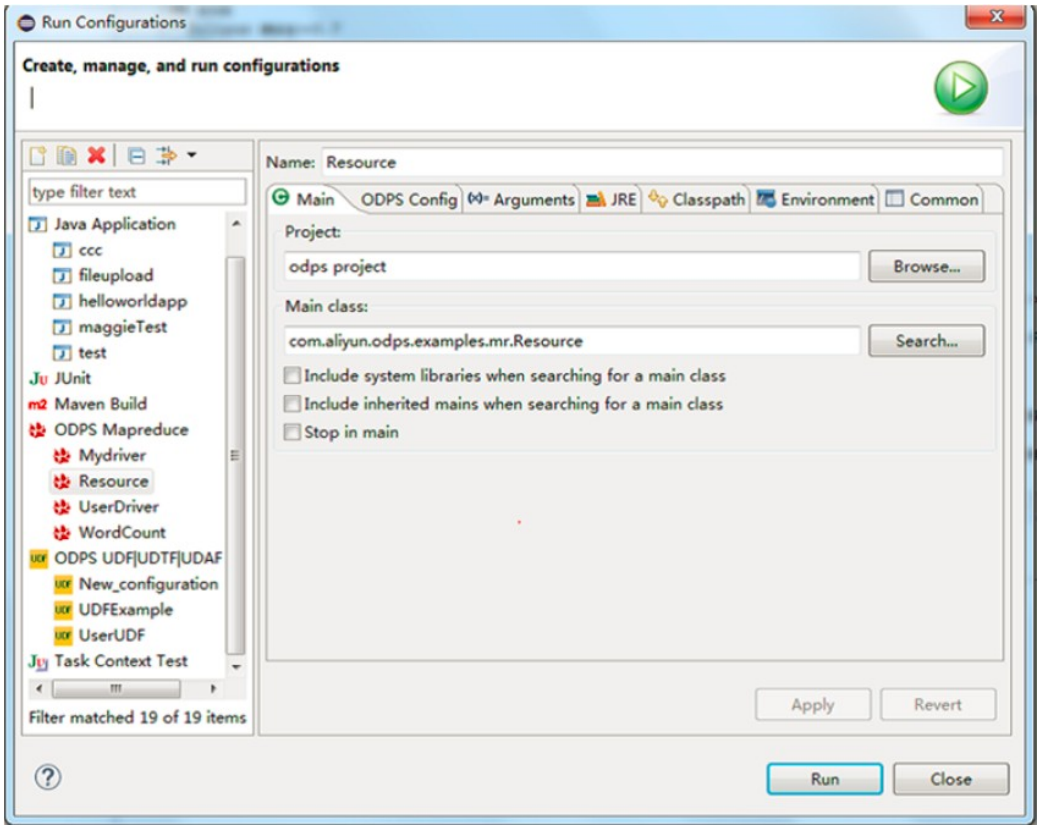
1.21.2.4.1.1. Run a UDF from the menu bar

This topic describes how to quickly run a UDF from the menu bar of the Eclipse plugin.

Procedure

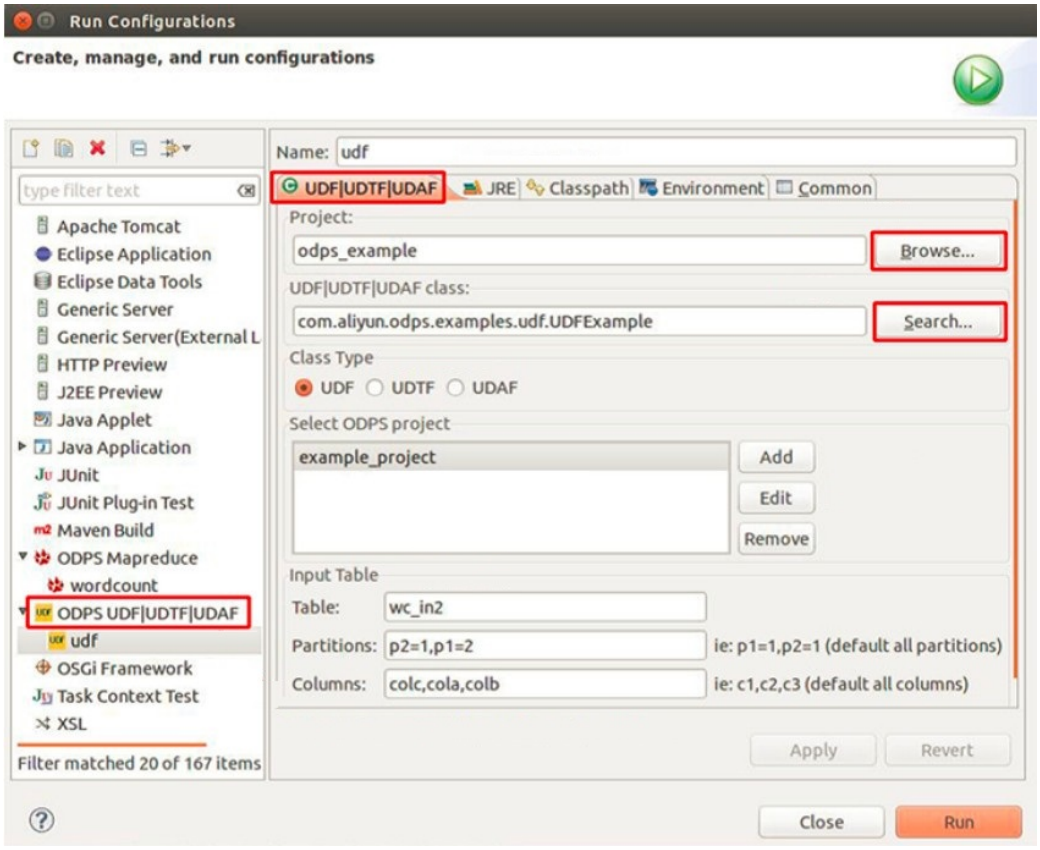
1. Choose **Run** > **Run Configurations** from the menu bar. A dialog box is displayed, as shown in the following figure.

   Run Configurations 1



2. To create a run configuration, select the UDF class and type to be run, select an ODPS project, and fill in the input table information, as shown in the following figure.

   Run Configurations 2



Note There are three parameters in the Input Table area: Enter the input table of the UDF in Table. Enter the partitions from which data is read in Partitions. Separate multiple partitions by commas (,). Enter the columns in which data is transmitted as UDF parameters in Columns. Separate multiple columns by commas (,).

3. Click **Run**. The running result is displayed in the console, as shown in the following figure.

   Console

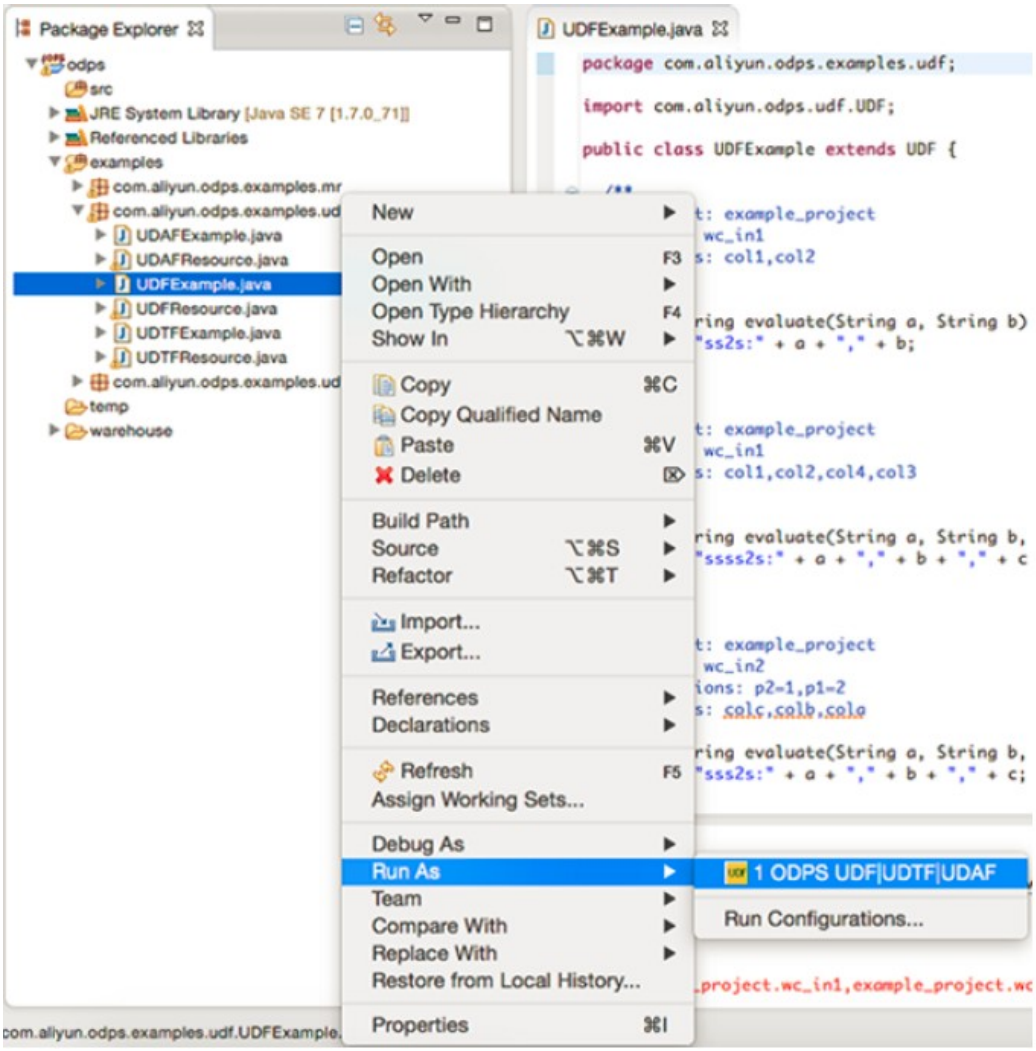
1.21.2.4.1.2. Use the right-click shortcut menu to quickly run a UDF

This topic describes how to use the right-click shortcut menu to quickly run a UDF in the Eclipse development plugin.

Procedure

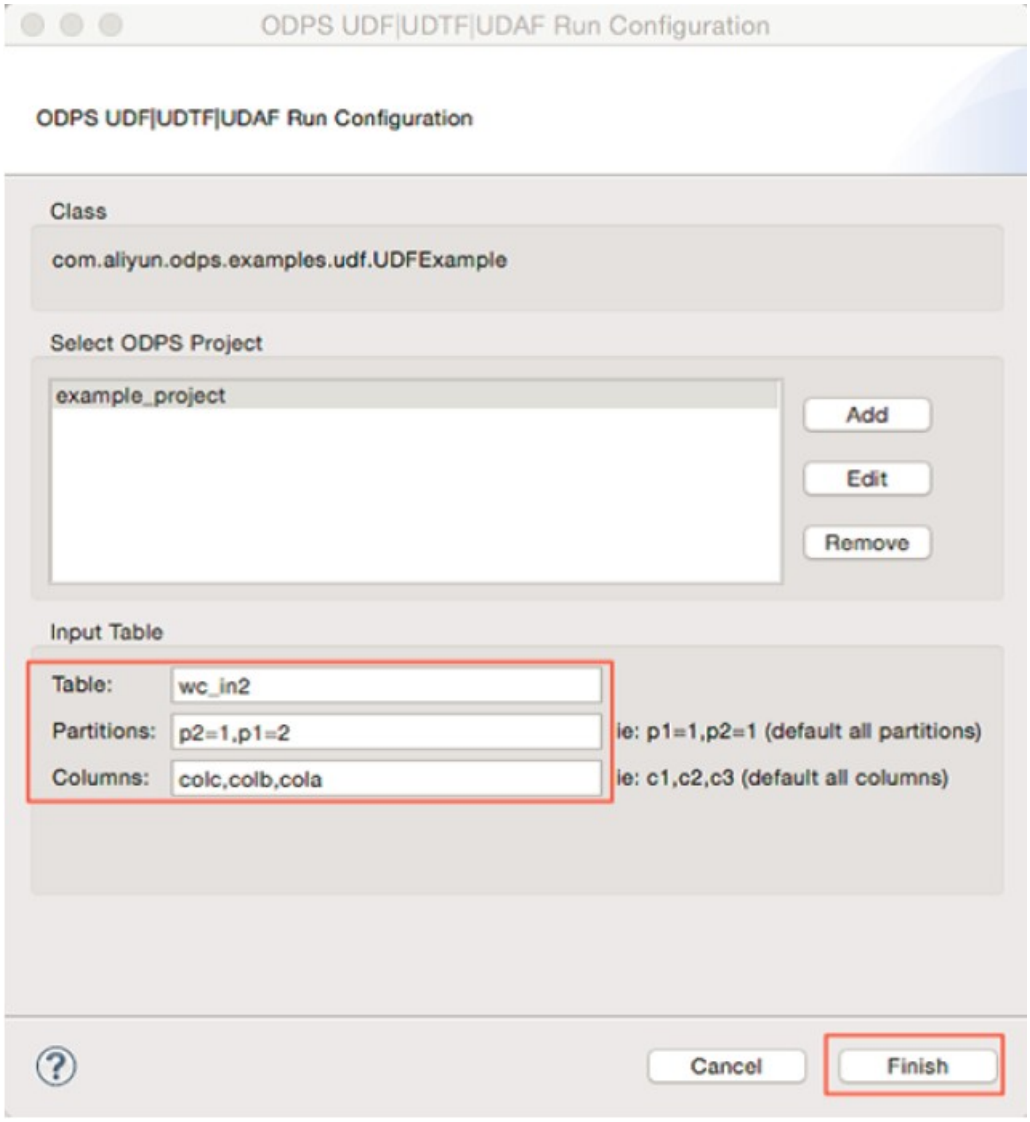
1. Right-click a udf.java file (such as UDFExample.java) and choose **Run As > Run UDF|UDAF|UDTF** from the shortcut menu, as shown in the following figure.

Step 1



2. In the dialog box that appears, configure the relevant parameters, as shown in the following figure.

Step 2



Note Table indicates the input table of the UDF. Partitions indicate the partitions from which data is read. Multiple partitions are separated by commas. Columns indicate the columns from which data is read. Multiple columns are separated by commas. These parameters are imported to the UDF as parameters.

3. Click **Finish** to run the UDF and obtain the result.

1.21.2.4.2. Run a UDF program

This topic describes how to run a UDF program in the Eclipse development plugin.

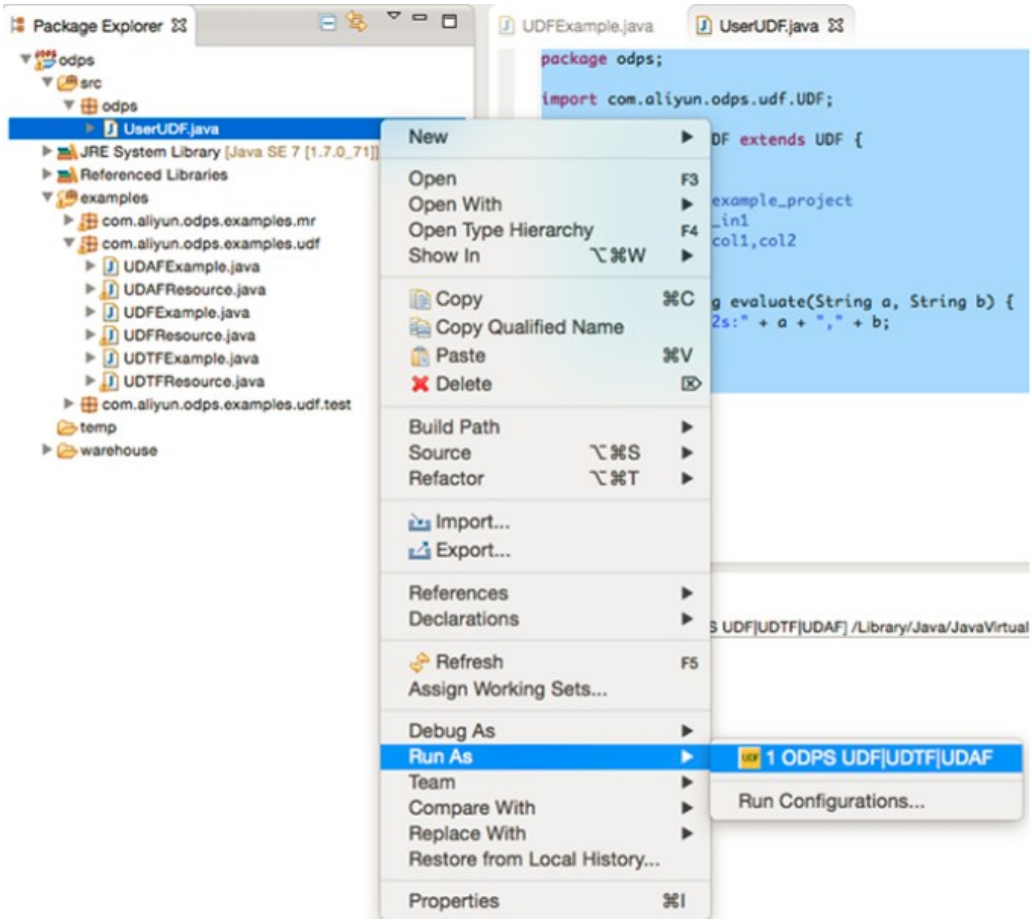
Procedure

1. Right-click a project and choose **New** > **UDF** (or choose **File** > **New** > **UDF** from the menu bar). Enter a UDF class name and click **Finish**. A Java file with the same name as the UDF class is generated in the **src** directory. Edit the content of the java file as follows:

```
package odps;
import com.aliyun.odps.udf.UDF;
public class UserUDF extends UDF {
/**
* project: example_project
* table: wc_in1
* columns: col1,col2
*
*/
public String evaluate(String a, String b) { return "ss2s:" + a + "," + b;
}
}
```

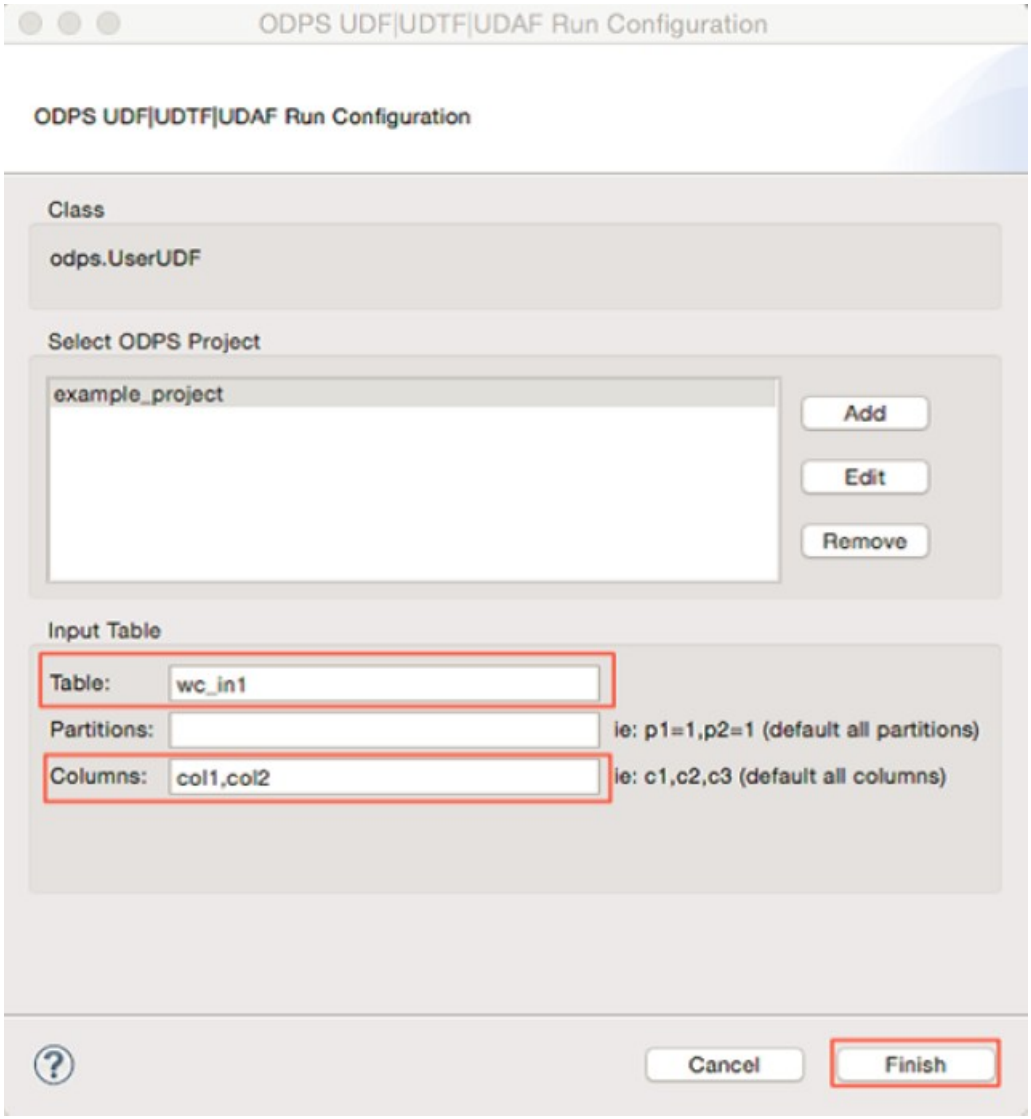
2. Right-click the Java file (such as UserUDF.java) and choose **Run As > ODPS UDF|UDTF|UDAF** from the shortcut menu, as shown in the following figure.

   Step 1



3. In the dialog box that appears, configure the relevant parameters, as shown in the following figure.

   Step 3-1



4. Click **Finish** to obtain the result.

```
ss2s:A1,A2
ss2s:A1,A2
ss2s:A1,A2
ss2s:A1,A2
```

> **Note** This example shows how to run a UDF program. You can use the same method to run a UDTF program.

1.21.2.5. Graph running example

After creating a MaxCompute project, you can write your own Graph program and debug it locally by performing the following steps.

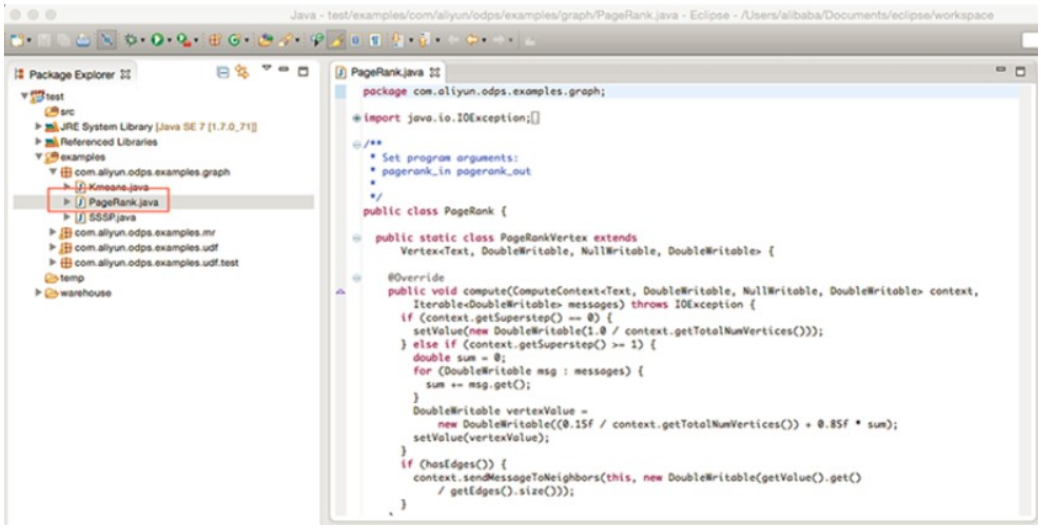
Context

In this example, you can use PageRank.java provided by the plugin to perform local debugging.

Procedure

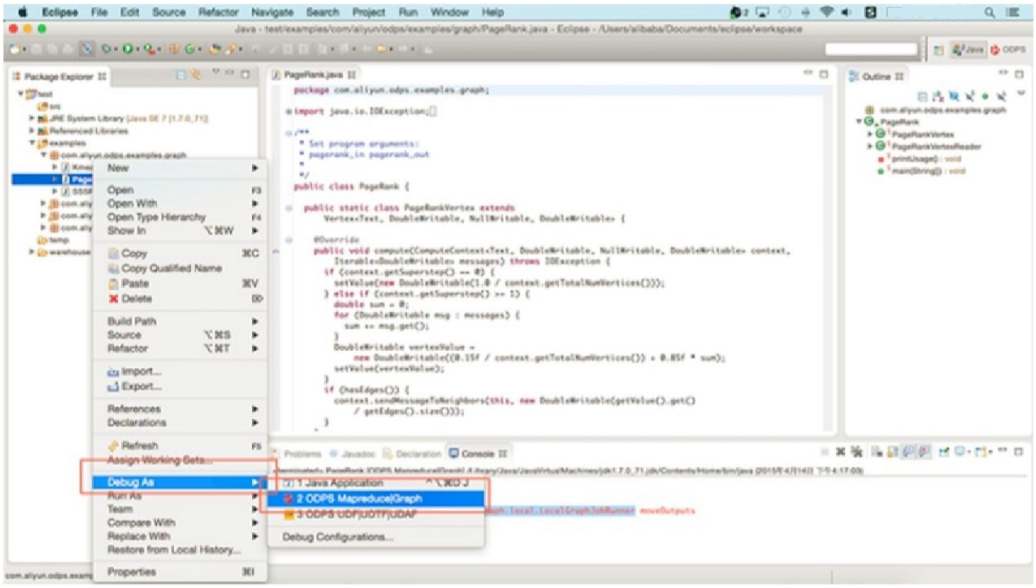
1. Choose **examples > PageRank.java**, as shown in the following figure.

   PageRank.java code 1

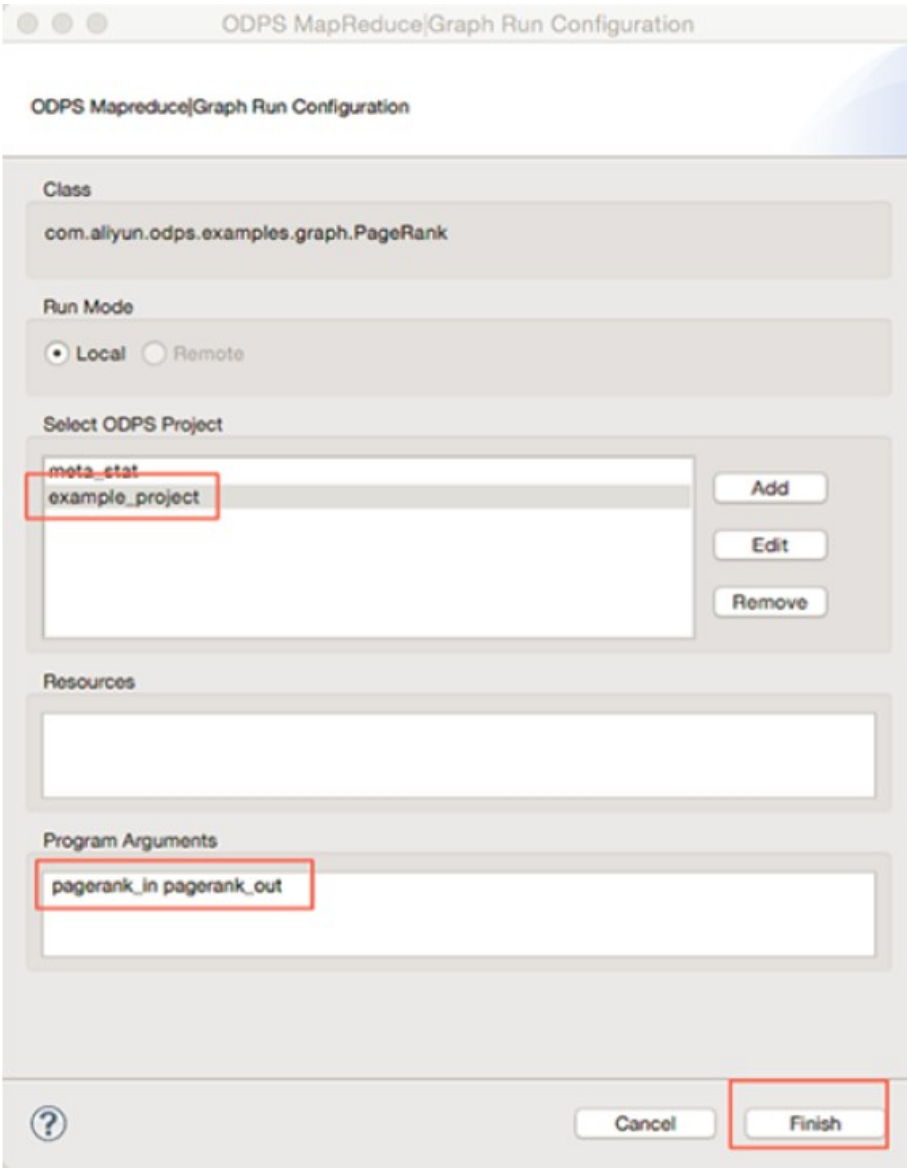
2. Right-click it and choose **Debug As > ODPS MapReduce|Graph**, as shown in the following figure.

   PageRank.java code 2

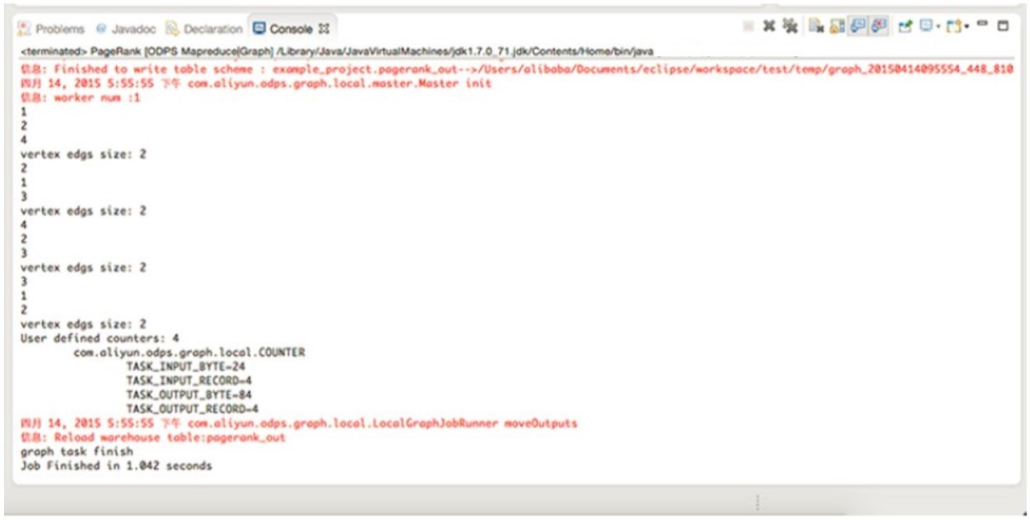
3. In the pop-up dialog box, enter the information as shown below.

   Configuration Drawings



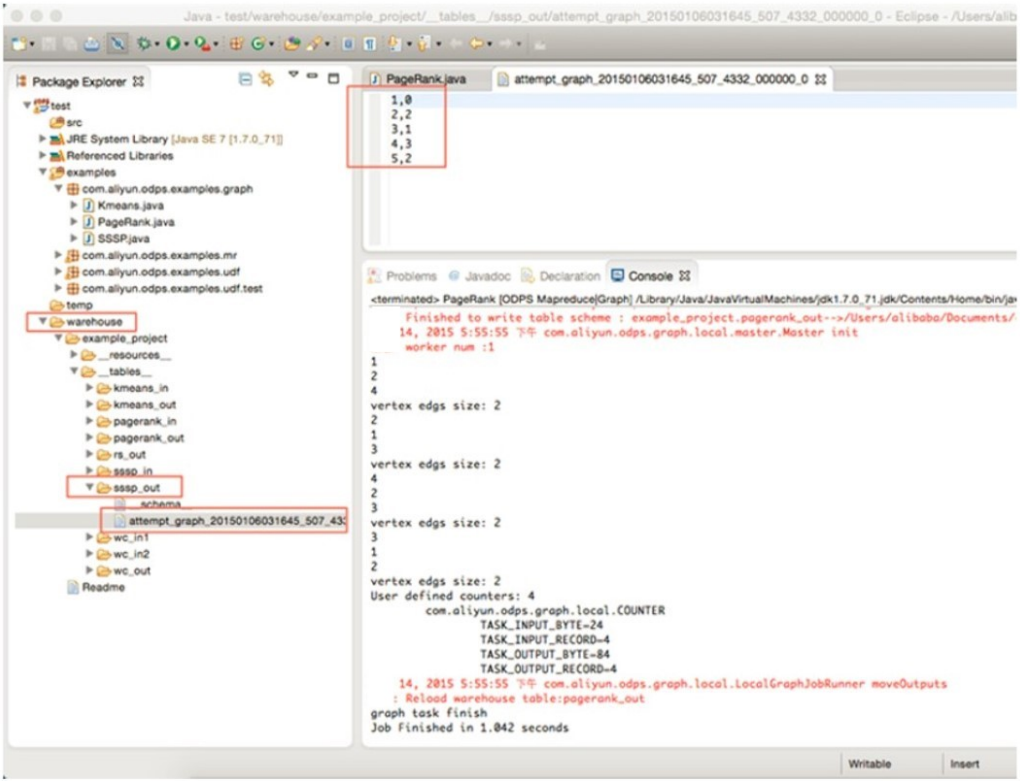
4. Click **Finish**. Check the running result, as shown in the following figure.

Running Result



Check the local computing result as shown below:

Local computing result



After passing the debugging, you can package the program, upload it to MaxCompute in the form of JAR resource, and submit the Graph job.

> **Note**
>
> - For more information about the packaging process, see MapReduce running example.
> - For more information about the directory structure of local results, see MapReduce running example.
> - For more information about uploading JAR resources, see Compile and run a Graph job.

1.22. MaxCompute FAQ

This topic describes MaxCompute FAQ and solutions.

SQL statement execution is slow. How do I check MaxCompute resource usage?

Log on to the MaxCompute AG as the admin user and perform the following steps:

1. Run the following command to display the remaining resources on the hosts in the MaxCompute cluster in ascending order:

```
r tfrl|sed 's/,//g'|sort -t "|" -k2 -n
```

2. Run the following command to view resource details of the hosts and the total cluster resources in MaxCompute:

```
r ttrl|sed 's/,//g'
```

3. Determine whether the remaining resources in MaxCompute are sufficient based on the ratio of remaining resources to total resources.

How do I handle the slow execution of jobs submitted by a project in a MaxCompute cluster with sufficient resources?

A possible cause is that the resources for the quota group where the project is located are exhausted. Perform the following steps to check whether the resources are exhausted and determine whether to add resources to the quota group:

1. Log on to the MaxCompute AG as the admin user and run the following command to check the resource usage of the quota group:

```
r quota
```

2. If you confirm that the resources for the quota group are exhausted, you can make modifications to the quota list on MaxCompute in Big Data Manager.

How do I modify quota group settings?

1. Run the following command in the MaxCompute AG to create or modify a quota:

```
sh/apsara/deploy/rpc_wrapper/rpc.sh setquota -i $QUOTAID -a $QUOTANAME -t fair -s$max_cpu_
quota $max_mem_quota -m $min_cpu_quota $min_mem_quota
```

> **Note** If $QUOTAID already exists, that quota is modified. Otherwise, a quota with that ID is created.

2. Log on to MaxCompute in Big Data Manager and configure relevant settings.

How do I perform simple operations on the metadata warehouse?

1. Log on to the MaxCompute AG.
2. Run the following commands:

```
/apsara/odps_tools/clt/bin/odpscmd
```

```
use meta;
```

3. Run the following command to view all tables in the metadata warehouse:

```
show tables;
```

4. Run the following command to obtain the description of a specific table:

```
desc <table>;
```

How do I use the smart metadata warehouse (package+view)?

You need to install the metadata warehouse enhancement package **package+view** first. Before you install the package, ensure that you are the owner of a project that is granted the package installation permission. After you have installed the package, you can follow the instructions provided in Package usage to use the smart metadata warehouse.

The following is a brief description on how to use the smart metadata warehouse:

- **Installation**

  package+view is a metadata warehouse enhancement package that depends on the metadata warehouse. You can install it by running the `odpscmd --config=odps_config.ini -f init.sql` command in the *system metadata warehouse* directory.

  > **Note**
  > - If the system asks you to re-install the package, remove the create package comment in the first line of init.sql and then run the preceding command again.
  > - **odps_config.ini**: This configuration file contains the configuration of the account used to access the metadata warehouse, which is also the project owner of the metadata warehouse.

- **Authorization**

  Run the following command to allow a project, such as p1, to install the package+view package:

  ```
  odpscmd --config=odps_config.ini -e "allow project p1 to install package systables;"
  ```

  Run the following command to allow all projects to install the package+view package:

  ```
  odpscmd --config=odps_config.ini -e "allow project * to install package systables;"
  ```

- **User operations**

  You can run the following command to install the package. Ensure that you are the owner of the project that is granted the package installation permission.

  ```
  install package meta.systables;
  ```

  After the installation is complete, you can run the following command to see the description of views in the package:

  ```
  desc package meta.systables;
  ```

  > **Note** After you have completed the preceding operations, you can start to use the smart metadata warehouse.

- **Views**

> **Note** To learn the definition of table schema, refer to the relevant content in the view description, which is available after you run the following command:
>
> ```
> desc viewname
> ```

View name	Content
allowed_package_installers	Information about the project that is granted the package installation permission
column_label_grants	Column label authorization information
column_labels	Column label information of a table
columns	Table schema information
installed_packages	Information about the package installed for the project
object_privileges	Table, UDF, resource authorization information
package_resources	Object information contained in the package
partitions	Partition information of a partitioned table
policies	User, role, and permission information defined in policies
resources	Resource information
roles	Role information
table_label_grants	Label authorization information of a table
table_labels	Label information of a table
tables	Table and view information
tasks	Job execution records
tunnels	Data upload and download records
udf_resources	Information about resources used in UDFs
udfs	Information about UDFs
user_roles	User and role association information
users	User information

- **Notes**

- By default, the smart metadata warehouse allows you to query data from the past 180 days. If you do not run a job on a specific day, you cannot obtain query results of that day from the smart metadata warehouse.
- We recommend that you specify a query range so that the system does not scan all data from the past 180 days.
- The time the data of the previous day is available depends on the specific output time of the metadata warehouse in the early morning. The data is available immediately after it is generated.
- The metadata warehouse does not provide metadata on the day when the project is created. The purpose is to avoid obtaining data of the project with the same name.

How do I grant Java sandbox permissions?

1. Log on to the AdminConsole and choose **MaxCompute Configuration > Project Management**. Select the project to which you want to grant Java sandbox permissions and double-click it to open the property dialog box.
2. In the **ODPS Sandbox Setting** area, enter the method or class you want to use in Sandbox Java Permissions.

   > **Note** Make sure that your input is in the correct format. The following example is for demonstration only. Enter each item in a single line and end it with a semicolon (;).

   ```
   permission java.lang.RuntimePermission "readSystemProperty"; permission java.lang.RuntimePermission "modifyThreadGroup"; permission java.security.AllPermission;
   ```

3. Click **Finish Modification**.

How do I handle exhausted disk capacity?

In most cases, you can clear scripts to free disk capacity. The most possible cause is that the root directory of MaxCompute AG or the /apsara directory occupies too much disk space. Therefore, you need to clear scripts in these two directories.

How do I find an AccessKey pair and configure correct AccessKey information?

1. Access the framework cluster management page of the Apsara Stack data center, and choose **Operations > Cluster Operations**. Select the cluster for which you want to find and configure the AccessKey pair, and access the cluster configuration page.
2. Double-click the kv.conf file in the file list to find the AccessKey information. You can also modify the information in this file and then save your modifications.

How do I add a MaxCompute host to a blacklist?

1. Log on to the Apsara AG as the admin user. Run the following command to enable the Fuxi blacklist function:

   ```
   r sgf fuximaster"{\"fuxi_Enable_BadNodeManager\":false}"
   ```

2. Run the following command to view the Fuxi blacklist:

```
/apsara/deploy/rpc_wrapper/rpc.shblacklist cluster get
```

3. Run the following command to add a MaxCompute host to the Fuxi blacklist:

```
/apsara/deploy/rpc_wrapper/rpc.shblacklist cluster add $hostname
```

4. Run the following command to view the Fuxi blacklist again and confirm that the host is added:

```
/apsara/deploy/rpc_wrapper/rpc.shblacklist cluster get
```

How do I export data from MaxCompute?

There are two methods to export data from MaxCompute: The first is to use the Tunnel command. The second is to configure synchronization tasks in DataWorks to export data from MaxCompute to other destinations.

How do I view the current MaxCompute version?

Run the following commands to view the MaxCompute version:

```
cat /apsara/odps_info/version|grep odps
```

```
cat /apsara/version
```

How do I restart MaxCompute services?

1. Run the following commands to save the configurations of resident MaxCompute services to a file. This configuration file is required when you restart MaxCompute services.

```
ssh odpsAG
cd /home/admin/
If you do not use a service, you can ignore the corresponding command.
You can use the r al command to view resident services.
r plan Odps/CGServiceControllerx > CGServiceControllerx
r plan sys/sqlonline-OTS >sqlonline-OTS
r plan Odps/MessagerServicex >MessagerServicex
r plan Odps/OdpsServicex >OdpsServicex
r plan Odps/HiveServerx >HiveServerx
r plan Odps/XStreamServicex >XStreamServicex
r plan Odps/QuotaServicex > QuotaServicex
r plan Odps/ReplicationServicex >ReplicationServicex
```

2. Run the following commands to stop MaxCompute services:

```
r sstop Odps/CGServiceControllerx
r sstop sys/sqlonline-OTS
r sstop Odps/MessagerServicex
r sstop Odps/OdpsServicex
r sstop Odps/HiveServerx
r sstop Odps/XStreamServicex
r sstop Odps/QuotaServicex
r sstop Odps/ReplicationServicex
```

3. Run the following commands to start MaxCompute services:

```
ssh odpsAG
cd /home/admin/
r start CGServiceControllerx
r start sqlonline-OTS
r start MessagerServicex.txt
r start OdpsServicex.txt
r start HiveServerx.txt
r start XStreamServicex.txt
r start QuotaServicex.txt
r start ReplicationServicex.txt
```

How do I power MaxCompute on and off?

1. Run the following commands to save the configurations of resident MaxCompute services to a file. This configuration file is required when you restart MaxCompute services.

```
ssh odpsAG
cd /home/admin/
If you do not use a service, you can ignore the corresponding command.
You can use the r al command to view resident services.
r plan Odps/CGServiceControllerx > CGServiceControllerx
r plan sys/sqlonline-OTS >sqlonline-OTS
r plan Odps/MessagerServicex >MessagerServicex
r plan Odps/OdpsServicex >OdpsServicex
r plan Odps/HiveServerx >HiveServerx
r plan Odps/XStreamServicex >XStreamServicex
r plan Odps/QuotaServicex > QuotaServicex
r plan Odps/ReplicationServicex >ReplicationServicex
```

2. Run the following commands to stop MaxCompute services:

```
r sstop Odps/CGServiceControllerx
r sstop sys/sqlonline-OTS
r sstop Odps/MessagerServicex
r sstop Odps/OdpsServicex
r sstop Odps/HiveServerx
r sstop Odps/XStreamServicex
r sstop Odps/QuotaServicex
r sstop Odps/ReplicationServicex
```

3. Run the following command to shut down the Apsara system:

```
/home/admin/dayu/bin/allapsara stop
```

4. Run the following command to shut down compute nodes gracefully:

```
Shutdown
```

5. Start compute nodes.
6. Run the following command to start the Apsara system:

```
/home/admin/dayu/bin/allapsara start
```

7. Run the following commands to start MaxCompute services:

```
ssh odpsAG
cd /home/admin/
r start CGServiceControllerx
r start sqlonline-OTS
r start MessagerServicex.txt
r start OdpsServicex.txt
r start HiveServerx.txt
r start XStreamServicex.txt
r start QuotaServicex.txt
r start ReplicationServicex.txt
```

How do I reduce the heavy load on a host?

1. Log on to the host with a heavy load and run the top command to check whether task processes occupy too many resources.
2. Generally, resources are occupied by user tasks. If task processes occupy too many resources, wait until these tasks are completed or ask users to stop these tasks.

1.23. Open source features of MaxCompute

This topic describes open source features related to MaxCompute.

SDKs

MaxCompute provides Java SDK and Python SDK interfaces to create, view, and delete MaxCompute tables. You can use the SDKs to manage MaxCompute by editing code.

How to obtain service support: Visit the official documentation or submit a ticket online.

MaxCompute RODPS

MaxCompute RODPS is an R plug-in for MaxCompute. For more information about the plug-in, see ODPS Plugin for R on GitHub.

How to obtain service support: Leave a message or create an issue in ODPS Plugin for R on GitHub.

MaxCompute JDBC

MaxCompute JDBC is an official JDBC driver provided by MaxCompute. It provides a set of interfaces to execute SQL tasks for Java programs. The project is hosted in ODPS JDBC on GitHub.

How to obtain service support: Leave a message or create an issue in ODPS JDBC on GitHub.

Mars

Mars is a tensor-based unified distributed computing framework. Mars makes it possible to execute large-scale scientific computing tasks by using only several lines of code, whereas MapReduce requires hundreds of lines of code. In addition, Mars improves computing performance.

The source code of Mars is now available on GitHub. You are welcome to contribute to Mars. You can visit Mars on GitHub to obtain its open source code.

For more information about Mars, see Mars Development Guide.

How to obtain service support: Leave a message or create an issue in Mars on GitHub.

Data Collector

Data Collector is a collection of the major open source data collection tools of MaxCompute, such as the Flume plug-in, OGG plug-in, Sqoop, Kettle plug-in, and Hive Data Transfer UDTF.

The Flume and OGG plug-ins are implemented based on the DataHub SDK, whereas Sqoop, the Kettle plug-in, and Hive Data Transfer UDTF are implemented based on the Tunnel SDK. DataHub is a real-time data transfer channel, and Tunnel is a batch data transfer channel. The Flume and OGG plug-ins are used to transfer data in real time. Sqoop, the Kettle plug-in, and Hive Data Transfer UDTF are used to transfer data in batches in offline mode.

For information about the source code, see Aliyun MaxCompute Data Collectors on GitHub. For more information about these tools, see wiki on GitHub.

How to obtain service support: Leave a message or create an issue in Aliyun MaxCompute Data Collectors on GitHub.

2.DataWorks

2.1. Log on to the DataWorks console

This topic describes how to log on to the DataWorks console.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

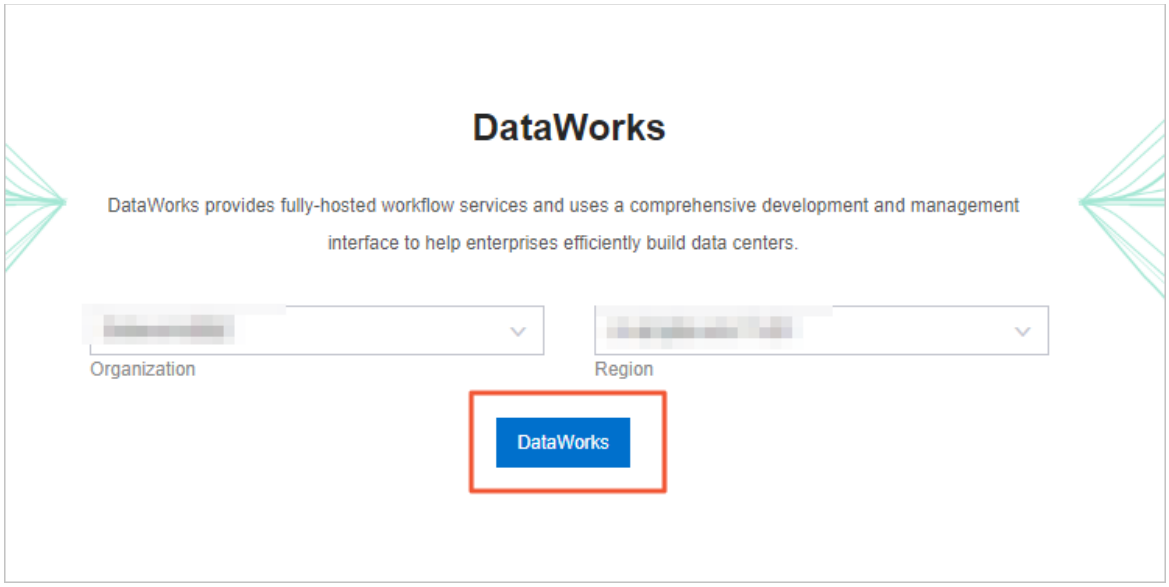
Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password used to log on to the console from the operations administrator.

   > **Note** When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters.
   > - Digits.
   > - Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Products > Big Data > DataWorks**.
5. On the page that appears, set the **Organization** and **Region** parameters and click **DataWorks**.



Notice You cannot log on to the DataWorks console by using the root organization.

2.2. Create a workspace

This topic describes how to create a workspace on the Project Management page.

Prerequisites

A compute engine is created to initialize MaxCompute projects.

Overview

DataWorks provides various preset templates for a workspace administrator to select when the administrator creates workspaces that contain one or more working environments, including development, testing, staging, and production. DataWorks can also automatically generate associations between workspaces. A one-to-many relationship exists between departments and workspaces. That is, multiple workspaces can be created under a department.

You can create a workspace in one of the following modes:

- **Standard Mode (Development and Production Environments)**: A DataWorks workspace corresponds to two MaxCompute projects. One MaxCompute project serves as the development environment and the other serves as the production environment.
- **Basic Mode (Production Environment Only)**: A DataWorks workspace corresponds to only one MaxCompute project.

Note For more information about the two workspace modes, see Workspace modes.

Procedure

1. Log on to the DataWorks console as a workspace administrator.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Project Management**. By default, the **Workspaces** page appears.
3. On the Workspaces page, click **Create Workspace** in the upper-right corner.

4. In the **Create Workspace** dialog box that appears, set the parameters in the Basic Information section.

   > **Note** If you select the standard mode, you must associate the workspace with two MaxCompute projects.

5. Set the parameters in the **Advanced Settings** section. You can select whether to enable the recurrence and whether to allow downloading the query results returned by SELECT statements. You must associate the workspace with MaxCompute projects.
6. Click **OK**.

2.3. Quick Start

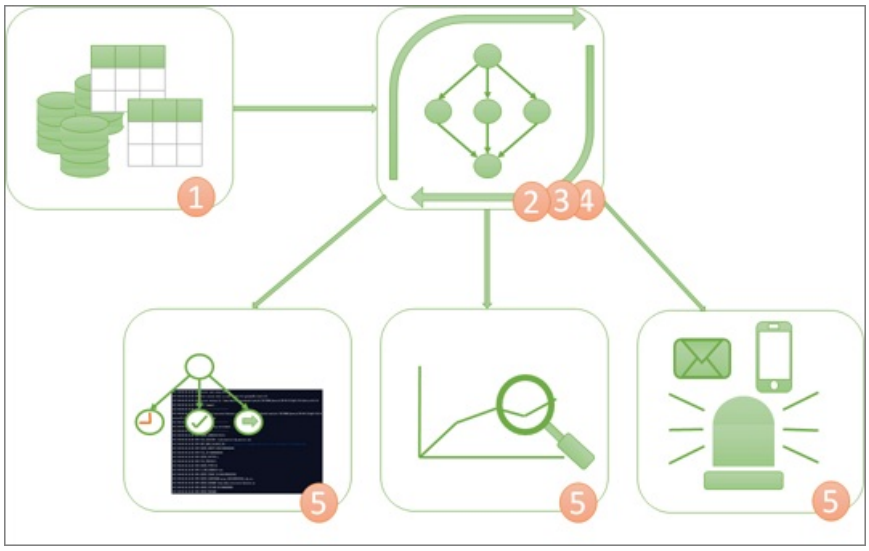
2.3.1. Overview

Quick Start guides you through a complete process of data analytics and O&M.

Generally, you can complete the following data analytics and O&M operations in a workspace of DataWorks:

1. Create tables and import data.
2. Create a workflow.
3. Create a sync node.
4. Configure recurrence and dependencies for a node.
5. Run a node and troubleshoot errors.

The following figure shows the basic process of data analytics and O&M.



2.3.2. Create tables and import data

This topic takes the bank_data and result_table tables as an example to describe how to create tables and import data in the DataWorks console.

Note The bank_data table stores business data, whereas the result_table table stores data analytics results.

Create the bank_data table

1. Log on to the DataWorks console.
2. On the **DataStudio** page that appears, move the pointer over the icon and click **Table**.
3. In the **Create Table** dialog box, set **Table Name** to bank_data.
4. Click **Commit**.
5. On the editing page of the created table, click **DDL Statement**.
6. In the **DDL Statement** dialog box, enter the table creation statement, and click **Generate Table Schema**. In the dialog box that appears, click **OK**.

   In this topic, the following statement is used as an example:

```
CREATE TABLE IF NOT EXISTS bank_data
(
 age           BIGINT COMMENT 'age',
 job           STRING COMMENT 'job type',
 marital       STRING COMMENT 'marital status',
 education     STRING COMMENT 'education level',
 default       STRING COMMENT 'credit card',
 housing       STRING COMMENT 'mortgage',
 loan          STRING COMMENT 'loan',
 contact       STRING COMMENT 'contact',
 month         STRING COMMENT 'month',
 day_of_week   STRING COMMENT 'day in a week',
 duration      STRING COMMENT 'duration',
 campaign      BIGINT COMMENT 'number of contacts during the campaign',
 pdays         DOUBLE COMMENT 'interval from the last contact',
 previous      DOUBLE COMMENT 'number of contacts with the customer',
 poutcome      STRING COMMENT 'result of the previous marketing campaign',
 emp_var_rate  DOUBLE COMMENT 'employment change rate',
 cons_price_idx DOUBLE COMMENT 'consumer price index',
 cons_conf_idx DOUBLE COMMENT 'consumer confidence index',
 euribor3m     DOUBLE COMMENT 'Euro deposit rate',
 nr_employed   DOUBLE COMMENT 'number of employees',
 y             BIGINT COMMENT 'whether time deposit is available'
);
```

7. After the table schema is generated, enter the display name of the table and click **Commit to Development Environment** or **Commit to Production Environment**.

> Note If you are using a workspace of the basic mode, click Commit to Production Environment.

8. In the left-side navigation pane, click **Workspace Tables**. On the page that appears, enter the table name to search for the created table. After you find the table, double-click the table name to view the table information.

Create the result_table table

1. On the **DataStudio** page that appears, move the pointer over the icon and click **Table**.
2. In the **Create Table** dialog box, set **Table Name** to result_table.
3. On the editing page of the created table, click **DDL Statement**.
4. In the **DDL Statement** dialog box, enter the table creation statement, and click **Generate Table Schema**. In the dialog box that appears, click **OK**.

   In this topic, the following statement is used as an example:

```
CREATE TABLE IF NOT EXISTS result_table
(
 education      STRING COMMENT 'education level',
 num        BIGINT COMMENT 'number of people'
);
```

5. After the table schema is generated, enter the display name of the table and click **Commit to Development Environment** or **Commit to Production Environment**.
6. In the left-side navigation pane, click **Workspace Tables**. On the page that appears, enter the table name to search for the created table. After you find the table, double-click the table name to view the table information.

Upload a local file to import its data to the bank_data table

You can perform the following operations in the DataWorks console:

- Upload a local text file to import its data to a table in a workspace.
- Use Data Integration to import business data from different data stores to a workspace.

> Note In this topic, a local file is used as the source of data. Comply with the following rules when uploading a local file:
>
> - File format: The file must be in the .txt, .csv, or .log format.
> - File size: The size of the file cannot exceed 10 MB.
> - Destination object: The destination object can be a partitioned table or a non-partitioned table. The partition key value cannot be in Chinese.

To upload the local file banking.txt to DataWorks, follow these steps:

1. On the **Data Analytics** tab, click the **Import** icon.
2. In the **Data Import Wizard** dialog box, select the table to which you want to import data and click **Next**.

3. Set **Select Data Import Method** to **Upload Local File** and click **Browse**. In the dialog box that appears, select the target local file and configure import information.

Parameter	Description
Select Data Import Method	The method of importing data. Valid values: **Upload Local File**, **DataService Studio**, and **Workbooks from Data Analysis**. In this example, select **Upload Local File**.
Select File	Click **Browse** and select the local file to upload.
Select Delimiter	The delimiter of fields in the file. Valid values: **Comma**, **Tab**, **Semicolon**, **Space**, **|**, **#**, and **&**. In this example, select **Comma**.
Original Character Set	The character set of the file. Valid values: **GBK**, **UTF-8**, **CP936**, and **ISO-8859**. In this example, select **GBK**.
Import First Row	The line from which data is to be imported. In this example, select **1**.
First Row as Field Names	Specifies whether to use the first line as the header line.
Data Preview	The preview of the data to import. **Note** If the data volume is large, only the data in the first 100 lines and 50 columns appears.

4. After the configuration is completed, click **Next**.
5. Select a matching mode for the fields in the source file and destination table. In this example, select **By Location**.
6. Click **Import Data**.

Data import methods

- Create a sync node

  This method is used to import data from various data stores, such as Relational Database Service (RDS), MySQL, SQL Server, PostgreSQL, MaxCompute, ApsaraDB for Memcache, Distribute Relational Database Service (DRDS), Object Storage Service (OSS), Oracle, FTP, DM, Hadoop Distributed File System (HDFS), and MongoDB.

- Upload a local file

  This method is used to upload .txt and .csv files not exceeding 10 MB. The destination object can be a partitioned table or a non-partitioned table. The partition key value cannot be in Chinese.

- Run Tunnel commands to upload a file

  This method is used to upload local files and other resource files of any size.

What to do next

Now you have learned how to create tables and import data. You can proceed with the next tutorial. In the next tutorial, you will learn how to create a workflow and how to compute and analyze data in a workspace. For more information, see Create a workflow.

2.3.3. Create a workflow

This topic describes how to create a workflow, create nodes in the workflow, and configure the dependencies among the nodes. After the configuration is completed, you can use the Data Analytics feature to further compute and analyze data in the workspace.

Prerequisites

The bank_data table for storing business data and the result_table table for storing data analytics results are created in the workspace. Data is imported to the bank_data table. For more information, see Create tables and import data.

Context

The Data Analytics feature of DataWorks allows you to drag and drop nodes in a workflow and configure the dependencies among the nodes. You can process data and configure dependencies in the data based on the workflow.

Create a workflow

1. Log on to the DataWorks console.
2. On the **DataStudio** page that appears, move the pointer over the **Create** icon and click **Workflow**.
3. In the **Create Workflow** dialog box, set the **Business Name** and **Description** parameters.
4. Click **Create**.

Create nodes and configure dependencies among the nodes

This section describes how to create a zero load node named start and an ODPS SQL node named insert_data in the workflow, and configure the insert_data node to depend on the start node.

> **Note** Pay attention to the following points when you use a zero load node:
>
> - A zero load node is a control node used to maintain and control its descendant nodes. When the zero load node runs in a workflow, it does not generate any data.
> - If other nodes are dependent on the zero load node and it is manually set to Failed by an administration expert, the pending descendant nodes cannot be triggered. During the O&M process, an administration expert can disable the zero load node to prevent errors of ancestor nodes from being further expanded.
> - Typically, the ancestor node of the zero load node in a workflow is set to the root node of the workspace. The root node of the workspace is named in the `Workspace name_root` format.

We recommend that you create a zero load node as the root node of a workflow to control the entire workflow.

1. Double-click the name of the workflow to go to the dashboard of the workflow. Move the

pointer over **Zero-Load Node** and drag it to the development panel on the right.

2. In the **Create Node** dialog box, set **Node Name** to start and click **Commit**.
3. Repeat steps 1 and 2 to create an **ODPS SQL** node and name it insert_data.
4. Draw a line to connect the nodes and set the start node as the ancestor node of the insert_data node.

Configure the ancestor node of the zero load node

The zero load node in a workflow is the controller of the entire workflow, and also the ancestor of all nodes in the workflow. Generally, the zero load node in a workflow depends on the root node of the workspace.

1. Double-click the name of the zero load node. On the page that appears, click the **Properties** tab in the right-side navigation pane.
2. In the **Properties** section, click **Use Root Node** and set the ancestor node of the zero load node as the root node of the workspace.
3. After the configuration is completed, click  in the upper-left corner.

Edit code in the ODPS SQL node

This section provides a sample SQL statement used to query and save the number of singles with different education levels who loan to buy houses in the ODPS SQL node insert_data. The queried data can be analyzed by and presented in descendant nodes of insert_data.

The SQL statement is as follows:

```
INSERT OVERWRITE TABLE result_table  --Insert data to the result_table table.
SELECT education
   , COUNT(marital) AS num
FROM bank_data
WHERE housing = 'yes'
   AND marital = 'single'
GROUP BY education
```

Run and debug the ODPS SQL node

1. After the SQL statement is entered in the insert_data node, click **Save**.
2. Click **Run** to view the runtime logs and result.

Commit the workflow

1. After running and debugging the ODPS SQL node insert_data, return to the workflow editing page and click **Commit**.
2. In the **Commit** dialog box, select the nodes to be committed, set **Description**, and then select **Ignore I/O Inconsistency Alerts**.
3. Click **Commit**.

What to do next

Now you have learned how to create and commit a workflow. You can proceed with the next tutorial. In the next tutorial, you will learn how to create a sync node to export data to different types of data stores. For more information, see Create a sync node.

2.3.4. Create a sync node

This topic describes how to create a sync node to export data from MaxCompute to a MySQL database.

Background

In DataWorks, Data Integration can be used to periodically transfer the business data generated in a business system to a workspace. After the data is computed in SQL nodes, Data Integration periodically exports the computing results to your specified data store for further display or use.

Add a connection

> **Note** Only the workspace administrator can create connections, and members of other roles can only view the connections.

1. Log on to the DataWorks console. On the DataSudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration**.
2. In the left-side navigation pane, choose **Sync Resources > Connections**. On the **Connections** page, click **Create Connection**.
3. In the **Create Connection** dialog box, set Data Source Type to **MySQL**.
4. Set parameters in the **Add MySQL Connection** dialog box. The following table lists the parameters that need to be set when the connection type is set to **User-Created Data Store**.

Parameter	Description
Data Source Type	The type of the connection. In this example, set the type to **MySQL > User-Created Data Store**.
Data Source Name	The name of the connection. The name can contain letters, digits, and underscores (_) and must start with a letter.
Description	The description of the connection. The description cannot exceed 80 characters in length.
Applicable Environment	The environment where the connection is configured. Valid values: **Development** and **Production**. **Note** This field is available only for workspaces in standard mode.
JDBC URL	The JDBC connectivity URL of the database, in the format of `jdbc:mysql://ServerIP:Port/Database`.

Parameter	Description
Username	The username for logging on to the database. Note You must enter the information of your MySQL database.
Password	The password for logging on to the database.

5. Click **Test Connection**.
6. If the connectivity test is successful, click **Complete**.

Verify that a table exists in the destination MySQL database

Use the following table creation statement to create the odps_result table in the MySQL database:

```
CREATE TABLE `ODPS_RESULT` (
`education` varchar(255) NULL ,
`num` int(10) NULL
);
```

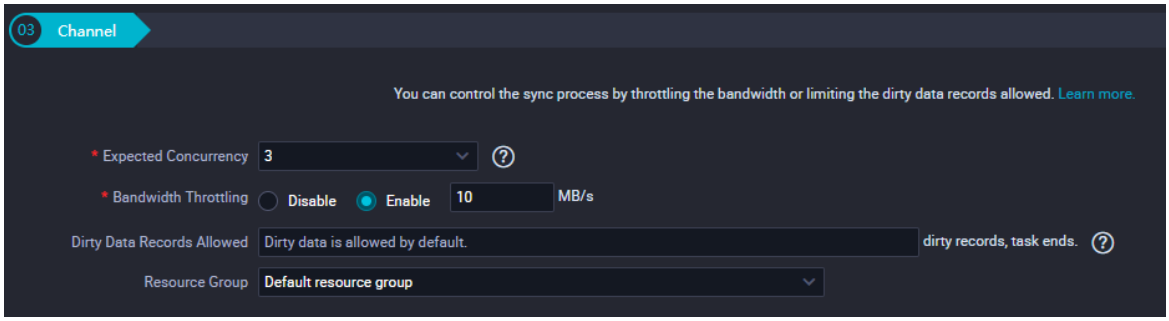
After the table is created, run the `desc odps_result;` statement to view the table details.

Create and configure a sync node

This section describes how to create and configure the sync node write_result to export data in the result_table table to your MySQL database. The procedure is as follows:

1. Go to the **Data Analytics** tab and create the sync node write_result.
2. Configure the insert_data node as the ancestor node of the write_result node.
3. Set **Data Source** to **MaxCompute > odps_first** and **Table** to result_table.
4. Select the odps_result table in your MySQL database as the destination table.
5. Configure the mapping between the fields in the source and destination tables.

   Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right. You can click **Add Line** to add a field or move the pointer over a field and click the **Delete** icon to delete the field.
6. In the Channel section, configure the synchronization rate limit and dirty data check rules.



Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The servers on which nodes are run. If an excessively large number of nodes are run in the default resource group, some nodes may be delayed due to insufficient resources. In this case, we recommend that you add a custom resource group.

7. Preview and save the configuration.

   After the configuration is completed, scroll up and down to view the node configuration. Verify that the configuration is correct and click **Save**.

Commit the sync node

Return to the workflow after saving the sync node. In the top navigation bar, click **Commit** to commit the sync node to scheduling system. The scheduling system automatically and periodically runs the node starting from the next day based on the configured properties of the node.

What to do next

Now you have learned how to create a sync node to export data to a specific data store. You can proceed with the next tutorial. In the next tutorial, you will learn how to configure recurrence and dependencies for a sync node. For more information, see Configure recurrence and dependencies for a node.

2.3.5. Configure recurrence and dependencies for a node

This topic describes how to configure recurrence and dependencies for a node in the DataWorks console.

> **Note** In this topic, the sync node write_result is used as an example and the recurrence is set to weekly.

DataWorks has a powerful scheduling engine to trigger nodes based on the recurrence and dependencies of nodes. DataWorks guarantees that tens of millions of nodes run accurately and punctually per day based on directed acyclic graphs (DAGs). In the DataWorks console, you can set the recurrence to minutely, hourly, daily, weekly, or monthly.

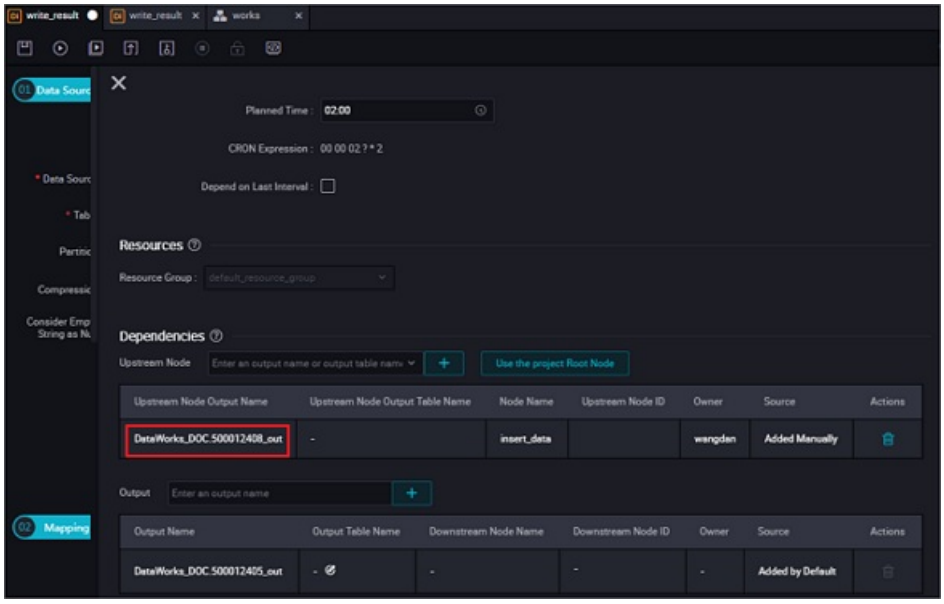
Configure recurrence for the sync node

1. After the sync node write_result is created, double-click the sync node to configure it.
2. Click the **Properties** tab in the right-side navigation pane to configure recurrence for the sync node.

Parameter	Description
Execution Mode	The mode in which the node is run. Valid values: **Normal** and **Dry-Run**. You can select one based on your own needs.
Retry Upon Error	Specifies whether to rerun the node upon an error.
Valid From	The date from which the node is effective.
Skip Execution	Specifies whether to skip execution of the node.
Cycle	The recurrence of the node, which can be monthly, weekly, daily, hourly, or minutely. In this example, the recurrence is set to weekly.
Customize Runtime	Specifies whether to run the node periodically. This field is selected by default.
Run Every or **Run At**	The specific day or time when the node is run. For example, you can configure a node to run at 02:00 every Tuesday.
CRON Expression	The value is `00 00 02 ? * 2` by default. It cannot be modified.
Cross-Cycle Dependencies	Specifies whether the node depends on the result of the last cycle.

Configure dependencies for the sync node

After configuring recurrence for the sync node write_result, you can continue to configure dependencies for the sync node.



You can configure the ancestor node on which the sync node depends. After that, the scheduling system can trigger the sync node when the specified time arrives, only after the instance of the ancestor node is run.

The configuration shown in the preceding figure indicates that the instance of the sync node is not triggered until the instance of the ancestor node insert_data is run.

The scheduling system creates the Workspace name_root node for each workspace as the root node by default. If no ancestor node is configured for the sync node, the sync node depends on the root node.

Commit the sync node

Save the configuration of the sync node write_result and click **Commit** to commit the node to the scheduling system.

Only after a node is committed, the scheduling system can automatically generate and run instances at the specified time starting from the next day according to the recurrence property.

> **Note** If a node is committed after 23:30, the scheduling system automatically generates and runs instances of the node starting from the third day.

What to do next

Now you have learned how to configure recurrence and dependencies for a sync node. You can proceed with the next tutorial. In the next tutorial, you will learn how to perform O&M on the committed node and troubleshoot errors based on the runtime logs. For more information, see Run a node and troubleshoot errors.

2.3.6. Run a node and troubleshoot errors

This topic describes how to run and maintain a node, and troubleshoot errors based on logs.

When you configure recurrence and dependencies for the sync node write_result, you have configured the sync node to run at 02:00 every Tuesday. After you commit this node, you have to wait until the next day to view the automatic execution result of this node. DataWorks allows you to run nodes in the following modes: test run, retroactive run, and periodic run. This helps you confirm the run time of each node instance, dependencies among node instances, and whether generated data meets your expectation.

- Test run: Nodes are triggered manually. This method is recommended if you only want to confirm the run time and running of a single node.
- Retroactive run: Nodes are triggered manually. This method is recommended if you want to confirm the run time of multiple nodes and dependencies among them, or if you want to re-perform data analysis and computing from the specific root node.
- Periodic run: Nodes are triggered automatically. The scheduling system automatically triggers the instances of committed nodes at the specified time points starting from 00:00 the next day after the nodes are committed. In addition, the scheduling system checks whether the ancestor instances of each instance have been run when the scheduled time arrives. If all the ancestor instances have been run when the scheduled time arrives, the current instance is automatically triggered without manual intervention.

Note The scheduling system generates instances for manually triggered nodes and auto triggered nodes based on the same rules.

- The scheduling system generates an instance for each recurrence, which can occur by day, hour, minute, month, or week.
- The scheduling system runs an instance only on the specified date and generates runtime logs for the instance.
- The scheduling system does not run an instance on other dates except the specified date. Instead, it directly change the status of the instance to successful when the running conditions are met. In this case, the scheduling system does not generate runtime logs.

Test run

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products** > **Operation Center** to go to the **Operation Center** page.
3. In the left-side navigation pane, click **Recurring**. On the page that appears, find the target node to run. Click **Test** next to the target node.
4. In the **Smoke Test** dialog box, set the **Smoke Test Instance Name** and **Data Timestamp** parameters and click **OK**.
5. On the **Smoke Test** page that appears, click an instance. The directed acyclic graph (DAG) of the instance appears on the right.

   Right-click the instance to view its dependencies and details, and stop or re-run this instance.

   Note
   - In test run mode, a node is triggered manually. The corresponding instance runs immediately when the scheduled time arrives, regardless of whether its ancestor instances have been run.
   - The sync node write_result is configured to run at 02:00 every Tuesday. According to the instance generation rules described earlier in this topic, if the data timestamp, which is one day before the run date, is set to Monday for a test run, the scheduling system runs the instance for the sync node write_result at 02:00 on Tuesday. If the data timestamp is not set to Monday for the test run, the scheduling system changes the status of the instance to successful at 02:00 on Tuesday with no runtime logs generated.

Retroactive run

A retroactive run is recommended if you want to confirm the run time of multiple nodes and dependencies among them, or if you want to re-perform data analysis and computing from the specific root node.

1. On the **Operation Center** page, choose **Task List** > **Recurring** in the left-side navigation pane.
2. Find the target node to run and choose **Patch Data** > **Current Node Retroactively** for the

target node.

3. In the **Patch Data** dialog box, set parameters and click **OK**.

Parameter	Description
Retroactive Instance Name	Enter the name of the retroactive instance.
Data Timestamp	Select the data timestamp of the retroactive instance. The retroactive instance is run on the next day of the specified timestamp.
Node	The default value is the current node, which cannot be changed.
Parallelism	Select **Disable** or specify several nodes to run concurrently.

4. On the **Retroactive** page that appears, click the retroactive instance to view the DAG of the instance.

   Right-click the instance to view its dependencies and details, and stop or re-run this instance.

   > **Note**
   > - In retroactive run mode, instance running requires the result of instance running on the previous day. For example, retroactive instances are configured to run between September 15, 2017 and September 18, 2017. If the instance on September 15 fails to run, the instance on September 16 cannot run.
   > - The sync node write_result is configured to run at 02:00 every Tuesday. According to the instance generation rules described earlier in this topic, if the data timestamp, which is one day before the run date, is set to Monday for a retroactive instance, the scheduling system runs the instance for the sync node write_result at 02:00 on Tuesday. If the data timestamp is not set to Monday for the retroactive instance, the scheduling system changes the status of the instance to successful at 02:00 on Tuesday with no runtime logs generated.

Periodic run

In periodic run mode, the scheduling system automatically triggers instances for all nodes based on the scheduling configuration. No menu item is provided for you to control the periodic run on the DataStudio page. You can view the instance information and runtime logs in either of the following ways:

- On the **Operation Center** page, choose **Operation Center** > **Node O&M** > **Recurring** in the left-side navigation pane. On the page that appears, set parameters such as the data timestamp or run date, find an instance of the sync node write_result, and then right-click the instance to view the instance information and runtime logs.
- On the **Recurring** page, click the instance of the target node to view the DAG of the instance.

  Right-click the instance to view its dependencies and details, and stop or re-run this instance.

> Note
>
> - If an ancestor node is not run, a descendant node does not run either.
> - If the initial status of an instance is pending, the scheduling system checks whether all its ancestor instances have been run when the scheduled time arrives.
> - The instance can be triggered and run only after all its ancestor instances have been run and the scheduled time arrives.
> - If an instance is pending, check whether all its ancestor instances have been run and whether the scheduled time arrives.

2.4. Data Integration

2.4.1. Overview

Data Integration is a stable, efficient, and scalable data synchronization service. It is designed to migrate and synchronize data between a wide range of heterogeneous data stores fast and stably in complex network environments.

Limits

- Data Integration can synchronize structured, semi-structured, and unstructured data. Structured data stores include Relational Database Service (RDS) and Distributed Relational Database Service (DRDS). Unstructured data, such as Object Storage Service (OSS) objects and text files, must be capable of being converted to structured data. Data Integration can only synchronize data that can be abstracted to two-dimensional logical tables to MaxCompute. It cannot synchronize unstructured data that cannot be converted to structured data, such as MP3 files stored in OSS, to MaxCompute.
- Data Integration supports data synchronization and exchange in one region or between regions.

  Data can be transmitted between regions over the classic network, but the network connectivity is not guaranteed. If the transmission fails over the classic network, we recommend that you use an Internet connection.
- Data Integration supports only data synchronization but not data consumption.

Batch data synchronization

Data Integration can be used to synchronize large amounts of data. Data Integration facilitates data transmission between diverse structured and semi-structured data stores. It provides readers and writers for the supported data stores and defines a transmission channel between the source and destination data stores and datasets, based on simplified data types.

Supported data stores

- Relational databases: MySQL, SQL Server, PostgreSQL, Oracle, Dameng, DRDS, PolarDB, HybridDB for MySQL, AnalyticDB for PostgreSQL, AnalyticDB for MySQL 2.0, and AnalyticDB for MySQL 3.0
- Big data storage: MaxCompute, DataHub, and Data Lake Analytics (DLA)
- Semi-structured storage: OSS, Hadoop Distributed File System (HDFS), and FTP
- NoSQL: MongoDB, Memcache, Redis, and Tablestore

- Message queue: LogHub
- Graph compute engine: GraphCompute

For more information, see Supported data sources.

> Note The connection configurations for data stores vary greatly. You can view the specific parameters that need to be set when you configure connections and sync nodes for data stores.

Development modes of sync nodes

You can develop sync nodes in one of the following modes:

- **Codeless UI**: Data Integration provides step-by-step instructions to help you configure a sync node. This mode is easy to use but provides only limited features.
- **Code editor**: You can write a JSON script to create a sync node. This mode supports advanced features to facilitate flexible configuration. It is suitable for experienced users and increases the cost of learning.

> Note
> - The code generated for a sync node on the codeless user interface (UI) can be converted to a script. This conversion is irreversible.
> - Before you write code, you must configure a connection and create the destination table.

Network types

A data store can reside on the classic network or in a virtual private cloud (VPC). The user-created IDC network type has been planned and will be supported soon.

- Classic network: a network deployed by Alibaba Cloud, which is shared with other tenants. This network is easy to use.
- VPC: a network created on Alibaba Cloud, which is available to only one Apsara Stack account. You have full control over your VPC, including customizing the IP address range, dividing the VPC to multiple subnets, and configuring routing tables and gateways.

  A VPC is an isolated network for which you can customize a wide range of parameters, such as the IP address range, subnets, and gateways. Based on wide deployment of VPCs, Data Integration provides the feature to automatically detect the reverse proxy for some data stores, including ApsaraDB RDS for MySQL, ApsaraDB RDS for PostgreSQL, ApsaraDB RDS for SQL Server, PolarDB, DRDS, HybridDB for MySQL, AnalyticDB for PostgreSQL, and AnalyticDB for MySQL 3.0. By using this feature, you do not need to purchase an extra Elastic Compute Service (ECS) instance in your VPC to configure sync nodes for these data stores. Instead, Data Integration automatically uses this feature to provide network connectivity to these data stores.

  When you configure sync nodes for other Alibaba Cloud data stores in a VPC, such as PPAS, ApsaraDB for OceanBase, ApsaraDB for Redis, ApsaraDB for MongoDB, ApsaraDB for Memcache, Tablestore, and ApsaraDB for HBase, you must purchase an ECS instance in the same VPC. This ECS instance is used to access the data stores.
- User-created IDC network: an IDC network deployed by yourself, which is isolated from the

Alibaba Cloud network.

> **Note** You can access data stores over the Internet. However, the access speed depends on the Internet bandwidth, and additional network access expenses are required. We recommend that you do not use Internet connections.

Terms

- Concurrency

  Concurrency indicates the maximum number of concurrent threads to read data from or write data to data storage within a single sync node.

- Bandwidth throttling

  Bandwidth throttling indicates that a maximum transmission rate is specified for a sync node of Data Integration.

- Dirty data

  Dirty data indicates meaningless data and data that does not match the specified data type. For example, you want to write data of the VARCHAR type in the source table to an INT-type field in the destination table. A data conversion error occurs and the data cannot be written to the destination table. In this case, the data is dirty.

- Connection

  A connection in DataWorks is used for accessing a data store, which can be a database or a data warehouse. DataWorks supports various types of data stores, and supports data synchronization between data stores of different types.

2.4.2. Homepage

The Data Integration homepage provides entries for you to create sync nodes, manage connections, maintain sync nodes, and view help documents.

Log on to the DataWorks console, click  in the upper-left corner, and choose **All Products** > **Data Aggregation** > **Data Integration**. The homepage of Data Integration appears by default.

On this page, you can perform the following operations:

- **New Task**: Click here to go to the **Data Analytics** page, where you can create sync nodes. For more information, see Create a sync node.
- **Connection**: Click here to go to the **Data Source** page, where you can view created connections and add a connection or multiple connections at a time.
- **Workbench**: Click here to go to the **Operation Center** > **Dashboard** page, where you can view the running status of created nodes. For more information, see O&M Overview.

2.4.3. Connectivity testing

This topic describes the FAQ about connectivity testing on connections.

When configuring a security group for a connection hosted on an Elastic Compute Service (ECS) instance, add the IP address of the scheduling cluster to the inbound and outbound rules of the security group. If the security group is not properly configured, data synchronization fails due to a connection failure.

To set a wide port range for a security group rule, call relevant API operations, instead of using the console.

Common scenarios of connectivity test failures

When a connection fails the connectivity test, check whether the region, network type, whitelist, database name, and username are properly configured for the connection. The following errors may occur during connectivity testing:

- The database password is incorrect.
- The network connection fails.
- A network error occurs during data synchronization.

  Check the log and determine which resource group is used. Check whether the resource group is a custom one.

  For a Relational Database Service (RDS) connection or a MongoDB connection, if a custom resource group is used, check whether its IP addresses are added to the whitelist of the connection.

  Check whether both the source and destination connections pass the connectivity test. For an RDS connection or a MongoDB connection, check whether all relevant IP addresses are added to the whitelist of the connection. If the IP address of a server is not added to the whitelist, the sync node fails when it runs on this server. However, the sync node succeeds when it runs on another server whose IP address is added to the whitelist.
- The result shows that a sync node is run but the log contains a disconnection error in port 8000.

  This issue occurs because a custom resource group is used and no inbound rule is configured for the corresponding IP address and port 8000 in the security group. To resolve the issue, add the IP address and port to the inbound rule of the security group and run the node again.

Examples of connectivity test failures

Example 1

- Symptom

  A connection failed the connectivity test. The database connection failed. The following information is involved: Database URL: jdbc:mysql://xx.xx.xx.x:xxxx/t_uoer_bradef. Username: xxxx_test. Error message: Access denied for user 'xxxx_test'@'%' to database 'yyyy_demo'.
- Troubleshooting
  i. Check whether the configuration of the connection is correct.
  ii. Check whether the database password is correct, the whitelist is properly configured, and your account has the permission to access the database. You can grant the required permissions in the RDS console.
- Example 2

- Symptom

  A connection failed the connectivity test. The following error message is returned:

  ```
  error message: Timed out after 5000 ms while waiting for a server that matches ReadPreferenceServerSelector{readPreference=primary}. Client view of cluster state is {type=UNKNOWN, servers=[(xxxxxxxxxx), type=UNKNOWN, state=CONNECTING, exception={com.mongodb.MongoSocketReadException: Prematurely reached end of stream}}]
  ```

- Troubleshooting

  Before testing the connectivity to a MongoDB connection that is not deployed in a Virtual Private Cloud (VPC), add relevant IP addresses to the whitelist of the connection.

2.4.4. Data sources

2.4.4.1. Supported data stores and plug-ins

Data Integration is a stable, efficient, and scalable data synchronization service. It provides transmission channels for batch data stored in Alibaba Cloud services such as MaxCompute, AnalyticDB for PostgreSQL, and Hologres.

The following table lists the data stores and plug-ins that Data Integration supports.

Data store	Reader	Writer
ApsaraDB for OceanBase	ApsaraDB for OceanBase	ApsaraDB for OceanBase
DataHub	DataHub Reader	DataHub Writer
Db2	DB2 Reader	DB2 Writer
DM	RDBMS Reader	RDBMS Writer
DRDS	DRDS Reader	DRDS Writer
Elasticsearch	Elasticsearch Reader	Elasticsearch Writer
FTP	FTP	FTP Writer
GBase8a	Supported	GBase8a Writer
HBase	HBase Reader	• HBase Writer • HBase11xsql Writer
HDFS	HDFS Reader	HDFS Writer
Hive	Hive Reader	Hive Writer
Hologres	Supported	Supported
HybridDB for MySQL	Supported	Supported

Data store	Reader	Writer
LogHub	LogHub Reader	LogHub Writer
MaxCompute	MaxCompute Reader	MaxCompute Writer
Memcache	Not supported	Memcache Writer
MongoDB	MongoDB Reader	MongoDB Writer
MySQL	MySQL Reader	MySQL Writer
Oracle	Oracle Reader	Oracle Writer
OSS	OSS Reader	OSS Writer
POLARDB	Supported	Supported
PostgreSQL	PostgreSQL Reader	PostgreSQL Writer
RDBMS	RDBMS Reader	RDBMS Writer
Redis	Not supported	Redis Writer
Stream	Stream Reader	Stream Writer
SQL Server	SQL Server Reader	SQL Server Writer
Tablestore	Tablestore Reader	Tablestore Writer
Vertica	Vertica Reader	Vertica Writer

2.4.4.2. Connection isolation

DataWorks provides the connection isolation feature to isolate data of the development environment from that of the production environment for workspaces in standard mode.

If a connection is configured in both the development and production environments, you can use the connection isolation feature to isolate the connection in the development environment from that in the production environment.

> **Note** Currently, only workspaces in standard mode support the connection isolation feature.

When you configure a sync node, the connection in the development environment is used. After you commit and deploy the sync node to the production environment for running, the connection in the production environment is used. To commit and deploy a node to the production environment for scheduling, you must configure a connection in both the development and production environments. The connection must have the same name in the development and production environments.

The connection isolation feature has the following impacts on workspaces:

- Workspaces in basic mode: The features and configuration dialog boxes of connections are the same as those before the connection isolation feature is added. For more information, see Connection configuration.
- Workspaces in standard mode: The Applicable Environment parameter is added to the configuration dialog boxes of connections.
- Workspaces upgraded from the basic mode to the standard mode: During the upgrade, you are prompted to upgrade connections. After the upgrade, the connections in the development environment are isolated from those in the production environment.

2.4.4.3. Sync data monitoring

The Sync Data Monitoring page displays the total number of sync node instances for different connections and the instance details based on the selected workspace and time range.

The cut-off time of data to be displayed is 0 minutes 0 seconds of the current hour. For example, if the current time is 2019-04-04 10:10:00, the page displays the data generated before 2019-04-04 10:00:00.

1. Log on to the DataWorks console and select a workspace.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration** to go to the **Data Integration** page.
3. In the left-side navigation pane, click **Sync Data Monitoring**. On the page that appears, view the total number of sync node instances for different connections and the instance details.
   - View summary data by connection type

     The Source and Target sections display the summary data of source connections and that of destination connections, respectively. Take source connections as an example. If the Source section displays MaxCompute with the value 1, a sync node instance whose source connection is MaxCompute is run in the selected time range.
   - View instance details

     The Sync Instances section displays the details of all sync node instances that are run in the selected time range. You can also perform the following operations:
     - Click a node in the **Node Name** column to go to the node configuration page.
     - Search for instances by condition, such as the ID, committer, node name, source connection type, and destination connection type. Sort search results based on the number of synchronized data entries or the size of synchronized data.

2.4.4.4. Manage connection permissions

DataWorks allows you to share connections among workspaces by managing permissions on the connections. After connections are shared, you can view the shared connections in the target workspaces. This topic describes how to manage permissions on connections and view shared connections.

Context

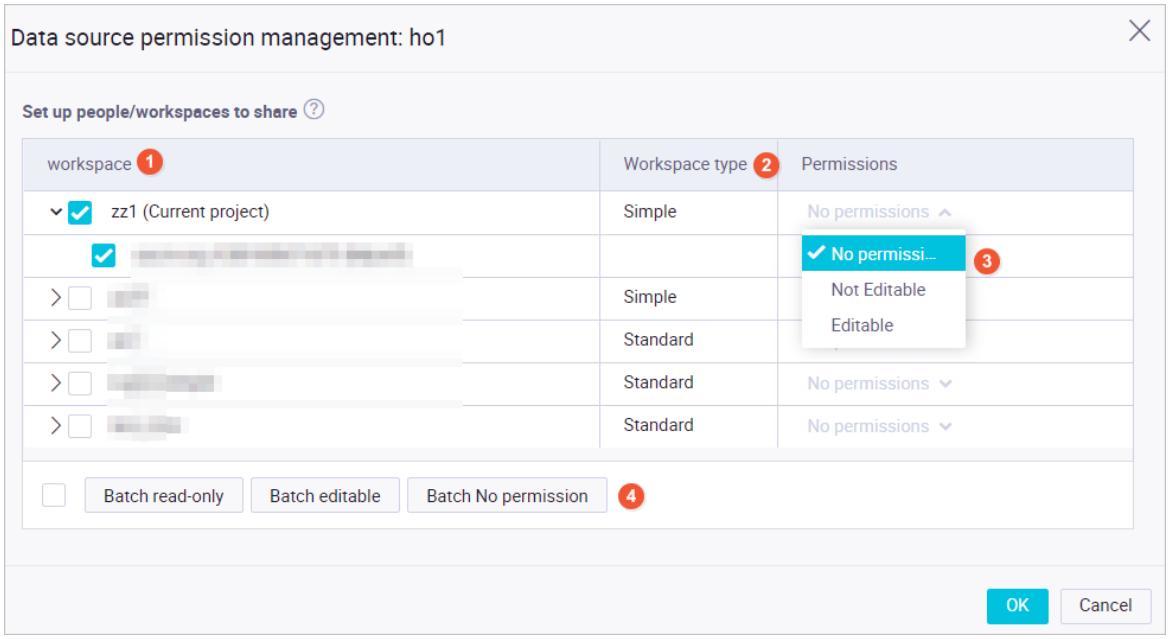
The configurations of a connection include sensitive information such as the endpoint of the data store, username, and password. Common developers only need to reference the connection to access the data store. Disclosing too much sensitive information or allowing

everyone to modify the configurations of the connection may cause security risks. If multiple users modify the configurations of a connection, the data store may fail to be connected. In this way, the nodes that reference the connection may fail.

Data Integration provides strict permission control. Only connection creators can manage the permissions on connections. They can grant permissions on connections to a specified workspace or user.

Go to the Data Source page

1. Log on to the DataWorks console.
2. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Integration**.
3. On the page that appears, click **Data Source** in the left-side navigation pane.
4. On the page that appears, find the target connection and click **Modify Permission** in the **Actions** column.
5. In the **Data source permission management** dialog box, set the parameters as described in the following table.



No.	Parameter	Description

No.	Parameter	Description
1	**Workspace**	All workspaces that the current user joins and all members in each workspace. You can share the connection with several or all members in a workspace. ◦ If no permission is set for a connection, the connection inherits the permissions from the connection that is created earlier than the current one. ◦ When you configure the permissions on a connection for a workspace, the permissions apply to all members in the workspace. Members that join the workspace after the permission configuration also have the specified permissions. After you configure the permissions for a workspace, you can still configure the permissions for a specific user in the workspace. For example, after you set the permission on a connection to **No permission** for a workspace, you can still set the permission of a specific user in the workspace to **Editable**. ◦ You can configure the permissions on a connection for members in the current workspace. ◦ Only the creator of a connection can modify and share the connection. Other users including the workspace administrator cannot modify the connection. ◦ A workspace administrator can use a connection only after the workspace administrator is granted the required permission.
2	**Workspace type**	The type of each workspace. Valid values: **Simple** and **Standard**.
3	**Permissions**	The permission of a workspace or a member on the connection. Valid values: ◦ **No permission**: The workspace or member has no permission on the connection. ◦ **Not Editable**: The workspace or member can use the connection but cannot modify or view the configurations of connection. ◦ **Editable**: The workspace or member can use and modify the connection. **Note** If you grant the Editable permission with a workspace or member, the workspace or member can modify the connection. Exercise caution when you grant the Editable permission.
4	Batch operations	The operations that you can perform on the selected workspaces or members at a time. Valid values: **Batch read-only**, **Batch editable**, and **Batch No permission**.

6. Click **OK**.You can share connections across workspaces based on the following rules:
   - Between workspaces in simple mode:
     - If the source workspace is upgraded to the standard mode, connections in the production environment are shared.
     - If the target workspace is upgraded to the standard mode, a connection is shared to both the development environment and production environment with the same content.
   - From a workspace in simple mode to a workspace in standard mode: A connection is shared to both the development environment and production environment with the same content.
   - Between workspaces in standard mode: Connections in the development environment and production environment are shared to the corresponding environment separately.
   - From a workspace in standard mode to a workspace in simple mode:
     - You can share connections in both the production environment and development environment. Only connections in the production environment or development environment exist in the target workspace. If you share a connection in both environments, the newly shared one overrides the existing one in the target workspace.
     - If the target workspace is upgraded to the standard mode, the shared connection exists in both the development environment and production environment with the same content.

View shared connections

In the top navigation bar, select a workspace with connections shared from other workspaces from the drop-down list in the upper-left corner. The **Data Source** page of the selected workspace appears. On this page, you can view shared connections on the **Normal** and **Has expired** tabs.

- **Normal tab**

  On the Normal tab, you can view the information about each connection, including the connection name, connection type, permission details, connection description, creation time, connection status, and the time when the data store was last connected.

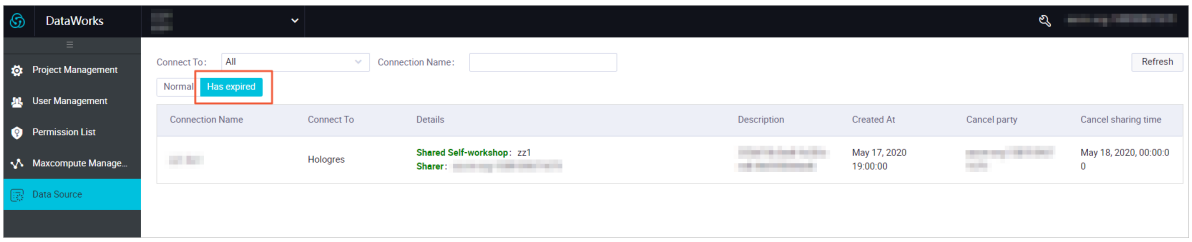
  The permission information appears in the **Details** column of the target connection. A shared connection is named in the Name of the workspace that shares the connection.Connection name format.

  
  If the current user has the Editable permission on the connection, **Modify** appears in the Actions column.

- **Has expired tab**

On the **Has expired** tab, you can view the connections for which your permissions have expired.

In the **Cancel party** column, you can view the member who revoked the permissions. In the **Created at** column, you can view the time when the permissions were revoked. The information helps you locate the cause of connection failures.



2.4.4.5. Configure a MySQL connection

A MySQL connection allows you to read data from and write data to MySQL by using MySQL Reader and Writer. You can configure sync nodes for MySQL by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data Aggregation > Data Integration.**
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **MySQL** in the Relational Databases section.
4. In the **Add MySQL Connection** dialog box, set the parameters as required.You can set Connect To parameter to **ApsaraDB for RDS** or **Connection Mode** for a MySQL connection.
   - The following table describes the parameters that appear after you set the **Connect To** parameter to **ApsaraDB for RDS**.

Parameter	Description
Connect To	The type of the connection. In this example, set the value to **ApsaraDB for RDS**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.

Parameter	Description
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. Note This parameter is available only when the workspace is in standard mode.
RDS Instance ID	The ID of the ApsaraDB RDS for MySQL instance. You can view the ID in the ApsaraDB for RDS console.
RDS Instance Account ID	The ID of the Apsara Stack tenant account that is used to purchase the ApsaraDB RDS for MySQL instance.
Database Name	The name of the database.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.

- The following table describes the parameters that appear after you set the **Connect To** parameter to **Connection Mode**.

Parameter	Description
Connect To	The type of the connection. In this example, set the value to **Connection Mode**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. Note This parameter is available only when the workspace is in standard mode.
JDBC URL	The JDBC URL of the database, in the format of `jdbc:mysql://ServerIP:Port/Database`.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.
Enable reverse VPC access	Specifies whether to enable reverse VPC access. Select the Enable check box if you cannot directly access the data store on an ECS instance but can access it by using a VPC.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

What's next

Now you have learned how to configure a MySQL connection. You can proceed with the next tutorial. In the next tutorial, you will learn how to configure MySQL Reader and Writer. For more information, see Configure the MySQL reader and Configure MySQL Writer.

2.4.4.6. Configure an SQL Server connection

An SQL Server connection allows you to read data from and write data to SQL Server by using SQL Server Reader and Writer. You can configure sync nodes for SQL Server by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click  in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **SQLServer** in the Relational Databases section.
4. In the **Add SQLServer Connection** dialog box, set the parameters as required.You can set the Connect To parameter to **ApsaraDB for RDS** or **Connection Mode** for an SQL Server connection
   - The following table describes the parameters that appear after you set the **Connect To** parameter to **ApsaraDB for RDS**.

Parameter	Description
Connect To	The type of the connection. In this example, set the value to **ApsaraDB for RDS**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.

Parameter	Description
RDS Instance ID	The ID of the ApsaraDB RDS for SQL Server instance. You can view the ID in the ApsaraDB for RDS console.
RDS Instance Account ID	The ID of the Apsara Stack tenant account that is used to purchase the ApsaraDB RDS for SQL Server instance.
Database Name	The name of the database.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.

- The following table describes the parameters that appear after you set the **Connect To** parameter to **Connection Mode**.

Parameter	Description
Connect To	The type of the connection. In this example, set the value to **Connection Mode**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
JDBC URL	The JDBC URL of the database, in the format of `jdbc:sqlserver://ServerIP:Port;DatabaseName=Database`.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.
Enable reverse VPC access	Specifies whether to enable reverse VPC access. Select the Enable check box if you cannot directly access the data store on an ECS instance but can access it by using a VPC.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

What's next

Now you have learned how to configure an SQL Server connection. You can proceed with the

next tutorial. In the next tutorial, you will learn how to configure SQL Server Reader and Writer. For more information, see Configure SQL Server Reader and Configure SQL Server Writer.

2.4.4.7. Configure a PostgreSQL connection

A PostgreSQL connection allows you to read data from and write data to PostgreSQL by using PostgreSQL Reader and Writer. You can configure sync nodes for PostgreSQL by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose **All Products** > **Data Aggregation** > **Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **PostgreSQL** in the Relational Databases section.
4. In the **Add PostgreSQL Connection** dialog box, set the required parameters.You can set the Connect To parameter to **ApsaraDB for RDS** or **Connection Mode** for a PostgreSQL connection.
   - The following table describes the parameters that appear after you set the **Connect To** parameter to **ApsaraDB for RDS**.

Parameter	Description
Connect To	The type of the connection. In this example, set the value to **ApsaraDB for RDS**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. Note This parameter is available only when the workspace is in standard mode.
RDS Instance ID	The ID of the ApsaraDB RDS for PostgreSQL instance. You can view the ID in the ApsaraDB for RDS console.

Parameter	Description
RDS Instance Account ID	The ID of the Apsara Stack tenant account that is used to purchase the ApsaraDB RDS for PostgreSQL instance. You can view your account ID on the **Security Settings** page.
Database Name	The name of the database.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.

- The following table describes the parameters that appear after you set the **Connect To** parameter to **Connection Mode**.

Parameter	Description
Connect To	The type of the connection. In this example, set the value to **Connection Mode**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
JDBC URL	The JDBC URL of the database, in the format of `jdbc:postgresql://ServerIP:Port/Database`.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.
Enable reverse VPC access	Specifies whether to enable reverse VPC access. Select the Enable check box if you cannot directly access the data store on an ECS instance but can access it by using a VPC.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.8. Configure an Oracle connection

An Oracle connection allows you to read data from and write data to Oracle by using Oracle Reader and Writer. You can configure sync nodes for Oracle by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **Oracle** in the Relational Databases section.
4. In the **Add Oracle Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
JDBC URL	The JDBC URL of the database, in the format of `jdbc:oracle:thin:@ServerIP:Port:Database`.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.
Enable reverse VPC access	Specifies whether to enable reverse VPC access. Select the Enable check box if you cannot directly access the data store on an ECS instance but can access it by using a VPC.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.9. Configure a Dameng connection

A Dameng connection allows you to read data from and write data to Dameng by using Dameng Reader and Writer. You can configure sync nodes for Dameng by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **DM** in the Relational Databases section.
4. In the **Add DM Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
JDBC URL	The JDBC URL of the database, in the format of `jdbc:dm://ServerIP:Port/Database`.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.
Enable reverse VPC access	Specifies whether to enable reverse VPC access. Select the Enable check box if you cannot directly access the data store on an ECS instance but can access it by using a VPC.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.10. Configure a DRDS connection

A DRDS connection allows you to read data from and write data to DRDS by using DRDS Reader and Writer. You can configure sync nodes for DRDS by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Aggregation > Data Integration.**
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **DRDS** in the Relational Databases section.
4. In the **Add DRDS Connection** dialog box, set the parameters as required.You can set the Connect To parameter to **ApsaraDB for DRDS** or **Connection Mode** for a DRDS connection.
   - The following table describes the parameters that appear after you set the Connect To parameter to **ApsaraDB for DRDS**.

Parameter	Description
Connect To	The type of the connection. In this example, set the value to **ApsaraDB for DRDS**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
Instance ID	The ID of the DRDS instance. You can view the ID in the DRDS console.
Tenant Account ID	The ID of the Apsara Stack tenant account that is used to purchase the DRDS instance. You can view your account ID on the **Security Settings** page.
Database Name	The name of the database.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.

   - The following table describes the parameters that appear after you set the Connect To parameter to **Connection Mode**.

Parameter	Description
Connect To	The type of the connection. In this example, set the value to **Connection Mode**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
JDBC URL	The JDBC URL of the database, in the format of `jdbc:mysql://ServerIP:Port/Database`.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

What's next

Now you have learned how to configure a DRDS connection. You can proceed with the next tutorial. In the next tutorial, you will learn how to configure DRDS Reader and Writer. For more information, see Configure the DRDS reader.

2.4.4.11. Configure a PolarDB connection

A PolarDB connection allows you to read data from and write data to PolarDB by using PolarDB Reader and Writer. You can configure sync nodes for PolarDB by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click  in the upper-left corner and choose **All Products** > **Data Aggregation** > **Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **POLARDB** in the Relational Databases section.

4. In the **Add POLARDB Connection** dialog box, set the parameters as required.

Parameter	Description
Connect To	The type of the connection. In this example, set the value to **Connection Mode**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
Database Type	The type of the database. Valid values: **MySql** and **Postgresql**.
JDBC URL	The JDBC URL of the database, in the format of `jdbc:mysql://ServerIP:Port/Database`.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.12. Configure a HybridDB for MySQL connection

A HybridDB for MySQL connection allows you to read data from and write data to HybridDB for MySQL by using HybridDB for MySQL Reader and Writer. You can configure sync nodes for HybridDB for MySQL by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **HybridDB for MySQL** in the Relational Databases

section.

4. In the **Add HybridDB for MySQL Connection** dialog box, set the parameters as required.

Parameter	Description
Connect To	The type of the connection. In this example, set the value to **ApsaraDB for AnalyticDB**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
Instance ID	The ID of the HybridDB for MySQL instance. You can view the ID in the HybridDB for MySQL console.
Tenant Account ID	The ID of the Apsara Stack tenant account that is used to purchase the HybridDB for MySQL instance.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.13. Configure a HybridDB for PostgreSQL connection

A HybridDB for PostgreSQL connection allows you to read data from and write data to HybridDB for PostgreSQL by using HybridDB for PostgreSQL Reader and Writer. You can configure sync nodes for HybridDB for PostgreSQL by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose **All Products** > **Data Aggregation** > **Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **HybridDB for PostgreSQL** in the Relational Databases section.

4. In the **Add HybridDB for PostgreSQL Connection** dialog box, set the parameters as required.

Parameter	Description
Connect To	The type of the connection. In this example, set the value to **ApsaraDB for AnalyticDB**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
Instance ID	The ID of the HybridDB for PostgreSQL instance. You can view the ID in the HybridDB for PostgreSQL console.
Tenant Account ID	The ID of the Apsara Stack tenant account that is used to purchase the HybridDB for PostgreSQL instance. You can view your account ID on the **Security Settings** page.
Database Name	The name of the database.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.14. Configure an ApsaraDB for OceanBase connection

An ApsaraDB for OceanBase connection allows you to read data from and write data to ApsaraDB for OceanBase by using ApsaraDB for OceanBase Reader and Writer. You can configure sync nodes for ApsaraDB for OceanBase by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click  in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.

3. In the **Add Connection** dialog box, click **ApsaraDB for OceanBase** in the Big Data Storage Systems section.
4. In the **Add ApsaraDB for OceanBase Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
JDBC URL	The JDBC URL of the ApsaraDB for OceanBase database, in the format `jdbc:oceanbase://ip:port/database`.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.15. Configure a MaxCompute connection

A MaxCompute connection allows you to read data from and write data to MaxCompute by using MaxCompute Reader and Writer.

Context

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click  in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **MaxCompute** in the Big Data Storage Systems section.
4. In the **Add MaxCompute Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
ODPS Endpoint	The endpoint of the MaxCompute project. This parameter is read-only, and the value is automatically obtained from system configurations.
Tunnel Endpoint	The endpoint of the MaxCompute Tunnel service.
MaxCompute Project Name	The name of the MaxCompute project.
AccessKey ID	The AccessKey ID for connecting to the MaxCompute project.
AccessKey Secret	The AccessKey secret for connecting to the MaxCompute project.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.16. Configure a DataHub connection

DataHub offers a comprehensive data import scheme to support fast computing for large amounts of data.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click  in the upper-left corner and choose **All Products** > **Data Aggregation** > **Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **DataHub** in the Big Data Storage Systems section.
4. In the **Add DataHub Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
DataHub Endpoint	The endpoint of DataHub. This parameter is read-only, and the value is automatically obtained from system configurations.
DataHub Project	The ID of the DataHub project.
AccessKey ID	The AccessKey ID for connecting to the DataHub project. You can view the AccessKey ID on the **User Info** page.
AceessKey Secret	The AccessKey secret for connecting to the DataHub project.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.17. Configure an AnalyticDB for MySQL connection

An AnalyticDB for MySQL connection allows you to write data to AnalyticDB for MySQL by using AnalyticDB for MySQL Writer. You can configure sync nodes for AnalyticDB for MySQL by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **ADS** in the Big Data Storage Systems section.
4. In the **Add ADS Connection** dialog box, set the parameters as required.

Parameter	Description

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
Connection URL	The connection URL of AnalyticDB for MySQL, in the format of `Address:Port`.
Database	The name of the database.
AccessKey ID	The AccessKey ID for connecting to the AnalyticDB for MySQL database.
AccessKey Secret	The AccessKey secret for connecting to the AnalyticDB for MySQL database.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.18. Configure a Vertica connection

A Vertica connection allows you to read data from and write data to Vertica by using Vertica Reader and Writer. You can configure sync nodes for Vertica by using the UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **Vertica** in the Big Data Storage Systems section.
4. In the **Add Vertica Connection** dialog box, set the parameters as required.

Parameter	Description

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
JDBC URL	The JDBC URL of the Vertica database, in the format of `jdbc:vertica://Server IP:Port/Database`.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.
Enable reverse VPC access	Specifies whether to enable reverse VPC access. Select the Enable check box if you cannot directly access the data store on an ECS instance but can access it by using a VPC.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.19. Configure a GBase8a connection

A GBase8a connection allows you to read data from and write data to GBase8a by using GBase8a Reader and Writer. You can configure sync nodes for GBase8a by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **GBase8a** in the Big Data Storage Systems section.
4. In the **Add GBase8a Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
JDBC URL	The JDBC URL of the database, in the format of `jdbc:mysql://ServerIP:Port/Database`.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.
Enable reverse VPC access	Specifies whether to enable reverse VPC access. Select the Enable check box if you cannot directly access the data store on an ECS instance but can access it by using a VPC.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.20. Configure a Lightning connection

MaxCompute Lightning is an interactive query service that MaxCompute provides. MaxCompute Lightning complies with the PostgreSQL standards and syntax and allows you to use common tools and standard SQL to query and analyze data in MaxCompute projects.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **Lightning** in the Big Data Storage Systems section.
4. In the **Add Lightning Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
Host	The endpoint of the MaxCompute Lightning server. Default value: `seahawks.aliyun-inc.com`.
Port	The port number of the MaxCompute Lightning server. Default value: 8099.
Database Name	The name of the database.
Username and Password	The username and password that you can use to connect to the database.
ODPS Endpoint	The endpoint of MaxCompute.
MaxCompute Project Name	The name of the MaxCompute project.
AccessKey ID	The AccessKey ID for connecting to the MaxCompute Lightning server.
AccessKey Secret	The AccessKey secret for connecting to the MaxCompute Lightning server.
JDBC Extension Parameters	The extension parameters used to establish a JDBC connection to MaxCompute Lightning. In this field, `prepareThreshold=0` is added by default and cannot be deleted. Otherwise, you cannot connect to MaxCompute Lightning.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.21. Configure an HBase connection

An HBase connection allows you to read data from and write data to HBase by using HBase Reader and Writer. You can configure sync nodes for HBase by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **HBase** in the Big Data Storage Systems section.
4. In the **Add HBase Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.

Parameter	Description
Configuration	The HBase cluster configuration for client connections. You can convert the hbase-site.xml parameter to the JSON format and add more HBase client properties, such as cache and batch for scan operations, to optimize the interaction between the cluster and the client. Based on the edition of ApsaraDB for HBase in use, you must configure different information: ○ If you are using ApsaraDB for HBase Standard Edition or less advanced editions, the default configuration is used. You only need to enter the corresponding ZooKeeper information. ○ If you are using ApsaraDB for HBase editions that are more advanced than Standard Edition, the endpoint parameter specific to advanced editions is used for connection, and the zookeeper.quorum parameter is not used. The following configuration is an example for an HBase connection of ApsaraDB for HBase Enhanced Edition (Lindorm): `"hbaseConfig": {` `"hbase.client.connection.impl" : "com.alibaba.hbase.client.AliHBaseUEConnection",` `"hbase.client.endpoint" : "host:30020",` `"hbase.client.username" : "root",` `"hbase.client.password" : "root"` `}`

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.22. Configure a Hologres connection

A Hologres connection allows you to read data from and write data to Hologres by using Hologres Reader and Writer. You can configure sync nodes for Hologres by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.

ii. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Aggregation > Data Integration.**

iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.

2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **Hologres** in the Big Data Storage Systems section.
4. In the **Add Hologres Connection** dialog box, set the parameters as required.

Parameter	Description
Connect To	The type of the connection. Default value: **ApsaraDB for RDS**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
Instance ID	The ID of the Hologres instance.
Database Name	The name of the database in the Hologres instance.
AccessKey ID	The AccessKey ID for connecting to the Hologres database.
AccessKey Secret	The AccessKey secret for connecting to the Hologres database.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.23. Configure a Hive connection

A Hive connection allows you to read data from and write data to Hive by using Hive Reader and Writer. You can configure sync nodes for Hive by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Aggregation > Data Integration.**

iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.

2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **Hive** in the Big Data Storage Systems section.
4. In the **Add Hive Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
HIVE JDBC URL	The JDBC URL of the Hive metadatabase.
Database Name	The name of the Hive database. You can run the `show databases` command on the Hive client to query the created databases.
Logon Method	The mode for connecting to the Hive database. Valid values: **Username and password** and **Anonymous logon**. If you select **Username and password**, enter the username and password that you can use to connect to the Hive database.
metastoreUris	The URIs of the Hive metadatabase, in the format of `thrift://ip1:port1,thrift://ip2:por2`.
defaultFS	The address of the NameNode in the Active state in the HDFS, in the format of `hdfs://ip:port`.

Parameter	Description
Extension Parameters	The advanced parameters of Hive, such as those related to high availability (HA). The following code is an example: "hadoopConfig":{ "dfs.nameservices": "testDfs", "dfs.ha.namenodes.testDfs": "namenode1,namenode2", "dfs.namenode.rpc-address.youkuDfs.namenode1": "", "dfs.namenode.rpc-address.youkuDfs.namenode2": "", "dfs.client.failover.proxy.provider.testDfs "org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider" }

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.24. Configure an OSS connection

Alibaba Cloud OSS is a secure and reliable service that allows you to store large amounts of objects.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **OSS** in the Semi-Structured Storage Systems section.
4. In the **Add OSS Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.

Parameter	Description
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
Endpoint	The OSS endpoint, in the format of `http://oss.aliyuncs.com`. The OSS endpoint varies with the region. **Note** If you add the bucket name before the domain name, for example, `http://xxx.oss.aliyuncs.com`, the connection can pass the connectivity test but data synchronization will fail.
Bucket	The name of the OSS bucket. A bucket is a storage space that serves as a container for storing objects. You can create one or more buckets and add one or more objects to each bucket. DataWorks can search for objects only in the bucket specified here during data synchronization.
AccessKey ID	The AccessKey ID for connecting to the OSS bucket.
AceessKey Secret	The AccessKey secret for connecting to the OSS bucket.

Notice When data in OSS is stored as CSV files, they must comply with the standard CSV format. For example, if the data in a column of a CSV file contains a double quotation mark ("), you must replace the double quotation mark with a pair of double quotation marks (""). Otherwise, the data in the CVS file may be incorrectly parsed.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.25. Configure an HDFS connection

A HDFS connection allows you to read data from and write data to HDFS by using HDFS Reader and Writer. You can configure sync nodes for HDFS by using the code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.

ii. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Aggregation > Data Integration.**

iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.

2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **HDFS** in the Semi-Structured Storage Systems section.
4. In the **Add HDFS Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
DefaultFS	The address of the NameNode in the HDFS, in the format of `hdfs://ServerIP:Port`.
Extension Parameters	The extension parameter hadoopConfig for HDFS Reader and Writer. You can configure the advanced parameters of Hadoop, such as those related to HA.

5. Click **Test Connection.**
6. After the connection passes the connectivity test, click **Complete.**

2.4.4.26. Configure an FTP connection

An FTP connection allows you to read data from and write data to FTP by using FTP Reader and Writer. You can configure sync nodes for FTP by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Aggregation > Data Integration.**
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.

2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **FTP** in the Semi-Structured Storage Systems section.
4. In the **Add FTP Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
Portocol	The protocol used by the FTP server. Only FTP and SFTP are supported.
Host	The address of the FTP server.
Port	The port of the FTP server. The default port is 21 for FTP and 22 for SFTP.
Username	The username that you can use to connect to the FTP server.
Password	The password that you can use to connect to the FTP server.
Enable reverse VPC access	Specifies whether to enable reverse VPC access. Select the Enable check box if you cannot directly access the data store on an ECS instance but can access it by using a VPC.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.27. Configure a MongoDB connection

MongoDB is a document-oriented database that is second only to Oracle and MySQL. A MongoDB connection allows you to read data from and write data to MongoDB by using MongoDB Reader and Writer. You can configure sync nodes for MongoDB by using the code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click  in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.

iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.

2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **MongoDB** in the NoSQL section.
4. In the **Add MongoDB Connection** dialog box, set the parameters as required.You can set the Connect To parameter to **ApsaraDB for RDS** or **Connection Mode** for a MongoDB connection.
   - **ApsaraDB for RDS**: Generally, the classic network is used to access the target ApsaraDB for MongoDB instance in this mode. You can access the ApsaraDB for MongoDB instance in the same region over the classic network. However, the access to the ApsaraDB for MongoDB instance from a different region over the classic network is not guaranteed to be successful.

Parameter	Description
Connect To	The connection type. In this example, set the value to **ApsaraDB for RDS**. **Note** If you have not assigned the default role to Data Integration, log on to the Resource Access Management (RAM) console with your Apsara Stack tenant account and perform authorization. Then, refresh this configuration page.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
Region	The region where the ApsaraDB for MongoDB instance resides.
Instance ID	The ID of the ApsaraDB for MongoDB instance. You can view the ID in the ApsaraDB for MongoDB console.
Database Name	The name of the database that you created in the ApsaraDB for MongoDB console. You can also specify the database username and password in the console.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.

- **Connection Mode**: Generally, the Internet is used to access the target database in this mode, which may cost you fees.

Parameter	Description
Connect To	The type of the connection. In this example, set the value to **Connection Mode**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
Address	The endpoint in the `host:port` format. To add an endpoint, click **Add Address** and specify the endpoint to add. To add more endpoints, repeat the preceding action. **Note** You must add either public endpoints or internal endpoints. Do not mix public endpoints with internal endpoints.
Database Name	The name of the database.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.28. Configure a Memcache connection

A Memcache connection allows you to write data to ApsaraDB for Memcache by using Memcache Writer. You can configure sync nodes for ApsaraDB for Memcache by using the code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.

iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.

2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **Memcache(OCS)** in the NoSQL section.
4. In the **Add Memcache(OCS) Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
Proxy Host	The IP address of the host or Memcache proxy. You can view the IP address on the basic information page of the ApsaraDB for Memcache console.
Port	The port for connecting to the ApsaraDB for Memcache instance. Default value: 11211.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.29. Configure a Redis connection

A Redis connection allows you to read data from and write data to Redis by using Redis Reader and Writer. You can configure sync nodes for Redis by using the code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click  in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.

3. In the **Add Connection** dialog box, click **Redis** in the **NoSQL** section.
4. In the **Add Redis Connection** dialog box, set the parameters as required.You can set the **Connect To** parameter to **ApsaraDB for RDS** or **Connection Mode** for a Redis connection.
   - The following table describes the parameters that appear after you set the **Connect To** parameter to **ApsaraDB for RDS**.

Parameter	Description
Connect To	The type of the connection. In this example, set the value to **ApsaraDB for RDS**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
Region	The region where the ApsaraDB for Redis instance resides.
Redis Instance ID	The ID of the ApsaraDB for Redis instance. You can view the ID in the ApsaraDB for Redis console.
Redis Password	The password that you can use to connect to the ApsaraDB for Redis instance. Leave it blank if no password is required.

   - The following table describes the parameters that appear after you set the **Connect To** parameter to **Connection Mode**.

Parameter	Description
Connect To	The type of the connection. In this example, set the value to **Connection Mode**.
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.

Parameter	Description
Server Address	The server address in the `host:port` format.
Add Server Address	Click **Add Server Address** to add a server address in the format of `host:port`.
Redis Password	The password that you can use to connect to Redis.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.30. Configure a Tablestore connection

Tablestore is a NoSQL database service built on Apsara distributed operating system. It allows you to store and access large amounts of structured data in real time.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **OTS** in the **NoSQL** section.
4. In the **Add OTS Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
Endpoint	The endpoint of the Tablestore service.
Table Store Instance ID	The name of the Tablestore instance.

Parameter	Description
AccessKey ID	The AccessKey ID for connecting to the Tablestore instance. You can view the AccessKey ID on the User Info page.
AccessKey Secret	The AccessKey secret for connecting to the Tablestore instance.

5. Click Test Connection.
6. After the connection passes the connectivity test, click Complete.

2.4.4.31. Configure an Elasticsearch connection

An Elasticsearch connection allows you to read data from and write data to Elasticsearch by using Elasticsearch Reader and Writer. You can configure sync nodes for Elasticsearch by using the code editor.

Procedure

1. Go to the Data Source page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose All Products > Data Aggregation > Data Integration.
   iii. On the page that appears, click Connection in the left-side navigation pane. The Data Source page appears.
2. On the Data Source page, click Add a Connection in the upper-right corner.
3. In the Add Connection dialog box, click ElasticSearch in the NoSQL section.
4. In the Add ElasticSearch Connection dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: Development and Production. Note This parameter is available only when the workspace is in standard mode.
Endpoint	The endpoint of Elasticsearch, in the format of `http://esxxxx.elasticsearch.aliyuncs.com:9200`.
Username	The username that you can use to connect to the database.

Parameter	Description
Password	The password that you can use to connect to the database.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.4.32. Configure a LogHub connection

A LogHub connection allows you to read data from and write data to LogHub by using LogHub Reader and Writer. You can configure sync nodes for LogHub by using the codeless UI or code editor.

Procedure

1. Go to the **Data Source** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click in the upper-left corner and choose **All Products** > **Data Aggregation** > **Data Integration**.
   iii. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
2. Click **Add Connection** in the upper-right corner.
3. In the **Add Connection** dialog box, click **LogHub** in the Message Queue section.
4. In the **Add LogHub Connection** dialog box, set the parameters as required.

Parameter	Description
Connection Name	The name of the connection. The name can contain letters, digits, and underscores (_). It must start with a letter.
Description	The description of the connection. The description can be up to 80 characters in length.
Applicable Environment	The environment in which the connection is used. Valid values: **Development** and **Production**. **Note** This parameter is available only when the workspace is in standard mode.
LogHub Endpoint	The LogHub endpoint, in the format of `http://cn-shanghai.log.aliyun.com`.
Project	The name of the LogHub project.
AccessKey ID	The AccessKey ID for connecting to the LogHub project. You can view the AccessKey ID on the **User Info** page.

Parameter	Description
AceessKey Secret	The AccessKey secret for connecting to the LogHub project.

5. Click **Test Connection**.
6. After the connection passes the connectivity test, click **Complete**.

2.4.5. Configure data synchronization tasks

2.4.5.1. Configure a sync node by using the codeless UI

This topic describes how to configure a sync node by using the codeless user interface (UI).

To configure a sync node, follow these steps:

1. Add connections.
2. Create a sync node.
3. Select a source connection.
4. Select a destination connection.
5. Map the fields in the source and destination tables.
6. Configure the channel, such as the maximum transmission rate and dirty data check rules.
7. Configure the node properties.

> **Note** The following sections describe the overall procedure. You can click the links in each step to read relevant instructions and then return to the current page to proceed with subsequent steps.

Add connections

Data synchronization is supported between various homogenous and heterogeneous connections. Before you configure a sync node, add required connections in Data Integration. Added connections are listed as options when you configure a sync node. For more information about connection types supported by Data Integration, see Supported data sources.

You can add connections of supported types to Data Integration. For more information about how to add a connection, see Data sources.

> **Note**
>
> - Data Integration does not support connectivity testing for some connection types. For more information, see Test data store connectivity.
> - Some connections are hosted on the premises. They do not have public IP addresses or network connections cannot be directly established. Such connections will fail the connectivity test. Data Integration allows you to add a custom resource group to resolve these issues. However, if you create sync nodes for such connections, you can only use the code editor. This is because you cannot obtain information such as table schema on the codeless UI if the network connection is unavailable.

Create a sync node

> Note This topic describes how to create and configure a sync node by using the codeless UI. Do not switch to the code editor.

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, move the pointer over the **Create** icon and select **Workflow**.
3. In the **Create Workflow** dialog box that appears, set **Workflow Name** and **Description**. Then, click **Create**.
4. In the left-side navigation pane, click the created workflow. Then, right-click **Data Integration** and choose **Create Data Integration Node > Sync**. In the Create Node dialog box that appears, set **Node Name**.
5. Click **Commit**.

Select a source connection

After the sync node is created, configure the source connection and source table.

> Note
> - For more information about how to configure the source connection, see Configure the reader.
> - Incremental data synchronization is required when you configure the source connection for some sync nodes. In this case, you can use the parameter configuration feature of DataWorks to obtain the date and time required by incremental data synchronization.

Select a destination connection

After the source connection is configured, configure the destination connection and destination table.

> Note
> - For more information about how to configure the destination connection, see Configure the writer.
> - You can select the writing method for most nodes. For example, the writing method can be overwriting or appending. Supported writing methods vary with the connection type.

Map the fields in the source and destination tables

After the source and destination connections are configured, specify the mapping between the fields in the source and destination tables. You can click **Map Fields with the Same Name**, **Map Fields in the Same Line**, **Delete All Mappings**, and **Auto Layout**.

Button or icon	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout. The fields are automatically sorted based on specified rules.
Change Fields	Click the Change Fields icon. In the Change Fields dialog box that appears, you can manually edit fields in the source table. Each field occupies a row. The first and the last blank rows are included, whereas other blank rows are ignored.
Add	• Click Add to add a field. You can enter constants. Each constant must be enclosed in single quotation marks (' '), such as 'abc' and '123'. • You can use scheduling parameters, such as ${bizdate}. • You can enter functions supported by relational databases, such as now() and count(1). • Fields that cannot be parsed are indicated by Unidentified.

Note Make sure that the data type of a source field is the same as or compatible with that of the mapped destination field.

Configure channel control policies

When the preceding steps are completed, configure the channel control policies of the corresponding sync node.

Parameter	Description
Expected Concurrency	The maximum number of concurrent threads to read data from or write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Parameter	Description
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure the node properties

This section describes how to use scheduling parameters for data filtering.

On the sync node configuration tab, click the **Properties** tab in the right-side navigation pane.

You can declare the scheduling parameters by using ${Variable name}. After a variable is declared, enter the initial value of the variable in the Arguments field. In this example, the initial value of the variable is identified by $[]. The content can be a time expression or a constant.

For example, if you write ${today} in the code and enter today=$[yyyymmdd] in the Arguments field, the value of the time variable is the current date. For more information about how to add and subtract the date, see Parameter configuration.

On the Properties tab, you can configure the properties of the sync node, such as the recurrence, scheduled time, and dependencies. Sync nodes have no ancestor nodes because their corresponding jobs are run before extract, transform, and load (ETL) jobs. We recommend that you specify the root node as their parent node.

Use custom scheduling parameters

To use custom scheduling parameters for the sync node, declare the following parameters in the code:

- bizdate: the timestamp of data to be used by the node. The value is one day before the running date of the node.
- cyctime: the time when the node is run, in the format of yyyymmddhhmiss.
- DataWorks provides the bizdate and cyctime parameters as default system parameters.

After the sync node is configured, save and commit the node.

2.4.5.2. Configure a sync node by using the code editor

This topic describes how to configure a sync node by using the code editor.

To configure a sync node, follow these steps:

1. Add connections.
2. Create a sync node.
3. Apply a template.
4. Configure the reader.
5. Configure the writer.
6. Map the fields in the source and destination tables.
7. Configure the channel, such as the maximum transmission rate and dirty data check rules.

8. Configure the node properties.

Add connections

Data synchronization is supported between various homogenous and heterogeneous connections. Before you configure a sync node, add required connections in Data Integration. Added connections are listed as options when you configure a sync node. For more information about connection types supported by Data Integration, see Supported data sources.

You can add connections of supported types to Data Integration. For more information about how to add a connection, see Data sources.

> **Note** Some connections are hosted on the premises. They do not have public IP addresses or network connections cannot be directly established. Such connections will fail the connectivity test. Data Integration allows you to add a custom resource group to resolve these issues. However, if you create sync nodes for such connections, you can only use the code editor. This is because you cannot obtain information such as table schema on the codeless user interface (UI) if the network connection is unavailable.

Create a sync node

> **Note** This topic describes how to create a sync node by using the codeless UI and configure the sync node by using the code editor.

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, move the pointer over the **Create** icon and select **Workflow**.
3. In the **Create Workflow** dialog box that appears, set **Workflow Name** and **Description**. Then, click **Create**.
4. In the left-side navigation pane, click the created workflow. Then, right-click **Data Integration** and choose **Create Data Integration Node > Sync**. In the Create Node dialog box that appears, set **Node Name**.
5. Click **Commit**.

Apply a template

1. After the sync node is created, the node configuration tab appears. Click the **Switch to Code Editor** icon in the toolbar.
2. In the **Confirm** dialog box that appears, click **OK** to switch to the code editor.

   > **Note** The code editor supports more features than the codeless UI. For example, you can configure sync nodes in the code editor even when the connectivity test fails.

3. Click the **Apply Template** icon in the toolbar.
4. In the **Apply Template** dialog box that appears, set **Source Connection Type**, **Connection**, **Target Connection Type**, and **Connection**.
5. Click **OK**.

Configure the reader

After the template is applied, the basic settings of the reader are configured. You can configure the source connection and source table as needed.

```
{"type": "job",
  "version": "2.0",
  "steps": [
    {
      "stepType": "mysql", // The reader type.
      "parameter": {
        "datasource": "MySQL", // The connection name.
        "column": [ // The columns to be synchronized.
          "id",
          "value",
          "table"
        ],
        "socketTimeout": 3600000, // The timeout period for reading data from and writing data to a s
ocket, in milliseconds.
        "connection": [
          {
            "datasource": "MySQL", // The connection name.
            "table": [
              "`case`" // The name of the table to be synchronized.
            ]
          }
        ],
        "where": "", // The WHERE clause.
        "splitPk": "", // The shard key.
        "encoding": "UTF-8" // The encoding format.
      },
      "name": "Reader",
      "category": "reader" // Indicates that these settings are related to the reader.
    },
```

The parameters are described as follows:

- type: the type of the sync node. You must set the value to job.
- version: the version number of the sync node. You can set the value to 1.0 or 2.0.

Note

- For more information about how to configure the source connection in the code editor, see Configure the reader.
- Incremental data synchronization is required when you configure the source connection for some sync nodes. In this case, you can use the parameter configuration feature of DataWorks to obtain the date and time required by incremental data synchronization.

Configure the writer

After the reader is configured, you can configure the destination connection and destination table as needed.

```
{
  "stepType": "odps", // The writer type.
  "parameter": {
     "partition": "", // The partitions that the reader reads.
     "truncate": true, // Specifies whether to clear up previous data and import new data when a write operation is performed again after failure. Set the value to true to guarantee the idempotence of write operations.
     "compress": false, // Specifies whether to enable compression.
     "datasource": "odps_first", // The connection name.
     "column": [ // The columns to be synchronized.
        "*"
     ],
     "emptyAsNull": false,
     "table": ""
    },
    "name": "Writer",
    "category": "writer" // Indicates that these settings are related to the writer.
  }
],
```

Note

- For more information about how to configure the destination connection in the code editor, see Configure the writer.
- You can select the writing method for most nodes. For example, the writing method can be overwriting or appending. Supported writing methods vary with the connection type.

Map the fields in the source and destination tables

The code editor only supports mapping of fields in the same row. Note that the data types of the fields must match.

> **Note** Make sure that the data type of a source field is the same as or compatible with that of the mapped destination field.

Configure channel control policies

When the preceding steps are completed, configure the channel control policies of the corresponding sync node. The setting parameter specifies the node efficiency, including the settings on the DUM number, thread concurrency, bandwidth throttling, dirty data policy, and resource group.

```
"setting": {
      "errorLimit": {
         "record": "1024" // The maximum number of dirty data records allowed.
      },
      "speed": {
         "throttle": false, // Specifies whether to enable bandwidth throttling.
         "concurrent": 1, // The maximum number of concurrent threads.
      }
   },
```

Setting	Description
Expected concurrency	The maximum number of concurrent threads to read data from or write data to data storage within the sync node. You can configure the concurrency for a node in the code editor.
Bandwidth throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty data records allowed	The maximum number of dirty data records allowed.
Resource group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure the node properties

This section describes how to use scheduling parameters for data filtering.

On the sync node configuration tab, click the **Properties** tab in the right-side navigation pane.

On the Properties tab, you can configure the properties of the sync node, such as the recurrence, scheduled time, and dependencies. Sync nodes have no ancestor nodes because their corresponding jobs are run before extract, transform, and load (ETL) jobs. We recommend that you specify the root node as their parent node.

After the sync node is configured, save and commit the node.

2.4.5.3. Configure the reader

2.4.5.3.1. Configure DRDS Reader

Distributed Relational Database Service (DRDS) Reader allows you to read data from DRDS. DRDS Reader connects to a remote DRDS database and runs a SELECT statement to select and read data from the database.

Currently, DRDS Reader only supports MySQL engines. DRDS is a distributed MySQL database service that complies with MySQL protocols in most cases.

Specifically, DRDS Reader connects to a remote DRDS database through Java Database Connectivity (JDBC), generates a SELECT statement based on your configurations, and then sends the statement to the database. The DRDS database runs the statement and returns the result. Then, DRDS Reader assembles the returned data to abstract datasets in custom data types supported by Data Integration, and passes the datasets to a writer.

DRDS Reader generates the SELECT statement based on the table, column, and where parameters that you have configured, and sends the generated SELECT statement to the DRDS database. DRDS does not support all MySQL specifications, such as JOIN statements.

DRDS Reader supports most DRDS data types. Make sure that your data types are supported.

The following table lists the data types supported by DRDS Reader.

Category	DRDS data type
Integer	INT, TINYINT, SMALLINT, MEDIUMINT, and BIGINT
Floating point	FLOAT, DOUBLE, and DECIMAL
String	VARCHAR, CHAR, TINYTEXT, TEXT, MEDIUMTEXT, and LONGTEXT
Date and time	DATE, DATETIME, TIMESTAMP, TIME, and YEAR
Boolean	BIT and BOOLEAN
Binary	TINYBLOB, MEDIUMBLOB, BLOB, LONGBLOB, and VARBINARY

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be identical to the name of the added connection. You can add connections in the code editor.	Yes	None

Parameter	Description	Required	Default value
table	The name of the table to be synchronized.	Yes	None
column	The columns to be synchronized from the source table. The columns are described in a JSON array. The default value is [*], which indicates all columns. • Column pruning is supported. You can select and export specific columns. • Change of the column order is supported. You can export the columns in an order different from that specified in the schema of the table. • Constants are supported. The column names must be arranged in compliance with the SQL syntax supported by MySQL, for example, `["id", "`table`", "1", "'bazhen.csy'", "null", "to_char(a + 1)", "2.3", "true"]`. ○ id: a column name. ○ table: the name of a column that contains reserved keywords. ○ 1: an integer constant. ○ bazhen.csy: a string constant. ○ null: a null pointer. ○ to_char(a + 1): a function expression. ○ 2.3: a floating-point constant. ○ true: a Boolean value. • The column parameter must explicitly specify a set of columns to be synchronized. The parameter cannot be left empty.	Yes	None
where	The WHERE clause. DRDS Reader generates a SELECT statement based on the table, column, and where parameters that you have configured, and uses the generated SELECT statement to select and read data. For example, set this parameter to `STRTODATE('${bdp.system.bizdate}', '%Y%m%d') <= today AND today < DATEADD(STRTODATE('${bdp.system.bizdate}', '%Y%m%d'), interval 1 day)`. • You can use the WHERE clause to synchronize incremental data. • If you do not specify the where parameter or leave it empty, all data is synchronized.	No	None

Configure DRDS Reader by using the codeless UI

1. Configure the connections.

   Configure the source and destination connections for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and enter the name of a connection that has been configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Filter	The filter condition for the data to be synchronized. Currently, filtering based on the limit keyword is not supported. The SQL syntax is determined by the selected connection.
Shard Key	The shard key. You can use a column in the source table as the shard key. We recommend that you use the primary key or an indexed column. Only integer fields are supported. If data sharding is performed based on the configured shard key, data can be read concurrently to improve data synchronization efficiency. Note The Shard Key parameter is displayed only when you configure the source connection for a sync node.

2. Configure field mapping, that is, the column parameter in the preceding parameter description.

   Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right. You can click **Add** to add a field, or move the pointer over a field and click the **Delete** icon to delete the field.

Parameter	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout. The fields are automatically sorted based on specified rules.
Change Fields	Click the Change Fields icon. In the Change Fields dialog box that appears, you can manually edit fields in the source table. Each field occupies a row. The first and the last blank rows are included, whereas other blank rows are ignored.

Parameter	Description
Add	Click Add to add a field. The rules for adding fields are described as follows: ○ You can enter constants. Each constant must be enclosed in single quotation marks (' '), such as 'abc' and '123'. ○ You can use scheduling parameters, such as ${bizdate}. ○ You can enter functions supported by relational databases, such as now() and count(1). ○ Fields that cannot be parsed are indicated by Unidentified.

3. Configure channel control policies.

Parameter	Description
Expected Concurrency	The maximum number of concurrent threads to read data from or write data to data storage within the sync node. You can configure the concurrency for a node on the codeless user interface (UI).
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure DRDS Reader by using the code editor

In the following code, a node is configured to read data from a DRDS database.

```
{
  "type":"job",
  "version":"2.0", // The version number.
  "steps":[
    {
      "stepType":"drds", // The reader type.
      "parameter":{
        "datasource":"", // The connection name.
        "column":[ // The columns to be synchronized.
          "id",
```

```
                "name"
            ],
            "where":"", // The WHERE clause.
            "table":"", // The name of the table to be synchronized.
            "splitPk": "" // The shard key.
        },
        "name":"Reader",
        "category":"reader"
      },
      {// The following template is used to configure Stream Writer. For more information about how to configure other writers, see the corresponding topic.
        "stepType":"stream", // The writer type.
        "parameter":{},
        "name":"Writer",
        "category":"writer"
      }
    ],
    "setting":{
      "errorLimit":{
        "record":"0" // The maximum number of dirty data records allowed.
      },
      "speed":{
        "throttle":false, // Specifies whether to enable bandwidth throttling.
        "concurrent":1, // The maximum number of concurrent threads.
      }
    },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
        }
      ]
    }
}:"Writer"
        }
      ]
    }
}
```

Additional instructions

- Consistency

  As a distributed database service, DRDS cannot provide a consistent view of multiple tables in multiple databases. Different from MySQL where data is synchronized in a single table of a single database, DRDS Reader cannot extract the snapshot of database and table shards at the same time slice. That is, DRDS Reader extracts different snapshots from different shards. As a result, this cannot guarantee strong consistency for data queries.

- Character encoding

  DRDS supports flexible encoding configurations. You can specify the encoding format for an instance, a field, a table, and a database. The configurations for the field, table, database, and instance are prioritized in descending order. We recommend that you use UTF-8 for a database.

  DRDS Reader uses JDBC, which can automatically convert the encoding of characters. Therefore, you do not need to specify the encoding format.

  If you specify the encoding format for a DRDS database but data is written to the DRDS database in a different encoding format, DRDS Reader cannot recognize this inconsistency and may export garbled characters.

- Incremental data synchronization

  DRDS Reader connects to a database through JDBC and uses a SELECT statement with a WHERE clause to read incremental data in the following ways:

  - For data in batches, incremental add, update, and delete operations (including logically delete operations) are distinguished by timestamps. Specify the WHERE clause based on the timestamp. The timestamp must be later than the latest timestamp in the last synchronization.
  - For streaming data, specify the WHERE clause based on the data record ID. The data record ID must be larger than the maximum ID involved in the last synchronization.

  If incremental data cannot be distinguished, DRDS Reader cannot perform incremental synchronization but can perform full synchronization only.

- Syntax validation

  DRDS Reader allows you to specify custom SELECT statements by using the querySql parameter but does not verify the syntax of the custom SELECT statements.

2.4.5.3.2. Configure HBase Reader

HBase Reader allows you to read data from HBase. HBase Reader connects to a remote HBase database through a Java client of HBase. Then, HBase Reader scans and reads data based on the specified rowkey range, assembles the data to abstract datasets in custom data types supported by Data Integration, and then passes the datasets to a writer.

Data types

The following table lists the data types supported by HBase Reader.

Category	Data Integration data type	HBase data type
Integer	LONG	Short, Int, and Long
Floating point	DOUBLE	Float and Double
String	STRING	Binary_String and String
Date and time	DATE	Date
Byte	BYTES	Bytes
Boolean	BOOLEAN	Boolean

Parameters

Parameter	Description	Required	Default value
haveKerberos	Specifies whether Kerberos authentication is required. A value of true indicates that Kerberos authentication is required. Note • If the value is true, the following five Kerberos-related parameters must be specified: ◦ kerberosKeytabFilePath ◦ kerberosPrincipal ◦ hbaseMasterKerberosPrincipal ◦ hbaseRegionserverKerberosPrincipal ◦ hbaseRpcProtection • If the value is false, Kerberos authentication is not required and you do not need to specify the preceding parameters.	No	*false*
hbaseConfig	The properties of the HBase cluster, in JSON format. The hbase.zookeeper.quorum parameter is required. It specifies the ZooKeeper ensemble servers. You can also configure other properties, such as those related to the cache and batch for scan operations.	Yes	None
mode	The mode in which data is read from the HBase connection. Valid values: normal and multiVersionFixedColumn.	Yes	None
table	The name of the HBase table from which data is read. The name is case-sensitive.	Yes	None

Parameter	Description	Required	Default value
encoding	The encoding format, by using which binary data stored in byte[] format is converted into strings. Currently, UTF-8 and GBK are supported.	No	UTF-8
column	The HBase columns from which data is read. • In normal mode: The name parameter specifies the name of the column in the HBase table. The format must be columnFamily:columnName except for the rowkey. The type parameter specifies the source data type. The format parameter specifies the date format. The value parameter specifies the column value if the column is a constant column. Example: "column": [{ "name": "rowkey", "type": "string" }, { "value": "test", "type": "string" }] For the column parameter, you must specify the type parameter and specify one of the name and value parameters. • In multiVersionFixedColumn mode: The name parameter specifies the name of the column in the HBase table. The format must be columnFamily:columnName except for the rowkey. The type parameter specifies the source data type. The format parameter specifies the date format. You cannot create constant columns in multiVersionFixedColumn mode. Example:	Yes	None

Parameter	Description	Required	Default value
	"column": [{ "name": "rowkey", "type": "string" }, { "name": "info:age", "type": "string" }]		
maxVersion	The number of versions read by HBase Reader when multiple versions are available. Valid values: -1 and integers greater than 1. A value of -1 indicates that all versions are read.	Required in multiVersionFixedColumn mode	None
range	The rowkey range that HBase Reader reads. • startRowkey: the start rowkey. • endRowkey: the end rowkey. • isBinaryRowkey: the method used to convert the specified start and end rowkeys into the byte[] format. Default value: false. If the value is true, Bytes.toBytesBinary(rowkey) is used. If the value is false, Bytes.toBytes(rowkey) is used. Example: "range": { "startRowkey": "aaa", "endRowkey": "ccc", "isBinaryRowkey":false }	No	None
scanCacheSize	The number of rows read by an HBase client with each remote procedure call (RPC) connection.	No	*256*
scanBatchSize	The number of columns read by an HBase client with each RPC connection.	No	*100*

Configure HBase Reader by using the codeless UI

Currently, the codeless user interface (UI) is not supported for HBase Reader.

Configure HBase Reader by using the code editor

In the following code, a node is configured to read data from an HBase connection in normal mode.

```
{
  "type": "job",
  "version": "2.0", // The version number.
  "steps": [
    {
      "stepType": "hbase", // The reader type.
      "parameter": {
        "mode": "normal",
        "scanCacheSize": 256, // The number of rows read by an HBase client with each RPC connecti
on.
        "scanBatchSize": 256, // The number of columns read by an HBase client with each RPC conne
ction.
        "hbaseVersion": "094x",
        "datasource": "demo_hbase", // The connection name.
        "column": [
          {
            "name": "info:idx",
            "type": "long"
          },
          {
            "name": "info:age",
            "type": "string"
          },
          {
            "name": "info:birthday",
            "format": "yyyy-MM-dd",
            "type": "date"
          }
        ],
        "range": {
          "startRowKey": "", // The start rowkey.
          "endRowKey": "", // The end rowkey.
          "isBinaryRowKey": false // The method used to convert the specified start and end rowkey
s into the byte[] format. Default value: false. If the value is true, Bytes.toBytesBinary(rowkey) is used.
If the value is false, Bytes.toBytes(rowkey) is used.
        },
        "maxVersion": , // The number of versions read by HBase Reader when multiple versions are
```

```
available. Valid values: -1 and integers greater than 1. A value of -1 indicates that all versions are rea
d.
            "encoding": "UTF-8",
            "table": "test" // The name of the HBase table from which data is read. The name is case-sen
sitive.
        },
        "name": "Reader",
        "category": "reader"
      },
        "tepType": "odps", // The writer type.
        "parameter": {},
        "name": "Writer",
        "category": "writer"
      }
    ],
    "setting": {
    },
    "order": {
      "hops": [
        {
          "from": "Reader",
          "to": "Writer"
        }
      ]
    }
}
```

In the following code, a node is configured to read data from an HBase connection in multiVersionFixedColumn mode.

```
{
    "type": "job",
    "version": "2.0", // The version number.
    "steps": [
      {
        "stepType": "hbase", // The reader type.
        "parameter": {
              "table": "users", // The name of the HBase table from which data is read. The name is case-
sensitive.
              "encoding": "utf-8", // The encoding format, by using which binary data stored in byte[] for
mat is converted into strings. Currently, UTF-8 and GBK are supported.
```

```
            "mode": "multiVersionFixedColumn",
            "maxVersion": "-1", // The number of versions read by HBase Reader when multiple version
s are available. Valid values: -1 and integers greater than 1. A value of -1 indicates that all versions ar
e read.
            "column": [ // The HBase columns from which data is read. The name parameter specifies th
e name of the column in the HBase table. The format must be columnFamily:columnName except for th
e rowkey. The type parameter specifies the source data type. The format parameter specifies the dat
e format. You cannot create constant columns in multiVersionFixedColumn mode.
              {
                "name": "rowkey",
                "type": "string"
              },
              {
                "name": "info: age",
                "type": "string"
              },
              {
                "name": "info: birthday",
                "type": "date",
                "format": "yyyy-MM-dd"
              }
            ],
            "range": { // The rowkey range that HBase Reader reads.
              "startRowkey": "",
              "endRowkey": ""
            }
          }
        },
        "name": "Reader",
        "category": "reader"
      },
      {
        "stepType": "odps", // The writer type.
        "parameter": {},
        "name": "Writer",
        "category": "writer"
      }
    ],
    "setting": {
    },
    "order": {
```

```
    "hops": [
      {
        "from": "Reader",
        "to": "Writer"
      }
    ]
  }
}
```

2.4.5.3.3. Configure HDFS Reader

HDFS Reader allows you to read data stored in a Hadoop Distributed File System (HDFS). HDFS Reader connects to an HDFS, reads data from files in the HDFS, converts the data into a format that is readable by Data Integration, and then sends the converted data to a writer.

Examples:

TextFile is the default storage format for creating Hive tables, without data compression. Essentially, a TextFile file is stored in HDFS as text. For Data Integration, the implementation of HDFS Reader is similar to that of OSS Reader.

Optimized Row Columnar File (ORCFile) is an optimized RCFile format. It provides an efficient method for storing Hive data. HDFS Reader uses the OrcSerde class provided by Hive to read and parse ORCFile data.

> Note
>
> - Considering that a complex network connection is required between the default resource group and HDFS, we recommend that you use a custom resource group to run sync nodes. Make sure that your custom resource group can access the NameNode and DataNode of HDFS through a network.
> - By default, HDFS uses a network whitelist to guarantee data security. In this case, we recommend that you use a custom resource group to run HDFS sync nodes.
> - If you configure an HDFS sync node in the code editor, the HDFS connection does not need to pass the connectivity test. In this case, you can temporarily ignore connectivity test errors.
> - To synchronize data in Data Integration, you must log on as an administrator. Make sure that you have the permissions to read data from and write data to relevant HDFS files.

Features

Currently, HDFS Reader supports the following features:

- Supports the TextFile, ORCFile, RCFile, SequenceFile, CSV, and Parquet file formats. What is stored in each file must be a logical two-dimensional table.
- Reads data of various types as strings. Supports constants and column pruning.
- Supports recursive reading. Supports regular expressions that contain asterisks (*) and question marks (?).

- Compresses ORCFile files in SNAPPY or ZLIB format.
- Compresses SequenceFile files in LZO format.
- Reads multiple files concurrently.
- Compresses CSV files in GZIP, BZIP2, ZIP, LZO, LZO_DEFLATE, or SNAPPY format.
- Supports Hive 1.1.1 and Hadoop 2.7.1 (compatible with Apache JDK 1.6). HDFS Reader can work properly with Hadoop 2.5.0, Hadoop 2.6.0, and Hive 1.2.0 during testing.

> **Note** Currently, HDFS Reader cannot use concurrent threads to read a single file.

Data types

RCFile

RCFile metadata is stored in databases managed by Hive, and in different formats depending on the data type. However, HDFS Reader cannot query metadata from such databases. If you want to synchronize a file of the RCFile format, you must specify the data type for each column. If the data type is BIGINT, DOUBLE, or FLOAT, specify the data type as BIGINT, DOUBLE, or FLOAT. If the data type is VARCHAR or CHAR, specify the data type as STRING.

RCFile data types are automatically converted into the data types supported by Data Integration. The following table lists the supported data types.

Category	HDFS data type
Integer	TINYINT, SMALLINT, INT, and BIGINT
Floating point	FLOAT, DOUBLE, and DECIMAL
String	STRING, CHAR, and VARCHAR
Date and time	DATE and TIMESTAMP
Boolean	BOOLEAN
Binary	BINARY

Parquet files

Parquet file data types are automatically converted into the data types supported by Data Integration. The following table lists the supported data types.

Category	HDFS data type
Integer	INT32, INT64, and INT96
Floating point	FLOAT and DOUBLE
String	FIXED_LEN_BYTE_ARRAY
Date and time	DATE and TIMESTAMP
Boolean	BOOLEAN

Category	HDFS data type
Binary	BINARY

TextFile, ORCFile, and SequenceFile

TextFile metadata and ORCFile metadata are stored in databases, such as MySQL databases, managed by Hive. However, HDFS Reader cannot query metadata from such databases. If you want to convert data types during data synchronization, you must specify the data types.

TextFile, ORCFile, and SequenceFile data types are automatically converted into the data types supported by Data Integration. The following table lists the supported data types.

Category	HDFS data type
Integer	TINYINT, SMALLINT, INT, and BIGINT
Floating point	FLOAT and DOUBLE
String	STRING, CHAR, VARCHAR, STRUCT, MAP, ARRAY, UNION, and BINARY
Date and time	DATE and TIMESTAMP
Boolean	BOOLEAN

The data types are described as follows:

- LONG: integer strings in HDFS files, such as 123456789.
- DOUBLE: double value strings in HDFS files, such as 3.1415.
- BOOLEAN: Boolean strings in HDFS files, such as true and false. The strings are case-insensitive.
- DATE: date and time strings in HDFS files, such as 2014-12-31 00:00:00.

Note The TIMESTAMP data type of Hive is accurate to nanoseconds. If you convert TIMESTAMP-type Hive data, such as 2015-08-21 22:40:47.397898389, in TextFile and ORCFile files into the DATE type in Data Integration, the converted data is accurate to seconds. If you need nanosecond-scale accuracy, convert TIMESTAMP-type data into the STRING type in Data Integration.

Parameters

Parameter	Description	Required	Default value

Parameter	Description	Required	Default value
path	The path of the file to read. To read multiple files, use a regular expression such as /hadoop/data_201704*. • If you specify a single HDFS file, HDFS Reader uses only one thread to read the file. • If you specify multiple HDFS files, HDFS Reader uses multiple threads. The number of threads is limited by the transmission rate, in Mbit/s. Note The actual number of threads is determined by both the number of HDFS files to be read and the specified transmission rate. • When a path contains a wildcard, HDFS Reader attempts to read all files that match the path. If the path is ended with a slash (/), HDFS Reader reads all files in the specified directory. For example, if you specify the path as /bazhen/, HDFS Reader reads all files in the bazhen directory. Currently, HDFS Reader only supports asterisks (*) and question marks (?) as file name wildcards. The syntax is similar to that of file name wildcards used on the Linux command line. Note • Data Integration considers all the files on a sync node as a single table. Make sure that all the files on each sync node can adapt to the same schema and Data Integration has the permission to read all these files. • Note: When creating Hive tables, you can specify partitions. For example, if you specify partition(day="20150820",hour="09"), a directory named /20150820 and a subdirectory named /09 are created in the corresponding table directory of the HDFS. Therefore, if you need HDFS Reader to read the data of a partition, specify the file path of the partition. For example, if you need HDFS Reader to read all the data in the partition with the date of 20150820 in the table named mytable01, specify the path as follows: "path": "/user/hive/warehouse/mytable01/20150820/*"	Yes	None

Parameter	Description	Required	Default value
defaultFS	The address of the NameNode of the HDFS. If a sync node is run on the default resource group, advanced parameter settings of Hadoop, such as those related to high availability, are not supported.	Yes	None

Parameter	Description	Required	Default value
fileType	The file format. Valid values: text, orc, rc, seq, csv, and parquet. HDFS Reader automatically recognizes the file format and uses corresponding read policies. Before data synchronization, HDFS Reader checks whether all the source files match the specified format. If any source file does not match the format, the sync node fails. The valid values of the fileType parameter are described as follows: • text: the TextFile format. • orc: the ORCFile format. • rc: the RCFile format. • seq: the SequenceFile format. • csv: the common HDFS file format, that is, the logical two-dimensional table. • parquet: the common Parquet file format. Note TextFile and ORCFile are different formats. HDFS Reader parses files in the two formats in different ways. After being converted from a composite data type of Hive into the STRING type of Data Integration, the data in a file of the TextFile format can be different from that in the same file of the ORCFile format. Composite data types include MAP, ARRAY, STRUCT, and UNION. The following example uses the conversion from the MAP type to the STRING type as an example: • HDFS Reader converts MAP-type ORCFile data into a string: {job=80, team=60, person=70}. • HDFS Reader converts MAP-type TextFile data into a string: job:80, team:60, person:70. The conversion results show that the data remains unchanged but the formats differ slightly. Therefore, if the data to be synchronized matches a composite data type of Hive, we recommend that you use a uniform file format. Recommendations: • To use a uniform file format, we recommend that you export TextFile tables as ORCFile tables on the Hive client. • If the file format is Parquet, the parquetSchema parameter is required, which specifies the schema of the Parquet table. For the column parameter, you must specify the type parameter and specify one of the index and value parameters.	Yes	None

Parameter	Description	Required	Default value
column	The columns to read. The type parameter specifies the source data type. The index parameter specifies the ID of the column in the source table, starting from 0. The value parameter specifies the column value if the column is a constant column. By default, HDFS Reader reads all data as strings. Specify this parameter as `"column":["*"]`. You can also specify the column parameter in the following way: { "type": "long", "index": 0 // The first INT-type column of the source file. }, { "type": "string", "value": "alibaba" // The value of the current column, that is, a constant "alibaba". }	Yes	None
fieldDelimiter	The column delimiter. To read TextFile data, you must specify the column delimiter. The default delimiter is comma (,). To read ORCFile data, you do not need to specify the column delimiter. The default delimiter is \u0001. • If you need each row to be converted into a column in the destination table, use a string that does not exist in every row, such as \u0001. • Do not use \n as the delimiter.	No	,
encoding	The encoding format of the file to read.	No	UTF-8
nullFormat	The string that represents null. No standard strings can represent null in text files. Therefore, Data Integration provides the nullFormat parameter to define which string represents a null pointer. For example, if you specify nullFormat:"null", Data Integration considers null as a null pointer.	No	None

Parameter	Description	Required	Default value
compress	The compression format. Available compression formats for CSV files are GZIP, BZIP2, ZIP, LZO, LZO_DEFLATE, and SNAPPY. Note • Do not mix up LZO with LZO_DEFLATE. • Snappy does not have a uniform stream format. Data Integration currently only supports the most popular two compression formats: hadoop-snappy (Snappy stream format in Hadoop) and framing-snappy (Snappy stream format recommended by Google). • rc indicates the RCFile format. • This parameter is not required for files of the ORCFile format.	No	None

Parameter	Description	Required	Default value
parquetSchema	The schema of the source file. This parameter is required only when the fileType parameter is set to parquet. Format: `message messageTypeName {` `required, dataType, columnName;` `..... ;` `}` The format is described as follows: • messageTypeName: the name of the MessageType object. • required: specifies whether the field is required or optional. We recommend that you set the parameter to optional for all fields. • dataType: the data type of the field. Supported data types: BOOLEAN, INT32, INT64, INT96, FLOAT, DOUBLE, BINARY, and FIXED_LEN_BYTE_ARRAY. Select BINARY if the data type is STRING. Note Each line, including the last one, must end with a semicolon (;). An example is provided as follows: `message m {` `optional int64 id;` `optional int64 date_id;` `optional binary datetimestring;` `optional int32 dspId;` `optional int32 advertiserId;` `optional int32 status;` `optional int64 bidding_req_num;` `optional int64 imp;` `optional int64 click_num;` `}`	No	None

Parameter	Description	Required	Default value
csvReaderConfig	The configurations for reading CSV files. The parameter value must match the MAP type. A specific CSV reader is used to read data from CSV files, which supports many configurations. The following example provides common configurations: `"csvReaderConfig":{` `"safetySwitch": false,` `"skipEmptyRecords": false,` `"useTextQualifier": false` `}` You can use the following parameters and their default values: `boolean caseSensitive = true;` `char textQualifier = 34;` `boolean trimWhitespace = true;` `boolean useTextQualifier = true; // Specifies whether to use escape characters for CSV files.` `char delimiter = 44; // The delimiter.` `char recordDelimiter = 0;` `char comment = 35;` `boolean useComments = false;` `int escapeMode = 1;` `boolean safetySwitch = true; // Specifies whether to limit the length of each column to 100,000 characters.` `boolean skipEmptyRecords = true; // Specifies whether to skip empty rows.` `boolean captureRawRecord = true;`	No	None

Parameter	Description	Required	Default value
hadoopConfig	The advanced parameter settings of Hadoop, such as those related to high availability. "hadoopConfig":{ "dfs.nameservices": "testDfs", "dfs.ha.namenodes.testDfs": "namenode1,namenode2", "dfs.namenode.rpc-address.youkuDfs.namenode1": "", "dfs.namenode.rpc-address.youkuDfs.namenode2": "", "dfs.client.failover.proxy.provider.testDfs": "org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider" }	No	None

Configure HDFS Reader by using the codeless UI

Currently, the codeless user interface (UI) is not supported for HDFS Reader.

Configure HDFS Reader by using the code editor

In the following code, a node is configured to read data from an HDFS. For more information about the parameters, see the preceding parameter description.

```
{
  "type": "job",
  "version": "2.0",
  "steps": [
    {
      "stepType": "hdfs", // The reader type.
      "parameter": {
        "path": "", // The path of the file to read.
        "datasource": "", // The connection name.
        "column": [
          {
            "index": 0, // The ID of the column in the source table.
            "type": "string" // The data type.
          },
          {
            "index": 1,
            "type": "long"
          },
          {
```

```
                "index": 2,
                "type": "double"
            },
            {
                "index": 3,
                "type": "boolean"
            },
            {
                "format": "yyyy-MM-dd HH:mm:ss", // The format of the time.
                "index": 4,
                "type": "date"
            }
        ],
        "fieldDelimiter": "," // The column delimiter.
        "encoding": "UTF-8", // The encoding format.
        "fileType": "" // The file format.
      },
      "name": "Reader",
      "category": "reader"
    },
    {// The following template is used to configure the writer. For more information, see the corresponding topic.
      "stepType": "stream",
      "parameter": {},
      "name": "Writer",
      "category": "writer"
    }
  ],
  "setting": {
    "errorLimit": {
      "record": "" // The maximum number of dirty data records allowed.
    },
    "speed": {
      "concurrent": 3, // The maximum number of concurrent threads.
      "throttle": false, // Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
    }
  },
  "order": {
    "hops": [
```

```
        "hops": [
          {
            "from": "Reader",
            "to": "Writer"
          }
        ]
      }
    }
```

2.4.5.3.4. Configure MaxCompute Reader

This topic describes the data types and parameters supported by MaxCompute Reader and how to configure it by using the codeless UI and code editor.

MaxCompute Reader can read data from a MaxCompute project by using the MaxCompute Tunnel service based on the source project, table, partition, and table fields that you have configured.

MaxCompute Reader cannot read views. It can read only partitioned tables and non-partitioned tables. To allow MaxCompute Reader to read partitioned tables, you must specify the partition information. For example, set pt to 1 and ds to hangzhou for the t0 table. The partition information is not required for non-partitioned tables. Additionally, you can select some or all of the table fields, change the order in which the fields are arranged, or add constant fields and partition key columns. Note that partition key columns are not table fields.

Data types

The following table lists the data types supported by MaxCompute Reader.

Category	Data Integration data type	MaxCompute data type
Integer	LONG	BIGINT, INT, TINYINT, and SMALLINT
Boolean	BOOLEAN	BOOLEAN
Date and time	DATE	DATETIME and TIMESTAMP
Floating point	DOUBLE	FLOAT, DOUBLE, and DECIMAL
Binary	BYTES	BINARY
Complex	STRING	ARRAY, MAP, and STRUCT

Parameters

Parameter	Description	Required	Default value

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the source table. The name is not case-sensitive.	Yes	None
partition	The partitions that MaxCompute Reader reads. Linux shell wildcards are supported. An asterisk (*) represents zero or more characters, and a question mark (?) represents that the previous character can be included or not. Assume that a partitioned table named test has four partitions: pt=1 and ds=hangzhou, pt=1 and ds=shanghai, pt=2 and ds=hangzhou, and pt=2 and ds=beijing. • To read data from the partition with pt=1 and ds=shanghai, enter `"partition":"pt=1/ds=shanghai"`. • To read data from all the partitions with pt=1, enter `"partition":"pt=1/ds=*"`. • To read data from all the partitions in the test table, enter `"partition":"pt=*/ds=*"`.	Required only for writing data to a partitioned table	None

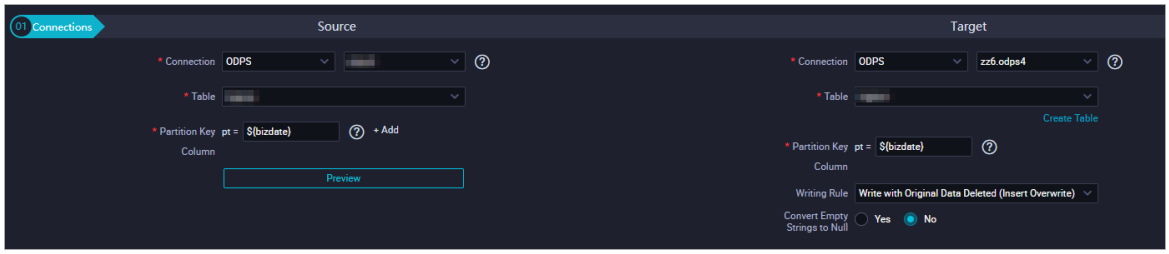
Parameter	Description	Required	Default value
column	The columns in the source table that MaxCompute Reader reads. Assume that the fields of a table named test are id, name, and age. • To read the fields in turn, enter `"column":["id","name","age"]` or `"column":["*"]`. Note We recommend that you do not set "column":["*"]. This is because data synchronization may fail if the source table changes in the column order, data type, or number of columns. • To read the name and id fields in turn, enter `"column":["name","id"]`. • You can add a constant field to extracted data for the purpose of proper mapping between source table columns and destination table columns. Each constant must be enclosed in single quotation marks (`''`). For example, if you set `"column":["age","name","'1988-08-08 08:08:08'","id"]`, the data extracted contains an age column, a name column, a constant "1988-08-08 08:08:08", and an id column in turn. The single quotation marks (`''`) are used to identify constant columns. The constant column values exclude the single quotation marks (`''`). Note ◦ MaxCompute Reader does not use SELECT statements to read data. Therefore, you cannot specify function fields. ◦ The column parameter must explicitly specify a set of columns to be synchronized. The parameter cannot be left empty.	Yes	None

Configure MaxCompute Reader by using the codeless UI

On the **DataStudio** page, create a sync node under a workflow and configure the node.

1. Configure the connections.

Configure the connections to the source and destination data stores for the sync node.



Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Partition Key Column	The partition information. You can click **Add** on the right to add partition key columns.

Note To synchronize all columns in the source table, enter "column":[""]. The partition parameter supports wildcards and includes one or more partitions.

- `"partition":"pt=20140501/ds=*"` specifies that all ds partitions with pt=20140501 are to be synchronized.
- `"partition":"pt=top?"` specifies that the partitions with pt=top and pt=to are to be synchronized.

You can specify the partition key columns to be synchronized, such as a partition key column named pt. Assume that the partition key column of a MaxCompute table is pt=${bdp.system.bizdate}. You can configure the column to be synchronized to pt. Ignore it if the column is marked as unidentified. To synchronize all partitions, enter pt=*. To synchronize specified partitions, specify the corresponding dates.

2. Configure field mapping. It is equivalent to setting the column parameter provided in the preceding parameter description.

   Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right. You can click **Add** to add a field, or move the pointer over a field and click the **Delete** icon to delete the field.

GUI element	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.

GUI element	Description
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout to sort the fields based on specified rules.
Change Fields	Click the Change Fields icon. In the Change Fields dialog box, you can manually edit fields in the source table. Each field occupies a row. The first and the last blank rows are included, whereas other blank rows are ignored.
Add	○ Click Add to add a field. You can enter constants. Each constant must be enclosed in single quotation marks (' '), such as 'abc' and '123'. ○ You can use scheduling parameters, such as ${bizdate}. ○ You can enter functions supported by relational databases, such as now() and count(1). ○ Fields that cannot be parsed are indicated by Unidentified.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure MaxCompute Reader by using the code editor

In the following code, a node is configured to read data from MaxCompute. For more information about the parameters, see the preceding parameter description.

```
{
   "type":"job", // The type of the sync node.
   "version":"2.0", // The version number.
   "steps":[
```

```
    {
      "stepType":"odps",// The reader type.
      "parameter":{
        "partition":[], // The partitions that MaxCompute Reader reads.
        "isCompress":false, // Specifies whether to enable compression.
        "datasource":"",// The connection name.
        "column":[// The columns to be synchronized.
          "id"
        ],
        "emptyAsNull":true,
        "table":""// The table name.
      },
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"stream", // The writer type.
      "parameter":{ // The parameters that you specify for the writer.
      },
      "name":"Writer",
      "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
      "record":"0" // The maximum number of dirty data records allowed.
    },
    "speed":{
      "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
      "concurrent":1,// The maximum number of concurrent threads.
    }
  },
  "order":{
    "hops":[
      {
        "from":"Reader", // The source connection of the node.
        "to":"Writer" // The destination connection of the node.
      }
```

```
    ]
  }
}
```

2.4.5.3.5. Configure MongoDB Reader

This topic describes the data types and parameters supported by MongoDB Reader and how to configure it by using the code editor.

MongoDB Reader connects to a remote MongoDB database by using the Java client named MongoClient and reads data from the database. The latest version of MongoDB has improved the locking feature from database locks to document locks. By using the powerful functionalities of indexes in MongoDB, MongoDB Reader can efficiently read data from MongoDB databases.

> Note
>
> - If you use ApsaraDB for MongoDB, the MongoDB database has a root account by default. For security concerns, Data Integration supports access to a MongoDB database only by using a MongoDB database account. When you add a MongoDB connection, do not use the root account for access.
> - JavaScript syntax is not supported for queries.

MongoDB Reader shards data in the MongoDB database based on specified rules, reads data from the database with multiple threads, and then converts the data to a format readable by Data Integration.

Data types

MongoDB Reader supports most MongoDB data types. Make sure that your data types are supported.

The following table lists the data types supported by MongoDB Reader.

Category	MongoDB data type
Long	INT, LONG, DOCUMENT.INT, and DOCUMENT.LONG
Double	DOUBLE and DOCUMENT.DOUBLE
String	STRING, ARRAY, DOCUMENT.STRING, DOCUMENT.ARRAY, and COMBINE
Date	DATE and DOCUMENT.DATE
Boolean	BOOLEAN and DOCUMENT.BOOLEAN
Bytes	BYTES and DOCUMENT.BYTES

Note

- The DOCUMENT data type is used to store embedded documents. It is also called the OBJECT data type.
- The following content describes how to use the COMBINE data type:

  When MongoDB Reader reads data from a MongoDB database, it combines and converts multiple fields in MongoDB documents to a JSON string.

  For example, doc1, doc2, and doc3 are three MongoDB documents with different fields, which are represented by keys instead of key-value pairs. The keys a and b represent common fields in all the three documents. The key x_n represents an unfixed field.

  ```
  doc1: a b x_1 x_2
  ```

  ```
  doc2: a b x_2 x_3 x_4
  ```

  ```
  doc3: a b x_5
  ```

  To import the preceding three MongoDB documents to MaxCompute, you must specify the fields to retain, set a name for each combined string, and set the data type of each combined string to COMBINE in the configuration file. Make sure that the name of each combined string is unique among all existing fields in the documents.

  ```
  "column": [
  {
  "name": "a",
  "type": "string",
  },
  {
  "name": "b",
  "type": "string",
  },
  {
  "name": "doc",
  "type": "combine",
  }
  ]
  ```

  The following table lists the output in MaxCompute.

odps_column1	odps_column2
a	b
a	b
a	b

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
collectionName	The name of the replica set in MongoDB.	Yes	None
column	The columns in MongoDB. • name: the name of the column. • type: the data type of the column. • splitter: the delimiter. Specify this parameter only when you need to convert the string to an array. MongoDB supports arrays, but Data Integration does not. The array elements read by MongoDB are joined to a string by using this delimiter.	Yes	None
query	The filter condition for obtaining data from MongoDB. Only the time type is supported. For example, you can use the statement `"query":"{'operationTime': {'$gte':ISODate('${last_day}T00:00:00.424+0800')}}"` to obtain data where the time specified by operationTime is not earlier than 00:00 on the day specified by ${last_day}. In the preceding JSON string, ${last_day} is a scheduling parameter of DataWorks. The format is $[yyyy-mm-dd]. You can use comparison operators (such as $gt, $lt, $gte, and $lte), logical operators (such as $and and $or), and functions (such as max, min, sum, avg, and ISODate) supported by MongoDB as needed.	No	None

Configure MongoDB Reader by using the codeless UI

The codeless UI is not supported for MongoDB Reader.

Configure MongoDB Reader by using the code editor

In the following code, a node is configured to read data from a MongoDB database. For more information about the parameters, see the preceding parameter description.

```
{
   "type":"job",
   "version":"2.0",// The version number.
   "steps":[
        "reader": {
        "plugin": "mongodb", // The reader type.
        "parameter": {
          "datasource": "datasourceName", // The connection name.
```

```
"collectionName": "tag_data", // The name of the MongoDB collection.
"query":"",
"column": [
      {
         "name": "unique_id", // The field name.
         "type": "string" // The data type.
      },
      {
         "name": "sid",
         "type": "string"
      },
      {
         "name": "user_id",
         "type": "string"
      },
      {
         "name": "auction_id",
         "type": "string"
      },
      {
         "name": "content_type",
         "type": "string"
      },
      {
         "name": "pool_type",
         "type": "string"
      },
      {
         "name": "frontcat_id",
         "type": "array",
         "splitter": ""
      },
      {
         "name": "categoryid",
         "type": "array",
         "splitter": ""
      },
      {
         "name": "gmt_create",
         "type": "string"
      }
```

```
                },
                {
                  "name": "taglist",
                  "type": "array",
                  "splitter": " "
                },
                {
                  "name": "property",
                  "type": "string"
                },
                {
                  "name": "scorea",
                  "type": "int"
                },
                {
                  "name": "scoreb",
                  "type": "int"
                },
                {
                  "name": "scorec",
                  "type": "int"
                },
        {
                   "name": "a.b",
                   "type": "document.int"
                },
                {
                   "name": "a.b.c",
                   "type": "document.array",
                   "splitter": " "
                }
          ]
        }
      },
      {
        "stepType":"stream",
        "parameter":{},
        "name":"Writer",
        "category":"writer"
      }
    ],
```

```
    "setting":{
        "errorLimit":{
            "record":"0"// The maximum number of dirty data records allowed.
        },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
            "concurrent":1,// The maximum number of concurrent threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

Note You cannot retrieve data elements from arrays.

2.4.5.3.6. Configure Db2 Reader

This topic describes the data types and parameters supported by Db2 Reader and how to configure it by using the code editor.

Db2 Reader allows you to read data from Db2. Db2 Reader connects to a remote Db2 database and runs a SELECT statement to select and read data from the database.

Specifically, Db2 Reader connects to a remote Db2 database through Java Database Connectivity (JDBC), generates a SELECT statement based on your configurations, and then sends the statement to the database. The Db2 database runs the statement and returns the result. Then, Db2 Reader assembles the returned data to abstract datasets in custom data types supported by Data Integration, and passes the datasets to a writer.

- Db2 Reader generates the SELECT statement based on the table, column, and where parameters that you have configured, and sends the generated SELECT statement to the Db2 database.
- If you specify the querySql parameter, Db2 Reader directly sends the value of this parameter to the Db2 database.

Db2 Reader supports most Db2 data types. Make sure that your data types are supported.

The following table lists the data types supported by Db2 Reader.

Category	Db2 data type
Integer	SMALLINT
Floating point	DECIMAL, REAL, and DOUBLE
String	CHAR, CHARACTER, VARCHAR, GRAPHIC, VARGRAPHIC, LONG VARCHAR, CLOB, LONG VARGRAPHIC, and DBCLOB
Date and time	DATE, TIME, and TIMESTAMP
Boolean	N/A
Binary	BLOB

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be identical to the name of the added connection. You can add connections in the code editor.	Yes	None
jdbcUrl	The JDBC URL for connecting to the Db2 database. In accordance with official Db2 specifications, the URL must be in the `jdbc:db2://ip:port/database` format. You can also specify the information of the attachment facility.	Yes	None
username	The username for connecting to the database.	Yes	None
password	The password for connecting to the database.	Yes	None
table	The name of the table to be synchronized. You can select only one source table for each sync node.	Yes	None

Parameter	Description	Required	Default value
column	The columns to be synchronized from the source table. The columns are described in a JSON array. The default value is [*], which indicates all columns. • Column pruning is supported. You can select and export specific columns. • Change of the column order is supported. You can export the columns in an order different from that specified in the schema of the table. • Constants are supported. The column names must be arranged in compliance with the SQL syntax supported by Db2, for example, `["id", "1", "'const name'", "null", "upper('abc_lower')", "2.3", "true"]`. ○ id: a column name. ○ 1: an integer constant. ○ 'const name': a string constant, which is enclosed in single quotation marks (' '). ○ null: a null pointer. ○ upper('abc_lower'): a function expression. ○ 2.3: a floating-point constant. ○ true: a Boolean value. • The column parameter must explicitly specify a set of columns to be synchronized. The parameter cannot be left empty.	Yes	None
splitPk	The field used for data sharding when Db2 Reader extracts data. If you specify the splitPk parameter, the table is sharded based on the shard key specified by this parameter. Data Integration then runs concurrent threads to synchronize data. This improves efficiency. • We recommend that you set the splitPk parameter to the primary key of the table. Based on the primary key, data can be well distributed to different shards, but not intensively distributed to certain shards. • Currently, the splitPk parameter supports data sharding only for integers but not for other data types such as string, floating point, and date. If you specify this parameter to a column of an unsupported type, Db2 Reader returns an error.	No	""
where	The WHERE clause. Db2 Reader generates a SELECT statement based on the table, column, and where parameters that you have configured, and uses the generated SELECT statement to select and read data. For example, set this parameter to `gmt_create>$bizdate`. You can use the WHERE clause to synchronize incremental data. If you do not specify the where parameter or leave it empty, all data is synchronized.	No	None

Parameter	Description	Required	Default value
querySql	The SELECT statement used for refined data filtering. If you specify this parameter, Data Integration directly filters data based on this parameter. For example, if you want to join multiple tables for data synchronization, set this parameter to `select a,b from table_a join table_b on table_a.id = table_b.id`. If you specify the querySql parameter, Db2 Reader ignores the table, column, and where parameters that you have configured.	No	None
fetchSize	The number of data records to read at a time. This parameter determines the number of interactions between Data Integration and the database and affects reading efficiency. Note A value greater than 2048 may lead to out of memory (OOM) during the data synchronization process.	No	*1024*

Configure Db2 Reader by using the codeless UI

Currently, the codeless user interface (UI) is not supported for Db2 Reader.

Configure Db2 Reader by using the code editor

In the following code, a node is configured to read data from a Db2 database.

```
{
  "type":"job",
  "version":"2.0", // The version number.
  "steps":[
    {
      "stepType":"db2", // The reader type.
      "parameter":{
        "password":"", // The password for connecting to the database.
        "jdbcUrl":"", // The JDBC URL for connecting to the Db2 database.
        "column":[
          "id"
        ],
        "where":"", // The WHERE clause.
        "splitPk":"", // The field used for data sharding. If you specify the splitPk parameter, the table is sharded based on the shard key specified by this parameter.
        "table":"", // The name of the table to be synchronized.
        "username":"" // The username for connecting to the database.
```

```
        },
        "name":"Reader",
        "category":"reader"
      },
      {
        "stepType":"stream",
        "parameter":{},
        "name":"Writer",
        "category":"writer"
      }
    ],
    "setting":{
      "errorLimit":{
        "record":"0" // The maximum number of dirty data records allowed.
      },
      "speed":{
        "throttle":false, // Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
        "concurrent":1, // The maximum number of concurrent threads.
      }
    },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
        }
      ]
    }
}
```

Additional instructions

- Data synchronization between primary and secondary databases

  A secondary Db2 database can be deployed for disaster recovery. The secondary database continuously synchronizes data from the primary database based on binlogs. Especially when network conditions are unfavorable, data latency between the primary and secondary databases is unavoidable, which can lead to data inconsistency.

- Concurrency control

Db2 is a relational database management system (RDBMS), which supports strong consistency for data queries. A database snapshot is created before a sync node starts. Db2 Reader reads data from the database snapshot. Therefore, if new data is written to the database during data synchronization, Db2 Reader cannot obtain the new data.

Data consistency cannot be guaranteed when you enable Db2 Reader to run concurrent threads on a single sync node.

Db2 Reader shards the table based on the splitPk parameter and runs multiple concurrent threads to synchronize data. These concurrent threads belong to different transactions. They read data at different time points. This means that the concurrent threads observe different snapshots.

Theoretically, the data inconsistency issue is unavoidable if a single sync node includes multiple threads. However, two workarounds are available:

- Do not enable concurrent threads on a single sync node. Essentially, do not specify the splitPk parameter. In this way, data consistency is guaranteed although data is synchronized at a low efficiency.
- Disable writers to make sure that the data is unchanged during data synchronization. For example, lock the table and disable data synchronization between primary and secondary databases. In this way, data is synchronized efficiently but your ongoing services may be interrupted.

- Character encoding

  Db2 Reader uses JDBC, which can automatically convert the encoding of characters. Therefore, you do not need to specify the encoding format.

- Incremental data synchronization

  Db2 Reader connects to a database through JDBC and uses a SELECT statement with a WHERE clause to read incremental data in the following ways:

  - For data in batches, incremental add, update, and delete operations (including logically delete operations) are distinguished by timestamps. Specify the WHERE clause based on the timestamp. The timestamp must be later than the latest timestamp in the last synchronization.
  - For streaming data, specify the WHERE clause based on the data record ID. The data record ID must be larger than the maximum ID involved in the last synchronization.

  If incremental data cannot be distinguished, Db2 Reader cannot perform incremental synchronization but can perform full synchronization only.

- Syntax validation

  Db2 Reader allows you to specify custom SELECT statements by using the querySql parameter but does not verify the syntax of the custom SELECT statements.

2.4.5.3.7. Configure MySQL Reader

This topic describes the data types and parameters supported by MySQL Reader and how to configure it by using the codeless user interface (UI) and code editor.

MySQL Reader connects to a remote MySQL database through Java Database Connectivity (JDBC), generates a SELECT statement based on your configurations, and then sends the statement to the database. The MySQL database runs the statement and returns the result. Then, MySQL Reader assembles the returned data to abstract datasets in custom data types supported by Data Integration, and passes the datasets to a writer.

In short, MySQL Reader connects to a remote MySQL database and runs a SELECT statement to select and read data from the database.

MySQL Reader can read tables and views. For table fields, you can specify all or some of the columns in sequence, adjust the column order, specify constant fields, and configure MySQL functions, such as now().

Data types

The following table lists the data types supported by MySQL Reader.

Category	MySQL data type
Integer	INT, TINYINT, SMALLINT, MEDIUMINT, and BIGINT
Floating point	FLOAT, DOUBLE, and DECIMAL
String	VARCHAR, CHAR, TINYTEXT, TEXT, MEDIUMTEXT, and LONGTEXT
Date and time	DATE, DATETIME, TIMESTAMP, TIME, and YEAR
Boolean	BIT and BOOLEAN
Binary	TINYBLOB, MEDIUMBLOB, BLOB, LONGBLOB, and VARBINARY

Note

- Data types that are not listed in the table are not supported.
- MySQL Reader considers tinyint(1) as the INTEGER type.
- Currently, MySQL Reader does not support MySQL 8.0 or later.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be identical to the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the table to be synchronized. You can select only one source table for each sync node.	Yes	None

Parameter	Description	Required	Default value
column	The columns to be synchronized from the source table. The columns are described in a JSON array. The default value is [*], which indicates all columns. • Column pruning is supported. You can select and export specific columns. • Change of the column order is supported. You can export the columns in an order different from that specified in the schema of the table. • Constants are supported. The column names must be arranged in compliance with the SQL syntax supported by MySQL, for example, `["id","table","1","'mingya.wmy'","'null'","to_char(a+1)","2.3","true"]`. ◦ id: a column name. ◦ table: the name of a column that contains reserved keywords. ◦ 1: an integer constant. ◦ 'mingya.wmy': a string constant, which is enclosed in single quotation marks (' '). ◦ null: ▪ " " indicates an empty value. ▪ null indicates a null value. ▪ 'null' indicates the string null. ◦ to_char(a + 1): a function expression. ◦ 2.3: a floating-point constant. ◦ true: a Boolean value. • The column parameter must explicitly specify a set of columns to be synchronized. The parameter cannot be left empty.	Yes	None

Parameter	Description	Required	Default value
splitPk	The field used for data sharding when MySQL Reader extracts data. If you specify the splitPk parameter, the table is sharded based on the shard key specified by this parameter. Data Integration then runs concurrent threads to synchronize data. This improves efficiency. • We recommend that you set the splitPk parameter to the primary key of the table. Based on the primary key, data can be well distributed to different shards, but not intensively distributed to certain shards. • Currently, the splitPk parameter supports data sharding only for integers but not for other data types such as string, floating point, and date. If you specify this parameter to a column of an unsupported type, MySQL Reader ignores the splitPk parameter and synchronizes data through a single thread. • If you do not specify the splitPk parameter or leave it empty, Data Integration synchronizes data through a single thread.	No	None
where	The WHERE clause. For example, set this parameter to `gmt_create>$bizdate`. • You can use the WHERE clause to synchronize incremental data. If you do not specify the where parameter or leave it empty, all data is synchronized. • Do not set the where parameter to limit 10, which does not conform to the constraints of MySQL on the SQL WHERE clause.	No	None
querySql (only available in the code editor)	The SELECT statement used for refined data filtering. If you specify this parameter, Data Integration directly filters data based on this parameter. For example, if you want to join multiple tables for data synchronization, set this parameter to `select a,b from table_a join table_b on table_a.id = table_b.id`. The priority of the querySql parameter is higher than those of the table, column, where, and splitPk parameters. If you specify the querySql parameter, MySQL Reader ignores the table, column, where, and splitPk parameters that you have configured. The datasource parameter parses information, including the username and password, from this parameter.	No	None

Parameter	Description	Required	Default value
singleOrMulti (applicable only to database and table sharding)	Specifies whether to shard the database or table. After you switch from the codeless UI to the code editor, the following configuration is automatically generated: `"singleOrMulti":"multi"`. However, if you use the code editor since the beginning, the configuration is not automatically generated and you must manually specify this parameter. If you do not specify this parameter or leave it empty, MySQL Reader can only read data from the first shard.	Yes	*multi*

Configure MySQL Reader by using the codeless UI

1. Configure the connections.

   Configure the source and destination connections for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and enter the name of a connection that has been configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Filter	The filter condition for the data to be synchronized. Currently, filtering based on the limit keyword is not supported. The SQL syntax is determined by the selected connection.
Shard Key	The shard key. You can use a column in the source table as the shard key. We recommend that you use the primary key or an indexed column. Only integer fields are supported. If data sharding is performed based on the configured shard key, data can be read concurrently to improve data synchronization efficiency. **Note** The Shard Key parameter is displayed only when you configure the source connection for a sync node.

2. Configure field mapping, that is, the column parameter in the preceding parameter description.

   Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right. You can click **Add** to add a field, or move the pointer over a field and click the **Delete** icon to delete the field.

Parameter	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.

Parameter	Description
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout. The fields are automatically sorted based on specified rules.
Change Fields	Click the Change Fields icon. In the Change Fields dialog box that appears, you can manually edit fields in the source table. Each field occupies a row. The first and the last blank rows are included, whereas other blank rows are ignored.
Add	○ Click Add to add a field. You can enter constants. Each constant must be enclosed in single quotation marks (' '), such as 'abc' and '123'. ○ You can use scheduling parameters, such as ${bizdate}. ○ You can enter functions supported by relational databases, such as now() and count(1). ○ Fields that cannot be parsed are indicated by Unidentified.

3. Configure channel control policies.

Parameter	Description
Expected Concurrency	The maximum number of concurrent threads to read data from or write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure MySQL Reader by using the code editor

In the following code, a node is configured to read data from a database or table that is not sharded. For more information about the parameters, see the preceding parameter description.

```
{
```

```
{
  "type":"job",
  "version":"2.0", // The version number.
  "steps":[
    {
      "stepType":"mysql", // The reader type.
      "parameter":{
        "column":[ // The columns to be synchronized.
          "id"
        ],
        "connection":[
          {  "querysql":["select a,b from join1 c join join2 d on c.id = d.id;"], // Specify the querySql parameter in the connection parameter as a string.
            "datasource":"", // The connection name.
            "table":[
              "xxx" // The name of the table to be synchronized.
            ]
          }
        ],
        "where":"", // The WHERE clause.
        "splitPk":"", // The shard key.
        "encoding":"UTF-8" // The encoding format.
      },
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Writer",
      "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
      "record":"0" // The maximum number of dirty data records allowed.
    },
    "speed":{
      "throttle":false, // Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
```

```
        "concurrent":1, // The maximum number of concurrent threads.
      }
    },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
        }
      ]
    }
}
```

In the following code, a node is configured to read data from a database or table that is sharded. For more information about the parameters, see the preceding parameter description.

> **Note** In the case of database and table sharding, MySQL Reader can read multiple MySQL tables with the same schema.

```
{
  "type": "job",
  "version": "1.0",
  "configuration": {
    "reader": {
      "plugin": "mysql",
      "parameter": {
        "connection": [
          {
            "table": [
              "tbl1",
              "tbl2",
              "tbl3"
            ],
            "datasource": "datasourceName1"
          },
          {
            "table": [
              "tbl4",
              "tbl5",
              "tbl6"
            ],
            "datasource": "datasourceName2"
          }
        ],
        "singleOrMulti": "multi",
        "splitPk": "db_id",
        "column": [
          "id", "name", "age"
        ],
        "where": "1 < id and id < 100"
      }
    },
    "writer": {
    }
  }
}
```

2.4.5.3.8. Configure Oracle Reader

This topic describes the data types and parameters supported by Oracle Reader and how to configure it by using the codeless user interface (UI) and code editor.

Oracle Reader allows you to read data from Oracle. Oracle Reader connects to a remote Oracle database and runs a SELECT statement to select and read data from the database.

Specifically, Oracle Reader connects to a remote Oracle database through Java Database Connectivity (JDBC), generates a SELECT statement based on your configurations, and then sends the statement to the database. The Oracle database runs the statement and returns the result. Then, Oracle Reader assembles the returned data to abstract datasets in custom data types supported by Data Integration, and passes the datasets to a writer.

- Oracle Reader generates the SELECT statement based on the table, column, and where parameters that you have configured, and sends the generated SELECT statement to the Oracle database.
- If you specify the querySql parameter, Oracle Reader directly sends the value of this parameter to the Oracle database.

Data types

Oracle Reader supports most Oracle data types. Make sure that your data types are supported.

The following table lists the data types supported by Oracle Reader.

Category	Oracle data type
Integer	NUMBER, ROWID, INTEGER, INT, and SMALLINT
Floating point	NUMERIC, DECIMAL, FLOAT, DOUBLE PRECISION, and REAL
String	LONG, CHAR, NCHAR, VARCHAR, VARCHAR2, NVARCHAR2, CLOB, NCLOB, CHARACTER, CHARACTER VARYING, CHAR VARYING, NATIONAL CHARACTER, NATIONAL CHAR, NATIONAL CHARACTER VARYING, NATIONAL CHAR VARYING, and NCHAR VARYING
Date and time	TIMESTAMP and DATE
Boolean	BIT and BOOLEAN
Binary	BLOB, BFILE, RAW, and LONG RAW

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be identical to the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the table to be synchronized.	Yes	None

Parameter	Description	Required	Default value
column	The columns to be synchronized from the source table. The columns are described in a JSON array. The default value is [*], which indicates all columns. • Column pruning is supported. You can select and export specific columns. • Change of the column order is supported. You can export the columns in an order different from that specified in the schema of the table. • Constants are supported. The column names must be arranged in JSON format. `["id", "1", "'mingya.wmy'", "null", "to_char(a + 1)", "2.3", "true"]` ◦ id: a column name. ◦ 1: an integer constant. ◦ 'mingya.wmy': a string constant, which is enclosed in single quotation marks (' '). ◦ null: a null pointer. ◦ to_char(a + 1): a function expression. ◦ 2.3: a floating-point constant. ◦ true: a Boolean value. • The column parameter must be specified.	Yes	None
splitPk	The field used for data sharding when Oracle Reader extracts data. If you specify the splitPk parameter, the table is sharded based on the shard key specified by this parameter. Data Integration then runs concurrent threads to synchronize data. This improves efficiency. • We recommend that you set the splitPk parameter to the primary key of the table. Based on the primary key, data can be well distributed to different shards, but not intensively distributed to certain shards. • The data types supported by the splitPk parameter include INTEGER, STRING, FLOAT, and DATE. • If you do not specify the splitPk parameter or leave it empty, Oracle Reader synchronizes data through a single thread.	No	None

Parameter	Description	Required	Default value
where	The WHERE clause. Oracle Reader generates a SELECT statement based on the table, column, and where parameters that you have configured, and uses the generated SELECT statement to select and read data. For example, set this parameter to row_number() or `id>2 and sex=1`. • You can use the WHERE clause to synchronize incremental data. • If you do not specify the where parameter or leave it empty, all data is synchronized.	No	None
querySql (only available in the code editor)	The SELECT statement used for refined data filtering. If you specify this parameter, Data Integration directly filters data based on this parameter. For example, if you want to join multiple tables for data synchronization, set this parameter to `select a,b from table_a join table_b on table_a.id = table_b.id`. If you specify the querySql parameter, Oracle Reader ignores the table, column, and where parameters that you have configured.	No	None
fetchSize	The number of data records to read at a time. This parameter determines the number of interactions between Data Integration and the database and affects reading efficiency. Note A value greater than 2048 may lead to out of memory (OOM) during the data synchronization process.	No	1024

Configure Oracle Reader by using the codeless UI

1. Configure the connections.

   Configure the source and destination connections for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and enter the name of a connection that has been configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Filter	The filter condition for the data to be synchronized. Currently, filtering based on the limit keyword is not supported. The SQL syntax is determined by the selected connection.

Parameter	Description
Shard Key	The shard key. You can use a column in the source table as the shard key. We recommend that you use the primary key or an indexed column. Only integer fields are supported. If data sharding is performed based on the configured shard key, data can be read concurrently to improve data synchronization efficiency. Note The Shard Key parameter is displayed only when you configure the source connection for a sync node.

2. Configure field mapping, that is, the column parameter in the preceding parameter description.

   Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right. You can click **Add** to add a field, or move the pointer over a field and click the **Delete** icon to delete the field.

Parameter	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout. The fields are automatically sorted based on specified rules.
Change Fields	Click the Change Fields icon. In the Change Fields dialog box that appears, you can manually edit fields in the source table. Each field occupies a row. The first and the last blank rows are included, whereas other blank rows are ignored.
Add	○ Click Add to add a field. You can enter constants. Each constant must be enclosed in single quotation marks (' '), such as 'abc' and '123'. ○ You can use scheduling parameters, such as ${bizdate}. ○ You can enter functions supported by relational databases, such as now() and count(1). ○ Fields that cannot be parsed are indicated by Unidentified.

3. Configure channel control policies.

Parameter	Description
Expected Concurrency	The maximum number of concurrent threads to read data from or write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure Oracle Reader by using the code editor

In the following code, a node is configured to read data from an Oracle database.

```
{
  "type":"job",
  "version":"2.0", // The version number.
  "steps":[
    {
      "stepType":"oracle",
      "parameter":{
        "fetchSize":1024, // The number of data records to read at a time.
        "datasource":"", // The connection name.
        "column":[ // The columns to be synchronized.
          "id",
          "name"
        ],
        "where":"", // The WHERE clause.
        "splitPk":"", // The shard key.
        "table":"" // The name of the table to be synchronized.
      },
      "name":"Reader",
      "category":"reader"
    },
    {// The following template is used to configure Stream Writer. For more information about how to
```

```
configure other writers, see the corresponding topic.
        "stepType":"stream",
        "parameter":{},
        "name":"Writer",
        "category":"writer"
      }
    ],
    "setting":{
      "errorLimit":{
        "record":"0" // The maximum number of dirty data records allowed.
      },
      "speed":{
        "throttle":false, // Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
        "concurrent":1, // The maximum number of concurrent threads.
      }
    },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
        }
      ]
    }
} "to":"Writer"
        }
      ]
    }
}
```

Additional instructions

- Data synchronization between primary and secondary databases

  A secondary Oracle database can be deployed for disaster recovery. The secondary database continuously synchronizes data from the primary database based on binlogs. Especially when network conditions are unfavorable, data latency between the primary and secondary databases is unavoidable, which can lead to data inconsistency.

- Concurrency control

Oracle is a relational database management system (RDBMS), which supports strong consistency for data queries. A database snapshot is created before a sync node starts. Oracle Reader reads data from the database snapshot. Therefore, if new data is written to the database during data synchronization, Oracle Reader cannot obtain the new data.

Data consistency cannot be guaranteed when you enable Oracle Reader to run concurrent threads on a single sync node.

Oracle Reader shards the table based on the splitPk parameter and runs multiple concurrent threads to synchronize data. These concurrent threads belong to different transactions. They read data at different time points. This means that the concurrent threads observe different snapshots.

Theoretically, the data inconsistency issue is unavoidable if a single sync node includes multiple threads. However, two workarounds are available:

- Do not enable concurrent threads on a single sync node. Essentially, do not specify the splitPk parameter. In this way, data consistency is guaranteed although data is synchronized at a low efficiency.
- Disable writers to make sure that the data is unchanged during data synchronization. For example, lock the table and disable data synchronization between primary and secondary databases. In this way, data is synchronized efficiently but your ongoing services may be interrupted.

- Character encoding

  Oracle Reader uses JDBC, which can automatically convert the encoding of characters. Therefore, you do not need to specify the encoding format.

- Incremental data synchronization

  Oracle Reader connects to a database through JDBC and uses a SELECT statement with a WHERE clause to read incremental data in the following ways:

  - For data in batches, incremental add, update, and delete operations (including logically delete operations) are distinguished by timestamps. Specify the WHERE clause based on the timestamp. The timestamp must be later than the latest timestamp in the last synchronization.
  - For streaming data, specify the WHERE clause based on the data record ID. The data record ID must be larger than the maximum ID involved in the last synchronization.

  If incremental data cannot be distinguished, Oracle Reader cannot perform incremental synchronization but can perform full synchronization only.

- Syntax validation

  Oracle Reader allows you to specify custom SELECT statements by using the querySql parameter but does not verify the syntax of the custom SELECT statements.

2.4.5.3.9. Configure OSS Reader

This topic describes the data types and parameters supported by OSS Reader and how to configure it by using the codeless UI and code editor.

OSS Reader can read data stored in OSS. OSS Reader connects to OSS by using the official OSS Java SDK, reads data from OSS, converts the data into a format that is readable by Data Integration, and then sends the converted data to a writer.

OSS stores unstructured data only. OSS Reader supports the following features:

- Reads TXT objects that store logical two-dimensional tables. OSS Reader can read only TXT objects.
- Reads data stored in formats similar to CSV with custom delimiters.
- Reads data of various types as strings and supports constants and column pruning.
- Supports recursive reading and object name-based filtering.
- Supports the following object compression formats: GZIP, BZIP2, and ZIP.

  > **Note** You cannot compress multiple objects into one package.

- Reads multiple objects concurrently.

OSS Reader does not support the following features:

- Uses concurrent threads to read an uncompressed object.
- Uses concurrent threads to read a compressed object.

OSS Reader supports the following OSS data types: Bigint, Double, String, Datatime, and Boolean.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None

Parameter	Description	Required	Default value
Object	The name of the OSS object to read. You can specify multiple object names. For example, if a bucket has a directory named yunshi and this directory contains an object named ll.txt, you can set this parameter to yunshi/ll.txt. • If you specify a single OSS object, OSS Reader uses only one thread to read the object. Concurrent multi-thread reading of a single uncompressed object is coming soon. • If you specify multiple OSS objects, OSS Reader uses multiple threads to read these objects. The actual number of threads is determined by the number of channels. • When a name contains a wildcard, OSS Reader attempts to read all objects that match the name. For example, if you set the value to abc[0-9], OSS Reader reads objects abc0 to abc9. We recommend that you do not use wildcards because wildcards may cause out of memory (OOM). For more information, see OSS documentation. Note • Data Integration considers all the objects on a sync node as a single table. Make sure that all the objects on each sync node can adapt to the same schema. • Control the number of objects stored in a single directory. If a directory contains excessive objects, an OOM error may be returned. In this case, store the objects in different directories and then synchronize data.	Yes	None

Parameter	Description	Required	Default value
column	The columns to read. The type parameter specifies the source data type. The index parameter specifies the ID of the column in the source table, starting from 0. The value parameter specifies the column value if the column is a constant column. By default, OSS Reader reads all data as strings. You can specify the column parameter in the following way: `json` `"column": ["*"]` You can also specify the column parameter in the following way: `json` `"column":` `{` `"type": "long",` `"index": 0 // The first INT-type column of the source object.` `},` `{` `"type": "string",` `"value": "alibaba" // The value of the current column. In this case, the value is a constant "alibaba."` `}` Note For the column parameter, you must specify the type parameter and specify one of the index and value parameters.	Yes	By default, OSS Reader reads all data as strings.
fieldDelimiter	The column delimiter. Note You must specify the column delimiter for OSS Reader. The default delimiter is comma (,). The default setting for the column delimiter on the codeless UI is comma (,), too.	Yes	,

Parameter	Description	Required	Default value
compress	The compression format of the object. By default, this parameter is left empty, indicating that objects are not compressed. OSS Reader supports the following object compression formats: GZIP, BZIP2, and ZIP.	No	*By default, objects are not compressed.*
encoding	The encoding format of the object to read.	No	*utf-8*
nullFormat	The string that represents null. No standard strings can represent null in TXT objects. Therefore, Data Integration provides the nullFormat parameter to define which string represents a null pointer. For example, if you specify `nullFormat="null"`, Data Integration considers null as a null pointer. You can use the following formula to escape empty strings: \N=\\N.	No	None
skipHeader	Specifies whether to skip the header (if exists) of a CSV-like object. The skipHeader parameter is not supported for compressed objects.	No	*false*
csvReaderConfig	The configurations for reading CSV objects. The parameter value must match the MAP type. A specific CSV reader is used to read data from CSV objects, which supports many configurations.	No	None

Configure OSS Reader by using the codeless UI

1. Configure the connections.

   Configure the connections to the source and destination data stores for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Object Name Prefix	The object parameter in the preceding parameter description. **Note** If an OSS object is named based on the date, for example, named as aaa/20171024abc.txt, you can set the object parameter to aaa/${bdp.system.bizdate}abc.txt.
Field Delimiter	The fieldDelimiter parameter in the preceding parameter description. The default delimiter is comma (,).
Encoding	The encoding parameter in the preceding parameter description. Default value: UTF-8.

Parameter	Description
Null String	The nullFormat parameter in the preceding parameter description. Enter a string that represents null. If the source connection contains the string, the string is replaced with null.
Compression Format	The compress parameter in the preceding parameter description. Default value: None.
Include Header	The skipHeader parameter in the preceding parameter description. Default value: No.

2. **Configure field mapping. It is equivalent to setting the column parameter provided in the preceding table.**

   Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right. You can click Add to add a field, or move the pointer over a field and click the Delete icon to delete the field.

Button	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.

3. **Configure channel control policies.**

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure OSS Reader by using the code editor

In the following code, a node is configured to read data from OSS. For more information about the parameters, see the preceding parameter description.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"oss",// The reader type.
      "parameter":{
        "nullFormat":"",// The string that represents null.
        "compress":"",// The compression format.
        "datasource":"",// The connection name.
        "column":[// The columns to be synchronized.
          {
            "index":0,// The ID of the column in the source table.
            "type":"string"// The data type.
          },
          {
            "index":1,
            "type":"long"
          },
          {
            "index":2,
            "type":"double"
          },
          {
            "index":3,
            "type":"boolean"
          },
          {
            "format":"yyyy-MM-dd HH:mm:ss", // The format of the time.
            "index":4,
            "type":"date"
          }
        ],
        "skipHeader":"", // Specifies whether to skip the header (if exists) of a CSV-like object.
        "encoding":"",// The encoding format.
        "fieldDelimiter":",",// The column delimiter.
        "fileFormat": "",// The format of the object saved by OSS Reader.
```

```
            "Object":[]// The name of the OSS object to read.
        },
        "name":"Reader",
        "category":"reader"
    },
    {
        "stepType":"stream",
        "parameter":{},
        "name":"Writer",
        "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
        "record":""// The maximum number of dirty data records allowed.
    },
    "speed":{
        "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
        "concurrent":1,// The maximum number of concurrent threads.
    }
  },
  "order":{
    "hops":[
        {
          "from":"Reader",
          "to":"Writer"
        }
    ]
  }
}
```

2.4.5.3.10. Configure FTP Reader

This topic describes the data types and parameters supported by File Transfer Protocol (FTP) Reader and how to configure it by using the codeless user interface (UI) and code editor.

FTP Reader allows you to read data from a remote FTP server. FTP Reader connects to an FTP server, reads data from the server, converts the data into a format that is readable by Data Integration, and then sends the converted data to a writer.

FTP Reader can read only FTP files that store logical two-dimensional tables, for example, text information in CSV format.

FTP servers store unstructured data only. Currently, FTP Reader supports the following features:

- Reads TXT files that store logical two-dimensional tables. FTP Reader can read only TXT files.
- Reads data stored in formats similar to CSV with custom delimiters.
- Reads data of various types as strings. Supports constants and column pruning.
- Supports recursive reading and file name-based filtering.
- Supports the following file compression formats: GZIP, BZIP2, ZIP, LZO, and LZO_DEFLATE.
- Reads multiple files concurrently.

Currently, FTP Reader does not support the following features:

- Uses concurrent threads to read an uncompressed file.
- Uses concurrent threads to read a compressed file.

The data types of remote FTP files are defined by FTP Reader.

Data Integration data type	FTP file data type
LONG	LONG
DOUBLE	DOUBLE
STRING	STRING
BOOLEAN	BOOLEAN
DATE	DATE

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be identical to the name of the added connection. You can add connections in the code editor.	Yes	None

Parameter	Description	Required	Default value
path	The path of the FTP file to read. You can specify multiple FTP file paths. • If you specify a single FTP file, FTP Reader uses only one thread to read the file. Concurrent multi-thread reading of a single uncompressed file is coming soon. • If you specify multiple FTP files, FTP Reader uses multiple threads to read these files. The actual number of threads is determined by the number of channels. • When a path contains a wildcard, FTP Reader attempts to read all files that match the path. If the path is ended with a slash (/), FTP Reader reads all files in the specified directory. For example, if you specify the path as /bazhen/, FTP Reader reads all files in the bazhen directory. Currently, FTP Reader only supports asterisks (*) as file name wildcards. Note • We recommend that you do not use asterisks (*) because this may cause out of memory (OOM) on a Java virtual machine (JVM). • Data Integration considers all the files on a sync node as a single table. Make sure that all the files on each sync node can adapt to the same schema and Data Integration has the permission to read all these files. • Make sure that the data format is similar to CSV. • An error occurs if no readable files exist in the specified path.	Yes	None

Parameter	Description	Required	Default value
column	The columns to read. The type parameter specifies the source data type. The index parameter specifies the ID of the column in the source table, starting from 0. The value parameter specifies the column value if the column is a constant column. By default, FTP Reader reads all data as strings. Specify this parameter as `"column":["*"]`. You can also specify the column parameter in the following way: `{ "type": "long", "index": 0 // The first INT-type column of the source file. }, { "type": "string", "value": "alibaba" // The value of the current column, that is, a constant "alibaba". }` For the column parameter, you must specify the type parameter and specify one of the index and value parameters.	Yes	By default, FTP Reader reads all data as strings.
fieldDelimiter	The column delimiter. Note You must specify the column delimiter for FTP Reader. The default delimiter is comma (,). The default setting for the column delimiter on the codeless UI is comma (,), too.	Yes	,
skipHeader	Specifies whether to skip the header (if exists) of a CSV-like file. The skipHeader parameter is not supported for compressed files.	No	false
encoding	The encoding format of the file to read.	No	*UTF-8*
nullFormat	The string that represents null. No standard strings can represent null in text files. Therefore, Data Integration provides the nullFormat parameter to define which string represents a null pointer. For example, if you specify `nullFormat:"null"`, Data Integration considers null as a null pointer.	No	None

Parameter	Description	Required	Default value
markDoneFileName	The name of the file used to indicate that the sync node can start. Data Integration checks whether the file exists before data synchronization. If the file does not exist, Data Integration checks again later. Data Integration starts the sync node only after the file is detected.	No	None
maxRetryTime	The maximum number of checks for the file used to indicate that the sync node can start. By default, 60 checks are allowed. Data Integration checks for the file every 1 minute. The whole process lasts at most 60 minutes.	No	*60*
csvReaderConfig	The configurations for reading CSV files. The parameter value must match the MAP type. A specific CSV reader is used to read data from CSV files, which supports many configurations.	No	None
fileFormat	The format of the file saved by FTP Reader. By default, FTP Reader converts the data into a two-dimensional table and stores the table in a CSV file. If you specify binary as the file format, Data Integration converts data into the binary format for replication and transmission. Generally, you need to specify this parameter only when you want to replicate the complete directory structure between storage systems such as FTP and Object Storage Service (OSS).	No	None

Configure FTP Reader by using the codeless UI

1. Configure the connections.

   Configure the source and destination connections for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and enter the name of a connection that has been configured in DataWorks.
File Path	The path parameter in the preceding parameter description.
File Type	The format of the file saved by FTP Reader. The default format is CSV.
Field Delimiter	The fieldDelimiter parameter in the preceding parameter description. The default delimiter is comma (,).
Encoding	The encoding parameter in the preceding parameter description. The default encoding format is *UTF-8*.
Null String	The nullFormat parameter in the preceding parameter description, which defines a string that represents the null value.

Parameter	Description
Compression Format	The compression format. By default, files are not compressed.
Include Header	The skipHeader parameter in the preceding parameter description. The default value is *No*.

2. Configure field mapping, that is, the column parameter in the preceding parameter description.

   Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right. You can click **Add** to add a field, or move the pointer over a field and click the **Delete** icon to delete the field.

Parameter	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.

3. Configure channel control policies.

Parameter	Description
Expected Concurrency	The maximum number of concurrent threads to read data from or write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure FTP Reader by using the code editor

In the following code, a node is configured to read data from an FTP server.

```
{
```

```
{
  "type":"job",
  "version":"2.0", // The version number.
  "steps":[
    {
      "stepType":"ftp", // The reader type.
      "parameter":{
        "path":[], // The file path.
        "nullFormat":"", // The string that represents null.
        "compress":"", // The compression format.
        "datasource":"", // The connection name.
        "column":[ // The columns to be synchronized.
          {
            "index":0, // The ID of the column in the source table.
            "type":"" // The data type.
          }
        ],
        "skipHeader":"", // Specifies whether to skip the file header.
        "fieldDelimiter":",", // The column delimiter.
        "encoding":"UTF-8", // The encoding format.
        "fileFormat":"csv" // The format of the file saved by FTP Reader.
      },
      "name":"Reader",
      "category":"reader"
    },
    {// The following template is used to configure the writer. For more information, see the corresponding topic.
      "stepType":"stream",
      "parameter":{},
      "name":"Writer",
      "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
      "record":"0" // The maximum number of dirty data records allowed.
    },
    "speed":{
      "throttle":false, // Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
```

```
        "concurrent":1, // The maximum number of concurrent threads.
      }
    },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
        }
      ]
    }
}
```

2.4.5.3.11. Configure Table Store Reader

This topic describes the data types and parameters supported by Table Store Reader and how to configure it by using the code editor.

Table Store Reader can read incremental data from Table Store based on the specified range. Currently, Table Store Reader can read incremental data in the following ways:

- Reads data from the entire table.
- Reads data based on the specified range.
- Reads data from the specified shard.

Table Store is a NoSQL database service built on the Apsara distributed operating system that allows you to store and access large amounts of structured data in real time. Table Store organizes data into instances and tables. Using data sharding and load balancing technologies, Table Store seamlessly expands the data scale.

Table Store Reader connects to the Table Store server through the official Table Store Java SDK and reads data from the server. Then, Table Store Reader converts the data into a format that is readable by Data Integration based on the official data synchronization protocols, and sends the converted data to a writer.

Table Store Reader splits a sync node into concurrent tasks based on the table range to synchronize data in a Table Store table. Each thread is responsible for running a task.

Table Store Reader supports all Table Store data types. The following table lists the data types supported by Table Store Reader.

Category	Table Store data type
Integer	INTEGER
Floating point	DOUBLE
String	STRING
Boolean	BOOLEAN

Category	Table Store data type
Binary	BINARY

Note Table Store does not support data of the DATE type. Applications use the LONG-type UNIX timestamp to indicate the time.

Parameters

Parameter	Description	Required	Default value
endpoint	The endpoint of the Table Store server.	Yes	None
accessId	The AccessKey ID for accessing Table Store.	Yes	None
accessKey	The AccessKey secret for accessing Table Store.	Yes	None
instanceName	The name of the Table Store instance. The instance is an entity for you to use and manage Table Store. After you activate the Table Store service, you must create an instance in the console before creating and managing tables. Instances are the basic unit for managing Table Store resources. All access control and resource measurement for applications are completed at the instance level.	Yes	None
table	The name of the source table. You can specify only one table as the source table. Multi-table synchronization is not required for Table Store.	Yes	None

Parameter	Description	Required	Default value
column	The columns to be synchronized from the source table. The columns are described in a JSON array. Table Store is a NoSQL database service. You must specify column names for Table Store Reader to read data. • You can specify common columns. For example, you can specify {"name":"col1"} for Table Store Reader to read data in column 1. • You can specify certain columns to read. Table Store Reader only reads specified columns. • You can specify constant columns. For example, you can specify {"type":"STRING", "value":"DataX"} to read the column in which data is of the STRING type and the data value is DataX. The type parameter specifies the constant type. The supported types are STRING, INT, DOUBLE, BOOLEAN, BINARY, INF_MIN, and INF_MAX. If the constant type is BINARY, the constant value must be Base64-encoded. INF_MIN indicates the minimum value specified by Table Store, and INF_MAX indicates the maximum value specified by Table Store. If you set the type to INF_MIN or INF_MAX, do not set the value. Otherwise, errors may occur. • You cannot specify a function or custom expression, because Table Store does not provide functions or expressions similar to those of SQL. Table Store Reader cannot read columns that contain functions or expressions.	Yes	None
	The Table Store table range from which data is to be read. You can specify both or neither of the two parameters. The begin and end parameters define the value ranges of primary key columns in the Table Store table. Make sure that you specify the value ranges for all primary key columns in the table. If you do not need to limit a range, specify the parameters as {"type":"INF_MIN"} and {"type":"INF_MAX"}. For example, to read certain data from a Table Store table with the primary key of [DeviceID, SellerID], specify the begin and end parameters in the following way:		

Parameter	Description	Required	Default value
begin and end	"range": { "begin": [{"type":"INF_MIN"}, // The minimum value of the DeviceID field. {"type":"INT", "value":"0"} // The minimum value of the SellerID field.], "end": [{"type":"INF_MAX"}, // The maximum value of the DeviceID field. {"type":"INT", "value":"9999"} // The maximum value of the SellerID field.] } To read all data from the table, specify the begin and end parameters in the following way: "range": { "begin": [{"type":"INF_MIN"}, // The minimum value of the DeviceID field. {"type":"INF_MIN"} // The minimum value of the SellerID field.], "end": [{"type":"INF_MAX"}, // The maximum value of the DeviceID field. {"type":"INF_MAX"} // The maximum value of the SellerID field.] }		
split	The custom rule for data sharding. This parameter is an advanced setting. We recommend that you do not set this parameter. If data is unevenly distributed in a Table Store table and the automatic sharding feature of Table Store Reader fails to work, you can customize a sharding rule. The sharding rule specified by the split parameter must fall in the range specified by the begin and end parameters and must be the values of partition key columns. That is, you only need to specify the values of partition key columns instead of the values of primary key columns in the split parameter. To read data from a Table Store table with the primary key of [DeviceID, SellerID], specify the following parameters:		

Parameter	Description	Required	Default value
split	"range": { "begin": { {"type":"INF_MIN"}, // The minimum value of the DeviceID field. {"type":"INF_MIN"} // The minimum value of the SellerID field. }, "end": { {"type":"INF_MAX"}, // The maximum value of the DeviceID field. {"type":"INF_MAX"} // The maximum value of the SellerID field. }, // The specified sharding rule. If you specify a sharding rule, the sync node is split into concurrent tasks based on the values of the begin, end, and split parameters. Data is sharded only based on the partition key, that is, the first column of the primary key. // The data type of the partition key can be INF_MIN, INF_MAX, STRING, or INT. "split":[{"type":"STRING", "value":"1"}, {"type":"STRING", "value":"2"}, {"type":"STRING", "value":"3"}, {"type":"STRING", "value":"4"}, {"type":"STRING", "value":"5"}] }	No	None

Parameter	Description	Required	Default value

Configure Table Store Reader by using the codeless UI

Currently, the codeless user interface (UI) is not supported for Table Store Reader.

Configure Table Store Reader by using the code editor

In the following code, a node is configured to read data from a Table Store table.

```
{
  "type":"job",
  "version":"2.0", // The version number.
  "steps":[
    {
      "stepType":"ots", // The reader type.
      "parameter":{
        "datasource":"", // The connection name.
        "column":[ // The columns to be synchronized.
          {
            "name":"column1" // The name of the column.
          },
          {
            "name":"column2"
          },
          {
            "name":"column3"
          },
          {
            "name":"column4"
          },
          {
            "name":"column5"
          }
        ],
        "range":{
```

```
"split":[
  {
    "type":"INF_MIN"
  },
  {
    "type":"STRING",
    "value":"splitPoint1"
  },
  {
    "type":"STRING",
    "value":"splitPoint2"
  },
  {
    "type":"STRING",
    "value":"splitPoint3"
  },
  {
    "type":"INF_MAX"
  }
],
"end":[
  {
    "type":"INF_MAX"
  },
  {
    "type":"INF_MAX"
  },
  {
    "type":"STRING",
    "value":"end1"
  },
  {
    "type":"INT",
    "value":"100"
  }
],
"begin":[
  {
    "type":"INF_MIN"
  },
  {
```

```
                {
                    "type":"INF_MIN"
                },
                {
                    "type":"STRING",
                    "value":"begin1"
                },
                {
                    "type":"INT",
                    "value":"0"
                }
            ]
          },
          "table":"" // The name of the table to be synchronized.
        },
        "name":"Reader",
        "category":"reader"
      },
      {
        "stepType":"stream",
        "parameter":{},
        "name":"Writer",
        "category":"writer"
      }
    ],
    "setting":{
      "errorLimit":{
        "record":"0" // The maximum number of dirty data records allowed.
      },
      "speed":{
        "throttle":false, // Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
        "concurrent":1, // The maximum number of concurrent threads.
      }
    },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
```

```
        }
      ]
    }
}
```

2.4.5.3.12. Configure PostgreSQL Reader

This topic describes the data types and parameters supported by PostgreSQL Reader and how to configure it by using the codeless UI and code editor.

PostgreSQL Reader connects to a remote PostgreSQL database and runs a SELECT statement to select and read data from the database. ApsaraDB for Relational Database Service (RDS) provides the PostgreSQL storage engine.

Specifically, PostgreSQL Reader connects to a remote PostgreSQL database through Java Database Connectivity (JDBC), generates a SELECT statement based on your configurations, and sends the statement to the database. The PostgreSQL database runs the statement and returns the result. Then, PostgreSQL Reader assembles the returned data to abstract datasets in custom data types supported by Data Integration, and passes the datasets to a writer.

- PostgreSQL Reader generates the SELECT statement based on the table, column, and where parameters that you have configured, and sends the generated SQL statement to the PostgreSQL database.
- If you specify the querySql parameter, PostgreSQL Reader directly sends the value of this parameter to the PostgreSQL database.

Data types

PostgreSQL Reader supports most PostgreSQL data types. Ensure that your data types are supported.

The following table lists the data types supported by PostgreSQL Reader.

Category	PostgreSQL data type
Integer	bigint, bigserial, integer, smallint, and serial
Float	double, precision, money, numeric, and real
String	varchar, char, text, bit, and inet
Date and time	date, time, and timestamp
Boolean	boolean
Binary	bytea

> **Note**
>
> - Except for the preceding data types, other types are not supported.
> - You need to convert the money, inet, and bit types by using syntax such as `a_inet::varchar`.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be identical to the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the table to be synchronized.	Yes	None
column	An array of columns to be synchronized from the configured table, in JSON format. The default value is [*], which indicates all columns. • Column pruning is supported, which means that you can select and export specific columns. • Change of the column order is supported, which means that you can export the columns in an order different from that specified in the schema of the table. • Constants are supported. The column names must be arranged in compliance with SQL syntax supported by MySQL. For example, `["id", "table","1", "'mingya.wmy'", "'null'", "to_char(a+1)", "2.3", "true"]`. ○ id: a column name. ○ table: the name of a column that contains reserved keywords. ○ 1: an integer constant. ○ 'mingya.wmy': a string constant, which is enclosed in a pair of single quotation marks ('). ○ 'null': a string. ○ to_char(a + 1): a function expression. ○ 2.3: a float value. ○ true: a Boolean value. • The column parameter must explicitly specify a set of columns to be synchronized. It cannot be left empty.	Yes	None

Parameter	Description	Required	Default value
splitPk	The field used for data sharding when PostgreSQL Reader extracts data. If you specify the splitPk parameter, the table is sharded based on the shard key specified by this parameter. Data Integration then initiates concurrent data synchronization threads, which improves efficiency. • We recommend that you set the splitPk parameter to the primary key of the table. Based on the primary key, data can be well distributed to different shards, but not intensively distributed to certain shards. • Currently, the splitPk parameter supports data sharding only for integers but not for other data types such as string, float, and date. If you specify this parameter to a column of an unsupported type, PostgreSQL Reader ignores the splitPk parameter and synchronizes data through a single thread. • If you do not specify the splitPk parameter or leave it empty, Data Integration synchronizes data through a single thread.	No	None
where	The WHERE clause. PostgreSQL Reader generates a SELECT statement based on the table, column, and where parameters that you have configured, and uses the generated SELECT statement to select and read data. For example, set this parameter to `id>2 and sex=1`. • The WHERE clause can be used for synchronizing incremental data. • If you do not specify the where parameter or leave it empty, all data is synchronized.	No	None
querySql (only available in the code editor)	The SELECT statement used for refined data filtering. If you specify this parameter, Data Integration directly filters data based on this parameter. For example, if you need to join multiple tables for data synchronization, set this parameter to `select a,b from table_a join table_b on table_a.id = table_b.id`. If you specify the querySql parameter, PostgreSQL Reader ignores the table, column, and where parameters that you have configured.	No	None
fetchSize	The number of data records to read at a time. This parameter determines the number of interactions between Data Integration and the database and affects reading efficiency. Note A value larger than 2048 may lead to the out of memory (OOM) error during the data synchronization process.	No	*512*

Configure PostgreSQL Reader by using the codeless UI

1. Configure the connections.

   Configure the source and destination connections for the data synchronization node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and enter the name of a connection that has been configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Filter	The filter condition for the data to be synchronized. Currently, filtering based on the limit keyword is not supported. The SQL syntax is determined by the selected data store.
Shard Key	The shard key. You can use a column in the source table as the shard key. We recommend that you use the primary key or an indexed column. Only integer fields are supported. If data sharding is performed based on the configured shard key, data can be read concurrently to improve data synchronization efficiency. Note The Shard Key parameter is displayed only when you configure the source connection for a data synchronization node.

2. Configure field mapping (the column parameter in the preceding parameter description).

   Fields in the source table (left) have a one-to-one mapping with fields in the destination table (right). You can click **Add** to add a field or move the pointer over a field and click the **Delete** icon to delete a field.

Configuration item	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	The fields are automatically sorted based on specified rules.
Change Fields	You can manually edit fields in the source table. Each field occupies a row. The first and the last blank rows are included, while other blank rows are ignored.

Configuration item	Description
Add	○ You can enter constants. Each constant must be enclosed in single quotation marks ('), such as 'abc' and '123'. ○ You can use scheduling parameters, such as ${bizdate}. ○ You can enter functions supported by relational databases, such as now() and count(1). ○ If the value you entered cannot be parsed, the type is displayed as Unidentified.

3. Configure the channel.

Parameter	Description
DMU	The billing unit of Data Integration. Note Use caution while setting the DMU parameter. Its value limits the maximum number of concurrent threads.
Concurrent Threads	The maximum number of concurrent data synchronization threads. If you specify this parameter, the data records are split based on the shard key specified for the reader so that they are synchronized in multiple threads concurrently. This improves the transmission rate.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the data synchronization node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the data synchronization node on the custom resource group. Set the resource group properly based on network conditions of the data stores, resource group usage, and business importance.

Configure PostgreSQL Reader by using the code editor

In the following code, a node is configured to read data from a PostgreSQL database.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"postgresql",// The reader type
```

```
        "stepType":"postgresql",// The reader type.
        "parameter":{
          "datasource":"",// The connection name.
          "column":[// The columns to be synchronized.
            "col1",
            "col2"
          ],
          "where":"",// The WHERE clause.
          "splitPk":"",// The shard key based on which the table is sharded. Data Integration initiates c
oncurrent threads to synchronize data.
          "table":""// The name of the table to be synchronized.
        },
        "name":"Reader",
        "category":"reader"
      },
      { // The following template is used to configure the writer. For more information, see the documen
t of the corresponding writer.
        "stepType":"stream",
        "parameter":{},
        "name":"Writer",
        "category":"writer"
      }
    ],
    "setting":{
      "errorLimit":{
        "record":"0"// The maximum number of dirty data records allowed.
      },
      "speed":{
        "throttle":false,// A value of false indicates that the bandwidth is not throttled. A value of true
indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set t
his parameter to true.
        "concurrent":1,// The maximum number of concurrent threads.
        "dmu":1// The DMU value.
      }
    },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
        }
```

```
    ]
  }
}
```

Additional instructions

- Data synchronization between primary and secondary databases

  A secondary PostgreSQL database can be deployed for disaster recovery. The secondary database continuously synchronizes data from the primary database based on binlogs. Especially when network conditions are unfavorable, data latency between the primary and secondary databases is unavoidable, which can lead to data inconsistency.

- Concurrency control

  PostgreSQL is a relational database management system (RDBMS), which supports strong consistency for data queries. A database snapshot is created before a data synchronization node starts. PostgreSQL Reader reads data from the database snapshot. Therefore, if new data is written to the database during data synchronization, the reader cannot obtain the new data.

  Data consistency cannot be ensured when you enable PostgreSQL Reader to run concurrent threads on a single data synchronization node.

  PostgreSQL Reader shards the table based on the splitPk parameter and runs multiple concurrent threads to synchronize data. These concurrent threads belong to different transactions, and they read data at different times. This means that the concurrent threads observe different snapshots.

  Theoretically, the data inconsistency issue is unavoidable if a single data synchronization node includes multiple threads. However, two workarounds are available:

  - Do not enable concurrent threads on a single data synchronization node. Essentially, do not specify the splitPk parameter. In this way, data consistency is ensured while data is synchronized at a low efficiency.
  - Disable writers to ensure that the data is unchanged during data synchronization. For example, lock the table and disable data synchronization between primary and secondary databases. In this way, data is synchronized efficiently but your ongoing services can be interrupted.

- Character encoding

  A PostgreSQL database supports only EUC_CN and UTF-8 encoding formats for simplified Chinese characters. PostgreSQL Reader uses JDBC, which can automatically convert encoding of characters. Therefore, you do not need to specify the encoding.

  If data is written to the PostgreSQL database in an encoding format different from that specified by the PostgreSQL database, PostgreSQL Reader cannot recognize this inconsistency and may export garbled characters.

- Incremental data synchronization

  PostgreSQL Reader connects to a database through JDBC and uses `a SELECT statement with a WHERE clause` to read incremental data in either of the following ways:

  - For batch data, incremental add, update, and delete operations (including logical delete operations) are distinguished by timestamps. Specify the WHERE clause based on the timestamp. The timestamp must be later than the latest timestamp in the last synchronization.
  - For streaming data, specify the WHERE clause based on the data record ID. The data record ID must be larger than the maximum ID involved in the last synchronization.

  If incremental data cannot be distinguished, PostgreSQL Reader cannot perform incremental synchronization but can perform full synchronization only.

- Syntax validation

  PostgreSQL Reader allows you to specify custom SELECT statements by using the querySql parameter but does not verify the syntax of the custom SELECT statements.

2.4.5.3.13. Configure SQL Server Reader

This topic describes the data types and parameters supported by SQL Server Reader and how to configure it by using the codeless user interface (UI) and code editor.

SQL Server Reader connects to a remote SQL Server database and runs a SELECT statement to select and read data from the database.

Specifically, SQL Server Reader connects to a remote SQL Server database through Java Database Connectivity (JDBC), generates a SELECT statement based on your configurations, and then sends the statement to the database. The SQL Server database runs the statement and returns the result. Then, SQL Server Reader assembles the returned data to abstract datasets in custom data types supported by Data Integration, and passes the datasets to a writer.

- SQL Server Reader generates the SELECT statement based on the table, column, and where parameters that you have configured, and sends the generated SELECT statement to the SQL Server database.
- If you specify the querySql parameter, SQL Server Reader directly sends the value of this parameter to the SQL Server database.

SQL Server Reader supports most SQL Server data types. Make sure that your data types are supported.

The following table lists the data types supported by SQL Server Reader.

Category	SQL Server data type
Integer	bigint, int, smallint, and tinyint
Floating point	float, decimal, real, and numeric
String	char, nchar, ntext, nvarchar, text, varchar, nvarchar (max), and varchar (max)
Date and time	date, datetime, and time
Boolean	bit
Binary	binary, varbinary, varbinary (max), and timestamp

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be identical to the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the table to be synchronized. You can select only one source table for each sync node.	Yes	None
column	The columns to be synchronized from the source table. The columns are described in a JSON array. The default value is [*], which indicates all columns. • Column pruning is supported. You can select and export specific columns. • Change of the column order is supported. You can export the columns in an order different from that specified in the schema of the table. • Constants are supported. The column names must be arranged in compliance with the SQL syntax supported by MySQL, for example, `["id", "table","1", "'mingya.wmy'", "'null'", "to_char(a+1)", "2.3", "true"]`. ◦ id: a column name. ◦ table: the name of a column that contains reserved keywords. ◦ 1: an integer constant. ◦ 'mingya.wmy': a string constant, which is enclosed in single quotation marks (' '). ◦ 'null': a string. ◦ to_char(a + 1): a function expression. ◦ 2.3: a floating-point constant. ◦ true: a Boolean value. • The column parameter must explicitly specify a set of columns to be synchronized. The parameter cannot be left empty.	Yes	None

Parameter	Description	Required	Default value
splitPk	The field used for data sharding when SQL Server Reader extracts data. If you specify the splitPk parameter, the table is sharded based on the shard key specified by this parameter. Data Integration then runs concurrent threads to synchronize data. This improves efficiency. • We recommend that you set the splitPk parameter to the primary key of the table. Based on the primary key, data can be well distributed to different shards, but not intensively distributed to certain shards. • Currently, the splitPk parameter supports data sharding only for integers but not for other data types such as string, floating point, and date. If you specify this parameter to a column of an unsupported type, SQL Server Reader returns an error.	No	None
where	The WHERE clause. SQL Server Reader generates a SELECT statement based on the table, column, and where parameters that you have configured, and uses the generated SELECT statement to select and read data. For example, set this parameter to limit 10 during a test. For example, if you need to synchronize data generated on the current day, set this parameter to `gmt_create > $bizdate`. • You can use the WHERE clause to synchronize incremental data. • If you do not specify the where parameter or leave it empty, all data is synchronized.	No	None
querySql	The SELECT statement used for refined data filtering. Specify this parameter in the following format: `"querysql" : "SELECT statement",`. If you specify this parameter, Data Integration directly filters data based on this parameter. For example, if you want to join multiple tables for data synchronization, set this parameter to `select a,b from table_a join table_b on table_a.id = table_b.id`. If you specify the querySql parameter, SQL Server Reader ignores the table, column, and where parameters that you have configured.	No	None
fetchSize	The number of data records to read at a time. This parameter determines the number of interactions between Data Integration and the database and affects reading efficiency. Note A value larger than 2048 may lead to the out of memory (OOM) error during the data synchronization process.	No	*1024*

Configure SQL Server Reader by using the codeless UI

1. Configure the connections.

   Configure the source and destination connections for the sync node.

Configuration item	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and enter the name of a connection that has been configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Filter	The filter condition for the data to be synchronized. Currently, filtering based on the limit keyword is not supported. The SQL syntax is determined by the selected connection.
Shard Key	The shard key. You can use a column in the source table as the shard key. We recommend that you use the primary key or an indexed column.

2. Configure field mapping, that is, the column parameter in the preceding parameter description.

   Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right. You can click **Add** to add a field, or move the pointer over a field and click the **Delete** icon to delete the field.

Configuration item	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout. The fields are automatically sorted based on specified rules.
Change Fields	Click the Change Fields icon. In the Change Fields dialog box that appears, you can manually edit fields in the source table. Each field occupies a row. The first and the last blank rows are included, whereas other blank rows are ignored.
Add	○ Click Add to add a field. You can enter constants. Each constant must be enclosed in single quotation marks (' '), such as 'abc' and '123'. ○ You can use scheduling parameters, such as ${bizdate}. ○ You can enter functions supported by relational databases, such as now() and count(1). ○ Fields that cannot be parsed are indicated by Unidentified.

3. Configure channel control policies.

Configuration item	Description
Expected Concurrency	The maximum number of concurrent threads to read data from or write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure SQL Server Reader by using the code editor

In the following code, a node is configured to read data from an SQL Server database.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"sqlserver",// The reader type.
      "parameter":{
        "datasource":"",// The connection name.
        "column":[// The columns to be synchronized.
          "id",
          "name"
        ],
        "where":"",// The WHERE clause.
        "splitPk":"",// The shard key based on which the table is sharded.
        "table":""// The name of the table to be synchronized.
      },
      "name":"Reader",
      "category":"reader"
    },
    {// The following template is used to configure the writer. For more information, see the correspo
```

```
nding topic.
            "stepType":"stream",
            "parameter":{},
            "name":"Writer",
            "category":"writer"
        }
    ],
    "setting":{
        "errorLimit":{
            "record":"0"// The maximum number of dirty data records allowed.
        },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
            "concurrent":1,// The maximum number of concurrent threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

If you want to use the querySql parameter to specify a SELECT statement to query data, see the following sample code in the script of SQL Server Reader. Assume that the SQL Server connection is sql_server_source, the table to be queried is dbo.test_table, and the column to be queried is name.

```
{
  "stepType": "sqlserver",
  "parameter": {
    "querySql": "select name from dbo.test_table",
    "datasource": "sql_server_source",
    "column": [
      "name"
    ],
    "where": "",
    "splitPk": "id"
  },
  "name": "Reader",
  "category": "reader"
},
```

Additional instructions

- Data synchronization between primary and secondary databases

  A secondary SQL Server database can be deployed for disaster recovery. The secondary database continuously synchronizes data from the primary database based on binlogs. Especially when network conditions are unfavorable, data latency between the primary and secondary databases is unavoidable, which can lead to data inconsistency.

- Concurrency control

  SQL Server is a relational database management system (RDBMS), which supports strong consistency for data queries. A database snapshot is created before a sync node starts. SQL Server Reader reads data from the database snapshot. Therefore, if new data is written to the database during data synchronization, the reader cannot obtain the new data.

  Data consistency cannot be guaranteed when you enable SQL Server Reader to run concurrent threads on a single sync node.

  SQL Server Reader shards the table based on the splitPk parameter and runs multiple concurrent threads to synchronize data. These concurrent threads belong to different transactions. They read data at different time points. This means that the concurrent threads observe different snapshots.

  Theoretically, the data inconsistency issue is unavoidable if a single sync node includes multiple threads. However, two workarounds are available:

  - Do not enable concurrent threads on a single sync node. Essentially, do not specify the splitPk parameter. In this way, data consistency is guaranteed although data is synchronized at a low efficiency.
  - Disable writers to make sure that the data is unchanged during data synchronization. For example, lock the table and disable data synchronization between primary and secondary databases. In this way, data is synchronized efficiently but your ongoing services may be interrupted.

- Character encoding

SQL Server Reader uses JDBC, which can automatically convert the encoding of characters. Therefore, you do not need to specify the encoding format.

- Incremental data synchronization

  SQL Server Reader connects to a database through JDBC and uses a SELECT statement with a WHERE clause to read incremental data in the following ways:

  - For data in batches, incremental add, update, and delete operations (including logically delete operations) are distinguished by timestamps. Specify the WHERE clause based on the timestamp. The timestamp must be later than the latest timestamp in the last synchronization.
  - For streaming data, specify the WHERE clause based on the data record ID. The data record ID must be larger than the maximum ID involved in the last synchronization.

  If incremental data cannot be distinguished, SQL Server Reader cannot perform incremental synchronization but can perform full synchronization only.

- Syntax validation

  SQL Server Reader allows you to specify custom SELECT statements by using the querySql parameter but does not verify the syntax of the custom SELECT statements.

2.4.5.3.14. Configure LogHub Reader

This topic describes the data types and parameters supported by LogHub Reader and how to configure it by using the codeless UI and code editor.

As an all-in-one real-time data logging service, Log Service provides features to collect, consume, deliver, query, and analyze log data. It can comprehensively improve the capabilities to process and analyze numerous logs. LogHub Reader consumes real-time log data in LogHub by using the Java SDK for Log Service, converts the data to a format that can be read by the Data Integration service, and sends the converted data to a writer.

How it works

LogHub Reader consumes real-time log data in LogHub by using the following version of the Java SDK for Log Service:

```
<dependency>
    <groupId>com.aliyun.openservices</groupId>
    <artifactId>aliyun-log</artifactId>
    <version>0.6.7</version>
</dependency>
```

In Log Service, Logstore is a basic unit for collecting, storing, and querying log data. The read and write logs of a Logstore are stored in a shard. Each Logstore consists of several shards, each of which is defined by a left-closed and right-open interval of MD5 values so that intervals do not overlap each other. The range of all intervals covers all the allowed MD5 values. Each shard can independently provide some services.

- Write: 5 Mbit/s, 2,000 times/s.
- Read: 10 Mbit/s, 100 times/s.

LogHub Reader consumes log data in shards by following this process in which the GetCursor and BatchGetLog API operations are called:

- Obtain a cursor based on the time range.
- Read logs based on the cursor and step parameters and return the next cursor.
- Keep moving the cursor to consume logs.
- Split the node to concurrent threads based on shards.

Data types

The following table lists the data types supported by LogHub Reader.

Data Integration data type	LogHub data type
STRING	STRING

Parameters

Parameter	Description	Required	Default value
endpoint	The Log Service endpoint, which is a URL for accessing a project and log data. It varies based on the Alibaba Cloud region where the project resides and the project name.	Yes	None
accessId	The AccessKey ID for connecting to Log Service.	Yes	None
accessKey	The AccessKey secret for connecting to Log Service.	Yes	None
project	The name of the project. A project is the basic unit for managing resources in Log Service. You can exercise access control at the project level, and isolate resources among different projects.	Yes	None
logstore	The name of the Logstore. A Logstore is the basic unit for collecting, storing, and querying log data in Log Service.	Yes	None
batchSize	The number of entries queried from Log Service at a time.	No	*128*
column	The column name in each log entry. You can configure a column that stores metadata in a source table of LogHub in such a way that the metadata in this column is inserted into the destination table. Supported metadata includes the log topic, unique identifier of the collection machine, host name, path, and log time. Note The column name is case-sensitive.	Yes	None

Parameter	Description	Required	Default value
beginDateTime	The start time of data consumption. The value is the time when log data arrives at LogHub. This parameter defines the left boundary of a left-closed and right-open interval in the format of yyyyMMddHHmmss, for example, 20180111013000. The parameter can work with the scheduling time parameter in DataWorks. Note The beginDateTime and endDateTime parameters must be used in pairs.	You must specify either beginDateTime or beginTimestampMillis, but not both.	None
endDateTime	The end time of data consumption in the format of yyyyMMddHHmmss, such as 20180111013010. This parameter defines the right boundary of a left-closed and right-open interval and can work with the scheduling time parameter in DataWorks. Note Make sure that the time specified by the endDateTime parameter of the previous interval is the same as or later than the time specified by the beginDateTime parameter of the current interval. If the intervals do not overlap, data may fail to be read in some regions.	You must specify either endDateTime or endTimestampMillis, but not both.	None
beginTimestampMillis	The start time of data consumption. This parameter specifies the left boundary of the left-closed and right-open interval, measured in milliseconds. Note The beginTimestampMillis and endTimestampMillis parameters must be used in pairs. A value of -1 indicates the position where the cursor starts in Log Service, which is specified by CursorMode.BEGIN. We recommend that you specify the beginDateTime parameter.	You must specify either beginTimestampMillis or beginDateTime, but not both.	None

Parameter	Description	Required	Default value
endTimestampMillis	The end time of data consumption, measured in milliseconds. This parameter defines the right boundary of the left-closed and right-open interval. Note The endTimestampMillis and beginTimestampMillis parameters must be used in pairs. A value of -1 indicates the position where the cursor ends in Log Service, which is specified by CursorMode.END. We recommend that you specify the endDateTime parameter.	You must specify either endTimestampMillis or endDateTime, but not both.	None

Configure LogHub Reader in the codeless UI

1. Configure the connections.

   Configure the connections to the source and destination data stores for the sync node.

Parameter	Description
Connection	The type and name of the source connection. Select a connection that you have configured in DataWorks.
Logstore	The name of the Logstore from which data is read.
Start Timestamp	The start time of data consumption. The value is the time when log data arrives at LogHub. This parameter defines the left boundary of a left-closed and right-open interval in the format of yyyyMMddHHmmss, for example, 20180111013000. The parameter can work with the scheduling time parameter in DataWorks.
End Timestamp	The end time of data consumption in the format of yyyyMMddHHmmss, such as 20180111013010. This parameter defines the right boundary of a left-closed and right-open interval and can work with the scheduling time parameter in DataWorks.
Records per Batch	The number of entries queried from Log Service at a time.

2. Configure field mapping. It is equivalent to setting the column parameter provided in the preceding parameter description.

   Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right. You can click **Add** to add a field, or move the pointer over a field and click the **Delete** icon to delete the field.

GUI element	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout to sort the fields based on specified rules.
Change Fields	Click the Change Fields icon. In the Change Fields dialog box, you can manually edit fields in the source table. Each field occupies a row. The first and the last blank rows are included, whereas other blank rows are ignored.
Add	○ Click Add to add a field. You can enter constants. Each constant must be enclosed in single quotation marks (' '), such as 'abc' and '123'. ○ You can use scheduling parameters, such as ${bizdate}. ○ You can enter functions supported by relational databases, such as now() and count(1). ○ Fields that cannot be parsed are indicated by Unidentified.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Parameter	Description
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure LogHub Reader by using the code editor

In the following code, a node is configured to read data from LogHub. For more information about the parameters, see the preceding parameter description.

```
{
 "type":"job",
 "version":"2.0",// The version number.
 "steps":[
   {
     "stepType":"loghub",// The reader type.
     "parameter":{
       "datasource":"",// The connection name.
       "column":[// The columns to be synchronized.
         "col0",
         "col1",
         "col2",
         "col3",
         "col4",
         "=Topic",// The log topic.
         "HostName",// The hostname.
         "Path",// The path.
         "LogTime"// The log time.
       ],
       "beginDateTime":"",// The start time of data consumption.
       "batchSize":"",// The number of entries that are queried from Log Service at a time.
       "endDateTime":"",// The end time of data consumption.
       "fieldDelimiter":",",// The column delimiter.
       "encoding":"UTF-8",// The encoding format.
       "logstore":"// The name of the target Logstore.
     },
     "name":"Reader",
     "category":"reader"
   },
   {
```

```
        "stepType":"stream",
        "parameter":{},
        "name":"Writer",
        "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
      "record":"0"// The maximum number of dirty data records allowed.
    },
    "speed":{
      "throttle":false, // Specifies whether to enable bandwidth throttling. A value of false indicates th
at the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxim
um transmission rate takes effect only if you set this parameter to true.
      "concurrent":1,// The maximum number of concurrent threads.
    }
  },
  "order":{
    "hops":[
      {
        "from":"Reader",
        "to":"Writer"
      }
    ]
  }
}
```

Note If the metadata in JSON format is prefixed by tag, delete the tag prefix. For example, change `__tag__:__client_ip__` to `__client_ip__`.

2.4.5.3.15. Configure Tablestore Reader-Internal

This topic describes the data types and parameters supported by Tablestore Reader-Internal and how to configure it by using the code editor.

Tablestore is a NoSQL database service built on the Apsara distributed operating system that allows you to store and access large amounts of structured data in real time. Tablestore organizes data into instances and tables. It can seamlessly expand the data scale by using data sharding and load balancing technologies.

Tablestore Reader-Internal is used to export data for the Tablestore Internal model, whereas Tablestore Reader is used to export data for the Tablestore Public model.

Tablestore Reader-Internal can export data in multi-version mode or normal mode:

- Multi-version mode: Tablestore stores multiple versions of column values, and this mode allows you to export data of multiple versions.

  Tablestore Reader-Internal converts a cell to a 4-tuple of a one-dimensional table: PrimaryKey (columns 1 to 4), ColumnName, Timestamp, and Value. This process is similar to that for the multi-version mode of HBase Reader. Each {PrimaryKey, ColumnName, Timestamp, Value} tuple is sent to a writer as four columns in Data Integration records.
- Normal mode: This mode allows you to export the latest version of each column in each row, which is the same as the normal mode of HBase Reader. For more information, see the normal mode of HBase Reader in Configure an HBase connection.

Tablestore Reader-Internal connects to a Tablestore server by using the official Java SDK for Tablestore and reads data from the server. Tablestore Reader-Internal optimizes the read process by providing features such as performing retry attempts when a timeout or exception occurs.

Tablestore Reader-Internal supports all Tablestore data types. The following table lists the data types supported by Tablestore Reader-Internal.

Data Integration data type	Tablestore data type
LONG	INTEGER
DOUBLE	DOUBLE
STRING	STRING
BOOLEAN	BOOLEAN
BYTES	BINARY

Parameters

Parameter	Description	Required	Default value
mode	The mode in which Tablestore Reader-Internal exports data. Valid values: *normal* and *multiVersion*.	Yes	None
endpoint	The endpoint of the Tablestore server.	Yes	None
accessId	The AccessKey ID for connecting to Tablestore.	Yes	None
accessKey	The AccessKey secret for connecting to Tablestore.	Yes	None

Parameter	Description	Required	Default value
instanceName	The name of the Tablestore instance. The instance is an entity for you to use and manage Tablestore. After you activate the Tablestore service, you must create an instance in the console before you create and manage tables. Instances are the basic units for managing Tablestore resources. All access control and resource measurement for applications are implemented at the instance level.	Yes	None
table	The name of the source table. You can specify only one table as the source table. Multi-table synchronization is not required for Tablestore.	Yes	None
range	The range of the data to export, in the format of [begin,end). • If the value of the begin parameter is smaller than that of the end parameter, data is read in forward order. • If the value of the begin parameter is larger than that of the end parameter, data is read in reverse order. • The value of the begin parameter cannot be the same as that of the end parameter. • The following value types are supported: STRING, INT, and BINARY. Binary data is passed in as Base64 strings in binary format. INF_MIN represents an infinitely small value and INF_MAX represents an infinitely large value.	No	By default, data is read from the beginning of the table to the end of the table.

Parameter	Description	Required	Default value
range: {"begin"}	The start of the data to export. Enter an empty array, a primary key prefix, or a complete primary key. In forward order, the default primary key suffix is INF_MIN. In reverse order, the default primary key suffix is INF_MAX. This parameter specifies the value range of the Tablestore primary key and is used for data filtering. If you do not specify this parameter, the minimum value is used by default. The JSON format does not support binary data. If the data type of the PrimaryKey column is BINARY, you must use the Java method Base64.encodeBase64String to convert binary data to a string, and then enter the string as the value of the parameter. Example: • `byte[] bytes = "hello".getBytes();` : constructs binary data, which is the byte value of the string hello. • `String inputValue = Base64.encodeBase64String(bytes)` : calls the Base64.encodeBase64String method to convert the binary data to a string. After you run the preceding code, the string `"aGVsbG8="` is returned for the inputValue parameter. Finally, set this parameter to `{"type":"binary","value" : "aGVsbG8="}` .	No	Data is read from the beginning of the table.
range: {"end "}	The end of the data to export. Enter an empty array, a primary key prefix, or a complete primary key. In forward order, the default primary key suffix is INF_MAX. In reverse order, the default primary key suffix is INF_MIN. The JSON format does not support binary data. If the data type of the PrimaryKey column is BINARY, you must use the Java method Base64.encodeBase64String to convert binary data to a string, and then enter the string as the value of the parameter. Example: • `byte[] bytes = "hello".getBytes();` : constructs binary data, which is the byte value of the string hello. • `String inputValue = Base64.encodeBase64String(bytes)` : calls the Base64.encodeBase64String method to convert the binary data to a string. After you run the preceding code, the string `"aGVsbG8="` is returned for the inputValue parameter. Finally, set this parameter to `{"type":"binary", "value":"aGVsbG8="}` .	No	Data is read until the end of the table.

Parameter	Description	Required	Default value
range: {"split"}	If an excessively large amount of data needs to be exported, you can specify this parameter to split one node to multiple concurrent threads. Note • The field based on which the node is split must be the shard key, which is the first column of the primary key, and the data type of the field must be the same as that of the partition key. • The specified field must be within the value range that is specified by the begin and end parameters. • The values of this field must be sorted in the descending or ascending order based on the data reading order that is determined by values of the begin and end parameters.	No	No sharding rule is specified.
column	The columns to be exported. Both regular and constant columns can be exported. A regular column is in the format of `{"name":"{your column name}"}` . Note • Constant columns cannot be exported in multi-version mode. • You cannot specify the PrimaryKey column. The exported tuple data contains the complete primary key by default. • Each column can be exported only once.	None	All versions of all columns are exported.
timeRange (applicable only to the multi-version mode)	The time range of the requested data, in the format of [begin,end). Note The value of the begin parameter must be smaller than that of the end parameter.	No	All the data is read.
timeRange: {"begin"} (applicable only to the multi-version mode)	The start time for reading data. Valid values: 0 to LONG_MAX.	No	0

Parameter	Description	Required	Default value
timeRange: {"end"} (applicable only to the multi-version mode)	The end time for reading data. Valid values: 0 to LONG_MAX.	No	*LONG_MAX (922337203685477 5806L)*
maxVersion (applicable only to the multi-version mode)	The specified version of the requested data. Valid values: 1 to INT32_MAX.	No	The data of all versions is read.

Configure Tablestore Reader-Internal by using the codeless UI

The codeless UI is not supported for Tablestore Reader-Internal.

Configure Tablestore Reader-Internal by using the code editor

- Multi-version mode

```
{
  "type": "job",
  "version": "1.0",
  "configuration": {
    "reader": {
      "plugin": "otsreader-internalreader",
      "parameter": {
        "mode": "multiVersion",
        "endpoint": "",
        "accessId": "",
        "accessKey": "",
        "instanceName": "",
        "table": "",
        "range": {
          "begin": [
            {
              "type": "string",
              "value": "a"
            },
            {
              "type": "INF_MIN"
            }
```

```
            ],
            "end": [
              {
                "type": "string",
                "value": "g"
              },
              {
                "type": "INF_MAX"
              }
            ],
            "split": [
              {
                "type": "string",
                "value": "b"
              },
              {
                "type": "string",
                "value": "c"
              }
            ]
          },
          "column": [
            {
              "name": "attr1"
            }
          ],
          "timeRange": {
            "begin": 1400000000,
            "end": 1600000000
          },
          "maxVersion": 10
        }
      }
    },
    "writer": {}

              {
                "type": "binary",
                "value": "aGVsbG8="
              }
            ]
          }
        }
    },
    "writer": {}
}
```

2.4.5.3.16. Configure OTSStream Reader

This topic describes the data types and parameters supported by OTSStream Reader and how to configure it by using the code editor.

OTSStream Reader is mainly used for exporting the incremental data of Table Store. Incremental data can be considered as operation logs that include data and operation information.

Unlike plug-ins for exporting full data, OTSStream Reader only supports the multi-version mode. You cannot export the data of specified columns when using OTSStream Reader for exporting incremental data. This restriction is related to the implementation of exporting incremental data. The following section describes the implementation process.

Before using OTSStream Reader, make sure that the Stream feature is enabled. You can enable this feature when creating the table or using the UpdateTable operation in the SDK.

The method for enabling Stream is described as follows:

```
SyncClient client = new SyncClient("", "", "", "");
Enable this feature when creating a table.
CreateTableRequest createTableRequest = new CreateTableRequest(tableMeta);
createTableRequest.setStreamSpecification(new StreamSpecification(true, 24)); // The value 24 indic
ates that the incremental data is retained for 24 hours.
client.createTable(createTableRequest);
If this feature is not enabled when the table is created, enable it by using the UpdateTable operation.
UpdateTableRequest updateTableRequest = new UpdateTableRequest("tableName");
updateTableRequest.setStreamSpecification(new StreamSpecification(true, 24));
client.updateTable(updateTableRequest);
```

Implementation

You can enable the Stream feature and set the expiration time by using the UpdateTable operation in the SDK. After the Stream feature is enabled, the Table Store server saves your operation logs additionally. Each partition has a sequential operation log queue. Each operation log is removed by garbage collection after the specified expiration time.

The Table Store SDK provides several Stream APIs for reading these operation logs. OTSStream Reader obtains incremental data by using these APIs, transforms incremental data into multiple 6-tuples (pk, colName, version, colValue, opType, and sequenceInfo), and imports them into MaxCompute.

Exported data format

In the multi-version mode of Table Store, table data is organized in a three-level architecture: row, column, and version. One row can have multiple columns. The column name is not fixed, and each column can have multiple versions. Each version has a specific timestamp (the version number).

You can perform read/write operations by using Table Store APIs. Table Store stores the incremental data by storing the records of recent write and modify operations on table data. Incremental data can be considered as a set of operation records.

Table Store supports the following three types of modify operations:

- PutRow: writes a row. If the row already exists, it is overwritten.
- UpdateRow: updates a row without changing other data of the original row. You can add column values, overwrite column values if the corresponding version of the column already exists, delete all the versions of a column, or delete a version of a column.
- DeleteRow: deletes a row.

Table Store generates incremental data records based on each type of operations. OTSStream Reader reads these records and exports the data in the format of DataX.

Table Store supports dynamic columns and the multi-version mode. Therefore, a row exported by OTSStream Reader corresponds to a version of a column rather than a row in Table Store. A row in Table Store may correspond to multiple exported rows. Each exported row includes the primary key value, column name, timestamp of the version for the column (version number), value of the version, and operation type. If the isExportSequenceInfo parameter is set to true, time series information is also included.

When the data is transformed into the DataX format, the following four types of operations are defined:

- U (UPDATE): Writes a version of a column.
- DO (DELETE_ONE_VERSION): Deletes a version of a column.
- DA (DELETE_ALL_VERSION): Deletes all the versions of a column. Delete all the versions of the corresponding column according to the primary key and the column name.
- DR (DELETE_ROW): Deletes a row. Delete all the data of the row according to the primary key.

In the following example, the table has two primary key columns: pkName1 and pkName2.

pkName1	pkName2	columnName	timestamp	columnValue	opType
pk1_V1	pk2_V1	col_a	1441803688001	col_val1	U
pk1_V1	pk2_V1	col_a	1441803688002	col_val2	U
pk1_V1	pk2_V1	col_b	1441803688003	col_val3	U
pk1_V2	pk2_V2	col_a	1441803688000	-	DO
pk1_V2	pk2_V2	col_b	-	-	DA
pk1_V3	pk2_V3	-	-	-	DR
pk1_V3	pk2_V3	col_a	1441803688005	col_val1	U

In this example, seven rows are exported, corresponding to three rows in the Table Store table. The primary keys for the three rows are (pk1_V1, pk2_V1), (pk1_V2, pk2_V2), and (pk1_V3, pk2_V3).

- For the row whose primary key is (pk1_V1, pk2_V1), three operations are included: writing two versions of column col_a and one version of column col_b.
- For the row whose primary key is (pk1_V2, pk2_V2), two operations are included: deleting one version of column col_a and deleting all versions of column col_b.
- For the row whose primary key is (pk1_V3, pk2_V3), two operations are included: deleting the row and writing one version of column col_a.

Data types supported by OTSStream Reader

Currently, OTSStream Reader supports all Table Store data types. The following table lists the data types supported by OTSStream Reader.

Category	OTSStream data type
Integer	INTEGER
Floating point	DOUBLE
String	STRING
Boolean	BOOLEAN
Binary	BINARY

Parameters

Parameter	Description	Required	Default value
dataSource	The connection name. It must be identical to the name of the added connection. You can add connections in the code editor.	Yes	None
dataTable	The name of the table from which incremental data is exported. You must enable the Stream feature for a table when creating the table, or by calling the UpdateTable operation after creating the table.	Yes	None

Parameter	Description	Required	Default value
statusTable	The name of the table used by OTSStream Reader to store status records. These records help to filter out the data that is not covered by the target range and improve export efficiency. A statusTable is the table to store status records. If no such table exists, the reader automatically creates one. When a task of exporting batch data is completed, you do not need to delete the table. The status records in the table can be used for the next export task. • You do not need to manually create a statusTable. You only need to provide a table name. The reader attempts to create a statusTable under your instance. If no such table exists, the reader automatically creates one. If such a table already exists, the reader determines whether the Meta of the table is proper. If not, an exception is thrown. • When an export task is completed, you do not need to delete the table. The status of the table can be used for the next export task. • The table enables TTL and data expires automatically. Therefore, the data volume is small. • You can use a statusTable to store status records of multiple dataTables that are managed by the same instance. The status records are independent of each other. In conclusion, you must configure a name such as TableStoreStreamReaderStatusTable. Note that the name must not be the same as that for any business-related table.	Yes	None
startTimestampMillis	The start time (included) in milliseconds of the incremental data. • The Reader plugin finds a point corresponding to startTimestampMillis from the statusTable, and starts to read and export data from this point. • If the reader cannot find the corresponding point, it starts to read incremental data retained by the system from the first entry, and skip the data which is written later than startTimestampMillis.	No	None
endTimestampMillis	The end time (excluded) in milliseconds of the incremental data. • The reader exports data from the time specified by the startTimestampMillis parameter and ends at the data entry with a timestamp that is later than or equal to endTimestampMillis. • If the reader has read all the incremental data, it stops reading data even before the time specified by the endTimestampMillis parameter.	No	None

Parameter	Description	Required	Default value
date	The date when data is exported. The format is yyyyMMdd, for example, 20151111. You must specify this parameter or the startTimestampMillis and endTimestampMillis parameters. For example, Alibaba Cloud Data Process Center performs scheduling only at the day level. Therefore, the date parameter is provided.	No	None
isExportSequenceInfo	Specifies whether to export time-series information. Time-series information includes the time when data is written. The default value is *false*, indicating that time series information is not exported.	No	None
maxRetries	The maximum number of retries for each request of reading incremental data from Table Store. The default value is 30. Retries are performed at certain intervals. The total time of 30 retries is approximately 5 minutes. Generally, you can keep the default settings.	No	None
startTimeString	The left boundary of the time range (left-closed and right-open) of incremental data, measured in milliseconds in the format of `yyyymmddhh24miss`.	No	None
endTimeString	The right boundary of the time range (left-closed and right-open) of incremental data, measured in milliseconds in the format of `yyyymmddhh24miss`.	No	None
mode	The export mode. If this parameter is set to single_version_and_update_only, data is exported by row. By default, data is not exported by column.	No	None

Configure OTSStream Reader by using the codeless UI

Currently, the codeless user interface (UI) is not supported for OTSStream Reader.

Configure OTSStream Reader by using the code editor

In the following code, a node is configured to export the incremental data of Table Store. For more information about the parameters, see the preceding parameter description.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"otsstream",// The reader type.
      "parameter":{
        "statusTable":"TableStoreStreamReaderStatusTable",// The name of the table that stores st
atus records.
```

```
            "maxRetries":30,// The maximum number of retries on each request of reading incremental d
ata from Table Store. It is set to 30 by default.
            "isExportSequenceInfo":false,// Specifies whether to export the time series information.
            "datasource":"$srcDatasource",// The connection.
            "startTimeString":"${startTime}",// The start time (included) of the incremental data.
            "table":"",// The name of the table to be synchronized.
            "endTimeString":"${endTime}"// The end time (excluded) of the incremental data.
        },
        "name":"Reader",
        "category":"reader"
    },
    {
        "stepType":"stream",
        "parameter":{},
        "name":"Writer",
        "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
        "record":"0"// The maximum number of dirty data records allowed.
    },
    "speed":{
        "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
        "concurrent":1,// The maximum number of concurrent threads.
    }
  },
  "order":{
    "hops":[
        {

    ]
  }
}
```

2.4.5.3.17. Configure RDBMS Reader

This topic describes the data types and parameters supported by RDBMS Reader and how to configure it by using the code editor.

Background information

RDBMS Reader allows you to read data from an RDBMS database. RDBMS Reader connects to a remote RDBMS database and runs a SELECT statement to select and read data from the database. RDBMS Reader can read data from databases such as Dameng, Db2, PPAS, and Sybase databases. If you need RDBMS Reader to read data from a common relational database, register the driver for the corresponding database type.

RDBMS Reader connects to a remote RDBMS database by using JDBC, generates a SELECT statement based on your configurations, and then sends the statement to the database. The RDBMS database runs the statement and returns the result. Then, RDBMS Reader assembles the returned data to abstract datasets in custom data types supported by Data Integration, and passes the datasets to a writer.

- RDBMS Reader generates the SQL statement based on the table, column, and where parameters that you have configured, and sends the generated SQL statement to the RDBMS database.
- If you specify the querySql parameter, RDBMS Reader directly sends the value of this parameter to the RDBMS database.

RDBMS Reader supports most data types of a common relational database, such as numbers and characters. Make sure that your data types are supported.

Parameters

Parameter	Description	Required	Default value
	The JDBC URL for connecting to the RDBMS database. The format must be in accordance with the official RDBMS specifications. You can also specify the information of the attachment facility. The format varies based on the database type. Data Integration selects an appropriate driver for data reading based on the format. • Format for DM databases: `jdbc:dm://ip:port/database` • Format for Db2 databases: `jdbc:db2://ip:port/database` • Format for PPAS databases: `jdbc:edb://ip:port/database` You can enable RDBMS Reader to support a new database by using the following method: • Go to the RDBMS Reader directory. In the directory, ${DATAX_HOME} indicates the main directory of Data Integration. • Open the *plugin.json* file in the RDBMS Reader directory, and add the driver of your database to the drivers array in the file. RDBMS Reader dynamically selects the appropriate database driver to connect to the database when nodes are run. `{ "name": "rdbmsreader", "class": "com.alibaba.datax.plugin.reader.rdbmsreader.Rdbms`		

Parameter	Description	Required	Default value
jdbcUrl	Reader", "description": "useScene: prod. mechanism: Jdbc connection using the database, execute select sql, retrieve data from the ResultSet. warn: The more you know about the database, the less problems you encounter.", "developer": "alibaba", "drivers": ["dm.jdbc.driver.DmDriver", "com.ibm.db2.jcc.DB2Driver", "com.sybase.jdbc3.jdbc.SybDriver", "com.edb.Driver"] } ``` - Add the driver package to the libs directory in the RDBMS Reader directory. ``` $tree . |-- libs | |-- Dm7JdbcDriver16.jar | |-- commons-collections-3.0.jar | |-- commons-io-2.4.jar | |-- commons-lang3-3.3.2.jar | |-- commons-math3-3.1.1.jar | |-- datax-common-0.0.1-SNAPSHOT.jar | |-- datax-service-face-1.0.23-20160120.024328-1.jar | |-- db2jcc4.jar | |-- druid-1.0.15.jar | |-- edb-jdbc16.jar | |-- fastjson-1.1.46.sec01.jar | |-- guava-r05.jar | |-- hamcrest-core-1.3.jar | |-- jconn3-1.0.0-SNAPSHOT.jar | |-- logback-classic-1.0.13.jar | |-- logback-core-1.0.13.jar | |-- plugin-rdbms-util-0.0.1-SNAPSHOT.jar | `-- slf4j-api-1.7.10.jar |-- plugin.json |-- plugin_job_template.json `-- rdbmsreader-0.0.1-SNAPSHOT.jar	Yes	None

Parameter	Description	Required	Default value
username	The username for connecting to the database.	Yes	None
password	The password for connecting to the database.	Yes	None
table	The name of the source table.	Yes	None
column	The columns to be synchronized from the source table. The columns are described in a JSON array. The default value is [*], which indicates all columns. • Column pruning is supported. You can select specific columns to export. • The column order can be changed. You can export the specified columns in an order different from that specified in the schema of the table. • Constants are supported. The column names must be arranged in JSON format, for example, `["id","1", "'bazhen.csy'", "null", "to_char(a + 1)", "2.3" , "true"]`. ○ id: a column name. ○ 1: an integer constant. ○ 'bazhen.csy': a string constant. ○ null: a null pointer. ○ to_char(a + 1): a function expression. ○ 2.3: a floating-point constant. ○ true: a Boolean value. • The column parameter must explicitly specify a set of columns to be synchronized, and cannot be left empty.	Yes	None
splitPk	The field used for data sharding when RDBMS Reader reads data. If you specify the splitPk parameter, the table is sharded based on the shard key specified by this parameter. Data Integration then runs concurrent threads to synchronize data. This improves efficiency. • We recommend that you set the splitPk parameter to the primary key of the table. Based on the primary key, data can be well distributed to different shards, but not intensively distributed to specific shards. • The splitPk parameter supports data sharding only for integers but not for other data types such as string, floating point, and date. If you specify this parameter to a column of an unsupported type, RDBMS Reader returns an error. • If you do not specify the splitPk parameter or leave it empty, RDBMS Reader synchronizes data by using a single thread.	No	An empty string

Parameter	Description	Required	Default value
where	The WHERE clause. RDBMS Reader generates a SELECT statement based on the table, column, and where parameters that you have configured, and uses the generated SELECT statement to select and read data. For example, set this parameter to limit 10. To synchronize data generated on the current day, set the where parameter to `gmt_create > $bizdate` . • You can use the WHERE clause to read incremental data. • If you do not specify the where parameter or leave it empty, all data is read.	No	None
querySql	The SELECT statement used to for refined data filtering. If you specify this parameter, Data Integration directly filters data based on this parameter. For example, if you need to join multiple tables for data synchronization, set this parameter to `select a,b from table_a join table_b on table_a.id = table_b.id` . If you specify the querySql parameter, RDBMS Reader ignores the table, column, and where parameters that you have configured.	No	None
fetchSize	The number of data records to read at a time. This parameter determines the number of interactions between Data Integration and the database and affects reading efficiency. Note A value greater than 2048 may lead to OOM during the data synchronization process.	No	*1,024*

Configure RDBMS Reader by using the codeless UI

The codeless UI is not supported for RDBMS Reader.

Configure RDBMS Reader by using the code editor

In the following code, a node is configured to read data from an RDBMS database.

```
{
  "order": {
    "hops": [
      {
        "from": "Reader",
        "to": "Writer"
      }
    ]
  },
```

```
"setting": {
  "errorLimit": {
    "record": "0"
  },
  "speed": {
    "concurrent": 1,
    "throttle": false
  }
},
"steps": [
  {
    "category": "reader",
    "name": "Reader",
    "parameter": {
      "connection": [
        {
          "jdbcUrl": [
            "jdbc:dm://ip:port/database"
          ],
          "table": [
            "table"
          ]
        }
      ],
      "username": "username",
      "password": "password",
      "table": "table",
      "column": [
        "*"
      ],
      "preSql": [
        "delete from XXX;"
      ]
    },
    "stepType": "rdbms"
  },
  {
    "category": "writer",
    "name": "Writer",
    "parameter": {},
    "stepType": "stream"
```

```
        "stepType": "stream"
      }
    ],
    "type": "job",
    "version": "2.0"
}
```

2.4.5.3.18. Configure Stream Reader

This topic describes the data types and parameters supported by Stream Reader and how to configure it by using the code editor.

Stream Reader automatically generates data from the memory. It is mainly used for performance testing for data synchronization and basic functional testing.

The following table lists the data types supported by Stream Reader.

Data type	Description
String	A sequence of characters.
Long	A long integer.
Date	A value that represents dates.
Boolean	A Boolean data type that has one of two possible values.
Bytes	An 8-bit signed two's complement integer.

Parameters

Parameter	Description	Required	Default value

Parameter	Description	Required	Default value
column	The column data and type of the source data. Multiple columns can be configured. You can set to generate random strings and specify the range. The example is as follows: `"column" : [ { "random": "8,15" }, { "random": "10,10" } ]` The parameters are described as follows: • "random": "8, 15": generates a random string that is 8 to 15 bytes in length. • "random": "10, 10": generates a 10-byte random string.	Yes	None
sliceRecordCount	The number of columns generated repeatedly.	Yes	None

Configure Stream Reader by using the codeless UI

Currently, the codeless user interface (UI) is not supported for Stream Reader.

Configure Stream Reader by using the code editor

In the following code, a node is configured to read data from the memory and then write the data to Stream Reader.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",// The reader type.
      "parameter":{
        "column":[// The columns to be synchronized.
          {
            "type":"string",// The data type.
```

```
                "value":"field" // The value.
            },
            {
                "type":"long",
                "value":100
            },
            {
                "dateFormat":"yyyy-MM-dd HH:mm:ss",// The format of the time.
                "type":"date",
                "value":"2014-12-12 12:12:12"
            },
            {
                "type":"bool",
                "value":true
            },
            {
                "type":"bytes",
                "value":"byte string"
            }
          ],
          "sliceRecordCount":"100000"// The number of columns repeatedly generated.
        },
        "name":"Reader",
        "category":"reader"
    },
    {// The following template is used to configure the writer. For more information, see the correspo
nding topic.
        "stepType":"stream",
        "parameter":{},
        "name":"Writer",
        "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
      "record":"0"// The maximum number of dirty data records allowed.
    },
    "speed":{
      "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
```

```
mum transmission rate takes effect only if you set this parameter to true.
        "concurrent":1,// The maximum number of concurrent threads.
      }
    },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
        }
      ]
    }
}
```

2.4.5.3.19. Configure Hive Reader

Parameters

Parameter	Description	Required	Default value
column	The fields to read. Example: `"column": ["id", "name"]`.	Yes	None
table	The name of the Hive table to read. The name is case sensitive.	Yes	None
partition	The partition information of the table to read. The last-level partition must be specified. For example, if you want to read data from a three-level partition table, set this parameter to a value that contains the last-level partition information, such as pt=20150101/type=1/biz=2.	Yes	None

Configure Hive Reader by using the code editor

In the following code, a node is configured to read data from a Hive data store.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Writer",
      "category":"writer"
    },
    {
      "stepType":"hive", // The reader type. The name is the same as that in MaxCompute.
      "parameter":{
        "parameter":{
          "column": [// The columns to be synchronized.
            "id",
            "name"
          ],
          "table": "student_tmp_2", // The name of the table to be synchronized.
          "partition": "academy=yx/class=001", // The partition settings.
          "datasource": "hive_demo"
        }
      },
      "name":"Reader",
      "category":"reader"
    }
  ],
  "setting":{
  },
  "order":{
    "hops":[// Synchronize data from the reader to the writer.
      {
        "from":"Reader",
        "to":"Writer"
      }
    ]
  }
}
```

2.4.5.3.20. Configure Elasticsearch Reader

This topic describes the working principles, features, and parameters of Elasticsearch Reader.

Working principles

- Elasticsearch Reader reads data from Elasticsearch by slicing scroll queries. The slices are processed by multiple threads of a data synchronization node.
- Data types are converted based on the mapping configuration of Elasticsearch.

Basic settings

```
{
  "order":{
    "hops":[
      {
        "from":"Reader",
        "to":"Writer"
      }
    ]
  },
  "setting":{
    "errorLimit":{
      "record":"0" // The maximum number of dirty data records allowed.
    },
    "jvmOption":"",
    "speed":{
      "concurrent":3,
      "throttle":false
    }
  },
  "steps":[
    {
      "category":"reader",
      "name":"Reader",
      "parameter":{
        "column":[ // The fields to read.
          "id",
          "name"
        ],
        "endpoint":"", // The endpoint.
        "index":"",  // The index name.
        "password":"",  // The password.
```

```
            "scroll":"",  // The scroll ID.
            "search":"",  // The search criteria. The value is the same as the Elasticsearch query that use
s the _search API.
            "type":"default",
            "username":""  // The username.
        },
        "stepType":"elasticsearch"
      },
      {
        "category":"writer",
        "name":"Writer",
        "parameter":{},
        "stepType":"stream"
      }
    ],
    "type":"job",
    "version":"2.0" // The version number.
}
```

Advanced features

- Supports storing all data of an Elasticsearch document in one column.

  You can create a column to store all data of an Elasticsearch document.

- Supports converting semi-structured data to structured data.

Item	Description
Background	Data in Elasticsearch is deeply nested. Elasticsearch may contain fields of various types and lengths and may use Chinese names. To facilitate data computing and storage in downstream businesses, Elasticsearch Reader supports converting semi-structured data to structured data.
Principle	Elasticsearch Reader flattens nested JSON data obtained from Elasticsearch to single-dimensional data based on the paths of properties in the JSON data. Then, Elasticsearch Reader maps the single-dimensional data to structured tables. In this way, Elasticsearch data in a complex structure is converted to multiple structured tables.

Item	Description
Solution	○ Elasticsearch Reader converts nested JSON data to single-dimensional data by using the following path formats: ■ Property ■ Property.Child property ■ Property[0].Child property ○ If a property has multiple child properties, Elasticsearch Reader traverses all data of the property and splits the data to multiple tables or multiple rows in the following format: Property[*].Child property ○ Elasticsearch Reader merges data in a string array to one property in the following format and removes duplicates: Property[] where duplicates are removed ○ Elasticsearch Reader merges multiple properties to one property in the following format: Property 1,Property 2 ○ Elasticsearch Reader presents optional properties in the following format: Property 1|Property 2

Parameters

Parameter	Description	Required	Default value
endpoint	The endpoint of Elasticsearch.	Yes	None
username	The username for HTTP authentication.	No	Empty string
password	The password for HTTP authentication.	No	Empty string
index	The index name in Elasticsearch.	Yes	None
type	The type name in the index of Elasticsearch.	No	Index name
pageSize	The number of data records to read at a time.	No	*100*
search	The query parameter of Elasticsearch.	Yes	None

Parameter	Description	Required	Default value
scroll	The scroll parameter of Elasticsearch, which sets the timestamp of the snapshot taken for a scroll.	Yes	None
sort	The field based on which the returned results are sorted.	No	None
retryCount	The number of retries after a failure.	No	*300*
connTimeOut	The connection timeout of the client.	No	*600,000*
readTimeOut	The data reading timeout of the client.	No	*600,000*
multiThread	Specifies whether to use multiple threads for an HTTP request.	No	*true*
column	The fields to read.	Yes	None
full	Specifies whether to create a column to record all data of an Elasticsearch document.	No	*false*
multi	Specifies whether to split an array to multiple rows. If you enable this feature, you need to specify additional settings.	No	*false*

Additional settings:

```
"full":false,
      "multi": {
        "multi": true,
        "key":"crn_list[*]"
      }
```

2.4.5.3.21. Configure Vertica Reader

Vertica is a column-oriented database using the Massively Parallel Processing (MPP) architecture. Vertica Reader allows you to read data from Vertica. This topic describes how Vertica Reader works, the supported parameter, and how to configure it by using the code editor.

How it works

Vertica Reader connects to a remote Vertica database by using JDBC and executes a SELECT statement to select and read data from the database.

Vertica Reader connects to a remote Vertica database by using JDBC, generates a SELECT statement based on your configurations, and then sends the statement to the database. The Vertica database executes the statement and returns the result. Then, Vertica Reader assembles the returned data to abstract datasets in custom data types supported by Data Integration, and sends the datasets to a writer.

- Vertica Reader generates the SELECT statement based on the table, column, and where parameters that you have configured, and sends the generated SELECT statement to the Vertica database.
- If you specify the querySql parameter, Vertica Reader directly sends the value of this parameter to the Vertica database.

Vertica Reader accesses a Vertica database by using the Vertica database driver. Confirm the compatibility between the driver version and your Vertica database. Vertica Reader uses the following version of the Vertica database driver:

```
<dependency>
   <groupId>com.vertica</groupId>
   <artifactId>vertica-jdbc</artifactId>
   <version>7.1.2</version>
</dependency>
```

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None

Parameter	Description	Required	Default value
jdbcUrl	The JDBC URL for connecting to the Vertica database. You can specify multiple JDBC URLs for a database. The JDBC URLs are described in a JSON array. If you specify multiple JDBC URLs, Vertica Reader verifies the connectivity of the URLs in sequence to find a valid URL. If no URL is valid, Vertica Reader returns an error. Note The jdbcUrl parameter must be included in the connection parameter. The value of the jdbcUrl parameter must be in compliance with the standard format supported by Vertica. You can also specify the information of the attachment facility. Example: `jdbc:vertica://1**.0.0.1:3306/database` .	No	None
username	The username for connecting to the Vertica database.	No	None
password	The password for connecting to the Vertica database.	No	None
table	The name of the source table from which Vertica Reader reads data. Vertica Reader can read data from multiple tables. The tables are described in a JSON array. If you specify multiple tables, make sure that the tables have the same schema. Vertica Reader does not check whether the tables have the same schema. Note The table parameter must be included in the connection parameter.	Yes	None
column	The columns to be synchronized from the source table. The columns are described in a JSON array. The default value is [*], which indicates all columns in the source table. • Column pruning is supported. You can select specific columns to export. • The column order can be changed. You can export the specified columns in an order different from that specified in the schema of the table. • Constants are supported. • The column parameter must explicitly specify a set of columns to be synchronized, and cannot be left empty.	Yes	None

Parameter	Description	Required	Default value
splitPk	The field used for data sharding when Vertica Reader reads data. If you specify the splitPk parameter, the table is sharded based on the shard key specified by this parameter. Data Integration then runs concurrent threads to synchronize data. This improves efficiency. • We recommend that you set the splitPk parameter to the primary key of the table. Based on the primary key, data can be well distributed to different shards, but not intensively distributed to specific shards. • The splitPk parameter supports data sharding only for integers but not for other data types such as string, floating point, and date. If you set this parameter to a column of an unsupported type, Vertica Reader returns an error. • If you leave the splitPk parameter empty, Vertica Reader reads data from the source table by using a single thread.	No	None
where	The WHERE clause. Vertica Reader generates a SELECT statement based on the table, column, and where parameters that you have configured, and uses the generated SELECT statement to select and read data. For example, you can specify the where parameter during testing. To synchronize data generated on the current day, set the where parameter to `gmt_create > $bizdate`. • You can use the WHERE clause to synchronize incremental data. • If you do not specify the where parameter or leave it empty, all data is read.	No	None
querySql	The SELECT statement used for refined data filtering. If you specify this parameter, Data Integration directly filters data based on this parameter. If you specify the querySql parameter, Vertica Reader ignores the table, column, and where parameters that you have configured.	No	None
fetchSize	The number of data records to read at a time. This parameter determines the number of interactions between Data Integration and the database and affects data reading efficiency. Note A value greater than 2048 may lead to OOM during the data synchronization process.	No	*1024*

Configure Vertica Reader by using the codeless UI

The codeless UI is not supported for Vertica Reader.

Configure Vertica Reader by using the code editor

In the following code, a node is configured to read data from a Vertica database.

```
{
  "type": "job",
  "steps": [
    {
      "stepType":"vertica", // The reader type.
       "parameter": {
        "datasource": "", // The connection name.
         "username": "",
        "password": "",
        "where": "",
        "column": [ // The columns to be synchronized.
            "id",
          "name"
        ],
        "splitPk": "id",
        "connection": [
          {
            "table": [ // The name of the table to be synchronized.
                "table"
            ],
            "jdbcUrl": [
              "jdbc:vertica://host:port/database"
            ]
          }
        ]
      },
      "name": "Reader",
      "category": "reader"
    },
    {
      "stepType": "stream",
      "parameter": {
        "print": false,
        "fieldDelimiter": ","
      },
      "name": "Writer",
      "category": "writer"
```

```
        "category": "writer"
      }
    ],
    "version": "2.0",
    "order": {
      "hops": [
        {
          "from": "Reader",
          "to": "Writer"
        }
      ]
    },
    "setting": {
      "errorLimit": {
        "record":"0" // The maximum number of dirty data records allowed.
      },
      "speed": {
        "throttle": false, // Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
        "concurrent": 1 // The maximum number of concurrent threads.
      }
    }
}
```

2.4.5.3.22. Configure GBase Reader

This topic describes how GBase Reader reads data and how to configure a sync node to read data from a GBase database.

GBase Reader connects to a remote GBase database through the MySQL Java Database Connectivity (JDBC) Driver, generates SQL statements based on your configurations, and then reads data from the remote GBase database. Then, GBase Reader assembles the returned data to abstract datasets in custom data types supported by Data Integration, and passes the datasets to a writer.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be identical to the name of the added connection. You can add connections in the code editor.	Yes	None

Parameter	Description	Required	Default value
table	The name of the table to be synchronized. You can select only one source table for each sync node.	Yes	None
column	The columns to be synchronized from the source table. The columns are described in a JSON array. The default value is [*], which indicates all columns. • Column pruning is supported. You can select and export specific columns. • Change of the column order is supported. You can export the columns in an order different from that specified in the schema of the table. • Constants are supported. The column names must be arranged in compliance with the SQL syntax supported by MySQL, for example, `["id","table","1","'mingya.wmy'","'null'","to_char(a+1)","2.3","true"]`. ○ id: a column name. ○ table: the name of a column that contains reserved keywords. ○ 1: an integer constant. ○ 'mingya.wmy': a string constant, which is enclosed in single quotation marks (' '). ○ null: ■ " " indicates an empty value. ■ null indicates a null value. ■ 'null' indicates the string null. ○ to_char(a+1): a function expression. ○ 2.3: a floating-point constant. ○ true: a Boolean value. • The column parameter must explicitly specify a set of columns to be synchronized. The parameter cannot be left empty.	Yes	None

Parameter	Description	Required	Default value
splitPk	The field used for data sharding when GBase Reader extracts data. If you specify the splitPk parameter, the table is sharded based on the shard key specified by this parameter. Data Integration then runs concurrent threads to synchronize data. This improves efficiency. • We recommend that you set the splitPk parameter to the primary key of the table. Based on the primary key, data can be well distributed to different shards, but not intensively distributed to certain shards. • Currently, the splitPk parameter supports data sharding only for integers but not for other data types such as string, floating point, and date. If you specify this parameter to a column of an unsupported type, GBase Reader ignores the splitPk parameter and synchronizes data through a single thread. • If you do not specify the splitPk parameter or leave it empty, Data Integration synchronizes data through a single thread.	No	None
where	The WHERE clause. For example, set this parameter to `gmt_create>$bizdate`. • You can use the WHERE clause to synchronize incremental data. If you do not specify the where parameter or leave it empty, all data is synchronized. • Do not set the where parameter to limit 10, which does not conform to the constraints of MySQL on the SQL WHERE clause.	No	None
querySql (only available in the code editor)	The SELECT statement used for refined data filtering. If you specify this parameter, Data Integration directly filters data based on this parameter. For example, if you want to join multiple tables for data synchronization, set this parameter to `select a,b from table_a join table_b on table_a.id = table_b.id`. The priority of the querySql parameter is higher than those of the table, column, where, and splitPk parameters. If you specify the querySql parameter, GBase Reader ignores the table, column, where, and splitPk parameters that you have configured. The datasource parameter parses information, including the username and password, from this parameter.	No	None

Configure GBase Reader by using the codeless UI

Currently, the codeless user interface (UI) is not supported for GBase Reader.

Configure GBase Reader by using the code editor

In the following code, a node is configured to read data from a GBase database.

```
{
   "type":"job",
   "version":"2.0",// The version number.
   "steps":[
      {
         "stepType":"gbase // The reader type.
         "parameter":{
            "column":[// The columns to be synchronized.
               "id"
            ],
            "connection":[
               {   "querysql":["select a,b from join1 c join join2 d on c.id = d.id;"], // Specify the querySql pa
rameter in the connection parameter as a string.
                  "datasource":"",// The connection name.
                  "table":[// The name of the table to be synchronized.
                     "xxx"
                  ]
               }
            ],
            "where":"",// The WHERE clause.
            "splitPk":"",// The shard key.
            "encoding":"UTF-8"// The encoding format.
         },
         "name":"Reader",
         "category":"reader"
      },
      {
         "stepType":"stream",
         "parameter":{},
         "name":"Writer",
         "category":"writer"
      }
   ],
   "setting":{
      "errorLimit":{
         "record":"0"// The maximum number of dirty data records allowed.
      }
```

```
    },
    "speed":{
      "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
      "concurrent":1,// The maximum number of concurrent threads.
    }
  },
  "order":{
    "hops":[
      {
        "from":"Reader",
        "to":"Writer"
      }
    ]
  }
}
```

2.4.5.4. Configure the writer

2.4.5.4.1. Configure AnalyticDB for MySQL 2.0 Writer

This topic describes the data types and parameters supported by AnalyticDB for MySQL 2.0 Writer and how to configure it by using the codeless UI and code editor.

Prerequisites

Data Integration can import data to AnalyticDB for MySQL 2.0 in real time. This method requires you to create real-time tables, which are fact tables, in the destination AnalyticDB for MySQL 2.0 database in advance. In real-time import mode, data is imported efficiently and the process is simple.

You must configure a connection before you configure AnalyticDB for MySQL 2.0 Writer.

Data types

The following table lists the data types supported by AnalyticDB for MySQL 2.0 Writer.

Category	AnalyticDB for MySQL 2.0 data type
Integer	INT, TINYINT, SMALLINT, and BIGINT
Floating point	FLOAT and DOUBLE
String	VARCHAR
Date and time	DATE and TIMESTAMP

Category	AnalyticDB for MySQL 2.0 data type
Boolean	BOOLEAN

Parameters

Parameter	Description	Required	Default value
connectionUrl	The URL for connecting to the AnalyticDB for MySQL 2.0 database. Specify the parameter in the IP address:Port format.	Yes	None
database	The name of the AnalyticDB for MySQL 2.0 database.	Yes	None
Access Id	The AccessKey ID that you can use to connect to the AnalyticDB for MySQL 2.0 database.	Yes	None
Access Key	The AccessKey secret that you can use to connect to the AnalyticDB for MySQL 2.0 database.	Yes	None
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the destination table.	Yes	None
partition	The partition name of the destination table. If the destination table is partitioned, this parameter is required.	No	None
writeMode	The write mode. Set the value to insert. In this mode, if a primary key conflict occurs, the conflicting rows are overwritten.	Yes	None
column	The columns in the destination table to which data is written. Separate the columns with commas (,), for example, ["a","b","c"]. Set the value to an asterisk (*) if data is written to all the columns in the destination table.	Yes	None
suffix	Optional. The suffix to the AnalyticDB for MySQL 2.0 URL that is in the format of `IP address:Port`. This suffix is a custom connection string. After this parameter is set, the URL changes to a JDBC connection string for connecting to AnalyticDB for MySQL 2.0. For example, set the suffix parameter to `autoReconnect=true&failOverReadOnly=false&maxReconnects=10`.	No	None

Parameter	Description	Required	Default value
batchSize	The number of data records to write at a time. This parameter is available only when the writeMode parameter is set to insert.	Required only when the writeMode parameter is set to insert	None
bufferSize	The size of the Data Integration data buffer, which is designed to improve the performance of AnalyticDB for MySQL 2.0. Data from the source database is sorted in the buffer before the data is committed to AnalyticDB for MySQL 2.0. The data in the buffer is sorted based on the partition key columns in AnalyticDB for MySQL 2.0. In this way, the data is organized in an order that can improve the performance of the AnalyticDB for MySQL 2.0 server. Data in the buffer is committed to AnalyticDB for MySQL 2.0 in batches based on the batchSize parameter. We recommend that you set the bufferSize value to a multiple of batchSize. This parameter is available only when the writeMode parameter is set to insert.	Required only when the writeMode parameter is set to insert	Disabled

Configure AnalyticDB for MySQL 2.0 Writer by using the codeless UI

1. Configure the connections.

   Configure the connections to the source and destination data stores for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Write Method	The writeMode parameter in the preceding parameter description.

2. Configure field mapping. It is equivalent to setting the column parameter in the preceding parameter description. Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right.

GUI element	Description
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.

GUI element	Description
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout to sort the fields based on specified rules.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Configure AnalyticDB for MySQL 2.0 Writer by using the code editor

```
{
  "type":"job",
  "version":"2.0",
  "steps":[
    {
      "stepType":"stream",
      "parameter":{
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"ads",// The writer type.
      "parameter":{
        "partition:"",// The partition name of the destination table.
        "datasource":"",// The connection name.
        "column":[// The columns to which data is written.
            "id"
        ],
        "writeMode":"insert",// The write mode.
        "batchSize":"256",// The number of data records to write at a time.
        "table":"".// The name of the destination table.
```

```
            "overWrite":"true"// Specifies whether to overwrite the destination table when data is writte
n to AnalyticDB for MySQL 2.0. A value of true indicates that the destination table is overwritten. A val
ue of false indicates that the destination table is not overwritten and the new data is appended to th
e existing data. This value takes effect only when the writeMode parameter is set to load.
        },
        "name":"Writer",
        "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
      "record":"0"// The maximum number of dirty data records allowed.
    },
    "speed":{
      "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
      "concurrent":1,// The maximum number of concurrent threads.
    }
  },
  "order":{
    "hops":[
      {
        "from":"Reader",
        "to":"Writer"
      }
    ]
  }
}
```

2.4.5.4.2. Configure DataHub Writer

This topic describes the data types and parameters supported by DataHub Writer and how to configure it by using the code editor.

DataHub is a real-time data distribution platform designed to process streaming data. You can publish and subscribe applications to streaming data in DataHub and distribute the data to other platforms. This allows you to easily analyze streaming data and build applications based on the streaming data.

Based on the Apsara system of Alibaba Cloud, DataHub features high availability, low latency, high scalability, and high throughput. Seamlessly integrated with Realtime Compute, DataHub allows you to easily use SQL to analyze streaming data. DataHub can also distribute streaming data to Alibaba Cloud services such as MaxCompute and OSS.

> **Note** Strings can only be UTF-8 encoded. The size of each string must not exceed 1 MB.

Parameter configuration

The source is connected to the destination through a single channel. Therefore, the channel type configured for the writer must be the same as that configured for the reader. Generally, channels are categorized into two types: memory andfile. The following configuration sets the channel type to file:

```
"agent.sinks.dataXSinkWrapper.channel": "file"
```

Parameters

Parameter	Description	Required	Default value
accessId	The AccessKey ID for accessing DataHub.	Yes	None
accessKey	The AccessKey secret for accessing DataHub.	Yes	None
endpoint	The endpoint of DataHub.	Yes	None
maxRetryCount	The maximum number of retries if a task fails.	No	None
mode	The mode for writing strings.	Yes	None
parseContent	The data that has been parsed.	Yes	None
project	The organizational unit in DataHub. Each project contains one or more topics. **Note** DataHub projects are independent from MaxCompute projects. Projects created in MaxCompute cannot be used in DataHub.	Yes	None
topic	The minimum unit for data subscription and publication. You can use topics to distinguish different types of streaming data.	Yes	None

Parameter	Description	Required	Default value
maxCommitSize	The amount of data, in MB, that DataHub Writer buffers before sending it to the destination. This mechanism aims to improve writing efficiency. The default value is 1048576, in KB, that is, 1 MB.	No	*1048576*
batchSize	The number of data records that DataHub Writer buffers before sending them to the destination. This mechanism aims to improve writing efficiency. The default value is 1024.	No	*1,024*
maxCommitInterval	The maximum interval at which DataHub Writer sends data to the destination. When an interval ends, DataHub Writer sends buffered data even if the data amount does not reach the preceding two thresholds. The default value is 30000, in milliseconds, that is, 30 seconds.	No	*30,000*
parseMode	The mode for parsing log entries. Valid values: *default* and *csv*. The value default indicates that no log parsing is required. The value csv indicates that a delimiter is inserted between fields for each log entry.	No	*default*

Configure DataHub Writer by using the codeless UI

Currently, the codeless UI is not supported for DataHub Writer.

Configure DataHub Writer by using the code editor

In the following code, a node is configured to read data from the memory and then write the data to DataHub.

```
{
  "type": "job",
  "version": "2.0", // The version number.
  "steps": [
    {
      "stepType": "stream",
      "parameter": {},
      "name": "Reader",
      "category": "reader"
    },
    {
      "stepType": "datahub", // The writer type.
      "parameter": {
        "datasource": "", // The connection name.
```

```
            "topic": "",// The minimum unit for data subscription and publication. You can use topics to di
stinguish different types of streaming data.
            "maxRetryCount":500,// The maximum number of retries if a task fails.
            "maxCommitSize": 1048576// The amount of data, in MB, that DataHub Writer buffers before s
ending it to the destination.
            "shardId": "xxxxxx" // The shard of the DataHub topic.
        },
        "name": "Writer",
        "category": "writer"
    }
  ],
  "setting": {
    "errorLimit": {
      "record": "" // The maximum number of dirty data records allowed.
    },
    "speed": {
      "concurrent": 20, // The maximum number of concurrent threads.
      "throttle": false, // The value false indicates that the bandwidth is not throttled. The value true
indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set t
his parameter to true.
    }
  },
  "order": {
    "hops": [
      {
        "from": "Reader",
        "to": "Writer"
      }
    ]
  }
}
```

2.4.5.4.3. Configure the DB2 writer

The DB2 writer enables writing data to tables stored on Db2 databases. To write data into a Db2 table, the DB2 writer connects to the remote Db2 database through JDBC, and runs `INSERT INTO` statements. Data is written into the Db2 table in batches.

The DB2 writer is designed for ETL developers to import data from data warehouses to Db2 databases. It also serves as a data migration tool for database administrators and other users.

The DB2 writer reads data from the channel, connects to a remote Db2 database through JDBC, and then runs `INSERT INTO` statements. The rows that violate the unique index constraint or primary key constraint cannot be written into the Db2 database. To improve performance, the DB2 writer makes `batch updates with the PreparedStatement method` and sets `rewriteBatchedStatements=true`. In this way, the DB2 writer buffers data, and submits a write request when the amount of data in the buffer reaches a specific threshold.

> **Note** The INSERT INTO privilege is required for data synchronization tasks with the DB2 writer. Whether other permissions are required depends on the SQL statements specified in the preSql and postSql parameters.

The DB2 writer supports most Db2 data types. Since still some of the Db2 data types are not supported, verify that your data types are supported.

The following table lists data types supported by the DB2 writer.

Data Integration data type	Db2 data type
Integer	SMALLINT
Floating point	DECIMAL, REAL, and DOUBLE
String	CHAR, CHARACTER, VARCHAR, GRAPHIC, VARGRAPHIC, LONG VARCHAR, CLOB, LONG VARGRAPHIC, and DBCLOB
Date and time	DATE, TIME, and TIMESTAMP
Boolean	N/A
Binary	BLOB

Parameters

Parameter	Description	Required	Default value
jdbcUrl	The JDBC connectivity URL, used to connect to the Db2 database. In accordance with Db2 official specifications, the URL format must be jdbc:db2://ip:port/database. You can also specify the information of the attachment facility.	Yes	None
username	The username used to connect to the data source.	Yes	None
password	The password used to connect to the data source.	Yes	None
table	The name of the destination table.	Yes	None

Parameter	Description	Required	Default value
column	The columns in the destination table to which data is written. Separate the columns with a comma (,). Example: "column": ["id", "name", "age"]. Set the value to an asterisk (*) if data is written to all the columns in the destination table. Example: "column": ["*"].	Yes	None
preSql	The SQL statement runs before the data synchronization task starts. Currently, you can run only one SQL statement. For example, you can run a statement to clear outdated data.	No	None
postSql	The SQL statement runs after the data synchronization task ends. Currently, you can run only one SQL statement in wizard mode but multiple SQL statements in script mode. For example, you can run a statement to add a timestamp.	No	None
batchSize	The number of data records to write per batch. Setting this parameter can greatly reduce the interactions between Data Integration and the Db2 database over the network, and increase the throughput. However, an excessively large value may cause the running Data Integration process to become out of memory (OOM).	No	1024

Configure the DB2 writer in wizard mode

Currently, wizard mode is not supported for the DB2 writer.

Configure the DB2 writer in script mode

In the following script, a task is configured to write data to a Db2 database.

```
{
   "type":"job",
   "version":"2.0", // The version number.
   "steps":[
      { // The following template is used to configure the reader. For more information, see the corresp
onding section.
         "stepType":"stream",
         "parameter":{},
         "name":"Reader",
         "category":"reader"
      },
      {
         "stepType":"db2", // The writer type.
         "parameter":{
            "postSql":[], // The SQL statement runs after the data synchronization task ends.
            "password":"", // The password.
            "jdbcUrl":"jdbc:db2://ip:port/database", //The JDBC connectivity URL used to connect to the
```

```
            "jdbcUrl": "jdbc:db2://ip:port/database", // The JDBC connectivity URL, used to connect to the
Db2 database.
            "column":[
              "id"
            ],
            "batchSize":1024, // The number of data records to write per batch.
            "table":"", // The table name.
            "username":"", // The username.
            "preSql": [] // The SQL statement runs before the data synchronization task starts.
          },
          "name":"Writer",
          "category":"writer"
        }
    ],
    "setting":{
        "errorLimit":{
            "record":"0" // The maximum number of dirty data records allowed.
        },
        "speed":{
            "throttle":false, // The value false means that the bandwidth is not throttled. The value true m
eans that the bandwidth is throttled. The maximum transmission rate takes effect only if you specify t
his parameter as true.
            "concurrent":1, // The maximum number of concurrent threads.
            "dmu":1 // The number of DMUs.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.4.5.4.4. Configure DRDS Writer

This topic describes the data types and parameters supported by DRDS Writer and how to configure it by using the codeless UI and code editor.

DRDS Writer allows you to write data to tables stored in DRDS databases. DRDS Writer connects to the proxy of a remote DRDS database by using JDBC, and executes a `REPLACE INTO` statement to write data to the DRDS database.

> **Note**
> - To execute the `REPLACE INTO` statement, make sure that your table has the primary key or a unique index to avoid replicated data.
> - You must configure a connection before you configure DRDS Writer.

DRDS Writer is designed for ETL developers to import data from data warehouses to DRDS databases. DRDS Writer can also be used as a data migration tool by users such as DBAs.

DRDS Writer obtains data from a Data Integration reader, and writes the data to the destination database by executing the `REPLACE INTO` statement. If no primary key conflict or unique index conflict occurs, the action is the same as that of the `INSERT INTO` statement. If a conflict occurs, original rows are replaced by new rows. DRDS Writer sends data to the DRDS proxy when the amount of buffered data reaches a specific threshold. The proxy determines whether to write the data to one or more tables and how to route the data when it is written to multiple tables.

> **Note** A sync node that uses DRDS Writer must have at least the permission to execute the REPLACE INTO statement. Whether other permissions are required depends on the SQL statements specified in the preSql and postSql parameters.

Similar to MySQL Writer, DRDS Writer supports most MySQL data types. Make sure that your data types are supported.

The following table lists the data types supported by DRDS Writer.

Category	DRDS data type
Integer	INT, TINYINT, SMALLINT, MEDIUMINT, BIGINT, and YEAR
Floating point	FLOAT, DOUBLE, and DECIMAL
String	VARCHAR, CHAR, TINYTEXT, TEXT, MEDIUMTEXT, and LONGTEXT
Date and time	DATE, DATETIME, TIMESTAMP, and TIME
Boolean	BIT and BOOLEAN
Binary	TINYBLOB, MEDIUMBLOB, BLOB, LONGBLOB, and VARBINARY

Parameters

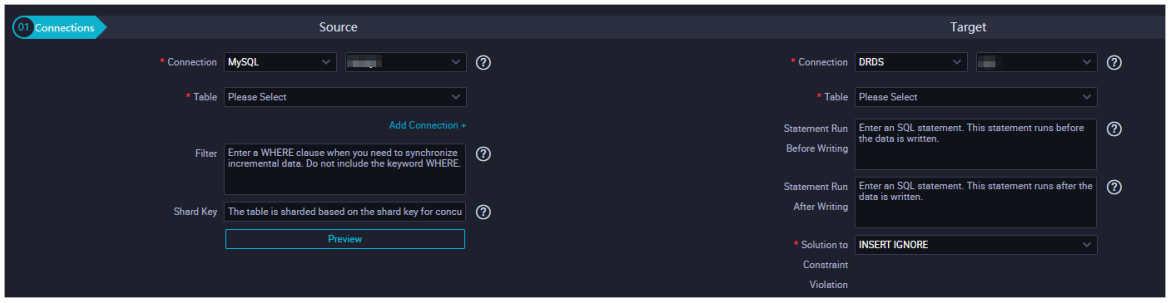
Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None

Parameter	Description	Required	Default value
table	The name of the destination table.	Yes	None
writeMode	The write mode. Valid values: *insert into*, *on duplicate key update*, and *replace into*. • *insert into*: If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows and is regarded as dirty data. • *on duplicate key update*: If no primary key conflict or unique index conflict occurs, the action is the same as that of `insert into`. If a conflict occurs, specified fields in original rows are updated. • *replace into*: If no primary key conflict or unique index conflict occurs, the action is the same as that of `insert into`. If a conflict occurs, original rows are deleted and new rows are inserted. This means that all the field values of the original rows are replaced.	No	*insert*
column	The columns in the destination table to which data is written. Separate the columns with commas (,), for example, "column": ["id","name","age"]. To write data to all the columns in the destination table, set the value to an asterisk (*), for example, "column":["*"].	Yes	None
preSql	The SQL statement to execute before the sync node is run. For example, you can clear outdated data before data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	None
postSql	The SQL statement to execute after the sync node is run. For example, you can add a timestamp after data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the DRDS database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	*1,024*

Configure DRDS Writer by using the codeless UI

1. Configure the connections.

Configure the connections to the source and destination data stores for the sync node.



Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Statement Run Before Writing	The preSql parameter in the preceding parameter description. Enter an SQL statement to execute before the sync node is run.
Statement Run After Writing	The postSql parameter in the preceding parameter description. Enter an SQL statement to execute after the sync node is run.
Solution to Constraint Violation	The writeMode parameter in the preceding parameter description. Select the required write mode.

2. Configure field mapping. It is equivalent to setting the column parameter in the preceding parameter description. Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right.

GUI element	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout to sort the fields based on specified rules.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.

Parameter	Description
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Configure DRDS Writer by using the code editor

In the following code, a node is configured to write data to a DRDS database.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
        },
    {
      "stepType":"drds",// The writer type.
      "parameter":{
        "postSql":[],// The SQL statement to execute after the sync node is run.
        "datasource":"",// The connection name.
        "column":[// The columns to which data is written.
        "id"
        ],
        "writeMode":"insert ignore",
        "batchSize":"1024",// The number of data records to write at a time.
        "table":"test",// The name of the destination table.
        "preSql":[]// The SQL statement to execute before the sync node is run.
        },
      "name":"Writer",
      "category":"writer"
        }
        ],
  "setting":{
    "errorLimit":{
```

```
        "record":"0"// The maximum number of dirty data records allowed.
          },
        "speed":{
          "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
          "concurrent":1 // The maximum number of concurrent threads.
            }
          },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
          }
        ]
      }
    }
```

2.4.5.4.5. Configure the FTP writer

The FTP writer allows you to write one or more files in CSV format into a remote FTP file. At the underlying level, this writer converts the data that is readable by the Data Integration service to CSV files, and writes these files into the remote FTP server using FTP network protocols. You must configure the data source before configuring the FTP writer.

> **Note** For more information, see Add FTP data sources.

The FTP writer can only write data into FTP files that store logical two-dimensional tables, for example, text information in the CSV format.

This writer enables you to convert data that is readable by the Data Integration service to FTP files. FTP files stores non-structured data. The advantages and disadvantages of the FTP writer are described as follows:

- Only supports text files and the schema in the text file must be a two-dimensional table. It does not support the blob type, such as video data.
- Supports CSV and text files with custom delimiters.
- Does not support text compression when data is written to the destination table.
- Supports multi-thread writing, with each thread performing write operations on a subfile.

Currently, the FTP writer does not support the following two features:

- Concurrent writing for a single file.
- Providing varying data types. The FTP does not provide data types, and the FTP writer writes data of the string type into FTP files.

Parameters

Parameter	Description	Required.	Default value
datasource	The name of the data source. You can add a data source either in wizard or script mode. The value of this parameter must be identical to the real data source name.	Yes	None
timeout	The timeout period for the connection to the FTP server, measured in milliseconds.	No	60000 (1 minute)
path	The path of the FTP file system. The write can write data into multiple files in the path.	Yes	None
FileName	The name of the file into which data is written. A random suffix is added to the file name to form the actual name of the file into which the data is written on each thread.	Yes	None
writeMode	The mode in which the FTP writer clears existing data before writing data. Valid values: • truncate: The writer clears all the files prefixed by fileName in the path before writing data. • append: No processing is performed on the file before the FTP writer imports data into this file. In the Data Integration service, the FTP writer uses the original file name in the data source. No duplicate file names are allowed. • nonConflict: An error is reported if a file prefixed by fileName exists in the path.	Yes	None
fieldDelimiter	The column delimiter of the file to be written.	Yes. A single character is used.	None
compress	The compress option. The gzip and bzip2 compression options are supported.	No	No
encoding	The encoding of the file to be read.	No	UTF-8
nullFormat	The string that represents null. Since no standard strings can represent null in text files, Data Integration provides the nullFormat parameter to define which string represents a null pointer. For example, if you specify `nullFormat:"null"`, Data Integration considers "null" as a null pointer.	No	None
dateFormat	The date format, for example, "dateFormat": "yyyy-MM-dd".	No	None

Parameter	Description	Required.	Default value
fileFormat	The file format, including CSV and text. For the CSV format, if you want to write the data that includes column delimiters, the delimiters are escaped with quotation marks. For text format, the data to be written is separated by column delimiters without being escaped.	No	text
header	The header used when a txt file is written, for example, ['id', 'name', 'age'].	No	None
Markdonefilename	The name of the file marked as "done". After a synchronization task is completed, a MarkDoneFile is generated, based on which you can determine whether the task is executed successfully.	No	None

Configure the FTP writer in wizard mode

1. Select data sources.

   Configure the source and destination for the data synchronization task.

Parameter	Description
Data Source	The datasource parameter provided in the preceding table. Select a data source type, and enter the name of a data source that has been configured in DataWorks.
File Path	The path parameter provided in the preceding table.
Column Delimiter	The fieldDelimiter parameter provided in the preceding table. Default value: a comma (,)
Encoding	The encoding parameter provided in the preceding table. Default value: UTF-8.
Null String	The nullFormat parameter provided in the preceding table, which defines a string that represents null.
Compression Format	The nullFormat parameter provided in the preceding table. Default value: No.
Include Header	The skipHeader parameter in the preceding table. Default value: No.
Prefix Conflict	The writeMode parameter provided in the preceding table, which defines a string that represents null.

2. Configure field mappings. It is equivalent to setting the column parameter provided in the preceding table.

   You can map the left-side source table fields to the right-side destination table fields. You can also click **Add** to add a field or click the **Delete** icon to delete a field in the source table.

After you click **Map Fields in the Same Line**, each source table field is mapped to the destination table field in the same line if exists. Ensure that the conversion between data types is feasible.

3. Configure the channel.

Parameter	Description
DMU	The data processing capabilities. A data migration unit (DMU) represents the data processing capabilities for data integration, given a minimum configuration of the CPU, memory, network, and other resources.
Concurrent Jobs	The maximum number of concurrent threads to read and write data to data storage within the data synchronization task.
Transmission Rate	You can throttle the bandwidth and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Task Resource Group	The servers on which tasks are run. If an excessively large number of tasks are run on the default resource group, some tasks may be delayed due to insufficient resources. In this case, you can configure additional servers.

Configure the FTP writer in script mode

In the following script, a task is configured to write data to an FTP database.

```
{
   "type":"job",
   "version":"2.0",// The version number.
   "steps":[
      { // The following template is used to configure the reader. For more information, see the corresp
onding section.
         "stepType":"stream",
         "Parameter ":{},
         "name":"Reader",
         "category":"reader"
      },
      {
         "stepType":"ftp",// The plug-in name.
         "parameter":{
            "path":""// The file path.
            "fileName": "",// The file name.
            "nullFormat": "null", // The string that represents null.
```

```
            "dateFormat":"yyyy-MM-dd HH:mm:ss", // The time format.
            "datasource": "", // The data source.
            "writeMode": "",// The writing method.
            "fieldDelimiter": "," ,// The column delimiter.
             "encoding":"",// The encoding.
            "fileFormat": "",// The file type.
        },
        "name":"Writer",
        "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
      "record":"0"// The maximum number of dirty data records allowed.
    },
    "speed":{
      "throttle":false,// The value false means that the bandwidth is not throttled. The value true me
ans that the bandwidth is throttled. The maximum transmission rate takes effect only if you specify th
is parameter as true.
      "concurrent":"1",// The maximum number of concurrent threads.
      "dmu":1// The number of DMUs.
    }
  },
  "order":{
    "hops":[
      {
        "from":"Reader",
        "to":"Writer"
      }
    ]
  }
}
```

2.4.5.4.6. Configure HBase Writer

This topic describes the features, data types, and parameters supported by HBase Writer and how to configure it by using the code editor.

HBase Writer allows you to write data to HBase data stores. Specifically, HBase Writer connects to a remote HBase data store through the Java client of HBase. Then, HBase Writer uses the PUT method to write data to the HBase data store.

Features

- HBase 0.94.x and 1.1.x are supported.
  - If you use HBase 0.94.x, set the hbaseVersion parameter to 094x for the writer.

    ```
    "writer": {
        "hbaseVersion": "094x"
      }
    ```

  - If you use HBase 1.1.x, set the hbaseVersion parameter to 11x for the writer.

    ```
    "writer": {
        "hbaseVersion": "11x"
      }
    ```

    Note Currently, HBase Writer for HBase 1.1.x is compatible with HBase 2.0. If you have any issues in using HBase Writer with HBase 2.0, submit a ticket.

- You can use concatenated fields as a rowkey.

  Currently, HBase Writer supports concatenating multiple fields to generate the rowkey of an HBase table.

- You can set the version of each HBase cell.

  The information that can be used as the version of an HBase cell includes:

  - Current time
  - Specified source column
  - Specified time

Data types

The following table lists the data types supported by HBase Writer.

Note
- The types of the specified columns must be the same as those in the HBase table.
- Data types that are not listed in the table are not supported.

Category	HBase data type
Integer	Int, Long, and Short
Floating point	Float and Double
Boolean	Boolean
String	String

Parameters

Parameter	Description	Required	Default value
haveKerberos	Specifies whether Kerberos authentication is required. A value of true indicates that Kerberos authentication is required. Note • If the value is true, the following five Kerberos-related parameters must be specified: ◦ kerberosKeytabFilePath ◦ kerberosPrincipal ◦ hbaseMasterKerberosPrincipal ◦ hbaseRegionserverKerberosPrincipal ◦ hbaseRpcProtection • If the value is false, Kerberos authentication is not required and you do not need to specify the preceding parameters.	No	*false*
hbaseConfig	The properties of the HBase cluster, in JSON format. The hbase.zookeeper.quorum parameter is required. It specifies the ZooKeeper ensemble servers. You can also configure other properties, such as those related to the cache and batch for scan operations.	Yes	None
mode	The mode in which data is written to the HBase data store. Currently, only the normal mode is supported. The dynamic column selection mode is coming soon.	Yes	None
table	The name of the HBase table to which data is written. The name is case-sensitive.	Yes	None
encoding	The encoding format in which a string is converted through byte[]. Currently, UTF-8 and GBK are supported.	No	*utf-8*
column	The HBase columns to which data is written. • index: the ID of the column in the source table, starting from 0. • name: the name of the column in the HBase table, in the columnFamily:column format. • type: the type of the data written, which is used by the byte[] constructor.	Yes	None

Parameter	Description	Required	Default value
maxVersion	The number of versions read by HBase Reader when multiple versions are available. Valid values: -1 and integers greater than 1. A value of -1 indicates that all versions are read.	Required in multiVersionFixedColumn mode	None
range	The rowkey range that HBase Reader reads. • startRowkey: the start rowkey. • endRowkey: the end rowkey. • isBinaryRowkey: the operation called by byte[] to convert the specified start and end rowkeys. Default value: false. If the value is true, Bytes.toBytesBinary(rowkey) is called. If the value is false, Bytes.toBytes(rowkey) is called. Example: `"range": { "startRowkey": "aaa", "endRowkey": "ccc", "isBinaryRowkey":false }` Example: `"column": [ { "index":1, "name": "cf1:q1", "type": "string" }, { "index":2, "name": "cf1:q2", "type": "string" } ]`	No	None

Parameter	Description	Required	Default value
rowkeyColumn	The rowkey of each HBase cell. • index: the ID of the column in the source table, starting from 0. If the column is a constant, set the value to -1. • type: the type of the data written, which is used by the byte[] constructor. • value: a constant, which is usually used as the delimiter between fields. HBase Writer sequentially concatenates all columns specified in this parameter to a string, and uses the string as the rowkey. The specified columns cannot be all constants. Example: `"rowkeyColumn": [ { "index":0, "type":"string" }, { "index":-1, "type":"string", "value":"_" } ]`	Yes	None

Parameter	Description	Required	Default value
versionColumn	The version of each HBase cell. You can use the current time, a specified source column, or a specified time as the version. If you do not specify this parameter, the current time is used. • index: the ID of the column in the source table, starting from 0. Make sure that the value can be properly converted to the Long type. • type: the data type. If the type is Date, HBase Writer converts the date to yyyy-MM-dd HH:mm:ss or yyyy-MM-dd HH:mm:ss SSS. If you want to use a specified time as the version, set the value to -1. • value: the specified time of the Long type. Example: "versionColumn":{ "index":1 } "versionColumn":{ "index": - 1, "value":123456789 }	No	None
nullMode	The method of processing null values. Valid values: • skip: HBase Writer does not write null values to the HBase data store. • empty: HBase Writer writes HConstants.EMPTY_BYTE_ARRAY (new byte [0]) to the HBase data store instead of null values.	No	skip
walFlag	Specifies whether to enable write ahead logging (WAL) for HBase. If the value is true, all edits requested by an HBase client for all Regions carried by the RegionServer are recorded first in the WAL (that is, the HLog). After the edits are successfully recorded in the WAL, they are implemented to the Memstore and a success indication is sent to the HBase client. If edits fail to be recorded in the WAL, a failure indication is sent to the HBase client without implementing the edits. If the value is false, WAL is disabled but writing efficiency is improved.	No	*false*

Parameter	Description	Required	Default value
writeBufferSize	The write buffer size, in bytes, of the HBase client. If you specify this parameter, you must also specify the autoflush parameter. autoflush: • If the value is true, the HBase client sends a PUT request each time it receives an edit. • If the value is false, the HBase client sends a PUT request only when its write buffer is full.	No	8 MB

Configure HBase Writer by using the codeless UI

Currently, the codeless user interface (UI) is not supported for HBase Writer.

Configure HBase Writer by using the code editor

In the following code, a node is configured to write data to an HBase 1.1.x data store.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"hbase",// The writer type.
      "parameter":{
        "mode":"normal",// The mode in which data is written to the HBase data store.
        "walFlag":"false",// WAL is disabled for HBase.
        "hbaseVersion":"094x",// The HBase version.
        "rowkeyColumn":[// The rowkey of each HBase cell.
          {
            "index":"0",// The ID of the column in the source table.
            "type":"string"// The data type.
          },
          {
            "index":"-1",
            "type":"string",
            "value":" "
```

```
                "value": "_
            }
          ],
          "nullMode":"skip",// The method of processing null values.
          "column":[// The HBase columns to which data is written.
            {
              "name":"columnFamilyName1:columnName1",// The name of the HBase column.
              "index":"0",// The ID of the column in the source table.
              "type":"string"// The data type.
            },
            {
              "name":"columnFamilyName2:columnName2",
              "index":"1",
              "type":"string"
            },
            {
              "name":"columnFamilyName3:columnName3",
              "index":"2",
              "type":"string"
            }
          ],
          "writeMode":"api",// The write mode.
          "encoding":"utf-8",// The encoding format.
          "table":"",// The name of the destination table.
          "hbaseConfig":{// The properties of the HBase cluster, in JSON format.
            "hbase.zookeeper.quorum":"hostname",
            "hbase.rootdir":"hdfs: //ip:port/database",
            "hbase.cluster.distributed":"true"
          }
        },
        "name":"Writer",
        "category":"writer"
      }
    ],
    "setting":{
      "errorLimit":{
        "record":"0"// The maximum number of dirty data records allowed.
      },
      "speed":{
        "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
```

```
mum transmission rate takes effect only if you set this parameter to true.
        "concurrent":1,// The maximum number of concurrent threads.
      }
    },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
        }
      ]
    }
}
```

2.4.5.4.7. Configure HBase11xsql Writer

This topic describes the features, data types, and parameters supported by HBase11xsql Writer and how to configure it by using the code editor.

Background information

HBase11xsql Writer allows you to write data in batches to HBase tables created by using Phoenix. Phoenix can encode the primary key to rowkey. If you directly use the HBase API to write data to an HBase table that is created by using Phoenix, you must manually convert data, which is troublesome and error-prone. HBase11xsql Writer allows you to write data to HBase tables that packs all values into a single cell per column family.

HBase11xsql Writer connects to a remote HBase data store by using JDBC, and executes an UPSERT statement to write data to the HBase data store.

Limits

- The column order specified in the writer must match that specified in the reader. When you configure the column order in the reader, you specify the order of columns in each row for the output data. When you configure the column order in the writer, you specify the expected order of columns for the input data. Example:

  Column order specified in the reader: c1, c2, c3, c4.

  Column order specified in the writer: x1, x2, x3, x4.

  In this case, the value of column c1 is assigned to column x1 in the writer. If the column order specified in the writer is x1, x2, x4, x3, the value of column c3 is assigned to column x4 and the value of column c4 is assigned to column x3.
- HBase11xsql Writer can write data only to HBase 1.x.
- HBase11xsql Writer can write data only to tables created by using Phoenix but not native HBase tables.
- HBase11xsql Writer cannot write data with timestamps.

Features

HBase11xsql Writer can write data of an indexed table and synchronously update all indexed tables.

How it works

HBase11xsql Writer connects to an HBase data store by using Phoenix, which is a JDBC driver, and executes an UPSERT statement to write data in batches to the destination table. Phoenix allows to synchronously update indexed tables when you write data.

Parameters

Parameter	Description	Required	Default value
plugin	The writer type. Set this value to hbase11xsql.	Yes	None
table	The name of the destination table. The name is case-sensitive. Generally, the name of a table that is created by using Phoenix consists of uppercase letters.	Yes	None
column	The name of the column. The name is case-sensitive. Generally, the name of each column in a table that is created by using Phoenix consists of uppercase letters. Note • HBase11xsql Writer writes data strictly in accordance with the order of the columns obtained from the reader. • You do not need to specify the data type for each column. HBase11xsql Writer automatically obtains the metadata of columns from Phoenix.	Yes	None
hbaseConfig	The properties of the HBase cluster. The hbase.zookeeper.quorum parameter is required. It specifies the ZooKeeper ensemble servers. Note • Separate the IP addresses with commas (,), for example, ip1,ip2,ip3. • The zookeeper.znode.parent parameter is optional. Default value: /hbase.	Yes	None
batchSize	The number of data records to write at a time.	No	*256*

Parameter	Description	Required	Default value
nullMode	The method of processing null values. Valid values: • *skip*: HBase11xsql Writer does not write null values to the HBase data store. • *empty*: HBase11xsql Writer writes 0 or an empty string instead of null values to the HBase data store. For a column of the numeric type, HBase11xsql Writer writes 0. For a column of the VARCHAR type, HBase11xsql Writer writes an empty string.	No	*skip*

Configure HBase11xsql Writer by using the code editor

In the following code, a node is configured to write data to an HBasae database.

```
{
 "type": "job",
 "version": "1.0",
 "configuration": {
  "setting": {
   "errorLimit": {
    "record": "0"
   },
   "speed": {
    "mbps": "1",
    "concurrent": "1"
   }
  },
  "reader": {
   "plugin": "odps",
   "parameter": {
    "datasource": "",
    "table": "",
    "column": [],
    "partition": ""
   }
  },
  "plugin": "hbase11xsql",
  "parameter": {
   "table": "The case-sensitive name of the destination table",
   "hbaseConfig": {
    "hbase.zookeeper.quorum": "The IP addresses of ZooKeeper ensemble servers of the destination HBase cluster. Obtain the IP addresses from product engineers (PEs).",
    "zookeeper.znode.parent": "The root znode of the destination HBase cluster. Obtain the IP addresses from PEs."
   },
   "column": [
    "columnName"
   ],
   "batchSize": 256,
   "nullMode": "skip"
  }
 }
}
```

FAQ

Q: What is the proper number of concurrent threads? Can I increase the number of concurrent threads to speed up the synchronization?

A: In the data import process, the default size of a JVM heap is 2 GB. Concurrent synchronization requires multiple threads. However, excessive threads sometimes cannot speed up the synchronization and may even deteriorate the performance because of frequent garbage collection (GC). We recommend that you set the number of concurrent threads within the range from 5 to 10.

Q: What is the proper value for the batchSize parameter?

A: The default value of the batchSize parameter is 256. You can set a proper value for the batchSize parameter based on the data volume of each row. Generally, the data volume of each write operation is 2 MB to 4 MB. You can set the value to the data volume of a write operation divided by the data volume of a row.

2.4.5.4.8. Configure HDFS Writer

This topic describes the data types and parameters supported by HDFS Writer and how to configure it by using the code editor.

HDFS Writer allows you to write text, ORC, or Parquet files to the specified directory in HDFS. In addition, you can associate the fields in the files with those in Hive tables. You must configure a connection before you configure HDFS Writer.

How it works

HDFS Writer writes files to HDFS in the following way:

1. Creates a temporary directory that does not exist in HDFS based on the path parameter you specified.

   The name of the temporary directory is in the format of path_Random suffix.
2. Writes files that are read by a Data Integration reader to the temporary directory.
3. Moves the files from the temporary directory to the specified directory in HDFS after all the files are written. HDFS Writer ensures that the file names do not conflict with existing files in HDFS when it moves the files.
4. Deletes the temporary directory. If the deletion is interrupted because HDFS Writer fails to connect to HDFS, you must manually delete the temporary directory.

> **Note** To synchronize data, use an administrator account with the read and write permissions.

Limits

- HDFS Writer can write only text, ORC, and Parquet files that store logical two-dimensional tables to HDFS.
- HDFS is a distributed file system and does not have a schema. Therefore, you cannot write only some of the columns in a file to HDFS.
- HDFS Writer supports only the following Hive data types:
  - Numeric: TINYINT, SMALLINT, INT, BIGINT, FLOAT, and DOUBLE

  - String: STRING, VARCHAR, and CHAR
  - Boolean: BOOLEAN
  - Date and time: DATE and TIMESTAMP
- HDFS Writer does not support other Hive data types, such as DECIMAL, BINARY, ARRAY, MAP, STRUCT, or UNION.
- HDFS Writer can write data to only one partition in a partitioned Hive table at a time.
- To write a text file to HDFS, make sure that the delimiter in the file is the same as that in the Hive table to be associated with the file. Otherwise, you cannot associate the fields in the file stored in HDFS with those in the Hive table.
- HDFS Writer can be used in the environment where Hive 1.1.1 and Hadoop 2.7.1 (JDK version: 1.7) are installed. HDFS Writer can write files to HDFS properly in testing environments where Hadoop 2.5.0, Hadoop 2.6.0, or Hive 1.2.0 is installed.

Data types

HDFS Writer supports most Hive data types. Make sure that your data types are supported.

The following table lists the Hive data types supported by HDFS Writer.

> **Note** The types of the specified columns must be the same as those of columns in the Hive table.

Category	Hive data type
Integer	TINYINT, SMALLINT, INT, and BIGINT
Floating point	FLOAT and DOUBLE
String	CHAR, VARCHAR, and STRING
Boolean	BOOLEAN
Date and time	DATE and TIMESTAMP

Parameters

Parameter	Description	Required	Default value
defaultFS	The address of the HDFS NameNode, for example, `hdfs://127.0.0.1:9000`. The default resource group does not support configuring advanced Hadoop parameters related to the high availability feature.	Yes	None

Parameter	Description	Required	Default value
fileType	The format of the files to be written to HDFS. Valid values: • *text*: the text file format. • *orc*: the ORC file format. • *parquet*: the common Parquet file format.	Yes	None
path	The directory in HDFS to which the files are written. HDFS Writer concurrently writes multiple files to the directory based on the concurrency setting. To associate the fields in a file with those in a Hive table, set the path parameter to the storage path of the Hive table in HDFS. Assume that the storage path specified for the data warehouse of Hive is `/user/hive/warehouse/`. The storage path of the hello table created in the test database is `/user/hive/warehouse/test.db/hello`.	Yes	None
fileName	The name prefix of the files to be written to HDFS. A random suffix is appended to the specified prefix to form the actual file name used by each thread.	Yes	None

Parameter	Description	Required	Default value
column	The columns to be written to HDFS. You cannot write only some of the columns in a file to HDFS. To associate the fields in a file with those in a Hive table, specify the name and type parameters for each field. You can also specify the column parameter in the following way: `"column": [ { "name": "userName", "type": "string" }, { "name": "age", "type": "long" } ]`	Yes (Not required if the fileType parameter is set to parquet)	None
writeMode	The mode in which HDFS Writer writes the files. Valid values: • *append*: writes the files based on the specified file name prefix and ensures that the actual file names do not conflict with those of existing files. • *nonConflict*: returns an error if a file with the specified file name prefix exists in the destination directory. Note Parquet files do not support the append mode. They support only the nonConflict mode.	Yes	None
fieldDelimiter	The column delimiter used in the files to be written to HDFS. Make sure that you use the same delimiter as that in the Hive table. Otherwise, you cannot query data in the Hive table.	Yes (Not required if the fileType parameter is set to parquet)	None

Parameter	Description	Required	Default value
compress	The compression format of the files to be written to HDFS. By default, this parameter is left empty, that is, files are not compressed. For a text file, the GZIP and BZIP2 compression formats are supported. For an ORC file, the SNAPPY compression format is supported. To compress an ORC file, you must install SnappyCodec.	No	None
encoding	The encoding format of the files to be written to HDFS.	No	None

Parameter	Description	Required	Default value
parquetSchema	The schema of the files to be written to HDFS. This parameter is required only when the fileType parameter is set to parquet. Format: `message messageTypeName {` `required, dataType, columnName;` `..... ;` `}` Parameter description: • messageTypeName: the name of the MessageType object. • required: specifies whether the field is required. We recommend that you set the parameter to optional for all fields. • dataType: the type of the field. Valid values: BOOLEAN, INT32, INT64, INT96, FLOAT, DOUBLE, BINARY, and FIXED_LEN_BYTE_ARRAY. Set this parameter to BINARY if the field stores strings. Note Each line, including the last one, must end with a semicolon (;). Example: `message m {` `optional int64 id;` `optional int64 date_id;` `optional binary datetimestring;` `optional int32 dspId;` `optional int32 advertiserId;` `optional int32 status;` `optional int64 bidding_req_num;` `optional int64 imp;` `optional int64 click_num;` `}`	No	None

Parameter	Description	Required	Default value
hadoopConfig	The advanced parameter settings of Hadoop, such as those related to high availability. The default resource group does not support configuring advanced Hadoop parameters related to the high availability feature. "hadoopConfig":{ "dfs.nameservices": "testDfs", "dfs.ha.namenodes.testDfs": "namenode1,namenode2", "dfs.namenode.rpc-address.youkuDfs.namenode1": "", "dfs.namenode.rpc-address.youkuDfs.namenode2": "", "dfs.client.failover.proxy.provider.testDfs": "org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider" }	No	None
	The synchronization mode for Parquet files. If the dataxParquetMode parameter is set to fields, you can write data of complex types, such as ARRAY, MAP, and STRUCT. Valid values: fields and columns. If the dataxParquetMode parameter is set to fields, HDFS Writer supports HDFS over OSS. HDFS uses OSS as the storage service and HDFS Writer writes Parquet files to OSS. In this case, you can add the following OSS-related parameters in the hadoopConfig parameter: • fs.oss.accessKeyId: the AccessKey ID for connecting to OSS. • fs.oss.accessKeySecret: the AccessKey secret for connecting to OSS. • fs.oss.endpoint: the endpoint for connecting to OSS. Example:		

Parameter	Description	Required	Default value
dataxParquetMode	```json "writer": { "name": "hdfswriter", "parameter": { "defaultFS": "oss://test-bucket", "fileType": "parquet", "path": "/datasets/oss_demo/kpt", "fileName": "test", "writeMode": "truncate", "compress": "SNAPPY", "encoding": "UTF-8", "hadoopConfig": { "fs.oss.accessKeyId": "the-access-id", "fs.oss.accessKeySecret": "the-access-key", "fs.oss.endpoint": "oss-cn-hangzhou.aliyuncs.com" }, "parquetSchema": "message test {\n required int64 id;\n optional binary name (UTF8);\n optional int64 gmt_create;\n required group map_col (MAP) {\n repeated group key_value {\n required binary key (UTF8);\n required binary value (UTF8);\n }\n }\n required group array_col (LIST) {\n repeated group list {\n required binary element (UTF8);\n }\n }\n required group struct_col {\n required int64 id;\n required binary name (UTF8);\n } \n}", "dataxParquetMode": "fields" } } ```	No	*columns*

Parameter	Description	Required	Default value
haveKerberos	Specifies whether Kerberos authentication is required. Default value: *false*.	If you set this parameter to *true*, you must also set the kerberosKeytabFilePath and kerberosPrincipal parameters.	*false*
kerberosKeytabFilePath	The absolute path of the keytab file for Kerberos authentication.	Required if the haveKerberos parameter is set to true	None
kerberosPrincipal	The Kerberos principal to which Kerberos can assign tickets. Example: ****/hadoopclient@**.***. Note The absolute path of the keytab file is required for Kerberos authentication. Therefore, you can configure Kerberos authentication only on a custom resource group. Example: "haveKerberos":true, "kerberosKeytabFilePath":"/opt/datax/**.keytab", "kerberosPrincipal":"**/hadoopclient@**.**"	Required if the haveKerberos parameter is set to true	None

Configure HDFS Writer by using the codeless UI

The codeless UI is not supported for HDFS Writer.

Configure HDFS Writer by using the code editor

In the following code, a node is configured to write files to HDFS. For more information about the parameters, see the preceding parameter description.

```
{
  "type": "job",
  "version": "2.0",// The version number.
  "steps": [
    {
      "stepType": "stream",
      "parameter": {},
```

```
        "name": "Reader",
        "category": "reader"
      },
      {
        "stepType": "hdfs",// The writer type.
        "parameter": {
          "path": "",// The directory in HDFS to which the files are written.
          "fileName": "",// The name prefix of the files to be written to HDFS.
          "compress": "",// The compression format of the files.
          "datasource": "",// The connection name.
          "column": [
            {
              "name": "col1",// The name of the column.
              "type": "string"// The data type of the column.
            },
            {
              "name": "col2",
              "type": "int"
            },
            {
              "name": "col3",
              "type": "double"
            },
            {
              "name": "col4",
              "type": "boolean"
            },
            {
              "name": "col5",
              "type": "date"
            }
          ],
          "writeMode": "",// The write mode.
          "fieldDelimiter": ",",// The column delimiter.
          "encoding": "",// The encoding format.
          "fileType": "text"// The file format.
        },
        "name": "Writer",
        "category": "writer"
      }
    ],
```

```
    "setting": {
      "errorLimit": {
        "record": ""// The maximum number of dirty data records allowed.
      },
      "speed": {
        "concurrent": 3,// The maximum number of concurrent threads.
        "throttle": false // Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
      }
    },
    "order": {
      "hops": [
        {
          "from": "Reader",
          "to": "Writer"
        }
      ]
    }
}
```

2.4.5.4.9. Configure MaxCompute Writer

This topic describes the data types and parameters supported by MaxCompute Writer and how to configure it by using the codeless UI and code editor.

MaxCompute Writer is designed for developers to insert data to or update data in MaxCompute. MaxCompute Writer is suitable for importing data at the GB or TB level to MaxCompute.

> **Note** You must configure a connection before you configure MaxCompute Writer.

Based on the specified information such as the source project, table, partition, and field, MaxCompute Writer writes data to MaxCompute by using Tunnel.

Data types

The following table lists the data types supported by MaxCompute Writer.

Category	MaxCompute data type
Integer	BIGINT
Floating point	DOUBLE and DECIMAL
String	STRING

Category	MaxCompute data type
Date and time	DATETIME
Boolean	BOOLEAN

Parameters

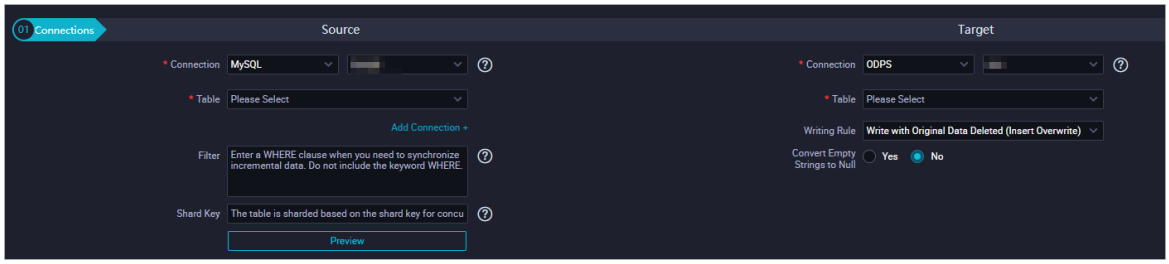
Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the destination table. The name is not case-sensitive. You can specify only one table as the destination table.	Yes	None
partition	The partition to which data is written. The last-level partition must be specified. For example, if you want to write data to a three-level partitioned table, set the partition parameter to a value that contains the third-level partition information, for example, `pt=20150101, type=1, biz=2`. • To write data to a non-partitioned table, do not set this parameter. The data is directly written to the destination table. • MaxCompute Writer does not support writing data based on the partition route. To write data to a partitioned table, make sure that data is written to the last-level partition.	Required only for writing data to a partitioned table	None
column	The columns in the destination table to which data is written. To write data to all the columns in the destination table, set the value to an asterisk (*), for example, `"column":["*"]`. Set the value to the specified columns if data is written to only some of the columns in the destination table. Separate the columns with commas (,). Example: `"column":["id","name"]`. • MaxCompute Writer can filter columns and change the order of columns. For example, a MaxCompute table has three columns: a, b, and c. If you want to write data only to column c and column b, you can set the column parameter in the format `"column":["c","b"]`. During data synchronization, column a is automatically set to null. • The column parameter must explicitly specify a set of columns to which data is written. The parameter cannot be left empty.	Yes	None

Parameter	Description	Required	Default value
truncate	To ensure the idempotence of write operations, set the truncate parameter in the format `"truncate":"true"`. When a failed sync node is rerun due to a write failure, MaxCompute Writer deletes the data that has been written before it imports the source data again. This ensure that the same data is written for each rerun. MaxCompute Writer uses MaxCompute SQL to delete data. MaxCompute SQL cannot ensure the atomicity. Therefore, the truncation operation is not an atomic operation. Conflicts may occur when concurrent nodes delete data from the same table or partition. To avoid this issue, we recommend that you do not run concurrent DDL nodes to write data to the same partition. You can create different partitions for nodes that need to run concurrently.	Yes	None

Configure MaxCompute Writer by using the codeless UI

1. Configure the connections.

   Configure the connections to the source and destination data stores for the sync node.



Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Table	The table parameter in the preceding parameter description.

Parameter	Description
Partition Key Column	To write data to all the columns in the destination table, set "column":["*"] for the column parameter in the preceding parameter description. The partition parameter allows you to use wildcards and specify one or more partitions. ○ `"partition":"pt=20140501/ds=*"` specifies that data is written to all ds partitions with pt=20140501. ○ `"partition":"pt=top?"` specifies that data is written to the partitions with pt=top and pt=to. You can specify the partition key columns to which data is written. Assume that the partition key column of a MaxCompute table is pt=${bdp.system.bizdate}. You can configure the column to which data is written to pt. Ignore it if the column is marked as unidentified. ○ To write data to all partitions, enter pt=*. ○ To write data to some of the partitions, specify the corresponding dates.
Writing Rule	○ **Write with Original Data Deleted (Insert Overwrite)**: All data in the table or partition is deleted before data import. This rule is equivalent to the `INSERT OVERWRITE` statement. ○ **Write with Original Data Retained (Insert Into)**: No data is deleted before data import. New data is always appended upon each run. This rule is equivalent to the `INSERT INTO` statement. **Note** ○ MaxCompute Reader reads data by using Tunnel. Sync nodes do not support data filtering. Instead, they must read all the data in a specific table or partition. ○ MaxCompute Writer writes data by using Tunnel instead of the INSERT INTO statement. You can view the complete data in the destination table only after a sync node is run. Pay attention to the node dependencies.
Convert Empty Strings to Null	Specifies whether to convert empty strings to null. Default value: *No*.

2. Configure field mapping. It is equivalent to setting the column parameter in the preceding parameter description. Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right.

GUI element	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout to sort the fields based on specified rules.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure MaxCompute Writer by using the code editor

In the following code, a node is configured to write data to a MaxCompute project. For more information about the parameters, see the preceding parameter description.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
```

```
      "category":"reader"
    },
    {
      "stepType":"odps",// The writer type.
      "parameter":{
        "partition":"",// The partition information.
        "truncate":true,// The write rule.
        "compress":false,// Specifies whether to enable compression.
        "datasource":"odps_first",// The connection name.
      "column":[// The columns to which data is written.
        "id",
        "name",
        "age",
        "sex",
        "salary",
        "interest"
        ],
        "emptyAsNull":false,// Specifies whether to convert empty strings to null.
        "table":""// The name of the destination table.
      },
      "name":"Writer",
      "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
      "record":"0"// The maximum number of dirty data records allowed.
    },
    "speed":{
      "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
      "concurrent":1 // The maximum number of concurrent threads.
    }
  },
  "order":{
    "hops":[
      {
        "from":"Reader",
        "to":"Writer"
      }
```

```
      ]
    }
}
```

Additional instructions

- Column filter

  By configuring MaxCompute Writer, you can perform operations that MaxCompute does not support, for example, filter columns, reorder columns, and set empty fields to null. To write data to all the columns in the destination table, set the column parameter in the format `"column":["*"]`.

  For example, a MaxCompute table has three columns: a, b, and c. If you want to write data only to column c and column b, you can set the column parameter in the format `"column":["c","b"]`. The first column and the second column of the source data are written to column c and column b in the MaxCompute table respectively. During data synchronization, column a is automatically set to null.

- Column configuration error handling

  To avoid losing the data of redundant columns and ensure high data reliability, MaxCompute Writer returns an error message if the number of columns to be written is more than that in the destination table. For example, if a MaxCompute table contains columns a, b, and c, MaxCompute Writer returns an error message if more than three columns are to be written to the table.

- Partition configuration

  MaxCompute Writer can write data only to the last-level partition, and cannot write data to the specified partition based on a field. To write data to a partitioned table, specify the last-level partition. For example, if you want to write data to a three-level partitioned table, set the partition parameter to a value that contains the third-level partition information, for example, `pt=20150101, type=1, biz=2`. The data cannot be written if you set the partition parameter to `pt=20150101, type=1` or `pt=20150101`.

- Node rerunning

  To ensure the idempotence of write operations, set the `truncate` parameter to true. When a failed sync node is rerun due to a write failure, MaxCompute Writer deletes the data that has been written before it imports the source data again. This ensures that the same data is written for each rerun. If a sync node is interrupted due to other exceptions, the data cannot be rolled back and the node cannot be rerun automatically. You can ensure the idempotence of write operations and the data integrity By setting the truncate parameter to true.

  > **Note** If the truncate parameter is set to true, all data of the specified partition or table is deleted before a rerun. Exercise caution when you set this parameter to true.

2.4.5.4.10. Configure Memcache Writer

This topic describes the data types and parameters supported by Memcache Writer and how to configure it by using the code editor.

ApsaraDB for Memcache is a distributed in-memory database service with high performance, reliability, and scalability. Based on the Apsara distributed operating system and high-performance storage technologies, ApsaraDB for Memcache provides a complete database solution with hot standby, fault recovery, business monitoring, and data migration features.

ApsaraDB for Memcache is immediately available after an instance is created. It relieves the load on databases from dynamic websites and applications by caching data in the memory and therefore improves the response speed of websites and applications.

Same as on-premises Memcached databases, ApsaraDB for Memcache databases are compatible with the Memcached protocol. ApsaraDB for Memcache databases can be directly used in your environments. The difference is that the data, hardware infrastructure, network security, and system maintenance services used by ApsaraDB for Memcache databases are all deployed in the cloud. These services are billed based on the pay-as-you-go billing method.

Memcache Writer writes data to ApsaraDB for Memcache databases based on the Memcached protocol.

Memcache Writer writes data only in text format. The method of converting data types varies based on the format of writing data.

- text: Memcache Writer uses the specified column delimiter to serialize source data to a string.
- binary: This format is not supported.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
writeMode	The write mode. Valid values: • *set*: stores the source data. • *add*: stores the source data only when its key does not exist in the destination ApsaraDB for Memcache database. This mode is not supported now. • *replace*: uses the source data to replace the data record with the same key in the destination ApsaraDB for Memcache database. This mode is not supported now. • *append*: adds the value of the source data to the end of the value of an existing data record with the same key in the destination ApsaraDB for Memcache database, but does not update the expiration time of the existing data record. This mode is not supported now. • *prepend*: adds the value of the source data to the beginning of the value of an existing data record with the same key in the destination ApsaraDB for Memcache database, but does not update the expiration time of the existing data record. This mode is not supported now.	Yes	None

Parameter	Description	Required	Default value
writeFormat	The format in which Memcache Writer writes the source data. Currently, only the text format is supported. text: serializes the source data to the text format. Memcache Writer uses the first column of the source data as the key and serializes the subsequent columns to the value by using the specified delimiter. Then, Memcache Writer writes the key-value pair to ApsaraDB for Memcache. Assume that the following source data exists: `| ID | NAME | COUNT|` `| ---- |:------|:-----|` `| 23 | "CDP" | 100 |` If you set the column delimiter to a backslash and a caret (\^), data is written to ApsaraDB for Memcache in the following format: `| KEY (OCS) | VALUE(OCS) |` `| --------- |:---------- |` `| 23 | CDP\^100 |`	No	None
expireTime	The expiration time of the source data to be cached in ApsaraDB for Memcache. ApsaraDB for Memcache supports the following two types of expiration time: • unixtime: the UNIX timestamp, indicating a specific time point in the future when the data expires. The UNIX timestamp represents the number of seconds that have elapsed since 00:00:00 on January 1, 1970. • seconds: the relative time in seconds starting from the current time point. It specifies the period during which data is valid. Note If the specified time exceeds 30 days, the server identifies the time as the UNIX timestamp.	No	*0*, indicating that the data never expires
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the ApsaraDB for Memcache database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	*1,024*

Configure Memcache Writer by using the codeless UI

The codeless UI is not supported for Memcache Writer.

Configure Memcache Writer by using the code editor

In the following code, a node is configured to write data to an ApsaraDB for Memcache database.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"ocs",// The writer type.
      "parameter":{
        "writeFormat":"text",// The format in which Memcache Writer writes the source data.
        "expireTime":1000,// The expiration time of the source data to be cached in ApsaraDB for Memcache.
        "indexes":0,
        "datasource":"",// The connection name.
        "writeMode":"set",// The write mode.
        "batchSize":"256"// The number of data records to write at a time.
      },
      "name":"Writer",
      "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
      "record":"0" // The maximum number of dirty data records allowed.
    },
    "speed":{
      "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
      "concurrent":1 // The maximum number of concurrent threads.
    }
  },
  "order":{
```

```
    "hops":[
      {
        "from":"Reader",
        "to":"Writer"
      }
    ]
  }
}
```

2.4.5.4.11. Configure MongoDB Writer

This topic describes the data types and parameters supported by MongoDB Writer and how to configure it by using the code editor.

MongoDB Writer connects to a remote MongoDB database by using the Java client named MongoClient and writes data to the database. The latest version of MongoDB has improved the locking feature from database locks to document locks. The powerful index functionalities of MongoDB enable MongoDB Writer to efficiently write data to MongoDB databases. If you want to update data, specify the primary key.

> Note
> - You must configure a connection before you configure MongoDB Writer.
> - If you use ApsaraDB for MongoDB, the MongoDB database has a root account by default.
> - For security concerns, Data Integration only supports access to a MongoDB database by using a MongoDB database account. When you add a MongoDB connection, do not use the root account for access.

MongoDB Writer obtains data from a Data Integration reader, and converts the data types to those supported by MongoDB. Data Integration does not support arrays. MongoDB supports arrays and the array index is useful.

To use MongoDB arrays, you can convert strings to MongoDB arrays by configuring a parameter and write the arrays to a MongoDB database.

Data types

MongoDB Writer supports most MongoDB data types. Make sure that your data types are supported.

The following table lists the data types supported by MongoDB Writer.

Category	MongoDB data type
Integer	INT and LONG
Floating point	DOUBLE
String	STRING and ARRAY

Category	MongoDB data type
Date and time	DATE
Boolean	BOOL
Binary	BYTES

Note When data of the DATE type is written to a MongoDB database, the type of the data is converted to DATETIME.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
collectionName	The name of the MongoDB collection.	Yes	None
column	The columns in MongoDB. • name: the name of the column. • type: the data type of the column. • splitter: the delimiter. Specify this field only when you want to convert the string to an array. The string is split based on the specified delimiter, and the split strings are saved in a MongoDB array.	Yes	None
writeMode	Specifies whether to overwrite data. • isReplace: If you set this parameter to true, MongoDB Writer overwrites the data in the destination table with the same primary key. If you set this parameter to false, the data is not overwritten. • replaceKey: the primary key for each record. Data is overwritten based on this primary key. The primary key must be unique.	No	None
	The action to perform before the sync node is run. For example, you can clear outdated data before data synchronization. If the preSql parameter is left empty, no action is performed before data synchronization. Make sure that the value of the preSql parameter complies with the JSON syntax. The format requirements for the preSql parameter are as follows: • Configure the type field to specify the action type. Valid values: drop and remove. Example: `"preSql":{"type":"remove"}` .		

Parameter	Description	Required	Default value
preSql	○ *drop*: deletes the collection specified by the collectionName parameter and the data in the collection. ○ *remove*: deletes data based on conditions. ○ *json*: the conditions for deleting data. Example: `"preSql":{"type":"remove", "json":"{'operationTime':{'$gte':ISODate('${last_day}T00:00:00.424+0800')}}"}`. In the preceding JSON string, `${last_day}` is a scheduling parameter of DataWorks. The format is `$[yyyy-mm-dd]`. You can use comparison operators (such as $gt, $lt, $gte, and $lte), logical operators (such as $and and $or), and functions (such as max, min, sum, avg, and ISODate) supported by MongoDB as needed. For more information, see the MongoDB query syntax. Data Integration uses the following standard MongoDB API to query and delete the specified data: `query=(BasicDBObject) com.mongodb.util.JSON.parse(json);` `col.deleteMany(query);` Note If you want to delete data based on conditions, we recommend that you specify the conditions in JSON format preferentially. ○ *item*: the name, condition, and value for filtering data. Example: `"preSql":{"type":"remove","item":[{"name":"pv","value":"100","condition":"$gt"},{"name":"pid","value":"10"}]}`. Data Integration sets query conditions based on the value of the item field and deletes data by using the standard MongoDB API. Example: `col.deleteMany(query);`. • If the value of the preSql parameter cannot be recognized, no action is performed.	No	None

Parameter	Description	Required	Default value

Configure MongoDB Writer by using the codeless UI

The codeless UI is not supported for MongoDB Writer.

Configure MongoDB Writer by using the code editor

In the following code, a node is configured to write data to a MongoDB database. For more information about the parameters, see the preceding parameter description.

```
{
  "type": "job",
  "version": "2.0",// The version number.
  "steps": [
    {
      "stepType": "stream",
      "parameter": {},
      "name": "Reader",
      "category": "reader"
    },
    {
      "stepType": "mongodb",// The writer type.
      "parameter": {
        "datasource": "",// The connection name.
        "column": [
          {
            "name": "_id",// The name of the column to which data is written.
            "type": "ObjectId"// The data type of the column to which data is written. If the replaceke
y parameter is set to _id, set the type parameter to ObjectId. If you set the type parameter to String, t
he data cannot be overwritten.
          },
          {
            "name": "age",
            "type": "int"
          },
          {
            "name": "id",
            "type": "long"
          },
          {
            "name": "wealth",
            "type": "double"
```

```
            },
            {
              "name": "hobby",
              "type": "array",
              "splitter": " "
            },
            {
              "name": "valid",
              "type": "boolean"
            },
            {
              "name": "date_of_join",
              "format": "yyyy-MM-dd HH:mm:ss",
              "type": "date"
            }
          ],
          "writeMode": {// The write mode.
            "isReplace": "true",
            "replaceKey": "_id"
          },
          "collectionName": "datax_test"// The name of the MongoDB collection.
        },
        "name": "Writer",
        "category": "writer"
      }
    ],
    "setting": {
      "errorLimit": {// The maximum number of dirty data records allowed.
        "record": "0"
      },
      "speed": {
        "jvmOption": "-Xms1024m -Xmx1024m",
        "throttle": true,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
        "concurrent":1,// The maximum number of concurrent threads.
        "mbps": "1"// The maximum transmission rate.
      }
    },
    "order": {
      "hops": [
```

```
      "hops": [
        {
          "from": "Reader",
          "to": "Writer"
        }
      ]
    }
}
```

2.4.5.4.12. Configure MySQL Writer

This topic describes the data types and parameters supported by MySQL Writer and how to configure it by using the codeless UI and code editor.

MySQL Writer allows you to write data to tables stored in MySQL databases. MySQL Writer connects to a remote MySQL database by using JDBC, and executes the `INSERT INTO` or `REPLACE INTO` statement to write data to the MySQL database. MySQL uses the InnoDB engine so that data is written to the database in batches.

> **Note**
> - You must configure a connection before you configure MySQL Writer.
> - MySQL Writer does not support MySQL 8.0 or later.

MySQL Writer can be used as a data migration tool by users such as DBAs. MySQL Writer obtains data from a Data Integration reader, and writes the data to the destination database based on value of the writeMode parameter.

> **Note** A sync node that uses MySQL Writer must have at least the permission to execute the `INSERT INTO or REPLACE INTO` statement. Whether other permissions are required depends on the SQL statements specified in the preSql and postSql parameters when you configure the node.

Data types

MySQL Writer supports most MySQL data types. Make sure that your data types are supported.

The following table lists the data types supported by MySQL Writer.

Category	MySQL data type
Integer	INT, TINYINT, SMALLINT, MEDIUMINT, BIGINT, and YEAR
Floating point	FLOAT, DOUBLE, and DECIMAL
String	VARCHAR, CHAR, TINYTEXT, TEXT, MEDIUMTEXT, and LONGTEXT
Date and time	DATE, DATETIME, TIMESTAMP, and TIME

Category	MySQL data type
Boolean	BOOL
Binary	TINYBLOB, MEDIUMBLOB, BLOB, LONGBLOB, and VARBINARY

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the destination table.	Yes	None
writeMode	The write mode. Valid values: • *insert into*: If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows and is regarded as dirty data. • *on duplicate key update*: If no primary key conflict or unique index conflict occurs, the action is the same as that of `insert into`. If a conflict occurs, specified fields in original rows are updated. • *replace into*: If no primary key conflict or unique index conflict occurs, the action is the same as that of `insert into`. If a conflict occurs, original rows are deleted and new rows are inserted. This means that all the field values of the original rows are replaced.	No	*insert*
column	The columns in the destination table to which data is written. Separate the columns with commas (,), for example, `"column":["id","name","age"]`. To write data to all the columns in the destination table, set the value to an asterisk (*), for example, `"column":["*"]`.	Yes	None
preSql	The SQL statement to execute before the sync node is run. For example, you can clear outdated data before data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor. **Note** If you specify multiple SQL statements in the code editor, the system may not execute them in the same transaction.	No	None

Parameter	Description	Required	Default value
postSql	The SQL statement to execute after the sync node is run. For example, you can add a timestamp after data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor. Note If you specify multiple SQL statements in the code editor, the system may not execute them in the same transaction.	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the MySQL database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	*1,024*

Configure MySQL Writer by using the codeless UI

1. Configure the connections.

   Configure the connections to the source and destination data stores for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Statement Run Before Writing	The preSql parameter in the preceding parameter description. Enter an SQL statement to execute before the sync node is run.
Statement Run After Writing	The postSql parameter in the preceding parameter description. Enter an SQL statement to execute after the sync node is run.
Solution to Primary Key Violation	The writeMode parameter in the preceding parameter description. Select the required write mode.

2. Configure field mapping. It is equivalent to setting the column parameter in the preceding parameter description. Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right.

GUI element	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.

GUI element	Description
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout to sort the fields based on specified rules.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure MySQL Writer by using the code editor

In the following code, a node is configured to write data to a MySQL database. For more information about the parameters, see the preceding parameter description.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"mysql",// The writer type
```

```
        "stepType" : "mysql",// The writer type.
        "parameter":{
          "postSql":[],// The SQL statement to execute after the sync node is run.
          "datasource":"",// The connection name.
          "column":[// The columns to which data is written.
            "id",
            "value"
          ],
          "writeMode":"insert",// The write mode.
          "batchSize":1024,// The number of data records to write at a time.
          "table":"",// The name of the destination table.
          "preSql":[]// The SQL statement to execute before the sync node is run.
        },
        "name":"Writer",
        "category":"writer"
      }
    ],
    "setting":{
      "errorLimit":{// The maximum number of dirty data records allowed.
        "record":"0"
      },
      "speed":{
        "throttle":false,// Specifies whether to enable bandwidth throttling.
        "concurrent":1 // The maximum number of concurrent threads.
      }
    },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
        }
      ]
    }
}
```

2.4.5.4.13. Configure Oracle Writer

This topic describes the data types and parameters supported by Oracle Writer and how to configure it by using the codeless UI and code editor.

Oracle Writer allows you to write data to tables stored in primary Oracle databases. Oracle Writer connects to a remote Oracle database by using JDBC, and executes an `INSERT INTO` statement to write data to the Oracle database.

> **Note** You must configure a connection before you configure Oracle Writer.

Oracle Writer is designed for ETL developers to import data from data warehouses to Oracle databases. Oracle Writer can also be used as a data migration tool by users such as DBAs.

Oracle Writer obtains data from a Data Integration reader, connects to a remote Oracle database by using JDBC, and then executes an SQL statement to write data to the Oracle database.

Data types

Oracle Writer supports most Oracle data types. Make sure that your data types are supported.

The following table lists the data types supported by Oracle Writer.

Category	Oracle data type
Integer	NUMBER, ROWID, INTEGER, INT, and SMALLINT
Floating point	NUMERIC, DECIMAL, FLOAT, DOUBLE PRECISION, and REAL
String	LONG, CHAR, NCHAR, VARCHAR, VARCHAR2, NVARCHAR2, CLOB, NCLOB, CHARACTER, CHARACTER VARYING, CHAR VARYING, NATIONAL CHARACTER, NATIONAL CHAR, NATIONAL CHARACTER VARYING, NATIONAL CHAR VARYING, and NCHAR VARYING
Date and time	TIMESTAMP and DATE
Boolean	BIT and BOOLEAN
Binary	BLOB, BFILE, RAW, and LONG RAW

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the destination table.	Yes	None

Parameter	Description	Required	Default value
writeMode	The write mode. Valid values: *insert into*, *on duplicate key update*, and *replace into*. • *insert into*: If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows and is regarded as dirty data. • *on duplicate key update*: If no primary key conflict or unique index conflict occurs, the action is the same as that of `insert into`. If a conflict occurs, specified fields in original rows are updated. • *replace into*: If no primary key conflict or unique index conflict occurs, the action is the same as that of `insert into`. If a conflict occurs, original rows are deleted and new rows are inserted. This means that all the field values of the original rows are replaced.	No	*insert*
column	The columns in the destination table to which data is written. Separate the columns with commas (,), for example, `"column":["id","name","age"]`. To write data to all the columns in the destination table, set the value to an asterisk (*), for example, `"column":["*"]`.	Yes	None
preSql	The SQL statement to execute before the sync node is run. For example, you can clear outdated data before data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	None
postSql	The SQL statement to execute after the sync node is run. For example, you can add a timestamp after data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the Oracle database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	*1,024*

Configure Oracle Writer by using the codeless UI

1. Configure the connections.

   Configure the connections to the source and destination data stores for the sync node.

Parameter	Description

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Statement Run Before Writing	The preSql parameter in the preceding parameter description. Enter an SQL statement to execute before the sync node is run.
Statement Run After Writing	The postSql parameter in the preceding parameter description. Enter an SQL statement to execute after the sync node is run.

2. Configure field mapping. It is equivalent to setting the column parameter in the preceding parameter description. Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right.

GUI element	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout to sort the fields based on specified rules.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Parameter	Description
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure Oracle Writer by using the code editor

In the following code, a node is configured to write data to an Oracle database.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"oracle",// The writer type.
      "parameter":{
        "postSql":[],// The SQL statement to execute after the sync node is run.
        "datasource":"",
        "session":[],// The settings of the session to the database.
        "column":[// The columns to which data is written.
          "id",
          "name"
        ],
        "encoding":"UTF-8",// The encoding format.
        "batchSize":1024,// The number of data records to write at a time.
        "table":"",// The name of the destination table.
        "preSql":[]// The SQL statement to execute before the sync node is run.
      },
      "name":"Writer",
      "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
```

```
            "record":"0"// The maximum number of dirty data records allowed.
        },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
            "concurrent":1 // The maximum number of concurrent threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.4.5.4.14. Configure OSS Writer

This topic describes the data types and parameters supported by OSS Writer and how to configure it by using the codeless UI and code editor.

OSS Writer allows you to write one or more CSV-like files to OSS.

> **Note** You must configure a connection before you configure OSS Writer.

OSS Writer can write files that store logical two-dimensional tables, such as CSV files that store text data, to OSS.

OSS Writer allows you to convert data obtained from a Data Integration reader to files and write the files to OSS. The OSS files store unstructured data only. OSS Writer supports the following features:

- Writes only files that store text data. The text data must be logical two-dimensional tables.
- Writes CSV-like files with custom delimiters.
- Uses concurrent threads to write files. Each thread writes a file.
- Supports file rotation. OSS Writer can write data to another file when the size of the current file exceeds a specific value. OSS Writer can also write data to another file when the number of rows in the current file exceeds a specific value.

OSS Writer does not support the following features:

- Uses concurrent threads.to write a single file.
- Distinguishes between data types. OSS does not distinguish between data types. Therefore,

OSS Writer writes all data as strings to files in OSS.

The following table lists the data types supported by OSS Writer.

Category	OSS data type
Integer	LONG
Floating point	DOUBLE
String	STRING
Boolean	BOOLEAN
Date and time	DATE

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
object	The name prefix of the files to be written to OSS as objects. OSS simulates the directory effect by adding separators to object names. You can set the object parameter based on the following rules: • `"object": "datax"`: The names of the files start with datax, which is followed by a random string as the suffix. • `"object": "cdo/datax"`: The names of the files start with `/cdo/datax`, which is followed by a random string as the suffix. OSS uses backslashes (/) in objects to simulate the directory effect. If you do not want to add a random universally unique identifier (UUID) as the suffix, we recommend that you set the writeSingleObject parameter to `true`.	Yes	None

Parameter	Description	Required	Default value
writeMode	The mode in which OSS Writer writes the files. Valid values: • *truncate*: deletes all existing objects with the specified object name prefix before writing files to OSS. For example, if you set the object parameter to `abc`, all objects whose names start with abc are deleted. • *append*: writes all files and ensures that the actual file names do not conflict with those of existing objects by suffixing the file names with random UUIDs. For example, if you set the object parameter to DI, the actual names of the files written to OSS are in the following format: DI_****_****_****. • *nonConflict*: returns an error message if an object with the specified object name exists. For example, if you set the `object` parameter to abc and the object named abc123 exists, an error message is returned.	Yes	None
fileFormat	The format in which the files are written to OSS. Valid values: csv and text. • If a file is written as a CSV file, the file strictly follows CSV specifications. If the data in the file contains the column delimiter, the column delimiter is escaped by using double quotation marks (" "). • If a file is written as a text file, the data in the file is separated with the column delimiter. If the data in the file contains the column delimiter, the column delimiter is not escaped.	No	*text*
fieldDelimiter	The column delimiter that is used in the files to be written to OSS.	No	,
encoding	The encoding format of the files to be written to OSS.	No	*utf-8*
nullFormat	The string that represents null. No standard strings can represent null in text files. Therefore, Data Integration provides the nullFormat parameter to define which string represents a null pointer. For example, if you specify `nullFormat="null"`, Data Integration considers null as a null pointer.	No	None
header (advanced parameter, which cannot be set on the codeless UI)	The table header in the files to be written to OSS, for example, ['id','name','age'].	No	None

Parameter	Description	Required	Default value
maxFileSize (advanced parameter, which cannot be set on the codeless UI)	The maximum size of a single file that can be written to OSS. Default value: 100000. Unit: MB. File rotation based on this maximum size is similar to log rotation of Log4j. When a file is uploaded to OSS in multiple parts, the minimum size of a part is 10 MB. This size is the minimum granularity for file rotation. That is, if you set the maxFileSize parameter to less than 10 MB, the minimum size of a file is still 10 MB. Each call of the InitiateMultipartUploadRequest operation supports writing up to 10,000 parts. If file rotation occurs, suffixes, such as _1, _2, and _3, are appended to the new file names that consist of file name prefixes and random UUIDs.	No	100,000MB
suffix (advanced parameter, which cannot be set on the codeless UI)	The file name extension of the files to be written to OSS. For example, if you set the suffix parameter to .csv, the final name of a file written to OSS is in the format fileName****.csv.	No	None

Configure OSS Writer by using the codeless UI

1. Configure the connections.

   Configure the connections to the source and destination data stores for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Object Name Prefix	The object parameter in the preceding parameter description. Enter the path of the directory for storing the files. Do not include the name of the OSS bucket in the path.
File Type	The fileFormat parameter in the preceding parameter description. Valid values: *csv* and *text*.
Field Delimiter	The fieldDelimiter parameter in the preceding parameter description. The default delimiter is comma (,).
Encoding	The encoding parameter in the preceding parameter description. Default value: *UTF-8*.

Parameter	Description
Null String	The nullFormat parameter in the preceding parameter description. Enter a string that represents null. If the data in the source data store contains the string, the string is replaced with null.
Time Format	The format in which the data of the DATE type is serialized in an object, for example, `"dateFormat": "yyyy-MM-dd"`.
Solution to Duplicate Prefixes	The solution to take when a prefix conflict occurs. If an object with the specified name prefix exists, replace the object with the new object, insert the new object, or return an error message.

2. Configure field mapping. Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right.

GUI element	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Parameter	Description
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure OSS Writer by using the code editor

In the following code, a node is configured to write files to OSS. For more information about the parameters, see the preceding parameter description.

```
{
  "type":"job",
  "version":"2.0",
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"oss",// The writer type.
      "parameter":{
        "nullFormat":"",// The string that represents null.
        "dateFormat":"",// The format in which the data of the DATE type is serialized in an object.
        "datasource":"",// The connection name.
        "writeMode":"",// The write mode.
        "encoding":"",// The encoding format.
        "fieldDelimiter":","// The column delimiter.
        "fileFormat":"",// The format in which the files are written to OSS.
        "object":""// The name prefix of the files to be written to OSS as objects.
      },
      "name":"Writer",
      "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
      "record":"0"// The maximum number of dirty data records allowed.
    },
```

```
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
            "concurrent":1 // The maximum number of concurrent threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.4.5.4.15. Configure PostgreSQL Writer

This topic describes the data types and parameters supported by PostgreSQL Writer and how to configure it by using the codeless UI and code editor.

PostgreSQL Writer allows you to write data to a PostgreSQL database. PostgreSQL Writer connects to a remote PostgreSQL database by using JDBC, and executes an SQL statement to write data to the PostgreSQL database.

> **Note** You must configure a connection before you configure PostgreSQL Writer.

- PostgreSQL Writer generates the SQL statement based on the table, column, and where parameters that you specified, and sends the generated SQL statement to the PostgreSQL database.
- If you specify the querySql parameter, PostgreSQL Writer directly sends the value of this parameter to the PostgreSQL database.

Data types

PostgreSQL Writer supports most PostgreSQL data types. Make sure that your data types are supported.

The following table lists the data types supported by PostgreSQL Writer.

Data Integration data type	PostgreSQL data type
LONG	BIGINT, BIGSERIAL, INTEGER, SMALLINT, and SERIAL
DOUBLE	DOUBLE, PRECISION, MONEY, NUMERIC, and REAL

Data Integration data type	PostgreSQL data type
STRING	VARCHAR, CHAR, TEXT, BIT, and INET
DATE	DATE, TIME, and TIMESTAMP
BOOLEAN	BOOL
BYTES	BYTEA

Note

- Data types that are not listed in the table are not supported.
- You can convert the MONEY, INET, and BIT types by using syntax such as `a_inet::varchar`.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the destination table.	Yes	None
writeMode	The write mode. Valid values: insert and copy. • *insert*: executes the `INSERT INTO` statement to write data to the PostgreSQL database. If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows and is regarded as dirty data. We recommend that you select the insert mode. • *copy*: copies data between tables and the standard input or output file. Data Integration supports the `COPY FROM` command, which allows you to copy data from files to tables. We recommend that you try this mode when performance issues occur.	No	*insert*
column	The columns in the destination table to which data is written. Separate the columns with commas (,), for example, `"column":["id","name","age"]`. To write data to all the columns in the destination table, set the value to an asterisk (*), for example, `"column":["*"]`.	Yes	None

Parameter	Description	Required	Default value
preSql	The SQL statement to execute before the sync node is run. For example, you can clear outdated data before data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	None
postSql	The SQL statement to execute after the sync node is run. For example, you can add a timestamp after data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the PostgreSQL database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	*1,024*

Parameter	Description	Required	Default value
pgType	The PostgreSQL configuration for converting data types. Valid values: bigint[], double[], text[], jsonb, and json. Example: { "job": { "content": [{ "reader": {...}, "writer": { "parameter": { "column": [// The columns in the destination table to which data is written. "bigint_arr", "double_arr", "text_arr", "jsonb_obj", "json_obj"], "pgType": { // The PostgreSQL configuration for converting data types. In each key-value pair, the key specifies the name of a field in the destination table, and the value specifies the data type of the field. "bigint_arr": "bigint[]", "double_arr": "double[]", "text_arr": "text[]", "jsonb_obj": "jsonb", "json_obj": "json" }}] } } }] } }	No	None

Configure PostgreSQL Writer by using the codeless UI

1. Configure the connections.

Configure the connections to the source and destination data stores for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Statement Run Before Writing	The preSql parameter in the preceding parameter description. Enter an SQL statement to execute before the sync node is run.
Statement Run After Writing	The postSql parameter in the preceding parameter description. Enter an SQL statement to execute after the sync node is run.
Write Method	The writeMode parameter in the preceding parameter description. Valid values: *Insert* and *Copy*.

2. Configure field mapping. It is equivalent to setting the column parameter in the preceding parameter description. Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right.

Button	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout to sort the fields based on specified rules.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.

Parameter	Description
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure PostgreSQL Writer by using the code editor

In the following code, a node is configured to write data to a PostgreSQL database. For more information about the parameters, see the preceding parameter description.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"postgresql",// The writer type.
      "parameter":{
        "postSql":[],// The SQL statement to execute after the sync node is run.
        "datasource":"// The connection name.
          "col1",
          "col2"
        ],
        "table":"",// The name of the destination table.
        "preSql":[]// The SQL statement to execute before the sync node is run.
      },
      "name":"Writer",
      "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
      "record":"0"// The maximum number of dirty data records allowed.
```

```
    },
    "speed":{
      "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
      "concurrent":1 // The maximum number of concurrent threads.
    }
  },
  "order":{
    "hops":[
      {
        "from":"Reader",
        "to":"Writer"
      }
    ]
  }
}
```

2.4.5.4.16. Configure Redis Writer

Redis Writer is a writer that is developed based on the Data Integration framework. It can be used to import data from data stores such as data warehouses to Redis databases.

Redis is a network-enabled key-value storage system that is either in-memory or permanent. It supports logs and delivers high performance. It can be used as a database, cache, and message broker. Redis supports diverse data types for values, including STRING, LIST, SET, ZSET (sorted set), and HASH.

Redis Writer interacts with a Redis server by using Jedis. As a preferred Java client development kit provided by Redis, Jedis supports almost all the features of Redis.

> **Note**
>
> - You must configure a connection before you configure Redis Writer.
> - If you write values of the LIST type to Redis by using Redis Writer, the result of rerunning a sync node is not idempotent. If the data type of the values is LIST, you must manually clear the corresponding data on Redis when you rerun a sync node.

Parameters

Parameter	Description	Required	Default value

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
keyIndexes	The columns used as the key. The index of the first column is 0. For example, if you want to set the first and second columns of the source data as the key, set the keyIndexes parameter to [0,1]. Note After you specify the keyIndexes parameter, Redis Writer specifies the remaining columns as the value. If you do not want to synchronize all the columns, filter columns when you configure the reader.	Yes	None
keyFieldDelimiter	The delimiter used to separate keys when data is written to Redis. Example: key=key1\u0001id. If multiple keys need to be concatenated, this parameter is required. If only one key exists, this parameter is not required.	No	*\u0001*
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the Redis database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	*1,000*
expireTime	The expiration time of the values to be cached in Redis. Unit: seconds. The data is valid permanently if you do not specify this parameter. • *seconds*: the relative time in seconds starting from the current time point. It specifies the time range during which data is valid. • *unixtime*: the UNIX timestamp, indicating that data is invalid at a specific time point in the future. The UNIX timestamp represents the number of seconds that have elapsed since 00:00:00 on January 1, 1970. Note If the specified expiration time is larger than 30 days, the server identifies the time as the UNIX timestamp.	No	*0*, indicating that the values never expire
timeout	The timeout period to connect to Redis when data is written to Redis. Unit: milliseconds.	No	*30,000*
dateFormat	The format in which the data of the DATE type is written to Redis. Set the value to yyyy-MM-dd HH:mm:ss.	No	None

Parameter	Description	Required	Default value
writeMode	The write mode. Redis supports diverse data types for values, including STRING, LIST, SET, ZSET (sorted set), and HASH. Redis Writer allows you to write values of the preceding types to Redis. The value of the writeMode parameter varies based on the specified data type of the values. Note When you configure Redis Writer, you can choose only one of the five data types described in the following table. If you do not specify a data type, the data type is STRING by default.	No	*string*

The following table lists the data types supported by Redis Writer.

Type	Parameter	Description	Required
String "writeMode":{ "type": "string", "mode": "set", "valueFieldDelimiter": "\u0001" }	type	The data type of the values is STRING.	Yes
	mode	The mode in which data of the STRING type is written to Redis.	Yes. Valid value: set (overwrites the existing data).
	valueFieldDelimiter	This parameter is required if two or more columns are specified as the values. This parameter is not required if only one column is specified as the values. The delimiter used to separate values if the data is of the STRING type. Example: value1\u0001value2\u0001value3.	No. Default value: \u0001.

Type	Parameter	Description	Required
LIST "writeMode":{ "type": "list", "mode": "lpush|rpush", "valueFieldDelimiter": "\u0001" }	type	The data type of the values is LIST.	Yes
	mode	The mode in which data of the LIST type is written to Redis.	Yes. Valid values: lpush (stores the data at the leftmost of the list) and rpush (stores the data at the rightmost of the list).
	valueFieldDelimiter	The delimiter used to separate values if the data is of the STRING type. Example: value1\u0001value2\u0001value3.	No. Default value: *\u0001*.
SET "writeMode":{ "type": "set", "mode": "sadd", "valueFieldDelimiter": "\u0001" }	type	The data type of the values is SET.	Yes
	mode	The mode in which data of the SET type is written to Redis.	Yes. Valid value: sadd (stores the data to a set, or overwrites the existing data).
	valueFieldDelimiter	The delimiter used to separate values if the data is of the STRING type. Example: value1\u0001value2\u0001value3.	No. Default value: *\u0001*.

Type	Parameter	Description	Required
ZSET (sorted set) "writeMode":{ "type": "zset", "mode": "zadd " }	type	The data type of the values is ZSET. Note If the data type of the values is ZSET, each data record must follow the following standard: Except for the key, a data record can contain only one score and one value. The score must be placed before the value. In this way, Redis Writer can identify which column is the score and which column is the value.	Yes
	mode	The mode in which data of the ZSET type is written to Redis.	Yes. Valid value: zadd (stores data to a sorted set, or overwrites the existing data).

Type	Parameter	Description	Required
HASH "writeMode":{ "type": "hash", "mode": "hset" }	type	The data type of the values is HASH. Note If the data type of the values is HASH, each data record must follow the following standards: Except for the key, a data record can contain only one attribute and one value. The attribute must be placed before the value. In this way, Redis Writer can identify which column is the attribute and which column is the value.	Yes
	mode	The mode in which data of the HASH type is written to Redis.	Yes. Valid value: hmset (stores data to a hash sorted set, or overwrites the existing data). If you do not specify a data type, the data type is STRING by default.

Configure Redis Writer by using the codeless UI

The codeless UI is not supported for Redis Reader.

Configure Redis Writer by using the code editor

In the following code, a node is configured to write data to Redis. For more information about parameters, see the preceding parameter description.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
```

```
        "parameter":{},
        "name":"Reader",
        "category":"reader"
      },
      {
        "stepType":"redis",// The writer type.
        "parameter":{
          "expireTime":{// The expiration time of the values to be cached in Redis.
            "seconds":"1000"
          },
          "keyFieldDelimiter":"u0001",// The delimiter used to separate keys when data is written to Redis.
          "dateFormat":"yyyy-MM-dd HH:mm:ss",// The format in which the data of the DATE type is written to Redis.
          "datasource":"",// The connection name.
          "writeMode":{// The write mode.
            "mode":"",// The write mode used to write data of a specified data type.
            "valueFieldDelimiter":"",// The delimiter used to separate values.
            "type":""// The data type of the values.
          },
          "keyIndexes":[// The columns used as the key.
            0,
            1
          ],
          "batchSize":"1000"// The number of data records to write at a time.
        },
        "name":"Writer",
        "category":"writer"
      }
    ],
    "setting":{
      "errorLimit":{
        "record":"0"// The maximum number of dirty data records allowed.
      },
      "speed":{
        "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
        "concurrent":1 // The maximum number of concurrent threads.
      }
    },
```

```
  },
  "order":{
    "hops":[
      {
        "from":"Reader",
        "to":"Writer"
      }
    ]
  }
}Writer"
      }
    ]
  }
}
```

2.4.5.4.17. Configure SQL Server Writer

This topic describes the data types and parameters supported by SQL Server Writer and how to configure it by using the codeless UI and code editor.

SQL Server Writer allows you to write data to tables stored in primary SQL Server databases. SQL Server Writer connects to a remote SQL Server database by using JDBC, and executes an `INSERT INTO` statement to write data to the SQL Server database. Internally, data is submitted to the database in batches.

SQL Server Writer is designed for ETL developers to import data from data warehouses to SQL Server databases. SQL Server Writer can also be used as a data migration tool by users such as DBAs.

SQL Server Writer obtains data from a Data Integration reader, and generates the `INSERT INTO` statement. If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows. To improve performance, SQL Server Writer makes batch updates with the `PreparedStatement` method and sets `rewriteBatchedStatements` to true. In this way, SQL Server Writer buffers data, and submits a write request when the amount of data in the buffer reaches a specific threshold.

> **Note**
>
> - Data can be written only to tables stored in the primary SQL Server database.
> - A sync node that uses SQL Server Writer must have at least the permission to execute the INSERT INTO statement. Whether other permissions are required depends on the SQL statements specified in the preSql and postSql parameters when you configure the node.

Data types

SQL Server Writer supports most SQL Server data types. Make sure that your data types are supported.

The following table lists the data types supported by SQL Server Writer.

Category	SQL Server data type
Integer	BIGINT, INT, SMALLINT, and TINYINT
Floating point	FLOAT, DECIMAL, REAL, and NUMERIC
String	CHAR, NCHAR, NTEXT, NVARCHAR, TEXT, VARCHAR, NVARCHAR (MAX), and VARCHAR (MAX)
Date and time	DATE, TIME, and DATETIME
Boolean	BIT
Binary	BINARY, VARBINARY, VARBINARY (MAX), and TIMESTAMP

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the destination table.	Yes	None
column	The columns in the destination table to which data is written. Separate the columns with commas (,). Example: `"column": ["id","name","age"]`. To write data to all the columns in the destination table, set the value to an asterisk (*), for example, `"column":["*"]`.	Yes	None
preSql	The SQL statement to execute before the sync node is run. For example, you can clear outdated data before data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	None
postSql	The SQL statement to execute after the sync node is run. For example, you can add a timestamp after data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	None
writeMode	The write mode. Valid value: *insert*. When a data record violates the primary key constraint or unique index constraint, Data Integration considers it dirty and retains the original data.	No	*insert*

Parameter	Description	Required	Default value
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the SQL Server database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	*1,024*

Configure SQL Serve Writer by using the codeless UI

1. Configure the connections.

   Configure the connections to the source and destination data stores for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Statement Run Before Writing	The preSql parameter in the preceding parameter description. Enter an SQL statement to execute before the sync node is run.
Statement Run After Writing	The postSql parameter in the preceding parameter description. Enter an SQL statement to execute after the sync node is run.
Solution to Primary Key Violation	The writeMode parameter in the preceding parameter description. Select the required write mode.

2. Configure field mapping. It is equivalent to setting the column parameter in the preceding parameter description.

   Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right. You can click **Add** to add a field, or move the pointer over a field and click the **Delete** icon to delete the field.

GUI element	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout to sort the fields based on specified rules.

GUI element	Description
Change Fields	Click the Change Fields icon. In the Change Fields dialog box, you can manually edit fields in the source table. Each field occupies a row. The first and the last blank rows are included, whereas other blank rows are ignored.
Add	○ Click Add to add a field. You can enter constants. Each constant must be enclosed in single quotation marks (' '), for example, 'abc' and '123'. ○ You can use scheduling parameters such as ${bizdate}. ○ You can enter functions supported by relational databases, for example, now() and count(1). ○ If the value you entered cannot be parsed, the type is displayed as Unidentified.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure SQL Server Writer by using the code editor

In the following code, a node is configured to write data to an SQL Server database. For more information about the parameters, see the preceding parameter description.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{}
```

```
        "parameter":{},
        "name":"Reader",
        "category":"reader"
      },
      {
        "stepType":"sqlserver",// The writer type.
        "parameter":{
          "postSql":[],// The SQL statement to execute after the sync node is run.
          "datasource":"",// The connection name.
          "column":[// The columns to which data is written.
            "id",
            "name"
          ],
          "table":"",// The name of the destination table.
          "preSql":[]// The SQL statement to execute before the sync node is run.
        },
        "name":"Writer",
        "category":"writer"
      }
    ],
    "setting":{
      "errorLimit":{
        "record":"0"// The maximum number of dirty data records allowed.
      },
      "speed":{
        "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
        "concurrent":1 // The maximum number of concurrent threads.
      }
    },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
        }
      ]
    }
}
```

2.4.5.4.18. Configure Elasticsearch Writer

This topic describes the data types and parameters supported by Elasticsearch Writer and how to configure it by using the code editor.

Elasticsearch is an open-source product that complies with the Apache open standards. It is the mainstream search engine for enterprise data. Elasticsearch is a Lucene-based data search and analysis tool that provides distributed services. The mappings between Elasticsearch core concepts and database core concepts are as follows:

```
Relational database (instance) -> database -> table -> row -> column
Elasticsearch -> index -> type -> document -> field
```

Elasticsearch can contain multiple indexes (databases). Each index can contain multiple types (tables). Each type can contain multiple documents (rows). Each document can contain multiple fields (columns). Elasticsearch Writer uses the RESTful API of Elasticsearch to write multiple data records retrieved by a reader to Elasticsearch at a time.

Parameters

Parameter	Description	Required	Default value
endpoint	The endpoint for accessing Elasticsearch, in the format of `http://xxxx.com:9999`.	No	None
accessId	The AccessKey ID for accessing Elasticsearch, which is used for authorization when a connection with Elasticsearch is established. **Note** The accessId and accessKey parameters are required. If you do not set the parameters, an error is returned. If you use on-premises Elasticsearch for which basic authentication is not configured, the AccessKey ID and AccessKey secret are not required. In this case, you can set the accessId and accessKey parameters to random values.	No	None
accessKey	The AccessKey secret for accessing Elasticsearch.	No	None
index	The index name in Elasticsearch.	No	None
indexType	The type name in the index of Elasticsearch.	No	*Elasticsearch*
cleanup	Specifies whether to clear existing data in the index. The method used to clear the data is to delete and rebuild the corresponding index. The default value false indicates that the existing data in the index is retained.	No	*false*

Parameter	Description	Required	Default value
batchSize	The number of data records to write at a time.	No	*1000*
trySize	The number of retries after a failure.	No	*30*
timeout	The connection timeout of the client. Unit: milliseconds.	No	*600000*
discovery	Specifies whether to enable Node Discovery. When Node Discovery is enabled, the server list in the client is polled and regularly updated.	No	*false*
compression	Specifies whether to enable compression for an HTTP request.	No	*true*
multiThread	Specifies whether to use multiple threads for an HTTP request.	No	*true*
ignoreWriteError	Specifies whether to ignore write errors and proceed with writing without retries.	No	*false*
ignoreParseError	Specifies whether to ignore format parsing errors and proceed with writing.	No	*true*
alias	The alias of the index. The alias feature of Elasticsearch is similar to the view feature of a traditional database. For example, if you create an alias named my_index_alias for the index my_index, the operations on my_index_alias also take effect on my_index. Configuring alias means that after the data import is completed, an alias is created for the specified index.	No	None
aliasMode	The mode in which an alias is added after the data is imported. Valid values: *append* and *exclusive*.	No	append

Parameter	Description	Required	Default value
settings	The delimiter (-,-) for splitting the source data if you are inserting an array to Elasticsearch. Example: The source column stores data `a-,-b-,-c-,-d` of the String type. Elasticsearch Writer uses the delimiter (-,-) to split the source data and obtains the array `["a", "b", "c", "d"]`. Then, Elasticsearch Writer writes the array to the corresponding field in Elasticsearch.	No	-,-
	The fields of the document. The parameters for each field include basic parameters such as name and type and advanced parameters such as analyzer, format, and array. The field types supported by Elasticsearch are as follows:		

Parameter	Description	Required	Default value
column	- id // The id type corresponds to the _id type in Elasticsearch, and can be considered as the unique primary key. Data with the same ID will be overwritten and not indexed. - string - text - keyword - long - integer - short - byte - double - float - date - boolean - binary - integer_range - float_range - long_range - double_range - date_range - geo_point - geo_shape - ip - token_count - array - object - nested • When the field type is Text, you can specify the analyzer, norms, and index_options parameters. Example: `{ "name": "col_text", "type": "text", "analyzer": "ik_max_word" }` • When the field type is date, you can specify the format and timezone parameters, indicating the date serialization format and the time zone, respectively. Example:	Yes	None

Parameter	Description	Required	Default value
	{ "name": "col_date", "type": "date", "format": "yyyy-MM-dd HH:mm:ss", "timezone": "UTC" } • When the field type is ge_shape, you can specify the tree (geohash or quadtree) and precision parameters. Example: { "name": "col_geo_shape", "type": "geo_shape", "tree": "quadtree", "precision": "10m" }		
dynamic	Specifies whether to use the mapping configuration of Elasticsearch. A value of *true* indicates that the mapping configuration of Elasticsearch, instead of the mapping configuration of Data Integration, is used.	No	*false*
	If you specify the array parameter for a field and set the array parameter to *true*, the field is an array column. Elasticsearch Writer uses the delimiter specified by the splitter to split the source data, converts the data to an array of strings, and writes the array to the destination. Only one delimiter is supported for one node. Example: { "name": "col_integer_array", "type": "integer", "array": true }		

Parameter	Description	Required	Default value
actionType	The type of the action for writing data to Elasticsearch. Currently, Data Integration supports only the following action types: *index* and *update*. Default value: *index*. • *index*: Data Integration uses Index.Builder of the Elasticsearch SDK to construct a request for writing multiple data records at a time. In *index* mode, Elasticsearch first checks whether an ID is specified for the document to be inserted. ◦ If the ID is not specified, Elasticsearch generates a unique ID by default. In this case, the document is directly inserted to Elasticsearch. ◦ If the ID is specified, Elasticsearch replaces the existing document with the document to be inserted. Note In this case, you cannot modify specific fields in the document. • *update*: Data Integration uses Update.Builder of the Elasticsearch SDK to construct a request for writing multiple data records at a time. In *update* mode, Elasticsearch calls the get method of InternalEngine to obtain the information of the original document for each update. In this way, you can modify specific fields. In update mode, you must obtain the information of the original document for each update, which greatly affects the performance. However, you can modify specific fields in this mode. If the original document does not exist, the new document is directly inserted.	No	*index*

Configure Elasticsearch Writer by using the code editor

In the following code, a node is configured to write data to Elasticsearch. For more information about the parameters, see the preceding parameter description.

```
{
  "order": {
    "hops": [
      {
        "from": "Reader",
        "to": "Writer"
      }
```

```
    ]
  },
  "setting": {
    "errorLimit": {
      "record": "0"
    },
    "speed": {
      "concurrent": 1,
      "throttle": false
    }
  },
  "steps": [
    {
      "category": "reader",
      "name": "Reader",
      "parameter": {

      },
      "stepType": "stream"
    },
    {
      "category": "writer",
      "name": "Writer",

},
{
  "name": "col_geo_point",
  "type": "geo_point"
},
{
  "name": "col_date",
  "type": "date",
  "format": "yyyy-MM-dd HH:mm:ss"
},
{
  "name": "col_nested1",
  "type": "nested"
```

```
            },
            {
              "name": "col_nested2",
              "type": "nested"
            },
            {
              "name": "col_object1",
              "type": "object"
            },
            {
              "name": "col_object2",
              "type": "object"
            },
            {
              "name": "col_integer_array",
              "type": "integer",
              "array": true
            },
            {
              "name": "col_geo_shape",
              "type": "geo_shape",
              "tree": "quadtree",
              "precision": "10m"
            }
          ]
        },
        "stepType": "elasticsearch"
      }
    ],
    "type": "job",
    "version": "2.0"
}
```

> **Note** Currently, Elasticsearch that is deployed in a Virtual Private Cloud (VPC) supports only custom resource groups. A sync node that is run on the default resource group may fail to connect to Elasticsearch.

2.4.5.4.19. Configure LogHub Writer

This topic describes the data types and parameters supported by LogHub Writer and how to configure it by using the code editor.

LogHub Writer allows you to transfer data from a Data Integration reader to LogHub through Log Service Java SDK.

> **Note** LogHub does not guarantee idempotence. Rerunning a node after the node fails may result in redundant data.

LogHub Writer obtains data from a Data Integration reader and converts the data types supported by Data Integration to String. When the number of the data records reaches the value specified for the batchSize parameter, LogHub Writer sends the data records to LogHub at a time through Log Service Java SDK. LogHub Writer sends 1,024 data records at a time by default. The batchSize parameter can be set to 4096 at most.

Data types

The following table lists the data types supported by LogHub Writer.

Data Integration data type	LogHub data type
LONG	STRING
DOUBLE	STRING
STRING	STRING
DATE	STRING
BOOLEAN	STRING
BYTES	STRING

Parameters

Parameter	Description	Required	Default value
endpoint	The endpoint for accessing Log Service.	Yes	None
accessKeyId	The AccessKey ID for accessing Log Service.	Yes	None
accessKeySecret	The AccessKey secret for accessing Log Service.	Yes	None
project	The name of the destination Log Service project.	Yes	None
logstore	The name of the destination Logstore.	Yes	None
topic	The name of the destination topic.	No	Empty string
batchSize	The number of data records to write at a time.	No	*1024*
column	The columns in each data record.	Yes	None

Configure LogHub Writer by using the codeless UI

Currently, the codeless user interface (UI) is not supported for LogHub Writer.

Configure LogHub Writer by using the code editor

In the following code, a node is configured to write data to LogHub. For more information about the parameters, see the preceding parameter description.

```
{
  "type": "job",
  "version": "2.0",// The version number.
  "steps": [
    { //
      "stepType": "stream",
      "parameter": {},
      "name": "Reader",
      "category": "reader"
    },
    {
      "stepType": "loghub",// The writer type.
      "parameter": {
        "datasource": "",// The connection name.
        "column": [// The columns in each data record.
          "col0",
          "col1",
          "col2",
          "col3",
          "col4",
          "col5"
        ],
        "topic": "",// The name of the destination topic.
        "batchSize": "1024",// The number of data records to write at a time.
        "logstore": ""// The name of the destination Logstore.
      },
      "name": "Writer",
      "category": "writer"
    }
  ],
  "setting": {
    "errorLimit": {
      "record": ""// The maximum number of dirty data records allowed.
    },
```

```
        "speed": {
            "concurrent": 3,// The maximum number of concurrent threads.
            "throttle": false,// Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
        }
    },
    "order": {
        "hops": [
            {
                "from": "Reader",
                "to": "Writer"
            }
        ]
    }
}
```

2.4.5.4.20. Configure Open Search Writer

This topic describes the data types and parameters supported by Open Search Writer and how to configure it by using the code editor.

How it works

Open Search Writer allows you to insert data to or update data in Open Search. Open Search Writer is designed for developers to import data to Open Search so that the data can be searched.

Specifically, Open Search Writer uses the search API provided by Open Search to import data.

> **Note**
>
> - Open Search V3 uses internal dependent databases, with POM of `com.aliyun.opensearch aliyun-sdk-opensearch 2.1.3`.
> - To use Open Search Writer, you must install JDK 1.6-32 or later. You can run the `java-version` command to view the JDK version.

Features

The columns in Open Search are unordered. Open Search Writer writes data strictly in accordance with the order of the specified columns. If the number of specified columns is less than that in Open Search, redundant columns in Open Search are set to the default value or null.

Assume that an Open Search table contains columns a, b, and c, and you only need to write data to columns b and c. You can set the column parameter to ["c","b"]. In this case, Open Search Writer imports the first and second columns of the source data obtained from a reader to columns c and b in the Open Search table respectively. Column a in the Open Search table is set to the default value or null.

Additional instructions:

- Handling of column configuration errors

  To avoid losing the data of redundant columns and ensure high data reliability, Open Search Writer returns an error message if the number of columns to be written is more than that in the destination Open Search table. For example, if an Open Search table contains columns a, b, and c, Open Search Writer returns an error if more than three columns are to be written to the table.

- Table configuration

  Open Search Writer can write data to only one table at a time.

- Node rerunning

  After a node is rerun, data is automatically overwritten based on IDs. Therefore, the data written to Open Search must contain one ID column. An ID is a unique identifier of a row in Open Search. The existing data with the same ID as the new data will be overwritten.

- Node rerunning

  After a node is rerun, data is automatically overwritten based on IDs.

Data types

Open Search Writer supports most Open Search data types. Make sure that your data types are supported.

The following table lists the data types supported by Open Search Writer.

Category	Open Search data type
Integer	INT
Floating point	DOUBLE and FLOAT
String	TEXT, LITERAL, and SHORT_TEXT
Date and time	INT
Boolean	LITERAL

Parameters

Parameter	Description	Required	Default value
accessId	The AccessKey ID for connecting to the Open Search database.	Yes	None

Parameter	Description	Required	Default value
accessKey	The AccessKey secret for connecting to the Open Search database.	Yes	None
host	The endpoint for connecting to Open Search. You can view the endpoint in the Apsara Stack console.	Yes	None
indexName	The name of the Open Search project.	Yes	None
table	The name of the table to which data is written. You can specify only one table name because Data Integration does not support importing data to multiple tables at a time.	Yes	None
column	The columns in the destination table to which data is written. To write data to all the columns in the destination table, set the value to an asterisk (*), for example, `"column":["*"]`. Separate the columns with a comma (,) if data is written to some of the columns in the destination table. Example: `"column":["id","name"]`. Open Search Writer supports filtering columns and changing the order of columns. Assume that an Open Search table has three columns: a, b, and c. If you want to write data only to columns c and b, you can set the column parameter in the format `"column":["c","b"]`. During data synchronization, column a is automatically set to null.	Yes	None
batchSize	The number of data records to write at a time. Data is written to Open Search in batches. The advantage of Open Search is data query. The transactions per second (TPS) of Open Search is generally not high. Set this parameter based on the resources available for the account that is used to connect to Open Search. Generally, the size of a data record must be less than 1 MB, and the size of the data records to write at a time must be less than 2 MB.	Required only for writing data to a partitioned table	*300*

Parameter	Description	Required	Default value
writeMode	The write mode. To ensure the idempotence of write operations, set the writeMode parameter to add/update when you configure Open Search Writer. • add: deletes the existing data record and inserts the new data record to Open Search, which is an atomic operation. • update: updates the existing data record based on the new data record, which is an atomic operation. Note Writing data to Open Search in batches is not an atomic operation. Part of the data may fail to be written. Exercise caution when you set the writeMode parameter. Open Search V3 does not support the update mode.	Yes	None
ignoreWriteError	Specifies whether to ignore failed write operations. Example: `"ignoreWriteError":true`. If data is written to Open Search in batches, this parameter specifies whether to ignore failed write operations in the current batch. If you set the parameter to true, Open Search Writer continues to perform other write operations. If you set the parameter to false, the sync node ends and an error message is returned. We recommend that you use the default value.	No	*false*
version	The version of Open Search, for example, `"version":"v3"`. We recommend that you use Open Search V3 because the push operation faces many constraints in Open Search V2.	No	*v2*

Configure Open Search Writer by using the code editor

In the following code, a node is configured to write data to Open Search.

```
{
  "type": "job",
  "version": "1.0",
  "configuration": {
    "reader": {},
    "writer": {
      "plugin": "opensearch",
      "parameter": {
        "accessId": "*********",
        "accessKey": "********",
        "host": "http://yyyy.aliyuncs.com",
        "indexName": "datax_xxx",
        "table": "datax_yyy",
        "column": [
        "appkey",
        "id",
        "title",
        "gmt_create",
        "pic_default"
        ],
        "batchSize": 500,
        "writeMode": add,
        "version":"v2",
        "ignoreWriteError": false
      }
    }
  }
}
```

2.4.5.4.21. Configure Table Store Writer

This topic describes the data types and parameters supported by Table Store Writer and how to configure it by using the code editor.

Table Store is a NoSQL database service built on the Apsara distributed operating system that allows you to store and access large amounts of structured data in real time. Table Store organizes data into instances and tables. Using data sharding and load balancing technologies, Table Store seamlessly expands the data scale.

Table Store Writer connects to a Table Store server by using the official Java SDK and writes data to the Table Store server by using the SDK. Table Store Writer has greatly optimized the write process, including retry upon write timeout, retry upon exceptions, and batch submission.

Currently, Table Store Writer supports all Table Store data types and supports the following two write modes:

- PutRow: the PutRow API operation for Table Store, which is used to insert data to a specified row. If this row does not exist, a new row is added. Otherwise, the original row is overwritten.
- UpdateRow: the UpdateRow API operation for Table Store, which is used to update the data of a specified row. If this row does not exist, a new row is added. Otherwise, the values of the specified columns are added, modified, or deleted as requested.

Currently, Table Store Writer supports all Table Store data types. The following table lists the data types supported by Table Store Writer.

Category	Table Store data type
Integer	INTEGER
Floating point	DOUBLE
String	STRING
Boolean	BOOLEAN
Binary	BINARY

Note To write data of the INTEGER type, set the data type to INT in the code editor. Then, DataWorks converts the INT type to the Integer type. If you set the data type to INTEGER for the data to be written to Table Store, an error is reported in the log and the sync node fails.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be identical to the name of the added connection. You can add connections in the code editor.	Yes	None
endPoint	The endpoint of the Table Store server.	Yes	None
accessId	The AccessKey ID for accessing Table Store.	Yes	None
accessKey	The AccessKey secret for accessing Table Store.	Yes	None
instanceName	The name of the Table Store instance to access. You access and manage the Table Store service through an instance. After activating Table Store, you can create an instance in the Table Store console and then create and manage tables in the instance. Instances are the basic unit for managing Table Store resources. All access control and resource measurement for applications are completed at the instance level.	Yes	None

Parameter	Description	Required	Default value
table	The name of the destination table. You can specify only one table as the destination table. Multi-table synchronization is not required for Table Store.	Yes	None
primaryKey	The primary keys of the destination table in Table Store. The primary keys are described in a JSON array. Table Store is a NoSQL database service. The field names must be specified for Table Store Writer to import data. Note The primary keys in Table Store only support the STRING and INT types. Therefore, you must set the data type of a primary key to either of the two types in the code editor. Data Integration supports converting data types. Table Store Writer can convert data that is not of the STRING or INT type to the STRING or INT type. Example: "primaryKey" : [{"name":"pk1", "type":"string"}, {"name":"pk2", "type":"int"}],	Yes	None
column	The columns in the destination table to which data is written. The columns are described in a JSON array. Format: {"name":"col2", "type":"INT"}, The name parameter specifies the name of the column to which data is written. The type parameter specifies the data type of the column. Data types supported by Table Store include String, Int, Double, Boolean, and Binary.	Yes	None

Parameter	Description	Required	Default value
writeMode	The write mode. Constants, functions, or custom statements are not supported during the write process. The following three modes are supported: • Single-row operations ○ GetRow: reads data from a single row. ○ PutRow: the PutRow API operation for Table Store, which is used to insert data to a specified row. If this row does not exist, a new row is added. Otherwise, the original row is overwritten. ○ UpdateRow: the UpdateRow API operation for Table Store, which is used to update the data of a specified row. If this row does not exist, a new row is added. Otherwise, the values of the specified columns are added, modified, or deleted as requested. ○ DeleteRow: deletes a row. • Multi-row operation BatchGetRow: reads data from multiple rows. • Range-based operation GetRange: reads data from a table within a range.	Yes	None

Configure Table Store Writer by using the codeless UI

Currently, the codeless user interface (UI) is not supported for Table Store Writer.

Configure Table Store Writer by using the code editor

In the following code, a node is configured to write data to Table Store.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"ots",// The writer type.
```

```
    "parameter":{
      "datasource":"",// The connection name.
      "column":[// The columns to which data is written.
        {
          "name":"columnName1",// The name of the column.
          "type": "INT" // The data type of the column.
        },
        {
          "name":"columnName2",
          "type":"STRING"
        },
        {
          "name":"columnName3",
          "type":"DOUBLE"
        },
        {
          "name":"columnName4",
          "type":"BOOLEAN"
        },
        {
          "name":"columnName5",
          "type":"BINARY"
        }
      ],
      "writeMode":"",// The write mode.
      "table":"",// The name of the destination table.
      "primaryKey":[// The primary keys of the destination table in Table Store.
        {
          "name":"pk1",
          "type":"STRING"
        },
        {
          "name":"pk2",
          "type":"INT"
        }
      ]
    },
    "name":"Writer",
    "category":"writer"
  }
```

```
    ],
    "setting":{
        "errorLimit":{
            "record":"0"// The maximum number of dirty data records allowed.
        },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
            "concurrent":1,// The maximum number of concurrent threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.4.5.4.22. Configure RDBMS Writer

This topic describes the data types and parameters supported by RDBMS Writer and how to configure it by using the code editor.

RDBMS Writer allows you to write data to tables stored in primary relational database management system (RDBMS) databases. Specifically, RDBMS Writer obtains data from a Data Integration reader, connects to a remote RDBMS database through Java Database Connectivity (JDBC), and then runs an `INSERT INTO` statement to write data to the RDBMS database. RDBMS Writer is a common writer for relational databases. To enable RDBMS Writer to support a new relational database, register the driver for the relational database.

RDBMS Writer is designed for extract-transform-load (ETL) developers to import data from data warehouses to RDBMS databases. RDBMS Writer can also be used as a data migration tool by users such as database administrators (DBAs).

Data types

RDBMS Writer supports most data types in relational databases, such as numbers and characters. Make sure that your data types are supported.

Parameters

Parameter	Description	Required	Default value
jdbcUrl	The JDBC URL for connecting to the database. The format must be in accordance with official specifications. You can also specify the information of the attachment facility. The format varies with the database type. Data Integration selects an appropriate driver for data reading based on the format. • Format for DM databases: `jdbc:dm://ip:port/database` • Format for Db2 databases: `jdbc:db2://ip:port/database` • Format for PPAS databases: `jdbc:edb://ip:port/database`	Yes	None
username	The username for connecting to the database.	Yes	None
password	The password for connecting to the database.	Yes	None
table	The name of the destination table.	Yes	None
column	The columns in the destination table to which data is written. Separate the columns with a comma (,). Note We recommend that you do not use the default setting.	Yes	None
preSql	The SQL statement to run before the sync node is run. For example, you can clear outdated data before data synchronization. Currently, you can run only one SQL statement. Note If you specify multiple SQL statements in the code editor, the system does not guarantee that they are run in the same transaction.	No	None

Parameter	Description	Required	Default value
postSql	The SQL statement to run after the sync node is run. For example, you can add a timestamp after data synchronization. Currently, you can run only one SQL statement. Note If you specify multiple SQL statements in the code editor, the system does not guarantee that they are run in the same transaction.	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the RDBMS database over the network, and increase the throughput. However, an excessively large value may lead to the out of memory (OOM) error during the data synchronization process.	No	1024

Configure RDBMS Writer by using the code editor

In the following code, a node is configured to write data to an RDBMS database.

```
{
  "job": {
    "setting": {
      "speed": {
        "channel": 1
      }
    },
    "content": [
      {
        "reader": {
          "name": "streamreader",
          "parameter": {
            "column": [
              {
                "value": "DataX",
                "type": "string"
              },
              {
                "value": 19880808,
```

```
                "type": "long"
              },
              {
                "value": "1988-08-08 08:08:08",
                "type": "date"
              },
              {
                "value": true,
                "type": "bool"
              },
              {
                "value": "test",
                "type": "bytes"
              }
            ],
            "sliceRecordCount": 1000
          }
        },
        "writer": {
          "name": "RDBMS Writer",
          "parameter": {
            "connection": [
              {
                "jdbcUrl": "jdbc:dm://ip:port/database",
                "table": [
                  "table"
                ]
              }
            ],
            "username": "username",
            "password": "password",
            "table": "table",
            "column": [
              "*"
            ],
            "preSql": [
              "delete from XXX;"
            ]
          }
        }
      }
```

```
        }
      ]
    }
}
```

You can enable RDBMS Writer to support a new database as follows:

1. Go to the directory of RDBMS Writer, *${DATAX_HOME}/plugin/writer/RDBMS Writer*. In the preceding directory, ${DATAX_HOME} indicates the main directory of Data Integration.
2. Add the driver of your database to the drivers array in the *plugin.json* file in the RDBMS Writer directory. RDBMS Writer automatically selects an appropriate driver for connecting to a database.

   ```
   {
     "name": "RDBMS Writer",
     "class": "com.alibaba.datax.plugin.reader.RDBMS Writer.RDBMS Writer",
     "description": "useScene: prod. mechanism: Jdbc connection using the database, execute select sql, retrieve data from the ResultSet. warn: The more you know about the database, the less pro blems you encounter.",
     "developer": "alibaba",
     "drivers": [
       "dm.jdbc.driver.DmDriver",
       "com.ibm.db2.jcc.DB2Driver",
       "com.sybase.jdbc3.jdbc.SybDriver",
       "com.edb.Driver"
     ]
   }
   ```

3. Add the package of the driver to the libs directory in the RDBMS Writer directory.

```
$tree
.
|-- libs
|   |-- Dm7JdbcDriver16.jar
|   |-- commons-collections-3.0.jar

```

2.4.5.4.23. Configure Stream Writer

This topic describes the data types and parameters supported by Stream Writer and how to configure it by using the code editor.

Stream Writer allows you to display the data obtained from a Data Integration reader on the screen or discard the data. Stream Writer is mainly applicable to performance testing for data synchronization and basic functional testing.

Parameters

print

- Description: specifies whether to display the data obtained from the reader on the screen.
- Required: No
- Default value: true

Configure Stream Writer by using the codeless UI

Currently, the codeless user interface (UI) is not supported for Stream Writer.

Configure Stream Writer by using the code editor

In the following code, a node is configured to display the data obtained from a Data Integration reader on the screen.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"stream",// The writer type.
      "parameter":{
        "print": false, // Specifies whether to display data on the screen.
        "fieldDelimiter":","// The column delimiter.
      },
      "name":"Writer",
      "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
      "record":"0"// The maximum number of dirty data records allowed.
    },
    "speed":{
      "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
      "concurrent":1,// The maximum number of concurrent threads.
    }
  },
  "order":{
    "hops":[
      {
        "from":"Reader",
        "to":"Writer"
      }
    ]
  }
}
```

2.4.5.4.24. Configure Hive Writer

Hive Writer allows you to write data to HDFS and load the data to Hive. This topic describes how Hive Writer works, its parameters, and how to configure it by using the codeless UI and code editor.

Background information

Hive is a Hadoop-based data warehouse tool that is used to process large amounts of structured logs. Hive maps structured data files to a table and allows you to execute SQL statements to query data in the table.

Essentially, Hive converts Hive Query Language (HQL) or SQL statements to MapReduce programs.

- Hive stores processed data in HDFS.
- Hive uses MapReduce programs to analyze data at the underlying layer.
- Hive runs MapReduce programs on Yarn.

How it works

Hive Writer accesses a Hive metastore, parses the configuration to obtain the file storage path, file format, and column delimiter of the file to which data is written, and then writes data to the HDFS file. Hive Writer loads data in the HDFS file to the destination Hive table by using JDBC.

The underlying logic of Hive Writer is the same as that of HDFS Writer. You can configure parameters of HDFS Writer in the parameters of Hive Writer. Data Integration transparently transmits the configured parameters to HDFS Writer.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection.	Yes	None
column	The columns to which data is written. Example: `"column": ["id","name"]`. • Column pruning is supported. You can select specific columns to export. • The column parameter must explicitly specify a set of columns to which data is written. The parameter cannot be left empty. • The column order cannot be changed.	Yes	None
table	The name of the Hive table to which data is written. Note The name is case-sensitive.	Yes	None

Parameter	Description	Required	Default value
partition	The partition in the Hive table to which data is written. • This parameter is required for a partitioned Hive table. The sync node writes data to the partition specified by the partition parameter. • This parameter is not required for a non-partitioned table.	No	None
writeMode	The mode in which data is loaded to the Hive table. After data is written to the HDFS file, Hive Writer executes the `LOAD DATA INPATH (overwrite) INTO TABLE` statement to load data to the Hive table. The writeMode parameter specifies the data loading mode. • *truncate*: deletes existing data before loading the data to the Hive table. • *append*: retains the existing data and appends the data to the Hive table. • If the writeMode parameter is set to Other, the data is written to the HDFS file but not loaded to the Hive table. Note Setting the writeMode parameter is a high-risk operation. Pay attention to the destination directory and the value of this parameter to avoid deleting data incorrectly. This parameter must be used together with the hiveConfig parameter.	Yes	None

Parameter	Description	Required	Default value
hiveConfig	The extended parameters for Hive, including hiveCommand, jdbcUrl, username, and password. • hiveCommand: the full path of the Hive client. After you run the `hive -e` command, the `LOAD DATA INPATH` statement is executed to load data based on the mode specified by the writeMode parameter. The client specified by the hiveCommand parameter provides access information about Hive. • jdbcUrl, username, and password: the information that is required to connect to Hive by using JDBC. After Hive Writer connects to Hive by using JDBC, Hive Writer executes the `LOAD DATA INPATH` statement to load data based on the mode specified by the writeMode parameter. `"hiveConfig": { "hiveCommand": "", "jdbcUrl": "", "username": "", "password": "" }` • Hive Writer allows you to write data to HDFS files by using an HDFS client. You can use the hiveConfig parameter to specify advanced settings for the HDFS client.	Yes	None

Configure Hive Writer by using the codeless UI

On the DataStudio page, double-click a data sync node, and perform the following operations on the node configuration tab that appears:

1. Configure the connections.

Configure the connections to the source and destination data stores for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Partition Key Column	The partition to which data is written. The last-level partition must be specified. Hive Writer can write data to only one partition.
Writing Rule	The writeMode parameter in the preceding parameter description.

2. Configure field mapping. It is equivalent to setting the column parameter in the preceding parameter description. Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right.

GUI Element	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that have been established.
Auto Layout	Click Auto Layout to sort the fields based on specified rules.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Parameter	Description
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure Hive Writer by using the code editor

In the following code, a node is configured to write data to Hive in JSON format.

```
{
  "type": "job",
  "steps": [
    {
      "stepType": "hive",
      "parameter": {
      },
      "name": "Reader",
      "category": "reader"
    },
    {
      "stepType": "hive",
      "parameter": {
        "partition": "year=a,month=b,day=c", // The partition to which data is written.
        "datasource": "hive_ha_shanghai", // The connection name.
        "table": "partitiontable2", // The name of the destination table.
        "column": [// The columns in the destination table to which data is written.
          "id",
          "name",
          "age"
        ],
        "writeMode": "append" // The write mode.
      },
      "name": "Writer",
      "category": "writer"
    }
  ],
  "version": "2.0",
  "order": {
    "hops": [
      {
```

```
            "from": "Reader",
            "to": "Writer"
          }
        ]
    },
    "setting": {
      "errorLimit": {
        "record": ""
      },
      "speed": {
        "throttle": false,
        "concurrent": 2
      }
    }
}
```

2.4.5.4.25. Configure Vertica Writer

Vertica is a column-oriented database using the MPP architecture. Vertica Writer allows you to write data to tables stored in Vertica databases. This topic describes how Vertica Writer works, its parameters, and how to configure it by using the code editor.

How it works

Vertica Writer connects to a remote Vertica database by using JDBC, and executes an `INSERT INTO` statement to write data to the Vertica database. Internally, data is submitted to the Vertica database in batches.

Vertica Writer is designed for ETL developers to import data from data warehouses to Vertica databases. Vertica Writer can also be used as a data migration tool by users such as DBAs.

Vertica Writer obtains data from a Data Integration reader, and generates the INSERT INTO statement based on your configurations.

- `INSERT INTO` : If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows.
- Data can be written only to tables stored in the primary Vertica database.

  > **Note** A sync node that uses Vertica Writer must have at least the permission to execute the `INSERT INTO` statement. Whether other permissions are required depends on the SQL statements specified in the preSql and postSql parameters when you configure the node.

- Vertica Writer does not support the writeMode parameter.
- Vertica Writer accesses a Vertica database by using the Vertica database driver. Confirm the compatibility between the driver version and your Vertica database. Vertica Writer uses the

following version of the Vertica database driver:

```
<dependency>
    <groupId>com.vertica</groupId>
    <artifactId>vertica-jdbc</artifactId>
    <version>7.1.2</version>
</dependency>
```

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
jdbcUrl	The JDBC URL for connecting to the Vertica database. You do not need to set this parameter because the system automatically obtains the value from the connection parameter. • You can configure only one JDBC URL for a database. Vertica Writer cannot write data to a database with multiple primary databases. • The format must be in accordance with Vertica official specifications. You can also specify the information of the attachment facility. Example: `jdbc:vertica://127.0.0.1:3306/database` .	Yes	None
username	The username that you can use to connect to the database.	Yes	None
password	The password that you can use to connect to the database.	Yes	None
table	The names of the destination tables, which are described in a JSON array. Note You do not need to set this parameter because the system automatically obtains the value from the connection parameter.	Yes	None
column	The columns in the destination table to which data is written. Separate the columns with a comma (,), for example, `"column":["id","name","age"]` .	Yes	None
preSql	The SQL statement to execute before the sync node is run. Use `@table` to specify the name of the destination table in the SQL statement. When you execute this SQL statement, DataWorks replaces @table with the name of the destination table.	No	None

Parameter	Description	Required	Default value
postSql	The SQL statement to execute after the sync node is run.	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the Vertica database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	*1,024*

Configure Vertica Writer by using the codeless UI

The codeless UI is not supported for Vertica Writer.

Configure Vertica Writer by using the code editor

In the following code, a node is configured to write data to a Vertica database.

```
{
   "type":"job",
   "version":"2.0",// The version number.
    "steps":[
      {
         "stepType":"stream",
         "parameter":{},
         "name":"Reader",
         "category":"reader"
      },
      {
         "stepType":"vertica",// The writer type.
          "parameter":{
            "datasource": "The connection name.",
            "username": "",
            "password": "",
            "column": [// The columns to which data is written.
                "id",
               "name"
            ],
            "connection": [
               {
                  "table": [// The name of the destination table.
                     "vertica_table"
                  ],
                  "jdbcUrl": "jdbc:vertica://ip:port/database"
```

```
            }
          ],
          "preSql": [ // The SQL statement to execute before the sync node is run.
            "delete from @table where db_id = -1"
          ],
          "postSql": [// The SQL statement to execute after the sync node is run.
            "update @table set db_modify_time = now() where db_id = 1"
          ]
        },
        "name":"Writer",
        "category":"writer"
      }
    ],
    "setting":{
      "errorLimit":{
        "record":"0"// The maximum number of dirty data records allowed.
      },
      "speed":{
        "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates t
hat the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maxi
mum transmission rate takes effect only if you set this parameter to true.
        "concurrent":1 // The maximum number of concurrent threads.
      }
    },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
        }
      ]
    }
}
```

2.4.5.4.26. Configure Gbase8a Writer

This topic describes the implementation principle and parameter configurations of Gbase8a Writer.

Gbase8a Writer allows you to write data to tables stored in Gbase8a databases. At the underlying implementation level, Gbase8a Writer connects to a remote Gbase8a database through the JDBC Driver and runs the relevant SQL statements to write data to the Gbase8a database.

> **Note** You must configure a connection before configuring Gbase8a Writer.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be identical to the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the table to be synchronized.	Yes	None
writeMode	The write mode. Valid values: *insert into*, *on duplicate key update*, and *replace into*. • *insert into*: If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows and is regarded as dirty data. • *on duplicate key update*: If no primary key conflict or unique index conflict occurs, the action is the same as that of `insert into`. If a conflict occurs, specified fields in original rows are updated. • *replace into*: If no primary key conflict or unique index conflict occurs, the action is the same as that of `insert into`. If a conflict occurs, original rows are deleted and new rows are inserted. That is, all fields of original rows are replaced.	No	*insert*
column	The columns in the destination table to which data is written. Separate the columns with a comma (,). Example: `"column": ["id", "name", "age"]`. Set the value to an asterisk (*) if data is written to all the columns in the destination table. That is, set the column parameter as follows: `"column":["*"]`.	Yes	None

Parameter	Description	Required	Default value
preSql	The SQL statement to run before the sync node is run. For example, you can clear outdated data before data synchronization. Currently, you can run only one SQL statement on the codeless user interface (UI), and multiple SQL statements in the code editor. Note If you specify multiple SQL statements in the code editor, the system does not guarantee that they are run in the same transaction.	No	None
postSql	The SQL statement to run after the sync node is run. For example, you can add a timestamp after data synchronization. Currently, you can run only one SQL statement on the codeless UI, and multiple SQL statements in the code editor. Note If you specify multiple SQL statements in the code editor, the system does not guarantee that they are run in the same transaction.	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the Gbase8a database over the network, and increase the throughput. However, an excessively large value may lead to the out of memory (OOM) error during the data synchronization process.	No	*1024*

Configure Gbase8a Writer by using the codeless UI

Currently, the codeless UI is not supported for Gbase8a Writer.

Configure Gbase8a Writer by using the code editor

In the following code, a node is configured to write data to the Gbase8a database. For more information about the parameters, see the preceding parameter description.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
    },
```

```
    {
      "stepType":"gbase8a",// The writer type.
      "parameter":{
        "postSql":[],// The SQL statement to run after the sync node is run.
        "datasource":"",// The connection name.
        "column":[// The columns to be synchronized.
          "id",
          "value"
        ],
        "writeMode":"insert",// The write mode.
        "batchSize":1024,// The number of data records to write at a time.
        "table":"",// The name of the table to be synchronized.
        "preSql":[]// The SQL statement to run before the sync node is run.
      },
      "name":"Writer",
      "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{// The maximum number of dirty data records allowed.
      "record":"0"
    },
    "speed":{
      "throttle":false,// Specifies whether to enable bandwidth throttling.
      "concurrent":1,// The maximum number of concurrent threads.
    }
  },
  "order":{
    "hops":[
      {
        "from":"Reader",
        "to":"Writer"
      }
    ]
  }
}
```

2.4.5.5. Optimize synchronization performance

This topic describes how to maximize the synchronization speed by adjusting the concurrency configuration, the difference between nodes that are configured with bandwidth throttling and those that are not, and precautions for custom resource groups.

Data Integration is a one-stop platform that supports real-time and offline data synchronization between any connections in any location and in any network environment. You can synchronize 10 TB of data between various types of cloud storage and local storage each day.

DataWorks provides excellent data transmission performance and supports data exchanges between more than 400 pairs of disparate connections. These features allow you to focus on the key issues on constructing big data solutions.

Factors affecting the speed of data synchronization

The factors that affect the speed of data synchronization are listed as follows:

- Source
  - Database performance: the performance of the CPU, memory module, SSD, network, and hard disk.
  - Concurrency: A high concurrency results in a heavy database workload.
  - Network: the bandwidth (throughput) and speed of the network. Generally, a database with better performance can support more concurrent nodes and a larger concurrency value can be set for sync nodes.
- Sync node
  - Synchronization speed: whether an upper limit is set for the synchronization speed.
  - Concurrency: a maximum number of concurrent threads to read data from the source and write data to destination data storage within a single sync node.
  - Nodes that are waiting for resources.
  - Bandwidth throttling: The bandwidth of a single thread is 1,048,576 bit/s. Timeout occurs when the business is sensitive to the network speed. We recommend that you set a smaller value.
  - Whether to create an index for query statements.
- Destination
  - Performance: the performance of the CPU, memory module, SSD, network, and hard disk.
  - Load: Excessive load in the destination database affects the write efficiency within the sync nodes.
  - Network: the bandwidth (throughput) and speed of the network.

You need to monitor and optimize the performance, load, and network of the source and destination databases. The following describes the optimal settings of a sync node.

Concurrency

You can configure the concurrency for a node on the codeless user interface (UI). The following is an example of how to configure the concurrency in the code editor:

```
"setting": {
    "speed": {
     "concurrent": 10
    }
  } }
```

Bandwidth throttling

By default, bandwidth throttling is disabled. In a sync node, data is synchronized at the maximum speed given the concurrency configured for the node. Considering that excessively fast synchronization may overstress the database and thus affect the production, Data Integration allows you to limit the synchronization speed and optimize the configuration as required. If bandwidth throttling is enabled, we recommend that you limit the maximum speed to 30 Mbit/s. The following is an example for configuring an upper limit for synchronization speed in the code editor, in which the transmission bandwidth is 1 Mbit/s:

```
"setting": {
    "speed": {
      "throttle": true // The bandwidth throttling is enabled.
      "mbps": 1, // The synchronization speed.
    }
  }
```

Note

- When the throttle parameter is set to false, throttling is disabled, and you do not need to configure the mbps parameter.
- The bandwidth value is a Data Integration metric and does not represent the actual network interface card (NIC) traffic. Generally, the NIC traffic is two to three times of the channel traffic, which depends on the serialization of the data storage system.
- A semi-structured file does not have shard keys. If multiple files exist, you can set the maximum job speed to increase the synchronization speed. However, the maximum job speed is limited by the number of files. For example, the maximum job speed limit is set to n Mbit/s for n files. If you set the limit to n+1 Mbit/s, the synchronization speed remains at n Mbit/s. If you set the limit to n-1 Mbit/s, the synchronization is performed at n-1 Mbit/s.
- A table can be partitioned according to the preset maximum job speed only when a maximum job speed and a shard key are configured for a relational database. Relational databases only support numeric shard keys, while Oracle databases support both numeric and string shard keys.

Scenarios of slow data synchronization

- Scenario 1: Resolve the issue that sync nodes to be run on the default resource group remain waiting for resources.

- Example

  When you test a sync node in DataWorks, the node remains waiting for resources and an internal system error occurs.

  For example, a sync node is configured to synchronize data from RDS to MaxCompute. The node has waited for about 800 seconds before it is run successfully. However, the log shows that the node runs for only 18 seconds and then stops. The sync node uses the default resource group. When you run other sync nodes, they also remain in the waiting state.

  The log is displayed as follows:

  ```
  2017-01-03 07:16:54 : State: 2(WAIT) | Total: 0R 0B | Speed: 0R/s 0B/s | Error: 0R 0B | Stage: 0.0%
  ```

- Solution

  The default resource group is not exclusively used by a single user. It is used by many projects concurrently, not just two or three nodes for a single user. If such resources are insufficient after you start to run a node, the node needs to wait for resources. In this case, the node is completed 800 seconds after you start running the node, but it only takes 10 seconds for the node to be executed.

  To improve the synchronization speed and reduce the waiting time, we recommend that you run sync nodes during off-peak hours. Typically, most sync nodes are run between 00:00 and 03:00.

- Scenario 2:

  Accelerate nodes that synchronize data from multiple source tables to the same destination table.

  - Example

    To synchronize data from tables of multiple data stores to a table, you configure multiple sync nodes to run in sequence. However, the synchronization takes a long time.

  - Solution

    To launch multiple concurrent nodes that write data to the same destination database, pay attention to the following points:

    - Ensure that the destination database can support the execution of all the concurrent nodes.
    - You can configure a sync node that synchronizes multiple source tables to the same destination table. Alternatively, you can configure multiple nodes to run concurrently in the same workflow.
    - If resources are insufficient, you can configure sync nodes to run during off-peak hours.

- Scenario 3:

  If no index is added when the WHERE clause is used, a full table scan slows down the data synchronization.

- Example

  SQL statement:

  ```
  select bid,inviter,uid,createTime from `relatives` where createTime>='2016-10-23 00:00:00'and rea
  teTime<'2016-10-24 00:00:00';
  ```

  Assume that the sync node started to run the preceding statement at 2016-10-25 11:01:24 and started to return results from 2016-10-25 11:11:05. It took a long time to finish the sync node.

- Cause

  When the WHERE clause is used for a query, the createTime column is not indexed, resulting in a full table scan.

- Solution

  We recommend that you use an indexed column or add an index to the column that you want to scan if you use the WHERE clause.

2.4.6. Full-database migration

2.4.6.1. Overview

This section describes the full-database migration feature in terms of its functions and limits.

Full-database migration is an easy-to-use tool that helps you to improve cost-efficiency. It can quickly upload all the tables in a MySQL database to MaxCompute at a time, saving time that is spent on creating batch tasks for initial data migration to the cloud.

For example, if a database contains 100 tables, you must configure 100 data synchronization tasks in a traditional way. With the full-database migration, you can upload all the tables at a time. However, an upload failure might occur due to the issues that involve the principles of designing database tables.

Task generation rules

After the configuration is completed, MaxCompute tables are created and data synchronization tasks are generated based on the selected tables to be synchronized.

The table names, field names, and field types of the MaxCompute tables are generated according to the advanced settings. If no advanced settings are configured, the structure of MaxCompute tables is identical to that of MySQL tables. The partition of these tables is pt, and its format is yyyymmdd.

The generated data synchronization tasks are daily scheduled tasks and run automatically on the early morning of the next day. The typical transmission rate is 1 Mbit/s, but it varies depending on the synchronization method and concurrency configurations. **To customize a data synchronization task, locate the task by choosing clone_database > Data Source Name > mysql2odps_table name**, and then specify its settings.

> **Note** We recommend that you perform smoke testing on a data synchronization task on the day when it is generated.To perform smoke testing, choose Administration Center > Task Management > project_etl_start > Upload Database > Data Source Name, find the synchronization task, right-click the task, and then test the task.

Limits

Full-database migration has the following limits due to the issues that involve the principles of designing database tables.

- Currently, only the full-database migration from a MySQL data source to MaxCompute is supported. We are working on support for full-database migration from a Hadoop or Hive data source to Oracle.
- Only the daily incremental and daily full upload modes are available.

  If you want to synchronize historical data at a time, this feature cannot meet your needs. We recommend that:

  - You configure daily tasks instead of synchronizing historical data at a time. You trace the historical data with the provided retrospective data import feature. This eliminates the need to run temporary SQL tasks to split data after all the historical data is synchronized.
  - To synchronize historical data at a time, configure a task on the task development page and click **Run**. Then, data is converted by using SQL statements. They are both one-time operations.

  If your daily incremental upload task uses a special business logic and cannot be identified by a date field, this feature cannot meet your needs. We provide the following suggestions:

  - The incremental data upload can be achieved by using two methods: binlog provided by the DTS product and the date field for data changes provided by databases.

    Currently, Data Integration supports the second method. Therefore, your database must contain the date field for data changes. The system determines whether your data is changed on the same day as the business date by using this field. If yes, all the changed data is synchronized.
  - To facilitate the incremental data uploading, we recommend that you include the gmt_create and gmt_modify fields when creating any database tables. Additionally, you can set the id field as the primary key to improve efficiency.
- Full-database migration supports batch upload and full upload modes.

  Batch upload is configured with time intervals. Currently, the connection pool protection feature for data sources is not supported, but will be available later.

  - To prevent overloads on the database, the full-database migration feature provides the batch upload mode. This mode enables you to upload tables in batches at a specified time interval and prevents compromised service functionality. We provide the following suggestions:
    - If you have master and slave databases, we recommend that you synchronize the data of the slave database.
    - In a batch upload task, each table has a database connection with a maximum transmission rate of 1 Mbit/s. For example, if you run a synchronization task for 100 tables at a time, 100 database connections are established. We recommend that you specify proper concurrency settings based on your business needs.
  - If you have special requirements for transmission efficiency, this feature cannot meet your needs. The maximum transmission of each generated tasks is 1 Mbit/s.
- Only the mapping of all table names, field names, and field types are supported.

  During the full-database migration process, MaxCompute tables are created automatically, where the partition field is pt, the field type is string, and the format is yyyymmdd.

  > **Note** When you select tables for synchronization, all fields must be synchronized and none of these fields can be edited.

2.4.6.2. Migrate a MySQL database

This topic describes how to migrate a MySQL database to MaxCompute.

The database migration feature improves efficiency and reduces costs. It can quickly upload all tables in a MySQL database to MaxCompute. For more information, see Overview.

Procedure

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration** to go to the **Data Integration** page.
3. In the left-side navigation pane, choose **Sync Resources > Connections**. On the page that appears, click **Add Connection**.
4. In the **Add Connection** dialog box that appears, select **MySQL**.
5. Add a MySQL connection named clone_database for database migration.
6. Click **Test Connection** and verify that the database can be accessed. Click **Complete**.
7. The added MySQL connection named clone_database appears in the connection list. Find the added connection and click **Migrate Database** in the Actions column.

   The database migration settings page consists of three functional modules.

Functional module	Description
Tables to migrate	This module lists all the tables in the MySQL connection named clone_database. Selected tables will be migrated.

Functional module	Description
Advanced Settings	You can configure the rules for converting the table name, column names, and data types.
Basic settings	You can select whether to synchronize full or incremental data, whether to upload data in one or more batches, and the synchronization efficiency. You can also view the migration progress and results.

8. Click **Advanced Settings** and configure conversion rules based on your needs. For example, you can add an ods_ prefix to the name of each MaxCompute table.
9. Specify basic settings. Set Sync Method to Synchronize Incremental Data Daily, and configure the incremental data to be determined based on the gmt_modified column. Data Integration will generate WHERE clauses based on the specified column and DataWorks scheduling parameters such as ${bdp.system.bizdate}.

   Data Integration reads data from MySQL tables by connecting to a remote MySQL database over JDBC and running SELECT statements. Data Integration uses standard SQL statements, and therefore you can configure WHERE clauses to filter data. The WHERE clause used in this example is provided as follows:

   ```
   STR_TO_DATE('${bdp.system.bizdate}', '%Y%m%d') <= gmt_modified AND gmt_modified < DATE_AD
   D(STR_TO_DATE('${bdp.system.bizdate}', '%Y%m%d'), interval 1 day)
   ```

   Select data upload in batches to protect the MySQL database from being overloaded. Let Data Integration start data synchronization for three tables every one hour from 00:00 each day.

   Click **Commit**. Then, you can view the migration progress and results of each table.
10. Find table a1 and click View Node to view the migration results.

You have configured a node for migrating a MySQL connection named clone_database to MaxCompute. This node is run based on the specified schedule, daily by default. You can also create retroactive node instances to transmit historical data. The database migration feature of **Data Integration** significantly simplifies the initial configurations for migrating your data to the cloud and reduces data migration costs.

You can view the migration success logs of table a1.

2.4.6.3. Migrate Oracle databases

This topic describes how to migrate an Oracle database to MaxCompute.

The database migration feature improves efficiency and reduces costs. It can quickly upload all tables in an Oracle database to MaxCompute. For more information, see Overview.

Procedure

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration** to go to the **Data Integration** page.
3. In the left-side navigation pane, choose **Sync Resources > Connections**. On the page that

appears, click **Add Connection** in the upper-right corner.

4. In the **Add Connection** dialog box that appears, select **Oracle**.
5. Add an Oracle connection named clone_databae for database migration.
6. Click **Test Connection** and verify that the database can be accessed. Click **Complete**.
7. The added Oracle connection named clone_databae appears in the connection list. Find the added connection and click **Migrate Database** in the Actions column.

   The database migration settings page consists of three functional modules.

Functional module	Description
Tables to migrate	This module lists all the tables in the Oracle connection named clone_databae. Selected tables will be migrated.
Advanced Settings	You can configure the rules for converting the table name, column names, and data types.
Basic settings	You can select whether to synchronize full or incremental data, whether to upload data in one or more batches, and the synchronization efficiency. You can also view the migration progress and results.

8. Click **Advanced Settings** and configure conversion rules based on your needs.
9. Set Sync Method to Synchronize All Data Daily.

   > **Note** If a date column exists in your table, you can select incremental migration and configure the incremental data to be determined based on the date column. Data Integration will generate WHERE clauses based on the specified column and DataWorks scheduling parameters such as ${bdp.system.bizdate}.

   Select data upload in batches to protect the Oracle database from being overloaded. Let Data Integration start data synchronization for three tables every one hour from 00:00 each day.

   Click **Commit**. Then, you can view the migration progress and results of each table.

10. Find a related table and click **View Node** to view the node details.

    You have configured a node for migrating an Oracle connection named clone_databae to MaxCompute. This node is run based on the specified schedule, daily by default. You can also create retroactive node instances to transmit historical data. The database migration feature of **Data Integration** significantly simplifies the initial configurations for migrating your data to the cloud and reduces data migration costs.

2.5. Data Analytics

2.5.1. Solution

The data analytics mode of DataWorks is upgraded so that you can group multiple workflows in a solution of a workspace.

Overview

DataWorks upgrades the data analytics mode to organize various types of nodes based on the business category. You can organize workflows to analyze data by business.

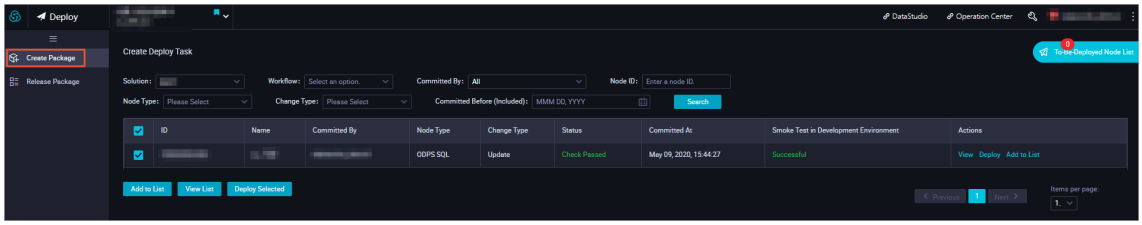
By using the data analytics mode that involves the **workspace**, **solution**, and **workflow**, DataWorks defines a new development process and improves user experience.

- A workspace is the basic organizational unit that manages the development and O&M permissions of users. The code of all nodes in a workspace can be collaboratively developed and managed by workspace members.
- A solution contains one or more workflows. It has the following advantages:
  - A solution can contain multiple workflows.
  - A workflow can be added to multiple solutions.
  - All solutions in a workspace can be collaboratively developed and managed by workspace members.
- A workflow is an abstract entity of business that enables you to develop data analytics code from a business perspective. A workflow can be added to multiple solutions. It has the following advantages:
  - Workflows facilitate business-oriented code development. Nodes in a workflow are organized by type. A hierarchical directory structure is supported. We recommend that you create a maximum of four levels of sub-directories. To create a sub-directory, right-click the target node type and select **Create Folder**.
  - You can view and optimize each workflow from a business perspective.
  - You can view each workflow on a dashboard to develop code with improved efficiency.
  - You can deploy and manage each workflow as a whole.

Develop a solution

If you double-click a solution in the left-side navigation pane, the left-side navigation pane only displays workflows in the solution. This prevents the development process from being affected by the code that is not related to the current solution in the workspace. To develop a solution, perform the following steps:

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, move the pointer over  and select **Solution**.
3. In the **Create Solution** dialog box, set **Solution Name** and **Description**, select a workflow from the **Workflows** drop-down list, and then click **Create**.
4. In the solution list, right-click the created solution and select **Solution Kanban**. On the solution dashboard that appears, you can view the selected workflows or modify the solution.
5. Move the pointer over the solution name. The  and  icons appear.
   - Click the  icon. The **Deploy** page appears. You can view the nodes to be deployed in the current solution.



> **Note** This icon is available only when the workspace is in standard mode.

- Click the icon to go to the **Cycle Instance** page under **Cycle Task Maintenance** in **Operation Center**. You can view recurring instances of all nodes in the current solution.

  In the left-side navigation pane, double-click the created solution. All the created workflows in the solution appear. You can click a workflow name to show the created nodes in it and perform operations on the nodes and the workflow.

  A workflow can be added to multiple solutions. After you develop a solution and add a workflow to the solution, other users can edit the workflow you referenced in their solutions for collaborative development.

2.5.2. SQL coding guidelines and specifications

This topic describes the basic guidelines and detailed specifications of SQL coding.

SQL coding guidelines

The SQL coding guidelines are as follows:

- Make sure that the code is comprehensive.
- Make sure that code lines are clear, neat, well-organized, and structured.
- Consider the optimal execution speed during SQL coding.
- Provide comments whenever necessary to enhance the readability of your code.
- The guidelines impose non-mandatory constraints on the coding behavior of developers. In practice, understandable deviations are allowed when developers obey general rules.
- Use lowercase letters for all keywords and reserved words. Keywords and reserved words include select, from, where, and, or, union, insert, delete, group, having, and count.
- In addition to keywords and reserved words, other code such as field names and table alias must be in lowercase.
- A unit of indentation contains four spaces. All indentations must be the integral multiple of an indentation unit. The code is aligned according to its hierarchy.
- The `select *` operation is prohibited. The column name must be specified for all operations.
- Matching opening and closing parentheses must be placed in the same column.

SQL coding specifications

The SQL coding specifications are as follows:

- Code header

The code header contains information such as the subject, description, author, and date. Reserve a line for change log and a title line so that later users can add change records. Each line can contain a maximum of 80 characters. The template is as follows:

```
-- MaxCompute(ODPS) SQL
--********************************************************************
-- ** Subject: Transaction
-- ** Description: Transaction refund analysis
-- ** Author: Youma
-- ** Created on: 20170616
-- ** Change log:
-- ** Modified on Modified by Content
-- yyyymmdd name comment
-- 20170831 Wuma Add a comment on the biz_type=1234 transaction
--********************************************************************
```

- Field arrangement
  - Use a line for each field that is selected for the SELECT statement.
  - Separate the first field from SELECT by one indentation unit.
  - Enter another field name in a separate line after two indentation units.
  - Place the comma (,) between two fields right before the second field.
  - Place the AS statement in the same line as the corresponding field. We recommend that you keep the AS statements of multiple fields in the same column.

```
select  channel_id            as channel_id
       ,trade_channel_desc    as trade_channel_desc
       ,trade_channel_edesc   as trade_channel_edesc
       ,inst_date             as inst_date
       ,trade_iswap           as trade_iswap
       ,channel_type          as channel_type
       ,channel_second_desc   as channel_second_desc
from   (
```

- Clause arrangement for an INSERT statement

  Arrange the clauses of an INSERT statement in the same line.

- Clause arrangement for a SELECT statement

  The clauses such as FROM, WHERE, GROUP BY, HAVING, ORDER BY, JOIN, and UNION in a SELECT statement must be arranged according to the following requirements:
  - Use a line for each clause.
  - Make sure that the clauses are left aligned with the SELECT statement.
  - Add two indentation units between the first word and the other code in a clause.
  - Keep the logical operators such as AND and OR in a WHERE clause left aligned with WHERE.

- If the length of a clause name exceeds two indentation units such as ORDER BY and GROUP BY, add a space between the clause name and its content.

```
select    trim(channel) channel
          ,min(id)      id
from      ods_trd_trade_base_dd
where     channel is not null
and       dt = ${tmp_uuuummdd}
and       trim(channel) <> ''
group by  trim(channel)
order by  trim(channel)
```

- Spacing before and after operators

  Keep one space before and one space after the arithmetic and logical operators and keep the operators in the same line, unless the clause contains more than 80 characters.

```
select      trim(channel) channel
            ,min(id)      id
from        ods_trd_trade_base_dd
where       channel is not null
and         dt = ${tmp_uuuummdd}
and         trim(channel) <> ''
group by    trim(channel)
order by    trim(channel)
```

- CASE statement

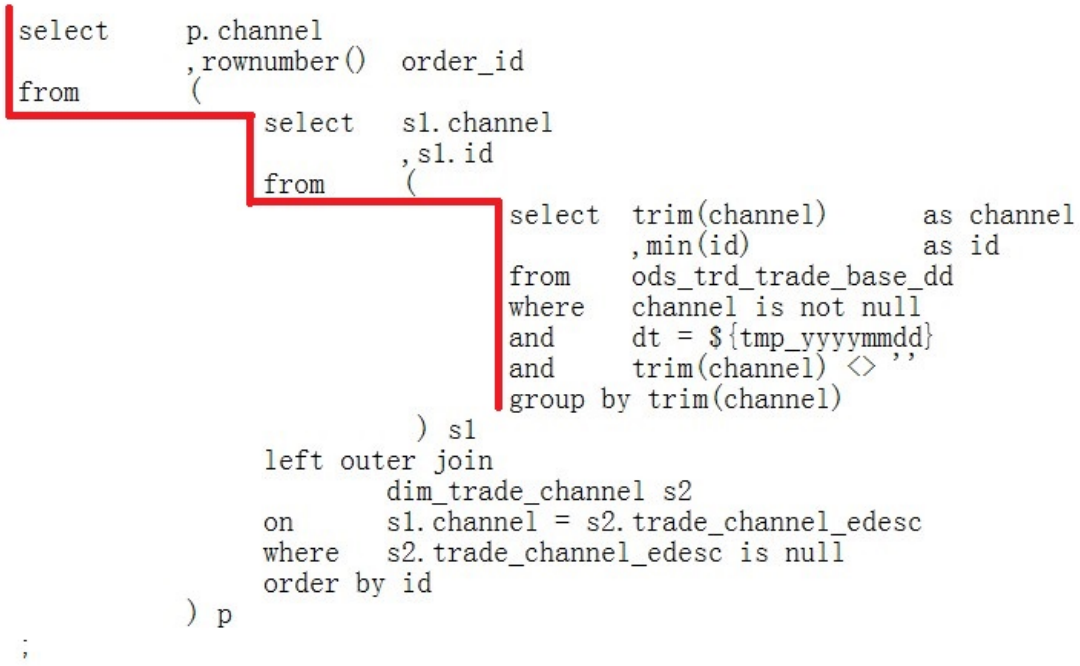
  The CASE statement can be used to determine the value of a field in a SELECT statement. Rules for writing CASE statements are as follows:

  - Place the WHEN clause in the same line as the CASE statement, with one indentation unit between them.
  - Keep a WHEN clause in one line whenever possible. If the statement is long, line breaks can be made.
  - A CASE statement must contain an ELSE clause. The ELSE clause must be aligned with the WHEN clause.

```
,case   when p1.trade_from = '3008' and p1.trade_email is null then 2
        when p1.trade_from = '4000' and p1.trade_email is null then 1
        when p9.trade_from_id is not null then p9.trade_from_id
 end                                as trade_from_id
,p1.trade_email                     as partner_id
```

- Nested query

Nested queries are often used in extract-transform-load (ETL) development of data warehouse systems. The following figure shows an example of a nested query.



```
select      p.channel
            ,rownumber()  order_id
from        (
                select    s1.channel
                          ,s1.id
                from      (
                                select  trim(channel)       as channel
                                        ,min(id)            as id
                                from    ods_trd_trade_base_dd
                                where   channel is not null
                                and     dt = ${tmp_yyyymmdd}
                                and     trim(channel) <> ''
                                group by trim(channel)
                           ) s1
                left outer join
                        dim_trade_channel s2
                on      s1.channel = s2.trade_channel_edesc
                where   s2.trade_channel_edesc is null
                order by id
            ) p
;
```

- Table alias
  - Once an alias is defined for a table in a SELECT statement, use the alias whenever you reference the table in the statement. Therefore, you must specify an alias for each table.
  - We recommend that you define the table aliases with simple characters, such as a, b, c, and d in sequence, and avoid using keywords.

- In the nested query, levels 1 to 4 of SQL statements are named part, segment, unit, and detail, which are abbreviated as P, S, U, and D. You can also use a, b, c, and d to represent levels 1 to 4.

  To differentiate multiple clauses at the same level, add numbers such as 1, 2, 3, and 4 next to the letters. Add comments to the table aliases as needed.

```
select     p.channel
           ,rownumber()  order_id
from       (
               select   s1.channel
                        ,s1.id
               from     (
                            select  trim(channel)      as channel
                                    ,min(id)           as id
                            from    ods_trd_trade_base_dd
                            where   channel is not null
                            and     dt = ${tmp_yyyymmdd}
                            and     trim(channel) <> ''
                            group by trim(channel)
                        ) s1
               left outer join
                       dim_trade_channel s2
               on      s1.channel = s2.trade_channel_edesc
               where   s2.trade_channel_edesc is null
               order by id
           ) p
;
```

- SQL comments
  - Add a comment for each SQL statement.
  - Use a separate line for the comment of each SQL statement and place the comment in front of the SQL statement.
  - Place the comment of a field right after the field.
  - Add comments for clauses that are difficult to understand.
  - Add comments for important code.
  - If a statement is long, we recommend that you add comments based on the purposes of each segment.
  - The description for a constant or variable is required. The comment on the valid value range is optional.

2.5.3. GUI elements

2.5.3.1. Overview

This topic describes the graphical user interface (GUI) elements on the DataStudio page and the configuration tab of an ODPS SQL node.

Log on to the DataWorks console. The **Data Analytics** page appears. You can double-click a created node to perform operations on the node configuration tab.

The following table describes the GUI elements.

No.	GUI element	Description
1	Show My Nodes Only icon	Click the icon to view your own nodes.
2	Search Code icon	Click the icon to search for a node or a code segment.
3	Create icon	Click the icon to create a solution, workflow, folder, node, table, resource, or function.
4	Refresh icon	Click the icon to refresh the directory tree in the left-side navigation pane.
5	Locate icon	Click the icon to find the current node in the left-side navigation pane.
6	Import icon	Click the icon to import local data to an online table. You must specify the encoding format. Note In a workspace of the standard mode, the local data is imported to a table in the development environment.
7	Filter icon	Click the icon to query nodes based on the specified filter conditions.
8	Save icon	Click the icon to save the code of the current node.
9	Save as Ad-Hoc Query Node icon	Click the icon to save the code of the current node in an ad-hoc query node. You can find the node on the Ad-Hoc Query tab.
10	Commit icon	Click the icon to commit the current node.
11	Commit and Unlock icon	Click the icon to commit and unlock the current node for editing.
12	Steal Lock icon	Click the icon to steal the lock of the current node and then edit it if you are not the owner of the node.
13	Run icon	Click the icon to run the code of the current node. You only need to assign values to variables in SQL statements once. The initial values are retained even if the node code changes.

No.	GUI element	Description
14	**Run with Arguments icon**	Click the icon to run the code of the current node with the configured parameters. You must manually assign values to variables in SQL statements each time you click this icon. The initial values are passed to the **Run with Arguments** feature, which replaces the initial values with the assigned values. For example, if the run date of a node is set to April 2, the node always runs on April 2 when you click the Run icon. After you click Run with Arguments icon and change the run date to April 3, the run date is updated. When you click the Run icon again, the node is run on April 3.
15	**Stop icon**	Click the icon to stop running the code of the current node.
16	**Reload icon**	Click the icon to reload the code of the current node. The code will be restored to the version last saved. Unsaved changes will be lost.
17	**Run Smoke Test icon**	Click the icon to test the code of the current node. A smoke test allows you to replace the values of scheduling parameters in the specified data timestamp with your simulated ones. This feature tests the effect of value changes for scheduling parameters. **Note** Each time after you modify the values of scheduling parameters, you must save and commit the modification before running the smoke test. Otherwise, the new values of scheduling parameters do not take effect.
18	**View Smoke Test Log icon**	Click the icon to view the runtime logs of the current script template.
19	**Format Code icon**	Click the icon to format the code to avoid excessively long code in a single line.
20	**Operation Center button**	Click the icon to go to Operation Center.
21	**Properties tab**	Click the tab to configure the properties such as the scheduling properties, parameters, and resource group for the current node.
22	**Lineage tab**	Click the tab to view the relationships between the current node and other nodes.
23	**Versions tab**	Click the tab to view the committed and deployed versions of the current node.

No.	GUI element	Description
24	Code Structure tab	Click the tab to view the code structure of the current node. If the code is excessively long, you can quickly find a code segment based on the key information in the structure.

2.5.3.2. Workflow Parameters

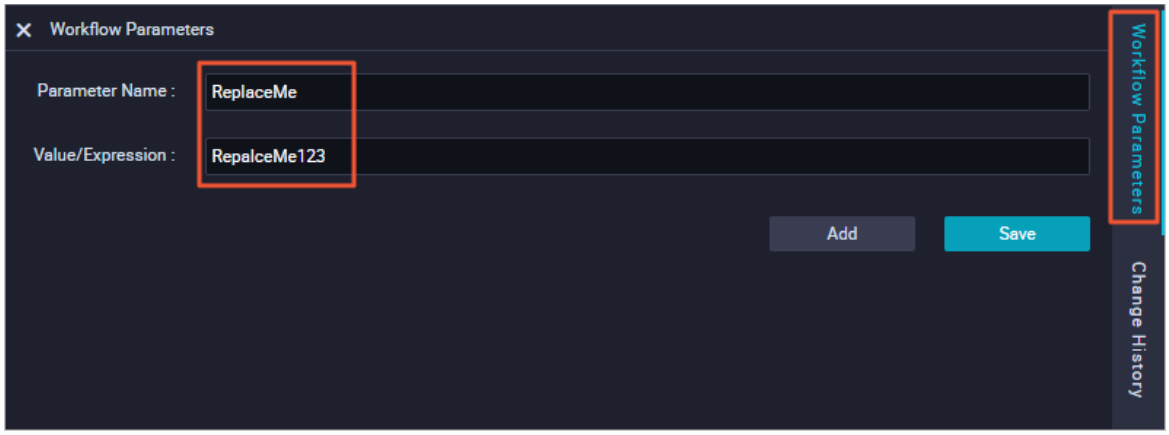
On the Workflow Parameters tab, you can assign a value to a variable or replace the value of a parameter for all nodes in the current workflow. This topic describes how to configure a workflow parameter by assuming that you want to replace the value of the ReplaceMe parameter with ReplaceMe123 in a manually triggered workflow.

Limits

- In manually triggered workflows, ODPS SQL nodes, Shell nodes, and sync nodes support global parameters. The format for specifying a global parameter varies based on the node type. For example, a global workflow parameter is specified as x=y1.
  - To configure the workflow parameter for an ODPS SQL node, double-click the target node and click the **General** tab in the right-side navigation pane. On the **General** tab, enter x=aaa in the Arguments field. When the node is run, x=aaa specified in the Arguments field is replaced with x=y1. You can use $x to reference the workflow parameter in the code.
  - To configure the workflow parameter for a Shell node, double-click the target node and click the **General** tab in the right-side navigation pane. On the **General** tab, enter $x in the Arguments field. When the node is run, x=aaa specified in the Arguments field is replaced with y1. You can use $1 to reference the workflow parameter in the code.
  - To configure the workflow parameter for a sync node, double-click the target node and click the **General** tab in the right-side navigation pane. On the **General** tab, enter -p"-Dx=aaa" in the Arguments field. When the node is run, x=aaa specified in the Arguments field is replaced with -p"-Dx=y1. You can use $x to reference the workflow parameter in the code.
- In auto triggered workflows, only ODPS SQL nodes support global parameters.
- Parameter names and values are case-sensitive.

Configure a workflow parameter

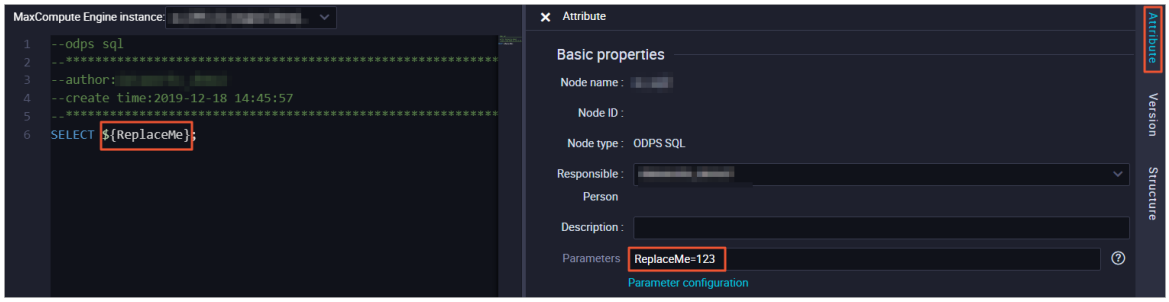
1. Log on to the DataWorks console.
2. In the left-side navigation pane, click **Manually Triggered Workflows**.
3. Double-click the target workflow to go to the workflow configuration tab.
4. In the right-side navigation pane, click the **Workflow Parameters** tab. In the Workflow Parameters pane, enter ReplaceMe in the **Parameter Name** field and ReplaceMe123 in the **Value/Expression** field.



5. Click in the toolbar.

Configure the workflow parameter for an ODPS SQL node

1. On the **DataStudio** page, click **Manually Triggered Workflows** in the left-side navigation pane.
2. Find the target workflow and choose **MaxCompute** > **Data Analytics** to show all the existing data analytics nodes. Double-click the target ODPS SQL node to go to the node configuration tab.
3. In the right-side navigation pane, click the **General** tab. In the General pane, enter ReplaceMe=123 in the **Arguments** field.

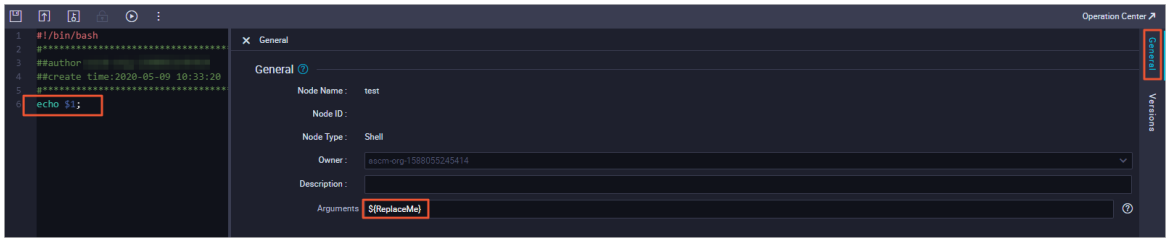


The workflow parameter is specified as ReplaceMe=ReplaceMe123. Therefore, the workflow parameter ReplaceMe is assigned the value ReplaceMe123 for this node when the workflow is run.

4. Click in the toolbar.

Configure the workflow parameter for a Shell node

1. On the **DataStudio** page, click **Manually Triggered Workflows** in the left-side navigation pane.
2. Find the target workflow and click **General** to show all the existing data analytics nodes. Double-click the target Shell node to go to the node configuration tab.
3. In the right-side navigation pane, click the **General** tab. In the General pane, enter ${ReplaceMe} in the **Arguments** field.



> **Note** Make sure that you enter the parameter in the correct format.

4. Click in the toolbar.

Configure the workflow parameter for a sync node

1. On the **DataStudio** page, click **Manually Triggered Workflows** in the left-side navigation pane.
2. Find the target workflow and click **Data Integration** to show all the existing data integration nodes. Double-click the target sync node to go to the node configuration tab.
3. In the right-side navigation pane, click the **General** tab. In the General pane, enter -p"ReplaceMe=abc" in the **Arguments** field.

> **Note** Make sure that you enter the parameter in the correct format, namely, -p"-DParameter name=Parameter value".

4. Click in the toolbar.

Run the workflow to view the result

On the configuration tab of the workflow, click in the toolbar. In the Warning dialog box, click

Settings. In the **Runtime Parameters** dialog box, set Arguments to ReplaceMe. The value of the workflow parameter is replaced when the workflow is run.

You can use the following methods to view the value assigned to the workflow parameter for different types of nodes:

- Right-click the ODPS SQL node and select **View Log**. Then, you can view the value assigned to the workflow parameter for the ODPS SQL node.
- Right-click the Shell node and select **View Log**. Then, you can view the value assigned to the workflow parameter for the Shell node.
- Right-click the sync node and select **View Log**. Then, you can view the value assigned to the workflow parameter for the sync node.

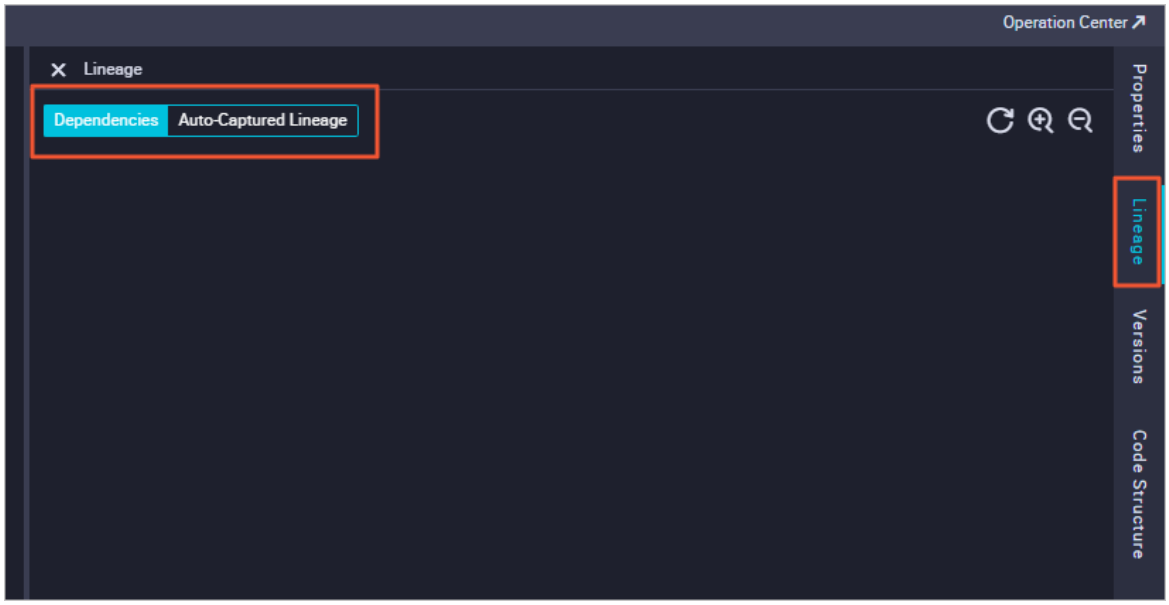
If you have not assigned a value to a workflow parameter on the **Workflow Parameters** tab for a manually triggered workflow, you must assign a value to the workflow parameter every time you run the workflow in the production environment.

2.5.3.3. Lineage

The Lineage tab displays the relationships between a node and other nodes. You can view the node dependencies and the lineage parsed from the code of the node.

Go to the Lineage tab

1. Log on to the DataWorks console.
2. Double-click the target node. For more information about how to create a node, see Create an ODPS SQL node.
3. On the node configuration tab that appears, click the **Lineage** tab in the right-side navigation pane.



On the **Lineage** tab, you can click **Dependencies** to view the dependencies or click **Auto-Captured Lineage** to view the lineage.

View the dependencies

You can check the node dependencies presented based on the current configuration. If the node dependencies fail to meet your expectations, you can reconfigure the node dependencies on the Properties tab.

View the auto-captured lineage

The lineage is parsed based on the code of the current node. For example, an ODPS SQL node contains the following SQL statements:

```
INSERT OVERWRITE TABLE dw_user_info_all_d PARTITION (dt='${bdp.system.bizdate}')
SELECT COALESCE(a.uid, b.uid) AS uid
  , b.gender
  , b.age_range
  , b.zodiac
  , a.region
  , a.device
  , a.identity
  , a.method
  , a.url
  , a.referer
  , a.time
FROM (
  SELECT *
  FROM ods_log_info_d
  WHERE dt = ${bdp.system.bizdate}
) a
LEFT OUTER JOIN (
  SELECT *
  FROM ods_user_info_d
  WHERE dt = ${bdp.system.bizdate}
) b
ON a.uid = b.uid;
```

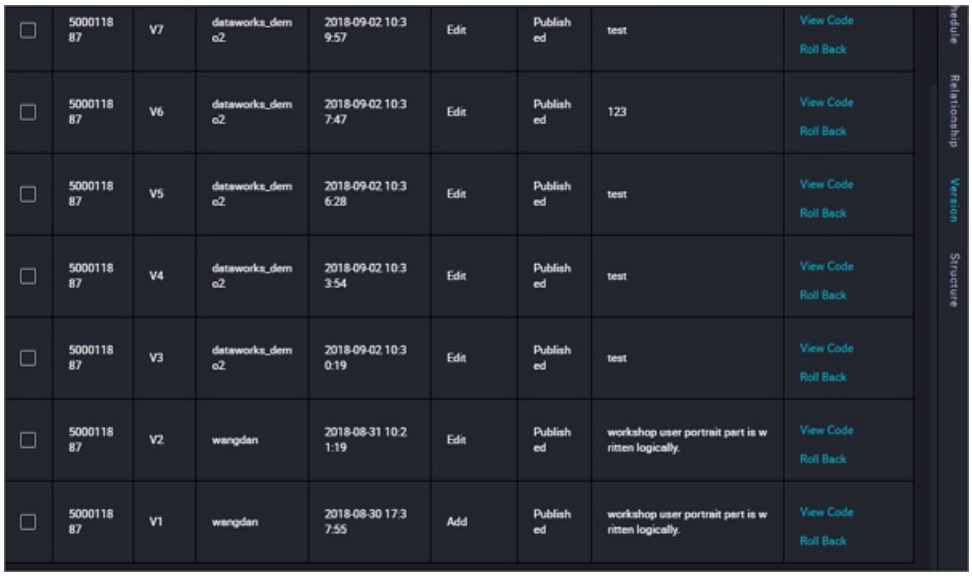
The following figure shows the lineage parsed from the preceding SQL statements. The results queried from the ods_log_info_d and ods_user_info_d tables are joined and then inserted into the dw_user_info_all_d table.

2.5.3.4. Versions

The Versions tab displays all committed and deployed versions of a node. You can view the historical versions and information about each version, including the user who committed the version, time when the version was committed, change type, status, and description.

> **Note** Only a committed node has the version information. Every time a node is committed, a version is generated and added to the **Versions** tab.

1. Log on to the DataWorks console.
2. On the **DataStudio** page, double-click the target node.
3. On the node configuration tab that appears, click the **Versions** tab in the right-side navigation pane. In the Versions pane, view the committed and deployed versions of the current node.



GUI element	Description
File ID	The ID of the node.
Versions	The version of the node. A version is generated each time the node is committed and deployed. V1 indicates version 1 and V2 indicates version 2. The version number is incremented by 1 each time.
Committed By	The user who committed the version.
Committed At	The time when the version was committed. If a version is committed and then deployed at a later time point, the value of this parameter is updated to the time when the version is deployed. By default, this column records the time when the version is last operated.
Change Type	The operation on the node. The value of this parameter is Create if the node is committed and deployed for the first time or Change if the node is modified, committed, and then deployed.

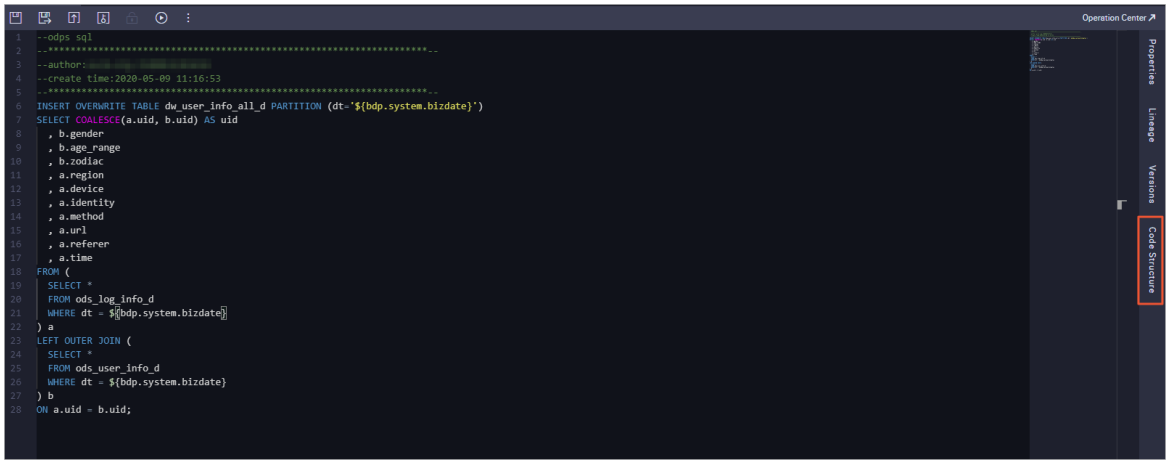
GUI element	Description
Status	The status of the version. Valid values: ○ **Yes**: The version is committed to the development environment but the related deployment task has not been created. The version has not been deployed in the production environment. ○ **Not Deployed**: The version is committed to the development environment and the deployment task is created. The version is pending for deployment. ○ **Deployed**: The version is committed to the development environment and deployed in the production environment.
Description	The change description of the version when it is committed. This description helps other users find the relevant version when they manage the node.
Actions	The actions that you can perform on the version. Two actions are available: **View Code** and **Roll Back**. ○ **View Code**: Click the button to view the code of the current version. ○ **Roll Back**: Click the button to roll back the node from the current version to the required version. After you roll back a node, you must commit and deploy it again.
Compare	Click the button to compare the code and properties between two selected versions.  Click **View Details**. On the details page that appears, you can view the changes in code and properties. **Note** You can only compare two versions and cannot compare one or more than two versions at a time.

2.5.3.5. Code Structure

The Code Structure tab displays the SQL code structure parsed from the code of a node. The code structure helps you view and modify the code.

1. Log on to the DataWorks console.

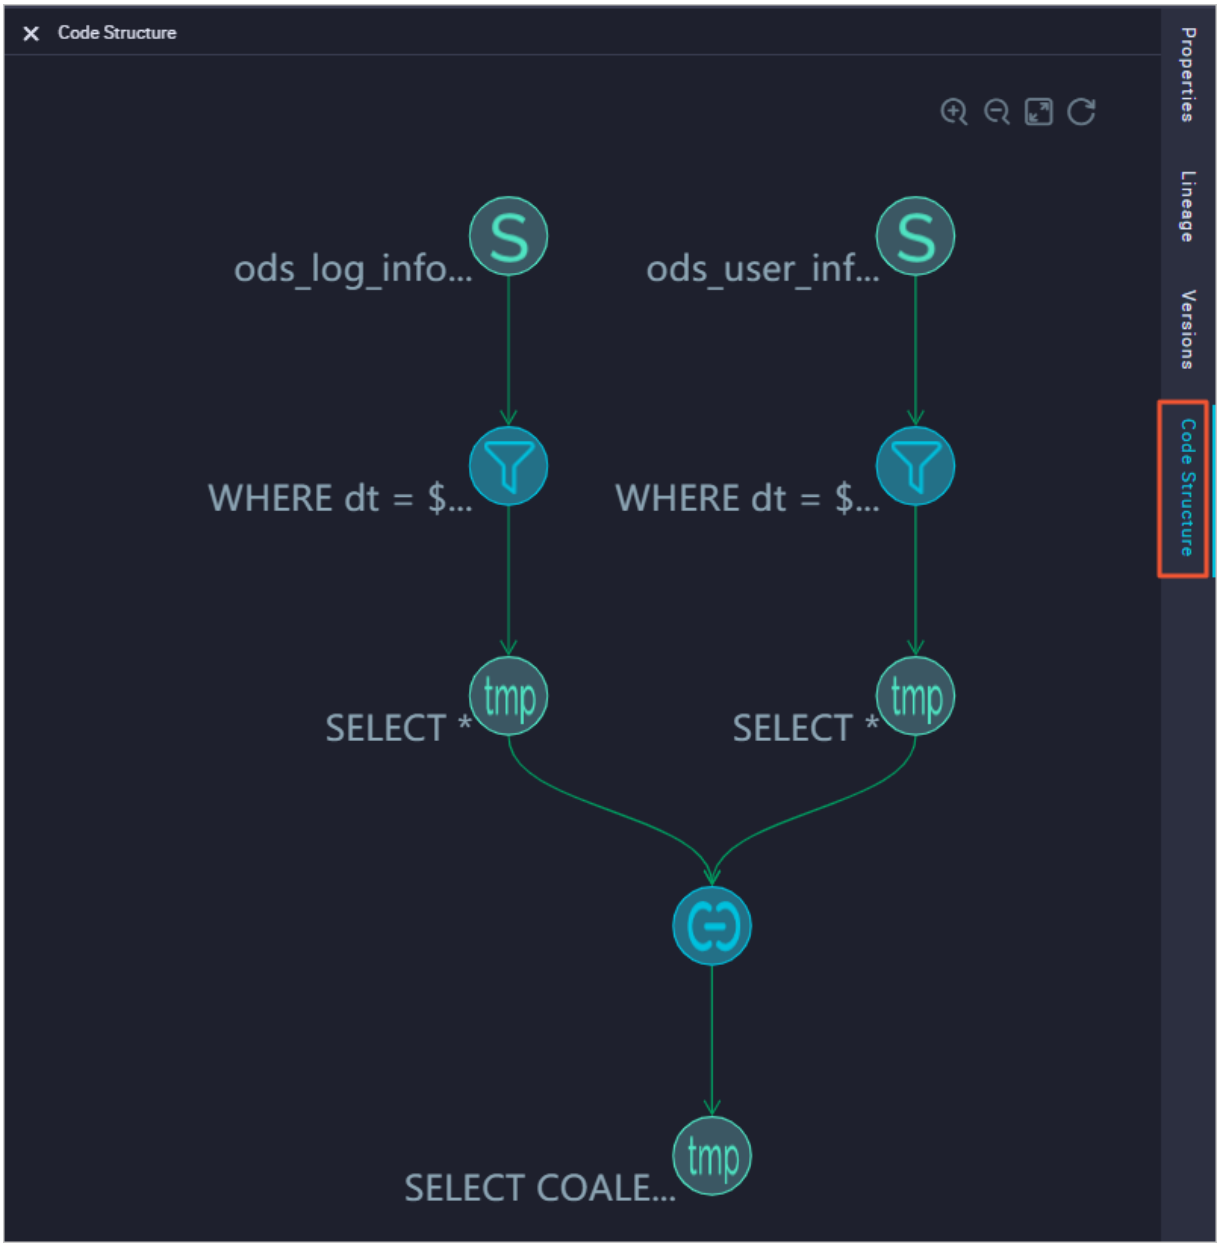
2. Double-click the ODPS SQL node whose code structure you want to view. For more information about how to create a node, see Create an ODPS SQL node.
3. On the node configuration tab that appears, click the **Code Structure** tab in the right-side navigation pane.



In this example, the ODPS SQL node contains the following SQL statement:

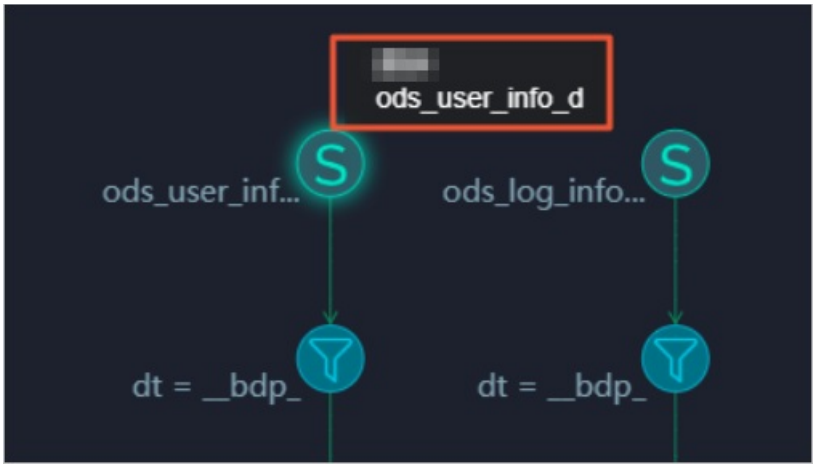
```
INSERT OVERWRITE TABLE dw_user_info_all_d PARTITION (dt='${bdp.system.bizdate}')
SELECT COALESCE(a.uid, b.uid) AS uid
  , b.gender
  , b.age_range
  , b.zodiac
  , a.region
  , a.device
  , a.identity
  , a.method
  , a.url
  , a.referer
  , a.time
FROM (
  SELECT *
  FROM ods_log_info_d
  WHERE dt = ${bdp.system.bizdate}
) a
LEFT OUTER JOIN (
  SELECT *
  FROM ods_user_info_d
  WHERE dt = ${bdp.system.bizdate}
) b
ON a.uid = b.uid;
```

The following figure shows the code structure parsed from the preceding SQL statement.

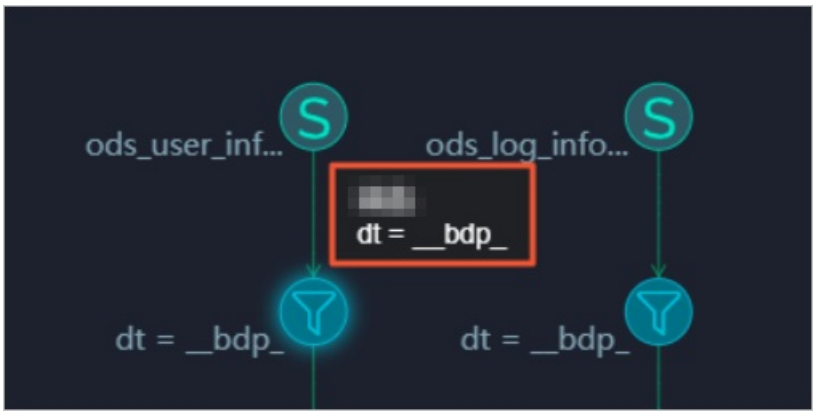


Move the pointer over a circle to view the description.

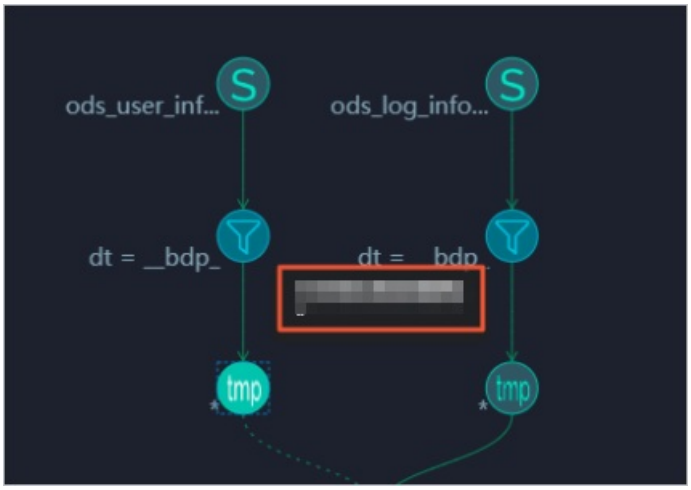
- **Source table**: the table to be queried.



- **Filter**: the condition for filtering the partitions in the table to be queried.

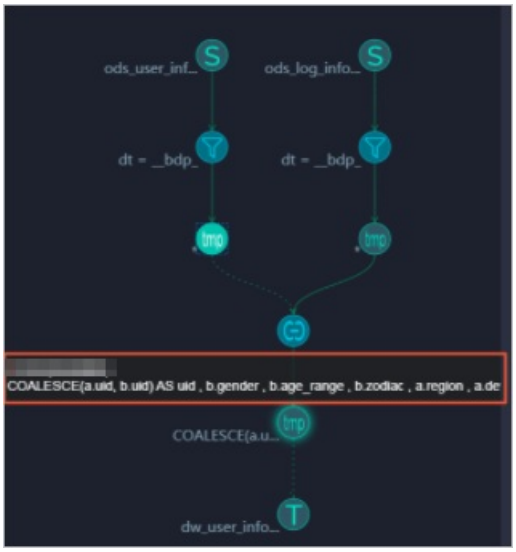


- **First intermediate table (view)**: the temporary table that stores the query results.

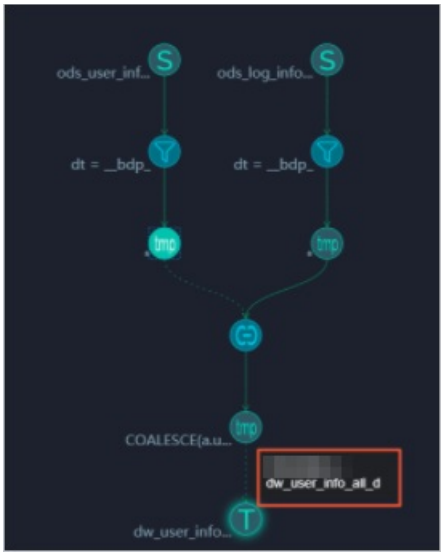


- **Join**: the operation for joining the query results.

- **Second intermediate table (view)**: the temporary table that stores the results of the JOIN operation. This temporary table can be stored for three days. After three days, this table is automatically deleted.



- **Destination table (insert)**: the destination table to which the query results are inserted by using an **INSERT OVERWRITE** statement.



2.5.4. Business flows

2.5.4.1. Overview

DataWorks organizes different types of nodes in a workflow by business category. This allows you to develop code by business.

DataWorks provides you with a dashboard for different types of nodes in each workflow. DataWorks also provides tools for you to optimize and manage nodes in each workflow. This promotes easy and intelligent development and management.

Workflow structure

A workspace supports multiple types of compute engines and multiple workflows. A workflow is a collection of various types of nodes that are closely associated with each other. DataWorks automatically generates a DAG so that you can view the workflow. A workflow supports the following types of nodes: data integration, data analytics, table, resource, function, and algorithm.

Each type of node has an independent folder. You can also create subfolders in each folder. To facilitate management, we recommend that you create a maximum of four levels of subfolders. If more than four subfolder levels are required, your workflow is too complex. We recommend that you split the workflow into two or more workflows and add the split workflows to one solution.

Create a workflow

1. Log on to the DataWorks console.
2. In the left-side navigation pane, click **Data Analytics**.
3. On the **Data Analytics** tab, right-click **Business Flow** and select **Create Workflow**.
4. In the **Create Workflow** dialog box, set **Workflow Name** and **Description**.

   > **Notice** The name of the workflow, which cannot exceed 128 characters in length.

5. Click **Create**.

Workflow nodes

A workflow consists of the following types of nodes:

- **Data integration**

  Click the target workflow and double-click **Data Integration** to view all data integration nodes of the workflow.

- **MaxCompute**

  The MaxCompute engine supports various data analytics nodes, such as ODPS SQL, SQL Snippet, ODPS Spark, PyODPS, ODPS Script, and ODPS MR nodes. You can also view and create tables, resources, and functions.

  - **Data analytics**

    Right-click Data Analytics under **MaxCompute** in the target workflow and select Create to create a data analytics node of a specific type.

  - **Table**

    Click the target workflow and choose **Create** > **Table** under **MaxCompute** to create a table. You can also view all the tables that are created in the current MaxCompute project.

  - **Resource**

    Click the target workflow, choose **Create** > **Resource** under **MaxCompute**, and then click a specific resource type to create a resource. You can also view all the resources that are created in the current MaxCompute project.

  - **Function**

    Click the target workflow and choose **Create** > **Function** under **MaxCompute** to create a function. You can also view all the functions that are created in the current MaxCompute project.

- **EMR**

  The E-MapReduce compute engine supports the following types of data analytics nodes: EMR Hive, EMR MR, EMR Spark, and EMR Spark SQL. You can also view and create E-MapReduce resources.

  > **Note** The **EMR** folder is available only after you create an E-MapReduce compute engine on the **Project Management** page.

  - **Data analytics**

    Click the target workflow, right-click **Data Analytics** under **EMR**, and then select Create to create a data analytics node of a specific type.

  - **Resource**

    Click the target workflow, right-click **Resource** under **EMR**, and then select Create to create a resource of a specific type. You can also view all the resources that are created in the current E-MapReduce compute engine.

- **Algorithm**

Click the target workflow, right-click **Algorithm**, and then choose Create > PAI Experiment to create a PAI Experiment node. You can also view all the PAI Experiment nodes that are created in the current workflow.

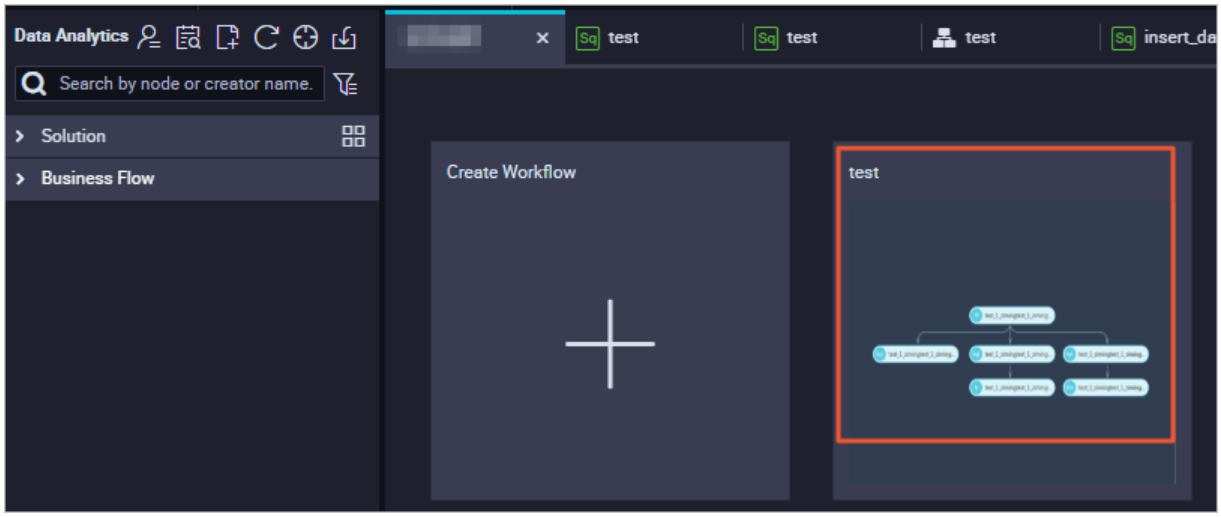
- **General**

  Click the target workflow, right-click **General**, and then select Create to create a node of a specific type.

View all workflows

On the **Data Analytics** tab, right-click **Business Flow** and select **All Workflows** to view all workflows that are created in the current workspace.

Click a workflow. The dashboard of the workflow appears.



View the dashboard for each node type

DataWorks provides a dashboard for each type of nodes in a workflow. On the dashboard, each node is presented by a card that offers operation and optimization suggestions, so that you can intelligently manage nodes.

For example, the card of each data analytics node provides two indicators to show whether baseline-based monitoring and event notification are enabled for the node. This allows you to understand the status of each node.

You can double-click a folder in a workflow to view the dashboard of the selected node type.

Commit a workflow

1. Go to the dashboard of a workflow and click in the toolbar.
2. In the **Commit** dialog box, select the nodes to be committed, set **Description**, and then select **Ignore I/O Inconsistency Alerts**.
3. Click **Commit**.

> **Note** If a node has been committed but the node code is not modified, the node cannot be selected again. In this case, you can enter your comments on the node and click **Commit**. The property changes of the node are automatically committed.

2.5.4.2. Create and reference a node group

This topic describes how to create and reference a node group.

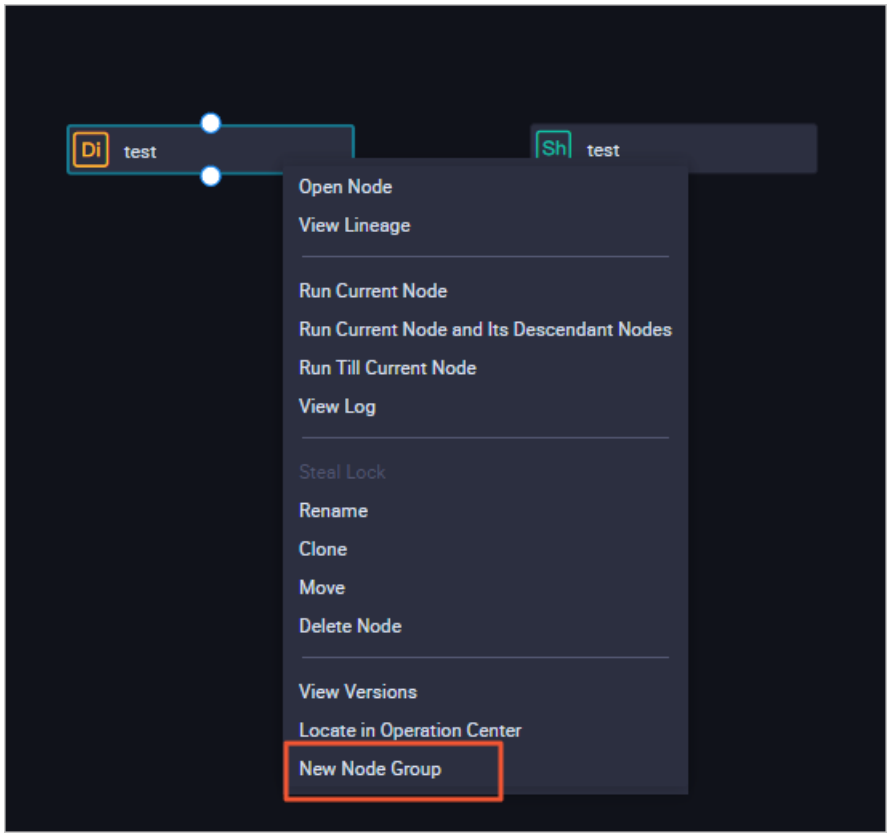
Context

You can group several nodes that are frequently reused together as a node group. The configuration of each node remains unchanged after the nodes are added to a node group. Later, you can directly reference the node group to reuse these nodes.

Create a node group

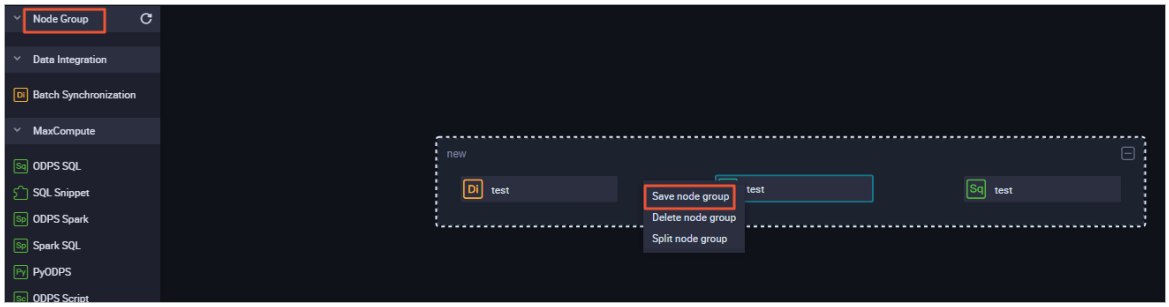
1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, create a workflow. For more information, see Create a workflow.
3. Go to the dashboard of the created workflow. Click in the upper-right corner and drag a box to select the target nodes to be included in a node group.

4. Right-click any node among the selected nodes and select **New Node Group**.



5. In the **New Node Group** dialog box, enter a name in the **Name** field and click **OK**.

6. Right-click the node group and select **Save node group**. In the dialog box that appears, click OK. Then, you can view the created node group in the **Node Group** section.



Menu item	Description
Save node group	Save the node group. The node group that you have created appears in the Node Group section only after you click **Save node group**. A node group that is not saved cannot be referenced in other workflows.
Delete node group	Delete the node group. Click **Delete node group** to delete all nodes in the selected node group.
Split node group	Dismiss the node group. After the node group is dismissed, the selected nodes no longer form a node group in the workflow. However, the node group still exists in the Node Group section.

> **Note** If the created node group contains a PAI Experiment node, create a PAI experiment in another workflow to reference the node group. If the created node group contains a branch node, add digits to the value in the **Associated Node Output** parameter.

Reference a node group

You can directly drag a node group to another workflow to reference the node group in the workflow. The dependencies among the nodes in the node group remain unchanged.

You can run the workflow or commit and deploy the workflow. Then, go to **Operation Center** to view the running result.

2.5.5. Node types

2.5.5.1. Data Integration

2.5.5.1.1. Create a batch sync node

Batch sync nodes support various types of data stores, including MaxCompute, MySQL, DRDS, SQL Server, PostgreSQL, Oracle, MongoDB, Db2, Table Store, OSS, FTP, HBase, LogHub, HDFS, and Stream.

Context

When you enter a table name, a drop-down list appears, displaying all matched tables. Only exact match is supported. Therefore, you must enter a complete table name. Tables are labeled as unsupported if they are not supported by batch sync nodes.

If you move the pointer over a table in the list, the details of the table appear, including the database, IP address, and owner of the table. After you select a table, the column information is automatically entered. You can add, move, and delete columns.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **Data Integration > Batch Synchronization**. Alternatively, you can click a workflow in the Business Flow section, right-click **Data Integration**, and then choose **Create > Batch Synchronization**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. Click **Commit**.
5. Configure the batch sync node. For more information, see Overview.
6. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.

   > **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

   i. Click in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the batch sync node. For more information, see Publish nodes.
8. Test the batch sync node. For more information, see Recurring tasks.

2.5.5.2. MaxCompute

2.5.5.2.1. Create an ODPS SQL node

Using the SQL-like syntax, ODPS SQL nodes can process terabytes of data in distributed processing scenarios that do not require real-time processing.

Context

Generally, it takes a long time from preparing to committing a job. You can use ODPS SQL nodes to process thousands to tens of thousands of transactions. ODPS SQL nodes are online analytical processing (OLAP) applications designed to deal with large amounts of data.

Limits

- You cannot use SET statements, USE statements, or SQL alias statements independently in the code of an ODPS SQL node. They must be executed together with other SQL statements. For example, you can use a SET statement together with a CREATE TABLE statement.

```
set a=b;
create table name(id string);
```

- You cannot add comments to statements containing keywords, including SET statements, USE statements, and SQL alias statements, in the code of an ODPS SQL node. For example, the following comment is not allowed:

```
create table name(id string);
set a=b; // Comment.
create table name1(id string);
```

- The running of an ODPS SQL node during workflow development and the scheduled running of an ODPS SQL node have the following differences:
  - Running during workflow development: combines all the statements containing keywords, including SET statements, USE statements, and SQL alias statements, in the node code and executes them before executing other SQL statements.
  - Scheduled running: executes all SQL statements in sequence.

```
set a=b;
create table name1(id string);
set c=d;
create table name2(id string);
```

The following table shows the differences between the two running modes for the preceding SQL statements.

SQL statement	Running during workflow development	Scheduled running
First SQL statement	`set a=b;` `set c=d;` `create table name1(id string);`	`set a=b;` `create table name1(id string);`
Second SQL statement	`set a=b;` `set c=d;` `create table name2(id string);`	`set c=d;` `create table name2(id string);`

- You must specify a scheduling parameter in the format of key=value. Do not add any spaces before or after the equation mark (=). Examples:

```
time = {yyyymmdd hh:mm:ss} // Incorrect format.
a =b // Incorrect format.
```

- If you use keywords such as bizdate and date as scheduling parameters, you must specify the values in the format of yyyymmdd. If you want to use other time formats, do not use the preceding keywords as scheduling parameters. Example:

```
bizdate=201908 // Incorrect format.
```

- You can only use statements starting with SELECT, READ, or WITH to query the result data for a node during the workflow development. Otherwise, no results are returned.
- Separate multiple SQL statements with semicolons (;) and place them in different lines.
  - Incorrect example

```
create table1;create table2
```

  - Correct example

```
create table1;
create table2;
```

Create an ODPS SQL node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **MaxCompute > ODPS SQL**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > ODPS SQL**.

   > **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. Click **Commit**.
5. Edit the code of the ODPS SQL node.Edit the code of the ODPS SQL node. The code must conform to the syntax. The following example creates a table, inserts data to the table, and queries data in the table:

i. Create a table named test1.

```
CREATE TABLE IF NOT EXISTS test1
( id BIGINT COMMENT '',
 name STRING COMMENT '',
 age BIGINT COMMENT '',
 sex STRING COMMENT '');
```

ii. Insert data to the table.

```
INSERT INTO test1 VALUES (1,'Zhang San',43,'Male');
INSERT INTO test1 VALUES (1,'Li Si',32,'Male');
INSERT INTO test1 VALUES (1,'Chen Xia',27,'Female');
INSERT INTO test1 VALUES (1,'Wang Wu',24,'Male');
INSERT INTO test1 VALUES (1,'Ma Jing',35,'Female');
INSERT INTO test1 VALUES (1,'Zhao Qian',22,'Female');
INSERT INTO test1 VALUES (1,'Zhou Zhuang',55,'Male');
```

iii. Query data in the table.

```
select * from test1;
```

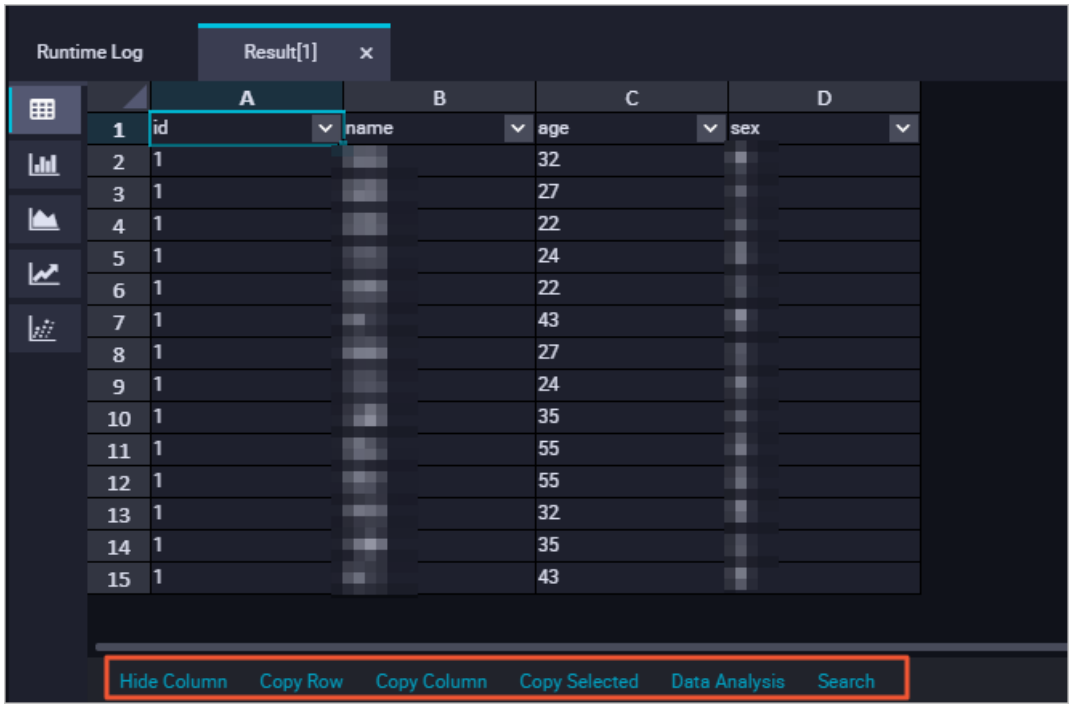
iv. After you enter the preceding SQL statements in the code editor, click  in the toolbar.

DataWorks executes your SQL statements from top to bottom and displays logs.The `INSERT INTO` statement may result in unexpected data duplication. Although DataWorks does not re-execute the `INSERT INTO` statement, it may rerun corresponding nodes. We recommend that you avoid using the `INSERT INTO` statement. When DataWorks executes the INSERT INTO statement, the following information appears in logs:

```
The INSERT INTO statement in SQL may cause repeated data insertion. Although SQL-level retries have been revoked for the INSERT INTO statement, task level retries may still happen. We recommend that you avoid the use of the INSERT INTO statement.
If you continue to use INSERT INTO statements, we deem that you are aware of the associated risks and are willing to take the consequences of potential data duplication.
```

v. View the query result.DataWorks displays the query result in a workbook.

You can view or manage the query result in the workbook, or copy the query result to a local Excel file.



Action	Description
Hide Column	Select one or more columns and click **Hide Column** at the bottom to hide the selected columns.
Copy Row	Select one or more rows and click **Copy Row** at the bottom to copy the selected rows.
Copy Column	Select one or more columns and click **Copy Column** at the bottom to copy the selected columns.
Copy Selected	Select one or more cells in the workbook and click **Copy Selected** at the bottom to copy the selected cells.
Data Analysis	Click **Data Analysis** at the bottom to go to the workbook editing page.
Search	Click **Search** at the bottom to search for data in the workbook. After you click the button, a search box appears in the upper-right corner of the Results tab.

6. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.

> **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

i. Click in the toolbar.

ii. In the **Commit Node** dialog box, ignore the alert on mismatch between the input and output that you set with those detected in code lineage analysis, enter your comments in the **Description** field, and then select **I confirm to proceed with the commission.**

iii. Click **OK.**

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the ODPS SQL node. For more information, see Publish nodes.

8. Test the batch sync node. For more information, see Recurring tasks.

2.5.5.2.2. Create an SQL Snippet node

SQL script templates are SQL templates that involve multiple input and output parameters. Each SQL script template involves one or more source tables. You can use an SQL script template to filter, join, or aggregate data in source tables.

Context

When a new version is released for a script template, you can decide whether to upgrade the version of the script template used in your nodes to the latest version.

The script template upgrade mechanism allows developers to continuously upgrade script template versions. This mechanism enhances the process execution efficiency and optimizes the business performance.

For example, User A uses V1.0 of a script template that belongs to User B. Then, User B releases V2.0 for the script template. User A receives a notification of the new version. After User A compares the code of the two versions, User A can decide whether to upgrade the script template to the latest version.

To upgrade an SQL script template, click **Update Code** and check whether the parameter configuration of the SQL script template is valid in the new version. Set parameters for the SQL script template of the new version based on the version description. Then, save the node and commit it for deployment.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **MaxCompute > SQL Snippet.**

   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > SQL Snippet.**

   > **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Node** dialog box, set **Node Name** and **Location.**

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. Click **Commit**.
5. On the node configuration tab, select a script template from the **Snippet** drop-down list. To improve development efficiency, you can create data analytics nodes by using the script templates provided by workspace members and tenants.
   - The script templates provided by members of the current workspace are available on the **Workspace-Specific** tab.
   - The script templates provided by tenants are available on the **Public** tab.
6. Click the **Parameters** tab in the right-side navigation pane and set parameters for the SQL script template.
7. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
8. Commit the node.

   > **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

   i. Click  in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the batch sync node. For more information, see Publish nodes.
9. Test the batch sync node. For more information, see Recurring tasks.

2.5.5.2.3. Create an ODPS Spark node

DataWorks supports ODPS Spark nodes. This topic uses the JAR resource type as an example to describe how to create and configure an ODPS Spark node.

Create and upload a resource

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **MaxCompute** > **Resource** > **JAR**. Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create** > **Resource** > **JAR**.

   > **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.
3. In the **Create Resource** dialog box, set **Resource Name** and **Location**.
4. Click **Upload** and select the target file to upload.
5. Click **OK**.

Create an ODPS Spark node

1. On the **Data Analytics** tab, move the pointer over and choose **MaxCompute > ODPS Spark**.

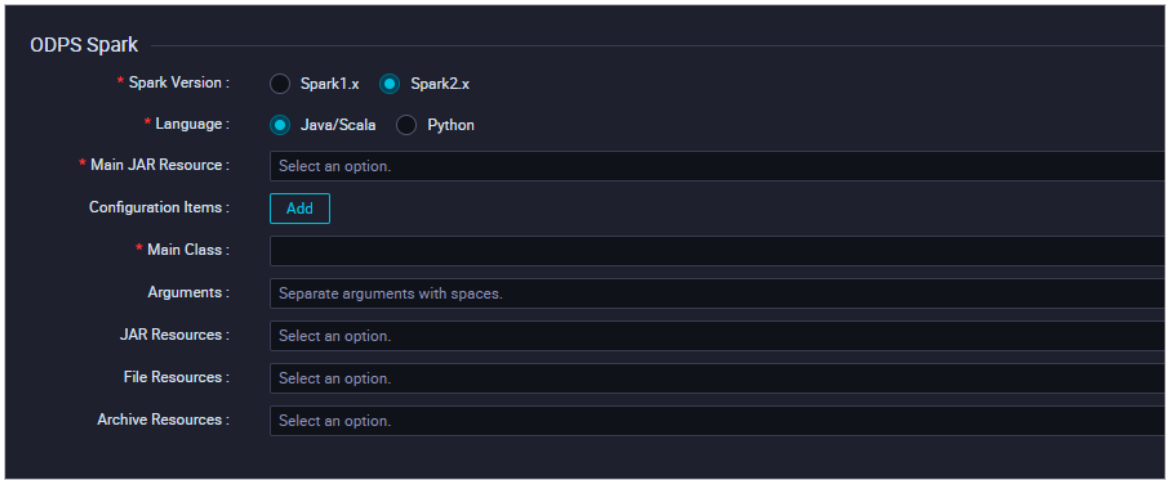
   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > ODPS Spark**.

2. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

3. Click **Commit**.

4. On the node configuration tab, set the parameters.



You can set **Spark Version** and **Language** as needed. The parameters vary with the value of the **Language** parameter. You can set the parameters as prompted.

The following table describes the parameters that appear after you set the Language parameter to **Java/Scala**.

Parameter	Description
Spark Version	The Spark version of the node. Valid values: **Spark1.x** and **Spark2.x**.
Language	The programming language of the node. Valid values: **Java/Scala** and **Python**. Select **Java/Scala**.
Main JAR Resource	The main JAR resource referenced by the node. Select a JAR resource that you uploaded from the drop-down list.
Configuration Items	The configuration items of the node. Click **Add** and set key and value to add a configuration item.
Main Class	The class name of the node.
Arguments	The parameter used to assign a value to a variable in the code during node scheduling. Separate multiple parameters with spaces.

Parameter	Description
JAR Resources	The JAR resource referenced by the node. Select a JAR resource that you uploaded from the drop-down list. The ODPS Spark node automatically finds the uploaded JAR resources based on the resource type.
File Resources	The file resource referenced by the node. Select a file resource that you uploaded from the drop-down list. The ODPS Spark node automatically finds the uploaded file resources based on the resource type.
Archive Resources	The archive resource referenced by the node. Select an archive resource that you uploaded from the drop-down list. The ODPS Spark node automatically finds the uploaded archive resources based on the resource type. Only compressed resources appear.

5. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
6. Commit the node.

   Notice You must set **Rerun** and **Parent Nodes** before you can commit the node.

   i. Click  in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the batch sync node. For more information, see Publish nodes.
7. Test the batch sync node. For more information, see Recurring tasks.

2.5.5.2.4. Create a PyODPS node

DataWorks supports PyODPS nodes, which are integrated with the Python SDK of MaxCompute. You can edit Python code in PyODPS nodes of DataWorks to process data in MaxCompute.

Context

You can also use the Python SDK of MaxCompute to process data in MaxCompute.

Note
- The Python version of PyODPS nodes is 2.7.
- Each PyODPS node can process a maximum of 50 MB data and can occupy a maximum of 1 GB memory. Otherwise, DataWorks terminates the PyODPS node. Avoid writing too much data processing code for a PyODPS node.

PyODPS nodes are designed to use the Python SDK of MaxCompute. If you want to run pure Python code, you can create a Shell node to run the Python scripts uploaded to DataWorks.

Create a PyODPS node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **MaxCompute > PyODPS**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > PyODPS**.

   > **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. Click **Commit**.
5. Edit the code of the PyODPS node on the node configuration tab.
   i. Use the MaxCompute entry.Each PyODPS node includes the global variable odps or o, which is the MaxCompute entry. Therefore, you do not need to manually specify the MaxCompute entry.

   ```
   print(odps.exist_table('PyODPS_iris'))
   ```

   ii. Run SQL statements. In PyODPS nodes, you can execute MaxCompute SQL statements to query data and obtain the query results. You can use the execute_sql or run_sql method to run MaxCompute job instances.

   To execute statements that are not directly compatible with the MaxCompute console, you can use some methods. For example, you cannot directly execute statements other than DDL and DML in the MaxCompute console.

   To execute a GRANT or REVOKE statement, use the run_security_query method. To run a PAI command, use the run_xflow or execute_xflow method.

   ```
   o.execute_sql('select * from dual')  # Execute the statement in synchronous mode. Other node
   s are blocked until the SQL statement is executed.
   instance = o.run_sql('select * from dual') # Execute the statement in asynchronous mode.
   print(instance.get_logview_address()) # Obtain the Logview URL of an instance.
   instance.wait_for_success() # Other nodes are blocked until the SQL statement is executed.
   ```

iii. Set runtime parameters. You can use the hints parameter to set the runtime parameters. The type of the hints parameter is DICT.

```
o.execute_sql('select * from PyODPS_iris', hints={'odps.sql.mapper.split.size': 16})
```

If you set the sql.settings parameter for the global configuration, you must set the runtime parameters each time you run the code.

```
from odps import options
options.sql.settings = {'odps.sql.mapper.split.size': 16}
o.execute_sql('select * from PyODPS_iris')  # The hints parameter is automatically set based o
n the global configuration.
```

iv. Obtain SQL query results. You can use the open_reader method to obtain query results in the following scenarios:

- The SQL statement returns structured data.

```
with o.execute_sql('select * from dual').open_reader() as reader:
for record in reader:  # Process each record.
```

- SQL statements such as DESC are executed. In this case, you can use the reader.raw property to obtain raw query results.

```
with o.execute_sql('desc dual').open_reader() as reader:
print(reader.raw)
```

> **Note** If you use a custom time variable, you must fix the variable to a time. PyODPS nodes do not support relative time variables.

6. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.

> **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

i. Click  in the toolbar.

ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the batch sync node. For more information, see Publish nodes.

8. Test the batch sync node. For more information, see Recurring tasks.

Built-in modules for PyODPS nodes

A PyODPS node contains the following built-in modules:

- setuptools

- cython
- psutil
- pytz
- dateutil
- requests
- pyDes
- numpy
- pandas
- scipy
- scikit_learn
- greenlet
- six
- Other built-in modules in Python 2.7, such as smtplib

2.5.5.2.5. Create an ODPS Script node

You can create an ODPS Script node to develop an SQL script by using the SQL engine provided by MaxCompute V2.0.

Context

The ODPS Script node allows DataWorks to compile the SQL script as a whole, instead of compiling the SQL statements in the script one by one. In this way, the SQL script is committed and run as a whole. This guarantees that an execution plan is only queued and executed once, making full use of MaxCompute computing resources.

Create an ODPS Script node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **MaxCompute > ODPS Script**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > ODPS Script**.

   > **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. Click **Commit**.
5. Edit the SQL script of the ODPS Script node as required.
6. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.

7. Commit the node.

   > **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

   i. Click  in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the batch sync node. For more information, see Publish nodes.

8. Test the batch sync node. For more information, see Recurring tasks.

SQL syntax and limits for ODPS Script nodes

Write SQL statements based on your business logic in a way similar to that of using a common programming language. You do not need to consider how to organize the SQL statements.

```
-- SET statements
set odps.sql.type.system.odps2=true;
[set odps.stage.reducer.num=***;]
[...]
-- DDL statements
create table table1 xxx;
[create table table2 xxx;]
[...]
-- DML statements
@var1 := SELECT [ALL | DISTINCT] select_expr, select_expr, ...
  FROM table3
  [WHERE where_condition];
@var2 := SELECT [ALL | DISTINCT] select_expr, select_expr, ...
  FROM table4
  [WHERE where_condition];
@var3 := SELECT [ALL | DISTINCT] var1.select_expr, var2.select_expr, ...
  FROM @var1 join @var2 on ... ;
INSERT OVERWRITE|INTO TABLE [PARTITION (partcol1=val1, partcol2=val2 ...)]
  SELECT [ALL | DISTINCT] select_expr, select_expr, ...
  FROM @var3;
[@var4 := SELECT [ALL | DISTINCT] var1.select_expr, var.select_expr, ... FROM @var1
  UNION ALL | UNION
  SELECT [ALL | DISTINCT] var1.select_expr, var.select_expr, ... FROM @var2;
CREATE [EXTERNAL] TABLE [IF NOT EXISTS] table_name
  AS
  SELECT [ALL | DISTINCT] select_expr, select_expr, ...
  FROM var4;]
```

SQL syntax and limits for ODPS Script nodes

- ODPS Script nodes support SET statements, DML statements, and some DDL statements. The DDL statements used to return data, such as DESC and SHOW statements, are not supported.
- A complete script consists of SET statements, DDL statements, and DML statements in sequence. You can write one or more statements of each type, or even skip a type without writing any statements of that type. However, you cannot mix different types of statements together. You must strictly follow the sequence of SET statements > DDL statements > DML statements.
- The at signs (@) residing before some statements indicate that these statements are connected by using variables.
- A script supports only one statement that returns data, such as an independent SELECT statement. If multiple such statements are provided, an error occurs. We recommend that you do not use SELECT statements in a script.

- A script supports only one `CREATE TABLE AS` statement, which must be the last statement. We recommend that you put CREATE TABLE statements and INSERT statements in different sections to separate them.
- If one statement in a script fails, the whole script fails.
- A job is generated to process data only after all the input data is prepared for a script.
- If a script writes data to a table and then reads the table, an error occurs. For example, an error occurs for the following statements:

```
insert overwrite table src2 select * from src where key > 0;
@a := select * from src2;
select * from @a;
```

To avoid the error, modify the statements to the following:

```
@a := select * from src where key > 0;
insert overwrite table src2 select * from @a;
select * from @a;
```

Sample script:

```
create table if not exists dest(key string , value bigint) partitioned by (d string);
create table if not exists dest2(key string,value bigint ) partitioned by (d string);
@a := select * from src where value >0;
@b := select * from src2 where key is not null;
@c := select * from src3 where value is not null;
@d := select a.key,b.value from @a left outer join @b on a.key=b.key and b.value>0;
@e := select a.key,c.value from @a inner join @c on a.key=c.key;
@f := select * from @d union select * from @e union select * from @a;
insert overwrite table dest partition (d='20171111') select * from @f;
@g := select e.key,c.value  from @e join @c on e.key=c.key;
insert overwrite table dest2 partition (d='20171111') SELECT * from @g;
```

Scenarios of ODPS Script nodes

- You can use an ODPS Script node to rewrite a single statement with nested subqueries, or a script that must be split into multiple statements due to its complexity.
- Data from different data stores may be prepared at different time points, and the time difference may be large. For example, the data from one data store can be prepared at 01:00, whereas that from another data store can be prepared at 07:00. In this case, table variables are not suitable for connecting statements. You can use an ODPS Script node to combine the statements to a script.

2.5.5.2.6. Create an ODPS MR node

MaxCompute supports the MapReduce API. You can create and commit ODPS MR nodes that call the Java API operations of MapReduce to develop MapReduce programs for processing data in MaxCompute.

Context

Before you create ODPS MR nodes, you must upload, commit, and then deploy required resources.

Create a resource

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **MaxCompute > Resource > JAR**. Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Resource > JAR**.

   > **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Resource** dialog box, set **Resource Name** and **Location**.

   > **Note**
   > - The resource name can be different from the name of the uploaded file.
   > - Convention for naming resources: A resource name can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive and must be 1 to 128 characters in length. A JAR resource name must end with .jar. A Python resource name must end with .py.

4. Click **Upload** and select the target file to upload.
5. Click **OK**.
6. Click in the toolbar to commit the resource to the development environment.

Create an ODPS MR node

1. On the **Data Analytics** tab, find the target workflow, right-click **MaxCompute**, and then choose **Create > ODPS MR**.
2. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

3. Click **Commit**.
4. Edit the ODPS MR node.

```
-- Create an input table.
CREATE TABLE if not exists jingyan_wc_in (key STRING, value STRING);
-- Create an output table.
CREATE TABLE if not exists jingyan_wc_out (key STRING, cnt BIGINT);
   --- Create the dual table.
   drop table if exists dual;
   create table dual(id bigint); -- Create the dual table if no dual table exists in the current works
pace and initialize the table.
   --- Initialize the dual table.
   insert overwrite table dual select count(*)from dual;
   --- Insert the sample data to the wc_in table.
   insert overwrite table jingyan_wc_in select * from (
   select 'project','val_pro' from dual
   union all
   select 'problem','val_pro' from dual
   union all
   select 'package','val_a' from dual
   union all
   select 'pad','val_a' from dual
    ) b;
-- Reference the uploaded JAR package. You can find the JAR package in the resource list, right-cli
ck the JAR resource, and select Insert Resource Path.
--@resource_reference{"mapreduce-examples.jar"}
jar -resources mapreduce-examples.jar -classpath ./mapreduce-examples.jar com.aliyun.odps.ma
pred.open.example.WordCount jingyan_wc_in jingyan_wc_out
```

Pay attention to the following information when you write the code:

- `--@resource_reference` : references a resource. Find the target resource, right-click it, and then select **Insert Resource Path** to generate the reference statement.
- `-resources` : the name of the referenced JAR resource.
- `-classpath` : the path of the JAR resource. You can enter ./Resource name because the resource has been referenced.
- `com.aliyun.odps.mapred.open.example.WordCount` : the main class in the JAR resource to be called during node running. It must be the same as the main class name in the JAR resource.
- `jingyan_wc_in` : the name of the input table of the ODPS MR node. The input table is created in the preceding code.
- `jingyan_wc_out` : the name of the output table of the ODPS MR node. The output table is created in the preceding code.
- If you use multiple JAR resources in a single ODPS MR node, separate the resource paths

with commas (,), for example, `-classpath ./xxxx1.jar,./xxxx2.jar` .

5. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
6. Commit the node.

   > **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

   i. Click  in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the batch sync node. For more information, see Publish nodes.
7. Test the batch sync node. For more information, see Recurring tasks.

2.5.5.2.7. Create a MaxCompute table

This topic describes how to create a MaxCompute table.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **MaxCompute > Table**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Table**.

   > **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.
3. In the **Create Table** dialog box, set **Table Name** and click **Commit**.

   > **Notice** A table name can be up to 64 characters in length. The table name must start with a letter and cannot contain Chinese or special characters.
4. On the table configuration tab that appears, set the parameters in the **General** section.

Parameter or button	Description
Display Name	The display name of the table.

Parameter or button	Description
Level 1 Folder	The name of the level-1 folder where the table resides. Note Level-1 and level-2 folders only show the table locations in DataWorks so that you can better manage tables.
Level 2 Folder	The name of the level-2 folder where the table resides.
Create Folder	Goes to the **Folder Management** tab. On this tab, you can create level-1 and level-2 folders for tables.
Description	The description of the table.

5. Create a table. Use one of the following methods to create a table:
   - Create a table by using DDL statements.

     Click **DDL Statement** in the top navigation bar. In the dialog box that appears, enter the statements for creating a table.

     After you finish editing the statements, click **Generate Table Schema**. Information is automatically entered in the General, Physical Model, and Schema sections.
   - Create a table on the graphical user interface (GUI).

     If DDL statements are inappropriate for you to create a table, try to use the GUI. The following table describes the relevant parameters for creating a table on the GUI.

Section	Parameter or button	Description
Physical Model	**Partitioning**	Specifies whether the table is partitioned. Valid values: **Partitioned Table** and **Non-Partitioned Table**.
	Time-to-Live	The time-to-live of data in MaxCompute. If you select this check box, you must enter a number in the **TTL** field. If the table or partition is stored for more than the specified number of days, data that has not been updated is cleared.
	Table Level	The level of the table. Generally, tables are divided into operation data store (ODS), common data model (CDM), and application data service (ADS) levels. You can specify a custom level name.

Section	Parameter or button	Description
	Categories	The category of the table. Tables are categorized into basic services, advanced services, and other services. You can specify a custom category name. If you want to create a table category or level, click **Create Level** to go to the **Level Management** tab. **Note** Categories are designed only for your management convenience and do not involve underlying implementation.
	Table Type	The type of the table. Default value: **Internal Table**.
Schema	Field Name	The name of the field. The name can contain letters, digits, and underscores (_).
	Display Name	The display name of the field.
	Data Type	The data type of the field.
	Definition or Maximum Value Length	The maximum value length of a field. You can set a maximum value length only for fields of the DECIMAL, VARCHAR, ARRAY, MAP, and STRUCT types.
	Description	The description of the field.
	Primary Key Field	Specifies whether the field serves as the primary key or part of a composite primary key.
	Create Field	Adds a field to the table.
	Delete Field	Deletes a field from the table. **Note** If you delete a field from an existing table, DataWorks requests you to delete the table and create another table with the same name. This operation is forbidden in the production environment.
	Move Up	Adjusts the field sequence of the table. If you adjust the sequence of fields in an existing table, DataWorks requests you to delete the table and create another table with the same name. This operation is forbidden in the production environment.
	Move Down	The description is the same as that of the **Move Up** operation.

Section	Parameter or button	Description
	Add	Adds a partition to the table. If you add a partition to an existing table, DataWorks requests you to delete the table and create another table with the same name. This operation is forbidden in the production environment.
	Delete	Deletes a partition from the table. If you delete a partition from an existing table, DataWorks requests you to delete the table and create another table with the same name. This operation is forbidden in the production environment.
	Actions	Commits a partition or deletes a field.
Partition Field Design Note This section is available only when Partitioning under Physical Model is set to Partitioned Table.	**Add**	Adds a partition field.
	Data Type	The data type of the partition field. We recommend that you use the STRING type for all partition fields.
	Length	The maximum length of the partition field. You can set the maximum length only for fields of the VARCHAR-type.
	Description	The description of the partition field.
	Partition Column Date Format	The format of the date partition. If the partition field is a date, although the data type may be STRING, select or enter a date format, such as *yyyy mmmdd* or *yyyy-mm-dd*.
	Partition Column Date Granularity	The granularity of the date partition. The granularities can be second, minute, hour, day, month, quarter, and year. You can enter a partition granularity as required. If you want to specify multiple partition granularities, note that a greater granularity corresponds to a higher partition level. For example, three partitions whose granularities are day, hour, and month, respectively, are available. Multi-level partitions are in the hierarchical order of level-1 partition (month), level-2 partition (day), and level-3 partition (hour).

6. Click **Commit in Development Environment** and **Commit to Production Environment** in sequence.If you are using a workspace in basic mode, you only need to click **Commit to Production Environment**.

Button	Description

Button	Description
Load from Development Environment	If the table has been committed to the development environment, the button is clickable. After you click the button, the information about the table you create in the development environment overwrites the table information on the current page. **Note** This feature is supported only for MaxCompute tables.
Commit in Development Environment	Before you click the button, make sure that you have filled in all required parameters on the table configuration tab. Do not click the button if any parameters are not specified.
Load from Production Environment	After you click the button, the information about the table that is committed to the production environment overwrites the table information on the current page. **Note** This feature is supported only for MaxCompute tables.
Commit to Production Environment	After you click the button, the table is created in the workspace of the production environment.

What's next

After the table is created, you can query the table data and modify or delete the table. For more information, see Manage tables.

2.5.5.2.8. Create, reference, and download resources

This topic describes how to create, reference, and download JAR and Python resources.

Context

If your code or function requires resource files such as.jar files, you can upload resources to your workspace and reference them.

If the existing built-in functions do not meet your requirements, DataWorks allows you to create user-defined functions (UDFs) and customize processing logic. You can upload the required JAR packages to your workspace so that you can reference them when you create UDFs.

Note

- You can view built-in functions on the **Built-In Functions** tab. For more information, see View built-in functions.
- You can view the UDFs that you have committed or deployed on the **MaxCompute Functions** tab.

The resources that you can upload to MaxCompute include text files, MaxCompute tables, Python code, and compressed packages in the .zip, .tgz, .tar.gz, .tar, and .jar formats. You can read or use these resources when you run UDFs or MapReduce.

MaxCompute provides API operations for you to read and use resources. The following types of MaxCompute resources are available:

- **Python**: the Python code you have written. You can use Python code to register Python UDFs.
- **JAR**: the compiled Java JAR packages.
- **Archive**: the compressed files that can be identified by the file name extension. Supported file types include .zip, .tgz, .tar.gz, .tar, and .jar.
- **File**: files in the .zip, .so, or .jar format.

JAR resources and **file** resources have the following differences:

- To create a JAR resource, write Java code in the offline Java environment, compress the code to a JAR package, and upload the package as a JAR resource to DataWorks.
- To create a file resource that is smaller than or equal to 500 KB in size, you can create and edit it in the DataWorks console.
- To create a file resource that is larger than 500 KB in size, select **Large File (more than 500 KB)** and click Upload to upload the file.

> **Note** Each resource file to be uploaded in the DataWorks console cannot exceed 30 MB.

Create a JAR resource

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **MaxCompute > Resource > JAR**. Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Resource > Python**.

   > **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Resource** dialog box, set **Resource Name** and **Location**.

   > **Note**
   > - The resource name can be different from the name of the uploaded file.
   > - A resource name can contain letters, digits, underscores (_), and periods (.), and is not case-sensitive. It must be 1 to 128 characters in length. A JAR resource name must end with .jar, and a Python resource name must end with .py.

4. Click **Upload** and select the target file to upload.
5. Click **OK**.
6. Click in the toolbar to commit the resource to the development environment.

Create a Python resource and register a UDF

1. Create a Python resource.
   i. On the **Data Analytics** tab, move the pointer over and choose **MaxCompute** > **Resource** > **Python**.Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create** > **Resource** > **Python**.
   ii. In the **Create Resource** dialog box, set **Resource Name** and **Location**.
   iii. Click **OK**.
   iv. On the configuration tab that appears, edit the code of the created resource. Sample code:

```
from odps.udf import annotate
@annotate("string->bigint")
class ipint(object):
    def evaluate(self, ip):
        try:
            return reduce(lambda x, y: (x << 8) + y, map(int, ip.split('.')))
        except:
            return 0
```

   v. Click in the toolbar.
2. Register a UDF.
   i. On the **Data Analytics** tab, move the pointer over and choose **MaxCompute** > **Function**. Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create** > **Function**.
   ii. In the **Create Function** dialog box, set **Function Name** and **Location**.
   iii. Click **Commit**.
   iv. In the **Register Function** section of the configuration tab that appears, enter the class name and the name of the Python resource that has been created, and then click in the toolbar. In this example, the class name is `ipint.ipint`.
   v. Check whether the ipint function is valid and meets your expectation. For example, you can create an ODPS SQL node to test the ipint function by running an SQL statement.

Reference and download resources

- For more information about how to reference resources for functions, see Register a UDF.
- For more information about how to reference resources for nodes, see Create an ODPS MR node.

To download a resource, double-click **Resource** under the target workflow. In the resource list that appears, move the pointer over the required resource and click **Download**.

2.5.5.2.9. Register a UDF

DataWorks allows you to develop UDFs in Python and Java. This topic describes how to register a UDF.

Prerequisites

Before you register a UDF, you must upload the related resource.

Procedure

1. Log on to the DataWorks console.
2. Create a workflow. For more information, see Create a workflow.
3. Write Java code in the offline Java environment, compress the code to a JAR package, and upload the package as a JAR resource to DataWorks. For more information, see Create a JAR resource.
4. Create a UDF.
   i. Find the target workflow, right-click **MaxCompute**, and then choose **Create** > **Function**.
   ii. In the **Create Function** dialog box, set **Function Name** and **Location** and click **OK**.

iii. In the **Register Function** section of the configuration tab that appears, set the parameters.

Parameter	Description
Function Type	The type of the function. Valid values: **Mathematical Function**, **Aggregate Function**, **String Function**, **Date Function**, **Analytic Function**, and **Other**.
Engine Instance MaxCompute	The MaxCompute engine instance bound to the current workspace. By default, you cannot change the engine instance.
Function Name	The name of the function, which is used to reference the function in SQL. The function name must be globally unique and cannot be modified after the function is registered.
Owner	The owner of the function. By default, this parameter is automatically set.
Class Name	Required. The name of the class for implementing the function. **Note** If the resource type is Python, enter the class name in the Python resource name.Class name format. Do not include the .py extension in the resource name.
Resources	Required. The list of resources. You can search for existing resources in the current workspace in fuzzy match mode.
Description	The description of the function.
Expression Syntax	The instructions on how to use the function, for example, `test`.
Parameter Description	The description of supported input and output parameter types.
Return Value	Optional. The value to return. Example: 1.
Example	Optional. An example of the function.

5. Click in the toolbar.
6. Commit the function.
   i. Click in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
   iii. Click **OK**.

2.5.5.3. EMR

2.5.5.3.1. Create an EMR MR node

You can create an EMR MR node to compute a large-scale dataset by using multiple Map tasks in a parallel manner.

Prerequisites

The EMR folder is available on the DataStudio page only after you bind an E-MapReduce compute engine to the current workspace on the **Project Management** page.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **EMR > EMR MR**. Alternatively, you can click a workflow in the Business Flow section, right-click **EMR**, and then choose **Create > EMR MR**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. Click **Commit**.
5. On the node configuration tab, select an E-MapReduce compute engine from the **Engine Instance EMR** drop-down list and edit the code of the node.
6. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.
   i. Click in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see Publish nodes.
8. Test the batch sync node. For more information, see Recurring tasks.

2.5.5.3.2. Create an EMR Spark SQL node

You can create an EMR Spark SQL node to use the distributed SQL query engine to process structured data, improving the task execution efficiency.

Prerequisites

The EMR folder is available on the DataStudio page only after you bind an E-MapReduce compute engine to the current workspace on the **Project Management** page.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **EMR > EMR Spark SQL**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **EMR**, and then choose **Create > EMR Spark SQL**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
4. Click **Commit**.
5. On the node configuration tab, select an E-MapReduce compute engine from the **Engine Instance EMR** drop-down list and edit the code of the node.
6. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.
   i. Click in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see Publish nodes.
8. Test the batch sync node. For more information, see Recurring tasks.

2.5.5.3.3. Create an EMR Spark node

You can create an EMR Spark node to perform complex memory analysis and build large and low-latency data analysis applications.

Prerequisites

The EMR folder is available on the DataStudio page only after you bind an E-MapReduce compute engine to the current workspace on the **Project Management** page.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **EMR > EMR Spark**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **EMR**, and then choose **Create > EMR Spark**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
4. Click **Commit**.

5. On the node configuration tab, select an E-MapReduce compute engine from the **Engine Instance EMR** drop-down list and edit the code of the node.
6. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.
   i. Click in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see Publish nodes.
8. Test the batch sync node. For more information, see Recurring tasks.

2.5.5.3.4. Create an EMR Hive node

This topic describes how to create an EMR Hive node. This type of node allows you to use SQL-like statements to read data from, write data to, and manage data warehouses with a large amount of data stored in a distributed storage system. By using this type of node, you can efficiently analyze a large amount of log data.

Prerequisites

The EMR folder is available on the DataStudio page only after you bind an E-MapReduce compute engine to the current workspace on the **Project Management** page.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **EMR > EMR Hive**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **EMR**, and then choose **Create > EMR Hive**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
4. Click **Commit**.
5. On the node configuration tab, select an E-MapReduce compute engine from the **Engine Instance EMR** drop-down list and edit the code of the node.
6. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.
   i. Click in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see Publish nodes.

8. Test the batch sync node. For more information, see Recurring tasks.

2.5.5.4. Algorithm

2.5.5.4.1. Create a PAI node

PAI nodes are used to call tasks that are created on PAI and schedule production activities based on the node configuration.

Prerequisites

To create a PAI node in DataWorks, you must first create a PAI experiment in PAI.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **Machine Learning** > **PAI Experiment**. Alternatively, you can click a workflow in the Business Flow section, right-click **Algorithm**, and then choose **Create** > **PAI Experiment**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. Click **Commit**.
5. Select the PAI experiment that you have created from the **Experiment** drop-down list and load it.If you want to modify the PAI experiment, click **Edit in PAI Console**.
6. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.

   i. Click in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see Publish nodes.

8. Test the batch sync node. For more information, see Recurring tasks.

2.5.5.5. General

2.5.5.5.1. Create a for-each node

This topic describes how to use a for-each node to repeat a loop twice and display the loop count.

Prerequisites

The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

Context

You can use a for-each node to repeat a loop for a maximum of 128 times. If the loop count exceeds this limit, an error occurs.

If the for-each node needs to perform logic judgment and result traversal, you can use the branch node. However, the branch node must be used with the merge node for result traversal.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General > for-each**.

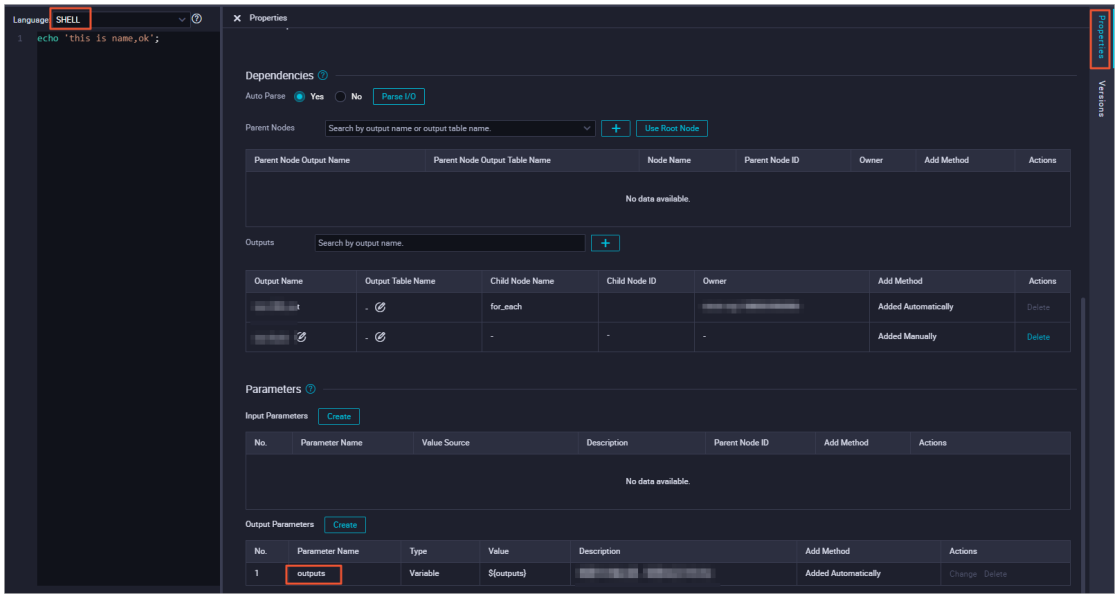
   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > for-each**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
4. Click **Commit**.
5. Create a workflow with an assignment node as the parent node and a for-each node as the child node. For more information, see Create a workflow.

i. Double-click the created assignment node. Set the language of the assignment node to SHELL, and enter the following code:

```
echo 'this is name,ok';
```

On the node configuration tab, click the **Properties** tab in the right-side navigation pane. By default, the **outputs** parameter appears in the **Output Parameters** section.



ii. Double-click the created for-each node. Enter the following code for the for-each node:

```
echo ${dag.loopTimes} ----Display the loop count.
```

> **Note**
>
> - The start and end nodes of the for-each node have fixed logic and cannot be edited.
> - After you modify the code of the Shell node, save the modification. No message will appear to remind you to save the modification when you commit the node. If you do not save the modification, the code cannot be updated to the latest version in time.

A for-each node supports the following environment variables:

- ${dag.foreach.current}: the current data row.
- ${dag.loopDataArray}: the input dataset.
- ${dag.offset}: the offset of the loop count to 1.
- ${dag.loopTimes}: the loop count, whose value equals to the value of ${dag.offset} plus 1.

```
// Compare the code of the Shell node with that of a common for loop.
data=[]  // It is equivalent to ${dag.loopDataArray}.
// i is equivalent to ${dag.offset}.
for(int i=0;i<data.length;i++) {
  print(data[i]);  // data[i] is equivalent to ${dag.foreach.current}.
}
```

The ${dag.loopDataArray} parameter is the default input parameter of the for-each node. Set this parameter to the value of the outputs parameter of the parent node. If you do not set this parameter, an error occurs when you commit the node.

6. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.

> **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

i. Click  in the toolbar.

ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the batch sync node. For more information, see Publish nodes.

8. Test the batch sync node. For more information, see Recurring tasks.

2.5.5.5.2. Create a do-while node

You can define mutually dependent nodes, including a loop decision node named end, in a do-while node. DataWorks repeatedly runs the nodes and exits the loop only when the end node returns False.

Context

> **Note** A loop can be repeated for a maximum of 128 times. If the loop count exceeds this limit, an error occurs.

The do-while node supports the MaxCompute SQL, SHELL, and Python languages. If you use MaxCompute SQL, you can use a `CASE WHEN` statement to evaluate whether the specified condition for exiting the loop is met.

Simple example

This section describes how to use a do-while node to repeat a loop five times and display the loop count each time the loop runs.

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General > do-while**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > do-while**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
4. Click **Commit**.
5. Define the loop body.By default, the do-while node consists of the start, SQL, and end nodes.
   - The start node marks the startup of a loop and does not have any business effect.
   - DataWorks provides the SQL node as a sample business processing node. You must replace the SQL node with your own business processing node, for example, a Shell node named Display loop count.

     
   - The end node marks the end of a loop and determines whether to start the loop again. In this example, it defines the condition for exiting the loop for the do-while node.

The end node is an assignment node. It generates only True or False, indicating whether to start the loop again or exit the loop.

The ${dag.loopTimes} variable is used in both the Display loop count node and the end node. It is a reserved variable of DataWorks. This variable indicates the loop count and the value increments from 1. All internal nodes of the do-while node can reference this variable.

In the code shown in the preceding figure, the value of the `dag.loopTimes` variable is compared with 5 to limit the loop count. The value of the dag.loopTimes variable is 1 when the loop runs for the first time and is incremented by 1 each time, for example, 2 for the second time. In the fifth loop, the value is 5. In this case, the result of ${dag.loopTimes}<5 is False, and the do-while node exits the loop.

6. Run the do-while node. You can configure the scheduling properties for the do-while node as needed and commit it to **Operation Center** for running.
   - do-while node: The do-while node appears as a whole node in Operation Center. To view the loop details about the do-while node, right-click the node in the DAG and select **View Internal Nodes**.
   - Internal loop body: This view is divided into three parts.
     - The left pane of the view lists the rerun history of the do-while node. A record is generated each time a do-while node instance is run.
     - The middle pane of the view shows a loop record list. A record is generated each time the loop of the do-while node is run. The running status of each loop also appears.
     - The right pane of the view shows the details about the do-while node each time the loop is run. You can click a record in the loop record list to view the running details.
7. View the running result. View the internal loop body. In the loop record list, click the record corresponding to the third loop. The loop count is 3 in the runtime logs.

   You can also view the runtime logs of the end node that are generated when the loop runs for the third time and for the fifth time, respectively.

   Based on the preceding simple example, the do-while node works in the following way:

   i. Run from the start node.
   ii. Run nodes in sequence based on the defined node dependencies.
   iii. Define the condition for exiting the loop in the end node.
   iv. Run the conditional statement of the end node after the loop ends for the first time.
   v. Record the loop count as 1 and start the loop again if the conditional statement returns True in the runtime logs of the end node.
   vi. Exit the loop if the conditional statement returns False in the runtime logs of the end node.

Complex example

In addition to simple scenarios, do-while nodes can also be used in complex scenarios where each row of data is processed in sequence by using a loop. Before you process data in such scenarios, make sure that:

- You have deployed a parent node that can export queried data to the do-while node. You can use an assignment node to meet this condition.

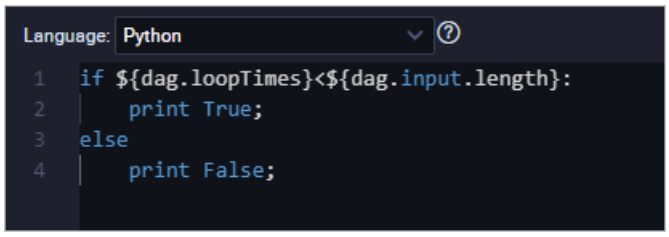
- The do-while node can obtain the output of the parent node. You can configure the node context and dependencies to meet this condition.
- The internal nodes of the do-while node can reference each row of data. In this example, the existing node context is enhanced and the system variable ${dag.offset} is used to reference the context of the do-while node.

This section describes how to use the do-while node to display the data entries in a table in sequence until all data entries in the table are displayed. Each time the loop runs, a data entry is displayed.

1. On the **Data Analytics** tab, double-click the created do-while node.
2. Define the loop body.
   i. Create an assignment node named Initialize dataset and add it as the parent node of the do-while node. The parent node generates a test dataset.
   ii. On the Properties tab of the do-while node, define an input parameter in the **Parameters** section. Set Parameter Name to input and Value Source to the output of the parent node.
   iii. Write code for the business processing node named Print each data row.
      - `${dag.offset}` : a reserved variable of DataWorks. This variable indicates the offset of the loop count to 1. For example, the offset is 0 when the loop runs for the first time and 1 for the second time. The offset equals to the loop count minus 1.
      - `${dag.input}` : the context that you configure for the do-while node. In the preceding steps, the input parameter is defined for the do-while node and the value of the input parameter is the output of the parent node named Initialize dataset.

        The internal nodes of the do-while node can directly use ${dag.${ctxKey}} to reference the context. In this example, ${ctxKey} is set to input. Therefore, you can use ${dag.input} to reference the context.
      - `${dag.input[${dag.offset}]}` : the data obtained from the table generated by the Initialize dataset node. DataWorks can obtain a row of data from the table based on the specified offset. The value of the ${dag.offset} variable increments from 0. Therefore, the data entries such as ${dag.input[0]} and ${dag.input[1]} are returned until all data entries in the dataset are returned.

iv. Define the condition for exiting the loop for the end node. The values of the ${dag.loopTimes} and ${dag.input.length} variables are compared, as shown in the following figure. If the value of the former is less than that of the latter, the end node returns True and the do-while node continues the loop. Otherwise, the end node returns False and the do-while node exits the loop.



Note The system automatically sets the ${dag.input.length} variable to the number of rows in the array specified by the input parameter based on the context configured for the do-while node.

3. Run the do-while node and view the running result.

Summary

- Compared with the while, foreach, and do...while statements, a do-while node has the following characteristics:
  - A do-while node contains a loop body that runs a loop before evaluating the conditional statement. This node functions the same as the do...while statement. A do-while node can also use the system variable ${dag.offset} and the node context to implement the feature of the foreach statement.
  - A do-while node cannot achieve the feature of the while statement because a do-while node runs a loop before evaluating the conditional statement.
- A do-while node works in the following way:
  i. Run nodes in the loop body starting from the start node based on node dependencies.
  ii. Run the code defined for the end node.
    - Run the loop again if the end node returns True.
    - Exit the loop if the end node returns False.
- How to use the node context: The internal nodes of a do-while node can use ${dag.${ctxKey}} to reference the context defined for the do-while node.
- System parameters: DataWorks provides the following system variables for the internal nodes of the do-while node:
  - ${dag.loopTimes}: the loop count, starting from 1.
  - ${dag.offset}: the offset of the loop count to 1, starting from 0.

2.5.5.5.3. Create an OSS Object Inspection node

If descendant nodes depend on specified OSS objects, you can use the OSS object inspection feature to check whether the OSS objects exist. For example, you can run a node for synchronizing OSS data files to DataWorks only after the OSS data files are generated. In this case, you can use the OSS object inspection feature to monitor the OSS data files.

The OSS object inspection feature can monitor OSS objects of all tenants. To create an OSS Object Inspection node, perform the following steps:

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General** > **OSS Object Inspection**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create** > **OSS Object Inspection**.
3. In the **Create Node** dialog box, set **Node Name** and **Location** and click **Commit**.

   > **Note** The node name must be 1 to 128 characters in length.
4. In the **OSS Object Inspection** section of the node configuration tab that appears, set the parameters.

No.	Parameter	Description
1	**OSS Object**	The storage path of the OSS object. You can add a scheduling parameter to the storage path.
2	**Timeout**	The timeout period during which DataWorks checks whether the OSS object exists in OSS every 5 seconds. If the OSS object is not detected before the timeout period ends, the OSS Object Inspection node fails.
3	**Storage Address**	The storage space of the OSS object. Valid values: ○ **Myself**: detects the OSS object in the storage space of the current tenant. ○ **Other**: detects the OSS object in the storage space of another tenant.

   > **Note**
   > ○ When an OSS Object Inspection node is running, it monitors the OSS object by using MaxCompute. Make sure that MaxCompute has the required permissions on the OSS bucket.
   > ○ In the development or production environment, the node monitors the OSS object by using the access identity of the development or production environment. Make sure that the access identity has the required permissions on the OSS bucket.
   > ○ You cannot specify an OSS object by using the wildcard (*), nor can you use the system parameters cyctime and bizdate. However, you can use custom parameters.
5. Grant MaxCompute the permission to access OSS in the RAM console.

   MaxCompute uses RAM and Security Token Service (STS) of Alibaba Cloud to resolve security issues of accounts.

   ○ If the owners of the MaxCompute project and OSS bucket are using the same Apsara Stack

tenant account, you can authorize MaxCompute to access OSS with one click in the RAM console.

- If the owners of the MaxCompute project and OSS bucket are using different Apsara Stack tenant accounts, you can perform the following steps to authorize MaxCompute to access OSS:

  a. Create a role in the RAM console.

  Create a role, such as AliyunODPSDefaultRole or AliyunODPSRoleForOtherUser, and set the following policy:

```
--The owners of the MaxCompute project and OSS bucket are using different Apsara Stack tenant accounts.
{
"Statement": [
{
"Action": "sts:AssumeRole",
"Effect": "Allow",
"Principal": {
"Service": [
"ID of the Apsara Stack tenant account that owns the MaxCompute project@odps.aliyuncs.com"
]
}
}
],
"Version": "1"
}
```

b. Create the AliyunODPSRolePolicy permission policy that contains the permissions required for accessing OSS.

```
{
"Version": "1",
"Statement": [
{
"Action": [
 "oss:ListBuckets",
 "oss:GetObject",
 "oss:ListObjects",
 "oss:PutObject",
 "oss:DeleteObject",
 "oss:AbortMultipartUpload",
 "oss:ListParts"
],
"Resource": "*",
"Effect": "Allow"
}
]
}
--You can also add other permissions as required.
```

c. Grant the AliyunODPSRolePolicy permission policy to the role.

6. Go to **Operation Center** to view the runtime logs.

   If the following error information appears, the OSS object is not detected:

```
<Error>
 <Code>NoSuchKey</Code>
 <Message>The specified key does not exist. </Message>
 <RequestId></RequestId>
 <HostId>OSS object</HostId>
 <Key>xc/111.txt</Key>
</Error>
```

2.5.5.5.4. Create a merge node

This topic describes the definition of merge nodes and how to create a merge node and define the merging logic. It also provides an example to show the scheduling configuration and running details of a merge node.

A merge node is a logical control node in DataStudio. It can merge the running results of its parent nodes, regardless of their running statuses. It aims at facilitating the running of nodes that depend on the output of the child nodes of a branch node.

You cannot change the running status of a merge node. A merge node merges the running results of multiple child nodes of a branch node and sets the running status to Successful. To guarantee the proper running of a node that depends on the output of the child nodes of a branch node, you can configure the node to directly depend on the merge node.

For example, Branch node C has two logically exclusive branches C1 and C2. These two branches use different logic to write data to the same MaxCompute table. Assume that Node B depends on the output of this MaxCompute table. To make sure that Node B can run properly, you must use Merge node J to merge the running results of branches C1 and C2, and then configure Merge node J as the parent node of Node B. If Node B directly depends on branches C1 and C2, one of the branches will fail to run because only one branch meets the branch condition each time Branch node C runs. In this case, Node B cannot be triggered as scheduled.

Create a merge node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **General > MERGE Nodes**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > MERGE Nodes**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
4. Click **Commit**.

Define the merging logic

After the merge node is created, the node configuration tab appears. Specify the branches to be merged for the node. Enter the output name or output table name of the parent node, and click the **Add** icon. You can view the running status in the Result section. The available running statuses are **Successful** and **Branch Not Running**.

Click the **Properties** tab in the right-side navigation pane and configure the scheduling properties of the merge node.

Run the merge node

If a branch meets the specified condition, the branch is run. You can select the branch and view the running details on the **Runtime Logs** tab.

If a branch does not meet the specified condition, the branch is skipped. You can select the branch and view related information on the **Runtime Logs** tab.

2.5.5.5.5. Create a branch node

A branch node is a logical control node in DataStudio. It can define the branch logic and the direction of branches under different logical conditions.

Prerequisites

Generally, branch nodes need to be used with assignment nodes.

Create a branch node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General > Branch Node**.Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Branch Node**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. Click **Commit**.
5. Define the branch logic
   i. In the **Definition** section, click **Add Branch**.
   ii. In the **Branch Definition** dialog box, set the parameters.

Parameter	Description
Condition	The condition of the branch. ■ You can only use Python comparison operators to define logical conditions for the branch node. ■ If the result of the expression is *true* when the node is running, the corresponding branch condition is met. ■ If the expression fails to be parsed when the node is running, the whole branch node fails. ■ To define branch conditions, you can use global variables and parameters defined in the node context. For example, the ${input} variable can be used as an input parameter of the branch node.
Associated Node Output	The associated node output of the branch. ■ The node output is used to configure dependencies for the child nodes of the branch node. ■ If the branch condition is met, the child node corresponding to the node output is run. If the child node also depends on the output of other nodes, the status of these nodes is considered. ■ If the branch condition is not met, the child node corresponding to the node output is not run. The child node is set to the `Not Running` state.
Description	The description of the branch. For example, the branches ${input}==1 and ${input}>2 are defined.

iii. Click **OK**.After you add a branch, you can click **Change** or **Delete** in the Actions column of the branch to modify or delete it.

- Click **Change** to modify the branch and related dependencies.
- Click **Delete** to delete the branch and related dependencies.

6. On the configuration tab of the branch node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section.After the branch conditions are defined, the output names are automatically added to the **Outputs** section on the **Properties** tab. Then, you can associate child nodes with the branch node based on the output names.

> **Note**
>
> - Child nodes inherit dry-run properties of the parent node. Therefore, we recommend that you do not create a node depending on its last-cycle instance as the branch.
> - The dependencies established by drawing lines between nodes on the dashboard of a workflow are not recorded on the Properties tab. You must manually enter these dependencies.

7. Commit the node.

> **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

i. Click  in the toolbar.

ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

iii. Click **OK**.

In a workspace in standard mode, you need to click **Deploy** in the upper-right corner after you commit the branch node.

8. Test the node.

Supported Python comparison operators

In the following table, assume that the value of the a variable is 10 and that of the b variable is 20.

Comparison operator	Description	Example
==	Equal: checks whether two objects are equal.	(a==b) returns false.
! =	Not equal: checks whether two objects are not equal.	(a! =b) returns true.
<>	Not equal: checks whether two objects are not equal.	(a<>b) returns true. This operator is similar to ! =.

Comparison operator	Description	Example
>	Greater than: checks whether the variable on the left side of the operator is greater than that on the right side.	(a>b) returns false.
<	Less than: checks whether the variable on the left side of the operator is less than that on the right side. If the return result is 0 or 1, 0 indicates false and 1 indicates true. These two results are equivalent to the special variables true and false, respectively.	(a<b) returns true.
>=	Greater than or equal to: checks whether the variable on the left side of the operator is greater than or equal to that on the right side.	(a>=b) returns false.
<=	Less than or equal to: checks whether the variable on the left side of the operator is less than or equal to that on the right side.	(a<=b) returns true.

2.5.5.5.6. Create an assignment node

An assignment node uses one of the three value assignment languages MaxCompute SQL, SHELL, and Python to assign values by using the outputs parameter. This node is used to transmit data between a parent node and a child node based on context-based parameters.

Context

The outputs parameter has the following limits:

- The value of the outputs parameter is taken only from the output of the last line of the code.
  - If you use MaxCompute SQL, the output of the SELECT statement in the last line is used.
  - If you use SHELL, the output of the ECHO statement in the last line is used.
  - If you use Python, the output of the PRINT statement in the last line is used.
- The passed value of the outputs parameter is limited to 2 MB in size. If the output of the assignment statement exceeds this limit, the assignment node fails to run.

> **Note** If you use Python or SHELL, the value of the outputs parameter is a one-dimensional array where elements are separated with commas (,). If you use MaxCompute SQL, the value of the outputs parameter is passed to child nodes as a two-dimensional array.

Create an assignment node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General > Assignment Node**.

Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Assignment Node**.

3. In the **Create Node** dialog box, set **Node Name** and **Location**.

> **Notice** A node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

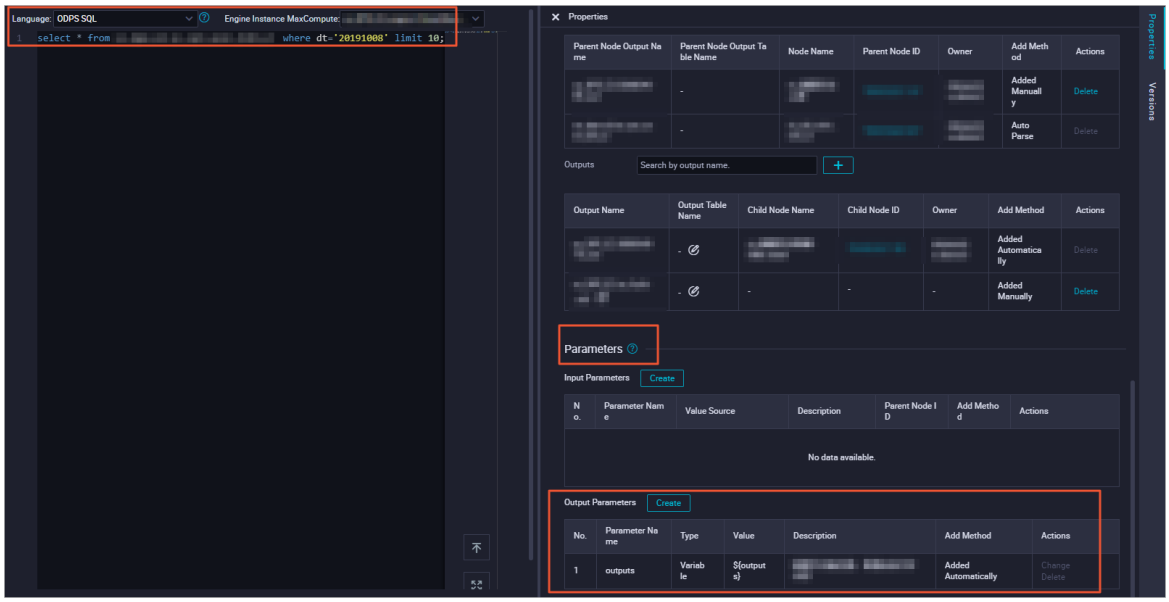
This following sections describe how to use assignment nodes that use the Python, MaxCompute SQL, and SHELL languages respectively to pass data between a parent node and a child node named Assignment node value comparison_shell by using context-based parameters.

After the assignment nodes that use the Python, MaxCompute SQL, and SHELL languages are created, you must set the dependencies so that the child node can reference the parameter values passed by these nodes.

4. Click **Commit**.

Configure the child node to reference the output values of the assignment node that uses MaxCompute SQL

1. Find the target workflow and double-click the assignment node fuzhi_sql that uses MaxCompute SQL.
2. On the configuration tab of the fuzhi_sql node that appears, click **Properties** in the right-side navigation pane.
3. Configure the fuzhi_sql node.The fuzhi_sql node assigns the results queried from a specified table to the outputs parameter.



4. Double-click the Assignment node value comparison_shell node, which is the child node of the fuzhi_sql node.
5. On the configuration tab of the Assignment node value comparison_shell node that appears, click **Properties** in the right-side navigation pane and configure the node.The Assignment node value comparison_shell node depends on the fuzhi_sql node and uses the value of the outputs parameter of the fuzhi_sql node as the value of its input parameter

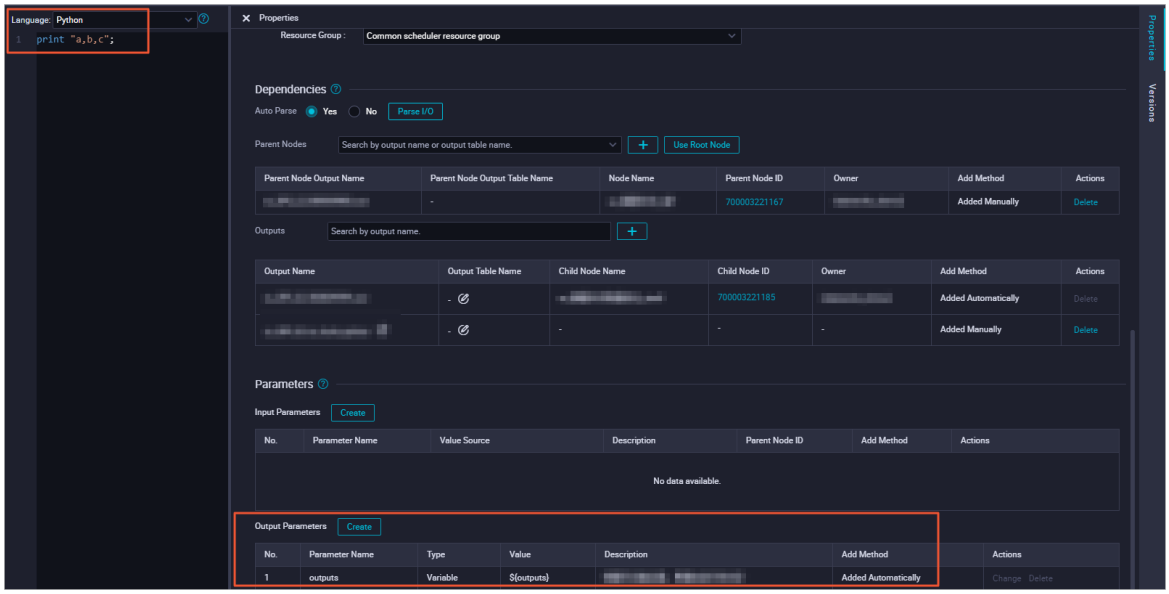
sql_inputs.

```
echo '${sql_inputs}';
echo 'Use the value in the first line in the output of the fuzhi_sql node as the input'${sql_inputs[0]};
echo 'Use the value in the second line in the output of the fuzhi_sql node as the input'${sql_inputs[1]};
echo 'Use the value of the second field in the first line in the output of the fuzhi_sql node as the input'${sql_inputs[0][1]};
echo 'Use the value of the third field in the second line in the output of the fuzhi_sql node as the input'${sql_inputs[1][2]};
```

6. Click in the toolbar.
7. In the **Warning** message, click **Continue to Run**.
8. View the result.

Configure the child node to reference the output values of the assignment node that uses Python

1. Find the target workflow and double-click the assignment node fuzhi_python that uses Python.
2. On the configuration tab of the fuzhi_python node that appears, click **Properties** in the right-side navigation pane.
3. Configure the fuzhi_python node.The fuzhi_python node assigns the values a,b,c to the outputs parameter.



4. Double-click the Assignment node value comparison_shell node, which is the child node of the fuzhi_python node.
5. On the configuration tab of the Assignment node value comparison_shell node that appears, click **Properties** in the right-side navigation pane and configure the node.The Assignment node value comparison_shell node depends on the fuzhi_python node and uses

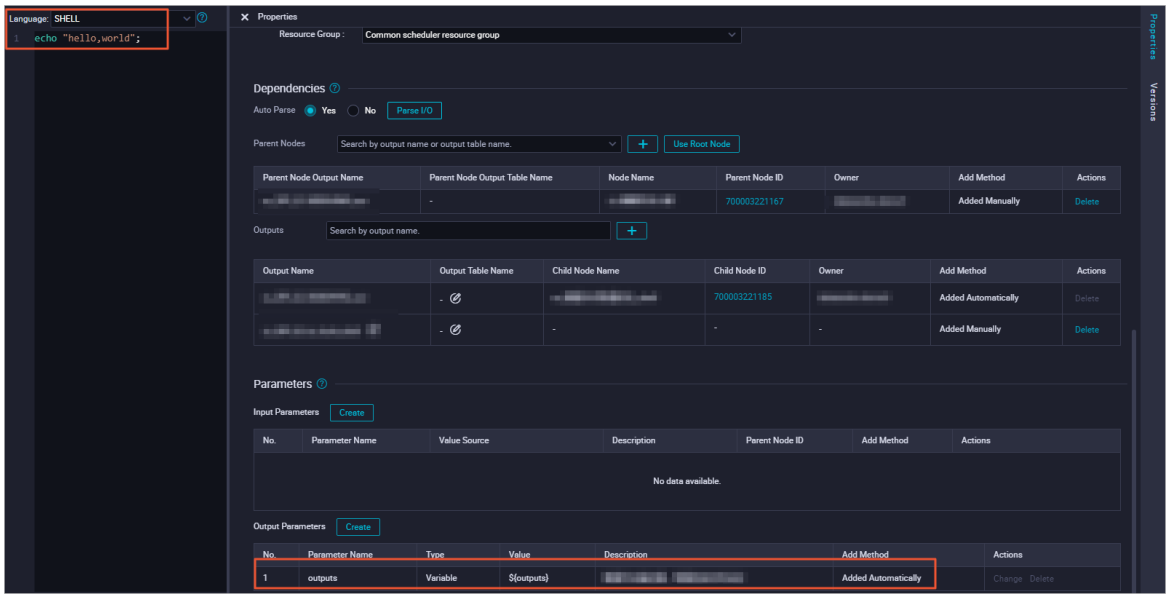
the value of the outputs parameter of the fuzhi_python node as the value of its input parameter python_inputs.

```
echo 'The output of the fuzhi_python node'${python_inputs};
echo 'Use the first value in the output of the fuzhi_python node as the input'${python_inputs[0]};
echo 'Use the second value in the output of the fuzhi_python node as the input'${python_inputs[1]};[1]}
```

6. Click in the toolbar.
7. In the **Warning** message, click **Continue to Run**.
8. View the result.

Configure the child node to reference the output values of the assignment node that uses SHELL

1. Find the target workflow and double-click the assignment node fuzhi_shell that uses SHELL.
2. On the configuration tab of the fuzhi_shell node that appears, click **Properties** in the right-side navigation pane.
3. Configure the fuzhi_shell node.The fuzhi_shell node assigns the values hello,world to the outputs parameter.



4. Double-click the Assignment node value comparison_shell node, which is the child node of the fuzhi_shell node.
5. On the configuration tab of the Assignment node value comparison_shell node that appears, click **Properties** in the right-side navigation pane and configure the node.The Assignment node value comparison_shell node depends on the fuzhi_shell node and uses the value of the outputs parameter of the fuzhi_shell node as the value of its input parameter shell_inputs.

```
echo 'The output of the fuzhi_shell node'${shell_inputs};
echo 'Use the first value in the output of the fuzhi_shell node as the input'${shell_inputs[0]};
echo 'Use the second value in the output of the fuzhi_shell node as the input'${shell_inputs[1]};
```

6. Click in the toolbar.
7. In the **Warning** message, click **Continue to Run**.
8. View the result.

2.5.5.5.7. Create a Shell node

Shell nodes support standard shell syntax but not interactive syntax.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General** > **Shell**.Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create** > **Shell**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. Click **Commit**.
5. Edit the Shell node.
   i. Edit the code on the configuration tab of the Shell node.To call the system scheduling parameters for the Shell node, execute the following statement:

   ```
   echo "$1 $2 $3"
   ```

   > **Note** Separate multiple parameters with spaces.

   i. Click in the toolbar to save the SQL statement to the server.

   ii. Click in the toolbar to execute the SQL statement you have saved.If you need to change the resource group used to test the Shell node on the **DataStudio** page, click in the toolbar and select your desired exclusive resource group.
6. On the configuration tab of the Shell node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section.
7. Commit the node.

   > **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

i. Click in the toolbar.

ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

iii. Click **OK**.

In a workspace in standard mode, you need to click **Deploy** in the upper-right corner after you commit the branch node.

8. Test the node.

2.5.5.5.8. Create a zero-load node

A zero-load node is a control node, which only supports dry-run scheduling and does not generate any data. It usually serves as the root node of a workflow.

Context

You can configure an output table for a zero-load node so that the output table can be used as an input table of another node. However, the zero-load node does not process the table data.

Procedure

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, move the pointer over and choose **General > Zero-Load Node**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Zero-Load Node**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. Click **Commit**.
5. On the configuration tab of the zero-load node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
6. Commit the node.

   > **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

   i. Click in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you need to click **Deploy** in the upper-right corner after you commit the branch node.
7. Test the node.

2.5.5.5.9. Create a cross-tenant collaboration node

Cross-tenant collaboration nodes are used to associate nodes from different tenants. Cross-tenant collaboration nodes are classified into sender nodes and receiver nodes.

Prerequisites

A sender node and its receiver node use the same CRON expression. You can click the **Properties** tab in the right-side navigation pane of a node configuration tab and view the CRON expression in the **Schedule** section.

Create a cross-tenant collaboration node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General > Cross-Tenant Collaboration**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Cross-Tenant Collaboration**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
4. On the node configuration tab, set the parameters in the **Cross-Tenant Collaboration** section.

Parameter	Description
Type	The type of the cross-tenant collaboration node. Valid values: **Sender** and **Receiver**.
Location	The path of the cross-tenant collaboration node. The node path cannot be modified.
Collaborative Workspaces	The workspace name and Apsara Stack tenant account of the peer node. This example sets the node type to Sender. Therefore, you must enter the workspace name and Apsara Stack tenant account of the receiver node.

5. After the sender node is created, follow the same procedure to create the receiver node under the Apsara Stack tenant account and workspace to which the receiver node belongs.

   Set the node type to **Receiver**. The information about available sender nodes appears. You must also set **Timeout**. This parameter indicates the timeout period of the receiver node after it starts running.

   The sender node first sends a message to the message center. After the message is delivered, the status of the sender node is set to successful. The receiver node continuously pulls messages from the message center. If a message is received within the timeout period, the status of the receiver node is set to successful.

   If the receiver node does not receive any messages within the timeout period, the receiver node fails. The lifecycle of a message is 24 hours.

Assume that an auto triggered instance was run on October 8, 2018. A message indicating the completion of the instance was then sent to the message center. If you create a retroactive instance for the receiver node with the data timestamp set to October 7, 2018, the status of the generated receiver node instance is set to successful.

6. After the configuration is completed, save and commit the node.

2.5.5.5.10. Create a data analysis report node

A data analysis report node is used to associate a report in the DataAnalysis module with the parent nodes on which the report depends and update the report as scheduled.

Prerequisites

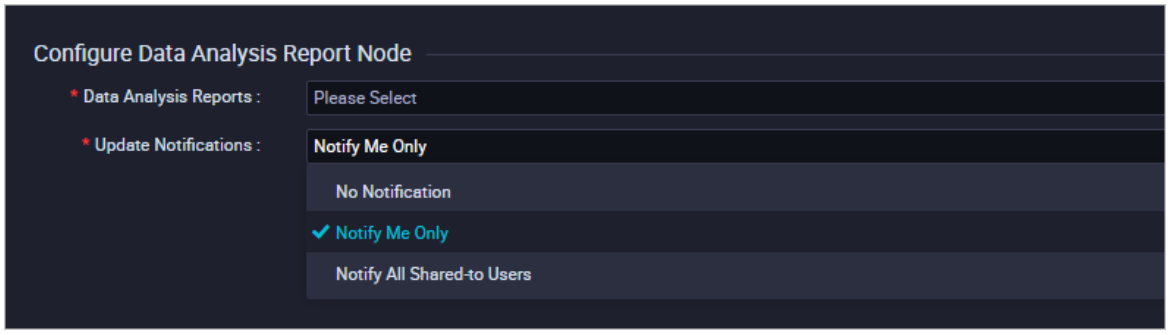
A table is created on the **Report** page of the **DataAnalysis** module.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General > Data Analysis Reports**. Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Data Analysis Reports**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   Note The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. Click **Commit**.
5. On the node configuration tab, set the parameters in the **Configure Data Analysis Report Node** section.



Parameter	Description
Data Analysis Reports	The report for which you want to receive the notifications about the updates. Select a report created on the **Report** page of the **DataAnalysis** module.
Update Notifications	Specifies the users who can receive the notifications when the report is updated. Valid values: **No Notification**, **Notify Me Only**, and **Notify All Shared to Users**.

6. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side

navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.

7. Commit the node.
   i. Click in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see Publish nodes.
8. Test the data analysis report node. For more information, see Recurring tasks.After the node is run in the production environment, you can view updates of the report on the Report page of the **DataAnalysis** module.

2.5.5.5.11. Create a real-time sync node check node

This topic describes how to create and configure a real-time sync node check node.

Context

DataWorks provides the real-time sync node check node for you to associate the status of the current node with scheduling of its child node, which is a batch sync node. After you set dependencies in the workflow, the scheduling of the child node is determined by the status of the current node. This node allows you to schedule real-time sync nodes and batch sync nodes in a unified manner.

Create a real-time sync node check node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General > Check Realtime Compute Node**. Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Check Realtime Compute Node**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   Note The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
4. Click **Commit**.
5. On the node configuration tab that appears, set the parameters in the **Check Realtime Compute Node** section.

Parameter	Description
StreamCompute Node	The real-time sync node in Stream Studio. Note The node must be deployed in Stream Studio.

Parameter	Description
Control rule	The control rule that determines whether to schedule or block the child node based on the status of the current node. ○ The status of the current node can be **Normal** or **Paused**. ■ **Normal**: The node is running and no error is reported. ■ **Paused**: The node is stopped or paused manually, or the node stops or cannot be restarted due to an exception. ○ The control method for the child node can be **Scheduled** or **Blocked**. ■ **Scheduled**: The child node can be run as scheduled. ■ **Blocked**: The child node cannot be scheduled, regardless of the settings.

6. Commit the node.
   i. Click in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the real-time sync node check node. For more information, see Publish nodes.

2.5.5.6. Custom

2.5.5.6.1. Create a Hologres development node

This topic describes how to create and modify a Hologres development node and update the node version.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **Custom > Hologres Development**. Alternatively, you can click a workflow in the Business Flow section, right-click **UserDefined**, and then choose **Create > Hologres Development**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. Click **Commit**.
5. On the node configuration tab that appears, select a Hologres development node.

If no Hologres node is available, click **Create** to create one. You can also click **Change** to modify an existing node.

6. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.
   i. Click  in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see Publish nodes.
8. Test the batch sync node. For more information, see Recurring tasks.

2.5.6. Schedule

2.5.6.1. Basic properties

On the Properties tab of a node, you can set parameters of the node in the General, Schedule, Dependencies, and Parameters sections. The General section allows you to set the basic properties of the node.

On the **Data Analytics** tab of the DataStudio page, double-click a node. On the node configuration tab that appears, click the **Properties** tab in the right-side navigation pane and set the parameters in the **General** section.

Parameter	Description
Node Name	The name of the node that you set when creating the node. To modify the name, right-click the node in the left-side navigation pane and select **Rename**.
Node ID	The unique ID of the node. The node ID is generated when the node is committed at the first time. The node ID cannot be modified.
Node Type	The type of the node that you set when creating the node. The node type cannot be modified.
Owner	The owner of the node. By default, the owner of a newly created node is the current logon user. You can change the owner. **Note** Only a member in the workspace where the node resides can be selected as the owner.
Description	The description of the node, such as the business and usage.
Arguments	The parameter used to assign a value to a variable in the code during node scheduling. You can enter multiple parameters. Separate multiple parameters with spaces.

Parameter value assignment formats for various node types

- Format for ODPS SQL and ODPS MR nodes: `Variable name 1=Parameter 1 Variable name 2=Parameter 2`. Separate multiple parameters with spaces.
- Format for Shell nodes: `Parameter 1 Parameter 2`. Separate multiple parameters with spaces.

For more information about the built-in scheduling parameters, see Parameter configuration.

2.5.6.2. Scheduling parameters

In common data development scenarios, the code of different types of nodes may be subject to change from time to time. You must dynamically modify the values of some parameters, such as the date and time, based on the requirement changes and time changes.

In this case, you can use the scheduling parameter configuration feature of DataWorks. After relevant parameters are set, auto triggered nodes can automatically parse the code to obtain required data. Configurable parameters in DataWorks are classified into system parameters and custom parameters. We recommend that you use custom parameters.

```
{
  "data":[
  {
    "beginRunningTime":"1564019679966",
    "beginWaitResTime":"1564019679966",
    "beginWaitTimeTime":"1564019679506",
    "bizdate":"1559318400000",
    "createTime":"1564019679464",
    "dagId":332455685,
    "dagType":5,
    "finishTime":"1564019679966",
    "instanceId":2427622331,
    "modifyTime":"1564019679966",
    "nodeName":"vi","status":6
  }
  ],
  "errCode":"0",
  "errMsg":"",
  "requestId":"E17535-8C06-43F6-B1EA-6236FE9",
  "success":true
  }
```

Auto-completion is supported when you specify a data type for a parameter.

Parameter types

Parameter type	Configuration method	Applicable to	Example
System parameters: including bdp.system.bizdate and bdp.system.cyctime	To use the system parameters in the scheduling system, reference ${bdp.system.bizdate} and ${bdp.system.cyctime} in the code, instead of setting them in the Arguments field. The system can automatically replace the values of the parameters that reference the system parameters in the code.	All nodes	N/A
Non-system parameters: custom parameters (recommended)	Reference ${key1} and ${key2} in the code and set them in the Arguments field, for example, `"key1=value1 key2=value2"`.	Non-Shell nodes	• **Constant parameters:** param1="abc"param2=1234. • **Variables:** param1=$[yyyymmdd], the value of which is calculated based on the value of bdp.system.cyctime.
	Reference $1, $2, and $3 in the code and set them in the Arguments field, for example, `"value1 value2 value3"`.	Shell nodes	• **Constant parameters:** "abc" 1234. • **Variables:** $[yyyymmdd], the value of which is calculated based on the value of bdp.system.cyctime.

As described in the preceding table, the values of custom variables are calculated based on the values of system parameters. You can use custom variables to flexibly define the data to be obtained and the data format. For custom parameters, the following types of brackets are used:

- Braces { } define the data timestamp. For example, the value of {yyyymmdd} is calculated based on the value of bdp.system.bizdate.
- Brackets [ ] define the running time. For example, the value of [yyyymmddhh] is calculated based on the value of bdp.system.cyctime.

> **Note** Nodes can be scheduled only in the production environment. Therefore, the values of scheduling variables are replaced only after nodes are run in the production environment.
>
> After you set the scheduling variables for a node, you can click the **Run Smoke Test in Development Environment** icon on the node configuration tab to test whether the values of scheduling variables can be replaced as expected during node scheduling.
>
> You can click the **Properties** tab in the right-side navigation pane, and assign values to scheduling variables in the **Arguments** field in the **General** section. Note the following issues when you set parameters:
>
> - Do not add spaces on either side of the equal sign (=) for a parameter. For example, enter `bizdate=$bizdate`.
> - Separate multiple parameters (if any) with spaces. For example, enter `bizdate=$bizdate datetime=${yyyymmdd}`.

System parameters

DataWorks provides the following system parameters:

- ${bdp.system.cyctime}: the scheduled time to run an instance. Default format: yyyymmddhh24miss. This parameter can specify the hour and minutes of the scheduled time.
- ${bdp.system.bizdate}: the timestamp of data to be analyzed by an instance. Default format: yyyymmdd. The default data timestamp is one day before the scheduled time.

Use the following formula to calculate the running time based on the data timestamp: `Running time = Data timestamp + 1`.

To use the system parameters, you can reference them in the code, instead of setting them in the Arguments field. The system can automatically replace the values of the parameters that reference the system parameters in the code.

> **Note** The scheduling properties of an auto triggered node are configured to define the scheduling rules of the running time. Therefore, you can calculate the data timestamp based on the scheduled time to run an instance and obtain the values of system parameters for the instance.

Example of system parameters

For example, to set an ODPS SQL node to run once per hour from 00:00 to 23:59 every day, perform the following steps if you want to use system parameters in the code:

1. Reference system parameters in the code.

```
insert overwrite table tb1 partition(ds ='20150304') select
c1,c2,c3
from (
select * from tb2
where ds ='${bdp.system.cyctime}') t
full outer join(
select * from tb3
where ds = '${bdp.system.bizdate}') y
on t.c1 = y.c1;
```

2. After the preceding step, your node is partitioned by using the system parameters. Set the scheduling properties and dependencies. For more information, see Schedule and Dependencies. In this example, the node is scheduled by hour.
3. After you set the recurrence and dependencies, commit and deploy the node. Then, you can check the node in Operation Center. The scheduling system generates instances for the auto triggered node from the second day. You can right-click an instance in the directed acyclic graph (DAG) and select **View Runtime Log** to view the parsed values of the system parameters.

   For example, the scheduling system generated 24 running instances for the node on January 14, 2019. The data timestamp is January 13, 2019 for all instances. Therefore, the value of ${bdp.system.bizdate} is 20190113. The running time is the running date appended with the scheduled time. Therefore, the value of ${bdp.system.cyctime} is 20190114000000 plus the scheduled time of each instance.

   Open the runtime logs of each instance and search for the replaced values of the system parameters in the code:

   - The scheduled time for the first instance is January 14, 2019 00:00:00. Therefore, bdp.system.bizdate is replaced with 20190113 and bdp.system.cyctime is replaced with 20190114000000.
   - The scheduled time for the second instance is January 14, 2019 01:00:00. Therefore, bdp.system.bizdate is replaced with 20190113 and bdp.system.cyctime is replaced with 20190114010000.
   - Similarly, the scheduled time for the twenty-fourth instance is January 14, 2019 23:00:00. Therefore, bdp.system.bizdate is replaced with 20190113 and bdp.system.cyctime is replaced with 20190114230000.

Custom parameters for non-Shell nodes

To set scheduling variables for a non-Shell node, add ${Variable name} in the code to reference the function and assign a value to the scheduling variable.

> **Note** The name of a variable in the SQL code can contain only letters, digits, and underscores (_). If the variable name is date, the value of $bizdate is automatically assigned to this variable. For more information, see the "Built-in scheduling parameters" section in this topic. You do not need to assign a value in the Arguments field. Even if another value is assigned, it is not used in the code because the value of $bizdate is automatically assigned in the code.

Example of custom parameters for non-Shell nodes

For example, to set an ODPS SQL node to run once per hour from 00:00 to 23:59 every day, perform the following steps if you want to use the hour-related custom variables thishour and lasthour in the code:

1. Reference the parameters in the code.

```
insert overwrite table tb1 partition(ds ='20150304')  select
 c1,c2,c3
from (
 select * from tb2
 where ds ='${thishour}') t
full outer join(
 select * from tb3
 where ds = '${lasthour}') y
on t.c1 = y.c1;
```

2. Click the **Properties** tab in the right-side navigation pane of the node configuration tab. Assign values to the custom parameters referenced in the code in the **Arguments** field in the **General** section.

   Set the custom parameters in the following formats:

   - thishour=$[yyyy-mm-dd/hh24:mi:ss]
   - lasthour=$[yyyy-mm-dd/hh24:mi:ss-1/24]

   > **Note** The value of yyyy-mm-dd/hh24:mi:ss corresponds to that of cyctime. For more information, see the "Custom parameters" section in this topic.

   You can enter `thishour=$[yyyy-mm-dd/hh24:mi:ss] lasthour=$[yyyy-mm-dd/hh24:mi:ss-1/24]` in the **Arguments** field.

3. Set the node to run once per hour.
4. After you set the recurrence and dependencies, commit and deploy the node. Then, you can check the node in Operation Center. The scheduling system generates instances for the auto triggered node from the second day. You can right-click an instance in the DAG and select **View Runtime Log** to view the parsed values of the custom parameters. The value of cyctime is 20190114010000. Therefore, the value of thishour is 2019-01-14/01:00:00 and the value of lasthour, which indicates the last hour, is 2019-01-14/00:00:00.

Custom parameters for Shell nodes

The parameter configuration procedure of a Shell node is similar to that of a non-Shell node, except that the variable naming rules are different. Variable names for a Shell node cannot be customized, but must follow the $1,$2,$3... format. For example, add $1 in the code of a Shell node and enter the built-in scheduling parameter $xxx in the Arguments field. Then, the value of $xxx can replace that of $1 in the code.

> **Note** If the number of parameters in a Shell node reaches 10, use ${10} to declare the tenth variable.

Example of custom parameters for Shell nodes

For example, set a Shell node to run at 01:00 every day. To use the custom constant parameter myname and the custom variable ct in the code, perform the following steps:

1. Reference the parameters in the code.

   ```
   echo "hello $1, two days ago is $2, the system param is ${bdp.system.cyctime}";
   ```

2. Click the **Properties** tab in the right-side navigation pane of the node configuration tab. Assign values to the custom parameters referenced in the code in the **Arguments** field in the **General** section. Separate multiple parameters with spaces, for example, enter Parameter 1 Parameter 2 Parameter 3. The custom parameters are parsed based on the parameter sequence. For example, $1 is replaced with the value of Parameter 1. In this example, enter abcd $[yyyy-mm-dd-2] in the Arguments field to set $1 and $2 to abcd and $[yyyy-mm-dd-2], respectively.
3. Set the node to run at 01:00 every day.
4. After you set the recurrence and dependencies, commit and deploy the node. Then, you can check the node in Operation Center. The scheduling system generates instances for the auto triggered node from the second day. Right-click an instance in the DAG and select **View Runtime Log**. The logs show that $1 in the code is replaced with abcd, $2 is replaced with 2019-01-12 (two days before the running date), and ${bdp.system.cyctime} is replaced with 20190114010000.

Custom parameters

Custom parameters are divided into constant parameters and variables based on the value type. DataWorks provides some built-in scheduling parameters as variables.

- Constant parameters

  For example, for an SQL node, add ${Variable name} in the code and set the following parameter for the node: Variable name=Fixed value.

  - Code: `select xxxxxx type='${type}'`
  - Value assigned to the scheduling variable: type='aaa'. When the node is run, the variable in the code is replaced with type='aaa'.

- Variables

  Variables are built-in scheduling parameters whose values depend on the system parameters ${bdp.system.bizdate} and ${bdp.system.cyctime}.

  For example, for an SQL node, add ${Variable name} in the code and set the following parameter for the node: Variable name=Scheduling parameter.

  - Code: `select xxxxxx dt=${datetime}`
  - Value assigned to the scheduling variable: datetime=$bizdate

    If the node is run on July 22, 2017, the variable in the code is replaced with dt=20170721.

Built-in scheduling parameters

- $bizdate
  - Parameter description: the data timestamp in the format of yyyymmdd. By default, the value of this parameter is one day before the scheduled time to run a node.
  - For example, the code of an ODPS SQL node includes pt=${datetime}, and the parameter configured for the node is datetime=$bizdate. If the node is run on July 22, 2017, $bizdate is replaced with pt=20170721.
- $cyctime
  - Parameter description: the scheduled time to run a node. If no scheduled time is configured for a node scheduled by day, $cyctime is set to 00:00 of the day. The time is accurate to seconds. This parameter is usually used for nodes scheduled by hour or minute.

    Note
    - Pay attention to the difference between the time parameters configured by using $[] and ${}. $bizdate specifies the data timestamp, which is one day before the current day by default.
    - $cyctime specifies the scheduled time to run a node. If no scheduled time is configured for a node scheduled by day, $cyctime is set to 00:00 of the day. The time is accurate to seconds. This parameter is usually used for nodes scheduled by hour or minute.

      For example, if a node is scheduled to run at 00:30 on the current day, $cyctime is set to yyyy-mm-dd 00:30:00.
    - If a time parameter is configured by using ${}, $bizdate is used as the benchmark for running nodes. The time parameter is replaced with the data timestamp selected for retroactive data generation.
    - If a time parameter is configured by using $[], $cyctime is used as the benchmark for running nodes. The time is calculated in the same way as the time in Oracle. The time parameter is replaced with the data timestamp selected for retroactive data generation plus one day.

      For example, if the data timestamp is set to 20140510 for retroactive data generation, $cyctime is replaced with 20140511.
  - The following examples show the values of custom parameters when $cyctime is set to 20140515103000:
    - $[yyyy] = 2014, $[yy] = 14, $[mm] = 05, $[dd] = 15, $[yyyy-mm-dd] = 2014-05-15, $[hh24:mi:ss] = 10:30:00, $[yyyy-mm-dd hh24:mi:ss] = 2014-05-1510:30:00
    - $[hh24:mi:ss - 1/24] = 09:30:00
    - $[yyyy-mm-dd hh24:mi:ss -1/24/60] = 2014-05-1510:29:00
    - $[yyyy-mm-dd hh24:mi:ss -1/24] = 2014-05-15 09:30:00
    - $[add_months(yyyymmdd,-1)] = 20140415
    - $[add_months(yyyymmdd,-12*1)] = 20130515
    - $[hh24] =10
    - $[mi] =30

  - Method for testing the $cyctime parameter:

    After an instance starts to run, right-click the instance in the DAG and select **More**. Check whether the scheduled time is the time at which the instance is run.

- $jobid
  - Parameter description: the ID of the workflow to which a node belongs.
  - Example: jobid=$jobid.
- $nodeid
  - Parameter description: the ID of a node.
  - Example: nodeid=$nodeid.
- $taskid
  - Parameter description: the instance ID of a node.
  - Example: taskid=$taskid.
- $bizmonth
  - Parameter description: the month of the data timestamp in the format of yyyymm. If the month of a data timestamp is the current month, the value of $bizmonth is the month of the data timestamp minus 1. Otherwise, the value of $bizmonth is the month of the data timestamp.
  - For example, the code of an ODPS SQL node includes pt=${datetime}, and the parameter configured for the node is datetime=$bizmonth.

    Assume that the current day is July 22, 2017. If the node is run on July 22, 2017, $bizmonth is replaced with pt=201706.
- ${...} custom parameters
  - You can customize a time format based on the value of $bizdate, where yyyy indicates the four-digit year, yy indicates the two-digit year, mm indicates the month, and dd indicates the day. You can use any combination of these parameters, for example, ${yyyy}, ${yyyymm}, ${yyyymmdd}, and ${yyyy-mm-dd}.
  - $bizdate is accurate to the day. Therefore, ${...} can specify only the year, month, or day.

- The following table describes how to specify other intervals based on $bizdate.

Interval	Expression
N years later	${yyyy+N}
N years before	${yyyy-N}
N months later	${yyyymm+N}
N months before	${yyyymm-N}
N weeks later	${yyyymmdd+7*N}
N weeks before	${yyyymmdd-7*N}
N days later	${yyyymmdd+N}
N days before	${yyyymmdd-N}

- $gmtdate
  - Parameter description: the current date in the format of yyyymmdd. By default, the value of this parameter is the current date. During retroactive data generation, the input value is the data timestamp plus one day.
  - For example, the code of an ODPS SQL node includes pt=${datetime}, and the parameter configured for the node is datetime=$gmtdate. Assume that the current day is July 22, 2017. If the node is run on July 22, 2017, $gmtdate is replaced with pt=20170722.
- ${yyyymmdd}
  - Parameter description: the data timestamp in the format of yyyymmdd. The value of this parameter is the same as that of $bizdate. This parameter supports delimiters, for example, yyyy-mm-dd.

    By default, the value of this parameter is one day before the scheduled time to run a node. You can customize a time format for this parameter, for example, yyyy-mm-dd for ${yyyy-mm-dd}.

- Examples:
  - The code of an ODPS SQL node includes pt=${datetime}, and the parameter configured for the node is datetime=${yyyy-mm-dd}. If the node is run on July 22, 2018, ${yyyy-mm-dd} is replaced with pt=2018-07-21.
  - The code of an ODPS SQL node includes pt=${datetime}, and the parameter configured for the node is datetime=${yyyymmdd-2}. If the node is run on July 22, 2018, ${yyyymmdd-2} is replaced with pt=20180719.
  - The code of an ODPS SQL node includes pt=${datetime}, and the parameter configured for the node is datetime=${yyyymm-2}. If the node is run on July 22, 2018, ${yyyymm-2} is replaced with pt=201805.
  - The code of an ODPS SQL node includes pt=${datetime}, and the parameter configured for the node is datetime=${yyyy-2}. If the node is run on July 22, 2018, ${yyyy-2} is replaced with pt=2016.
  - You can assign values to multiple parameters when configuring an ODPS SQL node. For example, set startdatetime=$bizdate enddatetime=${yyyymmdd+1} starttime=${yyyy-mm-dd} endtime=${yyyy-mm-dd+1}.

FAQ

- Q: The table partition format is pt=yyyy-mm-dd hh24:mi:ss, but spaces are not allowed in scheduling parameters. How can I configure the format of $[yyyy-mm-dd hh24:mi:ss]?

  A: Use the custom variables datetime=$[yyyy-mm-dd] and hour=$[hh24:mi:ss] to obtain the date and time. Then, join them together to form pt="${datetime} ${hour}" in the code. Separate the two variables with a space.

- Q: The table partition is pt="${datetime} ${hour}" in the code. To obtain the data for the last hour when the node is run, the custom variables datetime=$[yyyymmdd] and hour=$[hh24-1/24] can be used to obtain the date and time, respectively. However, for an instance running at 00:00, it analyzes data for 23:00 of the current day, instead of 23:00 of the previous day. What measures can I take in this case?

  A: Modify the formula of datetime to $[yyyymmdd-1/24] and keep the formula of hour unchanged at $[hh24-1/24]. Then, the node can be run properly.

  - For an instance that is scheduled to run at 2015-10-27 00:00:00, the values of $[yyyymmdd-1/24] and $[hh24-1/24] are 20151026 and 23, respectively. This is because the scheduled time minus 1 hour is a time value that belongs to yesterday.
  - For an instance that is scheduled to run at 2015-10-27 01:00:00, the values of $[yyyymmdd-1/24] and $[hh24-1/24] are 20151027 and 00, respectively. This is because the scheduled time minus 1 hour is a time value that belongs to the current day.

DataWorks offers the following node running modes:

- Manually run a node in DataStudio: You must assign temporary values to parameters in the code to ensure proper running of the node. The assigned values are not saved as node properties and do not take effect in other node running modes.
- Automatically run a node at specified intervals: No configuration is needed in the Arguments field. The scheduling system automatically replaces the values of parameters based on the scheduled time of the current instance.
- Test a node or generate retroactive data: You must specify the data timestamp. The scheduled time of each instance can be calculated based on the formula described earlier in this topic.

2.5.6.3. Scheduling properties

This topic describes how to configure the scheduling properties of a node, including the recurrence and dependencies.

You can click the **Properties** tab in the right-side navigation pane of the node configuration tab and set the parameters in the **Schedule** section.

Node status

- **Normal:** If you select this option, the node is run based on the recurrence. By default, this option is selected for a node.
- **Dry Run:** If you select this option, the node is run based on the recurrence. However, the scheduling system does not actually run the code but directly returns a success response.
- **Retry Upon Error:** If you select this check box, the node is rerun when it encounters an error. By default, a node can be automatically rerun for a maximum of three times at an interval of 2 minutes.
- **Skip Execution:** If you select this check box, the node is run based on the recurrence. However, the scheduling system does not actually run the code but directly returns a failure response. You can select this check box if you want to suspend a node and run it later.

Recurrence

After a node is committed and deployed, the scheduling system generates instances every day from the next day based on the scheduling properties of the node. Then, the scheduling system runs the instances based on the running results of ancestor instances and the scheduled time. If a node is committed and deployed after 23:30, the scheduling system generates instances for it from the third day.

> **Note**
>
> If you schedule a node to run every Monday, the node is run only on Mondays. On the other days, the scheduling system does not actually run the code but directly returns a success response. When you test a node scheduled by week or generate retroactive data for the node, you must set the data timestamp to one day earlier than the scheduled time to run the node.
>
> For an auto triggered node, its dependencies take priority over other scheduling properties. That is, when the scheduled time arrives, the scheduling system does not immediately run a node instance but first checks whether all the ancestor instances are run.
>
> - The node instance is in the Not Running state if any ancestor instances are not run when the scheduled time arrives.
> - The node instance is in the Pending (Schedule) state if the scheduled time does not arrive but all the ancestor instances are run.
> - The node instance is in the Pending (Resources) state if all the ancestor instances are run and the scheduled time arrives.

Cross-cycle dependencies

DataWorks supports the following three types of cross-cycle dependencies:

- Dependency on instances of child nodes
  - Node dependency: The current node depends on the last-cycle instances of its child nodes. For example, Node A has three child nodes B, C, and D. If you select this node dependency, Node A depends on the last-cycle instances of nodes B, C, and D.
  - Business scenario: The current node depends on instances of child nodes in the last cycle to cleanse the output tables of the current node and check whether the final result is generated properly.
- Dependency on instances of the current node
  - Node dependency: The current node depends on its last-cycle instances.
  - Business scenario: The current node depends on the data output result of its last-cycle instances.
- Dependency on instances of custom nodes: If you select this node dependency, enter the IDs of the nodes on which the current node depends. You can specify multiple nodes and separate their IDs with commas (,). For example, enter 12345,23456.
  - Node dependency: The current node depends on the last-cycle instances of custom nodes.
  - Business scenario: In the business logic, the current node depends on the proper output of other business data that is not processed by the current node.

> **Note** The difference between cross-cycle dependencies and dependencies in the current cycle lies in that cross-cycle dependencies are displayed as dotted lines in Operation Center.
>
> Before deleting a node from Operation Center, you must delete all dependencies of the node so that other nodes can run properly.

Scheduled by day

Nodes scheduled by day are automatically run once per day. When you create an auto triggered node, the node is set to run at 00:00 every day by default. You can specify another time as needed. In the example shown in the following figure, the time is specified as 13:00.

- If you select Customize Runtime, the node is run at the specified time every day. The time format is YYYY-MM-DD HH:MM:SS.

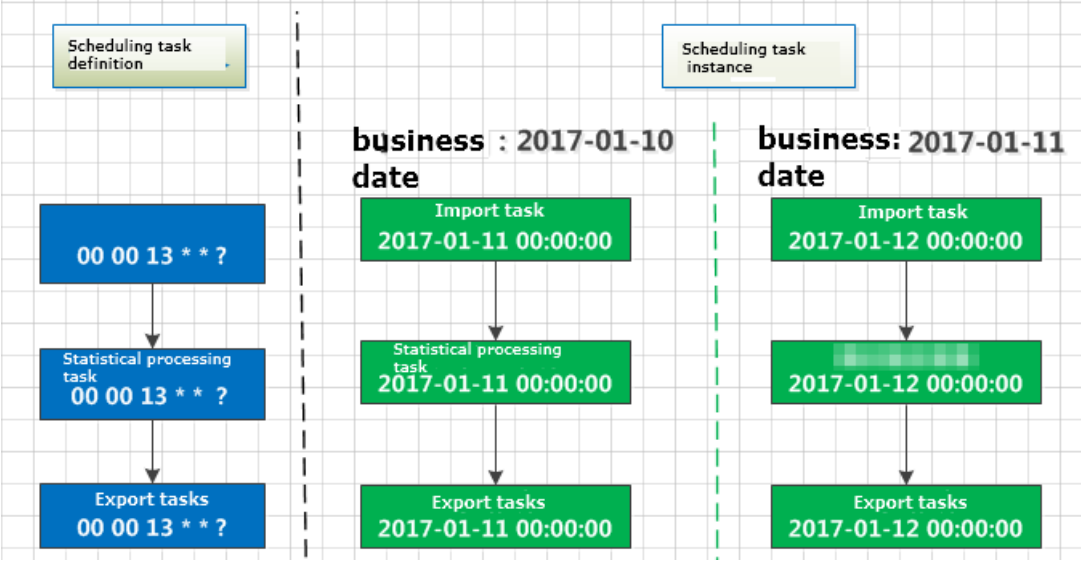
  > **Note** An auto triggered node can be run only when all the ancestor instances are run and the scheduled time arrives. Both prerequisites are indispensable and have no specific chronological order.

- If you clear Customize Runtime, the scheduled time of the node is randomly set in the range of 00:00 to 00:30.

Scenarios:

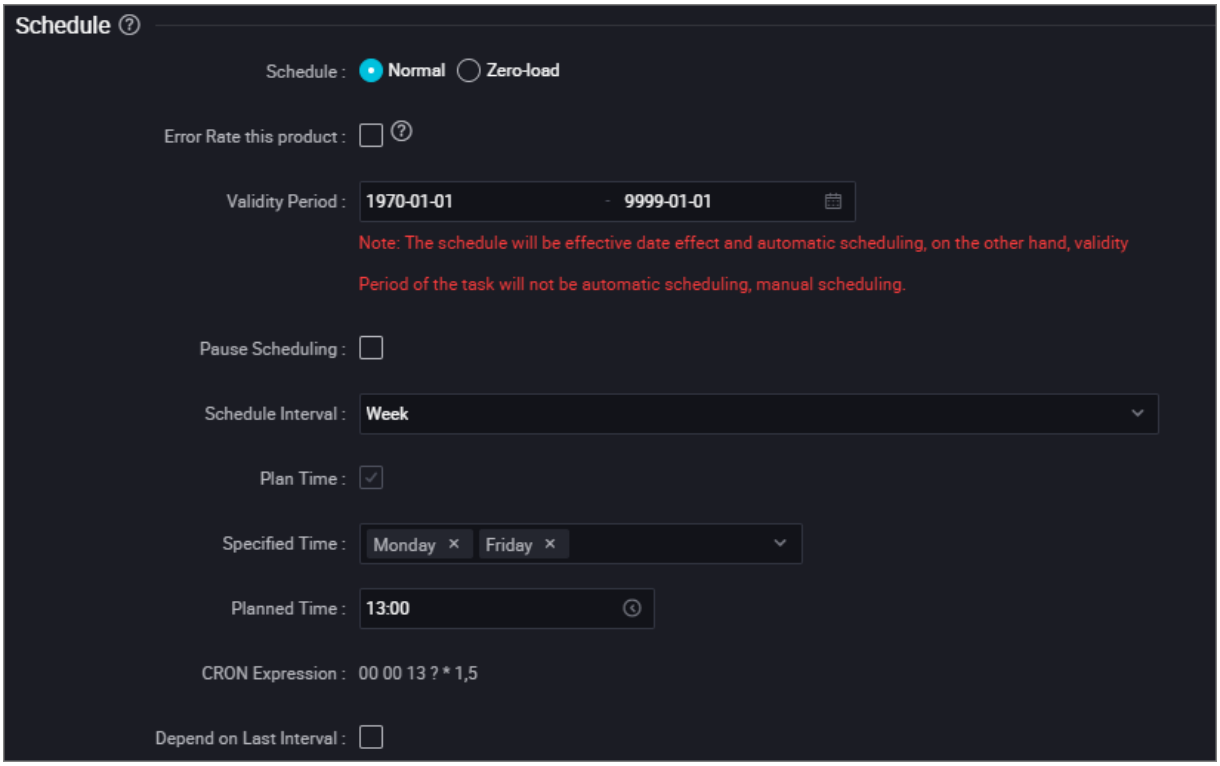
For example, you have created an import node, an analytics node, and an export node. They are all scheduled to run at 13:00 every day. The analytics node depends on the import node, and the export node depends on the analytics node. The following figure shows that the analytics node is configured to depend on the import node.

Based on the preceding node scheduling properties, the scheduling system automatically generates and runs instances for the nodes, as shown in the following figure.



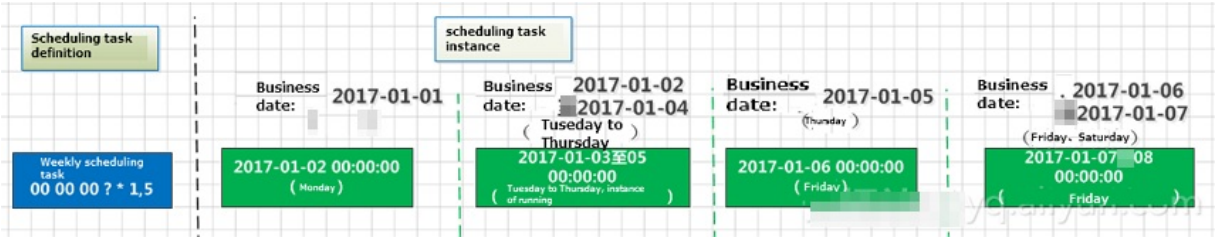
Scheduled by week

Nodes scheduled by week are automatically run at a specified time of specified days every week. On the other days, the scheduling system still generates instances to make sure the proper running of descendant instances. However, the system does not actually run the code or consume resources but directly returns a success response.



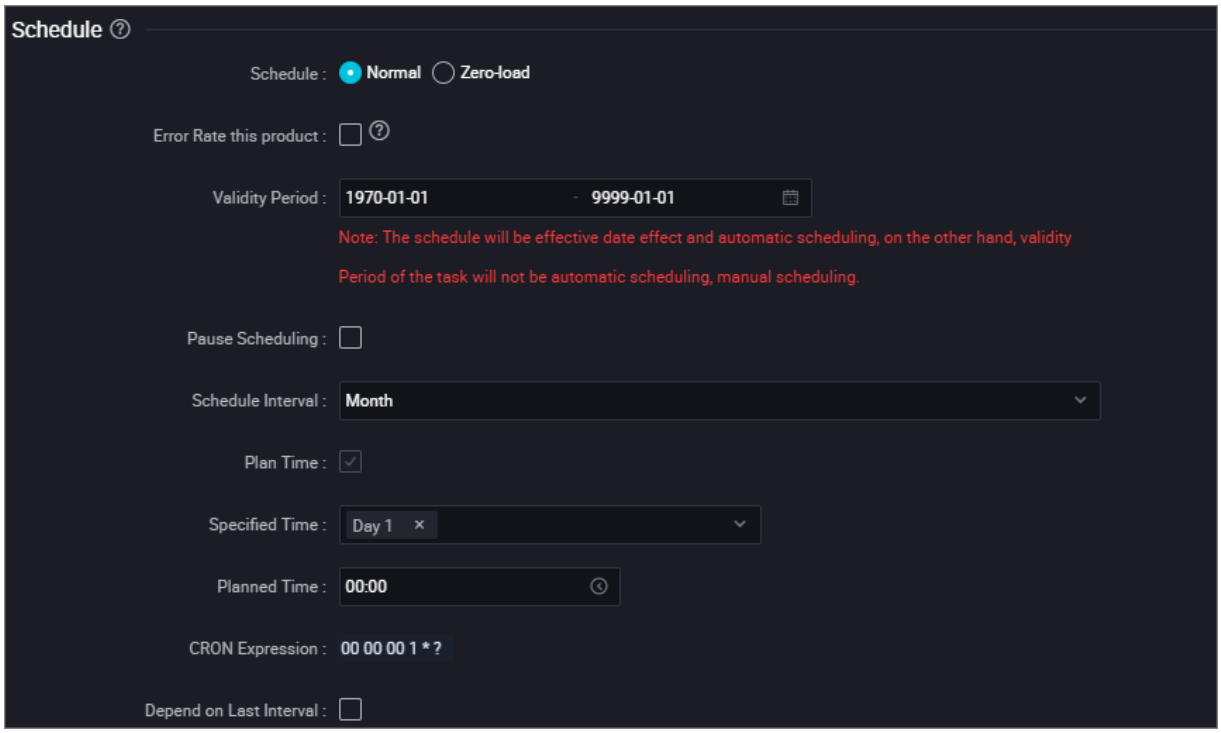
For example, you have created a node. As shown in the preceding figure, the scheduling system runs instances generated on Mondays and Fridays, but returns success responses without running the code for instances generated on Tuesdays, Wednesdays, Thursdays, Saturdays, and Sundays.

Based on the preceding node scheduling properties, the scheduling system automatically generates and runs instances for the node, as shown in the following figure.



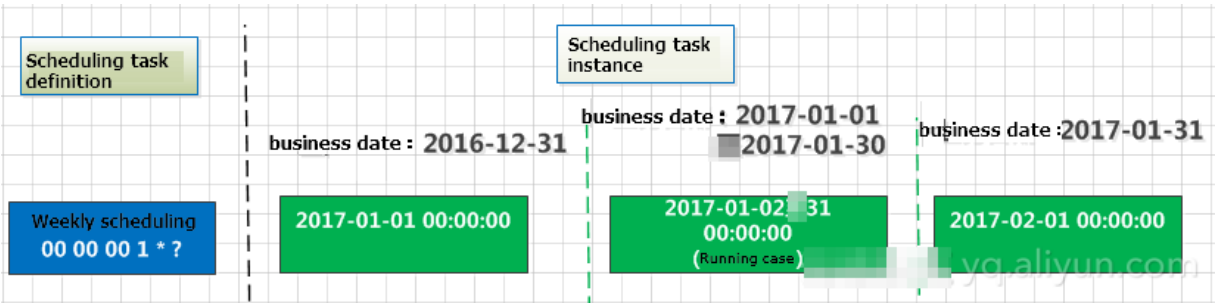
Scheduled by month

Nodes scheduled by month are automatically run at a specified time of specified days every month. On the other days, the scheduling system still generates instances to make sure the proper running of descendant instances. However, the system does not actually run the code or consume resources but directly returns a success response.



For example, you have created a node. As shown in the preceding figure, the scheduling system runs the instance generated on the first day of each month, but returns success responses without running the code for instances generated on the other days.

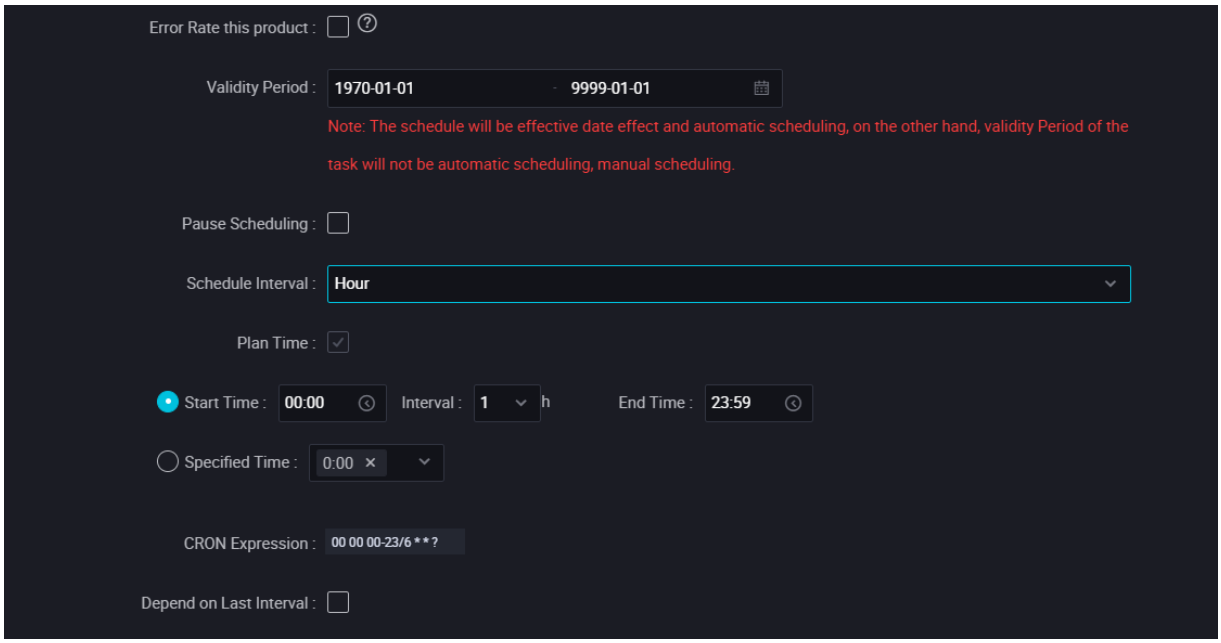
Based on the preceding node scheduling properties, the scheduling system automatically generates and runs instances for the node, as shown in the following figure.



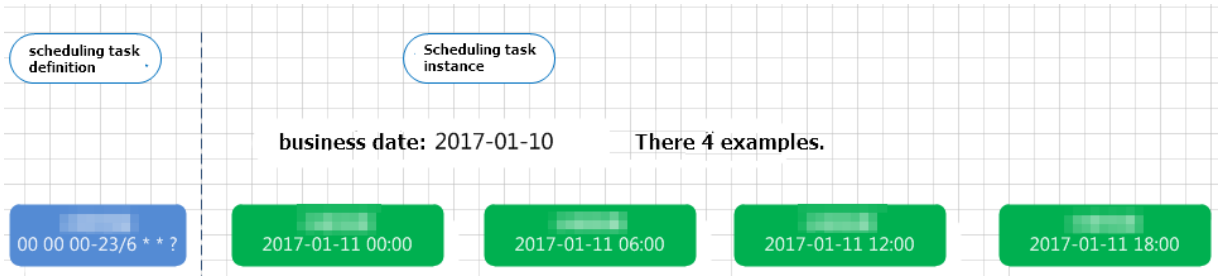
Scheduled by hour

Nodes scheduled by hour are automatically run once every N hours in a specific time period every day. For example, a node is run once per hour from 01:00 to 04:00 every day.

> **Note** The time period is a closed interval. For example, if a node is scheduled to run once per hour in the period from 00:00 to 03:00, the scheduling system generates four instances every day, which are run at 00:00, 01:00, 02:00, and 03:00, respectively.



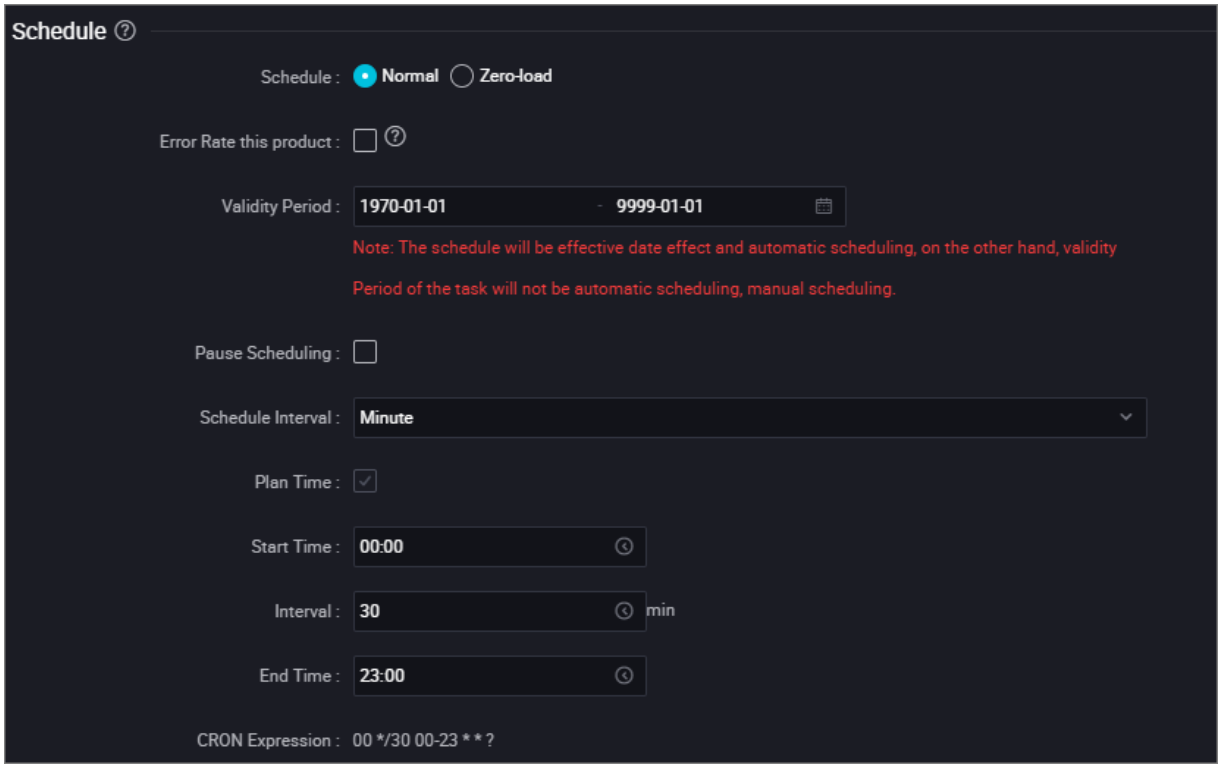
For example, you have created a node. As shown in the preceding figure, the node is automatically run every 6 hours in the period from 00:00 to 23:59 every day. In this case, the scheduling system automatically generates and runs instances for the node, as shown in the following figure.



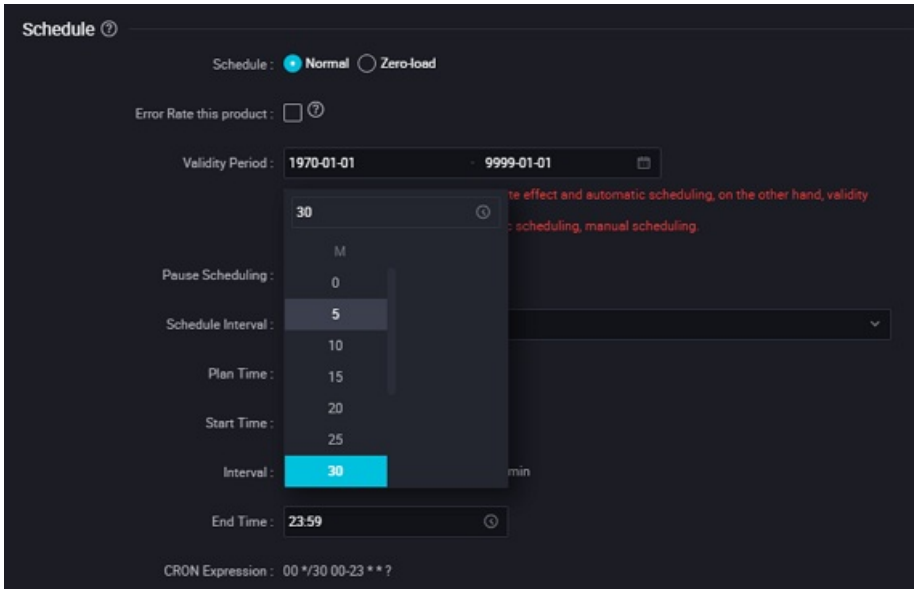
Scheduled by minute

Nodes scheduled by minute are automatically run once every N minutes in a specific time period every day.

For example, you have created a node. As shown in the following figure, the node is run every 30 minutes in the period from 00:00 to 23:00 every day.



Currently, a minimum interval of 5 minutes is supported. The time expression is automatically generated based on the time you select and cannot be modified.



FAQ

- Q: Node A is scheduled by hour and Node B is scheduled by day. How do I enable Node B to automatically run every day after all instances of Node A are run?

A: A node scheduled by day can depend on a node scheduled by hour. To enable Node B to automatically run every day after all 24 instances of Node A are run, do not specify the time to run Node B every day. Then, configure Node A as an ancestor of Node B. For more information, see the Dependencies topic. A node can depend on any other node, regardless of the recurrence. The recurrence of each node is specified in its scheduling properties.

- Q: Node A is run once per hour on the hour every day and Node B is run once per day. How do I enable Node B to automatically run after Node A is run for the first time every day?

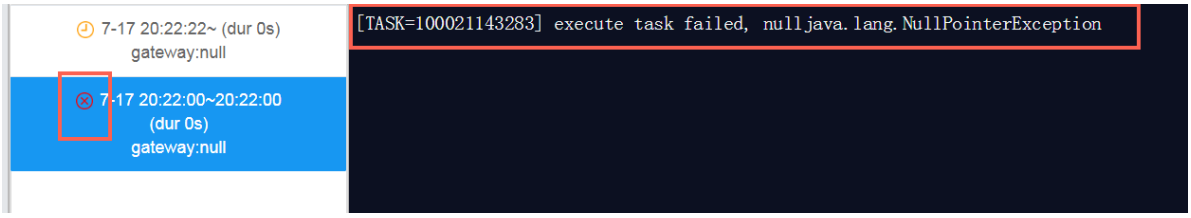
  A: When configuring the scheduling properties of Node A, select **Cross-Cycle Dependencies** and select **Instances of Current Node** from the Depend On drop-down list. When configuring the scheduling properties of Node B, configure Node B to depend on Node A and set the scheduled time of Node B to 00:00 every day. In this way, instances of Node B only depend on the instance of Node A generated at 00:00 every day, that is, the first instance of Node A.

- Q: Node A is run once every Monday and Node B depends on Node A. How do I enable Node B to run once every Monday?

  A: Set the scheduling properties of Node B to be the same as those of Node A. That is, select **Week** as the instance recurrence and select **Monday**.

- Q: How are the instances of a node affected when the node is deleted?

  A: When a node is deleted, its instances are retained because the scheduling system still generates one or more instances for the node based on the scheduling properties. However, when the scheduling system runs such instances after the node is deleted, an error message appears because the required code is unavailable, as shown in the following figure.



- Q: Can I enable a node to process monthly data on the last day of each month?

  A: No, DataWorks does not support setting a node to run on the last day of each month. If you enable a node to run on the thirty-first day of each month, the scheduling system runs a node instance in each month that has 31 days and returns a success response without running the code in any other month.

  We recommend that you configure a node to process the data of the past month on the first day of each month.

- Q: If a node scheduled by day depends on a node scheduled by hour, how do I enable the node scheduled by day to run at 00:00 every day?

  A: You can configure the node scheduled by day to depend on the data generated on the day before for the node scheduled by hour. If the node scheduled by day depends on the data generated on the current day for the node scheduled by hour, the instances of the node scheduled by day can be run only on the next day.

  In the Schedule section of the node scheduled by day, select **Cross-Cycle Dependencies**, select **Instances of Custom Nodes** from the Depend On drop-down list, and then enter the ID of the node scheduled by hour on which the node scheduled by day depends. Commit and deploy the node scheduled by day.

- Q: What can I do if I do not know when the output data of the ancestor node is generated?

A: You can set the cross-cycle dependency for the current node to depend on the last-cycle instances of the ancestor node.

- Q: After a modified node is committed and deployed to the production environment, will the node instances that were originally faulty in the production environment be overwritten?

  A: No, the node instances that have been generated will not be overwritten. The updated code is used to run the node instances that are newly generated and have not been run. If the scheduling properties are modified, the modified configuration also applies to the newly generated node instances.

2.5.6.4. Dependencies

Scheduling dependencies are the foundation for building orderly workflows. You must configure correct dependencies between nodes to make sure that business data is produced effectively and in a timely manner. This helps standardize data development activities.

DataWorks allows you to automatically parse node dependencies from the code or manually customize node dependencies. You can configure correct relationships between ancestor and descendant nodes and monitor the running status of nodes to make sure the orderly production of business data.

The purpose of configuring node dependencies is to check the data output time of the table queried by SQL statements and check whether data is properly produced from an ancestor node based on the node status.

You can set the output of an ancestor node as the input of a descendant node to configure a dependency between the two nodes.

Regardless of the dependency configuration mode, the overall scheduling logic is that descendant nodes can be run only after ancestor nodes are run. Therefore, each node in a workflow must have at least one parent node. The dependencies between the parent nodes and child nodes are the core of scheduling dependencies. The following sections describe the principles and configuration methods of scheduling dependencies in detail.

Differences between automatic parsing and custom dependencies

DataWorks can automatically parse the input and output of a node based on the lineage parsed from the code.

If the lineage parsed from the code is inaccurate, you can add custom dependencies as needed. We recommend that you write the code correctly to parse the lineage from the code and reduce custom dependencies. The following example shows how to configure the input and output of a node.

Auto Parse: If you select Yes, node dependencies are automatically parsed from the code.

For example, the code of an ODPS SQL node is as follows:

```
insert overwrite table table_a as select * from project_b_name.table_b;
```

From the code, DataWorks determines that the current node depends on the node that generates table_b and the current node generates table_a. Therefore, the output name of the parent node is project_b_name.table_b and the output name of the current node is project_name.table_a.

- If you do not want to parse node dependencies from the code, select **No** for Auto Parse.
- If a table in an SQL statement is both an output table and a referenced table on which another node depends, the table is parsed only as an output table.
- If a table in an SQL statement is used as an output table or a referenced table multiple times, only one scheduling dependency is parsed.
- If the SQL code contains a temporary table, the table is not involved in a scheduling dependency. Temporary tables are prefixed with t_. For more information, see Project Configuration.

Parent nodes

In the Dependencies section of a node, you must specify an ancestor node as the parent node on which the current node depends. You must enter the output name of the ancestor node, rather than the ancestor node name. A node may have multiple output names. Enter an output name as needed. You can search for an output name of the ancestor node to be added, or click Parse I/O to parse the output name based on the lineage parsed from the code.

> **Note** You must enter an output name or output table name to search for the ancestor node.
>
> If you enter an output name to search for the ancestor node, DataWorks searches for the output name among the output names of nodes that have been committed to the scheduling system.

- Search by entering an output name

  You can enter an output name to search for the ancestor node and configure the node as the parent node of the current node to create a dependency.

- Search by entering an output table name

  When using this method, make sure that the entered output table name of the ancestor node is the table name used in the INSERT or CREATE statement of the current node, such as Project name.Table name . Such output names can be automatically parsed.

  After you click the **Submit** icon, the output table name of the parent node configured for the current node can be found when you enter an output table name to search for the ancestor node for other nodes.

Outputs

You can click the **Properties** tab in the right-side navigation pane to view and configure the output of the current node.

DataWorks assigns a default output name that ends with .out to each node. You can also customize an output name or click Parse I/O to parse the output name based on the lineage parsed from the code.

> **Note** The output name of each node must be globally unique.

FAQ

- Q: After DataWorks automatically parses the input and output of a node, the node fails to be committed. An error message appears to indicate that the parsed output name

workshop_yanshi.tb_2 of the parent node does not exist and you must commit the parent node before committing the current node. Why does this error occur?

A: The possible causes are as follows:

- The ancestor node is not committed. Commit the ancestor node and try again.
- The ancestor node is committed, but workshop_yanshi.tb_2 is not an output name of the ancestor node.

> **Note** Usually, the output names of the parent node and the current node are automatically parsed based on the table name that is used in the INSERT or CREATE statement or follows the FROM keyword. Make sure that you follow the principles of automatic parsing in the Differences between automatic parsing and custom dependencies section.

- Q: In the output of the current node, the descendant node name and ID are empty and cannot be specified. Why does this happen?

  A: If the current node does not have a descendant node, the descendant node name and ID are empty. After a descendant node is configured for the current node, the corresponding content can be automatically parsed.

- Q: What is the output name of a node used for?

  A: The output name of a node is used to establish dependencies between nodes. For example, if the output name of Node A is ABC and Node B uses ABC as its input, a dependency is established between nodes A and B.

- Q: Can a node have multiple output names?

  A: Yes, a node can have multiple output names. If a descendant node references an output name of the current node as the output name of the parent node, a dependency is established between the descendant node and the current node.

- Q: Can multiple nodes have the same output name?

  A: No, the output name of each node must be unique under your Apsara Stack tenant account. If multiple nodes export data to the same MaxCompute table, we recommend that you use Table name_Partition ID as the output name format of these nodes.

- Q: How can I avoid intermediate tables when I enable DataWorks to automatically parse node dependencies?

  A: Right-click an intermediate table name in the SQL code and select **Delete Input** or **Delete Output**. Then, click Parse I/O to parse the input and output of the node.

- Q: How do I configure dependencies for the upmost node in a workflow?

  A: You can set the node to depend on the root node of the current workspace.

- Q: Why do I find a non-existent output name of Node B when I enter an output name to search for the ancestor node for Node A?

  A: DataWorks searches for the output name among the output names of nodes that have been committed to the scheduling system. After Node B is committed, if you delete the output name of Node B and does not commit Node B to the scheduling system again, the deleted output name of Node B can still be found.

- Q: How do I enable nodes A, B, and C to run in sequence once per hour?

A: Set the output of Node A as the input of Node B and the output of Node B as the input of Node C. Also, set nodes A, B, and C to run once per hour.

- Q: An error message is returned to indicate that the parent node ID fails to be automatically parsed based on an output table name. Why does this error occur?

  A: This error does not indicate that the table does not exist. Instead, it indicates that the table is not the output of a specific node. Therefore, the table name cannot be used to find the node that generates the table data. In this case, the dependency on the node cannot be created.

  According to the principles of automatic parsing described in this topic, a dependency is created after the output of an ancestor node is set as the input of a descendant node. If no ancestor node can be parsed based on the xc_demo_partition table referenced in SQL statements, no node uses the xc_demo_partition table as its output.

  You can resolve this problem in the following way:

  i. Find the node that generates the table data and view the node output.

     If you do not know which the target node is, you can enter keywords to search the code for the node in fuzzy match mode.

  ii. If the table data is uploaded from a local server or you do not need to depend on the node, you can right-click the table name in the code and select **Delete Input**.

  > **Note** We recommend that you write the code correctly to parse the lineage from the code and reduce custom dependencies.

2.5.7. Components

2.5.7.1. Create a script template

This topic describes the definition and composition of script templates and how to create a script template.

Definition

A script template defines an SQL code process that involves multiple input and output parameters. Each SQL code process references one or more source tables. You can filter source table data, join source tables, and aggregate them to generate a result table required for new business.

Value

In actual business, many SQL code processes are similar. The input and output tables in these processes may have the same or compatible schema but different names. In this case, developers can abstract an SQL code process as a script template to reuse the SQL code. The script template extracts input parameters from input tables and generates output parameters in output tables.

To create SQL script templates, you can select script templates from the script template list based on your business process and configure specific input and output tables in your business for the selected script templates, without repeatedly copying the code. This greatly improves the development efficiency and avoids repeated development. You can deploy and run the created SQL script templates in the same way as other SQL nodes.

Composition

Similar to a function, a script template consists of input parameters, output parameters, and an SQL code process.

Input parameters

The input parameters of a script template have the properties such as the parameter name, parameter type, parameter description, and parameter definition. The parameter type can be table or string.

- A table-type parameter specifies the table to be referenced in an SQL code process. When you use a script template, you can specify the input table required for the specific business.
- A string-type parameter specifies the variable control parameter in an SQL code process. For example, to export only the sales amount of the top N cities in each region in a result table of an SQL code process, you can use a string-type parameter to specify the value of N.

  To export the total sales amount of a province in a result table of an SQL code process, you can set a string-type parameter to specify the province and obtain the sales data of the specified province.
- The parameter description specifies the role of a parameter in an SQL code process.
- The parameter definition is a text definition of the table schema, which is required only for table-type parameters. When you specify the parameter definition for a table-type parameter, you must provide an input table that contains the same field names and compatible types defined by the table-type parameter so that the SQL code process can run properly. Otherwise, an error is returned when the SQL code process runs because the specified field name cannot be found in the input table. The input table must contain the field names and types defined by the table-type parameter. The input table can also contain other fields. The field names and types in the input table can be in any order. The parameter definition is for reference only.
- We recommend that you enter the parameter definition in the following format:

  ```
  Name of field 1 Type of field 1 Description of field 1
  Name of field 2 Type of field 2 Description of field 2
  Name of field n Type of field n Description of field n
  ```

  Examples:

  ```
  area_id string 'Region ID'
  city_id string 'City ID'
  order_amt double 'Order amount'
  ```

Output parameters

- The output parameters of a script template have the properties such as the parameter name,

parameter type, parameter description, and parameter definition. The parameter type must be table. A string-type output parameter has no logical meaning.

- A table-type parameter specifies the table to be generated in an SQL code process. When you use a script template, you can specify the result table that the SQL code process generates for the specific business.
- The parameter description specifies the role of a parameter in an SQL code process.
- The parameter definition is a text definition of the table schema. When you specify the parameter definition for a table-type parameter, you must provide an output table that contains the same number of fields and compatible types defined by the table-type parameter so that the SQL code process can run properly. Otherwise, an error is returned when the SQL code process runs because the number of fields does not match or the field type is incompatible. The field names of the output table do not need to be consistent with those defined by the table-type parameter. The parameter definition is for reference only.
- We recommend that you enter the parameter definition in the following format:

```
Name of field 1 Type of field 1 Description of field 1
Name of field 2 Type of field 2 Description of field 2
Name of field n Type of field n Description of field n
```

Examples:

```
area_id string 'Region ID'
city_id string 'City ID'
order_amt double 'Order amount'
rank bigint 'Ranking'
```

SQL code process

The parameters in an SQL code process are referenced in the following format: `@@{Parameter name}` .

By containing an abstract SQL code process, a script template controls and processes an input table based on input parameters to generate an output table with business value.

To develop an SQL code process, you must use input and output parameters in the code properly to make sure that they can be set as needed and correct SQL code can be generated and run during the process.

Create a script template

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Snippets** icon.
3. On the Snippets tab, move the pointer over and choose **Create** > **Snippet**.
4. In the **Create Snippet** dialog box, set **Snippet Name**, **Description**, and **Location**.
5. Click **Commit**.

Source table schema

The following table describes the schema of a source MySQL table that contains sales data.

Field	Data type	Description
order_id	varchar	The ID of the order.
report_date	datetime	The date of the order.
customer_name	varchar	The name of the customer.
order_level	varchar	The level of the order.
order_number	double	The number of orders.
order_amt	double	The amount of the order.
back_point	double	The discount.
shipping_type	varchar	The transportation method.
profit_amt	double	The amount of the profit.
price	double	The unit price.
shipping_cost	double	The transportation cost.
area	varchar	The region.
province	varchar	The province.
city	varchar	The city.
product_type	varchar	The type of the product.
product_sub_type	varchar	The subtype of the product.
product_name	varchar	The name of the product.
product_box	varchar	The packaging of the product.
shipping_date	datetime	The shipping date.

Business implication

Script template name: get_top_n

This script template uses the specified sales data table as the table-type input parameter, the number of the top cities as the string-type input parameter, and the total sales amount of the cities for ranking. By using this SQL code process, you can obtain the rankings of the specified top cities in each region with ease.

Script template parameters

Input parameter 1

- Parameter name: myinputtable
- Type: table

Input parameter 2

- Parameter name: topn
- Type: string

Output parameter 3

- Parameter name: myoutput
- Type: table

Parameter definition:

- area_id string
- city_id string
- order_amt double
- rank bigint

You can execute the following statement to create a table for storing the sales data of a specified number of top cities:

```
CREATE TABLE IF NOT EXISTS company_sales_top_n
(
area STRING COMMENT 'Region',
city STRING COMMENT 'City',
sales_amount DOUBLE COMMENT 'Sales amount',
rank BIGINT COMMENT 'Ranking'
)
COMMENT 'Company sales rankings'
PARTITIONED BY (pt STRING COMMENT '')
LIFECYCLE 365;
```

Example of defining an SQL code process

```
INSERT OVERWRITE TABLE @@{myoutput} PARTITION (pt='${bizdate}')
   SELECT r3.area_id,
   r3.city_id,
   r3.order_amt,
   r3.rank
from (
SELECT
   area_id,
   city_id,
   rank,
   order_amt_1505468133993_sum as order_amt ,
   order_number_150546813****_sum,
   profit_amt_15054681****_sum
FROM
```

```
   (SELECT
   area_id,
   city_id,
   ROW_NUMBER() OVER (PARTITION BY r1.area_id ORDER BY r1.order_amt_1505468133993_sum DESC)
AS rank,
   order_amt_15054681****_sum,
   order_number_15054681****sum,
   profit_amt_1505468****_sum
FROM
   (SELECT area AS area_id,
    city AS city_id,
    SUM(order_amt) AS order_amt_1505468****_sum,
    SUM(order_number) AS order_number_15054681****_sum,
    SUM(profit_amt) AS profit_amt_1505468****_sum
FROM
   @@{myinputtable}
WHERE
   SUBSTR(pt, 1, 8) IN ( '${bizdate}' )
GROUP BY
   area,
   city )
   r1 ) r2
WHERE
   r2.rank >= 1 AND r2.rank <= @@{topn}
ORDER BY
   area_id,
   rank limit 10000) r3;
```

Sharing scope

Script templates can be shared within a workspace or made public.

By default, a deployed script template is visible and available to users within the current workspace. The developer of a script template can click the **Publish Snippet** icon to make the general-purpose script template public to the current tenant account so that all users under the account can view and use the script template.

You can view the **Publish Snippet** icon in the toolbar of the configuration tab of a script template. If the icon is clickable, the script template is made public.

Use of script templates

For more information about how to use a developed script template, see Use components.

Reference records

In the script template list, double-click a script template. On the configuration tab that appears, click the **Snippet Nodes** tab in the right-side navigation pane to view the reference records of the script template.

2.5.7.2. Use a script template

To improve development efficiency, you can create data analytics nodes by using the script templates provided by workspace members and tenants.

Note the following points when you use script templates:

- The script templates provided by members of the current workspace are available on the **Workspace-Specific** tab.
- The script templates provided by tenants are available on the **Public** tab.

GUI elements

Icon or tab	Description
Save icon	Saves the settings of the current script template.
Steal Lock icon	Allows you to steal the lock of the current script template and then edit it if you are not the owner of the script template.
Submit icon	Commits the current script template to the development environment.
Publish Snippet icon	Makes the current general-purpose script template public to the current tenant account so that all users under the account can view and use the script template.
Parse I/O Parameters icon	Parses input and output parameters from the code. **Note** Typically, the parameters entered here are table names instead of scheduling parameters.
Run icon	Runs the current script template in the development environment.
Stop icon	Stops running the current script template.
Format icon	Formats the code based on keywords.
Parameters tab	Allows you to view the basic information and set input and output parameters for the current script template.
Versions tab	Allows you to view the deployed versions of the current script template.
Snippet Nodes tab	Lists the reference records of the current script template.

2.5.8. Custom node type

2.5.8.1. Overview

DataStudio supports default node types such as ODPS SQL and Shell nodes. You can also create custom node types to meet your requirements.

To create a custom node type, you need to create a custom wrapper and use it to define a custom node type.

Entry

1. Log on to the DataWorks console.
2. Click **Node Market** in the upper-right corner to go to the node configuration page.

> **Note** Only the workspace owner and administrators can access this page.

View the list of wrappers

The Wrappers page displays all the wrappers you have created. You can click **Create** in the upper-right corner to create a custom wrapper.

The values displayed in the Latest Version, Version in Development, and Version in Production Environment columns for the created wrappers follow these rules:

- If a created wrapper has not been deployed, the values of both the Version in Development and Version in Production Environment columns are **Not Deployed**.
- If a wrapper has been deployed, the version and the deployment time appear in these columns.
- If a wrapper is under deployment, the values of both the Version in Development and Version in Production Environment columns are **Deploying**.

You can click **Settings**, **View Versions**, or **Delete** in the Actions column of each wrapper.

Action	Description
Settings	You can click **Settings** to configure the wrapper. The page that appears depends on the wrapper status. The **Deploy in Production Environment** page appears if the wrapper has been deployed in the production environment.
View Versions	You can click **View Versions** to view all historical versions of the wrapper. • **View**: You can click this button to view the settings of the selected version. • **Roll Back**: You can click this button to roll back to the selected version. After you click this button, the system creates a new version for the wrapper. In the new version, the wrapper uses the basic settings and the resource file of the selected version. The new version number equals the latest version number among all the versions plus 1. • **Download**: You can click **Download** to download the resource file of the selected version.

Action	Description
Delete	If an error occurs while a node type is using the wrapper, you need to delete the node type. Note Before deleting a wrapper, ensure that no node type is associated with the wrapper.

Create a custom wrapper

A wrapper is the core processing logic of a node type. For example, after you compile an SQL statement in the editor for an ODPS SQL node and submit the statement, the system calls the corresponding wrapper to parse and run the statement. You need to create a wrapper before creating a custom node type. Currently, only the Java programming language is supported.

The procedure of creating a wrapper includes four steps: specify settings for the wrapper, deploy the wrapper in the development environment, test the wrapper in the development environment, and deploy the wrapper in the production environment. For more information, see Create a custom wrapper.

View the list of custom node types

The Custom Node Types page displays all custom node types in the workspace. You can click **Create** in the upper-right corner to create a custom node type. For more information, see Create a custom node type.

Currently, you can only create custom node types in DataStudio.

The workspace owner or node type creator can **change** or **delete** existing node types.

- **Change**: You can click **Change** to edit the settings for the node type as needed.
- **Delete**: You can click this button to delete the node type that no node uses. If any node uses the node type, a message appears, indicating that you need to disable the node first before deleting the node type.

Use a custom node type

After creating a custom node type, go to the **Data Analytics** page.

Move the pointer over the **Create** icon and click **Data Analytics**. In the list that appears, select the created node type to create a node.

2.5.8.2. Create a custom wrapper

The procedure of creating a wrapper includes four steps: specify settings for a wrapper, deploy the wrapper in the development environment, test the wrapper in the development environment, and deploy the wrapper in the production environment.

Specify settings for a wrapper

1. Click **Wrappers** in the left-side navigation pane. On the page that appears, click **Create** in the upper-right corner.
2. Specify the parameters in the **Settings** step.

Parameter	Description
Name	The name of the wrapper. It must start with a letter and can only contain letters, digits, and underscores (_).
Owner	The owner of the wrapper. You can select an owner from the workspace members. You are not allowed to edit wrappers owned by other members even if you are an administrator. Only the workspace owner can edit the wrappers of other members.
Resource Type	The type of the resource package for configuring the wrapper. Valid values: **JAR** and **Archive**. The size of the resource package can be up to 50 MB.
Resource File	The local resource file or OSS object for configuring the wrapper. **Note** The size of a local file can be up to 50 MB, and the size of a file that is stored in an OSS bucket can be up to 200 MB.
Class Name	The full path of the class for implementing the user wrapper.
Parameter Example	The parameters designed based on the JAR package you upload.
Version	The version of the configured wrapper. Select Create Version if you are creating a new wrapper. Select Overwrite Version if you are editing and rolling back a version. **Note** The version number is automatically generated.
Description	The description of the wrapper version.

3. Click **Save** and then click **Next**.

Note The settings are updated to the database after you click Save.

- If you only modify basic settings of a wrapper without changing the resource file, the modification takes immediate effect after you click Save.
- If you change the resource file, the change only applies after deployment.

Deploy the wrapper in the development environment

After you specify the parameters in the **Settings** step and click **Next**, the information in the Deploy in Development Environment step is updated accordingly. You can identify the changes by checking the file name and MD5 checksum.

Click **Deploy in Development Environment**. You can view the **deployment progress** in real time. After the wrapper is deployed, click **Next**.

Test the wrapper in the development environment

Specify the parameters for testing and click **Test** to send the parameters to the wrapper. This step is to validate the deployment and logic of the wrapper. You can also locally test the wrapper before uploading it for deployment.

After the test, review the output logs in the Test Results section on the right to determine whether the test is passed. If the test is passed, select **Test Passed** and click **Next**.

> **Note** The **Next** button is operable only after you select **Test Passed**.

Deploy the wrapper in the production environment

Click **Deploy in Production Environment**. In the **Confirm** dialog box that appears, click **OK**. The wrapper is deployed in the production environment. You can view the deployment progress in real time.

> **Note** The wrapper to be deployed in the production environment must be of the latest version, have been deployed in the development environment, and have passed the test. Otherwise, a message appears, indicating that the deployment in the production environment fails.

Click **Complete**. You can view and edit the created wrapper on the **Wrappers** page.

2.5.8.3. Create a custom node type

The Configure Custom Node Type page consists of three sections: Basic Information, Interaction, and Wrapper.

1. On the DataStudio page, click **Node Market** in the top navigation bar. On the page that appears, click **Custom Node Types** in the left-side navigation pane.
2. Click **Create** in the upper-right corner.
3. Specify the parameters in the **Basic Information** section.

Parameter	Description
Name	The name of the node type, which cannot be changed after being saved. Each node type has a unique name within the workspace. The name can be up to 20 characters in length, and can only contain letters, spaces, and underscores (_).
Icon	The icon of the node type.
Tabs	The template of the node type. Currently, only **Data Analytics** is available.
Folder	The folder where the node type belongs. You can select **Data Integration** or **Data Analytics**.

4. Specify the parameters in the **Interaction** section.

Parameter	Description

Parameter	Description
Shortcut Menu	○ The options to appear in the shortcut menu. The following options are selected by default: Rename, Move, Clone, Steal Lock, View Versions, Locate in Operation Center, Delete, and Submit for Review. ○ More options include Edit, Copy Resource Name, and Send to DataWorks Desktop (Shortcut).
Tool Bar	○ The options to appear in the top navigation bar. The following options are selected by default: Save, Commit, Commit and Unlock, Steal Lock, Run, Show/Hide, Run with Arguments, Stop, Reload, Run Smoke Test in Development Environment, View Smoke Test Log in Development Environment, Run Smoke Test, View Smoke Test Log, Go to Operation Center of Development Environment, and Format. ○ More options include Operation Center, Deploy, and Precompile.
Editor Type	The type of the editor. Currently, only **Editor Only** is available.
Right-Side Bar	○ The options to appear in the right-side bar. The following options are selected by default: Code Structure and Properties. ○ More options include Version, Lineage, and Parameters.
Auto Parse Option	Specifies whether to display the Auto Parse option for this type of node. If you turn on this switch, the Auto Parse option is displayed on the Properties tab. Otherwise, it is not displayed. In an automatic parsing process, the system parses the input and output of a node based on the lineage specified in the code.

5. Specify the parameters in the **Wrapper** section.

Parameter	Description
Wrapper	The wrapper used for running the type of node. Select a wrapper that has been deployed.
Editor Language	The language used for writing the code in the editor. Currently, only ODPS SQL is available.
Use MaxCompute as Engine	Specifies whether to use MaxCompute as the compute engine. If your wrapper uses MaxCompute as the compute engine, select Yes. Otherwise, select No. Default value: Yes.

6. Click **Save and Exit**. Then, go to the **Data Analytics** page to use the custom node type that is created.

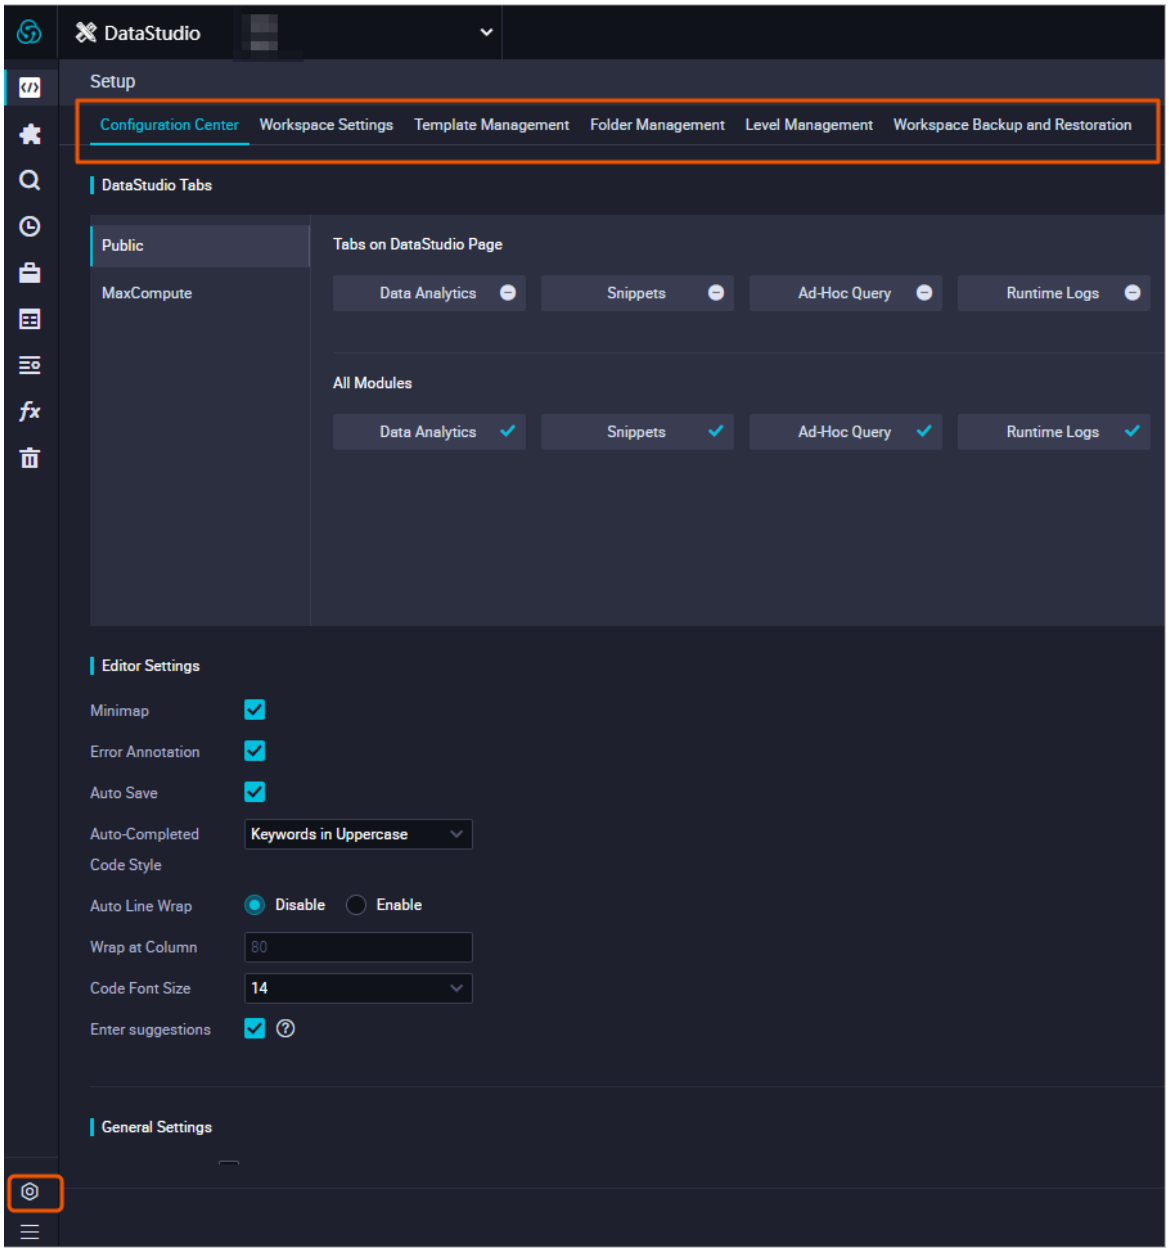
2.5.9. Manage configurations

2.5.9.1. Setup

On the Setup page, you can add and delete modules. You can also configure code templates, folders, and table levels on this page.

Procedure

1. Log on to the DataWorks console.
2. Click in the lower-left corner of the **DataStudio** page to go to the **Setup** page.



You can perform operations on the following tabs:

- Configuration Center

- Project Configuration
- Templates
- Theme Management
- Table Levels

2.5.9.2. Configuration center

You can combine your DataStudio modules and specify editor settings on the Configuration Center tab.

Go to Configuration Center

1. Log on to the DataWorks console.
2. Click in the lower-left corner of the **DataStudio** page. The **Configuration Center** tab appears.

   The Configuration Center tab includes three sections: **DataStudio Tabs**, **Editor Settings**, and **General Settings**. After the configurations are completed, you can click **Apply to All Workspaces** in the lower-right corner of the page to apply the settings to all existing workspaces.

DataStudio tabs

On the **DataStudio Tabs** tab, you can add and delete public and MaxCompute functional modules, and drag modules to change their orders.

- Under **Tabs on DataStudio Page**, click next to a module to delete it. Deleted modules will not appear in the left-side navigation pane of the **DataStudio** page.
- Under **All Modules**, click the desired module to add it. Added modules will appear in the left-side navigation pane of the **DataStudio** page.

> **Note** The module settings take effect immediately for the current workspace. To make the module settings effective for all workspaces, click **Apply to All Workspaces** in the lower-right corner of the page.

Editor settings

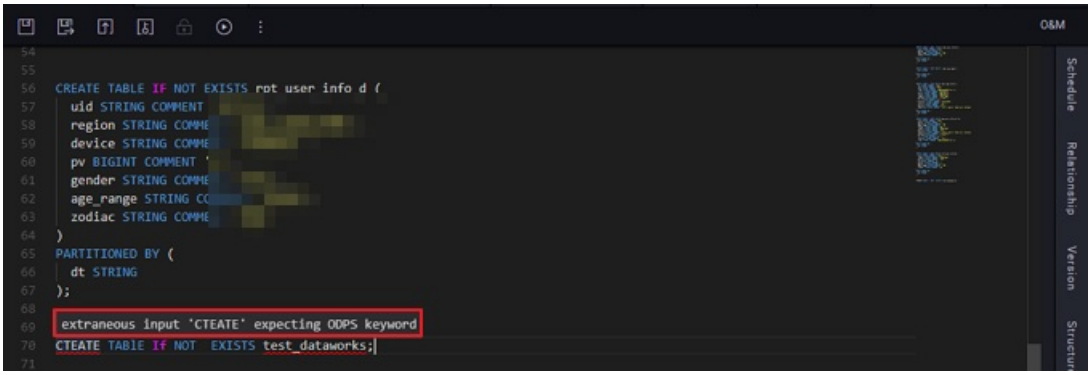
You can configure the code editor in the Editor Settings section. The editor settings take effect immediately for the current workspace without requiring you to refresh the page.

- **Minimap**

The masked code in the current interface is displayed in the minimap in the upper-right corner of the page. When the code is long, you can move the pointer to specify the code block to be displayed in the minimap.

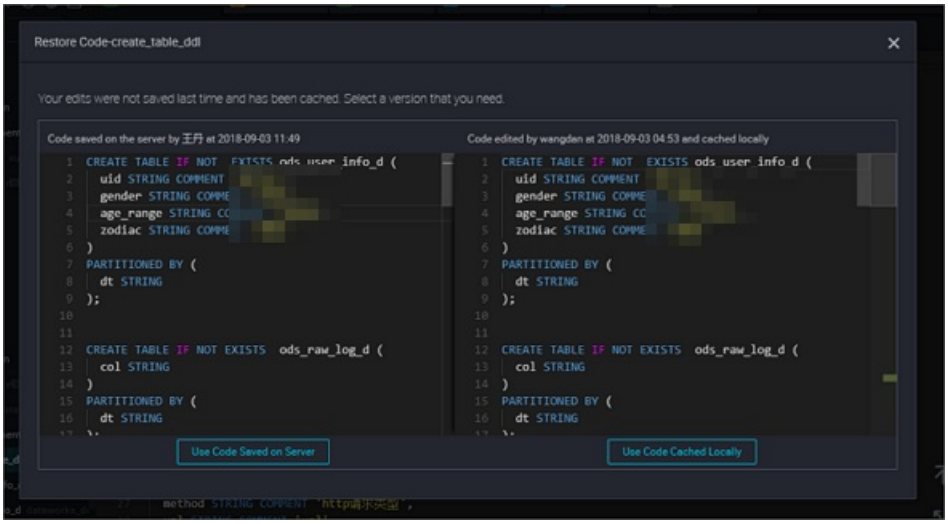
- **Error Annotation**

  If you select this check box, DataWorks marks potential syntax errors with a red squiggly line. When you see a syntax error, you can move the pointer over the underlined code to view the error message.



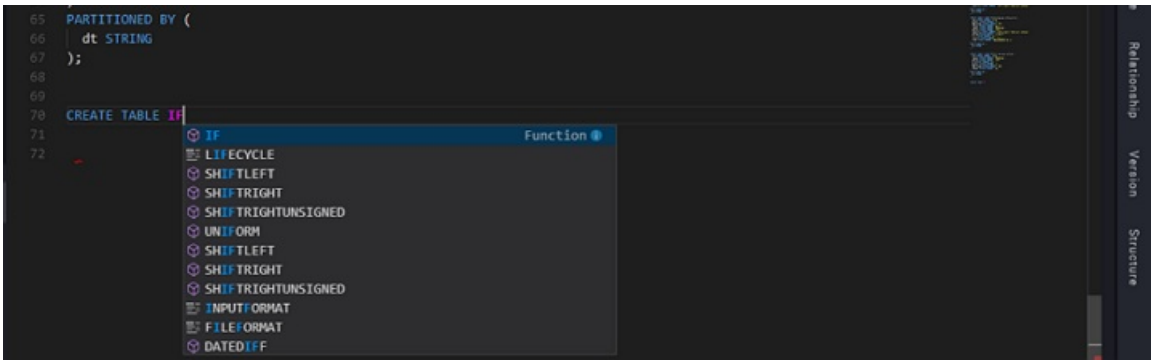
- **Auto Save**

  If you select this check box, DataWorks automatically saves the code being edited at a specific interval. In this way, if the code editor of a node is closed unexpectedly, you can click **Use Version Saved on Server** or **Use Version Saved in Local Cache** to re-open the node.



- **Auto-Completed Code Style**

You can set the code style to uppercase or lowercase as required.



- **Auto Line Wrap**

  You can set Auto Line Wrap to **Disable** or **Enable**.

- **Wrap at Column**
  - If Auto Line Wrap is set to **Disable**, the value of Wrap at Column is 80 by default, which cannot be modified.
  - If Auto Line Wrap is set to **Enable**, you can set a value for Wrap at Column as required.

- **Code Font Size**

  Valid values: 12 to 18. You can change the font size based on your habits and code size.

- **Enter suggestions**

  If you select this check box, the system automatically displays suggestions on how to set a field when you press Enter. If you clear this check box, a new line is started after you press Enter. In addition to the Enter key, you can also use the Tab key to enter prompted suggestions.

- **Auto Completion**

  You can specify whether to enable the following code hints when you enter the code:
  - **Continuous Smart Tips**: specifies whether to automatically add a space after each auto-completed term such as a keyword, table name, or field name.
  - **Keyword**: specifies whether to enable keyword hints.
  - **Syntax Template**: specifies whether to enable syntax template hints.
  - **Project**: specifies whether to enable project name hints.
  - **Table Name**: specifies whether to enable table name hints. When this feature is enabled, the system gives higher priority to tables used recently.
  - **Field**: specifies whether to enable field name hints.

General settings

- **Display Node Engine Information on DAG**

  You can specify whether to display node engine information on the DAG.

- **Theme**

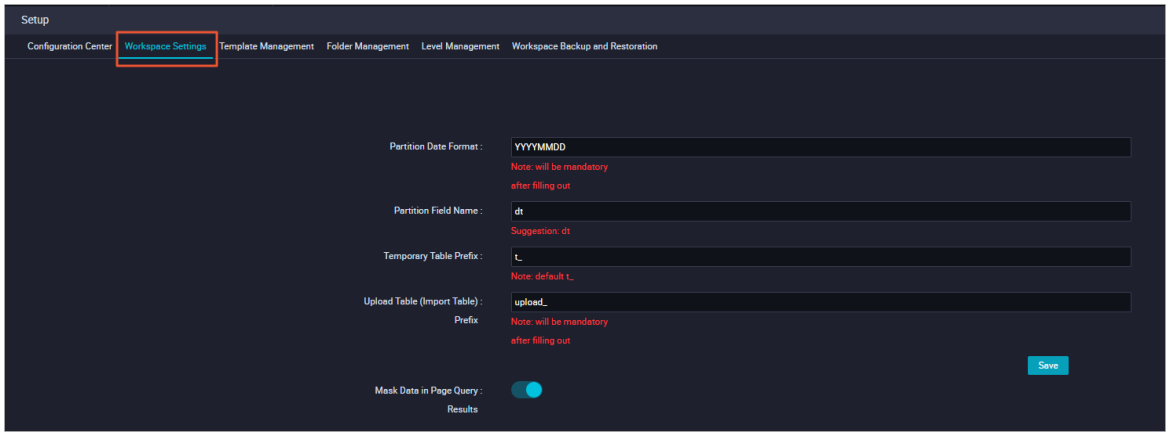
  You can set the DataStudio theme to black or white.

2.5.9.3. Workspace settings

The Workspace Settings tab displays five parameters: Partition Date Format, Partition Field Name, Temporary Table Prefix, Upload Table (Import Table) Prefix, and Mask Data in Page Query Results.

Go to the Workspace Settings tab

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, click in the lower-left corner.
3. On the **Setup** page, click the **Workspace Settings** tab.



Parameter	Description
Partition Date Format	The default date format of partition field values. You can modify the format as required.
Partition Field Name	The default name of a partition field.
Temporary Table Prefix	The prefix of temporary table names. By default, tables with the prefix t_ in their names are identified as temporary tables.
Upload Table (Import Table) Prefix	The prefix of the names of tables uploaded on the **DataStudio** page.
Mask Data in Page Query Results	Specifies whether to de-identify data in the query results. When the switch is turned on, the result returned for an ad hoc query node in the current workspace will be de-identified.

Enable de-identification for DataWorks workspaces

Data de-identification for DataWorks needs to be enabled in workspaces one by one. After data de-identification is enabled, the result returned for an ad hoc query node in the current workspace will be de-identified. The underlying storage data is not affected because only dynamic de-identification is performed.

> **Note** For example, data de-identification is enabled in workspace A but not workspace B. If you initiate a request in workspace B to query tables in workspace A, the query result is displayed in plaintext.

On the **Workspace Settings** tab, turn on **Mask Data in Page Query Results**. After you click **Save**, the result returned for an ad hoc query node in the current workspace will be de-identified.

> **Note** By default, the Mask Data in Page Query Results switch is turned off and you are not allowed to download de-identified data.

After data de-identification is enabled for DataWorks workspaces, the data types listed in the following table are de-identified by default.

Type	Data de-identification rule	Raw data	De-identified data
ID card number	Only the first and last digits in a 15-digit or an 18-digit ID card number are displayed in plaintext. All the other digits are displayed as asterisks (*).	512345678943215678	5**********8
Mobile number	Only the first three and last two digits in a mobile number in mainland China are displayed in plaintext. All the other digits are displayed as asterisks (*).	18112345678	181******78
Email address	If the string before the at sign (@) in an email address contains three or more characters, only the leftmost three characters are displayed in plaintext, followed by three asterisks (*). If the string before the at sign (@) contains only one or two characters, the entire string is displayed in plaintext, followed by three asterisks (*).	• eftry.abc@gmail.com • af@abc.com	• eft***@gmail.com • af***@abc.com
Bank card number	Only the last four digits in a credit card number or deposit card number are displayed in plaintext. All the other digits are displayed as asterisks (*).	• 1234576834509782 • 643257829145430986	• **********9782 • **********0986
IP address or MAC address	Only the first segment in an IP address or a MAC address is displayed in plaintext. All the other characters are displayed as asterisks (*).	• 192.000.0.0 • ab:cd:11:a3:a0:50	• 192.***. *. * • ab:**:**:**:**:**

Type	Data de-identification rule	Raw data	De-identified data
License plate number	Only the one-character provincial abbreviation and the last three characters in a license plate number in mainland China are displayed in plaintext. All the other characters are displayed as asterisks (*).	• (One-character provincial abbreviation)AP555B • (One-character provincial abbreviation)ADP555T	• (One-character provincial abbreviation)A**55B • (One-character provincial abbreviation)A***55T

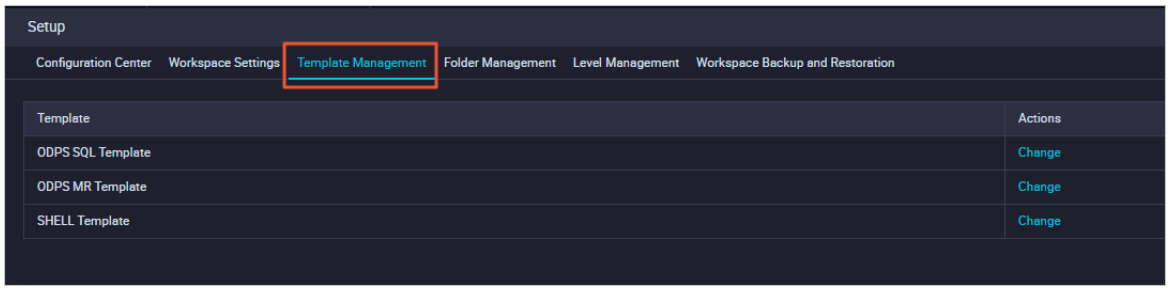
Note If you want to de-identify more data types or have special requirements on the de-identified data formats, complete your de-identification settings in Data Security Guard. The feature of de-identifying data for DataWorks workspaces must work with Data Security Guard. For more information, see Data security guard.

2.5.9.4. Template management

The Template Management page displays code templates. Workspace administrators can change the display formats of the templates as required.

Procedure

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, click in the lower-left corner.
3. On the **Setup** page, click the **Template Management** tab.



Note Templates are only available for ODPS SQL, ODPS MR, and Shell nodes.

4. Find the target template and click **Change** in the Actions column.
5. In the **Node Template** dialog box, enter the template as required.
6. Click **Save**.

2.5.9.5. Folder management

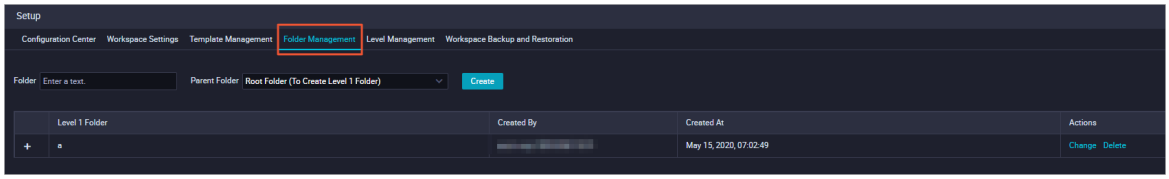
Each workspace can hold a great number of tables. For easy management, you can organize tables in two levels of folders.

Context

Folders are used to store tables. A workspace administrator can add multiple folders and classify tables by purpose and name.

Procedure

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, click in the lower-left corner.
3. On the **Setup** page, click the **Folder Management** tab.



On the page that appears, you can add, modify, and delete folders.

- Add a folder

  Enter a custom folder name in the **Folder** field, select a parent folder from the **Parent Folder** drop-down list, and then click **Create**.

- Modify a folder

  Find the target folder and click **Change** in the Actions column. In the **Change Folder** dialog box, enter a new folder name and click **OK**.

- Delete a folder

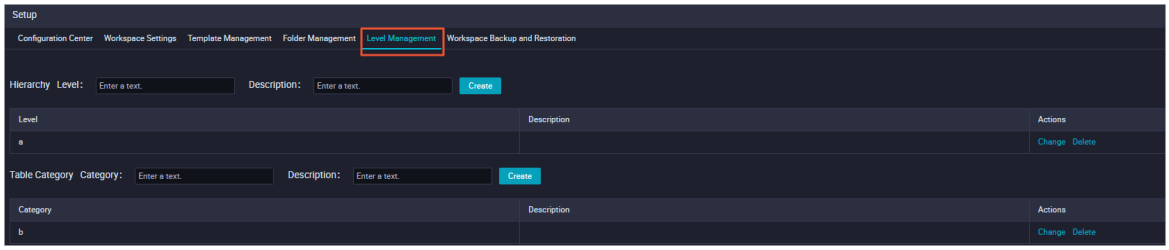
  Find the target folder and click **Delete** in the Actions column. In the **Delete Folder** message, click **OK**.

2.5.9.6. Level management

On the Level Management tab, you can design physical levels of tables.

Procedure

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, click in the lower-left corner.
3. On the **Setup** page, click the **Level Management** tab.



You can classify tables based on their importance. Level management allows you to precisely locate incorrectly organized tables and ensures normal running of published jobs.

If a workspace does not contain default table levels, the workspace owner or workspace administrator must add them as required.

On the **Level Management** tab, you can add, modify, and delete table levels.

- To add a table level, perform the following steps:
  a. In the **Hierarchy** section, set **Level** and **Description**.
  b. Click **Create**.
- To modify a table level, perform the following steps:
  a. Find the target table level and click **Change** in the Actions column.
  b. In the **Change Level** dialog box, modify **Level** and **Description** as needed.
  c. Click **OK**.
- To delete a table level, perform the following steps:
  a. Find the target table level and click **Delete** in the Actions column.
  b. In the **Delete Level** message, click **OK**.

On the **Level Management** tab, you can also add, modify, and delete table categories.

- To add a table category, perform the following steps:
  a. In the **Table Category** section, set **Category** and **Description**.
  b. Click **Create**.
- To modify a table category, perform the following steps:
  a. Find the target table category and click **Change** in the Actions column.
  b. In the **Change Category** dialog box, modify **Category** and **Description** as needed.
  c. Click **OK**.
- To delete a table category, perform the following steps:
  a. Find the target table category and click **Delete** in the Actions column.
  b. In the **Delete Category** message, click **OK**.

2.5.9.7. Workspace backup and restore

On the Workspace Backup and Restoration tab, you can migrate code between workspaces. This topic describes how to back up and restore a workspace.

Prerequisites

Workspaces are created. For more information, see Create a workspace.

Go to the Workspace Backup and Restoration tab

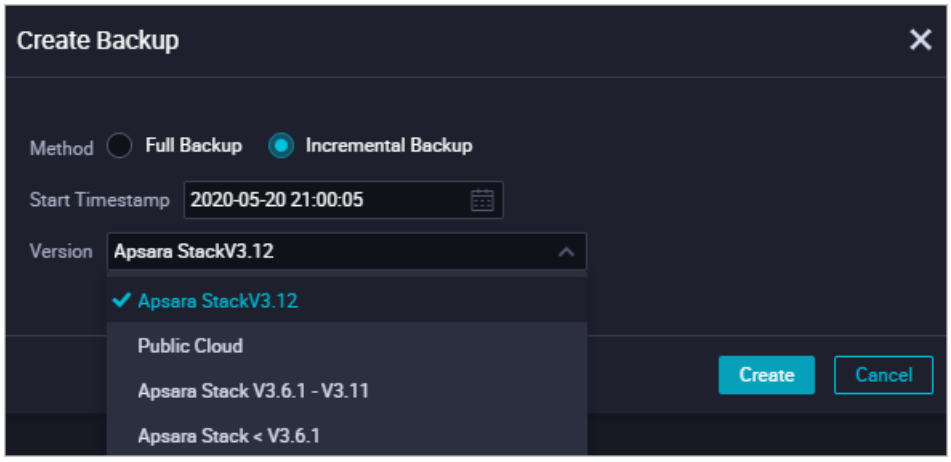
1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, click  in the lower-left corner.
3. On the **Setup** page, click the **Workspace Backup and Restoration** tab.On the page that appears, you can back up and restore workspaces.
   - On the Backup tab, you can compress the node code, node dependencies, resources, and functions in a workspace into one package.
   - On the Restore tab, you can restore a workspace to its original scheduling settings. After the workspace is restored, all nodes in the workspace are saved but not committed.

Back up a workspace

A workspace backup is a compressed package containing the node code, node dependencies, resources, and functions in the workspace.

- Only workspace administrators can export backups and restore data from backups.
- Workflows and node groups of earlier versions cannot be backed up. We recommend that you use the latest version for data analytics.
- A node backed up to a path in the workspace will override the original node with the same name in the path. We recommend that you create another workspace to restore data.
- Data in tables is not backed up when you back up a workspace. You can synchronize the table data in the following ways:
  - Click the **Workspace Manage** icon in the upper-right corner. On the page that appears, click **Data Source** and configure a MaxCompute connection. Then, create a sync node to back up the data.
  - In workspace A, run the data definition language (DDL) statement `create table select * from workspace B. Table name` to migrate data.

1. On the **Workspace Backup and Restoration** tab, click **Backup**.
2. Click **Create Backup** in the upper-right corner.
3. In the **Create Backup** dialog box, set the parameters as required.



Parameter	Description
Method	The method used to back up the workspace. Valid values: ○ **Full Backup**: Back up all the node code, node dependencies, resources, and functions in the workspace. ○ **Incremental Backup**: Back up all the new or modified nodes from the timestamp specified by the **Start Timestamp** parameter to the current time. **Note** If you use the incremental backup method, make sure that the dependencies between incremental sync nodes are correct. Otherwise, the workspace may fail to be restored. We recommend that you set this parameter to **Full Backup**.

Parameter	Description
Start Timestamp	The start time point at which data in the workspace is backed up. This parameter is available only when you set **Method** to **Incremental Backup**.
Version	The version of the workspace to be backed up. Valid values: **Apsara StackV3.12**, **Public Cloud**, **Apsara Stack V3.6.1 - V3.11**, and **Apsara Stack < V3.6.1**.

4. Click **Create**.After the data is backed up, click **Download** to download the backup data to a local device.

Restore a workspace

1. On the **Workspace Backup and Restoration** tab, click **Restore**.
2. Click **Restore** in the upper-right corner.
3. In the **Restore** dialog box, click **Select File**.

> **Note** You can upload the compressed package that you previously backed up to the workspace.

4. Click **Restore**.
5. Click **Set Compute Engine Mapping**. In the dialog box that appears, set the mapping between the compute engines of the current workspace and the destination workspace.
6. Click **OK**.If the workspace that you backed up contains multiple compute engines, the system scans all compute engine instances during restoration. The system only restores nodes of the existing compute engines in the workspace to be restored. In this case, you must configure the mappings between the compute engines before restoring the destination workspace.

> **Note**
>
> - If the workspace to be restored does not contain a compute engine type such as E-MapReduce, or no instance is available for the compute engine type, nodes of this engine type are not restored.
> - Compute engine mappings must be configured for custom node types.

2.5.10. Deploy

2.5.10.1. Deploy nodes

In a rigorous data development process, developers develop and debug code and configure dependencies and scheduling properties for nodes in the development environment. Then, developers commit and deploy the nodes to run them in the production environment.

DataWorks workspaces in standard mode can process data seamlessly from the development environment to the production environment within a single workspace. We recommend that you use workspaces in standard mode to develop and produce data.

Deploy nodes in a workspace in standard mode

Each DataWorks workspace in standard mode is linked with two MaxCompute projects, one as the development environment and the other as the production environment. You can directly commit and deploy nodes from the development environment to the production environment.

Follow these steps:

1. On the **DataStudio** page, configure and debug the code of nodes. Then, double-click the target workflow in the left-side navigation pane. On the dashboard of the workflow that appears, click the **Submit** icon to check whether the dependencies between nodes are correct and commit the nodes.
2. After the nodes are committed, click the **Deploy** icon.
3. On the **Create Deploy Task** page that appears, select the target nodes and click **Add to List**. The nodes are added to the to-be-deployed node list.

   You can search for nodes by condition, such as the committer, node type, change type, time when a node is committed, node name, and node ID. If you click Deploy Selected, the selected nodes are deployed to the production environment.
4. Click **View List**. In the Nodes to Deploy dialog box that appears, click **Deploy All**. All nodes in the list are deployed to the production environment.

> **Note** Workspaces in standard mode protect tables in the production environment from being manipulated, and therefore provide the stable, secure, and reliable production environment. We recommend that you use workspaces in standard mode to deploy and run nodes.

Clone nodes between workspaces in basic mode

You cannot deploy nodes in workspaces in basic mode. If you want to isolate the development environment from the production environment for workspaces in basic mode, create two workspaces, one for development and the other for production. You can clone nodes from the development workspace to the production workspace.

As shown in the following figure, two workspaces in basic mode are created, one for development and the other for production. You can use the cross-workspace cloning feature to clone nodes from Workspace A to Workspace B, and then commit the cloned nodes to the scheduler for scheduling.

> **Note**
>
> - Permission requirement: Only workspace administrators and Resource Access Management (RAM) users who have the O&M permissions can clone nodes.
> - Workspace type: You can only clone nodes in workspaces in basic mode, but cannot clone those in workspaces in standard mode.
> - Prerequisites: The source workspace in basic mode and the destination workspace in basic mode are created.

1. Commit nodes.

   After you create and configure nodes in the source workspace, commit the nodes on the dashboard of the target workflow.

2. Click **Cross-Workspace Cloning**.
3. On the Create Clone Task page that appears, select the target nodes and the destination workspace, and then click **Add to List**.
4. Clone the nodes. Click **View List**. In the To-Be-Cloned Nodes dialog box that appears, check the nodes to be cloned and click **Clone All**.

   In the Create Clone Task dialog box that appears, click **Clone**.
5. View the cloned nodes.

   You can view the successfully cloned nodes on the View Clone Tasks page of the source workspace.

   Switch to the destination workspace. You can find that the nodes are cloned from the source workspace.

2.5.10.2. Overview of cross-workspace cloning

For workspaces under the same Apsara Stack tenant account, you can use the cross-workspace cloning feature to clone and deploy workflows across these workspaces. You can also use this feature to clone nodes, such as computing or sync nodes, across workspaces. This topic describes how to process the dependencies between nodes during cross-workspace cloning.

If you clone nodes across workspaces by using the **cross-workspace cloning** feature, DataWorks automatically changes the output names of the cloned nodes in the destination workspace to distinguish nodes in different workspaces under the same Apsara Stack tenant account. This allows you to successfully clone node dependencies.

> **Note** Cross-workspace cloning cannot be used to clone nodes across workspaces in different regions.

You can set the owner of cloned nodes in the destination workspace to **Default** or **Clone Task Creator**.

- If you clone nodes owned by the workspace administrator:

  After the nodes are cloned to the destination workspace, their owner is set to the original owner preferentially. If the original owner is not added to the destination workspace, you will become the owner.
- If you clone nodes owned by yourself:

  After the nodes are cloned to the destination workspace, their owner is set to you preferentially. If you are not added to the destination workspace, you are asked whether to change the owner. If you agree to change the owner, you will be added to the destination workspace and become the owner of the cloned nodes. If you do not agree to change the owner, the clone task is canceled.

Clone a workflow

Assume that the output of the task_A node in the project_1 workspace is project_1.task_A_out. If you clone a workflow that contains the task_A node to the destination workspace project_2, the node output name changes to project_2.task_A_out in the destination workspace.

Clone node dependencies

Assume that the task_ B node in the project_1 workspace depends on the task_A node in the project_3 workspace. If you clone the task_B node in the project_1 workspace to the destination workspace project_2, the dependency between the task_A and task_B nodes is also cloned. The task_B node in the project_2 workspace also depends on the task_A node in the project_3 workspace.

2.5.10.3. Clone nodes across workspaces

This topic describes how to clone nodes across workspaces with an example of cloning a workflow from one workspace to another.

Prerequisites

Two workspaces named Weisong_dataworks_test and Weisong_dataworks_test2 respectively are created. For more information about how to create a workspace, see Create a workspace.

Context

You can clone nodes across workspaces in the following scenarios:

- Clone nodes from a workspace in the basic mode to another workspace in the basic mode.
- Clone nodes from a workspace in the basic mode to another workspace in the standard mode.

After you clone a node, the folder and workflow to which the node belongs are cloned to the destination workspace. Any change to the node, folder, or workflow can also be cloned to the destination workspace.

Procedure

1. Log on to the DataWorks console. On the DataStudio page that appears, switch to the Weisong_dataworks_test workspace in the top navigation bar.
2. Select the target workflow. In the Data Analytics section, double-click the target workflow. On the workflow configuration page that appears, click **Cross-Workspace Cloning** in the upper-right corner. The Create Clone Task page appears.
3. Select the destination workspace, node type, and change type. On the **Create Clone Task** page, set **Target Workspace** to Weisong_dataworks_test2. Select the node type and change type of the node for the clone task as required, and select one or more target nodes that appear in the list. Then, click **Clone Selected**.
4. In the **Create Clone Task** dialog box that appears, check the destination workspace, target node, and change type, and then click **Clone**.
5. After the system message that indicates the target node is cloned successfully and is being committed to the destination workspace appears, switch to the Weisong_dataworks_test2 workspace. In the **Data Analytics** section, view the workflow that has been successfully cloned to the current workspace.

2.5.11. Create an ad hoc query node

The Ad-Hoc Query tab allows you to test your code in the development environment. You can check for errors and check whether your code works as expected.

Context

You do not need to commit and deploy ad hoc query nodes or configure scheduling policies for ad hoc query nodes. You can configure scheduling policies only for nodes created under **Business Flow** on the **Data Analytics** tab.

Create a folder

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Ad-Hoc Query** icon.Click in the lower-left corner to show or hide the left-side navigation pane.
3. On the Ad-Hoc Query tab, move the pointer over and select **Folder**.
4. In the **Create Folder** dialog box, set **Folder Name** and **Location**.

   > **Note**
   > - The folder name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
   > - DataWorks supports multi-level folders. You can save a newly created folder under another folder that already exists.

5. Click **Commit**.

Create an ad hoc query node

You can create **ODPS SQL** and **Shell** nodes on the **Ad-Hoc Query** tab. This topic describes how to create an ODPS SQL node.

1. On the **Ad-Hoc Query** tab, right-click the target folder and choose **Create Node > ODPS SQL**.
2. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

3. Click **Commit**.
4. On the node configuration tab that appears, enter an SQL statement.
5. Click in the toolbar.

2.5.12. View runtime logs

The Runtime Logs tab displays the records of all nodes that have been run in the last three days. You can click a node to view its runtime logs.

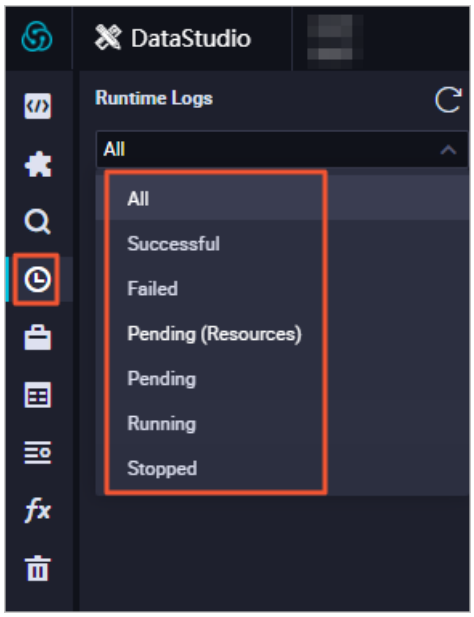
Context

The runtime logs are retained for only three days.

Procedure

1. Log on to the DataWorks console.

2. On the left-side navigation submenu, click the **Runtime Logs** icon. Click in the lower-left corner to show or hide the left-side navigation pane.
3. Select a node state from the drop-down list to view the runtime logs of nodes in the specified state.



4. Click a record to view the runtime log on the right. If you need to save the SQL statements in the runtime log, click in the toolbar. In the **Create Node** dialog box, set the parameters and click **Commit** to save the SQL statements that have been run as an ad hoc query node.

2.5.13. View tenant tables

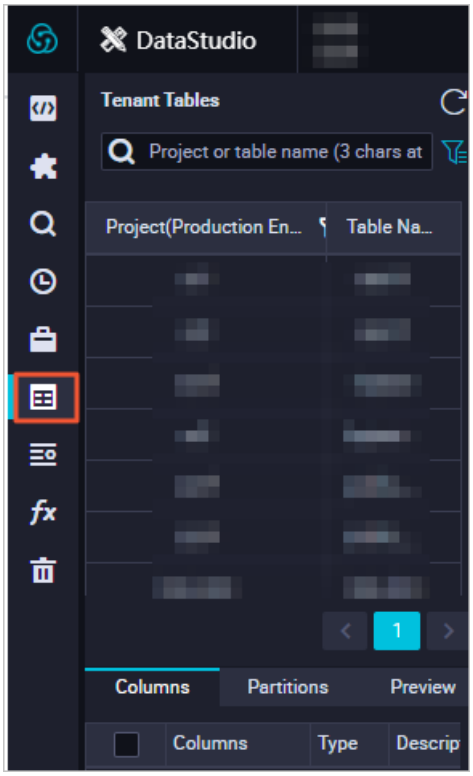
On the Tenant Tables tab, you can view tables of all workspaces of the current tenant account.

Prerequisites

The **Tenant Tables** tab appears only after you bind a MaxCompute compute engine on the **Project Management** page. For more information, see Configure a workspace.

Procedure

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Tenant Tables** icon.Click in the lower-left corner to show or hide the left-side navigation pane.
3. View MaxCompute tenant tables.



Parameter or tab	Description
Project Name	The name of the workspace in the corresponding environment. Click next to the search box and select the target environment to switch to the environment. **Note** ◦ For a workspace in standard mode, the **Tenant Tables** tab displays tables in both the development environment and the production environment. For a workspace in basic mode, the **Tenant Tables** tab displays only the tables in the production environment. ◦ The current environment is marked in blue.
Table Name	The name of the table in the corresponding workspace.
Columns tab	Displays the name, data type, and description of fields in the table.

Parameter or tab	Description
Partitions tab	Displays the partition information of the current table. A maximum of 60,000 partitions are supported. If you have specified the TTL for partitions, the number of partitions depends on the TTL. Notice The partition information is displayed only for MaxCompute tenant tables.
Preview tab	Displays the data of the current table. Notice You can preview only the data of MaxCompute tenant tables.

2.5.14. Manage tables

This topic describes how to view, modify, and delete MaxCompute tables, and the basic knowledge about data hierarchy.

Prerequisites

The **Workspace Tables** tab appears only after you bind a MaxCompute compute engine on the **Project Management** page. For more information, see Configure a workspace.

Manage tables

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Workspace Tables** icon.Click ☰ in the lower-left corner to show or hide the left-side navigation pane.
3. View and manage tables.The following section describes how to view, modify, and delete a MaxCompute table. For more information about how to create a table, see Create a MaxCompute table.

Operation	Description

Operation	Description
View a table	Click  next to the search box and select the target environment to switch to the environment. **Note** ◦ For a workspace in standard mode, the **Workspace Tables** tab displays tables in both the development environment and the production environment. For a workspace in basic mode, the **Workspace Tables** tab displays only the tables in the production environment. ◦ The current environment is marked in blue. Double-click a table to view its details on the table configuration tab.
Import data to a table	On the **Workspace Tables** tab, click  to import data to a table. For more information, see Create tables and import data.

Divide a data warehouse into layers

In the **Physical Model** section of the configuration tab of a table, you can define table layers for a data warehouse. This allows you to have better planning and control over your data.

Typically, a data warehouse consists of the following layers:

- ODS: The ODS layer stores raw data of the source system based on the original data structure. The ODS layer serves as the data staging area of the data warehouse. It imports basic data to MaxCompute and records historical changes of basic data.
- CDM: The CDM layer consists of the dimension data (DIM), data warehouse detail (DWD), and data warehouse service (DWS) layers. The CDM layer processes and integrates the data of the ODS layer to define conformed dimensions, create reusable detailed fact tables for data analysis and statistics collection, and aggregate common metrics.
  - The DIM layer defines conformed dimensions for an enterprise based on the concepts of dimensional modeling. It reduces the risk of inconsistent statistical criteria and algorithms.

    Tables at the DIM layer are also called logical dimension tables. Generally, each dimension corresponds to a logical dimension table.
  - The DWS layer is driven by analyzed subjects during data modeling. Based on the metric requirements of upper-layer applications and products, the DWS layer creates fact tables to aggregate common metrics and builds a physical data model by using wide tables. The DWS layer creates statistical metrics in compliance with uniform naming conventions and statistical criteria, provides common metrics for the upper layer, and generates aggregate wide tables and detailed fact tables.

    Tables at the DWS layer are also called logical aggregate tables, which are used to store derived metrics.

- The DWD layer is driven by business processes during data modeling. It creates detailed fact tables at the finest granularity based on each specific business process. In combination with the data usage habits of an enterprise, you can duplicate some key attribute fields of dimensions in detailed fact tables to create wide tables.

  Tables at the DWD layer are also called logical fact tables.

- ADS: The ADS layer stores personalized statistical metrics of data products. It processes the data of the CDM and ODS layers.

2.5.15. View built-in functions

The Built-In Functions tab displays functions built in MaxCompute. You can view the types, description, and examples of functions on this tab.

Procedure

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Built-In Functions** icon.Click ☰ in the lower-left corner to show or hide the left-side navigation pane.
3. View the types, description, and examples of the built-in functions.Functions are categorized into aggregate functions, analytic functions, date functions, mathematical functions, string functions, and other functions. The preceding functions are built in MaxCompute. You can click a function to view its description.

2.5.16. Manage deleted nodes

DataWorks provides a recycle bin to store all deleted nodes in the current workspace. You can restore or permanently delete the nodes.

Go to the Recycle Bin tab

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Recycle Bin** icon. Click ☰ in the lower-left corner to show or hide the left-side navigation pane.
3. View all the deleted nodes in the current workspace. On this tab, you can delete or restore a deleted node.

   > **Notice**
   > - The recycle bin displays only 100 nodes. If more than 100 nodes are deleted, the nodes deleted earlier are deleted permanently from the recycle bin.
   > - Deleted node groups are not displayed in the recycle bin.

Restore a node in the recycle bin

1. On the **Recycle Bin** tab, right-click a deleted node.
2. Select **Restore**.
3. In the **Restore Node** message, click **OK**.

> **Note** After you restore a node, a new node ID is generated for scheduling and all the information about the node is restored.

Permanently delete a node from the recycle bin

1. On the **Recycle Bin** tab, right-click a deleted node.
2. Select **Delete**.
3. In the **Delete** message, click **OK**.

> **Note** Nodes permanently deleted from the recycle bin cannot be restored. The recycle bin displays only deleted nodes.

2.5.17. Create a manually triggered workflow

In a manually triggered workflow, all nodes must be manually triggered, and cannot be automatically scheduled by DataWorks. Therefore, you do not need to specify parent nodes or outputs for nodes in manually triggered workflows.

Create a manually triggered workflow

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Manually Triggered Workflows** icon.

   Click ☰ in the lower-left corner to show or hide the left-side navigation pane.
3. Right-click **Manually Triggered Workflows** and select **Create Workflow**.
4. In the **Create Workflow** dialog box, set **Workflow Name** and **Description**.

   > **Notice** The workflow name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
5. Click **Create**.

Composition of a manually triggered workflow

> **Note** We recommend that you create a maximum of 100 nodes in a manually triggered workflow.

A manually triggered workflow consists of the nodes of the following modules. After you create a manually triggered workflow, open this workflow and create nodes of various types for each module. For more information, see Node types.

- **Data Integration**

  Double-click **Data Integration** under the created workflow to view all the data integration nodes.

  Right-click **Data Integration** and choose **Create > Batch Synchronization** to create a batch sync node. For more information, see Create a batch sync node.

- **MaxCompute**

  The MaxCompute compute engine consists of data analytics nodes, such as ODPS SQL, SQL Snippet, ODPS Spark, PyODPS, ODPS Script, and ODPS MR nodes. You can also view and create tables, resources, and functions.

  - **Data Analytics**

    Show **MaxCompute** under the created workflow and right-click **Data Analytics** to create a data analytics node. For more information, see Create an ODPS SQL node, Create an SQL Snippet node, Create an ODPS Spark node, Create a PyODPS node, Create an ODPS Script node, and Create an ODPS MR node.

  - **Table**

    Show **MaxCompute** under the created workflow and right-click **Table** to create a table. You can also view all the tables created for the current MaxCompute compute engine. For more information, see Create a MaxCompute table.

  - **Resource**

    Show **MaxCompute** under the created workflow and right-click **Resource** to create a resource. You can also view all the resources created for the current MaxCompute compute engine. For more information, see Create, reference, and download resources.

  - **Function**

    Show **MaxCompute** under the created workflow and right-click **Function** to create a function. You can also view all the functions created for the current MaxCompute compute engine. For more information, see Register a UDF.

- **Algorithm**

  Click the created workflow and right-click **Algorithm** to create an algorithm. You can also view all the PAI nodes created in the current manually triggered workflow. For more information, see Create a PAI node.

- **General**

  Click the created workflow and right-click **General** to create relevant nodes. For more information, see Create a Shell node and Create a zero load node.

- **UserDefined**

  Click the created workflow and right-click **UserDefined** to create relevant nodes. For more information, see Create a Hologres development node.

GUI elements

The following table describes the icons and tabs on the Manually Triggered Workflows page.

No.	Icon or tab	Description
1	Submit icon	Commits all nodes in the current manually triggered workflow.
2	Run icon	Runs all nodes in the current manually triggered workflow. Nodes in this workflow do not have dependencies, and therefore they can run at a time.
3	Stop icon	Stops all running nodes in the current manually triggered workflow.
4	Deploy icon	Navigates to the Deploy page. On this page, you can deploy some or all nodes that are committed but not deployed to the production environment. Note This icon is available only when the workspace is in standard mode.
5	Go to Operation Center icon	Navigates to the Operation Center page.
6	Box. icon	Box-selects a node group consisting of required nodes.
7	Refresh icon	Refreshes the page of the current manually triggered workflow.
8	Auto Layout icon	Sorts the nodes in the current manually triggered workflow.
9	Zoom In icon	Zooms in the current page.
10	Zoom Out icon	Zooms out the current page.
11	Search icon	Searches for a node in the current manually triggered workflow.

No.	Icon or tab	Description
12	Toggle Full Screen View icon	Displays nodes in the current manually triggered workflow in the full screen.
13	Show Engine Information/Hide Engine Information icon	Shows or hides engine information.
14	Workflow Parameters tab	Allows you to set parameters. Parameters set on this tab have a higher priority than those specified on the corresponding node configuration tab. If two values are set separately, the value set on the Workflow Parameters tab takes effect.
15	Change History tab	Allows you to view the operation records of all nodes in the current manually triggered workflow.
16	Versions tab	Allows you to view the deployment records of all nodes in the current manually triggered workflow.

2.5.18. Editor keyboard shortcuts

This section describes keyboard shortcuts available for the code editor.

Google Chrome in Windows OS

`Ctrl + S` : Save changes to a node.

`Ctrl + Z` : Undo an action.

`Ctrl + Y` : Redo an action.

`Ctrl + D` : Select occurrences.

`Ctrl + X` : Cut a line.

`Ctrl + Shift + K` : Delete a line.

`Ctrl + C` : Copy a line.

`Ctrl + I` : Select a line.

`Alt + Shift + Drag` : Select a block.

`Alt + Click` : Insert an additional cursor.

`Ctrl + Shift + L` : Select all occurrences.

`Ctrl + F` : Search for text in a node.

`Ctrl + H` : Replace text in a node.

`Ctrl + G` : Locate a line.

`Alt + Enter` : Select all matched strings.

`Alt + Up or down arrow` : Move a line up or down.

`Alt + Shift + Up or down arrow` : Duplicate a line.

`Ctrl + Shift + K` : Delete a line.

`Ctrl + Enter or Ctrl + Shift + Enter` : Insert a line break downwards or upwards.

`Ctrl + Shift + Back slash (\)` : Jump to the parenthesis, bracket, or brace that matches the adjacent one.

`Ctrl + Left bracket (]) or right bracket ([)` : Increase or decrease the indent of a line.

`Home or End` : Move the cursor to the beginning or end of a line.

`Ctrl + Home or End` : Move the cursor to the top or bottom of a node.

`Ctrl + Left or Right arrow` : Move the cursor one word to left or right.

`Ctrl + Shift + Left bracket (]) or right bracket ([)` : Hide or show a block.

`Ctrl + K + Left bracket (]) or right bracket ([)` : Hide or show sub-blocks in a block.

`Ctrl + K + 0 or J` : Hide or show all blocks.

`Ctrl + Slash (/)` : Comment out or uncomment the selected lines or blocks.

Google Chrome in Mac OS

`Command-S` : Save changes to a node.

`Command-Z` : Undo an action.

`Command-Y` : Redo an action.

`Command-D` : Select occurrences.

`Command-X` : Cut a line.

`Shift-Command-K` : Delete a line.

`Command-C` : Copy a line.

`Command-I` : Select a line.

`Command-F` : Search for text in a node.

`Option-Command-F` : Replace text in a node.

`Option-Up or down arrow` : Move a line up or down.

`Option-Shift-Up or down arrow` : Duplicate a line.

`Shift-Command-K` : Delete a line.

`Command-Enter or Shift-Command-Enter` : Insert a line break downwards or upwards.

`Shift-Command-Back slash (\)` : Jump to the parenthesis, bracket, or brace that matches the adjacent one.

`Command-Left bracket (]) or right bracket ([)` : Increase or decrease the indent of a line.

`Command-Left or right arrow` : Move the cursor to the beginning or end of a line.

`Command-Up or down arrow` : Move the cursor to the top or bottom of a node.

`Option-Left or right arrow` : Move the cursor one word to left or right.

`Option-Command-Left bracket (]) or right bracket ([)` : Hide or show a block.

`Command-K-Left bracket (]) or right bracket ([)` : Hide or show sub-blocks in a block.

`Command-K-0 or J` : Hide or show all blocks.

`Command-Slash (/)` : Comment out or uncomment the selected lines or blocks.

Insert multiple cursors and select multiple occurrences or lines

`Option-Click` : Insert an additional cursor.

`Option-Command-Up or down arrow` : Insert an additional cursor to the previous or next line.

`Command-U` : Undo a cursor-related operation.

`Option-Shift-I` : Insert a cursor at the end of each selected line.

`Command-G or Shift-Command-G` : Select the next or previous matched string.

`Command-F2` : Select the nearest character of each cursor.

`Shift-Command-L` : Select the nearest word of each cursor.

`Option-Enter` : Select all the matched strings.

`Option-Shift-Drag` : Multi-select lines

`Option-Shift-Command-Up or down arrow` : Extend a selection one line up or down.

`Option-Shift-Command-Left or right arrow` : Extend a selection one character to the left or right.

2.5.19. Use E-MapReduce in DataWorks

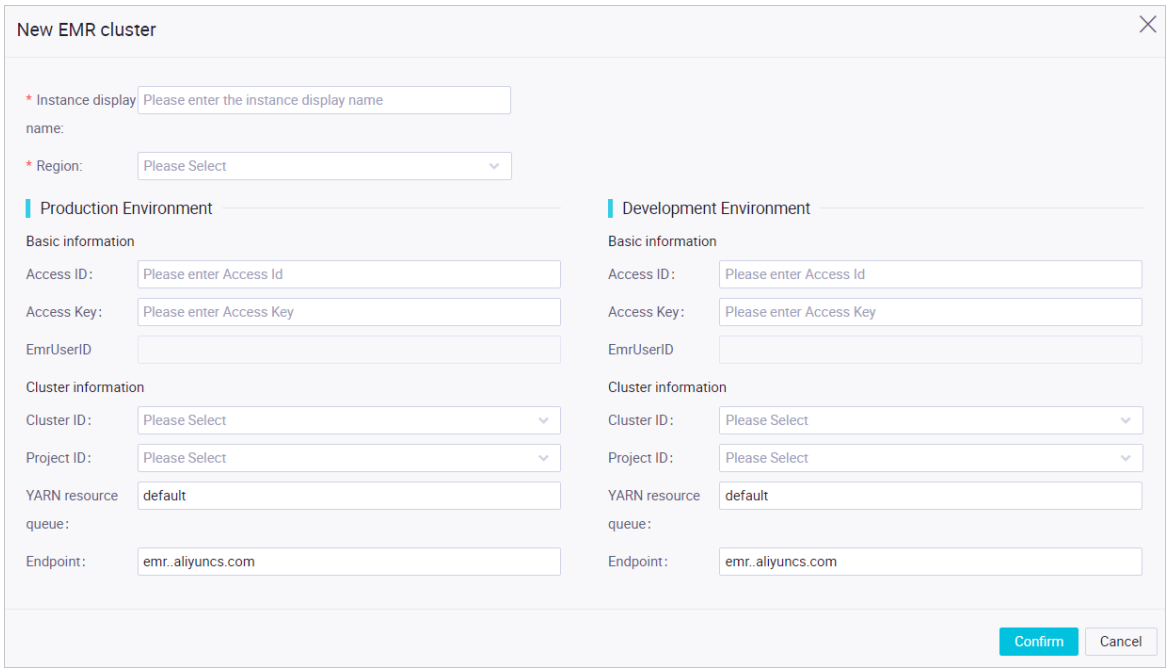
This topic describes how to use E-MapReduce in DataWorks.

Bind an E-MapReduce project to a DataWorks workspace

> **Note** Before you bind an E-MapReduce project to a DataWorks workspace, you must obtain the information about the E-MapReduce project.

1. Log on to the DataWorks console.
2. On the DataStudio page, click  in the upper-right corner. The **Project Management** page appears.

3. Click the **E-MapReduce** tab in the **Computing Engine Information** section. On this tab, you can view the information about all available E-MapReduce compute engines in the current workspace.
4. Click **Add instances**.
5. In the **New EMR cluster** dialog box, set the parameters as required.



Parameter	Description
Instance display name	The name of the E-MapReduce compute engine instance.
Region	The region of the workspace.
Access ID	The AccessKey ID of the account authorized to access the E-MapReduce cluster.
Access Key	The AccessKey secret of the account authorized to access the E-MapReduce cluster.
EmrClusterID	The ID of the E-MapReduce cluster.
Cluster ID	The ID of the user who created the E-MapReduce cluster.
Project ID	The ID of the project in the E-MapReduce cluster.
YARN resource queue	The name of the resource queue in the E-MapReduce cluster. Unless otherwise specified, set the value to *default*.
Endpoint	The endpoint of the E-MapReduce cluster. You can obtain the endpoint in the Apsara Stack Operations console. For more information, see Obtain an endpoint.

6. Click **Confirm**. After the E-MapReduce cluster is bound to your workspace, you can create E-MapReduce nodes on the **DataStudio** page.

> Note If the binding fails, check whether the failure is caused by one of the following reasons:
>
> - The E-MapReduce user ID is bound to another tenant account.
> - The specified cluster name already exists.

Create an E-MapReduce node

E-MapReduce nodes are categorized into four types: EMR Hive, EMR Spark SQL, EMR Spark, and EMR MR. For more information, see Create an EMR MR node.

Reference resource files

E-MapReduce resource files are categorized into two resource types: EMR JAR and EMR File.

Reference E-MapReduce resource files by using the following methods:

- For EMR Hive and EMR MR nodes, add `--@resource_reference{"Resource name"}` at the first line of the code.
- For EMR Spark nodes, add `##@resource_reference{"Resource name"}` at the first line of the code.

Manage data

DataWorks allows you to query E-MapReduce metadata and synchronize the data for data development.

2.6. HoloStudio

2.6.1. Overview

This topic describes what is HoloStudio and the features of HoloStudio.

HoloStudio, which is developed based on Hologres, is an all-in-one online analytical processing (OLAP) development platform deeply integrated with DataWorks. HoloStudio provides Hologres users with standardized and easy-to-use development services and one-stop real-time data warehouse building services by using a visualized and wizard-based user interface. In addition to standard management available in PostgreSQL, HoloStudio provides more interactive analytics features. HoloStudio supports the following features:

- Table management

  HoloStudio allows you to create a PostgreSQL table on a visualized user interface or by using SQL statements. HoloStudio also allows you to create a foreign table sourced from MaxCompute by synchronize the schema with one click and preview and analyze MaxCompute data.

- SQL Console

  The SQL Console module of HoloStudio allows you to use an SQL editor to obtain query results in seconds.

- Data analytics

Based on the underlying capabilities of DataWorks, HoloStudio allows you to create multiple foreign tables at a time and synchronize data with one click and provides you with the one-stop, stable, and efficient extract-transform-load (ETL) service.

- Seamless connection to the Hologres console

  HoloStudio is seamlessly connected to the Hologres console. In the Hologres console, you can manage Hologres instances, users, and databases on a visualized user interface.

2.6.2. Bind a Hologres database to the current workspace

This topic describes how to bind a Hologres database to the current workspace.

If you need to use HoloStudio for data development, bind a Hologres database to the current workspace. Perform the following steps:

1. Log on to HoloStudio.

   On the left-side navigation submenu, click **PG management**. On the PG management tab, move the pointer over the Create icon and select **Database**.

2. In the Create Database dialog box, set relevant parameters.

   In the **Create Database** dialog box, set relevant parameters and click **Test connectivity**. If the system message indicating that the connectivity test is passed appears, the specified database is connected. Then, click **Complete**.

Parameter	Description	Remarks
Connect To	The type of the data store.	The value is automatically generated and cannot be changed.
Server	The endpoint of the Hologres instance.	You can view the endpoint on the Basic Information page of the Hologres instance in the Hologres console.
Port	The port number of the Hologres instance.	You can view the port number on the Basic Information page of the Hologres instance in the Hologres console.
Database Name	The name of the Hologres database to be bound to the current workspace.	In actual scenarios, create a Hologres database and set this parameter to the name of the database to bind the database to the current workspace.
User name	The AccessKey ID of your Apsara Stack tenant account.	You can click the username in the upper-right corner to view the AccessKey ID.

Parameter	Description	Remarks
Password	The AccessKey secret of your Apsara Stack tenant account.	You can click the username in the upper-right corner to view the AccessKey secret.
JDBC Extension	The extension parameters used to establish a Java Database Connectivity (JDBC) connection to Hologres.	Example: `?preferQueryMode=simple&tcpKeepAlive=true`
Test connectivity	Tests whether the database is connected.	N/A

3. Use the Hologres database in HoloStudio.

   After the Hologres database is bound to the current workspace, click the Refresh icon on the **PG management** tab. After the database appears, you can use the database in HoloStudio.

2.6.3. SQL Console

The SQL Console in HoloStudio is an editor for executing SQL statements. In the SQL Console, you can execute SQL statements to analyze data in Hologres and obtain the query results. This topic describes the basic features and usage of the SQL Console in HoloStudio.

Folder

The Folder module stores new ad hoc queries, which helps you manage ad hoc queries.

In the left-side navigation pane, click **SQL Console**. Move the pointer over the Create icon and select **Folder**. In the Create Folder dialog box, enter a folder name and click Commit to create a folder. You can create an ad hoc query in the folder and execute standard SQL statements on tables. You can also right-click a table in the folder and select the relevant menu item to move, rename, or delete the table.

SQL Console

The SQL Console module allows you to create ad hoc queries and execute standard SQL statements.

1. Create an ad hoc query.

   In the left-side navigation pane, click **SQL Console**. Move the pointer over the Create icon and select **SQL Console**. In the Create Node dialog box, set relevant parameters.

   The following table describes the parameters for creating an ad hoc query.

Parameter	Description
Node Name	The name of the ad hoc query. The name can contain letters, digits, underscores (_), and periods (`.`).
Location	The folder where the ad hoc query is stored.

Parameter	Description
Database	The target database in which the ad hoc query is run.

2. Run the ad hoc query.

   Write the SQL statements used in the ad hoc query and click the **Run** icon to run the query. Then, you can check the query result. The following example shows how to create a table, import data to the table, and then query the table:

```
CREATE TABLE supplier (
 s_suppkey bigint NOT NULL,
 s_name text NOT NULL,
 s_address text NOT NULL,
 s_nationkey bigint NOT NULL,
 s_phone text NOT NULL,
 s_acctbal bigint NOT NULL,
 s_comment text NOT NULL,
PRIMARY KEY (s_suppkey)
);

INSERT INTO supplier VALUES
(1, 'Supplier#000000001', 'gf0JBoQDd7tgrzrddZ', 17, '27-918-335-1736', 575594, 'each slyly above the careful'),
(6, 'Supplier#000000006', 'tQxuVm7s7CnK', 14, '24-696-997-4969', 136579, 'final accounts. regular dolphins use against the furiously ironic decoys. '),
(10, 'Supplier#000000010', 'Saygah3gYWMp72i PY', 24, '34-852-489-8585', 389191, 'ing waters. regular requests ar'),
(18, 'Supplier#00000001', 'PGGVE5PWAMwKDZw', 16, '26-729-551-1115', 704082, 'accounts snooze slyly furiously bold'),
(39, 'Supplier#000000039', 'SYpEPWr1yAFHaC91qjFcijjeU5eH', 8, '18-851-856-5633 611565', 88990, 'le slyly requests. special packages shall are blithely. slyly unusual packages sleep'),
(48, 'Supplier#000000048', 'FNPMQDuyuKvTnLXXaLf3Wl6OtONA6mQlWJ', 14, '24-722-551-9498',563062, 'xpress instructions affix. fluffily even requests boos');

SELECT * FROM supplier;
```

   The following table describes the GUI elements on the node editing tab.

GUI element	Description
SQL editor	You can write SQL statements in the SQL editor.

GUI element	Description
Save icon	You can click this icon to save all statements in the SQL editor.
Run icon	You can click this icon to execute all statements in the SQL editor. The result appears on the Result tab. You can also select an SQL statement to be executed. In this case, the system only executes this statement.
Refresh icon	You can click this icon to refresh the content in the SQL editor. The system retains only the saved content after the refresh.
Stop icon	You can click this icon to stop executing SQL statements.
Runtime Log	You can check the execution results and, if any, error messages.
Result	You can check the table content after the SQL statements are executed.
Steal Lock icon	You can click this icon to unlock the locked SQL Console.

HoloStudio also allows you to directly manage the queried data. For example, you can hide columns, copy data, and search for data.

Note For statements without results returned, such as the `CREATE TABLE` statement, only operational logs are generated after the statements are executed.

2.6.4. PostgreSQL management

2.6.4.1. Manage databases

The PG management module of HoloStudio allows you to manage databases and tables with one click in a visualized manner. In addition, HoloStudio supports interactive queries with a response time within seconds. This topic describes how to use the PG management module to manage databases.

Create a database

The PG management module allows you to connect databases to HoloStudio and manage the connected databases in a visualized manner. Before you connect a database to HoloStudio, create the database in the Hologres console or by executing SQL statements in the SQL Console. The following example demonstrates how to create a database by executing SQL statements in the SQL Console and connect the database to HoloStudio:

1. Create an ad hoc query.

Log on to the DataWorks console as a superuser and go to the HoloStudio page. In the SQL Console, execute the following SQL statement:

```
create database dbname;
create database testdb; // Create a database named testdb.
```

2. Bind the Hologres database to the current workspace.

   On the HoloStudio page, click **PG management** on the left-side navigation submenu. On the PG management tab, move the pointer over the Create icon and select **Database**.

3. In the Create Database dialog box, set relevant parameters.

   In the **Create Database** dialog box, set relevant parameters and click **Test connectivity**. If the system message indicating that the connectivity test is passed appears, the specified database is connected. Then, click **Complete**.

Parameter	Description	Remarks
Connect To	The type of the data store. Default value: Hologres.	The value is automatically generated and cannot be changed.
Server	The endpoint of the Hologres instance.	You can view the endpoint on the Basic Information page of the Hologres instance in the Hologres console.
Port	The port number of the Hologres instance.	You can view the port number on the Basic Information page of the Hologres instance in the Hologres console.
Database Name	The name of the database to be bound to the current workspace.	The value must be the same as the database name in the CREATE DATABASE statement, for example, **testdb**.
User name	The AccessKey ID of your Apsara Stack tenant account.	You can click the username in the upper-right corner to view the AccessKey ID.
Password	The AccessKey secret of your Apsara Stack tenant account.	You can click the username in the upper-right corner to view the AccessKey secret.
JDBC Extension	The extension parameters used to establish a JDBC connection to Hologres.	Example: `?preferQueryMode=simple&tcpKeepAlive=true`
Test connectivity	Tests whether the database is connected.	If the system message indicating that the connectivity test is passed appears, the specified database is connected.

Delete a database

The PG management module of HoloStudio allows you to delete databases. On the left-side navigation submenu, click **PG management**. On the PG management tab, right-click the database you want to delete and select **Delete Database**.

In the Delete Database message, click **Ok** to delete the database.

> **Note** Only a superuser of a database or the database owner configured by a superuser can delete the database.

View database details

On the left-side navigation submenu, click **PG management**. On the PG management tab, right-click the database for which you want to view details and select **Database details**.

2.6.4.2. Manage tables

Similar to PostgreSQL, Hologres manages data by using tables. The PG management module of HoloStudio allows you to manage tables in a visualized manner. You can create, check, or delete a table with one click. This topic describes how to use the PG management module of HoloStudio to manage tables.

Create a table

1. Create a table.

   On the homepage of HoloStudio, click **Create Table**. Alternatively, click **PG management** on the left-side navigation submenu. On the PG management tab, move the pointer over the Create icon and select **Table**.

2. Edit the table content and attributes.

   On the tab that appears, edit the table content and attributes, and click **Commit**. The following figure shows an example of a column-oriented table with primary keys.

Section or tab	Parameter	Description
General	Interactive Analytics Database	The database where the table resides.
	Table Name	The name of the table.
	Description	The description of the table.
	Field Name	The name of the field in the table.
	Data Type	The data type of the field.
	Primary Key Field	Specifies whether to use the field as the primary key for the table.

Section or tab	Parameter	Description
Field	Optional	Specifies whether the field can be null.
	Array	Specifies whether the field is an ordered array of elements.
	Description	The description of the field.
	Actions	The actions that you can perform on the field. For example, you can delete the field from the table, or move up or down the position of the field in the table.
Properties	Storage Mode	The storage mode of the table. Valid values: Row Store and Column Store. Default value: Column Store.
	Lifecycle (Seconds)	The lifecycle of the table. Default value: Permanent.
	Clustered Index	The index used for sorting.
	Dictionary Code Columns	The column based on whose values a dictionary mapping is built.
	Bitmap Column	The column on which bit code is built.
Partitioned Table	PARTITION BY LIST	The partition field.

Check a table

1. View the DDL statement used to create the table.

   On the left-side navigation submenu, click **PG management**. Double-click the table you want to check and click **Generate DDL Statement** to check the SQL statement used to create the table.

2. Preview data.

   On the left-side navigation submenu, click **PG management**. Double-click the table you want to check and click **Data Preview** to check the content of the table. If the table contains no data, you can only view the fields of the table.

Delete a table

On the left-side navigation submenu, click **PG management**. On the PG management tab, right-click the table you want to delete and select **Delete Table**.

In the Delete message, click **Ok**.

2.6.4.3. Manage foreign tables

In Hologres, a foreign table does not store data but maps the table from the external data source. The PG management module of HoloStudio allows you to create, query, or delete foreign tables. You can only analyze foreign tables sourced from MaxCompute. This helps you obtain the query results.

This topic describes how to use the PG management module of HoloStudio to manage foreign tables.

Create a foreign table

On the left-side navigation submenu, click **PG management**. On the PG management tab, move the pointer over the Create icon and select **External Table**. On the tab that appears, set parameters for creating a foreign table and click **Commit**. An existing MaxCompute table is used in the following example. After you search for a MaxCompute table by entering its name, HoloStudio automatically generates a foreign table based on the fields of the MaxCompute table after you click Commit.

> **Note**
>
> 1. Before you create a foreign table in Hologres, make sure that its source table exists in a MaxCompute project.
> 2. The fields of a foreign table in Hologres have a one-to-one mapping with those of the source table in MaxCompute. You can query specific fields or all fields.

Section or icon	Parameter	Description
General	Interactive Analytics Database	The database where the foreign table to be created resides.
	Table Name	The name of the foreign table.
External Service	Types	The service type of the external table. You can only set this parameter to MaxCompute.
Table	Table	The source table in MaxCompute to be mapped.
Commit	Commit	You can click this button to commit the foreign table that you create.

Check a foreign table

1. **Preview data.**

   On the left-side navigation submenu, click **PG management**. On the PG management tab, double-click the foreign table you want to check, and click **Data Preview** to check the content of the foreign table.

2. **View the DDL statement used to create the table.**

   On the left-side navigation submenu, click **PG management**. On the PG management tab, double-click the foreign table you want to check, and click **Generate DDL Statement** to check the SQL statement used to create the foreign table.

Delete a foreign table

On the left-side navigation submenu, click **PG management**. On the PG management tab, right-click the foreign table you want to delete and select **Delete Table**. In the Delete message, click **Ok** to delete the foreign table.

2.6.5. Data analytics

2.6.5.1. Overview

The Data Analytics module of HoloStudio is seamlessly integrated with DataWorks for node scheduling and provides all-in-one, stable, and efficient extract, transform, load (ETL) services. It can also synchronize MaxCompute table schemas and data and allows you to upload local files for data analytics.

The Data Analytics module consists of the following submodules:

1. Folder: stores data analytics nodes, helping you manage data analytics nodes of each database.
2. Interactive Analytics Development: is integrated with DataWorks to schedule ETL nodes.
3. One-click MaxCompute table structure synchronization: allows you to create multiple foreign tables sourced from MaxCompute at a time.
4. One-click MaxCompute data synchronization: provides a visualized user interface for you to synchronize MaxCompute data to Hologres.
5. One-click local file Upload: allows you to upload local files to Hologres.

Folder

Folders store data analytics nodes, helping you manage data analytics nodes of each database.

On the left-side navigation submenu, click **Data Analytics**. On the Data Analytics tab, move the pointer over the Create icon and select **Folder**. In the Create Folder dialog box, enter a folder name and click **Commit**.

2.6.5.2. Use the Interactive Analytics Development submodule

The Interactive Analytics Development submodule is seamlessly integrated with DataWorks. You can use HoloStudio to import data from MaxCompute to Hologres. You can also use DataWorks to schedule nodes to periodically import data to Hologres. This topic describes how to use HoloStudio to map the source data stored in a MaxCompute table to Hologres for periodic scheduling.

1. **Prepare a MaxCompute table.**

Create a table in MaxCompute and import data to the table. You can also select a table with data from Data Map. In this example, an existing table in Data Map is used. The following Data Definition Language (DDL) statement is used to create the table:

```
CREATE TABLE IF NOT EXISTS bank_data_odps
(
 age           BIGINT COMMENT 'age',
 job           STRING COMMENT 'job type',
 marital       STRING COMMENT 'marital status',
 education     STRING COMMENT 'education level',
 card          STRING COMMENT 'credit card available or not',
 housing       STRING COMMENT 'mortgage',
 loan          STRING COMMENT 'loan',
 contact       STRING COMMENT 'contact',
 month         STRING COMMENT 'month',
 day_of_week   STRING COMMENT 'day in a week',
 duration      STRING COMMENT 'duration',
 campaign      BIGINT COMMENT 'number of contacts during the campaign',
 pdays         DOUBLE COMMENT 'interval from the last contact',
 previous      DOUBLE COMMENT 'number of contacts with the customer',
 poutcome      STRING COMMENT 'result of the previous marketing campaign',
 emp_var_rate  DOUBLE COMMENT 'employment change rate',
 cons_price_idx DOUBLE COMMENT 'consumer price index',
 cons_conf_idx DOUBLE COMMENT 'consumer confidence index',
 euribor3m     DOUBLE COMMENT 'euro deposit rate',
 nr_employed   DOUBLE COMMENT 'number of employees',
 y             BIGINT COMMENT 'fixed time deposit available or not'
);
```

2. **Create a foreign table.**

   Go to the HoloStudio page. On the left-side navigation submenu, click **PG management** or **SQL Console**. On the tab that appears, create a foreign table for mapping data in the MaxCompute source table. In this example, use the following SQL statements to create a foreign table:

```
BEGIN;
CREATE FOREIGN TABLE if not EXISTS bank_data_foreign_holo (
 age int8,
 job text,
 marital text,
 education text,
 card text,
 housing text,
 loan text,
 contact text,
 month text,
 day_of_week text,
 duration text,
 campaign int8,
 pdays float8,
 previous float8,
 poutcome text,
 emp_var_rate float8,
 cons_price_idx float8,
 cons_conf_idx float8,
 euribor3m float8,
 nr_employed float8,
 y int8
)
SERVER odps_server
OPTIONS (project_name 'projectname', table_name 'bank_data_odps');
GRANT SELECT ON bank_data_foreign_holo TO PUBLIC;
COMMIT;
```

Note The OPTIONS parameter contains two fields: project_name, which is the name of the MaxCompute project, and table_name, which is the name of the MaxCompute table.

3. **Create a data storage table.**

   Create a table in HoloStudio to receive and store data. The fields in this table must be of the same data types as those in the foreign table. In this example, use the following SQL statements to create the storage table:

```
BEGIN;
CREATE TABLE if not EXISTS bank_data_holo (
 age int8,
 job text,
 marital text,
 education text,
 card text,
 housing text,
 loan text,
 contact text,
 month text,
 day_of_week text,
 duration text,
 campaign int8,
 pdays float8,
 previous float8,
 poutcome text,
 emp_var_rate float8,
 cons_price_idx float8,
 cons_conf_idx float8,
 euribor3m float8,
 nr_employed float8,
 y int8,
 ds text NOT NULL
)
PARTITION  BY LIST(ds);
CALL SET_TABLE_PROPERTY('bank_data_holo', 'orientation', 'column');
CALL SET_TABLE_PROPERTY('bank_data_holo', 'time_to_live_in_seconds', '700000');
COMMIT;
```

4. **Create a partitioned table.**

   On the HoloStudio page, click **Data Analytics** on the left-side navigation submenu. On the Data Analytics tab, move the pointer over the Create icon and select **Interactive Analytics Development** to create a Hologres development node. Then, go to the SQL editor of the node and enter SQL statements to create a partitioned table for obtaining the required data. After you enter the SQL statements, click the **Run** icon. In the Field dialog box, set a value for the ${bizdate} parameter. After the SQL statements are executed, click the **Save** icon and then **Go to DataStudio for Scheduling** to schedule the node. You can enter the following sample SQL statements:

```
create table if not exists bank_data_holo_1_${bizdate} partition of bank_data_holo
 for values in ('${bizdate}');

insert into bank_data_holo_1_${bizdate}
select
   age as age,
   job as job,
   marital as marital,
   education as education,
   card as card,
    housing as housing,
   loan as loan,
   contact as contact,
   month as month,
   day_of_week as day_of_week,
    duration as duration,
   campaign as campaign,
    pdays as pdays,
   previous as previous,
   poutcome as poutcome,
    emp_var_rate as emp_var_rate,
   cons_price_idx as cons_price_idx,
   cons_conf_idx as cons_conf_idx,
   euribor3m as euribor3m,
   nr_employed as nr_employed,
   y as y,
   '${bizdate}' as ds
from bank_data_foreign_holo;
```

5. **Schedule the partitioned table.**

   Go to the DataStudio page and create a Hologres development node. In the SQL editor of the node, enter SQL statements to synchronize the partitioned table information to the node and click **Update Code**. Before you create the node, make sure that a workflow is created.

6. **Set parameters for scheduling the data analytics node.**

   On the editing tab of the Hologres development node, click the **Properties** tab in the right-side navigation pane to set parameters for scheduling the node.

   i. **Set parameters in the General section.**

      In the **Arguments** field, specify a value for the ${bizdate} variable.

ii. **Set parameters in the Schedule section.**

Select Normal for **Execution Mode** and set other parameters as required.

iii. **Set parameters in the Dependencies section.**

Select **Yes** for **Auto Parse** and click **Use Root Node**. After DataStudio automatically parses and displays the root node as a parent node, change the value of Auto Parse to **No**. You can also select a table that is scheduled as a parent node.

7. **Save and deploy the node for scheduling.**

After you set the scheduling parameters for the node, click the **Save** icon and then the **Submit** icon. After that, click **Deploy** in the upper-right corner.

8. **Deploy the node in Operation Center.**

On the **Create Package** page, find the target node and click Publish in the Actions column. After the node is deployed, click **Operation Center** in the top navigation bar to generate retroactive data for the node.

In **Operation Center**, right-click the published node and choose **Run** > **Current Node Retroactively**. Configure the node based on your business requirements.

9. **Check the content of the table in HoloStudio.**

After the retroactive data generation node is run, go back to HoloStudio. On the left-side navigation submenu, click **PG management**. On the PG management tab, click a database and choose Mode > public > **Table**. Double-click the partitioned table that is scheduled and click **Data Preview** to check whether the data is imported to the table.

2.6.5.3. Create multiple foreign tables at a time

Seamlessly integrated with MaxCompute at the underlying layer, Hologres allows you to create foreign tables to query MaxCompute data in an accelerated manner. You can create multiple foreign tables at a time by using the IMPORT FOREIGN TABLE statement. To free you from SQL operations, HoloStudio provides the following submodule for you to create foreign tables in a visualized manner: One-click MaxCompute table structure synchronization.

1. **Create a schema sync node.**

On the HoloStudio page, click **Data Analytics** on the left-side navigation submenu. On the Data Analytics tab, move the pointer over the Create icon and select **One-click MaxCompute table structure synchronization**. In the Create Node dialog box, set relevant parameters and click Commit. The schema sync node is created.

2. **Set parameters for synchronizing the table schema.**

After the schema sync node is created, you must set parameters for synchronizing the table schema based on your needs.

Parameter	Description	Remarks
Target Library	The name of the Hologres database where the foreign tables are to be created.	N/A

Parameter	Description	Remarks
Target Schema	The name of the schema in the specified Hologres database.	The default value is public. If you have created a schema, you can select the created schema.
Remote Service type	The type of the external service. You can create only foreign tables sourced from MaxCompute.	The default value is odps.
Remote server	The external server. The default value is odps_server.	After you purchase a Hologres instance, the system automatically creates a server named odps_server. You can directly use it.
Remote library	The name of the MaxCompute project where the tables mapping the foreign tables to be created reside.	N/A
Table name rules	The regular expression for specifying the tables whose schema is to be synchronized. By default, the schema of all tables in the specified MaxCompute project will be synchronized.	◦ If a foreign table to be created is named the same as an existing foreign table in Hologres, the foreign table is not created. ◦ If a MaxCompute table whose schema is to be synchronized contains data types that Hologres does not support, an error is thrown. In this case, exclude this MaxCompute table in the regular expression. ◦ For more information, see IMPORT FOREIGN SCHEMA.
Regular preview	The execution result of the regular expression.	N/A

3. **Run the schema sync node.**

   Click the **Save** icon and then click the **Run** icon to run the schema sync node. After the schema sync node is run, click **PG management** on the left-side navigation submenu. The created foreign tables appear. You can query the table data.

2.6.5.4. Import MaxCompute data

To improve the efficiency of querying MaxCompute data, Hologres allows you to import MaxCompute data to Hologres for queries. HoloStudio provides the following submodule for you to directly import MaxCompute data in a visualized manner: One-click MaxCompute data synchronization.

1. **Create a data sync node.**

   On the HoloStudio page, click Data Analytics on the left-side navigation submenu. On the Data Analytics tab, move the pointer over the Create icon and select **One-click MaxCompute data synchronization**. In the Create Node dialog box, enter the node information and click Commit. The data sync node is created.

2. **Set parameters for synchronizing data.**

   After the data sync node is created, you must set parameters for synchronizing data.

Section	Parameter	Description	Remarks
MaxCompute Source table selection	External table source	The source of the foreign table. Valid values: External table already exists and New external table.	◦ If you select External table already exists, the existing foreign table mapping the MaxCompute table will be used. ◦ If you select New external table, you must create a foreign table mapping the MaxCompute table.
	External table table name	The name of the existing foreign table.	The foreign table must map the MaxCompute table whose data will be synchronized.
Target table settings	Target Library	The name of the Hologres database to which the MaxCompute data will be synchronized.	N/A
	Target schema	The name of the schema in the specified Hologres database.	The default value is public. If you have created a schema, you can select the created schema.
	Destination Table Name	The name of the target table to which the MaxCompute data will be synchronized.	The table name can be customized.

Section	Parameter	Description	Remarks
	Target table description	The description of the target table.	N/A
Synchronization settings	Synchronization field	The fields to be synchronized from the specified MaxCompute table.	You can select specific or all fields in the MaxCompute table.
	Partition configuration	The partition fields to be synchronized.	Hologres supports a maximum of one level of partitions.
	Index configuration	The index to be built for the target table.	N/A
SQL Script	SQL Script	The SQL statements that are executed when the data sync node is run.	N/A

3. **Run the data sync node.**

   Click the **Save** icon and then click the **Run** icon to run the data sync node. After the node is run, you can query the imported data in SQL Console or PG management.

2.6.5.5. Upload local files

This topic describes how to upload local files in HoloStudio in a visualized manner.

Hologres allows you to use the COPY statement to import data from the standard input of a client to a specified table. For more information, see COPY. HoloStudio allows you to import data in a local file to a specified table by uploading the local file in a visualized manner. To upload a local file in HoloStudio, perform the following steps:

1. **Create a table.**

   In SQL Console or PG management, create a table to which data in the local file will be imported. In this example, use the following SQL statements to create a table:

```
BEGIN;
CREATE TABLE if not EXISTS holo_bank (
 age int8,
 job text,
 marital text,
 education text,
 card text,
 housing text,
 loan text,
 contact text,
 month text,
 day_of_week text,
 duration text,
 campaign int8,
 pdays float8,
 previous float8,
 poutcome text,
 emp_var_rate float8,
 cons_price_idx float8,
 cons_conf_idx float8,
 euribor3m float8,
 nr_employed float8,
 y int8
);
COMMIT;
```

2. **Create a node for uploading the local file.**

   Go to the HoloStudio page. On the left-side navigation submenu, click Data Analytics. On the Data Analytics tab, move the pointer over the Create icon and select **Upload files locally with one click.**

3. **Enter the node information.**

   In the **One-click local file Upload** dialog box, set the parameters based on your business needs and click Next Step.

Parameter	Description	Remarks
Target Library	The name of the Hologres database where the target table resides.	N/A

Parameter	Description	Remarks
Target Schema	The name of the schema where the target table resides.	The default value is public. If you have created a schema, you can select the created schema.
Select the data table to import	The name of the target table to which data in the local file will be imported.	N/A

4. **Select the local file to upload and set other required parameters.**

   After you click Next Step, select the local file to upload, set other required parameters, and then click Commit.

Parameter	Description	Remarks
Select File	The local file to upload.	You can select a local file only in the .txt, .csv, or .log format.
Select separator	The delimiter of fields in the file. Select Comma (,) or Space ( ).	N/A
Original character set	The character set of the file.	○ GBK ○ UTF-8 ○ CP936 ○ ISO-8859
First behavior title	Specifies whether to use the first line as the header line.	N/A

5. **View the imported data.**

   After you click **Commit**, data in the selected local file is imported to the specified table. You can go to SQL Console or PG management to view the imported data.

2.6.6. Hologres console

2.6.6.1. Overview

Hologres is a real-time interactive analytics service that is fully compatible with PostgreSQL and seamlessly integrated with the big data ecosystem. Hologres delivers high-concurrency and low-latency performance in analyzing terabyte-scale data. Hologres allows you to use mainstream Business Intelligence (BI) tools to get an analytical insight into data from multiple dimensions and explore business data in an efficient and cost-effective manner.

For convenience of business, Apsara Stack provides the Hologres console independent from the DataWorks console for different users to managing Hologres instances, users, and databases.

Log on to the Apsara Stack console. In the top navigation bar, choose **Products** > **Interactive Analytics** to go to the Hologres console. The following figure shows the Overview page in the Hologres console.

2.6.6.2. View the instance list
