24 rows in set (0.01 sec)
```

According to the sharding rule of the logical table, you can see that both database sharding and table sharding use the hash function, except that the database shard key is id and the table shard key is bid.

```
mysql> show rule from multi_db_multi_tbl;
+-----+-----+-----+-----+-----+-----+-----+-----+
| ID | TABLE_NAME | BROADCAST | DB_PARTITION_KEY | DB_PARTITION_POLICY | DB_PARTITION_COUNT | TB_PARTITION_KEY | TB_PARTITION_POLICY | TB_PARTITION_COUNT |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 0 | multi_db_multi_tbl | 0 | id | hash | 8 | bid | hash | 3 |
+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

Use RANGE_HASH for sharding

- Requirements

The shard key must be a character or a number.

- Routing method

Calculate a hash value based on the last N digits of any shard key, and then calculate the route by using RANGE_HASH. The number N is the third parameter in the function. For example, during calculation of the RANGE_HASH(COL1, COL2, N) function, COL1 is preferentially selected and then truncated to obtain the last N digits for calculation. If COL1 does not exist, COL2 is selected and truncated for calculation.

- Scenarios

RANGE_HASH is applicable to scenarios where two shard keys are used for sharding but only the value of one shard is used for SQL query. Assume that a PolarDB-X database is partitioned into eight physical databases. Our customer has the following requirements:

- i. The order table of each service needs to be partitioned into database shards by buyer ID and order ID.
- ii. The query is executed based on either the buyer ID or order ID as the condition.

In this case, you can run the following DDL statement to create the order table:

```
create table test_order_tb (
    id int,
    seller_id varchar(30) DEFAULT NULL,
    order_id varchar(30) DEFAULT NULL,
    buyer_id varchar(30) DEFAULT NULL,
    create_time datetime DEFAULT NULL,
    primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8 dbpartition by RANGE_HASH(buyer_id, order_id, 10) tpartition by RANGE_HASH(buyer_id, order_id, 10) tpartitions 3;
```

 Note

- Neither of the two shard keys can be modified.
- Data insertion fails if the two shard keys point to different database shards or table shards.

Use date functions for sharding

In addition to using the hash function as the sharding algorithm, you can also use the date functions MM, DD, WEEK, and MMDD as the table sharding algorithms. For more information, see the following examples:

- Create a table that is partitioned into table shards in database shards. The database sharding process calculates the hash by using `userId` as the shard key, and the table sharding process calculates `DAY_OF_WEEK` through the `WEEK(actionDate)` function and then partitions the table into table shards based on the `actionDate` column, with one week counted as seven days.

For example, if the value in the `actionDate` column is 2017-02-27, which is on Monday, the value obtained by calculating the `WEEK(actionDate)` function is 2. In this case, the record is stored in table shard 2, because $2 \% 7 = 2$. This table shard is located in a database shard and is named `user_log_2`. For another example, if the value in the `actionDate` column is 2017-02-26, which is on Sunday, the value obtained by calculating the `WEEK(actionDate)` function is 1. In this case, the record is stored in table shard 1, because $1 \% 7 = 1$. This table shard is located in a database shard and is named `user_log_1`.

```
CREATE TABLE user_log(  
  userId int,  
  name varchar(30),  
  operation varchar(30),  
  actionDate DATE  
) dbpartition by hash(userId) tpartition by WEEK(actionDate) tpartitions 7;
```

According to the node topology of the logical table, you can see that seven table shards are created in each database shard, because one week is counted as seven days in the function. The responses are very long, and therefore are omitted by using an ellipsis (...).

```
mysql> show topology from user_log;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| ID | GROUP_NAME | TABLE_NAME |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+

56 rows in set (0.01 sec)
```

According to the sharding rule of the logical table, you can see that the database sharding process calculates the hash by using `userId` as the shard key, and the table sharding process calculates the WEEK function by using `actionDate` as the shard key.

```
mysql> show rule from user_log;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| ID | TABLE_NAME | BROADCAST | DB_PARTITION_KEY | DB_PARTITION_POLICY | DB_PARTITION_COUNT | TB_PARTITION_KEY | TB_PARTITION_POLICY | TB_PARTITION_COUNT |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 0 | user_log | 0 | userId | hash | 8 | actionDate | week | 7 |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

According to the specified database and table shard key parameters, you can see the specific physical table in the specific physical database to which the SQL statement is routed.

View the route of the SQL statement

```
mysql> explain select name from user_log where userId = 1 and actionDate = '2017-02-27'\G
***** 1_row *****
GROUP_NAME: SANGUAN_1490167540907XNDV5SANGUAN_B5QT_0001_RDS
SQL: select `user_log`.`name` from `user_log_2` `user_log` where ((`user_log`.`userId` = 1) AND (`user_log`.`actionDate` = '2017-02-27'))
PARAMS: {}
1 row in set (0.01 sec)
```

- Create a table that is partitioned into table shards in database shards. The database sharding process calculates the hash by using `userId` as the shard key, and the table sharding process calculates `MONTH_OF_YEAR` through the `MM(actionDate)` function and then partitions the table into table shards based on the `actionDate` column, with one year counted as 12 months.

For example, if the value in the `actionDate` column is 2017-02-27, the value obtained by calculating the `MM(actionDate)` function is 02. In this case, the record is stored in table shard 02, because $02 \% 12 = 02$. This table shard is located in a database shard and is named `user_log_02`. For another example, if the value in the `actionDate` column is 2016-12-27, the value obtained by calculating the `MM(actionDate)` function is 12. In this case, the record is stored in table shard 00, because $12 \% 12 = 00$. This table shard is located in a database shard and is named `user_log_00`.

```
CREATE TABLE user_log2(
  userId int,
  name varchar(30),
  operation varchar(30),
  actionDate DATE
) dbpartition by hash(userId) tpartition by MM(actionDate) tpartitions 12;
```

According to the node topology of the logical table, you can see that 12 table shards are created in each database shard, because one year is counted as 12 months in the function. The responses are very long, and therefore are omitted by using an ellipsis (...).

```
mysql> show topology from user_log2;

+-----+-----+-----+-----+
96 rows in set (0.02 sec)
```

According to the sharding rule of the logical table, you can see that the database sharding process calculates the hash by using `userId` as the shard key, and the table sharding process calculates the `MM` function by using `actionDate` as the shard key.

```
mysql> show rule from user_log2;
+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+
| ID | TABLE_NAME | BROADCAST | DB_PARTITION_KEY | DB_PARTITION_POLICY | DB_PARTITION_COUNT | TB_PARTITION_KEY | TB_PARTITION_POLICY | TB_PARTITION_COUNT |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 0 | user_log2 | 0 | userId | hash | 8 | actionDate | mm | 12 |
+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

- Create a table that is partitioned into table shards in database shards. The database sharding process calculates the hash by using `userId` as the shard key, and the table sharding process calculates `DAY_OF_MONTH` through the `DD(actionDate)` function and then partitions the table into table shards, with one month counted as 31 days.

For example, if the value in the `actionDate` column is 2017-02-27, the value obtained by calculating the `DD(actionDate)` function is 27. In this case, the record is stored in table shard 27, because $27 \% 31 = 27$. This table shard is located in a database shard and is named `user_log_27`.

```
CREATE TABLE user_log3(
  userId int,
  name varchar(30),
  operation varchar(30),
  actionDate DATE
) dbpartition by hash(userId) tpartition by DD(actionDate) tpartitions 31;
```

According to the node topology of the logical table, you can see that 31 table shards are created in each database shard, because one month is counted as 31 days in the function. The responses are very long, and therefore are omitted by using an ellipsis (...).

```
mysql> show topology from user_log3;

+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
248 rows in set (0.01 sec)

```

According to the sharding rule of the logical table, you can see that the database sharding process calculates the hash by using `userId` as the shard key, and the table sharding process calculates the DD function by using `actionDate` as the shard key.

```
mysql> show rule from user_log3;
+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+
| ID | TABLE_NAME | BROADCAST | DB_PARTITION_KEY | DB_PARTITION_POLICY | DB_PARTITION_COUNT | TB_PARTITION_KEY | TB_PARTITION_POLICY | TB_PARTITION_COUNT |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 0 | user_log3 | 0 | userId | hash | 8 | actionDate | dd | 31 |
+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

- Create a table that is partitioned into table shards in database shards. The database sharding process calculates the hash by using `userId` as the shard key, and the table sharding process calculates `DAY_OF_YEAR % 365` through the `MMDD(actionDate) tpartitions 365` function and then partitions the table into 365 physical tables, with one year counted as 365 days.

For example, if the value in the `actionDate` column is 2017-02-27, the value obtained by calculating the `MMDD(actionDate)` function is 58. In this case, the record is stored in table shard 58. This table shard is located in a database shard and is named `user_log_58`.

```
CREATE TABLE user_log4(
  userId int,
  name varchar(30),
  operation varchar(30),
  actionDate DATE
) dbpartition by hash(userId) tpartition by MMDD(actionDate) tpartitions 365;
```

According to the node topology of the logical table, you can see that 365 table shards are created in each database shard, because one year is counted as 365 days in the function. The responses are very long, and therefore are omitted by using an ellipsis (...).

```
mysql> show topology from user_log4;
+-----+-----+-----+-----+-----+-----+
| ID | GROUP_NAME | TABLE_NAME |

2920 rows in set (0.07 sec)
```

According to the sharding rule of the logical table, you can see that the database sharding process calculates the hash by using `userId` as the shard key, and the table sharding process calculates the MMDD function by using `actionDate` as the shard key.

```
mysql> show rule from user_log4;
+-----+-----+-----+-----+-----+-----+-----+-----+
| ID | TABLE_NAME | BROADCAST | DB_PARTITION_KEY | DB_PARTITION_POLICY | DB_PARTITION_COUNT | TB_PARTITION_KEY | TB_PARTITION_POLICY | TB_PARTITION_COUNT |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 0 | user_log4 | 0 | userId | hash | 8 | actionDate | mmdd | 365 |
+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.02 sec)
```

- Create a table that is partitioned into table shards in database shards. The database sharding process calculates the hash by using `userId` as the shard key, and the table sharding process calculates `DAY_OF_YEAR % 10` through the `MMDD(actionDate)` `tbpartitions 10` function and then partitions the table into 10 physical tables, with one year counted as 365 days.

```
CREATE TABLE user_log5(
  userId int,
  name varchar(30),
  operation varchar(30),
  actionDate DATE
) dbpartition by hash(userId) tbpartition by MMDD(actionDate) tbpartitions 10;
```

According to the node topology of the logical table, you can see that 10 table shards are created in each database shard, because one year is counted as 365 days in the function and the table data is routed to 10 physical tables. The responses are very long, and therefore are omitted by using an ellipsis (...).

```
mysql> show topology from user_log5;

| ID | TABLE_NAME | BROADCAST | DB_PARTITION_KEY | DB_PARTITION_POLICY | DB_PARTITION_COUNT | TB_PARTITION_KEY | TB_PARTITION_POLICY | TB_PARTITION_COUNT |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 0 | user_log5 | 0 | userId | hash | 8 | actionDate | mmdd | 10 |
+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

13.11.2.5. Use the primary key as the shard key

When no shard key is specified for the sharding algorithm, the system uses the primary key as the shard key by default. The following illustrates how to use the primary key as the database shard key and the table shard key.

Use the primary key as the database shard key

```
CREATE TABLE prmkey_tbl(
id int,
name varchar(30),
primary key(id)
) dbpartition by hash();
```

Use the primary key as the database shard key and the table shard key

```
CREATE TABLE prmkey_multi_tbl(
id int,
name varchar(30),
primary key(id)
) dbpartition by hash() tpartition by hash() tpartitions 3;
```

13.11.2.6. Create a broadcast table

The BROADCAST clause is used to specify a broadcast table to be created. A broadcast table is replicated to each database shard and data consistency is ensured between the database shards by using a synchronization mechanism with a delay of several seconds. This feature allows you to route a JOIN operation from a Cloud Native Distributed Database PolarDB-X (PolarDB-X) instance to an underlying ApsaraDB RDS for MySQL instance to prevent the JOIN operation from being performed in multiple databases. [Overview](#) describes how to optimize SQL statements by using broadcast tables.

The following is an example statement for creating a broadcast table:

```
CREATE TABLE brd_tbl(
  id int,
  name varchar(30),
  primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8 BROADCAST;
```

13.11.2.7. Other attributes of the MySQL CREATE TABLE statement

When creating table shards in database shards, you can also specify other attributes of the table shards in the MySQL CREATE TABLE statement. For example, you can specify other attributes as follows:

```
CREATE TABLE multi_db_multi_tbl(
  id int,
  name varchar(30),
  primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8 dbpartition by hash(id) tpartition by hash(id) tpartitions 3;
```

13.11.3. ALTER TABLE statement

The syntax of the ALTER TABLE statement used to modify a table is as follows:

```
ALTER [ONLINE|OFFLINE] [IGNORE] TABLE tbl_name
  [alter_specification [, alter_specification] ...]
  [partition_options]
```

In a PolarDB-X instance, you can use this data definition language (DDL) statement to perform routine DDL operations, such as adding a column, adding an index, and modifying a data definition. For more information about the syntax, see [MySQL ALTER TABLE Statement](#).

 **Note** If you need to modify a table shard, you are not allowed to modify the shard key.

- Add a column:

```
ALTER TABLE user_log
  ADD COLUMN idcard varchar(30);
```

- Add an index:

```
ALTER TABLE user_log
  ADD INDEX idcard_idx (idcard);
```

- Delete an index:

```
ALTER TABLE user_log
  DROP INDEX idcard_idx;
```

- Modify a field:

```
ALTER TABLE user_log
  MODIFY COLUMN idcard varchar(40);
```

13.11.4. DROP TABLE statement

The syntax of the DROP TABLE statement used to delete a table is as follows:

```
DROP [TEMPORARY] TABLE [IF EXISTS]
tbl_name [, tbl_name] ...
[RESTRICT | CASCADE]
```

The DROP TABLE statement in a PolarDB-X instance is the same as the DROP TABLE statement in a MySQL database. After the statement is executed, the system automatically deletes the corresponding physical table. For more information about the syntax, see [MySQL DROP TABLE Statement](#).

For example, you can run the following statement to delete the user_log table:

```
DROP TABLE user_log;
```

13.11.5. FAQ about DDL statements

What can I do if an error occurs during table creation?

Data definition language (DDL) statements in a PolarDB-X instance are processed in a distributed manner. If an error occurs, the structures of all table shards are inconsistent from each other. Therefore, you need to perform manual cleanup.

Perform the following steps:

1. Check the basic error descriptions provided by the PolarDB-X instance, such as syntax errors. If the error message is too long, the system will prompt you to call the SHOW WARNINGS command to view the failure cause of each database shard.
2. Run the SHOW TOPOLOGY command to view the topology of physical tables.

```
SHOW TOPOLOGY FROM multi_db_multi_tbl;
+-----+-----+-----+
| ID | GROUP_NAME | TABLE_NAME |
+-----+-----+-----+
| 0 | corona_qatest_0 | multi_db_multi_tbl_00 |
| 1 | corona_qatest_0 | multi_db_multi_tbl_01 |
| 2 | corona_qatest_0 | multi_db_multi_tbl_02 |
| 3 | corona_qatest_1 | multi_db_multi_tbl_03 |
| 4 | corona_qatest_1 | multi_db_multi_tbl_04 |
| 5 | corona_qatest_1 | multi_db_multi_tbl_05 |
| 6 | corona_qatest_2 | multi_db_multi_tbl_06 |
| 7 | corona_qatest_2 | multi_db_multi_tbl_07 |
| 8 | corona_qatest_2 | multi_db_multi_tbl_08 |
| 9 | corona_qatest_3 | multi_db_multi_tbl_09 |
| 10 | corona_qatest_3 | multi_db_multi_tbl_10 |
| 11 | corona_qatest_3 | multi_db_multi_tbl_11 |
+-----+-----+-----+
12 rows in set (0.21 sec)
```

3. Run the `CHECK TABLE tablename` command to check whether the logical table has been created. For example, the following response indicates that a physical table corresponding to the logical table

multi_db_multi_tbl failed to be created.

```
mysql> check table multi_db_multi_tbl;
+-----+-----+-----+-----+
| TABLE                | OP | MSG_TYPE | MSG_TEXT                |
+-----+-----+-----+-----+
| andor_mysql_qatest. multi_db_multi_tbl | check | Error   | Table 'corona_qatest_0. multi_db_multi_tbl_02' doesn't exist |
+-----+-----+-----+-----+
1 row in set (0.16 sec)
```

- Continue to create or delete the table in idempotent mode to create or delete the remaining physical tables.

```
CREATE TABLE IF NOT EXISTS table1
(id int, name varchar(30), primary key(id))
dbpartition by hash(id);
DROP TABLE IF EXISTS table1;
```

What can I do if I failed to create an index or add a column?

The method for handling the failure in creating an index or adding a column is similar to that for the failure in creating a table. For more information, see [Handle DDL exceptions](#).

13.11.6. DDL functions for sharding

13.11.6.1. Overview

PolarDB-X is a database service that supports both database sharding and table sharding.

Support for PolarDB-X database sharding and table sharding

The following table lists the support for database sharding and table sharding in PolarDB-X data definition language (DDL) sharding functions.

Sharding function	Description	Support for database sharding	Support for table sharding
HASH	Performs a simple modulus operation.	Yes	Yes
UNI_HASH	Performs a simple modulus operation.	Yes	Yes
RIGHT_SHIFT	Shifts the value to the right.	Yes	Yes
RANGE_HASH	Performs double hashing.	Yes	Yes
MM	Performs hashing by month.	No	Yes
DD	Performs hashing by date.	No	Yes
WEEK	Performs hashing by week.	No	Yes

Sharding function	Description	Support for database sharding	Support for table sharding
MMDD	Performs hashing by month and date.	No	Yes
YYYYMM	Performs hashing by year and month.	Yes	Yes
YYYYWEEK	Performs hashing by year and week.	Yes	Yes
YYYYDD	Performs hashing by year and date.	Yes	Yes
YYYYMM_OPT	Performs optimized hashing by year and month.	Yes	Yes
YYYYWEEK_OPT	Performs optimized hashing by year and week.	Yes	Yes
YYYYDD_OPT	Performs optimized hashing by year and date.	Yes	Yes

-  **Note** When using database sharding and table sharding in PolarDB-X, note the following:
- In a PolarDB-X instance, the sharding method of a logical table is defined jointly by a sharding function and a shard key. The sharding function contains the number of shards to be created and the routing algorithm. The shard key also specifies the MySQL data type of the shard key.
 - When the database sharding function is the same as the table sharding function and the database shard key is the same as the table shard key in a PolarDB-X instance, the same sharding method is used for database sharding and table sharding. This allows the PolarDB-X instance to uniquely locate one physical table in a physical database based on the value of the shard key.
 - If the database sharding method and the table sharding method of a logical table are different and an SQL query does not contain both database shard key and table shard key, the PolarDB-X instance scans all database shards or all table shards when processing the SQL query.

Support for data types of PolarDB-X DDL sharding functions

Different PolarDB-X DDL sharding functions support different data types. The following table lists the support for various data types in PolarDB-X sharding functions (✓ indicates supported and × indicates not supported).

Support for data types in PolarDB-X DDL sharding functions

Sharding function	BIGINT	INT	MEDIUMINT	SMALLINT	TINYINT	VARCHAR	CHAR	DATE	DATETIME	TIMESTAMP	Other types
HASH	√	√	√	√	√	√	√	x	x	x	x
UNI_HASH	√	√	√	√	√	√	√	x	x	x	x
RANGE_HASH	√	√	√	√	√	√	√	x	x	x	x
RIGHT_SHIFT	√	√	√	√	√	x	x	x	x	x	x
MM	x	x	x	x	x	x	x	√	√	√	x
DD	x	x	x	x	x	x	x	√	√	√	x
WEEK	x	x	x	x	x	x	x	√	√	√	x
MMDD	x	x	x	x	x	x	x	√	√	√	x
YYYYMM	x	x	x	x	x	x	x	√	√	√	x
YYYYWEEK	x	x	x	x	x	x	x	√	√	√	x
YYYYDD	x	x	x	x	x	x	x	√	√	√	x
YYYYMM_OPT	x	x	x	x	x	x	x	√	√	√	x
YYYYWEEK_OPT	x	x	x	x	x	x	x	√	√	√	x
YYYYDD_OPT	x	x	x	x	x	x	x	√	√	√	x

Syntax description for PolarDB-X DDL sharding functions

PolarDB-X is compatible with the CREATE TABLE statement in MySQL, and additionally provides the `drds_partition_options` keyword to support database sharding and table sharding:

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    (create_definition,...)
    [table_options]
    [drds_partition_options]
    [partition_options]
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    [(create_definition,...)]
    [table_options]
    [drds_partition_options]
    [partition_options]
    select_statement
drds_partition_options:
    DBPARTITION BY
        { {HASH|YYYYMM|YYYYWEEK|YYYYDD|YYYYMM_OPT|YYYYWEEK_OPT|YYYYDD_OPT}{(column)}}
    [TBPARTITION BY
        { {HASH|MM|DD|WEEK|MMDD|YYYYMM|YYYYWEEK|YYYYDD|YYYYMM_OPT|YYYYWEEK_OPT|YYYYDD_OPT}(column)
    }
    [TBPARTITIONS num]
]
```

13.11.6.2. HASH

Requirements

- The shard key must be an integer or a string.
- This sharding function has no requirements on the version of a PolarDB-X instance. It supports all PolarDB-X instances by default.

Routing method

When the HASH function is run by using different shard keys for database sharding and table sharding, perform the remainder operation on the value of the database shard key based on the number of database shards. If the value of the shard key is a string, the string is converted to a hash value before route calculation. For example, `HASH('8')` is equivalent to $8 \% D$, where `D` indicates the number of database shards.

When the HASH function is run by using the same shard key for both database sharding and table sharding, perform the remainder operation on the value of the shard key based on the total number of table shards. For example, assume that two database shards are created, each database shard contains four table shards, table shards 0 to 3 are stored in database shard 0, and table shards 4 to 7 are stored in database shard 1. If a key value is 15, the key value 15 is distributed to table shard 7 in database shard 1, because $15 \% (2 \times 4) = 7$.

Scenarios

- HASH is applicable when database sharding is implemented by user ID or order ID.
- HASH is also applicable when the shard key is a string.

Examples

If you need to create a non-partition table in database shards by using the HASH function based on the ID column, you can use the following CREATE TABLE statement:

```
create table test_hash_tb (  
  id int,  
  name varchar(30) DEFAULT NULL,  
  create_time datetime DEFAULT NULL,  
  primary key(id)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8 dbpartition by HASH(ID);
```

Precautions

The HASH is a simple modulus operation. The output distribution of the HASH function can be even only when the values in the partition column are evenly distributed.

13.11.6.3. UNI_HASH

Requirements

- The shard key must be an integer or a string.
- The version of the PolarDB-X instance must be 5.1.28-1508068 or later. For more information about the PolarDB-X release notes, see [View the instance version](#).

Routing method

When the UNI_HASH function is used for database sharding, perform a remainder operation on the value of the database shard key based on the number of database shards. If the value of the shard key is a string, the string is converted to a hash value before route calculation. For example, `HASH('8')` is equivalent to $8 \% D$, where `D` indicates the number of database shards.

When the UNI_HASH function is run by using the same shard key for both database sharding and table sharding, perform the remainder operation on the value of the database shard key based on the number of database shards first (this step is different from that in the HASH function). Then, the data is evenly distributed to the table shards in the database shard.

Scenarios

- UNI_HASH is applicable when database sharding is implemented by user ID or order ID.
- UNI_HASH is also applicable when the shard key is an integer or a string.

- UNI_HASH can be used when the following conditions are met: Two logical tables need to be partitioned into different numbers of table shards in database shards based on the same shard key. In addition, the two tables are frequently joined by using a JOIN statement based on the shard key.

Comparison with HASH

When you use the UNI_HASH function to create a non-partition table in database shards, the routing method is the same as that used in the HASH function. Specifically, the route is calculated by performing the remainder operation on the key value of the database shard key based on the number of database shards.

When the UNI_HASH function is run by using the same shard key for both database sharding and table sharding, as the number of table shards changes, the database shard route calculated based on the same key value may also change.

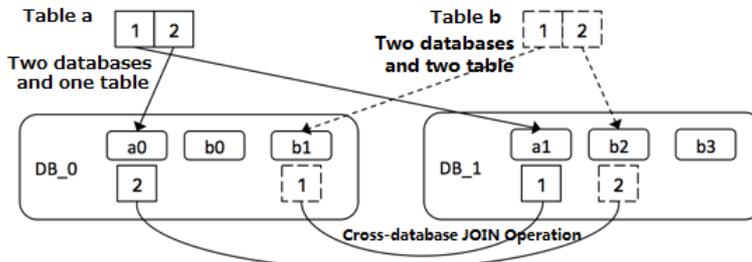

When the UNI_HASH function is run by using the same shard key for both database sharding and table sharding, the database shard route calculated based on the same key value is always the same regardless of the number of table shards.

If two logical tables need to be partitioned into different table shards in database shards based on the same shard key, when the two tables are joined by using the HASH function based on the shard key, multi-database join may occur. However, when the two tables are joined by using the UNI_HASH function based on the shard key, multi-database join does not occur.

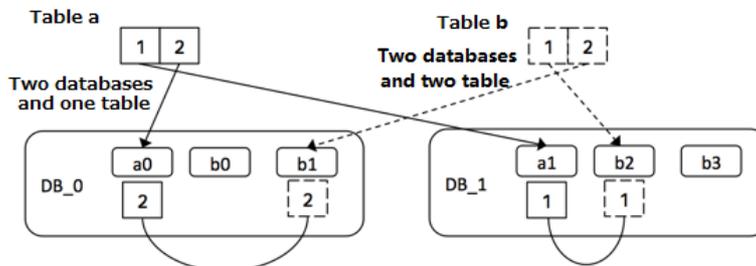

Assume that you have two database shards and two logical tables, and each database shard in logical table a stores one table shard and each database shard in logical table b stores two table shards. The following figures separately show the results of a JOIN query for logical tables a and b after the HASH function is used for sharding and the results of a JOIN query for logical tables a and b after the HASH function is used for sharding.

Comparison between HASH and UNI_HASH

HASH sharding: Two logical tables have different numbers of physical table shards. The same shard key is used in different database shards. Cross-database JOIN queries may be performed.

UNI_HASH sharding: Two logical tables have different numbers of physical table shards. The same shard key is used in the same database shard. No cross-database JOIN queries are performed.

Examples

If you need to create four table shards in each database shard by using the UNI_HASH function based on the ID column, you can run the following CREATE TABLE statement:

```
create table test_hash_tb (  
  id int,  
  name varchar(30) DEFAULT NULL,  
  create_time datetime DEFAULT NULL,  
  primary key(id)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8  
dbpartition by UNI_HASH(ID)  
tbpartmention by UNI_HASH(ID) tpartitions 4;
```

Precautions

The UNI_HASH is a simple modulus operation. The output distribution of the UNI_HASH function can be even only when the values in the shard column are evenly distributed.

13.11.6.4. RIGHT_SHIFT

Requirements

- The shard key must be an integer.
- The version of the PolarDB-X instance must be 5.1.28-1320920 or later. For more information, see [View the instance version](#).

Routing method

Shift the value of the database shard key to the right by a specified number of binary digits, and then perform the remainder operation on the obtained integer based on the number of database shards or table shards. In particular, you can specify the number of shifted digits by running a data definition language (DDL) statement.

Scenarios

RIGHT_SHIFT is applicable to improve the evenness of the hash results when the lower-digit parts of most shard key values are very similar to each other but the higher-digit parts vary greatly.

Assume that four shard key values are available: 12340000, 12350000, 12460000, and 12330000. The four lower digits of the four values are all 0000. Directly hashing the values of the shard keys outputs poor results. However, if you run the RIGHT_SHIFT(shardKey, 4) statement to shift the values of the shard keys to the right by four digits, to obtain 1234, 1235, 1246, and 1233, the hashing results are improved.

Examples

If you need to use the ID column as a shard key and shift the values of the ID column to the right by four binary digits to obtain hash values, you can run the following CREATE TABLE statement:

```
create table test_hash_tb (  
  id int,  
  name varchar(30) DEFAULT NULL,  
  create_time datetime DEFAULT NULL,  
  primary key(id)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8  
dbpartition by RIGHT_SHIFT(id, 4)  
tbpartmention by RIGHT_SHIFT(id, 4) tpartitions 2;
```

Precautions

The number of shifted digits cannot exceed the number of digits occupied by the integer.

13.11.6.5. RANGE_HASH

Requirements

- The shard key must be a character or a number.
- The version of the PolarDB-X instance must be 5.1.28-1320920 or later. For more information, see [View the instance version](#).

Routing method

Calculate the hash value based on the last N digits of any shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes the route computing. The number N is the third parameter in the function.

For example, during calculation of the RANGE_HASH(COL1, COL2, N) function, COL1 is preferentially selected and then truncated to obtain the last N digits for calculation. If COL1 does not exist, COL2 is selected and truncated for calculation.

Scenarios

RANGE_HASH is applicable to scenarios where a table needs to be partitioned by two shard keys but query is performed only based on the value of one shard key.

Examples

Assume that a PolarDB-X database is partitioned into eight physical databases. Our customer has the following requirements:

The order table of a business needs to be partitioned into database shards by buyer ID and order ID. The query is executed based on either the buyer ID or order ID as the condition.

In this case, you can run the following DDL statement to create the order table:

```
create table test_order_tb (
  id int,
  buyer_id varchar(30) DEFAULT NULL,
  order_id varchar(30) DEFAULT NULL,
  create_time datetime DEFAULT NULL,
  primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
dbpartition by RANGE_HASH(buyer_id,order_id, 10)
tbpartment by RANGE_HASH (buyer_id,order_id, 10) tbpartitions 3;
```

Precautions

- Neither of the two shard keys can be modified.
- Data insertion fails if the two shard keys point to different database shards or table shards.

13.11.6.6. MM

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- MM is only applicable to table sharding.
- The version of the PolarDB-X instance must be 5.1.28-1320920 or later. For more information, see [View the instance version](#).

Routing method

Perform the remainder operation based on the month that corresponds to the time value of the database shard key to obtain the table shard subscript.

Scenarios

MM can be used to partition tables by month. The table shard name indicates a specific month.

Examples

Assume that we need to perform database sharding by ID, perform table sharding for the create_time column by month, and map every month to a physical table. The data definition language (DDL) statement is as follows:

```
create table test_mm_tb (  
  id int,  
  name varchar(30) DEFAULT NULL,  
  create_time datetime DEFAULT NULL,  
  primary key(id)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8  
dbpartition by HASH(id)  
tbpartmention by MM(create_time) tpartitions 12;
```

Precautions

When you partition tables with MM, ensure that each database shard has no more than 12 table shards because a year has 12 months.

13.11.6.7. DD

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- DD is only applicable to table sharding.
- The version of the PolarDB-X instance must be 5.1.28-1320920 or later. For more information, see [View the instance version](#).

Routing method

Perform the remainder operation based on the day of the month that corresponds to the time value of the database shard key to obtain the table shard subscript.

Scenarios

DD can be used to partition tables based on a specified number of days in a month, that is, a date. The subscript of the table shard name indicates the day in a month. A month has 31 days at most.

Examples

Assume that we need to perform database sharding by ID, perform table sharding for the create_time column by day, and map every day to a physical table. The data definition language (DDL) statement is as follows:

```
create table test_dd_tb (  
  id int,  
  name varchar(30) DEFAULT NULL,  
  create_time datetime DEFAULT NULL,  
  primary key(id)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8  
dbpartition by HASH(id)  
tbpartmention by DD(create_time) tpartitions 31;
```

Precautions

When you partition tables with DD, ensure that each database shard has no more than 31 table shards because a month has 31 days at most.

13.11.6.8. WEEK

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- WEEK is only applicable to table sharding.
- The version of the PolarDB-X instance must be 5.1.28-1320920 or later. For more information, see [View the instance version](#).

Routing method

Perform the remainder operation based on the day of a week that corresponds to the time value of the database shard key to obtain the table shard subscript.

Scenarios

WEEK can be used to partition tables based on days in a week. The subscript of the table shard name corresponds to each day of a week, from Monday to Sunday.

Examples

Assume that we need to perform database sharding by ID, perform table sharding for the create_time column by week, and map every day of a week (from Monday to Sunday) to a physical table. The data definition language (DDL) statement is as follows:

```
create table test_week_tb (  
  id int,  
  name varchar(30) DEFAULT NULL,  
  create_time datetime DEFAULT NULL,  
  primary key(id)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8  
dbpartition by HASH(name)  
tbpartmention by WEEK(create_time) tpartitions 7;
```

Precautions

When you partition tables with WEEK, ensure that each database shard has no more than seven table shards because a week has seven days.

13.11.6.9. MMDD

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- MMDD is only applicable to table sharding.
- The version of the PolarDB-X instance must be 5.1.28-1320920 or later. For more information, see [View the instance version](#).

Routing method

Perform the remainder operation based on the number of days in a year that corresponds to the time value of the database shard key to obtain the table sharding subscript.

Scenarios

MMDD can be used to partition tables based on the number of days in a year that corresponds to a date in that year. The subscript of the table shard name indicates the day in that year, with a maximum of 366 days in a year.

Examples

Assume that we need to perform database sharding by ID, create tables for the create_time column by date (month-day), and map every day of a year to a physical table. The data definition language (DDL) statement is as follows.

```
create table test_mmdd_tb (  
  id int,  
  name varchar(30) DEFAULT NULL,  
  create_time datetime DEFAULT NULL,  
  primary key(id)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8  
dbpartition by HASH(name)  
tbpartment by MMDD(create_time) tpartitions 365;
```

Precautions

When you partition tables with MMDD, ensure that each database shard has no more than 366 table shards because a year has 366 days at most.

13.11.6.10. YYYYMM

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- The version of the PolarDB-X instance must be 5.1.28-1320920 or later. For more information, see [View the instance version](#).

Routing method

Calculate the hash value based on the year and months of the year in the time value of the database shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes route computing.

For example, YYYYMM('2012-12-31 12:12:12') is equivalent to $(2012 \times 12 + 12) \% D$, where D indicates the number of database shards.

Scenarios

YYYYMM can be used to partition databases by year and month. We recommend that you use YYYYMM with tbpartition YYYYMM(ShardKey).

Assume that a PolarDB-X database is partitioned into eight physical databases. Our customer has the following requirements:

- Perform database sharding for a service by year and month.
- Distribute data from every month within two years to a separate table shard.
- Distribute a query with the database and table shard keys to a physical table shard of a physical database shard.

The preceding requirements can be met by using YYYYMM. For the requirement of distributing data from every month within two years to a table shard (that is, one table shard stores the data of one month), create at least 24 physical table shards because a year has 12 months. Create three physical table shards for each database shard because the PolarDB-X instance contains eight database shards. The data definition language (DDL) statement is as follows.

```
create table test_yyyymm_tb (
  id int,
  name varchar(30) DEFAULT NULL,
  create_time datetime DEFAULT NULL,
  primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
dbpartition by YYYYMM(create_time)
tbpartmention by YYYYMM(create_time) tbpartitions 3;
```

Precautions

- YYYYMM does not support distributing data from every month in every year to a separate table shard. Instead, the number of table shards must be fixed.
- After a cycle over months (for example, a cycle exists between 2012-03 and 2013-03), data from the same month may be routed to the same database or table shard, depending on the actual number of table shards.

13.11.6.11. YYYYWEEK

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- The version of the PolarDB-X instance must be 5.1.28-1320920 or later. For more information, see [View the instance version](#).

Routing method

Calculate the hash value based on the year and weeks of the year in the time value of the database shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes route computing.

For example, YYYYWEEK('2012-12-31 12:12:12') is equivalent to $(2013 \times 52 + 1) \% D$, with the date 2012-12-31 falling on the first week of 2013, where D indicates the number of database shards.

Scenarios

YYYYWEEK can be used to partition databases by year and the number of weeks in a year. We recommend that you use YYYYWEEK with tbpartition YYYYWEEK(ShardKey).

Assume that a PolarDB-X database is partitioned into eight physical databases. Our customer has the following requirements:

- Perform database sharding for a service by year and by week.
- Distribute data from every week within two years to a separate table shard.
- Distribute a query with the database and table shard keys to a physical table shard of a physical database shard.

The preceding requirements can be met by using YYYYWEEK. For the requirement of distributing data from every week within two years to a table shard (that is, one table shard stores the data of one week), create at least 106 physical table shards because a year has roughly 53 weeks (rounded). Create 14 physical table shards for each database shard because the PolarDB-X instance contains eight database shards ($14 \times 8 = 112 > 106$). We recommend that the number of table shards be an integer multiple of the number of database shards. The data definition language (DDL) statement is as follows:

```
create table test_yyyymm_tb (
  id int,
  name varchar(30) DEFAULT NULL,
  create_time datetime DEFAULT NULL,
  primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
dbpartition by YYYYWEEK(create_time)
tbpartment by YYYYWEEK(create_time) tbpartitions 14;
```

Precautions

- YYYYWEEK does not support distributing data from every week in every year to a separate table shard. Instead, the number of table shards must be fixed.
- After a cycle over weeks (for example, a cycle exists between the first week of 2012 and the first week of 2013), data from the same week after a cycle may be routed to the same database shard or table shard, depending on the actual number of table shards.

13.11.6.12. YYYYDD

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- The version of the PolarDB-X instance must be 5.1.28-1320920 or later. For more information, see [View the instance version](#).

Routing method

Calculate the hash value based on the year and days of the year in the time value of the database shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes route computing.

For example, YYYYDD('2012-12-31 12:12:12') is equivalent to $(2012 \times 366 + 365) \% D$, with 2012-12-31 as the 365th day of 2012, where D indicates the number of database shards.

Scenarios

Database sharding is performed by year and the number of days in a year. We recommend that you use YYYYDD with tbpartition YYYYDD(ShardKey).

Assume that a PolarDB-X database is partitioned into eight physical databases. Our customer has the following requirements:

- Perform database sharding for a service by year and day.
- Distribute data from every week within two years to a separate table shard.
- Distribute a query with the database and table shard keys to a physical table shard of a physical database shard.

The preceding requirements can be met by using YYYYDD. For the requirement of distributing data from every day within two years to a table shard (that is, one table shard stores the data of one day), create at least 732 physical table shards because a year has up to 366 days. Create 92 physical table shards for each database shard because the PolarDB-X instance contains eight database shards ($732/8 = 91.5$, rounded to 92). We recommend that the number of table shards be an integer multiple of the number of database shards. The data definition language (DDL) statement is as follows:

```
create table test_yyyydd_tb (  
    id int,  
    name varchar(30) DEFAULT NULL,  
    create_time datetime DEFAULT NULL,  
    primary key(id)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8  
dbpartition by YYYYDD(create_time)  
tbpartment by YYYYDD(create_time) tbpartitions 92;
```

Precautions

- YYYYDD does not support distributing data from every day in every year to a separate table shard. Instead, the number of table shards must be fixed.
- After a cycle of a specific date (for example, a cycle exists between 2012-03-01 and 2013-03-01), data from the same date may be routed to the same database shard or table shard, depending on the actual number of table shards.

13.11.6.13. YYYYMM_OPT

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- The year and month of user data increase naturally over time, rather than randomly.
- The version of the PolarDB-X instance must be 5.1.28-1320920 or later. For more information, see [View the instance version](#).

Optimizations

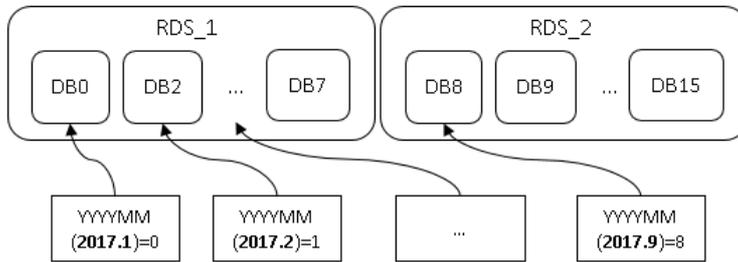

Compared with YYYYMM, YYYYMM_OPT maintains the even distribution of data among ApsaraDB RDS for MySQL instances as the timeline increases.

For example, assume that two ApsaraDB RDS for MySQL instances are attached to a PolarDB-X instance, with 16 database shards. DB0 to DB7 shards are located on one ApsaraDB RDS for MySQL instance, and DB8 to DB15 shards are located on the other ApsaraDB RDS for MySQL instance.

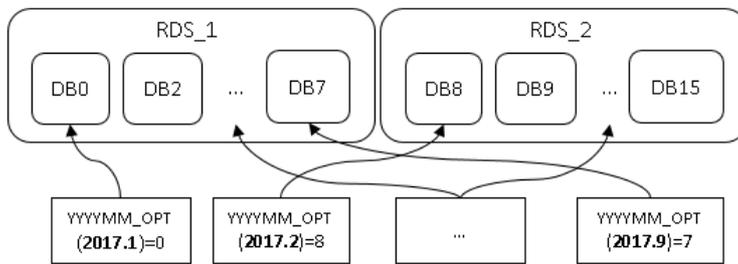

The following figure shows the mappings when YYYYMM and YYYYMM_OPT are used for database sharding, respectively.

Comparison between YYYYMM and YYYYMM_OPT

As the time goes on linearly, YYYYMM fills data in ApsaraDB for RDS instances in sequence (data is first distributed to the database shards of RDS_1, then to the database shards of RDS_2, and then to the database shards of RDS_1 again).

YYYYMM_OPT evenly distributes data between ApsaraDB for RDS instances as the time goes on (data is alternately distributed between RDS_1 and RDS_2, so that the data size of the two RDS instances is balanced).

- YYYYMM_OPT distributes data evenly to each ApsaraDB RDS for MySQL instance, helping to maximize the performance of each ApsaraDB RDS for MySQL instance.
- How to choose between YYYYMM and YYYYMM_OPT:
 - YYYYMM_OPT can be used to distribute data evenly to each ApsaraDB RDS for MySQL instance if the time of service data generation increases sequentially and the data volume does not differ much between the time points.
 - YYYYMM is applicable if the time of data generation increases randomly rather than sequentially.

Routing method

- Calculate the hash value based on the year and months of the year in the time value of the database shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes route computing.
- The hash calculation based on the database and table shard key considers the data distribution among the ApsaraDB RDS for MySQL instances that connect to the PolarDB-X instances.

Scenarios

- Databases and tables need to be partitioned by year and month, respectively.
- Data must be evenly distributed to each ApsaraDB RDS for MySQL instance that connects to the PolarDB-X instance.
- The time of the shard key increases sequentially rather than randomly, and the data volume is relatively average from month to month. For example, the number of monthly journal logs increases every month, and the log data is not concentrated on the same ApsaraDB RDS for MySQL instance.

Precautions

- YYYYMM_OPT does not support distributing data from every month in every year to a separate table shard. Instead, the number of table shards must be fixed.

- After a cycle over months (for example, a cycle exists between 2012-03 and 2013-03), data from the same month may be routed to the same database or table shard, depending on the actual number of table shards.

13.11.6.14. YYYYWEEK_OPT

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- The version of the PolarDB-X instance must be 5.1.28-1320920 or later. For more information, see [View the instance version](#).

Optimizations

- Compared with YYYYWEEK, YYYYWEEK_OPT maintains the even distribution of data among ApsaraDB RDS for MySQL instances as the timeline increases. The effect is similar to [YYYYMM_OPT](#).
- YYYYWEEK_OPT distributes data evenly to each ApsaraDB RDS for MySQL instance, helping to maximize the performance of each ApsaraDB RDS for MySQL instance.
- How to choose between YYYYWEEK and YYYYWEEK_OPT:
 - YYYYWEEK_OPT can be used to distribute data evenly to each ApsaraDB RDS for MySQL instance if the time of service data increases sequentially and the data volume does not differ much between time points.
 - YYYYWEEK is applicable if the time of data generation increases randomly rather than sequentially.

Routing method

- Calculate the hash value based on the year and weeks of the year in the time value of the database shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes route computing.
- The hash calculation based on the database and table shard key considers the data distribution among the ApsaraDB RDS for MySQL instances that connect to the PolarDB-X instances.

Scenarios

- Databases and tables are partitioned by year and week, respectively.
- Data must be evenly distributed to each ApsaraDB RDS for MySQL instance that connects to the PolarDB-X instance.
- The time of the shard key increases sequentially rather than randomly, and the data volume is relatively average from week to week. For example, the number of weekly journal logs increases every week, and the log data is not concentrated on the same ApsaraDB RDS for MySQL instance.

Precautions

- YYYYWEEK_OPT does not support distributing data from every week in every year to a separate table shard. Instead, the number of table shards must be fixed.
- After a cycle over weeks (for example, a cycle exists between the first week of 2012 and the first week of 2013), data from the same week after a cycle may be routed to the same database shard or table shard, depending on the actual number of table shards.

13.11.6.15. YYYYDD_OPT

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- The version of the PolarDB-X instance must be 5.1.28-1320920 or later. For more information, see [View the instance version](#).

Optimizations

- Compared with YYYYDD, YYYYDD_OPT maintains the even distribution of data among ApsaraDB RDS for MySQL instances as the timeline increases. The effect is similar to [YYYYMM_OPT](#).

- YYYYYD_OPT distributes data evenly to each ApsaraDB RDS for MySQL instance, helping to maximize the performance of each ApsaraDB RDS for MySQL instance.
- How to choose between YYYYYD and YYYYYD_OPT:
 - YYYYYD_OPT can be used to distribute data evenly to each ApsaraDB RDS for MySQL instance if the time of service data generation increases sequentially and the data volume does not differ much between time points.
 - YYYYYD is applicable if the time of data generation increases randomly rather than sequentially.

Routing method

- Calculate the hash value based on the year and days of the year in the time value of the database shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes route computing.
- The hash calculation based on the database and table shard key considers the data distribution among the ApsaraDB RDS for MySQL instances that connect to the PolarDB-X instances.

Scenarios

- Databases and tables need to be partitioned by year and by day, respectively.
- Data must be evenly distributed to each ApsaraDB RDS for MySQL instance that connects to the PolarDB-X instance.
- The time of the shard key increases sequentially rather than randomly, and the data volume is relatively average from day to day. For example, the number of daily journal logs increases every day, and the log data is not concentrated on the same ApsaraDB RDS for MySQL instance.

Precautions

- YYYYYD_OPT does not support distributing data from every day in every year to a separate table shard. Instead, the number of table shards must be fixed.
- After a cycle of a specific date (for example, a cycle exists between 2012-03-01 and 2013-03-01), data from the same date may be routed to the same database shard or table shard, depending on the actual number of table shards.

13.12. Automatic protection of high-risk SQL statements

In PolarDB-X, the data manipulation language (DML) statements are the same as MySQL statements.

We recommend that you include the shard key in the **SELECT** and **UPDATE** statements of PolarDB-X. The **INSERT** statement of PolarDB-X must include the shard key and a non-null key value.

By default, PolarDB-X disables full-table deletion and updating to prevent misoperation.

The following statements are prohibited by default:

- A **DELETE** statement without the **WHERE** or **LIMIT** condition
- An **UPDATE** statement without the **WHERE** or **LIMIT** condition

If you need to perform full-table deletion or update, you can temporarily skip this limit by using the following hint:

```
HINT: /*! TDDL:FORBID_EXECUTE_DML_ALL=false*/
```

Examples

- Full-table deletion is intercepted by default.

```
mysql> delete from tt;
ERR-CODE: [TDDL-4620][ERR_FORBID_EXECUTE_DML_ALL] Forbid execute DELETE ALL or UPDATE ALL sql. More: [http://
/middleware.alibaba-inc.com/faq/faqByFaqCode.html?faqCode=TDDL-4620]
```

The operation is successful if the following HINT is added:

```
mysql> /*! TDDL:FORBID_EXECUTE_DML_ALL=false*/delete from tt;
Query OK, 10 row affected (0.21 sec)
```

- Full-table update is intercepted by default.

```
mysql> update tt set id = 1;
ERR-CODE: [TDDL-4620][ERR_FORBID_EXECUTE_DML_ALL] Forbid execute DELETE ALL or UPDATE ALL sql. More: [http://
/middleware.alibaba-inc.com/faq/faqByFaqCode.html?faqCode=TDDL-4620]
```

The operation is successful if the following HINT is added:

```
mysql> /*! TDDL:FORBID_EXECUTE_DML_ALL=false*/update tt set id = 1;
Query OK, 10 row affected (0.21 sec)
```

- This limit does not apply to DELETE or UPDATE statements that contain the WHERE or LIMIT condition.

```
mysql> delete from tt where id = 1;
Query OK, 1 row affected (0.21 sec)
```

13.13. PolarDB-X sequence

13.13.1. Overview

A PolarDB-X sequence (a 64-digit number of the signed BIGINT type in MySQL) is used to create a globally unique and sequentially incremental numeric sequence, such as values of primary key columns and unique key columns.

PolarDB-X sequences are used in the following two ways:

- Explicit sequences are created and maintained by using sequence-specific data definition language (DDL) syntax and can be used independently. The sequence value can be retrieved by using `select seq.nextval;`, where `seq` indicates the sequence name.
- Implicit sequences are used to automatically fill in primary keys with `AUTO_INCREMENT` defined and are automatically maintained by PolarDB-X.

 **Notice** PolarDB-X creates implicit sequences only after `AUTO_INCREMENT` is defined for partitioned tables and broadcast tables. This is not the case for non-partition tables. The `AUTO_INCREMENT` value of a non-partition table is created by ApsaraDB RDS for MySQL.

Types and features of PolarDB-X sequences

Currently, three types of PolarDB-X sequences are supported.

Type (abbreviation)	Globally unique	Consecutive	Monotonically increasing	Monotonically increasing within the same connection	Non-single point	Date types	Readability
Group sequence (GROUP)	Yes	No	No	Yes	Yes	All integer types	High
Time-based sequence (TIME)	Yes	No	Monotonically increasing at the macro level and non-monotonically increasing at the micro level	Yes	Yes	Only BIGINT	Low
Simple sequence (SIMPLE)	Yes	Yes	Yes	Yes	No	All integer types	High

Concepts:

- **Consecutive:** If the current value is n , the next value must be $n + 1$. If the next value is not $n + 1$, it is nonconsecutive.
- **Monotonically increasing:** If the current value is n , the next value must be a number greater than n .
- **Single point:** The risk of a single point of failure (SPOF) exists.
- **Monotonically increasing at the macro level and non-monotonically increasing at the micro level:** An example of this is 1, 3, 2, 4, 5, 7, 6, 8, ... Such a sequence is monotonically increasing at the macro level and non-monotonically increasing at the micro level.

Group sequence (GROUP, used by default)

Features

A group sequence is a globally unique sequence with natural numeric values, which are not necessarily consecutive or monotonically increasing. If the sequence type is not specified, PolarDB-X uses the group sequence type by default.

- **Advantages:** A group sequence is globally unique and provides excellent performance, preventing single points of failure (SPOFs).
- **Disadvantages:** A group sequence may contain nonconsecutive values, which may not necessarily start from the initial value and do not cycle.

Implementation

The values of a group sequence are created by multiple nodes to ensure high availability. The values in a segment are nonconsecutive if the values are not all used, such as in the case of disconnection.

Time-based sequence (TIME)

Features

A time-based sequence consists of a timestamp, node ID, and serial number. It is globally unique and automatically increments at the macro level. Value updates are database-independent and not persistently stored in databases. Only names and types are stored in databases. This delivers good performance to time-based sequences, which create values like 776668092129345536, 776668098018148352, 776668111578333184, and 776668114812141568.

 **Notice** Sequence values must be of the BIGINT type when used in the auto-increment columns of tables.

- **Advantages:** Time-based sequences are globally unique with good performance.
- **Disadvantages:** The values of a time-based sequence are nonconsecutive. The START WITH, INCREMENT BY, MAXVALUE, and CYCLE or NOCYCLE parameters are invalid for time-based sequences.

Simple sequence (SIMPLE)

Features

Only simple sequences support the START WITH, INCREMENT BY, MAXVALUE, and CYCLE or NOCYCLE parameters.

- **Advantages:** Simple sequences are globally unique and monotonically increasing with consecutive values.
- **Disadvantages:** Simple sequences are prone to SPOFs, poor performance, and bottlenecks. Use them with caution.

Implementation

Each sequence value must be persistently stored.

Scenarios

Group sequences, time-based sequences, and simple sequences are globally unique and can be used in primary key columns and unique index columns.

- We recommend that you use group sequences.
- Use only simple sequences for services that strongly depend on consecutive sequence values. Pay attention to sequence performance.
- We recommend that you use time-based sequences if you have high requirements for sequence performance, the amount of data inserted to tables is small, and large sequence values are acceptable. It is CPU-bound with no requirements on computing lock, database dependence, or persistent storage.

The following example shows how to create a sequence with a start value value of 100000 and a step of 1.

- A simple sequence creates globally unique, consecutive, and monotonically increasing values, such as 100000, 100001, 100002, 100003, 100004, ..., 200000, 200001, 200002, 200003... Simple sequences are persistently stored. Even after services are restarted upon an SPOF, values are still created consecutively from the breakpoint. However, simple sequences have poor performance because each value is persistently stored once it is created.
- A group sequence may create values like 200001, 200002, 200003, 200004, 100001, 100002, 100003...

Notice

- The start value of a group sequence is not necessarily the same as the START WITH value (which is 100000 in this example) but is invariably greater than this value. In this example, the start value is 200001.
- A group sequence is globally unique but may contain nonconsecutive values, for example, when a node is faulty or the connection that only uses partial values is closed. The group sequence in this example contains nonconsecutive values because the values between 200004 and 100001 are missing.

- A time-based sequence may create values like 776668092129345536, 776668098018148352, 776668111578333184, 776668114812141568...

13.13.2. Explicit sequence usage

This topic describes how to use data definition language (DDL) statements to create, modify, delete, and query sequences and how to retrieve the values of explicit sequences.

Create a sequence

Syntax:

```
CREATE [ GROUP | SIMPLE | TIME ] SEQUENCE <name>
[ START WITH <numeric value> ] [ INCREMENT BY <numeric value> ]
[ MAXVALUE <numeric value> ] [ CYCLE | NOCYCLE ]
```

Parameter description:

Parameter	Description	Applicable To
START WITH	The initial sequence value. If it is not set, the default value is 1.	Simple sequence and group sequence
INCREMENT BY	The increment (or interval value or step) of each sequence increase. If it is not set, the default value is 1.	Simple Sequence
MAXVALUE	The maximum sequence value. If it is not specified, the default value is the maximum value of the signed BIGINT type.	Simple Sequence
CYCLE or NOCYCLE	Indicates whether to repeat the sequence value which starts from the value specified by START WITH after the sequence value reaches the maximum value. If it is not specified, the default value is NOCYCLE.	Simple Sequence

Note

- If the sequence type is not specified, the group sequence type is used by default.
- INCREMENT BY, MAXVALUE, and CYCLE or NOCYCLE do not take effect for group sequences.
- START WITH, INCREMENT BY, MAXVALUE, and CYCLE or NOCYCLE do not take effect for time-based sequences.
- Group sequences are nonconsecutive. The START WITH parameter only provides reference for group sequences. The start value of a group sequence is not necessarily the same as the START WITH value but is invariably greater than this value.

Example 1: Create a group sequence.

- Method 1:

```
mysql> CREATE SEQUENCE seq1;
Query OK, 1 row affected (0.27 sec)
```

- Method 2:

```
mysql> CREATE GROUP SEQUENCE seq1;
Query OK, 1 row affected (0.27 sec)
```

Example 2: Create a time-based sequence.

```
mysql> CREATE TIME SEQUENCE seq1;
Query OK, 1 row affected (0.27 sec)
```

Example 3: Create a simple sequence with a start value of 1,000, a step size of 2, and a maximum value of 9999999999, which does not repeat after increasing to the maximum value.

```
mysql> CREATE SIMPLE SEQUENCE seq2 START WITH 1000 INCREMENT BY 2 MAXVALUE 9999999999 NOCYCLE;
Query OK, 1 row affected (0.03 sec)
```

Modify a sequence

PolarDB-X allows you to modify sequences in the following ways:

- For simple sequences, change the values of **START WITH**, **INCREMENT BY**, **MAXVALUE**, and **CYCLE** or **NOCYCLE**.
- For group sequences, change the value of **START WITH**.
- Convert the sequence type to another.

Syntax:

```
ALTER SEQUENCE <name> [ CHANGE TO GROUP | SIMPLE | TIME ]
START WITH <numeric value> [ INCREMENT BY <numeric value> ]
[ MAXVALUE <numeric value> ] [ CYCLE | NOCYCLE ]
```

Parameter description:

Parameter	Description	Applicable To
START WITH	The initial sequence value. If it is not set, the default value is 1.	Simple sequence and group sequence
INCREMENT BY	The increment (or interval value or step) of each sequence increase. If it is not set, the default value is 1.	Simple Sequence
MAXVALUE	The maximum sequence value. If it is not specified, the default value is the maximum value of the signed BIGINT type.	Simple Sequence
CYCLE or NOCYCLE	Indicates whether to repeat the sequence value which starts from the value specified by START WITH after the sequence value reaches the maximum value. If it is not specified, the default value is NOCYCLE .	Simple Sequence

Note

- Group sequences are nonconsecutive. The **START WITH** parameter only provides reference for group sequences. The start value of a group sequence is not necessarily the same as the **START WITH** value but is invariably greater than this value.
- If you set **START WITH** when modifying a simple sequence, the **START WITH** value takes effect immediately. The next automatically generated sequence value starts from the new **START WITH** value. For example, if you change the **START WITH** value to 200 when the sequence value increases to 100, the next automatically generated sequence value starts from 200.
- Before changing the **START WITH** value, you need to analyze the existing sequence values and the speed of creating sequence values to avoid conflicts. Exercise caution when you modify the **START WITH** value.

For example, change the start value of the simple sequence seq2 to 3000, the step size to 5, and the maximum value to 1000000. The sequence value repeats after increasing to the maximum value.

```
mysql> ALTER SEQUENCE seq2 START WITH 3000 INCREMENT BY 5 MAXVALUE 1000000 CYCLE;
Query OK, 1 row affected (0.01 sec)
```

Convert the sequence type to another.

- Use the `CHANGE TO <sequence_type>` clause of `ALTER SEQUENCE`.
- If you specify the `CHANGE TO` clause in `ALTER SEQUENCE`, the `START WITH` parameter must be added to avoid forgetting to specify the start value and get duplicate values. If the `CHANGE TO` clause is not specified, it is not required to add the `START WITH` parameter.

Example: Convert a group sequence to a simple sequence.

```
mysql> ALTER SEQUENCE seq1 CHANGE TO SIMPLE START WITH 1000000;
Query OK, 1 row affected (0.02 sec)
```

Delete a sequence

Syntax:

```
DROP SEQUENCE <name>
```

Example:

```
mysql> DROP SEQUENCE seq3;
Query OK, 1 row affected (0.02 sec)
```

Query sequences

Syntax:

```
SHOW SEQUENCES
```

Example: The TYPE column lists the abbreviations of sequence types.

```
mysql> SHOW SEQUENCES;
+-----+-----+-----+-----+-----+-----+-----+
| NAME   | VALUE      | INCREMENT_BY | START_WITH | MAX_VALUE   | CYCLE | TYPE |
+-----+-----+-----+-----+-----+-----+-----+
| AUTO_SEQ_1 | 91820513   | 1             | 91820200  | 9223372036854775807 | N     | SIMPLE |
| AUTO_SEQ_4 | 91820200   | 2             | 1000      | 9223372036854775807 | Y     | SIMPLE |
| seq_test  | N/A        | N/A           | N/A       | N/A         | N/A   | TIME   |
| AUTO_SEQ_2 | 100000     | N/A           | N/A       | N/A         | N/A   | GROUP  |
| AUTO_SEQ_3 | 200000     | N/A           | N/A       | N/A         | N/A   | GROUP  |
+-----+-----+-----+-----+-----+-----+-----+
5 rows in set (0.01 sec)
```

Retrieve a sequence value

Syntax:

```
< sequence name >.NEXTVAL
```

Example:

```
SELECT sample_seq.nextVal FROM dual;
+-----+
| SAMPLE_SEQ.NEXTVAL |
+-----+
|      101001 |
+-----+
1 row in set (0.04 sec)
```

You can also write `SAMPLE_SEQ.nextVal` as a value to the SQL statement:

```
mysql> INSERT INTO some_users (name,address,gmt_create,gmt_modified,intro) VALUES ('sun',SAMPLE_SEQ.nextVal,now(),now(),'aa');
Query OK, 1 row affected (0.01 sec)
```

 **Note** If you set the `AUTO_INCREMENT` parameter when creating a table, you do not need to specify an auto-increment column when running the `INSERT` statement. The auto-increment column is automatically maintained by PolarDB-X.

Retrieve sequence values in batches**Syntax:**

```
SELECT < sequence name >.NEXTVAL FROM DUAL WHERE COUNT = < numeric value >
```

Example:

```
SELECT sample_seq.nextVal FROM dual WHERE count = 10;
+-----+
| SAMPLE_SEQ.NEXTVAL |
+-----+
|      101002 |
|      101003 |
|      101004 |
|      101005 |
|      101006 |
|      101007 |
|      101008 |
|      101009 |
|      101010 |
|      101011 |
+-----+
10 row in set (0.04 sec)
```

13.13.3. Implicit sequence usage

After AUTO_INCREMENT is set for a primary key, the primary key is automatically filled in by using a sequence which is maintained by PolarDB-X.

CREATE TABLE

The standard CREATE TABLE syntax is extended to add the sequence type for auto-increment columns. If the type keyword is not specified, the default type is GROUP. Sequence names automatically created by PolarDB-X and associated with tables are all prefixed with AUTO_SEQ_ and followed by the table names.

```
CREATE TABLE <name> (
  <column> ... AUTO_INCREMENT [ BY GROUP | SIMPLE | TIME ],
  <column definition>,
  ...
) ... AUTO_INCREMENT=<start value>
```

SHOW CREATE TABLE

The sequence type is displayed for the auto-increment column of a table shard or broadcast table.

```
SHOW CREATE TABLE <name>
```

Examples

- If AUTO_INCREMENT is set but the sequence type is not specified when a table is created, a group sequence is used by default.

Example 1

```
mysql> CREATE TABLE `xkv_shard` (
  -> `id` bigint(20) unsigned NOT NULL AUTO_INCREMENT COMMENT 'id',
  -> `gmt_create` timestamp NOT NULL DEFAULT '0000-00-00 00:00:00' ON UPDATE CURRENT_TIMESTAMP COMMENT 'gmt_create',
  -> `uid` bigint(20) unsigned DEFAULT '10' COMMENT 'uid',
  -> `msg` varchar(40) DEFAULT '127.0.0.1' COMMENT 'desc',
  -> `val` float DEFAULT '0' COMMENT 'val',
  -> `time` time DEFAULT NULL COMMENT 'time',
  -> PRIMARY KEY (`id`),
  -> UNIQUE KEY `msg` (`msg`)
  -> ) ENGINE=InnoDB AUTO_INCREMENT=100009 DEFAULT CHARSET=utf8 dbpartition by hash(`id`);
Query OK, 0 rows affected (1.24 sec)

mysql> show create table xkv_shard;
+-----+-----+
| Table | Create Table |
+-----+-----+
| xkv_shard | CREATE TABLE `xkv_shard` (
  `id` bigint(20) unsigned NOT NULL AUTO_INCREMENT BY GROUP COMMENT 'id',
  `gmt_create` timestamp NOT NULL DEFAULT '0000-00-00 00:00:00' ON UPDATE CURRENT_TIMESTAMP COMMENT 'gmt_create',
  `uid` bigint(20) unsigned DEFAULT '10' COMMENT 'uid',
  `msg` varchar(40) DEFAULT '127.0.0.1' COMMENT 'desc',
  `val` float DEFAULT '0' COMMENT 'val',
  `time` time DEFAULT NULL COMMENT 'time',
  PRIMARY KEY (`id`),
  UNIQUE KEY `msg` (`msg`)
) ENGINE=InnoDB AUTO_INCREMENT=100009 DEFAULT CHARSET=utf8 dbpartition by hash(`id`) |
+-----+-----+
1 row in set (0.02 sec)

mysql> drop table xkv_shard;
```

- When creating a table, set AUTO_INCREMENT and specify a time-based sequence as the primary key value.

Example 2

```
mysql> CREATE TABLE `timeseq_test` (
  -> `id` bigint(20) unsigned NOT NULL AUTO_INCREMENT BY TIME COMMENT ' ',
  -> `gmt_create` timestamp NOT NULL DEFAULT '0000-00-00 00:00:00' ON UPDATE CURRENT_TIMESTAMP COMMENT ' ',
  -> `uid` bigint(20) unsigned DEFAULT '10' COMMENT 'uid',
  -> `msg` varchar(40) DEFAULT '127.0.0.1' COMMENT 'desc',
  -> `val` float DEFAULT '0' COMMENT 'val',
  -> `time` time DEFAULT NULL COMMENT 'time',
  -> PRIMARY KEY (`id`),
  -> UNIQUE KEY `msg` (`msg`)
  -> ) ENGINE=InnoDB AUTO_INCREMENT=100009 DEFAULT CHARSET=utf8 dbpartition by hash(`id`);
Query OK, 0 rows affected (1.27 sec)

mysql> show create table timeseq_test;
+-----+-----+
| Table | Create Table |
+-----+-----+
| timeseq_test | CREATE TABLE `timeseq_test` (
  `id` bigint(20) unsigned NOT NULL AUTO_INCREMENT BY TIME COMMENT ' ',
  `gmt_create` timestamp NOT NULL DEFAULT '0000-00-00 00:00:00' ON UPDATE CURRENT_TIMESTAMP COMMENT ' ',
  `uid` bigint(20) unsigned DEFAULT '10' COMMENT 'uid',
  `msg` varchar(40) DEFAULT '127.0.0.1' COMMENT 'desc',
  `val` float DEFAULT '0' COMMENT 'val',
  `time` time DEFAULT NULL COMMENT 'time',
  PRIMARY KEY (`id`),
  UNIQUE KEY `msg` (`msg`)
) ENGINE=InnoDB AUTO_INCREMENT=100009 DEFAULT CHARSET=utf8 dbpartition by hash(`id`) |
+-----+-----+
1 row in set (0.04 sec)
```

ALTER TABLE

Currently, **ALTER TABLE** cannot be used to change the sequence type but can be used to change the initial value. To modify the implicit sequence type in a table, use the **SHOW SEQUENCES** command to find the sequence names and types, and then use the **ALTER SEQUENCE** command to modify the sequences.

```
ALTER TABLE <name> ... AUTO_INCREMENT=<start value>
```

Notice If a PolarDB-X sequence is used, exercise caution when modifying the start value of **AUTO_INCREMENT**. You need to carefully evaluate the already generated sequence values and the speed of generating new sequence values to prevent conflicts.

13.13.4. Limits and precautions for sequences

This topic describes the limits and precautions for sequences.

Limits and precautions

- When a time-based sequence is used in the auto-increment column of a table, the column must be of the **BIGINT** type.
- **START WITH** must be set when the sequence is changed to another type.
- When the **INSERT** statement is executed on a PolarDB-X database in non-partition mode where only one ApsaraDB RDS for MySQL database is bound or on a database in partition mode that has only one table but no broadcast table, PolarDB-X automatically optimizes and sends the statement, and bypasses the part of the optimizer that allocates the sequence value. In this case, **INSERT INTO ... VALUES (seq.nextval, ...)** is not supported. We recommend that you use the ApsaraDB RDS for MySQL auto-increment column feature instead.
- If the hint for a specific database shard is used by the **INSERT** statement such as **INSERT INTO ... VALUES ...** or **INSERT INTO ... SELECT...** and the target table uses a sequence, PolarDB-X bypasses the optimizer and directly sends the statement so that the sequence does not take effect. The target table creates an ID by using the auto-increment feature of the ApsaraDB RDS for MySQL table.
- The auto-increment ID allocation method for the same table must be kept consistent, which may be based on PolarDB-X sequences or the auto-increment column of the ApsaraDB RDS for MySQL. If both of the two allocation methods are used for the same table, duplicate IDs may be created and making location difficult.

Troubleshoot primary key conflicts

Assume that data is directly written to ApsaraDB RDS for MySQL and that the related primary key value is not the sequence value created by PolarDB-X. If PolarDB-X automatically creates a primary key and writes it to the database, this primary key may conflict with that of the directly written data. This problem can be resolved as follows:

1. View the existing sequences by using the PolarDB-X-specified SQL statement. The sequence prefixed with `AUTO_SEQ_` is an implicit sequence. This sequence is generated when a table is created with the `AUTO_INCREMENT` parameter.

```
mysql> SHOW SEQUENCES;
+-----+-----+-----+-----+-----+-----+-----+
| NAME          | VALUE | INCREMENT_BY | START_WITH | MAX_VALUE | CYCLE | TYPE |
+-----+-----+-----+-----+-----+-----+-----+
| AUTO_SEQ_timeseq_test | N/A | N/A | N/A | N/A | N/A | TIME |
| AUTO_SEQ_xkv_shard_tbl1 | 0 | N/A | N/A | N/A | N/A | GROUP |
| AUTO_SEQ_xkv_shard | 0 | N/A | N/A | N/A | N/A | GROUP |
+-----+-----+-----+-----+-----+-----+-----+
3 rows in set (0.04 sec)
```

2. For example, if the `t_item` table contains conflicts and its primary key is `ID`, then retrieve the maximum primary key value of this table from PolarDB-X:

```
mysql> SELECT MAX(id) FROM t_item;
+-----+
| max(id) |
+-----+
| 8231 |
+-----+
1 row in set (0.01 sec)
```

3. Update the related value in the PolarDB-X sequence table to a value greater than 8231, such as 9000. Then, no error is returned for the auto-increment primary key created by the subsequent `INSERT` statement.

```
mysql> ALTER SEQUENCE AUTO_SEQ_USERS START WITH 9000;
Query OK, 1 row affected (0.01 sec)
```

13.14. Best practices

13.14.1. Select a shard key

A shard key is a field for database sharding and table sharding, which is used to create sharding rules during horizontal partitioning. PolarDB-X partitions a logical table horizontally into the physical database shards on each ApsaraDB RDS for MySQL instance based on the shard key.

The primary principle of sharding is to identify the business logic-specific subject of data in a table as much as possible and confirm that most (or core) database operations are performed based on this subject. Then, use the subject-related field as the shard key to perform database sharding and table sharding.

The business logic-specific subject is related to business scenarios. The following typical scenarios include business logic-specific subjects that can be used as shard keys:

- User-oriented Internet applications are operated to meet user requirements. Users are the business logic-specific subject and the user-related field can be used as the shard key.

- Seller-oriented e-commerce applications are operated to meet seller requirements. Sellers are the business logic-specific subject and the seller-related field can be used as the shard key.
- Game-oriented applications are operated to meet gamer requirements. Gamers are the business logic-specific subject and the gamer-related field can be used as the shard key.
- Internet of Vehicles (IoV) applications are operated based on vehicle information. Vehicles are the business logic-specific subject and the vehicle-related field can be used as the shard key.
- Tax-oriented applications are operated based on taxpayer information to provide frontend services. Taxpayers are the business logic-specific subject and the taxpayer-related field can be used as the shard key.

In other scenarios, you can also use the appropriate subject of business logic as the shard key.

For example, in a seller-oriented e-commerce application, the following single table must be horizontally partitioned:

```
CREATE TABLE sample_order (  
  id INT(11) NOT NULL,  
  sellerId INT(11) NOT NULL,  
  trade_id INT(11) NOT NULL,  
  buyer_id INT(11) NOT NULL,  
  buyer_nick VARCHAR(64) DEFAULT NULL,  
  PRIMARY KEY (id)  
)
```

The sellerId field is used as the shard key because seller is the business logic-specific subject. In the case of database sharding but no table sharding, the distributed data definition language (DDL) statement for table creation is as follows:

```
CREATE TABLE sample_order (  
  id INT(11) NOT NULL,  
  sellerId INT(11) NOT NULL,  
  trade_id INT(11) NOT NULL,  
  buyer_id INT(11) NOT NULL,  
  buyer_nick VARCHAR(64) DEFAULT NULL,  
  PRIMARY KEY (id)  
) DBPARTITION BY HASH(sellerId)
```

If no business logic-specific subject can be used as the shard key, use the following methods to select an appropriate shard key:

- Determine the shard key based on the distribution and access of data. Distribute the data in a table to different physical database shards and table shards as evenly as possible. This method is applicable to scenarios with massive analytical queries, in which query concurrency stays at 1.
- Determine the shard key for database sharding and table sharding by combining fields of the numeric (string) type and time type. This method is applicable to log retrieval.

For example, a log system records all user operations and needs to horizontally partition the following single log table:

```
CREATE TABLE user_log (
  userId INT(11) NOT NULL,
  name VARCHAR(64) NOT NULL,
  operation VARCHAR(128) DEFAULT NULL,
  actionDate DATE DEFAULT NULL
)
```

You can combine the user identifier with the time field to create a shard key for partitioning the table by week. The distributed DDL statement for table creation is as follows:

```
CREATE TABLE user_log (
  userId INT(11) NOT NULL,
  name VARCHAR(64) NOT NULL,
  operation VARCHAR(128) DEFAULT NULL,
  actionDate DATE DEFAULT NULL
) DBPARTITION BY HASH(userId) TBPARTITION BY WEEK(actionDate) TBPARTITIONS 7
```

For more information about shard key selection and table shard forms, see [DDL statements](#).

 Notice Avoid using hotspot data as the shard key if possible.

13.14.2. Select the number of shards

PolarDB-X supports horizontal partitioning of databases and tables. Eight physical database shards are created on each ApsaraDB RDS for MySQL instance by default, and one or more physical table shards can be created on each physical database shard. The number of table shards is also called the number of shards.

Generally, we recommend that each physical table shard contain no more than 5 million rows of data. Generally, you can estimate the data growth in one to two years. Divide the estimated total data size by the total number of physical database shards, and then divide the result by the recommended maximum data size of 5 million, to obtain the number of physical table shards to be created on each physical database shard:

$$\text{Number of physical table shards in each physical database shard} = \text{CEILING}(\text{Estimated total data size} / (\text{Number of ApsaraDB RDS for MySQL instances} \times 8) / 5,000,000)$$

Therefore, when the calculated number of physical table shards is equal to 1, only database sharding needs to be performed, that is, a physical table shard is created in each physical database shard. If the calculation result is greater than 1, we recommend that you perform both database sharding and table sharding, that is, there are multiple physical table shards in each physical database shard.

For example, if a user estimates that the total data size of a table will be about 0.1 billion rows two years later and the user has four ApsaraDB RDS for MySQL instances, then according to the preceding formula:

$$\text{Number of physical table shards in each physical database shard} = \text{CEILING}(100,000,000 / (4 \times 8) / 5,000,000) = \text{CEILING}(0.625) = 1$$

The result is 1, so only database sharding is needed, that is, one physical table shard is created in each physical database shard.

If only one ApsaraDB RDS for MySQL instance is used in the preceding example, the formula is as follows:

$$\text{Number of physical table shards in each physical database shard} = \text{CEILING}(100,000,000 / (1 \times 8) / 5,000,000) = \text{CEILING}(2.5) = 3$$

The result is 3, so we recommend that you create three physical table shards in each physical database shard.

13.14.3. Basic concepts of SQL optimization

PolarDB-X is an efficient and stable distributed relational database service that processes distributed relational computing. PolarDB-X optimizes SQL statements differently from single-instance relational databases such as MySQL. PolarDB-X focuses on the network I/O overheads in a distributed environment and pushes SQL operations down to the underlying database shards (such as ApsaraDB RDS for MySQL) for execution, thereby reducing the network I/O overheads and improving the SQL execution efficiency.

PolarDB-X provides commands for obtaining the SQL execution information to help SQL optimization, for example, EXPLAIN commands for obtaining SQL execution plans and TRACE commands for obtaining SQL execution processes and overheads. This topic describes the basic concepts and common commands related to SQL optimization in PolarDB-X.

Execution plan

An SQL execution plan (or execution plan) is a set of ordered operation steps generated to access data. In PolarDB-X, the execution plan is divided into the execution plan at the PolarDB-X layer and the execution plan at the ApsaraDB RDS for MySQL layer. Execution plan analysis is an effective way to optimize SQL statements. Through execution plan analysis, you can know whether PolarDB-X or ApsaraDB RDS for MySQL has generated optimal execution plans for SQL statements and whether further optimization can be made.

During SQL statement execution, based on the basic information of the SQL statement and related tables, the PolarDB-X optimizer determines on which database shards the SQL statement should be executed, and the specific SQL statement form, execution policy, and data merging and computing policy for each database shard. This process optimizes SQL statement execution and generates execution plans at the PolarDB-X layer. The execution plan at the ApsaraDB RDS for MySQL layer is the native MySQL execution plan.

PolarDB-X provides a set of EXPLAIN commands to display execution plans at different levels or with different levels of detail.

The following table briefly describes the EXPLAIN commands in PolarDB-X.

EXPLAIN command description

Command	Description	Example
EXPLAIN { SQL }	Displays the summary execution plan of SQL statements at the PolarDB-X layer, including the database shards on which the SQL statement is run, physical statements, and general parameters.	EXPLAIN SELECT * FROM test
EXPLAIN DETAIL { SQL }	Displays the detailed execution plans of SQL statements at the PolarDB-X layer, including the statement type, concurrency, returned field information, physical tables, and database groups.	EXPLAIN DETAIL SELECT * FROM test
EXPLAIN EXECUTE { SQL }	Displays the execution plan of the underlying ApsaraDB RDS for MySQL instance, which is equivalent to the EXPLAIN statement of MySQL.	EXPLAIN EXECUTE SELECT * FROM test

Execution plan at the PolarDB-X layer

The following table describes the fields in the results returned for the execution plan at the PolarDB-X layer.

Description of fields in execution plans at the PolarDB-X layer

Field	Description
GROUP_NAME	The name of the PolarDB-X database shard. The suffix identifies the specific database shard. The value is consistent with the result of the SHOW NODE command.
SQL	The SQL statement run on this database shard.
PARAMS	The SQL statement parameters used when PolarDB-X communicates with ApsaraDB RDS for MySQL over the Prepare protocol.

The SQL field can be in two forms:

1. If an SQL statement does not contain the following parts, the execution plan is displayed as an SQL statement:
 - Aggregate function involving multiple database shards.
 - Distributed JOIN queries involving multiple shards.
 - Complex subqueries.

Examples:

```
mysql> EXPLAIN SELECT * FROM test;
+-----+-----+-----+
| GROUP_NAME          | SQL                                | PARAMS |
+-----+-----+-----+
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0000_RDS | select `test`.`c1`,`test`.`c2` from `test` | {} |
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0001_RDS | select `test`.`c1`,`test`.`c2` from `test` | {} |
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0002_RDS | select `test`.`c1`,`test`.`c2` from `test` | {} |
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0003_RDS | select `test`.`c1`,`test`.`c2` from `test` | {} |
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0004_RDS | select `test`.`c1`,`test`.`c2` from `test` | {} |
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0005_RDS | select `test`.`c1`,`test`.`c2` from `test` | {} |
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0006_RDS | select `test`.`c1`,`test`.`c2` from `test` | {} |
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0007_RDS | select `test`.`c1`,`test`.`c2` from `test` | {} |
+-----+-----+-----+
8 rows in set (0.04 sec)
```

The group names displayed in the GROUP_NAME field can be found in the returned result of SHOW NODE:

```
mysql> SHOW NODE;
+-----+-----+-----+-----+-----+
--+
| ID | NAME                               | MASTER_READ_COUNT | SLAVE_READ_COUNT | MASTER_READ_PERCENT | SLAVE_R
EAD_PERCENT |
+-----+-----+-----+-----+-----+
--+
| 0 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0000_RDS |      69 |      0 | 100% | 0% |
| 1 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0001_RDS |      45 |      0 | 100% | 0% |
| 2 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0002_RDS |      30 |      0 | 100% | 0% |
| 3 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0003_RDS |      29 |      0 | 100% | 0% |
| 4 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0004_RDS |      11 |      0 | 100% | 0% |
| 5 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0005_RDS |       1 |      0 | 100% | 0% |
| 6 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0006_RDS |       8 |      0 | 100% | 0% |
| 7 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0007_RDS |      50 |      0 | 100% | 0% |
+-----+-----+-----+-----+-----+
--+
8 rows in set (0.10 sec)
```

2. Execution plans that cannot be expressed by SQL statements can be expressed by PolarDB-X in custom format.

Examples:

```
mysql> EXPLAIN DETAIL SELECT COUNT(*) FROM test;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| GROUP_NAME          | SQL          | PARAMS |
+-----+-----+-----+-----+-----+-----+-----+
| TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0000_RDS | Merge as test
  queryConcurrency:GROUP_CONCURRENT
  columns:[count(*)]
  executeOn: TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0000_RDS
  Query from test as test
    queryConcurrency:SEQUENTIAL
    columns:[count(*)]
    tableName:test
    executeOn: TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0000_RDS
  Query from test as test
    queryConcurrency:SEQUENTIAL
    columns:[count(*)]
    tableName:test
    executeOn: TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0001_RDS
  ... ..
  Query from test as test
    queryConcurrency:SEQUENTIAL
    columns:[count(*)]
    tableName:test
    executeOn: TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0007_RDS
| NULL |
+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

executeOn in the SQL statement field indicates the database shard on which the SQL statement is run. PolarDB-X finally merges the results returned by the database shards.

Execution plans at the ApsaraDB RDS for MySQL layer

The execution plans at the ApsaraDB RDS for MySQL layer are the same as the native MySQL execution plan. For more information, see [official MySQL documentation](#).

One PolarDB-X logical table may consist of multiple table shards distributed in different database shards. Therefore, you can view the execution plans at the ApsaraDB RDS for MySQL layer in multiple ways.

1. View the execution plan of an ApsaraDB RDS for MySQL database shard.

If the query condition contains a shard key, directly run the EXPLAIN EXECUTE command to display the execution plan on the corresponding database shard. Examples:

```
mysql> EXPLAIN EXECUTE SELECT * FROM test WHERE c1 = 1;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | test | const | PRIMARY | PRIMARY | 4 | const | 1 | NULL |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.04 sec)
```

Notice If an SQL statement involves multiple shards (for example, its condition does not contain a shard key), the EXPLAIN EXECUTE command returns an execution plan on a random ApsaraDB RDS for MySQL database shard.

To view the execution plan of an SQL statement on a specified database shard, you can add a hint.
Examples:

```
mysql> /*! TDDL:node='TESTDB_1478746391548CDTCTESTDB_OXGJ_0000_RDS'*/EXPLAIN SELECT * FROM test;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | test | ALL | NULL | NULL | NULL | NULL | 2 | NULL |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.04 sec)
```

2. View the execution plans of all ApsaraDB RDS for MySQL database shards.

You can run SCAN HINT to display the execution plans of SQL statements on all database shards:

```
mysql> /*! TDDL:scan='test'*/EXPLAIN SELECT * FROM test;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | test | ALL | NULL | NULL | NULL | NULL | 2 | NULL |
| 1 | SIMPLE | test | ALL | NULL | NULL | NULL | NULL | 3 | NULL |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
2 rows in set (0.08 sec)
```

Notice

- i. In hint mode, PolarDB-X only replaces the table names in case of database or table sharding, and then directly sends the logical SQL statement to ApsaraDB RDS for MySQL for execution. It will not process the result.
- ii. Execution plans obtained by using an EXPLAIN command are generated by static analysis and are not actually executed in databases.

TRACE command

The TRACE command in PolarDB-X can track the SQL execution process and the overheads in each stage. It can be used together with the execution plan to facilitate SQL statement optimization.

The TRACE command contains two related commands: TRACE and SHOW TRACE, which must be used together.

13.14.4. SQL optimization methods

13.14.4.1. Overview

This topic describes the SQL optimization principles and methods for optimizing different types of SQL statements in PolarDB-X.

Basic principles of SQL optimization

In PolarDB-X, SQL computing that can be performed by ApsaraDB RDS for MySQL instances is called push-down computing. Push-down computing reduces data transmission, decreases overheads at the network layer and PolarDB-X layer, and improves the execution efficiency of SQL statements.

Therefore, the basic principle for SQL statement optimization in PolarDB-X is as follows: Push down as many computations as possible to ApsaraDB RDS for MySQL instances.

Push-down computations include:

- JOIN connections
- Filter conditions, such as `WHERE` or `HAVING` conditions
- Aggregate computing, such as `COUNT` and `GROUP BY`
- Sorting, such as `ORDER BY`
- Deduplication, such as `DISTINCT`
- Function computing, such as the `NOW()` function
- Subqueries

 **Notice** The preceding list only describes possible forms of push-down computations. It does not mean that all clauses or conditions or combinations of clauses or conditions can be pushed down for computing.

SQL statements of different types and containing different conditions can be optimized in different ways. The following uses some examples to describe how to optimize SQL statements:

- Single-table SQL optimization
 - Filter condition optimization
 - Optimization of the number of returned rows for a query
 - Grouping and sorting optimization
- JOIN query optimization
 - Optimization of push-down JOIN queries
 - Optimization of distributed JOIN queries
- Subquery optimization

13.14.4.2. Single-table SQL optimization

Single-table SQL optimization must follow the following principles:

- Make sure that the SQL statements contain the shard key.
- Use an equivalence condition for the shard key whenever possible.
- If the shard key is an IN condition, the number of values after IN should be as small as possible (far fewer than the number of shards, and remain unchanged as the business grows).
- If SQL statements do not contain a shard key, use only one of `DISTINCT`, `GROUP BY`, and `ORDER BY` in the same SQL statement.

Filter condition optimization

PolarDB-X partitions data horizontally by the shard key. Therefore, the filter condition must contain the shard key as much as possible so that PolarDB-X can push queries down to specific database shards based on the shard key values, to avoid scanning all tables in the PolarDB-X instance.

For example, the shard key of the test table is c1. If the filter condition does not contain this shard key, full table scan is performed:

```
mysql> SELECT * FROM test WHERE c2 = 2;
+----+----+
| c1 | c2 |
+----+----+
| 2 | 2 |
+----+----+
1 row in set (0.05 sec)
```

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT * FROM test WHERE c2 = 2;
+-----+-----+-----+-----+-----+-----+
| GROUP_NAME          | SQL                                          | PARAMS |
+-----+-----+-----+-----+-----+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0004_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0007_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0005_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0003_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0006_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0000_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0001_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {} |
+-----+-----+-----+-----+-----+
8 rows in set (0.00 sec)
```

The smaller the value range of the filter condition that contains the shard key, the faster the PolarDB-X query speed.

For example, a query on the test table contains a range filter condition with the shard key c1:

```
mysql> SELECT * FROM test WHERE c1 > 1 AND c1 < 4;
+----+----+
| c1 | c2 |
+----+----+
| 2 | 2 |
| 3 | 3 |
+----+----+
2 rows in set (0.04 sec)
```

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT * FROM test WHERE c1 > 1 AND c1 < 4;
+-----+-----+
--+-----+
| GROUP_NAME          | SQL                                                                 | PARAMS |
+-----+-----+
--+-----+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `test`.`c1`,`test`.`c2` from `test` where ((`test`.`c1` > 1) AND (`test`.`c1` < 4)) | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0003_RDS | select `test`.`c1`,`test`.`c2` from `test` where ((`test`.`c1` > 1) AND (`test`.`c1` < 4)) | {} |
+-----+-----+
--+-----+
2 rows in set (0.00 sec)
```

The equivalence condition is executed faster than the range condition. Examples:

```
mysql> SELECT * FROM test WHERE c1 = 2;
+----+----+
| c1 | c2 |
+----+----+
| 2 | 2 |
+----+----+
1 row in set (0.03 sec)
```

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT * FROM test WHERE c1 = 2;
+-----+-----+-----+
| GROUP_NAME          | SQL                                                                 | PARAMS |
+-----+-----+-----+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c1` = 2) | {} |
+-----+-----+-----+
1 row in set (0.00 sec)
```

In addition, if you want to insert data into a table shard, the inserted field must contain a shard key.

For example, the data inserted into the test table contains the shard key c1:

```
mysql> INSERT INTO test(c1,c2) VALUES(8,8);
Query OK, 1 row affected (0.07 sec)
```

Optimization of the number of returned rows for a query

When PolarDB-X runs a query that contains `LIMIT [offset,] row_count`, PolarDB-X actually reads records before `offset` in order and directly discards them. In this way, when the value of `offset` is large, the query is slow even if the value of `row_count` is small. For example, run the following SQL statement:

```
SELECT *  
FROM sample_order  
ORDER BY sample_order.id  
LIMIT 10000, 2
```

Although only the 10000th and 10001st records are returned, it takes about 12 seconds to run the SQL statement because PolarDB-X actually reads 10,002 records.

```
mysql> SELECT * FROM sample_order ORDER BY sample_order.id LIMIT 10000,2;  
+-----+-----+-----+-----+-----+  
| id      | sellerId | trade_id | buyer_id | buyer_nick |  
+-----+-----+-----+-----+-----+  
| 242012755468 | 1711939506 | 242012755467 | 244148116334 | zhangsan |  
| 242012759093 | 1711939506 | 242012759092 | 244148138304 | wangwu  |  
+-----+-----+-----+-----+-----+  
2 rows in set (11.93 sec)
```

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT * FROM sample_order ORDER BY sample_order.id LIMIT 10000,2;
+-----+-----+-----+
| GROUP_NAME | SQL | PARAMS |
+-----+-----+-----+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0004_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0007_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0005_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0003_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0006_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0000_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0001_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {} |
+-----+-----+-----+
8 rows in set (0.01 sec)
```

To optimize the preceding SQL statement, find the ID set, and use IN to match the actual records. The modified SQL query is as follows:

```
SELECT *
FROM sample_order o
WHERE o.id IN (
    SELECT id
    FROM sample_order
    ORDER BY id
    LIMIT 10000, 2 )
```

The purpose is to cache IDs in the memory first (on the premise that the number of IDs is small). If the shard key of the sample_order table is an ID, PolarDB-X can also push down such an IN query to different database shards through rule-based calculation, avoiding full table scan and unnecessary network I/O operations. Observe the effect of the modified SQL query:

```
mysql> SELECT *
-> FROM sample_order o
-> WHERE o.id IN ( SELECT id FROM sample_order ORDER BY id LIMIT 10000,2);
+-----+-----+-----+-----+-----+
| id      | sellerId | trade_id | buyer_id | buyer_nick |
+-----+-----+-----+-----+-----+
| 242012755468 | 1711939506 | 242012755467 | 244148116334 | zhangsan |
| 242012759093 | 1711939506 | 242012759092 | 244148138304 | wangwu |
+-----+-----+-----+-----+-----+
2 rows in set (1.08 sec)
```

The execution time is significantly reduced from 12 seconds to 1.08 seconds.

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT *
-> FROM sample_order o
-> WHERE o.id IN ( SELECT id FROM sample_order ORDER BY id LIMIT 10000,2);
+-----+-----+-----+-----+-----+
| GROUP_NAME          | SQL                                                                 | PARAMS |
+-----+-----+-----+-----+-----+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `o`.`id`,`o`.`sellerId`,`o`.`trade_id`,`o`.`buyer_id`,`o`.`buyer_nick` from `sample_order` `o` where (`o`.`id` IN (10002)) | {} |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0001_RDS | select `o`.`id`,`o`.`sellerId`,`o`.`trade_id`,`o`.`buyer_id`,`o`.`buyer_nick` from `sample_order` `o` where (`o`.`id` IN (10001)) | {} |
+-----+-----+-----+-----+-----+
2 rows in set (0.03 sec)
```

Grouping and sorting optimization

In PolarDB-X, if an SQL query must use all of DISTINCT, GROUP BY, and ORDER BY, try to ensure that the fields after DISTINCT, GROUP BY, and ORDER BY are the same and the fields are shard keys. In this way, only a small amount of data is returned for the SQL query. This minimizes the network bandwidth consumed by distributed queries and removes the need to retrieve a large amount of data and sort the data in a temporary table, thereby maximizing the system performance.

13.14.4.3. JOIN query optimization

JOIN queries in PolarDB-X are classified into push-down JOIN queries and non-push-down JOIN queries (distributed JOIN queries). The optimization policies for these two types of JOIN queries are different.

Optimize push-down JOIN queries

Push-down JOIN queries are classified into the following types:

- JOIN queries between single tables (non-partition tables).
- The tables involved in the JOIN query contain the shard key in the filter condition and use the same sharding algorithm (that is, the data calculated by the sharding algorithm is distributed to the same shard).

- Tables involved in the JOIN query use the shard key as the JOIN condition and use the same sharding algorithm.
- JOIN query between broadcast tables (or small table broadcast) and table shards.

In PolarDB-X, optimize JOIN queries to push-down JOIN queries that can be executed on database shards.

Take a JOIN query between a broadcast table and table shards as an example. The broadcast table is used as the JOIN driving table (the left table in the JOIN query is called the driving table). The PolarDB-X broadcast table stores the same data in each database shard. When the broadcast table is used as the JOIN driving table, the JOIN query between this broadcast table and table shards can be converted into single-database JOIN queries and combined for computing to improve query performance.

For example, a JOIN query is performed on the following three tables, among which the sample_area table is the broadcast table, and the sample_item and sample_buyer tables are table shards. The query execution time is about 15s:

```
mysql> SELECT sample_area.name
-> FROM sample_item i JOIN sample_buyer b ON i.sellerId = b.sellerId JOIN sample_area a ON b.province = a.id
-> WHERE a.id < 110107
-> LIMIT 0, 10;
+-----+
| name |
+-----+
| BJ |
+-----+
10 rows in set (14.88 sec)
```

If you adjust the JOIN query order and move the broadcast table to the farthest left as the JOIN driving table, the JOIN query is pushed down to a single database shard in the PolarDB-X instance:

```
mysql> SELECT sample_area.name
-> FROM sample_area a JOIN sample_buyer b ON b.province = a.id JOIN sample_item i ON i.sellerId = b.sellerId
-> WHERE a.id < 110107
-> LIMIT 0, 10;
+-----+
| name |
+-----+
| BJ |
+-----+
10 rows in set (0.04 sec)
```

The query execution time decreases from 15 seconds to 0.04 seconds, which is a significant improvement to the query performance.

Notice The broadcast table achieves data consistency through the synchronization mechanism on database shards, with a latency of several seconds.

Optimize distributed JOIN queries

If a JOIN query cannot be pushed down (that is, the JOIN condition and filter condition do not contain the shard key), PolarDB-X must complete part of the computing in the query. Such a query is a distributed JOIN query.

Tables in a distributed JOIN query are classified into two types based on the data size:

- **Small table:** A table that contains a small amount of data (less than 100 data records or less data than other tables) that is involved in JOIN computing after filtering.
- **Large table:** A table that contains a large amount of data (more than 100 data records or more data than other tables) that is involved in JOIN computing after filtering.

In most cases, Nested Loop and its derived algorithms are used in JOIN computing at the PolarDB-X layer. If sorting is required for JOIN queries, the Sort Merge algorithm is used. When the Nested Loop algorithm is used, a smaller data size in the left table in a JOIN query indicates a smaller number of queries performed by PolarDB-X on the right table. If the right table has indexes or contains a small amount of data, the JOIN query is even faster. In PolarDB-X, the left table of a distributed JOIN query is called the driving table. To optimize a distributed JOIN query, use a small table as the driving table and set as many filter conditions as possible for the driving table.

Take the following distributed JOIN query as an example. The query takes about 24 seconds:

```
mysql> SELECT t.title, t.price
-> FROM sample_order o,
-> ( SELECT * FROM sample_item i WHERE i.id = 242002396687 ) t
-> WHERE t.source_id = o.source_item_id AND o.sellerId < 1733635660;
+-----+-----+
| title          | price |
+-----+-----+
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
+-----+-----+
10 rows in set (23.79 sec)
```

The preceding JOIN query is an INNER JOIN query, with the actual size of the intermediate data involved in JOIN computing unknown. In this case, perform COUNT() on the o table and t table respectively to obtain the actual data size.

For the o table, o.sellerId < 1733635660 in the WHERE condition is only related to the o table. Then, extract and add it to the COUNT() condition of the o table. The following query result is returned:

```
mysql> SELECT COUNT(*) FROM sample_order o WHERE o.sellerId < 1733635660;
+-----+
| count(*) |
+-----+
| 504018 |
+-----+
1 row in set (0.10 sec)
```

The intermediate result of the o table contains about 500,000 records. Similarly, the t table is a subquery, which can be extracted directly for the COUNT() query:

```
mysql> SELECT COUNT(*) FROM sample_item i WHERE i.id = 242002396687;
+-----+
| count(*) |
+-----+
| 1 |
+-----+
1 row in set (0.01 sec)
```

The intermediate result of the t table contains only one record. Therefore, the o table is a large table and the t table is a small table. Use the small table as the driving table of the distributed JOIN query. The result of the adjusted JOIN query is as follows:

```
mysql> SELECT t.title, t.price
-> FROM ( SELECT * FROM sample_item i WHERE i.id = 242002396687 ) t,
-> sample_order o
-> WHERE t.source_id = o.source_item_id AND o.sellerId < 1733635660;
+-----+-----+
| title          | price |
+-----+-----+
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
+-----+-----+
10 rows in set (0.15 sec)
```

The query execution time decreases from about 24 seconds to 0.15 seconds, with the query performance significantly improved.

13.14.4.4. Subquery optimization

When optimizing an SQL statement that contains subqueries, push the subqueries down to database shards as much as possible to reduce the computing workload at the PolarDB-X layer.

For this purpose, you can try two optimization methods:

- Rewrite subqueries into multi-table JOIN queries, and optimize the JOIN queries.
- Use the shard key in the JOIN condition or filter condition so that PolarDB-X can push the query down to a specific database shard to avoid full table scan.

The following subquery is used as an example:

```
SELECT o.*
FROM sample_order o
WHERE NOT EXISTS
  (SELECT sellerId FROM sample_seller s WHERE o.sellerId = s.id)
```

Rewrite the subquery into a JOIN query:

```
SELECT o.*
FROM sample_order o LEFT JOIN sample_seller s ON o.sellerId = s.id
WHERE s.id IS NULL
```

13.14.5. Select connection pools for an application

A database connection pool is used to manage database connections in a centralized manner, so as to improve application performance and reduce database loads.

- **Reuse resources:** Connections can be reused to avoid high performance overheads caused by frequent connection creation and release. Resource reuse can also improve the system stability.
- **Improve the system response efficiency:** After the connection initialization is complete, all requests can directly use the existing connections, which avoids the overheads of connection initialization and release and improves the system response efficiency.
- **Avoid connection leakage:** The connection pool forcibly revokes connections based on the preset de-allocation policy to avoid connection resource leakage.

We recommend that you use a connection pool to connect applications and databases for service operations. For Java programs, we recommend that you use the [Druid connection pool](#).

The following is an example of standard Druid Spring configuration:

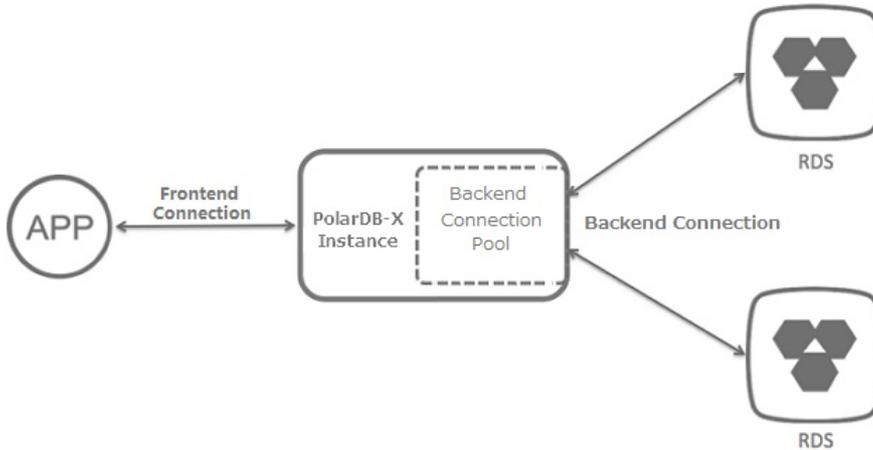

```
<bean id="dataSource" class="com.alibaba.druid.pool.DruidDataSource" init-method="init" destroy-method="close">
  <property name="driverClassName" value="com.mysql.jdbc.Driver" />
  <!-- Basic attributes URL, user, and password -->
  <property name="url" value="jdbc:mysql://ip:port/db? autoReconnect=true&rewriteBatchedStatements=true&socketTimeout=30000&connectTimeout=3000" />
  <property name="username" value="root" />
  <property name="password" value="123456" />
  <!-- Configure the initial size, minimum value, and maximum value -->
  <property name="maxActive" value="20" />
  <property name="initialSize" value="3" />
  <property name="minIdle" value="3" />
  <!-- maxWait indicates the time-out period for obtaining the connection -->
  <property name="maxWait" value="60000" />
  <!-- timeBetweenEvictionRunsMillis indicates the interval for detecting idle connections to be closed, in milliseconds -->
  <property name="timeBetweenEvictionRunsMillis" value="60000" />
  <!-- minEvictableIdleTimeMillis indicates the minimum idle time of a connection in the connection pool, in milliseconds -->
  <property name="minEvictableIdleTimeMillis" value="300000" />
  <!-- SQL statement used to check whether connections are available -->
  <property name="validationQuery" value="SELECT 'z'" />
  <!-- Whether to enable idle connection check -->
  <property name="testWhileIdle" value="true" />
  <!-- Whether to check the connection status before obtaining a connection -->
  <property name="testOnBorrow" value="false" />
  <!-- Whether to check the connection status before releasing a connection -->
  <property name="testOnReturn" value="false" />
</bean>
```

13.14.6. Connections to PolarDB-X instances

When an application connects to a PolarDB-X instance for operation, there are two types of connections from the perspective of the PolarDB-X instance:

- **Frontend connection:** a connection established by an application to the logical database in the PolarDB-X instance.
- **Backend connection:** a connection established by a node in a PolarDB-X instance to a physical database in a backend ApsaraDB RDS for MySQL instance.

PolarDB-X instance connection diagram

Frontend connection

Theoretically, the number of frontend connections is limited by the available memory size and the number of network connections to the nodes of the PolarDB-X instance. However, in actual application scenarios, when an application connects to a PolarDB-X instance, the nodes of the PolarDB-X instance usually manage a limited number of connections to perform requested operations, and do not maintain a large number of concurrent persistent connections (for example, tens of thousands of concurrent persistent connections). Therefore, the number of frontend connections that a PolarDB-X instance can accept can be considered to be unlimited.

Considering that the number of frontend connections is unlimited and a large number of idle connections are allowed, this method applies to scenarios where a large number of servers are deployed and need to maintain their connections to the PolarDB-X instance.

Note Although the number of frontend connections is considered as unlimited, operation requests obtained from frontend connections are actually executed by internal threads of the PolarDB-X instance through backend connections. Due to the limited number of internal threads and backend connections, the total number of concurrent requests that can be processed by the PolarDB-X instance is limited.

Backend connection

Each node of a PolarDB-X instance creates a backend connection pool to automatically manage and maintain the backend connections to the physical databases in the ApsaraDB RDS for MySQL instance. Therefore, the maximum number of connections in the backend connection pool of a PolarDB-X instance is directly related to the maximum number of connections supported by the ApsaraDB RDS for MySQL instance. You can use the following formula to calculate the maximum number of connections in the backend connection pool of a PolarDB-X instance:

$$\text{Maximum number of connections in a backend connection pool of a PolarDB-X instance} = \text{FLOOR}(\text{Maximum number of connections in an ApsaraDB RDS for MySQL instance} / \text{Number of physical database shards in the ApsaraDB RDS for MySQL instance} / \text{Number of nodes on the PolarDB-X instance})$$

For example, a user has purchased an ApsaraDB RDS for MySQL instance and a PolarDB-X instance of the following types:

- The ApsaraDB RDS for MySQL instance has eight physical database shards, four cores, and 16 GB memory, supporting a maximum number of 4,000 connections.
- The PolarDB-X dedicated instance has 32 cores and 32 GB memory, with each PolarDB-X node having two cores and 2 GB memory (that is, the instance has 16 PolarDB-X nodes).

You can use the following formula to calculate the maximum number of connections in the backend connection pool of the PolarDB-X instance:

```
Maximum number of connections in the backend connection pool of the PolarDB-X instance = FLOOR (4000/8/16) = FLOOR (31.25) = 31
```

Note

- The calculation result of the preceding formula is the maximum number of connections in the backend connection pool of the PolarDB-X instance. In actual use, to reduce the connection pressure on the ApsaraDB RDS for MySQL instance, the PolarDB-X instance adjusts the maximum number of connections in the backend connection pool to make it smaller than the upper limit.
- We recommend that you create databases in a PolarDB-X instance on a dedicated ApsaraDB RDS for MySQL instance. Do not create databases for other applications or PolarDB-X instances on the dedicated ApsaraDB RDS for MySQL instance.

Relationship between frontend and backend connections

After an application establishes frontend connections to a PolarDB-X instance and sends SQL statement execution requests, the PolarDB-X nodes process the requests asynchronously and obtain backend connections through the internal backend connection pool, and then run optimized SQL statements on one or more physical databases.

PolarDB-X nodes process requests asynchronously and frontend connections are not bound to backend connections. Therefore, a small number of backend connections can process a large number of requests for short transactions and simple queries from many concurrent frontend connections. This is why you need to focus on the queries per second (QPS) in PolarDB-X, rather than the number of concurrent connections.

Although the number of frontend connections is considered to be unlimited, the maximum number of connections maintained in the backend connection pool of a PolarDB-X instance is limited. For more information, see "Backend connections." Therefore, note the following points in actual application scenarios:

- Avoid long or large transactions in applications. These transactions occupy many or even all backend connections when they are not committed or rolled back for a long time, which reduces the overall concurrent processing capability and increases the response time (RT).
- Monitor and optimize or remove slow SQL queries run in the PolarDB-X instance, to prevent them from occupying too many backend connections. Otherwise, the PolarDB-X instance or the ApsaraDB RDS for MySQL instance is under greater processing pressure, which may lead to reduced concurrent processing capability, increased RT, or higher SQL execution failure rate due to execution timeout. For troubleshooting and optimization of slow SQL queries, see [Troubleshoot slow SQL statements in PolarDB-X](#) and [Overview](#).
- Under normal use of connections and execution of queries, if the maximum number of connections in the backend connection pool of the PolarDB-X instance is reached, contact Customer Services for assistance.

13.14.7. Perform instance upgrade

Database performance can be measured by the response time (RT) and queries per second (QPS). RT reflects the performance of a single SQL statement. This type of performance problem can be solved through SQL optimization. PolarDB-X upgrade expands the capacity to improve performance, and is suitable for database access services with low latency and high QPS.

The performance of a PolarDB-X instance depends on the performance of PolarDB-X and ApsaraDB RDS for MySQL. Insufficient performance of any PolarDB-X or ApsaraDB RDS for MySQL node can create a bottleneck in the overall performance. This topic describes how to observe the performance metrics of a PolarDB-X instance and upgrade the PolarDB-X instance to solve the performance bottleneck. For more information about how to determine the performance of an ApsaraDB RDS for MySQL instance and upgrade the ApsaraDB RDS for MySQL instance, see the ApsaraDB RDS for MySQL documentation.

Determine the performance bottleneck of a PolarDB-X instance

The QPS and CPU performance of a PolarDB-X instance are in positive correlation. When a PolarDB-X instance encounters a performance bottleneck, the CPU utilization of the PolarDB-X instance remains high.

Observe the CPU utilization

1. On the **Basic Information** page of the PolarDB-X instance, choose **Monitoring and Alerts > Instance Monitoring** from the left-side navigation pane.
2. On the **Instance Monitoring** page, select a monitoring dimension and the corresponding metrics to view details.

If the CPU utilization exceeds 90% or remains above 80%, the PolarDB-X instance faces a performance bottleneck. If there is no bottleneck for the ApsaraDB RDS for MySQL instance, the current PolarDB-X instance specifications cannot meet the QPS performance requirements of the business. In this case, the PolarDB-X instance needs to be upgraded.

For more performance-related service monitoring scenarios and methods for configuring the PolarDB-X CPU utilization alert, see [View monitoring information](#).

Upgrade PolarDB-X

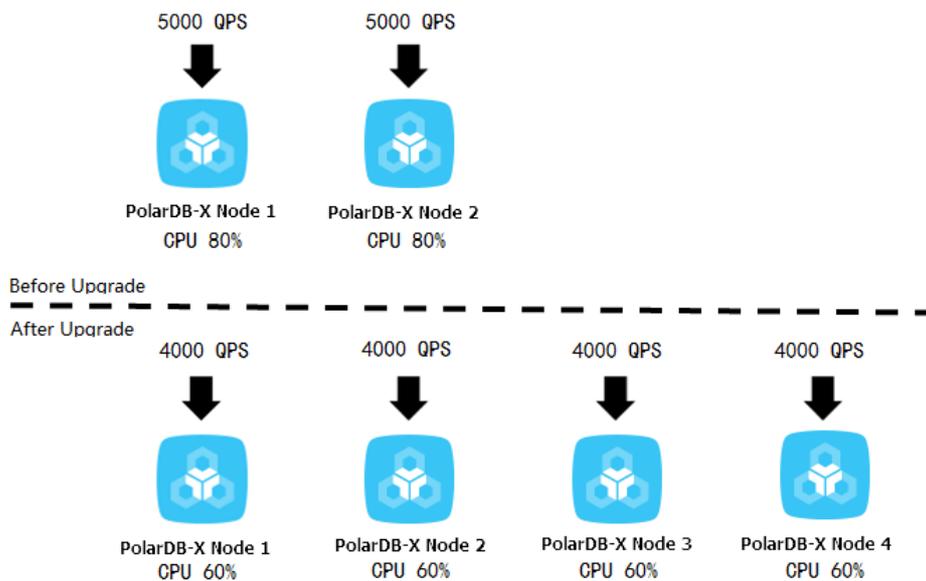

QPS is an important metric for determining whether the PolarDB-X instance specifications can meet the business requirements. Each type of instance specifications corresponds to a reference QPS value.

Some special SQL statements require more computing (such as temporary table sorting and aggregate computing) in PolarDB-X. In this case, the QPS supported by each PolarDB-X instance is lower than the standard value in its type.

PolarDB-X upgrade improves the processing performance of a PolarDB-X instance by adding nodes to share the QPS. As PolarDB-X nodes are stateless, this upgrade method linearly improves the performance of PolarDB-X instances.

For example, service A requires QPS of about 15 thousand. The current PolarDB-X instance has a 4-core virtual CPU (vCPU), 4 GB memory, and two nodes, supporting QPS of only 10 thousand. After finding that the CPU utilization of the PolarDB-X instance remains high, we upgraded the instance to 8-core vCPU and 8 GB memory, with each node handling about 4,000 QPS. Then, the performance meets service requirements, and the CPU utilization also drops to a reasonable level, as shown in the following figure.

PolarDB-X upgrade

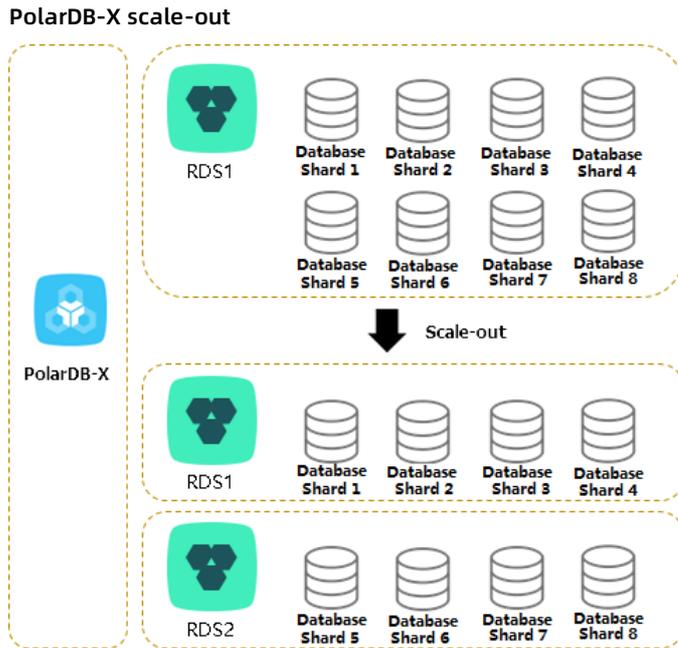

For more information about how to upgrade a PolarDB-X instance, see [Change specifications](#).

13.14.8. Perform scale-out

In PolarDB-X, smooth scale-out improves the overall performance by increasing the number of ApsaraDB RDS for MySQL instances. You can increase the number of ApsaraDB RDS for MySQL instances through PolarDB-X smooth scale-out to increase the PolarDB-X database capacity when the following conditions are met: 1. The input/output operations per second (IOPS), CPU utilization, disk space, and other metrics of the ApsaraDB RDS for MySQL instance reach their bottlenecks. 2. The bottlenecks cannot be removed through SQL optimization or ApsaraDB RDS for MySQL upgrade (for example, the disk has been upgraded to the top configuration).

PolarDB-X smooth scale-out reduces the pressure on the original ApsaraDB RDS for MySQL instance by migrating database shards to the new ApsaraDB RDS for MySQL instance. For example, before scale-out, all the eight databases are deployed in one ApsaraDB RDS for MySQL instance. After scale-out, the eight databases are deployed in two ApsaraDB RDS for MySQL instances, and the pressure on a single ApsaraDB RDS for MySQL instance is significantly reduced, as shown in the following figure.

After multiple scale-out operations, if the number of ApsaraDB RDS for MySQL instances is equal to the number of database shards, you need to create another PolarDB-X instance and ApsaraDB RDS for MySQL databases with the expected capacity, and then migrate data to further increase the data capacity. This process is complex. We recommend that you consider the data growth expected in the next two to three years and plan the number of ApsaraDB RDS for MySQL instances properly when creating a PolarDB-X database.

Determine whether scale-out is required

You can determine whether PolarDB-X smooth scale-out is required based on three ApsaraDB RDS for MySQL metrics: IOPS, CPU utilization, and disk space. You can view these metrics in the ApsaraDB RDS for MySQL console. For more information, see the ApsaraDB RDS for MySQL documentation.

IOPS and CPU utilization

If you find that the IOPS or CPU utilization remains above 80% for a long time or you frequently receive alerts, follow these steps:

1. Optimize SQL statements. Generally, you can solve the high CPU utilization problem by this method.
2. If the problem persists, upgrade the ApsaraDB RDS for MySQL instance. For more information, see the ApsaraDB RDS for MySQL documentation.
3. When the CPU utilization or IOPS exceeds the threshold, you can set read-only databases to share the load on the primary database. However, read/write splitting affects read consistency. For more information, see the [Read/write splitting](#) documentation.
4. If the problem persists, scale out the PolarDB-X instance.

Disk space

ApsaraDB RDS for MySQL has the following types of disk space:

1. **Data space:** the space occupied by data. The space usage continues increasing as more data is inserted. We recommend that you keep the remaining disk space above 30%.
2. **System file space:** the space occupied by shared tables and error log files.
3. **Binary log file space:** the space occupied by binary logs generated during database operation. The more update transactions there are, the larger the occupied space is.

Whether scale-out is required depends on the data space. When the data space is about to or expected to exceed the disk capacity, you can distribute the data to the databases on multiple ApsaraDB RDS for MySQL instances through scale-out.

Scale-out risks and precautions

PolarDB-X scale-out consists of four steps: **configuration > migration > switchover > cleanup**. For more information, see the [Perform smooth scale-out](#) documentation.

Note the following points before scale-out:

- To reduce the pressure of read operations on the source ApsaraDB RDS for MySQL instance, perform scale-out when the load on the source ApsaraDB RDS for MySQL instance is low.
- During scale-out, do not submit data definition language (DDL) tasks in the console or connect to the PolarDB-X instance to directly run DDL SQL statements. Otherwise, the scale-out task may fail.
- Scale-out requires that the source database table have a primary key. If the source database does not have a primary key, add one first.
- During scale-out, the read and write traffic is switched to the new ApsaraDB RDS for MySQL instance. The switchover process takes three to five minutes. We recommend that you perform a switchover during off-peak hours.
- Scale-out does not affect the PolarDB-X instance before the switchover. Therefore, you can cancel the scale-out through rollback before the switchover.
- Scale-out creates pressure on databases. We recommend that you perform this operation during off-peak hours.

13.14.9. Troubleshoot slow SQL statements in PolarDB-X

13.14.9.1. Details about a slow SQL statement

PolarDB-X defines an SQL statement that takes more than 1 second to run as a slow SQL statement. Slow SQL statements in PolarDB-X are classified into slow logical SQL statements and slow physical SQL statements. In PolarDB-X, an SQL statement is run step by step on PolarDB-X and ApsaraDB RDS for MySQL nodes. Large execution loss on any node will result in slow SQL statements.

- Slow logical SQL statements are slow SQL statements sent by an application to PolarDB-X.
- Slow physical SQL statements are slow SQL statements sent by PolarDB-X to ApsaraDB RDS for MySQL.

Syntax

```
SHOW FULL {SLOW | PHYSICAL_SLOW} [WHERE where_condition]
      [ORDER BY col_name [ASC | DESC], ...]
      [LIMIT {[offset,] row_count | row_count OFFSET offset}]
```

Description

The `SHOW FULL SLOW` command shows slow logical SQL statements, that is, SQL statements sent by an application to PolarDB-X.

The result set of the `SHOW FULL SLOW` command contains the following columns:

- **TRACE_ID:** the unique identifier of the SQL statement. A logical SQL statement and the physical SQL

statements generated by the logical SQL statement have the same TRACE_ID. The TRACE_ID is also sent as a comment to ApsaraDB RDS for MySQL.

- **HOST**: the IP address of the client that sends the SQL statement.

 **Notice** The client IP address may not be obtained when the network type is Virtual Private Cloud (VPC).

- **START_TIME**: the time when PolarDB-X starts running the SQL statement.
- **EXECUTE_TIME**: the time consumed by PolarDB-X to run the SQL statement.
- **AFFECT_ROW**: the number of records returned or the number of rows affected by the SQL statement.
- **SQL**: the statement that is run.

The `SHOW FULL PHYSICAL_SLOW` command shows the slow physical SQL statements, that is, SQL statements sent by PolarDB-X to ApsaraDB RDS for MySQL.

The result set of `SHOW FULL PHYSICAL_SLOW` contains the following columns:

- **TRACE_ID**: the unique identifier of the SQL statement. A logical SQL statement and the physical SQL statements generated by the logical SQL statement have the same TRACE_ID. The TRACE_ID is also sent as a comment to ApsaraDB RDS for MySQL.
- **GROUP_NAME**: the name of a database group. Grouping aims to manage multiple groups of databases with identical data, such as the primary and secondary databases after data replication through ApsaraDB RDS for MySQL, which are mainly used for read/write splitting and primary/secondary switchover.
- **DBKEY_NAME**: the name of the database shard on which the SQL statement is run.
- **START_TIME**: the time when PolarDB-X starts running the SQL statement.
- **EXECUTE_TIME**: the time consumed by PolarDB-X to run the SQL statement.
- **SQL_EXECUTE_TIME**: the time consumed by PolarDB-X to call ApsaraDB RDS for MySQL to run this SQL statement.
- **GETLOCK_CONNECTION_TIME**: the time that PolarDB-X takes to get connections from the connection pool. If the value is large, the ApsaraDB RDS for MySQL connections have been exhausted. This is typically due to a large number of slow SQL statements. You can log on to the corresponding ApsaraDB RDS for MySQL instance and run `SHOW PROCESSLIST` for troubleshooting.
- **CREATE_CONNECTION_TIME**: the time consumed by PolarDB-X to establish a connection to ApsaraDB RDS for MySQL. If the value is large, it is largely because the ApsaraDB RDS for MySQL instance is overloaded or faulty.
- **AFFECT_ROW**: the number of records returned or the number of rows affected by the SQL statement.
- **SQL**: the statement that is run.

Example 1

The following example describes how to locate the execution of a slow SQL statement on PolarDB-X and between PolarDB-X and ApsaraDB RDS for MySQL.

1. You can use certain conditions, such as the execution time and SQL string match, to obtain the specified slow SQL statement:

```
mysql> show full slow where `SQL` like '%select sleep(50)%';
+-----+-----+-----+-----+-----+-----+
| TRACE_ID | HOST | START_TIME | EXECUTE_TIME | AFFECT_ROW | SQL |
+-----+-----+-----+-----+-----+-----+
| ae0e565b8c00000 | 127.0.0.1 | 2017-03-29 19:28:43.028 | 50009 | 1 | select sleep(50) |
+-----+-----+-----+-----+-----+-----+
1 row in set (0.02 sec)
```

2. Based on the TRACE_ID of the slow logical SQL statement, run `SHOW FULL PHYSICAL_SLOW` to obtain the physical execution information of this SQL statement.

```
mysql> show full physical_slow where trace_id = 'ae0e565b8c00000';
+-----+-----+-----+-----+-----+
| TRACE_ID | GROUP_NAME | DBKEY_NAME | START_TIME | EXEC
UTE_TIME | SQL_EXECUTE_TIME | GETLOCK_CONNECTION_TIME | CREATE_CONNECTION_TIME | AFFECT_ROW | SQL
|
+-----+-----+-----+-----+-----+
| ae0e565b8c00000 | PRIV_TEST_1489167306631PJAFPRIV_TEST_APKK_0000_RDS | rdso6g5b6206sdq832ow_priv_test_a
pkk_0000_nfup | 2017-03-29 19:27:53.02 | 50001 | 50001 | 0 | 0 | 1 | select slee
p(50) |
+-----+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

3. In the SQL statement details and slow SQL statement records of the ApsaraDB RDS for MySQL instance, you can query the execution information of this SQL statement on the ApsaraDB RDS for MySQL instance based on TRACE_ID.

Slow query logs

Example 2

This example describes how to locate the original SQL statement in PolarDB-X based on the slow SQL statement located in ApsaraDB RDS for MySQL.

1. Based on the slow SQL query log in ApsaraDB RDS for MySQL, TRACE_ID of the slow SQL statement is ae0e55660c00000.
2. Based on the TRACE_ID obtained in Step 1, run `SHOW FULL PHYSICAL_SLOW` to obtain the physical execution information of this SQL statement.

```
mysql> show full physical_slow where trace_id = 'ae0e55660c00000';
+-----+-----+-----+-----+-----+
| TRACE_ID | GROUP_NAME | DBKEY_NAME | START_TIME | EXEC
UTE_TIME | SQL_EXECUTE_TIME | GETLOCK_CONNECTION_TIME | CREATE_CONNECTION_TIME | AFFECT_ROW | SQL
|
+-----+-----+-----+-----+-----+
| ae0e55660c00000 | PRIV_TEST_1489167306631PJAFPRIV_TEST_APKK_0000_RDS | rdso6g5b6206sdq832ow_priv_test_a
pkk_0000_nfup | 2017-03-29 19:27:37.308 | 10003 | 10001 | 0 | 0 | 1 | select sle
ep(10) |
+-----+-----+-----+-----+-----+
1 row in set (0.02 sec)
```

13.14.9.2. Locate slow SQL statements

Generally, you can locate a slow SQL statement in two ways: Obtain historical information about slow SQL statements from slow SQL statement records, or run `SHOW PROCESSLIST` to display the real-time execution information about slow SQL statements.

You can troubleshoot slow SQL statements as follows:

1. Locate slow SQL statements.
2. Locate nodes with performance loss.
3. Troubleshoot the performance loss.

 **Note** During troubleshooting, we recommend that you use the MySQL command line `mysql -hIP -PPORT -uUSER -pPASSWORD -c` to create the connection. Be sure to add `-c` to prevent the MySQL client from filtering out the comments (default operation) and therefore affecting the execution of HINT.

- View slow SQL statement records

Run the following command to query top 10 slow SQL statements. This command can query logical SQL statements in PolarDB-X. One logical SQL statement corresponds to SQL statements of one or more databases or tables of the ApsaraDB RDS for MySQL instance. For more information, see [Details about a low SQL statement](#).

```
mysql> SHOW SLOW limit 10;
+-----+-----+-----+-----+-----+-----+
| TRACE_ID | HOST | START_TIME | EXECUTE_TIME | AFFECT_ROW | SQL |
|-----+-----+-----+-----+-----+-----+
| ac3133132801001 | xx.xxx.xx.97 | 2017-03-06 15:48:32.330 | 900392 | -1 | select detail_url, sum(price) from t_item group by detail_url; |
.....
+-----+-----+-----+-----+-----+-----+
10 rows in set (0.01 sec)
```

- View real-time SQL execution information

If the execution of an SQL statement is slow in the current server, run `SHOW PROCESSLIST` to view the real-time SQL execution information in the current PolarDB-X database. The value in the TIME column indicates how long the current SQL statement has been run.

```
mysql> SHOW PROCESSLIST WHERE COMMAND != 'Sleep';
+-----+-----+-----+-----+-----+-----+-----+-----+
-----+-----+
----+-----+
| ID      | USER      | DB          | COMMAND | TIME | STATE | DB          | INFO |
| ROWS_SENT | ROWS_EXAMINED | ROWS_READ |         |      |       |            |      |
+-----+-----+-----+-----+-----+-----+-----+-----+
-----+-----+
| 0-0-352724126 | ifisibhk0 | test_123_wvvp_0000 | Query | 13 | Sending data | NULL | /*
DRDS /42.120.74.88/ac47e5a72801000/ */select `t_item`.`detail_url`,SUM(`t_item`.`price`) from `t_i | NULL | NU
LL | NULL |
| 0-0-352864311 | cowxhthg0 | NULL | Binlog Dump | 17 | Master has sent all binlog to slave; waiting for binl
og to be updated | NULL | NULL | NULL | NULL |
| 0-0-402714795 | ifisibhk0 | test_123_wvvp_0005 | Alter | 114 | Sending data | NULL | /*D
RDS /42.120.74.88/ac47e5a72801000/ */ALTER TABLE `Persons` ADD `Birthday` date | NULL | NULL |
NULL |
.....
+-----+-----+-----+-----+-----+-----+-----+-----+
-----+-----+
----+-----+
12 rows in set (0.03 sec)
```

The following describes each column:

- **ID:** the ID of the connection.
- **USER:** the user name of the database shard in which this SQL statement is run.
- **DB:** the specified database. If no database is specified, the value is NULL.
- **COMMAND:** the type of the command being executed. SLEEP indicates an idle connection. For more information about other commands, see [MySQL thread information documentation](#).
- **TIME:** the elapsed execution time of the SQL statement, in seconds.
- **STATE:** the current execution status. For more information, see [MySQL thread status documentation](#).
- **INFO:** the SQL statement being executed. The SQL statement may be too long to be displayed completely. You can derive the complete SQL statement based on information such as service parameters.

In the current example, the following slow SQL statement is identified:

```
ALTER TABLE `Persons` ADD `Birthday` date
```

13.14.9.3. Locate nodes with performance loss

When you locate a slow SQL statement in slow SQL statement records or real-time SQL execution information, you can run the TRACE command to trace the running time of the SQL statement in PolarDB-X and ApsaraDB RDS for MySQL to locate the bottleneck.

The TRACE command actually runs the SQL statement, records the time consumed on all nodes, and returns the execution result. For more information about TRACE and other control commands, see [Help statements](#).

 **Note** The PolarDB-X TRACE command needs to maintain the context information of the connection. Some GUI clients may use connection pools, which results in command exceptions. Therefore, we recommend that you use the MySQL command line to run the TRACE command.

Run the following command for the identified slow SQL statement:

```
mysql> trace select detail_url, sum(distinct price) from t_item group by detail_url;
+-----+-----+
| detail_url | sum(price) |
+-----+-----+
| www.xxx.com | 1084326800.00 |
| www.xx1.com | 1084326800.00 |
| www.xx2.com | 1084326800.00 |
| www.xx3.com | 1084326800.00 |
| www.xx4.com | 1084326800.00 |
| www.xx5.com | 1084326800.00 |
.....
+-----+-----+
1 row in set (7 min 2.72 sec)
```

After the TRACE command is run, run SHOW TRACE to view the result. You can identify the bottleneck of the slow SQL statement based on the time consumption of each component.

```
mysql> SHOW TRACE;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| ID | TIMESTAMP | TYPE      | GROUP_NAME                | DBKEY_NAME                | TIME_COST
(MS) | CONNECTION_TIME_COST(MS) | ROWS | STATEMENT
| PARAMS |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 0 | 0.000 | Optimize  | DRDS                      | DRDS                      | 2      | 0.00
| 0 | select detail_url, sum(price) from t_item group by detail_url | NULL |
| 1 | 423507.342 | Merge Sorted | DRDS                      | DRDS                      | 411307 | 0.00
| 8 | Using Merge Sorted, Order By (`t_item`.`detail_url` asc) | NULL |

+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
11 rows in set (0.01 sec)
```

In the returned results of SHOW TRACE, you can determine which node has a long execution time based on the values (in milliseconds) in the TIME_COST column. You can also see the corresponding GROUP_NAME (that is, the PolarDB-X or ApsaraDB RDS for MySQL node) and the STATEMENT column information (that is, the SQL statement being executed). By checking whether the value of GROUP_NAME is PolarDB-X, you can determine whether the slow node exists in PolarDB-X or ApsaraDB RDS for MySQL.

According to the preceding results, the Merge Sorted action on the PolarDB-X node and the TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0005_RDS node of ApsaraDB RDS for MySQL take a lot of time.

13.14.9.4. Troubleshoot the performance loss

Slow nodes may exist on the PolarDB-X or ApsaraDB RDS for MySQL instance. Troubleshoot the fault accordingly after the cause is determined.

Solution for slow PolarDB-X nodes

When the GROUP_NAME of a slow node is in the PolarDB-X instance, check whether time-consuming computing operations such as Merge Sorted, Temp Table Merge, and Aggregate exist during SQL statement execution. If so, rectify it. For more information, see [Overview](#).

Solution for slow ApsaraDB RDS for MySQL nodes

When the slow node is on the ApsaraDB RDS for MySQL instance, check the execution plan of this SQL statement on the ApsaraDB RDS for MySQL instance.

In PolarDB-X, you can run `/*! TDDL:node={GROUP_NAME}*/ EXPLAIN` to check the SQL execution plan of an ApsaraDB RDS for MySQL instance. The execution plan displays the SQL execution process information, including inter-table association and index information.

The detailed process is as follows:

1. Based on GROUP_NAME, assemble the HINT: `/*! TDDL:node='TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0005_RDS'*/`.
2. Combine the assembled HINT and the statement prefixed by EXPLAIN to form a new SQL statement and run it. The EXPLAIN command does not actually run. It only displays the execution plan of the SQL statement.

The following example describes how to query the execution plan of the identified slow node.

```
mysql> /*! TDDL:node='TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0005_RDS'*/ EXPLAIN select `t_item`.`detail_url`,SUM(distinct `t_item`.`price`) from `t_item` group by `t_item`.`detail_url` order by `t_item`.`detail_url` asc;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | t_item | ALL | NULL | NULL | NULL | NULL | 1322263 | Using temporary; Using filesort |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

When the preceding SQL statement is run in ApsaraDB RDS for MySQL, the message `Using temporary; Using filesort` is returned. It indicates that low SQL statement execution is caused by improper use of the index. In this case, you can correct the index and run the SQL statement again.

13.14.10. Handle DDL exceptions

When you run any data definition language (DDL) commands of PolarDB-X, PolarDB-X performs the corresponding DDL operation on all table shards.

Failures can be divided into two types:

1. A DDL statement fails to be executed in a database shard. DDL execution failure in any database shard may result in inconsistent table shard structures.
2. The system does not respond for a long time after a DDL statement is executed. When you perform a DDL statement on a large table, the system may make no response for a long time due to the long execution time of the DDL statement in a database shard.

Execution failures in database shards may occur for various reasons. For example, the table you want to create already exists, the column you want to add already exists, or the disk space is insufficient.

No response for a long time is generally caused by the long execution time of a DDL statement in a database shard. Taking ApsaraDB RDS for MySQL as an example, the DDL execution time depends mostly on whether the operation is an in-place (directly modifying the source table) or copy (copying data in the table) operation. An in-place operation only requires modification of metadata, while a copy operation reconstructs the whole table and also involves log and buffer operations.

To determine whether a DDL operation is an in-place or copy operation, you can view the returned value of "rows affected" after the operation is completed.

Example:

- Change the default value of a column (this operation is very fast and does not affect the table data at all):

```
Query OK, 0 rows affected (0.07 sec)
```

- Add an index (this operation takes some time, but "0 rows affected" indicates that the table data is not replicated):

```
Query OK, 0 rows affected (21.42 sec)
```

- Change the data type of column (this operation takes a long time and reconstructs all data rows in the table):

```
Query OK, 1671168 rows affected (1 min 35.54 sec)
```

Therefore, before executing a DDL operation on a large table, perform the following steps to determine whether the operation is a fast or slow operation:

1. Copy the table structure to generate a cloned table.
2. Insert some data.
3. Perform the DDL operation on the cloned table.
4. Check whether the value of "rows affected" is 0 after the operation is completed. A non-zero value means that this operation reconstructs the entire table. In this case, you need to perform this operation in off-peak hours.

Solution for failures

PolarDB-X DDL operations distribute all SQL statements to all database shards for parallel execution. Execution failure on any database shard does not affect the execution on other database shards. In addition, PolarDB-X provides the CHECK TABLE command to check the structure consistency of the table shards. Therefore, failed DDL operations can be performed again, and errors reported on database shards on which the operations have been executed do not affect the execution on other database shards. Make sure that all table shards ultimately have the same structure.

Procedure for handling DDL operation failures

1. Run the CHECK TABLE command to check the table structure. If the returned result contains only one row and the status is normal, the table statuses are consistent. In this case, go to Step 2. Otherwise, go to Step 3.
2. Run the SHOW CREATE TABLE command to check the table structure. If the displayed table structure is the same as the expected structure after the DDL statement is run, the DDL statement is run. Otherwise, go to Step 3.
3. Run the SHOW PROCESSLIST command to check the statuses of all SQL statements being executed. If any

ongoing DDL operations are detected, wait until these operations are completed, and then perform Steps 1 and 2 to check the table structure. Otherwise, go to Step 4.

4. Perform the DDL operation again on PolarDB-X. If the Lock conflict error is reported, go to Step 5. Otherwise, go to Step 3.
5. Run the **RELEASE DBLOCK** command to release the DDL operation lock, and then go to Step 4.

The procedure is as follows:

1. Check the table structure consistency

Run the **CHECK TABLE** command to check the table structure. When the returned result contains only one row and the displayed status is OK, the table structures are consistent.

 **Notice** If no result is returned after you run **CHECK TABLE**, retry by using the CLI.

```
mysql> check table `xxxx`;
+-----+-----+-----+-----+
| TABLE      | OP | MSG_TYPE | MSG_TEXT |
+-----+-----+-----+-----+
| TDDL5_APP.xxxx | check | status | OK |
+-----+-----+-----+-----+
1 row in set (0.05 sec)
```

2. Check the table structure

Run the **SHOW CREATE TABLE** command to check the table structure. If table structures are consistent and correct, the DDL statement has been run.

```
mysql> show create table `xxxx`;
+-----+-----+-----+-----+
| Table | Create Table |
+-----+-----+-----+-----+
| xxxx | CREATE TABLE `xxxx` (
`id` int(11) NOT NULL DEFAULT '0',
`NAME` varchar(1024) NOT NULL DEFAULT "",
PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8 dbpartition by hash(`id`) tpartition by hash(`id`) tpartitions 3
|
+-----+-----+-----+-----+
1 row in set (0.05 sec)
```

3. Check the SQL statements being executed.

If some DDL statement executions are slow and no response is received for a long time, you can run the **SHOW PROCESSLIST** command to check the status of all SQL statements being executed.

```
mysql> SHOW PROCESSLIST WHERE COMMAND != 'Sleep';
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+
| ID      | USER  | DB      | COMMAND | TIME | STATE | INFO
| ROWS_SENT | ROWS_EXAMINED | ROWS_READ |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+
| 0-0-352724126 | ifisibhk0 | test_123_wvvp_0000 | Query | 15 | Sending data | /
*DRDS /xx.xxx.xx.88/ac47e5a72801000/ */select `t_item`.`detail_url`,SUM(`t_item`.`price`) from `t_i | NULL |
NULL | NULL |
| 0-0-352864311 | cowxhthg0 | NULL | Binlog Dump | 13 | Master has sent all binlog to slave; waiting for bi
nlog to be updated | NULL | NULL | NULL | NULL |
| 0-0-402714566 | ifisibhk0 | test_123_wvvp_0005 | Query | 14 | Sending data | /
*DRDS /xx.xxx.xx.88/ac47e5a72801000/ */select `t_item`.`detail_url`,`t_item`.`price` from `t_i | NULL | NU
LL | NULL |
| 0-0-402714795 | ifisibhk0 | test_123_wvvp_0005 | Alter | 114 | Sending data | /
*DRDS /xx.xxx.xx.88/ac47e5a72801000/ */ALTER TABLE `Persons` ADD `Birthday` date | NULL | N
ULL | NULL |
.....
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+
+-----+-----+
12 rows in set (0.03 sec)
```

The value in the TIME column indicates the number of seconds that the command has been executed. If a command execution is too slow, as shown in the figure, you can run the KILL '0-0-402714795' command to cancel the slow command.

 **Notice** In PolarDB-X, one logical SQL statement corresponds to multiple statements on database shards. Therefore, you may need to kill multiple commands to stop a logical DDL statement. You can determine the logical SQL statement to which a command belongs based on the INFO column in the SHOW PROCESSLIST result set.

4. Handle the lock conflict error

PolarDB-X adds a database lock before performing a DDL operation and releases the lock after the operation. The KILL DDL operation may not release the lock. If you perform the DDL operation again, the following error message will be returned:

```
Lock conflict , maybe last DDL is still running
```

In this case, run **RELEASE DBLOCK** to release the lock. After the command is canceled and the lock is released, run the DDL statement again during off-peak hours or when the service is stopped.

Other problems

Clients cannot display the modified table structures.

To enable some clients to obtain table structures from system tables (such as COLUMNS or TABLES), PolarDB-X creates a shadow database in database shard 0 on your ApsaraDB RDS for MySQL instance. The shadow database name must be the same as the name of your PolarDB-X logical database. It stores all table structures and other information in the user database.

The client obtains the PolarDB-X table structure from the system table of the shadow database. During the processing of DDL exceptions, the table structure may be modified normally in the user database but not in the shadow database due to some reasons. In this case, you need to connect to the shadow database and perform the DDL operation on the table again in the database.

 **Notice** The CHECK TABLE command does not check whether the table structure in the shadow database is consistent with that in the user database.

13.14.11. Efficiently scan PolarDB-X data

PolarDB-X supports efficient data scanning and uses aggregate functions for statistical summary during full table scan.

The following describes common scanning scenarios:

- **Scan of tables without database or table shards:** PolarDB-X transmits the original SQL statement to the backend ApsaraDB RDS for MySQL database for execution. In this case, PolarDB-X supports any aggregate functions.
- **Non-full table scan:** PolarDB-X transmits the original SQL statement to each single ApsaraDB RDS for MySQL database for execution. For example, when the shard key in the WHERE clause is Equal, non-full table scan is performed. In this case, PolarDB-X also supports any aggregate functions.
- **Full table scan:** Currently, the supported aggregate functions are COUNT, MAX, MIN, and SUM. In addition, LIKE, ORDER BY, LIMIT, and GROUP BY are also supported during full table scan.
- **Parallel scan of all table shards:** If you need to export data from all databases, you can run the SHOW command to view the table topology and scan all table shards in parallel. For more information, see the following section.

Traverse tables by using a hint

1. Run the SHOW TOPOLOGY FROM TABLE_NAME command to obtain the table topology.

```
mysql:> SHOW TOPOLOGY FROM DRDS_USERS;
+----+-----+-----+
| ID | GROUP_NAME | TABLE_NAME |
+----+-----+-----+
| 0 | DRDS_00_RDS | drds_users |
| 1 | DRDS_01_RDS | drds_users |
+----+-----+-----+
2 rows in set (0.06 sec)
```

By default, the non-partition table is stored in database shard 0.

2. Traverse each table for TOPOLOGY.
 - i. Run the current SQL statement in database shard 0.

```
/*! TDDL:node='DRDS_00_RDS'*/ SELECT * FROM DRDS_USERS;
```

- ii. Run the current SQL statement in database shard 1.

```
/*! TDDL:node='DRDS_01_RDS'*/ SELECT * FROM DRDS_USERS;
```

 **Notice** We recommend that you run `SHOW TOPOLOGY FROM TABLE_NAME` to obtain the latest table topology before each scan.

Scan data in parallel

PolarDB-X allows you to run `mysqldump` to export data. However, if you want to scan data faster, you can establish multiple sessions for each table shard to scan tables in parallel.

```
mysql> SHOW TOPOLOGY FROM LJLTEST;
+-----+-----+-----+
| ID | GROUP_NAME | TABLE_NAME |
+-----+-----+-----+
| 0 | TDDL5_00_GROUP | ljlttest_00 |
| 1 | TDDL5_00_GROUP | ljlttest_01 |
| 2 | TDDL5_00_GROUP | ljlttest_02 |
| 3 | TDDL5_01_GROUP | ljlttest_03 |
| 4 | TDDL5_01_GROUP | ljlttest_04 |
| 5 | TDDL5_01_GROUP | ljlttest_05 |
| 6 | TDDL5_02_GROUP | ljlttest_06 |
| 7 | TDDL5_02_GROUP | ljlttest_07 |
| 8 | TDDL5_02_GROUP | ljlttest_08 |
| 9 | TDDL5_03_GROUP | ljlttest_09 |
| 10 | TDDL5_03_GROUP | ljlttest_10 |
| 11 | TDDL5_03_GROUP | ljlttest_11 |
+-----+-----+-----+
12 rows in set (0.06 sec)
```

As shown above, the table has four database shards, and each database shard has three table shards. Run the following SQL statement to operate on the table shards of the `TDDL5_00_GROUP` database:

```
#!/ TDDL:node='TDDL5_00_GROUP'*/ select * from ljlttest_00;
```

 **Note** `TDDL5_00_GROUP` in HINT corresponds to the `GROUP_NAME` column in the execution results of the `SHOW TOPOLOGY` command. In addition, the table name in the SQL statement is the table shard name.

At this time, you can establish up to 12 sessions (corresponding to 12 table shards respectively) to process data in parallel.

13.15. Appendix: PolarDB-X terms

This topic lists common terms of PolarDB-X for your reference.

Term	Description	Remarks
Cloud Native Distributed Database PolarDB-X	PolarDB-X is a distributed database service that was independently developed by Alibaba to solve the bottlenecks of single-instance database services. PolarDB-X is compatible with MySQL protocols and syntax. It supports automatic sharding, smooth scale-out, auto scaling, and transparent read/write splitting, and provides O&M capabilities for distributed databases throughout their entire lifecycle.	-

Term	Description	Remarks
TDDL	Taobao Distributed Data Layer (TDDL) was developed by Alibaba and has become a preferred component for nearly 1,000 core applications of Alibaba.	-
PolarDB-X Console	PolarDB-X Console is designed for database administrators (DBAs) to isolate resources as required and perform operations, such as instance management, database and table management, read/write splitting configuration, smooth scale-out, monitoring data display, and IP address whitelist.	-
PolarDB-X Manager	PolarDB-X Manager is designed for global O&M personnel and DBAs to manage all PolarDB-X resources and monitor the system.	-
PolarDB-X Server	PolarDB-X Server is the service layer of PolarDB-X. Multiple server nodes make up a server cluster to provide distributed database services, including the read/write splitting, routed SQL execution, result merging, dynamic database configuration, and globally unique ID (GUID).	-
Load balancer	PolarDB-X server nodes are stateless, and therefore requests can be randomly routed to any PolarDB-X server node. The load balancer is used to complete this task. Server Load Balancer (SLB) is used for overall output by Apsara Stack. VIPServer is typically used for Alibaba middleware output.	-
Diamond	Diamond manages the configuration and storage of PolarDB-X. It provides the configuration functions for storage, query, and notification. In PolarDB-X, Diamond stores the source data of databases, and configuration data including the sharding rules, and switches.	-
Data Replication System	Data Replication System migrates and synchronizes data for PolarDB-X. Its core capabilities include full data migration and incremental data synchronization. Its derived features include smooth data import, smooth scale-out, and global secondary index. Data Replication System requires the support of ZooKeeper and PolarDB-X Rtools.	-
PolarDB-X instance (PolarDB-X instance)	A PolarDB-X instance consists of multiple PolarDB-X server nodes. A PolarDB-X instance can contain multiple PolarDB-X databases.	-
PolarDB-X instance ID (PolarDB-X instance ID)	An instance ID uniquely identifies an PolarDB-X instance.	-
Number of nodes on a PolarDB-X instance	The number of PolarDB-X server nodes in a PolarDB-X instance.	-
VIP	The virtual IP addresses (VIPs) of the load balancer can be classified as: <ul style="list-style-type: none"> 1. Public VIP, which is accessible from the Internet. It is used for testing. 2. Private VIP, which is accessible only from the Alibaba Cloud internal network. 	-
VPC	Virtual Private Cloud (VPC) is generally used on Alibaba Cloud.	-
Region	A region is a geographical location, such as East China. This concept is generally used for Alibaba Cloud.	-

Term	Description	Remarks
Azone	A physical area with independent power grids and networks within one region, such as Hangzhou Zone A. This concept is generally used for Alibaba Cloud.	-
Logical SQL statement	A logical SQL statement is an SQL statement sent from an application to PolarDB-X.	-
Physical SQL statement	A physical SQL statement is an SQL statement obtained after PolarDB-X parses a logical SQL statement and sends it to ApsaraDB RDS for MySQL for execution.	Logical SQL statements and physical SQL statements may be the same or different. Logical and physical SQL statements may be in a one-to-one or one-to-many mapping.
QPS	The queries per second (QPS) is the average number of logical SQL statements executed by PolarDB-X per second in a statistical period,	instead of the number of transactions. Most control statements, such as COMMIT and SET, are not counted in QPS.
RT	The response time (RT) is the average response time (in milliseconds) of logical SQL statements executed by PolarDB-X in a statistical period. The RT of an SQL statement is calculated as follows: (Time when PolarDB-X writes the last packet of the result set) - (Time when PolarDB-X receives the SQL statement)	-
Physical QPS	The physical QPS is the average number of physical SQL statements that PolarDB-X executes on ApsaraDB RDS for MySQL per second in a statistical period.	-
Physical RT	The physical RT is the average response time (in milliseconds) of physical SQL statements executed by PolarDB-X on ApsaraDB RDS for MySQL in a statistical period. The RT of a physical SQL statement is calculated as follows: (Time when PolarDB-X receives the result set returned by ApsaraDB RDS for MySQL) - (Time when PolarDB-X starts to obtain the connection to ApsaraDB RDS for MySQL)	This includes the time of establishing a connection to ApsaraDB RDS for MySQL or obtaining a connection from the connection pool, the network transmission time, and the time of executing the SQL statement by ApsaraDB RDS for MySQL.

Term	Description	Remarks
Connections	The number of connections established between the application and PolarDB-X,	instead of the number of connections established between PolarDB-X and ApsaraDB RDS for MySQL.
Inbound traffic	The network traffic generated when the application sends SQL statements to PolarDB-X.	This traffic is irrelevant to the traffic used for interaction between PolarDB-X and ApsaraDB RDS for MySQL.
Outbound traffic	The network traffic generated when PolarDB-X sends the result set to the application.	This traffic is irrelevant to the traffic used for interaction between PolarDB-X and ApsaraDB RDS for MySQL.
Number of active threads (ThreadRunning)	The number of threads running on a PolarDB-X instance. This parameter can be used to indicate the load of the PolarDB-X instance.	-
Global	The total monitoring data of all databases on a PolarDB-X instance.	-
Memory usage	The Java Virtual Machine (JVM) memory usage of a PolarDB-X server process.	-
Total memory usage	The memory usage of the machine where the PolarDB-X server node is located.	This metric is available only when PolarDB-X servers are deployed on ECS instances. Generally, this metric is used for Alibaba Cloud.
CPU utilization	The CPU utilization of the machine where a PolarDB-X server node is located.	This metric is available only when PolarDB-X servers are deployed on ECS instances. Generally, this metric is used for Alibaba Cloud.
System load	The load of the machine where a PolarDB-X server node is located.	This metric is available only when PolarDB-X servers are deployed on ECS instances. Generally, this metric is used for Alibaba Cloud.

Term	Description	Remarks
Service port	The port used by PolarDB-X servers to provide MySQL-based services to external applications.	Generally, the port number is 3306. However, when multiple PolarDB-X nodes (mostly physical machines) are deployed on one machine, the port number will change accordingly.
Management port	The port used by PolarDB-X servers to provide management application program interfaces (APIs).	Generally, the port number is the service port number plus 100.
Start time	The time when PolarDB-X servers start.	-
Running time	The continuous running time of the PolarDB-X servers since the last startup time.	-
Total memory size	The maximum JVM memory size of a PolarDB-X server node.	-
Memory usage	The JVM memory that is already used by the PolarDB-X server nodes.	-
Number of nodes	Required. The number of machines. A PolarDB-X instance is essentially a PolarDB-X cluster, and the number of nodes refers to the number of machines in the cluster.	-
Instance type	Required. The type of the instance, including dedicated and shared instances. A dedicated instance works in the exclusive mode. A shared instance works in the multi-tenant mode, which is generally used in Alibaba Cloud.	-
Machine type	Required. The type of the machine where a PolarDB-X server node is deployed. Valid values are Auto-selected, PHY, and ECS. The PolarDB-X inventory is divided into physical machine inventory and virtual machine inventory according to the type of machines where the PolarDB-X servers are deployed. The two types cannot be mixed because their deployment and O&M methods are different.	-
AliUid	Required. The UID of the instance. In Apsara Stack, this ID is provided by the account system in the deployment environment.	-
Backend port	The backend port of the VIP. For a PolarDB-X server node, this port is the service port of machine where the PolarDB-X server node is deployed.	-
Frontend port	The frontend port of the VIP for user access. Each VIP has a set of frontend ports and backend ports. The VIP forwards data from frontend ports to backend ports.	-
Private network/Internet	The network type of the VIP. Valid values: <ul style="list-style-type: none"> Internet: the public VIP, which is accessible from the Internet. Private network: the private VIP (including VPC VIP), which is accessible from private networks. 	-
lbld	The ID of an SLB instance, which is the unique ID of VIP. A VIP is managed based on this ID.	-

Term	Description	Remarks
Forwarding mode	<p>The port forwarding mode of the VIP. The following modes are supported:</p> <ul style="list-style-type: none"> • FNAT: This mode is recommended when the backend machine is a virtual machine or VPC needs to be supported. • NAT: This mode can be selected when the backend machine is a physical machine. Currently, this mode is only used on Alibaba Cloud. • Open FNAT: This mode is applicable only to Alibaba Cloud. 	-
VPC ID	The ID of the destination VPC, that is, the VPC to be accessed.	-
VSwitch ID	The ID of the destination VSwitch, which determines the CIDR block where the VPC VIP of the instance is in.	-
APPName	The app name of the destination PolarDB-X database. Each PolarDB-X database has a corresponding app name for loading configurations.	-
UserName	The user name used to log on to the destination PolarDB-X database.	-
DBName	The name of the destination PolarDB-X database you want to log on to.	-
IP address whitelist	Only the IP addresses specified in the IP address whitelist can access the PolarDB-X instance.	-
Read-only instance	<p>ApsaraDB RDS for MySQL instances where physical databases reside are divided into the following two types based on whether data can be written into the instances:</p> <ul style="list-style-type: none"> • Primary instance: Both read and write requests are allowed on such an instance. In Apsara Stack, ApsaraDB RDS for MySQL is supported. In Alibaba Cloud, ApsaraDB for RDS is supported. • Read-only instance: Only read requests are allowed on such an instance. In Apsara Stack, ApsaraDB RDS for MySQL is supported. In Alibaba Cloud, ApsaraDB for RDS is supported. 	-
Read SQL statement	A type of SQL statements used to read data, such as the SELECT statement. PolarDB-X determines whether an SQL statement is a read-only SQL statement when it is not in a transaction. If the SQL statement is in a transaction, PolarDB-X treats it as a write SQL statement during read/write splitting.	-
Read/write splitting	If read-only ApsaraDB RDS for MySQL instances exist, you can configure in the PolarDB-X console to allocate read SQL statements to the primary and read-only instances proportionally. PolarDB-X automatically identifies the type of SQL statements and allocates them proportionally.	-
Smooth scale-out	On the basis of horizontal partitioning, the data distribution on ApsaraDB RDS for MySQL instances is dynamically adjusted for scale-out. Generally, scale-out is completed asynchronously without any modification to the business code.	-
Broadcast of small tables	You can synchronize the data in a single table in a database to all database shards in advance, to convert the cross-database JOIN query into a JOIN query that can be completed on physical databases.	-

Term	Description	Remarks
Horizontal partitioning	Horizontal partitioning distributes the data rows originally stored in one table to multiple tables based on specified rules to achieve horizontal linear scaling.	-
Partition mode	This mode allows you to create multiple database shards on an ApsaraDB RDS for MySQL instance. These database shards make up a PolarDB-X database. In this mode, all PolarDB-X functions can be used.	-
Non-partition mode	In this mode, a database that has been created on an ApsaraDB RDS for MySQL instance is used as a PolarDB-X database. In this mode, only PolarDB-X read/write splitting is allowed, while other PolarDB-X features such as database sharding and table sharding are not allowed.	-
Imported database	An existing database on the ApsaraDB RDS for MySQL instance selected for creating a PolarDB-X database. This is a unique concept for the creation of a PolarDB-X database.	-
Read policy	The ratio of read SQL statements assigned by PolarDB-X to the primary and read-only ApsaraDB RDS for MySQL instances.	-
Full table scan	If no shard field is specified in a SQL statement, PolarDB-X runs the SQL statement on all table shards and summarizes the results. You can disable this function because of its high overheads.	-
Shard key	A column in a logical table. PolarDB-X routes data and SQL statements to a physical table based on this column.	-
Data import	The operation of importing data from an existing ApsaraDB RDS for MySQL instance to a PolarDB-X database.	-
Full data migration	The operation of migrating all existing records from a database to PolarDB-X. An offset is recorded before full migration starts.	-
Offset	In a MySQL binary log file, each row represents a data change operation. The position of a line in the binary log file is called an offset.	-
Incremental data migration	The operation of reading all MySQL binary log records from the recorded offset, converting them into SQL statements, and then running them in PolarDB-X. Incremental migration continues before the switchover.	-
Switchover	A step of data import and smooth scale-out, which writes all the remaining incremental records from MySQL binary logs to PolarDB-X.	-
Cleanup	The last step of smooth scale-out, which cleans redundant data and configurations generated during smooth scale-out.	-
Heterogeneous indexing	For table shards of a PolarDB-X database, the WHERE condition of a SQL statement for query must contain the shard key whenever possible. In this way, PolarDB-X routes the query request to a specific database shard, improving the query efficiency. If the WHERE condition of the SQL statement does not contain the shard key, PolarDB-X performs a full table scan. PolarDB-X provides heterogeneous indexing to solve this problem. The data in a database shard or table shard of a PolarDB-X instance is fully or partially synchronized to another table based on different shard keys. The destination table to which the data is synchronized is called a heterogeneous index table.	-

Term	Description	Remarks
PolarDB-X sequence	A PolarDB-X sequence (a 64-digit number of the BIGINT data type in MySQL) aims to ensure that the data (for example, PRIMARY KEY and UNIQUE KEY) in the defined unique field is globally unique and in ordered increments.	-
PolarDB-X hint	To facilitate PolarDB-X usage, PolarDB-X defines some hints to specify special actions.	-

14. AnalyticDB for MySQL

14.1. What is AnalyticDB for MySQL?

AnalyticDB for MySQL is a real-time online analytical processing (RT-OLAP) service that is developed by Alibaba Cloud to analyze large amounts of data at high concurrency. AnalyticDB for MySQL can analyze hundreds of billions of data records across multiple dimensions within milliseconds and provide you with data-driven insights into your business.

Note OLAP systems are often compared with online transaction processing (OLTP) systems. OLAP systems are ideal for systems that require complex multidimensional queries and analytics on large amounts of data. The OLAP model is commonly adopted in analytical databases. OLTP systems are suitable for transactional processing, and ensures strong atomicity and consistency in data manipulation. The OLTP model supports frequent INSERT and UPDATE operations and is often used for relational database management systems, such as MySQL and Microsoft SQL Server.

AnalyticDB for MySQL is an RT-OLAP system that offers the following benefits:

- Compatible with MySQL, business intelligence (BI) tools, and extract, transform, and load (ETL) tools for easy, cost-effective, and efficient analysis and integration of data.
- Uses relational models to store data and provides SQL statements to flexibly compute and analyze data. You do not need to create a data model in advance.
- Uses distributed computing technologies to provide excellent real-time computing capabilities.

When AnalyticDB for MySQL processes tens of billions of data records or more, its performance can match or even surpass that of multidimensional online analytical processing (MOLAP) systems. AnalyticDB for MySQL can compute tens of billions of data records within several hundred milliseconds. You can then explore large amounts of data without constraints, instead of viewing data reports based on a predefined logic.

- Computes hundreds of billions of data records in real time.

AnalyticDB for MySQL uses all data generated in your business system for data analysis, rather than sampling a portion of the data. This maximizes the effectiveness of analysis results.

- Supports a large number of concurrent queries and ensures high system availability through dynamic multi-copy storage and computing technology. Therefore, AnalyticDB for MySQL can serve as a backend system for various products, including user-facing and enterprise-facing products.

AnalyticDB for MySQL is used in Internet business systems that have hundreds of thousands to tens of millions of users, such as Data Cube, Taobao Index, Kuaidi Dache, Alimama DMP, and Taobao Groceries.

AnalyticDB for MySQL is a real-time computing system that provides rapid and flexible online data analysis and computation.

14.2. Limits

Take note of the following limits before you use AnalyticDB for MySQL.

Object	Naming convention	Limit
Database name	A database name can be up to 64 characters in length, and can contain letters, digits, and underscores (_). It must start with a lowercase letter and cannot contain consecutive underscores (_).	Do not use analyticdb as the database name. The name analyticdb is reserved for a built-in database.

Object	Naming convention	Limit
Table name	A table name must be 1 to 127 characters in length, and can contain letters, digits, and underscores (_). It must start with a letter or underscore (_).	<ul style="list-style-type: none"> A table name cannot contain single quotation marks ('), double quotation marks ("), exclamation points (!), or spaces. A table name cannot be SQL reserved keywords.
Column name	A column name must be 1 to 127 characters in length, and can contain letters, digits, and underscores (_). It must start with a letter or underscore (_).	<ul style="list-style-type: none"> A column name cannot contain single quotation marks ('), double quotation marks ("), exclamation points (!), or spaces. A column name cannot be SQL reserved keywords.
Account name	An account name must be 2 to 16 characters in length, and can contain lowercase letters, digits, and underscores (_). It must start with a lowercase letter and end with a lowercase letter or digit.	None
Password	A password must be 8 to 32 characters in length and must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. Special characters include ! @ # \$ % ^ & * () _ + - =	None
Comment in a table	None	A table comment can be up to 1,024 characters in length.
Comment in a column	None	A column comment can be up to 1,024 characters in length.
Index name	None	An index name can be up to 64 characters in length.
Default value of a column	None	The default value of a column can be up to 127 characters in length.

14.3. Quick start

14.3.1. Log on to the AnalyticDB for MySQL console

This topic describes how to log on to the AnalyticDB for MySQL console.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

- In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.

2. Enter your username and password.

Obtain the username and password used to log on to the console from the operations administrator.

Note When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:

- Uppercase or lowercase letters.
- Digits.
- Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click Login to go to the ASCM console homepage.

4. In the top navigation bar, choose Products > Database Services > AnalyticDB for MySQL.

14.3.2. Create a database cluster

This topic describes how to create an AnalyticDB for MySQL cluster.

Procedure

1. [Log on to the AnalyticDB for MySQL console.](#)
2. Click **Create Cluster** in the upper-right corner of the Clusters page and configure the parameters.

Parameter	Description
Region	The region where the cluster resides. You cannot change the region after the cluster is created. We recommend that you select a region that is closest to the geographic area of your business to improve access speed and stability.
Zone	The zone where the new cluster resides. A zone is an independent physical location within a region. There are no substantial differences between different zones within the same region.
Organization	The organization to which the cluster belongs.
Resource Set	The resource set of the cluster.
Version	Only version 3.0 is supported.
Edition	Only Basic is supported.
Network Type	AnalyticDB for MySQL supports two types of networks. <ul style="list-style-type: none"> ○ <i>VPC</i>: A VPC helps you build an isolated network environment in Apsara Stack. You can customize the route table, CIDR blocks, and gateway of a VPC. We recommend that you select VPC for higher security. ○ <i>Classic Network</i>: Cloud services in the classic network are not isolated. Access control to cloud services in a classic network is implemented by the security groups or whitelist policies of the services.
Specifications	The ECU specifications.

Parameter	Description
Node Groups	The number of node groups. By default, each node group consists of three replicas.
Storage	The storage space of a node group.

3. After you configure the preceding parameters, click **Submit**.

14.3.3. Configure a whitelist

This topic describes how to configure a whitelist for a cluster in the AnalyticDB for MySQL console.

Context

After you create an AnalyticDB for MySQL cluster, you must configure a whitelist for the cluster to allow external devices to access the cluster. The default whitelist contains only the default IP address 127.0.0.1, which indicates that no devices are allowed to access the cluster. The whitelist can enhance access security of AnalyticDB for MySQL clusters. We recommend that you maintain the whitelist on a regular basis. The whitelist does not affect the normal operation of AnalyticDB for MySQL clusters.

Procedure

1. [Log on to the AnalyticDB for MySQL console](#).
2. In the upper-left corner of the page, select the region where the cluster resides.
3. On the Clusters page, click **Cluster ID** corresponding to the cluster for which you want to configure a whitelist.
4. In the left-side navigation pane, click **Data Security**.
5. On the **Whitelist Settings** tab, click **Edit** to the right of the default whitelist.

 **Note** You can also click **Create Whitelist** to create a whitelist.

6. In the **Edit Whitelist** dialog box, delete the default IP address 127.0.0.1, enter the IP addresses or CIDR blocks that you want to allow, and then click **OK**.
 - o The CIDR block 0.0.0.0/0 indicates that all IP addresses are allowed to access the cluster. Exercise caution when you add this CIDR block.
 - o If you enter a CIDR block such as 10.10.10.0/24, any IP addresses in the 10.10.10.X format can access the cluster.
 - o If you want to add multiple IP addresses or CIDR blocks, separate multiple entries with commas (,). Do not add spaces before or after the commas. Example: 192.168.0.1,172.16.213.9.
 - o The whitelist modification takes effect within one minute.

14.3.4. Create a database account

This topic describes the database account types in AnalyticDB for MySQL and how to create database accounts.

Account types

AnalyticDB for MySQL supports two types of database accounts: privileged accounts and standard accounts.

Account types

Account type	Description
--------------	-------------

Account type	Description
Privileged account	<ul style="list-style-type: none"> You can create and manage privileged accounts only in the console. You can create only one privileged account for a cluster. You can use the privileged account to manage all standard accounts and databases of the cluster. You can use the privileged account of a cluster to disconnect any standard account of the cluster from AnalyticDB for MySQL. A privileged account has more permissions, which allows you to perform fine-grained management operations. For example, you can grant query permissions on different tables to different users. The privileged account in AnalyticDB for MySQL is equivalent to the root account in MySQL.
Standard account	<ul style="list-style-type: none"> You can use only SQL statements to create and manage standard accounts. You can create up to 256 standard accounts for a cluster. You must manually grant a standard account the permissions to access a specific database. You cannot use a standard account to disconnect other accounts from AnalyticDB for MySQL.

Create a privileged account

1. [Log on to the AnalyticDB for MySQL console](#)
2. In the upper-left corner of the page, select the region where the cluster resides.
3. On the Clusters page, click **Cluster ID** corresponding to the cluster for which you want to create a privileged account.
4. In the left-side navigation pane, click **Accounts**. On the **Accounts** page, click **Create Account**.
5. In the **Create Account** pane, configure the following parameters.

Parameter	Description
Account	<p>The name of the privileged account.</p> <p>The name must be 2 to 16 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a lowercase letter and end with a lowercase letter or digit.</p>
Account Type	<p>The type of the account. The value is Privileged Account. This value cannot be changed.</p>
Password	<p>The password of the privileged account.</p> <p>The password must be 8 to 32 characters in length and contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. Special characters include ! @ # \$ % ^ & * () _ + - =</p>

Parameter	Description
Confirm Password	Enter the password of the privileged account again.
Description	Optional. The description of the privileged account.

6. Click **OK** to create the privileged account.

Create a standard account

For more information about how to create a standard account and grant permissions to the standard account, see [CREATE USER](#).

What to do next

[Create a database](#)

14.3.5. Create a database

You can use a MySQL client (such as Navicat for MySQL, DBeaver, DbVisualizer, or SQL Workbench/J), application code, or the MySQL command-line tool to connect to an AnalyticDB for MySQL cluster, and execute the CREATE DATABASE statement to create a database.

Prerequisites

You have connected to a database cluster. For more information, see [Connect to a database cluster](#).

Syntax

```
CREATE DATABASE [IF NOT EXISTS] db_name;
```

Example

You can execute the following statement to create a database named adb_demo:

```
create database adb_demo;
```

14.3.6. Connect to a database cluster

This topic describes how to connect to an AnalyticDB for MySQL cluster.

Prerequisites

After you configure a whitelist and create a database account, you can use a MySQL client (such as Navicat for MySQL, DBeaver, DbVisualizer, or SQL Workbench/J), or the MySQL command-line tool to connect to the AnalyticDB for MySQL cluster. For more information, see [Configure a whitelist](#) and [Create a database account](#). You can also configure the connection information such as the endpoint, port, and account of an AnalyticDB for MySQL cluster in an application to connect to the cluster.

Use the code in an application to connect to AnalyticDB for MySQL

- [C#](#)
- [PHP](#)
- [Python](#)
- [Configure the Druid connection pool](#)
- [Java](#)

Use the MySQL command-line tool to connect to AnalyticDB for MySQL

Use the [MySQL command-line tool](#) to connect to AnalyticDB for MySQL

Use a client to connect to AnalyticDB for MySQL

- [SQL Workbench/J](#)
- [DbVisualizer](#)
- [DBeaver](#)
- [Navicat](#)

14.3.7. Apply for a public endpoint

This topic describes how to use the AnalyticDB for MySQL console to apply for a public endpoint for a cluster.

Context

- You must manually apply for a public endpoint. You can release the public endpoint if you do not need it.
- The public endpoint applies to the following scenarios:
 - You want to access an AnalyticDB for MySQL cluster on devices that are not deployed in the Alibaba Cloud environment.
 - You want to access an AnalyticDB for MySQL cluster from a region or of a network type that is different from the cluster.

Apply for a public endpoint

1. [Log on to the AnalyticDB for MySQL console](#).
2. In the upper-left corner of the page, select the region where the cluster resides.
3. On the Clusters page, click **Cluster ID** corresponding to the cluster for which you want to apply for a public endpoint.
4. In the **Network Information** section of the **Cluster Information** page, click **Apply for Public Endpoint**.
5. In the **Apply for Public Endpoint** message, click **OK** to obtain a public endpoint.

 **Note** Before you use the public endpoint to access the AnalyticDB for MySQL cluster, you must add the IP address of the device that you use to access the cluster to the whitelist. For more information, see [Configure a whitelist](#).

Release a public endpoint

1. [Log on to the AnalyticDB for MySQL console](#).
2. In the upper-left corner of the page, select the region where the cluster resides.
3. On the Clusters page, click **Cluster ID** corresponding to the cluster for which you want to release a public endpoint.
4. On the **Cluster Information** page, click **Release Public Endpoint**.
5. In the **Release Public Endpoint** message, click **OK** to release the public endpoint.

14.3.8. Synchronize data

To synchronize data in different scenarios, you can use the following data loading solutions provided by AnalyticDB for MySQL:

- Use Kettle to synchronize data from relational databases, NoSQL databases such as HBase, or Microsoft Office Excel or Access to AnalyticDB for MySQL.
- Use external tables to import data from OSS to AnalyticDB for MySQL or export data from AnalyticDB for MySQL to OSS.
- Use the Load Data statement to write local data to AnalyticDB for MySQL.
- If the data already exists in AnalyticDB for MySQL tables, use the `INSERT INTO...SELECT FROM` statement to

synchronize data.

14.4. Connect to a database cluster

14.4.1. Use the MySQL command-line tool to connect to AnalyticDB for MySQL

This topic describes how to use the MySQL command-line tool to connect to an AnalyticDB for MySQL cluster.

Syntax

```
mysql -hadb_url -P3306 -uadb_user -padb_password
```

Parameters

- `adb_url` : the endpoint of the AnalyticDB for MySQL cluster to which you want to connect. You can obtain the endpoint of the cluster in the **Network Information** section of the **Cluster Information** page in the **AnalyticDB for MySQL console**.
- `3306` : the port number of the AnalyticDB for MySQL cluster endpoint. The default port number is `3306` .
- `adb_user` : the account used to connect to the AnalyticDB for MySQL cluster. The account can be a privileged account or a standard account that has the required permissions.
- `adb_password` : the password of the account used to connect to the AnalyticDB for MySQL cluster.

Example

```
mysql -ham-bp****.ads.aliyuncs.com -P3306 -utest -pTest123
```

14.4.2. Use the code in a business system to connect to AnalyticDB for MySQL

14.4.2.1. C#

This topic describes how to use the MySQL Connector/NET connector to connect to an AnalyticDB for MySQL cluster.

```

using System;
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
namespace adbdemo
{
    public class Tutorial2
    {
        public static void Main()
        {
            // server: the endpoint of the AnalyticDB for MySQL cluster to which you want to connect. You can obtain the endpoint on the Cluster Information page of the AnalyticDB for MySQL console.
            // UID: the account used to connect to the AnalyticDB for MySQL cluster. AnalyticDB for MySQL offers the following types of accounts: privileged accounts and standard accounts.
            // database: the name of the database in the AnalyticDB for MySQL cluster.
            // port: the port number of the AnalyticDB for MySQL cluster endpoint.
            // password: the password of the account used to connect to the AnalyticDB for MySQL cluster.
            string connStr = "server=...;UID=...;database=...;port=...;password=...;SslMode=none;";
            MySqlConnection conn = new MySqlConnection(connStr);
            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();
                string sql = "select c_custkey, c_name from customer limit 1";
                MySqlCommand cmd = new MySqlCommand(sql, conn);
                MySqlDataReader rdr = cmd.ExecuteReader();
                while (rdr.Read())
                {
                    Console.WriteLine(rdr[0] + " --- " + rdr[1]);
                }
                rdr.Close();
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }
            conn.Close();
            Console.WriteLine("Done.");
        }
    }
}

```

14.4.2.2. PHP

This topic describes how to connect to an AnalyticDB for MySQL cluster in PHP.

Precautions

- If your operating system is Linux, you must install the php-mysql 5.1.x module.
- If your operating system is Windows, you must install the php_MySQL.dll library.
- For more information about how to enable PreparedStatement if you use PDO to connect to AnalyticDB for MySQL, see Enable PreparedStatement for a client in different programming languages.

Use MySQLi to connect to AnalyticDB for MySQL

```
// am-bp***.ads.aliyuncs.com: the endpoint of the AnalyticDB for MySQL cluster to which you want to connect. You can
obtain the endpoint on the Cluster Information page of the AnalyticDB for MySQL console.
$ads_server_name="am-bp***.ads.aliyuncs.com";
// account_name: the account used to connect to the AnalyticDB for MySQL cluster. AnalyticDB for MySQL offers the fo
llowing types of accounts: privileged accounts and standard accounts.
$ads_username="account_name";
// account_password: the password of the account used to connect to the AnalyticDB for MySQL cluster.
$ads_password="account_password";
// db_name: the name of the database in the AnalyticDB for MySQL cluster.
$ads_database="db_name";
// 3306: the port number of the AnalyticDB for MySQL cluster endpoint.
$ads_port=3306;
// Connect to the AnalyticDB for MySQL cluster.
$ads_conn=mysqli_connect($ads_server_name,$ads_username,$ads_password,$ads_database, $ads_port);
```

```
$strsql="SELECT user_id FROM my_ads_db.my_first_table limit 20;";
$result=mysqli_query($ads_conn, $strsql);
while($row = mysqli_fetch_array($result)) {
// user_id: the name of the column to be queried.
echo $row["user_id"] ;
}
```

Use PDO to connect to AnalyticDB for MySQL

```
// am-bp***.ads.aliyuncs.com: the endpoint of the AnalyticDB for MySQL cluster to which you want to connect. You can
obtain the endpoint on the Cluster Information page of the AnalyticDB for MySQL console.
$ads_server_name = "am-bp***.ads.aliyuncs.com";
// account_name: the account used to connect to the AnalyticDB for MySQL cluster. AnalyticDB for MySQL offers the fo
llowing types of accounts: privileged accounts and standard accounts.
$ads_username = "account_name";
// account_password: the password of the account used to connect to the AnalyticDB for MySQL cluster.
$ads_password = "account_password";
// db_name: the name of the database in the AnalyticDB for MySQL cluster.
$ads_database = 'db_name';
// 3306: the port number of the AnalyticDB for MySQL cluster endpoint.
$ads_port = 3306;
$dsn = "mysql:host={$ads_server_name};dbname={$ads_database};port={$ads_port}";
try {
    $dbh = new PDO($dsn, $ads_username, $ads_password);
    echo 'PDO Success !';
} catch (PDOException $e) {
    echo 'PDO Connection failed: '. $e->getCode() ."\n" . $e->getMessage() ."\n". $e->getTraceAsString();
}
}
```

14.4.2.3. Python

This topic describes how to use Python MySQLdb to connect to an AnalyticDB for MySQL cluster.

```
#!/usr/bin/python
# -*- coding: UTF-8 -*-
import MySQLdb
# Create a database connection.
# host: the endpoint or IP address of the AnalyticDB for MySQL cluster to which you want to connect.
# port: the port number of the AnalyticDB for MySQL cluster endpoint.
# user: the account used to connect to the AnalyticDB for MySQL cluster. AnalyticDB for MySQL offers the following ty
pes of accounts: privileged accounts and standard accounts.
# passwd: the password of the account used to connect to the AnalyticDB for MySQL cluster.
# db: the name of the database in the AnalyticDB for MySQL cluster.
db = MySQLdb.connect(host='am-bp***.ads.aliyuncs.com', port=3306, user='account_name', passwd='account_password'
, db='db_name')
# Use the cursor() method to obtain an operation cursor.
cursor = db.cursor()
# Use the execute() method to execute SQL statements.
cursor.execute("SELECT VERSION()")
# Use the fetchone() method to obtain a data entry.
data = cursor.fetchone()
print "Database version : %s " % data
# Close the database connection.
db.close()
```

14.4.2.4. Druid connection pool

This topic describes how to use the Java Database Connectivity (JDBC) Druid connection pool to connect to an AnalyticDB for MySQL cluster.

Precautions

- When you use the Druid connection pool to connect to an AnalyticDB for MySQL cluster, we recommend that you set `keepAlive` to true. In this way, you can reuse connections and avoid short-lived connections.
- Use Druid 1.1.12 or later.

Configure the Druid connection pool

```
<bean id="dataSource" class="com.alibaba.druid.pool.DruidDataSource" init-method="init" destroy-method="close">
  <!-- jdbc_url: the endpoint of the AnalyticDB for MySQL cluster to which you want to connect. You can obtain the endpoint on the Cluster Information page of the AnalyticDB for MySQL console.-->
  <property name="url" value="{jdbc_url}" />
  <!-- jdbc_user: the account used to connect to the AnalyticDB for MySQL cluster. AnalyticDB for MySQL offers the following types of accounts: privileged accounts and standard accounts.-->
  <property name="username" value="{jdbc_user}" />
  <!-- jdbc_password: the password of the account used to connect to the AnalyticDB for MySQL cluster.-->
  <property name="password" value="{jdbc_password}" />
  <!-- Set the initial size of the connection pool, and the minimum and maximum numbers of connections.-->
  <property name="initialSize" value="5" />
  <property name="minIdle" value="10" />
  <property name="maxActive" value="20" />
  <!-- Set the timeout period for obtaining a connection from the connection pool.-->
  <property name="maxWait" value="60000" />
  <!-- Set the interval for detecting idle connections to be closed. Unit: milliseconds.-->
  <property name="timeBetweenEvictionRunsMillis" value="2000" />
  <!-- Set the minimum validity period of a connection in the connection pool. Unit: milliseconds.-->
  <property name="minEvictableIdleTimeMillis" value="600000" />
  <property name="maxEvictableIdleTimeMillis" value="900000" />
  <property name="validationQuery" value="select 1" />
  <property name="testWhileIdle" value="true" />
  <!-- Specify whether to check the validity of the connection each time you obtain a connection from the connection pool. A value of true indicates that the validity of the connection is checked. A value of false indicates that the validity of the connection is not checked.-->
  <property name="testOnBorrow" value="false" />
  <!-- Specify whether to check the validity of the connection each time you return a connection to the connection pool. A value of true indicates that the validity of the connection is checked. A value of false indicates that the validity of the connection is not checked.-->
  <property name="testOnReturn" value="false" />
  <property name="keepAlive" value="true" />
  <property name="phyMaxUseCount" value="100000" />
  <!-- Set the filters to be used for monitoring statistics.-->
  <property name="filters" value="stat" />
</bean>
```

14.4.2.5. Java

This topic describes how to use MySQL Connector/J to connect to an AnalyticDB for MySQL cluster.

Supported MySQL Connector/J versions

AnalyticDB for MySQL supports the following MySQL Connector/J versions:

- 5.0 series: 5.0.2, 5.0.3, 5.0.4, 5.0.5, 5.0.7, and 5.0.8.
- 5.1 series: 5.1.1, 5.1.2, 5.1.3, 5.1.4, 5.1.5, 5.1.6, 5.1.7, 5.1.8, 5.1.11, 5.1.12, 5.1.13, 5.1.14, 5.1.15, 5.1.16, 5.1.17, 5.1.18, 5.1.19, 5.1.20, 5.1.21, 5.1.22, 5.1.23, 5.1.24, 5.1.25, 5.1.26, 5.1.27, 5.1.28, 5.1.29, 5.1.31, 5.1.32, 5.1.33, and 5.1.34.

Precautions

To create MySQL Connector/J connections in Java, you must add the MySQL Connector/J package to your project. You must add the path of the `mysql-connector-java-x.x.x.jar` file to the value of the `CLASSPATH` variable in your project. Otherwise, you cannot create a MySQL Connector/J connection.

Sample code for creating a MySQL Connector/J connection without retries

To connect to AnalyticDB for MySQL databases through MySQL Connector/J, you can add the following Java code to your business system:

```

Connection connection = null;
Statement statement = null;
ResultSet rs = null;
try {
    Class.forName("com.mysql.jdbc.Driver");
    // adb_url: the endpoint of the AnalyticDB for MySQL cluster to which you want to connect. You can obtain the endpoint on the Cluster Information page of the AnalyticDB for MySQL console. The default port number is 3306.
    // db_name: the name of the database in the AnalyticDB for MySQL cluster.
    String url = "jdbc:mysql://adb_url:3306/db_name? useUnicode=true&characterEncoding=UTF-8";
    Properties connectionProps = new Properties();
    // account_name: the account used to connect to the AnalyticDB for MySQL cluster. AnalyticDB for MySQL offers the following types of accounts: privileged accounts and standard accounts.
    connectionProps.put("user", "account_name");
    // account_password: the password of the account used to connect to the AnalyticDB for MySQL cluster.
    connectionProps.put("password", "account_password");
    connection = DriverManager.getConnection(url, connectionProps);
    statement = connection.createStatement();
    String query = "select count(*) from information_schema.tables";
    rs = statement.executeQuery(query);
    while (rs.next()) {
        System.out.println(rs.getObject(1));
    }
} catch (ClassNotFoundException e) {
    e.printStackTrace();
} catch (SQLException e) {
    e.printStackTrace();
} catch (Exception e) {
    e.printStackTrace();
} finally {
    if (rs != null) {

```

```

if (rs != null) {
    try {
        rs.close();
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
if (statement != null) {
    try {
        statement.close();
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
if (connection != null) {
    try {
        connection.close();
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
}
}

```

Sample code for creating a MySQL Connector/J connection with retries

When you create a MySQL Connector/J connection, you can configure the following parameters to implement a retry mechanism:

```

public static final int MAX_QUERY_RETRY_TIMES = 3;
public static Connection conn = null;
public static Statement statement = null;
public static ResultSet rs = null;
public static void main(String[] args) throws ClassNotFoundException {
    // db_name: the name of the database in the AnalyticDB for MySQL cluster.
    String yourDB = "db_name";
    // account_name: the account used to connect to the AnalyticDB for MySQL cluster. AnalyticDB for MySQL offers the
    following types of accounts: privileged accounts and standard accounts.
    String username = "account_name";
    // account_password: the password of the account used to connect to the AnalyticDB for MySQL cluster.
    String password = "account_password";
    Class.forName("com.mysql.jdbc.Driver");
    // adb_url: the endpoint of the AnalyticDB for MySQL cluster to which you want to connect. You can obtain the endp
    oint on the Cluster Information page of the AnalyticDB for MySQL console. The default port number is 3306.
    String url = "jdbc:mysql://adb_url:3306/" + yourDB + "? useUnicode=true&characterEncoding=UTF-8";
    Properties connectionProps = new Properties();
    connectionProps.put("user", username);
    connectionProps.put("password", password);
    String query = "select id from test4dmp.test limit 10";

```

```

int retryTimes = 0;
// Run automatic retries by using loops.
while (retryTimes < MAX_QUERY_RETRY_TIMES) {
    try {
        getConn(url, connectionProps);
        execQuery(query);// Run a query.
        break; // If the query is run, exit the loop.
    } catch (SQLException e) {
        System.out.println("Met SQL exception: " + e.getMessage() + ", then go to retry task ...");
        try {
            if (conn == null || conn.isClosed()) {
                retryTimes++;
            }
        } catch (SQLException e1) {
            if (conn != null) {
                try {
                    conn.close();
                } catch (SQLException e2) {
                    e.printStackTrace();
                }
            }
        }
    }
}
// Clear connection resource.
closeResource();
}
/**
 * Get connection.
 *
 * @param url
 * @param connectionProps
 * @throws SQLException
 */
public static void getConn(String url, Properties connectionProps) throws SQLException {
    conn = DriverManager.getConnection(url, connectionProps);
}
/**
 * Query task execution logic.
 *
 * @param sql
 * @throws SQLException
 */
public static void execQuery(String sql) throws SQLException {
    Statement statement = null;
    ResultSet rs = null;
    statement = conn.createStatement();
}

```

```
for (int i = 0; i < 10; i++) {
    long startTs = System.currentTimeMillis();
    rs = statement.executeQuery(sql);
    int cnt = 0;
    while (rs.next()) {
        cnt++;
        System.out.println(rs.getObject(1) + " ");
    }
    long endTs = System.currentTimeMillis();
    System.out.println("Elapse Time: " + (endTs - startTs));
    System.out.println("Row count: " + cnt);
    try {
        Thread.sleep(160000);
    } catch (InterruptedException e) {
        e.printStackTrace();
    }
}
/**
 * Close connection resource.
 */
public static void closeResource() {
    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
    if (statement != null) {
        try {
            statement.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
    if (conn != null) {
        try {
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

14.4.3. Enable PreparedStatement for a client in different programming languages

Background information

In most databases, SQL statements can be preprocessed on the server to improve database performance. AnalyticDB for MySQL databases deliver high performance without preprocessing SQL statements on the server side because these databases have the strong query capability, computing power, and plan cache feature.

AnalyticDB for MySQL databases do not support the protocol for preprocessing SQL statements on the server. In most programming languages, you can enable PreparedStatement for a client to prepare statements or interpolate parameters on the client.

This topic describes how to enable PreparedStatement for a client in different programming languages.

MySQL Connector/J (JDBC) driver

You can enable PreparedStatement for the MySQL Connector/J (JDBC) driver when the following condition is met:

`useServerPrepStmts=false` . For more information, visit [Configuration Properties for Connector/J](#).

 **Note** If the `useCursorFetch=true` condition is met, the `useServerPrepStmts=false` condition is overwritten and PreparedStatement cannot be enabled.

MariaDB Connector/J

You can enable PreparedStatement for MariaDB Connector/J if the following condition is met:

`useServerPrepStmts=false` . For more information, visit [About MariaDB Connector/J](#).

Go MySQL driver

You can enable PreparedStatement for the Go MySQL driver if the following condition is met:

`interpolateParams=true` . For more information, visit [go-sql-driver](#).

PDO

You can enable PreparedStatement for PDO if the following condition is met:

`PDO::ATTR_EMULATE_PREPARES=TRUE` . For more information, visit [setAttribute](#).

14.4.4. Use a client to connect to AnalyticDB for MySQL

14.4.4.1. SQL Workbench/J

SQL Workbench/J is a DBMS-independent, cross-platform SQL query tool. This topic describes how to use SQL Workbench/J to connect to an AnalyticDB for MySQL cluster.

Preparations

Before you use SQL Workbench/J, complete the following steps:

- Install the MySQL JDBC driver.
- Install SQL Workbench/J.
- Add the IP address of the device on which SQL Workbench/J is installed to the whitelist of the AnalyticDB for MySQL cluster. For more information, see [Configure a whitelist](#).

Precautions

For more information about how to enable PreparedStatement in SQL Workbench/J, see [Enable PreparedStatement for a client in different programming languages](#).

Procedure

1. Start SQL Workbench/J and choose **File > Manage Drivers....**

 **Note** If you use SQL Workbench/J for the first time, you must add the JDBC driver and its JAR file. When you use SQL Workbench/J later, you can skip step 2.

2. In the **Manage drivers** dialog box that appears, select **MySQL** as the driver, add the JAR file of the driver, and then click **OK**.
3. Choose **File > Connect window**. In the **Select Connection Profile** dialog box that appears, configure the connection parameters as required.

Parameter	Description
New profile	The name of the connection, which facilitates subsequent management.
Driver	The type of the driver. Select MySQL from the drop-down list.
URL	The endpoint of the AnalyticDB for MySQL cluster to which you want to connect, including the endpoint, port number, and database name. The format is <code>jdbc:mysql://hostname:port/name_of_database</code> , where: <ul style="list-style-type: none"> ◦ <code>hostname</code>: the public endpoint or VPC endpoint of the cluster. ◦ <code>port</code>: the port number of the AnalyticDB for MySQL cluster endpoint. The default port number is 3306. ◦ <code>name_of_database</code>: the name of the database in the cluster. This parameter is optional.
Username	The account used to connect to the AnalyticDB for MySQL cluster. You can use either of the following accounts: <ul style="list-style-type: none"> ◦ Privileged accounts. ◦ Standard accounts that have the permissions to connect to the cluster.
Password	The password of the account used to connect to the AnalyticDB for MySQL cluster.

4. After configuring the preceding parameters, click **Test** to test connectivity. After the connection passes the test, click **OK** to connect to the AnalyticDB for MySQL database.

14.4.4.2. DbVisualizer

This topic describes how to use DbVisualizer to connect to an AnalyticDB for MySQL cluster.

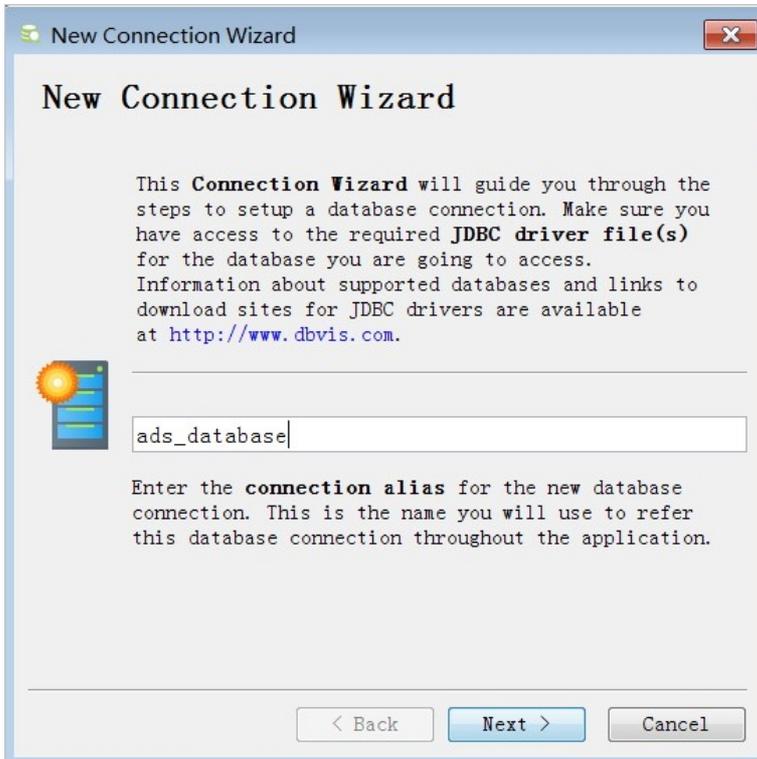

Preparations

Before you use DbVisualizer, complete the following steps:

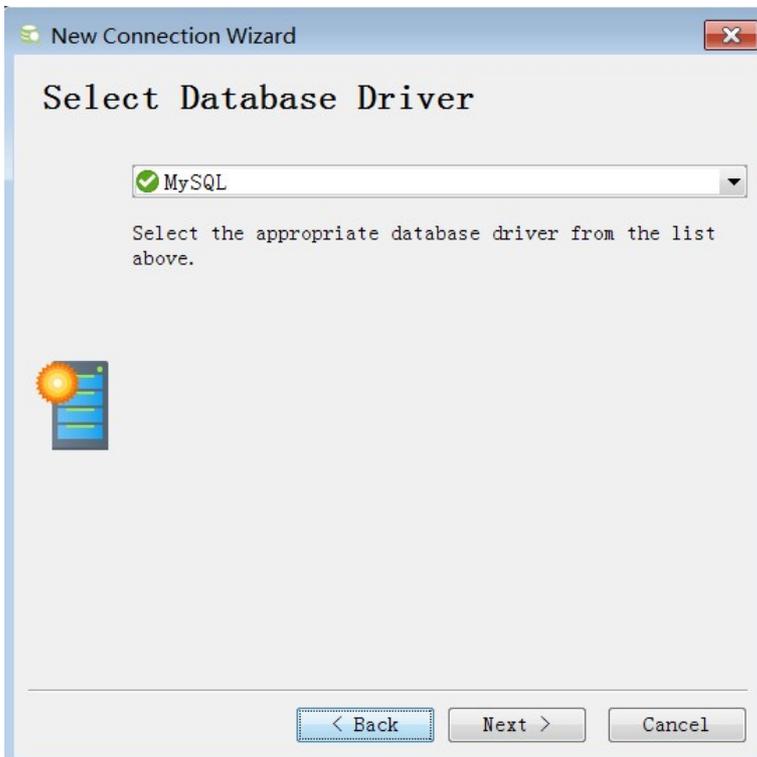

- Install MySQL Connector/J.
- Install DbVisualizer.
- Add the IP address of the device on which DbVisualizer is installed to the whitelist of the AnalyticDB for MySQL cluster. For more information, see [Configure a whitelist](#).

Procedure

1. Start DbVisualizer and choose **Tools > Connection Wizard**. In the **New Connection Wizard** dialog box, enter a name for the connection to facilitate subsequent management.

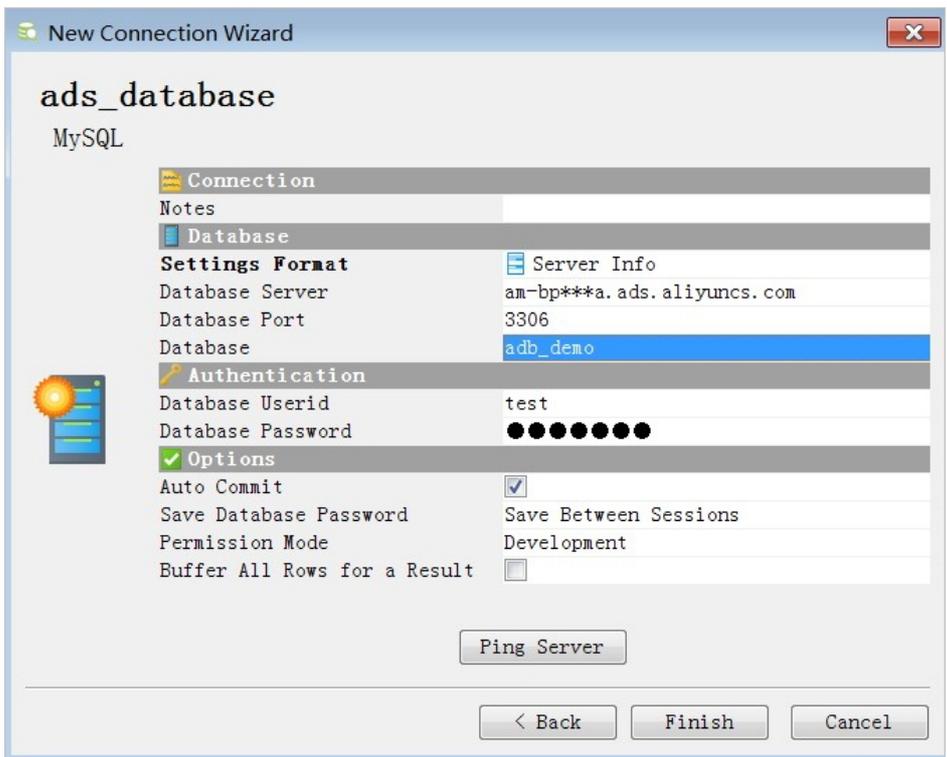

2. Click **Next** and select **MySQL** as the database driver from the drop-down list.

3. Click **Next** and configure the connection parameters.

Parameter	Description
Notes	The description of the connection.
Database Server	The endpoint of the AnalyticDB for MySQL cluster to which you want to connect. You can view the connection information about the cluster on the Cluster Information page of the AnalyticDB for MySQL console.
Database Port	The port number of the AnalyticDB for MySQL cluster endpoint. The default port number is 3306.
Database	The name of the database in the AnalyticDB for MySQL cluster.
Database Userid	The account used to connect to the AnalyticDB for MySQL cluster. You can use one of the following account types: <ul style="list-style-type: none"> ○ Privileged accounts. ○ Standard accounts that have the permissions to connect to the cluster.
Database Password	The password of the account used to connect to the AnalyticDB for MySQL cluster.

4. After you configure the preceding parameters, click **Ping Server** to test connectivity. After the connection passes the test, click **Finish**.

After the AnalyticDB for MySQL cluster is connected, you can use DbVisualizer to manage data.

14.4.4.3. DBeaver

This topic describes how to use DBeaver to connect to an AnalyticDB for MySQL cluster.

Context

DBeaver is a free and open source database management tool distributed under General Public License (GPL). It is designed for developers and database administrators. DBeaver supports databases that are compatible with Java Database Connectivity (JDBC), such as MySQL, PostgreSQL, Oracle, DB2, SQL Server, and Sybase. DBeaver provides a graphical user interface (GUI), on which you can view database schemas, execute SQL statements and scripts, view and export data, and process binary large object (BLOB) or character large object (CLOB) data.

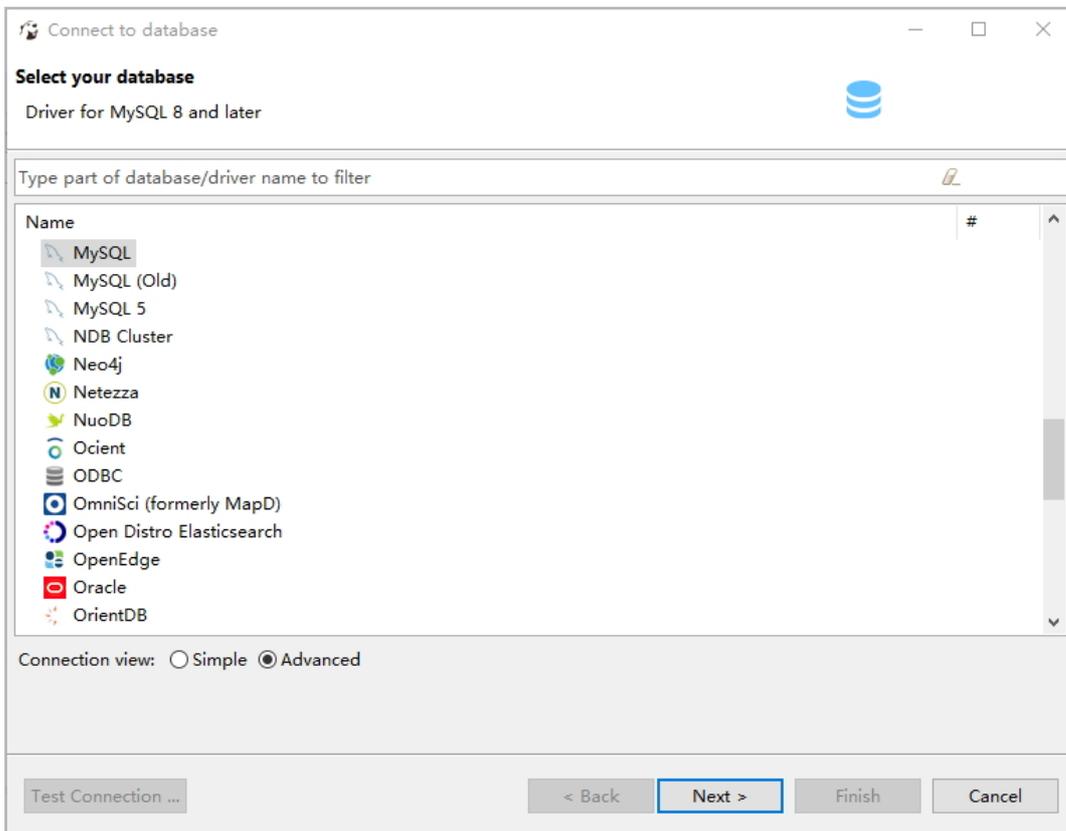

Preparations

Before you use DBeaver, complete the following steps:

- Click [here](#) to download and install DBeaver.
- Install MySQL Connector/J.
- Add the IP address of the device on which DBeaver is installed to the whitelist of the AnalyticDB for MySQL cluster. For more information, see [Configure a whitelist](#).

Procedure

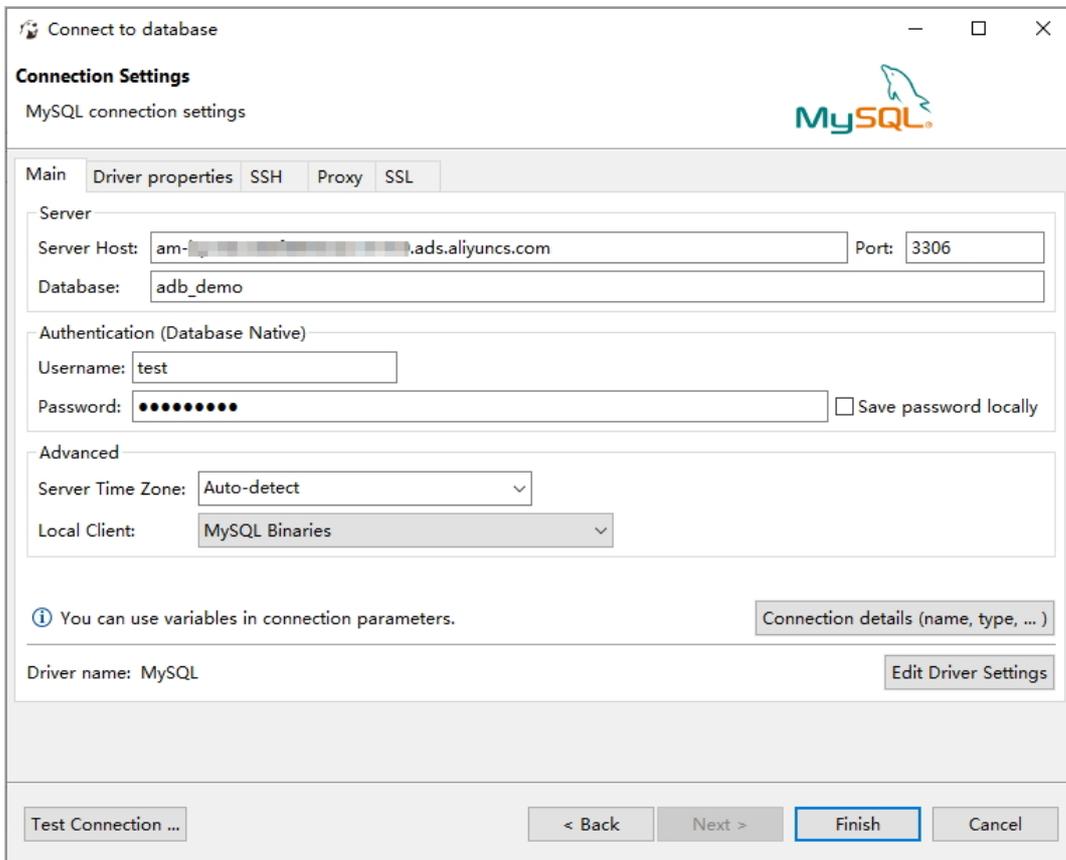

1. Start DBeaver and choose **Database > New Connection**.
2. In the **Create new connection** dialog box, select **MySQL** as the connection type and click **Next**.

3. On the **General** tab of the **Create new connection** dialog box, configure the connection parameters.

Parameter	Description
Server Host	The endpoint of the AnalyticDB for MySQL cluster to which you want to connect. You can view the connection information about the cluster on the Cluster Information page of the AnalyticDB for MySQL console.

Parameter	Description
Port	The port number of the AnalyticDB for MySQL cluster endpoint. The default port number is 3306.
Database	The name of the database in the AnalyticDB for MySQL cluster.
User Name	The account used to connect to the AnalyticDB for MySQL cluster. You can use one of the following account types: <ul style="list-style-type: none"> Privileged accounts. Standard accounts that have the permissions to connect to the cluster.
Password	The password of the account used to connect to the AnalyticDB for MySQL cluster.

- After you configure the preceding parameters, click **Test Connection...**. After the connection passes the test, click **Finish** to connect to the cluster.

14.4.4.4. Navicat

This topic describes how to use Navicat to connect to an AnalyticDB for MySQL cluster.

Context

Navicat is a fast, reliable, and cost-effective database management tool designed to simplify database management and reduce costs. Navicat provides a graphical user interface (GUI) for you to create remote connections from the local computer to AnalyticDB for MySQL clusters and manage data.

Preparations

Before you use Navicat for MySQL, complete the following steps:

- Click [here](#) to download and install Navicat for MySQL.
- Add the IP address of the device on which Navicat for MySQL is installed to the whitelist of the AnalyticDB for MySQL cluster to which you want to connect. For more information, see [Configure a whitelist](#).

Procedure

1. Start Navicat for MySQL and choose **File > New Connection > MySQL**. In the **New Connection** dialog box, configure the connection parameters.

Parameter	Description
Connection Name	The name of the connection. We recommend that you choose an identifiable name to facilitate subsequent management.
Host	The endpoint of the AnalyticDB for MySQL cluster to which you want to connect. You can view the connection information about the cluster on the Cluster Information page of the AnalyticDB for MySQL console.
Port	The port number of the AnalyticDB for MySQL cluster endpoint. The default port number is 3306.
User Name	The account used to connect to the AnalyticDB for MySQL cluster. You can use one of the following account types: <ul style="list-style-type: none"> ◦ Privileged accounts. ◦ Standard accounts that have the permissions to connect to the cluster.
Password	The password of the account used to connect to the AnalyticDB for MySQL cluster.

If your operating system is macOS, add the database name after you configure the connection information.

2. Click **Test Connection**. After the connection passes the test, click **OK**.

The connection to the AnalyticDB for MySQL cluster is created but is not enabled. You must manually enable the connection.

3. Right-click a connection name and select **Open Connection**. Right-click a database name to enable the database connection. Then, you can use Navicat for MySQL to manage data.

14.5. Manage database clusters

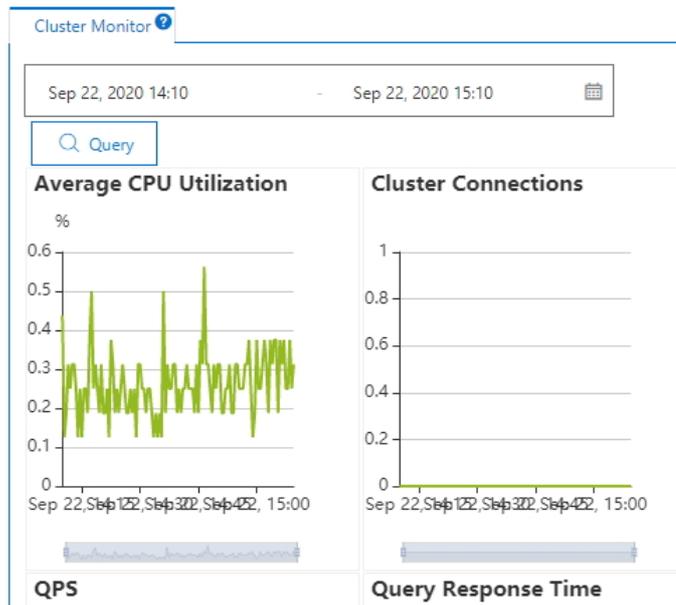

14.5.1. View monitoring information

You can view cluster monitoring information in real time in the AnalyticDB for MySQL console.

Procedure

1. [Log on to the AnalyticDB for MySQL console](#).
2. In the upper-left corner of the page, select the region where the cluster resides.
3. On the Clusters page, click **Cluster ID** corresponding to the cluster for which you want to view monitoring information.
4. In the left-side navigation pane, click **Monitoring Information** to view monitoring information of the cluster.

Monitoring Informat...

The monitoring information includes CPU utilization, cluster connections, QPS, and query response time.

14.5.2. Change specifications

This topic describes how to change the specifications of AnalyticDB for MySQL clusters.

Context

Note You can modify only the number of node groups.

Procedure

1. Log on to the [AnalyticDB for MySQL console](#).
2. In the upper-left corner of the page, select the region where the cluster resides.
3. Click **Change Specifications** in the Actions column corresponding to the cluster.
4. On the **Change Specifications** page, set **Node Groups** and click **Submit**.

14.5.3. Delete a cluster

You can delete AnalyticDB for MySQL clusters.

Procedure

1. Log on to the [AnalyticDB for MySQL console](#).
2. In the upper-left corner of the page, select the region where the cluster resides.
3. Choose **More > Delete** in the Actions column corresponding to the cluster that you want to delete.
4. In the **Delete Cluster** message, click **OK**.

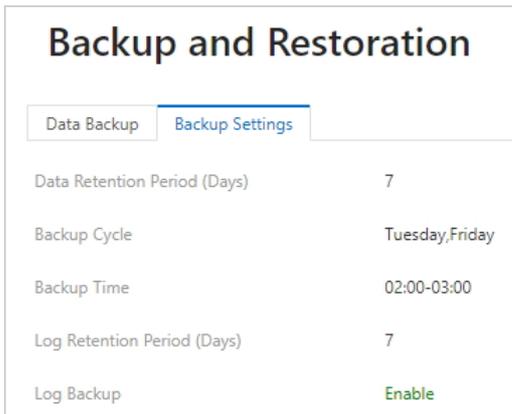

14.6. Backup and restoration

14.6.1. Back up data

AnalyticDB for MySQL uses physical backups (snapshots) to automatically back up data every Tuesday and Friday from 02:00 to 03:00. The backup files are retained for seven days.

Procedure

1. [Log on to the AnalyticDB for MySQL console.](#)
2. In the upper-left corner of the page, select the region where the cluster resides.
3. On the Clusters page, click **Cluster ID** corresponding to the cluster for which you want to back up data.
4. In the left-side navigation pane, click **Backup and Restoration**.
5. Click the **Backup Settings** tab to view the automatic settings.

14.6.2. Restore data

In AnalyticDB for MySQL, the cluster administrator can restore data from backup sets.

14.7. Diagnostics and optimization

14.7.1. Use functions related to slow SQL queries

AnalyticDB for MySQL provides the slow SQL analysis feature. You can view the trends and statistics of slow query logs and obtain diagnostic analysis and suggestions.

Procedure

1. [Log on to the AnalyticDB for MySQL console.](#)
2. In the upper-left corner of the page, select the region where the cluster resides.
3. On the Clusters page, click **Cluster ID** corresponding to the cluster for which you want to view slow query logs.
4. In the left-side navigation pane, click **Query**.

You can use one of the following methods to view slow query logs:

- Slow SQL Trend: displays the trend line chart of the slow query logs.
- Slow SQL Details: displays the detailed data of the slow query logs.

14.8. Account and permission management

14.8.1. Permission model

Permission levels

An AnalyticDB for MySQL cluster supports the following four levels of permission control:

- **GLOBAL** : cluster-level permissions
- **DB** : database-level permissions
- **TABLE** : table-level permissions
- **COLUMN** : column-level (field) permissions

If you want a user to query the data of one specific column in a table, you can grant the **SELECT** permission on the column to the user. Example: `GRANT select (customer_id) ON customer TO 'test321'` .

Operations and corresponding permissions

Operation	Required permission	Supported permission level
SELECT	SELECT	<ul style="list-style-type: none"> • DB • TABLE • COLUMN
INSERT	INSERT	<ul style="list-style-type: none"> • DB • TABLE • COLUMN
INSERT...SELECT...FROM...	<ul style="list-style-type: none"> • INSERT • SELECT 	<ul style="list-style-type: none"> • DB • TABLE • COLUMN
UPDATE	UPDATE	<ul style="list-style-type: none"> • DB • TABLE • COLUMN
DELETE	DELETE	<ul style="list-style-type: none"> • DB • TABLE
TRUNCATE TABLE	DROP	<ul style="list-style-type: none"> • DB • TABLE
ALTER TABLE	<ul style="list-style-type: none"> • ALTER • INSERT • CREATE 	<ul style="list-style-type: none"> • DB • TABLE
CREATE DATABASE	CREATE	N/A
CREATE TABLE	CREATE	<ul style="list-style-type: none"> • DB • TABLE
SHOW CREATE TABLE	SELECT	<ul style="list-style-type: none"> • DB • TABLE
DROP DATABASE	DROP	DB

Operation	Required permission	Supported permission level
DROP TABLE	DROP	<ul style="list-style-type: none"> DB TABLE
CREATE VIEW	<ul style="list-style-type: none"> CREATE_VIEW SELECT 	<ul style="list-style-type: none"> DB TABLE <p>To execute the <code>CREATE VIEW REPLACE</code> statement, the DROP permission is also required in addition to the preceding permissions.</p>
DROP VIEW	DROP	<ul style="list-style-type: none"> DB TABLE
SHOW CREATE VIEW	<ul style="list-style-type: none"> SHOW_VIEW SELECT 	<ul style="list-style-type: none"> DB TABLE
CREATE_PROCEDURE	CREATE_ROUTINE	N/A
DROP_PROCEDURE	ALTER_ROUTINE	N/A
CREATE_EVENT	EVENT	N/A
DROP_EVENT	EVENT	N/A
CREATE USER/DROP USER/RENAME USER	CREATE_USER	N/A
SET PASSWORD	SUPER	N/A
GRANT/REVOKE	GRANT	N/A

14.8.2. Manage database accounts and permissions

- For more information about how to create a RAM user, see `CREATE USER`.
- For more information about how to grant permissions to a RAM user, see `GRANT`.
- For more information about how to revoke the permissions of a RAM user, see `REVOKE`.
- For more information about how to modify the name of a database account, see `RENAME USER`.
- For more information about how to delete a database account, see `DROP USER`.

14.9. Data visualization

14.9.1. Tableau

This topic describes how to use Tableau to connect to an AnalyticDB for MySQL cluster and perform data analytics and visualization.

Preparations

Before you use Tableau, complete the following steps:

- Install the MySQL Open Database Connectivity (ODBC) driver. We recommend that you use MySQL Connector/ODBC 3.5.1 or 5.3.
- Install Tableau 9.0 or later.

Procedure

1. Start Tableau and click **MySQL** in the left-side navigation pane to create a MySQL connection. In the MySQL dialog box, configure the connection parameters.

Parameter	Description
Server	The endpoint of the AnalyticDB for MySQL cluster to which you want to connect.
Port	The port number of the AnalyticDB for MySQL cluster endpoint.
User Name	The account used to connect to the AnalyticDB for MySQL cluster. You can use one of the following account types: <ul style="list-style-type: none"> ◦ Privileged accounts. ◦ Standard accounts that have the permissions to connect to the cluster.
Password	The password of the account used to connect to the AnalyticDB for MySQL cluster.

2. After you configure the preceding parameters, click **Log On** to connect to the AnalyticDB for MySQL cluster.

Use Tableau

In Tableau, you can view the databases on which you have permissions. After you select a database, you can read tables, preview data, and generate visual reports. For more information about how to use Tableau, visit [Tableau](#).

14.9.2. QlikView

This topic describes how to use QlikView to connect to an AnalyticDB for MySQL cluster and build a business intelligence (BI) system.

Preparations

Before you use QlikView, complete the following steps:

- Install the MySQL Open Database Connectivity (ODBC) driver. We recommend that you use MySQL Connector/ODBC 3.5.1 or 5.3.
- Install QlikView 11.20.x.

Procedure

1. On the host where QlikView is installed, click **Control Panel**, and choose **System and Security > Administrative Tools > ODBC Data Sources**. This path may vary with different operating systems. In the ODBC Data Source Administrator dialog box, add a system data source name (DSN) and select **MySQL ODBC 5.xx Driver** as the data source.

Parameter	Description
Data Source Name	The name of the database in the AnalyticDB for MySQL cluster.

Parameter	Description
TCP/IP Server	The endpoint of the AnalyticDB for MySQL cluster to which you want to connect.
Port	The port number of the AnalyticDB for MySQL cluster endpoint.
User	The account used to connect to the AnalyticDB for MySQL cluster. You can use one of the following account types: <ul style="list-style-type: none"> Privileged accounts. Standard accounts that have the permissions to connect to the cluster.
Password	The password of the account used to connect to the AnalyticDB for MySQL cluster.

- After you configure the preceding parameters, click **Test** to test connectivity. After the connection passes the test, click **OK** to create the ODBC connection.
- Start QlikView and choose **File > Edit Script**. Select the database name specified in Step 1 to test connectivity.
- After the database passes the connectivity test, you can use the following **SELECT** statement to obtain the data in the AnalyticDB for MySQL database:

```
SELECT * FROM DATABASE_NAME.TABLE_NAME;
```

For example, use the following statement to obtain data from the user_info table:

```
SELECT * FROM adb_database.user_info;
```

Use QlikView

After you obtain data from AnalyticDB for MySQL databases, you can use QlikView to perform more operations. For more information about how to use QlikView, visit [QlikView](#).

14.9.3. FineReport

This topic describes how to use FineReport to connect to an AnalyticDB for MySQL cluster and manage reports.

Preparations

Before you use FineReport, complete the following steps:

- Install MySQL Connector/J.
- Install FineReport.

Procedure

- Start FineReport and choose **Server > Define Data Connection**.
- In the **Define Data Connection** dialog box, configure the parameters.

Parameter	Description
Database	The type of the database. Select MySQL from the drop-down list.
Driver	The type of the driver. Select MySQL JDBC driver from the drop-down list.

Parameter	Description
URL	<p>The connection string of the AnalyticDB for MySQL cluster to which you want to connect. The format is <code>jdbc:mysql://hostname:port</code>.</p> <ul style="list-style-type: none"> <code>hostname</code>: the public or VPC endpoint of the cluster. <code>port</code>: the port number of the AnalyticDB for MySQL cluster endpoint. The default port number is 3306.
User Name	<p>The account used to connect to the AnalyticDB for MySQL cluster. You can use one of the following account types:</p> <ul style="list-style-type: none"> Privileged accounts. Standard accounts that have the permissions to connect to the cluster.
Password	<p>The password of the account used to connect to the AnalyticDB for MySQL cluster.</p>

- After you configure the preceding parameters, click **Test Connection**. After the connection passes the test, click **Confirm** to the AnalyticDB for MySQL cluster.

Use FineReport

After FineReport is connected to the AnalyticDB for MySQL cluster, you can obtain the data in AnalyticDB for MySQL databases and use FineReport to generate reports. For more information about how to use FineReport, visit [FineReport](#).

14.10. Data migration and synchronization

14.10.1. Use Kettle to synchronize local data to AnalyticDB for MySQL

This topic describes how to use Kettle to synchronize local data to AnalyticDB for MySQL. Excel data is used in the example.

Background information

Kettle is a popular open source extract-transform-load (ETL) tool used for data collection, conversion, and migration. Kettle supports not only various relational databases and NoSQL databases such as HBase and MongoDB, but also niche data sources such as Microsoft Office Excel and Access. Kettle can support more data sources by using extensions and plug-ins.

For more information, visit [Kettle](#).

Preparations

Before you use Kettle, complete the following steps:

- Click [here](#) to download and install Kettle.
- Create a database and a table in an AnalyticDB for MySQL cluster.

For more information about how to create databases and tables, see [Create a database](#) and [CREATE TABLE](#).

- Add the IP address of the device on which Kettle is installed to the whitelist of the AnalyticDB for MySQL cluster. For more information, see [Configure a whitelist](#).

Procedure

1. Start Kettle, and choose **File > New > Conversion** to create a conversion task.
2. Choose **File > New > Database Connection** to create a database connection for the conversion task.

Parameter	Description
Connection Name	The name of the connection. We recommend that you choose an identifiable name, which facilitates subsequent management.
Connection Type	The type of the connection. Select MySQL from the drop-down list.
Access	The access mode of the connection. Select Native (JDBC) .
Host Name	The endpoint of the AnalyticDB for MySQL cluster to which you want to connect. You can view the connection information about the cluster on the Cluster Information page of the AnalyticDB for MySQL console.
Database Name	The name of the database in the AnalyticDB for MySQL cluster.
Port Number	The port number of the AnalyticDB for MySQL cluster endpoint. The default port number is 3306.
User Name	The account used to connect to the AnalyticDB for MySQL cluster. You can use one of the following account types: <ul style="list-style-type: none"> ◦ Privileged accounts. ◦ Standard accounts that have the permissions to connect to the cluster.
Password	The password of the account used to connect to the AnalyticDB for MySQL cluster.

 **Note** Do not select **Use Result Streaming Cursor** when you configure the parameters.

3. After you configure the preceding parameters, click **Test**. In the **Database Connection Test** dialog box, follow the prompts to verify if the connection to the database is successful. After the connection passes the test, click **OK**.
4. In the left-side navigation pane of Kettle, click the **Core objects** tab, and choose **Input > Excel Input**. Drag and drop **Excel Input** to the workspace.
5. Double-click **Excel Input** in the workspace. In the **Excel Input** dialog box, click **Browse** and **Add** to add an Excel file to **Selected Files**.
Configure parameters on tabs such as **Worksheet**, **Content**, and **Field**, and click **Preview** to check whether the specified values meet your requirements.
6. In the left-side navigation pane of Kettle, click the **Core objects** tab, and choose **Output > Table Output**. Drag and drop **Table Output** to the workspace.
7. Add a connection line from **Excel Input** to **Table Output**.
8. Double-click **Table Output** in the workspace. In the **Table Output** dialog box, configure the parameters.
 - **Target Schema**: Enter the name of the AnalyticDB for MySQL database.
 - **Target Table**: Enter the name of the table in the AnalyticDB for MySQL database.

- Select **Specify database fields**.
- Select **Use batch update for inserts**.

On the Database fields tab of the **Table Output** dialog box, click **Get fields** and **Enter field mapping** to map columns in the Excel file to those in the AnalyticDB for MySQL table.

9. Click the white arrow to perform the conversion. During this period, you can check the operation logs and operating statuses.

After the data in the Excel file is synchronized to the AnalyticDB for MySQL database, you can use AnalyticDB for MySQL to analyze the data.

14.11. SQL manual

14.11.1. Data types

Data types supported by AnalyticDB for MySQL

Keyword	Data type	Valid value
BOOLEAN	The Boolean type	Valid values: <code>0</code> and <code>1</code> . A value of <code>0</code> indicates false. A value of <code>1</code> indicates true. A BOOLEAN value is 1 bit in size.
TINYINT	The tiny integer type	Valid values: <code>-128 to 127</code> . A TINYINT value is 1 byte in size.
SMALLINT	The small integer type	Valid values: <code>-32768 to 32767</code> . A SMALLINT value is 2 bytes in size.
INT or INTEGER	The integer type	Valid values: <code>-2147483648 to 2147483647</code> . An INT value is 4 bytes in size.
BIGINT	The big integer type	Valid values: <code>-9223372036854775808 to 9223372036854775807</code> . A BIGINT value is 8 bytes in size.
FLOAT	The single-precision floating-point type	Valid values: <code>-3.402823466E+38 to -1.175494351E-38</code> , <code>0</code> , and <code>1.175494351E-38 to 3.402823466E+38</code> . The FLOAT type follows the IEEE standard. A FLOAT value is 4 bytes in size.
DOUBLE	The double-precision floating-point type	Valid values: <code>-1.7976931348623157E+308 to -2.2250738585072014E-308</code> , <code>0</code> , and <code>2.2250738585072014E-308 to 1.7976931348623157E+308</code> . The DOUBLE type follows the IEEE standard. A DOUBLE value is 8 bytes in size.

Keyword	Data type	Valid value
DECIMAL(M,D)	The decimal type	M is the maximum precision, and its value range is 1 to 1000. D is the decimal scale. The value of D must be less than or equal to that of M.
VARCHAR	The variable-length string type	A VARCHAR value can be up to 16 MB in size. You do not need to specify the size when you use VARCHAR.
DATE	The date type	Valid values: '0001-01-01' to '9999-12-31'. A DATE value is in the 'YYYY-MM-DD' format and is 4 bytes in size.
TIME	The time type	Valid values: '00:00:00' to '23:59:59'. A TIME value is in the 'HH:MM:SS' format and is 8 bytes in size.
DATETIME	The date and time type	Valid values: '0001-01-01 00:00:00.000' to '9999-12-31 23:59:59.999'. A DATETIME value is in the 'YYYY-MM-DD HH:MM:SS' format. It is 8 bytes in size and in the UTC format.  Note DATETIME uses UTC time. You cannot change the time zone for DATETIME values.
TIMESTAMP	The timestamp type	Valid values: '0001-01-01 00:00:00.000' to '9999-12-31 23:59:59.999'. A TIMESTAMP value is in the 'YYYY-MM-DD HH:MM:SS' format. It is 4 bytes in size and in the UTC format.  Note TIMESTAMP uses the time zone of the database system by default. You can specify the time zone for each session.

Comparison with MySQL data types

AnalyticDB for MySQL	MySQL	Difference
BOOLEAN	BOOL and BOOLEAN	No difference.

AnalyticDB for MySQL	MySQL	Difference
TINYINT	TINYINT	No difference.
SMALLINT	SMALLINT	No difference.
INT and INTEGER	INT and INTEGER	No difference.
BIGINT	BIGINT	No difference.
FLOAT	FLOAT[(M,D)]	No difference.
DOUBLE	DOUBLE[(M,D)]	No difference.
DECIMAL	DECIMAL	AnalyticDB for MySQL supports a maximum precision of 1,000 digits, while MySQL supports a maximum precision of only 65 digits.
VARCHAR	VARCHAR	The VARCHAR type in AnalyticDB for MySQL corresponds to the CHAR, VARCHAR, TEXT, MEDIUMTEXT, and LONGTEXT types in MySQL.
DATE	DATE	MySQL supports the value 0000-00-00, whereas AnalyticDB for MySQL automatically converts the value 0000-00-00 to NULL.
TIME	TIME	AnalyticDB for MySQL is precise to the millisecond. MySQL supports custom precision levels.
DATETIME	DATETIME	MySQL supports the value 0000-00-00 00:00:00, whereas AnalyticDB for MySQL automatically converts the value 0000-00-00 00:00:00 to NULL. AnalyticDB for MySQL is precise to the millisecond. MySQL supports custom precision levels.
TIMESTAMP	TIMESTAMP	AnalyticDB for MySQL is precise to the millisecond. MySQL supports custom precision levels.

14.11.2. Data definition statements

14.11.2.1. CREATE DATABASE

Create a database

 **Note** You can create up to 256 databases in each AnalyticDB for MySQL cluster.

Syntax

```
CREATE DATABASE [IF NOT EXISTS] db_name
```

Parameters

`db_name` : the name of the database. The database name can be up to 64 characters in length, and can contain letters, digits, and underscores (_). It must start with a lowercase letter and cannot contain consecutive underscores (_).

 **Note** Do not use `analyticdb` as the database name. The name `analyticdb` is reserved for a built-in database.

Example

```
CREATE DATABASE adb_demo;
```

Use a database

You can execute the `USE db_name` statement to use a database after it is created.

Syntax

```
USE db_name
```

Example

```
use adb_demo;
show tables;
+-----+
|Tables_in_adb_demo      |
+-----+
|customer                |
|test_table               |
```

14.11.2.2. CREATE TABLE

You can execute the `CREATE TABLE` statement to create a table in AnalyticDB for MySQL.

Syntax

```
CREATE TABLE [IF NOT EXISTS] table_name
({column_name column_type [column_attributes] [ column_constraints ] [COMMENT 'string']
| table_constraints}
[, ... ] )
table_attribute
[partition_options]
[AS] query_expression
COMMENT 'string'
```

column_attributes:
 [DEFAULT default_expr]
 [AUTO_INCREMENT]

column_constraints:
 [{(NOT NULL|NULL)}]
 [PRIMARY KEY]

table_constraints:
 [{(INDEX|KEY) [index_name] (column_name,...)}]
 [PRIMARY KEY [index_name] (column_name,...)]
 [CLUSTERED KEY [index_name] (column_name,...)]

table_attribute:
 DISTRIBUTED BY HASH(column_name,...) | DISTRIBUTED BY BROADCAST

partition_options:
 PARTITION BY
 {VALUE(column_name) | VALUE(date_format(column_name, ?))}
 [LIFECYCLE N]

Parameters

Parameter	Description
table_name	<p>The name of the table.</p> <p>The table name must be 1 to 127 characters in length, and can contain letters, digits, and underscores (_). The table name must start with a letter or underscore (_).</p> <p>Specify the table name in the db_name.table_name format to distinguish tables that have the same name across different databases.</p>
column_name	<p>The name of the column.</p> <p>The column name must be 1 to 127 characters in length and can contain letters, digits, and underscores (_). The table name must start with a letter or underscore (_).</p>

Parameter	Description
<code>column_type</code>	<p>The data type of the column to be added.</p> <p>For more information about the data types supported by AnalyticDB for MySQL, see Data types.</p>
<code>column_attributes</code>	<ul style="list-style-type: none"> <code>DEFAULT default_expr</code> : the default value of the column. Enter an expression without variables, such as <code>current_timestamp</code> . <p>If this parameter is not specified, the default value is NULL.</p> <ul style="list-style-type: none"> <code>AUTO_INCREMENT</code> : optional. Specifies whether the column is an auto-increment column. The data type of an auto-increment column must be BIGINT. This is because AnalyticDB for MySQL provides unique values for an auto-increment column, but these values are not incremented in sequence.
<code>column_constraints</code>	<ul style="list-style-type: none"> <code>NOT NULL NULL</code> : specifies whether the column accepts the NULL value. A value of <code>NOT NULL</code> indicates that the column does not accept the <code>NULL</code> value. A value of <code>NULL</code> indicates that the column accepts the <code>NULL</code> value. Default value: NULL. <code>PRIMARY KEY</code> : the primary key of the column. You can define multiple primary keys in the <code>PRIMARY KEY(column_name [, ...])</code> format.
<code>table_constraints</code>	<p><code>INDEX KEY</code> : the inverted index.</p> <p>AnalyticDB for MySQL automatically creates indexes for whole tables. You do not need to manually create an index.</p>
<code>PRIMARY KEY</code>	<p>The index for the primary keys.</p> <ul style="list-style-type: none"> Only tables with primary keys support the DELETE and UPDATE operations. The primary keys must include the partition key. We recommend that you put the partition key before the primary key combination.
<code>CLUSTERED KEY</code>	<p>The clustered index. It defines the columns used for sorting data in the table. The logical order of the key values in the clustered index determines the physical order of the corresponding rows in the table. You can add only one clustered index for each table.</p> <p>For example, <code>clustered key col5_col6_cls_index(col5,col6)</code> specifies the <code>col5 col6</code> clustered index. <code>col5 col6</code> and <code>col6 col5</code> are different clustered indexes.</p>

Parameter	Description
<code>DISTRIBUTED BY HASH(column_name,...)</code>	<p>The distribution key of the fact table. The data of the table is distributed based on the hash value of the columns specified by <code>column_name</code> .</p> <p>AnalyticDB for MySQL allows you to select multiple fields as the partition key.</p>
<code>DISTRIBUTED BY BROADCAST</code>	<p>The dimension table. The dimension table is stored on each node of a cluster. For performance reasons, we recommend that you do not store large amounts of data in the dimension table.</p>
<code>partition_options</code>	<p>The options for fact table partitions.</p> <p>AnalyticDB for MySQL manages the lifecycle of tables based on the <code>LIFECYCLE N</code> parameter. That is, AnalyticDB for MySQL only stores N number of partitions. All other partitions are deleted.</p> <p>For example, <code>PARTITION BY VALUE(column_name)</code> specifies that the table is partitioned based on the column specified by <code>column_name</code> . <code>PARTITION BY VALUE(DATE_FORMAT(column_name, '%Y%m%d'))</code> specifies that the table is partitioned based on the column specified by <code>column_name</code> after the column is formatted to a date format such as <code>20190101</code> .</p> <p><code>LIFECYCLE 365</code> specifies that a maximum of 365 partitions can be retained on each node. That is, only data of the last 365 days is stored. When you write data on the 366th day, the data from the first day is deleted.</p>

Precautions

- AnalyticDB for MySQL clusters use the UTF-8 encoding format during table creation. This encoding format is equivalent to the utf8mb4 format in MySQL. AnalyticDB for MySQL does not support other encoding formats.
- You can create up to `256 × Number of node groups` tables in an AnalyticDB for MySQL cluster.

Examples

- Create a test table.

```
create table test (
  id bigint auto_increment,
  name varchar,
  value int,
  ts timestamp
)
DISTRIBUTED BY HASH(id)
```

The test table is a fact table. The `id` column is an auto-increment column. The distribution key is `id`. The data of the table is distributed based on the hash value of the `id` column.

- Create a customer table.

```
CREATE TABLE customer (
  customer_id bigint NOT NULL COMMENT 'Customer ID',
  customer_name varchar NOT NULL COMMENT 'Customer name',
  phone_num bigint NOT NULL COMMENT 'Phone number',
  city_name varchar NOT NULL COMMENT 'City',
  sex int NOT NULL COMMENT 'Gender',
  id_number varchar NOT NULL COMMENT 'ID card number',
  home_address varchar NOT NULL COMMENT 'Home address',
  office_address varchar NOT NULL COMMENT 'Office address',
  age int NOT NULL COMMENT 'Age',
  login_time timestamp NOT NULL COMMENT 'Logon time',
  PRIMARY KEY (login_time,customer_id,phone_num)
) DISTRIBUTED BY HASH(customer_id)
PARTITION BY VALUE(DATE_FORMAT(login_time, '%Y%m%d')) LIFECYCLE 30
COMMENT 'Customer information table';
```

The customer table is a fact table. In the table, the distribution key is `customer_id`. The partition key is `login_time`. `login_time`, `customer_id`, and `phone_num` form the primary key combination.

14.11.2.3. ALTER TABLE

You can execute the ALTER TABLE statement to modify a table.

 **Note** You cannot modify the data type of a column in AnalyticDB for MySQL.

Syntax

```
ALTER TABLE table_name
  ADD COLUMN (column_name column_definition,...)
| ADD {INDEX|KEY} [index_name] (column_name,...)
| ADD CLUSTERED [INDEX|KEY] [index_name] (column_name,...)
| DROP COLUMN column_name
| DROP {INDEX|KEY} index_name
| DROP CLUSTERED [INDEX|KEY] index_name
| MODIFY COLUMN column_name column_definition
| RENAME new_table_name
| TRUNCATE PARTITION {partition_names | ALL}
```

Add a column

Syntax

```
ALTER TABLE db_name.table_name ADD column_name data_type;
```

Example

Add the `province` column of the `VARCHAR` type to the customer table.

```
ALTER TABLE adb_demo.customer ADD COLUMN province varchar comment 'Province';
```

Delete a column

Syntax

```
ALTER TABLE db_name.table_name DROP column_name data_type;
```

Example

Delete the `province` column of the `VARCHAR` type from the customer table.

Modify the comments of a column

Syntax

```
ALTER TABLE db_name.table_name MODIFY COLUMN column_name data_type comment 'new_comment';
```

Example

Modify the `COMMENT` of the `province` column to the province where the customer locates in the customer table.

```
ALTER TABLE adb_demo.customer MODIFY COLUMN province varchar comment 'Province where the customer locates';
```

Change the value constraint for a column from NOT NULL to NULL

 **Note** You can change the value constraint only from NOT NULL to NULL, but not from NULL to NOT NULL.

Syntax

```
ALTER TABLE db_name.table_name MODIFY COLUMN column_name data_type {NULL}
```

Example

Change the value of the `province` column to `NULL` in the customer table.

```
ALTER TABLE adb_demo.customer MODIFY COLUMN province varchar NULL;
```

Change the default value of a column**Syntax**

```
ALTER TABLE db_name.table_name MODIFY COLUMN column_name data_type DEFAULT 'default'
```

Example

Change the default value of the `sex` column to `0` (indicating male) in the customer table.

```
ALTER TABLE adb_demo.customer MODIFY COLUMN sex int(11) NOT NULL DEFAULT 0;
```

Add a clustered index

 **Note** You can add only one clustered index for each table.

Syntax

```
ALTER TABLE db_name.table_name ADD CLUSTERED KEY index_name(column_name1,column_name2);
```

```
ALTER TABLE db_name.table_name ADD CLUSTERED KEY index_name(column_name1);
```

Example

Create a clustered index for the `customer_id` and `id_number` columns in the customer table.

```
ALTER TABLE adb_demo.customer ADD CLUSTERED KEY c_k(customer_id, id_number);
```

Delete a clustered index**Syntax**

```
ALTER TABLE db_name.table_name DROP CLUSTERED KEY index_name;
```

Example

Delete the clustered index of the customer table.

```
ALTER TABLE adb_demo.customer DROP CLUSTERED KEY c_k;
```

14.11.2.4. CREATE VIEW

You can execute the `CREATE VIEW` statement to create a view.

Syntax

```
CREATE VIEW view_name AS select_stmt
```

Parameters

- `view_name` : the name of the view to create. You can prefix the view name with the database name to distinguish views with the same name in different databases.
- `select_stmt` : the data source of the view.

Example

Create a view named `v` and set its data source to the `customer` table.

```
CREATE VIEW adb_demo.v AS SELECT * FROM customer;
```

14.11.2.5. DROP DATABASE

You can execute the `DROP DATABASE` statement to delete a database.

Syntax

```
DROP DATABASE db_name;
```

 **Note** Before you delete a database, you must first delete the tables in the database.

Example

```
use adb_demo2;
+-----+
show tables;
+-----+
|Tables_in_adb_demo2  |
+-----+
| test2                |
+-----+
drop table test2;
drop database adb_demo2;
```

14.11.2.6. DROP TABLE

You can execute the `DROP TABLE` statement to delete a table.

Syntax

```
DROP TABLE db_name.table_name;
```

 **Note** When you execute this statement, both the table data and schema are deleted.

Example

```
DROP TABLE adb_demo.customer;
```

14.11.2.7. DROP VIEW

You can execute the DROP VIEW statement to delete a view.

Syntax

```
DROP VIEW [IF EXISTS] view_name, [, view_name] ...
```

Parameters

`view_name` : the name of the view to delete. You can prefix the view name with the database name to distinguish views with the same name in different databases.

Example

Delete the view named v.

```
DROP VIEW v;
```

14.11.3. Data manipulation statements

14.11.3.1. INSERT INTO

You can execute the `INSERT INTO` statement to insert data to a table. If a primary key is the same as an existing one in the records, the new record is not inserted. This statement is equivalent to the `INSERT IGNORE INTO` statement.

Syntax

```
INSERT [IGNORE]
  INTO table_name
  [( column_name [, ...] )]
  [VALUES]
  [(value_list[, ...])]
  [query];
```

Parameters

- `IGNORE` : optional. Specifies that a new record is not inserted if the primary key of the record is the same as that of an existing record.
- `column_name` : optional. The name of the column.
- `query` : inserts one or more records queried from another table to this table.

Precautions

If the column names are not specified, the sequence of the columns in the data to be inserted must be the same as that specified in the CREATE TABLE statement.

Example

Create the customer and courses tables.

```
CREATE TABLE customer (
  customer_id bigint NOT NULL COMMENT 'Customer ID',
  customer_name varchar NOT NULL COMMENT 'Customer name',
  phone_num bigint NOT NULL COMMENT 'Phone number',
  city_name varchar NOT NULL COMMENT 'City',
  sex int NOT NULL COMMENT 'Gender',
  id_number varchar NOT NULL COMMENT 'ID card number',
  home_address varchar NOT NULL COMMENT 'Home address',
  office_address varchar NOT NULL COMMENT 'Office address',
  age int NOT NULL COMMENT 'Age',
  login_time timestamp NOT NULL COMMENT 'Logon time',
  PRIMARY KEY (login_time,customer_id,phone_num)
)DISTRIBUTED BY HASH(customer_id)
PARTITION BY VALUE(DATE_FORMAT(login_time, '%Y%m%d')) LIFECYCLE 30
COMMENT 'Customer information table';
```

```
CREATE TABLE courses(
  id bigint AUTO_INCREMENT PRIMARY KEY,
  name varchar(20) NOT NULL,
  grade varchar(20) default 'Grade 3',
  submission_date timestamp)DISTRIBUTED BY HASH(id)
```

- Insert a record to the customer table.

```
INSERT INTO customer(customer_id,customer_name,phone_num,city_name,sex,id_number,home_address,office_address,age,login_time)
values
(002367,'Alan','13678973421','Hangzhou',0,'987300','West Lake','Cloud Town',23,'2018-03-02 10:00:00');
```

- Insert multiple records to the customer table.

```
INSERT INTO customer(customer_id,customer_name,phone_num,city_name,sex,id_number,home_address,office_address,age,login_time)
values
customer values(002367,'Tom','13678973421','Hangzhou',0,'987300','West Lake','Cloud Town',23,'2018-03-02 10:00:00'),(
002368,'Alex','13878971234','Hangzhou',0,'987300','West Lake','Cloud Town',28,'2018-08-01 11:00:00'),(002369,'Eric','1396
8075284','Hangzhou',1,'987300','West Lake','Cloud Town',35,'2018-09-12 08:11:00');
```

- Insert multiple records to the customer table without specifying the column names.

```
INSERT INTO customer
values(002367,'Tom','13678973421','Hangzhou',0,'987300','West Lake','Cloud Town',23,'2018-03-02 10:00:00'),(002368,'Al
ex','13878971234','Hangzhou',0,'987300','West Lake','Cloud Town',28,'2018-08-01 11:00:00'),(002369,'Eric','13968075284','H
angzhou',1,'987300','West Lake','Cloud Town',35,'2018-09-12 08:11:00');
```

- Insert a record to the courses table.

```
insert into courses (name,submission_date) values("Jams",NOW());
```

14.11.3.2. REPLACE INTO

You can execute the `REPLACE INTO` statement to insert data to a table by overwriting the existing data in real time. The system first checks whether the primary key of a record to be inserted is the same as that of an existing record. If they are the same, the system deletes the existing record and inserts the new record. Otherwise, the system only inserts the new record.

Syntax

```
REPLACE INTO table_name [(column_name,...)] VALUES ((Constant|NULL|DEFAULT),...),(...),...
```

Example

- Insert a record to the customer table by specifying the column names in the `REPLACE INTO` statement.

```
REPLACE INTO customer(customer_id,customer_name,phone_num,city_name,sex,id_number,home_address,office_address,age,login_time) values (002367,'Alan','13678973421','Hangzhou','0','987300','West Lake','Cloud Town','23','2018-03-02 10:00:00');
```

- Insert multiple records to the customer table without specifying the column names.

```
REPLACE INTO customer values(002367,'Tom','13678973421','Hangzhou','0','987300','West Lake','Cloud Town','23','2018-03-02 10:00:00'),(002368,'Alex','13878971234','Hangzhou','0','987300','West Lake','Cloud Town','28','2018-08-01 11:00:00'),(002369,'Eric','13968075284','Hangzhou','1','987300','West Lake','Cloud Town','35','2018-09-12 08:11:00');
```

14.11.3.3. INSERT SELECT FROM

You can execute the `INSERT SELECT FROM` statement to copy records from one table to another.

Syntax

```
INSERT INTO table_name [( column_name [, ...] )]query;
```

Parameters

- `column_name` : the name of the column. If you want to copy data in only some columns of the source table to the target table, the columns specified in the `SELECT` clause must have the same sequence and data types as those specified in the `INSERT` clause.
- `query` : the `SELECT FROM TABLE` or `SELECT FROM VIEW` statement.

Example

- Copy data only in the specified columns of the customer table to the `new_customer` table by specifying the column names.

```
INSERT INTO new_customer (customer_id, customer_name, phone_num)
SELECT customer_id, customer_name, phone_num FROM customer
WHERE customer.customer_name = 'Alan';
```

- Copy data in all columns of the customer table to the `new_customer` table and do not specify the column names.

```
INSERT INTO new_customer
SELECT customer_id,customer_name,phone_num,city_name,sex,id_number,home_address,office_address,age,login_
time)
FROM customer
WHERE customer.customer_name = 'Alan';
```

14.11.3.4. REPLACE SELECT FROM

You can execute the `REPLACE SELECT FROM` statement to copy records from one table to another by overwriting existing data in real time. The system first checks whether the primary key of a record to be inserted is the same as that of an existing record. If they are the same, the system deletes the existing record and inserts the new record. If they are not the same, the system inserts the new record.

Syntax

```
REPLACE INTO table_name [(column_name,...)]query;
```

Parameter

- `query` : the `SELECT FROM TABLE` or `SELECT FROM VIEW` statement.
- `column_name` : the name of the column. If you want to copy data in only some columns of the source table to the target table, the columns specified in the `SELECT` clause must have the same sequence and data types as those specified in the `REPLACE` clause.

Precautions

The target table to which the records are inserted must exist before you execute the `REPLACE SELECT FROM` statement.

Example

Copy data only in the specified columns of the `customer` table to the `new_customer` table by specifying the column names.

```
REPLACE INTO new_customer (customer_id, customer_name, phone_num)
SELECT customer_id, customer_name, phone_num
FROM customer
WHERE customer.customer_name = 'Alan';
```

14.11.3.5. INSERT OVERWRITE INTO SELECT

You can execute the `INSERT OVERWRITE INTO SELECT` statement to insert multiple records to a table at a time.

Syntax

```
INSERT OVERWRITE INTO table_name [(column_name,...)]
SELECT select_statement FROM from_statement
```

Precautions

- The target table to which the records are inserted must exist before you execute the `INSERT OVERWRITE INTO SELECT` statement.

- The existing data in the target table will not change before the `INSERT OVERWRITE INTO SELECT` statement is completed. The system writes data to the target table after the `INSERT OVERWRITE INTO SELECT` statement is completed.
- If you execute the `INSERT OVERWRITE INTO SELECT` statement to insert a primary key that is the same as an existing one in the records, the new record is not inserted.

14.11.3.6. UPDATE

You can execute the `UPDATE` statement to update data in a table.

Syntax

```
UPDATE table_reference
SET assignment_list
[WHERE where_condition]
[ORDER BY ...]
```

Precautions

The table on which you execute the `UPDATE` statement must have a primary key.

Example

Change the name of the customer who has the `customer_id = '2369'` attribute to Claire in the customer table.

```
update customer set customer_name = 'Claire' where customer_id = '2369';
```

14.11.3.7. DELETE

You can execute the `DELETE` statement to delete records from a table.

Syntax

```
DELETE FROM table_name[ WHERE condition ]
```

Precautions

- The table on which you execute the `DELETE` statement must have a primary key.
- You cannot use the alias of a table to execute the `DELETE` statement.
- If you need to delete all records of a table or all partitions, we recommend that you use the `TRUNCATE TABLE` or `TRUNCATE PARTITION` statement, instead of the `DELETE` statement.

Example

- Delete the record where `name` is Alex from the customer table.

```
DELETE FROM customer WHERE customer_name='Alex';
```

- Delete the records where age is less than 18 from the customer table.

```
DELETE FROM customer WHERE age<18;
```

14.11.3.8. TRUNCATE TABLE

You can execute the `TRUNCATE TABLE` statement to clear the data of a table or specified partitions in a table.

Syntax

- Clear the data of a table.

```
TRUNCATE TABLE db_name.table_name;
```

- Clear the data of specified partitions in a table.

```
TRUNCATE TABLE db_name.table_name PARTITION partition_name;
```

- The data type of partition names is `BIGINT`. You can execute the following SQL statement to obtain the names of all partitions in a table:

```
select partition_name from information_schema.partitions where table_name = 'your_table_name' order by partition_name desc limit 100;
```

Precautions

When you execute the `TRUNCATE TABLE` statement to clear the data of a table, the table schema is not deleted.

Example

- Clear the data of the customer table.

```
TRUNCATE TABLE adb_demo.customer;
```

- Clear the data of specified partitions in the customer table.

```
TRUNCATE TABLE adb_demo.customer partition 20170103,20170104,20170108
```

14.11.3.9. KILL PROCESS

You can execute the `KILL PROCESS` statement to terminate a running process.

Syntax

```
KILL PROCESS process_id
```

Parameters

`process_id` : the ID of the process to terminate. You can query the process ID by executing the `SHOW PROCESSLIST` statement and checking the `Processid` field.

Permission

- You can execute the `KILL PROCESS` statement to terminate the running processes under your account.
- The privileged account can grant the `PROCESS` permission to a standard account by using the `GRANT` statement. The standard account can then terminate the running processes of all accounts in the cluster.

```
GRANT process on *.* to account_name;
```

14.11.3.10. SHOW PROCESSLIST

You can execute the `SHOW PROCESSLIST` statement to view the running processes.

Note You can also execute the `INFORMATION_SCHEMA PROCESSLIST` statement to view the running processes.

Syntax

```
SHOW [FULL] PROCESSLIST
```

Response parameters

The following response parameters are returned after you execute the `SHOW FULL PROCESSLIST` or `SHOW PROCESSLIST` statement:

- **Id**: the ID of the process.
- **Processid** : the unique ID of the task. This parameter is required when you execute the `KILL PROCESS` statement.
- **User** : the current account.
- **Host** : the hostname of the client that sends the `SHOW PROCESSLIST` statement, which consists of the IP address and port number.
- **DB** : the database to which the process is connected.
- **Command** : the command that is executed in the current connection. The command types include `sleep` , `query` , and `connect` .
- **Time** : the time when the `Command` is executed. Unit: seconds.
- **State** : the execution status of the SQL statement in the current connection.
- **Info** : the SQL statement.

Note If you do not specify the `FULL` keyword, you can view only the first 100 characters of the `Info` field in each record.

Permission

- You can execute the `SHOW PROCESSLIST` statement to view the processes running under your account.
- A privileged account can grant the `PROCESS` permission to a standard account by using the `GRANT` statement. The standard account can then view the running processes of all accounts in the cluster.

```
GRANT process on *.* to account_name;
```

14.11.4. SELECT

14.11.4.1. Syntax

You can use the `SELECT` statement to query data from one or more tables. The syntax is as follows:

```
[ WITH with_query [, ...] ]
SELECT
[ ALL | DISTINCT ] select_expr [, ...]
[ FROM table_reference [, ...] ]
[ WHERE condition ]
[ GROUP BY [ ALL | DISTINCT ] grouping_element [, ...] ]
[ HAVING condition]
[ WINDOW window_name AS (window_spec) [, window_name AS (window_spec)] ...]
[ { UNION | INTERSECT | EXCEPT } [ ALL | DISTINCT ] select ]
[ ORDER BY {column_name | expr | position} [ASC | DESC], ... [WITH ROLLUP]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]
```

- `table_reference` : the data source from which data is queried. The source can be a table, view, associative table, or subquery.
- Table names and column names are not case-sensitive.
- If a table name or column name contains keywords or space characters, you can quote the table name or column name with backticks (` `).

WHERE

You can enter a `BOOLEAN` expression in the `WHERE` keyword to query data records that meet the specified condition. For example, you can execute the following statement to query the information of the customer whose `customer_id` is 2368.

```
SELECT * FROM CUSTOMER where customer_id=2368;
```

ALL and DISTINCT

You can use the `ALL` and `DISTINCT` keywords to specify whether duplicate rows are retained in the query result. The default value is `ALL`, indicating that all rows are returned. The `DISTINCT` keyword indicates that duplicate rows are deleted in the query result.

```
SELECT col1, col2 FROM t1;SELECT DISTINCT col1, col2 FROM t1;
```

The following methods show you how to use other keywords.

14.11.4.2. WITH

This topic describes how to use the `WITH` clause in a `SELECT` statement.

You can use the `WITH` clause to define subqueries by using common table expressions (CTEs) in a `SELECT` statement. The subqueries defined in the `WITH` clause can be referenced in the `SELECT` statement. The `WITH` clause can be used to flatten nested queries or simplify subqueries. Each subquery is performed only once in the `SELECT` statement. This improves the query performance.

Note

- A CTE is a named temporary result set, and is valid only in a single SQL statement, such as a `SELECT`, `INSERT`, and `DELETE` statement.
- A CTE is valid only during the period when the SQL statement is executing.

Precautions

- A CTE can be followed by a SQL statement, such as a SELECT, INSERT, or UPDATE statement, or other CTEs in the same WITH clause. Separate multiple CTEs with commas (,). Otherwise, the CTEs will not take effect.
- The paging feature is not supported in a CTE.

Use the WITH clause

- The following queries are equivalent:

```
SELECT a, b FROM (SELECT a, MAX(b) AS b FROM t GROUP BY a) AS x;
```

```
WITH x AS (SELECT a, MAX(b) AS b FROM t GROUP BY a) SELECT a, b FROM x;
```

- The WITH clause can be used to define multiple subqueries.

```
WITH
  t1 AS (SELECT a, MAX(b) AS b FROM x GROUP BY a),
  t2 AS (SELECT a, AVG(d) AS d FROM y GROUP BY a)
SELECT t1.*, t2.*
FROM t1 JOIN t2 ON t1.a = t2.a;
```

- After a subquery is defined, other subqueries following this subquery in the same WITH clause can reference this subquery.

```
WITH
  x AS (SELECT a FROM t),
  y AS (SELECT a AS b FROM x),
  z AS (SELECT b AS c FROM y)
SELECT c FROM z;
```

14.11.4.3. GROUP BY

You can use the `GROUP BY` clause to group the query result. You can use the `GROUPING SETS`, `CUBE`, and `ROLLUP` options in the `GROUP BY` clause to display the grouping result in different forms.

Syntax

```
GROUP BY expression [, ...]
```

- **GROUPING SETS**

The `GROUPING SETS` option is used to specify multiple `GROUP BY` conditions for one query, which is equal to the `UNION` of multiple `GROUP BY` clauses.

```
SELECT origin_state, origin_zip, destination_state, sum(package_weight)
FROM shipping
GROUP BY GROUPING SETS (
  (origin_state),
  (origin_state, origin_zip),
  (destination_state));
```

The preceding statement is equal to the following statement:

```
SELECT origin_state, NULL, NULL, sum(package_weight)
FROM shipping GROUP BY origin_state
UNION ALL
SELECT origin_state, origin_zip, NULL, sum(package_weight)
FROM shipping GROUP BY origin_state, origin_zip
UNION ALL
SELECT NULL, NULL, destination_state, sum(package_weight)
FROM shipping GROUP BY destination_state;
```

- **CUBE**

The `CUBE` option is used to list all possible grouping sets.

```
SELECT origin_state, destination_state, sum(package_weight)
FROM shipping
GROUP BY origin_state, destination_state WITH CUBE
```

The preceding statement is equal to the following statement:

```
SELECT origin_state, destination_state, sum(package_weight)
FROM shipping
GROUP BY GROUPING SETS (
  (origin_state, destination_state),
  (origin_state),
  (destination_state),
  ())
```

- **ROLLUP**

The `ROLLUP` option is used to list the grouping sets in a hierarchical manner.

```
SELECT origin_state, origin_zip, sum(package_weight)
FROM shipping
GROUP BY ROLLUP (origin_state, origin_zip)
```

The preceding statement is equal to the following statement:

```
SELECT origin_state, origin_zip, sum(package_weight)
FROM shipping
GROUP BY GROUPING SETS ((origin_state, origin_zip), (origin_state), ())
```

Precautions

- You must use standard aggregate functions such as `SUM`, `AVG`, and `COUNT` to specify the columns that are not used for grouping. Otherwise, the `GROUP BY` clause does not take effect.
- The `GROUP BY` clause must contain all the columns and non-aggregate expressions specified for the `SELECT` statement.

Example

The following statement contains two aggregate expressions. The first aggregate expression uses the `SUM` function, and the second uses the `COUNT` function. The `LISTID` and `EVENTID` columns are the columns that are used for grouping.

```

select listid, eventid, sum(pricepaid) as revenue,
count(qtysold) as numtix
from sales
group by listid, eventid
order by 3, 4, 2, 1
limit 5;
listid | eventid | revenue | numtix
-----+-----+-----+-----
89397 | 47 | 20.00 | 1
106590 | 76 | 20.00 | 1
124683 | 393 | 20.00 | 1
103037 | 403 | 20.00 | 1
47685 | 429 | 20.00 | 1
(5 rows)

```

You can also use the sequence numbers to reference columns in the **GROUP BY** clause.

For example, you can modify the preceding statement as follows:

```

select listid, eventid, sum(pricepaid) as revenue,
count(qtysold) as numtix
from sales
group by 1,2
order by 3, 4, 2, 1
limit 5;
listid | eventid | revenue | numtix
-----+-----+-----+-----
89397 | 47 | 20.00 | 1
106590 | 76 | 20.00 | 1
124683 | 393 | 20.00 | 1
103037 | 403 | 20.00 | 1
147685 | 429 | 20.00 | 1

```

14.11.4.4. HAVING

You can use the **HAVING** clause with the **GROUP BY** clause and aggregate functions to display groups that only meet certain conditions after grouping and aggregation.

Syntax

```
[ HAVING condition ]
```

Precautions

- The columns that you reference in the **HAVING** clause must be used for grouping or contain an aggregate function.
- The **HAVING** clause must be used together with aggregate functions and the **GROUP BY** clause to display groups that only meet certain conditions after grouping based on **GROUP BY**.

Example

Group records in the CUSTOMER table and query the records whose account balance is greater than the specified value.

```
SELECT count(*), mktsegment, nationkey,
       CAST(sum(acctbal) AS bigint) AS totalbal
FROM customer
GROUP BY mktsegment, nationkey
HAVING sum(acctbal) > 5700000
ORDER BY totalbal DESC;
_col0 | mktsegment | nationkey | totalbal
```

```
-----+-----+-----+-----
1272 | AUTOMOBILE | 19 | 5856939
1253 | FURNITURE  | 14 | 5794887
1248 | FURNITURE  | 9  | 5784628
1243 | FURNITURE  | 12 | 5757371
1231 | HOUSEHOLD  | 3  | 5753216
1251 | MACHINERY  | 2  | 5719140
1247 | FURNITURE  | 8  | 5701952
```

14.11.4.5. JOIN

Syntax

```
join_table:
  table_reference [INNER] JOIN table_factor [join_condition]
| table_reference {LEFT|RIGHT|FULL} [OUTER] JOIN table_reference join_condition
| table_reference CROSS JOIN table_reference [join_condition])

table_reference:
  table_factor
| join_table

table_factor:
  tbl_name [alias]
| table_subquery alias
| ( table_references )

join_condition:
  ON expression
```

Example

```

select catgroup1, sold, unsold
from
(select catgroup, sum(qtysold) as sold
from category c, event e, sales s
where c.catid = e.catid and e.eventid = s.eventid
group by catgroup) as a(catgroup1, sold)
join
(select catgroup, sum(numtickets)-sum(qtysold) as unsold
from category c, event e, sales s, listing l
where c.catid = e.catid and e.eventid = s.eventid
and s.listid = l.listid
group by catgroup) as b(catgroup2, unsold)
on a.catgroup1 = b.catgroup2
order by 1;

```

14.11.4.6. LIMIT

You can use the **LIMIT** clause to specify the maximum number of rows to return in a query. Typically, you must specify one or two numbers in the **LIMIT** clause. The first number specifies the number of rows to skip from the beginning, and the second number specifies the maximum number of rows to return.

Example

Query the orders table and limit the number of rows to return to five by using the **LIMIT** clause.

```

SELECT orderdate FROM orders LIMIT 5;
-----
o_orderdate
-----
1996-04-14
1992-01-15
1995-02-01
1995-11-12
1992-04-26

```

Query the customer table and return the information of the third customer to the seventh customer sorted by the creation date.

```

SELECT * FROM customer ORDER BY create_date LIMIT 2,5;

```

14.11.4.7. ORDER BY

You can use the **ORDER BY** clause to sort the query result. Each expression in the **ORDER BY** clause consists of column names or the sequence numbers (starting from 1) of columns.

Syntax

```
[ ORDER BY expression
 [ ASC | DESC ]
 [ NULLS FIRST | NULLS LAST ]
 [ LIMIT { count | ALL } ]
```

14.11.4.8. Subqueries

The following example shows how to query the top ten sellers in ticket sales. The WHERE clause defines a table subquery, and the result of the subquery consists of multiple rows and one column.

 **Note** The result of a table subquery can contain multiple rows and columns.

```
select firstname, lastname, cityname, max(qtysold) as maxsold
from users join sales on users.userid=sales.sellerid
where users.city not in(select venuecity from venue)
group by firstname, lastname, city
order by maxsold desc, city desc
limit 10;
```

```
firstname | lastname | cityname | maxsold
-----+-----+-----+-----
Noah      | Guerrero | Worcester | 8
Isadora   | Moss     | Winooski  | 8
Kieran    | Harrison | Westminster | 8
Heidi     | Davis    | Warwick   | 8
Sara      | Anthony  | Waco      | 8
Bree      | Buck     | Valdez    | 8
Evangeline | Sampson  | Trenton   | 8
Kendall   | Keith    | Stillwater | 8
Bertha    | Bishop   | Stevens Point | 8
Patricia  | Anderson | South Portland | 8
```

14.11.4.9. UNION, INTERSECT, and EXCEPT

You can use the UNION, INTERSECT, and EXCEPT operators to combine multiple query result sets to a single result set.

Syntax

```
query
{ UNION [ ALL ] | INTERSECT | EXCEPT | MINUS }
query
```

Parameters

- **UNION** : returns the union of two result sets.
- **UNION ALL** : returns the union of two result sets where duplicate rows are retained. The **ALL** keyword indicates that the duplicate rows are retained after the **UNION** calculation.

- **INTERSECT** : returns the intersection of two result sets.
- **EXCEPT | MINUS** : returns rows that appear in the first result set, but not in the other result set. The **MINUS** operator is equivalent to the **EXCEPT** operator.

Calculation sequence

- The **UNION** and **EXCEPT** operators are left-associative. That is, if you do not use parentheses () to change the calculation sequence, the calculation starts from left to right.

For example, in the following statement, the **UNION** operator returns the union of T1 and T2. Then the **EXCEPT** operator returns the rows that appear only in the union returned by the **UNION** operator, but not T3.

```
select * from t1
union
select * from t2
except
select * from t3
order by c1;
```

- In the same statement, the **INTERSECT** operator is prioritized over the **UNION** and **EXCEPT** operators.

For example, the following statement finds the intersection of T2 and T3, and then the union of the intersection and T1.

```
select * from t1
union
select * from t2
intersect
select * from t3
order by c1;
```

- You can use parentheses () to change the calculation sequence of these operators.

For example, the following statement finds the union of T1 and T2, and then the intersection of the union and T3.

```
(select * from t1
union
select * from t2)
intersect
(select * from t3)
order by c1;
```

14.11.5. CREATE USER

You can execute the **CREATE USER** statement to create an account.

Syntax

```
CREATE USER
[if not exists] user [auth_option] [, [if not exists] user [auth_option]] ...
```

Precautions

To create an account by executing the CREATE USER statement, you must have the `CREATE_USER` permission.

Examples

Create an account named account2 and set the password to Account2.

```
CREATE USER if not exists 'account2' IDENTIFIED BY 'Account2';
```

14.11.6. GRANT

You can execute the GRANT statement to grant permissions to an account.

Syntax

```
GRANT
  priv_type [(column_list)]
  [, priv_type [(column_list)]] ...
ON priv_level
TO user [auth_option]
[WITH {GRANT OPTION}]
```

Parameters

- `priv_type` : the type of permission to grant.
- `column_list` : optional. If the `priv_type` parameter is set to `SELECT`, you can enter the names of columns to grant the `SELECT` permission on these columns.
- `priv_level` : the level of the permission to grant.
 - `*.*` : the cluster level.
 - `db_name.*` : the database level.
 - `db_name.table_name` or `table_name` : the table level.

Precautions

To grant permissions to the other accounts by executing the `GRANT` statement, you must have the `GRANT OPTION` permission.

Examples

- Grant the cluster-level `all` permission to account2.

```
GRANT all ON *.* TO 'account2';
```

- Grant the database-level `all` permission to account3.

```
GRANT all ON adb_demo.* TO 'account3';
```

- Execute the `GRANT` statement to create and grant permissions to an account. For example, create an account with the cluster-level data manipulation permissions.

```
GRANT insert,select,update,delete on *.* to 'test'@%' identified by 'Testpassword1';
```

Create an account with the database-level data manipulation permissions.

```
GRANT insert,select,update,delete on adb_demo.* to 'test123' identified by 'Testpassword123';
```

- Create an account that has the `SELECT` permission on the specified columns.

```
GRANT select (customer_id, sex) ON customer TO 'test321' identified by 'Testpassword321';
```

14.11.7. REVOKE

You can execute the REVOKE statement to revoke permissions from an account.

Syntax

```
REVOKE
  priv_type [(column_list)]
  [, priv_type [(column_list)]] ...
  ON [object_type] priv_level
  FROM user
```

Parameters

- `priv_type` : the type of permission to revoke.
- `column_list` : optional. If the `priv_type` parameter is set to `SELECT`, you can enter the names of columns to revoke the `SELECT` permission on these columns.
- `priv_level` : the level of the permission to revoke.
 - `*, *` : the cluster level.
 - `db_name.*` : the database level.
 - `db_name.table_name` or `table_name` : the table level.

Precautions

To revoke permissions from other accounts by executing the REVOKE statement, you must have the `GRANT OPTION` permission.

Examples

Revoke the database-level `all` permission of account3.

```
REVOKE all ON adb_demo.* FROM 'account3';
```

14.11.8. Query users

AnalyticDB for MySQL is compatible with MySQL databases. AnalyticDB for MySQL provides a built-in database named MySQL, which stores user information, permission information, and stored procedures of AnalyticDB for MySQL. You can execute a SELECT statement to query user information of AnalyticDB for MySQL.

Precautions

- In AnalyticDB for MySQL, only the privileged account can query user information.
- The privileged account in AnalyticDB for MySQL is equivalent to the root account in MySQL.

Example

```
USE MYSQL;
SELECT User, Host, Password FROM mysql.user;
+-----+-----+-----+
| User | Host| Password |
+-----+-----+-----+
| account1| % | *61f3777f02386598cd**** |
| account2| % | *0fe79c07e168cab99**** |
```

14.11.9. RENAME USER

You can execute the RENAME USER statement to modify the name of an account.

Syntax

```
RENAME USER old_user TO new_user [, old_user TO new_user] ...
```

Examples

```
RENAME USER account2 TO account_2;
SELECT User, Host, Password FROM mysql.user;
+-----+-----+-----+
| User | Host| Password |
+-----+-----+-----+
| account2| % | *61f3777f02386598cda**** |
| account_2| % | *0fe79c07e168cab99b**** |
```

14.11.10. DROP USER

You can execute the DROP USER statement to delete an account.

Syntax

```
DROP USER [if exists] user [, [if exists] user] ...
```

Precautions

To delete an account by executing the DROP USER statement, you must have the `CREATE_USER` permission.

Examples

```
DROP USER account_2;
```

14.11.11. SHOW

SHOW DATABASES

You can execute the SHOW DATABASES statement to view the databases.

Syntax

```
SHOW DATABASES [EXTRA];
```

You can specify the `EXTRA` parameter to view extra information about the databases, such as the IDs of the creators and the connection information.

Examples

```
SHOW DATABASES EXTRA;
+-----+
| Database      |
+-----+
| adb_demo      |
| MYSQL         |
| INFORMATION_SCHEMA |
| adb_demo2     |
```

SHOW TABLES

Syntax

You can execute the `SHOW TABLES` statement to view the tables in the current database.

```
SHOW TABLES [IN db_name];
```

Examples

```
SHOW TABLES IN adb_demo;
+-----+
| Tables_in_adb_demo |
+-----+
| customer           |
| customer2          |
| new_customer       |
| test_table         |
| v                  |
```

SHOW COLUMNS

You can execute the `SHOW COLUMNS` statement to view the columns in a table.

Syntax

```
SHOW COLUMNS IN db_name.table_name;
```

Examples

```
SHOW COLUMNS IN adb_demo.test_table;
```

SHOW CREATE TABLE

You can execute the `SHOW CREATE TABLE` statement to view the statement that is used to create a table.

Syntax

```
SHOW CREATE TABLE db_name.table_name;
```

Examples

```
SHOW CREATE TABLE adb_demo.customer;
```

SHOW GRANTS

You can execute the `SHOW GRANTS` statement to view the permissions that are granted to the current account.

Syntax

```
SHOW GRANTS;
```

14.12. System functions

This topic describes the system functions supported by AnalyticDB for MySQL.

14.12.1. Aggregate functions

The aggregate functions described in this topic use the `testtable` table as test data.

```
create table testtable(a int) distributed by hash(a);
```

```
insert into testtable values (1),(2),(3);
```

14.12.1.1. AVG

This function calculates the average value of all input values.

```
AVG(bigint x)
```

```
AVG(double x)
```

```
AVG(float x)
```

- Return value type: `DOUBLE`.
- Example:

```
select avg(a) from testtable;
+-----+
| avg(a) |
+-----+
|  2.0  |
```

14.12.1.2. BIT_AND

This function returns the result of bitwise `AND` of all bits in the parameter.

```
BIT_AND(float x)
BIT_AND(bigint x)
BIT_AND(double x)
```

- Return value type: BIGINT.
- Example:

```
select bit_and(a) from testtable;
+-----+
| bit_and(a) |
+-----+
|    0 |
```

14.12.1.3. BIT_OR

This function returns the result of bitwise OR of all bits in the parameter.

```
BIT_OR(float x)
BIT_OR(bigint x)
BIT_OR(double x)
```

- Return value type: BIGINT.
- Example:

```
select bit_or(a) from testtable;
+-----+
| bit_or(a) |
+-----+
|    3 |
```

14.12.1.4. BIT_XOR

This function returns the result of bitwise XOR of all bits in the parameter.

```
BIT_XOR(double x)
BIT_XOR(bigint x)
bit_xor(float x)
```

- Return value type: BIGINT.
- Example:

```
select bit_xor(a) from testtable;
+-----+
| bit_xor(a) |
+-----+
|    0 |
```

14.12.1.5. COUNT

This function counts the number of records.

```
COUNT([distinct|all] value x)
```

- **Description:** `distinct` and `all` specify whether to exclude duplicate records in the counting process. The default value is `all`, indicating that all records are counted. If `distinct` is specified, only records with distinct values are counted.
- **Return value type:** `BIGINT`.
- **Example:**

```
select count(distinct a) from testtable;
+-----+
| count(DISTINCT a) |
+-----+
|          3 |
```

14.12.1.6. MAX

This function returns the maximum value of all input values.

```
MAX(value x)
```

- **Description:** value can be of any data type. However, data of the `BOOLEAN` type is not supported in the calculation. If the value for a row in the specified column is null, this row is ignored.
- **Return value type:** `LONG`.
- **Example:**

```
select max(a) from testtable;
+-----+
| max(a) |
+-----+
|    3 |
```

14.12.1.7. MIN

This function returns the minimum value of all input values.

```
MIN(value x)
```

- **Description:** value can be of any data type. However, data of the `BOOLEAN` type is not supported in the calculation. If the value for a row in the specified column is null, this row is ignored.
- **Return value type:** `LONG`.
- **Example:**

```
select min(a) from testtable;
+-----+
| min(a) |
+-----+
|    1 |
```

14.12.1.8. STD/STDDEV

This function returns the sample standard deviation of all input values.

```
STD(double x)
STD(bigint x)
STDDEV(double x)
STDDEV(bigint x)
```

- Return value type: DOUBLE.
- Example:

```
select std(a) from testtable;
+-----+
| std(a) |
+-----+
| 0.816496580927726 |
```

14.12.1.9. STDDEV_POP

This function returns the population standard deviation of all input values.

```
STDDEV_POP(double x)
STDDEV_POP(bigint x)
```

- Return value type: DOUBLE.
- Example:

```
select stddev_pop(a) from testtable;
+-----+
| stddev_pop(a) |
+-----+
| 0.816496580927726 |
```

14.12.1.10. STDDEV_SAMP

This function returns the population standard deviation for a group of integers, decimals, or floating-point numbers.

```
STDDEV_SAMP(double x)
STDDEV_SAMP(bigint x)
```

- Return value type: DOUBLE.
- Example:

```
select stddev_samp(a) from testtable;
+-----+
| stddev_samp(a) |
+-----+
| 1.0            |
```

14.12.1.11. SUM

This function calculates the sum of all input values.

```
SUM(double x)
SUM(float x)
SUM(bigint x)
```

- Return value type: BIGINT.
- Example:

```
select sum(a) from testtable;
+-----+
| sum(a) |
+-----+
| 6      |
```

14.12.1.12. VAR_POP

This function returns the population variance for a group of integers, decimals, or floating-point numbers.

```
VAR_POP(double x)
VAR_POP(bigint x)
```

- Description: You can also use the `VARIANCE()` function, which is equivalent to the `VAR_POP` function. However, the `VARIANCE()` function is not a standard SQL function. If no matches are found, `VAR_POP()` returns the value `NULL`.
- Return value type: DOUBLE.
- Example:

```
select var_pop(a) from testtable;
+-----+
| var_pop(a) |
+-----+
| 0.6666666666666666 |
```

14.12.1.13. VAR_SAMP

This function returns the sample variance for a group of integers, decimals, or floating-point numbers.

```
VAR_SAMP(double x)
VAR_SAMP(bigint x)
```

- Return value type: DOUBLE.
- Example:

```
select var_samp(a) from testtable;
+-----+
|  var_samp(a)  |
+-----+
|      1.0      |
```

14.12.1.14. VARIANCE

This function returns the population variance for a group of integers, decimals, or floating-point numbers.

```
VARIANCE(double x)
VARIANCE(bigint x)
```

- Description: The `VARIANCE()` function is an extension to standard SQL and can be replaced by the standard SQL function `VAR_POP()`. If no matches are found, `VARIANCE()` returns the value NULL.
- Return value type: DOUBLE.
- Example:

```
select variance(a) from testtable;
+-----+
|  variance(a)  |
+-----+
| 0.6666666666666666  |
```

14.12.2. Date and time functions

14.12.2.1. ADDDATE/DATE_ADD

This function adds an interval to a specified date.

```
ADDDATE(date,INTERVAL expr unit)
ADDDATE(expr,days)
```

- Description:
 - Valid values of unit: second, minute, hour, day, month, year, minute_second, hour_second, hour_minute, day_second, day_minute, day_hour, and year_month. Default value of unit: day.
 - days and expr: This function returns the value of expr plus days.
- Parameter types:

```

adddate(date, INTERVAL expr unit)
adddate(timestamp, INTERVAL expr unit)
adddate(datetime, INTERVAL expr unit)
adddate(varchar, INTERVAL expr unit)
adddate(date, varchar)
adddate(date, bigint)
adddate(datetime, bigint)
adddate(datetime, varchar)
adddate(timestamp, varchar)
adddate(timestamp, bigint)
adddate(varchar, bigint)
adddate(varchar, varchar)
    
```

- Return value type: DATE.
- Example:

```

select adddate(date '2001-1-22',interval '3' day);
+-----+
| adddate(DATE '2001-1-22', INTERVAL '3' DAY) |
+-----+
| 2001-01-25          |
    
```

```

select adddate(timestamp '2001-1-22',interval '3' day);
+-----+
| adddate(TIMESTAMP '2001-1-22', INTERVAL '3' DAY) |
+-----+
| 2001-01-25 00:00:00          |
    
```

```

select adddate(datetime '2001-1-22',interval '3' day);
+-----+
| adddate(DATETIME '2001-1-22', INTERVAL '3' DAY) |
+-----+
| 2001-01-25 00:00:00          |
    
```

```

select adddate('2001-1-22',interval '3' day);
+-----+
| adddate('2001-1-22', INTERVAL '3' DAY) |
+-----+
| 2001-01-25          |
    
```

```

select adddate(datetime '2001-1-22',interval '3' second);
+-----+
| adddate(DATETIME '2001-1-22', INTERVAL '3' SECOND) |
+-----+
|                2001-01-22 00:00:03 |
    
```

14.12.2.2. ADDTIME

This function adds time to a specified time. That is, this function returns the result of expr1 plus expr2.

```
ADDTIME(expr1,expr2)
```

- Parameter types:

```
addtime(date,varchar)
addtime(time,varchar)
addtime(datetime,varchar)
addtime(timestamp,varchar)
addtime(varchar,varchar)
```

- Return value type: VARCHAR.

- Example:

```
select addtime(date '1998-01-01','01:01:01');
+-----+
| addtime(DATE '1998-01-01', '01:01:01') |
+-----+
| 1998-01-01 01:01:01          |
```

14.12.2.3. CONVERT_TZ

This function converts the value of dt from from_tz to to_tz and returns the result.

```
CONVERT_TZ(dt,from_tz,to_tz)
```

- Parameter types:

```
convert_tz(varchar, varchar, varchar)
```

- Return value type: DATETIME.

- Example:

```
select convert_tz('2004-01-01 12:00:00','+00:00','+10:00');
+-----+
| convert_tz('2004-01-01 12:00:00', '+00:00', '+10:00') |
+-----+
|                2004-01-01 22:00:00 |
```

14.12.2.4. CURDATE

This function returns the current date.

```
CURDATE()
```

- Return value type: DATE.

- Example:

```
select curdate;
+-----+
| curdate() |
+-----+
| 2019-05-25 |
```

14.12.2.5. CURTIME

This function returns the current time.

```
CURTIME()
```

- Return value type: TIME.
- Example:

```
select curtime();
+-----+
| curtime() |
+-----+
| 14:39:22.109 |
```

14.12.2.6. DATE

This function returns the date part of a date or datetime expression.

```
DATE(expr)
```

- Parameter types:

```
date(timestamp)
date(datetime)
date(varchar)
```

- Return value type: DATE.
- Example:

```
select date(timestamp '2003-12-31 01:02:03');
+-----+
| date(TIMESTAMP '2003-12-31 01:02:03') |
+-----+
| 2003-12-31 |
```

14.12.2.7. DATE_FORMAT

This function returns a date as a string in the specified format.

```
DATE_FORMAT(date,format)
```

- Description: The following table describes the format specifiers.

Specifier	Description
%a	The abbreviation of a day of a week. Valid values: Sun to Sat.
%b	The abbreviation of a month name. Valid values: Jan to Dec.
%c	The month in numeric format. Valid values: 0 to 12.
%d	The day of the month in numeric format. Valid values: 00 to 31.
%e	The day of the month in numeric format. Valid values: 0 to 31.
%f	The microseconds. Valid values: 000000 to 999999.
%H	The hour. Valid values: 00 to 23.
%h	The hour. Valid values: 01 to 12.
%I	The hour. Valid values: 01 to 12.
%i	The minutes in numeric format. Valid values: 00 to 59.
%j	The day of the year. Valid values: 001 to 366.
%k	The hour. Valid values: 0 to 23.
%l	The hour. Valid values: 1 to 12.
%M	The name of the month. Valid values: January to December.
%m	The month in numeric format. Valid values: 00 to 12.
%p	The abbreviation of a time period in 12-hour format. Valid values: AM and PM.
%r	The time in 12-hour format (hh:mm:ss AM or hh:mm:ss PM).
%S	The seconds. Valid values: 00 to 59.
%s	The seconds. Valid values: 00 to 59.
%T	The time in 24-hour format (hh:mm:ss).
%v	The week number. Monday is the first day of a week. This specifier applies to WEEK() mode 3 and is used with %x.
%W	The name of the weekday. Valid values: Sunday to Saturday.
%x	The year of the week in numeric format. Monday is the first day of a week. This specifier is used with %v, and the value contains four digits.
%Y	The year of the week in numeric format. The value contains four digits.

Specifier	Description
%y	The year of the week in numeric format. The value contains two digits.
%%	The percent sign (%).
%x	x, for any "x" not listed above.

- Parameter types:

```
date_format(timestamp, varchar)
date_format(varchar, varchar)
date_format(datetime, varchar)
date_format(date, varchar)
```

- Return value type: VARCHAR.
- Example:

```
select date_format(timestamp '2019-05-27 13:23:00', '%W %M %Y')as result;
+-----+
| result |
+-----+
| Monday May 2019 |
```

14.12.2.8. SUBDATE/DATE_SUB

This function returns the value of date minus the specified INTERVAL.

```
DATE_SUB(date,INTERVAL expr unit)
```

- Description: Valid values of unit: second, minute, hour, day, month, year, minute_second, hour_second, hour_minute, day_second, day_minute, day_hour, and year_month. Default value of unit: day.
- Parameter types:

```
subdate(date, INTERVAL expr unit)
subdate(timestamp, INTERVAL expr unit)
subdate(datetime, INTERVAL expr unit)
subdate(varchar, INTERVAL expr unit)
subdate(date, bigint)
subdate(date, varchar)
subdate(datetime, bigint)
subdate(datetime, varchar)
subdate(timestamp, bigint)
subdate(timestamp, varchar)
subdate(varchar, bigint)
subdate(varchar, varchar)
```

- Return value type: DATE.
- Example:

```
select date_sub(date '2001-1-22',interval '3' day);
+-----+
| date_sub(DATE '2001-1-22', INTERVAL '3' DAY) |
+-----+
| 2001-01-19          |
```

14.12.2.9. DATEDIFF

This function returns the number of days between expr1 and expr2.

```
DATEDIFF(expr1,expr2)
```

- Parameter types:

```
datediff(varchar, varchar)
datediff(datetime, varchar)
datediff(varchar, datetime)
datediff(datetime, datetime)
datediff(varchar, timestamp)
datediff(timestamp, timestamp)
datediff(timestamp, varchar)
datediff(date, date)
datediff(date, varchar)
datediff(varchar, date)
```

- Return value type: BIGINT.

- Example:

```
select datediff('2007-12-31 23:59:59','2007-12-30');
+-----+
| datediff('2007-12-31 23:59:59', '2007-12-30') |
+-----+
|                1 |
```

14.12.2.10. DAY/DAYOFMONTH

This function returns the day in date. Valid values: [1,31] .

```
DAY(date)
DAYOFMONTH(date)
```

- Parameter types:

```
dayofmonth(timestamp)
dayofmonth(datetime)
dayofmonth(date)
dayofmonth(time)
dayofmonth(varchar)
```

- Return value type: BIGINT.

- Example:

```
select dayofmonth(timestamp '2007-02-03 12:23:09');
+-----+
| dayofmonth(TIMESTAMP '2007-02-03 12:23:09') |
+-----+
|                3 |
```

14.12.2.11. DAYNAME

This function returns the day of the week for a date, such as Monday.

```
DAYNAME(date)
```

- Parameter types:

```
dayname(timestamp)
dayname(datetime)
dayname(date)
dayname(varchar)
```

- Return value type: VARCHAR.

- Example:

```
select dayname(timestamp '2007-02-03 00:00:00');
+-----+
| dayname(TIMESTAMP '2007-02-03 00:00:00') |
+-----+
| Saturday                |
```

14.12.2.12. DAYOFWEEK

This function returns the weekday index for a date. For example, the weekday indexes for Sunday, Monday, and Saturday are 1, 2, and 7, respectively.

```
DAYOFWEEK(date)
```

- Parameter types:

```
dayofweek(timestamp)
dayofweek(datetime)
dayofweek(date)
dayofweek(varchar)
```

- Return value type: BIGINT.

- Example:

```

select dayofweek(timestamp '2007-02-03 00:00:00');
+-----+
| dayofweek(TIMESTAMP '2007-02-03 00:00:00') |
+-----+
|                7 |

```

14.12.2.13. DAYOFYEAR

This function returns the day of the year for a date. Valid values: [1,366] .

```
DAYOFYEAR(date)
```

- Parameter types:

```

dayofyear(timestamp)
dayofyear(datetime)
dayofyear(date)
dayofyear(varchar)

```

- Return value type: BIGINT.

- Example:

```

select dayofyear(timestamp '2007-02-03 00:12:12');
+-----+
| dayofyear(TIMESTAMP '2007-02-03 00:12:12') |
+-----+
|                34 |

```

14.12.2.14. EXTRACT

This function returns a part of a date or time, which is specified by unit. For example, this function can return the year, month, day, hour, or minute of a date or time.

```
EXTRACT(unit FROM date)
```

- Valid values of unit: second, minute, hour, day, month, year, minute_second, hour_second, hour_minute, day_second, day_minute, day_hour, and year_month.
- Supported parameter types: VARCHAR, TIMESTAMP, DATETIME, and TIME.
- Return value type: BIGINT.
- Example:

```

select extract(second from '2019-07-02 00:12:34');
+-----+
| _col0 |
+-----+
|    34 |

```

14.12.2.15. FROM_DAYS

This function returns a DATE value based on the parameter N indicating the number of days.

FROM_DAYS(N)

- Parameter types:

```
from_days(varchar)
from_days(bigint)
```

- Return value type: DATE.
- Example:

```
select from_days(730669);
+-----+
| from_days(730669) |
+-----+
| 2000-07-03      |
```

14.12.2.16. FROM_UNIXTIME

This function returns a Unix timestamp in the specified format.

FROM_UNIXTIME(unix_timestamp[,format])

- Description: The format parameter conforms to the format in the DATE_FORMAT function.
- Parameter types:

```
from_unixtime(varchar, varchar)
from_unixtime(varchar)
from_unixtime(double, varchar)
from_unixtime(double)
```

- Return value type: DATETIME.
- Example:

```
select from_unixtime('1447430881','%Y %M %h:%i:%s %x');
+-----+
| from_unixtime('1447430881','%Y %M %h:%i:%s %x') |
+-----+
| 2015 November 12:08:01 2015      |
```

14.12.2.17. HOUR

This function returns the hour part of a specified time.

HOUR(time)

- Parameter types:

```
hour(timestamp)
hour(datetime)
hour(date)
hour(time)
hour(varchar)
```

- Return value type: BIGINT.
- Example:

```
select hour(timestamp '2019-12-07 10:05:03');
+-----+
| hour(TIMESTAMP '2019-12-07 10:05:03') |
+-----+
|                10 |
```

14.12.2.18. LAST_DAY

This function returns the last day of the month for a date or datetime.

```
LAST_DAY(date)
```

- Parameter types:

```
last_day(varchar)
last_day(timestamp)
last_day(datetime)
last_day(date)
```

- Return value type: DATE.
- Example:

```
select last_day('2003-02-05');
+-----+
| last_day('2003-02-05') |
+-----+
| 2003-02-28           |
```

14.12.2.19. LOCALTIME/LOCALTIMESTAMP/NOW

This function returns the current timestamp.

```
localtime
localtime()
localtimestamp
localtimestamp()
now()
```

- Return value type: DATETIME.
- Example:

```
select now();
+-----+
| now() |
+-----+
| 2019-05-25 00:28:37 |
```

14.12.2.20. MAKEDATE

This function returns a date based on the year and dayofyear parameters.

```
MAKEDATE(year,dayofyear)
```

- Parameter types:

```
makedate(bigint, bigint)
makedate(varchar, varchar)
```

- Return value type: DATE.
- Example:

```
select makedate(2011,31), makedate(2011,32);
+-----+-----+
| makedate(2011, 31) | makedate(2011, 32) |
+-----+-----+
| 2011-01-31 | 2011-02-01 |
```

14.12.2.21. MAKETIME

This function returns a time based on the hour, minute, and second parameters.

```
MAKETIME(hour,minute,second)
```

- Parameter types:

```
maketime(bigint, bigint, bigint)
maketime(varchar, varchar, varchar)
```

- Return value type: TIME.
- Example:

```
select maketime(12,15,30);
+-----+
| maketime(12, 15, 30) |
+-----+
| 12:15:30 |
```

14.12.2.22. MINUTE

This function returns the minute part of a specified time.

```
MINUTE(time)
```

- Parameter types:

```
minute(timestamp)
minute(datetime)
minute(date)
minute(time)
minute(varchar)
```

- Return value type: BIGINT.
- Example:

```
select minute(timestamp '2008-02-03 10:05:03');
+-----+
| minute(TIMESTAMP '2008-02-03 10:05:03') |
+-----+
|                5 |
```

14.12.2.23. MONTH

This function returns the month for a date.

```
MONTH(date)
```

- Parameter types:

```
month(timestamp)
month(datetime)
month(date)
month(time)
month(varchar)
```

- Return value type: BIGINT.
- Example:

```
select month(timestamp '2008-02-03 00:00:00');
+-----+
| month(TIMESTAMP '2008-02-03 00:00:00') |
+-----+
|                2 |
```

14.12.2.24. MONTHNAME

This function returns the full name of the month for a date.

```
MONTHNAME(date)
```

- Parameter types:

```
monthname(timestamp)
monthname(datetime)
monthname(date)
monthname(varchar)
```

- Return value type: VARCHAR.
- Example:

```
select monthname(datetime '2008-02-03 00:00:00');
+-----+
| monthname(DATETIME '2008-02-03 00:00:00') |
+-----+
| February          |
```

14.12.2.25. PERIOD_ADD

This function adds N months to period P.

```
PERIOD_ADD(P,N)
```

- Parameter types:

```
period_add(bigint, bigint)
period_add(varchar, varchar)
period_add(varchar, bigint)
```

- Return value type: BIGINT.
- Example:

```
select period_add(200801,2);
+-----+
| period_add(200801, 2) |
+-----+
|          200803 |
```

14.12.2.26. PERIOD_DIFF

This function returns the number of months between periods P1 and P2.

```
PERIOD_DIFF(P1,P2)
```

- Parameter types:

```
period_diff(bigint, bigint)
period_diff(varchar, varchar)
```

- Return value type: BIGINT.
- Example:

```

select period_diff(200802,200703);
+-----+
| period_diff(200802, 200703) |
+-----+
|          11 |

```

14.12.2.27. QUARTER

This function returns the quarter of the year for a date. Valid values: [1,4] .

QUARTER(date)

- Parameter types:

```

quarter(datetime)
quarter(varchar)
quarter(timestamp)
quarter(date)

```

- Return value type: BIGINT.

- Example:

```

select quarter(datetime '2008-04-01 12:12:12');
+-----+
| quarter(DATETIME '2008-04-01 12:12:12') |
+-----+
|          2 |

```

14.12.2.28. SEC_TO_TIME

This function converts seconds to time.

SEC_TO_TIME(seconds)

- Parameter types:

```

sec_to_time(bigint)
sec_to_time(varchar)

```

- Return value type: TIME.

- Example:

```

select sec_to_time(2378);
+-----+
| sec_to_time(2378) |
+-----+
| 00:39:38 |

```

14.12.2.29. SECOND

This function returns the second part of a specified time. Valid values: [0,59] .

```
SECOND(time)
```

- Parameter types:

```
second(timestamp)
second(datetime)
second(date)
second(time)
second(varchar)
```

- Return value type: BIGINT.

- Example:

```
select second(timestamp '2019-03-12 12:13:14');
+-----+
| second(TIMESTAMP '2019-03-12 12:13:14') |
+-----+
|                14 |
```

14.12.2.30. STR_TO_DATE

This function converts a string to a date or datetime in the specified format.

```
STR_TO_DATE(str,format)
```

- Parameter types:

```
str_to_date(varchar, varchar)
```

- Return value type: DATETIME.

- Example:

```
select str_to_date('2017-01-06 10:20:30','%Y-%m-%d %H:%i:%s') as result;
+-----+
| result      |
+-----+
| 2017-01-06 10:20:30 |
```

14.12.2.31. SUBTIME

This function subtracts expr2 from expr1.

```
SUBTIME(expr1,expr2)
```

- Parameter types:

```
subtime(date, varchar)
subtime(datetime, varchar)
subtime(timestamp, varchar)
subtime(time, varchar)
subtime(varchar, varchar)
```

- Return value type: DATETIME.
- Example:

```
select subtime(date '2018-10-31','0:1:1');
+-----+
| subtime(DATE '2018-10-31', '0:1:1') |
+-----+
|          2018-10-30 23:58:59 |
```

14.12.2.32. SYSDATE

This function returns the system time.

```
SYSDATE()
```

- Return value type: DATETIME.
- Example:

```
select sysdate();
+-----+
| sysdate() |
+-----+
| 2019-05-26 00:47:21 |
```

14.12.2.33. TIME

This function returns the time in expr as a string.

```
TIME(expr)
```

- Parameter types:

```
time(varchar)
time(datetime)
time(timestamp)
```

- Return value type: VARCHAR.
- Example:

```
select time('2003-12-31 01:02:03');
+-----+
| time('2003-12-31 01:02:03') |
+-----+
| 01:02:03 |
```

14.12.2.34. TIME_FORMAT

This function returns time as a string in the specified format.

```
TIME_FORMAT(time,format)
```

- Description: The format parameter conforms to the format in the [DATE_FORMAT](#) function.
- Parameter types:

```
time_format(varchar, varchar)
time_format(timestamp, varchar)
time_format(datetime, varchar)
time_format(time, varchar)
time_format(date, varchar)
```

- Return value type: VARCHAR.
- Example:

```
select time_format('12:00:00', '%H %k %h %l %I');
+-----+
| time_format('12:00:00', '%H %k %h %l %I') |
+-----+
| 12 12 12 12 12 |
```

14.12.2.35. TIME_TO_SEC

This function converts time to seconds.

```
TIME_TO_SEC(time)
```

- Parameter types:

```
time_to_sec(varchar)
time_to_sec(datetime)
time_to_sec(timestamp)
time_to_sec(date)
time_to_sec(time)
```

- Return value type: BIGINT.
- Example:

```
select time_to_sec(datetime '2009-12-12 22:23:00');
+-----+
| time_to_sec(DATETIME '2009-12-12 22:23:00') |
+-----+
| 80580 |
```

14.12.2.36. TIMEDIFF

This function subtracts expr2 from expr1.

```
TIMEDIFF(expr1,expr2)
```

- Parameter types:

```
timediff(time, varchar)
timediff(time, time)
timediff(varchar, varchar)
```

- Return value type: DATETIME.
- Example:

```
select timediff(time '12:00:00','10:00:00');
+-----+
| timediff(TIME '12:00:00', '10:00:00') |
+-----+
| 02:00:00          |
```

14.12.2.37. TIMESTAMP

This function returns expr as a datetime value.

```
TIMESTAMP(expr)
```

- Parameter types:

```
timestamp(date)
timestamp(varchar)
```

- Return value type: DATETIME.
- Example:

```
select timestamp(date '2019-05-27');
+-----+
| timestamp(DATE '2019-05-27') |
+-----+
| 2019-05-27 00:00:00          |
```

14.12.2.38. TIMESTAMPADD

This function adds interval to datetime_expr.

```
TIMESTAMPADD(unit,interval,datetime_expr)
```

- Description: unit specifies the unit of interval. Valid values of unit: second, minute, hour, day, week, month, quarter, and year.
- Parameter types:

```
timestampadd(vchar, varchar, timestamp)
timestampadd(vchar, bigint, timestamp)
timestampadd(vchar, varchar, date)
timestampadd(vchar, bigint, date)
timestampadd(vchar, varchar, datetime)
timestampadd(vchar, bigint, datetime)
timestampadd(vchar, varchar, varchar)
timestampadd(vchar, bigint, varchar)
```

- Return value type: DATETIME.
- Example:

```
select timestampadd(second,'1',timestamp '2003-01-02 12:12:12')as result;
+-----+
| result |
+-----+
| 2003-01-02 12:12:13 |
```

14.12.2.39. TIMESTAMPDIFF

This function subtracts datetime_expr2 from datetime_expr1. unit specifies the unit of the result.

```
TIMESTAMPDIFF(unit,datetime_expr1,datetime_expr2)
```

- Description: Valid values of unit: second, minute, hour, day, week, month, quarter, and year. Use this function in the same way as the TIMESTAMPADD function.
- Parameter types:

```
timestampdiff(vchar, timestamp, timestamp)
timestampdiff(vchar, date, date)
timestampdiff(vchar, datetime, datetime)
timestampdiff(vchar, varchar, varchar)
```

- Return value type: BIGINT.
- Example:

```
select timestampdiff(second,datetime '2003-02-01 10:12:13',datetime '2003-05-01 10:12:13')as result;
+-----+
| result |
+-----+
| 7689600 |
```

14.12.2.40. TO_DAYS

This function returns the number of days since year 0 based on date.

```
TO_DAYS(date)
```

- Parameter types:

```
to_days(date)
to_days(time)
to_days(varchar)
to_days(timestamp)
to_days(datetime)
```

- Return value type: BIGINT.
- Example:

```
select to_days(date '2018-12-12');
+-----+
| to_days(DATE '2018-12-12') |
+-----+
|           737405 |
```

14.12.2.41. TO_SECONDS

This function returns the number of seconds since year 0 based on expr.

```
TO_SECONDS(expr)
```

- Parameter types:

```
to_seconds(date)
to_seconds(datetime)
to_seconds(timestamp)
to_seconds(varchar)
to_seconds(time)
```

- Return value type: BIGINT.
- Example:

```
select to_seconds(date '2019-09-08');
+-----+
| to_seconds(DATE '2019-09-08') |
+-----+
|           63735120000 |
```

14.12.2.42. UNIX_TIMESTAMP

UNIX_TIMESTAMP returns the Unix timestamp for the current time in seconds since '1970-01-01 00:00:00' UTC.

```
UNIX_TIMESTAMP([date])
```

- Description: UNIX_TIMESTAMP(date) returns the Unix timestamp for the date parameter in seconds since '1970-01-01 00:00:00' UTC.
- Parameter types:

```

unix_timestamp()
unix_timestamp(varchar)
unix_timestamp(timestamp)
unix_timestamp(date)
unix_timestamp(datetime)

```

- Return value type: BIGINT.
- Example:

```

select unix_timestamp();
+-----+
| unix_timestamp() |
+-----+
| 1558935850 |

```

14.12.2.43. UTC_DATE

This function returns the UTC date.

```
UTC_DATE()
```

- Return value type: VARCHAR.
- Example:

```

select utc_date();
+-----+
| utc_date() |
+-----+
| 2019-05-27 |

```

14.12.2.44. UTC_TIME

This function returns the UTC time.

```
UTC_TIME()
```

- Return value type: VARCHAR.
- Example:

```

select utc_time();
+-----+
| utc_time() |
+-----+
| 05:53:19 |

```

14.12.2.45. UTC_TIMESTAMP

This function returns the UTC timestamp.

```
utc_timestamp()
```

- Return value type: VARCHAR.
- Example:

```
select utc_timestamp();
+-----+
| utc_timestamp() |
+-----+
| 2019-05-27 05:55:15 |
```

14.12.2.46. WEEK

This function returns the week number for date, which is the week to which date belongs in the year.

```
WEEK(date[,mode])
```

- Description:
 - date specifies the date for which you want to obtain the week number.
 - mode is an optional parameter that specifies the logic for calculating the week number. It allows you to specify whether the week starts from Monday or Sunday. The returned value ranges from 0 to 52 or from 1 to 53. The following table describes the formats that mode supports.

Mode	First day of the week	Range
0	Sunday	0 to 53
1	Monday	0 to 53
2	Sunday	1 to 53
3	Monday	1 to 53
4	Sunday	0 to 53
5	Monday	0 to 53
6	Sunday	1 to 53
7	Monday	1 to 53

- Parameter types:

```
week(varchar)
week(varchar, bigint)
week(date)
week(date, bigint)
week(datetime)
week(datetime, bigint)
week(timestamp)
week(timestamp, bigint)
```

- Return value type: BIGINT.
- Example:

```
select week('2019-05-27');
+-----+
| week('2019-05-27') |
+-----+
|          21 |
```

14.12.2.47. WEEKDAY

This function returns the weekday for date. The result is an integer indicating the weekday. The mapping is as follows: 0 = Monday , 1 = Tuesday , and 6 = Sunday .

WEEKDAY(date)

- Parameter types:

```
weekday(timestamp)
weekday(datetime)
weekday(date)
weekday(varchar)
```

- Return value type: BIGINT.

- Example:

```
select weekday(timestamp '2019-05-27 00:09:00');
+-----+
| weekday(TIMESTAMP '2019-05-27 00:09:00') |
+-----+
|          0 |
```

14.12.2.48. WEEKOFYEAR

This function returns the calendar week for date. Valid values: [1, 53] .

WEEKOFYEAR(date)

- Parameter types:

```
weekofyear(timestamp)
weekofyear(datetime)
weekofyear(date)
weekofyear(varchar)
```

- Return value type: BIGINT.

- Example:

```
select weekofyear(timestamp '2019-05-27 09:00:00');
+-----+
| weekofyear(TIMESTAMP '2019-05-27 09:00:00') |
+-----+
|          22 |
```

14.12.2.49. YEAR

This function returns the year for date.

```
YEAR(date)
```

- Parameter types:

```
year(timestamp)
year(datetime)
year(date)
year(time)
year(varchar)
```

- Return value type: BIGINT.

- Example:

```
select year(timestamp '2019-05-27 00:00:00');
+-----+
| year(TIMESTAMP '2019-05-27 00:00:00') |
+-----+
|                2019 |
```

14.12.2.50. YEARWEEK

This function returns the year and week for a date.

```
YEARWEEK(date)
YEARWEEK(date,mode)
```

- Description: The year in the result may be different from the year in the date parameter for the first and the last week of the year.

mode works in the same way as mode in the [WEEK](#) function. For the single-parameter syntax, the value of mode is 0.

- Parameter types:

```
yearweek(timestamp)
yearweek(timestamp, bigint)
yearweek(datetime)
yearweek(datetime, bigint)
yearweek(date, bigint)
yearweek(date)
yearweek(varchar)
yearweek(varchar, bigint)
```

- Return value type: BIGINT.

- Example:

```
select yearweek(timestamp '2019-05-27 00:00:00');
+-----+
| yearweek(TIMESTAMP '2019-05-27 00:00:00') |
+-----+
|                201921 |
```

14.12.3. String functions

14.12.3.1. ASCII

This function returns the decimal ASCII code of the str character or the leftmost character in the string str.

```
ASCII(varchar str)
```

- Return value type: BIGINT.
- Example:

```
select ascii('2');
+-----+
| ascii('2') |
+-----+
|      50 |
```

14.12.3.2. BIN

This function returns the binary string of the integer N.

```
BIN(bigint N)
```

- Description: If N is null, null is returned.
- Return value type: VARCHAR.
- Example:

```
select bin(12);
+-----+
| bin(12) |
+-----+
| 1100 |
```

14.12.3.3. BIT_LENGTH

This function returns the length of the string str, measured in bits.

```
BIT_LENGTH(varchar str)
```

- Return value type: BIGINT.
- Example:

```
select bit_length('text');
+-----+
| bit_length('text') |
+-----+
|          32 |
```

14.12.3.4. CHAR

This function returns a string of decimal ASCII codes of the integers N1, N2, and so on.

```
CHAR(bigint N1, bigint N2...)
```

- Return value type: VARBINARY.
- Example:

```
select char(97,110,97,108,121,116,105,99,100,98);
+-----+
| char(97, 110, 97, 108, 121, 116, 105, 99, 100, 98) |
+-----+
| analyticdb |
```

14.12.3.5. CHAR_LENGTH/CHARACTER_LENGTH

This function returns the length of the string str, measured in characters.

```
CHAR_LENGTH(varchar str)
```

- Return value type: BIGINT.
- Example:

```
select char_length('China');
+-----+
| char_length('China') |
+-----+
|          2 |
```

14.12.3.6. CONCAT

This function concatenates strings. If any of the parameters is null, null is returned.

```
concat(varchar str1, ..., varchar strn)
```

- Return value type: VARCHAR.
- Example:

```
select concat('aliyun', ',', 'analyticdb');
+-----+
| concat('aliyun', ',', 'analyticdb') |
+-----+
| aliyun, analyticdb          |
```

14.12.3.7. CONCAT_WS

This function concatenates strings and separates them with delimiters. The separator parameter specifies the delimiter. Parameters whose value is null are not included in the final string.

```
concat_ws(vchar separator, varchar str1, ..., varchar strn)
```

- Return value type: VARCHAR.
- Example:

```
select concat_ws(',', 'First name', 'Second name', 'Last Name') as result;
+-----+
| result          |
+-----+
| First name,Second name,Last Name |
```

14.12.3.8. ELT

This function returns the string specified by the integer N.

```
ELT(bigint N, varchar str1, varchar str2, varchar str3,...)
```

- If N is less than 1 or greater than the number of the specified strings, null is returned.
- Return value type: VARCHAR.
- Example:

```
select elt(4, 'Aa', 'Bb', 'Cc', 'Dd');
+-----+
| elt(4, 'Aa', 'Bb', 'Cc', 'Dd') |
+-----+
| Dd          |
```

14.12.3.9. EXPORT_SET

This function returns a string in which the strings on and off are placed based on the bits 0 or 1 from right to left (from low-order to high-order) in the binary value of the bits integer.

```
EXPORT_SET(bigint bits, varchar on, varchar off[, varchar separator[, bigint number_of_bits]])EXPORT_SET(bigint bits, v
archar on, varchar off[, varchar separator[, bigint number_of_bits]])
```

- Description: The string on is placed for bit 1, and the string off is placed for bit 0. These strings are separated by delimiters. The default delimiter is a comma (.). The number_of_bits parameter specifies the number of bits that are checked. Default value: 64.

If the value of the number_of_bits parameter is greater than 64, the parameter is silently clipped to 64.

The same value is returned when the `number_of_bits` parameter is set to -1 or 64.

- Return value type: VARCHAR.
- Example:

```
select export_set(5,'1','0','','2);
+-----+
| export_set(5, '1', '0', '', 2) |
+-----+
| 1,0          |
```

14.12.3.10. FIELD

This function returns the position of the string `str` in the strings such as `str1`, `str2`, and `str3`. If the string `str` is not found, 0 is returned.

```
field(varchar str, varchar str1, varchar str2, varchar str3,...)
```

- Return value type: BIGINT.
- Example:

```
select field('Bb', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
+-----+
| field('Bb', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff') |
+-----+
|                2 |
```

14.12.3.11. FIND_IN_SET

This function returns the position of the string `str` in the string list `strlist`.

```
FIND_IN_SET(varchar str, varchar strlist)
```

- Description: If `str` is not found in `strlist` or `strlist` is empty, 0 is returned.
If either `str` or `strlist` is null, null is returned.
- Return value type: BIGINT.
- Example:

```
select find_in_set('b','a,b,c,d');
+-----+
| find_in_set('b', 'a,b,c,d') |
+-----+
|                2 |
```

14.12.3.12. FORMAT

This function formats the integer `X` to the `###,###.##` format rounded to `D` decimal places, and returns the result as a string.

```
format(double X, bigint D)
```

- Description: If D is 0, the result has no decimal point or fractional part.
- Return value type: BIGINT.
- Example:

```
select format(12332.123456, 4)as result1, format(12332.1,4)as result2, format(12332.2,0)as result3;
+-----+-----+-----+
| result1 | result2 | result3 |
+-----+-----+-----+
| 12,332.1235 | 12,332.1000 | 12,332 |
```

14.12.3.13. HEX

This function returns the hexadecimal string of the integer N, or returns a string consisting of the hexadecimal values of all characters in the string str.

```
HEX(bigint N)
HEX(varchar str)
```

- Return value type: VARCHAR.
- Example:

```
select hex(16);
+-----+
| hex(16) |
+-----+
| 10      |
```

14.12.3.14. INSTR

This function returns the position of the first occurrence of the substring substr in the string str.

```
INSTR(varchar str, varchar substr)
```

- Return value type: BIGINT.
- Example:

```
select instr('foobarbar', 'bar');
+-----+
| instr('foobarbar', 'bar') |
+-----+
|                4 |
```

14.12.3.15. LEFT

This function returns the leftmost len characters of the string str.

```
LEFT(varchar str, bigint len)
```

- Description: If str or len is null, null is returned.
- Return value type: VARCHAR.

- Example:

```
select left('foobarbar', 5);
+-----+
| left('foobarbar', 5) |
+-----+
| fooba                |
```

14.12.3.16. LENGTH/OCTET_LENGTH

This function returns the length of the string str.

```
length(varchar str)
```

- Return value type: BIGINT.
- Example:

```
select length('aliyun');
+-----+
| length('aliyun') |
+-----+
|          6      |
```

14.12.3.17. LIKE

The LIKE operator is used to match the string expression with the string pattern. If the two strings match, 1 is returned. Otherwise, 0 is returned.

```
expression [ NOT ] LIKE pattern [ESCAPE 'escape_char']
```

- Description: The string pattern can contain the following wildcard characters:
 - %: matches strings in any length.
 - _: matches a single character.

escape_char: escapes the percent signs (%) and underscores (_) in the string pattern. The percent signs (%) and underscores (_) following the escape character are not used as wildcard characters.
- Return value type: BIGINT.
- Example:

```
select 'David!' like 'David_' as result1, 'David!' not like 'David_' as result2, 'David!' like '%D%v%' as result3;
+-----+-----+-----+
| result1 | result2 | result3 |
+-----+-----+-----+
| 1      | 0      | 1      |
```

14.12.3.18. LOCATE

This function returns the position of the first occurrence of substring substr in string str, or returns the position of the first occurrence of the substring substr in the string str, starting at position pos.

```
LOCATE(varchar substr, varchar str)
LOCATE(varchar substr, varchar str, bigint pos)
```

- **Description:** If substr is not found in str, 0 is returned.
If substr or str is null, null is returned.
- **Return value type:** BIGINT.
- **Example:**

```
select locate('bar', 'foobarbar');
+-----+
| locate('bar', 'foobarbar') |
+-----+
|                4 |
```

14.12.3.19. LOWER/LCASE

This function converts the string str to lowercase.

```
lower(varchar str)
```

- **Return value type:** VARCHAR.
- **Example:**

```
select lower('Aliyun');
+-----+
| lower('Aliyun') |
+-----+
| aliyun      |
```

14.12.3.20. LPAD

This function returns the string str, left-padded with the string padstr to a length of len characters.

```
lpad(varchar str, bigint len, varchar padstr)
```

- **Description:** If str is longer than len, the return value is shortened to len characters.
- **Return value type:** VARCHAR.
- **Example:**

```
select lpad('Aliyun',9,'#');
+-----+
| lpad('Aliyun', 9, '#') |
+-----+
| ###Aliyun      |
```

14.12.3.21. LTRIM

This function removes the leading space characters of the string str.

```
LTRIM(varchar str)
```

- Return value type: VARCHAR.
- Example:

```
select ltrim(' abc');
+-----+
| ltrim(' abc') |
+-----+
| abc      |
```

14.12.3.22. MAKE_SET

This function returns a set value (a string containing substrings separated by delimiters) consisting of the string that have the corresponding bit in the bits set.

```
MAKE_SET(bits, str1, str2,...)
```

- Description: The string str1 corresponds to bit 0 and the string str2 corresponds to bit 1. The same rule applies to the rest numbers. The strings whose value is null are not included in the final string.
- Return value type: VARCHAR.
- Example:

```
select make_set(5,'hello','nice','world');
+-----+
| make_set(5, 'hello', 'nice', 'world') |
+-----+
| hello,world      |
```

14.12.3.23. MID

This function returns a substring that contains len characters in length from the string str, starting from the pos position.

```
MID(varchar str, bigint pos, bigint len)
```

- Return value type: VARCHAR.
- Example:

```
select mid('Quadratically',5,6);
+-----+
| mid('Quadratically', 5, 6) |
+-----+
| ratica      |
```

14.12.3.24. OCT

This function returns the octal string of the integer N.

```
OCT(bigint N)
```

- Description: If N is null, null is returned.
- Return value type: VARCHAR.
- Example:

```
select oct(12);
+-----+
| oct(12) |
+-----+
| 14    |
```

14.12.3.25. POSITION

This function returns the position of the first occurrence of the substring `substr` in the string `str`, starting from position 1. If `substr` is not found in `str`, 0 is returned.

```
POSITION(varchar substr IN varchar str)
```

- Return value type: BIGINT.
- Example:

```
select position('bar' in 'foobarbar');
+-----+
| locate('bar', 'foobarbar') |
+-----+
|                4 |
```

14.12.3.26. REPEAT

This function repeats the string `str` for `count` times.

```
REPEAT(varchar str, bigint count)
```

- If `count < 1`, an empty string is returned.
If `str` or `count` is null, null is returned.
- Return value type: VARCHAR.
- Example:

```
select repeat('a', 3);
+-----+
| repeat('a', 3) |
+-----+
| aaa          |
```

14.12.3.27. REPLACE

This function replaces all occurrences of the string `from_str` in the string `str` with the string `to_str`.

```
REPLACE(varchar str, varchar from_str, varchar to_str)
```

- Return value type: VARCHAR.

- Example:

```
select replace('WWW.aliyun.com', 'W', 'w');
+-----+
| replace('WWW.aliyun.com', 'W', 'w') |
+-----+
| www.aliyun.com           |
```

14.12.3.28. REVERSE

This function returns the string str with the order of the characters reversed.

```
REVERSE(varchar str)
```

- Return value type: VARCHAR.
- Example:

```
select reverse('123456');
+-----+
| reverse('123456') |
+-----+
| 654321           |
```

14.12.3.29. RIGHT

This function returns the rightmost len characters from the string str.

```
RIGHT(varchar str, bigint len)
```

- Description: If str or len is null, null is returned.
- Return value type: VARCHAR.
- Example:

```
select right('abc',3);
+-----+
| presto_right('abc', 3) |
+-----+
| abc                   |
```

14.12.3.30. RLIKE/REGEXP

This function matches the expression string with the pattern string, which is a regular expression. If the two strings match, 1 is returned. Otherwise, 0 is returned.

```
expression RLIKE pattern
expression REGEXP pattern
```

- If expression or pattern is null, null is returned.
- Return value type: BIGINT.
- Example:

```

select 'Michael!' regexp '.*';
+-----+
| regexp_like('Michael!', '.*') |
+-----+
|                1 |

```

14.12.3.31. RPAD

This function returns the string `str`, right-padded with the string `padstr` to a length of `len` characters.

```
rpad(vvarchar str, bigint len, varchar padstr)
```

- If `str` is longer than `len`, the return value is shortened to `len` characters.
- Return value type: VARCHAR.
- Example:

```

select rpad('Aliyun',9,'#');
+-----+
| rpad('Aliyun', 9, '#') |
+-----+
| Aliyun###           |

```

14.12.3.32. RTRIM

This function removes the trailing space characters of the string `str`.

```
RTRIM(vvarchar str)
```

- Return value type: VARCHAR.
- Example:

```

select rtrim('barbar ');
+-----+
| rtrim('barbar ') |
+-----+
| barbar          |

```

14.12.3.33. SPACE

This function returns a string consisting of a specified number of space characters.

```
SPACE(bigint N)
```

- Return value type: VARCHAR.
- Example:

```
select concat("#", space(6), "#");
+-----+
| concat('#', space(6), '#') |
+-----+
| # #           |
```

14.12.3.34. STRCMP

If the string str1 is the same as the string str2, 0 is returned. If the string str1 is smaller than the string str2 based on the current sort order, -1 is returned. Otherwise, 1 is returned.

```
STRCMP(varchar str1, varchar str2)
```

- Return value type: BIGINT.
- Example:

```
select strcmp('text', 'text2');
+-----+
| strcmp('text', 'text2') |
+-----+
|           -1 |
```

14.12.3.35. SUBSTR/SUBSTRING

```
SUBSTRING(varchar str, bigint pos)
SUBSTRING(varchar str FROM pos)
SUBSTRING(varchar str, bigint pos, bigint len)
SUBSTRING(varchar str FROM pos FOR len)
```

- Description:
 - SUBSTRING(varchar str, bigint pos) or SUBSTRING(varchar str FROM pos): returns the substring starting from the pos position to the end of the string. If pos < 0, the beginning of the substring is pos characters from the end of the string.
 - SUBSTRING(varchar str, bigint pos, bigint len) or SUBSTRING(varchar str FROM pos FOR len): returns a substring that contains len characters in length from the string, starting from the pos position. If pos < 0, the beginning of the substring is pos characters from the end of the string.
- Return value type: VARCHAR.
- Example:

```
select substr('helloworld', 6);
+-----+
| substr('helloworld', 6) |
+-----+
| world           |
```

14.12.3.36. SUBSTRING_INDEX

This function returns the substring before the last occurrence of the delim delimiter in the str string.

```
SUBSTRING_INDEX(varchar str, varchar delim, bigint count)
```

- **Description:**
 - If count > 0, this function returns all the characters to the left of the last delim delimiter.
 - If count < 0, this function returns all the characters to the right of the last delim delimiter.
 - The SUBSTRING_INDEX function performs a case-sensitive match when searching for the delim delimiter.
- **Return value type:** VARCHAR.
- **Example:**

```
select substring_index('www.aliyun.com', '.', 2);
+-----+
| substring_index('www.aliyun.com', '.', 2) |
+-----+
| www.aliyun                               |
```

14.12.3.37. TRIM

This function removes the leading and trailing space characters or other specified characters from a string.

```
TRIM([remstr FROM] str)
TRIM([{BOTH | LEADING | TRAILING} [remstr] FROM] str)
```

- **Return value type:** VARCHAR.
- **Example:**

```
select trim(' bar ');
+-----+
| trim(' bar ') |
+-----+
| bar          |
```

14.12.3.38. UPPER/UCASE

This function converts the string str to uppercase.

```
upper(varchar str)
```

- **Return value type:** VARCHAR.
- **Example:**

```
select upper('Aliyun');
+-----+
| upper('Aliyun') |
+-----+
| ALIYUN          |
```

14.12.4. Numeric functions

14.12.4.1. ABS

This function returns the absolute value of *x*.

```
abs(tinyint x)
abs(smallint x)
abs(int x)
abs(bigint x)
abs(float x)
abs(double x)
abs(decimal x)
```

- Return value types: LONG, DECIMAL, and DOUBLE.
- Example:

```
select abs(4.5);
+-----+
| abs(4.5) |
+-----+
| 4.5 |
```

14.12.4.2. ROUND

This function rounds the parameter *x*. *d* specifies the number of decimal places. The default value of *d* is 0. The rounding algorithm changes based on the data type of *x*.

```
round(tinyint x)
round(smallint x)
round(int x)
round(bigint x)
round(float x)
round(double x)
round(x, d)
```

- Description:
 - If *x* is null, null is returned.
 - If *d* > 0, the parameter is rounded to the specified decimal place.
 - If *d* = 0, the parameter is rounded to the nearest integer.
 - If *d* < 0, digits to the left of the decimal point of the parameter are rounded.
- Return value types: LONG, DECIMAL, and DOUBLE.
- Example:

```
select round(4);
+-----+
| round(4) |
+-----+
| 4 |
```

14.12.4.3. SQRT

This function returns the square root of x.

```
sqrt(double x)
```

- Return value type: DOUBLE.
- Example:

```
select sqrt(4.222);
+-----+
| sqrt(4.222) |
+-----+
| 2.054750593137766 |
```

14.12.4.4. LN

This function returns the natural logarithm of x.

```
ln(double x)
```

- Return value type: DOUBLE.
- Example:

```
select ln(2.718281828459045);
+-----+
| ln(2.718281828459045) |
+-----+
| 1.0 |
```

14.12.4.5. LOG

If called with one parameter, this function returns the natural logarithm of x. If called with two parameters, this function returns the logarithm of y to the base x.

- Return value type: DOUBLE.
- Example:

```
select log(16);
+-----+
| log(16) |
+-----+
| 2.772588722239781 |
```

14.12.4.6. LOG2

This function returns the base-2 logarithm of the parameter.

- Return value type: DOUBLE.
- Example:

```
select log2(8.7654);
+-----+
| log2(8.7654) |
+-----+
| 3.131819928389146 |
```

14.12.4.7. PI

This function returns the value of Pi.

```
pi()
```

- Return value type: DOUBLE.
- Example:

```
select pi();
+-----+
| pi() |
+-----+
| 3.141592653589793 |
```

14.12.4.8. LOG10

This function returns the base-10 logarithm of the parameter.

```
log10(double x)
```

- Return value type: DOUBLE.
- Example:

```
select log10(100.876);
+-----+
| log10(100.876) |
+-----+
| 2.0037878529824615 |
```

14.12.4.9. POWER/POW

This function returns the value of x raised to the power of y.

```
power(double x, double y)
pow(double x, double y)
```

- Return value type: DOUBLE.
- Example:

```
select power(1.2,3.4);
+-----+
| power(1.2, 3.4) |
+-----+
| 1.858729691979481 |
```

14.12.4.10. RADIANS

This function converts degrees to radians.

```
radians(double x)
```

- Return value type: DOUBLE.
- Example:

```
select radians(60.0);
+-----+
| radians(60.0) |
+-----+
| 1.0471975511965976 |
```

14.12.4.11. DEGREES

This function converts radians to degrees.

```
degrees(double x)
```

- Return value type: DOUBLE.
- Example:

```
select degrees(1.3);
+-----+
| degrees(1.3) |
+-----+
| 74.48451336700703 |
```

14.12.4.12. SIGN

This function returns the sign of x.

```
sign(smallint x)
sign(tinyint x)
sign(int x)
sign(bigint x)
sign(float x)
sign(double x)
sign(decimal x)
```

- Return value type: LONG.

- Example:

```
select sign(12);
+-----+
| sign(12) |
+-----+
|    1 |
```

14.12.4.13. CEILING/CEIL

This function returns the minimum integer value that is greater than the value of x.

```
ceiling(tinyint x)
ceiling(smallint x)
ceiling(int x)
ceiling(bigint x)
ceiling(float x)
ceiling(double x)
```

- Return value types: LONG, DECIMAL, and DOUBLE.
- Example:

```
select ceiling(4);
+-----+
| ceiling(4) |
+-----+
|    4 |
```

14.12.4.14. FLOOR

This function returns the maximum integer value that is less than the value of x.

```
floor(tinyint x)
floor(smallint x)
floor(int x)
floor(bigint x)
floor(float x)
floor(double x)
```

- Return value types: LONG, DECIMAL, and DOUBLE.
- Example:

```
select floor(4.5);
+-----+
| floor(4.5) |
+-----+
|    4.0 |
```

14.12.4.15. EXP

This function returns the value of e (the base of natural logarithms) raised to the power of x.

```
exp(double x)
```

- Return value type: DOUBLE.
- Example:

```
select exp(4.5);
+-----+
| exp(4.5) |
+-----+
| 90.01713130052181 |
```

14.12.4.16. COS

This function returns the cosine of x.

```
cos(double x)
```

- Return value type: DOUBLE.
- Example:

```
select cos(1.3);
+-----+
| cos(1.3) |
+-----+
| 0.26749882862458735 |
```

14.12.4.17. ACOS

This function returns the arc cosine of x.

```
acos(double x)
```

- Description: If $x > 1$ or $x < -1$, null is returned.
- Return value type: DOUBLE.
- Example:

```
select acos(0.5);
+-----+
| acos(0.5) |
+-----+
| 1.0471975511965979 |
```

14.12.4.18. TAN

This function returns the tangent of x.

```
tan(double x)
```

- Return value type: DOUBLE.

- Example:

```
select tan(8);
+-----+
| tan(8) |
+-----+
| -6.799711455220379 |
```

14.12.4.19. ATAN

This function returns the arc tangent of x.

```
atan(double x)
```

- Return value type: DOUBLE.
- Example:

```
select atan(0.5);
+-----+
| atan(0.5) |
+-----+
| 0.4636476090008061 |
```

14.12.4.20. ATAN2

This function returns the arc tangent of the result of x divided by y.

```
atan2(double x, double y)
atan(double x, double y)
```

- Return value type: DOUBLE.
- Example:

```
select atan2(0.5,0.3);
+-----+
| atan2(0.5, 0.3) |
+-----+
| 1.0303768265243125 |
```

14.12.4.21. COT

This function returns the cotangent of x.

```
cot(double x)
```

- Return value type: DOUBLE.
- Example:

```

select cot(1.234);
+-----+
| cot(1.234) |
+-----+
| 0.35013639786701445 |

```

14.12.4.22. ASIN

This function returns the arc sine of x.

```
asin(double x)
```

- Return value type: DOUBLE.
- Example:

```

select asin(0.5);
+-----+
| asin(0.5) |
+-----+
| 0.5235987755982989 |

```

14.12.4.23. SIN

This function returns the sine of x.

```
sin(double x)
```

- Return value type: DOUBLE.
- Example:

```

select sin(1.234);
+-----+
| sin(1.234) |
+-----+
| 0.9438182093746337 |

```

14.12.5. Arithmetic operators

+

- Description: This operator is used for addition.
- Example:

```

select 3+5;
+-----+
| _col0 |
+-----+
| 8 |

```

-

- **Description:** This operator is used for subtraction.
- **Example:**

```
select 3-5;
+-----+
|_col0|
+-----+
|  -2|
```

*

- **Description:** This operator is used for multiplication.
- **Example:**

```
select 3*pi();
+-----+
|_col0|
+-----+
| 9.42477796076938|
```

/

- **Description:** This operator is used for division.
- **Example:**

```
select 3/pi();
+-----+
|_col0|
+-----+
| 0.954929658551372|
```

DIV

- **Description:** This operator is used for division. The decimal part of the result is discarded.
- **Example:**

```
select 3 div pi();
+-----+
|_col0|
+-----+
|  0|
```

% or MOD

- **Description:** This operator returns the remainder of one argument divided by the other argument.
- **Example:**

```
select 3 mod pi();
+-----+
|_col0|
+-----+
|  3.0|
```

-

- **Description:** This operator converts a positive number to a negative number or a negative number to a positive number.
- **Example:**

```
select - 2;
+-----+
| _col0 |
+-----+
|  -2 |
```

14.12.6. Bit functions and operators

BIT_COUNT

- **Description:** This function converts the parameter to a binary value, and then returns the number of bits that are set to 1 in the value.
- **Return value type:** BIGINT.
- **Example:**

```
select bit_count(2);
+-----+
| bit_count(2) |
+-----+
|      1 |
```

&

- **Description:** This function is used for bitwise AND.
- **Return value type:** BIGINT.
- **Example:**

```
select 12 & 15;
+-----+
| bitwise_and(12, 15) |
+-----+
|      12 |
```

~

- **Description:** This function inverts all bits.
- **Return value type:** BIGINT.
- **Example:**

```
select 2 & ~1;
+-----+
| bitwise_and(2, bitwise_not(1)) |
+-----+
|      2 |
```

|

- Description: This function is used for bitwise OR.
- Return value type: BIGINT.
- Example:

```
select 29 | 15;
+-----+
| bitwise_or(29, 15) |
+-----+
|          31 |
```

^

- Description: This function is used for bitwise XOR.
- Return value type: BIGINT.
- Example:

```
select 1 ^ 10;
+-----+
| bitwise_xor(1, 10) |
+-----+
|          11 |
```

>>(BITWISE_RIGHT_SHIFT)

```
bitwise_right_shift(double x, double y)
bitwise_right_shift(varchar x, varchar y)
bitwise_right_shift(bigint x, bigint y)
```

- Description: This function shifts a value to the right.
- Return value type: BIGINT.
- Example:

```
select 3 >> 2;
+-----+
| bitwise_right_shift(3, 2) |
+-----+
|          0 |
```

<<(BITWISE_LEFT_SHIFT)

```
bitwise_left_shift(double x, double y)
bitwise_left_shift(varchar x, varchar y)
bitwise_left_shift(bigint x, bigint y)
```

- Description: This function shifts a value to the left.
- Return value type: BIGINT.
- Example:

```

SELECT 3 << 2;
+-----+
| bitwise_left_shift(3, 2) |
+-----+
|          12 |

```

14.12.7. Control flow functions

The control flow functions described in this topic use the conditiontest table as test data.

```
create table conditiontest(a int) distributed by hash(a);
```

```
insert into conditiontest values (1),(2),(3);
```

```

SELECT * FROM conditiontest;
+----+
| a |
+----+
| 2 |
| 1 |
| 3 |

```

CASE

```

CASE expression
  WHEN value THEN result
  [ WHEN ... ]
  [ ELSE result ]
END

```

- **Description:** A simple CASE expression checks each value from left to right, and returns the result for the first value that is equal to the expression. If no match is found, result is returned.
- **Example:**

```

SELECT a,
  CASE a
    WHEN 1 THEN 'one'
    WHEN 2 THEN 'two'
    ELSE 'three'
  END as caseresult
FROM conditiontest;
+----+-----+
| a | caseresult |
+----+-----+
| 2 | two      |
| 1 | one      |
| 3 | three    |

```

```

CASE
  WHEN condition THEN result
  [ WHEN ... ]
  [ ELSE result ]
END

```

- **Description:** An advanced CASE expression calculates conditions from left to right, and returns the result for the first condition that is TRUE. If no condition is TRUE, result is returned.
- **Example:**

```

SELECT a,
       CASE a
         WHEN a=1 THEN 'one1'
         WHEN a=2 THEN 'two2'
         ELSE 'three3'
       END as caseresult
FROM conditiontest;
+---+-----+
| a | caseresult |
+---+-----+
| 1 | one1      |
| 3 | three3    |
| 2 | three3    |

```

IF

```
if(condition, true_value)
```

- **Description:** If the condition is true, true_value is returned. Otherwise, null is returned.
- **Example:**

```

SELECT IF((2+3)>4,5);
+-----+
| _col0 |
+-----+
| 5 |

```

```
if(condition, true_value, false_value)
```

- **Description:** If the condition is true, true_value is returned. Otherwise, false_value is returned.
- **Example:**

```

SELECT IF((2+3)<5,5,6);
+-----+
| _col0 |
+-----+
| 6 |

```

IFNULL

```
IFNULL(expr1,expr2)
```

- **Description:** If expr1 is not null, expr1 is returned. Otherwise, expr2 is returned.
- **Example:**

```
SELECT IFNULL(NULL,2);
+-----+
|_col0|
+-----+
|  2 |
SELECT IFNULL(1,0);
+-----+
|_col0|
+-----+
|  1 |
```

NULLIF

```
NULLIF(expr1,expr2)
```

- **Description:** If expr1 is equal to expr2, null is returned. Otherwise, expr1 is returned.
- **Example:**

```
SELECT NULLIF (2,1);
+-----+
|_col0|
+-----+
|  2 |
SELECT NULLIF (2,2);
+-----+
|_col0|
+-----+
| NULL |
```

15. AnalyticDB for PostgreSQL

15.1. What is AnalyticDB for PostgreSQL?

AnalyticDB for PostgreSQL (formerly known as HybridDB for PostgreSQL) is a distributed cloud database service that uses multiple compute nodes to provide massively parallel processing (MPP) data warehousing services.

AnalyticDB for PostgreSQL is developed based on the open source Greenplum database project and enhanced by Alibaba Cloud. This service has the following features:

- Compatible with Greenplum and all tools that support it.
- Supports OSS, JSON, and HyperLogLog, a probability cardinality estimation algorithm.
- Supports SQL:2003-compliant syntax and OLAP aggregate functions to provide flexible hybrid analysis.
- Supports both row store and column store to enhance analytics performance.
- Leverages data compression technologies to reduce storage costs.
- Provides online expansion and performance monitoring services to enable DBAs, developers, and data analysts to focus on improving enterprise productivity and creating core business value instead of managing and maintaining large numbers of MPP clusters.

15.2. Quick start

15.2.1. Overview

This topic provides a quick start guide about how to perform management tasks for AnalyticDB for PostgreSQL instances such as creating an instance and logging on to a database.

- [Log on to the AnalyticDB for PostgreSQL console](#)

This topic describes how to log on to the AnalyticDB for PostgreSQL console.

- [Create an instance](#)

You can create an instance in the console and then manage the instance.

- [Configure a whitelist](#)

To ensure a secure and stable database, you must add IP addresses or CIDR blocks that are allowed to access the database to a whitelist of the instance before you use the AnalyticDB for PostgreSQL instance.

- [Create an initial account](#)

After you create an instance, you must create an initial account to log on to the database.

- [Connect to a database](#)

You can use a client that supports PostgreSQL or Greenplum to connect to the database.

15.2.2. Log on to the AnalyticDB for PostgreSQL console

This topic describes how to log on to the AnalyticDB for PostgreSQL console.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

1. In the address bar, enter the URL used to access the ASCM console. Press the Enter key.
2. Enter your username and password.

Obtain the username and password for logging on to the console from the operations administrator.

Note When you log on to the ASCM console for the first time, you must change the password of your username as prompted. Due to security concerns, your password must meet the minimum complexity requirements: The password must be 8 to 20 characters in length and must contain at least two of the following character types: uppercase letters, lowercase letters, digits, and special characters such as exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Products > AnalyticDB for PostgreSQL**.

15.2.3. Create an instance

You can create an instance in the console and then manage the instance.

1. **Log on to the AnalyticDB for PostgreSQL console.**
2. In the upper-right corner of the page, click **Create Instance**.
3. On the **AnalyticDB for PostgreSQL buy page**, configure the following parameters.

Section	Parameter	Description
Region	Organization	The organization to which the instance belongs.
	Resource Set	The resource set to which the instance belongs.
	Region	The region of the instance. Note If you need to access the AnalyticDB for PostgreSQL instance from an ECS instance over VPC, you must deploy the instance in the same region and zone as those of the ECS instance.
	Zone	The zone of the instance.
Basic Settings	Engine	Currently, only the integrated computing and storage version is supported.
	Engine Version	The engine version of the instance.
	Node Type	The unit of computing resources. Different group types have different storage capacities and computing capabilities.
	Nodes	The number of compute nodes. An instance must contain at least two compute nodes. The performance of an instance scales linearly with the number of compute nodes.
	Network Type	Valid values: <ul style="list-style-type: none"> ◦ <i>Classic Network</i>: Cloud services on a classic network are not isolated from each other. Unauthorized access to a cloud service is blocked only by the security group or whitelist policy of the service. ◦ <i>VPC</i>: A VPC helps you to build an isolated network environment in Alibaba Cloud. You can customize the route table, IP address range, and gateway in a VPC. We recommend that you select VPC for enhanced security. You can create a VPC in advance, or change the network type to VPC after instance creation.

Network Section	Parameter	Description
	VPC	The VPC where the AnalyticDB for PostgreSQL instance is located.  Note Virtual Private Cloud (VPC): You can use a VPC to build an isolated network environment in Alibaba Cloud. You can customize the route table, IP address range, and gateway in a VPC.
	VSwitch	The VSwitch where the AnalyticDB for PostgreSQL instance is located.
	IP Whitelist	The IP addresses that are allowed to access the instance.

- After you have configured the preceding parameters, click **Submit**.

15.2.4. Configure a whitelist

To ensure a secure and stable database, you must add IP addresses or CIDR blocks that are allowed to access the database to a whitelist.

- Log on to the [AnalyticDB for PostgreSQL console](#).
- Find the target instance and click its ID. The **Basic Information** page appears.
- In the left-side navigation pane, click **Security Controls**. The **Security Controls** page appears.
- On the **Whitelist Settings** tab, click **Modify** corresponding to the *default* whitelist. The **Modify Group** page appears.

 **Note** You can also click **Clear** corresponding to the *default* whitelist to delete the IP addresses of the default whitelist, and then click **Add Group** to create a new whitelist.

- Delete 127.0.0.1 from the *default* whitelist and enter your IP addresses in the whitelist. The following table lists the parameters.

Parameter	Description
Whitelist Name	Specify the name of the whitelist. The whitelist name must be 2 to 32 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a lowercase letter and end with a letter or digit. The default whitelist cannot be modified or deleted.
IP Addresses	Enter the CIDR blocks or IP addresses that are allowed to access the database. Use commas (,) to separate multiple CIDR blocks or IP addresses. <ul style="list-style-type: none"> A whitelist can contain IP addresses such as 10.10.10.1 and CIDR blocks such as 10.10.10.0/24. This CIDR block indicates that any IP addresses in the 10.10.10.X format have access to the database. The percent sign (%) or 0.0.0.0/0 indicates that any IP addresses are allowed to access the database.  Notice This configuration is not recommended because it reduces the security of the database. <ul style="list-style-type: none"> Default whitelists of new instances contain the loopback address 127.0.0.1. This configuration allows no access from external IP addresses. You can add up to 999 IP addresses or CIDR blocks to a whitelist group.

- Click **OK** to create a whitelist.

What's next

- We recommend that you regularly maintain the whitelist to ensure secure access for AnalyticDB for PostgreSQL.
- You can click **Modify** or **Delete** to modify or delete custom whitelists.

15.2.5. Create an initial account

After you create an instance, you must create an initial account to log on to the database.

1. [Log on to the AnalyticDB for PostgreSQL console](#).
2. Find the target instance and click its ID. The **Basic Information** page appears.
3. In the left-side navigation pane, click **Account Management**. The **Account Management** page appears.
4. In the upper-right corner of the page, click **Create Account**. The **Create Account** page appears.
5. Enter the database account and password, and click **OK**.

Parameter	Description
Account	The name of the account must be 2 to 16 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a letter and end with a letter or digit.
New Password	The password must be 8 to 32 characters in length. It must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters.
Password	Enter the password again.

15.2.6. Obtain the client tool

The interface protocol of AnalyticDB for PostgreSQL is compatible with Greenplum Community Edition and PostgreSQL 8.2. Because of this, you can use the Greenplum or PostgreSQL client to connect to AnalyticDB for PostgreSQL.

Note

Apsara Stack is an isolated environment. You must deploy software installation packages to the internal environment.

Graphical client tools

AnalyticDB for PostgreSQL users can directly use client tools that support Greenplum, such as [SQL Workbench](#), [Navicat Premium](#), [Navicat for PostgreSQL](#), and [pgAdmin III \(1.6.3\)](#).

Command-line client psql (for RHEL 6, RHEL 7, CentOS 6, and CentOS 7)

For Red Hat Enterprise Linux (RHEL) and CentOS 6 or 7, you can download the tools from the following addresses and decompress the packages to use them:

- For RHEL 6 or CentOS 6, click [hybriddb_client_package_el6](#).
- For RHEL version 7 or CentOS version 7, click [hybriddb_client_package_el7](#).

Command-line client psql (for other Linux systems)

The compilation methods for client tools applicable to other Linux systems are as follows:

1. Obtain the source code by using one of the following methods:
 - Obtain the git directory. You must first install the git tool.

```
git clone https://github.com/greenplum-db/gpdb.git
cd gpdb
git checkout 5d870156
```

- Download the code.

```
wget https://github.com/greenplum-db/gpdb/archive/5d87015609abd330c68a5402c1267fc86cbc9e1f.zip
unzip 5d87015609abd330c68a5402c1267fc86cbc9e1f.zip
cd gpdb-5d87015609abd330c68a5402c1267fc86cbc9e1f
```

2. Use gcc and other compilers.

```
./configure
make -j32
make install
```

3. Use psql and pg_dump. The paths of the two tools are as follows:

```
psql: /usr/local/pgsql/bin/psql
```

```
pg_dump: /usr/local/pgsql/bin/pg_dump
```

Command-line client psql (for Windows and other systems)

For client tools for Windows and other systems, go to the Pivotal website to download [HybridDB Client](#)

15.2.7. Connect to a database

The Greenplum Database and AnalyticDB for PostgreSQL are both developed based on PostgreSQL 8.2 and fully compatible with its messaging protocol. AnalyticDB for PostgreSQL users can use tools that support the PostgreSQL 8.2 message protocol, such as libpq, JDBC, ODBC, psycopg2, and pgAdmin III.

Context

AnalyticDB for PostgreSQL provides psql, a binary program of Red Hat. For more information about the download link, see [Obtain the client tool](#). The Greenplum official website provides an easy-to-install installation package that includes JDBC, ODBC, and libpq. For more information, see [Greenplum official documentation](#).

Note

- Apsara Stack is an isolated environment. To access Apsara Stack, you must prepare the necessary software installation packages in advance.
- AnalyticDB for PostgreSQL instances can only be accessed by clients deployed on ECS instances within the same region and zone.

psql

psql is a common tool used together with Greenplum, and provides a variety of command functions. Its binary files are located in the *bin* directory of Greenplum. The procedure is as follows:

1. Connect to AnalyticDB for PostgreSQL by using one of the following methods:

- Connection string

```
psql "host=yourgpdbaddress.gpdb.rds.aliyuncs.com port=3432 dbname=postgres user=gpdbaccount password=gpdbpassword"
```

- Specified parameters

```
psql -h yourgpdbaddress.gp.aliyun-inc.com -p 3432 -d postgres -U gpdbaccount
```

Parameters:

- -h: specifies the host address.
- -p: specifies the port number.
- -d: specifies the database. The default database is postgres.
- -U: specifies the user to connect to the database.

In psql, you can run the `psql --help` command to view more options. You can run the `\?` command to view the commands supported in psql.

2. Enter the password to go to the psql shell interface.

```
postgres=>
```

References

- For more information about the Greenplum psql usage, see [psql](#).
- AnalyticDB for PostgreSQL also supports psql statements of PostgreSQL. Pay attention to the differences between Greenplum psql and PostgreSQL psql. For more information, see [PostgreSQL 8.3.23 Documentation - psql](#).

pgAdmin III

pgAdmin III is a PostgreSQL graphical client and can be directly used to connect to AnalyticDB for PostgreSQL. For more information, click [here](#). For more information about other graphical clients, see [Obtain the client tool](#).

1. Download pgAdmin III 1.6.3 or earlier versions.

You can download pgAdmin III 1.6.3 from the [PostgreSQL website](#). PgAdmin III 1.6.3 supports various operating systems, such as Windows, macOS, and Linux.

 **Note** AnalyticDB for PostgreSQL is compatible with PostgreSQL 8.2. Therefore, you must use pgAdmin III 1.6.3 or earlier to connect to AnalyticDB for PostgreSQL. pgAdmin 4 and later versions are not supported.

2. Choose **File > Add Server**.
3. In the New Server Registration dialog box that appears, enter the configuration information.
4. Click **OK** to connect to AnalyticDB for PostgreSQL.

JDBC

JDBC uses the interface provided by PostgreSQL. The download methods are as follows:

- Click [PostgreSQL JDBC Driver](#) to download the official JDBC of PostgreSQL, and then add it to the environment variables.
- Use the tools provided by the Greenplum website. For more information, see [Greenplum Database 4.3 Connectivity Tools for UNIX](#).

The sample code is as follows:

```
import java.sql.Connection; import java.sql.DriverManager; import java.sql.ResultSet; import java.sql.SQLException; import java.sql.Statement; public class gp_conn { public static void main(String[] args) { try { Class.forName("org.postgresql.Driver"); Connection db = DriverManager.getConnection("jdbc:postgresql://mygpdbpub.gpdb.rds.aliyuncs.com:3432/postgres","mygpdb","mygpdb"); Statement st = db.createStatement(); ResultSet rs = st.executeQuery("select * from gp_segment_configuration;"); while (rs.next()) { System.out.print(rs.getString(1)); System.out.print(" | "); System.out.print(rs.getString(2)); System.out.print(" | "); System.out.print(rs.getString(3)); System.out.print(" | "); System.out.print(rs.getString(4)); System.out.print(" | "); System.out.print(rs.getString(5)); System.out.print(" | "); System.out.print(rs.getString(6)); System.out.print(" | "); System.out.print(rs.getString(7)); System.out.print(" | "); System.out.print(rs.getString(8)); System.out.print(" | "); System.out.print(rs.getString(9)); System.out.print(" | "); System.out.print(rs.getString(10)); System.out.print(" | "); System.out.println(rs.getString(11)); } rs.close(); st.close(); } catch (ClassNotFoundException) { e.printStackTrace(); } catch (SQLException e) { e.printStackTrace(); }}
```

Python

Python uses `psycopg2` to connect to Greenplum and PostgreSQL. Procedure:

1. Install `psycopg2`. There are three installation methods in CentOS:

- Method 1: Run the `yum -y install python-psycopg2` command.
- Method 2: Run the `pip install psycopg2` command.
- Method 3: Run the source code:

```
yum install -y postgresql-devel*
wget http://initd.org/psycopg/tarballs/PSYCOPG-2-6/psycopg2-2.6.tar.gz
tar xf psycopg2-2.6.tar.gz
cd psycopg2-2.6
python setup.py build
sudo python setup.py install
```

2. Run the following commands to set `PYTHONPATH` and reference it:

```
import psycopg2
sql = 'select * from gp_segment_configuration;'
conn = psycopg2.connect(database='gpdb', user='mygpdb', password='mygpdb', host='mygpdbpub.gpdb.rds.aliyuncs.com', port=3432)
conn.autocommit = True
cursor = conn.cursor()
cursor.execute(sql)
rows = cursor.fetchall()
for row in rows:
    print row
conn.commit()
conn.close()
```

A similar output is displayed:

```
(1, -1, 'p', 'p', 's', 'u', 3022, '192.168.2.158', '192.168.2.158', None, None)(6, -1, 'm', 'm', 's', 'u', 3019, '192.168.2.47', '192.168.2.47', None, None)(2, 0, 'p', 'p', 's', 'u', 3025, '192.168.2.148', '192.168.2.148', 3525, None)(4, 0, 'm', 'm', 's', 'u', 3024, '192.168.2.158', '192.168.2.158', 3524, None)(3, 1, 'p', 'p', 's', 'u', 3023, '192.168.2.158', '192.168.2.158', 3523, None)(5, 1, 'm', 'm', 's', 'u', 3026, '192.168.2.148', '192.168.2.148', 3526, None)
```

libpq

libpq is the C language interface to AnalyticDB for PostgreSQL. You can use the libpq library to access and manage PostgreSQL databases in a C program. You can locate its static and dynamic libraries under the lib directory.

For the example programs, visit [Example Programs](#).

For more information about libpq, see [PostgreSQL 9.4.17 Documentation - Chapter 31. libpq - C Library](#).

ODBC

PostgreSQL ODBC is an open-source version based on the GNU Lesser General Public License (LGPL) protocol. You can download it from the [PostgreSQL website](#).

1. Install the driver.

```
yum install -y unixODBC.x86_64
yum install -y postgresql-odbc.x86_64
```

2. View the driver configuration.

```
cat /etc/odbcinst.ini
# Example driver definitions
# Driver from the postgresql-odbc package
# Setup from the unixODBC package
[PostgreSQL]
Description = ODBC for PostgreSQL
Driver = /usr/lib/psqlodbcw.so
Setup = /usr/lib/libodbcpsqlS.so
Driver64 = /usr/lib64/psqlodbcw.so
Setup64 = /usr/lib64/libodbcpsqlS.so
FileUsage = 1
# Driver from the mysql-connector-odbc package
# Setup from the unixODBC package
[MySQL]
Description = ODBC for MySQL
Driver = /usr/lib/libmyodbc5.so
Setup = /usr/lib/libodbcmyS.so
Driver64 = /usr/lib64/libmyodbc5.so
Setup64 = /usr/lib64/libodbcmyS.so
FileUsage = 1
```

3. Configure the DSN. Replace the `****` in the following code with the corresponding connection information.

```
[mygpdb]
Description = Test to gp
Driver = PostgreSQL
Database = ****
Servername = ****.gpdb.rds.aliyuncs.com
UserName = ****
Password = ****
Port = ****
ReadOnly = 0
```

4. Test connectivity.

```

echo "select count(*) from pg_class" | isql mygpdb
+-----+
| Connected!          |
|                    |
| sql-statement      |
| help [tablename]   |
| quit               |
|                    |
+-----+
SQL> select count(*) from pg_class
+-----+
| count  |
+-----+
| 388    |
+-----+
SQLRowCount returns 1
1 rows fetched

```

5. After ODBC is connected to the instance, connect the application to ODBC. For more information, see [PostgreSQL ODBC Driver](#) and [psqlODBC HOWTO - C#](#).

References

- [Pivotal Greenplum documentation](#)

15.3. Instances

15.3.1. Reset the password

If you forget the password of your database account, you can reset the password in the AnalyticDB for PostgreSQL console.

 **Note** We recommend that you change your password periodically to ensure data security.

1. [Log on to the AnalyticDB for PostgreSQL console](#).
2. Find the target instance and click its ID. The **Basic Information** page appears.
3. In the left-side navigation pane, click **Account Management**. The **Account Management** page appears.
4. Click **Reset Password** in the corresponding **Actions** column of the account. The **Reset Account Password** page appears.
5. After you enter and confirm the new password, click **OK**.

 **Note** The password must be 8 to 32 characters in length. It must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. We recommend that you do not use a previously used password.

15.3.2. View monitoring information

You can go to the monitoring information page in the console to view the operation status of an instance.

1. [Log on to the AnalyticDB for PostgreSQL console.](#)
2. Find the target instance and click its ID. The **Basic Information** page appears.
3. In the left-side navigation pane, click **Monitoring and Alarms**. The **Monitoring and Alarms** page appears. Specify a duration of time n up to seven days in length to view the metrics for that last n period.

15.3.3. Switch the network type of an instance

The default network type of an instance is Virtual Private Cloud (VPC). After an instance is created, you can switch its network type between classic network and VPC as needed.

Context

AnalyticDB for PostgreSQL supports two network types: classic network and VPC. Both network types use BGP connections, and are independent of the public network of your service provider. These network types only differ in functions, and you can choose a network type based on your requirements. The two network types are applicable to different scenarios:

- **Classic network:** IP addresses are allocated by Alibaba Cloud. Classic networks are easy to configure and use. This network type is suitable for users who do not need to perform complex operations, or who only require short deployment cycles.
- **VPC:** a logically isolated private network. You can customize the network topology and IP addresses and connect through a leased line. This network type is suitable for advanced users.

 **Warning** Switching the network type will cause the database service to stop. Proceed with caution.

1. [Log on to the AnalyticDB for PostgreSQL console.](#)
2. Find the target instance and click its ID. The **Basic Information** page appears.
3. In the left-side navigation pane, click **Database Connection**. The **Database Connection** page appears.
4. In the upper-right corner of the page, click **Switch to Classic Network** or **Switch to VPC**.
5. If you click **Switch to VPC**, you must select the destination VPC and VSwitch. Click **OK**.

 **Note** To switch the network type to VPC, a VPC and a VSwitch must exist or be created in the zone where the instance is located.

6. If you click **Switch to Classic Network**, click **OK** in the displayed message.

 **Note** After you switch the network type, it takes 3 to 30 minutes for the instance to enter the running state.

15.3.4. Restart an instance

To better meet your needs, AnalyticDB for PostgreSQL automatically updates the database kernel version. When you create an instance, the latest database kernel is used by default. After a new version is released, you can restart your instance to update the database kernel and use its extended features. This topic describes how to restart an instance.

 **Warning** Restarting an instance will cause the database service to stop. Proceed with caution.

1. [Log on to the AnalyticDB for PostgreSQL console](#).
2. Find the target instance and click its ID. The **Basic Information** page appears.
3. In the upper-right corner of the page, click **Restart Instance**.

 **Note** The restart process typically takes from 3 to 30 minutes. During the restart period, the instance cannot provide external services. We recommend that you take precautionary measures before restarting instances. After the instance has been restarted and enters the running state, you can access the database.

15.3.5. Import data

15.3.5.1. Import or export data from or to OSS in parallel

AnalyticDB for PostgreSQL can import or export data from or to OSS tables in parallel by using the OSS external table feature, `gpossex`. AnalyticDB for PostgreSQL also supports GZIP compression for OSS external tables to reduce file size and storage costs. `gpossex` can read from and write to TEXT and CSV files, even when they are compressed in GZIP packages.

- Create an OSS external table extension (`oss_ext`)

To use an OSS external table, you must first create an OSS external table extension in AnalyticDB for PostgreSQL. You must create an extension for each database that you need to access.

- Creation statement: `CREATE EXTENSION IF NOT EXISTS oss_ext;`
- Deletion statement: `DROP EXTENSION IF EXISTS oss_ext;`

- Import data in parallel

- i. Distribute data evenly among multiple OSS files for storage. We recommend that you set the number of OSS files to an integer that is the multiple of the number of compute nodes in AnalyticDB for PostgreSQL.
- ii. Create a `READABLE` external table in AnalyticDB for PostgreSQL.
- iii. Execute the following statement to import data in parallel:

```
INSERT INTO <destination table> SELECT * FROM <external table>
```

 **Note**

- The data import performance depends on the OSS performance and resources of the AnalyticDB for PostgreSQL instance, such as CPU, I/O, memory, and network resources. To ensure the best import performance, we recommend that you use column store and compression when you create a table. For example, you can specify the following clause: `WITH (APPENDONLY=true, ORIENTATION=column, COMPRESSTYPE=zlib, COMPRESSLEVEL=5, BLOCKSIZE=1048576)`. For more information, see [Greenplum Database official documentation on database table creation syntax](#).
- We recommend that you configure OSS and AnalyticDB for PostgreSQL instances within the same region to implement the best import performance.

- Export data in parallel

- i. Create a `WRITABLE` external table in AnalyticDB for PostgreSQL.
- ii. Execute the following statement to export data to OSS in parallel:

```
INSERT INTO <external table> SELECT * FROM <source table>
```

- Create OSS external tables

 **Note** The syntax to create and use external tables is the same as that of Greenplum Database, except for the syntax of location-related parameters.

```

CREATE [READABLE] EXTERNAL TABLE tablename
( columnname datatype [, ...] | LIKE othertable )
LOCATION ('ossprotocol')
FORMAT 'TEXT'
  (( [HEADER]
    [DELIMITER [AS] 'delimiter' | 'OFF']
    [NULL [AS] 'null string']
    [ESCAPE [AS] 'escape' | 'OFF']
    [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
    [FILL MISSING FIELDS] ))
| 'CSV'
  (( [HEADER]
    [QUOTE [AS] 'quote']
    [DELIMITER [AS] 'delimiter']
    [NULL [AS] 'null string']
    [FORCE NOT NULL column [, ...]]

ossprotocol:
  oss://oss_endpoint filepath=[folder/[folder/]...]/file_name
  id=userossid key=userosskey bucket=ossbucket compressiontype=[none|gzip] async=[true|false]

```

Parameters

Common parameters

Parameter	Description
Protocol and endpoint	<p>It is in the <code>protocol name://oss_endpoint</code> format. The protocol name is <code>oss</code>. <code>oss_endpoint</code> is the domain name used by users to access OSS in a region.</p> <p> Note You can access the database from a VPC host by using an internal endpoint containing "internal" in the name to avoid generating public traffic.</p>
id	The AccessKey ID of the OSS account.
key	The AccessKey secret of the OSS account.
bucket	The bucket where the data file is located. You must use OSS to create the bucket before data import.
prefix	<p>The prefix of the path name corresponding to the data file. Prefixes are directly matched and cannot be controlled by regular expressions. The <code>prefix</code>, <code>filepath</code>, and <code>dir</code> parameters are mutually exclusive and only one parameter can be specified at a time.</p> <ul style="list-style-type: none"> • If you create a <code>READABLE</code> external table for data import, all OSS files that contain the specified prefix will be imported. <ul style="list-style-type: none"> ◦ If you set <code>prefix</code> to <code>test/filename</code>, the following files will be imported: <ul style="list-style-type: none"> ▪ <code>test/filename</code> ▪ <code>test/filenameexxx</code> ▪ <code>test/filename/aa</code> ▪ <code>test/filenameyyy/aa</code> ▪ <code>test/filenameyyy/bb/aa</code> ◦ If you set <code>prefix</code> to <code>test/filename/</code>, only the following file out of the preceding files will be imported: <ul style="list-style-type: none"> <code>test/filename/aa</code> • if you create a <code>WRITABLE</code> external table for data export, each exported file will have a unique name based on this parameter. <p> Note One or more files can be exported for each compute node. The names of exported files are in the <code>prefix_tablename_uuid.x</code> format. <code>uuid</code> indicates a timestamp in microseconds as an <code>int64</code> value. <code>x</code> indicates the node ID. You can use an external table for multiple export operations. Each export operation is assigned to a <code>uuid</code> value. The files exported during each operation share a <code>uuid</code> value.</p>

Parameter	Description
dir	<p>The virtual folder path in OSS. The prefix, filepath, and dir parameters are mutually exclusive and only one parameter can be specified at a time.</p> <ul style="list-style-type: none"> A folder path must end with a forward slash (/) such as <code>test/mydir/</code>. If you use this parameter when creating an external table for data import, all files under the specified virtual directory (except for its subdirectories and contained files) will be imported. Unlike filepath, dir does not require you to specify the names of files in the directory. If this parameter is used in creating an external table for data export, all data will be exported to multiple files within the specified directory. The names of exported files are in the <code>filename.x</code> format, where x is a digit. The values of x may not be consecutive.
filepath	<p>The file name that contains a path in OSS. The prefix, filepath, and dir parameters are mutually exclusive and only one parameter can be specified at a time. You can only specify the filepath parameter when you create a READABLE external table for data import.</p> <ul style="list-style-type: none"> The file name includes the file path, but not the bucket name. The filename specified for data import must be in the <code>filename</code> or <code>filename.x</code> format. The values of x must be consecutive digits starting from 1. <p>For example, if filepath is set to filename and OSS contains the following files, the imported files include filename, filename.1, and filename.2, but filename.4 is not imported because filename.3 does not exist.</p> <pre>filename filename.1 filename.2 filename.4</pre>

Import mode parameters

Parameter	Description
async	<p>Specifies whether to load data asynchronously.</p> <ul style="list-style-type: none"> Asynchronous data import is enabled by default. You can set <code>async</code> to <code>false</code> or <code>f</code> to disable asynchronous data import. Enables the worker thread to load data from OSS to accelerate the import performance. The default import mode is asynchronous mode. Asynchronous data import consumes more hardware resources than normal data import.
compressiontype	<p>The compression format of the imported file. Valid values:</p> <ul style="list-style-type: none"> <code>none</code>: specifies to import files without compressing them. This is the default value. <code>gzip</code>: specifies compress imported files in the GZIP format. Only the GZIP format is supported.
compressionlevel	<p>The compression level of the files written to OSS. Valid values: 1 to 9. Default value: 6.</p>

Export mode parameters

Parameter	Description
oss_flush_block_size	The size of each data block written to OSS. Valid values: 1 MB to 128 MB. Default value: 32 MB.
oss_file_max_size	The maximum size of each file written to OSS. If the limit is exceeded, subsequent data is written to another file. Valid values: 8 MB to 4000 MB. Default value: 1024 MB.
num_parallel_worker	The number of parallel compression threads for data written to OSS. Valid values: 1 to 8. Default value: 3.

Additionally, you must pay attention to the following items for the export mode:

- **WRITABLE** is the keyword of the external table for data export. You must specify this keyword when creating an external table.
- Only the **prefix** and **dir** parameters are supported for data export. The **filepath** parameter is not supported.
- You can use the **DISTRIBUTED BY** clause to write data from compute nodes to OSS based on the specified distribution keys.

Other common parameters

The following error-tolerance parameters can be used for data import and export:

Error-tolerance parameters

Parameter	Description
oss_connect_timeout	The connection timeout period. Unit: seconds. Default value: 10.
oss_dns_cache_timeout	The DNS timeout period. Unit: seconds. Default value: 60.
oss_speed_limit	The minimum rate tolerated. Default value: 1024 bit/s (1 Kbit/s).
oss_speed_time	The maximum amount of time tolerated. Unit: seconds. Default value: 15.

If the default values are used for the preceding parameters, a timeout will occur when the transmission rate is lower than 1 Kbit/s for 15 consecutive seconds. For more information, see [Troubleshooting in OSS SDK reference](#).

The other parameters are compatible with the original external table syntax of Greenplum Database. For more information about the syntax, see [Greenplum Database official documentation on external table syntax](#). These parameters include:

- **FORMAT**: indicates the supported file format, such as **TEXT** and **CSV**.
- **ENCODING**: indicates the data encoding format of a file, such as **UTF-8**.
- **LOG ERRORS**: indicates that the clause can ignore imported erroneous data and write the data to `error_table`. You can also use the **count** parameter to specify the error reporting threshold.

Examples

```
# Create a READABLE external table of OSS.
create readable external table ossexample
  (date text, time text, open float, high float,
  low float, volume int)
  location('oss://oss-cn-hangzhou.aliyuncs.com
  prefix=osstest/example id=XXX
  key=XXX bucket=testbucket compressiontype=gzip')
```

```

FORMAT 'csv' (QUOTE '"' DELIMITER E'\t')
ENCODING 'utf8'
LOG ERRORS INTO my_error_rows SEGMENT REJECT LIMIT 5;
create readable external table ossexample
(date text, time text, open float, high float,
low float, volume int)
location('oss://oss-cn-hangzhou.aliyuncs.com
dir=osstest/ id=XXX
key=XXX bucket=testbucket')
FORMAT 'csv'
LOG ERRORS SEGMENT REJECT LIMIT 5;
create readable external table ossexample
(date text, time text, open float, high float,
low float, volume int)
location('oss://oss-cn-hangzhou.aliyuncs.com
filepath=osstest/example.csv id=XXX
key=XXX bucket=testbucket')
FORMAT 'csv'
LOG ERRORS SEGMENT REJECT LIMIT 5;
# Create a WRITABLE external table of OSS.
create WRITABLE external table ossexample_exp
(date text, time text, open float, high float,
low float, volume int)
location('oss://oss-cn-hangzhou.aliyuncs.com
prefix=osstest/exp/outfromhdb id=XXX
key=XXX bucket=testbucket') FORMAT 'csv'
DISTRIBUTED BY (date);
create WRITABLE external table ossexample_exp
(date text, time text, open float, high float,
low float, volume int)
location('oss://oss-cn-hangzhou.aliyuncs.com
dir=osstest/exp/ id=XXX
key=XXX bucket=testbucket') FORMAT 'csv'
DISTRIBUTED BY (date);
# Create a heap table named example to which you want to import data.
create table example
(date text, time text, open float,
high float, low float, volume int)
DISTRIBUTED BY (date);
# Import data to the example heap table from the ossexample table in parallel.
insert into example select * from ossexample;
# Export data from example to OSS in parallel
insert into ossexample_exp select * from example;
# As shown in the following execution plan, all compute nodes are involved in the task.
# All compute nodes read data from OSS in parallel. AnalyticDB for PostgreSQL performs a redistribution motion operation to compute the data by using a hash algorithm, and then distributes the data to its compute nodes after computing. After a compute node receives data, it performs an insert operation to add the data to AnalyticDB for PostgreSQL.

```

```

explain insert into example select * from ossexample;
          QUERY PLAN
-----
Insert (slice0; segments: 4) (rows=250000 width=92)
-> Redistribute Motion 4:4 (slice1; segments: 4) (cost=0.00..11000.00 rows=250000 width=92)
    Hash Key: ossexample.date
    -> External Scan on ossexample (cost=0.00..11000.00 rows=250000 width=92)
(4 rows)
# As shown in the following query plan, each compute node exports local data directly to OSS without redistributing the data.
explain insert into ossexample_exp select * from example;
          QUERY PLAN
-----
Insert (slice0; segments: 3) (rows=1 width=92)
-> Seq Scan on example (cost=0.00..0.00 rows=1 width=92)
(2 rows)
    
```

TEXT and CSV format description

The following parameters specify the formats of files read from and written to OSS. You can specify the parameters in the external DDL parameters.

- `\n`: a line delimiter or line break for TEXT and CSV files.
- **DELIMITER**: specifies the delimiter of columns.
 - If the **DELIMITER** parameter is specified, the **QUOTE** parameter must also be specified.
 - Recommended column delimiters include commas (`,`), vertical bars (`|`), `\t`, and other special characters.
- **QUOTE**: encloses user data that contains special characters by column.
 - Strings that contain special characters will be enclosed by **QUOTE** to differentiate user data from the control characters.
 - To optimize the efficiency, it is unnecessary to enclose data such as integers in **QUOTE** characters.
 - **QUOTE** cannot be the same string as specified in **DELIMITER**. The default value of **QUOTE** is double quotation marks (`"`).
 - User data that contains **QUOTE** characters must also contain **ESCAPE** characters to differentiate user data from machine code.
- **ESCAPE**: specifies the escape character.
 - Place an escape character before a special character that needs to be escaped to indicate that it is not a special character.
 - If **ESCAPE** is not specified, the default value is the same as **QUOTE**.
 - You can also use other characters as **ESCAPE** characters such as backslashes (`\`), which is used by MySQL.

Default control characters for TEXT and CSV files

Default control characters for TEXT and CSV files

Control character	TEXT	CSV
DELIMITER	<code>\t</code> (tab)	<code>,</code> (comma)
QUOTE	<code>"</code> (double quotation mark)	<code>"</code> (double quotation mark)
ESCAPE	N/A	Same as QUOTE

Control character	TEXT	CSV
NULL	\N (backslash-N)	Empty string without quotation marks

 **Note** All control characters must be single-byte characters.

SDK troubleshooting

The following **Error log information** table lists the error logs generated when an error occurs during the import or export process.

Error log information

Keyword	Description
code	The HTTP status code of the error request.
error_code	The error code returned by OSS.
error_msg	The error message returned by OSS.
req_id	The UUID used to identify the request. If you require assistance in solving a problem, you can submit a ticket containing the req_id of the failed request to OSS developers.

For more information, see . You can handle timeout-related errors by using parameters related to oss_ext.

- [Greenplum Database official documentation on table creation syntax](#)

15.3.5.2. Import data from MySQL

You can use the mysql2pgsql tool to migrate tables from MySQL to AnalyticDB for PostgreSQL, Greenplum Database, PostgreSQL, or PPAS.

Background information

mysql2pgsql connects a source MySQL database to a destination AnalyticDB for PostgreSQL database, queries data to be exported from the MySQL database, and then imports the data to the destination database by using the \COPY statement. The tool supports multi-thread import. Each worker thread imports a part of database tables.

To download the binary installation package of mysql2pgsql, click [here](#).

To view instructions on source code compilation of mysql2pgsql, click [here](#).

Procedure

1. Modify the my.cfg configuration file to configure the connection information of source and destination databases.

i. Modify the connection information of the source MySQL database.

 **Note** You must have the read permissions on all user tables.

```
[src.mysql]
host = "192.168.1.1"
port = "3306"
user = "test"
password = "test"
db = "test"
encodingdir = "share"
encoding = "utf8"
```

ii. Modify the connection information of the destination PostgreSQL, PPAS, or AnalyticDB for PostgreSQL database.

 **Note** You must have the write permissions on the destination table.

```
[desc.pgsql]
connect_string = "host=192.168.1.2 dbname=test port=3432 user=test password=pgsql"
```

2. Import data by using mysql2pgsql.

```
./mysql2pgsql -l <tables_list_file> -d -n -j <number of threads> -s <schema of target table>
```

Parameters

Parameter	Description
-l	Optional. Used to specify a text file that contains tables to be synchronized. If you do not specify this parameter, all the tables in the database that is specified in the configuration file will be synchronized. <tables_list_file> is the name of a file that contains a collection of tables to be synchronized and conditions for table queries. The content format is as follows: <pre>table1 : select * from table_big where column1 < '2016-08-05'</pre> <pre>table2 :</pre> <pre>table3</pre> <pre>table4: select column1, column2 from tableX where column1 != 10</pre> <pre>table5: select * from table_big where column1 >= '2016-08-05'</pre>
-d	Optional. Indicates the table creation DDL statement that creates the destination table but does not synchronize data.
-n	Optional. Must be used along with -d to specify that the table partition definition is not included in the DDL statement.

Parameter	Description
-j	Optional. Used to specify the number of threads used for data synchronization. If you do not specify this parameter, five concurrent threads will be used by default.
-s	Optional. Used to specify the schema of the destination table. Only one schema at a time can be specified by the command. If you do not specify the parameter, the data is imported into the table under the public schema.

Typical usage

Full database migration

1. Obtain the DDL statements of the corresponding destination table by running the following command:

```
./mysql2pgsql -d
```

2. Create a table in the destination database based on these DDL statements with the distribution key information added.
3. Run the following command to synchronize all tables:

```
./mysql2pgsql
```

This command will migrate the data from all MySQL tables in the database that is specified in the configuration file to the destination database. By default, five concurrent threads are used to read and import data from involved tables.

Partial table migration

1. Create a new file tab_list.txt and enter the following content:

```
t1
t2 : select * from t2 where c1 > 138888
```

2. Run the following command to synchronize the specified t1 and t2 tables (note that for the t2 table, only data that meets the c1 > 138888 condition is migrated):

```
./mysql2pgsql -l tab_list.txt
```

15.3.5.3. Import data from PostgreSQL

You can use the pgsq2pgsql tool to migrate tables across AnalyticDB for PostgreSQL, Greenplum Database, PostgreSQL, and PPAS.

Context

pgsq2pgsql supports the following features:

- Full migration across PostgreSQL, PPAS, Greenplum Database, and AnalyticDB for PostgreSQL.
- Full migration and incremental migration from PostgreSQL or PPAS (version 9.4 or later) to AnalyticDB for PostgreSQL or ApsaraDB RDS for PPAS.

You can download the software packages from the [dbsync project](#) library.

- To download the binary installation package of pgsq2pgsql, click [here](#).
- To view instructions on source code compilation of pgsq2pgsql, click [here](#).

Procedure

1. Modify the my.cfg configuration file to configure the connection information of source and destination databases.

- i. Modify the connection information of the source PostgreSQL database.

 **Note** In the connection information of the source PostgreSQL database, we recommend that you set the user to the owner of the source database.

```
[src.pgsql]
connect_string = "host=192.168.1.1 dbname=test port=3432 user=test password=pgsql"
```

- ii. Modify the connection information of the local temporary PostgreSQL database.

```
[local.pgsql]
connect_string = "host=192.168.1.2 dbname=test port=3432 user=test2 password=pgsql"
```

- iii. Modify the connection information of the destination PostgreSQL database.

 **Note** You must have the write permissions on the destination table.

```
[desc.pgsql]
connect_string = "host=192.168.1.2 dbname=test port=3432 user=test3 password=pgsql"
```

 **Note**

- If you need to synchronize incremental data, you must have the permissions to create replication slots in the source database.
- PostgreSQL versions 9.4 and later support logic flow replication, meaning that source databases of the versions support incremental migration. The kernel supports logic flow replication only if you configure the following kernel parameters:

```
wal_level = logical
max_wal_senders = 6
max_replication_slots = 6
```

2. Use `pgsql2pgsql` to perform full database migration. `./pgsql2pgsql`

By default, the migration program migrates the table data of all users from the source PostgreSQL database to the destination PostgreSQL database.

3. View the status information.

You can view the status information in a single migration process by connecting to the local temporary database. The information is stored in the `db_sync_status` table, including the start and end time of the full migration, the start time of the incremental migration, and the status of incremental synchronization.

15.3.5.4. Import data by using the `\COPY` statement

You can use the `\COPY` statement to import the data of local text files into AnalyticDB for PostgreSQL databases. The local text files must be formatted, such as files that use commas (,), semicolons (;), or special characters as delimiters.

Context

- Parallel writing of large amounts of data is not available because the `\COPY` statement writes data in serial using the coordinator node. If you need to import a large amount of data in parallel, you can use the OSS-based data import method.
- The `\COPY` statement is a psql instruction. If you use the database statement `COPY` instead of the `\COPY` statement, you must note that only `stdin` is supported. This `COPY` statement does not support file because

the root user does not have the superuser permissions to perform operations on files.

- AnalyticDB for PostgreSQL also allows you to use JDBC to execute the COPY statement. The CopyIn method is encapsulated within JDBC. For more information, see [Interface CopyIn](#).
- For more information about how to use the COPY statement, see [COPY](#).

Procedure

1. Import data by using the following sample code:

```
\COPY table [(column [, ...])] FROM {'file' | STDIN}
[ [WITH]
  [OIDS]
  [HEADER]
  [DELIMITER [ AS ] 'delimiter']
  [NULL [ AS ] 'null string']
  [ESCAPE [ AS ] 'escape' | 'OFF']

```

15.4. Databases

15.4.1. Overview

The operations based on the Greenplum Database in AnalyticDB for PostgreSQL are the same as those in the Greenplum Database, including schema, supported data types, and user permissions. Except for certain operations exclusive to the Greenplum Database (such as the partition keys and AO tables), you can refer to PostgreSQL for other operations.

References

- [Pivotal Greenplum Official Documentation](#)
- [Greenplum 4.3 Best Practices](#)
- [Golden Rules of Greenplum Data Distribution](#)

15.4.2. Create a database

After you log on to the AnalyticDB for PostgreSQL instance, you can execute SQL statements to create databases.

Similar to PostgreSQL, in AnalyticDB for PostgreSQL you can execute SQL statements to create databases. For example, after psql is connected to Greenplum, execute the following statements:

```
=> create database mygpdb;
CREATE DATABASE
=> \c mygpdb
psql (9.4.4, server 8.3devel)
You are now connected to database "mygpdb" as user "mygpdb".
```

15.4.3. Create a partition key

AnalyticDB for PostgreSQL is a distributed database and data is distributed across all the data nodes. You must create partition keys to distribute the data. The partition keys are vital to query performance. Partition keys are used to ensure even data distribution. Proper selection of keys can significantly improve query performance.

Specify a partition key

In AnalyticDB for PostgreSQL, tables can be distributed across all compute nodes in either hash or random mode. You must specify the partition key when creating a table. Imported data will be distributed to the specific compute node based on the hash value calculated by the partition key.

```
=> create table vtbl(id serial, key integer, value text, shape cuboid, location geometry, comment text) distributed by (key);
CREATE TABLE
```

If you do not specify the partition key (that means a statement without the `distributed by (key)` field), AnalyticDB for PostgreSQL will randomly allocate the ID field by using the round-robin algorithm.

Rules for selecting the partition key

- Select evenly distributed columns or multiple columns to prevent data skew.
- Select fields commonly used for connection operations, especially for highly concurrent statements.
- Select the condition columns that feature high concurrency queries and high filterability.
- Do not use random distribution.

15.4.4. Construct data

In some test scenarios, you must construct data to fill the database.

1. Create a function that generates random strings.

```
CREATE OR REPLACE FUNCTION random_string(integer) RETURNS text AS $body$
SELECT array_to_string(array
    (SELECT substr('0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz'
        FROM (ceil(random()*62))::int
        FOR 1)
    FROM generate_series(1, $1)), '');
$body$
LANGUAGE SQL VOLATILE;
```

2. Create a partition key.

```
CREATE TABLE tbl(id serial, KEY integer, locate geometry, COMMENT text) distributed by (key);
```

3. Construct data.

```
INSERT INTO tbl(KEY, COMMENT, locate)
SELECT
  KEY,
  COMMENT,
  ST_GeomFromText(locate) AS locate
FROM
  (SELECT
    (a + 1) AS KEY,
    random_string(ceil(random() * 24)::integer) AS COMMENT,
    'POINT(' || ceil(random() * 36 + 99) || ' ' || ceil(random() * 24 + 50) || ')' AS locate
  FROM
    generate_series(0, 99999) AS a)
AS t;
```

15.4.5. Query data

This topic describes the query statements and how to view the query plans.

Query statement sample

```
=> select * from tbl where key = 751;
| id | key | value | shape | locate | comment |
+----+----+-----+-----+-----+-----+
| 751 | 751 | red | 010100000000000000000000C05B40000000000004A40 | B9hPhjeNWPqV |
(1 row)
Time: 513.101 ms
```

View a query plan

```
=> explain select * from tbl where key = 751;
Gather Motion 1:1 (slice1; segments: 1) (cost=0.00..1519.28 rows=1 width=53)
-> Seq Scan on tbl (cost=0.00..1519.28 rows=1 width=53)
    Filter: key = 751
Settings: effective_cache_size=8GB; gp_statistics_use_fkeys=on
Optimizer status: legacy query optimizer
```

15.4.6. Manage extensions

You can use extensions to expand database features. AnalyticDB for PostgreSQL enables you to manage extensions.

Extension types

AnalyticDB for PostgreSQL supports the following extensions:

- PostGIS: supports geographic information data.
- MADlib: supports the machine learning function library.
- fuzzystrmatch: supports the fuzzy matching of strings.
- orafunc: compatible with some Oracle functions.
- oss_ext: supports reading data from OSS.
- hll: collects statistics by using the HyperLogLog algorithm.
- pljava: supports compiling user-defined functions (UDF) in the PL/Java language.
- pgcrypto: supports cryptographic hash functions.
- intarray: supports integer array-related functions, operators, and indexes.

Create an extension

Execute the following statements to create an extension:

```
CREATE EXTENSION <extension name>;
CREATE SCHEMA <schema name>;
CREATE EXTENSION IF NOT EXISTS <extension name> WITH SCHEMA <schema name>;
```

Note

Before you create the MADlib extension, you must create the plpythonu extension first.

```
CREATE EXTENSION plpythonu;
CREATE EXTENSION madlib;
```

Delete an extension

Execute the following statements to delete an extension:

```
DROP EXTENSION <extension name>;
DROP EXTENSION IF EXISTS <extension name> CASCADE;
```

 **Note** If there are objects dependent on the extension, you must add the CASCADE keyword to delete all dependent objects.

15.4.7. Manage users and permissions

This topic describes how to manage users and permissions in AnalyticDB for PostgreSQL.

Manage users

The system prompts you to specify an initial username and password when you create an instance. This initial user is the root user. After the instance is created, you can use the root user account to connect to the database. The system also creates superusers such as aurora and replicator for internal management.

You can run the `\du+` command to view the information of all the users after you connect to the database by using the client tool of PostgreSQL or Greenplum. Example:

```
postgres=> \du+
                List of roles
Role name | Attributes | Member of | Description
-----+-----+-----+-----
root_user |           | rds_superuser
...
```

AnalyticDB for PostgreSQL does not provide superuser permissions, but offers a similar role, `RDS_SUPERUSER`, which is consistent with the permission system of ApsaraDB RDS for PostgreSQL. The root user (such as `root_user` in the preceding example) has the permissions of the `RDS_SUPERUSER` role. You can only identify this permission attribute by viewing the user description.

The root user has the following permissions:

- Can create databases and users and perform actions such as `LOGIN`, excluding the `SUPERUSER` permissions.
- Can view and modify the data tables of other users and perform actions such as `SELECT`, `UPDATE`, `DELETE`, and changing owners.
- Can view the connection information of other users, cancel their SQL statements, and kill their connections.
- Can create and delete extensions.
- Can create other users with `RDS_SUPERUSER` permissions. Example:

```
CREATE ROLE root_user2 RDS_SUPERUSER LOGIN PASSWORD 'xyz' ;
```

Manage permissions

You can manage permissions at the database, schema, and table levels. For example, if you want to grant read permissions on a table to a user and revoke their write permissions, you can execute the following statements:

```
GRANT SELECT ON TABLE t1 TO normal_user1;
REVOKE UPDATE ON TABLE t1 FROM normal_user1;
REVOKE DELETE ON TABLE t1 FROM normal_user1;
```

15.4.8. Manage JSON data

JavaScript Object Notation (JSON) has become a basic data type in the Internet and IoT fields. For more information about JSON, visit [JSON official website](#). PostgreSQL support for JSON has been well developed. Optimized by Alibaba Cloud, AnalyticDB for PostgreSQL supports the JSON type based on the PostgreSQL syntax.

Check whether the current version supports JSON

Execute the following statement to check whether the current version supports JSON:

```
=> SELECT ''::json;
```

If the following output is displayed, it indicates the JSON type is supported and the instance is ready for use. If the operation fails, restart the instance.

```
json
-----
""
(1 row)
```

If the following output is displayed, it indicates the JSON type is not supported.

```
ERROR: type "json" does not exist
LINE 1: SELECT ""::json;
          ^
```

The preceding command converts data from the string type to the JSON type. PostgreSQL supports operations on JSON data based on this conversion.

JSON conversion in the database

Database operations include reading and writing. The written data is typically converted from the string type to the JSON type. The contents of a string must meet the JSON standard, such as strings, digits, arrays, and objects. Example:

String

```
=> SELECT "hjson"::json;
 json
-----
 "hjson"
(1 row)
```

`::` is used for explicit type conversion in PostgreSQL, Greenplum, and AnalyticDB for PostgreSQL. The database calls the input function in JSON type during the conversion. Therefore, the JSON format check is performed as follows:

```
=> SELECT '{hjson:1024}'::json;
ERROR: invalid input syntax for type json
LINE 1: SELECT '{hjson:1024}'::json;
          ^
DETAIL:  Token "hjson" is invalid.
CONTEXT:  JSON data, line 1: {hjson...
=>
```

In the preceding example, `hjson` must be enclosed in double quotation marks (`" "`) because JSON requires the KEY value to be a string. A syntax error is returned when `{hjson:1024}` is entered.

Apart from explicit type conversion, database records can also be converted to JSON.

Typically, JSON is not used for a string or a digit, but an object that contains one or more key-value pairs. AnalyticDB for PostgreSQL can support most JSON scenarios after data is converted from the string type to objects. Example:

```
=> select row_to_json(row({'a':"a"}, 'b'));
 row_to_json
-----
 {"f1":{"a":"a"},"f2":"b"}
(1 row)
=> select row_to_json(row({'a':"a"}::json, 'b'));
 row_to_json
-----
 {"f1":{"a":"a"},"f2":"b"}
(1 row)
```

You can see the differences between the string and JSON here. The whole record is conveniently converted into the JSON type.

JSON data types

- Object

The object is the most frequently used data type in JSON. Example:

```
=> select '{"key":"value"}::json;
      json
-----
{"key":"value"}
(1 row)
```

- Integer and floating point number

JSON only supports three data types for numeric values: integer, floating point number, and constant expression. AnalyticDB for PostgreSQL supports all three types.

```
=> SELECT '1024'::json;
      json
-----
1024
(1 row)

=> SELECT '0.1'::json;
      json
-----
0.1
(1 row)
```

The following information is required in some special situations:

```
=> SELECT '1e100'::json;
      json
-----
1e100
(1 row)

=> SELECT '{"f":1e100}'::json;
      json
-----
{"f":1e100}
(1 row)
```

Extra-long numbers are also supported. Example:

```
=> SELECT '9223372036854775808'::json;
      json
-----
9223372036854775808
(1 row)
```

- Array

```
=> SELECT '[[1,2], [3,4,5]]':json;
      json
-----
 [[1,2], [3,4,5]]
(1 row)
```

Operators

Operators supported by JSON

```
=> select oprname,oprcode from pg_operator where oprleft = 3114;
oprname |      oprcode
-----+-----
-> | json_object_field
->> | json_object_field_text
-> | json_array_element
->> | json_array_element_text
#> | json_extract_path_op
#>> | json_extract_path_text_op
(6 rows)
```

Basic usage

```
=> SELECT '{"f":"1e100"}':json -> 'f';
? column?
-----
"1e100"
(1 row)
=> SELECT '{"f":"1e100"}':json ->> 'f';
? column?
-----
1e100
(1 row)
=> select '{"f2":{"f3":1},"f4":{"f5":99,"f6":"stringy"}}':json#>array['f4','f6'];
? column?
-----
"stringy"
(1 row)
=> select '{"f2":{"f3":1},"f4":{"f5":99,"f6":"stringy"}}':json#>'f4,f6';
? column?
-----
"stringy"
(1 row)
=> select '{"f2":["f3",1],"f4":{"f5":99,"f6":"stringy"}}':json#>>'f2,0';
? column?
-----
f3
(1 row)
```

JSON functions

Supported JSON functions

```
postgres=# \df *json*
```

Schema	Name	Result data type	Argument data types	Type
pg_catalog	array_to_json	json	anyarray	normal
pg_catalog	array_to_json	json	anyarray, boolean	normal

(5 rows)
=> select json_each_text('{"f1":[1,2,3],"f2":{"f3":1},"f4":null,"f5":"null"}');
 json_each_text
-----
(f1,[1,2,3])
(f2,{"f3":1})
(f4,)
(f5,null)
(4 rows)
=> select json_array_elements('[1,true,[1,2,3],null,{"f1":1,"f2":[7,8,9]},false]');
 json_array_elements
-----
 1
 true
 [1,2,3]
 null
 {"f1":1,"f2":[7,8,9]}
 false
(6 rows)
create type jpop as (a text, b int, c timestamp);
=> select * from json_populate_record(null::jpop, '{"a":"blurfl","x":43.2}', false) q;
  a  | b | c
-----+-----
 blurfl |  |
(1 row)
=> select * from json_populate_recordset(null::jpop, [{"a":"blurfl","x":43.2}, {"b":3,"c":"2012-01-20 10:42:53"}], false) q;
  a  | b | c
-----+-----
 blurfl |  |
      | 3 | Fri Jan 20 10:42:53 2012
(2 rows)

```

Code examples

Create a table

```

create table tj(id serial, ary int[], obj json, num integer);
=> insert into tj(ary, obj, num) values('{1,5}::int[], '{"obj":1}', 5);
INSERT 0 1
=> select row_to_json(q) from (select id, ary, obj, num from tj) as q;
      row_to_json
-----
{"f1":1,"f2":[1,5],"f3":{"obj":1},"f4":5}
(1 row)
=> insert into tj(ary, obj, num) values('{2,5}::int[], '{"obj":2}', 5);
INSERT 0 1
=> select row_to_json(q) from (select id, ary, obj, num from tj) as q;
      row_to_json
-----
{"f1":1,"f2":[1,5],"f3":{"obj":1},"f4":5}
{"f1":2,"f2":[2,5],"f3":{"obj":2},"f4":5}
(2 rows)

```

Join multiple tables

```

create table tj2(id serial, ary int[], obj json, num integer);
=> insert into tj2(ary, obj, num) values('{2,5}::int[], '{"obj":2}', 5);
INSERT 0 1
=> select * from tj, tj2 where tj.obj->>'obj' = tj2.obj->>'obj';
 id | ary | obj | num | id | ary | obj | num
-----+-----+-----+-----+-----+-----+-----+-----
  2 | {2,5} | {"obj":2} | 5 | 1 | {2,5} | {"obj":2} | 5
(1 row)
=> select * from tj, tj2 where json_object_field_text(tj.obj, 'obj') = json_object_field_text(tj2.obj, 'obj');
 id | ary | obj | num | id | ary | obj | num
-----+-----+-----+-----+-----+-----+-----+-----
  2 | {2,5} | {"obj":2} | 5 | 1 | {2,5} | {"obj":2} | 5
(1 row)

```

Use the JSON function index

```

CREATE TEMP TABLE test_json (
  json_type text,
  obj json
);
=> insert into test_json values('aa', '{"f2":{"f3":1},"f4":{"f5":99,"f6":"foo"}}');
INSERT 0 1
=> insert into test_json values('cc', '{"f7":{"f3":1},"f8":{"f5":99,"f6":"foo"}}');
INSERT 0 1
=> select obj->'f2' from test_json where json_type = 'aa';
? column?
-----
{"f3":1}
(1 row)
=> create index i on test_json (json_extract_path_text(obj, 'f4'));
CREATE INDEX
=> select * from test_json where json_extract_path_text(obj, 'f4') = '{"f5":99,"f6":"foo"}';
 json_type |          obj
-----+-----
aa        | {"f2":{"f3":1},"f4":{"f5":99,"f6":"foo"}}
(1 row)

```

Note

JSON data cannot be used as the partition key and does not support JSON aggregate functions.

Example of using Python to access the database:

```

#!/bin/env python
import time
import json
import psycopg2
def gpquery(sql):
    conn = None
    try:
        conn = psycopg2.connect("dbname=sanity1x2")
        conn.autocommit = True
        cur = conn.cursor()
        cur.execute(sql)
        return cur.fetchall()
    except Exception as e:
        if conn:
            try:
                conn.close()
            except:
                pass
            time.sleep(10)
        print e
    return None
def main(_):
    sql = "select obj from tj;"
    #rows = Connection(host, port, user, pwd, dbname).query(sql)
    rows = gpquery(sql)
    for row in rows:
        print json.loads(row[0])
if __name__ == '__main__':
    main()

```

15.4.9. Use HyperLogLog

AnalyticDB for PostgreSQL is highly optimized by Alibaba Cloud, and not only has the features of Greenplum Database, but also supports HyperLogLog. It is suitable for industries such as Internet advertising and estimation analysis that require quick estimation of business metrics such as PV and UV.

Create a HyperLogLog extension

You can execute the following statement to create a HyperLogLog extension:

```
CREATE EXTENSION hll;
```

Basic types

- Execute the following statement to create a table containing the hll field:

```
create table agg (id int primary key,userids hll);
```

- Execute the following statement to convert int to hll_hashval:

```
select 1::hll_hashval;
```

Basic operators

- The hll type supports =, !=, <>, ||, and #.

```
select hll_add_agg(1::hll_hashval) = hll_add_agg(2::hll_hashval);
select hll_add_agg(1::hll_hashval) || hll_add_agg(2::hll_hashval);
select #hll_add_agg(1::hll_hashval);
```

- The hll_hashval type supports =, !=, and <>.

```
select 1::hll_hashval = 2::hll_hashval;
select 1::hll_hashval <> 2::hll_hashval;
```

Basic functions

- Hash functions such as Hll_hash_boolean, hll_hash_smallint, and hll_hash_bigint.

```
select hll_hash_boolean(true);
select hll_hash_integer(1);
```

- hll_add_agg: converts the int format to the hll format.

```
select hll_add_agg(1::hll_hashval);
```

- hll_union: aggregates the hll fields.

```
select hll_union(hll_add_agg(1::hll_hashval),hll_add_agg(2::hll_hashval));
```

- hll_set_defaults: sets the precision.

```
select hll_set_defaults(15,5,-1,1);
```

- hll_print: displays debug information.

```
select hll_print(hll_add_agg(1::hll_hashval));
```

Examples

```

create table access_date (acc_date date unique, userids hll);
insert into access_date select current_date, hll_add_agg(hll_hash_integer(user_id)) from generate_series(1,10000) t(u
ser_id);
insert into access_date select current_date-1, hll_add_agg(hll_hash_integer(user_id)) from generate_series(5000,2000
0) t(user_id);
insert into access_date select current_date-2, hll_add_agg(hll_hash_integer(user_id)) from generate_series(9000,4000
0) t(user_id);
postgres=# select #userids from access_date where acc_date=current_date;
? column?
-----
9725.85273370708
(1 row)
postgres=# select #userids from access_date where acc_date=current_date-1;
? column?
-----
14968.6596883279
(1 row)
postgres=# select #userids from access_date where acc_date=current_date-2;
? column?
-----
29361.5209149911
(1 row)

```

15.4.10. Use the CREATE LIBRARY statement

AnalyticDB for PostgreSQL introduces the CREATE LIBRARY and DROP LIBRARY statements to allow you to import custom software packages.

Syntax

```

CREATE LIBRARY library_name LANGUAGE [JAVA] FROM oss_location OWNER ownername
CREATE LIBRARY library_name LANGUAGE [JAVA] VALUES file_content_hex OWNER ownername
DROP LIBRARY library_name

```

Parameters

Parameter	Description
library_name	The name of the library to be installed. If the library to be installed has the same name as an existing library, you must delete the existing library before installing the new one.
LANGUAGE [JAVA]	The programming language to be used. Only PL/Java is supported.

Parameter	Description
oss_location	The location of the package. You can specify the OSS bucket and object names. Only one object can be specified and the specified object cannot be a compressed file. The format is as follows: <pre>oss://oss_endpoint filepath=[folder/[folder/]...]/file_name id=userossid key=userosskey bucket=ossbucket</pre>
file_content_hex	The content of the file. The byte stream is in hexadecimal notation. For example, 73656c6563742031 indicates the hexadecimal byte stream of "select 1". You can use this syntax to import packages without using OSS.
ownername	Specifies the user.
DROP LIBRARY	Deletes a library.

Examples

- Example 1: Install a JAR package named analytics.jar.

```
create library example language java from 'oss://oss-cn-hangzhou.aliyuncs.com filepath=analytics.jar id=xxx key=yy bucket=zzz';
```

- Example 2: Import the file content with the byte stream in hexadecimal notation.

```
create library pglib LANGUAGE java VALUES '73656c6563742031' OWNER "myuser";
```

- Example 3: Delete a library.

```
drop library example;
```

- Example 4: View installed libraries.

```
select name, lanname from pg_library;
```

15.4.11. Create and use the PL/Java UDF

AnalyticDB for PostgreSQL allows you to compile and upload JAR software packages written in PL/Java language, and use these JAR packages to create user-defined functions (UDFs). The PL/Java language supported by AnalyticDB for PostgreSQL is Community Edition PL/Java 1.5.0 and the JVM version is 1.8. This topic describes how to create a PL/Java UDF. For more information about PL/Java examples, see [PL/Java code](#). For more information about the compiling method, see [PL/Java documentation](#).

Procedure

1. In AnalyticDB for PostgreSQL, execute the following statement to create a PL/Java extension. You only need to execute the statement once for each database.

```
create extension pljava;
```

2. Compile the UDF based on your business needs. For example, you can use the following code to compile the Test.java file:

```
public class Test
{
    public static String substring(String text, int beginIndex,
        int endIndex)
    {
        try {
            Process process = null;
            process = Runtime.getRuntime().exec("ech Test running");
        } catch (Exception e) {
            return "" + e;
        }
        return text.substring(beginIndex, endIndex);
    }
}
```

3. Compile the manifest.txt file:

```
Manifest-Version: 1.0
Main-Class: Test
Specification-Title: "Test"
Specification-Version: "1.0"
Created-By: 1.7.0_99
Build-Date: 01/20/2016 21:00 AM
```

4. Run the following commands to compile and package the program:

```
javac Test.java
jar cfm analytics.jar manifest.txt Test.class
```

5. Upload the analytics.jar file generated in step 4 to OSS by using the following OSS console command. `osscli`

```
md put analytics.jar oss://zzz
```

6. In AnalyticDB for PostgreSQL, execute the CREATE LIBRARY statement to import the file to AnalyticDB for PostgreSQL:

```
create library example language java from 'oss://oss-cn-hangzhou.aliyuncs.com filepath=analytics.jar id=xxx key=yyy bucket=zzz';
```

 **Note** You can only use the filepath variable in the CREATE LIBRARY statement to import files one at a time. Additionally, the CREATE LIBRARY statement also supports byte streams to import files without using OSS. For more information, see [Use the CREATE LIBRARY statement](#).

7. In AnalyticDB for PostgreSQL, execute the following statements to create and use the UDF.

```
create table temp (a varchar) distributed randomly;
insert into temp values ('my string');
create or replace function java_substring(varchar, int, int) returns varchar as 'Test.substring' language java;
select java_substring(a, 1, 5) from temp;
```

15.5. Table

15.5.1. Create a table

You can create tables within your databases.

Syntax

The complete syntax for creating a table is as follows. Depending on your business needs, not all clauses will be required. Use the clauses that can fulfill your business needs.

```
CREATE [[GLOBAL | LOCAL] {TEMPORARY | TEMP}] TABLE table_name (
  [ { column_namedata_type [ DEFAULT default_expr ]
    [column_constraint [ ... ]
  [ ENCODING ( storage_directive [,...] ) ]
]
  | table_constraint
  | LIKE other_table [{INCLUDING | EXCLUDING}
    {DEFAULTS | CONSTRAINTS}] ...}
[, ... ]
)
[ INHERITS ( parent_table [, ... ] ) ]
[ WITH ( storage_parameter=value [, ... ] ) ]
[ ON COMMIT {PRESERVE ROWS | DELETE ROWS | DROP} ]
[ TABLESPACE tablespace ]
[ DISTRIBUTED BY (column, [ ... ] ) | DISTRIBUTED RANDOMLY ]
[ PARTITION BY partition_type (column)
  [ SUBPARTITION BY partition_type (column) ]
  [ SUBPARTITION TEMPLATE ( template_spec ) ]
  [...]
( partition_spec )
  | [ SUBPARTITION BY partition_type (column) ]
  [...]
( partition_spec
  [ ( subpartition_spec
    [(...)]
  ) ]
)
)
```

The column_constraint clause can be defined as follows:

```
[CONSTRAINT constraint_name]
  NOT NULL | NULL
| UNIQUE [USING INDEX TABLESPACE tablespace]
  [WITH ( FILLFACTOR = value )]
| PRIMARY KEY [USING INDEX TABLESPACE tablespace]
  [WITH ( FILLFACTOR = value )]
| CHECK ( expression )
| REFERENCES table_name [ ( column_name [, ... ] ) ]
  [ key_match_type ]
  [ key_action ]
```

The `storage_directive` clause of columns can be defined as follows:

```
COMPRESSTYPE={ZLIB | QUICKLZ | RLE_TYPE | NONE}
[COMPRESSLEVEL={0-9} ]
[BLOCKSIZE={8192-2097152} ]
```

The `storage_parameter` clause of tables can be defined as follows:

```
APPENDONLY={TRUE|FALSE}
BLOCKSIZE={8192-2097152}
ORIENTATION={COLUMN|ROW}
CHECKSUM={TRUE|FALSE}
COMPRESSTYPE={ZLIB|QUICKLZ|RLE_TYPE|NONE}
COMPRESSLEVEL={0-9}
FILLFACTOR={10-100}
OIDS={TRUE|FALSE}
```

The `table_constraint` clause can be defined as follows:

```
[CONSTRAINT constraint_name]
  UNIQUE ( column_name [, ... ] )
    [USING INDEX TABLESPACE tablespace]
    [WITH ( FILLFACTOR=value )]
| PRIMARY KEY ( column_name [, ... ] )
    [USING INDEX TABLESPACE tablespace]
    [WITH ( FILLFACTOR=value )]
| CHECK ( expression )
| FOREIGN KEY ( column_name [, ... ] )
    REFERENCES table_name [ ( column_name [, ... ] ) ]
    [ key_match_type ]
    [ key_action ]
    [ key_checking_mode ]
```

Valid values of `key_match_type`:

```
MATCH FULL
| SIMPLE
```

Valid values of `key_action`:

```
ON DELETE
| ON UPDATE
| NO ACTION
| RESTRICT
| CASCADE
| SET NULL
| SET DEFAULT
```

Valid values of `key_checking_mode`:

```
DEFERRABLE
| NOT DEFERRABLE
| INITIALLY DEFERRED
| INITIALLY IMMEDIATE
```

Valid values of `partition_type`:

```
LIST
| RANGE
```

The `partition_specification` clause can be defined as follows:

```
partition_element [, ...]
```

The `partition_element` clause can be defined as follows:

```
DEFAULT PARTITION name
| [PARTITION name] VALUES (list_value [,...])
| [PARTITION name]
  START ([datatype] 'start_value') [INCLUSIVE | EXCLUSIVE]
  [ END ([datatype] 'end_value') [INCLUSIVE | EXCLUSIVE] ]
  [ EVERY ([datatype] [number | INTERVAL] 'interval_value') ]
| [PARTITION name]
  END ([datatype] 'end_value') [INCLUSIVE | EXCLUSIVE]
  [ EVERY ([datatype] [number | INTERVAL] 'interval_value') ]
[ WITH ( partition_storage_parameter=value [, ... ] ) ]
[ TABLESPACE tablespace ]
```

The `subpartition_spec` or `template_spec` clause can be defined as follows:

```
subpartition_element [, ...]
```

The `subpartition_element` clause can be defined as follows:

```

DEFAULT SUBPARTITION name
| [SUBPARTITION name] VALUES (list_value [,...])
| [SUBPARTITION name]
  START ([datatype] 'start_value') [INCLUSIVE | EXCLUSIVE]
  [ END ([datatype] 'end_value') [INCLUSIVE | EXCLUSIVE] ]
  [ EVERY ([datatype] [number | INTERVAL] 'interval_value') ]
| [SUBPARTITION name]
  END ([datatype] 'end_value') [INCLUSIVE | EXCLUSIVE]
  [ EVERY ([datatype] [number | INTERVAL] 'interval_value') ]
[ WITH ( partition_storage_parameter=value [, ... ] ) ]
[ TABLESPACE tablespace ]

```

The `storage_parameter` clause of partitions can be defined as follows:

```

APPENDONLY={TRUE|FALSE}
BLOCKSIZE={8192-2097152}
ORIENTATION={COLUMN|ROW}
CHECKSUM={TRUE|FALSE}
COMPRESSTYPE={ZLIB|QUICKLZ|RLE_TYPE|NONE}
COMPRESLEVEL={1-9}
FILLFACTOR={10-100}
OIDS={TRUE|FALSE}

```

Parameters

The [Table creation parameters](#) table describes the key parameters for creating a table.

Table creation parameters

Parameter	Description
TABLE_NAME	The name of the table to be created.
column_name	The name of a column to be created in the new table.
data_type	The data type of the column. For columns that contain textual data, set the data type to VARCHAR or TEXT. We do not recommend the CHAR type.
DEFAULT default_expr	Specifies a default value for the column. The system will assign this default value to all columns that do not have a value. The default values can be any variable-free expression. Subqueries or cross-references to other columns in the table are not allowed. The data type of the default expression must match the data type of the column. If a column does not have a default value, the default value is null.
ENCODING storage_directive	Specifies the type of compression and block size for the column data. This clause is valid only for append-optimized, column-oriented tables. Column compression settings are inherited from the table level to the partition level to the sub-partition level. The lowest-level settings have priority over inherited settings.

Parameter	Description
INHERITS	Specifies that all columns in the new table automatically inherit a parent table. You can use INHERITS to create a persistent relationship between the new child table and its parent table. Schema modifications to the parent table are applied to the child table as well. When the parent table is also scanned, the data of the child table is scanned as well.
LIKE other_table	Specifies a table from which the new table automatically copies all column names, data types, NOT NULL constraints, and distribution policies. Storage properties such as append-optimized or partition structure are not copied. Unlike INHERITS, the new table is completely decoupled from the original table after the new table is created.
CONSTRAINT constraint_name	Configures a column or table constraint. When a constraint is violated, the constraint name will be displayed in the error message. Constraint names can be used to communicate helpful information to client applications. Constraint names that contain spaces must be enclosed by double quotation marks ("").
WITH (storage_option=value)	Configures storage options for the table or its indexes.
ON COMMIT	The operation that the system performs on the temporary tables at the end of a transaction. Valid values: <ul style="list-style-type: none"> • PRESERVE ROWS: No special action is taken. The data will be retained after the transaction is complete. The data will only be released when the session is disconnected. • DELETE ROWS: All rows in the temporary table are deleted. • DROP: The temporary table is deleted.
TABLESPACE tablespace	Specifies the name of the tablespace in which the new table is to be created. If not specified, the default tablespace of the database is used.
DISTRIBUTED BY	Specifies the distribution policy for the database. <ul style="list-style-type: none"> • DISTRIBUTED BY (column, [...]): specifies the partition key. The system uses hash distribution based on the distribution key. To evenly distribute data, you must set the partition key to the primary key of the table or a unique column or a set of columns. • DISTRIBUTED RANDOMLY: distributes data randomly. <div style="background-color: #e0f2f7; padding: 5px; margin-top: 10px;"> ? Note We recommend that you do not use random distribution. </div>
PARTITION BY	Configures the partition key to partition the table. Partitioning large tables improves data access efficiency. To partition a table is to create a top-level (parent) table and multiple lower-level (child) tables. A parent table is always empty when the partition table is created. Data is stored in the lowest-level child tables. In a multi-level partition table, data is only stored in the lowest-level sub-partitions. Valid values: RANGE, LIST, and a combination of the two.
SUBPARTITION BY	Configures a multi-level partitioned table.

Parameter	Description
SUBPARTITION TEMPLATE	You can specify a sub-partition template to create sub-partitions (lower-level child tables). This sub-partition template is applied to all parent partitions to ensure the same sub-partition structure.

Examples

Create a table and configure the partition key. The primary key is the default partition key in AnalyticDB for PostgreSQL.

```
CREATE TABLE films (
code    char(5) CONSTRAINT firstkey PRIMARY KEY,
title   varchar(40) NOT NULL,
did     integer NOT NULL,
date_prod date,
kind    varchar(10),
len     interval hour to minute
);

CREATE TABLE distributors (
did     integer PRIMARY KEY DEFAULT nextval('serial'),
name    varchar(40) NOT NULL CHECK (name <> '')
);
```

Create a compressed table and configure the partition key.

```
CREATE TABLE sales (txn_id int, qty int, date date)
WITH (appendonly=true, compresslevel=5)
DISTRIBUTED BY (txn_id);
```

Use sub-partition templates of each level and the default partition to create a three-level partition table.

```
CREATE TABLE sales (id int, year int, month int, day int,
region text)
DISTRIBUTED BY (id)
PARTITION BY RANGE (year)

SUBPARTITION BY RANGE (month)
SUBPARTITION TEMPLATE (
START (1) END (13) EVERY (1),
DEFAULT SUBPARTITION other_months )

SUBPARTITION BY LIST (region)
SUBPARTITION TEMPLATE (
SUBPARTITION usa VALUES ('usa'),
SUBPARTITION europe VALUES ('europe'),
SUBPARTITION asia VALUES ('asia'),
DEFAULT SUBPARTITION other_regions)

( START (2008) END (2016) EVERY (1),
DEFAULT PARTITION outlying_years);
```

15.5.2. Principles and scenarios of row store, column store, heap tables, and AO tables

AnalyticDB for PostgreSQL supports row store, column store, heap tables, and AO tables. This topic describes their principles and scenarios.

Row store and column store

Comparison

Dimension	Row store	Column store
Definition	Row store stores data in the form of rows. Each row is a tuple. To read a column, you must deform all of the columns that precede the target column. Because of this, the costs for accessing the first and the last columns are different.	Column store stores data as columns corresponding to a file or a batch of files. The cost of reading any column is the same. However, if you need to read multiple columns, you must access multiple files. The more columns you access, the higher the overheads are.
Compression ratio	Low.	High.
Cost of reading any column	Columns with larger column numbers cost more.	Same.
Vector computing and JIT architecture	Not suitable. Not suitable for batch computation.	Suitable. More efficient when accessing and obtaining statistics of a batch of data.

Dimension	Row store	Column store
Scenarios	<p>If you need to perform a large number of update and delete operations due to OLTP requirements such as when querying table details where multiple columns are returned, you can use row store.</p> <p>You can use partition tables if you have diversified requirements. For example, if you need to partition the data based on time, you can use row store to query the details of recent data and use column store to obtain more statistics from historical data.</p>	<p>You can use column store if you need data statistics because of the OLAP requirements.</p> <p>If you need a higher compression ratio, you can use column store.</p>

Heap tables

A heap table is heap storage. All changes to the heap table generate redo logs that can be used to restore data by time point. However, heap tables cannot implement logical incremental backup because any data block in the table may be changed and it is not convenient to record the position by using the heap storage.

Commit and redo logs are used to ensure reliability when transactions are finished. You can also implement redundancy by building secondary nodes through redo logs.

Append-optimized (AO) tables

AO tables are used to append data for storage. When you delete the updated data, you can use another bitmap file to mark the row to be deleted and use the bit and offset to determine whether a row is deleted.

When the transaction is finished, you must call the fsync function to record the offset of the data block that performs the last write operation. Even if the data block only contains one record, a new data block will be appended for the next transaction. The data block is synchronized to the secondary node for data redundancy.

AO tables are not suitable for small transactions because the fsync function is called at the end of each transaction, and this data block will not be reused even if there is space left.

AO tables are suitable for OLAP scenarios, batch data writing, high compression ratio, and logical backup that supports incremental backup. During backup, you only need to record the offset from the backup and the bitmap deletion mark for each full backup.

Usage scenarios of heap tables

- When multiple small transactions are handled, use a heap table.
- When you need to restore data by time point, use a heap table.

Usage scenarios of AO tables

- When you need to use column store, use an AO table.
- When data is written in batches, use an AO table.

15.5.3. Enable the column store and compression features

If you want to improve performance, speed up data import, or reduce costs for tables with infrequent updates and multiple fields, we recommend that you use column store and compression. This will increase the compression ratio threefold to ensure faster performance and import speed.

To enable the column store and compression features, you must specify the column store and compression options when creating a table. For example, you can add the following clause to the CREATE statement to enable the two features. For more information about the table creation syntax, see [Create a table](#).

with (APPENDONLY=true, ORIENTATION=column, COMPRESSTYPE=zlib, COMPRESSLEVEL=5, BLOCKSIZE=1048576, OIDS=false)

 **Note** AnalyticDB for PostgreSQL only supports zlib and RLE_TYPE compression algorithms. If you specify the quicklz algorithm, it is automatically converted to zlib.

15.5.4. Add a field to a column store table and set the default value

This topic describes how to add a field to a column store table and set the default value for the field, and how to use the ANALYZE statement to view the impact of updated data on the size of the column store table.

Context

In a column store table, each column is stored as a file, and two columns in the same row correspond to each other by using the offset. For example, if you add two fields of the INT8 type, you can quickly locate column B from column A by using the offset.

When you add the field, AO tables are not rewritten. If an AO table contains the records of deleted data, the added field must be filled with the deleted records before using the offset.

Procedure

1. Create three AO column store tables.

```
postgres=# create table tbl1 (id int, info text) with (appendonly=true, blocksize=8192, compresstype=none, orientation=column);
```

NOTICE: Table doesn't have 'DISTRIBUTED BY' clause -- Using column named 'id' as the Greenplum Database data distribution key for this table.

HINT: The 'DISTRIBUTED BY' clause determines the distribution of data. Make sure column(s) chosen are the optimal data distribution key to minimize skew.

CREATE TABLE

```
postgres=# create table tbl2 (id int, info text) with (appendonly=true, blocksize=8192, compresstype=none, orientation=column);
```

NOTICE: Table doesn't have 'DISTRIBUTED BY' clause -- Using column named 'id' as the Greenplum Database data distribution key for this table.

HINT: The 'DISTRIBUTED BY' clause determines the distribution of data. Make sure column(s) chosen are the optimal data distribution key to minimize skew.

CREATE TABLE

```
postgres=# create table tbl3 (id int, info text) with (appendonly=true, blocksize=8192, compresstype=none, orientation=column);
```

NOTICE: Table doesn't have 'DISTRIBUTED BY' clause -- Using column named 'id' as the Greenplum Database data distribution key for this table.

HINT: The 'DISTRIBUTED BY' clause determines the distribution of data. Make sure column(s) chosen are the optimal data distribution key to minimize skew.

CREATE TABLE

2. Insert 10 million entries to the first two tables and 20 million entries to the third one.

```

postgres=# insert into tbl1 select generate_series(1,10000000),'test';
INSERT 0 10000000
postgres=# insert into tbl2 select generate_series(1,10000000),'test';
INSERT 0 10000000
postgres=# insert into tbl3 select generate_series(1,20000000),'test';
INSERT 0 20000000

```

3. Analyze the tables and display their sizes.

```

postgres=# analyze tbl1;
ANALYZE
postgres=# analyze tbl2;
ANALYZE
postgres=# analyze tbl3;
ANALYZE

postgres=# select pg_size_pretty(pg_relation_size('tbl1'));
pg_size_pretty
-----
88 MB
(1 row)
postgres=# select pg_size_pretty(pg_relation_size('tbl2'));
pg_size_pretty
-----
88 MB
(1 row)
postgres=# select pg_size_pretty(pg_relation_size('tbl3'));
pg_size_pretty
-----
173 MB
(1 row)

```

4. Update all the data in the first table. Display the table size after the update. The size is twice as large as the size before the update.

```

postgres=# update tbl1 set info='test';
UPDATE 10000000
postgres=# analyze tbl1;
ANALYZE
postgres=# select pg_size_pretty(pg_relation_size('tbl1'));
pg_size_pretty
-----
173 MB
(1 row)

```

5. Add fields to the three tables and set the default values.

```
postgres=# alter table tbl1 add column c1 int8 default 1;
ALTER TABLE
postgres=# alter table tbl2 add column c1 int8 default 1;
ALTER TABLE
postgres=# alter table tbl3 add column c1 int8 default 1;
ALTER TABLE
```

6. Analyze the tables and view the table sizes.

```
postgres=# analyze tbl1;
ANALYZE
postgres=# analyze tbl2;
ANALYZE
postgres=# analyze tbl3;
ANALYZE

postgres=# select pg_size_pretty(pg_relation_size('tbl1'));
pg_size_pretty
-----
325 MB
(1 row)

postgres=# select pg_size_pretty(pg_relation_size('tbl2'));
pg_size_pretty
-----
163 MB
(1 row)

postgres=# select pg_size_pretty(pg_relation_size('tbl3'));
pg_size_pretty
-----
325 MB
(1 row)
```

When you add fields to the AO tables, the number of entries in the existing files will prevail. Even if all the entries are deleted, you must initialize the original data in the newly added fields.

15.5.5. Configure the table partition

For fact tables or large-sized tables in the database, we recommend that you configure table partitions.

Configure the table partition

You can use the table partitioning feature to delete data by using the `ALTER TABLE DROP PARTITION` statement to delete all the data in a partition, and import data by using the `ALTER TABLE EXCHANGE PARTITION` statement to add a new data partition on a regular basis.

AnalyticDB for PostgreSQL supports range partitioning, list partitioning, and composite partitioning. Range partitioning only supports partitioning by fields of the numeric or datetime data types.

The following example shows a table that uses range partitioning.

```

CREATE TABLE LINEITEM (
L_ORDERKEY          BIGINT NOT NULL,
L_PARTKEY           BIGINT NOT NULL,
L_SUPPKEY           BIGINT NOT NULL,
L_LINENUMBER       INTEGER,
L_QUANTITY          FLOAT8,
L_EXTENDEDPRICE    FLOAT8,
L_DISCOUNT        FLOAT8,
L_TAX              FLOAT8,
L_RETURNFLAG       CHAR(1),
L_LINESTATUS       CHAR(1),
L_SHIPDATE         DATE,
L_COMMITDATE       DATE,
L_RECEIPTDATE      DATE,
L_SHIPINSTRUCT     CHAR(25),
L_SHIPMODE         CHAR(10),
L_COMMENT          VARCHAR(44)
) WITH (APPENDONLY=true, ORIENTATION=column, COMPRESSTYPE=zlib, COMPRESSLEVEL=5, BLOCKSIZE=1048576, OIDS
=false) DISTRIBUTED BY (L_orderkey)
PARTITION BY RANGE (L_SHIPDATE) (START (date '1992-01-01') INCLUSIVE END (date '2000-01-01') EXCLUSIVE EVERY (INT
ERVAL '1 month' ));

```

Principles of table partitioning

The purpose of partitioning is to minimize the amount of data that needs to be scanned during a query, so partitions must be associated with the query conditions.

- Principle 1: Select the fields related to the query conditions to configure partitions and reduce the amount of data to be scanned.
- Principle 2: When multiple query conditions exist, configure sub-partitions to further reduce the amount of data to be scanned.

15.5.6. Configure the sort key

A sort key is an attribute of a table. Data on disks is stored in the order of the sort key.

Context

Sort keys have two major advantages:

- Speed up and optimize column-store operations. The min and max meta information the system collects seldom overlaps with each other, which features good filterability.
- Eliminate the need to perform ORDER BY and GROUP BY operations. The data directly read from the disk is ordered as required by the sorting conditions.

Create a table

Command: CREATE TABLE

Description: define a new table

Syntax:

```
CREATE [[GLOBAL | LOCAL] {TEMPORARY | TEMP}] TABLE table_name (
[ { column_name data_type [ DEFAULT default_expr ] [column_constraint [ ... ]
[ ENCODING ( storage_directive [,...] ) ]
]
| table_constraint
| LIKE other_table [{INCLUDING | EXCLUDING}
{DEFAULTS | CONSTRAINTS}] ...}
[, ... ] ]
[column_reference_storage_directive [, ] ]
)
[ INHERITS ( parent_table [, ... ] ) ]
[ WITH ( storage_parameter=value [, ... ] )
[ ON COMMIT {PRESERVE ROWS | DELETE ROWS | DROP} ]
[ TABLESPACE tablespace ]
[ DISTRIBUTED BY (column, [ ... ] ) | DISTRIBUTED RANDOMLY ]
[ SORTKEY (column, [ ... ] ) ]
[ PARTITION BY partition_type (column)
[ SUBPARTITION BY partition_type (column) ]
[ SUBPARTITION TEMPLATE ( template_spec ) ]
[... ]
( partition_spec )
| [ SUBPARTITION BY partition_type (column) ]
[... ]
( partition_spec
[ ( subpartition_spec
[ (... ) ]
) ]
) ]
)
```

Examples:

```
create table test(date text, time text, open float, high float, low float, volume int) with(APPENDONLY=true,ORIENTATIO
N=column) sortkey (volume);
```

Sort the table

```
VACUUM SORT ONLY [tablename]
```

Modify the sort key

This statement only modifies the catalog and does not sort data. You must execute the `VACUUM SORT ONLY` statement to sort the table.

```
ALTER [[GLOBAL | LOCAL] {TEMPORARY | TEMP}] TABLE table_name SET SORTKEY (column, [ ... ] )
```

Examples:

```
alter table test set sortkey (high,low);
```

15.6. Best practices

15.6.1. Configure memory and load parameters

You must configure memory and load parameters to improve database stability.

Background information

AnalyticDB for PostgreSQL is an MPP database with high computational and resource requirements. It consumes all of the resources provided to it, allowing AnalyticDB for PostgreSQL to have higher processing speeds but making it very easy to reach its limits.

The worst-case scenario in the event of the CPU, network, or hard disk exceeding its limits is a hardware bottleneck. However, in the event that memory is completely consumed, the database may crash.

How to avoid OOM errors

Out of memory (OOM) indicates that the system is unable to provide sufficient memory requested by a process. The following prompt appears when OOM errors occur:

```
Out of memory (seg27 host.example.com pid=47093) VM Protect failed to allocate 4096 bytes, 0 MB available
```

Causes

Possible causes of the OOM error include:

- The memory of the database node is insufficient.
- Kernel parameters related to the memory of the operating system are incorrectly configured.
- Data skew has occurred, causing a compute node to request a large amount of memory.
- Query skew has occurred. For example, if the grouping fields of some aggregate or window functions are not distribution keys, the data must be redistributed. After redistribution, data will be skewed in a certain computer node and result in the node requesting a large amount of memory.

Solutions

1. Modify the queries to request less memory.
2. Use the resource queue provided by AnalyticDB for PostgreSQL to limit the number of concurrent queries. Reduce the number of queries executed within the cluster at the same time to reduce the overall memory requested by the system.
3. Reduce the number of compute nodes deployed on a host. For example, deploy 8 compute nodes instead of 16 compute nodes on a host with 128 GB of memory. This allows each compute node to use twice the amount of memory compared with the latter.
4. Increase the memory of a host.
5. Set the `gp_vmem_protect_limit` parameter to limit the maximum VMEM that can be used by a single compute node. The memory size of a single host and the number of compute nodes deployed on the host determine the maximum memory size that a single compute node can use on average.
6. For SQL statements that have unpredictable memory usage, you can set the `statement_mem` parameter in the session to limit the memory usage of a single SQL statement, so as to prevent a single SQL statement from consuming all available memory.
7. Set the `statement_mem` parameter at the database level to apply to all the sessions in the database.
8. Use the resource queue to limit the maximum memory usage of the resource group. Add database users to the resource group to limit the overall memory used by these users.

Configure memory-related parameters

Properly configuring the operating system, database parameters, and resource queue can effectively reduce the probability of OOM.

When calculating the average memory usage of a single compute node on a single host, you must consider both the primary and secondary compute nodes. When the cluster encounters a host failure, the system will switch the service from primary compute nodes to the corresponding secondary compute nodes. During this time, the number of compute nodes on the host will be greater than usual. Therefore, you must consider the number of resources that will be occupied by the secondary compute nodes during failover.

The following tables describe how to configure parameters of the operating system kernel and database to avoid OOM.

The following **Operating system kernel parameters** table describes the parameter configuration of the operating system kernel.

Operating system kernel parameters

Parameter	Description
huge page	Do not configure the huge page parameter of the system. AnalyticDB for PostgreSQL does not support the latest version of PostgreSQL and therefore does not support the huge page feature. The huge page parameter locks a part of the allocated memory. Database nodes will not be able to use this part of the memory.
vm.overcommit_memory	<p>If you use the swap space, set this parameter to 2. If you do not use the swap space, set this parameter to 0.</p> <p>Valid values:</p> <ul style="list-style-type: none"> 0: The requested memory space cannot exceed the difference between the total memory and the resident set size (RSS). An error is returned only when the memory has been exceeded. 1: Most processes use the malloc function to apply for the memory, but do not use all the memory applied. When this parameter is set to 1, the memory requested by the malloc function will be allocated under any circumstances unless there is not sufficient memory. 2: The swap space is also considered when the system calculates the memory space that can be applied for. You can apply for a large amount of memory even if the swap space is triggered.
overcommit_ratio	<p>The larger the value, the more memory that process can apply for and the less that will be reserved for the operating system. For the formula used to calculate the memory parameters, see Examples to calculate the memory parameters.</p> <p>When this parameter is set to 2, the memory address that can be applied for cannot exceed $\text{swap} + \text{memory} \times \text{overcommit_ratio}$.</p>

The following **Database parameters** table describes the parameter configuration of the database.

Database parameters

Parameter	Description
gp_vmem_protect_limit	Specifies the maximum amount of memory that all processes can apply for on each node. If the value is too large, it may result in a system OOM error or even more serious problems. If the value is too small, SQL statements may not be executed even when the system has enough memory.

Parameter	Description
runaway_detector_activation_percent	<p>Default value: 90. This value is specified as a percentage. When the memory used by any compute node exceeds $\text{runaway_detector_activation_percent} \times \text{gp_vmem_protect_limit}/100$, the query is terminated to prevent OOM.</p> <p>The termination starts from the query that occupies the maximum memory until the memory reaches a value lower than $\text{runaway_detector_activation_percent} \times \text{gp_vmem_protect_limit}/100$.</p> <p>You can use the <code>gp_toolkit.session_level_memory_consumption</code> view to observe the memory usage of each session and runaway information.</p>
statement_mem	<p>Specifies the maximum amount of memory that a single SQL statement can apply. When the maximum memory is exceeded, spill files are created. Default value: 125. Unit: MB.</p> <p>We recommend that you set this parameter according to the following formula:</p> <div style="background-color: #f0f0f0; padding: 5px; margin: 10px 0;"> $(\text{gp_vmem_protect_limit} \times 0.9) / \text{max_expected_concurrent_queries}$ </div> <div style="background-color: #e0f2f7; padding: 10px; margin: 10px 0;"> <p> Note</p> <ul style="list-style-type: none"> You can specify the <code>statement_mem</code> parameter in a session. If the current concurrency is low and a session needs to run a query that requires a large amount of memory, you must specify this parameter in the session. <code>Statement_mem</code> is suitable for limiting memory usage in low concurrency scenarios. If you use <code>statement_mem</code> to limit the memory for high concurrency scenarios, each query is allocated with a very small amount of memory. As a result, the performance of a small number of queries with high memory requirements in high concurrency scenarios is affected. We recommend that you use the resource queue to limit the maximum memory usage in high concurrency scenarios. </div>
gp_workfile_limit_files_per_query	<p>Specifies the maximum number of spill files that can be created by each query. When the memory requested by the query exceeds the <code>statement_mem</code> limit, spill files (also known as work files) are created, which is similar to the swap space of the operating system. When the number of spill files used exceeds the limit, the query will be terminated.</p> <p>Default value: 0, which indicates that an unlimited number of spill files can be created.</p>
gp_workfile_compress_algorithm	<p>Specifies the compression algorithm for spill files. Valid values: none and zlib.</p> <p>Specifies the compression algorithm. The values optimize storage space or I/O by sacrificing CPU. You can set this parameter when the disk is insufficient or the spill files meet a write bottleneck.</p>

Examples to calculate the memory parameters

The environment is as follows:

- Host configuration:

Total RAM = 256 GB

SWAP = 64 GB

- Four hosts, each deployed with eight primary compute nodes and eight secondary compute nodes.

When a host fails, the eight primary compute nodes are distributed to the remaining three hosts. A single host can be deployed with at most three extra primary compute nodes from the failed host. A single host can be deployed with at most 11 primary compute nodes.

1. Calculate the total memory allocated to AnalyticDB for PostgreSQL by the operating system.

Reserve 7.5 GB and 5% of memory for the operating system and calculate the available memory for all applications, and divide the available memory by the empirical coefficient of 1.7.

```
gp_vmem = ((SWAP + RAM) - (7.5 GB + 0.05 × RAM))/1.7
         = ((64 + 256) - (7.5 + 0.05 × 256))/1.7
         = 176
```

2. Use the empirical coefficient of 0.026 to calculate `overcommit_ratio`.

```
vm.overcommit_ratio = (RAM - (0.026 × gp_vmem))/RAM
                    = (256 - (0.026 × 176))/256
                    = .982
```

Set `vm.overcommit_ratio` to 98.

3. Calculate `gp_vmem_protect_limit` (the protection parameter of the maximum memory usage for each compute node), and divide `gp_vmem` by `maximum_acting_primary_segments` (the number of primary compute nodes to be run on each other host after one host fails).

```
gp_vmem_protect_limit calculation
gp_vmem_protect_limit = gp_vmem/maximum_acting_primary_segments
                    = 176/11
                    = 16 GB
                    = 16384 MB
```

Configure the resource queue

You can use resource queues to limit the number of concurrent queries and the total memory usage. When a query is running, it is added to the corresponding queue and the resources used are recorded in the queue. The resource limit of the queue is applied to all sessions in the queue.

The resource queue in AnalyticDB for PostgreSQL is similar to `cgroup` in Linux.

The syntax to create a resource queue is as follows:

Command: CREATE RESOURCE QUEUE

Description: create a new resource queue for workload management

Syntax:

```
CREATE RESOURCE QUEUE name WITH (queue_attribute=value [, ... ])
```

where queue_attribute is:

ACTIVE_STATEMENTS=integer

[MAX_COST=float [COST_OVERCOMMIT={TRUE|FALSE}]]

[MIN_COST=float]

[PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}]

[MEMORY_LIMIT='memory_units']

```
| MAX_COST=float [ COST_OVERCOMMIT={TRUE|FALSE} ]
```

[ACTIVE_STATEMENTS=integer]

[MIN_COST=float]

[PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}]

[MEMORY_LIMIT='memory_units']

The [Resource queue creation parameters](#) table describes the parameters for creating the resource queue.

Resource queue creation parameters

Parameter	Description
ACTIVE_STATEMENTS	<p>The number of SQL statements that are allowed to run (in the active state) concurrently.</p> <p>The value -1 indicates an unlimited number of SQL statements can run concurrently.</p>

Parameter	Description
<p>MEMORY_LIMIT 'memory_units kB, MB or GB'</p>	<p>Specifies the maximum memory usage allowed by all SQL statements in the resource queue. The value -1 indicates unlimited memory usage, but it is easy to trigger OOM errors because it is limited by the database or system parameters mentioned in the preceding sections.</p> <p>The memory usage of SQL statements is limited by resource queues and parameters.</p> <ul style="list-style-type: none"> When the <code>gp_resqueue_memory_policy</code> parameter is set to <code>none</code>, the limit is the same as that in the Greenplum databases earlier than version 4.1. When the <code>gp_resqueue_memory_policy</code> parameter is set to <code>auto</code> and you have specified the <code>statement_mem</code> parameter for a session or at the database level, the allowed memory of a single query will exceed the <code>MEMORY_LIMIT</code> of the resource queue. <p>Example:</p> <pre>=> SET statement_mem='2GB'; => SELECT * FROM my_big_table WHERE column='value' ORDER BY id; => RESET statement_mem;</pre> <ul style="list-style-type: none"> The system parameter <code>max_statement_mem</code> can limit the maximum memory usage at the compute node level. The memory requested by a single query cannot exceed <code>max_statement_mem</code>. <p>You can modify the <code>statement_mem</code> parameter at the session level, but do not modify the <code>max_statement_mem</code> parameter. We recommend that you specify <code>max_statement_mem</code> as follows:</p> <pre>(segghost_physical_memory) / (average_number_concurrent_queries)</pre> <ul style="list-style-type: none"> When the <code>gp_resqueue_memory_policy</code> parameter is set to <code>eager_free</code>, it indicates that the query is divided into several stages and that the database allocates the memory requested in the current stage. For example, if a query requests 1 GB of memory in total but only needs 100 MB during each stage, the database will allocate 100 MB of memory to the query. You can use <code>eager_free</code> to reduce the possibility of insufficient memory for the query.
<p>MAX_COST float</p>	<p>The maximum cost of the queries that are allowed to execute concurrently by the resource group. The cost is the estimated total cost in the SQL execution plan.</p> <p>The value of the parameter can be specified as a floating-point number (such as 100.0) or an exponent (such as 1e+2). A value of -1 indicates the cost is unlimited.</p>
<p>COST_OVERCOMMIT boolean</p>	<p>Specifies whether the limit of <code>max_cost</code> can be exceeded when the system is idle. The value <code>TRUE</code> indicates the limit can be exceeded.</p>
<p>MIN_COST float</p>	<p>When the resources requested exceed the limit, the queries are queued. However, when the cost of a query is lower than the <code>min_cost</code>, the query can run without queuing.</p>
<p>PRIORITY= {MIN LOW MEDIUM HIGH MAX}</p>	<p>The priority of the current resource queue. When resources are insufficient, CPU resources are allocated to the resource queue with a higher priority. The SQL statements in the resource queue with a higher priority can obtain CPU resources first. We recommend that you allocate users that initiate queries with high real-time requirements to resource queues with higher priority.</p> <p>This parameter is similar to the CPU resource group in the Linux <code>cgroup</code> and the time slice policy of real-time and common tasks.</p>

Example of modifying resource queue limits:

```
ALTER RESOURCE QUEUE myqueue WITH (MAX_COST=-1.0, MIN_COST= -1.0);
```

Example of putting the user in the resource queue:

```
ALTER ROLE sammy RESOURCE QUEUE poweruser;
```

The following table describes the parameters of resource queues.

Resource queue parameters

Parameter	Description
<code>gp_resqueue_memory_policy</code>	Specifies the memory management policy of the resource queue.
<code>gp_resqueue_priority</code>	Specifies whether to enable query prioritization. Valid values: <ul style="list-style-type: none"> On. Off. If this parameter is disabled, existing priority settings are not evaluated.
<code>gp_resqueue_priority_cpucore_per_segment</code>	Specifies the number of CPU cores allocated to each compute node. For example, if an 8-core host is configured with two primary compute nodes, you can set the parameter to 4. If there are no other nodes on the primary node, set the parameter to 8. When the CPU is preempted, the SQL statements running in the resource group with higher priority are allocated with CPU resources first.
<code>gp_resqueue_priority_sweeper_interval</code>	Specifies the interval at which CPU utilization is recalculated for all active statements. The share value is calculated when the SQL statement is executed. You can calculate the share value based on the priority and <code>gp_resqueue_priority_cpucore_per_segment</code> . The smaller the value and the more frequent the calculation, the better the result brought by the priority settings and the larger the overhead.

Tips for configuring resource queues:

- We recommend that you create a resource queue for each user.

The default resource queue of AnalyticDB for PostgreSQL is `pg_default`. If no queue is created, all users are assigned to `pg_default`. This operation is not recommended. We recommend that you create a resource queue for each user. Typically, a database user corresponds to a business. Different database users may correspond to different businesses or users, such as business users, analysts, developers, and DBAs.

- We do not recommend that you use superusers to execute queries.

Queries initiated by superusers are only limited by the preceding parameters and not by the resource queue. We do not recommend that you use superusers to execute queries if you want to use resource queues to limit the use of resources.

- `ACTIVE_STATEMENTS` indicates the SQL statements that can be executed concurrently within the resource queue. When the cost of a query is lower than the `min_cost`, the query can run without queuing.
- You can specify the `MEMORY_LIMIT` parameter to set the allowed maximum memory usage of all the SQL statements in a resource queue. The `statement_mem` parameter has higher priority that can break through the limit of resource queues.

 **Note** The memory of all resource queues cannot exceed `gp_vmem_protect_limit`.

- You can distinguish businesses by configuring the priorities of resource queues.

For example, assume that report forms have top priority, while common businesses and analysts have lower priorities. In this case, you can create three resource queues with the max, high, and medium priorities, respectively.

- If the number of resources requested at different times vary, you can use the `crontab` command to adjust the limits of resource queues periodically based on usage patterns.

For example, the queue of analysts has top priority during the day, while the queue of forms has lower priority at night. AnalyticDB for PostgreSQL does not support resource limits by time period. Therefore, you can only deploy tasks externally by using the `ALTER RESOURCE QUEUE` statement.

- You can use the view provided by `gp_toolkit` to observe the resource usage of the resource queues.

```
gp_toolkit.gp_resq_activity
```

```
gp_toolkit.gp_resq_activity_by_queue
```

```
gp_toolkit.gp_resq_priority_backend
```

```
gp_toolkit.gp_resq_priority_statement
```

```
gp_toolkit.gp_resq_role
```

```
gp_toolkit.gp_resqueue_status
```

16.KVStore for Redis

16.1. What is KVStore for Redis?

KVStore for Redis is a key-value storage database service that is compatible with open source Redis protocols. KVStore for Redis supports various data types, such as strings, lists, sets, sorted sets, and hash tables. The service also provides advanced features, such as transactions, message subscription, and message publishing.

You can easily deploy and manage KVStore for Redis databases in the KVStore for Redis console.

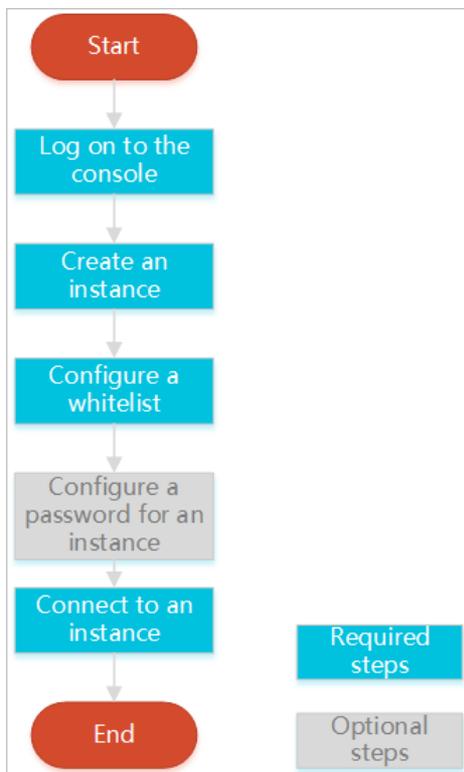

- You can create an instance to initialize a database.
- Before you use a KVStore for Redis instance, add IP addresses or CIDR blocks that are used to access the database to the instance whitelist.
- You can manage instances in the KVStore for Redis console.
- To secure data, you can periodically or immediately back up or restore databases in the KVStore for Redis console.
- You can log on to a database by using a client and then execute SQL statements to perform database operations.

16.2. Quick Start

16.2.1. Get started with KVStore for Redis

This topic describes all operations on an instance, from creating an instance to logging on to a database. This allows you to understand how to create and manage an instance.

The following figure shows the flowchart of managing a KVStore for Redis instance.

- **Log on to the KVStore for Redis console**
This topic describes how to log on to the KVStore for Redis console.
- **Create an instance**

KVStore for Redis supports two types of networks: classic network and Virtual Private Cloud (VPC). You can create KVStore for Redis instances of one of these network types.

- **Configure a whitelist**

Before you use a KVStore for Redis instance, add IP addresses or CIDR blocks that are used to access the database to the instance whitelist to enhance database security and stability.

- If you have not specified a password when you create the instance, set the password of the instance on the **Instance Information** page.

- **Connect to the instance**

You can use a client that supports Redis protocols or use the Redis command-line interface (redis-cli) tool to connect to the KVStore for Redis instance.

16.2.2. Log on to the KVStore for Redis console

This topic describes how to log on to the KVStore for Redis console.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
2. Enter your username and password.

Obtain the username and password used to log on to the console from the operations administrator.

 **Note** When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:

- Uppercase or lowercase letters.
- Digits.
- Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Products > KVStore for Redis**.

16.2.3. Create an instance

This topic describes how to create an instance in the KVStore for Redis console.

Prerequisites

To use the Virtual Private Cloud (VPC) service, you must create a VPC network in the same region where you create the KVStore for Redis instance.

 **Note** The network type cannot be changed after the instance is created.

Procedure

1. **Log on to the KVStore for Redis console.**
2. Click **Create Instance** in the upper-right corner.

3. Set the following parameters.

KVStore for Redis instance parameters

Section	Parameter	Description
Basic	Organization	The organization to which the KVStore for Redis instance to be created belongs.
	Resource Set	The resource set to which the KVStore for Redis instance belongs.  Notice After you select a resource set, the KVStore for Redis instance is accessible only to the members of the specified resource set.
Region	Region	Specifies the region where the KVStore for Redis instance is deployed.
	Zone	Specifies the zone where the KVStore for Redis instance is deployed.
Specifications	Engine Version	The following engine versions are supported: <ul style="list-style-type: none"> Redis2.8 Redis4.0
	Architecture Type	The architecture type of the KVStore for Redis instance. KVStore for Redis provides cluster and standard architectures. The cluster architecture meets large-capacity or high-performance requirements. Native Redis databases run in a single-threading model. If your database does not require high performance, we recommend that you use a standard instance. For higher performance, select a cluster architecture.
	Node Type	The node type for the KVStore for Redis instance. KVStore for Redis supports the primary-secondary dual-node structure.
	Instance Type	The specification of the instance. The maximum connections and maximum internal network bandwidth vary among different instance specifications.
Network	Network Type	The network type of the instance. On the Apsara Stack, a classic network and a VPC network have the following differences: <ul style="list-style-type: none"> Classic network: Cloud services in a classic network are not isolated. Unauthorized access to a cloud service is blocked by only security groups or the service whitelist policy. VPC: A VPC helps you build an isolated network environment on Apsara Stack. You can customize the routing table, Classless Inter-Domain Routing (CIDR) blocks, and gateway of a VPC network. You can also migrate applications to the cloud by using a leased line or virtual private network (VPN) without service interruption to integrate your on-premises data center and cloud resources in a VPC network into a virtual data center.  Note Before you select the VPC type, create a VPC network. For more information, see <i>Create a VPC network</i> and <i>Create a VSwitch</i> in <i>VPC User Guide</i> .

Section	Parameter	Description
Password	Instance Name	Enter the name of the KVStore for Redis instance. <ul style="list-style-type: none"> ◦ The name must be 2 to 128 characters in length ◦ and can contain uppercase and lowercase letters, digits, underscores (_), and hyphens (-). It must start with a lowercase letter or Chinese character.
	Password Setting	You can select Now or Later .
	Password	Set a password used to connect to the instance. The password must follow these rules: <ul style="list-style-type: none"> ◦ The password must be 8 to 30 characters in length. ◦ The password must contain uppercase letters, lowercase letters, and digits. Special characters are not supported.
	Confirm Password	Enter the specified password again.

4. After you set the parameters, click **Submit**.

16.2.4. Configure a whitelist

Before using a KVStore for Redis instance, add IP addresses or CIDR blocks used to access the database to the instance whitelist to improve database security and stability.

Context

 **Note** A properly configured whitelist can guarantee the highest-level security protection for your KVStore for Redis instance. We recommend that you maintain the whitelist on a regular basis.

Procedure

1. [Log on to the KVStore for Redis console](#).
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. On the **Instance Information** page, click **Whitelist Settings** in the left-side navigation pane.
4. On the **Whitelist Settings** page, proceed in either of the following ways:
 - To customize the whitelist group name, create a new whitelist group:
 - a. Click **Add a Whitelist Group** in the upper-right corner.
 - b. In the **Add a Whitelist Group** dialog box that appears, set **Group Name**.

 **Note** A group name must be 2 to 32 characters in length and contain lowercase letters, digits, or underscores (_). The group name must start with a lowercase letter and end with a letter or digit. You cannot change this name after you create the whitelist group.

- If you do not require a custom whitelist group, click **Modify** next to the target whitelist group.
5. In the **Add a Whitelist Group** or **Modify Whitelist of Group** dialog box that appears, proceed in either of the following ways:
 - Manually modify the **Whitelist of Group** field:

- a. In the **Whitelist of Group** field, enter the IP addresses or CIDR blocks that you can use to connect to the KVStore for Redis instance.

Manually modify the whitelist group

Note

- Set the whitelist to `0.0.0.0/0` to allow connections from all IP addresses.
- Set the whitelist to `127.0.0.1` to block connections from all IP addresses.
- Set the whitelist to a CIDR block to allow connections from the IP addresses within the CIDR block, such as `10.10.10.0/24`.
- When you enter multiple IP addresses or CIDR blocks, separate them with commas (,) and leave no space before or after each comma.
- You can add 1,000 or fewer IP addresses or CIDR blocks to each whitelist group.

- b. Click **OK**.

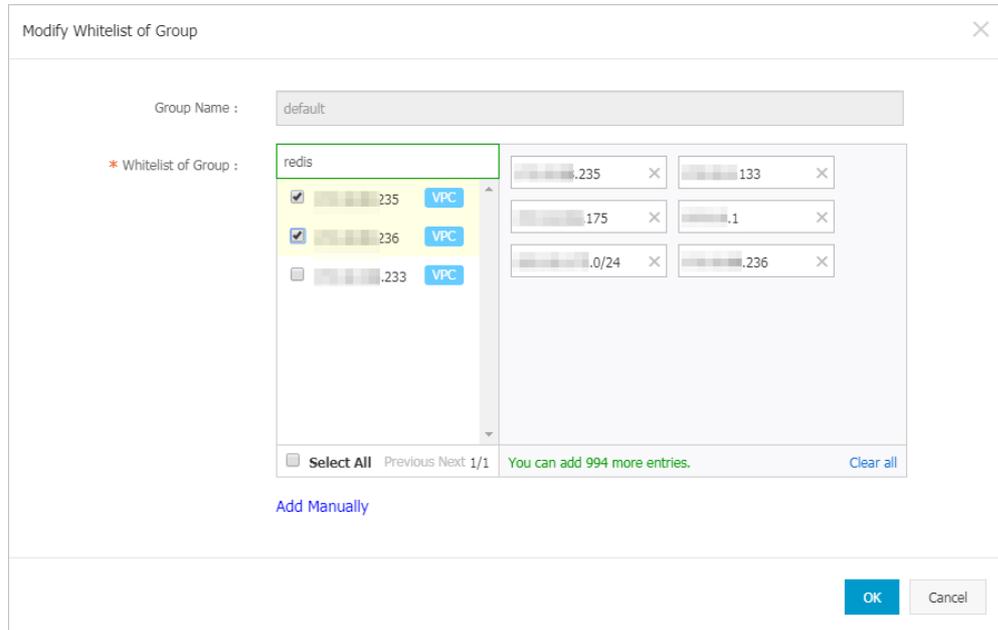

- o Load internal IP addresses of target ECS instances under the current Alibaba Cloud account:

- a. Click **Load ECS Internal IP Addresses**.

Load internal IP addresses of target ECS instances

b. Select internal IP addresses of target ECS instances.

Select internal IP addresses of target ECS instances

Note You can perform a fuzzy search by ECS instance name, ID, or IP address on the search bar above the list of ECS internal IP addresses.

c. Click OK.

16.2.5. Connect to an instance

16.2.5.1. Use a Redis client

You can connect to an KVStore for Redis instance by using clients for different programming languages.

The database service of KVStore for Redis is compatible with that of native Redis. Therefore, you can connect to both database services in similar ways. All clients that are compatible with the Redis protocol support connections to KVStore for Redis. You can use any of these clients that are suitable for your applications.

For more information about Redis clients, visit <https://redis.io/clients>.

Prerequisites

- The internal IP address of the Elastic Compute Service (ECS) instance or the public IP address of the local host has been added to a whitelist of the KVStore for Redis instance. For more information, see [Configure a whitelist](#).
- If you use a custom account to connect to the KVStore for Redis instance, the connection password must be in the format of `<user>:<password>`. For example, if the username of a custom account is `admin` and the password is `password`, the password used to connect to the KVStore for Redis instance must be in the format of `admin:password`.

Jedis clien

You can use a Jedis client to connect to KVStore for Redis in any of the following ways:

- Single Jedis connection. This method is not recommended because a client cannot automatically reconnect to KVStore for Redis after a connection times out.
- JedisPool-based connection. This method is recommended.

To use a Jedis client to connect to an KVStore for Redis instance, perform the following steps:

1. Download and install the Jedis client. For more information, see [Jedis](#).
2. Example of single Jedis connection
 - i. Open the Eclipse client, create a project, and then enter the following code:

```
import redis.clients.jedis.Jedis;
public class jedistest {
public static void main(String[] args) {
try {
    String host = "xx.kvstore.aliyuncs.com";//You can view the connection address of the target instance in the console.
    int port = 6379;
    Jedis jedis = new Jedis(host, port);
    //Authentication information.
    jedis.auth("password");//password
    String key = "redis";
    String value = "aliyun-redis";
    //Select a database. Default value: 0.
    jedis.select(1);
    //Set a key.
    jedis.set(key, value);
    System.out.println("Set Key " + key + " Value: " + value);
    //Obtain the configured key and value.
    String getvalue = jedis.get(key);
    System.out.println("Get Key " + key + " ReturnValue: " + getvalue);
    jedis.quit();
    jedis.close();
}
catch (Exception e) {
    e.printStackTrace();
}
}
}
```

- ii. Run the project. You have connected to KVStore for Redis if you see the following result in the Eclipse console.

```
Set Key redis Value aliyun-redis
Get Key redis ReturnValue aliyun-redis
```

Then, you can use a Jedis client to manage your KVStore for Redis instance. You can also connect to your KVStore for Redis instance by using JedisPool.

3. Example of JedisPool-based connection

- i. Open the Eclipse client, create a project, and then configure the following pom file:

```
<dependency>
<groupId>redis.clients</groupId>
<artifactId>jedis</artifactId>
<version>2.7.2</version>
<type>jar</type>
<scope>compile</scope>
</dependency>
```

- ii. Add the following application to the project:

```
import org.apache.commons.pool2.PooledObject;
import org.apache.commons.pool2.PooledObjectFactory;
import org.apache.commons.pool2.impl.DefaultPooledObject;
import org.apache.commons.pool2.impl.GenericObjectPoolConfig;
import redis.clients.jedis.HostAndPort;
import redis.clients.jedis.Jedis;
import redis.clients.jedis.JedisPool;
import redis.clients.jedis.JedisPoolConfig;
```

- iii. If your Jedis client version is Jedis-2.7.2, enter the following code in the project:

```
JedisPoolConfig config = new JedisPoolConfig();
//Maximum number of idle connections. You can customize this parameter. Make sure that the specified maximum number of idle connections does not exceed the maximum number of connections that the KVStore for Redis instance supports.
config.setMaxIdle(200);
//Maximum number of connections. You can customize this parameter. Make sure that the specified maximum number of connections does not exceed the maximum number of connections that the KVStore for Redis instance supports.
config.setMaxTotal(300);
config.setTestOnBorrow(false);
config.setTestOnReturn(false);
String host = "*.aliyuncs.com";
String password = "Password";
JedisPool pool = new JedisPool(config, host, 6379, 3000, password);
Jedis jedis = null;
try {
jedis = pool.getResource();
/// ... do stuff here ... for example
jedis.set("foo", "bar");
String foobar = jedis.get("foo");
jedis.zadd("sose", 0, "car");
jedis.zadd("sose", 0, "bike");
Set<String> sose = jedis.zrange("sose", 0, -1);
} finally {
if (jedis != null) {
jedis.close();
}
}
/// ... when closing your application:
pool.destroy();
```

- iv. If your Jedis client version is Jedis-2.6 or Jedis-2.5, enter the following code in the project:

```
JedisPoolConfig config = new JedisPoolConfig();
//Maximum number of idle connections. You can customize this parameter. Make sure that the specified maximum number of idle connections does not exceed the maximum number of connections that the KVStore for Redis instance supports.
config.setMaxIdle(200);
//Maximum number of connections. You can customize this parameter. Make sure that the specified maximum number of connections does not exceed the maximum number of connections that the KVStore for Redis instance supports.
config.setMaxTotal(300);
config.setTestOnBorrow(false);
config.setTestOnReturn(false);
String host = "*.aliyuncs.com";
String password = "Password";
JedisPool pool = new JedisPool(config, host, 6379, 3000, password);
Jedis jedis = null;
boolean broken = false;
try {
    jedis = pool.getResource();
    /// ... do stuff here ... for example
    jedis.set("foo", "bar");
    String foobar = jedis.get("foo");
    jedis.zadd("sose", 0, "car");
    jedis.zadd("sose", 0, "bike");
    Set<String> sose = jedis.zrange("sose", 0, -1);
}
catch(Exception e)
{
    broken = true;
} finally {
    if (broken) {
        pool.returnBrokenResource(jedis);
    } else if (jedis != null) {
        pool.returnResource(jedis);
    }
}
```

- v. Run the project. You have connected to KVStore for Redis if you see the following result in the Eclipse console.

```
Set Key redis Value aliyun-redis
Get Key redis ReturnValue aliyun-redis
```

Then, you can use a Jedis client to manage your KVStore for Redis instance.

PhpRedis client

To use a PhpRedis client to connect to an KVStore for Redis instance, perform the following steps:

1. Download and install the PhpRedis client. For more information, see [PhpRedis](#).

2. In an editor that supports PHP editing, enter the following code:

```
<? php
/* Replace the following parameter values with the host name and port number of the target instance. */
$host = "localhost";
$port = 6379;
/* Replace the following parameter values with the ID and password of the target instance. */
$user = "test_username";
$pwd = "test_password";
$redis = new Redis();
if ($redis->connect($host, $port) == false) {
    die($redis->getLastError());
}
if ($redis->auth($pwd) == false) {
    die($redis->getLastError());
}
/* You can perform database operations after authentication. For more information, visit https://github.com/php
Redis/phpredis. */.
if ($redis->set("foo", "bar") == false) {
    die($redis->getLastError());
}
$value = $redis->get("foo");
echo $value;
? >
```

3. Run the code. Then, you can use a PhpRedis client to connect to your KVStore for Redis instance. For more information, visit <https://github.com/phpredis/phpredis>.

Redis-py client

To use a redis-py client to connect to an KVStore for Redis instance, perform the following steps:

1. Download and install the redis-py client. For more information, see [redis-py](#).
2. In an editor that supports Python editing, enter the following code. You can use a redis-py client to connect to the KVStore for Redis instance and perform database operations.

```
#!/usr/bin/env python
#-*- coding: utf-8 -*-
import redis
#Replace the following parameter values with the host name and port number of the target instance.
host = 'localhost'
port = 6379
#Replace the following parameter value with the password of the target instance.
pwd = 'test_password'
r = redis.StrictRedis(host=host, port=port, password=pwd)
#You can perform database operations after you establish a connection. For more information, visit https://github.co
m/andymccurdy/redis-py.
r.set('foo', 'bar');
print r.get('foo')
```

C or C++ client

To use a C or C++ client to connect to an KVStore for Redis instance, perform the following steps:

1. Download, compile, and install the C client by using the following code:

```
git clone https://github.com/redis/hiredis.git
cd hiredis
make
sudo make install
```

2. Enter the following code in the C or C++ editor:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <hiredis.h>
int main(int argc, char **argv) {
    unsigned int j;
    redisContext *c;
    redisReply *reply;
    if (argc < 4) {
        printf("Usage: example xxx.kvstore.aliyuncs.com 6379 instance_id password\n");
        exit(0);
    }
    const char *hostname = argv[1];
    const int port = atoi(argv[2]);
    const char *instance_id = argv[3];
    const char *password = argv[4];
    struct timeval timeout = { 1, 500000 }; // 1.5 seconds
    c = redisConnectWithTimeout(hostname, port, timeout);
    if (c == NULL || c->err) {
        if (c) {
            printf("Connection error: %s\n", c->errstr);
            redisFree(c);
        } else {
            printf("Connection error: can't allocate redis context\n");
        }
        exit(1);
    }
    /* AUTH */
    reply = redisCommand(c, "AUTH %s", password);
    printf("AUTH: %s\n", reply->str);
    freeReplyObject(reply);
    /* PING server */
    reply = redisCommand(c, "PING");
    printf("PING: %s\n", reply->str);
    freeReplyObject(reply);
    /* Set a key */
    reply = redisCommand(c, "SET %s %s", "foo", "hello world");
```

```

printf("SET: %s\n", reply->str);
freeReplyObject(reply);
/* Set a key using binary safe API */
reply = redisCommand(c,"SET %b %b", "bar", (size_t) 3, "hello", (size_t) 5);
printf("SET (binary API): %s\n", reply->str);
freeReplyObject(reply);
/* Try a GET and two INCR */
reply = redisCommand(c,"GET foo");
printf("GET foo: %s\n", reply->str);
freeReplyObject(reply);
reply = redisCommand(c,"INCR counter");
printf("INCR counter: %lld\n", reply->integer);
freeReplyObject(reply);
/* again ... */
reply = redisCommand(c,"INCR counter");
printf("INCR counter: %lld\n", reply->integer);
freeReplyObject(reply);
/* Create a list of numbers, from 0 to 9 */
reply = redisCommand(c,"DEL mylist");
freeReplyObject(reply);
for (j = 0; j < 10; j++) {
    char buf[64];
    snprintf(buf,64,"%d",j);
    reply = redisCommand(c,"LPUSH mylist element-%s", buf);
    freeReplyObject(reply);
}
/* Let's check what we have inside the list */
reply = redisCommand(c,"LRANGE mylist 0 -1");
if (reply->type == REDIS_REPLY_ARRAY) {
    for (j = 0; j < reply->elements; j++) {
        printf("%u) %s\n", j, reply->element[j]->str);
    }
}
freeReplyObject(reply);
/* Disconnects and frees the context */
redisFree(c);
return 0;
}

```

3. Compile the code.

```
gcc -o example -g example.c -I /usr/local/include/hiredis -lhiredis
```

4. Run a test.

```
example xxx.kvstore.aliyuncs.com 6379 instance_id password
```

Now, the C or C++ client is connected to the KVStore for Redis instance.

.NET client

To use a .NET client to connect to an KVStore for Redis instance, perform the following steps:

1. Download and use the .NET client.

```
git clone https://github.com/ServiceStack/ServiceStack.Redis
```

2. Create a .NET project on the .NET client.
3. Add the reference file stored in the library file directory `ServiceStack.Redis/lib/tests` to the client.
4. Enter the following code in the .NET project to connect to the KVStore for Redis instance. For more information about API operations, visit <https://github.com/ServiceStack/ServiceStack.Redis>.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Threading.Tasks;
using ServiceStack.Redis;
namespace ServiceStack.Redis.Tests
{
    class Program
    {
        public static void RedisClientTest()
        {
            string host = "127.0.0.1"; /*IP address of the host that you want to connect to*/
            string password = "password"; /*Password*/
            RedisClient redisClient = new RedisClient(host, 6379, password);
            string key = "test-aliyun";
            string value = "test-aliyun-value";
            redisClient.Set(key, value);
            string listKey = "test-aliyun-list";
            System.Console.WriteLine("set key " + key + " value " + value);
            string getValue = System.Text.Encoding.Default.GetString(redisClient.Get(key));
            System.Console.WriteLine("get key " + key + " value " + getValue);
            System.Console.Read();
        }
        public static void RedisPoolClientTest()
        {
            string[] testReadWriteHosts = new[] {
                "redis://password@127.0.0.1:6379" /*redis://Password@IP address that you want to connect to:Port*/
            };
            RedisConfig.VerifyMasterConnections = false; /*You must set the parameter.*/
            PooledRedisClientManager redisPoolManager = new PooledRedisClientManager(10 /*Number of connections in the pool*/, 10 /*Connection pool timeout value*/, testReadWriteHosts);
            for (int i = 0; i < 100; i++){
                IRedisClient redisClient = redisPoolManager.GetClient(); /*Obtain the connection.*/
                RedisNativeClient redisNativeClient = (RedisNativeClient)redisClient;
                redisNativeClient.Client = null; /*KVStore for Redis does not support the CLIENT SETNAME command. Set Client to null.*/
            }
        }
    }
}
```

```

try
{
    string key = "test-aliyun1111";
    string value = "test-aliyun-value1111";
    redisClient.Set(key, value);
    string listKey = "test-aliyun-list";
    redisClient.AddItemToList(listKey, value);
    System.Console.WriteLine("set key " + key + " value " + value);
    string getValue = redisClient.GetValue(key);
    System.Console.WriteLine("get key " + getValue);
    redisClient.Dispose();//
}
catch (Exception e)
{
    System.Console.WriteLine(e.Message);
}
}
}
System.Console.Read();
}
static void Main(string[] args)
{
    //Single-connection mode.
    RedisClientTest();
    //Connection-pool mode.
    RedisPoolClientTest();
}
}
}

```

node-redis client

To use a node-redis client to connect to an KVStore for Redis instance, perform the following steps:

1. Download and install a node-redis client.

```
npm install hiredis redis
```

2. Enter and run the following code on the node-redis client to connect to the KVStore for Redis instance.

```

var redis = require("redis"),
client = redis.createClient(<port>, <"host">, {detect_buffers: true});
client.auth("password", redis.print)

```

Note In the code, the port field specifies the port of the KVStore for Redis instance. Default value: 6379. The host field specifies the endpoint of the KVStore for Redis instance. The following example shows the settings of the port and host fields:

```
client = redis.createClient(6379, "r-abcdefg.redis.rds.aliyuncs.com", {detect_buffers: true});
```

3. Use the KVStore for Redis instance.

```

// Write data to the instance.
client.set("key", "OK");
// Query data on the instance. The instance returns data of the String type.
client.get("key", function (err, reply) {
  console.log(reply.toString()); // print `OK`
});
// If a buffer is imported, a buffer is returned.
client.get(new Buffer("key"), function (err, reply) {
  console.log(reply.toString()); // print ``
});
client.quit();

```

C# client StackExchange.Redis

To use the C# client StackExchange.Redis to connect to an KVStore for Redis instance, perform the following steps:

1. Download and install [StackExchange.Redis](#).
2. Add a reference.

```
using StackExchange.Redis;
```

3. Initialize ConnectionMultiplexer.

ConnectionMultiplexer is the core of StackExchange.Redis, and shared and reused in the entire application. You must use ConnectionMultiplexer as a singleton. ConnectionMultiplexer is initialized in the following way:

```

// redis config
private static ConfigurationOptions configurationOptions = ConfigurationOptions.Parse("127.0.0.1:6379,password=xxx,connectTimeout=2000");
//the lock for singleton
private static readonly object Locker = new object();
//singleton
private static ConnectionMultiplexer redisConn;
//singleton
public static ConnectionMultiplexer getRedisConn()
{
  if (redisConn == null)
  {
    lock (Locker)
    {
      if (redisConn == null || ! redisConn.IsConnected)
      {
        redisConn = ConnectionMultiplexer.Connect(configurationOptions);
      }
    }
  }
  return redisConn;
}

```

Note

ConfigurationOptions contains multiple options, such as keepAlive, connectRetry, and name. For more information, see [StackExchange.Redis.ConfigurationOptions](#).

4. `GetDatabase()` returns a lightweight object. You can obtain this object from the object of `ConnectionMultiplexer`.

```
redisConn = getRedisConn();
var db = redisConn.GetDatabase();
```

5. The following examples show five types of data structures, which are strings, hashes, lists, sets, and sorted sets. The API operations used in these examples are different from their usage in the native Redis service.

- string

```
//set get
string strKey = "hello";
string strValue = "world";
bool setResult = db.StringSet(strKey, strValue);
Console.WriteLine("set " + strKey + " " + strValue + ", result is " + setResult);
//incr
string counterKey = "counter";
long counterValue = db.StringIncrement(counterKey);
Console.WriteLine("incr " + counterKey + ", result is " + counterValue);
//expire
db.KeyExpire(strKey, new TimeSpan(0, 0, 5));
Thread.Sleep(5 * 1000);
Console.WriteLine("expire " + strKey + ", after 5 seconds, value is " + db.StringGet(strKey));
//mset mget
KeyValuePair<RedisKey, RedisValue> kv1 = new KeyValuePair<RedisKey, RedisValue>("key1", "value1");
KeyValuePair<RedisKey, RedisValue> kv2 = new KeyValuePair<RedisKey, RedisValue>("key2", "value2");
db.StringSet(new KeyValuePair<RedisKey, RedisValue>[] {kv1, kv2});
RedisValue[] values = db.StringGet(new RedisKey[] {kv1.Key, kv2.Key});
Console.WriteLine("mget " + kv1.Key.ToString() + " " + kv2.Key.ToString() + ", result is " + values[0] + "&&" + values[1]);
```

- hash

```
string hashKey = "myhash";
//hset
db.HashSet(hashKey,"f1","v1");
db.HashSet(hashKey,"f2","v2");
HashEntry[] values = db.HashGetAll(hashKey);
//hgetall
Console.WriteLine("hgetall " + hashKey + ", result is");
for (int i = 0; i < values.Length; i++)
{
    HashEntry hashEntry = values[i];
    Console.WriteLine(" " + hashEntry.Name.ToString() + " " + hashEntry.Value.ToString());
}
Console.WriteLine();
```

- list

```
//list key
string listKey = "myList";
//rpush
db.ListRightPush(listKey, "a");
db.ListRightPush(listKey, "b");
db.ListRightPush(listKey, "c");
//lrange
RedisValue[] values = db.ListRange(listKey, 0, -1);
Console.WriteLine("lrange " + listKey + " 0 -1, result is ");
for (int i = 0; i < values.Length; i++)
{
    Console.WriteLine(values[i] + " ");
}
Console.WriteLine();
```

- set

```
//set key
string setKey = "mySet";
//sadd
db.SetAdd(setKey, "a");
db.SetAdd(setKey, "b");
db.SetAdd(setKey, "c");
//sismember
bool isContains = db.SetContains(setKey, "a");
Console.WriteLine("set " + setKey + " contains a is " + isContains );
```

- sorted set

```

string sortedSetKey = "myZset";
//sadd
db.SortedSetAdd(sortedSetKey, "xiaoming", 85);
db.SortedSetAdd(sortedSetKey, "xiaohong", 100);
db.SortedSetAdd(sortedSetKey, "xiaofei", 62);
db.SortedSetAdd(sortedSetKey, "xiaotang", 73);
//zrevrangebyscore
RedisValue[] names = db.SortedSetRangeByRank(sortedSetKey, 0, 2, Order.Ascending);
Console.WriteLine("zrevrangebyscore " + sortedSetKey + " 0 2, result is ");
for (int i = 0; i < names.Length; i++)
{
    Console.WriteLine(names[i] + " ");
}
Console.WriteLine();

```

16.2.5.2. Use redis-cli

You can use the Redis command-line interface (`redis-cli`) tool to connect to a KVStore for Redis instance.

 **Notice** KVStore for Redis only supports connections over an internal network. Therefore, you must install `redis-cli` on an Elastic Compute Service (ECS) instance in the same VPC network as an KVStore for Redis instance, and connect the ECS instance to the KVStore for Redis instance to manage data.

Install redis-cli

Install a Linux-based version of Redis to use `redis-cli`. For more information, visit the [Redis official website](#).

Prerequisites

Connections over an internal network

- If the KVStore for Redis instance and the ECS instance run in a classic network, both instances must be deployed in the same region.
- You have added the internal IP address of the ECS instance to an whitelist of the KVStore for Redis instance.
- The operating system of the local host must be Linux.
- You have installed the Linux-based version of Redis on the ECS instance.
- If you use a custom account to connect to the KVStore for Redis instance, the connection password must be in the format of `<user>:<password>`. For example, if the username of a custom account is `admin` and the password is `password`, the password used to connect to the KVStore for Redis instance must be in the format of `admin:password`.

Connect to a KVStore for Redis instance

On the command line, run the following command to connect to the KVStore for Redis instance.

```
redis-cli -h <host> -p <port> -a <password>
```

Parameters

Parameter	Description
<code>-h</code>	Specifies the endpoint of the KVStore for Redis instance.

Parameter	Description
-p	Specifies the service port of the KVStore for Redis instance. The default port number is 6379 and cannot be changed.
-a	Specifies the password used to connect to the KVStore for Redis instance. To enhance data security, you can skip this parameter to avoid revealing the password in plaintext. After you run the preceding command, you can enter <code>auth <password></code> to complete the authentication. The following figure shows an example.

Example

```
[root@ ~]# redis-cli -h r-bp1.redis.rds.aliyuncs.com -p 6379
r-bp1.redis.rds.aliyuncs.com:6379> auth a
OK
r-bp1.redis.rds.aliyuncs.com:6379>
```

16.3. Instance management

16.3.1. Change the password

If you forget your password, need to change your password, or have not set a password for an instance, you can set a new password for the instance.

Procedure

1. [Log on to the KVStore for Redis console.](#)
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. In the upper-right corner of the **Basic Information** page, click **Modify Password**.
4. In the **Change Password** dialog box that appears, set **Old Password**, **New Password**, **Confirm Password**.

Note

- If you forget your password, you can click **Forgot password?** in the **Change Password** dialog box. In the **Reset Password** dialog box that appears, you can set a new password.
- The password must be 8 to 32 characters in length.
- The password must contain characters from at least three of the following categories: uppercase letters, lowercase letters, digits, and special characters. Special characters include ! @ # \$ % ^ & * () _ + - =

16.3.2. Configure a whitelist

Before using a KVStore for Redis instance, add IP addresses or CIDR blocks used to access the database to the instance whitelist to improve database security and stability.

Context

Note A properly configured whitelist can guarantee the highest-level security protection for your KVStore for Redis instance. We recommend that you maintain the whitelist on a regular basis.

Procedure

1. [Log on to the KVStore for Redis console.](#)
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions**

column.

3. On the **Instance Information** page, click **Whitelist Settings** in the left-side navigation pane.

4. On the **Whitelist Settings** page, proceed in either of the following ways:

- To customize the whitelist group name, create a new whitelist group:
 - a. Click **Add a Whitelist Group** in the upper-right corner.
 - b. In the **Add a Whitelist Group** dialog box that appears, set **Group Name**.

Note A group name must be 2 to 32 characters in length and contain lowercase letters, digits, or underscores (_). The group name must start with a lowercase letter and end with a letter or digit. You cannot change this name after you create the whitelist group.

- If you do not require a custom whitelist group, click **Modify** next to the target whitelist group.

5. In the **Add a Whitelist Group** or **Modify Whitelist of Group** dialog box that appears, proceed in either of the following ways:

- **Manually modify the Whitelist of Group field:**
 - a. In the **Whitelist of Group** field, enter the IP addresses or CIDR blocks that you can use to connect to the KVStore for Redis instance.

Manually modify the whitelist group

Note

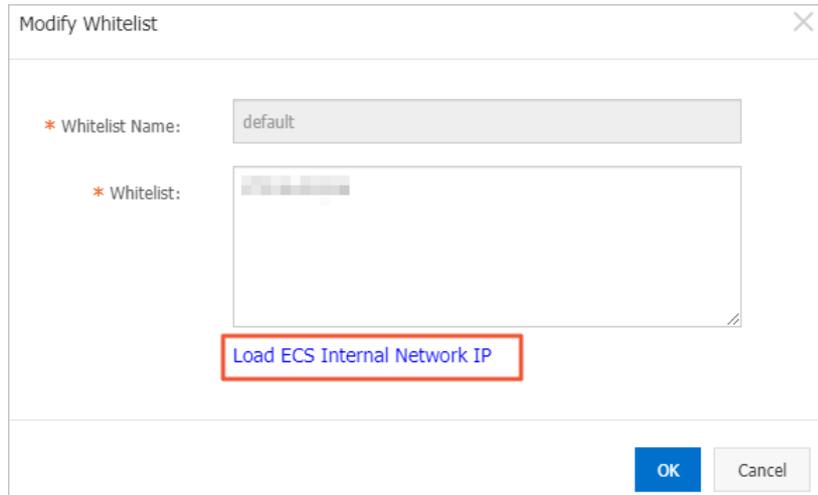

- Set the whitelist to `0.0.0.0/0` to allow connections from all IP addresses.
- Set the whitelist to `127.0.0.1` to block connections from all IP addresses.
- Set the whitelist to a CIDR block to allow connections from the IP addresses within the CIDR block, such as `10.10.10.0/24`.
- When you enter multiple IP addresses or CIDR blocks, separate them with commas (,) and leave no space before or after each comma.
- You can add 1,000 or fewer IP addresses or CIDR blocks to each whitelist group.

b. Click **OK**.

- Load internal IP addresses of target ECS instances under the current Alibaba Cloud account:

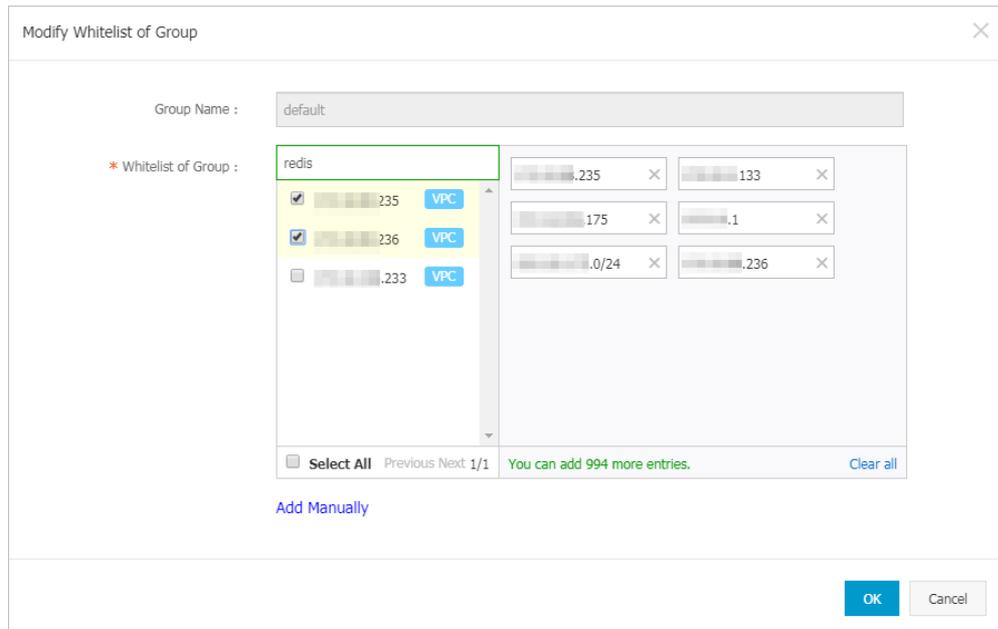

a. Click Load ECS Internal IP Addresses.

Load internal IP addresses of target ECS instances

b. Select internal IP addresses of target ECS instances.

Select internal IP addresses of target ECS instances

Note You can perform a fuzzy search by ECS instance name, ID, or IP address on the search bar above the list of ECS internal IP addresses.

c. Click OK.

16.3.3. Change configurations

This topic describes how to change the configuration of a KVStore for Redis instance.

Context

 **Note** After configuration changes have been completed, the system will migrate data and experience transient disconnection for a few seconds during this process. We recommend that you upgrade or downgrade the instance configuration during off-peak hours.

Procedure

1. [Log on to the KVStore for Redis console.](#)
2. On the **Instance List** page, find the target instance. Then, click the instance ID or click **Change Configurations** in the **Actions** column.
3. On the **Change Configurations** page, change the configurations and click **Submit**. The following example provides common configurations:

Configuration	Description
Architecture Type	The architecture type of the KVStore for Redis instance. KVStore for Redis provides cluster and standard architectures. The cluster architecture meets large-capacity or high-performance requirements. Native Redis databases run in a single-threading model. If your database does not require high performance, we recommend that you use a standard instance. To achieve higher performance, select a cluster instance.
Instance Class	The specification of the instance. The maximum number of connections and maximum internal bandwidth vary, depending on the instance specification.

16.3.4. Set a maintenance window

You can modify the default maintenance window to perform maintenance on KVStore for Redis during off-peak hours.

Context

To ensure the stability of KVStore for Redis instances on the Alibaba Cloud platform, the backend system performs maintenance on instances and servers occasionally.

To guarantee the stability of the maintenance process, instances will enter the **Maintaining Instance** status before the preset maintenance window on the day of maintenance. While an instance is in this state, data in the database can still be accessed and query operations such as performance monitoring are still available. However, change operations such as configuration change are temporarily unavailable for this instance in the console.

 **Note** During the maintenance process, instances may be disconnected in the process of maintenance. We recommend that you set the maintenance window to a period during off-peak hours.

Procedure

1. [Log on to the KVStore for Redis console.](#)
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. On the **Instance Information** page, click **Settings** to the right of the **Maintenance Window** field in the **Basic Information** section.
4. Select time periods and click **Save**.

 **Note** The time periods are in UTC+8.

16.3.5. Upgrade the minor version

Alibaba Cloud has continuously optimized the kernel of KVStore for Redis to fix security vulnerabilities and provide more stable services. You can upgrade the kernel version (minor version) of a KVStore for Redis instance with one click in the console.

Context

Note

- We recommend that you upgrade instance versions during off-peak hours and ensure that your application supports automatic reconnection.
- The system automatically checks the kernel version of an instance. If the current version is the latest, the **Minor Version Upgrade** button in the upper-right corner of the **Basic Information** section for this instance will appear dimmed.

Procedure

1. [Log on to the KVStore for Redis console.](#)
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. On the **Instance Information** page, click **Minor Version Upgrade** in the upper-right corner of the **Basic Information** section.
4. In the **Minor Version Upgrade** dialog box that appears, click **Upgrade Now**. On the **Instance Information** page, the instance status will become **Upgrading a minor version**. When the instance status returns to **Available**, the upgrade has been completed.

16.3.6. Configure SSL encryption

The standard and cluster Instances of Redis 2.8 and the cluster instances of Redis 4.0 support secure sockets layer (SSL) encryption. You can enable SSL encryption to ensure more secure data transmission.

Context

 **Note** SSL encryption may increase the network response time of instances. We recommend that you enable this feature only when necessary.

Procedure

1. [Log on to the KVStore for Redis console.](#)
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. In the left-side navigation pane of the **Instance Information** page, click **SSL Settings**.
4. In the upper-right corner of the **SSL Settings** page, click **Configure SSL**.
5. In the **Configure SSL** dialog box that appears, turn on the **Enable** switch. The switch will turn from green to gray when it is enabled. Click **OK**.
 - If an error message is displayed to indicate that the instance is in an abnormal state, click **OK** in the message that appears.
 - If an error message is displayed to indicate that the feature is not supported in this version, upgrade the minor version of the instance. For more information, see [Upgrade the minor version](#).
 - After the operation, you must wait for a short period of time before the system displays the operation result.
 - You can also click **Update Validity** and **Download CA Certificate** in the upper-right corner of the **SSL**

Settings page to perform relevant operations.

16.3.7. Clear data

You can clear the data of a KVStore for Redis instance in the console.

Context

 **Warning** This operation will delete all data contained on an instance. Deleted data cannot be restored. Proceed with caution.

Procedure

1. [Log on to the KVStore for Redis console.](#)
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. In the upper-right corner of the **Instance Information** page, click **Clear Data**.
4. In the **Clear Data** message that appears, click **OK**.

16.3.8. Release an instance

You can release a KVStore for Redis instance at any time based on your business needs. This topic describes how to release a KVStore for Redis instance.

Procedure

1. [Log on to the KVStore for Redis console.](#)
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. On the **Instance List** page, find the target instance. Then, click **Release** in the **Actions** column.

 **Warning** After an instance is released, it cannot be restored. Proceed with caution. We recommend that you back up your data before releasing the instance.

4. In the **Release Instance** message that appears, click **OK**.

16.3.9. Manage database accounts

KVStore for Redis allows you to create up to 20 database accounts for an instance. You can grant permissions to these accounts and manage your instance based on the actual needs to minimize misoperations.

Prerequisites

The engine version of the instance is Redis 4.0 or later.

 **Note** If the engine version of the instance is not Redis 4.0, only the default account is available. The default account is created when you create the instance. For more information about how to change the password of the default account, see [Change the password](#).

Context

You can create accounts, delete accounts, reset the password, and change the permissions. After an account is created, you can use this account to log on to the database and use the command-line tool to perform operations on the database with the account and granted permissions.

Create an account

1. [Log on to the KVStore for Redis console.](#)
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. On the **Instances** page, find the instance that you want to manage and click the instance ID. By default, the **Instance Information** page is displayed. In the left-side navigation pane, click **Account Management**.

 **Note** If **Account Management** is not available for an instance of Redis 4.0 or later, you can try to upgrade the minor version. For more information, see [Upgrade the minor version](#).

4. In the upper-right corner of the **Account Management** page, click **Create**.
5. In the **Create Account** dialog box that appears, set the following parameters and click **OK**.

 **Note**

16.3.10. Use a Lua script

KVStore for Redis instances of all editions support Lua commands.

Support for Lua commands

Lua scripts improve the performance of KVStore for Redis. With support for the Lua environment, KVStore for Redis is able to perform check-and-set (CAS) operations, allowing you to combine and run multiple commands in an efficient manner.

 **Note** If the `Eval` command cannot be executed, such as when the "ERR command eval not support for normal user" message is displayed, you can try to [Upgrade the minor version](#). During the upgrade, the instance may be disconnected and become read-only for a few seconds. We recommend that you upgrade the version of an instance during off-peak hours.

Limits on Lua scripts

To ensure that all operations in a Lua script are performed within the same hash slot, the cluster edition of KVStore for Redis sets the following limits on a Lua script:

- The Lua script uses the `redis.call/redis.pcall` function to call Redis commands. For these commands, all the keys must be passed by using the `KEYS` array, which cannot be replaced by Lua variables. Otherwise, the following error message is returned:

```
-ERR bad lua script for redis cluster, all the keys that the script uses should be passed using the KEYS arrayrn
```

- All the keys that the script uses must be allocated in the same hash slot. Otherwise, the following error message is returned:

```
-ERR eval/evalsha command keys must be in same slotrn
```

- Keys must be passed for all the commands to be called. Otherwise, the following error message is returned:

```
-ERR for redis cluster, eval/evalsha number of keys can't be negative or zerorn
```

 **Note** If you want to break the Lua limits of Redis Cluster and can ensure that all operations are performed in the same hash slot in the code, you can set the `script_check_enable` parameter to 0 in the console to disable the backend script check.

16.3.11. Restart an instance

You can restart an instance from the Instance List page of the console.

Procedure

1. [Log on to the KVStore for Redis console.](#)
2. On the Instance List page, find the target instance. Then, click **Restart** in the Actions column.

 **Notice** During the restart, the instance may be disconnected for a few seconds. We recommend that you restart instances during off-peak hours and ensure that your application supports automatic reconnection.

3. In the dialog box that appears, select a restart time and click **OK**.
 - **Restart Immediately:** restarts the instance immediately.
 - **Restart Within Maintenance Window:** restarts the instance within the preset [maintenance window](#).

16.3.12. Export the list of instances

You can export the list of KVStore for Redis instances from the KVStore for Redis console for offline management.

Procedure

1. [Log on to the KVStore for Redis console.](#)
2. In the upper-right corner of the Instance List page, click the **Export Instances** icon.
3. In the **Export Instance List** dialog box that appears, select the columns to export and click **OK**.

 **Note** After you click **OK**, the browser begins to download the CSV file. You can use Excel or a text editor to view this file.

16.4. Connection management

16.4.1. View connection strings

You can view the internal and public endpoints of instances in the KVStore for Redis console.

Context

-  **Note**
- The virtual IP address of a KVStore for Redis instance may change when you maintain or modify the service. To ensure connection availability, we recommend that you use a connection string to access the KVStore for Redis instance.
 - For more information about how to apply for a public connection string, see [Applies for a public connection string](#).

Procedure

1. [Log on to the KVStore for Redis console.](#)

2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. On the **Instance Information** page, view **Internal Connection Address (Host)** and **Public Endpoint (Host)** in the **Connection Information** section.

16.4.2. Apply for a public endpoint

This topic describes how to apply for a public endpoint.

Procedure

1. [Log on to the KVStore for Redis console.](#)
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. On the **Instance Information** page, click **Apply for External IP Address** in the **Connection Information** section.
4. In the **Apply for External IP Address** dialog box that appears, enter an endpoint and port number, and click **OK**.

Note

- The custom endpoint prefix must be 8 to 64 characters in length and can contain lowercase letters and digits. It must start with a lowercase letter.
- The custom port ranges from 1024 to 65535. The default value is 6379.
- After you apply for a public endpoint, you must add the public IP address to an IP address whitelist of the instance to connect to the instance over the Internet. For more information, see [Configure a whitelist](#).

5. On the **Instance Information** page, view the **Public Endpoint** in the **Connection Information** section.

 **Note** If a public endpoint is no longer needed, you can click **Release Public Endpoint** next to the **Public Endpoint** to release the endpoint.

16.4.3. Change the connection string of an instance

KVStore for Redis allows you to modify internal and public endpoints for instances. When changing the KVStore for Redis instance, you can change the endpoint of the new instance to the endpoint of the original instance without modifying the application.

Prerequisites

The instance is in the **Running** state.

Procedure

1. [Log on to the KVStore for Redis console.](#)
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. On the **Instance Information** page, click **Modify Public Endpoint** in the **Connection Information** section.
4. In the **Modify Public Endpoint** dialog box that appears, set **Connection Type**, **Endpoint**, and **Port**. Click **OK**.

Note

- The custom endpoint prefix must be 8 to 64 characters in length and can contain lowercase letters and digits. It must start with a lowercase letter.
- The custom port range is 1024 to 65535. The default value is 6379.
- If **Connection Type** is set to **Internal Address**, you cannot set **Port**.

16.5. Parameter configuration

KVStore for Redis allows you to customize certain instance parameters. This topic describes parameters and the common methods to modify them in the KVStore for Redis console.

Context

KVStore for Redis is completely compatible with the native database services of Redis. The method to set parameters for KVStore for Redis is similar to that of an on-premises Redis database. You can set the parameters described in this topic in the KVStore for Redis console.

Parameters

Parameters

Parameter	Description
#no_loose_check-whitelist-always	Specifies whether to check whether the client IP address is in the whitelist of the KVStore for Redis instance after password-free access is enabled in Virtual Private Cloud (VPC). Default value: no. If you set this parameter to yes, the whitelist will still take effect in password-free access mode for VPC. Valid values: <ul style="list-style-type: none"> • yes • no
#no_loose_disabled-commands	Specifies the disabled commands. Separate multiple commands with commas (,). You can disable the following commands: FLUSHALL, FLUSHDB, KEYS, HGETALL, EVAL, EVALSHA, and SCRIPT.
#no_loose_ssl-enabled	Specifies whether to enable SSL encryption. Default value: no. Valid values: <ul style="list-style-type: none"> • yes • no
#no_loose_sentinel-enabled	Specifies whether to enable Sentinel-compatible mode. Default value: no. Valid values: <ul style="list-style-type: none"> • yes • no
client-output-buffer-limit pubsub	Limits the size of output buffers for Pub/Sub clients. This parameter can contain options in the following format: <code><hard limit> <soft limit> <soft seconds></code> . <ul style="list-style-type: none"> • Hard limit: If the output buffer of a Pub/Sub client reaches or exceeds the number of bytes specified by hard limit, the client is immediately disconnected. • soft limit and soft seconds: If the output buffer of a Pub/Sub client reaches or exceeds the size in bytes specified by soft limit for a period of time in seconds specified by soft seconds, the client will be disconnected.

Parameter	Description
dynamic-hz	<p>Specifies whether to enable dynamic frequency control for background tasks. Default value: yes. Valid values:</p> <ul style="list-style-type: none"> • yes • no
hash-max-ziplist-entries	<p>Specifies the maximum size of each key-value pair stored within a hash in bytes. A hash is encoded using ziplist when it meets the following conditions:</p> <ol style="list-style-type: none"> 1. The maximum size of each key-value pair stored within the hash in bytes must be less than the value of the hash-max-ziplist-value parameter. 2. The number of key-value pairs stored within the hash must be less than the value of the hash-max-ziplist-entries parameter.
hash-max-ziplist-value	<p>Specifies the maximum size of each key-value pair stored within a hash in bytes. A hash is encoded using ziplist when it meets the following conditions:</p> <ol style="list-style-type: none"> 1. The maximum size of each key-value pair stored within the hash in bytes must be less than the value of the hash-max-ziplist-value parameter. 2. The number of key-value pairs stored within the hash must be less than the value of the hash-max-ziplist-entries parameter.
hz	<p>Specifies the execution frequency for background tasks, such as tasks to evict expired keys. Valid values: 1 to 500. Default value: 10. The larger the value of the hz parameter, the more frequently background tasks are performed and the more precisely timeout events are handled, but the more CPU KVStore for Redis consumes. We recommend that you do not set the hz parameter to a value greater than 100.</p>
lazyfree-lazy-eviction	<p>Specifies whether to enable lazyfree for the eviction feature. Default value: no. Valid values:</p> <ul style="list-style-type: none"> • yes • no
lazyfree-lazy-expire	<p>Specifies whether to enable lazyfree to delete expired keys. Default value: yes. Valid values:</p> <ul style="list-style-type: none"> • yes • no
lazyfree-lazy-server-del	<p>Specifies whether to enable lazyfree to asynchronously delete data with the DEL command. Default value: yes. Valid values:</p> <ul style="list-style-type: none"> • yes • no

Parameter	Description
list-compress-depth	<p>Specifies the number of nodes that are not compressed at each side in a list. Default value: 0. Valid values:</p> <ul style="list-style-type: none"> • 0: does not compress any nodes in the list. • 1: does not compress the first node from each side of the list, but compresses all nodes in between. • 2: does not compress the first two nodes from each side of the list, but compresses all nodes in between. • 3: does not compress the first three nodes from each side of the list, but compresses all nodes in between. • And so on up to 65535.
list-max-ziplist-size	<ul style="list-style-type: none"> • Specifies the maximum size of each ziplist in a quicklist. A positive number indicates the maximum number of elements in each ziplist of a quicklist. For example, if you set this parameter to 5, each ziplist of a quicklist can contain a maximum of five elements. • A negative number indicates the maximum number of bytes in each ziplist of a quicklist. Default value: -2. Valid values: <ul style="list-style-type: none"> ◦ -5: indicates that each ziplist of a quicklist cannot exceed 64 KB (1 KB = 1,024 bytes). ◦ -4: indicates that each ziplist of a quicklist cannot exceed 32 KB. ◦ -3: indicates that each ziplist of a quicklist cannot exceed 16 KB. ◦ -2: indicates that each ziplist of a quicklist cannot exceed 8 KB. ◦ -1: indicates that each ziplist of a quicklist cannot exceed 4 KB.
maxmemory-policy	<p>Specifies the policy used to evict keys if the memory is fully occupied. Valid values: LRU means least recently used. LFU means least frequently used. LRU, LFU, and TTL are implemented by using approximated randomized algorithms.</p> <ul style="list-style-type: none"> • volatile-lru: evicts the approximated least recently used (LRU) keys among keys with a preset expiration time. • allkeys-lru: evicts the approximated LRU keys. • volatile-lfu: evicts the approximated least frequently used (LFU) keys among keys with a preset expiration time. • allkeys-lfu: evicts the approximated LFU keys. • volatile-random: evicts random keys among keys with a preset expiration time. • allkeys-random: evicts random keys. • volatile-ttl: evicts keys with the nearest time to live (TTL) among keys with a preset expiration time. • noeviction: does not evict any keys, but returns an error on write operations.

Parameter	Description
notify-keyspace-events	<p>Specifies the events that the Redis server can notify clients of. The value of this parameter is any combination of the following characters, each of which specifies a type of event to be notified:</p> <ul style="list-style-type: none"> • • K: keyspace events, published with the <code>__keyspace@<db>__</code> prefix. • E: keyevent events, published with the <code>__keyevent@<db>__</code> prefix. • g: generic commands that are non-type specific, such as DEL, EXPIRE, and RENAME. • l: list commands. • s: set commands. • h: hash commands. • z: sorted set commands. • x: expired key events. An expired key event is generated when a key expires. • e: evicted key events. An evicted key event is generated when a key is evicted due to the policy specified by the <code>maxmemory-policy</code> parameter. • A: the alias for <code>g\$lshzxe</code>.
set-max-intset-entries	<p>Specifies the maximum number of data entries in a set. A set is encoded by using intset when it meets the following conditions:</p> <ol style="list-style-type: none"> 1. The set is composed of just strings. The number of strings is less than the value of this parameter. 2. All strings are integers in radix 10 in the range of 64-bit signed integers.
slowlog-log-slower-than	<p>Specifies whether to log slow queries.</p> <ul style="list-style-type: none"> • Negative number: does not log slow queries. • 0: logs all queries. • Positive number: logs queries that exceed an execution time specified by this positive number, in microseconds. <p>Valid values: 0 to 10,000,000. Default value: 10,000.</p>
slowlog-max-len	<p>Specifies the maximum number of slow query log entries that can be stored.</p> <p>Valid values: 100 to 10,000. Default value: 1,024.</p>
stream-node-max-bytes	<p>Specifies the maximum memory that can be used by each macro node in streams. Valid values: 0 to 999,999,999,999,999. If you set the parameter to 0, each macro node can use an unlimited amount of memory.</p>
stream-node-max-entries	<p>Specifies the maximum number of stream entries that can be stored within each macro node. Valid values: 0 to 999,999,999,999,999. If you set the parameter to 0, each macro node can store unlimited stream entries.</p>
timeout	<p>Specifies a timeout period for client connections. Unit: seconds. Valid values: 0 to 100,000. 0 indicates that client connections never time out.</p>

Parameter	Description
zset-max-ziplist-entries	<p>Specifies the maximum size of each key-value pair stored within a sorted set in bytes. A sorted set is encoded using ziplist when it meets the following conditions:</p> <ol style="list-style-type: none"> 1. The maximum size of each key-value pair stored within the sorted set in bytes must be less than the value of the zset-max-ziplist-value parameter. 2. The number of key-value pairs stored within the sorted set must be less than the value of the zset-max-ziplist-entries parameter.
zset-max-ziplist-value	<p>Specifies the maximum size of each key-value pair stored within a sorted set in bytes. A sorted set is encoded using ziplist when it meets the following conditions:</p> <ol style="list-style-type: none"> 1. The maximum size of each key-value pair stored within the sorted set in bytes must be less than the value of the zset-max-ziplist-value parameter. 2. The number of key-value pairs stored within the sorted set must be less than the value of the zset-max-ziplist-entries parameter.
list-max-ziplist-entries	<p>Specifies the maximum size of each key-value pair stored within a list in bytes. A list is encoded using ziplist when it meets the following conditions:</p> <ol style="list-style-type: none"> 1. The maximum size of each key-value pair stored within the list in bytes must be less than the value of the list-max-ziplist-value parameter. 2. The number of elements stored within the list is less than the value of the list-max-ziplist-entries parameter.
list-max-ziplist-value	<p>Specifies the maximum size of each key-value pair stored within a list in bytes. A list is encoded using ziplist when it meets the following conditions:</p> <ol style="list-style-type: none"> 1. The maximum size of each key-value pair stored within the list in bytes must be less than the value of the list-max-ziplist-value parameter. 2. The number of elements stored within the list is less than the value of the list-max-ziplist-entries parameter.
cluster_compat_enable	<p>Specifies whether to enable compatibility with the syntax of Redis Cluster. Default value: 1. Valid values:</p> <ul style="list-style-type: none"> • 0: no • 1: yes
script_check_enable	<p>Specifies whether to confirm that all the keys used in a Lua script are in the same hash slot. Default value: 1. Valid values:</p> <ul style="list-style-type: none"> • 0: no • 1: yes

 **Note** The maxclients parameter, which is used to specify the maximum number of connections to Redis data nodes, is fixed to 10,000. You cannot modify the value of this parameter.

Configure parameters in the KVStore for Redis console

1. [Log on to the KVStore for Redis console.](#)
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.

3. In the left-side navigation pane of the Instance Information page, click **System Parameters**.
4. Find the target parameter and click **Modify** in the Action column.
5. In the dialog box that appears, modify the parameter value and click **OK**.

16.6. Backup and recovery

16.6.1. Back up data automatically

An increasing number of applications use KVStore for Redis for persistent storage. Because of this, KVStore for Redis supports routine backup mechanisms to restore data after misoperations occur. Alibaba Cloud provides secondary nodes to back up .rdb files as snapshots. Backup operations do not affect the performance of your instance. You can customize the backup operation in the console.

Procedure

1. [Log on to the KVStore for Redis console](#).
2. On the Instance List page, find the target instance. Click the instance ID or click **Manage** in the Actions column.
3. In the left-side navigation pane of the Instance Information page, click **Backup and Recovery**.
4. On the Backup and Recovery page, click the Backup Settings tab.
5. Click **Edit** to customize the automatic backup cycle and backup time.

 **Note** Backup data is retained for seven days. You cannot modify this configuration.

6. Click **OK**.

16.6.2. Back up data manually

You can initiate a manual backup task in the console at any time.

Procedure

1. [Log on to the KVStore for Redis console](#).
2. On the Instance List page, find the target instance. Click the instance ID or click **Manage** in the Actions column.
3. In the left-side navigation pane of the Instance Information page, click **Backup and Recovery**.
4. In the upper-right corner of the Data Backup tab, click **Create Backup**.
5. In the message that appears, click **Confirm**.

 **Note** On the Data Backup tab, you can select a time range to query historical backup data. Backup data is retained for seven days, so you can query historical backup data in the past seven days.

16.6.3. Download backup files

To archive these backup files for a longer period, you can copy their URLs in the console and download the database backup files to a local directory.

Procedure

1. [Log on to the KVStore for Redis console](#).
2. On the Instance List page, find the target instance. Click the instance ID or click **Manage** in the Actions column.
3. In the left-side navigation pane of the Instance Information page, click **Backup and Recovery**.

4. On the **Data Backup** tab, select the backup set to be archived and click **Download**.
5. In the **Download Backup File** dialog box that appears, click one of the following buttons to continue with the procedure:
 - **Download**: downloads the backup file to a local directory.
 - **Get URL for Internet**: copies the public URL for downloading the backup file, and downloads the backup file over the Internet.
 - **Get URL for Intranet**: copies the internal URL for downloading the backup file, and downloads the backup file over the internal network.
 - **Cancel**: cancels downloading the backup file.

16.6.4. Restore data

You can use backup files to restore data in the console.

Context

Notice

- Data restoration is highly risky. Check the data to be restored before performing this operation. Proceed with caution.
- This feature is not applicable to non-cluster KVStore for Redis instances.

Procedure

1. [Log on to the KVStore for Redis console](#).
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. In the left-side navigation pane of the **Instance Information** page, click **Backup and Recovery**.
4. On the **Data Backup** tab, select the target backup file and click **Restore Data**.
5. In the **Restore Data** dialog box that appears, click **Continue**. You can apply backup files to a new instance by [cloning an instance](#).

16.6.5. Clone an instance

You can apply backup files to a new instance by cloning an instance.

Context

Note This feature is applicable to non-cluster KVStore for Redis instances.

Procedure

1. [Log on to the KVStore for Redis console](#).
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. In the left-side navigation pane of the **Instance Information** page, click **Backup and Recovery**.
4. On the **Data Backup** tab, select the target backup set and click **Clone Instance**.
5. In the **Clone Instance** message that appears, click **OK**.

16.7. Performance monitoring

16.7.1. View monitoring data

You can query the monitoring data of a KVStore for Redis instance for a specified period within the last month.

Procedure

1. [Log on to the KVStore for Redis console](#).
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. In the left-side navigation pane of the **Instance Information** page, click **Performance Monitor**.
4. On the **Historical Monitoring Data** page, click the calendar icon next to **Query Time**.
5. Set a time range in which you want to query monitoring data and click **OK**.

 **Note** For more information about the monitoring metrics, see [Understand metrics](#).

16.7.2. Customize metrics

You can select the metrics to be displayed on the **Historical Monitoring Data** page of the KVStore for Redis console as needed.

Context

KVStore for Redis supports more than 10 groups of monitoring metrics. By default, the **Performance Monitor** page displays the monitoring metrics of the basic monitoring group. You can click the **Custom Metrics** button to switch to the metrics of other monitoring groups. The following table describes the monitoring groups.

Monitoring group	Description
Basic monitoring group	The basic instance monitoring information, such as the QPS, bandwidth, and memory usage.
Key monitoring group	The monitoring information on the use of key-value related commands, such as the number of times DEL and EXITS are called.
String monitoring group	The monitoring information on the use of string-related commands, such as the number of times APPEND and MGET are called.
Hash monitoring group	The monitoring information on the use of hash-related commands, such as the number of times HGET and HDEL are called.
List monitoring group	The monitoring information on the use of list-related commands, such as the number of times BLPOP and BRPOP are called.
Set monitoring group	The monitoring information on the use of set-related commands, such as the number of times SADD and SCARD are called.
Zset monitoring group	The monitoring information on the use of zset-related commands, such as the number of times ZADD and ZCARD are called.
HyperLog monitoring group	The monitoring information on the use of HyperLogLog-related commands, such as the number of times PFADD and PFCOUNT are called.
Pub/Sub monitoring group	The monitoring information on the use of publication and subscription-related commands, such as the number of times PUBLISH and SUBSCRIBE are called.
Transaction monitoring group	The monitoring information on the use of transaction-related commands, such as the number of times WATCH, MULTI, and EXEC are called.
Lua script monitoring group	The monitoring information on the use of Lua script-related commands, such as the number of times EVAL and SCRIPT are called.

Procedure

1. [Log on to the KVStore for Redis console.](#)
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. In the left-side navigation pane of the **Instance Information** page, click **Performance Monitor**.
4. On the **Historical Monitoring Data** page, click **Customize Metrics** in the **Data Index** section.
5. In the **Customize Metrics** dialog box that appears, select the new monitoring group and click **OK**.

16.7.3. Modify monitoring frequency

KVStore for Redis console allows you to set the frequency at which monitoring data is collected.

Context

You can set the monitoring frequency to either 5 or 60 seconds to specify how often monitoring data to be collected by KVStore for Redis. The default monitoring time of 60 seconds is sufficient to meet common monitoring requirements. If you need to observe certain metrics at a higher frequency and lower latency, you can change the monitoring frequency to 5 seconds as described in the following section. Monitoring data does not occupy instance storage space, and collection of monitoring data does not affect normal running of the instance.

Procedure

1. [Log on to the KVStore for Redis console.](#)
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. In the left-side navigation pane of the **Instance Information** page, click **Performance Monitor**.
4. In the upper-right corner of the **Historical Monitoring Data** page, click **Monitoring Frequency**.
5. In the **Monitoring Frequency** dialog box that appears, select the new monitoring frequency and click **OK**.

16.7.4. Monitoring metrics

KVStore for Redis monitors more than 10 groups of metrics in real time. This allows you to monitor the running status of KVStore for Redis instances. This topic describes these metrics.

Basic monitoring metrics

Metric	Unit	Description	Statistical method
CpuUsage	%	The CPU usage.	Monitor the CPU usage when collecting monitoring data.
UsedMemory	Bytes	The amount of the used memory.	Monitor the amount of the used memory when collecting monitoring data.
TotalQps	Counts/s	The number of requests received by an instance per second.	Divide the number of requests in a monitoring cycle by the number of seconds in the monitoring cycle.
ConnCount	Counts	The number of connections.	Monitor the number of connections when collecting monitoring data.

Metric	Unit	Description	Statistical method
InFlow	KBps	The amount of data received by an instance per second.	Divide the amount of data received in a monitoring cycle by the number of seconds in the monitoring cycle.
OutFlow	KBps	The amount of data sent by an instance per second.	Divide the amount of data sent in a monitoring cycle by the number of seconds in the monitoring cycle.
FailedCount	Counts/s	The average number of abnormal requests per second.	Divide the total number of abnormal requests in a monitoring cycle by the number of seconds in the monitoring cycle.
AvgRt	us	The average response time of all requests.  Note For more information, see Response time (RT) metrics .	Divide the processing time of all requests in a monitoring cycle by the number of requests in the monitoring cycle.
MaxRt	us	The maximum response time of requests.  Note For more information, see Response time (RT) metrics .	Monitor the maximum amount of time consumed for processing a single request in a monitoring cycle.
Keys	Counts	The total number of keys.	Monitor the number of keys when collecting monitoring data.
Expires	Counts	The total number of keys for which an expiration time is set.	Monitor the total number of keys for which an expiration time is set when collecting monitoring data.
ExpiredKeys	Counts	The total number of expired keys.	Monitor the cumulative sum when collecting monitoring data. After the instance is restarted, the cumulative sum is calculated again.
EvictedKeys	Counts	The total number of keys that are evicted because the memory is fully occupied.	Monitor the cumulative sum when collecting monitoring data. After the instance is restarted, the cumulative sum is calculated again.

Metric	Unit	Description	Statistical method
request	Bytes	The total amount of request data received by KVStore for Redis nodes in a monitoring cycle.	See the description of this metric.
response	Bytes	The total amount of response data sent by KVStore for Redis nodes in a monitoring cycle.	See the description of this metric.
request_max	Bytes	The maximum amount of data that a single request has in a monitoring cycle.	See the description of this metric.
response_max	Bytes	The maximum amount of data that a single response has in a monitoring cycle.	See the description of this metric.
traffic_control_input	Counts	The number of times that downstream throttling is triggered.	Monitor the cumulative sum in a monitoring cycle.
traffic_control_output	Counts	The number of times that upstream throttling is triggered.	Monitor the cumulative sum in a monitoring cycle.
traffic_control_input_status	Counts	Indicates whether downstream throttling has been triggered in a monitoring cycle. A value of 0 indicates that throttling has not been triggered. A value of 1 indicates that throttling has been triggered.	See the description of this metric.
traffic_control_output_status	Counts	Indicates whether upstream throttling has been triggered in a monitoring cycle. A value of 0 indicates that throttling has not been triggered. A value of 1 indicates that throttling has been triggered.	See the description of this metric.
hit_rate	%	The request hit ratio. This metric indicates the probability that data exists in a KVStore for Redis instance when the data is requested.	Calculate the percentage of the hit requests to the total number of requests in a monitoring cycle.
hit	Counts	The number of hit requests.	Monitor the number of hit requests in a monitoring cycle.
miss	Counts	The number of missed requests.	Monitor the number of missed requests in a monitoring cycle.

Metric	Unit	Description	Statistical method
evicted_keys_per_sec	Counts/s	The number of keys that are evicted per second.	Divide the total number of keys evicted in a monitoring cycle by the number of seconds in the monitoring cycle.

Other monitoring metrics

The system also uses other monitoring metrics to monitor specific types of data or specific features. These monitoring metrics are classified into:

- Metrics that reflect the number of times that commands are used. For example, the del, dump, and exists metrics for keys monitoring indicate the number of times the DEL, DUMP, and EXISTS commands are used.
- **Response time (RT) metrics** of commands. For example, the metrics that end with avg_rt such as del_avg_rt, dump_avg_rt, and exists_avg_rt in the key monitoring group are used to monitor the average response time of the DEL, DUMP, and EXISTS commands in a monitoring cycle.

Response time (RT) metrics

All groups of monitoring metrics include response time metrics. Such metrics end with Rt or rt. For example, the AvgRt and MaxRt metrics in the basic monitoring metrics or the del_avg_rt and exists_avg_rt metrics in the keys monitoring.

The AvgRt and MaxRt metrics in the basic monitoring group are the most frequently used response time metrics. These metrics have different meanings for proxy nodes and data nodes.

- For a cluster instance or a read/write splitting instance, the AvgRt metric of a proxy node reflects the average time consumed by the proxy node to process all commands. A proxy node processes a command by following these steps:
 - i. The proxy node receives a command and forwards the command to a data node.
 - ii. The data node processes the command and responds to the proxy node.
 - iii. The proxy node returns the command processing result.

The AvgRt metric of the proxy node includes the amount of time consumed by the data node to process a command and the waiting time. It also includes the amount of time consumed for network communication between the proxy node and the data node.

- For data nodes of a cluster instance or a read/write splitting instance or for a standard instance, the AvgRt metric reflects the average time consumed by a data node to process all commands. This metric records the period from the time when the data node receives the command to the time when the data node returns the result. This metric does not include the time consumed by the proxy node to process a command and the time consumed for network communication.
- The MaxRt metric specifies the maximum response time of requests. The statistical method of this metric is similar to that of the AvgRt metric for all KVStore for Redis instances.

17. ApsaraDB for MongoDB

17.1. Before you start

You must get familiar with the precautions and limits of ApsaraDB for MongoDB before you start.

To ensure the stability and security of ApsaraDB for MongoDB instances, pay attention to the limits described in [ApsaraDB for MongoDB limits](#).

ApsaraDB for MongoDB limits

Operation	Limit
Create a database replica	<ul style="list-style-type: none"> The system automatically creates a three-node replica set. The replica set consists of a primary node, a secondary node, and a hidden secondary node (invisible to you). You cannot manually create a secondary node.
Restart a database	You must restart an ApsaraDB for MongoDB instance in the ApsaraDB for MongoDB console or by using OpenAPI Explorer.

17.2. Log on to the ApsaraDB for MongoDB console

This topic describes how to log on to the ApsaraDB for MongoDB console.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

- In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
- Enter your username and password.

Obtain the username and password used to log on to the console from the operations administrator.

Note When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:

- Uppercase or lowercase letters.
- Digits.
- Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

- Click **Login** to go to the ASCM console homepage.
- In the top navigation bar, choose **Products > Database Services > ApsaraDB for MongoDB**.

17.3. Quick start

17.3.1. Use ApsaraDB for MongoDB

This topic is a quick start guide to basic usage operations for ApsaraDB for MongoDB, such as creating an instance, configuring a whitelist, and connecting to an instance. Flowcharts are used to describe the basic procedures in ApsaraDB for MongoDB, and guide you to create an ApsaraDB for MongoDB instance.

- **Create an ApsaraDB for MongoDB instance**

An instance is a virtual database server on which you can create and manage multiple databases.

- **Configure a whitelist for an ApsaraDB for MongoDB instance**

After you create an ApsaraDB for MongoDB instance, you need to configure a whitelist for the instance to allow external devices to access the instance.

A whitelist can enhance access security for ApsaraDB for MongoDB instances. We recommend that you update the whitelist on a regular basis. The normal services of the instance are not affected if you configure a whitelist.

- **Connect to a replica set instance by using the mongo shell**

After you create an instance and configure a whitelist, you can use the mongo shell to connect to the instance.

17.3.2. Create an ApsaraDB for MongoDB instance

This topic describes how to create an instance in the ApsaraDB for MongoDB console.

Prerequisites

An account is obtained to log on to the ApsaraDB for MongoDB console.

Procedure

1. **Log on to the ApsaraDB for MongoDB console.**
2. Click **Create Instance** to go to the **Create MongoDB Instance** page and configure the parameters.

The following table describes the required parameters.

Parameters for creating an instance

Section	Parameter	Description
Basic Settings	Organization	Select an organization for the new instance.
	Resource Set	Select a resource set for the new instance.

Section	Parameter	Description
Region	Region	Select a region for the new instance.
	Zone	Select a zone for the new instance.
Specifications	Database Engine	Select a database engine for the new instance. In this case, you can select only MongoDB.
	Engine Version	Select a database version for the new instance. Valid values: <ul style="list-style-type: none"> ○ 3.0 ○ 3.4 ○ 4.0
	Node Type	ApsaraDB for MongoDB supports the following options: <ul style="list-style-type: none"> ○ Three-node Replica Set: uses dedicated memory and I/O resources but shares CPU and storage resources with other general-purpose instances on the same server. ○ Dedicated Instance: uses dedicated CPU, memory, storage, and I/O resources to ensure long-term performance. In this case, an instance is not affected by other instances on the same server. ○ Dedicated Host: exclusively uses all resources of a server. This is the top configuration of exclusive specifications.
	Node Specifications	Select a node specification for the new instance. Available specifications are displayed on the Create MongoDB Instance page.
	Storage Capacity	Specify the storage capacity for the new instance to store data, system files, log files, and transaction files.
Network	Network Type	ApsaraDB for MongoDB supports the following options: <ul style="list-style-type: none"> ○ Classic Network: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. ○ VPC: A VPC helps you to build an isolated network in Apsara Stack. You can customize route tables, CIDR blocks, and gateways in a VPC. We recommend that you select VPC for enhanced security. <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> ? Note If you select VPC, you must configure the VPC and VSwitch parameters. </div>
Password	Instance Name	Set the name for the new instance. The name must be 2 to 256 characters in length and can contain digits, letters, underscores (_), and hyphens (-). It must start with a letter.
	Set Password	Determine when to set the password for logging on to databases in the new instance. You can select Now to set the logon password immediately, or select Later to set the logon password after you create the instance. For more information, see Reset the password for an ApsaraDB for MongoDB instance .
	Password	Set a password, which must meet the following requirements: <ul style="list-style-type: none"> ○ It must be 8 to 30 characters in length. ○ It must contain uppercase letters, lowercase letters, and digits. Special characters are not allowed.

Section	Parameter	Description
	Confirm Password	Enter the password again. The password you enter here must be the same as that in Password.

3. Click **Submit** to create the instance.

17.3.3. Configure a whitelist for an ApsaraDB for MongoDB instance

This topic describes how to configure a whitelist for an ApsaraDB for MongoDB instance. Before you use an ApsaraDB for MongoDB instance, you must add the IP addresses or Classless Inter-Domain Routing (CIDR) blocks that you use for database access to a whitelist of this instance. This improves database security and stability. Proper configuration of whitelists can enhance access security of ApsaraDB for MongoDB. We recommend that you maintain the whitelists on a regular basis.

Context

The system creates a default whitelist for each instance. This whitelist can be modified or cleared, but it cannot be deleted. After an ApsaraDB for MongoDB instance is created, the system automatically adds the IP address 0.0.0.0/0 to the default whitelist. The IP address 0.0.0.0/0 indicates that all IP addresses are allowed to access this instance. For database security, we recommend that you remove the IP address 0.0.0.0/0 and add only IP addresses or CIDR blocks that you allow to whitelists.

Procedure

1. [Log on to the ApsaraDB for MongoDB console.](#)
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **Data Security > Whitelist Setting**.
5. You can manually configure a whitelist or import ECS Internal IP addresses to the whitelist. **Manually modify a whitelist**
 - i. Find the whitelist you want to modify and choose  > **Manually Modify** in the **Operation** column.
 - ii. Enter IP addresses or CIDR blocks.

Note

- Separate multiple IP addresses with commas (,). You can add a maximum of 1,000 different IP addresses to a whitelist. Supported formats are IP addresses such as 0.0.0.0/0 and 10.23.12.24, or CIDR blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix. The IP address prefix can consist of 1 to 32 bits.
- 0.0.0.0/0 or a blank field indicates that there is no IP access restrictions. In this case, the database may be at high security risk. We recommend that you set the access permission only for the IP address or CIDR block of your Web server.

Load IP addresses of ECS instances

- i. Find the target whitelist and choose  > **Import ECS Intranet IP** in the **Operation** column.
- ii. From the displayed internal IP addresses of ECS instances under the current account, find the target IP addresses and click  to add them to the whitelist.

iii. Click OK.

17.3.4. Overview of replica set instance connections

This topic describes how to obtain connection strings and connection string URIs that are supported by ApsaraDB for MongoDB, as well as how to use them to connect to replica set instances. You can use a connection string to connect to either the primary or secondary node, and use a connection string URI to connect to both of them. For high availability, we recommend that you connect your application to both primary and secondary nodes by using connection string URIs.

View connection information

1. [Log on to the ApsaraDB for MongoDB console.](#)
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Database Connection** to view connection information.

Intranet Connection - Classic Network	
Role	Address
Primary	ods-  .mongodb.rds.intra.env17e.shuguang.com:3717
Secondary	ods-  .mongodb.rds.intra.env17e.shuguang.com:3717
ConnectionStringURI	mongodb://root:****@dds-  .mongodb.rds.intra.env17e.shuguang.com:3717

Description of connection information

Item	Description
Address	<ul style="list-style-type: none"> • Intranet Connection - Classic Network: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. • Intranet Connection - VPC: A VPC is an isolated network with higher security and performance than the classic network. By default, ApsaraDB for MongoDB provides endpoints on a VPC.
Role	<ul style="list-style-type: none"> • Primary: the primary node in the replica set instance. If you connect to this node, you can perform read and write operations on the databases of the replica set instance. • Secondary: the secondary node in the replica set instance. If you connect to this node, you can perform only read operations on the databases of the replica set instance.
Primary/Secondary	<p>The connection string of a primary or secondary node is in the following format:</p> <pre><host>:<port></pre> <ul style="list-style-type: none"> • <host>: the endpoint you use to connect to the replica set instance. • <port>: the port you use to connect to the replica set instance.

Item	Description
ConnectionStringURI	<p>A connection string URI is in the following format:</p> <pre data-bbox="405 315 1386 412">mongodb://[username:password@]host1[:port1][,host2[:port2],...[,hostN[:portN]]][/[database][? options]]</pre> <ul style="list-style-type: none"> • <code>mongodb://</code>: the prefix of the connection string URI. It indicates a connection string URI. • <code>username:password@</code>: the username and password you use to log on to a database of the replica set instance. You must separate them with a colon (:). • <code>hostX:portX</code>: the endpoint and port of a node in the replica set instance. • <code>/database</code>: the name of the authentication database. It is the database where the database user is created. • <code>? options</code>: additional connection options. <p> Note If your application is in a production environment, we recommend that you use a connection string URI to connect to the instance. This way, when a node fails, the read and write operations of your application are not affected as a result of the failover.</p>

Related information

- [Connect to a replica set instance by using the mongo shell](#)

17.3.5. Use the mongo shell to connect to a replica set instance

This topic describes how to use the mongo shell to connect to a replica set instance. The mongo shell is a database management tool provided by ApsaraDB for MongoDB. You can install it on your client or in an ECS instance.

Prerequisites

- The version of the mongo shell is the same as your replica set instance. This ensures successful authentication. For information about the installation procedure, visit [MongoDB official documentation](#). Choose the version in the upper-left corner of the page based on your client version.
- The IP address of your client is added to a whitelist of the replica set instance. For more information, see [Configure a whitelist for an ApsaraDB for MongoDB instance](#).

Procedure

1. [Log on to the ApsaraDB for MongoDB console](#).
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Database Connection** to obtain the connection string of a node and the connection string URI.

 **Note** For more information about the connection strings, see [Overview of replica set instance connections](#).

5. Connect to the replica set instance from your client or ECS instance where the mongo shell is installed.
 - Single-node connection.

During regular tests, you can directly connect to a primary or secondary node. Take note that after the primary node fails, the system automatically switches to the secondary node, and the roles of connected nodes change. This affects the read and write operations of your application.

Command format:

```
mongo --host <host> -u <username> -p --authenticationDatabase <database>
```

- **<host>**: the connection string of the primary or secondary node.
 - **Primary**: the primary node in the replica set instance. If you connect to this node, you can perform read and write operations on the databases of the replica set instance.
 - **Secondary**: the secondary node in the replica set instance. If you connect to this node, you can perform only read operations on the databases of the replica set instance.
- **<username>**: the username you use to log on to a database of the replica set instance. The initial username is root.
- **<database>**: the name of the authentication database. It is the database where the database user is created. If the username is root, enter admin.

Example:

```
mongo --host dds-bp*****.mongodb.rds.aliyuncs.com:3717 -u root -p --authenticationDatabase admin
```

When `Enter password:` is displayed, enter the password of the database user and press Enter. If you forget the password of the root user, you can reset it. For more information, see [Reset the password for an ApsaraDB for MongoDB instance](#).

 **Note** The password you enter is not displayed.

- **HA connection (recommended)**: You can use a connection string URI to connect to both the primary and secondary nodes of a replica set instance. This ensures that your application is always connected to the primary node and the read and write operations of your application are not affected even if the roles of the primary and secondary nodes are switched.

Command format:

```
mongo "<ConnectionStringURI>"
```

- The connection string URI must be enclosed in a pair of double quotation marks ("").
- **<ConnectionStringURI>**: the connection string URI of the replica set instance.

You must replace `****` in the connection string URI with the database password. For more information about how to set a database password, see [Reset the password for an ApsaraDB for MongoDB instance](#).

17.4. Instances

17.4.1. Create an ApsaraDB for MongoDB instance

This topic describes how to create an instance in the ApsaraDB for MongoDB console.

Prerequisites

An account is obtained to log on to the ApsaraDB for MongoDB console.

Procedure

1. [Log on to the ApsaraDB for MongoDB console](#).
2. Click **Create Instance** to go to the **Create MongoDB Instance** page and configure the parameters.

The following table describes the required parameters.

Parameters for creating an instance

Section	Parameter	Description
Basic Settings	Organization	Select an organization for the new instance.
	Resource Set	Select a resource set for the new instance.
Region	Region	Select a region for the new instance.
	Zone	Select a zone for the new instance
Specifications	Database Engine	Select a database engine for the new instance. In this case, you can select only MongoDB.
	Engine Version	Select a database engine version for the new instance. Valid values : <ul style="list-style-type: none"> ◦ 3.0 ◦ 3.4 ◦ 4.0
	Node Type	ApsaraDB for MongoDB supports the following options: <ul style="list-style-type: none"> ◦ Three-node Replica Set: uses dedicated memory and I/O resources but shares CPU and storage resources with other general-purpose instances on the same server. ◦ Dedicated Instance: uses dedicated CPU, memory, storage, and I/O resources to ensure long-term performance. In this case, an instance is not affected by other instances on the same server. ◦ Dedicated Host: exclusively uses all resources of a server. This is the top configuration of exclusive specifications.
	Node Specifications	Select a node specification for the new instance. Available specifications are displayed on the Create MongoDB Instance page.
	Storage Capacity	Specify the storage capacity for the new instance to store data, system files, log files, and transaction files.
Network	Network Type	ApsaraDB for MongoDB supports the following options: <ul style="list-style-type: none"> ◦ Classic Network: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. ◦ VPC: A VPC helps you build an isolated network in Apsara Stack. You can customize route tables, CIDR blocks, and gateways in a VPC. We recommend that you select VPC for enhanced security. <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> ? Note If you select VPC, you must configure the VPC and VSwitch parameters </div>
	Instance Name	Set the name for the new instance. The name must be 2 to 256 characters in length, and can contain digits, letters, underscores (_), and hyphens (-). It must start with a letter.
	Set Password	Determine when to set the password for logging on to databases in the new instance. You can select Now to set the logon password immediately, or select Later to set the logon password after you create the instance. For more information, see Reset the password for an ApsaraDB for MongoDB instance .

Password Section	Parameter	Description
	Password	Set a password. The password must meet the following requirements: <ul style="list-style-type: none"> It must be 8 to 32 characters in length. It must contain uppercase letters, lowercase letters, and digits. Special characters are not allowed.
	Confirm Password	Enter the password again. The password you enter here must be the same as that in Password.

- Click **Submit** to create the instance.

17.4.2. View the details of an ApsaraDB for MongoDB instance

This topic describes how to view the details of an ApsaraDB for MongoDB instance, such as the basic information, internal network connection information, status, and configurations.

Procedure

- Log on to the [ApsaraDB for MongoDB console](#).
- Go to the instance details page. Either of the following methods can be used:
 - Find the target instance and click its ID to go to the **Basic Information** page, where you can view the details of the instance.
 - In the **Operations** column corresponding to the target instance, choose  > **Manage** to go to the **Basic Information** page, where you can view the details of the instance.

17.4.3. Restart an ApsaraDB for MongoDB instance

This topic describes how to restart an ApsaraDB for MongoDB instance if the number of connections exceeds the upper limit or the performance of the instance deteriorates.

Context

 **Note** When an ApsaraDB for MongoDB instance is restarted, all its connections are terminated. Make appropriate service arrangements before you restart an ApsaraDB for MongoDB instance. Proceed with caution.

Procedure

- Log on to the [ApsaraDB for MongoDB console](#).
- On the **Replica Set Instances** page, find the target instance.
- Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
- In the upper-right corner of the page, click **Restart Instance**.

 **Note** You can also choose  > **Restart** in the **Operations** column corresponding to the target instance.

- In the **Restart Instance** message, click **OK**.

17.4.4. Change the specifications of an ApsaraDB for MongoDB instance

This topic describes how to change the specifications of an ApsaraDB for MongoDB instance. You can upgrade or downgrade an ApsaraDB for MongoDB instance to meet your business needs.

Procedure

1. [Log on to the ApsaraDB for MongoDB console.](#)
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. Click **Change Configuration** in the upper right corner of the **Specification Information** section to go to the **Modify Instance** page.

 **Note** To go to the **Modify Instance** page, you can also choose  > **Change Configuration** in the **Operations** column corresponding to the target instance on the **Replica Set Instances** page.

5. On the **Modify Instance** page, change the instance specifications. You can change values of the following parameters:
 - **Node Type**
 - **Node Specifications**
 - **Storage Capacity**
6. Click **Submit**.

17.4.5. Change the name of an ApsaraDB for MongoDB instance

This topic describes how to change the name of an ApsaraDB for MongoDB instance.

Procedure

1. [Log on to the ApsaraDB for MongoDB console.](#)
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. Click **Edit** to the right of **Instance Name**.

 **Note**

- The instance name must be 2 to 128 characters in length.
- It can contain letters, underscores (_), hyphens (-), and digits.
- It must start with a letter and cannot start with `http://` or `https://`.

5. Click **OK**.

17.4.6. Reset the password for an ApsaraDB for MongoDB instance

This topic describes how to reset your password in the ApsaraDB for MongoDB console.

Context

 **Notice** For data security, we recommend that you change your password on a regular basis.

Procedure

1. [Log on to the ApsaraDB for MongoDB console.](#)
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Accounts**.
5. Click **Reset Password** in the **Operation** column and configure the parameters in the **Reset Password** pane. [Parameters for resetting a password](#) describes the parameter configurations.

Parameters for resetting a password

Parameter	Description
New Password	<ul style="list-style-type: none"> ◦ The password must be 8 to 32 characters in length and must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. ◦ Special characters include ! # \$ % ^ & * () _ + - =
Confirm New Password	Enter the password again. The password you enter here must be the same as that in New Password.

6. Click **OK**.

17.4.7. Release an ApsaraDB for MongoDB instance

This topic describes how to manually release an ApsaraDB for MongoDB instance to meet your business needs.

Procedure

1. [Log on to the ApsaraDB for MongoDB console.](#)
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the lower-right corner of the **Basic Information** section, click **Release**.

 **Note** You can also go to the **Replica Set Instances** page, find the target instance, click the  icon in the **Operations** column, and then choose **Release**.

5. In the **Release Instance** message, click **OK**.

 **Warning** After you release an ApsaraDB for MongoDB instance, data in the instance can no longer be recovered. Proceed with caution.

17.4.8. Back up an ApsaraDB for MongoDB instance

17.4.8.1. Configure automatic backup for an ApsaraDB for MongoDB instance

This topic describes how to configure automatic backup for an ApsaraDB for MongoDB instance. ApsaraDB for MongoDB automatically backs up data based on the backup policy you specify.

Procedure

1. [Log on to the ApsaraDB for MongoDB console.](#)
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **Backup and Recovery** > **Backup Settings**. Configure the parameters in the Backup Settings pane.

[Backup policy parameters](#) describes the parameter configurations.

Backup policy parameters

Parameter	Description
Retention Days	The number of days for which you want to retain backup files. This parameter can only be set to seven days.
Backup Time	The hour at which you want to perform the backup task.
Day of Week	The backup cycle. You can select one or more days in a week.

5. Click **OK**.

17.4.8.2. Manually back up an ApsaraDB for MongoDB instance

This topic describes how to manually back up an ApsaraDB for MongoDB instance.

Procedure

1. [Log on to the ApsaraDB for MongoDB console.](#)
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the upper-right corner of the page, click **Backup Instance**.
□
5. In the **Backup Instance** pane, click **OK**.

17.4.9. Monitoring

This topic describes the performance metrics provided by ApsaraDB for MongoDB to check the status of ApsaraDB for MongoDB instances. You can view these performance metrics in the ApsaraDB for MongoDB console.

Procedure

1. [Log on to the ApsaraDB for MongoDB console.](#)
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Monitoring Info**.

You can select a time range to query historical performance metrics. [Performance metrics](#) describes the metric details.

Performance metrics

Performance metric	Description	Monitoring interval
CPU Usage	cpu_usage: the CPU utilization of the instance.	300 seconds
Memory Usage	mem_usage: the memory usage of the instance.	300 seconds
IOPS Usage	The IOPS used by the instance. The following items are included: <ul style="list-style-type: none"> ◦ data_iops: the IOPS of the data disk ◦ log_iops: the IOPS of the log disk 	300 seconds
IOPS Usage	iops_usage: the ratio of the IOPS used by the instance to the maximum IOPS allowed.	300 seconds
Disk Space Usage	The total disk space used by the instance. The following items are included: <ul style="list-style-type: none"> ◦ ins_size: the total space used ◦ data_size: the space used by the data disk ◦ log_size: the space used by the log disk 	300 seconds
Disk Space Usage	disk_usage: the ratio of the total disk space used by the instance to the maximum disk space that can be used.	300 seconds

Performance metric	Description	Monitoring interval
Opcounters	<p>The queries per second (QPS) of the instance. The following items are included:</p> <ul style="list-style-type: none"> ◦ The number of insert operations ◦ The number of query operations ◦ The number of update operations ◦ The number of delete operations ◦ The number of getmore operations ◦ The number of command operations 	300 seconds
Connections	<p>current_conn: the number of current connections to the instance.</p>	300 seconds
Cursors	<p>The number of cursors used by the instance. The following items are included:</p> <ul style="list-style-type: none"> ◦ total_open: the number of cursors that are opened ◦ timed_out: the number of cursors that timed out 	300 seconds
Network	<p>The network traffic of the instance. The following items are included:</p> <ul style="list-style-type: none"> ◦ bytes_in: the inbound network traffic ◦ bytes_out: the outbound network traffic ◦ num_requests: the number of requests that are processed 	300 seconds
Global Lock	<p>The length of the queue waiting for global locks in the instance. The following items are included:</p> <ul style="list-style-type: none"> ◦ gl_cq_total: the length of the queue waiting for both global read and write locks ◦ gl_cq_readers: the length of the queue waiting for global read locks ◦ gl_cq_writers: the length of the queue waiting for global write locks 	300 seconds

Performance metric	Description	Monitoring interval
WiredTiger	<p>The cache metrics of the WiredTiger engine used by the instance. The following items are included:</p> <ul style="list-style-type: none"> ◦ <code>bytes_read_into_cache</code>: the amount of data that is read into the cache ◦ <code>bytes_written_from_cache</code>: the amount of data that is written from the cache to the disk ◦ <code>maximum_bytes_configured</code>: the size of the maximum available disk space that is configured 	300 seconds
Master-slave Delay	<p><code>repl_lag</code>: the latency in data synchronization between the primary and secondary nodes of the instance.</p>	300 seconds

17.5. Database connection

17.5.1. Use the mongo shell to connect to a replica set instance

This topic describes how to use the mongo shell to connect to a replica set instance. The mongo shell is a database management tool provided by ApsaraDB for MongoDB. You can install it on your client or in an ECS instance.

Prerequisites

- The version of the mongo shell is the same as your replica set instance. This ensures successful authentication. For information about the installation procedure, visit [MongoDB official documentation](#). Choose the version in the upper-left corner of the page based on your client version.
- The IP address of your client is added to a whitelist of the replica set instance. For more information, see [Configure a whitelist for an ApsaraDB for MongoDB instance](#).

Procedure

1. [Log on to the ApsaraDB for MongoDB console](#).
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Database Connection** to obtain the connection string of a node and the connection string URI.

 **Note** For more information about the connection strings, see [Overview of replica set instance connections](#).

5. Connect to the replica set instance from your client or ECS instance where the mongo shell is installed.
 - Single-node connection.

During regular tests, you can directly connect to a primary or secondary node. Take note that after the primary node fails, the system automatically switches to the secondary node, and the roles of connected nodes change. This affects the read and write operations of your application.

Command format:

```
mongo --host <host> -u <username> -p --authenticationDatabase <database>
```

- **<host>**: the connection string of the primary or secondary node.
 - **Primary**: the primary node in the replica set instance. If you connect to this node, you can perform read and write operations on the databases of the replica set instance.
 - **Secondary**: the secondary node in the replica set instance. If you connect to this node, you can perform only read operations on the databases of the replica set instance.
- **<username>**: the username you use to log on to a database of the replica set instance. The initial username is `root`.
- **<database>**: the name of the authentication database. It is the database where the database user is created. If the username is `root`, enter `admin`.

Example:

```
mongo --host dds-bp*****.mongodb.rds.aliyuncs.com:3717 -u root -p --authenticationDatabase admin
```

When `Enter password:` is displayed, enter the password of the database user and press Enter. If you forget the password of the root user, you can reset it. For more information, see [Reset the password for an ApsaraDB for MongoDB instance](#).

 **Note** The password you enter is not displayed.

- **HA connection (recommended)**: You can use a connection string URI to connect to both the primary and secondary nodes of a replica set instance. This ensures that your application is always connected to the primary node and the read and write operations of your application are not affected even if the roles of the primary and secondary nodes are switched.

Command format:

```
mongo "<ConnectionStringURI>"
```

- The connection string URI must be enclosed in a pair of double quotation marks ("").
- **<ConnectionStringURI>**: the connection string URI of the replica set instance.

You must replace `****` in the connection string URI with the database password. For more information about how to set a database password, see [Reset the password for an ApsaraDB for MongoDB instance](#).

17.5.2. Use DMS to log on to a replica set instance of ApsaraDB for MongoDB

You can use DMS to connect to an ApsaraDB for RDS instance.

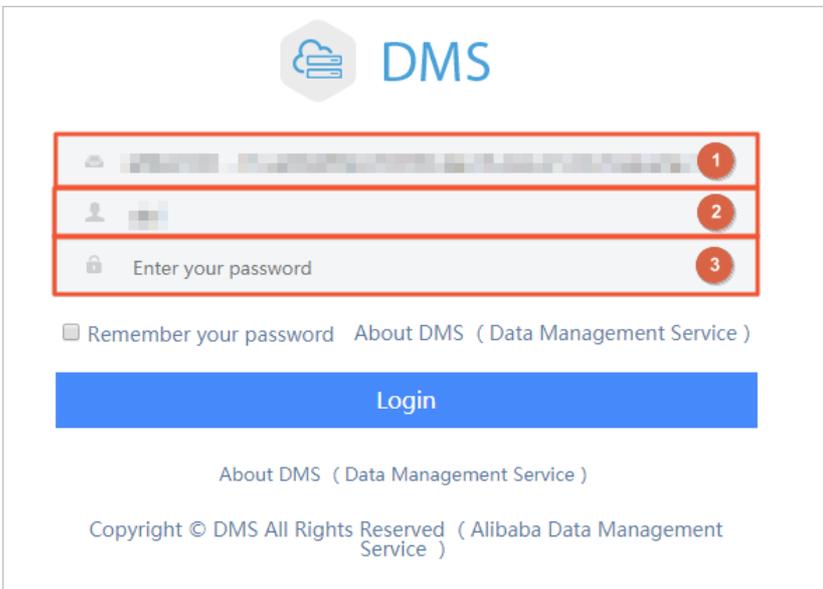

Prerequisites

The IP address whitelist is configured. For more information about how to configure the IP address whitelist, see [Configure a whitelist for an ApsaraDB for MongoDB instance](#).

Procedure

1. [Log on to the ApsaraDB for MongoDB console](#).

2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the upper-right corner of the page, click **Logon** to go to the DMS logon page.
5. On the DMS logon page, set the following parameters:

- ①: the combination of the internal endpoint and port number of an instance, which is in the `<internal endpoint>:<port number>` format. For more information about how to view the internal endpoint and port number of an instance, see [Overview of replica set instance connections](#).
 - ②: the account used to access the instance.
 - ③: the password of the account used to access the database.
6. Click **Login**.

 **Note** If you want your web browser to remember the password, select **Remember your password** before you click **Login**.

17.5.3. Overview of replica set instance connections

This topic describes how to obtain connection strings and connection string URIs that are supported by ApsaraDB for MongoDB, as well as how to use them to connect to replica set instances. You can use a connection string to connect to either the primary or secondary node, and use a connection string URI to connect to both of them. For high availability, we recommend that you connect your application to both primary and secondary nodes by using connection string URIs.

View connection information

1. [Log on to the ApsaraDB for MongoDB console](#).
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Database Connection** to view connection information.

Basic Information	Intranet Connection - Classic Network	
Accounts	Role	Address
Database Connection	Primary	dds-*****.mongodb.rds.intra.env17e.shuguang.com:3717
Backup and Recovery	Secondary	dds-*****.mongodb.rds.intra.env17e.shuguang.com:3717
Monitoring Info	ConnectionStringURI	mongodb://root:****@dds-*****.mongodb.rds.intra.env17e.shuguang.com:3717
Service Availability		

Description of connection information

Item	Description
Address	<ul style="list-style-type: none"> Intranet Connection - Classic Network: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. Intranet Connection - VPC: A VPC is an isolated network with higher security and performance than the classic network. By default, ApsaraDB for MongoDB provides endpoints on a VPC.
Role	<ul style="list-style-type: none"> Primary: the primary node in the replica set instance. If you connect to this node, you can perform read and write operations on the databases of the replica set instance. Secondary: the secondary node in the replica set instance. If you connect to this node, you can perform only read operations on the databases of the replica set instance.
Primary/Secondary	<p>The connection string of a primary or secondary node is in the following format:</p> <pre><host>:<port></pre> <ul style="list-style-type: none"> <host>: the endpoint you use to connect to the replica set instance. <port>: the port you use to connect to the replica set instance.
ConnectionStringURI	<p>A connection string URI is in the following format:</p> <pre>mongodb://[username:password@]host1[:port1][,host2[:port2],...[,hostN[:portN]]][/[database] [? options]]</pre> <ul style="list-style-type: none"> mongodb://: the prefix of the connection string URI. It indicates a connection string URI. username:password@: the username and password you use to log on to a database of the replica set instance. You must separate them with a colon (:). hostX:portX: the endpoint and port of a node in the replica set instance. /database: the name of the authentication database. It is the database where the database user is created. ? options: additional connection options. <p>Note If your application is in a production environment, we recommend that you use a connection string URI to connect to the instance. This way, when a node fails, the read and write operations of your application are not affected as a result of the failover.</p>

Related information

- [Connect to a replica set instance by using the mongo shell](#)

17.6. Security and audit

17.6.1. Configure a whitelist for an ApsaraDB for MongoDB instance

This topic describes how to configure a whitelist for an ApsaraDB for MongoDB instance. Before you use an ApsaraDB for MongoDB instance, you must add the IP addresses or Classless Inter-Domain Routing (CIDR) blocks that you use for database access to a whitelist of this instance. This improves database security and stability. Proper configuration of whitelists can enhance access security of ApsaraDB for MongoDB. We recommend that you maintain the whitelists on a regular basis.

Context

The system creates a default whitelist for each instance. This whitelist can be modified or cleared, but it cannot be deleted. After an ApsaraDB for MongoDB instance is created, the system automatically adds the IP address 0.0.0.0/0 to the default whitelist. The IP address 0.0.0.0/0 indicates that all IP addresses are allowed to access this instance. For database security, we recommend that you remove the IP address 0.0.0.0/0 and add only IP addresses or CIDR blocks that you allow to whitelists.

Procedure

1. [Log on to the ApsaraDB for MongoDB console](#).
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **Data Security** > **Whitelist Setting**.
5. You can manually configure a whitelist or import ECS Internal IP addresses to the whitelist. **Manually modify a whitelist**
 - i. Find the whitelist you want to modify and choose  > **Manually Modify** in the **Operation** column.
 - ii. Enter IP addresses or CIDR blocks.

Note

- Separate multiple IP addresses with commas (,). You can add a maximum of 1,000 different IP addresses to a whitelist. Supported formats are IP addresses such as 0.0.0.0/0 and 10.23.12.24, or CIDR blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix. The IP address prefix can consist of 1 to 32 bits.
- 0.0.0.0/0 or a blank field indicates that there is no IP access restrictions. In this case, the database may be at high security risk. We recommend that you set the access permission only for the IP address or CIDR block of your Web server.

Load IP addresses of ECS instances

- i. Find the target whitelist and choose  > **Import ECS Intranet IP** in the **Operation** column.
- ii. From the displayed internal IP addresses of ECS instances under the current account, find the target IP addresses and click  to add them to the whitelist.
- iii. Click **OK**.

17.6.2. Add or delete a whitelist

This topic describes how to add or delete whitelists that consist of the IP addresses allowed to access the databases.

Context

If your business involves multiple applications and you need to add an IP whitelist for each of them, you can sort the IP addresses into different whitelists.

Create a whitelist

1. Log on to the ApsaraDB for MongoDB console.
2. On the Replica Set Instances page, find the target instance.
3. Click the instance ID or choose  > Manage in the Operations column. Then, the Basic Information page appears.
4. In the left-side navigation pane, choose Data Security > Whitelist Setting.
5. Click Add a Whitelist Group in the upper-left corner of the page.
6. In the pane that appears on the right side of the page, configure Group Name and IP White List and click OK.

Note

- **Group Name:** The group name must be 2 to 32 characters in length, and can contain lowercase letters, digits, and underscores (_). It must start with a lowercase letter and end with a lowercase letter or digit.
- **IP White List**
 - Separate multiple IP addresses with commas (,). You can add a maximum of 1,000 different IP addresses to a whitelist. Supported formats are IP addresses such as 0.0.0.0/0 and 10.23.12.24, or CIDR blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix. The IP address prefix can consist of 1 to 32 bits.
 - 0.0.0.0/0 or a blank field indicates that there is no IP access restrictions. In this case, the database may be at high security risk. We recommend that you set the access permission only for the IP address or CIDR block of your Web server.

Delete an IP address whitelist

1. Log on to the ApsaraDB for MongoDB console.
2. On the Replica Set Instances page, find the target instance.
3. Click the instance ID or choose  > Manage in the Operations column. Then, the Basic Information page appears.
4. In the left-side navigation pane, choose Data Security > Whitelist Setting.
5. Find the target whitelist, and choose  > Delete Whitelist Group in the Operation column.

 **Note** You cannot delete the default whitelist.

6. In the Delete Whitelist Group message, click OK.

17.6.3. Audit logs

This topic describes audit logs provided in the ApsaraDB for MongoDB console. You can query the statement execution logs, operations logs, and error logs of an ApsaraDB for MongoDB instance to locate and analyze faults.

Context

The audit log feature records all operations that a client performs on a connected database. This feature provides references for you to perform fault analysis, behavior analysis, and security auditing because you can obtain the operation execution details from the audit logs. Audit logs are essential in the regulatory operations of Finance Cloud and other core business scenarios.

 **Note** Audit logs are stored for seven days, after which they are deleted.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. On the Replica Set Instances page, find the target instance.
3. Click the instance ID or choose  > Manage in the Operations column. Then, the Basic Information page appears.
4. In the left-side navigation pane, choose Data Security > Audit Log.
5. Click Enable Audit Log in the upper-left corner. In the Enable Audit message, click OK.

Result

On the Audit Log page, specify the time range, database name, database user, and keyword to query audit logs. You can also perform the following operations:

- **Export File:** exports an audit log file.
- **File List:** displays a list of audit logs.
- **Disable Audit Log:** stops the collection of information on database operations and deletes the saved audit logs.

17.6.4. Configure SSL encryption

This topic describes how to enhance link security by enabling Secure Sockets Layer (SSL) encryption and installing SSL CA certificates on your application services. The SSL encryption feature encrypts network connections at the transport layer to improve data security and ensure data integrity during communication.

Prerequisites

- The instance is a replica set instance.
- The database version of the instance is 3.4 or 4.0.

Impacts

When you enable or disable SSL encryption or update SSL CA certificates for an instance, the instance is restarted. Make appropriate service arrangements and make sure that your application can reconnect to the instance after it is disconnected.

 **Note** When an instance is restarted, all its nodes are restarted in turn, and each node goes through a transient connection of about 30 seconds. If the instance houses more than 10,000 collections, the transient connections last longer.

Precautions

- You can download SSL CA certificate files only from the ApsaraDB for MongoDB console.
- After you enable SSL encryption for an instance, the CPU utilization of the instance is significantly increased. We recommend that you enable SSL encryption only when necessary. For example, you can enable SSL encryption when you connect to an ApsaraDB for MongoDB instance over the Internet.

 **Note** In most cases, connections that use an internal endpoint do not require SSL encryption.

- After you enable SSL encryption for an instance, both SSL and non-SSL connections are supported.

Procedure

1. Log on to the ApsaraDB for MongoDB console.

2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **Data Security** > **SSL**.
5. Perform one of the following operations.

 **Note** When you enable or disable SSL encryption or update SSL CA certificates for an instance, the instance is restarted. Make appropriate service arrangements and make sure that your application can reconnect to the instance after it is disconnected.

Operation	Prerequisite	Procedure
Enable SSL encryption	The SSL encryption status is Disabled .	Turn on SSL Status . In the message that appears, click OK .
Update an SSL CA certificate	The SSL encryption status is Enabled .	Click Update Certificate . In the message that appears, click OK .
Download an SSL CA certificate file	The SSL encryption status is Enabled .	Click Download Certificate to download an SSL CA certificate file to your computer.
Disable SSL encryption	The SSL encryption status is Enabled .	Turn off SSL Status . In the message that appears, click OK .

17.6.5. Configure TDE

Transparent data encryption (TDE) encrypts and decrypts data files in real time. It encrypts data files when they are written to disks, and decrypts data files when they are loaded to the memory from disks. TDE does not increase the sizes of data files. When you use TDE, you do not need to modify your application that uses the ApsaraDB for MongoDB instance. To enhance data security, you can enable the TDE feature for an instance in the ApsaraDB for MongoDB console.

Prerequisites

The database version of the instance is 4.0.

 **Note** Before you enable TDE, you can create a MongoDB 4.0 instance to test the compatibility between your application and the database version. You can release the instance after the test is complete.

Impacts

- When you enable TDE, your instance is restarted, and your application is disconnected from the instance. We recommend that you enable TDE during off-peak hours and make sure that your application can reconnect to the instance after it is disconnected.
- TDE increases the CPU utilization of your instance.

Precautions

- You cannot disable TDE after it is enabled.
- You can enable TDE for an instance and disable encryption for a collection.

 **Note** In special business scenarios, you can choose not to encrypt a collection when you create it. For more information, see [Disable encryption for a specified collection](#).

- After you enable TDE, only new collections are encrypted. Existing collections are not encrypted.

- Key Management Service (KMS) generates and manages the keys used by TDE. ApsaraDB for MongoDB does not provide keys or certificates required for encryption.

Procedure

1. Log on to the [ApsaraDB for MongoDB console](#).
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **Data Security** > **TDE**.
5. Turn on **TDE Status** to enable TDE.

6. In the **Restart Instance** dialog box, click **OK**.
The instance status changes to **Modifying TDE**. After the status changes to **Running**, TDE is enabled.

Disable encryption for a specified collection

After you enable TDE, all new collections are encrypted. In special business scenarios, you can choose not to encrypt a collection when you create it. To create a collection with encryption disabled, follow these steps:

1. Connect to a replica set instance by using the mongo shell. For more information, see [Connect to a replica set instance by using the mongo shell](#).
2. Run the following command to create a collection with encryption disabled:

```
db.createCollection("<collection_name>",{ storageEngine: { wiredTiger: { configString: "encryption=(name=none)"
}}})
```

 **Note** <collection_name>: the name of the collection.

Example

```
db.createCollection("customer",{ storageEngine: { wiredTiger: { configString: "encryption=(name=none)" }}})
```

17.6.6. Use the mongo shell to connect to an ApsaraDB for MongoDB database in SSL encryption mode

This topic describes how to use the mongo shell to connect to an ApsaraDB for MongoDB database in Secure Sockets Layer (SSL) encryption mode. SSL encryption can encrypt network connections at the transport layer to improve data security and ensure data integrity.

Prerequisites

- The instance is a replica set instance, and the database version of the instance is 3.4 or 4.0.
- SSL encryption is enabled for the instance. For more information, see [Configure SSL encryption](#).
- Mongo shell 3.0 or later is installed on the local server or ECS instance from which you want to connect to the database. For more information about the installation procedure, visit [MongoDB official documentation](#).
- The IP address of the local server or the ECS instance is added to a whitelist of the ApsaraDB for MongoDB instance. For more information, see [Configure a whitelist for an ApsaraDB for MongoDB instance](#).

Precautions

After you enable SSL encryption for an instance, the CPU utilization of the instance is significantly increased. We recommend that you enable SSL encryption only when necessary.

Procedure

A local server with a Linux operating system is used in the following example:

1. Download an SSL CA certificate package. For more information, see [Configure SSL encryption](#).
2. Decompress the package and upload the certificate files to the local server or the ECS instance where the mongo shell is installed.

 **Note** In this example, the `.pem` file is uploaded to the `/root/sslcafile/` directory of the local server.

3. On the local server or in the ECS instance, run the following command to connect to a database of the ApsaraDB for MongoDB instance:

```
mongo --host <host> -u <username> -p --authenticationDatabase <database> --ssl --sslCAFile <sslCAFile_path> -
--sslAllowInvalidHostnames
```

Note

- `<host>`: the connection string, including the port number, of the primary or secondary node in the ApsaraDB for MongoDB instance. For more information, see [Overview of replica set instance connections](#). If you want to connect to a database of the ApsaraDB for MongoDB instance over an internal network, make sure that the ApsaraDB for MongoDB instance has the same network type as the ECS instance. If the network type is VPC, make sure that the two instances are in the same VPC.
- `<username>`: the username you use to log on to a database of the replica set instance. The initial username is root.
- `<database>`: the name of the authentication database. It is the database where the database user is created. If the username is root, enter admin.
- `<sslCAFile_path>`: the path of the SSL CA certificate files.

Example:

```
mongo --host dds-bpxxxxxxx-pub.mongodb.rds.aliyuncs.com:3717 -u root -p --authenticationDatabase admin --s
sl --sslCAFile /root/sslcafile/ApsaraDB-CA-Chain.pem --sslAllowInvalidHostnames
```

- When `Enter password:` is displayed, enter the password of the database user and press Enter.

 Note

- The password characters are not displayed when you enter the password.
- If you forget the password of the root user, you can reset it. For more information, see [Reset the password for an ApsaraDB for MongoDB instance](#).

17.7. CloudDBA

17.7.1. Authorize DAS to manage ApsaraDB for MongoDB instances

Database Autonomy Service (DAS) supports fast scaling, switchover, and centralized management of multiple environments. DAS is integrated into ApsaraDB for MongoDB to facilitate operations and maintenance (O&M). This topic describes how to authorize DAS to manage your ApsaraDB for MongoDB instances when you use the real-time performance, session, and capacity analysis features of CloudDBA for the first time.

Procedure

- [Log on to the ApsaraDB for MongoDB console](#).
- On the **Replica Set Instances** page, find the target instance.
- Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
- In the left-side navigation pane, choose **CloudDBA > Realtime performance**.
- Specify **Database Account and Password**, and click **Authorize**.

Result

The page is refreshed. Then, you can use the real-time performance, session, and capacity analysis features. You will not be prompted for authorization again.

17.7.2. Performance trends

This topic describes how to view performance trends in specific ranges, compare performance trends, and customize charts to view performance trends on your ApsaraDB for MongoDB instances.

Go to the Performance page

- [Log on to the ApsaraDB for MongoDB console](#).
- On the **Replica Set Instances** page, find the target instance.
- Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
- In the left-side navigation pane, choose **CloudDBA > Performance**.

 Note For more information about performance trends, see relevant topics in Database Autonomy Service (DAS) User Guide.

17.7.3. Real-time performance

This topic describes how to view real-time monitoring statistics of your ApsaraDB for MongoDB instances, such as read/write latency, queries per second (QPS), operations, connections, and network traffic.

Prerequisites

Database Autonomy Service (DAS) is authorized to manage ApsaraDB for MongoDB instances. For more information, see [Authorize DAS to manage ApsaraDB for MongoDB instances](#).

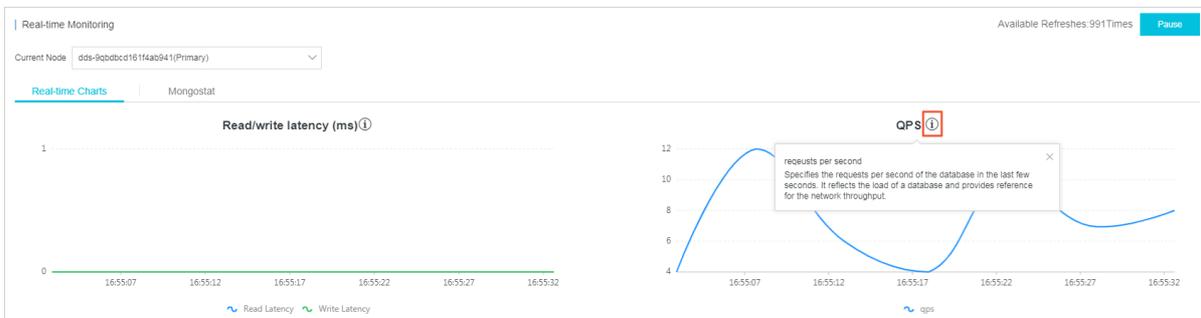

Procedure

1. [Log on to the ApsaraDB for MongoDB console](#).
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **CloudDBA** > **Realtime performance**.

Real-time Monitoring

On the Real-time Monitoring page, you can select the Real-time Charts or Mongostat tab to view monitoring statistics. When you refresh or go to the Real-time Monitoring page, the information on the Real-time Charts and Mongostat tabs is refreshed, and the number of available refreshes is reset in the upper-right corner.

Real-time Charts

The Real-time Charts tab is displayed on the Real-time Monitoring page. Line charts on the tab are refreshed every five seconds.

 **Note** For more information about individual metrics, click the  icon above each chart.

mongostat

time	query	insert	update	delete	getmore	cmd	dirty	used	qr/qw	ar/aw	vsize	mapped	in(Byte/s)	out(Byte/s)

16:55:32	0	0	0	0	4	36	0%	2%	0/0	0/0	1.6G	0	2.43 k	24.82 k
16:55:27	0	0	0	0	2	36	0.24%	2%	0/0	0/0	1.6G	0	1.48 k	11.96 k

Click the **Mongostat** tab. On the tab, you can view Mongostat command outputs. A new line of monitoring data is added every five seconds. The tab can contain up to 999 lines of information.

 **Note** For more information about Mongostat command outputs, visit [MongoDB official documentation](#).

17.7.4. Instance sessions

This topic describes how to view real-time monitoring statistics of your ApsaraDB for MongoDB instances, such as read/write latency, queries per second (QPS), operations, connections, and network traffic.

Prerequisites

Database Autonomy Service (DAS) is authorized to manage your ApsaraDB for MongoDB instances. For more information, see [Authorize DAS to manage ApsaraDB for MongoDB instances](#).

View instance sessions

1. [Log on to the ApsaraDB for MongoDB console](#).
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **CloudDBA > Session**.

-  **Note**
- If you turn on **Auto Refresh**, the system updates session data on the page every 30 seconds.
 - By default, the system displays only active sessions. You can turn on **Display All** to view both active and inactive sessions.
 - In the **Session Statistics** section, you can view information about sessions in the **Overview**, **Statistics by Client**, and **Statistics by Namespace** charts.

Terminate instance sessions

 **Warning** To avoid unexpected results, we recommend that you do not terminate system-level sessions.

1. In the **Instance Sessions** section, select the sessions you want to terminate and click **Kill Selected**.

Instance Sessions (Data Update Time:)

Refresh Auto Refresh Display All Enter a value Current Node dds-bp-... (Primary)

You can select multiple sessions by holding Shift. Inactive sessions cannot be killed. Kill Selected 2

Opld	A...	Operation	Operation Type	Time Spent (s) ↓↑	Execution Plan	Hostname	IP Address	Connection Description	Namespace
34631	●	{"getMore":5.894006457...	getmore	4	COLLSCAN	...	11.2...	conn68	local.oplog.rs

2. In the message that appears, click OK.

17.7.5. Capacity analysis

This topic describes how to view information about the capacity analysis feature, including storage, exceptions, storage trend, tablespaces, and data space. The information helps you detect and resolve exceptions in the database storage to ensure database stability.

Prerequisites

Database Autonomy Service (DAS) is authorized to manage ApsaraDB for MongoDB instances. For more information, see [Authorize DAS to manage ApsaraDB for MongoDB instances](#).

Procedure

1. Log on to the [ApsaraDB for MongoDB console](#).
2. On the **Replica Set Instances** page, find the target instance.
3. Click the instance ID or choose  > **Manage** in the **Operations** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **CloudDBA** > **Capacity analysis**.
5. In the upper-right corner, click **Re-analyze**. Then, wait until the analysis is complete.
6. On the **Storage Overview** or **Data Space** tab, view the analysis results.

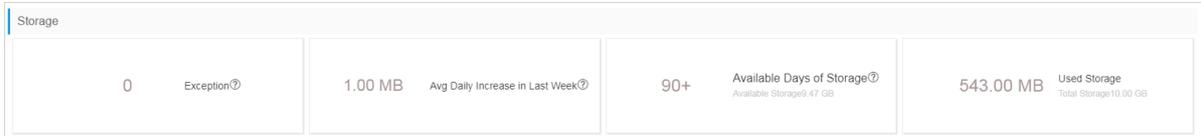

For more information about Storage Overview, see [Storage Overview](#).

For more information about Data Space, see [Data Space](#).

Storage Overview

On the Storage Overview tab, you can view information in the Storage, Exceptions, Storage Trend, and Tablespaces sections.

- Storage Overview

Item	Description
Exceptions	<p>The number of detected storage exceptions. ApsaraDB for MongoDB can detect the following types of exceptions:</p> <ul style="list-style-type: none"> Over 90% of the storage capacity is used. The total physical storage will be unavailable in seven days. The number of indexes in a collection exceeds 10.
Avg Daily Increase in Last Week	<p>The average daily increase of storage usage over the last seven days. Formula: (Storage usage at the time of collection - Storage usage seven days ago)/7.</p> <div style="background-color: #e6f2ff; padding: 5px;"> <p>Note</p> <ul style="list-style-type: none"> The increase speed is the average value during the seven days before the collection time. This parameter is only used as a reference for scenarios in which the traffic remains stable. Abrupt storage changes caused by batch imports, deletion of historical data, instance migration, or instance re-creation affect the accuracy of the data. </div>
Available Days of Storage	<p>The estimated number of days during which storage space is available. Formula: Size of available storage space/Average daily increase over the last week.</p> <div style="background-color: #e6f2ff; padding: 5px;"> <p>Note</p> <ul style="list-style-type: none"> 90+ indicates that the disk storage is sufficient for more than 90 days of usage. This parameter is used only as a reference for scenarios in which the traffic remains stable. Abrupt storage changes caused by batch imports, deletion of historical data, instance migration, or instance re-creation affect the accuracy of the data. </div>
Used Storage	The size of used storage space in contrast to the total size of storage space.

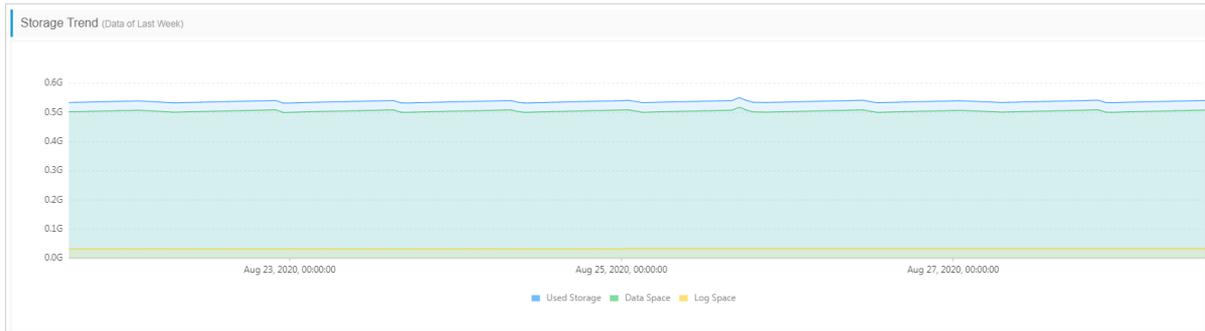

- Exceptions

Information about detected storage exceptions. You can resolve the exceptions based on information in this section.

Table/Collection Name (Click to View)	DB	Exception	Start Time
No storage exceptions found			

- Storage Trend

Changes of storage usage over the last week, such as changes of used storage, data space, and log space.

• **Tablespaces**

Information of all tables, such as the database name, storage engine, and collection storage.

Collection Name (Click to View) ↑	DB ↑	Storage Engine ↑	Collection Storage ↑	Collection Storage Percentage ↑	Index Storage ↑	Data Space ↑	Data Size ↑	Compression Percentage (↑) ↓	Collection Rows ↑	Avg Row Size ↑
No table information										

Note You can click a collection name to view its indexes.

Data Space

The Data Space tab shows the total storage capacity and tablespace information of each database.

Note

- You can click a data space to view its tablespace information.
- You can click a collection name to view its indexes.

Collection Name (Click to View) ↑	DB ↑	Storage Engine ↑	Collection Storage ↑	Collection Storage Percentage ↑	Index Storage ↑	Data Space ↑	Data Size ↑	Compression Percentage (↑) ↓	Collection Rows ↑	Avg Row Size ↑
No table information										

17.7.6. Slow query logs

This topic describes how to view slow query logs of ApsaraDB for MongoDB instances. You can locate, analyze, diagnose, and track slow query logs to create indexes, which improves the utilization of resources in the instances.

Procedure

- Log on to the ApsaraDB for MongoDB console.
- On the Replica Set Instances page, find the target instance.
- Click the instance ID or choose  > **Manage** in the Operations column. Then, the Basic Information page appears.
- In the left-side navigation pane, choose **CloudDBA > Slow query log**.

Note By default, slow query logs generated in the past 15 minutes are displayed in the trend chart. You can specify the time range and click Search to view slow query logs in specific periods of time. The maximum time range is one day.

5. View details of slow query logs by using one of the following methods: Method 1:
 - i. Click the **Slow Log Details** tab in the lower part of the page.
 - ii. On the **Slow Log Details** tab, select the database that you want to query.

Note If the request content of the target database is hidden, you can move the pointer over the corresponding request content and view the complete content.

Method 2:

- i. In the slow log trend chart, click the time of a specific slow query log and view its details on the **Slow Log Statistical** tab.

- ii. On the **Slow Log Statistical** tab, click **Sample** in the **Actions** column. In the **Slow Log Sample** dialog box, you can view details of the slow query log.

Slow Log Sample Note: Binary data in the sample is replaced with the \$binData string.

Execution Finish Time	Actions	Namespace	Request Content	User	Client	Avg Execution Duration (ms)	docsExamined	keysExamined	Avg Returned Rows
Aug 28, 2020, 14:04:25	ismaster	admin.\$cmd	["op":"command","ns":"admin.\$cmd","command":{"ismaster":1,"client":{"driver":...		11.200.150.7	295.00	-	-	-

Operation Type	Namespace	Request Template	Total Executions ↓↑	Avg Execution Duration (ms) ↓↑	Max Execution Duration (ms) ↓↑	Avg DocsExamined ↓↑	Max DocsExamined ↓↑	Avg KeysExamined ↓↑	Max KeysExamined ↓↑	Avg Returned Rows ↓↑	Max Returned Rows ↓↑	Actions
ismaster	admin.\$cmd	0	2	247.000	295	-	-	-	-	-	-	Sample Optimize
isMaster	admin.\$cmd	0	1	117.000	117	-	-	-	-	-	-	Sample Optimize

Note If the request content of the target database is hidden, you can move the pointer over the corresponding request content and view the complete content.

Export slow query logs

You can click **Export Slow Log** on the **Slow Log Statistical** tab to save the slow query log information to your computer.

18. ApsaraDB for OceanBase

18.1. What is ApsaraDB for OceanBase?

ApsaraDB for OceanBase is a financial-grade, distributed relational database service that features high performance, high availability, and high scalability. It supports active geo-redundancy and geo-disaster recovery to ensure high availability. It also supports high scalability to meet the increasing business requirements.

These features of ApsaraDB for OceanBase help you handle the challenges that are brought by rapid business growth. ApsaraDB for OceanBase also provides scalable and low latency database services in high throughput scenarios. This ensures improved user experience. For example, during the Double 11 in 2017, ApsaraDB for OceanBase handled all the transactions and payment requests. The maximum number of transactions that were made on Alipay reached 256,000 per second. The maximum number of processed requests per second reached 42 million. ApsaraDB for OceanBase accelerates the development of Internet finance.

The distributed engine of ApsaraDB for OceanBase uses the Paxos protocol and maintains multiple replicas. For the Paxos protocol, transactions can be committed only after they are approved by a majority of the acceptors. The Paxos protocol and multiple-replica design allow ApsaraDB for OceanBase to offer high availability and disaster recovery capabilities. ApsaraDB for OceanBase can help you achieve zero downtime. ApsaraDB for OceanBase supports high-availability architectures, such as active geo-redundancy and geo-disaster recovery. You can deploy the ApsaraDB for OceanBase service across data centers, regions, or continents. ApsaraDB for OceanBase provides financial-grade availability features and ensures strong consistency of transactions.

ApsaraDB for OceanBase is similar to an in-memory database and adopts a read/write splitting architecture. To ensure high efficiency for the storage engine, ApsaraDB for OceanBase stores baseline data in solid-state drives (SSDs) and stores incremental data in memory. This ensures that ApsaraDB for OceanBase offers high performance services. ApsaraDB for OceanBase is a cloud-based database service that supports multi-tenant data isolation. Each cluster of ApsaraDB for OceanBase can provide services for multiple tenants. The tenants are isolated so that they are not affected by each other.

ApsaraDB for OceanBase is compatible with most of the MySQL 5.6 features. This allows you to migrate MySQL-based services to ApsaraDB for OceanBase based on zero or small code modifications. This improves the efficiency of developing applications and migrating services. In ApsaraDB for OceanBase, you can create partitioned tables and use subpartitions. This serves as an alternative to MySQL sharding solutions. The ApsaraDB for OceanBase console provides an easy way for you to manage complex databases. For example, you can use the console to upgrade or downgrade instances, view performance data, and view optimization suggestions.

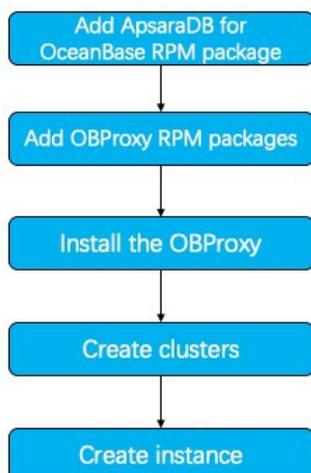

18.2. Quick start

18.2.1. Overview

This topic provides a quick start for ApsaraDB for OceanBase. This topic describes how to log on to the ApsaraDB for OceanBase console, add RPM packages of ApsaraDB for OceanBase and the OBProxy, install the OBProxy, create clusters, and create instances. After you perform these steps, you can use the created instances.

For more information about the steps, see [Quick start flowchart](#).

Quick start flowchart

The following section describes each step in the flowchart:

1. **Add ApsaraDB for OceanBase RPM packages**

You can use RPM packages or the source code to install ApsaraDB for OceanBase. In the ApsaraDB for OceanBase console, you can manage the RPM packages.

2. **Add OBProxy RPM packages**

In this step, add the RPM package of the OBProxy for ApsaraDB for OceanBase.

3. **Install the OBProxy**

The OBProxy is a reverse proxy server that is specific to ApsaraDB for OceanBase. ApsaraDB for OceanBase provides distributed relational database services. You can use the OBProxy to prevent transient connections and ensure that backend exceptions and operations such as breakdowns, upgrades, and network jitters are transparent to users. The OBProxy is also compatible with the MySQL protocol. The OBProxy supports strong checks, hot upgrades, and multiple clusters. In terms of frontend user requests, the OBProxy provides routing and forwarding services that feature high performance and high accuracy. In terms of backend server services, the OBProxy provides disaster recovery solutions that feature high availability and high scalability.

4. **Create clusters**

In this step, create an ApsaraDB for OceanBase cluster and configure the relevant parameters.

5. **Create instances**

In this step, create an ApsaraDB for OceanBase instance and configure the relevant parameters.

18.2.2. Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase

This topic describes how to use the Apsara Stack O&M system to log on to the Apsara Stack Operations console for ApsaraDB for OceanBase. The Google Chrome browser is used as an example in this topic.

Prerequisites

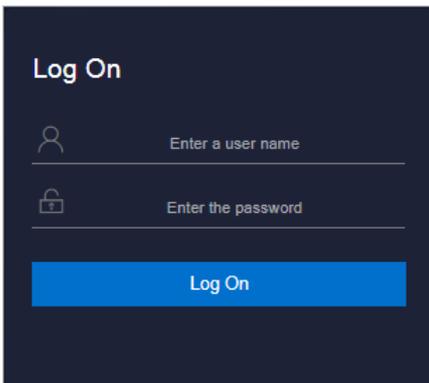

- The URL of the ASO console, and the username and password used for logging on to the console are obtained from the deployment personnel or an administrator.

The URL of the ASO console is in the following format: *region-id.aso.intranet-domain-id.com*.

- A browser is available. We recommend that you use Google Chrome.

Procedure

1. In the address bar, enter the URL *region-id.aso.intranet-domain-id.com* and press the Enter key.

Note You can select a language from the drop-down list in the upper-right corner of the page.

2. Enter your username and password.

Note Obtain the username and password for logging on to the ASO console from the deployment personnel or an administrator.

When you log on to the ASO console for the first time, you must change the password of your username as prompted.

To enhance security, a password must meet the following requirements:

- It must contain uppercase and lowercase letters.
 - It must contain digits.
 - It must contain special characters such as exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).
 - It must be 10 to 20 characters in length.
3. Click **Log On** to go to the ASO console.
 4. In the left-side navigation pane, click **Products**. Then, choose **Product List > Database Services** and click **OceanBase Cloud Platform**. You are directed to the Apsara Stack Operations console for ApsaraDB for OceanBase.

18.2.3. Log on to the ApsaraDB for OceanBase console

This topic describes how to use the Apsara Stack Cloud Management (ASCM) console to log on to the ApsaraDB for OceanBase console. The Google Chrome browser is used as an example in this topic.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use Google Chrome.

Context

If you use the ASCM console to log on to the ApsaraDB for OceanBase console, you can only view monitoring information and manage instances. If you need to perform operations and maintenance (O&M) tasks on clusters, you must log on to the Apsara Stack Operations console. For more information, see [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase](#).

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.

2. Enter your username and password.

Obtain the username and password used to log on to the console from the operations administrator.

 **Note** When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:

- Uppercase or lowercase letters.
- Digits.
- Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, click **Products** and choose **Database Services > ApsaraDB for OceanBase**.
5. Select an organization from the **Organization** drop-down list and select a region from the **Region** drop-down list. Then, click **OceanBase Cloud Platform** to navigate to the ApsaraDB for OceanBase console.

18.2.4. Add ApsaraDB for OceanBase RPM packages

In the Apsara Stack Operations console for ApsaraDB for OceanBase, you can add an RPM Package Manager (RPM) package of the current ApsaraDB for OceanBase version.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)
2. In the left-side navigation pane, click **O&M**. In the list that appears, select **RPM Package Management**.
3. On the RPM Package Management page, click the **Database** tab. On the tab, click **Upload RPM Package**.
4. In the Upload RPM Package dialog box, select observer from the File Type drop-down list and click **Upload**. Then, select the RPM package that you want to upload from the local directory.
5. Click **OK**.

18.2.5. Add OBProxy RPM packages

In the Apsara Stack Operations console for ApsaraDB for OceanBase, you can add an RPM package of the OBProxy that matches the current ApsaraDB for OceanBase version.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)
2. In the left-side navigation pane, click **O&M**. In the list that appears, select **RPM Package Management**.
3. On the RPM Package Management page, click the **Database** tab. On the tab, click **Upload RPM Package**.
4. In the dialog box that appears, select obproxy from the File Type drop-down list, and click **Upload**. Then, select the RPM package that you want to upload.
5. Click **OK**.

18.2.6. Install the OBProxy

After you add an OBProxy RPM package, you can install the OBProxy.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)
2. In the left-side navigation pane, click **O&M**. In the list that appears, select **OBProxy**.

3. On the **Servers** tab of the **OBProxy** page, find the IP address of the **OBProxy** server to be installed. In the **Actions** column for the IP address, click **Install**.
4. In the dialog box that appears, set **OBProxy Name** to the name of the **OBProxy** based on your project name. From the **OBProxy Version** drop-down list, select an **OBProxy** version, such as **obproxy-1.5.0-1410335.el7.x86_64.rpm**. You can select the current time for **Start Time**.
5. Click **OK**.

18.2.7. Create clusters

Before you use **ApsaraDB for OceanBase**, create clusters in the **Apsara Stack Operations** console for **ApsaraDB for OceanBase**.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)
2. In the left-side navigation pane, click **Clusters**.
3. On the page that appears, click **Create Cluster**. In the **Create Cluster** dialog box, configure the parameters as prompted. For more information about the parameters, see [Parameters for creating a cluster](#).

Parameters for creating a cluster

Parameter	Description
Cluster Name	The name of the ApsaraDB for OceanBase cluster.
OceanBase Version	The version of the ApsaraDB for OceanBase cluster. We recommend that you select the latest version.
Cluster Group	The group to which the cluster belongs. You can enter the name of the cluster group.
Cluster Model	The cluster model. If the minimal specifications are used for ApsaraDB for OceanBase , the cluster model is 1-1-1. You can set this parameter to 2-2-2 or 3-3-3 based on your cluster model. If five replicas are deployed, set this parameter to 2-2-2-2-2. To obtain the cluster model, contact the owner of the ApsaraDB for OceanBase project.
Data Center & Model Distribution	The data center and the machine model. Select the data center and the machine model based on the specified cluster model.

The screenshot shows the 'Create Cluster' interface. On the left is a navigation menu with 'Clusters' selected. The main area contains the following fields:

- Cluster Name:** A text input field with a placeholder 'Enter a cluster name'. Below it, a note states: 'The cluster name only supports English, numbers, and underscores, and cannot exceed 48 in length.'
- OceanBase Version:** A dropdown menu with the placeholder 'Select an OceanBase version'.
- Cluster Group:** A text input field with a placeholder 'Enter the name of the new cluster group'. Below it, a note states: 'The cluster group name only supports English, numbers, and underscores, and cannot exceed 48 in length.'
- Cluster Model:** A series of five input boxes for specifying server counts in each zone. To the right is a button labeled 'Data Center & Model Distribution'. Below this, a note states: 'The number of servers in each zone. After completing the cluster model configuration, add the information about the corresponding data center and model.'

At the bottom of the dialog are two buttons: 'Create' (in blue) and 'Cancel'.

4. After you specify the preceding parameters, click **Create**.

18.2.8. Create instances

After you create ApsaraDB for OceanBase clusters, you can create OceanBase instances in the ApsaraDB for OceanBase console.

Procedure

1. Log on to the [Apsara Stack Operations console for ApsaraDB for OceanBase](#).
2. In the left-side navigation pane, click **Instances**.
3. On the page that appears, click **Create Instance**. In the **Create Instance** dialog box, configure the parameters as prompted. [Parameters for creating an instance](#) describes the relevant parameters.

Parameters for creating an instance

Parameter	Description
OceanBase Version	The ApsaraDB for OceanBase version. Specify this parameter based on your business requirements.
Cluster Group	The cluster group where the instance is created.
Instance Name	The name of the instance. Specify this parameter based on your business requirements.
Zone	The zone where the instance is deployed. From the Zone drop-down list, select Default Zone.
Instance Specifications	The type of the instance. Specify this parameter based on your business requirements.
Tenant Whitelist	The tenant whitelist of the instance. Separate IP addresses or CIDR blocks with commas (,). The parameter value % indicates that all the tenants of the instance are added to the whitelist. We recommend that you use the default value %.
Tenants	The total number of tenants that are bound to the instance.

The screenshot shows the 'Create Instance' dialog box in the ApsaraDB for OceanBase console. The left sidebar contains navigation options: Dashboard, Clusters, Instances (selected), Alarm, Monitoring, O&M, Resources, and Systems. The main content area shows the 'Create Instance' form with the following fields:

- OceanBase Version:** A radio button group with options 1.0, 2.0, 2.1, and 2.2. 1.0 is selected.
- Cluster Group:** A dropdown menu with the text 'Select a cluster group'.
- Instance Name:** A text input field with the placeholder 'Enter an instance name'. Below it, a note states: 'The value must be 5 to 24 characters in length and can contain only digits, letters, and underscores (.).'
- Instance Specifications:** Two dropdown menus. The first is labeled 'Select an instance type' and the second is labeled 'Select a specification'.
- Zone:** A dropdown menu with the text 'Default Zone'.
- Tenant Whitelist:** A text input field with the placeholder '%'. Below it, a note states: 'The parameter value % indicates that all the tenants of the instance are added to the whitelist. We recommend that you use the default value %.'
- Tenants:** A text input field with the placeholder 'Enter the total number of tenants'.

At the bottom of the dialog box, there are two buttons: 'OK' and 'Cancel'.

4. Click **OK**.

18.3. Clusters

18.3.1. Overview

Before you use ApsaraDB for OceanBase, create ApsaraDB for OceanBase clusters in the ApsaraDB for OceanBase console. After you create clusters, you can view the basic information and the operation logs of the clusters. You can also restart, upgrade, scale out, and delete the clusters, and perform other operations on the clusters.

18.3.2. Scale out clusters online

In the ApsaraDB for OceanBase console, you can scale out ApsaraDB for OceanBase clusters based on your business requirements.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)
2. In the left-side navigation pane, click **Clusters**. The Clusters page appears.
3. In the Actions column for the cluster that you want to scale out, choose **More > Scale Out Cluster**.
4. In the Scale out Cluster dialog box, specify **New Servers**. In the **Model** column, select the model of the servers that you want to add. Then, select the current date and time from the **Start Time** date and time picker and click **OK**.

18.3.3. Restart clusters

You can restart clusters in the ApsaraDB for OceanBase console.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)
2. In the left-side navigation pane, click **Clusters**. The Clusters page appears.
3. In the Actions column for the cluster that you want to restart, choose **Routine Actions > Restart Cluster**.
4. In the Restart Cluster dialog box, select the zones of the cluster that you want to restart and click the **Start Time** field. In the date and time picker that appears, click **Now** and then click **OK**.

18.3.4. Delete clusters

You can delete clusters in the ApsaraDB for OceanBase console.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)
2. In the left-side navigation pane, click **Clusters**. The Clusters page appears.
3. In the Actions column for the cluster that you want to remove, choose **More > Delete Cluster**.
4. In the Delete Cluster dialog box, click the **Start Time** field. In the date and time picker that appears, click **Now** and then click **OK**.

18.3.5. Upgrade clusters

In the ApsaraDB for OceanBase console, you can perform online upgrades to upgrade ApsaraDB for OceanBase clusters to the specified versions.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)
2. In the left-side navigation pane, click **Clusters**. The Clusters page appears.
3. In the Actions column for the cluster that you want to upgrade, choose **Routine Operations > Cluster Upgrade**.

4. In the Cluster Upgrade dialog box, select all the rows. Each row corresponds to one zone of the cluster. From the Upgrade Version drop-down list, select the cluster version that you want to upgrade. Then, click the Start Time field. In the date and time picker that appears, click Now and then click OK.

18.3.6. View the monitoring information about clusters

In the ApsaraDB for OceanBase console, you can view the monitoring information about the major resources of each cluster, including CPU usage, memory usage, and disk usage.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)
2. In the left-side navigation pane, click **Monitoring** and then click **OceanBase Data Trends**.
3. On the **OceanBase Data Trends** page, view the performance information. By default, the page shows the performance information about all the clusters. To view the performance information based on different dimensions, specify **Cluster Group**, **Clusters**, **Time**, **Zone**, and **Server** parameters based on your business requirements. Then, click **Search**.

18.3.7. View the real-time monitoring information about clusters

In the ApsaraDB for OceanBase console, you can view the real-time monitoring information about clusters, including queries per second (QPS) and transactions per second (TPS).

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)
2. In the left-side navigation pane, click **Monitoring** and then click **Real-time Monitoring**. The Real-time Monitoring page appears.
3. On the **Real-time Monitoring** page, view the real-time monitoring information. By default, the page shows the performance information of all the clusters. To view the real-time performance information about a specific cluster group, click the name of the cluster group and then click **Search**. The **Real-time Performance Data** section appears. In this section, you can view the performance information about the cluster group.

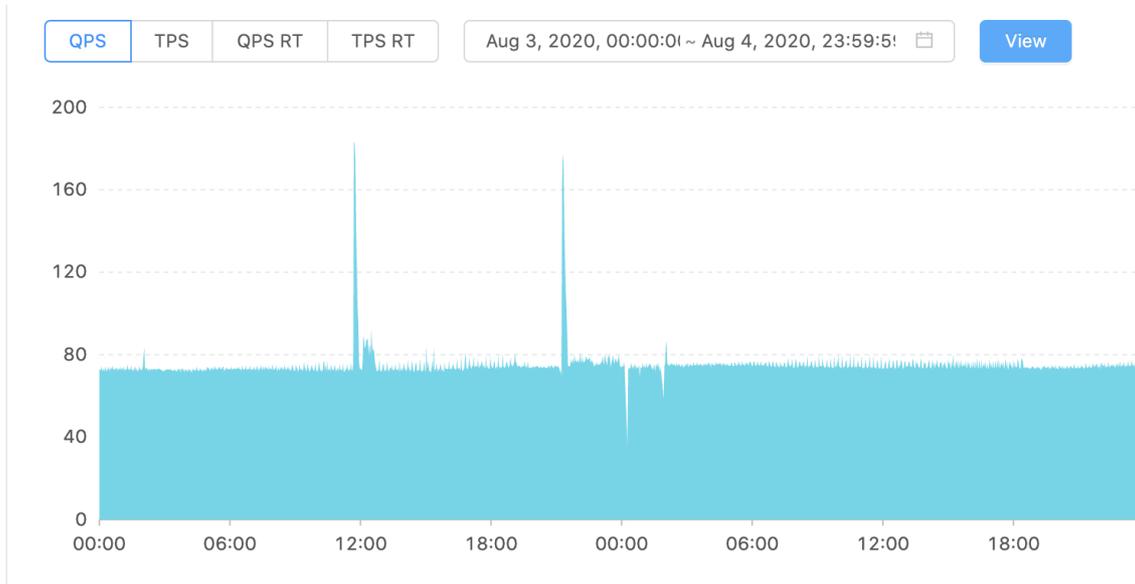

18.3.8. View performance metrics

You can view a wide range of performance metrics of clusters. For example, you can view the information about QPS, TPS, QPS response time (RT), TPS RT, top five clusters by major freeze time, O&M tasks, inspection data, and server usage.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#) After you log on to the ApsaraDB for OceanBase console, you can view the information about performance metrics on the **Dashboard** page. For example, you can view the information about QPS, TPS, QPS RT, TPS RT, top five clusters by major freeze time, O&M tasks, inspection data, and server usage. You can also view the performance trend of each metric by performing the following steps:
2. In the left-side navigation pane, click **Monitoring** and then click **OceanBase Data Trends**. The **OceanBase Data Trends** page appears.
3. On the **OceanBase Data Trends** page, click **QPS**, **TPS**, **QPS RT** or **TPS RT**. On the corresponding tab for the performance metric, specify the start time and end time for the search and click **View**.

Note In the lower part of the date and time picker for each performance metric, you can also select a time duration to specify the start time and the end time for the search. By default, the performance data in the last *X* period is displayed and the end time of the period is the current time. *X* represents the time duration that you select.

18.4. Instances

18.4.1. Overview

After you create instances, you can manage the instances. For example, you can view the basic information about the instances, reset the instance passwords, change the instance names, and start or stop the instances. You can also view the performance metrics, the change history, and the performance overview of each instance.

18.4.2. Change instance passwords

After you create instances, the default passwords for the instances are unknown. Therefore, you must log on to the console as an administrator and change the passwords.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)
2. In the left-side navigation pane, click **Instances**. The **Instances** page appears.
3. In the **Instance Name** column, click the name of the instance for which you want to change the password. The **Basic Information** tab appears.
4. In the lower-left corner of the tab, click **Reset Password**.
5. In the **Reset Password** dialog box, enter and confirm the new password and click **OK**.

18.4.3. View instance details

You can view the basic information about instances, such as connection strings, instance information, and maintenance windows.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)

2. In the left-side navigation pane, click **Instances**. The **Instances** page appears.
3. In the **Instance Name** column, click the name of the instance whose basic information you want to view. On the **Basic Information** tab, view the basic information about the instance.

18.4.4. Change instance specifications

You can change instance specifications based on your business requirements.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)
2. In the left-side navigation pane, click **Instances**. The **Instances** page appears.
3. In the **Instance Name** column, click the name of the instance whose specifications that you want to change. The **Basic Information** page appears.
4. In the lower-left corner of the page that appears, click **Modify Instance Specifications**.
5. In the **Modify Instance Specifications** dialog box, change the instance specifications.
6. Click **OK**.

18.4.5. Delete instances

To ensure efficient usage of resources, you can delete the instances that are no longer required.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)
2. In the left-side navigation pane, click **Instances**. The **Instances** page appears.
3. In the **Instance Name** column, click the name of the instance that you want to delete. The **Basic Information** tab appears.
4. In the lower-left corner of the page that appears, click **Delete**.
5. In the message that appears, click **OK**.

 **Note** The instance cannot be recovered after the instance is deleted. Proceed with caution.

18.4.6. View the performance metrics of instances

You can view the major performance metrics of running instances, such as QPS and TPS.

Procedure

1. [Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase.](#)
2. In the left-side navigation pane, click **Instances**. The **Instances** page appears.
3. In the **Instance Name** column, click the name of the instance whose performance metrics you want to view. The **Basic Information** tab appears.
4. Click the **Performance Metrics** tab. On the tab, view the performance information about the instance.

18.5. SQL syntax reference

18.5.1. Introduction to ApsaraDB for OceanBase SQL

ApsaraDB for OceanBase supports Structured Query Language (SQL). SQL is a computer language that you can use to organize, manage, and retrieve data in databases.

ApsaraDB for OceanBase is fully compatible with the MySQL protocol. Therefore, users of ApsaraDB for OceanBase SQL can connect to ApsaraDB for OceanBase by using MySQL clients, such as MySQL command-line, Java, and C clients.

18.5.2. Overview of ApsaraDB for OceanBase SQL

18.5.2.1. Identifiers

Use identifiers

In ApsaraDB for OceanBase, identifiers are the names of schema objects in SQL statements. The schema objects include tenants, databases, tables, views, indexes, table groups, columns, and aliases.

Before you use ApsaraDB for OceanBase identifiers, pay attention to the following considerations:

ApsaraDB for OceanBase identifiers describes the maximum length and the supported characters for each identifier.

ApsaraDB for OceanBase identifiers

Identifier	Maximum length (bytes)	Supported character
Username	16	A username can contain letters, digits, and underscores (_). It must start with a letter or an underscore (_). You cannot use ApsaraDB for OceanBase keywords when you specify the name.
Tenant name	64	A tenant name can contain letters, digits and underscores (_). It must start with a letter or an underscore (_). You cannot use ApsaraDB for OceanBase keywords when you specify the name.
Database name	64	A database name can contain letters, digits, underscores (_), and dollar signs (\$).
Table group name	64	A table group name can contain letters, digits and underscores (_). It must start with a letter or an underscore (_). You cannot use ApsaraDB for OceanBase keywords when you specify the name.
Table name	64	A table name can contain letters, digits, underscores (_), and dollar signs (\$).
Column name	64	A column name can contain letters, digits, underscores (_), and dollar signs (\$).
Index name	64	An index name can contain letters, digits, underscores (_), and dollar signs (\$).
Alias	255	An alias can contain letters, digits, underscores (_), and dollar signs (\$).

Identifier	Maximum length (bytes)	Supported character
Variable name	64	A variable name can contain alphanumericals, periods (.), underscores (_), and dollar signs (\$).

 Note

- In addition to the limits in the preceding table, you must meet some other identifier limits. For example, each identifier cannot contain the ASCII control character 0 or the eight-bit byte that represents 255.
- The names of databases, tables, or columns cannot end with spaces.
- We recommend that you do not use quotation marks in identifiers.

You can determine whether to use backticks (`) to enclose each identifier based on the actual scenarios. If identifiers are reserved keywords or contain special characters, you must use backticks (`) to enclose the identifiers. In ApsaraDB for OceanBase, you can use only backticks (`) to enclose identifiers.

```
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

Reference identifiers

ApsaraDB for OceanBase allows you to use a name that consists of one or more identifiers. If a name consists of multiple identifiers, separate the identifiers with periods (.).

[Referable columns and descriptions](#) lists the columns that you can reference in ApsaraDB for OceanBase.

Referable columns and descriptions

Column reference	Description
col_name	The col_name column in the table. The query retrieves data from the table.
tbl_name.col_name	The col_name column in the tbl_name table of the default database.
db_name.tbl_name.col_name	The col_name column in the tbl_name table of the db_name database.

If the identifiers that compose a name must be enclosed in backticks (`), enclose each identifier instead of the entire name. For example, `my-tables`.`my-column` is valid and `my-tables.my-column` is invalid.

If columns can be uniquely identified by column names, you do not need to specify the tbl_name prefix or the db_name.tbl_name prefix for the columns in statements. If columns cannot be uniquely identified by column names, you must specify one of the two prefixes. For example, the t1 table contains one c column and the t2 table also contains one c column. You want to execute a single SELECT statement to retrieve the c column in the t1 and t2 tables. In this scenario, the c column cannot be uniquely identified by the column name because this column exists in both t1 and t2 tables. You must specify prefixes for the two c columns to distinguish the c column in the t1 table from the c column in the t2 table: t1.c and t2.c. Similarly, you may need to execute a single statement to retrieve columns from the t table in the db1 database and the t table in the db2 database. In this scenario, you must use db1.t.col_name and db2.t.col_name to specify the databases that store the t tables.

In qualified names, each word that follows a period must be an identifier. Therefore, the word does not need to be enclosed in backticks (`). This rule applies even if the word is a reserved keyword.

The `.tbl_name` syntax specifies the `tbl_name` table in the current database. This syntax is compatible with the Open Database Connectivity (ODBC) API because table names are also prefixed with periods (`.`) in some ODBC programs.

Identifier case sensitivity

In ApsaraDB for OceanBase, identifiers are not case-sensitive. To ensure compatibility with MySQL, ApsaraDB for OceanBase introduces the `lower_case_tables_name` system parameter that is used in MySQL. This system parameter specifies whether table names and database names that function as identifiers are case-sensitive.

[Description of lower_case_tables_name values](#) describes the values of the `lower_case_tables_name` parameters.

Description of lower_case_tables_name values

Value	Description
0	Table names and database names are case-sensitive.
1	Table names and database names are not case-sensitive.

18.5.2.2. Supported SQL statements

ApsaraDB for OceanBase supports the following SQL statements:

- Data definition language (DDL) statements
CREATE DATABASE, ALTER DATABASE, DROP DATABASE, CREATE TABLE, ALTER TABLE, DROP TABLE, CREATE INDEX, DROP INDEX, CREATE VIEW, DROP VIEW, ALTER VIEW, TRUNCATE TABLE, and RENAME TABLE
- Data manipulation language (DML) statements
INSERT, REPLACE, DELETE, UPDATE, and SELECT statements and clauses
- Transaction statements
START TRANSACTION, COMMIT, and ROLLBACK
- Prepared statements
PREPARE, SET, EXECUTE, DEALLOCATE, DROP PREPARE, and DROP PREPARE
- Database administration statements
CREATE RESOURCE UNIT, DROP RESOURCE UNIT, CREATE RESOURCE POOL, ALTER RESOURCE POOL, DROP RESOURCE POOL, CREATE TENANT, ALTER TENANT, DROP TENANT, CREATE TABLEGROUP, DROP TABLEGROUP, ALTER TABLEGROUP, CREATE USER, DROP USER, RENAME USER, ALTER USER, GRANTS, REVOKE, SET, SET PASSWORD, SET GLOBAL, ALTER SYSTEM, GRANT, and REVOKE
- Useful SQL statements
SHOW, KILL, USE, DESCRIBE, EXPLAIN, HINT, HELP, and other SQL statements

18.5.2.3. SQL limits

This topic describes the following limits of SQL statements in ApsaraDB for OceanBase:

- ApsaraDB for OceanBase does not support custom data types or custom functions.
- ApsaraDB for OceanBase does not support updatable views, stored procedures, triggers, or cursors.
- ApsaraDB for OceanBase does not support temporary tables.
- ApsaraDB for OceanBase does not support compound statements, such as BEGIN...END, LOOP...END LOOP, REPEAT ...UNTIL...END REPEAT, and WHILE...DO...END WHILE.
- ApsaraDB for OceanBase does not support flow control statements, such as IF and WHILE.
- The INSERT or REPLACE statements that contain SELECT clauses cannot be executed to modify data. The DELETE statements cannot be executed to delete data from multiple tables. The UPDATE statements cannot

be executed to update data that is stored in multiple tables.

- The following list describes the quantity and maximum length limits:
 - When a table or an index is created, the maximum length of the primary key is 16 KB and the maximum length of a single row is 1.5 MB.
 - A single column of the VARCHAR data type can store a maximum of 262,143 bytes. The maximum length for the column of this type is 256 KB.
 - You can create a maximum of 64 primary keys.
 - You can store a maximum of 512 columns in a single table.
 - You can create a maximum of 128 indexes for a single table.
- The `SELECT... FOR UPDATE` statement supports only single-table queries.
- In ApsaraDB for OceanBase, you can execute the TRUNCATE TABLE statement on only a table that has one partition.

18.5.3. Partitions

18.5.3.1. Overview

ApsaraDB for OceanBase is a distributed database. If you need to distribute data in a table to multiple servers, you must create the table as a partitioned table. ApsaraDB for OceanBase automatically distributes data across ApsaraDB for OceanBase servers based on your partitions. You can also create non-partitioned tables. The data in each non-partitioned table is stored on only one ApsaraDB for OceanBase server.

The following list describes the characteristics of ApsaraDB for OceanBase partitioned tables:

- ApsaraDB for OceanBase supports `hash partitioning` , `key partitioning` and `range partitioning` .
- Tables are partitioned based on the partition key fields that you specify in the `CREATE TABLE` statements.
- The number of partitions in each partitioned table is specified in the `CREATE TABLE` statement.
- You can create non-partitioned tables. For example, you can create metadata tables that store only a few rows of service data as non-partitioned tables.
- In ApsaraDB for OceanBase, table data is distributed based on partitions. Therefore, to ensure high performance, the WHERE clauses in INSERT, REPLACE, SELECT, UPDATE, and DELETE statements must contain `PARTITION(partition_list)` . If this field is not contained, the system reports an error.
- In ApsaraDB for OceanBase, you can create a maximum of 8,192 partitions in a single partitioned table.

Introduction to partitions

In ApsaraDB for OceanBase, you can create partitions for each table based on the specified rules. The partitions can be distributed across ApsaraDB for OceanBase servers.

Partitioning functions specify the rules that you use to distribute data across partitions. Partitioning functions must be system functions.

Partitioning functions can be modulus functions, internal hash functions, or linear hash functions. To simplify the partitioning process, you can also use partitioning functions to match data against a range of continuous numeric values or a list of numeric values.

Partitioning functions are selected based on the partitioning types that you use. The partitioning functions use the values of the expressions that you provide as arguments. The expressions can represent the column values of the INT type. The expressions can also be the functions that are applied on one or more column values and return integers. The values of the expressions are passed to the partitioning functions. Then, the partitioning functions return sequence numbers that specify the partitions where the specific rows are stored. The specific rows are distinguished by the expression values.

You cannot use the partitioning functions to represent constants or random numbers.

The partitioning functions can use valid SQL expressions that return positive values. The positive values must be smaller than the maximum allowed positive integer that is specified by MAXVALUE.

Partitioning must be implemented on both data and indexes of each partitioned table. This means that you must create partitions for both data and indexes for each entire partitioned table. You cannot create partitions for only partial data of each partitioned table.

Partitioning benefits

- Partitioning offers an easy way for you to delete and add data. In most cases, you can delete the data that does not need to be stored by deleting the partitions that store the data. You can add data by creating partitions for the data.
- Partitioning allows you to optimize some queries. You can store the data that meets the conditions in the specified WHERE clauses in one or more partitions. In this scenario, when you run the corresponding queries, the system does not need to scan the other partitions. After you create partitioned tables, you can modify the partitions of the partitioned tables. Therefore, if this query optimization method is not used when you configure the partitioning scheme for the first time, you can modify the partitions to reorganize your data. This improves the efficiency of frequently run queries.
- Partitioning offers an easy method for you to process the queries that involve aggregate functions such as SUM() and COUNT() in parallel. The `SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;` statement is used as an example. In this example, the query can be performed on each table partition in parallel. The statement returns the final result by summarizing the result of each partition.
- Partitioning allows you to run data queries across disks to maximize the I/O throughput.

Partitioning types

The following list describes the supported partitioning types:

- Range partitioning

Rows are assigned to partitions based on a range of continuous column values that you specify for each partition.

- Hash partitioning

Data is assigned to partitions based on the results that are returned by user-defined expressions. The expressions use the column values in the rows that are to be inserted into the specified tables to calculate results.

Hash functions can contain valid expressions that return non-negative integers in ApsaraDB for OceanBase.

Partitions are automatically numbered when you create the partitions, regardless of partitioning types. The sequence numbers of partitions start from 0. When you insert a row into a partitioned table, the system uses the partition sequence number to identify the partition into which the row is inserted.

For example, if your partitioned table has four partitions, the sequence numbers of the four tables are 0, 1, 2, and 3. If you use range partitioning, make sure that you define a range for each partition. If you use hash partitioning, each user-defined function must return an integer that is greater than zero. Partition names are not case-sensitive.

- Key partitioning

Key partitioning is similar to hash partitioning. Hash partitioning uses user-defined expressions, and key partitioning uses hash functions that are provided by ApsaraDB for OceanBase servers. The column values on which key partitioning is implemented can be integers or values of other data types.

 **Note** Key partitioning in ApsaraDB for OceanBase uses MurmurHash functions.

18.5.3.2. Range partitioning

Syntax

```

...
PARTITION BY RANGE {(expr) | COLUMNS(column_list)}
  (partition_definition [, partition_definition] ...)
partition_definition:
  PARTITION partitionname
  VALUES {LESS THAN {(expr | value_list) | MAXVALUE}

```

For range partitioning, the specified ranges must be continuous and cannot overlap with each other. You must define the ranges by using the `VALUES LESS THAN` operator.

Examples

If you use range partitioning, each partition contains the rows in which the values fall in the specified range of continuous numeric values. The row values are returned by the expressions that you specify to implement range partitioning.

In the following examples, the `employees` table is used. The table stores employee records for 20 video stores that are numbered from 1 to 20.

The `employees` table is created by executing the following statement:

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);

```

You can use multiple methods to implement range partitioning on the `employees` table based on your business requirements.

In one of these methods, you can use the `store_id` column. For example, you can split the table into four partitions by adding a `PARTITION BY RANGE` clause to the statement.

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN (21)
);

```

In this partitioning scheme, p0 stores the rows for the employees of stores 1 to 5, p1 stores the rows for the employees of stores 6 to 10, and so on.

 **Notice** The sequence numbers of the stores are sorted in ascending order. Each partition is defined based on the specified range of store sequence numbers. This meets the requirements of the `PARTITION BY RANGE` syntax. The requirements are similar to the syntax requirements of C or Java `switch ... case` statements.

A new row that contains the data such as `72, 'Michael', 'Widenius', '1998-06-25', NULL, 13` can be inserted into the p2 partition as expected. However, if you need to insert rows for store 21, errors are reported. This is because no rules cover the rows whose `store_id` values are greater than 20 and ApsaraDB for OceanBase servers cannot determine the partitions that store the rows.

To prevent errors of this type, you can execute a `CREATE TABLE` statement that includes the `catchall VALUES LESS THAN` clause. You can use the clause to specify the partition in which you store the values that are greater than the explicitly specified maximum value.

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

MAXVALUE specifies the maximum allowed integer. All the rows whose store_id column values are greater than or equal 16 are stored in the p3 partition. In this example, the number 16 is the maximum value that is specified in an explicit way. When the number of stores increases to 25, 30, or another larger value, you can execute the ALTER TABLE statement to add partitions for the added stores. For example, you can add a partition for stores 21 to 25 and add another partition for stores 26 to 30.

The table in the following example has the same schema as that in the preceding example. You can partition the table based on the continuous ranges of job_code column values. The job_code column values specify the job codes of employees. In this example, two-digit job codes represent regular in-store workers, three-digit job codes represent office and support personnel, and four-digit codes represent management personnel. You can execute the following statement to create the partitioned table:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
  PARTITION p0 VALUES LESS THAN (100),
  PARTITION p1 VALUES LESS THAN (1000),
  PARTITION p2 VALUES LESS THAN (10000)
);
```

In this example, the rows for the in-store workers are stored in the p0 partition. The rows for the office and support personnel are stored in the p1 partition, and the rows for the management personnel are stored in the p2 partition.

You can also use an expression in the VALUES LESS THAN clause. Note that the returned values of the expression must be able to be used for LESS THAN (<) comparison to determine the ranges into which the returned values fall. Therefore, the returned values cannot be NULL. Due to the same reason, the values in the hired, separated, job_code, and store_id columns of the employees table are defined as non-NULL values.

In the first example, the employees table is partitioned based on the sequence numbers of stores. You can also partition the table by using an expression based on onboarding dates or offboarding dates. For example, you want to partition the table based on the YEAR (separated) values. The values specify the years when employees left the company. In this example, the following CREATE TABLE statement is executed to implement the partitioning scheme:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY RANGE (YEAR(separated)) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1996),
  PARTITION p2 VALUES LESS THAN (2001),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this partitioning scheme, the p0 partition stores the rows for the employees who left the company before 1991. The p1 partition stores the rows for the employees who left the company between 1991 and 1995. The p2 partition stores the rows for the employees who left the company between 1996 and 2000. The p3 partition stores the rows for the employees who left the company after 2000.

Scenarios

- You need to delete the previous data.
- You need to use a column that stores date or time values that are sorted in ascending order.
- You need to frequently run the queries that are based on partition key columns.

18.5.3.3. Hash partitioning

Syntax

If you use hash partitioning, you must specify column values or expressions for the columns on which hashing is to be implemented. You must also specify the number of partitions for each partitioned table. ApsaraDB for OceanBase automatically implements hash partitioning based on the specified settings.

```
...
PARTITION BY HASH (expr)
PARTITIONS num
```

If you use hash partitioning to partition a table, you must add the following clause to the `CREATE TABLE` statement: `PARTITION BY HASH (expr)`. In the clause, `expr` specifies an expression that returns integers. You can also specify `expr` as the name of a column. The column must store integers in ApsaraDB for OceanBase. You may need to append a `PARTITIONS num` clause to the `PARTITION BY HASH (expr)` clause. In the `PARTITIONS num` clause, `num` specifies the number of partitions for the table. You must specify this parameter as a positive integer.

Examples

You can partition the table based on the years when employees were hired by executing the following statement:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH(YEAR(hired))
PARTITIONS 4
```

Scenarios

Hash partitioning ensures that data in tables is evenly distributed across table partitions. The number of partitions for each table is specified when you create the table.

18.5.3.4. Key partitioning

Syntax

If you use key partitioning to partition tables, the tables are partitioned based on the hash functions that are provided by ApsaraDB for OceanBase. Key partitioning uses one column or a list of columns as the partition key.

```
...
PARTITION BY KEY(column_list)
PARTITIONS num
```

Examples

Execute the following statement to create the k1 table and partition the table based on the id field:

```
mysql> create table k2(id int primary key, name varchar(20))
-> partition by key() partitions 2;
Query OK, 0 rows affected (0.29 sec)
```

In this example, id is the primary key field. `partition by key()` and `partition by key(id)` are equivalent.

18.5.3.5. Subpartitioning

Syntax

Subpartitioning is also known as composite partitioning. Subpartitioning divides each partition of a partitioned table into subpartitions.

```

...
PARTITION BY RANGE(expr)
SUBPARTITION BY [HASH|KEY](expr) SUBPARTITIONS N
(PARTITION P0 VALUES LESS THAN (V0), ...)
PARTITION BY [HASH|KEY](expr)
SUBPARTITION BY RANGE(expr) SUBPARTITION TEMPLATE (SUBPARTITION P0
VALUES LESS THAN (V0), ...)
PARTITIONS N
...

```

Examples

```

CREATE TABLE ts (id INT, purchased DATE, PRIMARY KEY (id, purchased))
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased))
SUBPARTITIONS 2
(
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE
)

```

In this example, the `ts` table has three range partitions: `p0`, `p1`, and `p2`. Each partition is divided into two subpartitions. As a result, the entire table is divided into six partitions. The number of partitions is calculated based on the formula: $3 \times 2 = 6$. Based on the settings in the `PARTITION BY RANGE` clause, the first two partitions store only the rows whose values in the `purchased` column are smaller than 1990. The preceding statement is equivalent to the following statement:

```

CREATE TABLE ts (id INT, purchased DATE, PRIMARY KEY (id, purchased))
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased))
(
  PARTITION p0 VALUES LESS THAN (1990)
  (
    SUBPARTITION s0,
    SUBPARTITION s1
  ),
  PARTITION p1 VALUES LESS THAN (2000)
  (
    SUBPARTITION s2,
    SUBPARTITION s3
  ),
  PARTITION p2 VALUES LESS THAN MAXVALUE
  (
    SUBPARTITION s4,
    SUBPARTITION s5
  )
);

```

Notes

Pay attention to the following syntax considerations when you implement subpartitioning:

- Each partition must have the same number of subpartitions.
- The primary key must cover all the partition key columns.
- If subpartitions are created based on ranges, we recommend that you use subpartitioning templates to create subpartitions.

```

CREATE TABLE ts (id INT, purchased DATE, PRIMARY KEY (id, purchased))
PARTITION BY HASH(id)
SUBPARTITION BY RANGE(YEAR(purchased))
SUBPARTITION TEMPLATE
(
  SUBPARTITION p0 VALUES LESS THAN (1990),
  SUBPARTITION p1 VALUES LESS THAN (2000),
  SUBPARTITION p2 VALUES LESS THAN MAXVALUE
)
PARTITIONS 2

```

- If you need to use the `SUBPARTITION` clause to define subpartitions for a partition of a partitioned table in an explicit way, you must define all the subpartitions of the partitioned table. Otherwise, the following statement fails to be executed:

```
CREATE TABLE ts (id INT, purchased DATE, PRIMARY KEY (id, purchased))
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased))
(
  PARTITION p0 VALUES LESS THAN (1990)
  (
    SUBPARTITION s0,
    SUBPARTITION s1
  ),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE
  (
    SUBPARTITION s2,
    SUBPARTITION s3
  )
)
```

An execution failure occurs even if the statement includes the `SUBPARTITIONS 2` clause.

- Each `SUBPARTITION` clause must include at least the subpartition name. Otherwise, you may need to specify a desired option for the subpartition or allow the subpartition to use the default settings for the option.
- Subpartition names must be unique across each partition. Subpartition names do not need to be unique across the entire table.

For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE ts (id INT, purchased DATE, PRIMARY KEY (id,
purchased) )
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased))
(
  PARTITION p0 VALUES LESS THAN (1990)
  (
    SUBPARTITION s0,
    SUBPARTITION s1
  ),
  PARTITION p1 VALUES LESS THAN (2000)
  (
    SUBPARTITION s0,
    SUBPARTITION s1
  ),
  PARTITION p2 VALUES LESS THAN MAXVALUE
  (
    SUBPARTITION s0,
    SUBPARTITION s1
  )
);
```

18.5.3.6. Handle NULL values

Handle NULL as zero

If a column value or the value of a user-defined expression is NULL, NULL must be handled to implement partitioning. In most cases, NULL is handled as zero.

If you do not want to use this method of handling NULL, you can implement the NOT NULL constraint when you create tables. To implement the constraint, we recommend that you declare `NOT NULL` for the columns when you create the tables.

 **Note** The NULL value indicates that the calculation result of an expression is NULL. NULL is handled as zero.

Examples

Assume that you insert a row that contains NULL values into a table that is partitioned by range. In the row, NULL is the column value that determines the partition. In this scenario, the system handles NULL as zero and assigns the row to the partition whose value range contains zero.

The tnrage and tnhash tables are used in the examples in this topic. In the following example, the tnrage table is created and a row is inserted into the table:

```
mysql> CREATE TABLE tnrage (
  -> id INT,
  -> name VARCHAR(5)
  -> )
  -> PARTITION BY RANGE(id) (
  -> PARTITION p1 VALUES LESS THAN (1),
  -> PARTITION p2 VALUES LESS THAN MAXVALUE
  -> );
mysql> INSERT INTO tnrage VALUES (NULL, 'jim');
mysql> SELECT * FROM tnrage;
+-----+-----+
| id | name |
+-----+-----+
| NULL | jim |
+-----+-----+
1 row in set (0.00 sec)
```

In the tnrage table, the `NOT NULL` constraint is not declared for the id column. Therefore, the id column can contain NULL values. In the following example, the ALTER TABLE statement is executed to delete the partition that contains NULL values. The SELECT statement is executed to check whether the rows that contain NULL values are stored in the p1 partition of the table.

```
mysql> ALTER TABLE tnrage DROP PARTITION p1;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM tnrage;
Empty set (0.00 sec)
```

If you use hash partitioning, an expression that returns NULL is handled as an expression that returns zero. To verify this rule, you can create a table that is partitioned based on hashing and insert a row that contains NULL into the table. Then, you can check whether the row is inserted into the table as expected. For example, execute the following statement to create the tnhash table in the test database:

```
CREATE TABLE tnhash (
  id INT,
  name VARCHAR(5)
)
PARTITION BY HASH(id)
PARTITIONS 2;
```

Execute the INSERT INTO statement to insert a row into the tnhash table. The value in the id column for this row is NULL. Then, execute the SELECT statement to check whether the row is inserted as expected.

```
mysql> INSERT INTO tnhash VALUES (NULL, 'sam');
Query OK, 1 row affected (0.00 sec)
mysql> SELECT * FROM tnhash;
+-----+-----+
| id | name |
+-----+-----+
| NULL | sam |
+-----+-----+
1 row in set (0.01 sec)
```

For an integer that is represented by N, the value of `NULL MOD N` is always NULL. The system handles NULL as zero when the data is assigned to partitions. This example assumes that the Bourne Again Shell (Bash) is used to check whether the row that contains NULL is inserted to the partition as expected. Therefore, you can go back to the system shell to perform the check. In the Bash shell, execute the SELECT statement to query the data that is stored in the p0 partition of the tnhash table. This allows you to check whether the row is inserted into the first partition whose default name is p0.

```
mysql> SELECT * FROM tnhash partition(p0);
+-----+-----+
| id | name |
+-----+-----+
| NULL | sam |
+-----+-----+
1 row in set (0.00 sec)
```

18.5.4. Data types

18.5.4.1. Overview

ApsaraDB for OceanBase supports three categories of data types: numeric types, string types, and date and time types. [Supported data types](#) describes the data types that ApsaraDB for OceanBase supports.

Supported data types

Category	Data type
Numeric types	<ul style="list-style-type: none"> TINYINT BOOL BOOLEAN SMALLINT MEDIUMINT INT INTEGER BIGINT FLOAT DOUBLE DECIMAL <div style="border: 1px solid #add8e6; padding: 5px; margin: 10px 0;"> <p> Note The precision for this data type is inconsistent with that for the DECIMAL data type in MySQL.</p> </div> <ul style="list-style-type: none"> DEC NUMERIC BIT
String types	<ul style="list-style-type: none"> CHAR VARCHAR BINARY VARBINARY ENUM SET
Date and time types	<ul style="list-style-type: none"> DATE DATETIME TIMESTAMP TIME YEAR

18.5.4.2. Numeric types

The numeric types are divided into the following groups:

- Integers

[Integer data types](#) describes the integer data types.

Integer data types

Data type	Storage size (bytes)	Range (signed or unsigned)	Minimum value (signed or unsigned)	Maximum value (signed or unsigned)
TINYINT	1	2^7-1	-128	127
		2^8-1	0	255
		$2^{15}-1$	-32768	32767

SMALLINT Data type	Storage size (bytes)	Range (signed or unsigned)	Minimum value (signed or unsigned)	Maximum value (signed or unsigned)
		$2^{16}-1$	0	65535
MEDIUMINT	3	$2^{23}-1$	-8388608	8388607
		$2^{24}-1$	0	16777215
INT	4	$2^{31}-1$	-2147483648	2147483647
		$2^{32}-1$	0	4294967295
BIGINT	8	$2^{63}-1$	-9223372036854775808	9223372036854775807
		$2^{64}-1$	0	18446744073709551615

- Floating-point numbers or decimal numbers

Floating-point data types describes the floating-point data types.

Floating-point data types

Data type	Storage size (bytes)	Description
FLOAT	4	This data type stores single-precision floating-point numbers.
FLOAT(<i>p</i>)	If $0 \leq p \leq 24$, the storage size is 4 bytes. If $25 \leq p \leq 53$, the storage size is 8 bytes.	If the precision ranges from 0 to 24 digits, the column type is FLOAT and each value in the FLOAT column is a single-precision floating-point number that occupies 4 bytes. If the precision ranges from 25 to 53 digits, the column type is DOUBLE and each value in the DOUBLE column is a double-precision floating-point number that occupies 8 bytes.
DOUBLE [PRECISION]	8	This data type stores double-precision floating-point numbers.
DECIMAL (M,D) NUMERIC (M,D)	Variable length	This data type stores fixed-point numbers.

Other types

Data type	Storage size (bytes)	Description
BIT(M)	The occupied bytes are calculated based on the formula: Number of occupied bytes = $(M + 7)/8$. The default value of M is 1 and the valid value range for M is 1 to 64.	This data type stores binary values.

Note

- You can specify the display width for the values of TINYINT, SMALLINT, MEDIUMINT, INT, and BIGINT data types. The format is data type(M), such as INT(20). In the format, M represents the maximum display width. The maximum valid display width is 255 bytes.

The display width is irrelevant to the storage size or the value range of each data type.

- The UNSIGNED modifier indicates that only positive values can be stored in the specified field.
- The ZEROFILL modifier indicates that output values are padded with 0 instead of spaces. If you specify the ZEROFILL attribute for a numeric column, the system automatically adds the UNSIGNED attribute to the column.
- SERIAL is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

In the definition of integer columns, `SERIAL DEFAULT VALUE` is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

TINYINT

```
TINYINT[(M)] [UNSIGNED] [ZEROFILL]
```

The TINYINT data type stores small one-byte integers.

The range of signed numbers for the data type is -128 to 127. The range of unsigned numbers for the data type is 0 to 255.

BOOL or BOOLEAN

BOOL or BOOLEAN is a synonym of TINYINT(1).

Zero values are handled as false, and non-zero values are handled as true.

SMALLINT

```
SMALLINT[(M)] [UNSIGNED] [ZEROFILL]
```

The SMALLINT data type stores small two-byte integers.

The range of signed numbers for the data type is -32768 to 32767. The range of unsigned numbers for the data type is 0 to 65535.

MEDIUMINT

```
MEDIUMINT[(M)] [UNSIGNED] [ZEROFILL]
```

The MEDIUMINT data type stores medium-sized integers.

The range of signed numbers for the data type is -8388608 to 8388607. The range of unsigned numbers for the data type is 0 to 16777215.

INT

```
INT[(M)] [UNSIGNED] [ZEROFILL]
```

The INT data type stores normal-size integers.

The range of signed numbers for the data type is -2147483648 to 2147483647. The range of unsigned numbers for the data type is 0 to 4294967295.

Before you insert an invalid integer value into a table, the system automatically converts the value to zero.

INTEGER

```
INTEGER[(M)] [UNSIGNED] [ZEROFILL]
```

INTEGER is a synonym for INT.

BIGINT

```
BIGINT[(M)] [UNSIGNED] [ZEROFILL]
```

The BIGINT data type stores large integers.

The range of signed numbers for the data type is -9223372036854775808 to 9223372036854775807. The range of unsigned numbers for the data type is 0 to 18446744073709551615.

Signed BIGINT or DOUBLE values are used for all the arithmetic operations. Therefore, you cannot use the unsigned large integers that are larger than 9223372036854775807 (63 bits) in arithmetic operations except bit functions. If you use the unsigned large integers that are larger than 9223372036854775807, the last few digits in the result may be inaccurate. This is because rounding is implemented when you convert the values of the BIGINT data type into the values of the DOUBLE data type.

The system handles the values of the BIGINT data type in the following scenarios:

- A column of the BIGINT data type stores large unsigned integers.
- In MIN(col_name) or MAX(col_name), col_name specifies a BIGINT column.
- Operators such as plus signs (+), minus signs (-), and asterisks (*) are used and both operands are integers.
- Strings can be used to store exact integer values in columns of the BIGINT type. In this scenario, strings are converted into numbers and no intermediate double-precision numbers are generated during the conversion.
- If both operands of each plus sign (+), minus sign (-), or asterisk (*) operator are integers, the corresponding operator performs BIGINT operations. In this scenario, if you multiply two large integers that are returned by functions and the product is greater than 9223372036854775807, unexpected results are returned.

BIT

```
BIT[(M)]
```

The BIT data type stores binary values. *M* specifies the number of bits that can be stored. The valid value ranges from 1 to 64.

For example, if you specify *M* as 4, the binary values that can be stored range from 0000 to 1111. You can insert data to a column of the BIT data type by using `b'value'` or `0bvalue`, such as `b'1001'` or `0b1001`.

Note In the contexts of numeric values, the BIT data type stores `numeric values`. In the contexts of strings, the BIT data type stores `string values`. The `numeric values` are the numbers that represent the binary values. The `string values` are the strings that represent the binary values. When you assign values of a BIT column to variables, the assigned values are `numeric values`.

FLOAT

```
FLOAT[(M,D)] [UNSIGNED] [ZEROFILL]
```

The FLOAT data type stores small single-precision floating-point numbers.

The valid value range is -2^{128} to $+2^{128}$. The valid value range can also be expressed as $-3.402823466E+38$ to $-1.175494351E-38$, 0 , and $1.175494351E-38$ to $3.402823466E+38$. This valid range specifies the theoretical limits based on the IEEE standard. The actual range may be smaller than the valid range because different hardware devices or operating systems are used.

M is the total number of digits and D is the number of digits that follow the decimal point. If M and D are not specified, values are stored based on the hardware limits. Each single-precision floating-point number is accurate to about seven decimal places.

Negative values are disallowed if the **UNSIGNED** attribute is specified.

 **Note** If you use the values of the **FLOAT** data type for calculations, unexpected errors may occur. To prevent these errors, the values of the **FLOAT** data type are converted into the values of the **DOUBLE** data type before calculations are performed.

DOUBLE

```
DOUBLE[(M,D)] [UNSIGNED] [ZEROFILL]
```

The **DOUBLE** data type stores normal-sized and double-precision floating-point numbers.

The valid value range is -2^{1024} to $+2^{1024}$. The valid value range can also be expressed as $-1.7976931348623157E+308$ to $-2.2250738585072014E-308$, 0 , and $2.2250738585072014E-308$ to $1.7976931348623157E+308$. This valid range specifies the theoretical limits based on the IEEE standard. The actual range may be smaller than the valid range because different hardware devices or operating systems are used.

M is the total number of digits and D is the number of digits that follow the decimal point. If M and D are not specified, values are stored based on the hardware limits. Each double-precision floating-point number is accurate to about 15 decimal places.

Negative values are disallowed if the **UNSIGNED** attribute is specified.

DOUBLE PRECISION

```
DOUBLE PRECISION [(M,D)] [UNSIGNED] [ZEROFILL], REAL[(M,D)] [UNSIGNED] [ZEROFILL]
```

DOUBLE PRECISION is a synonym of **DOUBLE**.

FLOAT(p)

```
FLOAT(p) [UNSIGNED] [ZEROFILL]
```

The **FLOAT(p)** data type stores floating-point numbers. p specifies the precision of a numeric value. The precision is represented by the number of digits in the numeric value. The value of the p parameter is used to only determine whether the data type of an output column is **FLOAT** or **DOUBLE**.

If the value of p ranges from 0 to 24, the data type is **FLOAT** and M or D values do not need to be specified. If the value of p ranges from 25 to 53, the data type is **DOUBLE** and M or D values do not need to be specified. The value range of the output column is the same as the value range for the **FLOAT** or **DOUBLE** data type that is described in this topic. The **FLOAT** data type stores single-precision floating-point numbers. The **DOUBLE** data type stores double-precision floating-point numbers.

DECIMAL (different from the DECIMAL type in MySQL)

```
DECIMAL[(M[,D])] [UNSIGNED] [ZEROFILL]
```

The DECIMAL data type stores packed exact fixed-point numbers. *M* is the total number of digits and specifies the precision of a numeric value. *D* is the number of digits that follow the decimal point and specifies the scale of the numeric value. The number of decimal points and negative number signs (-) is excluded from the *M* value. If the value of *D* is 0, values does not have decimal points or fractional parts. For the DECIMAL data type in ApsaraDB for OceanBase, the maximum number of digits that is specified by *M* is 38. In MySQL, the maximum number of digits is 65. *D* specifies the number of digits that follow the decimal point. The maximum number of digits that follow the decimal point for decimal numeric values is 30. If *D* is not specified, the default value 0 is used. If *M* is not specified, the default value 10 is used.

Negative values are disallowed if the UNSIGNED attribute is specified.

For DECIMAL columns in ApsaraDB for OceanBase, basic operations are performed based on a precision of 38 digits. The basic operations are addition (+), subtraction (-), multiplication (*), and division (/). In MySQL, the basic operations are performed based on a precision of 65 digits.

`DEC[(M,D)] [UNSIGNED] [ZEROFILL]`, `NUMERIC[(M,D)] [UNSIGNED] [ZEROFILL]` are synonyms of DECIMAL.

NUMERIC

`NUMERIC[(M,D)] [UNSIGNED] [ZEROFILL]` is a synonym of DECIMAL.

18.5.4.3. String types

String types describes the string types that ApsaraDB for OceanBase supports.

String types

String type	Number of bytes	Description
CHAR	0-255	<p>The length of a CHAR column is the fixed length that you specify when you create your table. The value length ranges from 0 to 255 bytes.</p> <p>When CHAR values are stored, spaces are padded to the right of each value until the specified length is reached.</p> <p>When CHAR values are retrieved, the trailing spaces of the values are removed.</p> <p>When CHAR values are stored or retrieved, uppercase and lowercase conversion is not performed.</p>
VARCHAR	0-262143	<p>The maximum length of a VARCHAR value is determined by the maximum length for the row values of the VARCHAR data type and the character set that you use.</p> <p>In ApsaraDB for OceanBase, the maximum valid length is 256 KB. In MySQL, the maximum value length is 64 KB.</p>
BINARY	0-255	<p>This data type is similar to the CHAR data type. The difference is that the columns of the BINARY data type store binary strings instead of non-binary strings.</p>

String type	Number of bytes	Description
VARBINARY	0-262143	This data type is similar to the VARCHAR data type. The difference is that the columns of the VARBINARY data type store binary strings instead of non-binary strings.

CHAR

```
CHAR[(M)] [CHARACTER SET charsetname] [COLLATE collationname]
```

CHAR is short for CHARACTER.

The length of a CHAR column is the fixed length that you specify when you create your table. The value length ranges from 0 to 255 bytes. When CHAR values are stored, spaces are padded to the right of each value until the specified length is reached.

VARCHAR

```
VARCHAR(M) [CHARACTER SET charsetname] [COLLATE collationname]
```

This data type stores variable-length strings.

M specifies the maximum value length of a column. The valid value range of *M* is 0 to 256 KB. The actual length that is required to store each value of a VARCHAR field is determined by the length of the real-time field value and the specific character set. For example, you can specify the maximum valid length as 256 KB characters.

If the system uses the UTF8MB4 character set, each character occupies 4 bytes and the maximum valid length is calculated based on the formula: 256 KB × 4 = 1 MB.

VARCHAR is short for CHAR VARYING.

When VARCHAR values are stored, the values are not padded with characters.

If the length of a value that is assigned to a CHAR or VARCHAR column exceeds the maximum length for the column, the value is truncated to meet the length requirement. If spaces are truncated, a warning message is returned. If non-space characters are truncated, an error message instead of a warning message is reported. You can enable the strict SQL mode to prevent the corresponding values from being inserted into the CHAR or the VARCHAR column.

BINARY, VARBINARY

BINARY and VARBINARY data types are similar to CHAR and VARCHAR data types. The difference is that the columns of BINARY and VARBINARY types store binary strings instead of non-binary strings. This means that the columns of the BINARY and VARBINARY types store byte strings instead of character strings. The columns of BINARY and VARBINARY types do not use character sets. The values in these columns are compared and sorted based on the numeric values that are converted from the byte values in the columns.

The maximum value length for a column of the BINARY or VARBINARY data type is the same as that for a column of the CHAR or VARCHAR data type. The maximum value length for a column of the BINARY or VARBINARY type is measured in bytes instead of characters.

18.5.4.4. Date and time data types

[Date and time data types](#) describes the date and time data types that are supported by ApsaraDB for OceanBase SQL.

Date and time data types

Date and time data type	Format	Value range	Size (bytes)
DATE	YYYY-MM-DD	'1000-01-01' to '9999-12-31'	3
DATETIME	YYYY-MM-DD HH:MM:SS	'1000-01-01 00:00:00' to '9999-12-31 23:59:59'	8
TIMESTAMP	YYYY-MM-DD HH:MM:SS	'1970-01-01 00:00:00' to '2037-12-31 23:59:59'	8
TIME	HH:MM:SS	'-838:59:59' to '838:59:59'	3
YEAR	YYYY (default format)	'1901 to 2155' and '0000'	1
	YY	'70 to 69'. This value range represents years 1970 to 2069.	

By default, the precision for the values of DATETIME, TIMESTAMP, and TIME data types is seconds in date and time functions. You can set the fsp parameter to specify the precision for the fractional second part.

You can specify the precision based on your storage requirements. The fractional second part occupies 0 to 3 bytes based on the specified precision. The most fine-grained time granularity for the fractional second part is microseconds. If you use the microsecond precision, the fractional second part occupies 3 bytes.

The syntax is `type_name(fsp)`.

The `type_name` parameter specifies the data type, such as DATETIME, TIMESTAMP, and TIME.

The `fsp` parameter specifies the precision of the fractional second part. The values of this parameter range from 0 to 6. The default value is 0. The largest value is 6. The value 6 indicates that the precision of the fractional second part is microseconds.

DATE

The DATE data type stores values that consist of only the date part. The supported value range is `1000-01-01` to `9999-12-31`.

ApsaraDB for OceanBase uses the `YYYY-MM-DD` format for DATE values. ApsaraDB for OceanBase allows you to use strings or numbers to assign values to DATE columns.

DATETIME

`DATETIME[(fsp)]`

The DATETIME data type stores values that consist of a date part and a time part. The supported value range is `1000-01-01 00:00:00.000000` to `9999-12-31 23:59:59.000000`. ApsaraDB for OceanBase uses the `YYYY-MM-DD HH:MM:SS[.fraction]` format for DATETIME values. ApsaraDB for OceanBase allows you to use strings or numbers to assign values to DATETIME columns.

The `fsp` parameter specifies the precision of the fractional second part. The values of this parameter range from 0 to 6. The default value is 0. The largest value is 6. The value 6 indicates that the precision of the fractional second part is microseconds.

DATETIME and TIMESTAMP data types support `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses.

TIMESTAMP

`TIMESTAMP[(fsp)]`

The `TIMESTAMP` data type in ApsaraDB for OceanBase is inconsistent with that in MySQL. This is because the format of the `TIMESTAMP` data type in ApsaraDB for OceanBase complies with strict mode requirements.

Invalid values such as `0000-00-00 00:00:00` are disallowed in ApsaraDB for OceanBase.

The following string values are invalid:

```
'2012^12^32'
'20070523'
'070523'
'071332'
```

The following integer values are invalid:

```
19830905
830905
```

`DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses

If you use `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses, the `TIMESTAMP` or `DATETIME` column uses the current timestamp as the default value. The timestamp in the column is automatically updated to the current timestamp.

If you specify the value in the first `TIMESTAMP` column in a table as the `default value`, the `DEFAULT` clause cannot be ignored. You can specify the `current timestamp` or a constant date and time value as the default value.

- For the first `TIMESTAMP` column in a table, the `DEFAULT NULL` clause is the same as the `DEFAULT CURRENT_TIMESTAMP` clause. For the other `TIMESTAMP` columns in the table, the `DEFAULT NULL` clause is considered as `DEFAULT 0`.
- In the `CREATE TABLE` statement, you can use the following methods to declare the first `TIMESTAMP` column:
 - If you use `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses, the column uses the current timestamp as the default value. The timestamp in the column is automatically updated to the current timestamp.
 - If you use the `DEFAULT CURRENT_TIMESTAMP` clause and do not use the `ON UPDATE` clause, the column uses the current timestamp as the default value. In this scenario, the timestamp in the column is not automatically updated to the current timestamp.
 - If you do not use the `DEFAULT` clause and use the `ON UPDATE CURRENT_TIMESTAMP` clause, the default value of the column is 0. The timestamp in the column is automatically updated to the current timestamp.
 - If you specify a constant in the `DEFAULT` clause, the column uses the specified constant as the default value. If the `ON UPDATE CURRENT_TIMESTAMP` clause is specified for the column, the timestamp of the column is automatically updated to the current timestamp. Otherwise, automatic updates are not performed.

In other words, you can use the current timestamp as either, neither, or both of the default value and the auto-update value.

For example, you can use `ON UPDATE` to enable automatic updates of timestamps and avoid automatic initialization for the column.

- In `DEFAULT` and `ON UPDATE` clauses, you can use `CURRENT_TIMESTAMP`, `CURRENT_TIMESTAMP()`, or `NOW()`. These functions are equivalent.

The order of the `DEFAULT` and `ON UPDATE` clauses in the statement does not affect the returned results. If the `DEFAULT` clause and the `ON UPDATE` clause are specified for a `TIMESTAMP` column at the same time, either of the clauses can occur first.

In the following examples, the statements are equivalent:

```
CREATE TABLE t (ts TIMESTAMP);

CREATE TABLE t (ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP);

CREATE TABLE t (ts TIMESTAMP ON UPDATE CURRENT_TIMESTAMP DEFAULT CURRENT_TIMESTAMP);
```

- Assume that you need to specify a default value or enable automatic updates of timestamps for all the `TIMESTAMP` columns instead of only the first `TIMESTAMP` column. In this case, you must specify a constant in the `DEFAULT` clause for the first `TIMESTAMP` column to disable automatic initialization and updates. For example, you can specify `DEFAULT 0` or `DEFAULT '2003-01-01 00:00:00'`. The rules for the other `TIMESTAMP` columns are the same as those for the first `TIMESTAMP` column, except that `DEFAULT` and `ON UPDATE` clauses cannot be ignored for the other columns. If the `DEFAULT` and `ON` clauses are ignored, automatic initialization and updates cannot apply to the timestamps.

In the following examples, the statements are equivalent:

```
CREATE TABLE t (
  ts1 TIMESTAMP DEFAULT 0,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP);

CREATE TABLE t (
  ts1 TIMESTAMP DEFAULT 0,
  ts2 TIMESTAMP ON UPDATE CURRENT_TIMESTAMP DEFAULT CURRENT_TIMESTAMP);
```

NULL values in `TIMESTAMP` columns

You can specify the `NULL` attribute for `TIMESTAMP` columns so that the columns can store `NULL` values.

Examples

```

CREATE TABLE tstest
(
  ts1 TIMESTAMP NULL DEFAULT NULL,
  ts2 TIMESTAMP NULL DEFAULT 0,
  ts3 TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP
);
INSERT INTO tstest values(NULL, NULL, NULL);
SELECT * FROM tstest;
//Result
mysql> SELECT * FROM tstest;
+-----+-----+-----+
| ts1 | ts2 | ts3 |
+-----+-----+-----+
| NULL | NULL | NULL |
+-----+-----+-----+
1 row in set (0.00 sec)

```

TIME

TIME[(fsp)]

The TIME data type stores values that consist of only the time part. The supported value range is - 838:59:59.000000 to 838:59:59.000000. ApsaraDB for OceanBase uses the HH:MM:SS[.fraction] format for TIME values. ApsaraDB for OceanBase allows you to use strings or numbers to assign values to TIME columns.

The fsp parameter specifies the precision of the fractional second part. The values of this parameter range from 0 to 6. The default value is 0. The largest value is 6. The value 6 indicates that the precision of the fractional second part is microseconds.

D TIME values can be strings in the D HH:MM:SS[.fraction] format. You can use the following non-strict SQL syntax: H:MM:SS[.fraction], HH:MM:SS, HH:MM, D HH:MM:SS, D HH:MM, D HH, or SS. D represents days. The valid values range from 0 to 34.

TIME values can be strings in the HHMMSS format. In the format, no delimiters are used. The system assumes that the strings specify valid time. For example, '101112' is valid and represents '10:11:12'. However, '109712' is invalid because the minute part 97 is invalid. The system changes the invalid string to '00:00:00'.

TIME values can be numeric values in the HHMMSS format. The system assumes that the numeric values specify valid time. For example, 101112 represents '10:11:12'. The system also supports numeric values in the following formats: SS, MMSS, HHMMSS, and HHMMSS.fraction.

TIME values can be the results that are returned by functions, such as CURRENT_TIME. The results must comply with the TIME value requirements.

Assume that a TIME value is a string where the hour, minute, and second parts are separated with colons (:). If the value for one of the parts is smaller than 10, you do not need to specify a two-digit value for the part. For example, '8:3:2' and '08:03:02' are equivalent.

When you assign an abbreviated value to a TIME column, you must pay attention to the impacts of colons (:). If a TIME value does not contain colons (:), the system identifies the two rightmost digits in the TIME value as the second part. In this case, the system does not interpret the TIME value as the time on the current day. For example, you may interpret '1112' and 1112 as 11:12:00 : 12 minutes past 11. However, the system interprets '1112' and 1112 as 00:11:12 : 11 minutes and 12 seconds. Similarly, the system interprets '12' and 12 as 00:00:12 . If a TIME value contains colons (:), the system interprets the TIME value as the time on the current day. For example, the system interprets '11:12' as '11:12:00' instead of '00:11:12' .

If valid values fall out of the TIME value range, the values are converted into the closest boundaries of the value range. For example, '-850:00:00' is converted into '-838:59:59' and '850:00:00' is converted into '838:59:59' .

Invalid TIME values are converted into '00:00:00' . Note that '00:00:00' is a valid TIME value. Based on only the stored values in the table, you cannot distinguish the original '00:00:00' values from the '00:00:00' values that are converted from invalid values.

YEAR

The YEAR data type stores two-digit or four-digit values that represent years. By default, YEAR values use the four-digit format. In the four-digit format, valid YEAR values consist of 0000 and values that range from 1901 to 2155. In the two-digit format, valid YEAR values range from 70 to 69. The values represent years 1970 to 2069. YEAR values are displayed in the YYYY format. You can use strings or numbers to assign values to YEAR columns.

You can specify YEAR values in the following formats:

- Four-digit strings: The value range is '1901' to '2155' .
- Four-digit numbers: The value range is 1901 to 2155.
- Two-digit strings: The value range is '00' to '99' . The values in the range of '00' to '69' are converted into years 2000 to 2069. The values in the range of '70' to '99' are converted into years 1970 to 1999.
- Two-digit integers: The value range is 1 to 99. The values in the range of 1 to 69 are converted into years 2001 to 2069. The values in the range of 70 to 99 are converted into years 1970 to 1999. The difference between the range of two-digit integers and that of two-digit strings is that the range of two-digit integers does not include 0. This is because 0 cannot be specified as a number or interpreted as 2000. To use 0 to represent the year 2000, you must specify 0 as the string '0' or '00' or enable the system to interpret 0 as 0000.
- Results that are returned by functions such as NOW(): The returned results must comply with the YEAR value requirements.

Invalid YEAR values are converted into 0000.

For DATETIME, DATE, TIMESTAMP, and YEAR data types, ApsaraDB for OceanBase use the following rules to interpret the dates that have ambiguous YEAR values:

- YEAR values in the range of 00 to 69 are converted into years 2000 to 2069.
- YEAR values in the range of 70 to 99 are converted into years 1970 to 1999.

You can use the ORDER BY clause to sort the two-digit YEAR values or the TIMESTAMP values that contain two-digit YEAR values.

You can use some functions such as MIN() and MAX() to convert TIMESTAMP values or YEAR values into numbers. Two-digit YEAR values are not applicable to these functions. In this case, you can convert the year parts of the TIMESTAMP values or the YEAR values into four-digit values. You can also use MIN(DATE_ADD(TIMESTAMP, INTERVAL 0 DAYS)) .

18.5.5. Character sets

A character set is a set of symbols and encodings. A collation is a set of rules that are used to compare characters in a character set.

Supported character sets

ApsaraDB for OceanBase supports the UTF8MB4 character set. UTF8MB4 is a superset of UTF8 and uses a maximum of four bytes for each character.

Compared with UTF8, UTF8MB4 supports new characters in the iOS operating system, such as emojis. Characters that are supported by UTF8 are known as Basic Multilingual Plane (BMP) characters. The new characters that are supported by UTF8MB4 are known as supplementary characters.

You can specify character sets at different levels: tenant, database, table, field, and session. ApsaraDB for OceanBase supports only the UTF8MB4 character set. By default, the UTF8MB4 character set is used. In most cases, you do not need to specify the character set.

 **Note** In ApsaraDB for OceanBase, the UTF8MB4 character set allows you to use UTF8. UTF8 is an alias for UTF8MB3.

Collation

In ApsaraDB for OceanBase, the supported collations for the UTF8MB4 character set are utf8mb4_bin and utf8mb4_general_ci. The default collation is utf8mb4_general_ci.

One of the main differences of the two collations is that they have different impacts on sorting orders and string comparisons. The utf8mb4_bin collation is case-sensitive and the utf8mb4_general_ci collation is not case-sensitive.

18.5.6. Auto-increment fields

18.5.6.1. Overview

This topic describes the AUTO_INCREMENT attribute of ApsaraDB for OceanBase.

ApsaraDB for OceanBase allows you to specify the AUTO_INCREMENT attribute for an integer field in a table. In this aspect, ApsaraDB for OceanBase is the same as MySQL. ApsaraDB for OceanBase can automatically generate unique values for auto-increment fields.

The following list describes the notes on the AUTO_INCREMENT attribute in ApsaraDB for OceanBase:

- You can specify the AUTO_INCREMENT attribute for fields of various integer data types, such as TINYINT, SMALLINT, MEDIUMINT, INT, INTEGER, BIGINT, FLOAT, and DOUBLE. You cannot specify the AUTO_INCREMENT attribute for fields of the other data types.

 **Note** In MySQL, you can specify the AUTO_INCREMENT attribute for fields of FLOAT, DOUBLE, and BOOLEAN data types. You cannot specify this attribute for fields of DECIMAL and BIT data types.

- You can specify the AUTO_INCREMENT attribute for only one field in a table.

```
mysql> create table t1 (id int auto_increment);
ERROR 1075 (42000): Incorrect table definition; there can be only one auto column and it must be defined as a key
#In MySQL, auto-increment fields must have indexes that can be primary key indexes or general indexes. Otherwise, the preceding error occurs. Indexes are not required for auto-increment fields in ApsaraDB for OceanBase. This is the difference between ApsaraDB for OceanBase and MySQL.
```

```
mysql> create table t1 (id int auto_increment,name VARCHAR(20) primary key,key(id));
Query OK, 0 rows affected (0.01 sec)
#The AUTO_INCREMENT attribute is specified for the id field. The id field is a general field that has an index. Indexes are not required for auto-increment fields in ApsaraDB for OceanBase. This is the difference between ApsaraDB for OceanBase and MySQL.
```

- In other cases, the following rules take effect:
 - i. If you insert a NULL value into an `AUTO_INCREMENT` column, MySQL automatically generates the next sequence number for the column.
 - ii. When you insert a row and do not explicitly specify a value for the `AUTO_INCREMENT` column, the system considers the value of the column as NULL. MySQL automatically generates the next sequence number for the column.
 - iii. In all the modes except `NO_AUTO_VALUE_ON_ZERO`, if you insert 0 into an `AUTO_INCREMENT` column, the system considers the value of the column as NULL. MySQL automatically generates the next sequence number for this column.

```
mysql> insert into t1 (id,name) values (null,'test');
Query OK, 1 row affected (0.00 sec)
mysql> select * from t1;
+----+-----+
| id | name |
+----+-----+
| 1 | test |
+----+-----+
1 row in set (0.00 sec)
```

The preceding statements are equivalent to the following statements:

```
mysql> insert into t1 (name) values ('test');

## Create a table.
mysql> CREATE TABLE t1 (id int AUTO_INCREMENT,PRIMARY KEY (id));

## Insert data into the table.
mysql> insert into t1 values (null),(null),(null);
Query OK, 3 rows affected (0.00 sec)

## Insert the value 7 into the table.
mysql> insert into t1 values (7);
Query OK, 1 row affected (0.00 sec)

## The value of the auto-increment column changes to 8.
mysql> show create table t1\G;
***** 1. row *****
      Table: t1
Create Table: CREATE TABLE `t1` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB AUTO_INCREMENT=8 DEFAULT CHARSET=utf8
```

18.5.6.2. System variables for auto-increment columns

```
mysql> show variables like '%auto_increment%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 1 |
| auto_increment_offset | 1 |
+-----+-----+
```

You can specify global or session values for the preceding two system variables. The `auto_increment_increment` variable specifies the interval between two successive values in an auto-increment column. The `auto_increment_offset` variable specifies the start value of an auto-increment column.

The default value of the `auto_increment_increment` variable is 1. The values of this variable range from 1 to 65535.

The default value of the `auto_increment_offset` variable is 1. The values of this variable range from 1 to 65535.

Examples

- Example 1

```
auto_increment_increment=2
auto_increment_offset=1

mysql>create table t1(id int auto_increment primary key);
Query OK, 0 rows affected (0.00 sec)

mysql> set session auto_increment_increment=2;
Query OK, 0 rows affected (0.00 sec)

mysql> set session auto_increment_offset=1;
Query OK, 0 rows affected (0.00 sec)

mysql> show session variables like '%auto_incre%';
+-----+-----+
| Variable_name      | Value |
+-----+-----+
| auto_increment_increment | 2   |
| auto_increment_offset  | 1   |
+-----+-----+
2 rows in set (0.00 sec)

mysql> insert into t1 values (null),(null),(null),(null),(null),(null);
Query OK, 6 rows affected (0.00 sec)
Records: 6 Duplicates: 0 Warnings: 0

mysql> select * from t1;
+----+
| id |
+----+
| 1  |
| 3  |
| 5  |
| 7  |
| 9  |
| 11 |
+----+
6 rows in set (0.00 sec)
```

- Example 2

```
auto_increment_increment=2
auto_increment_offset=2

mysql> truncate t1;
Query OK, 0 rows affected (0.00 sec)

mysql>
mysql> set session auto_increment_increment=2;
Query OK, 0 rows affected (0.00 sec)

mysql> set session auto_increment_offset=2;
Query OK, 0 rows affected (0.00 sec)

mysql> show session variables like '%auto_incre%';
+-----+-----+
| Variable_name      | Value |
+-----+-----+
| auto_increment_increment | 2   |
| auto_increment_offset  | 2   |
+-----+-----+
2 rows in set (0.00 sec)

mysql> insert into t1 values (null),(null),(null),(null),(null),(null);
Query OK, 6 rows affected (0.00 sec)
Records: 6 Duplicates: 0 Warnings: 0

mysql> select * from t1;
+----+
| id |
+----+
| 2 |
| 4 |
| 6 |
| 8 |
| 10 |
| 12 |
+----+
6 rows in set (0.00 sec)
```

- Example 3

```

auto_increment_increment=10
auto_increment_offset=5

mysql> truncate t1;
Query OK, 0 rows affected (0.00 sec)

mysql> set session auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> set session auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> show session variables like '%auto_incre%';
+-----+-----+
| Variable_name      | Value |
+-----+-----+
| auto_increment_increment | 10   |
| auto_increment_offset  | 5    |
+-----+-----+
2 rows in set (0.00 sec)

mysql> insert into t1 values (null),(null),(null),(null),(null),(null);
Query OK, 6 rows affected (0.00 sec)
Records: 6 Duplicates: 0 Warnings: 0

mysql> select * from t1;
+-----+
| id |
+-----+
| 5 |
| 15 |
| 25 |
| 35 |
| 45 |
| 55 |
+-----+
6 rows in set (0.00 sec)

```

18.5.6.3. Change start values of auto-increment columns

You can specify the start value of an auto-increment column when you execute `CREATE TABLE` to create a table. You can also execute `ALTER TABLE table_name AUTO_INCREMENT=n` to change the start value of an `AUTO_INCREMENT` column. The specified value `n` may be smaller than the current value of the `AUTO_INCREMENT` column. If this occurs, the system does not report an error for the executed statement, but the value `n` does not take effect.

Examples

Examples

```
mysql>select LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|          5 |
+-----+
1 row in set (0.00 sec)
```

18.5.6.5. Limits

The following list describes the limits of auto-increment fields:

- The values of auto-increment fields must be unique. The values of auto-increment fields may not be continuous. For example, if you execute the `INSERT ...SELECT...` statement to insert data in batches, the values that are generated for an auto-increment field may not be continuous.
- You can execute a single `INSERT` statement on only one partition. If you execute a single `INSERT` statement across partitions, the system reports an error.

18.5.7. Functions

18.5.7.1. Overview

ApsaraDB for OceanBase supports date and time functions, string functions, type conversion functions, aggregate functions, flow control functions, mathematical functions, comparison functions, information functions, and other functions.

Expressions can be used in SQL statements and clauses, such as `ORDER BY` and `HAVING` clauses in `SELECT` statements, `WHERE` clauses in `SELECT`, `DELETE`, and `UPDATE` statements, and `SET` statements. You can define expressions by using literal values, column values, `NULL` values, functions, and operators.

In most cases, an expression that contains a `NULL` value returns a `NULL` value.

Supported functions describes the functions that ApsaraDB for OceanBase supports.

Supported functions

Function type	Function description	Function name
---------------	----------------------	---------------

Function type	Function description	Function name
Date and time functions	Return date and time information.	<ul style="list-style-type: none"> • CURRENT_TIME • CURTIME • CURRENT_TIMESTAMP • CURRENT_DATE • CURDATE • DATE_ADD • DATE_FORMAT • DATE_SUB • EXTRACT • NOW • STR_TO_DATE • TIME_TO_USEC • USEC_TO_TIME • UNIX_TIMESTAMP • DATEDIFF • TIMEDIFF • TIMESTAMPDIFF • PERIOD_DIFF • TO_DAYS • FROM_DAYS
String functions	Manipulate n-base numbers, strings, and expressions. For example, you can use a function of this type to retrieve the start position of a string or the number of returned strings.	<ul style="list-style-type: none"> • CONCAT • SUBSTRING • SUBSTR • TRIM • LENGTH • UPPER • LOWER • HEX • UNHEX • INT2IP • IP2INT • LIKE • REGEXP • REPEAT • SUBSTRING_INDEX • LOCATE • INSTR • REPLACE • FIELD • ELT
Type conversion functions	Convert values from a data type to another data type.	CAST

Function type	Function description	Function name
Aggregate functions	Perform calculations on a set of values and return a single value. In most cases, aggregate functions are used in conjunction with <code>GROUP BY</code> clauses of <code>SELECT</code> statements. If an aggregate function is used in conjunction with a <code>GROUP BY</code> clause, the aggregate functions return a single value for each group instead of the entire table.	<ul style="list-style-type: none"> • AVG • COUNT • MAX • MIN • SUM • GROUP_CONCAT
Mathematical functions	Perform mathematical calculations based on numeric expressions.	<ul style="list-style-type: none"> • ROUND • CEIL • FLOOR • ABS • NEG • SIGN • CONV • MOD • POW • POWER
Comparison functions	Compare input values.	<ul style="list-style-type: none"> • GREATEST • LEAST • ISNULL
Flow control functions	Control flows.	<ul style="list-style-type: none"> • CASE • IF • IFNULL • NULLIF
Information functions	Retrieve dynamic database information.	<ul style="list-style-type: none"> • FOUND_ROWS • LAST_INSERT_ID
Other functions	The other functions.	<ul style="list-style-type: none"> • COALESCE • NVL • DECODE

18.5.7.2. Date and time functions

The functions of this type return date and time information.

CURRENT_TIME() and **CURRENT_TIMESTAMP()**

 **Notice** You can pass a number that ranges from 0 to 6 into a `CURRENT_TIME()` or a `CURRENT_TIMESTAMP()` function. The number specifies the precision of the fractional second part.

The following list describes the notes on `CURRENT_TIME()` and `CURRENT_TIMESTAMP()` functions:

- `CURRENT_TIME()` and `CURRENT_TIMESTAMP()` functions return the current time of the system. The two functions return the time in different formats.

- `CURRENT_TIME()` returns the current time in the `HH:MI:SS` format. The returned value excludes the date part.
- `CURRENT_TIMESTAMP()` returns the current date and time in the `YYYY-MM-DD HH:MI:SS` format.

Examples

```
root@test 04:09:10>SELECT CURRENT_TIME(), CURRENT_TIMESTAMP();
+-----+-----+
| CURRENT_TIME() | CURRENT_TIMESTAMP() |
+-----+-----+
| 16:24:09      | 2014-10-31 16:24:09 |
+-----+-----+
1 row in set (0.00 sec)
root@(none) 09:59:30>select CURRENT_TIME(1);
#You can specify the precision of the fractional second part.
+-----+
| CURRENT_TIME(1) |
+-----+
| 09:59:32.4      |
+-----+
1 row in set (0.00 sec)
root@(none) 09:59:32>select CURRENT_TIME(7);
ERROR 1426 (42000): Too big precision 7 specified for column 'curtime'. Maximum is 6.
#The value that you can specify for the precision ranges from 0 to 6. If the value that you specify is not in this range, the system reports the 1426 (42000) error.
```

 **Note** If `CURRENT_TIME()` or `CURRENT_TIMESTAMP()` is run for different transactions in the same session, the returned results may not be incremental in chronological order. This is because the time of one server is different from that of another server.

CURTIME()

`CURTIME()` is a synonym for `CURRENT_TIME()` or `CURRENT_TIME`.

```
mysql> select curtime(), current_time(), current_time;
+-----+-----+-----+
| curtime() | current_time() | current_time |
+-----+-----+-----+
| 14:45:37 | 14:45:37      | 14:45:37     |
+-----+-----+-----+
1 row in set (0.00 sec)
```

CURRENT_DATE()

`CURRENT_DATE()` returns the current date in the `'YYYY-MM-DD'` or `YYYYMMDD` format.

The returned date format varies based on the date format that is specified in the function. If the date format in the function is a string, the returned date is a string. If the date format in the function is a numeric value, the returned date is a numeric value.

Examples

```
mysql> select current_date, current_date+5;
+-----+-----+
| current_date | current_date+5 |
+-----+-----+
| 2015-08-27 | 20150832 |
+-----+-----+
1 row in set (0.00 sec)
```

CURDATE()

CURDATE() is a synonym for CURRENT_DATE() and CURRENT_DATE .

```
mysql> select curdate(), current_date(), current_date;
+-----+-----+-----+
| curdate() | current_date() | current_date |
+-----+-----+-----+
| 2015-08-27 | 2015-08-27 | 2015-08-27 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

DATE_ADD(date, INTERVAL exprunit)

This function adds a specified interval to a date. The *date* parameter specifies the start date to which an interval is added. The *expr* parameter specifies the interval to be added. The values of *expr* can be negative. Based on the internal configurations and the time zone, the operating system determines whether to use daylight saving time (DST) for the DATE_ADD() function.

The following list describes the notes on the DATE_ADD() function:

- The data types of *date* values must be string or date and time data types, such as DATETIME and TIMESTAMP. The other data types are not supported. If you use string data types, the strings must represent time values.
- The valid format of the *date* parameter is YYYY-MM-DD HH:MM:SS.SSSSSS .

MySQL supports non-strict syntax for parsing date strings. If a string contains digits and non-digit characters, MySQL parses only the digits as time values and assigns the values to the year, month, and day parts in sequence. For example, the Ywwe1990d07 09,12:45-08&900 string represents the same time as 1990-07-09 12:45:08.900 . Strict syntax is applied in ApsaraDB for OceanBase. The system reports errors for invalid date types. For example, if you set the date parameter to the invalid date ABC , the system reports an error.

- You must specify the date part in a *date* string. The time part in a date string is optional. If you do not specify the time part, the default values are used. For example, 1990-07-09 is valid. By default, the time values that follow 1990-07-09 are set to 0 values: 1990-07-09 00:00:00.000000 . 1990-07 and 1990 are invalid date values.
- The DATE_ADD() function cannot parse TIMESTAMP strings, such as 990309 .
- In ApsaraDB for OceanBase, you can use the results of invoking other system functions as the values of *date*.
- ApsaraDB for OceanBase does not support fuzzy match for two-digit years. For example, MySQL interprets the 12 year as the 2012 year, but ApsaraDB for OceanBase interprets the 12 year as the year 12.
- The values of *expr* can be negative. If you specify a negative value for the *expr* parameter, the function subtracts the corresponding interval from the start date. You can use the results of invoking system functions as *expr* values. All the results are processed as strings.

- The *unit* parameter specifies the unit of the interval that is to be added or subtracted. The valid values of the parameter are MICROSECOND, SECOND, MINUTE, HOUR, DAY, WEEK, MONTH, QUARTER, YEAR, SECOND_MICROSECOND, MINUTE_MICROSECOND, MINUTE_SECOND, HOUR_MICROSECOND, HOUR_SECOND, HOUR_MINUTE, DAY_MICROSECOND, DAY_SECOND, DAY_MINUTE, DAY_HOUR, and YEAR_MONTH. QUARTER represents quarters.
- If the *unit* value is a compound unit, you must enclose *expr* values in single quotation marks (').

 **Note** In MySQL command-line clients, if a single line is excessively long and compromises read experience, you can add `\G` to the end of the SELECT statement. `\G` is used to align the query results in a vertical way.

Examples

```
mysql> SELECT DATE_ADD(now(), INTERVAL 5 DAY),
-> DATE_ADD('2014-01-10', INTERVAL 5 MICROSECOND),
-> DATE_ADD('2014-01-10', INTERVAL 5 SECOND),
-> DATE_ADD('2014-01-10', INTERVAL 5 MINUTE),
-> DATE_ADD('2014-01-10', INTERVAL 5 HOUR),
-> DATE_ADD('2014-01-10', INTERVAL 5 DAY),
-> DATE_ADD('2014-01-10', INTERVAL 5 WEEK),
-> DATE_ADD('2014-01-10', INTERVAL 5 MONTH),
-> DATE_ADD('2014-01-10', INTERVAL 5 QUARTER),
-> DATE_ADD('2014-01-10', INTERVAL 5 YEAR),
-> DATE_ADD('2014-01-10', INTERVAL '5.000005' SECOND_MICROSECOND),
-> DATE_ADD('2014-01-10', INTERVAL '05:05.000005' MINUTE_MICROSECOND),
-> DATE_ADD('2014-01-10', INTERVAL '05:05' MINUTE_SECOND),
-> DATE_ADD('2014-01-10', INTERVAL '05:05:05.000005' HOUR_MICROSECOND),
-> DATE_ADD('2014-01-10', INTERVAL '05:05:05' HOUR_SECOND),
-> DATE_ADD('2014-01-10', INTERVAL '05:05' HOUR_MINUTE),
-> DATE_ADD('2014-01-10', INTERVAL '01 05:05:05.000005' DAY_MICROSECOND),
-> DATE_ADD('2014-01-10', INTERVAL '01 05:05:05' DAY_SECOND),
-> DATE_ADD('2014-01-10', INTERVAL '01 05:05' DAY_MINUTE),
-> DATE_ADD('2014-01-10', INTERVAL '01 05' DAY_HOUR),
-> DATE_ADD('2014-01-10', INTERVAL '1-01' YEAR_MONTH) \G
***** 1. row *****
      DATE_ADD(now(), INTERVAL 5 DAY): 2016-03-19 13:56:45
      DATE_ADD('2014-01-10', INTERVAL 5 MICROSECOND): 2014-01-10 00:00:00.000005
      DATE_ADD('2014-01-10', INTERVAL 5 SECOND): 2014-01-10 00:00:05
      DATE_ADD('2014-01-10', INTERVAL 5 MINUTE): 2014-01-10 00:05:00
      DATE_ADD('2014-01-10', INTERVAL 5 HOUR): 2014-01-10 05:00:00
      DATE_ADD('2014-01-10', INTERVAL 5 DAY): 2014-01-15
      DATE_ADD('2014-01-10', INTERVAL 5 WEEK): 2014-02-14 00:00:00
      DATE_ADD('2014-01-10', INTERVAL 5 MONTH): 2014-06-10
      DATE_ADD('2014-01-10', INTERVAL 5 QUARTER): 2015-04-10 00:00:00

      DATE_ADD('2014-01-10', INTERVAL '5.000005' SECOND_MICROSECOND): 2014-01-10 00:00:05.000005
      DATE_ADD('2014-01-10', INTERVAL '05:05.000005' MINUTE_MICROSECOND): 2014-01-10 00:05:05.000005
      DATE_ADD('2014-01-10', INTERVAL '05:05' MINUTE_SECOND): 2014-01-10 00:05:05
      DATE_ADD('2014-01-10', INTERVAL '05:05:05.000005' HOUR_MICROSECOND): 2014-01-10 05:05:05.000005
      DATE_ADD('2014-01-10', INTERVAL '05:05:05' HOUR_SECOND): 2014-01-10 05:05:05
      DATE_ADD('2014-01-10', INTERVAL '05:05' HOUR_MINUTE): 2014-01-10 05:05:00
      DATE_ADD('2014-01-10', INTERVAL '01 05:05:05.000005' DAY_MICROSECOND): 2014-01-11 05:05:05.000005
      DATE_ADD('2014-01-10', INTERVAL '01 05:05:05' DAY_SECOND): 2014-01-11 05:05:05
      DATE_ADD('2014-01-10', INTERVAL '01 05:05' DAY_MINUTE): 2014-01-11 05:05:00
      DATE_ADD('2014-01-10', INTERVAL '01 05' DAY_HOUR): 2014-01-11 05:00:00
      DATE_ADD('2014-01-10', INTERVAL '1-01' YEAR_MONTH): 2015-02-10
1 row in set (0.01 sec)
```

In the `DATE_ADD()` function, you can place addition (+) or subtraction operators (-) before `INTERVAL`, as shown in the following examples:

```
date + INTERVAL expr unit
date - INTERVAL expr unit
```

For addition operations, `INTERVAL expr unit` can be placed on the right of the *date* parameter. The value of the *date* parameter can be a date value or a date and time value. For subtraction operations, `INTERVAL expr unit` can be placed only on the right of the *date* parameter. If `INTERVAL expr unit` is placed on the left of the *date* parameter, a date value is subtracted from an interval. This computing process does not return a valid result.

Examples

```
mysql> SELECT '2008-12-31 23:59:59' + INTERVAL 1 SECOND , '2005-01-01' - INTERVAL 1 SECOND\G;
***** 1. row *****
'2008-12-31 23:59:59' + INTERVAL 1 SECOND: 2009-01-01 00:00:00
'2005-01-01' - INTERVAL 1 SECOND: 2004-12-31 23:59:59
1 row in set (0.00 sec)
```

DATE_FORMAT(*date*, *format*)

`DATE_FORMAT()` is an inverse function of `STR_TO_DATE()`. `DATE_FORMAT()` converts a specified value of the *date* parameter into a time string based on the specified *format*.

The *date* parameter specifies the time value to be converted. The *date* values can be date and time values of the `STRING` data type. For more information, see the description of the *date* parameter in `DATE_ADD()`.

Values of the *format* parameter in `DATE_FORMAT()` describes the *format* values that can be used in a format string.

Values of the format parameter in DATE_FORMAT()

Format	Description	Returned value range or format
%a	The abbreviation of the day of the week.	Sun..Sat
%b	The abbreviation of the month.	Jan to Dec.
%c	The month of the numeric type.	1 to 12.
%D	The day that ends with an ordinal indicator: st, nd, rd, or th.	1st to 31st.
%d	The day of the numeric type in the month.	01 to 31.
%e	The day of the numeric type in the month.	1 to 31.
%f	The microsecond.	000000 to 999999.
%H	The hour.	00 to 23.
%h	The hour.	01 to 12.
%I	The hour.	01 to 12.
%i	The minute.	00 to 59.

Format	Description	Returned value range or format
%j	The sequence number of the day in the year.	000 to 366.
%k	The hour.	0 to 23.
%l	The hour.	01 to 12.
%M	The name of the month.	January to December.
%m	The month of the numeric type.	01 to 12.
%p	The morning or the afternoon.	AM and PM.
%r	The time in the 12-hour clock.	hh:mm:ss AM/PM
%S	The seconds.	00 to 59.
%s	The seconds.	00 to 59.
%T	The time in the 24-hour clock.	hh:mm:ss
%U	The sequence number of the week in the year when Sunday is the first day of each week.	00 to 53.
%u	The sequence number of the week in the year when Monday is the first day of each week.	00 to 53.
%V	The sequence number of the week in the year when Sunday is the first day of each week. This option is used in conjunction with %X. Notes: A date may fall within the first week of a year or the last week of the previous year. If this occurs, the sequence number of the week varies based on the format values. Wednesday, January 01, 2014 is used as an example to explain this rule. If the format value is %U or %u, the date falls within week 00 in 2014. If the format value is %V or %v, the date falls within week 52 in 2013.	01 to 53.
%v	The sequence number of the week in the year when Monday is the first day of each week. This option is used in conjunction with %x.	01 to 53.
%W	The day of the week.	Sunday to Saturday.
%w	The sequence number of the day in the week.	0 to 6. The value 0 represents Sunday. The value 6 represents Saturday. Similar rules apply to values 1 to 5.

Format	Description	Returned value range or format
%X	The year of the week when Sunday is the first day of each week. The year is represented by a number that consists of four digits. %X is used in conjunction with %V.	-
%x	The year of the week when Monday is the first day of each week. The year is represented by a number that consists of four digits. %x is used in conjunction with %v.	-
%Y	The year in the four-digit format.	-
%y	The year in the two-digit format.	-
%%	The literal character %.	-

Examples

```
mysql> SELECT DATE_FORMAT('2014-01-01', '%Y-%M-%d'),
DATE_FORMAT('2014-01-01', '%X-%V'),DATE_FORMAT('2014-01-01', '%U') \G
***** 1. row *****
DATE_FORMAT('2014-01-01', '%Y-%M-%d'): 2014-January-01
DATE_FORMAT('2014-01-01', '%X-%V'): 2013-52
DATE_FORMAT('2014-01-01', '%U'): 00
1 row in set (0.00 sec)
```

DATE_SUB(*date*, INTERVAL *expr unit*)

This function subtracts a specified interval from a date. The *date* parameter specifies the start date from which an interval is subtracted. The *expr* parameter specifies the interval to be subtracted from the start date. The values of *expr* can be negative. If you specify a negative value for the *expr* parameter, the function adds the corresponding interval to the start date.

For more information about the parameter description, see `DATE_ADD()` .

Examples

```
mysql> SELECT DATE_SUB('2014-01-10', INTERVAL 5 HOUR),
DATE_SUB('2014-01-10', INTERVAL '05:05:05.000005' HOUR_MICROSECOND)\G;
***** 1. row *****
DATE_SUB('2014-01-10', INTERVAL 5 HOUR): 2014-01-09 19:00:00
DATE_SUB('2014-01-10', INTERVAL '05:05:05.000005' HOUR_MICROSECOND): 2014-01-09 18:54:54.999995
1 row in set (0.00 sec)
```

EXTRACT(*unit* FROM *date*)

This function extracts parts from a date based on the specified units. The *date* parameter specifies the date. The *unit* parameter specifies the units.

For more information about the parameter description, see `DATE_ADD()` .

- The data type of the results that the EXTRACT function returns is BIGINT.
- For a single unit, such as microseconds to years, the EXTRACT function returns the corresponding integer.

- If the *unit* value is WEEK, the function returns the sequence number of the week in the year of the date that you specify in the *date* expression. ApsaraDB for OceanBase considers the first Sunday of the year as the beginning of the first week in the year. If the first Sunday of a year is not January 1, January 1 and the days between the first Sunday and January 1 are in week 0. For example, the first Sunday in 2013 is January 6. Therefore, `SELECT EXTRACT(WEEK FROM '2013-01-01')` returns 0 and `SELECT EXTRACT(WEEK FROM '2013-01-06')` returns 1.
- For compound units such as SECOND_MICROSECOND, ApsaraDB for OceanBase combines the values for the specified units and returns a single value. For example, `SELECT EXTRACT(YEAR_MONTH FROM '2012-03-09')` returns 201203 .

```
mysql> SELECT EXTRACT(WEEK FROM '2013-01-01'),
EXTRACT(WEEK FROM '2013-01-06'),
EXTRACT(YEAR_MONTH FROM '2012-03-09'),
EXTRACT(DAY FROM NOW())\G;
***** 1. row *****
EXTRACT(WEEK FROM '2013-01-01'): 0
EXTRACT(WEEK FROM '2013-01-06'): 1
EXTRACT(YEAR_MONTH FROM '2012-03-09'): 201203
EXTRACT(DAY FROM NOW()): 18
1 row in set (0.00 sec)
```

NOW()

This function returns the current system time that is accurate to seconds. The time format is `YYYY-MM-DD HH:MI:SS` .

 **Notice** You can pass a number that ranges from 0 to 6 into a NOW() function. The number specifies the precision of the fractional second part. By default, `NOW()` is equivalent to `NOW(0)` .

Examples

```

mysql> SELECT NOW();
+-----+
| NOW()          |
+-----+
| 2014-02-17 11:46:15|
+-----+
1 row in set (0.00 sec)
root@(none) 09:52:46>select now(0);
+-----+
| now(0)         |
+-----+
| 2014-11-03 09:55:01 |
+-----+
1 row in set (0.00 sec)
root@(none) 09:55:01>select now(1);
+-----+
| now(1)         |
+-----+
| 2014-11-03 09:55:04.2 |
+-----+
1 row in set (0.00 sec)
root@(none) 09:55:04>select now(2);
+-----+
| now(2)         |
+-----+
| 2014-11-03 09:55:06.57 |
+-----+
1 row in set (0.00 sec)
root@(none) 09:55:06>select now(3);
+-----+
| now(3)         |
+-----+
| 2014-11-03 09:55:09.576 |
+-----+
1 row in set (0.00 sec)
root@(none) 09:55:09>select now(7);
ERROR 1426 (42000): Too big precision 7 specified for column 'now'. Maximum is 6.

```

STR_TO_DATE(*str*,*format*)

This function converts a string that is specified by *str* into a value of the DATETIME, DATE, or TIME type based on the *format* string. If the format string contains date and time parts, STR_TO_DATE() returns a DATETIME value. If the format string contains only the date part, this function returns a DATE value. If the format string contains only the time part, this function returns a TIME value.

The format of the DATE, TIME, or DATETIME value in *str* must be specified in *format*. If the *str* value contains an invalid DATE, TIME, or DATETIME value, STR_TO_DATE() returns NULL. In this case, the system returns a warning message for the invalid value.

Values of the format parameter in STR_TO_DATE() describes the *format* values that can be used in a format string.

Values of the format parameter in STR_TO_DATE()

Format	Description	Returned value range or format
%b	The abbreviation of the month.	Jan to Dec
%c	The month of the numeric type.	1 to 12
%D	The day that ends with an ordinal indicator: st, nd, rd, or th.	1st to 31st
%d	The day of the numeric type in the month.	01 to 31
%e	The day of the numeric type in the month.	1 to 31
%f	The microsecond.	000000 to 999999
%H	The hour.	00 to 23
%h	The hour.	01 to 12
%l	The hour.	01 to 12
%i	The minute.	00 to 59
%k	The hour.	0 to 23
%l	Hours.	01 to 12
%M	The name of the month.	January to December
%m	The month of the numeric type.	01 to 12
%p	The morning or the afternoon.	AM and PM
%r	The time in the 12-hour clock.	hh:mm:ss AM/PM
%S	The seconds.	00 to 59
%s	The seconds.	00 to 59
%T	The time in the 24-hour clock.	hh:mm:ss
%Y	The year in the four-digit format.	-

Examples

```
mysql> SELECT STR_TO_DATE('2014-Jan-1st 5:5:5', '%Y-%b-%D');
+-----+
| STR_TO_DATE('2014-Jan-1st 5:5:5 pm', '%Y-%b-%D') |
+-----+
| 2014-01-01 05:05:05          |
+-----+
1 row in set (0.00 sec)
```

TIME_TO_USEC(*date*)

This function converts the internal time of ApsaraDB for OceanBase into the number of microseconds. The returned result of this function indicates the number of microseconds from 1970-01-01 00:00:00 to the time that is specified by *date*. The returned result is the UTC time and uses the UTC+0 time zone.

The following list describes the notes on the TIME_TO_USEC(*date*) function:

- The *date* parameter specifies the date that is to be converted into the number of microseconds. The date uses the time zone that is specified in the system. The value of the date parameter is a string of the `TIMESTAMP` or `TIME` data type.
- The `TIME_TO_USEC` function can use the results of invoking other functions as the values of the date parameter. Note that the results must be strings of the `TIMESTAMP` or `TIME` data type.
- The returned values of the `TIME_TO_USEC` function are measured in microseconds. The data type of the returned values is `INT`.

Examples

```
mysql> SELECT TIME_TO_USEC('2014-03-25'), TIME_TO_USEC(now(6));
+-----+-----+
| TIME_TO_USEC('2014-03-25') | TIME_TO_USEC(now(6)) |
+-----+-----+
|      1395676800000000 | 1395735415207794 |
+-----+-----+
1 row in set (0.00 sec)
```

USEC_TO_TIME(*usec*)

This function is an inverse function of `TIME_TO_USEC(date)`. The `USEC_TO_TIME(usec)` function adds the value of *usec* to 1970-01-01 00:00:00 and returns a result that uses the required time zone. For example, if you invoke the `USEC_TO_TIME(1)` function in the UTC+8 time zone, the function returns 1970-01-01 08:00:01.

The following list describes the notes on the `USEC_TO_TIME(usec)` function:

- The *usec* parameter specifies the number of microseconds.
- This function returns a value of the `TIMESTAMP` data type.

Examples

```
mysql> SELECT USEC_TO_TIME(1);
+-----+
| USEC_TO_TIME(1) |
+-----+
| 1970-01-01 08:00:00.000001 |
+-----+
1 row in set (0.00 sec)
```

UNIX_TIMESTAMP(),UNIX_TIMESTAMP(*date*)

If you do not pass arguments into the `UNIX_TIMESTAMP()` function, the function returns a `UNIX timestamp`. A `UNIX timestamp` is the number of seconds that have elapsed since '1970-01-01 00:00:00' GMT. The returned result is an unsigned integer.

If you pass a *date* value into the UNIX_TIMESTAMP() function, the function returns the value as the number of seconds that have elapsed since '1970-01-01 00:00:00' GMT . The values of the *date* parameter can be DATE strings, DATETIME strings, TIMESTAMP strings, or numbers in the YYMMDD or YYYYMMDD format. Note that the numbers represent the local time.

Examples

```
mysql> SELECT UNIX_TIMESTAMP();
+-----+
| UNIX_TIMESTAMP() |
+-----+
|      1427176668 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT UNIX_TIMESTAMP('1997-10-04 22:23:00')
+-----+
| UNIX_TIMESTAMP('1997-10-04 22:23:00') |
+-----+
|                875974980 |
+-----+
1 row in set (0.00 sec)
```

If the values in the `TIMESTAMP` column are used as the values of the date parameter for the `UNIX_TIMESTAMP` function, the function returns internal timestamps.

If you pass a date that does not fall within the basic date ranges into the UNIX_TIMESTAMP() function, the function returns 0. The function checks the specified date values against only the basic date ranges. In the basic date ranges, year values range from 1970 to 2037, month values range from 01 to 12, and day values range from 01 to 31.

DATEDIFF(*expr1*,*expr2*)

The DATEDIFF() function returns the number of days between the start date that is specified by *expr1* and the end date that is specified by *expr2*. *expr1* and *expr2* are date or date and time expressions. Only the date parts in the expressions are used to calculate the returned result.

You must specify two arguments for this function. If the number of the specified arguments is not two, the system reports an error.

Examples

```
mysql> select datediff('2015-06-19','1994-12-17'), datediff('2015-06-19','1998-06-27 10:10:10'), datediff(now(), '2014-01-02')\G;
***** 1. row *****
      datediff('2015-06-19','1994-12-17'): 7489
      datediff('2015-06-19','1998-06-27 10:10:10'): 6201
      datediff(now(), '2014-01-02'): 533
1 row in set (0.00 sec)
```

TIMEDIFF(*expr1*,*expr2*)

The TIMEDIFF() function returns the time interval between the start time that is specified by *expr1* and the end time that is specified by *expr2*. *expr1* and *expr2* are time or date and time expressions. The data types of *expr1* and *expr2* values must be the same.

The result that is returned by the `TIMEDIFF()` function must fall within the valid range of time values. You can also use the `TIMESTAMPDIFF()` and `UNIX_TIMESTAMP()` functions. These functions return integer values.

Examples

```
mysql> select timediff(now(), '2017-06-06 11:11:22'), timediff('2015-06-06 12:12:12', '2014-06-05 11:11:11')\G;
***** 1. row *****
      timediff(now(), '2017-06-06 11:11:22'): 315:00:15
      timediff('2015-06-06 12:12:12', '2014-06-05 11:11:11'): 838:59:59
1 row in set, 1 warning (0.00 sec)
```

TIMESTAMPDIFF(*unit*,*datetime_expr1*,*datetime_expr2*)

This function returns the difference between the value that is specified by *datetime_expr1* and the value that is specified by *datetime_expr2*. The returned result is an integer. The *unit* parameter specifies the unit of the returned result.

Valid values of the *unit* parameter are `MICROSECOND` (microsecond) , `SECOND`, `MINUTE`, `HOUR`, `DAY`, `WEEK`, `MONTH`, `QUARTER`, and `YEAR`.

Examples

```
mysql> select timestampdiff(second,now(), '2011-01-01 11:11:11'), timestampdiff(second, '2011-01-01 11:11:11', now())
\G;
***** 1. row *****
      timestampdiff(second,now(), '2011-01-01 11:11:11'): -140843995
      timestampdiff(second, '2011-01-01 11:11:11', now()): 140843995
1 row in set (0.00 sec)
```

PERIOD_DIFF(*p1*,*p2*)

This function returns the number of months between the *p1* period and the *p2* period. *p1* and *p2* values must use the YYMM or YYYYMM format.

 **Notice** *p1* and *p2* values are not date values.

Examples

```
mysql> select period_diff(20150702, 20790503), period_diff(150702, 790503);
+-----+-----+
| period_diff(20150702, 20790503) | period_diff(150702, 790503) |
+-----+-----+
|          -76777 |          -76777 |
+-----+-----+
1 row in set (0.00 sec)
```

TO_DAYS(*date*)

This function returns the number of days between the zero year and the date that is specified by the *date* parameter.

Examples

```
mysql> SELECT TO_DAYS('2015-11-04'), TO_DAYS('20151104');
+-----+-----+
| TO_DAYS('2015-11-04') | TO_DAYS('20151104') |
+-----+-----+
|          736271 |          736271 |
+-----+-----+
1 row in set (0.00 sec)
```

TO_DAYS() is not used for the dates that are earlier than the year 1582 when the Gregorian calendar was first introduced. This is because some days were lost when the Julian calendar was switched to the Gregorian calendar. The lost days are not considered in this function.

Two-digit year values in dates are converted into four-digit year values. For example, '2015-11-04' and '15-11-04' represent the same date.

Examples

```
mysql> SELECT TO_DAYS('2015-11-04'), TO_DAYS('151104');
+-----+-----+
| TO_DAYS('2015-11-04') | TO_DAYS('151104') |
+-----+-----+
|          736271 |          736271 |
+-----+-----+
1 row in set (0.00 sec)
```

The system considers the zero date '0000-00-00' as an invalid date. The TO_DAYS() function returns the following result for the zero date:

```
mysql> SELECT TO_DAYS('0000-00-00');
+-----+
| TO_DAYS('0000-00-00') |
+-----+
|          NULL |
+-----+
1 row in set, 1 warning (0.01 sec)
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+-----+-----+-----+
1 row in set (0.00 sec)
```

FROM_DAYS(N)

The function returns a DATE value based on the number of days that you specify by N.

Examples

```
mysql> SELECT FROM_DAYS(736271), FROM_DAYS(700000);
+-----+-----+
| FROM_DAYS(736271) | FROM_DAYS(700000) |
+-----+-----+
| 2015-11-04   | 1916-07-15   |
+-----+-----+
1 row in set (0.00 sec)
```

 **Note** Use caution when you use the FROM_DAYS() function to process ancient dates. This function is not used to process the dates that are earlier than the 1582 year when the Gregorian calendar was first introduced.

FROM_UNIXTIME(unix_timestamp[,format])

```
FROM_UNIXTIME(unix_timestamp) , FROM_UNIXTIME(unix_timestamp,format)
```

This function converts a unix_timestamp value into a value in the 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format. The format depends on whether the function uses strings or numbers as arguments.

If you set the format parameter to a format string, the function returns the result based on the specified format. The format values in this function support those for the format input parameter in the DATE_FORMAT() function.

Values of the format parameter in FROM_UNIXTIME() describes the format values that can be used in a format string.

Values of the format parameter in FROM_UNIXTIME()

Format	Description
%a	The abbreviation of the day of the week. The returned values range from Sun to Sat.
%b	The abbreviation of the day of the week. The returned values range from Jan to Dec.
%c	The month of the numeric data type. The returned values range from 0 to 12.
%D	The day that ends with an ordinal indicator: st, nd, rd, or th. The returned values range from 0th to 31st.
%d	The day of the numeric data type in the month. The returned values range from 00 to 31.
%e	The day of the numeric data type in the month. The returned values range from 0 to 31.
%f	The microsecond. The returned values range from 000000 to 999999.
%H	The hour. The returned values range from 00 to 23.
%h	The hour. The returned values range from 01 to 12.
%l	The hour. The returned values range from 01 to 12.

Format	Description
%i	The minute of the numeric data type. The returned values range from 00 to 59.
%j	The number of days in the year. The returned values range from 001 to 366.
%k	The hour. The returned values range from 0 to 23.
%l	The hour. The returned values range from 1 to 12.
%M	The name of the month. The returned values range from January to December.
%m	The month of the numeric data type. The returned values range from 00 to 12.
%p	The morning or the afternoon. The returned value for the morning is AM. The returned value for the afternoon is PM.
%r	The time in the 12-hour clock. The returned value uses the hh:mm:ss format and ends with AM or PM. hh represents hours, mm represents minutes, and ss represents seconds.
%S	The seconds. The returned values range from 00 to 59.
%s	The seconds. The returned values range from 00 to 59.
%T	The time in the 24-hour clock. The returned value uses the hh:mm:ss format.
%U	The sequence number of the week in the year when Sunday is the first day of each week. The returned values range from 00 to 53.
%u	The sequence number of the week in the year when Monday is the first day of each week. The returned values range from 00 to 53.
%V	The sequence number of the week in the year when Sunday is the first day of each week. This option is used in conjunction with %X. The returned values range from 01 to 53.
%v	The sequence number of the week in the year when Monday is the first day of each week. This option is used in conjunction with %x. The returned values range from 01 to 53.
%W	The day of the week. The returned values range from Sunday to Saturday.
%w	The day of the week. The returned values range from 0 to 6. The value 0 represents Sunday. The value 6 represents Saturday. Similar rules apply to numbers 1 to 5.

Format	Description
%X	The year of the week when Sunday is the first day of each week. The year is represented by a number that consists of four digits. This option is used in conjunction with %V.
%x	The year of the week when Monday is the first day of each week. The year is represented by a number that consists of four digits. This option is used in conjunction with %v.
%Y	The year of the numeric data type. The year is represented by a number that consists of four digits.
%y	The year of the numeric data type. The year is represented by a number that consists of two digits.
%%	The literal character %.

All the other characters are copied into the returned result and do not need to be interpreted.

 **Note** The % characters must be placed before the format values.

Examples

```
mysql> SELECT FROM_UNIXTIME(875996580);
+-----+
| FROM_UNIXTIME(875996580) |
+-----+
| 1997-10-05 04:23:00   |
+-----+
1 row in set (0.00 sec)

mysql> SELECT FROM_UNIXTIME(875996580) + 0;
+-----+
| FROM_UNIXTIME(875996580) + 0 |
+-----+
|          19971005042300 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT FROM_UNIXTIME(UNIX_TIMESTAMP(), '%Y %D %M %h:%i:%s %x');
+-----+
| FROM_UNIXTIME(UNIX_TIMESTAMP(), '%Y %D %M %h:%i:%s %x') |
+-----+
| 2016 6th January 10:18:22 2016          |
+-----+
1 row in set (0.01 sec)
```

18.5.7.3. String functions

 **Note** ApsaraDB for OceanBase supports only the UTF8MB4 character set.

CONCAT(*str1*,..., *strN*)

This function concatenates one or more strings into a single string. Each input value in CONCAT functions must be a string or a NULL value. Otherwise, the system reports an error. If the concatenation is successful, the function returns the concatenated string. If an argument is NULL, the function returns NULL.

 **Note** If the data types of the *str* parameter are numeric data types, the system converts numeric values into strings in an implicit way.

Examples

```
mysql> select concat('test'), concat('test','OceanBase'), concat('test', 'OceanBase', '1.0'), concat('test','OceanBase','1.0',
NULL)\G;
***** 1. row *****
      concat('test'): test
      concat('test','OceanBase'): testOceanBase
      concat('test', 'OceanBase', '1.0'): testOceanBase1.0
      concat('test','OceanBase','1.0', NULL): NULL
1 row in set (0.00 sec)
```

Errors

- If the syntax of the function is invalid, the system reports the following error: **ERROR 1064 (42000): You have an error in your SQL syntax; .**
- If the format of a data type is invalid, the system reports the following error: **ERROR 1054 (42S22): Unknown column .** For example, if you do not enclose a string in double quotations marks ("), the system reports the error.

SUBSTRING

SUBSTRING(*str*,*pos*)

SUBSTRING(*str* FROM *pos*)

SUBSTRING(*str*,*pos*,*len*)

SUBSTRING(*str* FROM *pos* FOR *len*)

This function has the same semantics as the SUBSTR function.

SUBSTR

```
SUBSTR(str,pos,len)
```

```
SUBSTR(str,pos)
```

```
SUBSTR(str FROM pos)
```

```
SUBSTR (str FROM pos FOR len)
```

This function extracts a substring from a specified string. The *pos* parameter specifies the start position of the returned substring. The *len* parameter specifies the length of the returned substring. To use the standard SQL syntax to specify the start position, specify the *pos* parameter in the FROM clause.

- The values of *str* must be strings. The values of *pos* and *len* must be integers. If an argument is NULL, the function returns NULL.
- The Chinese characters that you specify in the values of *str* are identified as byte streams.
- If you do not specify the *len* parameter in the function, the returned substring starts from the position *pos* and ends with the last character of the source string.
- If you specify the *pos* parameter as a negative value, the function determines the start position of the returned substring based on the right-of-left order. If you specify the *pos* parameter as 0, the system considers 0 as 1. This means that the returned substring starts with the first character of the source string.
- If the *len* value is smaller than or equal to 0 or no character exists at the *pos* position, the returned result is an empty string.

```
mysql> SELECT SUBSTR('abcdefg',3), SUBSTR('abcdefg',3,2), SUBSTR('abcdefg',-3), SUBSTR('abcdefg',3,-2), SUBSTR('abcdefg' from -4 for 2)\G;
***** 1. row *****
SUBSTR('abcdefg',3): cdefg
SUBSTR('abcdefg',3,2): cd
SUBSTR('abcdefg',-3): efg
SUBSTR('abcdefg',3,-2):
SUBSTR('abcdefg' from -4 for 2): de
1 row in set (0.00 sec)
```

Errors

If the syntax is invalid, the system reports the following error: **ERROR 1064 (42000): You have an error in your SQL syntax; .**

TRIM([BOTH | LEADING | TRAILING]) [remstr] FROM] str)

This function can remove leading and trailing characters from a specified string at a time. This function can also remove only leading or trailing characters from a sting at a time.

- The values of *remstr* and *str* parameters must be strings or NULL. If an argument is NULL, the function returns NULL.
- If you do not specify BOTH, LEADIN, or TRAILING, BOTH is used by default.
- The *remstr* parameter is optional. If you do not specify this parameter, the function removes spaces from a specified string.

```
mysql> SELECT TRIM(' bar '),
TRIM(LEADING 'x' FROM 'xxxbarxxx'),
TRIM(BOTH 'x' FROM 'xxxbarxxx'),
TRIM(TRAILING 'x' FROM 'xxxbarxxx')\G;
***** 1. row *****
TRIM(' bar '): bar
TRIM(LEADING 'x' FROM 'xxxbarxxx'): barxxx
TRIM(BOTH 'x' FROM 'xxxbarxxx'): bar
TRIM(TRAILING 'x' FROM 'xxxbarxxx'): xxxbar
1 row in set (0.00 sec)
```

LENGTH(*str*)

This function returns the length of a specified string. The returned length is measured in bytes. The values of the input parameter must be strings or NULL. Otherwise, the system reports an error. If the operation is successful, the function returns an integer of the INT data type. The returned integer indicates the string length. If an argument is NULL, the function returns NULL.

If the data types of the *str* parameter are numeric data types, the system converts numeric values into strings in an implicit way.

```
mysql> SELECT LENGTH('text');
+-----+
| LENGTH('text') |
+-----+
|          4 |
+-----+
1 row in set (0.00 sec)
mysql> select length(-1.23);
+-----+
| length(-1.23) |
+-----+
|          5 |
+-----+
1 row in set (0.00 sec)
mysql> select length(1233e);
mysql> select length(1233e);
ERROR 1054 (42S22): Unknown column '1233e' in 'field list'
```

Errors

If the data type of the *str* parameter is invalid, the system reports the following error: **ERROR 1054 (42S22):** Unknown column 'XXXX' in 'field list' .

UPPER(*str*)

This function converts a specified string into uppercase characters. The values of the *str* parameter must be strings. If the *str* value is NULL, the function returns NULL.

If the data types of the *str* parameter are numeric data types, the system converts numeric values into strings in an implicit way.

The byte range of the Chinese character set does not overlap with that of the ASCII character set. Therefore, you can specify Chinese characters in the input values of the UPPER function.

```
mysql> SELECT UPPER ('Hello, OceanBase!') ;
+-----+
| UPPER('Hello, OceanBase!') |
+-----+
| HELLO, OCEANBASE!        |
+-----+
1 row in set (0.00 sec)

mysql> select upper(e);
ERROR 1054 (42S22): Unknown column 'e' in 'field list'

mysql> select upper(1.235.) ;
ERROR 1064 (42000): You have an error in your SQL syntax;
```

Errors

- If the data type of the `str` parameter is invalid, the system reports the following error: **ERROR 1064 (42000):** You have an error in your SQL syntax; .
- If you do not use double quotation marks (") to enclose a string, the system reports the following error: **ERROR 1054 (42S22):** Unknown column 'XX' in 'field list' . This error is different from the following error: **ERROR 1166 (42703):** Unknown column Name that ApsaraDB for OceanBase reports.

LOWER(*str*)

This function converts a specified string into lowercase characters. The values of the `str` parameter must be strings. If the `str` value is NULL, the function returns NULL.

If the data types of the `str` parameter are numeric data types, the system converts numeric values into strings in an implicit way.

The byte range of the Chinese character set does not overlap with that of the ASCII character set. Therefore, you can specify Chinese characters in the input values of the LOWER function.

Examples

```
mysql> SELECT LOWER ('Hello, OceanBase!') ;
+-----+
| LOWER('Hello, OceanBase!') |
+-----+
| hello, oceanbase!        |
+-----+
1 row in set (0.00 sec)
mysql> select lower(1.23) ;
+-----+
| lower(1.23) |
+-----+
| 1.23      |
+-----+
1 row in set (0.00 sec)
mysql> select lower(1.23h);
ERROR 1583 (42000): Incorrect parameters in the call to native function 'lower'
mysql> select lower(1.23e);
ERROR 1582 (42000): Incorrect parameter count in the call to native function 'lower'
```

Errors

- If the syntax is invalid, the system reports the following error: `ERROR 1064 (42000): You have an error in your SQL syntax; .`
- If the specified value of an input parameter is invalid, the system reports the following errors: `ERROR 1582 (42000): Incorrect parameter count in the call to native function 'lower'` or `ERROR 1583 (42000): Incorrect parameters in the call to native function 'lower'`.

HEX(*str*)

This function converts a specified string into a hexadecimal string. If the *str* value is NULL, the function returns NULL.

If the *str* value is a numeric value, this function converts the integer part of the numeric value into a hexadecimal string.

If the *str* value is a string, the function returns a hexadecimal string for the *str* value. Each character in the *str* value is converted into two hexadecimal digits.

Examples

```
mysql> SELECT HEX(255);
-> 'FF'
mysql> SELECT HEX('abc');
-> 616263
mysql> SELECT HEX('OceanBase'),
HEX(123),
HEX(0x0123);
+-----+-----+-----+
| HEX('OceanBase') | HEX(123) | HEX(0x0123) |
+-----+-----+-----+
| 4F6365616E42617365 | 7B   | 0123   |
+-----+-----+-----+
1 row in set (0.00 sec)
mysql> select hex(0x012);
+-----+
| hex(0x012) |
+-----+
| 0012   |
+-----+
1 row in set (0.00 sec)
```

Errors

If the syntax is invalid, the system reports the following error: **ERROR 1064 (42000): You have an error in your SQL syntax;** .

UNHEX(*str*)

This function is an inverse function of HEX(*str*). The UNHEX(*str*) function interprets each pair of hexadecimal digits in the *str* value as a number and converts this number into a character. The returned value is a binary string.

The values of *str* must be strings or NULL. If the *str* value is a valid hexadecimal string, the UNHEX(*str*) function uses an algorithm to convert hexadecimal values into byte streams. If the *str* value is not a hexadecimal string, the function returns NULL. If the *str* value is NULL, the function returns NULL.

Examples

```
mysql> SELECT HEX('OceanBase'),
UNHEX('4f6365616e42617365'),
UNHEX(HEX('OceanBase')),
UNHEX(NULL)\G;
***** 1. row *****
HEX('OceanBase'): 4F6365616E42617365
UNHEX('4f6365616e42617365'): OceanBase
UNHEX(HEX('OceanBase')): OceanBase
UNHEX(NULL): NULL
1 row in set (0.00 sec)
mysql> select unhex(abc);
ERROR 1054 (42S22): Unknown column 'abc' in 'field list';
```

Errors

If the data type of the `str` parameter is invalid, the system reports the following error: `ERROR 1054 (42522): Unknown column 'abc' in 'field list'` .

INT2IP(*int_value*)

 **Note** The `INT2IP` function is available only in ApsaraDB for OceanBase.

This function converts a specified integer into an IP address.

The data type of the `int_value` parameter must be `INT`. If the value of the `int_value` parameter is `NULL`, the function returns `NULL`. If the specified integer is greater than `MAX_INT32` or smaller than `0`, the function returns `NULL`. `MAX_INT32` is the maximum signed 32-bit integer.

Examples

```
mysql> SELECT INT2IP(16777216),
-> HEX(16777216),
-> INT2IP(1);
+-----+-----+-----+
| INT2IP(16777216) | HEX(16777216) | INT2IP(1) |
+-----+-----+-----+
| 1.0.0.0      | 1000000      | 0.0.0.1   |
+-----+-----+-----+
1 row in set (0.00 sec)
```

IP2INT('ip_addr')

 **Note** The `IP2INT` function is available only in ApsaraDB for OceanBase.

This function converts an IP address of the `STRING` data type into an integer.

Pay attention to the following considerations when you use the function:

- The values of the `ip_addr` parameter must be strings.
If the value of the `ip_addr` parameter is `NULL`, the function returns `NULL`. If the specified IP address is invalid, the function returns `NULL`. For example, the IP address contains non-digit characters, or the number in each segment of an IP address is larger than `256`.
- This function supports only IPv4 addresses.

Examples

```
mysql> SELECT IP2INT('0.0.0.1'),
HEX(IP2INT('0.0.0.1')),
HEX(IP2INT('1.0.0.0')),
IP2INT('1.0.0.257')\G;
***** 1. row *****
IP2INT('0.0.0.1'): 1
HEX(IP2INT('0.0.0.1')): 1
HEX(IP2INT('1.0.0.0')): 1000000
IP2INT('1.0.0.257'): NULL
1 row in set (0.01 sec)
```

[NOT] LIKE *str2* [ESCAPE *str3*]

This function compares strings based on wildcards. The arguments on the left of the LIKE or NOT LIKE keyword and those on the right of the keyword must be strings or NULL. Otherwise, the system reports an error. If the left argument matches the right argument, the LIKE or NOT LIKE function returns TRUE. If the left argument does not match the right argument, the LIKE or NOT LIKE function returns FALSE. If an argument is NULL, the function returns NULL.

The function supports the following wildcards: percent signs (%) and underscores (_).

- A percent sign (%) matches a string of zero or more characters.
- An underscore (_) matches a single character. The matched character must exist.

If you need to search for `a_c` instead of `abc`, you can use `a_c`. ApsaraDB for OceanBase uses double backslashes (\\) as escape characters. In `a_c`, the double backslashes (\\) are used to escape the underscore (_).

You can use the ESCAPE clause to specify an escape character. If the *str2* value contains the *str3* value, the *str2* characters that follow the *str3* value are processed as general characters. For example, in `LIKE 'abc%' ESCAPE 'c'`, `c` is an escape character. In this case, the percent sign (%) is a general character instead of an escape character. The matched string for this SQL statement is `ab%`.

```
mysql> SELECT 'ab%' LIKE 'abc%' ESCAPE 'c';
+-----+
| 'ab%' LIKE 'abc%' ESCAPE 'c' |
+-----+
|          1 |
+-----+
1 row in set (0.00 sec)
```

 **Note** When you use the ESCAPE clause to specify an escape character, the escape character must be a one-character string. In the ESCAPE clause, percent signs (%) or underscores (_) cannot be specified as escape characters.

Examples

```
mysql> select 'a_c' like 'a\\_c';
+-----+
| 'a_c' like 'a\\_c' |
+-----+
|          1 |
+-----+
1 row in set (0.00 sec)

mysql> select 'abc_' like 'abcdd_' escape 'dd';
ERROR 1064 (42000): Incorrect arguments to ESCAPE
```

expr* [NOT] REGEXP | RLIKE *pat

This function compares a specified string expression with a pattern. The *expr* parameter specifies the string. The *pat* parameter specifies the pattern.

If the *expr* value matches the *pat* value, the function returns 1. Otherwise, the function returns 0. If the *expr* value or the *pat* value is NULL, the function returns NULL.

RLIKE is a synonym for REGEXP.

The values of *expr* and *pat* must be strings or NULL. If the values of the two parameters are numeric values, the system converts the values into strings in an implicit way. If the data type of the *expr* or *pat* parameter is invalid, the system reports an error.

The specified pattern must be a valid regular expression. Otherwise, the system reports an error.

```
mysql> select 1234 regexp 1;
+-----+
| 1234 regexp 1 |
+-----+
|          1 |
+-----+
1 row in set (0.00 sec)
mysql> select 'hello' rlike 'h%';
+-----+
| 'hello' rlike 'h%' |
+-----+
|          0 |
+-----+
1 row in set (0.00 sec)
mysql> select 1234 regexp ^y;
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near '^y' at line 1
mysql> select yunzhi regexp ^y;
ERROR 1054 (42522): Unknown column 'yunzhi' in 'field list'
mysql> select 'hello' not rlike '*h*';
ERROR 1139 (42000): Got error 'repetition-operator operand invalid' from regexp
mysql> select 'hello' not rlike '*h*';
ERROR 1139 (42000): Got error 'repetition-operator operand invalid' from regexp
```

Errors

- If the syntax of is invalid, the system reports the following error: `ERROR 1064 (42000): You have an error in your SQL syntax; .`
- If the data type of the *expr* or *pat* argument is invalid, the system reports the following error: `ERROR 1054 (42522): Unknown column 'yunzhi' in 'field list' .`
- If the system cannot identify the specified regular expression, the system reports the following error: `ERROR 1139 (42000): Got error 'repetition-operator operand invalid' from regexp .`

REPEAT(*str*, *count*)

This function repeats a string for a specified number of times. The *str* parameter specifies the string to be repeated. The *count* parameter specifies the number of times. If the specified *count* value is smaller than or equal to 0 , the function returns an empty string.

If the value of *str* or *count* is NULL, the function returns NULL.

If the data types of the *str* parameter are numeric data types, the system converts numeric values into strings in an implicit way.

The system can convert the data type of the *count* parameter into a numeric data type in an implicit way. If the conversion fails, the systems considers the *count* value as 0.

Examples

```
mysql> select repeat('1',-1), repeat(null,null),repeat('test',4);
+-----+-----+-----+
| repeat('1',-1) | repeat(null,null) | repeat('test',4) |
+-----+-----+-----+
|          | NULL          | testtesttesttest |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> select repeat(11111,'2');
+-----+
| repeat(11111,'2') |
+-----+
| 1111111111      |
+-----+
1 row in set (0.00 sec)
```

SUBSTRING_INDEX(*str*, *delim*, *count*)

This function returns a specified substring of a string. The returned substring is located before the position where a specified delimiter last occurs in the specified string. In this function, the *delim* parameter specifies the delimiter. The *count* parameter specifies the number of occurrences for the delimiter. The *str* parameter specifies the string from which you want to extract the substring.

If the *count* value is positive, the function determines the last delimiter in the string based on the left-to-right order. In this case, the function returns the characters that are located on the left of the last delimiter. If the *count* value is negative, the function determines the last delimiter in the string based on the right-to-left order. In this case, the function returns the characters that are located on the right of the last delimiter.

If an argument is NULL, the function returns NULL. If the value of the *str* or *delim* parameter is an empty string, the function returns an empty string. If the *count* value is 0, the function returns an empty string.

If the data types of the *str*, *delim*, and *count* parameters are numeric data types, the system converts numeric values into strings in an implicit way.

Examples

```
mysql> select substring_index('abcdabc', 'abc', 0), substring_index('abcdabc', 'abc', 1), substring_index('abcdabc', 'abc',
2), substring_index('abcdabc', 'abc', 3), substring_index('abcdabc', 'abc', -1), substring_index('abcdabc', 'abc', -2), substri
ng_index('abcdabc', 'abc', -3)\G;
***** 1. row *****
substring_index('abcdabc', 'abc', 0):
substring_index('abcdabc', 'abc', 1):
substring_index('abcdabc', 'abc', 2): abcd
substring_index('abcdabc', 'abc', 3): abcdabc
substring_index('abcdabc', 'abc', -1):
substring_index('abcdabc', 'abc', -2): dabc
substring_index('abcdabc', 'abc', -3): abcdabc
1 row in set (0.00 sec)
```

LOCATE(*substr*,*str*) , LOCATE(*substr*,*str*,*pos*)

The `LOCATE(substr,str)` function returns the position of the first occurrence for a specified substring in a string. The `substr` parameter specifies the substring and the `str` parameter specifies the source string. The `LOCATE(substr,str,pos)` function also returns the position of the first occurrence for a specified string in a string. However, this function adds the following input parameter to the `LOCATE(substr,str)` function: `pos`. The `pos` parameter specifies the position where the function starts to search for the substring. The `substr` parameter specifies the substring and the `str` parameter specifies the source string. If the `substr` substring is not included in the `str` source string, the function returns 0.

Examples

```
mysql> SELECT LOCATE('bar', 'foobarbar');
      -> 4
mysql> SELECT LOCATE('xbar', 'foobar');
      -> 0
mysql> SELECT LOCATE('bar', 'foobarbar',5);
      -> 7
```

INSTR(*str,substr*)

This function returns the position of the first occurrence for a specified substring in a string that is specified by `str`. This function is the same as the `LOCATE(substr,str)` function, except that the order of the arguments is reversed.

Examples

```
mysql> SELECT INSTR('foobarbar', 'bar');
      -> 4
mysql> SELECT INSTR('xbar', 'foobar');
      -> 0
```

REPLACE(*str, from_str, to_str*)

This function replaces each specified substring in a string with a new substring. The `from_str` parameter specifies the substring to be replaced. The `to_str` parameter specifies the substring that replaces the specified substring. The `str` parameter specifies the source string.

Examples

```
mysql> SELECT REPLACE('abc.efg.gpg.nowdew.abc.dabc.e', 'abc.', 'www');
+-----+
| REPLACE('abc.efg.gpg.nowdew.abc.dabc.e', 'abc.', 'www') |
+-----+
| wwwefg.gpg.nowdew.wwwdwww                               |
+-----+
1 row in set (0.00 sec)
```

FIELD(*str,str1,str2,str3,...*)

This function returns the index position of a specified string in a list of strings. In this function, `str` specifies the string and `str1,str2,str3,...` specifies the list of strings. The sequence numbers for index positions start from 1. If the `str` value is not found, the function returns 0.

If all the input values in the `FIELD()` function are strings, the function compares the input values based on the strings. If all the input values are numbers, the function compares the input values based on the numbers. In other scenarios, the function compares the input values based on the `DOUBLE` numbers.

If the *str* value is NULL, the function returns 0. This is because NULL cannot be compared with the other values. FIELD() is a supplement to ELT().

Examples

```
mysql> select field('abc','abc1','abc2','abc','abc4','abc'), field(NULL, 'null1', NULL);
+-----+-----+
| field('abc','abc1','abc2','abc','abc4','abc') | field(NULL, 'null1', NULL) |
+-----+-----+
|          3 |          0 |
+-----+-----+
1 row in set (0.00 sec)
```

ELT(N, *str1*, *str2*, *str3*,...)

This function returns a specified string in a list of strings. The returned string is specified by the index number N. For example, if you set N to 1, the function returns the *str1* value. If you set N to 2, the function returns the *str2* value. If N is smaller than 1 or greater than the number of strings in the function, the function returns NULL. ELT() is a supplement to FIELD().

```
mysql> select elt(3, 'abc1', 'abc2', 'abc', 'abc4', 'abc'), elt(0, 'null1', NULL);
+-----+-----+
| elt(3, 'abc1', 'abc2', 'abc', 'abc4', 'abc') | elt(0, 'null1', NULL) |
+-----+-----+
| abc          | NULL          |
+-----+-----+
1 row in set (0.00 sec)
```

INSERT (*str1*,*pos*,*len*,*str2*)

This function replaces a specified substring of a string with a new substring. The *str1* parameter specifies the source string and the *str2* parameter specifies the substring that replaces the original substring. The *pos* parameter specifies the start position of the original substring and the *len* parameter specifies the length of the original substring. If the *pos* value is greater than the length of the source string, the function returns the source string. If the *len* value is greater than the length of the *str1* or *str2* string, the function replaces the original substring that starts at the *pos* position. If an argument is NULL, the function returns NULL. This function supports multibyte characters.

- The values of *str1* and *str2* must be strings. The values of *pos* and *len* must be integers. If an argument is NULL, the function returns NULL.
- The text characters in *str1* and *str2* are identified as byte streams.
- If the *pos* value is negative or greater than the length of the *str1* value, the function returns the *str1* value.
- If the *len* value is smaller than 0 or greater than the length of the *str1* value, the function returns a string that consists of the *str2* value and a substring of the *str1* string. The substring starts from the first character of the *str1* value and ends at the position that is specified by the *pos* parameter.

Examples

```
mysql> select insert('Quadratic',-2,100,'What'), insert('Quadratic',7,3,'What'), insert('Quadratic',1,3,'What'), insert('Quadratic',10,3,'What'), insert('Quadratic',5,-1,''), insert('Quadratic',7,-1,'What')\G;
***** 1. row *****
insert('Quadratic',-2,100,'What'): Quadratic
insert('Quadratic',7,3,'What'): QuadraWhat
insert('Quadratic',1,3,'What'): QWhatratic
insert('Quadratic',10,3,'What'): Quadratic
insert('Quadratic',5,-1,''): Quad
insert('Quadratic',7,-1,'What'): QuadraWhat
1 row in set (0.00 sec)
```

18.5.7.4. Type conversion functions

CAST(*expr AS type*)

This function converts a value of *expr* to a value of a data type that is specified by *type*. For more information about data types, see [Data types](#).

Parameter description

expr specifies the valid SQL expression.

AS separates the two parameters. The parameter before AS specifies the data to be processed. The parameter after AS specifies the destination data type.

type specifies the destination data type. This function converts the *expr* value into a value of the specified data type. You can use one of the following data types as the destination data type:

- CHAR[(N)]. If you use CHAR[N] as the destination data type in the CAST function, the value of the CHAR data type cannot exceed N characters in length.
- DATE
- DATETIME
- DECIMAL
- SIGNED [INTEGER]
- TIME
- UNSIGNED [INTEGER]

The CAST function is applicable when one of the following conditions is met:

- The data types of the two expressions are the same.
- The data types of the two expressions can be converted in an implicit way.
- The data types must be converted in an explicit way.

If an attempt is made to perform an invalid conversion, ApsaraDB for OceanBase returns an error message.

If the length of a data type is not specified, the system uses the maximum length that is supported for the data type in ApsaraDB for OceanBase. For example, the maximum length for the VARCHAR data type is 262,143 bytes. The maximum length for a numeric data type is 65 bits for floating-point numbers.

You can use the CAST function to convert signed and unsigned 64-bit values. If you use a numeric operator such as a plus sign (+) and one of the operands is an unsigned integer, the function returns an unsigned value. To override the numeric operator, you can use the SIGNED or UNSIGNED cast operator. The SIGNED operator converts a value into a signed 64-bit integer and the UNSIGNED cast operator converts a value into an unsigned 64-bit integers.

If an operand is a floating-point value, the result is a floating-point value.

Examples

```
mysql> select cast(1-2 as unsigned), cast(cast(1-2 as unsigned) as signed);
+-----+-----+
| cast(1-2 as unsigned) | cast(cast(1-2 as unsigned) as signed) |
+-----+-----+
| 18446744073709551615 | -1 |
+-----+-----+
1 row in set (0.00 sec)
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
+-----+
| CAST(1 AS UNSIGNED) - 2.0 |
+-----+
| -1.0 |
+-----+
1 row in set (0.00 sec)
mysql> select cast(0 as date);
+-----+
| cast(0 as date) |
+-----+
| 0000-00-00 |
+-----+
1 row in set (0.00 sec)
```

18.5.7.5. Aggregate functions

Aggregate functions perform calculations on a set of values and return a single value. Aggregate functions ignore NULL values. In most cases, aggregate functions are used in conjunction with GROUP BY clauses of SELECT statements.

All the aggregate functions are deterministic. If aggregate functions are invoked by using the same set of input values, the aggregate functions return the same value.

In ApsaraDB for OceanBase, you can specify only one argument for each aggregate function. For example, `COUNT(c1, c2)` is not supported and `COUNT(c1)` is supported.

AVG(**[DISTINCT]** *expr*)

This function returns the average for a specified data set. This function ignores the NULL values in the specified data set. The DISTINCT keyword is used to return the average of distinct expr values. If no matched rows are found, the AVG() function returns NULL.

Examples

```
mysql> select * from oceanbasetest;
+----+-----+-----+
| id | ip | ip2 |
+----+-----+-----+
| 1 | 4 | NULL |
| 3 | 3 | NULL |
| 4 | 3 | NULL |
+----+-----+-----+
3 rows in set (0.01 sec)

mysql> select avg(ip2), avg(ip), avg(distinct(ip)) from oceanbasetest;
+-----+-----+-----+
| avg(ip2) | avg(ip) | avg(distinct(ip)) |
+-----+-----+-----+
| NULL | 3.3333 | 3.5000 |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> select avg(distinct(ip)),avg(ip),avg(ip2) from oceanbasetest;
+-----+-----+-----+
| avg(distinct(ip)) | avg(ip) | avg(ip2) |
+-----+-----+-----+
| 3.5000 | 3.3333 | NULL |
+-----+-----+-----+
1 row in set (0.00 sec)
```

COUNT([DISTINCT] *expr*)

COUNT([DISTINCT] *expr*) returns the number of non-NULL values in the rows that are retrieved by a specified SELECT statement. If no matched rows are found, COUNT() returns 0. The DISTINCT keyword is used to return the number of distinct *expr* values.

COUNT(*) returns the number of retrieved rows. The retrieved rows may contain NULL values.

Examples

```
mysql> select * from oceanbasetest;
+----+-----+-----+
| id | ip  | ip2 |
+----+-----+-----+
| 1  | 4  | NULL |
| 3  | 3  | NULL |
| 4  | 3  | NULL |
+----+-----+-----+
3 rows in set (0.00 sec)

mysql> select count(ip2), count(ip), count(distinct(ip)), count(*) from oceanbasetest;
+-----+-----+-----+-----+
| count(ip2) | count(ip) | count(distinct(ip)) | count(*) |
+-----+-----+-----+-----+
| 0 | 3 | 2 | 3 |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

MAX([DISTINCT] *expr*)

This function returns the maximum value among a specified data set.

You can pass strings into the MAX() function as arguments. If this occurs, the strings are sorted in alphabetical order and the maximum string is returned. You can use the DISTINCT keyword in the function to obtain the maximum value among distinct *expr* value. The function returns the same maximum value if you do not use the DISTINCT keyword.

For example, the a table has three rows of data: `id=1,num=10, id=2,num=20, and id=3,num=30` .

```
mysql> SELECT MAX(num) FROM a;
+-----+
| MAX(num) |
+-----+
| 30 |
+-----+
1 row in set (0.00 sec)
```

MIN([DISTINCT] *expr*)

This function returns the minimum value among a specified data set.

You can pass strings into the MIN() function as arguments. If this occurs, the strings are sorted in alphabetical order and the minimum string is returned. You can use the DISTINCT keyword in the function to obtain the minimum value of distinct *expr* values. The function returns the same minimum value if you do not use the DISTINCT keyword.

For example, the a table has three rows of data: `id=1,num=10, id=2,num=20, and id=3,num=30` .

```
mysql> SELECT MIN(num) FROM a;
+-----+
| MIN(num) |
+-----+
|      10 |
+-----+
1 row in set (0.00 sec)
```

SUM([DISTINCT] *expr*)

This function returns the sum of *expr* values. If no rows are found for *expr*, the SUM() function returns NULL. You can use the DISTINCT keyword to obtain the sum of distinct *expr* values.

If no matched rows are found, the SUM() function returns NULL.

Examples

```
mysql> select * from oceanbasetest;
+-----+-----+-----+
| id | ip | ip2 |
+-----+-----+-----+
|  1 |  4 | NULL |
|  3 |  3 | NULL |
|  4 |  3 | NULL |
+-----+-----+-----+
3 rows in set (0.00 sec)

mysql> select sum(ip2),sum(ip),sum(distinct(ip)) from oceanbasetest;
+-----+-----+-----+
| sum(ip2) | sum(ip) | sum(distinct(ip)) |
+-----+-----+-----+
|  NULL |  10 |      7 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

GROUP_CONCAT([DISTINCT] *expr*)

This function concatenates non-NULL strings from a specified group into a single string.

- Syntax

```
GROUP_CONCAT([DISTINCT] expr [,expr ...]
[ORDER BY {unsigned_integer | col_name | expr}
[ASC | DESC] [,col_name ...]]
[SEPARATOR str_val])
```

- Examples

```

mysql> select * from book; //The table named book (book number, book title, publisher) +-----+-----+
-----+-----+
| bookid | bookname          | publishname      |
+-----+-----+-----+
| 1 | git help          | alibaba group publisher |
| 2 | MySQL Optimization | Zhejiang University Press |
| 3 | Java Programming Guide | Machinery Industry Press |
| 3 | Java Programming Guide | Machinery Industry Press |
| 4 | Large-Scale Distributed Storage System | Machinery Industry Press |
+-----+-----+-----+
5 rows in set (0.00 sec)

//Retrieve book titles.
mysql> select group_concat(bookname) from book group by bookname;
+-----+
| group_concat(bookname) |
+-----+
| git help              |
| Java Programming Guide, Java Programming Guide |
| MySQL Optimization    |
| Large-Scale Distributed Storage System |
+-----+
4 rows in set (0.00 sec)

//Retrieve distinct book titles.
mysql> select group_concat(distinct(bookname)) from book group by bookname;
+-----+
| group_concat(distinct(bookname)) |
+-----+
| git help                        |
| Java Programming Guide          |
| MySQL Optimization              |
| Large-Scale Distributed Storage System |
+-----+
4 rows in set (0.01 sec)

mysql> select bookname, group_concat(publishname order by publishname desc separator ';') from book group by
bookname;
+-----+-----+-----+
| bookname          | group_concat(publishname order by publishname desc separator ';') |
+-----+-----+-----+
| git help          | alibaba group publisher |
+-----+-----+-----+
+-----+-----+-----+
4 rows in set (0.00 sec)

```

18.5.7.6. Mathematical functions

The functions of this type perform mathematical calculations based on numeric expressions.

ROUND(X), ROUND(X,D)

The ROUND() function returns a number that is rounded to the specified length or precision.

This function rounds the X argument to the nearest integer. If you specify two arguments for the function, the function rounds X to D decimal places. The Dth digit is obtained by rounding. To keep D digits of the X value to the left of the decimal point, set D to a negative value.

The data type of the returned value is the same as that of the first argument. You can assume that the value is an integer, double-precision floating-point number, or decimal value. This means that the returned result for an integer argument is also an integer. No fractional part is included in the returned result.

- For exact-value numbers, the ROUND() function rounds values to the nearest integer.
 - If the fractional part of a positive value is `.5` or greater than `.5`, the function rounds the positive value up to the next integer. If the fractional part of a negative value is greater than or equal to `.5`, the function rounds the negative value down to the next integer. In other words, the value is rounded based on the distance between zero and the specified value along the X-axis.
 - If the fractional part of a positive value is smaller than `.5`, the function rounds the value down to the next integer. If the fractional part of a negative value is smaller than `.5`, the function rounds the negative value down to the next integer.
- For approximate-value numbers, the ROUND() function follows the bankers rounding rule. If a value has a fractional part, the function rounds the value to the nearest even integer based on the rule.

Examples

```
mysql> select round(2.15,2);
+-----+
| round(2.15,2) |
+-----+
|      2.15 |
+-----+
1 row in set (0.00 sec)

mysql> select round(2555e-2,1);
+-----+
| round(2555e-2,1) |
+-----+
|      25.6 |
mysql> select round(25e-1), round(25.3e-1),round(35e-1);
+-----+-----+-----+
| round(25e-1) | round(25.3e-1) | round(35e-1) |
+-----+-----+-----+
|      3 |      3 |      4 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

CEIL(expr)

This function rounds a specified expression value up to the next largest integer.

The function supports comparison operations. The comparison result is a BOOLEAN value. The BOOLEAN value is converted into a numeric value: 1 for TRUE or 0 for FALSE.

If the value of `expr` is `NULL`, the function returns `NULL`.

If you specify a string of numbers, the system converts the string into a numeric value in an implicit way.

The returned value is converted into a `BIGINT` number.

Examples

```
mysql> select ceil(1.2), ceil(-1.2), ceil(1+1.5), ceil(1=1),ceil(1<1),ceil(null);
+-----+-----+-----+-----+-----+-----+
| ceil(1.2) | ceil(-1.2) | ceil(1+1.5) | ceil(1=1) | ceil(1<1) | ceil(null) |
+-----+-----+-----+-----+-----+-----+
|      2 |      -1 |          3 |          1 |          0 |        NULL |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> select ceil(name);
ERROR 1166 (42703): Unkown column name 'name'

mysql> select ceil('2');
+-----+
| ceil('2') |
+-----+
|      2 |
+-----+
1 row in set (0.00 sec)
```

FLOOR(*expr*)

This function is similar to the `CEIL(expr)` function. This function rounds a specified expression value down to the next smallest integer.

The function supports comparison operations. The comparison result is a `BOOLEAN` value. The `BOOLEAN` value is converted into a numeric value: 1 for `TRUE` or 0 for `FALSE`.

If the value of `expr` is `NULL`, the function returns `NULL`.

If you specify a string of numbers, the system converts the string into a numeric value in an implicit way.

The returned value is converted into a `BIGINT` number.

Examples

```
mysql> select floor(1.2), floor(-1.2), floor(1+1.5), floor(1=1), floor(1<1), floor(null);
+-----+-----+-----+-----+-----+-----+
| floor(1.2) | floor(-1.2) | floor(1+1.5) | floor(1=1) | floor(1<1) | floor(null) |
+-----+-----+-----+-----+-----+-----+
| 1 | -2 | 2 | 1 | 0 | NULL |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> select floor(name);
ERROR 1166 (42703): Unkown column name 'name'

mysql> select floor('2');
+-----+
| floor('2') |
+-----+
| 2 |
+-----+
1 row in set (0.00 sec)
```

ABS(*expr*)

This function returns the absolute value for a specified numeric expression. The data type of the returned value is the same as that of the expression value.

The function supports comparison operations. The comparison result is a BOOLEAN value. The BOOLEAN value is converted into a numeric value: 1 for TRUE or 0 for FALSE.

If the value of *expr* is NULL, the function returns NULL.

If you specify a string of numbers, the system converts the string into a numeric value in an implicit way.

The returned value is converted into a BIGINT number.

Examples

```
mysql> select abs(5), abs(-5.777), abs(0), abs(1/2), abs(1-5);
+-----+-----+-----+-----+-----+
| abs(5) | abs(-5.777) | abs(0) | abs(1/2) | abs(1-5) |
+-----+-----+-----+-----+-----+
| 5 | 5.777 | 0 | 0.5 | 4 |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

NEG(*expr*)

This function is a negation function that subtracts a specified operand from zero and returns the final result.

The function supports comparison operations. The comparison result is a BOOLEAN value. The NEG function performs the NOT operation. The returned result is 1 or 0: 1 for TRUE and 0 for FALSE.

Examples

```
mysql> select neg(1),neg(1+1),neg(2*3),neg(1=1),neg(5<1);
+-----+-----+-----+-----+-----+
| neg(1) | neg(1+1) | neg(2*3) | neg(1=1) | neg(5<1) |
+-----+-----+-----+-----+-----+
| -1 | -2 | -6 | -1 | 0 |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

SIGN(X)

This function returns the sign of a specified number. The function returns -1, 0, or 1 based on whether the specified X value is negative, zero, or positive.

The function supports comparison operations. The comparison result is a BOOLEAN value. The BOOLEAN value is converted into a numeric value: 1 for TRUE and 0 for FALSE.

If the value of expr is NULL, the function returns NULL.

The function supports floating-point numbers and hexadecimal numbers.

Examples

```
mysql> SELECT SIGN(-32);
-> -1
mysql> SELECT SIGN(0);
-> 0
mysql> SELECT SIGN(234);
-> 1
mysql> select sign(null),sign(false),sign(0x01);
+-----+-----+-----+
| sign(null) | sign(false) | sign(0x01) |
+-----+-----+-----+
| NULL | 0 | 1 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

CONV(N, from_base, to_base)

This function converts a number from one base to another base.

The function converts a number from the *from_base* based to the *to_base* base. The returned result is a string. The value of the N input parameter can be an integer or a string. The minimum base is 2 and the maximum base is 36. If the *to_base* value is a negative number, N is processed as a signed number. Otherwise, N is processed as an unsigned number. If the *from_base* value is a negative number, the value is processed as an integer and the value sign is ignored. The data types of the N argument must be INT or STRING.

The values of *from_base* and *to_base* parameters must be decimal INT values. The value range is the union of [-36,-2] and [2,36].

Invalid input values result in errors. In the following scenarios, the input values are invalid:

- The values of the *from_base* or *to_base* parameter are not valid decimal INT values.
- The values of the *from_base* or *to_base* parameter do not fall within the valid value range: union of [-36,-2] and [2,36] .
- N is an invalid numeric value. For example, N falls out of the following character range: 0 to 9, a to z, or A to Z.

```
mysql> select mod(29,19), 29 mod 19, 29 % 19;
```

```
+-----+-----+-----+
| mod(29,19) | 29 mod 19 | 29 % 19 |
+-----+-----+-----+
|    10 |    10 |    10 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

```
mysql> select mod(19.5, 29);
```

```
+-----+
| mod(19.5, 29) |
+-----+
|    19.5 |
+-----+
1 row in set (0.00 sec)
```

```
mysql> select mod(29, null);
```

```
+-----+
| mod(29, null) |
+-----+
|    NULL |
+-----+
1 row in set (0.00 sec)
```

```
mysql> select mod(100,0);
```

```
+-----+
| mod(100,0) |
+-----+
|    NULL |
+-----+
1 row in set (0.00 sec)
```

POW(X, Y)

This function raises X to the power of Y.

Examples

```
mysql> select pow(4,2), pow(4,-2), pow(1,null);
```

```
+-----+-----+-----+
| pow(4,2) | pow(4,-2) | pow(1,null) |
+-----+-----+-----+
|    16 |    0.0625 |    NULL |
+-----+-----+-----+
1 row in set (0.00 sec)
```

POWER(X, Y)

POWER(X, Y) and POW(X, Y) are equivalent.

RAND([N])

The RAND([N]) function accepts zero or one argument N and returns a random floating-point number that falls within the range of [0,1.0). N is called a random seed. If you need to retrieve a random integer that falls within the range of [i, j), you can use the expression FLOOR(I + RAND() * (j - i)).

If you do not specify N, a random seed is generated during initialization. The RAND() function generates a random number based on this random seed. Therefore, the RAND() function generates a different random number each time the function is invoked.

Examples

```
mysql> select a, b, rand() from t3;
+-----+-----+-----+
| a | b | rand() |
+-----+-----+-----+
| 1 | 1 | 0.641815407799385 |
| 2 | 2 | 0.16825051248841966 |
| 3 | 3 | 0.9158063697775886 |
+-----+-----+-----+
3 rows in set (0.00 sec)

mysql> select a, b, rand() from t3;
+-----+-----+-----+
| a | b | rand() |
+-----+-----+-----+
| 1 | 1 | 0.07428034215632857 |
| 2 | 2 | 0.6239826321825224 |
| 3 | 3 | 0.897072165177271 |
+-----+-----+-----+
3 rows in set (0.00 sec)
```

If you specify N, N is used as the random seed to generate random numbers. The function generates random numbers based on whether N is a constant:

- If N is a constant, N is used as the random seed during initialization. Then, the RAND(N) function generates a random number based on the initialized value. If the values of N are the same, the generated random number sequences are the same.

```
mysql> select a, b, rand(3) from t3;
+-----+-----+-----+
| a | b | rand(3) |
+-----+-----+-----+
| 1 | 1 | 0.9057697559760601 |
| 2 | 2 | 0.37307905813034536 |
| 3 | 3 | 0.14808605345719125 |
+-----+-----+-----+
3 rows in set (0.00 sec)
```

```
mysql> select a, b, rand(3) from t3;
+-----+-----+-----+
| a | b | rand(3) |
+-----+-----+-----+
| 1 | 1 | 0.9057697559760601 |
| 2 | 2 | 0.37307905813034536 |
| 3 | 3 | 0.14808605345719125 |
+-----+-----+-----+
3 rows in set (0.00 sec)
```

- If N is a variable, such as a column name, N is used as the random seed to generate a random number in each function call. If the values of N are the same, the generated random numbers are the same.

```
mysql> select a, b, rand(a), rand(b) from t3;
+-----+-----+-----+-----+
| a | b | rand(a) | rand(b) |
+-----+-----+-----+-----+
| 1 | 1 | 0.40540353712197724 | 0.40540353712197724 |
| 2 | 2 | 0.6555866465490187 | 0.6555866465490187 |
| 3 | 3 | 0.9057697559760601 | 0.9057697559760601 |
+-----+-----+-----+-----+
3 rows in set (0.00 sec)
```

The `RAND([N])` function can be used in SELECT statements and the following clauses: `WHERE` , `ORDER BY` , and `GROUP BY` . This function in the clauses runs based on the preceding rules.

For example, if you need to sort a table in a random way, you can execute the following SQL statement: `select * from t1 order by rand()` . If you need to sample 100 rows of a table in a random way, you can execute the following SQL statement: `select * from t1 order by rand() limit 100` .

18.5.7.7. Comparison functions

Comparison functions compare input values of parameters. The values that can be compared include numbers, characters, and dates.

GREATEST(*value1*, ...)

This function returns the maximum value among the specified input values. This function performs the opposite operation of the `LEAST()` function.

You must specify at least two arguments. If an argument is NULL, the function returns NULL.

If the specified arguments contain numeric values and strings, the system converts the strings to numeric values in an implicit way. If the conversion fails, the system reports errors.

Examples

```
mysql> select greatest('2',1,0), greatest('a','b','c'), greatest('a', NULL, 'c'), greatest('2014-05-15','2014-06-01')\G;
***** 1. row *****
      greatest('2',1,0): 2
      greatest('a','b','c'): c
      greatest('a', NULL, 'c'): NULL
      greatest('2014-05-15','2014-06-01'): 2014-06-01
1 row in set (0.00 sec)
```

LEAST(*value1*, ...)

This function returns the minimum value among the specified arguments. This function performs the opposite operation of the `GREATEST()` function.

You must specify at least two arguments. If an argument is NULL, the function returns NULL.

If the specified arguments contain numeric values and strings, the system converts the strings to numeric values in an implicit way. If the conversion fails, the system reports errors.

Examples

```
mysql> select least('2',4,9), least('a','b','c'), least('a',NULL,'c'), least('2014-05-15','2014-06-01')\G;
***** 1. row *****
      least('2',4,9): 2
      least('a','b','c'): a
      least('a',NULL,'c'): NULL
      least('2014-05-15','2014-06-01'): 2014-05-15
1 row in set (0.00 sec)
```

ISNULL(*expr*)

This function checks whether a specified value of an expression is NULL. If the *expr* value is NULL, the `ISNULL()` function returns 1. Otherwise, the function returns 0.

Examples

```
mysql> SELECT ISNULL(null), ISNULL('test'), ISNULL(123.456), ISNULL('10:00');
+-----+-----+-----+-----+
| ISNULL(null) | ISNULL('test') | ISNULL(123.456) | ISNULL('10:00') |
+-----+-----+-----+-----+
|      1 |      0 |      0 |      0 |
+-----+-----+-----+-----+
1 row in set (0.01 sec)

mysql> SELECT ISNULL(null+1);
+-----+
| ISNULL(null+1) |
+-----+
|      1 |
+-----+
1 row in set (0.00 sec)
```

The ISNULL() function can be used as an alternative to the equal sign (=) comparison. You can use an equal sign (=) operator to check whether an expression value is NULL.

Note If the equal sign (=) operator is used to check whether an expression value is NULL, the returned result is invalid in most cases.

The ISNULL() function provides some features that are the same as the IS NULL operator.

18.5.7.8. Flow control functions

CASE

You can use the following syntax:

```
CASE value WHEN [compare-value] THEN result [WHEN [compare-value] THEN result ...] [ELSE result] END
```

You can also use the following syntax:

```
CASE WHEN [condition] THEN result [WHEN [condition] THEN result ...] [ELSE result] END
```

For the former syntax, the function returns `value=compare-value` .

For the latter syntax, the function returns the result if the first condition is met. If no matched results are available, the function returns the result of the ELSE part. If the ELSE part is unavailable, the function returns NULL.

Examples

```
mysql> select CASE 'b' when 'a' then 1 when 'b' then 2 END;
+-----+
| CASE 'b' when 'a' then 1 when 'b' then 2 END |
+-----+
|                2 |
+-----+
1 row in set (0.00 sec)

mysql> select CASE concat('a','b') when concat('ab') then 'a' when 'b' then 'b' end;
+-----+
| CASE concat('a','b') when concat('ab') then 'a' when 'b' then 'b' end|
+-----+
| a                |
+-----+
1 row in set (0.00 sec)

mysql> select case when 1>0 then 'true' else 'false' end;
+-----+
| case when 1>0 then 'true' else 'false' end |
+-----+
| true                |
+-----+
1 row in set (0.00 sec)
```

IF(*expr1*,*expr2*,*expr3*)

If the *expr1* condition is met, such as *expr1*<>0 and *expr1*<>NULL, the function returns the *expr2* value. Otherwise, the function returns the *expr3* value.

The IF() function returns numeric values or strings based on the data types of *expr2* and *expr3* values.

Examples

```
mysql> select if(5>6, 'T','F'), if (5>6, 1, 0), if(null, 'True', 'False'), if(0, 'True', 'False')\G;
***** 1. row *****
if(5>6, 'T','F'): F
if (5>6, 1, 0): 0
if(null, 'True', 'False'): False
if(0, 'True', 'False'): False
1 row in set (0.00 sec)
```

If one of *expr2* and *expr3* values is NULL, the data type of the IF() function result is the same as that of the non-null expression value.

Default data types of returned values describes the default data types of the values that are returned by the IF() function.

Default data types of returned values

Expression value	Default data type of the returned values
<i>expr2</i> or <i>expr3</i> returns a string.	String
<i>expr2</i> or <i>expr3</i> returns a floating-point number.	Float-pointing number

Expression value	Default data type of the returned values
<i>expr2</i> or <i>expr3</i> returns an integer.	Integer

If *expr2* and *expr3* values are strings and one of the strings is case-sensitive, the returned value is case-sensitive.

IFNULL(*expr1*,*expr2*)

If the *expr1* value is not NULL, the IFNULL() function returns the *expr1* value. Otherwise, the function returns the *expr2* value.

The IFNULL() function returns numeric values or strings based on the data types of arguments.

Examples

```
mysql> SELECT IFNULL('abc', null), IFNULL(NULL+1, NULL+2), IFNULL(1/0, 0/1);
+-----+-----+-----+
| IFNULL('abc', null) | IFNULL(NULL+1, NULL+2) | IFNULL(1/0, 0/1) |
+-----+-----+-----+
| abc          |          NULL |          0.0000 |
+-----+-----+-----+
1 row in set (0.01 sec)
```

NULLIF(*expr1*,*expr2*)

For *expr1=expr2*, the function returns NULL. Otherwise, the function returns the *expr1* value. This rule is the same as that for CASE WHEN *expr2=expr2* THEN NULL ELSE *expr1* END .

Examples

```
mysql> SELECT NULLIF('ABC', 123), NULLIF('123',123), NULLIF(NULL, 'abc');
+-----+-----+-----+
| NULLIF('ABC', 123) | NULLIF('123',123) | NULLIF(NULL, 'abc') |
+-----+-----+-----+
| ABC          | NULL          | NULL          |
+-----+-----+-----+
1 row in set, 1 warning (0.01 sec)
```

 Note

18.5.7.9. Information functions

FOUND_ROWS()

You may use a LIMIT clause in a SELECT statement to limit the number of rows that are returned from the database server to the client.

In some cases, you need to retrieve the actual number of rows that the statement returns if the statement does not have the LIMIT clause. To retrieve the actual number of rows, you can execute the statement that does not have the LIMIT clause again. If you do not want to execute the statement again, you can use `SQL_CALC_FOUND_ROWS` in the SELECT statement. This way, you can invoke the `FOUND_ROW()` function to retrieve the actual number of rows that are returned by the SELECT statement that does not have the LIMIT clause.

Examples

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
-> WHERE id > 100 LIMIT 10;
mysql> SELECT FOUND_ROWS();
```

The second SELECT statement returns a number that may be different from that for the first SELECT statement. The number indicates how many rows are returned by the first SELECT statement if the first statement does not have the LIMIT clause.

 **Note** Assume that `SQL_CALC_FOUND_ROWS` is not used in the first SELECT statement. When you use the LIMIT clause in the statement, the `FOUND_ROWS()` function returns a value. The returned value may be different from the value that is returned when you do not use the LIMIT clause.

For the SELECT `SQL_CALC_FOUND_ROWS` statement in the preceding example, the returned value of the `FOUND_ROWS()` function is valid only for a short period. The returned value becomes invalid when the statement that follows the `SELECT SQL_CALC_FOUND_ROWS` statement is executed. If you need to use the returned number of rows later, you must save the number.

Examples

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you use `SQL_CALC_FOUND_ROWS` in a query, the system calculates the number of rows in the full result set. This process requires less time than the process of running another query that does not use the LIMIT clause. This is because the result set in the former process does not need to be sent to the client.

Assume that you want to limit the number of rows that a query returns and do not want to run another query to retrieve the number of rows in the full result set. In this case, you can use `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()`. For example, you can use a web script for a paged display. The displayed information contains the links to pages for the other parts of the query results. You can use the `FOUND_ROWS()` function to determine the number of additional pages that are required to show the remaining results.

The implementation of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` in UNION queries is more complex than that in simple SELECT statements. This is because a UNION query may contain more than one LIMIT clause. For example, you may use LIMIT clauses in the SELECT statements of a UNION query, or you may use the clauses to limit the UNION results.

If `SQL_CALC_FOUND_ROWS` is used for a UNION query, the expected returned result is the row count that is not limited by the global LIMIT clause.

If you need to use `SQL_CALC_FOUND_ROWS` in a UNION query, make sure the following requirements are met:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first SELECT statement of the UNION query.
- The UNION ALL syntax is used. The returned value of the `FOUND_ROWS()` function is accurate only if `UNION ALL` is used.
- If the UNION query does not contain LIMIT clauses, `SQL_CALC_FOUND_ROWS` is ignored. In this case, the query returns the number of rows in the temporary table that is created to process the UNION query.

LAST_INSERT_ID()

This function returns the auto-increment field value that is latest inserted in the current session. If you insert multiple rows into the table in the latest operation, the `LAST_INSERT_ID()` function returns the auto-increment field value of the first row.

Examples

```
mysql>select LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|          5 |
+-----+
1 row in set (0.00 sec)
```

18.5.7.10. Other functions

COALESCE(*expr, expr, expr,...*)

The function evaluates the argument expressions in sequence until the function finds a non-NULL value. Then, the function returns the non-NULL value. If the values of all the expressions are NULL, the function returns a NULL value.

The data types of all the expressions must be the same. If the data types are different, the system converts the data types into the same type in an implicit way.

```
mysql> SELECT COALESCE(NULL,NULL,3,4,5), COALESCE(NULL,NULL,NULL);
+-----+-----+
| COALESCE(NULL,NULL,3,4,5) | COALESCE(NULL,NULL,NULL) |
+-----+-----+
|          3 |          NULL |
+-----+-----+
1 row in set (0.00 sec)
```

NVL(*str1,replace_with*)

If the *str1* value is NULL, this function replaces the value with the *replace_with* value.

If you set *str1* to NULL, the function returns a value that you specify for the *replace_with* parameter. This helps you retrieve complete outputs. In most cases, the *str1* value is a column name. No limits are placed on the values of `replace_with`. For example, you can specify hard-coded values, references to other columns, or expressions for the *replace_with* parameter.

Examples

```
mysql> SELECT NVL(NULL, 0), NVL(NULL, 'a');
+-----+-----+
| NVL(NULL, 0) | NVL(NULL, 'a') |
+-----+-----+
|          0 | a |
+-----+-----+
1 row in set (0.00 sec)
```

ORA_DECODE()

The `ORA_DECODE()` function runs in the same way as the Oracle `DECODE()` function.

Note ApsaraDB for OceanBase is compatible with MySQL and supports some functions of Oracle. The names of the Oracle functions that are used in ApsaraDB for OceanBase start with `ORA_`.

```
ora_decode (condition, value 1, returned value 1, value 2, returned value 2, ... value n, returned value n, default value)
```

The following section describes the meaning of this function:

```
IF condition = value 1 THEN
....RETURN (returned value 1)
ELSIF condition = value 2 THEN
....RETURN (returned value 2)
.....
ELSIF condition = value n THEN
....RETURN (returned value n)
ELSE
....RETURN (default value)
END IF
```

SLEEP(duration)

This function suspends an SQL query for a specified duration that is measured in seconds. The function returns 0 after the suspension ends.

If only the SLEEP function is run in a query that is not interrupted, the function returns 0, as shown in the following example:

```
mysql> SELECT SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
| 0 |
+-----+
```

If only the SLEEP function is run in a query that is interrupted, the function returns 1 and does not return error codes, as shown in the following example:

```
mysql> SELECT SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
| 1 |
+-----+
```

If the SLEEP function is part of a query and the query is interrupted due to the suspension, the function returns the error code 1317, as shown in the following example:

```
mysql> SELECT 1 FROM t1 WHERE SLEEP(1000);
ERROR 1317 (70100): Query execution was interrupted
```

18.5.7.11. Full-text search functions

```
MATCH (col1,col2,...) AGAINST (expr [search_modifier])
search_modifier:
{
  IN NATURAL LANGUAGE MODE
| IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION
| IN BOOLEAN MODE
| WITH QUERY EXPANSION
}
```

ApsaraDB for OceanBase allows you to use full-text search functions to search for full-text indexes.

When you use the full-text search functions, make sure that the following requirements are met:

- Full-text indexes are created on the columns that are specified in the `MATCH(col1,col2,...)` function. The function supports only `FULLTEXT CTXCAT` indexes.
- For `FULLTEXT CTXCAT` indexes, the columns in the `MATCH(col1,col2,...)` function must include the columns that are specified for the CTXCAT indexes. For example, you can create the `FULLTEXT INDEX(c1, c2, c3) CTXCAT(c2, c3)` index. In this scenario, the retrieved data can be matched only if the function is `MATCH(c2,c3)`.
- You can use search modifiers that are included in the preceding statement to specify the search mode for full-text search functions. The default search mode is `NATURAL LANGUAGE MODE`.

 **Note** ApsaraDB for OceanBase supports only two search modes: `NATURAL LANGUAGE MODE` and `BOOLEAN MODE`.

Full-text search: NATURAL LANGUAGE MODE

If you use the default mode or specify the `IN NATURAL LANGUAGE MODE` search modifier, the `MATCH...AGAINST` function uses the `NATURAL LANGUAGE` mode to run a full-text search. In the `NATURAL LANGUAGE` mode, specify the `AGAINST` argument as a search string. In the index, the function searches for the string by comparing strings based on the character set. For each row in the table, the `MATCH` function returns a relevance value. The value indicates the relevance between the search string and the row data. To be more specific, the value indicates the similarity between the text of the search string and the text in the data table.

By default, string columns in ApsaraDB for OceanBase are not case-sensitive. Therefore, the keywords for full-text searches are not case-sensitive. If you need to run case-sensitive full-text searches, you can specify case-sensitive data types for the columns on which full-text indexes is created. For example, you can specify the data type of the columns as `UTF8MB4_BIN`.

If the `MATCH...AGAINST` function is used in the `WHERE` clause, `MATCH` is used to filter data that is irrelevant to the keywords in the function. ApsaraDB for OceanBase supports only `MATCH...AGAINST=0` and `MATCH...AGAINST>0`. `MATCH...AGAINST=0` indicates that no data matches the keywords and `MATCH...AGAINST>0` indicates that at least one keyword is matched.

You can specify multiple keywords for the `AGAINST` parameter. You must separate the keywords with spaces and enclose the keywords in a single quotation mark ('). This means that the `OR` logical operator is applied on the specified keywords. If the text in the table matches one of the keywords, a match occurs.

Full-text search: BOOLEAN MODE

In ApsaraDB for OceanBase, you can run boolean full-text searches by using the `IN BOOLEAN MODE` search modifier. In this mode, some special operators at the beginning of the keywords in search strings have special meanings.

Examples:

```
SELECT * FROM t1 WHERE MATCH (a, b)
    AGAINST ('Chrysanthemum Jasmine' IN BOOLEAN MODE);
```

id	a	b
1	Alipay	Chrysanthemum tea
2	Taobao	Jasmine

```
SELECT * FROM t1 WHERE MATCH (a, b)
    AGAINST ('+Chrysanthemum -Jasmine tea' IN BOOLEAN MODE);
```

id	a	b
1	Alipay	Chrysanthemum tea

In ApsaraDB for OceanBase, boolean full-text searches support the following operators:

- The plus sign (+) represents the AND operator. The AND operator indicates that the search results must include the keyword that is preceded by the plus sign (+).
- The minus sign (-) represents the NOT operator. The NOT operator indicates that the search results must exclude the keyword that is preceded by the minus sign (-).
- If *no operator* is specified, the OR operator is applied on the specified keywords. The OR operator indicates that the search results must include at least one of the specified keywords.

When you run boolean full-text searches, make sure the following requirements are met:

- All the operators must be placed at the beginning of keywords. The operators at the end of keywords are ignored. For example, the plus sign (+) in `+Chrysanthemums` is valid and takes effect. The plus sign (+) in `Chrysanthemums+` is invalid and ignored.
- Operators and keywords cannot be separated with other characters. If operators and keywords are separated with other characters, the operators are ignored. For example, the plus sign (+) in `+ Chrysanthemums` is ignored.

18.5.8. Operators and precedences

18.5.8.1. Overview

ApsaraDB for OceanBase supports a wide range of operators: arithmetic operators, comparison operators, vector comparison operators, logical operators, and bitwise operators. The other topics in the "Operators and precedences" chapter describe each of the listed operators and their precedences.

18.5.8.2. Logical operators

In ApsaraDB for OceanBase, the logical operators convert left and right operands into the values of the BOOLEAN data type before the operators perform calculations. If Error is returned for logical operations, calculation errors occur.

In ApsaraDB for OceanBase, you must comply with the following rules when you convert the specified values into the values of the BOOLEAN data type:

- Only the following strings can be converted into the values of the BOOLEAN data type: True, False, 1, and 0. The strings True and 1 are converted into True Boolean values. The strings False and 0 are converted into False Boolean values.
- If a numeric value of the INT, FLOAT, DOUBLE, or DECIMAL data type is converted into a value of the BOOLEAN data type and the numeric value is not zero, the result value is True. If the numeric value to be converted is zero, the result value is False.

NOT!

The logical NOT operator. If you need to use the operator to perform calculations, you must convert the data types of input values based on the specified rules. The following table describes the rules of converting the data types for the operator.

INT	FLOAT	DOUBLE	TIMESTAMP	VARCHAR	BOOL	NULL
True/False	True/False	True/False	Error	True/False/E	True/False	NULL

Example:

```
mysql> SELECT NOT 0, NOT 1, NOT NULL;
+-----+-----+-----+
| NOT 0 | NOT 1 | NOT NULL |
+-----+-----+-----+
|  1   |  0   |  NULL   |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> select not current_timestamp;
+-----+
| not current_timestamp |
+-----+
|          0           |
+-----+
1 row in set (0.00 sec)

mysql> select not now();
+-----+
| not now() |
+-----+
|    0     |
+-----+
1 row in set (0.00 sec)
```

AND &&

The logical AND operator. If you need to use the operator to perform calculations, you must convert the data types of input values based on the specified rules. The following table describes the rules of converting the data types for the operator.

- INT FLOAT DOUBLE TIMESTAMP VARCHAR BOOL NULL INT True/False True/False True/False Error
 True/False/Error True/False False/NULL FLOAT - True/False True/False Error True/False/Error True/False
 False/NULL DOUBLE - - True/False Error True/False/Error True/False False/NULL TIMESTAMP - - - Error Error
 True/False Error VARCHAR - - - - True/False/Error True/False/Error False/NULL BOOL - - - - True/False
 False/NULL NULL - - - - - NULL

Examples:

```
mysql> SELECT (0 AND 0), (0 AND 1), (1 AND 1), (1 AND NULL);
+-----+-----+-----+-----+
| (0 AND 0) | (0 AND 1) | (1 AND 1) | (1 AND NULL) |
+-----+-----+-----+-----+
| 0 | 0 | 1 | NULL |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

OR ||

The logical OR operator. If you need to use the operator to perform calculations, you must convert the data types of input values based on the specified rules. The following table describes the rules of converting the data types for the operator.

-	INT	FLOAT	DOUBLE	TIMESTAMP	VARCHAR	BOOL	NULL	INT	True/False	True/False	True/False	Error	True/False/Error	True/False	True/NULL	FLOAT	-	True/False	True/False	Error	True/False/Error	True/False	True/NULL	DOUBLE	-	-	True/False	Error	True/False/Error	True/False	True/NULL	TIMESTAMP	-	-	Error	Error	Error	Error	VARCHAR	-	-	-	-	True/False/Error	True/False/Error	True/NULL	BOOL	-	-	-	-	True/False	True/NULL	NULL	-	-	-	-	NULL
---	-----	-------	--------	-----------	---------	------	------	-----	------------	------------	------------	-------	------------------	------------	-----------	-------	---	------------	------------	-------	------------------	------------	-----------	--------	---	---	------------	-------	------------------	------------	-----------	-----------	---	---	-------	-------	-------	-------	---------	---	---	---	---	------------------	------------------	-----------	------	---	---	---	---	------------	-----------	------	---	---	---	---	------

Example:

```
mysql> SELECT (0 OR 0), (0 OR 1), (1 OR 1), (1 AND NULL);
+-----+-----+-----+-----+
| (0 OR 0) | (0 OR 1) | (1 OR 1) | (1 AND NULL) |
+-----+-----+-----+-----+
| 0 | 1 | 1 | NULL |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

18.5.8.3. Arithmetic operators

In ApsaraDB for OceanBase, you can perform arithmetic operations on only the values of the numeric data types or the VARCHAR data type. If you perform arithmetic operations on the values of other data types, errors are reported. If you perform arithmetic operations on strings and the strings cannot be converted to the values of the DOUBLE data type, errors are reported. For example, if you perform the '3.4he' + 3 operation, an error is reported.

Strings can be converted into the values of the DOUBLE data type only in two scenarios. In one of the scenarios, each character in the strings is a digit. In the other scenario, the strings start with plus signs (+) or minus signs (-) and the characters that follow the plus signs (+) or the minus signs (-) are digits.

Supported arithmetic operators describes the arithmetic operators that ApsaraDB for OceanBase supports.

Supported arithmetic operators

Expression	Description	Example
+	The addition operator.	SELECT 2+3;
-	The minus operator.	SELECT 2-3;
*	The multiplication operator.	SELECT 2*3;

Expression	Description	Example
/	The division operator. The returned results are quotients. If the divisor is 0, NULL is returned.	SELECT 2/3;
% or MOD	The modulo operator. The returned results are remainders. If the divisor is 0, NULL is returned.	SELECT 2%3, 2 MOD 3;
^	Raises the specified number to the power of another number.	SELECT 2^2

If you need to use the addition (+), minus (-), and asterisk (*) operators to perform calculations, you must convert the data types of input values based on the specified rules. The following table describes the rules of converting the data types for these operators. - INT FLOAT DOUBLE TIMESTAMP VARCHAR BOOL INT INT DOUBLE DOUBLE Error DOUBLE/Error Error FLOAT - DOUBLE DOUBLE Error DOUBLE/Error Error DOUBLE - - DOUBLE Error DOUBLE/Error Error TIMESTAMP - - - Error Error Error VARCHAR - - - - DOUBLE/Error Error BOOL - - - - Error

If you need to use the division (/) operator to perform calculations, you must convert the data types of input values based on the specified rules. The following table describes the rules of converting the data types for the operator. If the divisor is zero, an error is returned.

- INT FLOAT DOUBLE TIMESTAMP VARCHAR BOOL NULL INT DOUBLE/Error DOUBLE/Error DOUBLE/Error Error DOUBLE/Error Error NULL/Error FLOAT - DOUBLE/Error DOUBLE/Error Error DOUBLE/Error Error NULL/Error DOUBLE - - DOUBLE/Error Error DOUBLE/Error Error NULL/Error TIMESTAMP - - - Error Error Error Error VARCHAR - - - - DOUBLE/Error Error NULL/Error BOOL - - - - Error Error NULL NULL

If you need to use the percent sign (%) and MOD operators to perform calculations, you must convert the data types of input values based on the specified rules. The following table describes the rules of converting the data types for these operators. - INT FLOAT DOUBLE TIMESTAMP VARCHAR BOOL NULL INT INT DOUBLE DOUBLE Error DOUBLE/Error Error NULL FLOAT - DOUBLE DOUBLE Error DOUBLE/Error Error NULL DOUBLE - - DOUBLE Error DOUBLE/Error Error NULL T IMESTAMP - - - Error Error Error Error VARCHAR - - - - DOUBLE/Error Error NULL/Error BOOL - - - - Error Error NULL NULL

18.5.8.4. Comparison operators

In ApsaraDB for OceanBase, operands are compared after they are converted into the values of the same type. You can use comparison operators to compare the operands. All the comparison operators return NULL or the values of the BOOLEAN data type. If the comparison result is true, 1 is returned. If the comparison result is false, 0 is returned. If the comparison result is unknown, NULL is returned.

Compare numeric values

You can use a comparison operator to compare two numeric values.

[Comparison operators](#) describes the comparison operators that ApsaraDB for OceanBase supports.

Comparison operators

Expression	Description	Example
=	Equal to	SELECT 1=0, 1=1, 1=NULL;
>=	Greater than or equal to	SELECT 1>=0, 1>=1, 1>=2, 1>=NULL;
>	Greater than	SELECT 1>0, 1>1, 1>2, 1>NULL;

Expression	Description	Example
<=	Less than or equal to	<code>SELECT 1<=0, 1<=1, 1<=2, 1<=NULL;</code>
<	Less than	<code>SELECT 1<0, 1<1, 1<2, 1<NULL;</code>
!= or <>	Not equal to	<code>SELECT 1!=0, 1!=1, 1<>0, 1<>1, 1!=NULL, 1<>NULL;</code>

If you need to use the comparison operators to perform calculations, you must convert the data types of the input values based on the specified rules. The following table describes the rules of converting the data types for the comparison operators.

- INT FLOAT DOUBLE TIMESTAMP VARCHAR BOOL NULL
 INT INT FLOAT DOUBLE Error ? INT Error NULL FLOAT - FLOAT DOUBLE Error ? FLOAT Error NULL DOUBLE - - DOUBLE Error ? DOUBLE Error NULL
 TIMESTAMP - - - TIMESTAMP ? TIMESTAMP Error NULL VARCHAR - - - - VARCHAR ? BOOL NULL BOOL - - - - - BOOL NULL NULL NULL

Note

- ? ApsaraDB for OceanBase attempts to convert the specified data types to the data types that start with question marks (?) before the comparisons are performed. If the type conversion fails, errors are reported.
- If you compare the values of the BOOLEAN data type, False is smaller than True.

[NOT] BETWEEN ... AND ...

Checks whether the specified value falls in or out of a range of values.

```
mysql> SELECT 2 BETWEEN 1 AND 2,
3 NOT BETWEEN 1 AND 2,
1 BETWEEN null AND 0,
1 NOT BETWEEN null AND 0\G;
***** 1. row *****
2 BETWEEN 1 AND 2: 1
3 NOT BETWEEN 1 AND 2: 1
1 BETWEEN null AND 0: 0
1 NOT BETWEEN null AND 0: 1
1 row in set (0.00 sec)
```

Example:

The following two tables are available: emp that stores the employee information and salgrade that stores the salary information. The employee information includes employee names and salaries. The salary information includes salary ranges and salary levels. In this example, you can execute the following statements to query the employee names, salaries, and salary levels.

```
mysql> select * from emp; //emp is the table that stores the employee information.
+-----+-----+
| ename | sal  |
+-----+-----+
| Jerry | 25000.00 |
| Larry | 40000.00 |
| Maggie | 46000.00 |
| Micky | 15000.00 |
+-----+-----+
4 rows in set (0.00 sec)
mysql> select * from salgrade; //salgrade is the table that stores the salary information.
+-----+-----+-----+
| grade | losal | hisal |
+-----+-----+-----+
| 1 | 10000.00 | 20000.00 |
| 2 | 20001.00 | 30000.00 |
| 3 | 30001.00 | 40000.00 |
| 4 | 40001.00 | 50000.00 |
| 5 | 50001.00 | 90000.00 |
+-----+-----+-----+
5 rows in set (0.00 sec)
mysql> select a1.ename, a1.sal, a2.grade from emp a1, salgrade a2 where a1.sal between a2.losal and a2.hisal; //The
BETWEEN...AND... operator specifies the query criteria.
+-----+-----+-----+
| ename | sal  | grade |
+-----+-----+-----+
| Micky | 15000.00 | 1 |
| Jerry | 25000.00 | 2 |
| Larry | 40000.00 | 3 |
| Maggie | 46000.00 | 4 |
+-----+-----+-----+
4 rows in set (0.00 sec)
```

[NOT] IN

Checks whether the specified value falls within a specified range.

Example:

```
mysql> SELECT 2 IN (1, 2), 3 IN (1, 2)\G;
***** 1. row *****
2 IN (1, 2): 1
3 IN (1, 2): 0
1 row in set (0.00 sec)
```

IS [NOT] NULL | TRUE | FALSE | UNKNOWN

Checks whether a value is NULL, true, false, or unknown. If the operation is successful, TRUE or FALSE is returned. In this scenario, NULL is not returned.

Example:

```
mysql> SELECT 0 IS NULL,
NULL IS NULL, NULL IS TRUE,
(0>1) IS FALSE,
NULL IS UNKNOWN,
0 IS NOT NULL,
NULL IS NOT NULL,
NULL IS NOT TRUE,
(0>1) IS NOT FALSE,
NULL IS NOT UNKNOWN\G;
***** 1. row *****
      0 IS NULL: 0
      NULL IS NULL: 1
      NULL IS TRUE: 0
      (0>1) IS FALSE: 1
      NULL IS UNKNOWN: 1
      0 IS NOT NULL: 1
      NULL IS NOT NULL: 0
      NULL IS NOT TRUE: 1
      (0>1) IS NOT FALSE: 0
      NULL IS NOT UNKNOWN: 0
1 row in set (0.00 sec)
```

Vector comparison operators

Vector comparison operators compare two vectors or rows. The supported operators are `<`, `>`, `=`, `<=`, `>=`, `!=`, `<=>`, `IN`, and `NOT IN`. All these operators are binary operators. Each two vectors to be compared must have the same number of dimensions.

The `<=>` operator represents `NULL-safe equal`. The `<=>` operator is similar to the equal to (`=`) operator and performs equality comparisons. However, if both operands are `NULL`, the `<=>` operator returns 1 instead of `NULL`. If only one operand is `NULL`, the `<=>` operator returns 0 instead of `NULL`.

The expressions `(1,2)` and `ROW(1,2)` are also known as row constructors. The expressions `(1,2)` and `ROW(1,2)` are equivalent. The two expressions are valid in other contexts. For example, the following two statements are equivalent. However, only the second statement can be optimized.

```
SELECT * FROM t1 WHERE (column1, column2) = (1, 1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

If comparison results are returned after the first `i` scalars of each two operands are compared, vector comparison operators do not continue to compare the other numeric values of the operands. This is the main difference between vector comparison operators and general operators.

When you use vector comparison operators, pay attention to the following considerations:

- To compare `n`-tuple vectors, you can omit the `ROW` keyword. Note that `n` must be larger than or equal to three. For example, `ROW(1,2,3) < ROW(1,3,5)` is equivalent to `(1,2,3) < (1,3,5)`.
- The `IN` and `NOT IN` operators can be used only in vector operations. The `IN` operator indicates that the left parameter value is included in the right value set. The `NOT IN` operator indicates that the left parameter value is excluded from the right value set. Each right value set is enclosed in parentheses `()`. For example, you can specify `1 in (2, 3, 1)` for comparison.

- For `IN` or `NOT IN` operators, the scalar operands in the corresponding positions must be comparable. Otherwise, errors are reported. For example, `ROW(1,2) in (ROW(1,2), ROW(2,3), ROW(3,4))` is valid and `ROW(1,2) in (ROW(2,1), ROW(2,3), ROW(1,3,4))` is invalid.

Examples:

```
mysql> SELECT ROW(1,2) < ROW(1, 3),
-> ROW(1,2,10) < ROW(1, 3, 0),
-> ROW(1,null) < ROW(1,0),
-> ROW(null, 1) < ROW(null, 2),
-> ROW(1,2) in (ROW(1,2), ROW(2,3), ROW(3,4), ROW(4,5)),
-> 1 in (1,2,3),
-> 1 not in (2,3,4),
-> ROW(1,2) not in (ROW(2,1),ROW(2,3), ROW(3,4)),
-> NULL = NULL,
-> NULL <=> NULL,
-> NULL <=> 1,
-> 1 <=> 0 \G;
***** 1. row *****
      ROW(1,2) < ROW(1, 3): 1
      ROW(1,2,10) < ROW(1, 3, 0): 1
      ROW(1,null) < ROW(1,0): NULL
      ROW(null, 1) < ROW(null, 2): NULL
ROW(1,2) in (ROW(1,2), ROW(2,3), ROW(3,4), ROW(4,5)): 1
      1 in (1,2,3): 1
      1 not in (2,3,4): 1
      ROW(1,2) not in (ROW(2,1),ROW(2,3), ROW(3,4)): 1
      NULL = NULL: NULL
      NULL <=> NULL: 1
      NULL <=> 1: 0
      1 <=> 0: 0
1 row in set (0.00 sec)
```

18.5.8.5. Vector comparison operators

Vector comparison operators compare two vectors or rows. The supported operators are less than (`<`), greater than (`>`), equal to (`=`), less than or equal to (`<=`), greater than or equal to (`>=`), not equal to (`!=`), `<=>`, `IN`, and `NOT IN`. All these operators are binary operators. Each two vectors to be compared must have the same number of dimensions.

The `<=>` operator represents NULL-safe equal. The `<=>` operator is similar to the equal to the (`=`) operator and performs equality comparisons. However, if both operands are NULL, the `<=>` operator returns 1 instead of NULL. If only one operand is NULL, the `<=>` operator returns 0 instead of NULL.

The expressions `(1,2)` and `ROW(1,2)` are also known as row constructors. The expressions `(1,2)` and `ROW(1,2)` are equivalent. The two expressions are valid in other contexts.

For example, the following two statements are equivalent. However, only the second statement can be optimized.

```
SELECT * FROM t1 WHERE (column1, column2) = (1, 1);
```

```
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

Vector comparison operators differ from general operators in the following aspects:

- If comparison results are returned after the first i scalars of each two operands are compared, vector comparison operators do not continue to compare the other numeric values of the operands.
- When you use vector comparison operators, pay attention to the following considerations:
 - To compare n -tuple vectors, you can omit the ROW keyword. Note that n must be larger than or equal to three.

For example, `ROW(1,2,3) < ROW(1,3,5)` is equivalent to `(1,2,3) < (1,3,5)`.

- The IN and NOT IN operators can be used only in vector operations. The IN operator indicates that the left parameter value is included in the right value set. The NOT IN operator indicates that the left parameter value is excluded from the right value set. Each right value set is enclosed in parentheses ().

For example, you can specify `1 in (2, 3, 1)` for comparison.

- For IN or NOT IN operators, the scalar operands in the corresponding positions must be comparable. Otherwise, errors are reported.

For example, `ROW(1,2) in (ROW(1,2), ROW(2,3), ROW(3,4))` is valid and `ROW(1,2) in (ROW(2,1), ROW(2,3), ROW(1,3, 4))` is invalid.

Examples

```
mysql> SELECT ROW(1,2) < ROW(1, 3),
-> ROW(1,2,10) < ROW(1, 3, 0),
-> ROW(1,null) < ROW(1,0),
-> ROW(null, 1) < ROW(null, 2),
-> ROW(1,2) in (ROW(1,2), ROW(2,3), ROW(3,4), ROW(4,5)),
-> 1 in (1,2,3),
-> 1 not in (2,3,4),
-> ROW(1,2) not in (ROW(2,1),ROW(2,3), ROW(3,4)),
-> NULL = NULL,
-> NULL <=> NULL,
-> NULL <=> 1,
-> 1 <=> 0 \G;
***** 1. row *****
      ROW(1,2) < ROW(1, 3): 1
      ROW(1,2,10) < ROW(1, 3, 0): 1
      ROW(1,null) < ROW(1,0): NULL
      ROW(null, 1) < ROW(null, 2): NULL
ROW(1,2) in (ROW(1,2), ROW(2,3), ROW(3,4), ROW(4,5)): 1
      1 in (1,2,3): 1
      1 not in (2,3,4): 1
      ROW(1,2) not in (ROW(2,1),ROW(2,3), ROW(3,4)): 1
      NULL = NULL: NULL
      NULL <=> NULL: 1
      NULL <=> 1: 0
      1 <=> 0: 0
1 row in set (0.00 sec)
```

18.5.8.6. Bitwise operators

In ApsaraDB for OceanBase, bit operations are performed on the values of the BIGINT data type. BIGINT is a data type that stores 64-bit integers. For bitwise operators, the maximum number of bits for each value is 64.

Bitwise operators describes the bitwise operators that ApsaraDB for OceanBase supports.

Bitwise operators

Expression	Description	Example
BIT_COUNT(N)	Returns the number of bits that are specified by the parameter N.	SELECT BIT_COUNT(29);-> 4
&	The bitwise AND operator.	SELECT 29 & 15;-> 13 The returned value is an unsigned 64-bit integer.

Expression	Description	Example
~	Inverts all the bits.	<pre>SELECT 29 & ~15;-> 16</pre> <p>The returned value is an unsigned 64-bit integer.</p>
	The bitwise OR operator.	<pre>SELECT 29 ~15;-> 31</pre> <p>The returned value is an unsigned 64-bit integer.</p>
^	The bitwise XOR operator.	<pre>SELECT 1 ^ 1;-> 0</pre> <p>The returned value is an unsigned 64-bit integer.</p>
<<	Shifts the specified value of the BIGINT data type to the left by two bits.	<pre>SELECT 1 << 2;-> 4</pre> <p>The returned value is an unsigned 64-bit integer.</p>
>>	Shifts the specified value of the BIGINT data type to the right by two bits.	<pre>SELECT 4 << 2;-> 1</pre> <p>The returned value is an unsigned 64-bit integer.</p>

18.5.8.7. Operator precedences

If you need to use ApsaraDB for OceanBase operators to perform mixed operations, you must familiarize yourself with the operator precedences.

Operator precedences describes the operators that ApsaraDB for OceanBase supports. The following table lists the operators based on precedences in descending order.

Operator precedences

Precedence	Operator
15	!
14	- (unary minus) and ~
13	^
12	*, /, %, and MOD
11	+, -
10	<<, >>
9	&

Precedence	Operator
8	
7	= (comparison operator: equal to), <=>, >, >=, <, <=, <>, !=, IS, LIKE, REGEXP, and IN
6	BETWEEN
5	NOT
4	AND and &&
3	XOR
2	OR and
1	= (assignment operator)

 **Note** You can use parentheses () to enclose the operations that you want to perform before the other operations. This also helps you identify the operations that have high precedences.

18.5.9. Escape characters

An escape character is a character sequence that is prefixed with a backslash (\) in a string and invokes an alternative interpretation on the subsequent characters.

Escape characters are case-sensitive. For example, `\b` represents the backspace and `\B` represents the B character.

Escape characters describes the escape characters that can be recognized by ApsaraDB for OceanBase.

Escape characters

Escape character	Description
<code>\b</code>	The backspace.
<code>\f</code>	The form feed.  Note MySQL does not support this escape character.
<code>\n</code>	The line feed.
<code>\r</code>	The carriage return.
<code>\t</code>	The tab character.
<code>\\</code>	The backslash (\).
<code>\'</code>	The single quotation mark (').
<code>\"</code>	The double quotation mark (").
<code>_</code>	The underscore (_).
<code>\%</code>	The percent sign (%).
<code>\0</code>	The NULL character.

Escape character	Description
\Z	<p>The ASCII 26 character. The corresponding key combination is Ctrl+Z.</p> <p>In Windows, ASCII 26 is the end-of-file indicator. You can encode the ASCII 26 character as \Z so that ASCII 26 is not interpreted as the end-of-file indicator.</p>

18.5.10. DDL statements

18.5.10.1. Overview

Data definition language (DDL) statements allow you to manage basic database components. For example, you can execute DDL statements to create, modify, and delete tables.

ApsaraDB for OceanBase supports a wide range of DDL statements. For example, the following statements are supported: CREATE DATABASE , ALTER DATABASE , DROP DATABASE , CREATE TABLE , DROP TABLE , ALTER TABLE , CREATE INDEX , DROP INDEX , CREATE VIEW , DROP VIEW , ALTER VIEW , TRUNCATE TABLE .

18.5.10.2. CREATE DATABASE

Syntax

```
CREATE DATABASE [IF NOT EXISTS] dbname
    [create_specification_list];

create_specification_list:
    create_specification [create_specification...]

create_specification:
    [DEFAULT] CHARACTER SET [=] charsetname
    | [DEFAULT] COLLATE [=] collationname
    | REPLICAS [=] num
    | PRIMARY_ZONE [=] zone
    | DEFAULT TABLEGROUP [=] {NULL | tablegroupname}
```

The CREATE DATABASE statement allows you to create a database. When you create the database, you can specify the default attributes for the database, such as the default character set and collation.

Notes:

- REPLICAS specifies the number of replicas.
- PRIMARY_ZONE specifies the primary zone of the database. Before you specify this attribute, make sure that the primary zone is included in the zone list of the tenant.
- DEFAULT TABLEGROUP specifies the default table group of the database. If you do not specify this parameter, the default value NULL is used.

Examples

```
root@(none) 01:36:27>create database test2 default CHARACTER SET UTF8;
Query OK, 1 row affected (0.00 sec)
root@(none) 01:36:44>create database test3 CHARACTER SET UTF8;
Query OK, 1 row affected (0.00 sec)
```

Errors

- If the database that you want to create already exists and you do not add `IF NOT EXISTS` to the statement, the system returns the following error: `ERROR 1007 (HY000): Can't create database 'test3'; database exists` .
- If a syntax error occurs, the system returns the following error: `ERROR 1064 (42000): You have an error in your SQL syntax` .
- If the length of the specified database name exceeds the maximum length, the system returns the following error: `ERROR 1059 (42000): Identifier name 'XXXX' is too long` .

18.5.10.3. ALTER_DATABASE

Syntax

```
ALTER DATABASE [dbname]
    alter_specification_list;

alter_specification_list:
    [SET] alter_specification [alter_specification...]

alter_specification:
    [DEFAULT] {CHARACTER SET | CHARSET} [=] charsetname
    | [DEFAULT] COLLATE [=] collationname
    | REPLICA_NUM [=] num
    | PRIMARY_ZONE [=] zonenumber
    | {READ ONLY | READ WRITE}
    | DEFAULT TABLEGROUP [=] {NULL | tablegroupname}
```

The `ALTER_DATABASE` statement allows you to change the attributes of a specified database. For example, you can change the following attributes: character set, collation, the number of replicas, primary zone, database permissions, and default table group. `REPLICA_NUM` specifies the number of replicas. `PRIMARY_ZONE` specifies the primary zone. `READ ONLY| READ WRITE` specifies whether the database is read-only. `READ ONLY` indicates that users can have only read access to the database, and `READ WRITE` indicates that users can have read and write access to the database. `DEFAULT TABLEGROUP` specifies the default table group of the database. If the value is `NULL`, the default table group is deleted.

The database name is optional. If you do not specify the database name, the statement takes effect on the current database.

Examples

```
alter database test2 DEFAULT CHARACTER SET UTF8;
```

Errors

- If a syntax error occurs, the system returns the following error: `ERROR 1064 (42000): You have an error in your SQL syntax .`
- If the specified database name is invalid or the database does not exist, the system returns the following error: `ERROR 1049 (42000): Unknown database .`

```
mysql> alter database notest default character set utf8;
ERROR 1049 (42000): Unknown database
```

18.5.10.4. DROP DATABASE

Syntax

```
DROP DATABASE [IF EXISTS] dbname;
```

The `DROP DATABASE` statement allows you to drop all the tables in a specified database and delete the database.

If you add `IF EXISTS` to the statement and the specified database does not exist, no errors are reported.

Examples

```
mysql> drop database notest;
ERROR 1008 (HY000): Can't drop database 'notest'; database doesn't exist
mysql> drop database if exists notest;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> show warnings;
+-----+-----+-----+-----+
| Level | Code | Message                               |      |
+-----+-----+-----+-----+
| Note  | 1008 | Can't drop database 'notest'; database doesn't exist |      |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

Errors

- If a syntax error occurs, the system returns the following error: `ERROR 1064 (42000): You have an error in your SQL syntax .`
- If the specified database does not exist, the system returns the following error: `ERROR 1008 (HY000): Can't drop database 'XXX'; database doesn't exist .`

18.5.10.5. CREATE TABLE

The `CREATE TABLE` statement allows you to create a table in a specified ApsaraDB for OceanBase database.

Syntax

```
CREATE TABLE [IF NOT EXIST] tblname
(create definition )
```

```

[create_definition,...]
[table_options]
[partition_options];

CREATE TABLE [IF NOT EXISTS] tblname
LIKE oldtblname

create_definition:
colname column_definition
| PRIMARY KEY (index_col_name [, index_col_name...]) [index_type] [index_options]...
  | {INDEX|KEY} [indexname] (index_col_name,...) [index_type] [index_options]...
  | UNIQUE [INDEX|KEY] [indexname] (index_col_name,...) [index_type] [index_options]...
| FULLTEXT [INDEX|KEY] [indexname] (index_col_name,...) CTXCAT(index_col_name,...) [index_options]...

column_definition:
  data_type [NOT NULL | NULL] [DEFAULT defaultvalue]
  [AUTO_INCREMENT] [UNIQUE [KEY]] | [[PRIMARY] KEY]
  [COMMENT 'string']
| [data_type] [GENERATED ALWAYS] AS (expression)
  [VIRTUAL | STORED] [UNIQUE [KEY]] [COMMENT comment]
  [NOT NULL | NULL] [[PRIMARY] KEY]

data_type:
TINYINT[(length)] [UNSIGNED] [ZEROFILL]
| SMALLINT[(length)] [UNSIGNED] [ZEROFILL]
| MEDIUMINT[(length)] [UNSIGNED] [ZEROFILL]
| INT[(length)] [UNSIGNED] [ZEROFILL]
| INTEGER[(length)] [UNSIGNED] [ZEROFILL]
| BIGINT[(length)] [UNSIGNED] [ZEROFILL]
| REAL[(length,decimals)] [UNSIGNED] [ZEROFILL]
| DOUBLE[(length,decimals)] [UNSIGNED] [ZEROFILL]
| FLOAT[(length,decimals)] [UNSIGNED] [ZEROFILL]
| DECIMAL[(length[,decimals])] [UNSIGNED] [ZEROFILL]
| NUMERIC[(length[,decimals])] [UNSIGNED] [ZEROFILL]
| DATE
| TIME[(fsp)]
| TIMESTAMP[(fsp)]
| DATETIME[(fsp)]
| YEAR
| CHAR[(length)]
  [CHARACTER SET charsetname] [COLLATE collationname]
| VARCHAR(length)
  [CHARACTER SET charsetname] [COLLATE collationname]
| BINARY[(length)]
| VARBINARY(length)

index_col_name:

```

```

colname [(length)] [ASC | DESC] ApsaraDB for OceanBase does not support prefix indexes.[(length)]

index_type:
    USING BTREE

index_options:
    index_option [index_option...]

index_option:
GLOBAL [LOCAL]
    |COMMENT 'string'
    |COMPRESSION [=] {NONE | LZ4_1.0 | LZO_1.0 | SNAPPY_1.0 | ZLIB_1.0}
    |BLOCK_SIZE [=] size
    |STORING(columnname_list)
| VISIBLE [INVISIBLE]

columnname_list:
    colname [, colname...]

table_options:
    table_option [table_option]...

table_option:
[DEFAULT] {CHARACTER SET| CHARSET} [=] charsetname
| [DEFAULT] COLLATE [=] collationname
| COMMENT [=] 'string'
| COMPRESSION [=] {NONE | LZ4_1.0 | LZO_1.0 | SNAPPY_1.0 | ZLIB_1.0}
| EXPIRE_INFO [=] expr
| REPLICANUM [=] num
| TABLE_ID [=] id
| BLOCK_SIZE [=] size
| USE_BLOOM_FILTER [=] {True | False}
| STEP_MERGE_NUM [=] num
    | TABLEGROUP [=] 'tablegroupname'
| PRIMARY_ZONE [=] zonelist
| AUTO_INCREMENT [=] num
| PCTFREE [=] integer
    | LOCALITY [=] locality

partition_options:
    PARTITION BY
    HASH(expr)
    |KEY(column_list)
    PARTITIONS num
    [partition_definition ...]

partition_definition:

```

```
COMMENT [=] 'string'
```

 **Note** B-tree indexes are created for the data that is stored in ApsaraDB for OceanBase. The data is sorted based on primary keys. In ApsaraDB for OceanBase, you do not need to specify primary keys because the system automatically generates the primary keys.

The `CREATE TABLE` statement supports the `UNIQUE` constraint. The `CREATE TABLE` statement does not support temporary tables or the `CHECK` constraint. When you execute the statement to create a table, you cannot import data from other tables to the table that you want to create.

Notes:

- If you add `IF NOT EXISTS` to the statement and the table that you want to create already exists, the system does not return an error. If you do not add `IF NOT EXISTS` to the statement, the system returns an error.
- For more information about the `data_type` parameter, see [Data types](#).
- `NOT NULL`, `DEFAULT`, and `AUTO_INCREMENT` are used to implement integrity constraints on columns.
- [Parameters of table_option](#) describes the `table_option` parameters. The parameters are separated with commas (,).

Parameters of table_option

Parameter	Description	Example
CHARACTER SET	The character set that is used to encode the strings in the table. The character set is used to provide the metadata information. Set the value to utf8mb4.	<code>CHARACTER SET = 'utf8mb4'</code>
COMMENT	The description of the table.	<code>COMMENT='create by Bruce'</code>
TABLE_ID	The ID of the table. If the specified table ID is smaller than 50,000, turn on the <code>enable_sy</code> switch of the <code>s_table_ddl</code> of the RootServer. If you are a general user, we recommend that you do not specify the table ID.	<code>TABLE_ID =4000</code>
BLOCK_SIZE	The micro-block size of a partition.	The default size is 16 KB.
USE_BLOOM_FILTER	Specifies whether to use a Bloom filter when the data in the table is read. Valid values: <ul style="list-style-type: none"> ◦ False: indicates that the Bloom filter is not used. False is the default value. ◦ True: indicates that the Bloom filter is used. 	<code>USE_BLOOM_FILTER = False</code>
TABLEGROUP	The table group to which the table belongs.	-

Parameter	Description	Example
REPLICA_NUM	The number of replicas for the partitions in the table. The default value is 3.	<code>REPLICA_NUM = 3</code>
ZONE_LIST	The list of clusters.	-
PRIMARY_ZONE	The primary zone.	-
AUTO_INCREMENT	The start value for an auto-increment field.	<code>AUTO_INCREMENT = 5</code>
PCTFREE	The percentage of the idle space that is reserved in a database macro-block.	<p>When you use the parameter, pay attention to the following syntax details:</p> <ul style="list-style-type: none"> In the Oracle syntax, the PCTFREE parameter specifies the similar setting. To ensure compatibility with the Oracle syntax, ApsaraDB for OceanBase uses the same parameter name. Use the following syntax to create a table: <pre>CREATE TABLE table_name (column_definition) PCTFREE [=] integer</pre> Use the following syntax to modify a table: <pre>ALTER TABLE table_name PCTFREE [=] integer</pre> <p>Note</p> <ul style="list-style-type: none"> If you do not specify the PCTFREE parameter when you create a table, the default value 10 is used. The specified value of the PCTFREE parameter must be an integer. The valid value range is [0,50).

- In `index_option`, you can use the GLOBAL keyword to specify global indexes and use the LOCAL keyword to specify local indexes. By default, global indexes are used. When you create a partitioned table, you must specify the LOCAL keyword to use local indexes. If you do not specify the LOCAL keyword, the system returns

an error.

Examples

The following example is used to illustrate how to create a database table and view the table information.

1. Execute the following statement to create a database table:

```
CREATE TABLE test (c1 int primary key, c2 VARCHAR(50)) REPLICAS_NUM = 3, PRIMARY_ZONE = 'zone1';
```

You can also execute the following statement:

```
CREATE TABLE test (c1 int, c2 VARCHAR(50), primary key(c1)) REPLICAS_NUM = 3, PRIMARY_ZONE = 'zone1';
```

2. Execute the following statement to view the table information:

```
SHOW tables;
DESCRIBE test;
```

Errors

- If a syntax error occurs, the system returns the following error: `ERROR 1064 (42000): You have an error in your SQL syntax .`
- If the table name already exists, the system returns the following error: `ERROR 1050 (42501): Table 'test' already exists .`
- If the length of the specified table name exceeds the maximum length, the system returns the following error: `ERROR 1059 (42000): Identifier name 'XXXX' is too long .`
- If duplicate partition names are found in the table to be created, the system returns the following error: `ERROR 1517 (HY000): Duplicate partition name XX .` The following example is provided to explain the error:

```
mysql> create table employeetest(id int) partition by range(id) (partition dPname values less than (10), partition dPname values less than (20));
ERROR 1517 (HY000): Duplicate partition name 'dPname'
```

18.5.10.6. ALTER TABLE

The ALTER TABLE statement allows you to update the schema of an existing table. For example, you can modify an existing table and table attributes, add columns, modify columns and column attributes, or delete columns.

Syntax

```
ALTER TABLE tblname
alter_specification [, alter_specification]...

alter_specification:
  ADD [COLUMN] colname column_definition
  | ADD [COLUMN] (colname column_definition,...)
  | ADD {INDEX | KEY} [indexname] (index_col_name,...) [index_tpye] [index_options]
  | ADD [CONSTRAINT [symbol]]
      PRIMARY KEY (index_col_name,...) [index_type] [index_options] #ApsaraDB for OceanBase does not support the AD
D PRIMARY KEY clause.
  | ADD [CONSTRAINT [symbol]]
      UNIQUE [INDEX | KEY] [indexname] (index_col_name,...) [index_type] [index_options]
```

```

| ALTER [COLUMN] colname {SET DEFAULT literal | DROP DEFAULT}
| CHANGE [COLUMN] oldcolname newcolname column_definition [FIRST|AFTER col_name]
| MODIFY [COLUMN] colname column_definition [FIRST | AFTER col_name]
| DROP [COLUMN] colname
| DROP PRIMARY KEY#ApsaraDB for OceanBase does not support the DROP PRIMARY KEY clause. You cannot use the
DROP PRIMARY KEY clause to drop a primary key.
| DROP {INDEX | KEY} indexname
| RENAME [TO | AS] newtblname
| ORDER BY colname
| CONVERT TO CHARACTER SET charsetname [COLLATE collationname]
| [DEFAULT] CHARACTER SET charsetname [COLLATE collationname]
| table_options
| partition_options
| ADD PARTITION partition_definition
| DROP PARTITION partition_names
| COALESCE PARTITION number
| REORGANIZE PARTITION partition_names INTO (partition_definitions)
| ANALYZE PARTITION partition_names
| CHECK PARTITION partition_names
| OPTIMIZE PARTITION partition_names
| REBUILD PARTITION partition_names
| REPAIR PARTITION partition_names
| DROP TABLEGROUP
| AUTO_INCREMENT [=] num

```

column_definition:

```

data_type [NOT NULL | NULL] [DEFAULT defaultvalue]
[AUTO_INCREMENT] [UNIQUE [KEY]] [[PRIMARY] KEY]
[COMMENT 'string']

```

table_options:

```
[SET] table_option [table_option]...
```

table_option:

```

[DEFAULT] {CHARACTER SET | CHARSET} [=] charsetname
| [DEFAULT] COLLATE [=] collationname
| COMMENT [=] 'string'
| COMPRESSION [=] {NONE | LZ4_1.0 | LZO_1.0 | SNAPPY_1.0 | ZLIB_1.0}
| EXPIRE_INFO [=] expr
| REPLICA_NUM [=] num
| TABLE_ID [=] id
| BLOCK_SIZE [=] size
| USE_BLOOM_FILTER [=] {True| False}
| STEP_MERGE_NUM [=] num
| TABLEGROUP [=] tablegroupname

```

```
| PRIMARY_ZONE [=] zoneid
| AUTO_INCREMENT [=] num
  | PCTFREE [=] integer
| {READ ONLY | READ WRITE}
  | LOCALITY [=] locality
```

partition_options:

```
PARTITION BY
  HASH(expr)
  | KEY(column_list)
  [PARTITIONS num]
  [partition_definition ...]
```

partition_definition:

```
COMMENT [=] 'commenttext'
```

ApsaraDB for OceanBase does not support the `alter_specification` clauses of the `ALTER TABLE` statement. In ApsaraDB for OceanBase, the table ID in `table_option` cannot be changed. However, if you attempt to change the table ID, the system does not return syntax errors. ApsaraDB for OceanBase supports the `alter_specification` clauses that are frequently used.

Add columns

```
ALTER TABLE tblname
  ADD [COLUMN] col_name column_definition;
```

For more information about the `data_type` parameter, see [Data types](#).

ApsaraDB for OceanBase does not allow you to add primary key columns.

Modify column attributes

```
ALTER TABLE tblname
  ALTER [COLUMN] colname
  [SET DEFAULT literal| DROP DEFAULT];
```

Drop columns

```
ALTER TABLE tblname
  DROP [COLUMN] colname;
```

ApsaraDB for OceanBase does not allow you to drop the primary key columns or the columns that have indexes.

Rename tables

```
ALTER TABLE tblname
  RENAME [TO] newtblname;
```

Rename columns

```
ALTER TABLE tblname  
    CHANGE [COLUMN] oldcolname newcolname column_definition;
```

 **Notice** For the columns of the VARCHAR data type, the values of only the VARCHAR data type can be increased. The other data types are not supported.

For example, execute the following statement to change the field name d in the t2 table to c and change the data type of the field.

```
ALTER TABLE t2 CHANGE COLUMN d c CHAR(10);
```

Specify the block size of a partitioned table

```
ALTER TABLE tblname  
    SET BLOCK_SIZE [=] blocksize;
```

Specify the number of replicas for a table

```
ALTER TABLE tblname  
    SET REPLICA_NUM [=] num;
```

REPLICA_NUM specifies the number of replicas for the specified table.

Specify the compression method for a table

```
ALTER TABLE tblname  
    SET COMPRESSION [=] '{NONE | LZ4_1.0 | LZ0_1.0 | SNAPPY_1.0 | ZLIB_1.0}';
```

Specify whether to use a Bloom filter

```
ALTER TABLE tblname  
    SET USE_BLOOM_FILTER [=] {True | False};
```

Add descriptions

```
ALTER TABLE tblname  
    SET COMMENT [=] 'commentstring';
```

Specify the number of macro-blocks that are to be merged at a time for progressive compaction

```
ALTER TABLE tblname  
    SET PROGRESSIVE_MERGE_NUM [=] num;
```

You can execute this statement to specify the number of macro-blocks that are to be merged at a time for progressive compaction. The value of the `PROGRESSIVE_MERGE_NUM` parameter ranges from 1 to 64.

Specify the zone for a table

```
ALTER TABLE tblname
  zone_specification...;
zone_specification:
  PRIMARY_ZONE [=] zone
```

Examples

Example 1:

1. Before you add columns, execute the following statement to view the table information. **Table information before you add columns** shows the table information:

```
DESCRIBE test;
```

Table information before you add columns

Field	Type	Null	Key	Default	Extra
c1	int(11)	NO	PRI	NULL	
c2	varchar(50)	YES		NULL	

2 rows in set (0.01 sec)

2. Execute the following statement to add the c3 column:

```
ALTER TABLE test ADD c3 int;
```

3. After you add the column, execute the following statement to view the table information that is shown in **Table information after you add the column**:

```
DESCRIBE test;
```

Table information after you add the column

Field	Type	Null	Key	Default	Extra
c1	int(11)	NO	PRI	NULL	
c2	varchar(50)	YES		NULL	
c3	int(11)	YES		NULL	

3 rows in set (0.02 sec)

4. Execute the following statement to delete the c3 column:

```
ALTER TABLE test DROP c3;
```

5. After you delete the column, execute the following statement to view the table information that is shown in **Table information after you delete the column**:

```
DESCRIBE test;
```

Table information after you delete the column

```

+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| c1    | int(11)       | NO   | PRI | NULL    |       |
| c2    | varchar(50)  | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.01 sec)
    
```

Example 2:

```
ALTER TABLE test SET REPLICA_NUM=2, ADD COLUMN c5 INT;
```

Errors

- If a syntax error occurs, the system returns the following error: **ERROR 1064 (42000): You have an error in your SQL syntax** .
- If the specified table does not exist, the system returns the following error: **ERROR 1146 (42S02): Table 'XXX' doesn't exist** .
- If you add primary key columns to an existing table, the system returns the following error: **ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table** .

```

mysql> select * from employees;
+-----+-----+-----+-----+-----+-----+
| id | frame | lname | hired   | separated | job_code | store_id |
+-----+-----+-----+-----+-----+-----+
| 4 | 4 | 4 | 2000-04-04 | 2044-04-04 | 1 | 4 |
| 5 | 5 | 5 | 2000-05-05 | 2022-05-05 | 123 | 5 |
| 8 | 8 | 8 | 2000-05-05 | 2001-08-08 | 123 | 9 |
| 2 | test | 2 | 2000-02-02 | 2024-02-02 | 2 | 2 |
| 7 | 7 | 7 | 1999-02-02 | 2007-07-07 | 7 | 10 |
| 3 | 3 | 3 | 2000-03-03 | 2034-03-03 | 3 | 3 |
| 11 | test | test | 2003-03-03 | 2003-05-05 | 11 | 11 |
+-----+-----+-----+-----+-----+-----+
7 rows in set (0.01 sec)

mysql> alter table employees add id2 int primary key;
ERROR 1068 (42000): Multiple primary key defined
    
```

- If the column that you want to delete does not exist, the system returns the following error: **ERROR 1091 (42000): Can't DROP 'XXX'; check that column/key exists** . The following example is provided to explain the error.

```

mysql> alter table employees drop id3;
ERROR 1091 (42000): Can't DROP 'id3'; check that column/key exists
    
```

- If the specified data type does not meet the requirements of the default data length, the system returns the following error: **ERROR 1067 (42000): Invalid default value for 'XXX'** . The following example is provided to explain the error.

```
mysql> alter table test1 add colum1 VARCHAR(10) default 'tttttttttttttttttttt';
ERROR 1067 (42000): Invalid default value for 'column1'
```

18.5.10.7. DROP TABLE

The **DROP TABLE** statement allows you to drop tables that are stored in an ApsaraDB for OceanBase database.

Syntax

```
DROP TABLE [IF EXISTS] tbl_list;
```

tbl_list:

```
tblname [, tblname ...]
```

If you add **IF EXISTS** to the statement and the table that you want to delete does not exist, the system does not return an error. If you do not add **IF EXISTS** to the statement, the system returns an error.

If you need to drop multiple tables at a time, separate the tables with commas (,).

Examples

```
DROP TABLE IF EXISTS test;
```

Errors

- If a syntax error occurs, the system returns the following error: **ERROR 1064 (42000): You have an error in your SQL syntax** .
- If the table that you want to delete does not exist, the system returns the following error: **ERROR 1051 (42S02): Unknown table 'XXXX'** .

18.5.10.8. CREATE INDEX

Indexes are created on tables to sort the values of one or more columns of the tables. Indexes are used to reduce the response time of queries and reduce the performance overhead of database systems.

Note

1. In ApsaraDB for OceanBase, a new index takes effect only after a daily major freeze operation is performed. For example, you can create a unique index. Before the unique index takes effect, you can insert indexes that violate the uniqueness constraint. After the major freeze operation is performed, the unique index cannot take effect because duplicate indexes exist. In this scenario, the system changes the status of the unique index to `index_error`.
2. You can execute the `SHOW INDEX from <table>` statement to view the index status.

Syntax

```

CREATE [UNIQUE] INDEX indexname
    ON tblname (index_col_name,...)
    [index_type] [index_options]
| CREATE FULLTEXT INDEX indexname ON tblname (index_col_name,...) CTXCAT(index_col_name,...) [index_options]
index_type:
    USING BTREE

index_options:
    index_option [index_option...]

index_option:
    GLOBAL [LOCAL]
    | COMMENT 'string'
    | COMPRESSION [=] {NONE | LZ4_1.0 | LZ0_1.0 | SNAPPY_1.0 | ZLIB_1.0}
    | BLOCK_SIZE [=] size
    | STORING(columnname_list)

index_col_name:
    colname [(length)] [ASC | DESC]

columnname_list:
    colname [, colname...]

```

Notes:

- In `index_col_name`, you can specify ASC or DESC for each column name. ASC indicates that the values are sorted in ascending order and DESC indicates that the values are sorted in descending order. By default, the values are sorted in ascending order.
- In the CREATE INDEX statement, the indexes are first sorted based on the values of the first column in `index_col_name`. If the values in the first column are the same, the indexes are sorted based on the values in the next column. Similar rules apply to the other columns.
- You can execute the `SHOW INDEX FROM tblname` statement to view the created indexes.
- In `index_option`, you can use the GLOBAL keyword to specify global indexes and use the LOCAL keyword to specify local indexes. By default, `global indexes` are used.

When you create a partitioned table, you must specify the LOCAL keyword to use local indexes. If you do not specify the LOCAL keyword, the system returns an error. Separate the `index option` parameters with spaces.

- STORING is an optional field. This field indicates that the specified columns are stored in the index table for redundant storage. This improves the query performance of systems. The STORING field is available only in ApsaraDB for OceanBase.

 **Note** B-tree indexes are created for the data that is stored in ApsaraDB for OceanBase.

Examples

1. Execute the following statement to create a table that is named test:

```
CREATE TABLE test (c1 int primary key, c2 VARCHAR(10));
```

2. Execute the following statement to create indexes on the test table:

```
CREATE INDEX test_index ON test (c1, c2 DESC);
```

3. Execute the following statement to view the indexes of the test table:

```
SHOW INDEX FROM test;
```

Errors

- If a syntax error occurs, the system returns the following error: `ERROR 1064 (42000): You have an error in your SQL syntax` .
- If the specified table name is invalid, the system returns the following error: `ERROR 1146 (42S02): Table 'XXX' doesn't exist` .
- If the length of the specified table name exceeds the maximum length, the system returns the following error: `ERROR 1059 (42000): Identifier name 'XXX' is too long` .
- If the specified column name is invalid, the system returns the following error: `ERROR 1072 (42000): Key column 'XXX' doesn't exist in table` .

Expression indexes

ApsaraDB for OceanBase allows you to use the specified syntax to create generated columns. Generated columns are divided into virtual columns and stored columns. Generated columns can be used to create indexes in the same way as general columns.

If INSERT, REPLACE, and UPDATE operations are performed on virtual columns, the values in the virtual columns are materialized into index tables. Stored columns are the same as general columns except that the values of the stored columns are obtained from expressions.

Prefix indexes

You can create indexes on the prefixes of string values that are stored in columns. You can use the `col_name(length)` syntax to specify the prefix length.

Notes:

- You can create prefix indexes on the columns of the CHAR, VARCHAR, BINARY, or VARBINARY data type.
- You must specify prefixes if you need to create indexes on the columns of the BLOB or TEXT data type.

FULLEXT CTXCAT indexes

ApsaraDB for OceanBase supports FULLTEXT CTXCAT indexes. The full-text indexes of this type can cover the columns that are used for text analysis and the columns that are not used for text analysis. General indexes can cover only the columns that are used for text analysis. You can use the following syntax to create FULLTEXT CTXCAT indexes.

```
CREATE FULLTEXT INDEX indexname ON tblname (index_col_name,...) CTXCAT(index_col_name,...) [index_options]
```

where:

- `tblname (index_col_name,...)` specifies the table columns on which the index is created. It also specifies the ordinal positions of the columns in the index.
- `CTXCAT(index_col_name,...)` specifies the columns that are used for full-text analysis.

In ApsaraDB for OceanBase, multiple columns can be used for full-text analysis. If multiple columns are used for full-text analysis, the text set for full-text analysis is the sum of the text sets that are stored in the corresponding columns. The OR logical operator is used to combine the text sets that are stored in the corresponding columns. Only the columns of the STRING data type can be used for full-text analysis.

In the column list for the index, you must declare the columns that are specified for full-text analysis if you execute a DDL statement to create a CTXCAT index. The ordinal positions of the specified columns that are used for full-text analysis must be continuous. The following examples are provided to explain these rules:

```
create table t1(a int primary key, b varchar(100), c varchar(100), d int);
create fulltext index i1 on t1(b, d) ctxcat(c);
ERROR 1072 (42000): Key column 'c' doesn't exist in table
```

In the preceding example, the specified column for full-text analysis is not included in the column list of the index.

```
create table t1(a int primary key, b varchar(100), c varchar(100), d int);
create fulltext index i1 on t1(b, d, c) ctxcat(b, c);
ERROR 5291 (HY000): The CTXCAT column must be contiguous in the index column list
```

In the column list of the index, the ordinal positions of the specified columns for full-text analysis are not continuous in the preceding example.

For more information about how to use `FULLTEXT CTXCAT` indexes, see `MATCH... AGAINST` in [Full-text search functions](#).

Invisible indexes

You can use invisible indexes in many scenarios. One example of the scenarios is that you do not want the optimizer to use an index. Another example is that an index has not been used by queries and is always in the idle state. However, you do not want to delete the index because the index may be used in subsequent queries or the risks of deleting the index cannot be assessed. In these scenarios, `invisible indexes` help you handle the challenges. You can mark the index as an invisible index so that the index is not used by the optimizer.

When you create an index, you can specify whether the index is an invisible index. The default status is visible. If you do not specify the index status, the default status is used.

You can specify whether indexes are invisible when you execute DDL statements to create tables and indexes or create only indexes. The following examples show how to specify the index status.

```
CREATE TABLE t1(c1 int primary key, c2 int, c3 int, c4 varchar(16), key idx1(c1) visible, index idx2(c2) invisible, unique key idx3(c3) visible, unique index idx4(c1, c2) invisible, unique idx5(c2,c3));
CREATE UNIQUE INDEX idx6 ON t1(c2) visible;
CREATE INDEX idx7 ON t1(c3) invisible;
CREATE INDEX idx8 ON t1(c4) ;
```

In the preceding example, the status of `idx1`, `idx3`, and `idx6` is specified as visible and the status of `idx2`, `idx4`, and `idx7` is specified as invisible. The status of `idx5` and `idx8` is not specified. Therefore, the default visible status is used for `idx5` and `idx8`.

You can also use the `ALTER TABLE ALTER INDEX` syntax to change the status of the created indexes.

`ALTER TABLE t1 ALTER INDEX idx8 invisible;` changes the status of the `idx8` index from visible to invisible. As a result, the optimizer cannot use the index.

18.5.10.9. DROP INDEX

High overheads are required to maintain a large number of indexes. We recommend that you drop the indexes that are not required.

 **Note** After you execute the DROP INDEX statement to drop the index, the index cannot be immediately dropped. You must wait for a period before the index is dropped.

Syntax

```
DROP INDEX indexname
ON tblname;
```

Examples

```
DROP INDEX test_index ON test;
```

Errors

- If a syntax error occurs, the system returns the following error: `ERROR 1064 (42000): You have an error in your SQL syntax` .
- If the specified table name is invalid, the system returns the following error: `ERROR 1146 (42502): Table 'XXX' doesn't exist` .
- If the length of the specified table name exceeds the maximum length, the system returns the following error: `ERROR 1059 (42000): Identifier name 'XXX' is too long` .
- If the specified index is invalid, the system returns the following error: `ERROR 1091 (42000): Can't DROP 'XXX'; check that column/key exists` .

18.5.10.10. CREATE VIEW

Syntax

```
CREATE [OR REPLACE] VIEW viewname
[(column_list)] AS select_stmt;
```

The CREATE VIEW statement allows you to create a view. If you add the `OR REPLACE` clause to the statement, you can execute the statement to replace an existing view.

In the syntax, `select_stmt` specifies a SELECT statement. The SELECT statement defines the view by selecting data from base tables or other views.

In views, column names must be unique. This rule for views is the same as that for base tables. By default, the column names that are returned by the SELECT statement are used as the column names for the view. To specify the column names of the view, use the optional `column_list` clause. You can use this clause to specify the column names. The specified column names are separated with commas (,). The number of the column names in the `column_list` clause must be equal to the number of columns that are returned by the SELECT statement.

The columns that are returned by the SELECT statement can be the specified columns of base tables. The columns that are returned by the SELECT statement can also store the computing results of the expressions that use functions, constant values, or operators.

Views are not stored as physical tables in databases. Views are generated each time you send a request to access the views. Views are created based on the outputs of the SELECT statements that are specified in the `CREATE VIEW` statements.

ApsaraDB for OceanBase supports only the views that cannot be updated.

18.5.10.11. DROP VIEW

Syntax

```
DROP VIEW [IF EXISTS]
viewname [, viewname ...] ;
```

The `DROP VIEW` statement allows you to delete one or more views. To drop the views, you must have the `DROP` permission on each view.

If you add `IF EXISTS` to the statement and the specified views do not exist, no errors are reported.

18.5.10.12. ALTER VIEW

Syntax

```
ALTER VIEW viewname [(column_list)]
[(column_list)] AS select_statement
```

The `ALTER VIEW` statement allows you to change the definition of an existing view. The syntax of the statement is similar to that of the `CREATE VIEW` statement.

Notice

- ApsaraDB for OceanBase does not support the `ALTER VIEW` statement. This indicates that views cannot be modified.
- Views are logical tables. If you need to modify views, you can delete the views and create new views based on your business needs.

18.5.10.13. TRUNCATE TABLE

Syntax

```
TRUNCATE [TABLE] tblname;
```

The `TRUNCATE TABLE` statement allows you to delete a specified table and retain the table schema that includes the partition information about the table. The `TRUNCATE TABLE` statement implements the same logic as the `DELETE FROM` statement. You can execute the `DELETE FROM` statement to delete all the rows in a table. To execute the `TRUNCATE TABLE` statement, you must have the permissions to create and delete tables. The `TRUNCATE TABLE` statement is a DDL statement.

The `TRUNCATE TABLE` and `DELETE FROM` statements have the following differences:

- The `TRUNCATE TABLE` statement deletes and recreates the table. The response time for the `TRUNCATE TABLE` statement is shorter than that for the `DELETE FROM` statement. This is because the `DELETE FROM` statement deletes rows one after one.
- The output of the `TRUNCATE TABLE` statement shows that the number of affected rows is always 0.
- If you execute the `TRUNCATE TABLE` statement, each auto-incremented value is reset to the start value. The table manager does not store the latest auto-incremented value.
- You cannot execute the `TRUNCATE TABLE` statement when a transaction is processed or the table is locked. If you execute the statement in these scenarios, the system returns errors.
- If the file that defines the table is valid, you can execute the `TRUNCATE TABLE` statement to recreate the table as an empty table. This occurs even if the data or the index file has been corrupted.

In ApsaraDB for OceanBase, the specified table in the `TRUNCATE TABLE` statement can have only one partition.

ApsaraDB for OceanBase supports the `ALTER TABLE TRUNCATE PARTITION` statement. This allows you to implement distributed transactions. This occurs only if you can execute the `TRUNCATE TABLE` statement on tables that have multiple partitions in the later versions of ApsaraDB for OceanBase.

18.5.10.14. RENAME TABLE

Syntax

```
RENAME TABLE tblname TO newtblname  
[, tblname2 TO newtblname ...];
```

The `RENAME TABLE` statement allows you to rename one or more tables.

After you execute the `RENAME TABLE` statement, the specified tables are automatically renamed. When the tables are renamed, other threads cannot read data from the tables.

Examples

For example, if you have a source table that is named `oldtable`, you can create an empty table that has the same schema as the source table. You can name the empty table `newtable` and replace the source table with this empty table:

```
CREATE TABLE newtable(...);  
RENAME TABLE oldtable TO backuptable, newtable TO oldtable;
```

If you execute this statement to rename multiple tables, the tables are renamed based on the left-to-right order.

If you need to swap the names of two tables and the `temptable` table does not exist, execute the following statement:

```
RENAME TABLE oldtable TO temptable,  
newtable TO oldtable,  
temptable TO newtable
```

For the same tenant, you can rename database tables and move the tables from the databases to other databases.

```
RENANME TABLE currentdb.tblname TO otherdb.tblname
```

Before you execute the `RENAME` statement to rename tables, make sure that no tables are locked or involved in active transactions. To execute the `RENAME TABLE` statement, you must have `ALTER` and `DROP` permissions on the source table. You must also have `CREATE` and `INSERT` permissions on the destination table.

You can execute the `RENAME TABLE` statement to rename views. Note that the source view and the destination view must belong to the same database.

18.5.10.15. CREATE SYNONYM

Synonyms are aliases of objects in databases. You can define aliases for most database objects, such as tables, views, materialized views, sequences, functions, stored procedures, packages, and synonyms.

Synonyms simplify the SQL-based development of applications. If you need to use objects in SQL statements and no synonyms are specified for the objects, you must obtain the locations where the objects are stored. For example, you must obtain the information about the database that stores the specified table object. If you have specified synonyms for the objects, you do not need to concern yourself with this issue.

Synonyms also offer other benefits. The following example is provided to explain another benefit. In the example, a developer writes an SQL statement. The SQL statement involves a table that is used in the production system. If a synonym is specified for the table, the developer can associate the synonym with a mock table during the initial test stage. After the test is passed, the developer can associate the synonym with the table that is stored in the production system. This avoids code modifications and reduces the impact of the test on the production system.

Syntax

```
CREATE [OR REPLACE] [PUBLIC] SYNONYM
[DATABASE.]synonym_name
FOR [DATABASE.]object_name;
```

You can use the `CREATE SYNONYM` syntax to create synonyms for objects. To create synonyms for objects, you do not need to have the permissions on the objects. However, you must have the permissions to create synonyms in the specified database. If you specify the `PUBLIC` keyword when you create a synonym, the synonym belongs to no databases. Therefore, the synonym does not share the same namespace with databases and belongs to the public namespace.

18.5.10.16. DROP SYNONYM

Syntax

```
DROP [PUBLIC] SYNONYM
[DATABASE.]synonym_name
[FORCE]
```

You can use the `DROP SYNONYM` syntax to drop synonyms. If you need to delete a public synonym, you must specify the `PUBLIC` keyword. In this scenario, you cannot specify the database for the synonym that is specified by the `synonym_name` parameter.

18.5.11. DML statements

18.5.11.1. Overview

Data manipulation language (DML) statements allow you to write, delete, and update data in databases.

ApsaraDB for OceanBase supports the following DML statements: `INSERT`, `REPLACE`, `SELECT`, `UPDATE`, and `DELETE`.

The following DML limits apply to partitioned tables:

- ApsaraDB for OceanBase distributes data across partitions. To ensure system performance, `WHERE` clauses in `SELECT`, `UPDATE`, and `DELETE` statements must include `partition(p0, p1,...)`. If `WHERE` clauses in `SELECT`, `UPDATE`, and `DELETE` statements do not include `partition(partition_list)`, all the partitions are scanned before the statements return data.
- If `SELECT`, `UPDATE`, and `DELETE` statements do not include `partition(partition_list)`, the system does not return syntax errors. In this scenario, the statements return results only after a full table scan is completed.
- You can specify only one partition in each `REPLACE`, `INSERT`, `UPDATE`, or `DELETE` statement. If you specify multiple partitions, the system returns errors.

If you need to specify multiple partitions in each `SELECT` statement, pay attention to the following considerations:

- If you send requests to read data from multiple `partition groups`, you can read data across partitions and only weak consistency is supported.
- If you send requests to read data from the same `partition group`, you can read data across partitions and strong consistency is supported. When data is migrated at the backend of ApsaraDB for OceanBase, partitions in the same `partition group` may be distributed across servers for a short period of several milliseconds. If this occurs, strong consistency cannot be ensured when you read data across partitions.

18.5.11.2. INSERT

The INSERT statement allows you to add one or more rows to a specified table.

Syntax

```
INSERT [INTO] tblname
    [(colname,...)]
    {VALUES|VALUE} ({expr | DEFAULT},...)
    [ ON DUPLICATE KEY UPDATE
        colname=expr
        [, colname=expr] ... ] ;
```

Or

```
INSERT [INTO] tblname
    [(colname,...)]
    {VALUES|VALUE} (colvalues,...)
    [ON DUPLICATE KEY UPDATE
        colname=expr
        [, colname=expr] ... ] ;
```

```

INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  {VALUES | VALUE} {(expr | DEFAULT),...}(...),...
  [ ON DUPLICATE KEY UPDATE
    col_name=expr
    [, col_name=expr] ... ]

```

Or:

```

INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  SET col_name={expr | DEFAULT}, ...
  [ ON DUPLICATE KEY UPDATE
    col_name=expr
    [, col_name=expr] ... ]

```

Or:

```

INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  SELECT ...
  [ ON DUPLICATE KEY UPDATE
    col_name=expr
    [, col_name=expr] ... ]

```

where:

- `[(colname,...)]` specifies the columns into which the data is inserted.
- If you need to insert multiple columns at a time, separate the columns with commas (,).
- The `ON DUPLICATE KEY UPDATE` clause is supported.
- The `INSERT` statement cannot be followed by `SET` operations.

If you execute the `INSERT... ON DUPLICATE KEY UPDATE...` statement, the number of `affected rows` is calculated based on the following rules:

- If you do not specify the `CLIENT_FOUND_ROWS` flag in `client_capabilities`, the number of affected rows is calculated based on this rule:
 - If a row is inserted as a new row, `affected_row= 1` is returned.
 - If an inserted row conflicts with an existing row in the table and the data in the table remains the same after the update, `affected_row = 0` is returned. If the data in the table before the update is different from that after the update, `affected_row= 2` is returned.
- If you specify the `CLIENT_FOUND_ROWS` flag, the number of affected rows is calculated based on the following rules:

- If a row is inserted as a new row, `affected_row=1` is returned.
- If the data in the table remains the same after the update, `affected_row=1` is returned.
- If the data in the table before the update is different from that after the update, `affected_row=2` is returned.
- If you do not specify the `CLIENT_FOUND_ROWS` flag, the value of the `affected_row` parameter is the number of updated rows. If you specify the `CLIENT_FOUND_ROWS` flag, the value of the `affected_row` parameter is the number of touched rows that conflict with existing rows. The data in the touched rows may not be modified.

Examples

1. Execute the following statement to insert rows:

```
INSERT INTO test VALUES (1, 'hello alipay'),(2, 'hello ob');
```

2. Execute the following statement to view the inserted rows that are shown in **Inserted rows**:

```
SELECT * FROM test;
```

Inserted rows

```
+-----+-----+
| c1    | c2    |
+-----+-----+
|      1 | hello alipay |
|      2 | hello ob     |
+-----+-----+
2 rows in set (0.01 sec)
```

3. Execute the following statements to create a partitioned table and insert a row to a partition of the table:

```
mysql> create table employees( id int not null, frame VARCHAR(20),lname VARCHAR(20), hired date not null default '1970-01-01', separated date not null default '9999-12-31', job_code int, store_id int ) partition by hash(store_id) partitions 4;
Query OK, 0 rows affected (0.34 sec)
mysql> insert into employees partition(p2) values (7,'7','7','1999-02-02','2007-07-07',7,10);
Query OK, 1 row affected (0.00 sec)
```

Errors

1. If an SQL syntax error occurs, the system returns the `1064` error.

```
mysql> insert employees into values employees(1, '1','1',2003-03-03,2003-03-03,1,1);
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near 'into values employees(1, '1','1',2003-03-03,2003-03-03,1,1)' at line 1
```

2. If the type of the specified data is inconsistent with the data type that is defined in the table, the system returns the 1366 error. For example, if the data type that is defined in a table is INT and the type of the specified data is VARCHAR, the system returns this error. The 1366 error code indicates the error that the type of the specified data is invalid.

```
mysql> desc employees ;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| id    | int(11) | NO | | NULL | |
| frame | VARCHAR(20) | YES | | NULL | |
| lname | VARCHAR(20) | YES | | NULL | |
| hired | date | NO | | 1970-01-01 | |
| separated | date | NO | | 9999-12-31 | |
| job_code | int(11) | YES | | 1 | |
| store_id | int(11) | YES | | NULL | |
+-----+-----+-----+-----+-----+-----+
7 rows in set (0.01 sec)

mysql> insert into employees values (1000, 1, '1', '2003-03-03', '2003-03-03', 'test', 1);
ERROR 1366 (HY000): Incorrect integer value: 'test' for column 'job_code' at row 1
```

3. If the type of the specified data cannot be recognized, the system returns the 1054 error. The 1054 error code indicates unknown column errors.

```
mysql> insert into employees values (1000, 1, '1', '2003-03-03', '2003-03-03', 'test', 1);
ERROR 1054 (42S22): Unknown column 'test' in 'field list'
```

4. If the format of the specified time is invalid, the system returns the 1292 error. The 1292 error code indicates the error that the date value is invalid.

```
mysql> create table t2(id int, work date);
Query OK, 0 rows affected (0.08 sec)

mysql> insert into t2 values(1, 2003-03-03);
ERROR 1292 (22007): Incorrect date value: '1997' for column 'work' at row 1

mysql> insert into t2 values(1, '2003-03-03');
Query OK, 1 row affected (0.02 sec)

mysql> insert into t2 values(1, test);
ERROR 1054 (42S22): Unknown column 'test' in 'field list'

mysql> insert into t2 values(1, 2003);
ERROR 1292 (22007): Incorrect date value: '2003' for column 'work' at row 1

mysql> insert into t2 values(1, 20030101);
Query OK, 1 row affected (0.01 sec)

mysql> insert into t2 values(1, 2003-01-01);
ERROR 1292 (22007): Incorrect date value: '2001' for column 'work' at row 1
```

5. If the specified numeric value is not in the specified range, the system returns the 1264 error.
6. If the length of the specified characters exceeds the maximum length, the system returns the 1406 error.

```
mysql> insert into employees partition(p5) values(3,1,1,'2001-01-01','2001-10-10',1,1);
ERROR 1735 (HY000): Unknown partition 'p5' in table 'employees'
```

12. If the information about the partitions into which data is inserted is inconsistent with the partition information that is parsed by the corresponding function, the system returns the 1748 error.

```
mysql> show create table employees;
+-----+-----+
| Table | Create Table
+-----+-----+
| employees | CREATE TABLE `employees` (
  `id` int(11) NOT NULL,
  `frame` VARCHAR(20) DEFAULT NULL,
  `lname` VARCHAR(20) DEFAULT NULL,
  `hired` date NOT NULL DEFAULT '1970-01-01',
  `separated` date NOT NULL DEFAULT '9999-12-31',
  `job_code` int(11) DEFAULT '1',
  `store_id` int(11) DEFAULT NULL
) DEFAULT CHARSET = utf8mb4 COMPRESSION = 'lz4_1.0' REPLICA_NUM = 1 BLOCK_SIZE = 16384 USE_BLOOM_FILTER =
FALSE TABLET_SIZE = 134217728 PCTFREE = 10 partition by hash(store_id) partitions 4 |
+-----+-----+
1 row in set (0.01 sec)

mysql> insert into employees partition(p2) values(3,1,1,'2001-01-01','2001-10-10',1,1);
ERROR 1748 (HY000): Found a row not matching the given partition set
```

13. If the inserted data is not in the data range that is defined in the partitions, the system returns the following error: ERROR 1526 (HY000): Table has no partition for value XX .

```
mysql> CREATE TABLE employees3 (
-> id INT NOT NULL,
-> fname VARCHAR(30),
-> lname VARCHAR(30),
-> hired DATE NOT NULL DEFAULT '1970-01-01',
-> separated DATE NOT NULL DEFAULT '9999-12-31',
-> job_code INT NOT NULL,
-> store_id INT NOT NULL
-> )
-> PARTITION BY RANGE (store_id) (
-> PARTITION ptest VALUES LESS THAN (6),
-> PARTITION ptestk VALUES LESS THAN (11),
-> PARTITION ptestl VALUES LESS THAN (16),
-> PARTITION ptestf VALUES LESS THAN (21)
-> );
Query OK, 0 rows affected (0.54 sec)

mysql> insert into employees3 values(3,'Meagge','simith','2011-01-10','2019-10-01',10,21);
ERROR 1526 (HY000): Table has no partition for value 21

mysql> insert into employees3 values(4,'Meery','simith','2012-01-10','2019-10-01',10,22);
ERROR 1526 (HY000): Table has no partition for value 22
```

14. If the inserted column values violate the unique index constraint, the system returns the following error:

```
ERROR 1062 (23000): Duplicate entry 'XXX' for key 'XXX' .
```

```
mysql> create table estest(c1 int primary key, c2 int, c3 int, c4 int);
Query OK, 0 rows affected (0.28 sec)
mysql> insert into estest values(1, 2, 3, 5), (2, 3, 4, 5), (5, 6, 7, 8);
Query OK, 3 rows affected (0.02 sec)
Records: 3 Duplicates: 0 Warnings: 0
mysql> create unique index uniindex on estest(c2); //The unique index uniindex is created.
Query OK, 0 rows affected (0.09 sec)
Records: 0 Duplicates: 0 Warnings: 0
mysql> select * from estest;
+----+-----+-----+-----+
| c1 | c2 | c3 | c4 |
+----+-----+-----+-----+
| 1 | 2 | 3 | 5 |
| 2 | 3 | 4 | 5 |
| 5 | 6 | 7 | 8 |
+----+-----+-----+-----+
3 rows in set (0.00 sec)
mysql> insert into estest values(7,6,8,9); //The value 6 in the inserted row is the same as an existing value that is
stored in the unique index column. This violates the constraint of the unique index.
ERROR 1062 (23000): Duplicate entry '6' for key 'uniindex'
```

18.5.11.3. REPLACE

Syntax

The REPLACE statement is executed in a similar way to the INSERT statement. Assume that a `primary key` value or a value of the unique index column for an existing row is the same as that for the new row. In this scenario, the REPLACE statement deletes the existing row before the statement inserts the new row. This is the only difference between the REPLACE statement and the INSERT statement.

To execute the REPLACE statement, you must have INSERT and DELETE permissions on the specified table.

Syntax

```
REPLACE [INTO] tblname
[(colname,...)]
{VALUES|VALUE} ({expr | DEFAULT},...);
```

The following code block describes the MySQL syntax of the REPLACE statement:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  {VALUES | VALUE} {(expr | DEFAULT),...},(...),...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  SET col_name={expr | DEFAULT}, ...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  SELECT ...
```

where:

- `[(colname,...)]` specifies the columns into which the data is inserted.
- If you need to replace data in multiple columns at a time, separate the columns with commas (,).

If you execute the REPLACE statement, the number of `affected rows` is calculated based on the following rules:

- If a row is inserted as a new row, `affected_row=1` is returned.
- If the data in the table before the replacement is different from that after the replacement, `affected_row=2` is returned. In this scenario, only one existing row has the same primary key value or the same unique index value as the new row. If multiple existing rows have the same primary key value or unique index value as the new row, the number of `affected rows` equals the number of conflicting rows plus 1.
- If the data remains the same after the replacement, the number of affected rows are calculated based on the following rules:
 - If a conflicting row is caused by the unique index in the table, the foreign key constraint is not used, and `ON DELETE TRIGGER` is not added to the REPLACE statement, `affected_row=1` is returned.
 - In other scenarios, `affected_row = 2` is returned.

Examples

1. Execute the following statement to replace the specified rows in the test table:

```
REPLACE INTO test VALUES (1, 'hello alibaba'),(2, 'hello ob');
```

2. Execute the following statement to view the inserted rows that are shown in the following figure:

```
SELECT * FROM test;
```

Replace the table rows

```

+-----+-----+
| c1    | c2    |
+-----+-----+
|      1 | hello alibaba |
|      2 | hello ob      |
+-----+-----+
2 rows in set (0.01 sec)

```

Errors

1. If an SQL syntax error occurs, the system returns the 1064 error.
2. If the type of the specified data is inconsistent with the data type that is defined in the table, the system returns the 1366 error. For example, if the data type that is defined in a table is INT and the type of the specified data is VARCHAR, the system returns this error. The 1366 error code indicates the error that the type of the specified data is invalid.
3. If the type of the specified data cannot be recognized, the system returns the 1054 error. The 1054 error code indicates unknown column errors.
4. If the format of the specified time is invalid, the system returns the 1292 error. The 1292 error code indicates the error that the date value is invalid.
5. If the specified numeric value is not in the specified range, the system returns the 1264 error.
6. If the length of the specified characters exceeds the maximum length, the system returns the 1406 error.
7. If NULL is inserted into a column that stores only non-null values, the system returns the 1048 error.
8. If the name of the specified table does not exist, the system returns the 1146 error.
9. If the number of inserted column values is different from the defined number of column values, the system returns the 1136 error.
10. If the names of the partitions into which data is inserted do not exist, the system returns the 1735 error.
11. If the information about the partitions into which data is inserted is inconsistent with the partition information that is parsed by the corresponding function, the system returns the 1748 error.

18.5.11.4. UPDATE

The UPDATE statement allows you to change field values in a specified table.

Syntax

Syntax

```
UPDATE tblname
SET colname=colvalues
    [, colname=colvalues...]
[WHERE where_condition]
[ORDER BY order_list]
[LIMIT row_count];

order_list:
colname [ASC|DESC] [, colname [ASC|DESC]...]
```

The following code block describes the MySQL syntax of the UPDATE statement:

```
Single-table syntax:

UPDATE [LOW_PRIORITY] [IGNORE] table_reference
    SET col_name1={expr1|DEFAULT} [, col_name2={expr2|DEFAULT}] ...
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]

Multiple-table syntax:

UPDATE [LOW_PRIORITY] [IGNORE] table_references
    SET col_name1={expr1|DEFAULT} [, col_name2={expr2|DEFAULT}] ...
    [WHERE where_condition]
```

Examples

1. Execute the following statement to change `hello ob` to `hello oceanbase` :

```
UPDATE test SET c2='hello oceanbase' WHERE c1=2;
```

2. Execute the following statement to view the changed information that is shown in [Update the test table](#):

```
SELECT * FROM test;
```

Update the test table

```

+-----+-----+
| c1      | c2      |
+-----+-----+
|        1 | hello alibaba |
|         2 | hello oceanbase |
+-----+-----+
2 rows in set (0.00 sec)

```

3. Update a column value in a partition.

Execute the following statements to change the value of `job_code` in the `p0` partition of the `employees` table to 1:

```

mysql> select * from employees;
+-----+-----+-----+-----+-----+-----+
| id | frame | lname | hired   | separated | job_code | store_id |
+-----+-----+-----+-----+-----+-----+-----+
| 4 | 4     | 4     | 2000-04-04 | 2044-04-04 | 4       | 4       |
| 1 | 1     | 1     | 2000-01-01 | 2014-01-01 | 1       | 1       |
| 5 | 5     | 5     | 2000-05-05 | 2022-05-05 | 5       | 5       |
| 2 | 2     | 2     | 2000-02-02 | 2024-02-02 | 2       | 2       |
| 6 | 6     | 6     | 2000-06-06 | 2022-06-06 | 6       | 6       |
| 7 | 7     | 7     | 1999-02-02 | 2007-07-07 | 7       | 10      |
| 3 | 3     | 3     | 2000-03-03 | 2034-03-03 | 3       | 3       |
+-----+-----+-----+-----+-----+-----+
7 rows in set (0.05 sec)

mysql> update employees partition (p0) set job_code=1;
Query OK, 1 row affected (0.02 sec)
Rows matched: 1 Changed: 1 Warnings: 0

```

Errors

1. If an SQL syntax error occurs, the system returns the `1064` error.
2. If the type of the specified data is inconsistent with the data type that is defined in the table, the system returns the `1366` error. For example, if the data type that is defined in a table is `INT` and the type of the specified data is `VARCHAR`, the system returns this error. The `1366` error code indicates the error that the type of the specified data is invalid.
3. If the type of the specified data cannot be recognized, the system returns the `1054` error. The `1054` error code indicates unknown column errors.
4. If the format of the specified time is invalid, the system returns the `1292` error. The `1292` error code indicates the error that the date value is invalid.
5. If the specified numeric value is not in the specified range, the system returns the `1264` error.
6. If the length of the specified characters exceeds the maximum length, the system returns the `1406` error.

7. If NULL is inserted into a column that stores only non-null values, the system returns the 1048 error.
8. If the name of the specified table does not exist, the system returns the 1146 error.
9. If an inserted value of the primary key is the same as an existing value of the primary key, the system returns the 1062 error.
10. If the names of the partitions where data is updated do not exist, the system returns the 1735 error.
11. If the information about the partitions where data is updated is inconsistent with the partition information that is parsed by the corresponding function, the system returns the 1748 error.

18.5.11.5. DELETE

The DELETE statement allows you to delete the table rows that meet the specified conditions.

Syntax

```
DELETE FROM tblname
  [WHERE where_condition]
  [ORDER BY order_list]
  [LIMIT row_count];
```

The following code block describes the MySQL syntax of the DELETE statement:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  tbl_name[*] [, tbl_name[*]] ...
  FROM table_references
  [WHERE where_condition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  FROM tbl_name[*] [, tbl_name[*]] ...
  USING table_references
  [WHERE where_condition]
```

Examples

1. Execute the following statement to delete the row that meets the c1=2 condition. The c1 column is the primary key in the test table.

```
DELETE FROM test WHERE c1 = 2;
```

2. Execute the following statement to view the table information after the row is deleted. **Delete the row** shows the output of the statement.

```
SELECT * FROM test;
```

Delete the row

```

+-----+-----+
| c1    | c2    |
+-----+-----+
|      1 | hello alibaba |
+-----+-----+
1 row in set (0.01 sec)

```

Errors

1. If an SQL syntax error occurs, the system returns the 1064 error.
2. If the type of the specified data cannot be recognized, the system returns the 1054 error. The 1054 error code indicates unknown column errors.
3. If the name of the specified table does not exist, the system returns the 1146 error.
4. If the names of the partitions into which data is inserted do not exist, the system returns the 1735 error.

18.5.11.6. SELECT

The SELECT statement allows you to query data that is stored in tables.

Basic queries

Syntax

```

SELECT
    [ALL | DISTINCT]
    selectexpr [[AS] othername] [, selectexpr ...]
    [FROM table_references ]
    [PARTITION(partitionid [, partitionid...])]
    [WHERE where_conditions]
    [GROUP BY group_by_list]
    [HAVING search_conditions]
    [ORDER BY order_list]
    [LIMIT {[offset,] row_count | row_count OFFSET offset}]
    [FOR UPDATE];

```

The following code block describes the MySQL syntax of the SELECT statement:

```

SELECT
[ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
select_expr [, select_expr ...]
[FROM table_references
  [PARTITION partition_list]
[WHERE where_condition]
[GROUP BY {col_name | expr | position}
  [ASC | DESC], ... [WITH ROLLUP]]
[HAVING where_condition]
[ORDER BY {col_name | expr | position}
  [ASC | DESC], ...]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]
[PROCEDURE procedure_name(argument_list)]
[INTO OUTFILE 'file_name'
  [CHARACTER SET charset_name]
  export_options
 | INTO DUMPFILE 'file_name'
 | INTO var_name [, var_name]]
[FOR UPDATE | LOCK IN SHARE MODE]]
    
```

SELECT clauses describes SELECT clauses.

SELECT clauses

Clause	Description
ALL DISTINCT	<p>Specifies whether the statement returns only distinct rows. A database table may contain duplicate values.</p> <ul style="list-style-type: none"> If you add DISTINCT to the statement, only distinct rows are returned in the query results. If you add ALL to the statement, all the matched rows are returned. If you do not add DISTINCT or ALL to the statement, the default setting ALL is used.
select_expr	<p>Specifies the required expressions or column names. The expressions specify the columns that you want to retrieve. If you need to specify multiple expressions or column names, separate the specified expressions or column names with commas (.). You can use an asterisk (*) to indicate that all the columns in the table are returned.</p>
AS othername	<p>Renames output fields.</p>

Clause	Description
FROM <i>table_references</i>	<ul style="list-style-type: none"> Specifies the tables from which data is read. Allows you to retrieve data from multiple tables.
WHERE <i>where_conditions</i>	<p>Specifies the filter conditions. The query results contain only the data that meets the filter conditions. This clause is optional.</p> <p><i>where_conditions</i> specifies an expression.</p>
GROUP BY <i>group_by_list</i>	Divides data into groups.
HAVING <i>search_conditions</i>	Specifies the filter conditions. HAVING clauses are similar to WHERE clauses. The difference between HAVING and WHERE clauses is that you can use aggregate functions in HAVING clauses, such as SUM and AVG.
ORDER BY <i>order_list</i> <i>order_list</i> : <i>colname</i> [ASC DESC] [, <i>colname</i> [ASC DESC]...]	<p>Displays the query results in ascending or descending order. ASC indicates the ascending order and DESC indicates the descending order.</p> <p>If you do not specify the order, the default order ASC is used.</p>
[LIMIT {[<i>offset</i> ,] <i>row_count</i> <i>row_count</i> OFFSET <i>offset</i> }]	<p>Limits the number of rows that are returned by the SELECT statement.</p> <p>You can specify one or two arguments of the numeric data type for the LIMIT clause. The arguments must be integer constants.</p> <ul style="list-style-type: none"> If you specify two arguments, the first argument specifies the offset for the first row to be returned and the second argument specifies the maximum number of rows to be returned. The initial offset for the first row is 0 instead of 1. If you specify only one argument, the argument specifies the maximum number of rows to be returned and the offset is 0.
FOR UPDATE	Applies an exclusive lock on each row of the query results. This prevents other transactions from concurrently updating the rows. This also prevents other transactions from concurrently reading the rows for which some transaction isolation levels are specified.
PARTITION(<i>partition_list</i>) Format: partition(p0,p1...)	Specifies the partition information of the specified tables.

JOIN syntax

Joins are divided into inner joins and outer joins. Outer joins are divided into left joins, right joins, and full joins. After two tables are joined, you can use the ON clause to filter the data in the tables.

In ApsaraDB for OceanBase, you can use USING clauses for joins. At least one of the join conditions must use the equal to (=) operator.

For inner joins, the query results contain only the matched rows in both tables.

For left joins, the query results contain all the rows in the table on the left of the `LEFT [OUTER] JOIN` keyword, and the matched rows in the table on the right of the keyword.

For right joins, the query results contain all the rows in the table on the right of the `[RIGHT] [OUTER] JOIN` keyword, and the matched rows in the table on the left of the keyword.

For full joins, the query results contain all the rows in both tables.

Set operations

In ApsaraDB for OceanBase, the main clauses for set operations are UNION, EXCEPT, and INTERSECT clauses.

- UNION clause

The UNION clause combines the result sets of two or more SELECT statements. To use the UNION clause, pay attention to the following considerations:

- For the UNION clause, the number of columns, the data types of the columns, and the column sequence for each of the SELECT statements must be the same.
- By default, the UNION operator returns result sets that do not contain duplicate values. If you need to obtain duplicate values, use the `UNION ALL` clause.
- The column names in each UNION result set are always the same as those in the first SELECT statement for the UNION clause.

The UNION clause combines the results of two or more SELECT statements. The JOIN clause retrieves data from two or more tables. Therefore, the UNION clause is similar to the JOIN clause. The difference between the two clauses is that the UNION clause combines the results of two or more SELECT statements and the JOIN clause joins two or more tables.

- EXCEPT clause

The EXCEPT clause returns the data that is included in the result set of the first SELECT statement but is excluded from the result set of the second SELECT statement.

- INTERSECT clause

The INTERSECT clause returns the data that is included in the result sets of both SELECT statements.

DUAL virtual table

DUAL is a virtual table. The DUAL virtual table can be considered as a special table that has one row and no columns. If you do not need to retrieve data from specific tables but need to execute the SELECT statement to retrieve some required information, DUAL helps you retrieve the required information. You can use the SELECT syntax that includes DUAL to retrieve the values of user variables or system variables.

If the SELECT statement does not include the FROM clause, `FROM DUAL` is equivalent to the FROM clause. In this scenario, the expressions in the SELECT statement can be only constant expressions.

Syntax

```
SELECT
    [ALL | DISTINCT]
    select_list
    [FROM DUAL [WHERE where_condition]]
    [LIMIT {[offset,] rowcount | rowcount OFFSET offset};
```

`SELECT... FOR UPDATE` statement

Syntax

```
SELECT ... FOR UPDATE [WAIT n| NOWAIT];
```

where:

- The `WAIT` clause specifies the number of seconds to wait. The current user must wait for the specified number of seconds before another user releases the row locks. This prevents endless waiting.
- `NOWAIT` indicates that the current user does not wait for the row locks to release.

You can execute the `SELECT ... FOR UPDATE` statement to apply an exclusive lock on each row in the query results. This prevents other transactions from concurrently updating these rows. This also prevents other transactions from concurrently reading the rows for which some transaction isolation levels are specified. To be more specific, you can use the `FOR UPDATE` clause to lock the tuples of the query results. In this scenario, the `UPDATE`, `DELETE` and `FOR UPDATE` operations cannot be performed on these tuples before the transaction is committed.

 **Notice** In ApsaraDB for OceanBase, you can run each query on only a single table.

Example:

```
SELECT * FROM a FOR UPDATE;
```

IN and OR logical operators

ApsaraDB for OceanBase supports `IN` and `OR` logical operators.

Errors

1. If an SQL syntax error occurs, the system returns the `1064` error.
2. If the type of the specified data cannot be recognized, the system returns the `1054` error. The `1054` error code indicates unknown column errors.
3. If the name of the specified table does not exist, the system returns the `1146` error.
4. If the names of the partitions from which data is retrieved do not exist, the system returns the `1735` error.
5. If a `SELECT` subquery returns multiple rows, the system returns the `1241` error. The `1241` error code indicates that the result violates the rule: The subquery results can contain only one field.

```
mysql> select * from employees where store_id=5;
+----+-----+-----+-----+-----+-----+-----+
| id | frame | lname | hired   | separated | job_code | store_id |
+----+-----+-----+-----+-----+-----+-----+
| 5 | 5   | 5   | 2000-05-05 | 2022-05-05 | 123 | 5 |
+----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> select (select id from employees where store_id=5);
+-----+
| (select id from employees where store_id=5) |
+-----+
| 5 |
+-----+
1 row in set (0.00 sec)

mysql> select (select id,frame from employees where store_id=5);
ERROR 1241 (21000): Operand should contain 1 column(s)
```

6. If the referenced group functions are invalid, the system returns the `1111` error.

```
mysql> CREATE TABLE t222 (s1 INT, s2 INT, s3 INT, PRIMARY KEY(s3) );
mysql> insert into t222 values(1, 1, 1), (1, 2, 2), (1, 2, 3);
mysql> select avg(sum(s1)) from t222 group by s1;
ERROR 1111 (HY000): Invalid use of group function
```

```
mysql> select avg(a1) from (select sum(s1) as a1 from t222 group by s1);
```

18.5.12. Transaction language

A database transaction is a single logical unit of work that consists of a collection of operations.

Transaction processing ensures that SQL operations in a batch are all executed or are not executed at all. You can use transactions to maintain the data integrity of databases.

An explicit transaction is a user-defined or user-specified transaction. An explicit transaction is a transaction that starts with the `BEGIN TRANSACTION`, `BEGIN`, or `BEGIN WORK` statement and ends with the `COMMIT` or `ROLLBACK` statement. `BEGIN` and `BEGIN WORK` are supported as aliases of the `START TRANSACTION` statement.

To start a transaction, use the following statement syntax:

```
START TRANSACTION
  [WITH CONSISTENT SNAPSHOT];
BEGIN [WORK] ;
COMMIT [WORK] ;
ROLLBACK [WORK];
```

ApsaraDB for OceanBase supports only the `READ COMMITTED` isolation level.

- The `WITH CONSISTENT SNAPSHOT` clause starts a consistent read. This clause has the same effect as issuing a `START TRANSACTION` statement that is followed by a `SELECT` statement that queries an ApsaraDB for OceanBase table.

You can specify the `WITH CONSISTENT SNAPSHOT` clause in the `START TRANSACTION` statement. However, the `WITH CONSISTENT SNAPSHOT` does not take effect.

- `BEGIN` and `BEGIN WORK` are supported as aliases of `START TRANSACTION` and are used to initialize a transaction. `START TRANSACTION` is a standard SQL syntax and is the recommended way to start an ad hoc transaction. After a transaction is started, the SQL statements that follow the `START TRANSACTION` statement such as `INSERT`, `UPDATE`, and `DELETE` take effect only when the transaction is explicitly committed. However, a `REPLACE` statement is not subject to this limit.

To commit a transaction, use the following statement syntax:

```
COMMIT [WORK];
```

To roll back a transaction, use the following statement syntax:

```
ROLLBACK [WORK];
```

Example:

Perform a transaction on Table A: Find the row whose id is 3, and change the value for the name column to c, and insert a new row about sale records for product a.

Table A

id	name	num	sell_date
1	a	100	2013-06-21 10:06:43
2	b	200	2013-06-21 13:07:21
3	a	50	2013-06-21 13:08:15

- Execute the following statements in sequence to start the transaction.

```
START TRANSACTION;
UPDATE a SET name = 'c' WHERE id = 3;
INSERT INTO a VALUES (4, 'a', 30, '2013-06-21 16:09:13');
COMMIT;
```

- After the transaction is committed, execute the following statement to query data of Table A. [Table A information](#) shows the execution result.

```
SELECT * FROM a;
```

Table A information

```
+-----+-----+-----+-----+
| id   | name | num  | sell_date          |
+-----+-----+-----+-----+
|    1 | a    | 100  | 2013-06-21 10:06:43 |
|    2 | b    | 200  | 2013-06-21 13:07:21 |
|    3 | c    | 50   | 2013-06-21 13:08:15 |
|    4 | a    | 30   | 2013-06-21 16:09:13 |
+-----+-----+-----+-----+
4 rows in set (0.01 sec)
```

Note

Before you commit a transaction, you can check whether the operations in the transaction have taken effect. For example, you can insert a `SELECT * FROM a;` statement before the `COMMIT` clause.

The session within which this transaction is executed can read the updated result. A session outside this transaction cannot read the updated result. Before the transaction is committed, your previous operations are invisible outside the transaction session. To roll back a transaction, execute the `ROLLBACK` statement to undo the `COMMIT` operation.

18.5.13. Database management language

18.5.13.1. CREATE RESOURCE UNIT

```
CREATE RESOURCE UNIT unitname
MAX_CPU [=] cpunum,
MAX_MEMORY [=] memsize,
MAX_IOPS [=] iopsnum,
MAX_DISK_SIZE [=] disksize,
MAX_SESSION_NUM [=] sessionnum,
[MIN_CPU [=] cpunum,]
[MIN_MEMORY [=] memsize,]
[MIN_IOPS [=] iopsnum] ;
```

When you create a resource unit, you must specify the values of `MAX_CPU`, `MAX_MEMORY`, `MAX_IOPS`, `MAX_DISK_SIZE`, and `MAX_SESSION_NUM`. `MIN_CPU`, `MIN_MEMORY`, and `MIN_IOPS` are optional. The default values of `MIN_CPU`, `MIN_MEMORY`, and `MIN_IOPS` are the same as the default values of `MAX_CPU`, `MAX_MEMORY`, and `MAX_IOPS`.

- The value range of `MAX_MEMORY` is [1073741824, +∞). The unit is byte. The minimum value is 1 GB.
- The value range of `MAX_IOPS` is [128, +∞).
- The value range of `MAX_DISK_SIZE` is [536870912, +∞). The unit is byte. The minimum value is 512 MB.
- The value range of `MAX_SESSION_NUM` is [64, +∞).

You can replace *memsize* or *disksize* with a value that is a combination of a number and a unit, for example, 1 GB or 100 MB. You can also specify the value in bytes, for example, 1073741824 or 104857600.

For example, the following two statements are equivalent:

```
mysql> CREATE RESOURCE UNIT unit1 max_cpu 1, max_memory '1G', max_iops 128,max_disk_size '10G', max_session_num
64, MIN_CPU=1, MIN_MEMORY='1G', MIN_IOPS=128;
Query OK, 0 rows affected (0.02 sec)
```

Equivalent to:

```
mysql> CREATE RESOURCE UNIT unit1 max_cpu 1, max_memory 1073741824, max_iops 128, max_disk_size 10737418240, m
ax_session_num 64, MIN_CPU=1, MIN_MEMORY=1073741824, MIN_IOPS=128;
Query OK, 0 rows affected (0.01 sec)
```

18.5.13.2. ALTER RESOURCE UNIT

```
ALTER RESOURCE UNIT unitname
MAX_CPU [=] cpunum,
MAX_MEMORY [=] memsize,
MAX_IOPS [=] iopsnum,
MAX_DISK_SIZE [=] disksize,
MAX_SESSION_NUM [=] sessionnum,
[MIN_CPU [=] cpunum,]
[MIN_MEMORY [=] memsize,]
[MIN_IOPS [=] iopsnum] ;
```

When you modify the properties of a resource unit, follow the same configuration rules that are described in the `CREATE RESOURCE UNIT` topic.

18.5.13.3. DROP RESOURCE UNIT

```
DROP RESOURCE UNIT unitname
```

You can execute this statement to delete a resource unit.

For example, execute the following statement to delete unit 1:

```
mysql> DROP RESOURCE UNIT unit1;  
Query OK, 0 rows affected (0.00 sec)
```

18.5.13.4. CREATE RESOURCE POOL

Syntax

```
CREATE RESOURCE POOL poolname  
UNIT [=] unitname,  
UNIT_NUM [=] unitnum,  
ZONE_LIST [=] ('zone' [, 'zone' ...]) ;
```

A resource pool contains multiple resource units. You must specify the zones to which the resource units belong.

ApsaraDB for OceanBase allows only one type of resource units in a resource pool. UNIT_NUM indicates the number of resource units in a zone. The UNIT_NUM value must be smaller than the number of OBServers in the zone.

Examples

```
mysql> CREATE RESOURCE POOL pool1 unit='unit1', unit_num=1, zone_list=('zone1');  
Query OK, 0 rows affected (0.01 sec)
```

18.5.13.5. ALTER RESOURCE POOL

Syntax

```
ALTER RESOURCE POOL poolname  
UNIT [=] unitname,  
UNIT_NUM [=] unitnum,  
ZONE [=] ('zone' [, 'zone' ...]) ;
```

You can execute this statement to modify the properties of a resource pool.

If your modification results in no resource unit in the resource pool, make sure that the resource pool is not used by a tenant when you execute the ALTER RESOURCE POOL statement. If the resource pool is in use, the system returns an error.

When you modify the properties of a resource pool by executing the ALTER RESOURCE POOL statement, you can modify only one property at a time. To modify two or more of the UNIT, UNIT_NUM, and ZONE properties, you must execute the ALTER RESOURCE POOL statement two or more times.

Examples

```
//If you modify multiple properties of a resource pool at a time, the system returns an error.
mysql> ALTER RESOURCE POOL pool1 unit='unit2', unit_num=1, zone_list=('zone1');
ERROR 1235 (0A000): alter unit_num, resource_unit, zone_list in one cmd not supported

//Modify one property at a time.
mysql> ALTER RESOURCE POOL pool1 unit='unit2';
Query OK, 0 rows affected (0.00 sec)
```

18.5.13.6. DROP RESOURCE POOL

Syntax

```
DROP RESOURCE POOL poolname;
```

You can execute this statement to delete a resource pool.

Examples

Execute the following statement to delete pool1:

```
mysql> DROP RESOURCE POOL pool1;
Query OK, 0 rows affected (0.00 sec)
```

18.5.13.7. CREATE TENANT

Syntax

```
CREATE TENANT [IF NOT EXISTS] tenantname
  [tenant_characteristic_list]

tenant_characteristic_list:
tenant_characteristic [, tenant_characteristic...]

tenant_characteristic:
COMMENT 'string'
|[CHARACTER SET | CHARSET] [=] charsetname
|COLLATE [=] collationname
|REPLICA_NUM [=] num
|ZONE_LIST [=] (zone [, zone...])
|PRIMARY_ZONE [=] zonelist
|DEFAULT TABLEGROUP [=] {NULL | tablegroup}
|RESOURCE_POOL_LIST [=](poolname [, poolname...])
|LOCALITY [=] locality
```

If the specified tenant name is already used and the `IF NOT EXISTS` option is not specified, the system returns an error.

The validity requirements for tenant names are the same as those for variable names. A tenant name must be up to 64 bytes in length and can contain only letters, digits, and underscores (_). The name must start with a letter or an underscore (_) and cannot be a keyword that is reserved for ApsaraDB for OceanBase.

Before you execute the `CREATE TENANT` statement to create a tenant, you must connect your root user to the root tenant (`root@ROOT`).

Note

You must specify `RESOURCE_POOL_LIST` when you create a tenant.

When you specify `RESOURCE_POOL_LIST` for the `CREATE TENANT` statement, only one resource pool is supported.

`DEFAULT TABLEGROUP` specifies a default table group for the tenant. If you do not specify this parameter, the value is `NULL`.

Examples

```
mysql> CREATE TENANT IF NOT EXISTS t1 charset='utf8mb4', replica_num=1, zone_list=('zone1'), primary_zone='zone1', resource_pool_list=('pool1');
Query OK, 0 rows affected (0.26 sec)
```

Errors

- If your statement has a syntax error, the system returns the following error: `ERROR 1064 (42000): You have an error in your SQL syntax; .`
- If the specified tenant name is already used and the `IF NOT EXISTS` option is not specified, the system returns the following error: `ERROR(OB_ERR_ALREADY_EXISTS, -5025, -1, "42501", "Already exist"); .`

18.5.13.8. ALTER TENANT

Syntax

```
ALTER TENANT tenantname [SET] [tenant_options]
```

tenant_options:

```
tenant_option [ tenant_option...]
```

tenant_options:

```
COMMENT [=]'string'
```

```
{{CHARACTER SET | CHARSET} [=] charsetname
```

```
[COLLATE [=] collationname
```

```
[REPLICA_NUM [=] num
```

```
[ZONE_LIST [=] (zone [, zone...])
```

```
[PRIMARY_ZONE [=] zonelist
```

```
[RESOURCE_POOL_LIST [=](poolname [, poolname...])
```

```
[DEFAULT TABLEGROUP [=] {NULL | tablegroupname}
```

```
{{READ ONLY | READ WRITE}
```

```
| LOCALITY [=] locality
```

 **Note** You must specify `RESOURCE_POOL_LIST` when you create a tenant.

The system tenant users and the administrator of the current tenant have the permission to execute the `ALTER TENANT` statement.

`DEFAULT TABLEGROUP` specifies a default table group for the tenant. A NULL value indicates no default table group for the database.

Errors

If your statement has a syntax error, the system returns the following error: `ERROR 1064 (42000): You have an error in your SQL syntax;` .

18.5.13.9. Lock or unlock a tenant

Syntax

```
ALTER TENANT tenantname LOCK|UNLOCK;
```

You can execute this statement to lock a tenant. After the tenant is locked, you cannot create sessions on the tenant. The existing sessions remain unchanged. You can lock a tenant if the subscription of the service is not renewed upon expiration. After the subscription is renewed, you can unlock the tenant.

Examples

- Execute the following statement to lock TENANT1:

```
ALTER TENANT TENANT1 LOCK;
```

- Execute the following statement to unlock TENANT1:

```
ALTER TENANT TENANT1 UNLOCK;
```

Errors

If your statement has a syntax error, the system returns the following error: `ERROR 1064 (42000): You have an error in your SQL syntax;` .

18.5.13.10. DROP TENANT

Syntax

```
DROP TENANT tenantname;
```

DROP You can execute this statement to delete an ApsaraDB for OceanBase tenant.

Before you execute the `DROP TENANT` statement to delete a tenant, you must connect your root user to the root tenant (`root@ROOT`).

You can delete a tenant only if the tenant is in the Locked state. If you execute the `DROP TENANT` statement to delete an unlocked tenant, the system returns an error.

Examples

Execute the following statement to delete TENANT1:

```
DROP TENANT TENANT1;
```

Errors

If your statement has a syntax error, the system returns the following error: `ERROR 1064 (42000): You have an error in your SQL syntax; .`

18.5.13.11. CREATE TABLEGROUP

Syntax

```
CREATE TABLEGROUP [IF NOT EXISTS] tablegroupname
```

If the specified table group name is already used and the `IF NOT EXISTS` option is not specified, the system returns an error.

A table group name must be up to 64 characters in length and can contain letters, digits, and underscores (_). The name must start with a letter or an underscore (_) and cannot be a keyword that is reserved for ApsaraDB for OceanBase.

Only the tenant administrator can create a table group.

Examples

```
CREATE TABLEGROUP myTableGroup1;
```

18.5.13.12. DROP TABLEGROUP

Syntax

```
DROP TABLEGROUP [IF EXISTS] tablegroupname
```

Examples

```
DROP TABLEGROUP myTableGroup1;
```

Errors

- If your statement has a syntax error, the system returns the following error: `ERROR 1064 (42000): You have an error in your SQL syntax; .`
- Before you delete a table group, make sure that no object such as a table or an index is using the table group. If the table group is still in use, the system returns an error.

18.5.13.13. ALTER TABLEGROUP

Syntax

```
ALTER TABLEGROUP tablegroupname ADD [TABLE] tblname [, tblname...]
```

You can execute this statement to add multiple tables to a table group. Table names are separated with commas (,).

If you add multiple tables at a time, you can specify duplicate table names. If a table to be added already exists in the table group that is specified by `tablegroupname`, the system does not return an error.

18.5.13.14. Users and permissions

You can manage users and permissions on databases. These management operations include creating a user, deleting a user, changing a password, changing a username, locking a user, granting permissions, and revoking permissions.

ApsaraDB for OceanBase users are divided into two types: users of the system tenant and users of general tenants.

When you create a user, if the current session is created on the system tenant, the new user is created for the system tenant. If the current session is created on a general tenant, the new user is created for the general tenant.

Username are unique within a tenant. Users under different tenants can have the same name. The Username@TenantName must be globally unique in the cluster. Usernames of users of the system tenant have a predetermined prefix. You can distinguish users of the system tenant from users of general tenants based on this characteristic. The system tenant or each general tenant has a built-in root user. The root user for a system tenant is the system administrator, and the root user for a general tenant is the tenant administrator. If you purchase a general tenant, you have the permissions to use the root user and the password of the general tenant to manage resources within the tenant.

Users of a general tenant can access only objects in the general tenant. This is the same as the logic of MySQL. Users of the system tenant can access objects that belong to different tenants. Users of the system tenant cannot access user tables that are stored in general tenants. When you log on to the ApsaraDB for OceanBase system, you must specify a unique tenant name. If you are using a user of the system tenant, you can execute the `CHANGE EFFECTIVE TENANT tenantname` statement to access another tenant after you log on to the system. However, if you are using a user of a general tenant, you cannot switch the tenant.

Create users

You can execute the `CREATE USER` statement to create an ApsaraDB for OceanBase user.

After a user is created, you can use the user to connect to ApsaraDB for OceanBase.

Syntax

```
CREATE USER user_specification_list;
user_specification_list:
    user_specification [, user_specification]...;
user_specification:
    user IDENTIFIED BY 'authstring'
    user IDENTIFIED BY PASSWORD 'hashstring'
```

Notes:

- To execute the `CREATE USER` statement, you must have the global `CREATE USER` permission.
- After a user is created, a new row is added for the user to the `mysql.user` table. If the username is already used by an existing user, the system returns an error.
- You can specify the `IDENTIFIED BY` clause to set the password for your user.
- `user IDENTIFIED BY` Specify user `IDENTIFIED BY 'authstring'` to set a plaintext password. After the password is saved to the `mysql.user` table, the password is stored in ciphertext on the server.
- Specify `user IDENTIFIED BY PASSWORD 'hashstring'` to set a ciphertext password.
- If you create multiple users at a time, separate pairs of user information with commas (,).

Examples

```
Oceanbase>CREATE USER 'sqluser01' IDENTIFIED BY '123456', 'sqluser02' IDENTIFIED BY '123456';
Query OK, 0 rows affected (0.07 sec)
Oceanbase>select user from user;
+-----+
| user  |
+-----+
| root  |
| test  |
| sqluser01 |
| sqluser02 |
+-----+
4 rows in set (0.01 sec)
```

Delete users

You can execute the `DROP USER` statement to delete one or more ApsaraDB for OceanBase users.

Syntax

```
DROP USER username [, username...];
```

Notes:

- To execute the `DROP USER` statement, you must have the global `CREATE USER` permission.
- You cannot delete a user by performing a `DELETE` operation on the `mysql.user` table.
- After a user is deleted, all permissions of the user are deleted.
- If you delete multiple users at a time, separate the usernames with commas (,).

Examples

Execute the following statement to delete the user `sqluser02` :

```
DROP USER 'sqluser02';
```

Change a password

You can change the password for a user that is used to log on to the ApsaraDB for OceanBase system.

Syntax

```
SET PASSWORD [FOR user] = password_option;
password_option: {
    PASSWORD('authstring')
    ['hashstring']
}
```

Or

```
ALTER USER username IDENTIFIED BY 'password';
```

Notes:

- If you do not specify the `FOR user` clause in the statement, the system changes the password for the current user. After a user logs on to the ApsaraDB for OceanBase system, the user can change the password.
- If you specify the `FOR user` clause in the statement, or you use the second syntax, the system changes the

password for the specified user. To change the password for a specified user, you must have the global `CREATE USER` permission.

Examples

Execute the following `ALTER USER` statement to change the password of `sqluser01` to `abc123` :

```
ALTER USER sqluser01 IDENTIFIED BY 'abc123';
```

Execute the following `SET PASSWORD` statement to change the password:

```
Oceanbase>set password for test = password('abc123');
Query OK, 0 rows affected (0.03 sec)
# If you do not specify the password function, the system returns the following error:
Oceanbase>set password for test = 'abc123';
ERROR 1827 (42000): The password hash doesn't have the expected format. Check if the correct password algorithm is being used with the PASSWORD() function.
```

Change a username

You can change the username of a user that is used to log on to the ApsaraDB for OceanBase system.

Syntax

```
RENAME USER
  'oldusername' TO 'newusername'
  [, 'oldusername' TO 'newusername'...];
```

Notes:

- To execute this statement, you must have the global `CREATE USER` permission.
- If you change multiple usernames at a time, separate the pairs of username information with commas (,).
- After you change the username for a user, the permissions of the user remain unchanged.
- The username must be up to 16 bytes in length.

Examples

```
Oceanbase>select user from user;
+-----+
| user  |
+-----+
| root  |
| testall |
+-----+
2 rows in set (0.00 sec)
```

Change a username.

```
Oceanbase>rename user testall to test;
Query OK, 0 rows affected (0.03 sec)
Oceanbase>select user from user;
+-----+
| user |
+-----+
| root |
| test |
+-----+
2 rows in set (0.00 sec)
```

Lock a user

You can lock or unlock a user. Locked users are not allowed to log on to the ApsaraDB for OceanBase system.

Syntax

```
ALTER USER user [lock_option]
lock_option:{
  ACCOUNT LOCK
  | ACCOUNT UNLOCK}
```

To execute this statement, you must have the global `UPDATE USER` permission.

Examples

- Lock a user.

```
Oceanbase>alter user test account lock;
Query OK, 0 rows affected (0.04 sec)
```

- Unlock a user.

```
Oceanbase>alter user test account unlock;
Query OK, 0 rows affected (0.02 sec)
```

Grant permissions to a user

You can execute the `GRANT` statement as a system administrator to grant permissions to a user.

Syntax

```

GRANT priv_type
    ON priv_level
    TO user_specification [, user_specification]...
    [WITH with_option ...]
priv_level:
    *
    | *.*
    | db_name.*
    | db_name.tbl_name
    | tbl_name
user_specification:
    user [IDENTIFIED BY [PASSWORD] 'password']
with_option:
    GRANT OPTION
    
```

Permissions can be divided into the following levels:

- **Global permissions**
Global permissions apply to all databases. To grant global permissions, use the `GRANT ALL ON *.*` syntax.
- **Database permissions**
Database permissions apply to all objects in a specified database. To grant permissions on a specified database, use the `GRANT ALL ON db_name.*` syntax.
- **Table permissions**
Table permissions apply to all columns in a specified table. To grant permissions on a specified table, use the `GRANT ALL ON db_name.tbl_name` syntax.

Notes:

- You must grant permissions to specific users. If a specified user does not exist, the system can create the user if the SQL mode is `NO_AUTO_CREATE_USER`. You can specify this SQL mode by executing `sql_mode='no_auto_create_user'`. If you do not use the `IDENTIFIED BY` clause to specify the password, the system cannot create the user.
- To grant permissions to a user, you must have the permission that you are granting. For example, if you use user1 to grant user2 the `SELECT` permission on table t1, user1 must have the `SELECT` permission on table t1. You must also have the `GRANT OPTION` permission.
- After a permission is granted, the authorized user must relog on to the ApsaraDB for OceanBase system so that the permission can take effect.
- You can use an asterisk (*) instead of specifying a table name to grant permissions on all tables in the specified database.
- If you grant multiple permissions to a user at a time, separate the permission types with commas (,).
- If you grant permissions to multiple users at a time, separate the usernames with commas (,).
- **Description of the priv_type values** lists the priv_type values that can be specified for the `GRANT` statement.

Description of the priv_type values

Permission	Description
ALL PRIVILEGES	All permissions except <code>GRANT OPTION</code> .

Permission	Description
ALTER	The permission to execute the <code>ALTER TABLE</code> statement.
CREATE	The permission to execute the <code>CREATE TABLE</code> statement.
CREATE USER	The permission to execute the <code>CREATE USER</code> , <code>DROP USER</code> , <code>RENAME USER</code> , and <code>REVOKE ALL PRIVILEGES</code> statements.
CREATE TABLEGROUP	The global permission to execute the <code>CREATE TABLEGROUP</code> statement.
DELETE	The permission to execute the <code>DELETE</code> statement.
DROP	The permission to execute the <code>DROP</code> statement.
GRANT OPTION	The permission to execute the <code>GRANT OPTION</code> statement.
INSERT	The permission to execute the <code>INSERT</code> statement.
SELECT	The permission to execute the <code>SELECT</code> statement.
UPDATE	The permission to execute the <code>UPDATE</code> statement.
SUPER	The permission to execute the <code>SET GLOBAL</code> statement to modify global system parameters.
SHOW DATABASES	The global permission to execute the <code>SHOW DATABASES</code> statement to display all databases.
INDEX	The permission to execute the <code>CREATE INDEX</code> and <code>DROP INDEX</code> statements.
CREATE VIEW	The permission to create or delete a view.
SHOW VIEW	The permission to execute the <code>SHOW CREATE VIEW</code> statement.

 **Note** You cannot grant users the permission to execute the `CHANGE EFFECTIVE TENANT` statement. However, all users of the system tenant have this permission.

Revoke permissions

You can execute the `REVOKE` statement as a system administrator to revoke the specified permissions from users.

Syntax

```
REVOKE priv_type
      ON database.tblname
      FROM 'user';
```

Notes:

- To revoke permissions from a user, you must have the permission that you are revoking. For example, if you use user1 to revoke the SELECT permission on table t1 from user2, user1 must have the SELECT permission on table t1. You must also have the GRANT OPTION permission.
- To revoke the ALL PRIVILEGES and GRANT OPTION permissions, you must have the global GRANT OPTION permission or the UPDATE and DELETE permissions on the permission list.
- Revocations do not have cascading effects. Assume that user1 grants permissions to user2. When the permissions are revoked from user1, the permissions are not revoked from user2.
- You can use an asterisk (*) instead of specifying a table name to revoke permissions on all tables in the specified database.
- If you revoke multiple permissions from a user at a time, separate the permission types with commas (,).
- If you revoke permissions from multiple users at a time, separate the usernames with commas (,).
- [Description of the priv_type values](#) lists the priv_type values that can be specified for the REVOKE statement.

Examples

Revoke all permissions from obsqluser01 .

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM 'obsqluser01';
```

View permissions

You can execute the SHOW GRANTS statement as a system administrator to view permissions that have been granted to a user.

Syntax

```
SHOW GRANTS [FOR username];
```

Notes:

- If you do not specify the username, this statement returns the permissions that have been granted to the current user. You can always view the permissions of the user that you are using.
- To view the permissions of a non-current user, you must have the SELECT permission on the mysql.user table.

Examples

```
Oceanbase>show grants for test;
+-----+
| Grants for test      |
+-----+
| GRANT USAGE ON *. * TO 'test'|
+-----+
1 row in set (0.01 sec)
```

18.5.13.15. Modify system variables

System variables such as autocommit and tx_isolation affect SQL functionality and are stored in the __all_sys_variable table.

ApsaraDB for OceanBase maintains two types of variables:

- Global variables

Global variables affect overall operations on the ApsaraDB for OceanBase system. When the ApsaraDB for OceanBase system starts, the system initializes all global variables to the default values. To modify global variables, you must have the SUPER permission.

- Session variables

Session variables affect operations on the clients that are connected to the ApsaraDB for OceanBase system. When a client connects to the ApsaraDB for OceanBase system, the system initializes the session variables of the client to the current values of the corresponding global variables. To set session variables, you do not need special permissions. You can modify only the session variables of your client. You cannot modify the session variables of other clients.

 **Note** Modifications to global variables do not affect the session variables of clients that are connected to the ApsaraDB for OceanBase system. This is true even if the `SET GLOBAL` statement is executed on the connected clients.

Syntax

- Set a global variable.

```
SET GLOBAL system_var_name = expr;
```

Or

```
SET @@GLOBAL.system_var_name = expr;
```

- Set a session variable.

```
SET [SESSION | @@SESSION. | LOCAL | LOCAL. | @@]system_var_name =expr;
```

- Display the values of system variables.

If the GLOBAL modifier is specified, the SHOW VARIABLES statement displays the values of global system variables. If the SESSION modifier is specified, this statement displays the values of system variables that are specific to the current session. If no modifier is specified, this statement displays the values of system variables that are specific to the current session.

```
SHOW [GLOBAL | SESSION]
  VARIABLES
  [LIKE 'system_var_name' | WHERE expr];
```

You can execute a `SELECT @@var_name` statement to search for a variable. If you do not specify the GLOBAL modifier, the system returns the value of a session-specific variable. If you specify the GLOBAL modifier, the system returns the value of a global variable.

Configure the READ ONLY property of a tenant

```
SET GLOBAL READ_ONLY={ON | OFF};
```

Or

```
SET @@GLOBAL.READ_ONLY={ON | OFF};
```

Examples

- Execute the following statement to change the value of the ob_trx_timeout session variable:

```
SET @@SESSION.ob_tx_timeout = 900000;
```

- Execute the following statement to query the value of the ob_trx_timeout variable:

```
Oceanbase>show variables like 'ob_trx_timeout';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| ob_trx_timeout | 100000000 |
+-----+-----+
1 row in set (0.02 sec)
```

- Execute the following SELECT statement to query the value of the wait_timeout system variable:

```
SELECT @@wait_timeout;
+-----+
| @@wait_timeout |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)
```

18.5.13.16. Modify user variables

A user variable in one statement stores a user-defined value that you can refer to later in another statement. This helps you pass values between statements. User variables are session-specific. A user variable that is defined by one client cannot be queried or used by another client. When a client exits, all variables that are specific to the client session are automatically released.

Syntax

```
SET @var_name = expr;
```

- User variables are expressed as @var_name. The variable name var_name consists of alphanumeric characters, decimal points (.), underscores (_), and dollar signs (\$) from the current character set.
- The expression of a variable can be an integer, real number, string, or NULL value.
- If you set multiple user variables at a time, separate the variable definitions with commas (,).

Examples

- Execute the following SET statements to set user variables:

```
Oceanbase>SET @a=2, @b=3;
Query OK, 0 rows affected (0.01 sec)

Oceanbase>SET @c = @a + @b;
Query OK, 0 rows affected (0.00 sec)
```

- Execute the following statement to query user variables:

```
Oceanbase>SELECT @a, @b, @c;
+-----+-----+-----+
| @a | @b | @c |
+-----+-----+-----+
| 2 | 3 | 5 |
+-----+-----+-----+
1 row in set (0.01 sec)
```

- Execute the following SELECT statement to set user variables:

```
Oceanbase> SELECT @a:=2, @b:=3, @c:=@a+@b;
+-----+-----+-----+
| @a:=2 | @b:=3 | @c:=@a+@b |
+-----+-----+-----+
| 2 | 3 | 5 |
+-----+-----+-----+
1 row in set (0.01 sec)
```

18.5.13.17. ALTER SYSTEM database management statements

18.5.13.17.1. Overview

You can execute ALTER SYSTEM statements to send commands to the ApsaraDB for OceanBase system to perform specified operations.

18.5.13.17.2. System-level management statements

Bootstrap the system

```
ALTER SYSTEM BOOTSTRAP
[REGION [=] 'region'] ZONE [=] 'zone' SERVER [=] 'ip:port'
[, [REGION [=] 'region'] ZONE [=] 'zone' SERVER [=] 'ip:port' ...] ;
```

To bootstrap the system, you must specify the root servers. Use commas (,) to separate multiple root servers.

REGION specifies a region. You must specify a region if your ApsaraDB for OceanBase service is deployed across zones in multiple regions.

A cluster can have only one root server to act as the leader to provide services.

Example:

```
ALTER SYSTEM BOOTSTRAP ZONE 'zone1' SERVER '10.218.248.178:55410';
```

Separate multiple root servers with commas (,).

```
ALTER SYSTEM BOOTSTRAP ZONE 'zone1' SERVER '172.24.65.24:55410', ZONE 'zone2' SERVER '172.24.65.114:55410';
```

Update the system version

```
ALTER SYSTEM BEGIN UPGRADE # Start the system update.  
ALTER SYSTEM END UPGRADE # End the system update.
```

Notes:

1. When the administrator executes `ALTER SYSTEM BEGIN UPGRADE` to update the system version, the leader root server performs a series of checks. For example, it checks the servers for version consistency and modifies the `enable_upgrade_mode` parameter.
2. The leader root server maintains the minimum server version of the cluster. The leader root server analyzes server versions in the `__all_server` table and saves the minimum version in the `min_observer_version` parameter.

 **Note** ApsaraDB for OceanBase supports 3-bit version numbers, such as V1.2.3. In a version number, the first digit represents `observer_major_version`, the second digit represents `observer_minor_version`, and the third digit represents `observer_patch_version`.

3. When a system update begins, the leader root server checks whether all servers in the cluster are of the same version and whether the version is the same as the minimum version.

When the `ALTER SYSTEM END UPGRADE` statement is executed to end the update, the leader root server checks whether all servers are updated and changes the `min_observer_version` value.

Manage the schema

To refresh the schema, execute the following statement:

```
ALTER SYSTEM REFRESH SCHEMA {SERVER='ip:port'} ZONE='zone';
```

When the system executes Data Definition Language (DDL) operations, the leader root server notifies all ODBServers to refresh the schema.

If an exception occurs to an ODBServer, the ODBServer is disconnected from the leader root server. You must manually refresh the schema. You can refresh the schema for an ODBServer or a cluster.

Examples:

- Refresh the schema for an ODBServer.

```
ALTER SYSTEM REFRESH SCHEMA SERVER='172.24.65.24:55410';
```

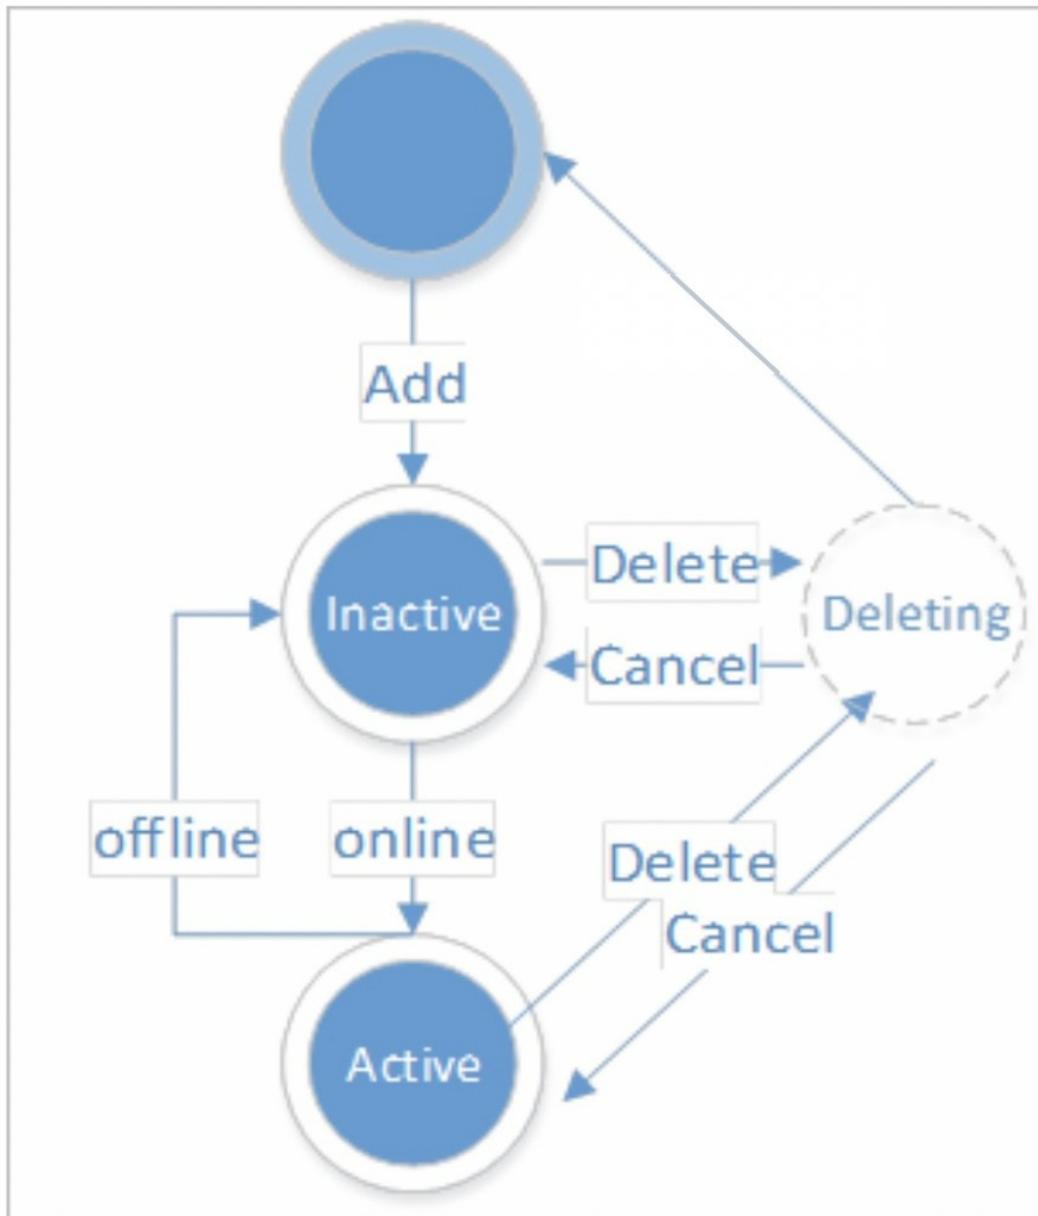

- Refresh the schema for all ODBServers that are deployed in a zone.

```
ALTER SYSTEM REFRESH SCHEMA ZONE='zone1';
```

Manage servers

Server status shows the status of a server when different operations are performed.

Server status

**Notes:**

1. You can execute the `ALTER SYSTEM ADD SERVER` or `ALTER SYSTEM DELETE SERVER` statement to add a server to or delete a server from the server list. Only servers on the list can provide services.
2. When the `ALTER SYSTEM DELETE SERVER` statement is executed, the ApsaraDB for OceanBase system selects a new replica leader and replicates replicas.
3. The `DELETE` operation is time-consuming. You can execute the `ALTER SYSTEM CANCEL DELETE SERVER` statement to abort this operation.

To add a server, execute the following statement:

```
ALTER SYSTEM ADD SERVER 'ip:port' [, 'ip:port'...] [ZONE='zone'];
```

If a zone is specified, the system checks whether the server that you want to add is deployed in the specified zone.

Example:

```
ALTER SYSTEM ADD SERVER '172.24.65.113:55410' ZONE 'zone1';
```

To delete and undelete a server, execute the following statements:

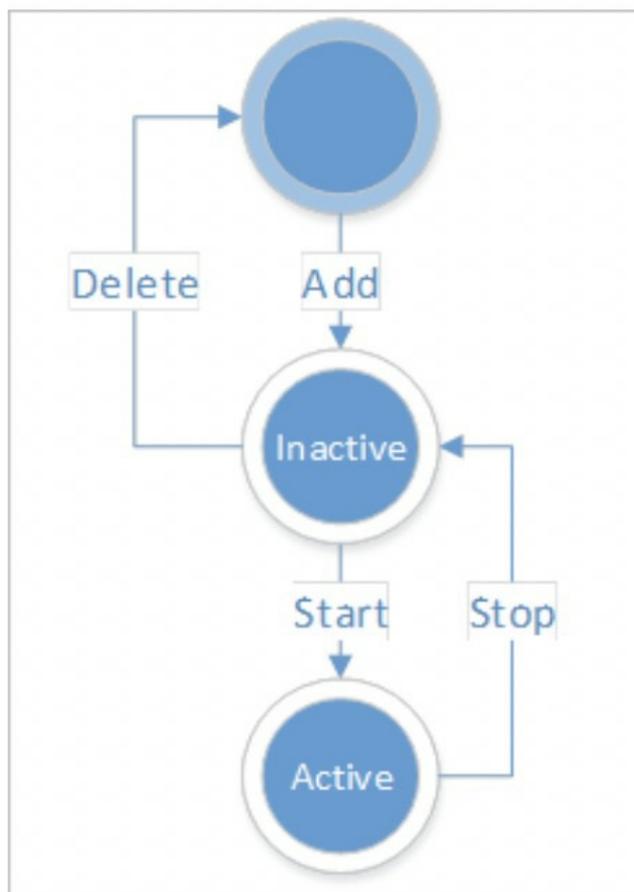

```
ALTER SYSTEM DELETE SERVER 'ip:port' [, 'ip:port!...'] [ZONE[='zone']]
```

```
ALTER SYSTEM CANCEL DELETE SERVER 'ip:port' [, 'ip:port!...'] [ZONE[='zone'];
```

Manage zones

Zone status shows the status of a zone when different operations are performed.

Zone status

- Add a zone.

```
ALTER SYSTEM ADD ZONE 'zone' [REGION 'region'];
```

- Delete a zone.

```
ALTER SYSTEM DELETE ZONE 'zone';
```

- Activate or deactivate a zone.

```
ALTER SYSTEM {START|STOP} ZONE 'zone';
```

Modify the region property for a zone

You can specify the region property for a zone in ApsaraDB for OceanBase V1.3 and later versions.

Syntax:

```
ALTER SYSTEM {ALTER|MODIFY|CHANGE} ZONE 'zone_name' [set] alter_zone_option
alter_zone_option: region [=] 'region_name'
```

Manage sessions

If you are a user of a general tenant, execute the following statement to close a session:

```
KILL [GLOBAL|LOCAL] [CONNECTION] 'sessionid';
```

If you are a system administrator, execute the following statement to close a session:

```
ALTER SYSTEM KILL [GLOBAL|LOCAL] SESSION 'sessionid';
```

Manage partitions

- Select a new replica leader.

```
ALTER SYSTEM
SWITCH REPLICA LEADER | FOLLOWER
(PARTITION_ID='partidx%partcount@tableid' SERVER='ip:port' | SERVER='ip:port' | ZONE='zone');
```

- Delete a replica.

```
ALTER SYSTEM
DROP REPLICA
PARTITION_ID = 'partidx%partcount@tableid'
SERVER = 'ip:port'
[CREATE_TIMESTAMP = ctimestamp]
[ ZONE='zone'];
```

To delete a replica on the specified OBServer, you must specify the following parameters: PARTITION_ID, SERVER, and CREATE_TIMESTAMP.

- Migrate or replicate a replica from one OBServer to another OBServer.

```
ALTER SYSTEM
{MOVE|COPY} REPLICA
PARTITION_ID 'part_idx%part_count@table_id'
SOURCE='ip:port'
DESTINATION='ip:port' ;
```

To migrate or replicate a replica, you must specify the source OBServer, the destination OBServer, and the partition ID.

- Cancel a replica migration or replication task.

```
ALTER SYSTEM
CANCEL [PARTITION MIGRATION] TASK 'task_id';
```

To cancel a migration task, you must specify the task ID. You can query task IDs from the `__all_virtual_sys_task_status` table.

- Report replicas.

```
ALTER SYSTEM
  REPORT REPLICA
  {SERVER = 'ip:port' | ZONE='zone'};
```

This statement requires an OBCServer or all OBCServers in a zone to report replicas.

- Recycle replicas that are not used.

```
ALTER SYSTEM RECYCLE REPLICA {SERVER = 'ip:port' | ZONE='zone'};
```

- Modify the properties of a replica.

```
ALTER SYSTEM
  {alter|change|modify} REPLICA
  PARTITION_ID 'part_idx%part_count@table_id'
  SERVER = 'ip:port'
  [set] change_actions;
change_actions: REPLICA_TYPE = 'replica_type'
```

This statement modifies the type of a specified replica.

The valid values of replica type are FULL, READONLY, and LOGONLY. You can set the value of `replica_type` to the full name or the abbreviation of a valid replica type, such as F, R, or L. The value is not case-sensitive.

Run a system job

To run a system job, execute the following statement:

```
ALTER SYSTEM RUN JOB 'job_name' {SERVER='ip:port' | ZONE='zone'}
```

If the specified job name contains a special character, enclose the job name in single quotation marks ('). In other cases, single quotation marks are optional.

The system supports the following jobs:

- `check_partition_table`

You can run this job to check partitioned tables on an OBCServer.

- `root_inspection`

You can run this job to trigger the leader root server to check the following information:

- Whether the hard-coded schema in the system table is the same as the schema in the internal table.
- Whether the hard-coded system variables are the same as the system variables in the internal table.
- Whether the hard-coded `zone_info` and `sys_stat` are the same as those in the internal table.

Perform daily major freeze operations

You can perform the following daily major freeze operations:

- Initiate a daily major freeze request.

```
ALTER SYSTEM MAJOR FREEZE
```

- Activate a manually triggered major freeze operation.

```
ALTER SYSTEM SET ENABLE_MANUAL_MERGE='True'
```

- Deactivate a manually triggered major freeze operation.

```
ALTER SYSTEM SET ENABLE_MANUAL_MERGE='False'
```

- Start the daily major freeze operation.

```
ALTER SYSTEM START MERGE ZONE='zone';
```

- Suspend the daily major freeze operation.

```
ALTER SYSTEM SUSPEND MERGE [ZONE='zone']
```

- Resume the daily major freeze operation.

```
ALTER SYSTEM RESUME MERGE [ZONE='zone']
```

```
ALTER SYSTEM CLEAR ROOTTABLE [TENANT='tenantname'];
```

Manage memory

You can perform the following memory management operations:

- Initiate a minor freeze request.

```
ALTER SYSTEM MINOR FREEZE
  [{TENANT [=] ('tt1' [, 'tt2'...]) | PARTITION_ID [=] 'partidx%partcount@tableid'}]
  [{SERVER [=] ('ip:port' [, 'ip:port'...])}] ;
```

- Clear a plan cache.

```
ALTER SYSTEM FLUSH PLAN CACHE
```

- Clear KV caches.

```
1. Clear the schema cache of the system tenant.
ALTER SYSTEM FLUSH KVCACHE TENANT='sys' CACHE='schema_cache';

2. Clear the KV caches of the system tenant.
ALTER SYSTEM FLUSH KVCACHE TENANT='sys';

3. Clear the KV caches of all tenants.
ALTER SYSTEM FLUSH KVCACHE;
```

Configure parameters

- Modify system parameters.

```
ALTER SYSTEM [SET] param_name [=] expr
  [COMMENT [=]'text']
  [SCOPE [=] conf_scope]
  {SERVER [=] 'ip:port' | ZONE [=] 'zone'};
```

For more information about how to modify system parameters, see [Clause description](#).

Clause description

Clause	Description
<i>param_name = expr</i>	The name of a system parameter.

Clause	Description
COMMENT ' <i>text</i> '	Optional. This clause is used to add a comment about the modification. We recommend that you add a comment.
SCOPE = <i>conf_scope</i>	<p>The effective range of the modification. The following three values are supported:</p> <ul style="list-style-type: none"> ◦ MEMORY: Only the parameter value in the memory is modified. The modified parameter takes effect immediately after the modification and becomes invalid after the server is restarted. However, no parameter supports this option. ◦ SPFILE: Only the parameter value in the configuration table is modified. The modified parameter takes effect after the server is restarted. ◦ BOTH: The parameter values in the configuration table and in the memory are modified. The modified parameter takes effect immediately after the modification and remains valid after the server is restarted. <p> Note The default value is BOTH. If you specify BOTH or MEMORY for a parameter that cannot take effect immediately after the modification, the system returns an error.</p>
SERVER_TYPE = <i>server_type</i>	The server type. Valid values: ROOTSERVER, UPDATESERVER, CHUNKSERVER, and MERGESERVER.
ZONE = ' <i>zone_name</i> '	The name of the zone, which indicates that the modified parameter applies to the specified type of servers in the specified cluster. If you do not specify the zone name, the modified parameter applies to the specified type of servers in all clusters.
SERVER = ' <i>ip:port</i> '	The IP address and port number of the server, which indicates that only the parameter of a specified server is modified.

If you modify multiple system parameters in one request, separate the parameters with commas (,).

- Query system parameters.

```
SHOW PARAMETERS [LIKE 'pattern' | WHERE expr];
```

Manage time zone information

```
ALTER SYSTEM REFRESH TIME_ZONE_INFO
```

ApsaraDB for OceanBase uses `mysql_tzinfo_to_sql` to generate an SQL script based on the time zone information in the operating system. The system then adds the time zone information into the following four system tables: `__all_time_zone`, `__all_time_zone_name`, `__all_time_zone_transition`, and `__all_time_zone_transition_type`.

The `ALTER SYSTEM REFRESH TIME_ZONE_INFO` statement notifies all servers in the cluster to update the local time zone information based on the related system tables.

Reset the valid flag for a disk

```
ALTER SYSTEM SET DISK VALID SERVER [=] 'ip:port'
```

ApsaraDB for OceanBase automatically checks whether a disk has failed. If a possible disk failure is detected, the system sets a flag to migrate the leader from the current OBServer to another OBServer.

This flag is valid for all partitions on the OBServer.

When the database administrator finds that the disk restores to a normal status, the administrator can execute this statement to reset the flag.

18.5.13.17.3. Tenant-level management statements

Modify tenant-level parameters

```
ALTER SYSTEM SET param_name = expr
  [COMMENT 'text']
  [SCOPE = conf_scope]
  [TENANT = 'tenantname']
```

Enable or disable the migration feature or the replication feature

- Enable or disable the migration feature.

```
ALTER SYSTEM SET ENABLE_REBALANCE = {true|false} [TENANT='tenantname'];
```

- Enable or disable the replication feature.

```
ALTER SYSTEM SET ENABLE_REREPLICATION= {true|false} [TENANT='tenantname'];
```

18.5.14. READ ONLY

18.5.14.1. Overview

ApsaraDB for OceanBase allows you to set the READ ONLY property at the tenant, database, or table level.

General syntax

The following rules apply:

1. To define the READ ONLY property, you can execute the following ALTER statement, which is consistent with Oracle in syntax.

```
ALTER {TENANT | DATABASE | TABLE }
 {tenant_name | database_name | table_name}
 {READ ONLY | READ WRITE}
```

2. To be compatible with MySQL instances, you can execute the `SET @@GLOBAL.READ_ONLY=ON|OFF` statement to set the READ ONLY property for a tenant.
3. After you configure the READ ONLY property at a specific level, the specified objects can be in one of the following states: READ ONLY, READ WRITE, and PARTIALLY READ ONLY. PARTIALLY READ ONLY is an intermediate status, which indicates that the specified objects are in the READ ONLY state on some OBServers.

Notes

When you set the READ ONLY property, follow these rules:

1. The READ ONLY property can apply to the following levels in descending order: tenant level, database level, or table level. The READ ONLY property at a higher level takes precedence over that at a lower level.
For example, if a tenant is in the READ ONLY state, the databases and tables within the tenant are in the READ ONLY state regardless of whether the READ ONLY property is set.
2. To be compatible with MySQL, you must have the SUPER permission to perform read and write operations on the objects that are in the READ ONLY state.

18.5.14.2. Tenant-level READ ONLY property

Configure the READ ONLY property

Use one of the following two methods based on your needs:

- In a system tenant, log on to the system by using a user that has the SUPER permission, and execute the following statement to set the READ ONLY property for all tenants:

```
ALTER TENANT tenant_name {READ ONLY | READ WRITE};
```

- In a general tenant, log on to the system by using a user that has the SUPER permission, and execute one of the following statements to set the READ ONLY property for the current tenant:

```
SET GLOBAL READ_ONLY={ON | OFF};  
Or  
SET @@GLOBAL.READ_ONLY={ON | OFF};
```

Query the READ ONLY property

Use one of the following three methods to query the READ ONLY property of the current tenant:

- Execute the `SHOW TENANT STATUS` statement.

```
SHOW TENANT STATUS;
```

Example:

```
OceanBase (admin@test)> show tenant status;  
+-----+-----+  
| Tenant | State |  
+-----+-----+  
| sys   | read only |  
+-----+-----+  
1 row in set (0.01 sec)
```

- Query the internal table `oceanbase.__tenant_virtual_tenant_status`.

```
OceanBase (admin@test)> select * from oceanbase.__tenant_virtual_tenant_status;  
+-----+-----+-----+-----+  
| tenant | host   | port | read_only |  
+-----+-----+-----+-----+  
| sys   | 172.24.65.24 | 55410 | 1 |  
+-----+-----+-----+-----+  
1 row in set (0.00 sec)
```

You can query the status of the current tenant on all OBServers based on the `oceanbase.__tenant_virtual_tenant_status` table.

- Query the `read_only` system variable.

```
show global variables like 'read_only'
```

Or

```
select @@global.read_only
```

18.5.14.3. Database-level READ ONLY property

Configure the READ ONLY property

```
ALTER DATABASE database_name {READ ONLY | READ WRITE};
```

Query the READ ONLY property

Use one of the following two methods to query the READ ONLY property of the databases under the current tenant:

- Execute the `SHOW DATABASES STATUS` statement to query the READ ONLY property of the specified databases.

The system returns the status information for each database. In the output, one column shows whether each database is in the READ ONLY state. Each database supports three states: READ ONLY, READ WRITE, and PARTIALLY READ ONLY. READ ONLY indicates that this database is only readable. READ WRITE indicates that this database is readable and writable. PARTIALLY READ ONLY indicates an intermediate status where the database is in the READ WRITE state on some OBServers and in the READ ONLY state on the other OBServers.

You can include a LIKE or WHERE clause in this statement. The clause is used to specify the databases for which you want to query the status.

- Query the internal table `oceanbase.__tenant_virtual_database_status`.

```
OceanBase (admin@test)> select * from oceanbase.__tenant_virtual_database_status;
+-----+-----+-----+-----+
| db   | host   | port | read_only |
+-----+-----+-----+-----+
| mysql | 172.24.65.24 | 55410 | 0 |
| test  | 172.24.65.24 | 55410 | 0 |
+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

You can query the status of all databases under the current tenant on all OBServers based on the `oceanbase.__tenant_virtual_database_status` table.

18.5.14.4. Table-level READ ONLY property

Configure the READ ONLY property

```
ALTER TABLE table_name [SET] {READ ONLY | READ WRITE}
```

Query the READ ONLY property

Use one of the following two methods to query the READ ONLY property of tables:

- Execute the `SHOW TABLE STATUS` statement.

```
SHOW TABLE STATUS
```

- Query the internal table `oceanbase.__tenant_virtual_table_status`.

You can query the status of all tables in all databases under the current tenant on all OBServers based on the `oceanbase.__tenant_virtual_table_status` table.

18.5.15. Other SQL statements

18.5.15.1. SHOW statements

You can execute SHOW statements to query information such as the status of databases, tables, columns, or servers in the ApsaraDB for OceanBase system.

SHOW CHARACTER SET

```
SHOW CHARACTER SET
[LIKE 'pattern' | WHERE expr]
```

The `SHOW CHARACTER SET` statement returns information about all available character sets.

This statement can contain a LIKE or WHERE clause.

The clause is used to specify the names of character sets or columns that you want to match.

```
mysql> SHOW CHARACTER SET WHERE charset='utf8mb4';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| utf8mb4 | UTF-8 Unicode | utf8mb4_general_ci | 4 |
+-----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SHOW CHARACTER SET like 'utf8%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| utf8 | UTF-8 Unicode | utf8_general_ci | 3 |
| utf8mb4 | UTF-8 Unicode | utf8mb4_general_ci | 4 |
+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

SHOW COLLATION

```
SHOW COLLATION
[LIKE 'pattern' | WHERE expr]
```

The `SHOW COLLATION` statement returns all available collations.

This statement can contain a LIKE or WHERE clause.

The clause is used to specify the names of character sets or columns that you want to match.

```
mysql> SHOW COLLATION LIKE 'utf8mb4_bin%';
+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+
| utf8mb4_bin | utf8mb4 | 46 | | Yes | 1 |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

```
mysql> SHOW COLLATION WHERE charset='utf8mb4';
+-----+-----+-----+-----+-----+
| Collation      | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+
| utf8mb4_general_ci | utf8mb4 | 45 | Yes | Yes | 1 |
| utf8mb4_bin      | utf8mb4 | 46 | | Yes | 1 |
+-----+-----+-----+-----+-----+
```

SHOW COLUMNS

```
SHOW [FULL] COLUMNS {FROM | IN} tblname [{FROM | IN} dbname]
[LIKE 'pattern' | WHERE expr]
```

The `SHOW COLUMNS` statement returns information about the columns of a specified table.

You can also execute this statement to return column information for a specified view.

`SHOW FIELDS` is equivalent to `SHOW COLUMNS`.

- If the `FULL` keyword is specified, the output contains the permissions that you have and the comments for each column.
- The `dbname.tblname` syntax is an alternative to `tblname FROM dbname`. These two statements are equivalent.

Example:

```
mysql> SHOW COLUMNS FROM mytable FROM mydb;

mysql> SHOW COLUMNS FROM mydb.mytable;
```

```
mysql> SHOW COLUMNS IN users IN test;
+-----+-----+-----+-----+-----+
| Field | Type  | Null | Key | Default | Extra  |
+-----+-----+-----+-----+-----+
| name  | varchar(30) | YES  |     | NULL    |       |
| class | varchar(30) | YES  |     | NULL    |       |
| hometown | varchar(30) | YES  |     | NULL    |       |
| id    | int(11)  | NO   | PRI | NULL    | auto_increment |
+-----+-----+-----+-----+-----+
4 rows in set (0.01 sec)

mysql> SHOW FULL COLUMNS IN users IN test;
+-----+-----+-----+-----+-----+-----+-----+
| Field | Type  | Collation | Null | Key | Default | Extra  | Privileges          | Comment |
+-----+-----+-----+-----+-----+-----+-----+
| name  | varchar(30) | utf8_general_ci | YES  |     | NULL    |       | select,insert,update,references |
| class | varchar(30) | utf8_general_ci | YES  |     | NULL    |       | select,insert,update,references |

+-----+-----+-----+-----+-----+-----+-----+
4 rows in set (0.03 sec)
```

SHOW CREATE DATABASE

```
SHOW CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] dbname
```

The SHOW CREATE DATABASE statement returns the CREATE DATABASE statement that creates a specified database. You can also execute the SHOW CREATE SCHEMA statement to accomplish the same effect.

SHOW DATABASES STATUS

```
SHOW DATABASES STATUS [LIKE 'pattern' | WHERE expr]
```

The SHOW DATABASES STATUS statement returns the status of databases. In the output, one column shows whether a database is read only. A database supports the following states: READ ONLY, READ WRITE, and PARTIALLY READ ONLY. READ ONLY indicates that the database is only readable. READ WRITE indicates that the database is readable and writable. PARTIALLY READ ONLY indicates an intermediate status where the database is in the READ WRITE state on some OBServers and in the READ ONLY state on the other OBServers.

This statement can contain a LIKE or WHERE clause. The clause is used to specify the databases that you want to match.

SHOW CREATE TABLE

```
SHOW CREATE TABLE tblName
```

The SHOW CREATE TABLE statement returns the CREATE TABLE statement that creates a specified table.

You can also execute this statement to return the CREATE TABLE statement that creates a specified view.

SHOW CREATE VIEW

```
SHOW CREATE VIEW viewname
```

The `SHOW CREATE VIEW` statement returns the `CREATE VIEW` statement that creates a specified view.

SHOW DATABASES

```
SHOW {DATABASES | SCHEMAS}
    [LIKE 'pattern' | WHERE expr]
```

The `SHOW DATABASES` statement returns information about ApsaraDB for OceanBase databases.

You can query information about only databases on which you have permissions unless you have the global `SHOW DATABASES` permission.

`SHOW SCHEMAS` is equivalent to `SHOW DATABASES`.

This statement can contain a `LIKE` or `WHERE` clause.

The clause is used to specify the databases that you want to match.

SHOW ERRORS

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS
```

The `SHOW ERRORS` statement is similar to the `SHOW WARNINGS` statement in the effect. The difference is that the `SHOW ERRORS` statement returns only errors, whereas the `SHOW WARNINGS` statement also returns warnings and notes.

The `SHOW COUNT(*) ERRORS` statement returns the number of errors.

SHOW WARNINGS

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

`SHOW WARNINGS [LIMIT [offset,]]` The `SHOW WARNINGS` statement returns the errors, warnings, and notes that were generated during the execution of the previous statement. The `LIMIT` clause specifies the number of rows that can be displayed.

The `SHOW COUNT(*) WARNINGS` statement returns the total number of errors, warnings, and notes.

SHOW GRANTS

```
SHOW GRANTS [FOR user]
```

The `SHOW GRANTS` statement returns information about the permissions that have been granted to an ApsaraDB for OceanBase user.

If you do not specify the username, this statement returns the permissions that have been granted to the current user.

SHOW INDEX

```
SHOW {INDEX | INDEXES | KEYS}
      {FROM | IN} tblname
      [{FROM | IN} dbname]
      [WHERE expr]
```

The `SHOW INDEX` statement returns information about the indexes of a table.

The `dbname.tblname` syntax is an alternative to `tblname FROM dbname`.

The following two statements are equivalent:

```
mysql> SHOW INDEX FROM mytable FROM mydb;
```

```
mysql> SHOW INDEX FROM mydb.mytable;
```

SHOW PRIVILEGES

```
SHOW PRIVILEGES
```

The `SHOW PRIVILEGES` statement returns the system permissions that are supported by ApsaraDB for OceanBase.

SHOW PROCESSLIST

```
SHOW [FULL] PROCESSLIST
```

The `SHOW PROCESSLIST` statement returns the information about running threads.

If you have the `SUPER` permission, you can view all threads. If you do not have the `SUPER` permission, you can view only your own threads.

If the `FULL` keyword is not specified, this statement returns only the first 100 characters of each query.

SHOW STATUS

```
SHOW [GLOBAL | SESSION] STATUS
      [LIKE 'pattern' | WHERE expr]
```

The `SHOW STATUS` statement returns information about server status.

If you specify the `GLOBAL` modifier, this statement returns the status values for all connections to the ApsaraDB for OceanBase system. If you specify the `SESSION` modifier, this statement returns status values for the current connection. If neither of the two modifiers is specified, the default is `SESSION`.

`LOCAL` is equivalent to `SESSION`.

Note

Some status variables have only global values.

For these variables, this statement returns the same result regardless of whether you use the `GLOBAL` or `SESSION` modifier.

SHOW TABLE STATUS

```
SHOW TABLE STATUS [{FROM | IN} dbname]
[LIKE 'pattern' | WHERE expr]
```

The `SHOW TABLE STATUS` statement is similar to the `SHOW TABLES` statement. However, the `SHOW TABLE STATUS` statement returns detailed information about each non-temporary table.

You can also execute this statement to return information about views.

SHOW TABLES

```
SHOW [FULL] TABLES [{FROM | IN} dbname]
[LIKE 'pattern' | WHERE expr]
```

The `SHOW TABLES` statement lists the non-temporary tables in a specified database.

This statement also lists the views in the database.

The `FULL` keyword is optional. If this keyword is specified, the `SHOW FULL TABLES` statement returns the second output column.

For a table, the value of the second column is `BASE TABLE`. For a view, the value of the second column is `VIEW`. If you do not have permissions on a table, this table is not displayed in the output from the `SHOW TABLES` statement.

SHOW VARIABLES

```
SHOW [GLOBAL | SESSION] VARIABLES
[LIKE 'pattern' | WHERE expr]
```

The `SHOW VARIABLES` statement returns the values of system variables that are supported by ApsaraDB for OceanBase.

If you specify the `GLOBAL` modifier, this statement returns the values that are used for new connections to the ApsaraDB for OceanBase system. If you specify the `SESSION` modifier, this statement returns the values that are in effect for the current connection. If neither of the two modifiers is specified, the default is `SESSION`.

`LOCAL` is equivalent to `SESSION`.

If you specify a `LIKE` or `WHERE` clause, this statement returns only variables that match the specified condition pattern.

SHOW PARAMETERS

```
SHOW PARAMETERS
[LIKE 'pattern' | WHERE expr]
```

The `SHOW PARAMETERS` statement returns the value of each parameter.

SHOW CREATE TENANT

```
SHOW CREATE TENANT tenantname
```

The `SHOW CREATE TENANT` statement returns the information about a specified tenant.

```
SHOW CREATE TENANT test;
+-----+-----+
| Tenant | Create Tenant |
+-----+-----+
| test | CREATE TENANT test
charset='utf8mb4', replica_num=1, zone_list=('zone1'), primary_zone='zone1', resource_pool_list=('p1'); |
+-----+-----+
1 row in set (0.00 sec)
```

SHOW TENANT

```
SHOW TENANT
```

The SHOW TENANT statement returns the information about the current tenant.

```
SHOW TENANT
+-----+
| CURRENT TENANT NAME |
+-----+
| test|
+-----+
1 row in set (0.00 sec)
```

SHOW TABLEGROUPS statement

```
SHOW TABLEGROUPS
[LIKE 'pattern' | WHERE expr]
```

The SHOW TABLEGROUPS statement returns the information about all table groups that are created in the current tenant.

This statement can contain a LIKE or WHERE clause.

The clause is used to specify the table groups you want to match. Then, you can query the tables that are contained in each specified table group.

18.5.15.2. KILL statement

```
KILL [GLOBAL | LOCAL] [CONNECTION | QUERY] 'sessionid'
```

Each connection to the ApsaraDB for OceanBase system runs in an independent thread. To query the running threads, execute the SHOW PROCESSLIST; statement. To kill a thread, execute the KILL sessionid statement.

When you execute the KILL statement, follow these rules:

- The KILL CONNECTION statement closes the connection that is associated with the specified thread. This is the same as a KILL statement that does not contain a modifier.
- The KILL QUERY statement terminates the statement that is being executed over the connection. The connection state remains unchanged.

If you have the PROCESS permission, you can view all threads.

If you have the SUPER permission, you can kill all threads and statements. If you do not have the PROCESS or SUPER permission, you can view or kill only your own threads and statements.

18.5.15.3. DESCRIBE statement

```
{DESCRIBE | DESC | EXPLAIN} tblname [colname | wild];
```

This statement is equivalent to the `SHOW COLUMNS FROM` statement.

Example:

```
mysql> DESCRIBE city;
+-----+-----+-----+-----+-----+-----+
| Field | Type  | Null | Key | Default | Extra      |
+-----+-----+-----+-----+-----+-----+
| Id    | int(11) | NO  | PRI | NULL    | auto_increment |
| Name  | char(35) | NO  |    |         |              |
| Country | char(3) | NO  | UNI |         |              |
| District | char(20) | YES | MUL |         |              |
| Population | int(11) | NO  |    | 0      |              |
+-----+-----+-----+-----+-----+-----+
```

Notes:

- The Key field indicates whether the column is indexed.

Valid values:

- PRI: indicates that the column is a primary key or is one of the columns in a multiple-column primary key of the table.
- UNI: indicates that the column is part of a unique index.
- MUL: indicates that a given value can appear in the column multiple times.

If a unique index is a composite unique index that consists of multiple columns, the value MUL is displayed in the unique index. Although the combination of columns is unique, each column may contain a given value that appears multiple times. Note that in a composite index, only the leftmost column of the index can be included in the Key field.

- The Default field indicates whether a default value is assigned to the column.
- The Extra field lists additional information about the given column.

In this example, the Extra field indicates that the AUTO_INCREMENT keyword is used when the Id column is created.

18.5.15.4. USE statement

Syntax

```
USE dbname
```

`USE The USE dbname` statement informs the client to use a specified database as the default database for subsequent statements. This database acts as the default database until the session ends or another USE statement is issued.

Examples

```
mysql> USE db1;
mysql> SELECT COUNT(*) FROM mytable; # selects from db1.mytable
mysql> USE db2;
mysql> SELECT COUNT(*) FROM mytable; # selects from db2.mytable
```

If you do not execute the USE statement to specify the current database, the following error is returned:

```
root@(none) 04:59:12>create table t1 (a int);
ERROR 1046 (3D000): No database selected
root@(none) 04:59:24>select * from t1;
ERROR 1046 (3D000): No database selected
```

If you execute the USE statement to specify a database as the current database, you can still access tables in other databases.

The following example shows how to access the author table from the db1 database and the editor table from the db2 database:

```
mysql> USE db1;
mysql> SELECT author_name,editor_name FROM author,db2.editor
-> WHERE author.editor_id = db2.editor.editor_id;
```

Errors

If the database name that follows the USE keyword is not found, the system returns the following error:

```
ERROR 1049 (42000): Unknown database 'test1' .
```

18.5.15.5. Hints

Syntax

Hints are a special type of comments for SQL statements. The general syntax for comments is `/* ... */`. This is the same as the syntax for C language comments. Based on the general comment syntax, the hint syntax adds a plus sign (+) that follows the `/*` comment opening sequence and is displayed as `/*+ ... */`.

If the server does not recognize the hint in your SQL statement, it ignores the hint and does not return an error. Therefore, when an SQL statement is distributed to different databases, the hints in this statement do not cause syntax errors.

Hints only affect the internal optimization logic of the database server. They do not affect the semantics of SQL statements.

ApsaraDB for OceanBase is compatible with Oracle in hint syntax, except for some unique hints that are specific to ApsaraDB for OceanBase databases.

Hints that are supported by ApsaraDB for OceanBase have the following characteristics:

- Some hints do not contain parameters, for example, `/*+ KAKA */`.
- Some hints contain parameters, for example, `/*+ HAHA(param) */`.
- Multiple hints can be included in one hint comment and are separated with commas (,). For example, `/*+ KAKA A, HAHA(param) */`.
- A hint in the SELECT statement must follow the SELECT keyword and precede other keywords. For example, `SELECT /*+ KAKA */ ...`.
- A hint in the UPDATE statement or the DELETE statement must follow the UPDATE or DELETE keyword.

Specify a valid subquery

In data manipulation language (DML) statements, QB_NAME indicates the name of a query block, which uniquely identifies the query block. The query block name can be system-generated or user-specified.

If you do not specify QB_NAME in the hint, the system assigns SEL\$1, SEL\$2, UPD\$1, and DEL\$1 to query blocks in sequence from left to right. The system also uses the same sequence to resolve these query block names.

You can find each table based on QB_NAME, or specify the actions on a specific query block.

You can specify QB_NAME in TBL_NAME to find the table. The first QB_NAME in the hint allows you to find the query block to which the hint applies.

For example, you can specify the primary key and the index for outer queries and subqueries in the following scenario:

```
OceanBase (root@test)> create table t1(c1 int, c2 int, key t_c1(c1));
select /*+INDEX(t@SEL$1 PRIMARY) INDEX(@SEL$2 t@SEL$2 t_c1)*/ *
from t ,
      (select * from t where c2 = 1) ta
where t.c1 = 1;

Query Plan: =====
|ID|OPERATOR          |NAME |EST. ROWS|COST |
-----
|0|NESTED-LOOP INNER JOIN CARTESIAN|    |1      |16166|
|1|TABLE SCAN         |t   |1      |1397 |
|2|TABLE SCAN         |t(t_c1)|1    |14743|
=====

Outputs & filters:
-----
0 - output([t.c1], [t.c2], [t.c1], [t.c2]), filter(nil),
   conds(nil), nl_params_(nil)
1 - output([t.c1], [t.c2]), filter([t.c1 = 1]),
   access([t.c1], [t.c2]), partitions(p0)
2 - output([t.c2], [t.c1]), filter([t.c2 = 1]),
   access([t.c2], [t.c1]), partitions(p0)
```

The following table lists the hints that are supported by ApsaraDB for OceanBase.

Hints

hint	Parameter	Applicable statement	Description
------	-----------	----------------------	-------------

hint	Parameter	Applicable statement	Description
READ_CONSISTENCY	WEAK, STRONG, or FROZEN	SELECT	<p>Indicates whether to perform strongly consistent reads or weakly consistent reads. If the value is not specified in the SQL statement, the default value depends on the value of the system variable <code>ob_read_consistency</code>.</p> <p>FROZEN indicates that the system reads the data from the latest frozen point. The frozen version is automatically selected by the system.</p>
FROZEN_VERSION	Frozen version	SELECT	Reads only the data of the specified version.
READ_ZONE	FOLLOWER or LEADER	SELECT	<p>Specifies the cluster to which the request is sent.</p> <p><code>READ_ZONE(FOLLOWER)</code> indicates that the system preferentially sends the request to a secondary cluster regardless of whether a secondary cluster exists.</p> <p>This hint only controls the routing policy of an ApsaraDB for OceanBase client on SQL statements. It is not associated with <code>READ_CONSISTENCY</code>.</p>
QUERY_TIMEOUT	Time-out period in microseconds	All DML statements	Defines the timeout period for SQL statements when they are executed on the server. After a statement times out, the server terminates the execution and returns a timeout error code.
USE_NL	USE_NL, which specifies the name of the right physical table	SELECT	Performs a NESTED LOOP JOIN to join two tables. For more information, see the usage of Oracle statements.

hint	Parameter	Applicable statement	Description
USE_MERGE	Table name	SELECT	In a MERGE JOIN, the system first sorts each table you want to join based on the column to be joined. Then, the system extracts data from the associated sorted tables to another sorted table to match data. MERGE JOINS require multiple sorts and are resource-consuming.
LEADING	Table name	SELECT	In a multi-table join query, this hint specifies the driving table and the table to which the optimizer firstly accesses.
ORDERED	-	SELECT	The system selects the driving table based on the sequence of the tables that follow the FROM keyword.
USE_PLAN_CACHE	DEFAULT / NONE	All DML statements	Defines an execution plan to be used.
INDEX	INDEX, which is in the <TableName IndexName> format	All DML statements	<p>Similar to the INDEX hint in Oracle, this hint specifies that the data from the specified table must be queried based on the index name. If the index does not exist or is unavailable, the system does not return an error.</p> <p>Example:</p> <pre>SELECT /*+ INDEX(t1 i1) , INDEX(t2 i2)*/ from t1, t2 WHERE t1.c1=t2.c1;</pre> <pre>DELETE /*+ INDEX(t1 i1) */ from t1 WHERE t1.c1= 1;</pre>

hint	Parameter	Applicable statement	Description
PARALLEL	PARALLEL(N)	SELECT	<p>Specifies the maximum number of SQL statements that can be concurrently executed.</p> <p>Only SELECT statements that meet one of the following conditions can be concurrently executed:</p> <ul style="list-style-type: none"> • SELECT statements that contain an aggregate function • SELECT statements that contain a GROUP BY clause • SELECT statements that contain an ORDER BY clause • SELECT statements that do not contain a LIMIT clause <p>Example: <code>select /*+ parallel(5) */ count(*) from t1;</code></p>

hint	Parameter	Applicable statement	Description
TOPK	TOPK(param1 param2)	SELECT	<p>Obtains an approximate value.</p> <p>On-Line Analytical Processing (OLAP) queries that retrieve large amounts of data are time-consuming. In some cases where accuracy is not the major concern, you can reduce the query time by setting a lower accuracy rate.</p> <pre>select /*+ topk(90 1000) */ sum(c2), c1 from t1 group by c1 order by sum(c2) limit 10</pre> <p>In the TOPK(param1 param2) syntax, note that no comma exists between the two parameters. The first parameter is an integer that ranges from 0 to 100. The value of the first parameter indicates the accuracy rate of results. For example, 100 indicates full accuracy, and 90 indicates 90% accuracy. A higher value of the first parameter indicates that the result is more accurate, but the query process consumes a longer length of time.</p> <p>The second parameter is a positive integer that starts from 1. This value is related to the execution of the SQL statement. This approximation algorithm takes effect for only queries that contain the GROUP BY, ORDER BY, and LIMIT clauses.</p>

hint	Parameter	Applicable statement	Description
LOG_LEVEL	<ul style="list-style-type: none"> • ERROR • USER_ERROR • WARN • INFO • TRACE • DEBUG 	All DML statements	<p>Defines the log level for a statement.</p> <p>Example:</p> <pre>select /*+log_level('debug')*/ * from t;</pre> <pre>select /*+log_level('sql.*:debug, common.*:info')*/ * from t;</pre>
USE_LATE_MATERIALIZATION NO_USE_LATE_MATERIALIZATION	N/A	N/A	<p>USE_LATE_MATERIALIZATION: generates a late materialization plan for a query.</p> <p>NO_USE_LATE_MATERIALIZATION: generates a materialization plan for a query. This plan is not a late materialization plan.</p> <p>ApsaraDB for OceanBase V1.0 provides the late materialization feature. The system determines whether to automatically rewrite an index scan in the form of <code>self join</code> based on the cost. You can use this feature if you need to rewrite a large number of SQL statements in the form of <code>self join</code>.</p>
USE_HASH NO_USE_HASH	USE_HASH(relation1 [comma] relation2) NO_USE_HASH(relation1 [comma] relation2)	SELECT	Specifies whether to use the <code>hash join</code> algorithm to join tables.

18.5.15.6. HELP statements

Syntax

- Query the help information for all SQL queries that are supported by ApsaraDB for OceanBase.

```
HELP
```

- Query the help information for the syntax that is used at the SQL server.

```
HELP contents
```

- Query the help information for a specified SQL query.

```
HELP searchstring
```

Examples

- Statement: `mysql> help;`

Output:

```
For information about MySQL products and services, visit:
  http://www.mysql.com/
For developer information, including the MySQL Reference Manual, visit:
  http://dev.mysql.com/
To buy MySQL Enterprise support, training, or other products, visit:
  https://shop.mysql.com/

List of all MySQL commands:
Note that all text commands must be first on line and end with ';'
?      (\?) Synonym for `help'.
clear  (\c) Clear the current input statement.
connect (\r) Reconnect to the server. Optional arguments are db and host.
delimiter (\d) Set statement delimiter.
edit   (\e) Edit command with $EDITOR.
ego    (\G) Send command to mysql server, display result vertically.
exit   (\q) Exit mysql. Same as quit.
go     (\g) Send command to mysql server.
help   (\h) Display this help.
nopager (\n) Disable pager, print to stdout.
notee  (\t) Don't write into outfile.
pager  (\P) Set PAGER [to_pager]. Print the query results via PAGER.
print  (\p) Print current command.
prompt (\R) Change your mysql prompt.
quit   (\q) Quit mysql.
rehash (\#) Rebuild completion hash.
source (\.) Execute an SQL script file. Takes a file name as an argument.
status (\s) Get status information from the server.
system (\!) Execute a system shell command.
tee    (\T) Set outfile [to_outfile]. Append everything into given outfile.
use    (\u) Use another database. Takes database name as argument.
charset (\C) Switch to another charset. Might be needed for processing binlog with multi-byte charsets.
warnings (\W) Show warnings after every statement.
nowarning (\w) Don't show warnings after every statement.

For server side help, type 'help contents'
ERROR 1046 (3D000): No database selected
root@(none) 04:59:24>select * from t1;
```

- Statement: `mysql> help contents;`

Output:

```
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the following
categories:
  Data Types
  Functions
  Operator
  Escape character
  Data Definition
  Data Manipulation
  Transaction Statements
  Prepared Statements
  Compound Statements
  Administration
  Utility
```

- **Statement:** `mysql> help use`

Output:

```
Name: 'USE'
Description:
```

18.5.16. OUTLINE

18.5.16.1. Overview

You can use the outline feature to specify throttling rules or execution plans for SQL statements.

When you test statements that include hints, you must enable the `-c` option on the MySQL client. If the `-c` option is disabled, the statements do not take effect.

18.5.16.2. CREATE OUTLINE

You can execute the `CREATE OUTLINE` statement to create an outline. Based on the outline, the optimizer of ApsaraDB for OceanBase generates a throttling rule or an execution plan for the specified SQL statements.

Syntax

```
CREATE [OR REPLACE] OUTLINE outline_name ON stmt [ TO target_stmt ];
```

where:

- The `stmt` parameter specifies a data manipulation language (DML) statement that contains a hint.
- The hint in `stmt` determines whether to implement the throttling or plan stability feature.
- `TO target_stmt` specifies the SQL statements on which you want to implement the throttling or plan stability feature.
- `OR REPLACE` indicates that you can replace an existing execution plan or a throttling rule.

 **Note** A throttling rule and an execution plan can replace each other.

Plan stability

The plan stability feature is used to generate the specified execution plans for SQL statements. After you create an outline to enable the plan stability feature, the optimizer of ApsaraDB for OceanBase generates an execution plan based on the specified hint for the specified SQL statements.

Notes:

- If the specified hint is not `MAX_CONCURRENT(NUM)`, the `CREATE OUTLINE` statement enables the plan stability feature instead of the throttling feature.
- If you create an outline to enable the throttling feature, you can specify question marks (`?`). However, if you create an outline to enable the plan stability feature, you cannot specify question marks (`?`). When the `CREATE OUTLINE` statement is executed, the portions that can be represented by parameters are converted to question marks (`?`). If you specify question marks (`?`) in this scenario, the system returns the following error: `invalid outline .`
- One `outline_name` is associated with only one execution plan.
- If you do not specify a hint in `stmt` for the `CREATE OUTLINE` statement, the statement creates an outline to enable the plan stability feature. In this scenario, the optimizer of ApsaraDB for OceanBase generates the execution plan based on the outline.

Example:

```
OceanBase (root@oceanbase)> create outline ol_1 on select /*+index(t1 c1)*/ from t1 where c1 =1;
```

In this example, the `ol_1` outline is created. For the statements that meet the `SELECT * FROM t1 WHERE c1 =?` condition, execution plans are generated based on `/*+ BEGIN_OUTLINE_DATA INDEX(@"SEL$1" "oceanbase.t1"@"SEL$1" "c1") END_OUTLINE_DATA */`.

Throttling

If you specify the `MAX_CONCURRENT(NUM)` hint in the `CREATE OUTLINE` statement, the statement applies a throttling rule on the specified SQL statements. The throttling rule controls the maximum number of SQL statements that can be concurrently executed in an OBCServer.

Notes:

- Similar to the plan stability feature, the throttling feature is implemented based on the specified hint. To use the throttling feature, specify the `MAX_CONCURRENT(NUM)` hint. In the hint, `NUM` specifies the maximum number of SQL statements that can be concurrently executed.

If the number of concurrent SQL statements exceeds the upper limit, the server returns the following error:

```
SQL
reach max concurrent num .
```

- You can execute the `CREATE OUTLINE` statement to enable the throttling or plan stability feature. To ensure the correctness and clarity of semantics, do not specify the throttling hint together with other types of hints in one `CREATE OUTLINE` statement.
- When you create throttling rules, you can use question marks (`?`) to distinguish variable parameters and constant parameters.

 **Note** If you execute the `CREATE OUTLINE` statement to enable the plan stability feature, you cannot specify question marks (`?`). In this scenario, you must use parameters to represent constants.

- One `outline_name` can be associated with multiple throttling rules that have the same signature.
- Each throttling rule specifies the maximum number of concurrent statements. If an SQL statement matches multiple throttling rules, the system uses the throttling rule that specifies the smallest value among the upper limits.

Example:

```
OceanBase (root@oceanbase)> create outline ol_1 on select /*+max_concurrent(1)*/ * from t2 where c1 = 1 and c2 = ? ;
```

In this example, the ol_1 outline is created. For the SQL statements that meet the `SELECT * FROM t2 WHERE c1 = 1 and c2 = ?` condition, only one of the statements is executed on a single OBServer.

`c2 = ?` indicates that the question mark can be replaced with a constant value.

For example, throttling is implemented on the following SQL statements:

```
select * from t2 where c1 = 1 and c2 = 1;
select * from t2 where c1 = 1 and c2 = 2;
select * from t2 where c1 = 1 and c2 = "2";
select * from t2 where c1 = 1 and c2 = true;
```

`c1=1` indicates that throttling is implemented on only SQL statements that contain `c1=1`. For example, throttling is not implemented on the following SQL statements:

```
select * from t2 where c1 = 2 and c2 = 1;
select * from t2 where c1 = "2" and c2 = 2;
select * from t2 where c1 = false and c2 = "2";
```

18.5.16.3. ALTER OUTLINE

Syntax

```
ALTER OUTLINE outline_name ADD stmt [ TO target_stmt ]
```

You can use `TO target_stmt` in this statement and `TO target_stmt` in the `CREATE OUTLINE` statement in the same way. You can specify `TO target_stmt` if you need to implement the throttling or plan stability feature on the SQL statements that contain the corresponding hints.

Examples

- Execute the ALTER OUTLINE statement to add a throttling rule.

```
OceanBase (root@oceanbase)> alter outline ol_1 add select /*+max_concurrent(1)*/ * from t1 where c1 = 1 and c2 = ? ;
OceanBase (root@oceanbase)> alter outline ol_1 add select /*+max_concurrent(1)*/ * from t1 where c1 = ? and c2 = 1;
```

- Execute the ALTER OUTLINE statement to add an execution plan.

```
OceanBase (root@oceanbase)> create outline ol_2 on select /*+max_concurrent(1)*/ * from t1,t2 where t1.c1 = 1;
OceanBase (root@oceanbase)> alter outline ol_2 add select /*+use_nl(t2)*/ * from t1,t2 where t1.c1 = 1;
```

Notes

- One outline_name is associated with only one execution plan. If you execute the `CREATE OUTLINE` statement to specify an execution plan, you cannot add another execution plan by executing the ALTER OUTLINE statement.
- When you execute the `ALTER OUTLINE` statement, you can specify only a throttling rule or an execution plan

for each execution. The similar rule applies to the `CREATE OUTLINE` statement.

- To ensure that the `ALTER OUTLINE` statement is valid, the value of the `outline_name` parameter must match the signature of the outline.

18.5.16.4. DROP OUTLINE

You can execute the `DROP OUTLINE` statement to drop an outline for an ApsaraDB for OceanBase database.

Syntax

```
DROP OUTLINE outline_name;
```

Examples

```
DROP OUTLINE ol_1;
```

Errors

- If the specified outline does not exist, the ApsaraDB for Oceanbase database returns the following error: `ERROR HY000: Outline 'XXX' doesn't exist` .
- If no database is selected for the current session, the ApsaraDB for Oceanbase database returns the following error: `ERROR 3D000: No database selected` .

18.5.16.5. Others

18.5.16.5.1. Considerations

Considerations on tenants

All outline-related features such as throttling and plan stability take effect within a tenant. You cannot use the system tenant to create, modify, or drop outlines for other tenants. To create an outline for a tenant, you must execute the `CREATE OUTLINE` statement within this tenant.

Considerations on databases

When you create an outline, the namespace of `stmt` is parsed based on the database of the current session. The throttling or plan stability feature takes effect only if the specified SQL statements are executed in this database.

The following scenarios are two examples:

- Assume that you execute the `CREATE OUTLINE ol_1 ON SELECT /*+use_nl(t1)*/ * FROM t2,t1` statement in the `db1` database. When you execute the `SELECT * FROM t2` statement in database `db2`, the query result is not affected by the `ol_1` outline.
- If an SQL statement is executed and no database is specified, you cannot create an outline for the SQL statement.

Considerations on MySQL clients

Assume that you execute the `CREATE OUTLINE` statement on a MySQL client. The MySQL client adds a space between the hint and the first `SELECT` expression in the statement if the two elements are not separated with characters. The test results show that this issue does not occur if Java and Python are used to establish connections.

The following code shows an example:

```
OceanBase (root@oceanbase)> create outline ol_1 on select /*+full(t1)*/ * from t1;
OceanBase (root@oceanbase)> select sql_text from __all_outline;
+-----+
| sql_text          |
+-----+
| select /*+full(t1)*/ * from t1 |
+-----+
1 row in set (0.60 sec)
```

Concurrency

The concurrency settings limit the number of SQL statements that can be concurrently executed on a single ODBServer based on physical execution plans. Therefore, the maximum number of the specified SQL statements that can be concurrently executed for a cluster is greater than that specified in the hint.

Assume that you specify a throttling rule that allows only one of the statements that meet the `SELECT * FROM t2 WHERE c1 = ?` condition to be executed on a single ODBServer. These statements are affected by the following factors:

The throttling feature is implemented on a per-ODBServer basis. If the OBProxy sends `SELECT * FROM t2 WHERE c1 = 1` to ODBServer 1 and ODBServer 2, two SQL statements are concurrently executed in the cluster.

ApsaraDB for OceanBase implements throttling by matching SQL statements to physical execution plans based on the signatures of the SQL statements. Therefore, the database separately controls the maximum number of concurrent SQL statements for each physical execution plan in the plan cache.

Signature

After you create an outline, a record is generated in the system table `__all_outline`. The signature column of the record indicates the unique identifier of the outline and is used in multiple scenarios.

A signature is generated based on the SQL statement and the corresponding `not_params`. In the SQL statement, the hint is excluded and constants are replaced with question marks (?).

 **Note** In the latest code, the parameter value of `not_param` is backfilled into the SQL statement. Therefore, the signature is generated based on only the SQL statement.

When a data manipulation language (DML) statement is executed, a signature is generated. The system checks whether an outline that has the same signature already exists.

When you create or add throttling rules or outlines, all throttling rules or outlines that are subordinate to the same outline name must have the same signature.

When you execute the `CREATE OUTLINE` statement, the system returns an `already exist` error if the outline name or the signature already exists.

When you create or replace an outline and use it to replace an existing outline, the operation succeeds only if the outline name and the signature are matched. If only one of the two attributes is matched, the system returns an `already exist` error.

When you modify an outline, the system checks whether the signature of the `stmt` that is specified in the `ALTER OUTLINE` statement matches the signature of the outline that is specified by `outline_name`.

18.5.16.5.2. Related system tables

Table name	Property	Description
__all_outline	System table	This table stores meta information about outlines.
__all_outline_history	System table	This table stores meta information about outlines.
__tenant_virtual_outline	Virtual table	This table shows the outline information for the current tenant. You can use this table to migrate outlines.
gv\$outline	View	This table is created based on the __tenant_virtual_outline table.
dba_outlines	View	This table is created based on the __all_outline table.
__tenant_virtual_concurrent_limit_sql	Virtual table	This table shows the throttling rules of the current tenant.
gv\$concurrent_limit_sql	View	This table is created based on the __tenant_virtual_concurrent_limit_sql table.

18.5.17. Hierarchical queries

You can use hierarchical queries to view hierarchical data that is organized based on hierarchy levels.

Hierarchical data is organized based on hierarchy levels. The hierarchy levels are frequent occurrences in real-life events. The following examples are used to explain hierarchy levels:

- Relationships between leaders and members in an organization
- Relationships between superior and subordinate departments in an enterprise
- Relationships between web pages that are connected by hyperlinks

ApsaraDB for OceanBase uses the `CONNECT BY` clause to perform hierarchical queries. ApsaraDB for OceanBase also provides relevant virtual columns and functions for hierarchical queries.

Syntax

```
SELECT select_list
FROM table_expression
[ WHERE ... ]
[ START WITH start_expression ]
CONNECT BY [NOCYCLE] { PRIOR child_expr = parent_expr | parent_expr = PRIOR child_expr }
[ ORDER SIBLINGS BY ...]
[ GROUP BY ... ]
[ HAVING ... ]
[ ORDER BY ... ]
```

Execution process

The key to using a hierarchical query is to understand the execution process. The following steps show the process to run a hierarchical query:

1. The ApsaraDB for OceanBase system performs the specified `SCAN` or `JOIN` operation that follows the `FROM` keyword.

2. The ApsaraDB for OceanBase system generates hierarchical relationships based on the `START WITH` and `CONNECT BY` clauses.
3. The ApsaraDB for OceanBase system executes the remaining clauses in the hierarchical query by following the same process of running general queries. The clauses include the `WHERE`, `GROUP`, and `ORDER BY` clauses.

The following steps show the detailed process to generate hierarchical relationships:

1. The ApsaraDB for OceanBase system queries the root rows based on the expression in the `START WITH` clause.
2. The ApsaraDB for OceanBase system generates the child rows of each root row based on the expression in the `CONNECT BY` clause.
3. The ApsaraDB for OceanBase system uses the generated child rows as new root rows to further generate child rows. The system repeats this step until no new row is generated.

18.5.18. Materialized views

Materialized views are a special type of views that store or materialize query results to accelerate specific queries. You can also use materialized views to implement read/write splitting.

Syntax

Create a materialized view

```
CREATE MATERIALIZED VIEW view_name AS subquery
```

Drop a materialized view

```
DROP MATERIALIZED VIEW [IF EXISTS] view_name
```

Limits

Only materialized views that join two tables can be created. The following limits apply to materialized views:

- Only user-created physical tables can be joined. Views, virtual tables, system tables, and other materialized views cannot be joined.
- A join condition must contain the primary key columns of the right table.
- You must specify `R{all_server}` for the right table. To simplify the procedure, specify the `ALL_SERVER` type for your cluster. This ensures that each server in the zone of your cluster has a read-only replica of the right table.
- Aliases cannot be specified for tables.
- The `PROJECTION`, `JOIN`, and `ORDER BY` operations are supported. You must include the `ORDER BY` clause in the statement.
- The `LIMIT` clause is not supported.
- `AGGREGATE` operations are not supported.
- Set operations such as `UNION`, `UNION ALL`, and `INTERSECT` are not supported.
- The `ROWNUM` clause is not supported.
- You can specify only original columns of the left table in the `ORDER BY` clause. You cannot specify expressions or generated columns in the clause.
- You can specify only original columns of the left table and the right table in the `PROJECTION` clause. You cannot specify expressions or generated columns in the clause.
- Each join condition must use the equal to (`=`) operator that is applied on an original column of the left table and an original column of the right table. You cannot specify expressions or generated columns in the join condition. You can use the `AND` operator to specify multiple join conditions. The `OR` operator is not supported. The specified original column in each join condition must uniquely identify each row of the right table. The primary key or unique key can uniquely identify each row. However, you can use only the primary key of the

right table when you specify the join condition.

- Nested subqueries are not supported.
- You cannot specify columns that have the same name in the PROJECTION clause.

The following limits apply to data definition language (DDL) operations on a materialized view:

- A materialized view takes effect only after a daily major freeze operation is performed.
- When you modify the attributes of a column in the left table or the right table, follow the existing modification rules if the column does not affect the materialized view.
- If the column affects the materialized view, modify the attributes in a compatible manner. For example, you can change the data type of a column from int to bigint, or from `varchar(10)` to `varchar(20)`.
- To delete a column that is used by a materialized view, you must drop the materialized view first.
- To truncate the left table or the right table that is used by the materialized view, you must drop the materialized view first.
- To drop a right table that is used by a materialized view, you must drop the materialized view first.
- When you drop a left table, the materialized view that uses the left table is also dropped.
- A materialized view cannot be truncated.
- After you drop a left table that is used by a materialized view, the table and the view cannot be recovered from the recycle bin.

Examples

```
create table collect_info (user_id int, item_id int, info_collect_time timestamp, primary key(user_id, item_id));

create table collect_item(item_id int primary key, item_url varchar(5000), item_price int) locality = 'FULL{1},READONLY{ALL_SERVER}@zone1';

create view info_item_view as select user_id, collect_info.item_id, info_collect_time, item_url from collect_info join collect_item on collect_info.item_id = collect_item.item_id order by user_id, info_collect_time; create materialized view info_item_mv as select user_id, collect_info.item_id, info_collect_time, item_url from collect_info join collect_item on collect_info.item_id = collect_item.item_id order by user_id, info_collect_time;
```

To query data from `info_item_view`, you can read the data that is stored in the materialized view `info_item_mv` and do not need to perform the JOIN operation.

The materialized view can also accelerate the following query:

```
select user_id, collect_info.item_id, info_collect_time, item_url from collect_info join collect_item on collect_info.item_id = collect_item.item_id where user_id = 1 order by user_id, info_collect_time;
```

This statement is rewritten to the following statement at the SQL layer:

```
select * from info_item_view where user_id = 1
```

You can execute the following EXPLAIN statement to identify whether a query is performed based on the materialized view:

```
mysql> explain select user_id, collect_info.item_id, info_collect_time, item_url from collect_info join collect_item on collect_info.item_id = collect_item.item_id where user_id = 1;
===== |ID|OPERATOR |NAME |EST. ROWS|COST| ----- |0 |TABLE SCAN|(info_item_mv)|1 |30 |===== Outputs & filters:
----- 0 - output([info_item_mv.user_id], [info_item_mv.item_id], [info_item_mv.info_collect_time], [info_item_mv.item_url]), filter([info_item_mv.item_id = info_item_mv.item_id]), access([info_item_mv.item_id], [info_item_mv.item_id], [info_item_mv.user_id], [info_item_mv.info_collect_time], [info_item_mv.item_url]), partitions(p0)
```

18.5.19. SQL modes

You can perform operations on an ApsaraDB for OceanBase server in different SQL modes for different clients. You can specify the SQL mode of the server for each application based on your business needs.

An SQL mode determines the SQL syntax that ApsaraDB for OceanBase supports and the data validation checks that ApsaraDB for OceanBase performs. This allows you to use ApsaraDB for OceanBase in different environments.

You can set the SQL mode by specifying the `--sql-mode="modes"` option. To enable the strict mode, specify either or both of the `STRICT_TRANS_TABLES` and `STRICT_ALL_TABLES` modes.

ApsaraDB for OceanBase supports the following SQL modes:

- **HIGH_NOT_PRECEDENCE**

By default, the NOT operator has a lower precedence than other operators. For example, the expression `NOT a BETWEEN b AND c` is parsed as `NOT (a BETWEEN b AND c)`. If you need the expression to be parsed as `(NOT a) BETWEEN b AND c`, enable the HIGH_NOT_PRECEDENCE SQL mode. This SQL mode improves the precedence of the NOT operator.

- **ONLY_FULL_GROUP_BY**

This SQL mode rejects queries for nonaggregated columns that are not specified in the `GROUP BY` clause.

- **PAD_CHAR_TO_FULL_LENGTH**

By default, spaces are truncated from values that are retrieved from CHAR columns. If the PAD_CHAR_TO_FULL_LENGTH mode is enabled, truncation does not occur. This mode does not apply if you retrieve values from VARCHAR columns.

Example:

```

mysql> CREATE TABLE t1 (c1 CHAR(10));
Query OK, 0 rows affected (0.09 sec)
mysql> INSERT INTO t1 (c1) VALUES('xy');
Query OK, 1 row affected (0.00 sec)
mysql> SET sql_mode = ""; //The default SQL mode
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1 | CHAR_LENGTH(c1) |
+-----+-----+
| xy |          2 |
+-----+-----+
1 row in set (0.00 sec)
mysql> SET sql_mode = 'PAD_CHAR_TO_FULL_LENGTH'; //Change the SQL mode.
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1 | CHAR_LENGTH(c1) |
+-----+-----+
| xy |          10 |
+-----+-----+
1 row in set (0.02 sec)

```

- **PIPES_AS_CONCAT**

This SQL mode treats `||` as a string concatenation operator (+) rather than as a synonym for the OR operator. It functions the same as `CONCAT()`.

- **STRICT_ALL_TABLES**

This SQL mode enables the strict SQL mode for all storage engines. Invalid values are rejected.

- **STRICT_TRANS_TABLES**

This SQL mode enables the strict SQL mode for transactional storage engines. In some cases, this SQL mode may also enable the strict mode for non-transactional storage engines.

The strict mode controls how ApsaraDB for OceanBase handles invalid or missing values in statements. A value can be invalid for several reasons. For example, a value is of an invalid data type for the column, or a value is out of a specified range. If a new row to be inserted does not contain a value for a column that has no explicit Default clause in its definition, the value is missing.

For transactional tables, if either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled, ApsaraDB for OceanBase returns an error if invalid or missing values are found in a statement. The statement is aborted and rolled back.

For non-transactional tables, if a bad value occurs in the first row to be inserted or updated, ApsaraDB for OceanBase handles in the same way under either of the two strict modes. The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and a bad value occurs in the second or later row, the processing method of ApsaraDB for OceanBase depends on the strict mode that is enabled:

- If `STRICT_ALL_TABLES` is enabled, ApsaraDB for OceanBase returns an error and ignores the rest of the rows. However, a partial update is complete because the earlier rows are inserted or updated. This may not meet your requirements. To avoid this issue, we recommend that you use single-row statements. If you abort a single-row statement, your original table remains unchanged.

- If `STRICT_TRANS_TABLES` is enabled, ApsaraDB for OceanBase converts an invalid value to the closest valid value for the column and inserts the adjusted value. If a value is missing, ApsaraDB for OceanBase inserts the implicit default value in the column. In all cases, ApsaraDB for OceanBase generates a warning rather than an error and continues to execute the statement.

In strict mode, invalid dates such as `2004-04-31` are not allowed. Dates that have zero parts, such as `2004-04-00`, or zero dates are also rejected as invalid dates.

If you do not enable the `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` mode, ApsaraDB for OceanBase adjusts the invalid or missing values, inserts the adjusted values, and then generates warnings.

- `NO_AUTO_VALUE_ON_ZERO`

`NO_AUTO_VALUE_ON_ZERO` affects how you handle `AUTO_INCREMENT` columns. In most cases, you can insert NULL or 0 into a column to generate the next sequence number for the column. However, 0 is disabled in `NO_AUTO_VALUE_ON_ZERO` mode. You can insert only NULL to generate the next sequence number.

18.5.20. System views

18.5.20.1. Overview

ApsaraDB for OceanBase provides a complete set of system views for you to check the running status of the system. The name of each system view starts with `v$` or `gv$`. `v$` indicates a view for a single OBServer and `gv$` indicates a view for all OBServers.

18.5.20.2. v\$statname

Shows definitions of all statistical events.

View definition

```
view_definition =
"select tenant_id as CON_ID,
stat_id as STAT_ID,
`statistic#` as `STATISTIC#`,
name as NAME,
display_name as DISPLAY_NAME,
class as CLASS
from oceanbase.__tenant_virtual_statname"
```

Fields

Name	Data type	Description
CON_ID	bigint(20)	The ID of the tenant.
STAT_ID	bigint(20)	The ID of the statistical event.
STATISTICS#	bigint(20)	The number that represents the statistical event.
NAME	varchar(64)	The name of the statistical event.
DISPLAY_NAME	varchar(64)	The alias of the statistical event.

Name	Data type	Description
CLASS	bigint(20)	The alias of the class of the statistical event.

18.5.20.3. v\$event_name

Shows definitions of all wait events.

View definition

```
view_definition =
"select tenant_id as CON_ID,
event_id as EVENT_ID,
`event#` as `EVENT#`,
name as NAME,
display_name as DISPLAY_NAME,
parameter1 as PARAMETER1,
parameter2 as PARAMETER2,
parameter3 as PARAMETER3,
wait_class_id as WAIT_CLASS_ID,
`wait_class#` as `WAIT_CLASS#`,
wait_class as WAIT_CLASS
from oceanbase.__tenant_virtual_event_name"
```

Fields

Name	Data type	Description
CON_ID	bigint(20)	The ID of the tenant.
EVENT_ID	bigint(20)	The ID of the wait event.
EVENT#	bigint(20)	The number that represents the wait event.
NAME	varchar(64)	The name of the wait event.
DISPLAY_NAME	varchar(64)	The alias of the wait event.
PARAMETER1	varchar(64)	The first parameter of the wait event.
PARAMETER2	varchar(64)	The second parameter of the wait event.
PARAMETER3	varchar(64)	The third parameter of the wait event.
WAIT_CLASS_ID	bigint(20)	The ID of the class of the wait event.
WAIT_CALSS#	bigint(20)	The number that represents the class of the wait event.

Name	Data type	Description
WAIT_CLASS	varchar(64)	The name of the class of the wait event.

18.5.20.4. v\$session_event

Shows the wait events that occur in each session.

View definition

```
view_definition =
"select SID,CON_ID,EVENT_ID,EVENT,WAIT_CLASS_ID,
`WAIT_CLASS#`,WAIT_CLASS,TOTAL_WAITS,TOTAL_TIMEOUTS,TIME_WAITED,
MAX_WAIT,AVERAGE_WAIT,TIME_WAITED_MICRO
from oceanbase.gv$session_event
where SVR_IP=host_ip() and SVR_PORT=rpc_port()"
```

Fields

Name	Data type	Description
SID	bigint(20)	The ID of the session.
CON_ID	bigint(20)	The ID of the tenant.
EVENT_ID	bigint(20)	The ID of the wait event.
EVENT	varchar(64)	The description of the wait event.
WAIT_CLASS_ID	bigint(20)	The ID of the class of the wait event.
WAIT_CLASS#	bigint(20)	The number that represents the class of the wait event.
WAIT_CLASS	varchar(64)	The name of the class of the wait event.
TOTAL_WAITS	bigint(20)	The total number of waits for the event.
TOTAL_TIMEOUTS	bigint(20)	The total number of wait time-outs for the event.
TIME_WAITED	double	The total amount of time that was spent on waiting for the event. Unit: 10 ms.
MAX_WAIT	double	The maximum amount of time that was spent on waiting for the event. Unit: 10 ms.
AVERAGE_WAIT	double	The average amount of time that was spent on waiting for the event. Unit: 10 ms.

Name	Data type	Description
TIME_WAITED_MICRO	bigint(20)	The total amount of time that was spent on waiting for the event. Unit: microseconds.

18.5.20.5. v\$session_wait

Shows details about the current wait event for each session. For each wait event, ApsaraDB for OceanBase provides three parameters to record the corresponding values.

View definition

```
view_definition =
"select SID,CON_ID,EVENT,P1TEXT,P1,
P2TEXT,P2,P3TEXT,P3,WAIT_CLASS_ID,
`WAIT_CLASS#`,WAIT_CLASS,STATE,WAIT_TIME_MICRO,TIME_REMAINING_MICRO,
TIME_SINCE_LAST_WAIT_MICRO
from oceanbase.gv$session_wait
where SVR_IP=host_ip() and SVR_PORT=rpc_port()"
```

Fields

Name	Data type	Description
SID	bigint(20)	The ID of the session.
CON_ID	bigint(20)	The ID of the tenant.
EVENT	varchar(64)	The description of the wait event.
P1TEXT	varchar(64)	The name of the first parameter of the wait event.
P1	bigint(20) unsigned	The value of the first parameter of the wait event.
P2TEXT	varchar(64)	The name of the second parameter of the wait event.
P2	bigint(20) unsigned	The value of the second parameter of the wait event.
P3TEXT	varchar(64)	The name of the third parameter of the wait event.
P3	bigint(20) unsigned	The value of the third parameter of the wait event.
WAIT_CLASS_ID	bigint(20)	The ID of the class of the wait event.
WAIT_CLASS#	bigint(20)	The number that represents the class of the wait event.
WAIT_CLASS	varchar(64)	The name of the class of the wait event.

Name	Data type	Description
STATE	varchar(19)	The state of the wait event.
WAIT_TIME_MICRO	bigint(20)	The amount of time that was spent on waiting for the event. Unit: microseconds.
TIME_REMAINING_MICRO	bigint(20)	The amount of time that is remaining for the current wait before it times out. Unit: microseconds.
TIME_SINCE_LAST_WAIT_MICRO	bigint(20)	The amount of time that elapsed between the current wait event and the previous wait event. Unit: microseconds.

18.5.20.6. v\$session_wait_history

Shows details about the last 10 wait events for each session.

View definition

```
view_definition =
"SELECT SID,CON_ID,`SEQ#`,`EVENT#`,`EVENT`,
P1TEXT,P1,P2TEXT,P2,P3TEXT,
P3,WAIT_TIME_MICRO,TIME_SINCE_LAST_WAIT_MICRO,WAIT_TIME
FROM oceanbase.gv$session_wait_history
WHERE SVR_IP=host_ip() and SVR_PORT=rpc_port()"
```

Fields

For more information about the fields, see the Fields section in [v\\$session_wait](#).

18.5.20.7. v\$sesstat

Shows summary information about statistical events based on sessions.

View definition

```
view_definition =
"select SID,CON_ID,`STATISTIC#`,`VALUE` from oceanbase.gv$sesstat"
where SVR_IP=host_ip() and SVR_PORT=rpc_port()"
```

Fields

Name	Data type	Description
SID	bigint(20)	The ID of the session.
CON_ID	bigint(20)	The ID of the tenant.
STATISTICS#	bigint(20)	The number that represents the statistical event.

Name	Data type	Description
VALUE	bigint(20)	The total number of occurrences of the statistical event.

18.5.20.8. v\$sysstat

Shows summary information about statistical events based on tenants.

View definition

```
view_definition =
"SELECT CON_ID,`STATISTIC#`,VALUE,STAT_ID,NAME,CLASS from oceanbase.gv$sysstat
WHERE SVR_IP=host_ip() and SVR_PORT=rpc_port()"
```

Fields

Name	Data type	Description
CON_ID	bigint(20)	The ID of the tenant.
STATISTICS#	bigint(20)	The number that represents the statistical event.
VALUE	bigint(20)	The result value of the statistical event.
STAT_ID	bigint(20)	The ID of the statistical event.
NAME	varchar(64)	The name of the statistical event.
CLASS	bigint(20)	The class of the statistical event.

18.5.20.9. v\$system_event

Shows statistics about wait events based on tenants.

View definition

```
view_definition =
"SELECT CON_ID,EVENT_ID,EVENT,WAIT_CLASS_ID,`WAIT_CLASS#`,WAIT_CLASS,TOTAL_WAITS,TOTAL_TIMEOUTS,TIME_W
AITED,AVERAGE_WAIT, TIME_WAITED_MICRO
FROM oceanbase.gv$system_event
WHERE SVR_IP=host_ip() and SVR_PORT=rpc_port()"
```

Fields

Name	Data type	Description
CON_ID	bigint(20)	The ID of the tenant.
EVENT_ID	bigint(20)	The ID of the wait event.
EVENT	varchar(64)	The description of the wait event.

Name	Data type	Description
WAIT_CLASS_ID	bigint(20)	The ID of the class of the wait event.
WAIT_CLASS#	bigint(20)	The number that represents the class of the wait event.
WAIT_CLASS	varchar(64)	The name of the class of the wait event.
TOTAL_WAITS	bigint(20)	The total number of waits for the event.
TOTAL_TIMEOUTS	bigint(20)	The total number of wait time-outs for the event.
TOTAL_WAITED	double	The total amount of time that was spent on waiting for the event. Unit: 10 ms.
AVERAGE_WAIT	double	The average amount of time that was spent on waiting for the event. Unit: 10 ms.
TOTAL_WAITED_MICRO	bigint(20)	The total amount of time that was spent on waiting for the event. Unit: microseconds.

18.5.20.10. v\$memory

Shows memory statistics based on tenants.

View definition

```
view_definition =
"SELECT TENANT_ID, CONTEXT, COUNT, USED, ALLOC_COUNT, FREE_COUNT
FROM oceanbase.gv$memory
WHERE IP=HOST_IP() AND PORT=RPC_PORT()"
```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
CONTEXT	varchar(256)	The name of the mod to which the memory belongs.
COUNT	bigint(20)	The number of memory units that are used in the mod, which is the difference between the number of allocated units and the number of available units.
USED	bigint(20)	The memory size that is used in the mod.
ALLOC_COUNT	bigint(20)	The total number of memory units that are allocated to the mod.

Name	Data type	Description
FREE_COUNT	bigint(20)	The total number of available memory units in the mod.

18.5.20.11. v\$memstore

Shows MemStore statistics based on tenants.

View definition

```
view_definition =
"SELECT TENANT_ID, ACTIVE, TOTAL, `FREEZE_TRIGGER`, `MEM_LIMIT`
FROM oceanbase.gv$memstore
WHERE SVR_IP=host_ip() and SVR_PORT=rpc_port()"
```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
ACTIVE	bigint(20)	The active MemStore size of the tenant.
TOTAL	bigint(20)	The total MemStore size of the tenant.
FREEZE_TRIGGER	bigint(20)	The MemStore size that triggers a major freeze action.
MEM_LIMIT	bigint(20)	The maximum MemStore size of the tenant.

18.5.20.12. v\$memstore_info

Shows MemStore statistics based on tenants. The statistics include the details about all partitions.

View definition

```
view_definition =
"SELECT TENANT_ID, IP, PORT, TABLE_ID, PARTITION_ID, VERSION, IS_ACTIVE, USED, HASH_ITEMS, BTREE_ITEMS
FROM oceanbase.gv$memstore_info
WHERE SVR_IP=host_ip() and SVR_PORT=rpc_port()"
```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
IP	varchar(32)	The IP address.
PORT	bigint(20)	The port number.

Name	Data type	Description
TABLE_ID	bigint(20)	The ID of the table.
PARTITION_ID	bigint(20)	The ID of the partition.
VERSION	varchar(128)	The version number.
IS_ACTIVE	bigint(20)	Indicates whether the MemStore is active.
USED	bigint(20)	The memory size that is used by the MemStore.
HASH_ITEMS	bigint(20)	The hash indexes that are contained in the MemStore.
BTREE_ITEMS	bigint(20)	The B-tree indexes that are contained in the MemStore.

18.5.20.13. v\$plan_cache_stat

Shows the basic status of a plan cache.

View definition

```
view_definition=
"SELECT tenant_id,svr_ip,svr_port,sql_num,mem_used,access_count,hit_count,hit_rate,plan_num,mem_limit,hash_bucket,stmtkey_num
FROM oceanbase.gv$plan_cache_stat
WHERE svr_ip=HOST_IP() AND svr_port=RPC_PORT()"
```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
SQL_NUM	bigint(20)	The number of SQL statements for which execution plans are stored in the plan cache for future use.
MEM_USED	bigint(20)	The memory size that is used by the plan cache.
ACCESS_COUNT	bigint(20)	The number of accesses to the plan cache.
HIT_COUNT	bigint(20)	The number of plan cache hits.
HIT_RATE	bigint(20)	The plan cache hit ratio.
PLAN_NUM	bigint(20)	The number of execution plans in the plan cache.

Name	Data type	Description
MEM_LIMIT	bigint(20)	The maximum memory size that can be used by the plan cache.
HASH_BUCKET	bigint(20)	The number of buckets that are contained in the <code>hash map</code> of the plan cache.
STMTKEY_NUM	bigint(20)	The number of <code>stmt_keys</code> in the plan cache.

18.5.20.14. v\$plan_cache_plan_stat

Shows the status of all execution plans in a plan cache.

View definition

view_definition=

```
"SELECT tenant_id, svr_ip, svr_port, plan_id, sql_id, type, statement, plan_hash, first_load_time, schema_version, merged_version, last_active_time, avg_exe_usec, slowest_exe_time, slowest_exe_usec, slow_count, hit_count, executions, disk_reads, direct_writes, buffer_gets, application_wait_time, concurrency_wait_time, user_io_wait_time, rows_processed, elapsed_time, cpu_time, large_queries, delayed_large_queries, outline_version, outline_id
FROM oceanbase.gv$plan_cache_plan_stat
WHERE svr_ip=HOST_IP() AND svr_port=RPC_PORT()"
```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
SVR_IP	varchar(32)	The IP address of the server.
SVR_PORT	bigint(20)	The port number of the server.
PLAN_ID	bigint(20)	The ID of the execution plan.
SQL_ID	varchar(32)	The ID of the SQL statement.
TYPE	bigint(20)	The type of the execution plan.
STATEMENT	varchar(4096)	The text of the SQL statement.
PLAN_HASH	bigint(20) unsigned	The hash value of the execution plan.
FIRST_LOAD_TIME	timestamp(6)	The time when the execution plan was loaded for the first time.
SCHEMA_VERSION	bigint(20)	The version number of the schema.
MERGED_VERSION	bigint(20)	The merge version number that corresponds to the cached execution plan.
LAST_ACTIVE_TIME	timestamp(6)	The time of the last execution.

Name	Data type	Description
AVG_EXE_USEC	bigint(20)	The average amount of execution time.
SLOWEST_EXE_TIME	timestamp(6)	The time when the slowest execution started.
SLOWEST_EXE_USEC	bigint(20)	The amount of time that was spent on the slowest execution.
SLOW_COUNT	bigint(20)	The number of slow queries.
HIT_COUNT	bigint(20)	The number of hits.
EXECUTIONS	bigint(20)	The number of executions.
DISK_READS	bigint(20)	The number of physical reads from disks.
DIRECT_WRITES	bigint(20)	The number of physical writes.
BUFFER_GETS	bigint(20)	The number of logical reads.
APPLICATION_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all application events.
CONCURRENCY_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all concurrency events.
USER_IO_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all user I/O events.
ROWS_PROCESSED	bigint(20)	The number of rows to be processed by the SQL statement. If a SELECT statement is executed, the value indicates the number of rows that are returned. If a DELETE, UPDATED, or INSERT statement is executed, the value indicates the number of rows that are affected.
ELAPSED_TIME	bigint(20) unsigned	The amount of time that was spent on processing the request after the request was received.
CPU_TIME	bigint(20) unsigned	The CPU time.

18.5.20.15. v\$sqlplan_cache_plan_explain

Shows basic information about all execution plans in a plan cache.

View definition

```
view_definition=
"SELECT *
FROM oceanbase.gv$sqlplan_cache_plan_explain
WHERE IP =HOST_IP() AND PORT = RPC_PORT()"
```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
IP	varchar(32)	The IP address.
PORT	bigint(20)	The port number.
PLAN_ID	bigint(20)	The ID of the execution plan.
OPERATOR	varchar(128)	The name of the operator.
NAME	varchar(256)	The name of the table.
ROWS	bigint(20)	The estimated number of result rows.
COST	bigint(20)	The estimated cost.
PROPERTY	varchar(256)	The information about the operator.

18.5.20.16. v\$sql_audit

Shows an SQL audit table that records the source and execution status of each SQL statement.

View definition

```
view_definition='SELECT * FROM oceanbase.gv$sql_audit WHERE svr_ip=HOST_IP() AND svr_port=RPC_PORT()'
```

Fields

Name	Data type	Description
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
REQUEST_ID	bigint(20)	The ID of the request.
SQL_EXEC_ID	bigint(20)	The unique ID of the SQL statement. This ID is the MD5 hash value of the parameterized string of the SQL statement.
TRACE_ID	varchar(128)	The trace ID of the SQL statement.
SID	bigint(20) unsigned	The ID of the session.
CLIENT_IP	varchar(32)	The IP address of the client that sent the request.
CLIENT_PORT	bigint(20)	The port number of the client that sent the request.

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant that sent the request.
TENANT_NAME	varchar(64)	The name of the tenant that sent the request.
USER_ID	bigint(20)	The ID of the user that sent the request.
USER_NAME	varchar(64)	The name of the user that sent the request.
DB_ID	bigint(20) unsigned	The ID of the database where the SQL statement was executed.
DB_NAME	varchar(128)	The name of the database where the SQL statement was executed.
SQL_ID	varchar(32)	The ID of the SQL statement.
QUERY_SQL	varchar(65536)	The text of the SQL statement.
AFFECTED_ROWS	bigint(20)	The number of affected rows.
RETURN_ROWS	bigint(20)	The number of returned rows.
RET_CODE	bigint(20)	The return code of the execution result.
EVENT	varchar(64)	The name of the event for which the amount of waited time is the longest.
P1TEXT	varchar(64)	The name of the first parameter of the wait event.
P1	bigint(20) unsigned	The value of the first parameter of the wait event.
P2TEXT	varchar(64)	The name of the second parameter of the wait event.
P2	bigint(20) unsigned	The value of the second parameter of the wait event.
P3TEXT	varchar(64)	The name of the third parameter of the wait event.
P3	bigint(20) unsigned	The value of the third parameter of the wait event.
LEVEL	bigint(20)	The level of the wait event.
WAIT_CLASS_ID	bigint(20)	The ID of the class of the wait event.
WAIT_CLASS#	bigint(20)	The number that represents the class of the wait event.

Name	Data type	Description
WAIT_CLASS	varchar(64)	The name of the class of the wait event.
STATE	varchar(19)	The state of the wait event.
WAIT_TIME_MICRO	bigint(20)	The amount of time that was spent on waiting for the event. Unit: microseconds.
TOTAL_WAIT_TIME_MICRO	bigint(20)	The total amount of time for all wait events during the execution. Unit: microseconds.
TOTAL_WAITS	bigint(20)	The total number of waits during the execution.
RPC_COUNT	bigint(20)	The number of RPC requests that were sent.
PLAN_TYPE	bigint(20)	The type of the execution plan. Valid values: local, remote, and distribute.
IS_INNER_SQL	tinyint(4)	Indicates whether the request is an internal SQL query.
IS_EXECUTOR_RPC	tinyint(4)	Indicates whether the request is an RPC request.
IS_HIT_PLAN	tinyint(4)	Indicates whether the plan cache is hit.
REQUEST_TIME	bigint(20)	The time when the execution started.
ELAPSED_TIME	bigint(20)	The amount of time that was spent on processing the request after the request was received.
NET_TIME	bigint(20)	The amount of time that elapsed from the time when the RPC request was sent to the time when the RPC request was received.
NET_WAIT_TIME	bigint(20)	The amount of time that elapsed from the time when the request was received to the time when the request was added to the queue.
QUEUE_TIME	bigint(20)	The amount of time for which the request waited in the queue.
DECODE_TIME	bigint(20)	The amount of time that was spent on decoding the request after the request exited the queue.
GET_PLAN_TIME	bigint(20)	The amount of time that elapsed from the time when the SQL statement was processed to the time when an execution plan was generated.

Name	Data type	Description
EXECUTE_TIME	bigint(20)	The amount of time that was spent on executing the execution plan.
APPLICATION_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all application events.
CONCURRENCY_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all concurrency events.
USER_IO_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all user I/O events.
SCHEDULE_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all schedule events.
ROW_CACHE_HIT	bigint(20)	The number of row cache hits.
BLOOM_FILTER_CACHE_HIT	bigint(20)	The number of Bloom filter cache hits.
BLOCK_CACHE_HIT	bigint(20)	The number of block cache hits.
BLOCK_INDEX_CACHE_HIT	bigint(20)	The number of block index cache hits.
DISK_READS	bigint(20)	The number of physical reads from disks.
RETRY_CNT	bigint(20)	The number of times the SQL statement was re-executed from the redo log.
TABLE_SCAN	tinyint(4)	Indicates a table scan.
CONSISTENCY_LEVEL	bigint(20)	The consistency level of the SQL statement.
MEMSTORE_READ_ROW_COUNT	bigint(20)	The number of rows in the SQL result set that was returned from the MemStore.
SSSTORE_READ_ROW_COUNT	bigint(20)	The number of rows in the SQL result set that was returned from the disk.
REQUEST_MEMOMERY_USED	bigint(20)	The memory size used by the SQL statement.

18.5.20.17. v\$latch

Shows latch information.

View definition

```
view_definition =
"SELECT *
FROM oceanbase.gv$latch
WHERE SVR_IP=host_ip() and SVR_PORT=rpc_port()"
```

Fields

Name	Data type	Description
CON_ID	bigint(20)	The ID of the tenant.
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
ADDR	varchar(256)	The value is displayed as NULL.
LATCH#	bigint(20)	The number that represents the class of the latch.
LEVEL#	bigint(20)	The number that represents the level of the latch.
NAME	varchar(256)	The name of the latch.
HASH	bigint(20)	The value is displayed as 0.
GETS	bigint(20)	The number of successful low_lock operations.
MISSES	bigint(20)	The number of waits after the low_lock operations are performed more than the yield operations.
SLEEPS	bigint(20)	The total number of yield operations.
IMMEDIATE_GETS	bigint(20)	The number of successful try_lock operations.
IMMEDIATE_MISSES	bigint(20)	The number of failed try_lock operations.
SPIN_GETS	bigint(20)	The total number of spin operations.
WAIT_TIME	bigint(20)	The amount of time that was spent on waiting for the latch.

18.5.20.18. v\$oobrpc_outgoing

Shows statistics about RPC requests that were sent from an OBServer for different tenants based on the RPC packet codes.

View definition

```
view_definition =
"SELECT *
FROM gv$obrpc_outgoing
WHERE IP=HOST_IP() AND PORT=RPC_PORT()"
```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
IP	varchar(32)	The IP address.
PORT	bigint(20)	The port number.
PCODE	bigint(20)	rpc packet code
PCODE_NAME	varchar(256)	The name that corresponds to the RPC packet code.
COUNT	bigint(20)	The number of times that the RPC packet code was used.
TOTAL_TIME	bigint(20)	The total amount of time that was spent.
TOTAL_SIZE	bigint(20)	The total amount of data that was sent.
FAILURE	bigint(20)	The number of RPC requests that have failed sending.
TIMEOUT	bigint(20)	The number of sending time-outs.
SYNC	bigint(20)	The number of RPC requests that were sent synchronously.
ASYNC	bigint(20)	The number of RPC requests that were sent asynchronously.
LAST_TIMESTAMP	timestamp(6)	The time when the statistics was last updated.

18.5.20.19. v\$obrpc_incoming

Shows statistics about RPC requests that were received by an OBServer for different tenants based on the RPC packet codes.

View definition

```
view_definition =
"SELECT *
FROM gv$obrpc_incoming
WHERE IP=HOST_IP() AND PORT=RPC_PORT()"
```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
IP	varchar(32)	The IP address.
PORT	bigint(20)	The port number.
PCODE	bigint(20)	rpc packet code
PCODE_NAME	varchar(256)	The name that corresponds to the RPC packet code.
COUNT	bigint(20)	The number of times that the RPC packet code was used.
TOTAL_SIZE	bigint(20)	The total amount of data that was received.
NET_TIME	bigint(20)	The network time.
WAIT_TIME	bigint(20)	The amount of time that elapsed from the time when the request was received to the time when the request was added to the queue.
QUEUE_TIME	bigint(20)	The amount of time for which the request waited in the queue.
PROCESS_TIME	bigint(20)	The amount of time that was spent on processing the request.
LAST_TIMESTAMP	timestamp(6)	The last update time.

18.5.20.20. v\$sql

Shows hot-updated SQL statistics for all execution plans. Each row in the table records the statistics of a single execution plan. The statistics contain summary information about multiple executions of the plan.

View definition

```
view_definition=
"SELECT *
FROM oceanbase.gv$sql
WHERE svr_ip=HOST_IP() AND svr_port=RPC_PORT()"
```

Fields

Name	Data type	Description
CON_ID	bigint(20)	The ID of the tenant.
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
PLAN_ID	bigint(20)	The ID of the execution plan.
SQL_ID	varchar(32)	The identifier of the SQL statement.

Name	Data type	Description
TYPE	bigint(20)	The type of the execution plan. Valid values: local, remote, and distribute.
SQL_TEXT	varchar(4096)	The text of the SQL statement.
PLAN_HASH_VALUE	bigint(20) unsigned	The hash value of the execution plan.
FIRST_LOAD_TIME	timestamp(6)	The time of the first execution.
LAST_ACTIVE_TIME	timestamp(6)	The time of the last execution.
AVG_EXE_USEC	bigint(20)	The average amount of execution time.
SLOWEST_EXE_TIME	timestamp(6)	The time when the slowest execution started.
SLOWEST_EXE_USEC	bigint(20)	The amount of time that was spent on the slowest execution.
SLOW_COUNT	bigint(20)	The number of slow queries.
HIT_COUNT	bigint(20)	The number of plan cache hits.
PLAN_SIZE	bigint(20)	
EXECUTIONS	bigint(20)	The number of executions.
DISK_READS	bigint(20)	The number of physical reads from disks.
DIRECT_WRITES	bigint(20)	The number of physical writes.
BUFFER_GETS	bigint(20)	The number of logical reads.
APPLICATION_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all application events.
CONCURRENCY_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all concurrency events.
USER_IO_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all user I/O events.
ROWS_PROCESSED	bigint(20)	The number of rows to be processed by the SQL statement. If a SELECT statement is executed, the value indicates the number of rows that are returned. If a DELETE, UPDATED, or INSERT statement is executed, the value indicates the number of rows that are affected.

Name	Data type	Description
ELAPSED_TIME	bigint(20) unsigned	The amount of time that was spent on processing the request after the request was received.
CPU_TIME	bigint(20) unsigned	The CPU time.

18.5.20.21. v\$sql_monitor

Shows statistics about slow SQL queries based on execution plans. Each slow SQL query has a statistical record that can be used to trace the execution plan.

View definition

```
view_definition=
"SELECT tenant_id as CON_ID,\
  request_id as SQL_EXEC_ID,\
  job_id as JOB_ID,\
  task_id as TASK_ID,\
  svr_ip as SVR_IP,\
  svr_port as SVR_PORT,\
  sql_exec_start as SQL_EXEC_START, \
  plan_id as PLAN_ID,\
  scheduler_ip as SCHEDULER_IP, \
  scheduler_port as SCHEDULER_PORT, \
  monitor_info as MONITOR_INFO,\
  extend_info as EXTEND_INFO FROM oceanbase.__all_virtual_sql_monitor \
WHERE is_serving_tenant(svr_ip, svr_port, effective_tenant_id()) \
and (tenant_id = effective_tenant_id() or effective_tenant_id() = 1) "
```

Fields

Name	Data type	Description
CON_ID	bigint(20)	The ID of the tenant.
SQL_EXEC_ID	bigint(20)	The unique ID of the SQL statement. This ID is the MD5 hash value of the parameterized string of the SQL statement.
JOB_ID	bigint(20)	The job ID. The executor uses this ID to identify a segment in the physical execution plan. Job IDs are globally incremental on a single OBServer.
TASK_ID	bigint(20)	The task ID, which uniquely identifies an execution of a segment that corresponds to a job ID in a distributed execution plan.
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.

Name	Data type	Description
SQL_EXEC_START	timestamp(6)	The time when the execution started.
PLAN_ID	bigint(20)	The plan ID, which uniquely identifies an execution plan in the plan cache on a single OBServer. Plan IDs are incremental values that are managed by the plan cache module. When a new execution plan is added to the plan cache, a plan ID is assigned to the new execution plan.
SCHEDULER_IP	varchar(32)	The IP address of the OBServer that is scheduled to execute the SQL statement.
SCHEDULER_PORT	bigint(20)	The port number of the OBServer that is scheduled to execute the SQL statement.
MONITOR_INFO	varchar(65535)	The relevant information such as the event for which the amount of waited time is the longest and the reception time.
EXTEND_INFO	varchar(65535)	The extended information such as all trace information that was generated in the process of executing the SQL statement.

18.5.20.22. v\$sql_plan_monitor

Shows statistics about slow SQL queries based on execution plans. Each slow SQL query has a statistical record that can be used to trace the execution plan.

View definition

```
view_definition='SELECT * from oceanbase.gv$sql_plan_monitor WHERE svr_ip=HOST_IP() AND svr_port=RPC_Port()'
```

Fields

Name	Data type	Description
CON_ID	bigint(20)	The ID of the tenant.
SQL_EXEC_ID	bigint(20)	The unique ID of the SQL statement. This ID is the MD5 hash value of the parameterized string of the SQL statement.
JOB_ID	bigint(20)	The job ID. The executor uses this ID to identify a segment in the physical execution plan. Job IDs are globally incremental on a single OBServer.

Name	Data type	Description
TASK_ID	bigint(20)	The task ID, which uniquely identifies an execution of a segment that corresponds to a job ID in a distributed execution plan.
OPERATION_ID	bigint(20)	The operator ID, which uniquely identifies an operator in a physical execution plan. Operator IDs are generated based on the postorder traversal of the physical execution plan tree.
SVR_IP	varchar(32)	The IP address of the OBServer.
SVR_PORT	bigint(20)	The port number of the OBServer.
SQL_EXEC_START	timestamp(6)	The time when the execution of the SQL statement started.
PLAN_ID	bigint(20)	The plan ID, which uniquely identifies an execution plan in the plan cache on a single OBServer. Plan IDs are incremental values that are managed by the plan cache module. When a new execution plan is added to the plan cache, a plan ID is assigned to the new execution plan.
SCHEDULER_IP	varchar(32)	The IP address of the OBServer that is scheduled to execute the SQL statement.
SCHEDULER_PORT	bigint(20)	The port number of the OBServer that is scheduled to execute the SQL statement.
PLAN_OPERATION	varchar(32)	The operators that are used in the execution plan.
MONITOR_INFO	varchar(65535)	The execution time statistics for each step in the execution plan.
EXTEND_INFO	varchar(65535)	The extended information.

18.5.20.23. gv\$plan_cache_stat

Shows the plan cache status in a cluster. A cluster consists of multiple OBServers where multiple OBSERVER instances are deployed.

View definition

```

view_definition='
"SELECT tenant_id,
    svr_ip,
    svr_port,
    sql_num,
    mem_used,
    access_count,
    hit_count,
    hit_rate,
    plan_num,
    mem_limit,
    hash_bucket,
    stmtkey_num
FROM oceanbase.__all_virtual_plan_cache_stat
WHERE is_serving_tenant(svr_ip, svr_port, effective_tenant_id()) and (tenant_id = effective_tenant_id() or effective_tenant_id() = 1) "

```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
SQL_NUM	bigint(20)	The number of SQL statements for which the execution plans are stored in all plan caches in the cluster.
MEM_USED	bigint(20)	The memory size used by all plan caches in the cluster.
ACCESS_COUNT	bigint(20)	The number of accesses to all plan caches in the cluster.
HIT_COUNT	bigint(20)	The number of plan cache hits of the cluster.
HIT_RATE	bigint(20)	The plan cache hit ratio of the cluster.
PLAN_NUM	bigint(20)	The number of execution plans that are stored in the plan caches in the cluster.
MEM_LIMIT	bigint(20)	The maximum memory size that can be used by the plan caches in the cluster.
HASH_BUCKET	bigint(20)	The number of buckets that are contained in the hash maps of all plan caches in the cluster.
STMTKEY_NUM	bigint(20)	The number of stmt_keys in all plan caches in the cluster.

18.5.20.24. gv\$sqlplan_cache_plan_stat

Shows the status of each execution plan in the plan caches of each OBCServer instance on all OBCServers in a cluster.

View definition

```
view_definition=
"SELECT tenant_id,
  svr_ip,
  svr_port,
  plan_id,
  sql_id,
  type,
  statement,
  plan_hash,
  first_load_time,
  schema_version,
  merged_version,
  last_active_time,

  delayed_large_querys,
  outline_version,
  outline_id
FROM
  oceanbase.__all_virtual_plan_stat
WHERE
  is_serving_tenant(svr_ip, svr_port, effective_tenant_id()) and (tenant_id = effective_tenant_id() or effective_tenant_id() = 1)'
```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.

Name	Data type	Description
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
PLAN_ID	bigint(20)	The ID of the execution plan.
SQL_ID	varchar(32)	The identifier of the SQL statement.
TYPE	bigint(20)	The type of the execution plan. Valid values: local, remote, and distribute.
STATEMENT	varchar(4096)	The text of the SQL statement.
PLAN_HASH	bigint(20) unsigned	The hash value of the execution plan.
FIRST_LOAD_TIME	timestamp(6)	The time when the execution plan was loaded for the first time.
SCHEMA_VERSION	bigint(20)	The version number of the schema.
MERGED_VERSION	bigint(20)	The merge version that corresponds to the execution plan in the plan cache.
LAST_ACTIVE_TIME	timestamp(6)	The time of the last execution.
AVG_EXE_USEC	bigint(20)	The average amount of execution time.
SLOWEST_EXE_TIME	bigint(20)	The time when the slowest execution started.
SLOWEST_EXE_USEC	bigint(20)	The amount of time that was spent on the slowest execution.
SLOW_COUNT	bigint(20)	The number of slow queries.
HIT_COUNT	bigint(20)	The number of plan cache hits.
EXECUTIONS	bigint(20)	The number of executions.
DISK_READS	bigint(20)	The number of physical reads from disks.
DIRECT_READS	bigint(20)	The number of direct reads.
DIRECT_WRITES	bigint(20)	The number of physical writes.
BUFFER_GETS	bigint(20)	The number of logical reads.
APPLICATION_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all application events.
CONCURRENCY_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all concurrency events.
USER_IO_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all user I/O events.

Name	Data type	Description
ROWS_PROCESSED	bigint(20)	The number of rows to be processed by the SQL statement. If a SELECT statement is executed, the value indicates the number of rows that are returned. If a DELETE, UPDATED, or INSERT statement is executed, the value indicates the number of rows that are affected.
ELAPSED_TIME	bigint(20) unsigned	The amount of time that was spent on processing the request after the request was received.
CPU_TIME	bigint(20) unsigned	The CPU time.
LARGE_QUERYYS	bigint(20)	
DELAYED_LARGE_QUERYYS	bigint(20)	
OUTLINE_ID	bigint(20)	

18.5.20.25. gv\$session_event

Shows information about wait events based on sessions for all OBServers in a cluster.

View definition

```
view_definition = "select session_id as SID, \
    tenant_id as CON_ID, \
    svr_ip as SVR_IP, \
    svr_port as SVR_PORT, \
    event_id as EVENT_ID, \
    event as EVENT, \
    wait_class_id as WAIT_CLASS_ID, \
    `wait_class#` as `WAIT_CLASS#`, \
    wait_class as WAIT_CLASS, \
    total_waits as TOTAL_WAITS, \
    total_timeouts as TOTAL_TIMEOUTS, \
    time_waited as TIME_WAITED, \

    average_wait as AVERAGE_WAIT, \
    time_waited_micro as TIME_WAITED_MICRO \
from oceanbase.__all_virtual_session_event where \
is_serving_tenant(svr_ip, svr_port, effective_tenant_id()) and \
(tenant_id = effective_tenant_id() or effective_tenant_id() = 1)"
```

Fields

Name	Data type	Description
SID	bigint(20)	The ID of the session.

Name	Data type	Description
CON_ID	bigint(20)	The ID of the tenant.
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
EVENT_ID	bigint(20)	The ID of the wait event.
EVENT	varchar(64)	The description of the wait event.
WAIT_CLASS_ID	bigint(20)	The ID of the class of the wait event.
WAIT_CLASS#	bigint(20)	The number that represents the class of the wait event.
WAIT_CLASS	varchar(64)	The name of the class of the wait event.
TOTAL_WAITS	bigint(20)	The total number of waits for the event.
TOTAL_TIMEOUTS	bigint(20)	The total number of wait time-outs for the event.
TIME_WAITED	double	The total amount of time that was spent on waiting for the event. Unit: 10 ms.
MAX_WAIT	double	The maximum amount of time that was spent on waiting for the event. Unit: 10 ms.
AVERAGE_WAIT	double	The average amount of time that was spent on waiting for the event. Unit: 10 ms.
TIME_WAITED_MICRO	bigint(20)	The total amount of time that was spent on waiting for the event. Unit: microseconds.

18.5.20.26. gv\$sqlsession_wait

Shows details about all wait events based on sessions for all OBServers in a cluster.

View definition

```
view_definition = "select session_id as SID, \
    tenant_id as CON_ID, \
    svr_ip as SVR_IP, \
    svr_port as SVR_PORT, \

```

Fields

Name	Data type	Description
SID	bigint(20)	The ID of the session.
CON_ID	bigint(20)	The ID of the tenant.
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
EVENT_ID	bigint(20)	The ID of the wait event.
EVENT	varchar(64)	The description of the wait event.
WAIT_CLASS_ID	bigint(20)	The ID of the class of the wait event.
WAIT_CLASS#	bigint(20)	The number that represents the class of the wait event.
WAIT_CLASS	varchar(64)	The name of the class of the wait event.
TOTAL_WAITS	bigint(20)	The total number of waits for the event.
TOTAL_TIMEOUTS	bigint(20)	The total number of wait time-outs for the event.
TIME_WAITED	double	The total amount of time that was spent on waiting for the event. Unit: 10 ms.
MAX_WAIT	double	The maximum amount of time that was spent on waiting for the event. Unit: 10 ms.
AVERAGE_WAIT	double	The average amount of time that was spent on waiting for the event.

Name	Data type	Description
TIME_WAITED_MICRO	bigint(20)	The total amount of time that was spent on waiting for the event. Unit: microseconds.

18.5.20.27. gv\$session_wait_history

Shows details about all wait events based on sessions for all OBServers in a cluster. This view shows more detailed history information than the gv\$session_wait view.

View definition

```
view_definition = "select session_id as SID, \

(tenant_id = effective_tenant_id() or effective_tenant_id() = 1)"
```

Fields

Name	Data type	Description
CON_ID	bigint(20)	The ID of the tenant.

Name	Data type	Description
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
EVENT_ID	bigint(20)	The ID of the wait event.
EVENT	varchar(64)	The description of the wait event.
WAIT_CLASS_ID	bigint(20)	The ID of the class of the wait event.
WAIT_CLASS#	bigint(20)	The number that represents the class of the wait event.
WAIT_CLASS	varchar(64)	The name of the class of the wait event.
TOTAL_WAITS	bigint(20)	The total number of waits for the event.
TOTAL_TIMEOUTS	bigint(20)	The total number of wait time-outs for the event.
TIME_WAITED	double	The total amount of time that was spent on waiting for the event. Unit: 10 ms.
MAX_WAIT	double	The maximum amount of time that was spent on waiting for the event. Unit: 10 ms.
AVERAGE_WAIT	double	The average amount of time that was spent on waiting for the event. Unit: 10 ms.
TIME_WAITED_MICRO	bigint(20)	The total amount of time that was spent on waiting for the event. Unit: microseconds.

18.5.20.29. gv\$sesstat

Shows information about statistical events based on sessions for all OBServers in a cluster.

View definition

```
view_definition = "select session_id as SID, \
    tenant_id as CON_ID, \
    svr_ip as SVR_IP, \
    svr_port as SVR_PORT, \
    `statistic#` as `STATISTIC#`, \
    value as VALUE \
from oceanbase.__all_virtual_sesstat \
where is_serving_tenant(svr_ip, svr_port, effective_tenant_id()) and can_visible = true and \
(tenant_id = effective_tenant_id() or effective_tenant_id() = 1)"
```

Fields

Name	Data type	Description
SID	bigint(20)	The ID of the session.
CON_ID	bigint(20)	The ID of the tenant.
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
STATISTIC#	bigint(20)	The number that represents the statistical event.
VALUE	bigint(20)	

18.5.20.30. gv\$sysstat

Shows information about statistical events based on tenants for all OBServers in a cluster.

View definition

```
view_definition = "select tenant_id as CON_ID, \
    svr_ip as SVR_IP, \
    svr_port as SVR_PORT, \
    `statistic#` as `STATISTIC#`, \

where is_serving_tenant(svr_ip, svr_port, effective_tenant_id()) and (tenant_id = effective_tenant_id() or
effective_tenant_id() = 1)'

```

Fields

Name	Data type	Description
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
REQUEST_ID	bigint(20)	The ID of the request.
EXECUTION_ID	bigint(20)	The unique ID of the SQL statement. This ID is the MD5 hash value of the parameterized string of the SQL statement.
TRACE_ID	varchar(128)	The trace ID of the SQL statement.
CLIENT_IP	varchar(32)	The IP address of the client that sent the request.
CLIENT_PORT	bigint(20)	The port number of the client that sent the request.
TENANT_ID	bigint(20)	The ID of the tenant that sent the request.
TENANT_NAME	varchar(64)	The name of the tenant that sent the request.
USER_ID	bigint(20)	The ID of the user that sent the request.
USER_NAME	varchar(64)	The name of the user that sent the request.
SQL_ID	varchar(32)	The identifier of the SQL statement.
QUERY_SQL	varchar(65536)	The text of the SQL statement.
PLAN_ID	bigint(20)	The ID of the execution plan.
AFFECTED_ROWS	bigint(20)	The number of affected rows.
RETURN_ROWS	bigint(20)	The number of returned rows.
RET_CODE	bigint(20)	The return code of the execution result.

Name	Data type	Description
EVENT	varchar(64)	The description of the wait event.
P1TEXT	varchar(64)	The name of the first parameter of the wait event.
P1	bigint(20) unsigned	The value of the first parameter of the wait event.
P2TEXT	varchar(64)	The name of the second parameter of the wait event.
P2	bigint(20) unsigned	The value of the second parameter of the wait event.
P3TEXT	varchar(64)	The name of the third parameter of the wait event.
P3	bigint(20) unsigned	The value of the third parameter of the wait event.
LEVEL	bigint(20)	The level of the wait event.
WAIT_CLASS_ID	bigint(20)	The ID of the class of the wait event.
WAIT_CLASS#	bigint(20)	The number that represents the class of the wait event.
WAIT_CLASS	varchar(64)	The name of the class of the wait event.
STATE	varchar(19)	The state of the wait event.
WAIT_TIME_MICRO	bigint(20)	The amount of time that was spent on waiting for the event. Unit: microseconds.
TOTAL_WAIT_TIME_MICRO	bigint(20)	The total amount of time for all wait events during the execution. Unit: microseconds.
TOTAL_WAITS	bigint(20)	The total number of waits during the execution.
RPC_COUNT	bigint(20)	The number of RPC requests that were sent.
PLAN_TYPE	bigint(20)	The type of the execution plan. Valid values: local, remote, and distribute.
IS_INNER_SQL	tinyint(4)	Indicates whether the request is an internal SQL query.
IS_EXECUTOR_RPC	tinyint(4)	Indicates whether the request is an RPC request.
IS_HIT_PLAN	tinyint(4)	Indicates whether the plan cache is hit.
REQUEST_TIME	bigint(20)	The time when the execution started.
ELAPSED_TIME	bigint(20)	The amount of time that was spent on processing the request after the request was received.

Name	Data type	Description
NET_TIME	bigint(20)	The amount of time that elapsed from the time when the RPC request was sent to the time when the RPC request was received.
NET_WAIT_TIME	bigint(20)	The amount of time that elapsed from the time when the request was received to the time when the request was added to the queue.
QUEUE_TIME	bigint(20)	The amount of time for which the request waited in the queue.
DECODE_TIME	bigint(20)	The amount of time that was spent on decoding the request after the request exited the queue.
GET_PLAN_TIME	bigint(20)	The amount of time that elapsed from the time when the SQL statement was processed to the time when an execution plan was generated.
EXECUTE_TIME	bigint(20)	The amount of time that was spent on executing the execution plan.
APPLICATION_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all application events.
CONCURRENCY_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all concurrency events.
USER_IO_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all user I/O events.
SCHEDULE_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all schedule events.
DISK_READS	bigint(20)	The number of physical reads from disks.

18.5.20.32. gv\$latch

Shows latch information for all OBServers in a cluster.

View definition

```

view_definition = 'select tenant_id as CON_ID, \
    svr_ip as SVR_IP, \
    svr_port as SVR_PORT, \
    addr as ADDR, \
    latch_id as `LATCH#`, \
    level as `LEVEL#`, \
    name as NAME, \
    hash as HASH, \
    gets as GETS, \
    misses as MISSES, \
    sleeps as SLEEPS, \

    spin_gets as SPIN_GETS, \
    wait_time as WAIT_TIME from oceanbase.__all_virtual_latch where \
    is_serving_tenant(svr_ip, svr_port, effective_tenant_id()) and \
    (tenant_id = effective_tenant_id() or effective_tenant_id() = 1)'

```

Fields

Name	Data type	Description
CON_ID	bigint(20)	The ID of the tenant.
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
ADDR	varchar(256)	The value is displayed as NULL.
LATCH_ID#	bigint(20)	The number that represents the class of the latch.
LEVEL#	bigint(20)	The number that represents the level of the latch.
NAME	varchar(256)	The name of the latch.
HASH	bigint(20)	The value is displayed as 0.
GETS	bigint(20)	The number of successful low_lock operations.
MISSES	bigint(20)	The number of waits after the low_lock operations are performed more than the yield operations.
SLEEPS	bigint(20)	The total number of yield operations.
IMMEDIATE_GETS	bigint(20)	The number of successful try_lock operations.
IMMEDIATE_MISSES	bigint(20)	The number of failed try_lock operations.

Name	Data type	Description
SPIN_GETS	bigint(20)	The total number of spin operations.
WAIT_TIME	bigint(20)	The amount of time that was spent on waiting for the latch.

18.5.20.33. gv\$memory

Shows memory statistics based on tenants for all OBServers in a cluster.

View definition

```
view_definition = ' SELECT \
  tenant_id as TENANT_ID, \
  svr_ip AS IP, \
  svr_port AS PORT, \
  mod_id as MOD_ID, \
  mod_type as MOD_TYPE, \
  mod_name AS CONTEXT, \
  count as COUNT, \
  zone as ZONE, \
  used as USED, \
  alloc_count as ALLOC_COUNT, \
  free_count as FREE_COUNT \
FROM \
  oceanbase.__all_virtual_memory_info \
WHERE \
  ( \
    effective_tenant_id()=1 \
    OR \
    tenant_id=effective_tenant_id() \
  ) \
AND \
  mod_type='user' \
AND \
  is_serving_tenant(svr_ip, svr_port, effective_tenant_id()) \'
```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
IP	varchar(32)	The IP address.
PORT	bigint(20)	The port number.
MOD_ID	bigint(20)	The ID of the mod.
MOD_TYPE	varchar(256)	The type of the mod.

Name	Data type	Description
CONTEXT	varchar(256)	The name of the mod to which the memory belongs.
COUNT	bigint(20)	The number of memory units that are used in the mod, which is the difference between the number of allocated units and the number of available units.
ZONE	varchar(256)	
USED	bigint(20)	The memory size that is used in the mod.
ALLOC_COUNT	bigint(20)	The total number of memory units that are allocated to the mod.
FREE_COUNT	bigint(20)	The total number of available memory units in the mod.

18.5.20.34. gv\$memstore

Shows MemStore statistics based on tenants for all OBServers in a cluster.

View definition

```
view_definition = ' SELECT
    TENANT_ID,
    SVR_IP AS IP,
    SVR_PORT AS PORT,
    ACTIVE_MEMSTORE_USED AS ACTIVE,
    TOTAL_MEMSTORE_USED AS TOTAL,
    MAJOR_FREEZE_TRIGGER AS `FREEZE_TRIGGER`,
    MEMSTORE_LIMIT AS `MEM_LIMIT`
FROM
    oceanbase.__all_virtual_tenant_memstore_info
WHERE
    (EFFECTIVE_TENANT_ID)=1
    OR
    TENANT_ID=EFFECTIVE_TENANT_ID()
    AND
    is_serving_tenant(svr_ip, svr_port, effective_tenant_id())
```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
IP	varchar(32)	The IP address.
PORT	bigint(20)	The port number.

Name	Data type	Description
ACTIVE	bigint(20)	The active MemStore size of the cluster.
TOTAL	bigint(20)	The total MemStore size of the cluster.
FREEZE_TRIGGER	bigint(20)	The MemStore size that triggers a major freeze action.
MEM_LIMIT	bigint(20)	The maximum memory size that can be used in the cluster.

18.5.20.35. gv\$memstore_info

Shows MemStore statistics based on tenants for all OBServers in a cluster. The statistics include the details about all partitions.

View definition

```
view_definition=
SELECT
    TENANT_ID,
    SVR_IP AS IP,
    SVR_PORT AS PORT,
    table_id AS TABLE_ID,
    partition_idx AS PARTITION_ID,
    VERSION,
    IS_ACTIVE,
    MEM_USED as USED,
    hash_item_count as HASH_ITEMS,
    btree_item_count as BTREE_ITEMS
FROM

WHERE
    (EFFECTIVE_TENANT_ID)=1
    OR
    TENANT_ID=EFFECTIVE_TENANT_ID()
AND
    is_serving_tenant(svr_ip, svr_port, effective_tenant_id())
```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
IP	varchar(32)	The IP address.
PORT	bigint(20)	The port number.
TABLE_ID	bigint(20)	The ID of the table.

Name	Data type	Description
PARTITION_ID	bigint(20)	The ID of the partition.
PARTITION_CNT	bigint(20)	The number of partitions.
VERSION	varchar(128)	The version number.
IS_ACTIVE	bigint(20)	Indicates whether the MemStore is active.
USED	bigint(20)	The memory size that is used by the MemStore.
HASH_ITEMS	bigint(20)	The hash indexes that are contained in the MemStore.
BTREE_ITEMS	bigint(20)	The B-tree indexes that are contained in the MemStore.

18.5.20.36. gv\$sqlplan_cache_plan_explain

View definition

```
view_definition='SELECT TENANT_ID,\n      SVR_IP as IP, \n      SVR_PORT as PORT, \n      PLAN_ID, \n      OPERATOR, \n      NAME,\n      ROWS,\n      COST,\n      PROPERTY \nFROM oceanbase.__all_virtual_plan_cache_plan_explain \nWHERE is_serving_tenant(svr_ip, svr_port, effective_tenant_id()) and (EFFECTIVE_TENANT_ID)=1 or TENANT_ID=EFFECTIVE_TENANT_ID()'

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
IP	varchar(32)	The IP address.
PORT	bigint(20)	The port number.
PLAN_ID	bigint(20)	The ID of the execution plan.
OPERATOR	varchar(128)	The name of the operator.
NAME	varchar(256)	The name of the table.
ROWS	bigint(20)	The estimated number of result rows.

Name	Data type	Description
COST	bigint(20)	The estimated cost.
PROPERTY	varchar(256)	-

18.5.20.37. gv\$obrpc_outgoing

Shows statistics about RPC requests that were sent from all OBServers in a cluster.

View definition

```

view_definition = ""
SELECT
  TENANT_ID,
  SVR_IP AS IP,
  SVR_PORT AS PORT,
  PCODE,
  PCODE_NAME,
  COUNT,
  TOTAL_TIME,
  TOTAL_SIZE,
  FAILURE,
  TIMEOUT,
  SYNC,
  ASYNC,
  LAST_TIMESTAMP
FROM
  oceanbase.__all_virtual_obrpc_stat
WHERE
  is_serving_tenant(svr_ip, svr_port, effective_tenant_id())
AND
  (EFFECTIVE_TENANT_ID)=1
OR
  TENANT_ID=EFFECTIVE_TENANT_ID()

```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
IP	varchar(32)	The IP address.
PORT	bigint(20)	The port number.
PCODE	bigint(20)	rpc packet code
PCODE_NAME	varchar(256)	The name that corresponds to the RPC packet code.

Name	Data type	Description
COUNT	bigint(20)	The total number of times that the RPC packet code was used.
TOTAL_TIME	bigint(20)	The total amount of time that was spent.
TOTAL_SIZE	bigint(20)	The total amount of data that was sent.
FAILURE	bigint(20)	The number of RPC requests that have failed sending.
TIMEOUT	bigint(20)	The number of sending time-outs.
SYNC	bigint(20)	The number of RPC requests that were sent synchronously.
ASYN	bigint(20)	The number of RPC requests that were sent asynchronously.
LAST_TIMESTAMP	timestamp(6)	The time when the statistics was last updated.

18.5.20.38. gv\$obrpc_incoming

Shows statistics about RPC requests that were received by all OBServers in a cluster.

View definition

```

view_definition = ""
SELECT
  TENANT_ID,
  SVR_IP AS IP,

WHERE
  EFFECTIVE_TENANT_ID()=1
OR
  TENANT_ID=EFFECTIVE_TENANT_ID()

```

Fields

Name	Data type	Description
TENANT_ID	bigint(20)	The ID of the tenant.
IP	varchar(32)	The IP address.
PORT	bigint(20)	The port number.
PCODE	bigint(20)	rpc packet code
PCODE_NAME	varchar(256)	The name that corresponds to the RPC packet code.
COUNT	bigint(20)	The number of times that the RPC packet code was used.
TOTAL_SIZE	bigint(20)	The total amount of data that was received.
NET_TIME	bigint(20)	The network time.
WAIT_TIME	bigint(20)	The amount of time that elapsed from the time when the request was received to the time when the request was added to the queue.
QUEUE_TIME	bigint(20)	The amount of time for which the request waited in the queue.
PROCESS_TIME	bigint(20)	The amount of time that was spent on processing the request.
LAST_TIMESTAMP	timestamp(6)	The last update time.

18.5.20.39. gv\$sql

Shows hot-updated SQL statistics for all execution plans of all OBServers in a cluster. Each row in the table records the statistics of a single execution plan. The statistics contain summary information about multiple executions of the plan.

View definition

```
view_definition='SELECT tenant_id AS CON_ID, \

WHERE is_serving_tenant(svr_ip, svr_port, effective_tenant_id()) and (tenant_id = effective_tenant_id() or effective_tenant_id() = 1)'
```

Fields

Name	Data type	Description
CON_ID	bigint(20)	The ID of the tenant.
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
PLAN_ID	bigint(20)	The ID of the execution plan.
SQL_ID	varchar(32)	The identifier of the SQL statement.
TYPE	bigint(20)	The type of the execution plan. Valid values: local, remote, and distribute.
SQL_TEXT	varchar(4096)	The text of the SQL statement.

Name	Data type	Description
PLAN_HASH_VALUE	bigint(20) unsigned	The hash value of the execution plan.
FIRST_LOAD_TIME	timestamp(6)	The time of the first execution.
LAST_ACTIVE_TIME	timestamp(6)	The time of the last execution.
AVG_EXE_USEC	bigint(20)	The average amount of execution time.
SLOWEST_EXE_TIME	timestamp(6)	The time when the slowest execution started.
SLOWEST_EXE_USEC	bigint(20)	The amount of time that was spent on the slowest execution.
SLOW_COUNT	bigint(20)	The number of slow queries.
HIT_COUNT	bigint(20)	The number of plan cache hits.
PLAN_SIZE	bigint(20)	
EXECUTIONS	bigint(20)	The number of executions.
DISK_READS	bigint(20)	The number of physical reads from disks.
DIRECT_WRITES	bigint(20)	The number of physical writes.
BUFFER_GETS	bigint(20)	The number of logical reads.
APPLICATION_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all application events.
CONCURRENCY_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all concurrency events.
USER_IO_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all user I/O events.
ROWS_PROCESSED	bigint(20)	The number of rows to be processed by the SQL statement. If a SELECT statement is executed, the value indicates the number of rows that are returned. If a DELETE, UPDATED, or INSERT statement is executed, the value indicates the number of rows that are affected.
ELAPSED_TIME	bigint(20) unsigned	The amount of time that was spent on processing the request after the request was received.
CPU_TIME	bigint(20) unsigned	The CPU time.
CON_ID	bigint(20)	The ID of the tenant.
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.

Name	Data type	Description
PLAN_ID	bigint(20)	The ID of the execution plan.
SQL_ID	varchar(32)	The identifier of the SQL statement.
TYPE	bigint(20)	The type of the execution plan. Valid values: local, remote, and distribute.
SQL_TEXT	varchar(4096)	The text of the SQL statement.
PLAN_HASH_VALUE	bigint(20) unsigned	The hash value of the execution plan.
FIRST_LOAD_TIME	timestamp(6)	The time of the first execution.
LAST_ACTIVE_TIME	timestamp(6)	The time of the last execution.
AVG_EXE_USEC	bigint(20)	The average amount of execution time.
SLOWEST_EXE_TIME	timestamp(6)	The time when the slowest execution started.
SLOWEST_EXE_USEC	bigint(20)	The amount of time that was spent on the slowest execution.
SLOW_COUNT	bigint(20)	The number of slow queries.
HIT_COUNT	bigint(20)	The number of plan cache hits.
PLAN_SIZE	bigint(20)	
EXECUTIONS	bigint(20)	The number of executions.
DISK_READS	bigint(20)	The number of physical reads from disks.
DIRECT_WRITES	bigint(20)	The number of physical writes.
BUFFER_GETS	bigint(20)	The number of logical reads.
APPLICATION_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all application events.
CONCURRENCY_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all concurrency events.
USER_IO_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all user I/O events.
ROWS_PROCESSED	bigint(20)	The number of rows to be processed by the SQL statement. If a SELECT statement is executed, the value indicates the number of rows that are returned. If a DELETE, UPDATED, or INSERT statement is executed, the value indicates the number of rows that are affected.
ELAPSED_TIME	bigint(20) unsigned	The amount of time that was spent on processing the request after the request was received.

Name	Data type	Description
CPU_TIME	bigint(20) unsigned	The CPU time.
CON_ID	bigint(20)	The ID of the tenant.
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
PLAN_ID	bigint(20)	The ID of the execution plan.
SQL_ID	varchar(32)	The identifier of the SQL statement.
TYPE	bigint(20)	The type of the execution plan. Valid values: local, remote, and distribute.
SQL_TEXT	varchar(4096)	The text of the SQL statement.
PLAN_HASH_VALUE	bigint(20) unsigned	The hash value of the execution plan.
FIRST_LOAD_TIME	timestamp(6)	The time of the first execution.
LAST_ACTIVE_TIME	timestamp(6)	The time of the last execution.
AVG_EXE_USEC	bigint(20)	The average amount of execution time.
SLOWEST_EXE_TIME	timestamp(6)	The time when the slowest execution started.
SLOWEST_EXE_USEC	bigint(20)	The amount of time that was spent on the slowest execution.
SLOW_COUNT	bigint(20)	The number of slow queries.
HIT_COUNT	bigint(20)	The number of plan cache hits.
PLAN_SIZE	bigint(20)	
EXECUTIONS	bigint(20)	The number of executions.
DISK_READS	bigint(20)	The number of physical reads from disks.
DIRECT_WRITES	bigint(20)	The number of physical writes.
BUFFER_GETS	bigint(20)	The number of logical reads.
APPLICATION_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all application events.
CONCURRENCY_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all concurrency events.
USER_IO_WAIT_TIME	bigint(20) unsigned	The amount of time that was spent on waiting for all user I/O events.

Name	Data type	Description
ROWS_PROCESSED	bigint(20)	The number of rows to be processed by the SQL statement. If a SELECT statement is executed, the value indicates the number of rows that are returned. If a DELETE, UPDATED, or INSERT statement is executed, the value indicates the number of rows that are affected.
ELAPSED_TIME	bigint(20) unsigned	The amount of time that was spent on processing the request after the request was received.
CPU_TIME	bigint(20) unsigned	The CPU time.

18.5.20.40. gv\$sql_monitor

Shows statistics about slow SQL queries based on execution plans for all OBServers in a cluster. Each slow SQL query has a statistical record that can be used to trace the execution plan.

View definition

```
view_definition='SELECT tenant_id as CON_ID,\
  request_id as SQL_EXEC_ID,\
  job_id as JOB_ID,\
  task_id as TASK_ID,\
  svr_ip as SVR_IP,\
  svr_port as SVR_PORT,\
  sql_exec_start as SQL_EXEC_START, \
  plan_id as PLAN_ID,\
  scheduler_ip as SCHEDULER_IP, \
  scheduler_port as SCHEDULER_PORT, \
  monitor_info as MONITOR_INFO,\
  extend_info as EXTEND_INFO FROM oceanbase.__all_virtual_sql_monitor \
WHERE is_serving_tenant(svr_ip, svr_port, effective_tenant_id()) \
and (tenant_id = effective_tenant_id() or effective_tenant_id() = 1)';
```

Fields

Name	Data type	Description
CON_ID	bigint(20)	The ID of the tenant.
SQL_EXEC_ID	bigint(20)	The unique ID of the SQL statement. This ID is the MD5 hash value of the parameterized string of the SQL statement.
JOB_ID	bigint(20)	The job ID. The executor uses this ID to identify a segment in the physical execution plan. Job IDs are globally incremental on a single OBServer.

Name	Data type	Description
TASK_ID	bigint(20)	The task ID, which uniquely identifies an execution of a segment that corresponds to a job ID in a distributed execution plan.
SVR_IP	varchar(32)	The IP address.
SVR_PORT	bigint(20)	The port number.
SQL_EXEC_START	timestamp(6)	The time when the execution started.
PLAN_ID	bigint(20)	The plan ID, which uniquely identifies an execution plan in the plan cache on a single OBServer. Plan IDs are incremental values that are managed by the plan cache module. When a new execution plan is added to the plan cache, a plan ID is assigned to the new execution plan.
SCHEDULER_IP	varchar(32)	The IP address of the OBServer that is scheduled to execute the SQL statement.
SCHEDULER_PORT	bigint(20)	The port number of the OBServer that is scheduled to execute the SQL statement.
MONITOR_INFO	varchar(65535)	The relevant information such as the event for which the amount of waited time is the longest and the reception time.
EXTEND_INFO	varchar(65535)	The extended information such as all trace information that was generated in the process of executing the SQL statement.

18.5.20.41. gv\$sql_plan_monitor

Shows statistics about slow SQL queries based on execution plans for all OBServers in a cluster. Each slow SQL query has a statistical record that can be used to trace the execution plan.

View definition

```

view_definition='SELECT tenant_id as CON_ID, \
  request_id as SQL_EXEC_ID, \
  job_id as JOB_ID, \
  task_id as TASK_ID, \

  extend_info as EXTEND_INFO FROM oceanbase.__all_virtual_sql_plan_monitor \
  WHERE is_serving_tenant(svr_ip, svr_port, effective_tenant_id()) \
  and (tenant_id = effective_tenant_id() or effective_tenant_id() = 1)'

```

Fields

Name	Data type	Description
CON_ID	bigint(20)	The ID of the tenant.
SQL_EXEC_ID	bigint(20)	The unique ID of the SQL statement. This ID is the MD5 hash value of the parameterized string of the SQL statement.
JOB_ID	bigint(20)	The job ID. The executor uses this ID to identify a segment in the physical execution plan. Job IDs are globally incremental on a single OBServer.
TASK_ID	bigint(20)	The task ID, which uniquely identifies an execution of a segment that corresponds to a job ID in a distributed execution plan.
OPERATION_ID	bigint(20)	The operator ID, which uniquely identifies an operator in a physical execution plan. Operator IDs are generated based on the postorder traversal of the physical execution plan tree.
SVR_IP	varchar(32)	The IP address of the OBServer.
SVR_PORT	bigint(20)	The port number of the OBServer.
SQL_EXEC_START	timestamp(6)	The time when the execution of the SQL statement started.
PLAN_ID	bigint(20)	The plan ID, which uniquely identifies an execution plan in the plan cache on a single OBServer. Plan IDs are incremental values that are managed by the plan cache module. When a new execution plan is added to the plan cache, a plan ID is assigned to the new execution plan.

Name	Data type	Description
SCHEDULER_IP	varchar(32)	The IP address of the OBServer that is scheduled to execute the SQL statement.
SCHEDULER_PORT	bigint(20)	The port number of the OBServer that is scheduled to execute the SQL statement.
PLAN_OPERATION	varchar(32)	The operators that are used in the execution plan.
MONITOR_INFO	varchar(65535)	The execution time statistics for each step in the execution plan.
EXTEND_INFO	varchar(65535)	The extended information.

18.5.21. Information Schema

18.5.21.1. Overview

ApsaraDB for OceanBase supports the INFORMATION_SCHEMA database of MySQL. The stored data in the INFORMATION_SCHEMA database depends on the data that is stored in ApsaraDB for OceanBase. If ApsaraDB for OceanBase does not support a field in the database, the field is retained but the field stores empty values.

The INFORMATION_SCHEMA database stores database metadata.

Metadata is data that provides information about other data, such as database names, table names, data types of columns, and access permissions.

The INFORMATION_SCHEMA database stores the information about all the other databases that are maintained by your server.

The INFORMATION_SCHEMA database contains multiple read-only tables. These read-only tables are views instead of base tables. Therefore, you cannot view the files that are associated with these read-only tables.

Each user can access only specific rows in these read-only tables. The specific rows include the objects on which the user has appropriate read permissions.

Advantages of executing SELECT statements to access metadata

`SELECT ... FROM INFORMATION_SCHEMA` statements are an alternative to SHOW statements. `SELECT...FROM INFORMATION_SCHEMA` statements provide a consistent method for you to access the information that is returned by the supported SHOW statements. The examples of the supported SHOW statements include SHOW DATABASES and SHOW TABLES statements.

`SELECT...FROM INFORMATION_SCHEMA` statements offer the following advantages over SHOW statements:

- `SELECT...FROM INFORMATION_SCHEMA` statements comply with Codd's rules. All the read and write operations are performed on tables.
- You need only to familiarize yourself with the syntax of SELECT statements. You do not need to familiarize yourself with other statements.

If you are familiar with the syntax of SELECT statements, you need only to know the object names.

- You do not need to concern yourself with the issues of adding keywords.
- `SELECT...FROM INFORMATION_SCHEMA` statements can return millions of results. This helps you meet various metadata requirements of applications.

Permissions

To query metadata, you can execute SHOW statements or `SELECT...FROM INFORMATION_SCHEMA` statements. The permissions that are required to execute the two types of statements are the same.

You must have permissions on objects to view the information about the objects.

18.5.21.2. INFORMATION_SCHEMA tables

Table	Description
INFORMATION_SCHEMA.CHARACTER_SETS	Provides the information about available character sets.
INFORMATION_SCHEMA.COLLATIONS	Provides the information about collations for character sets.
INFORMATION_SCHEMA.COLLATION_CHARACTER_SET_APPLICABILITY	Specifies the character set that is used for the collation.
INFORMATION_SCHEMA.COLUMNS	Provides the information about table columns.
INFORMATION_SCHEMA.COLUMN_PRIVILEGES	Provides the information about column permissions.
INFORMATION_SCHEMA.ENGINES	Provides the information about storage engines.
INFORMATION_SCHEMA.EVENTS	Provides the information about events.
INFORMATION_SCHEMA.FILES	Provides the information about tablespace data.
INFORMATION_SCHEMA.GLOBAL_STATUS	Provides the information about the status of the global server variables.
INFORMATION_SCHEMA.GLOBAL_VARIABLES	Provides the information about global server variables.
INFORMATION_SCHEMA.KEY_COLUMN_USAGE	Describes key columns that have constraints.
INFORMATION_SCHEMA.OPTIMIZER_TRACE	Provides the information that is produced by the optimizer tracing feature.
INFORMATION_SCHEMA.PARAMETERS	Provides the information about function and method parameters.
INFORMATION_SCHEMA.PARTITIONS	Provides the information about table partitions.
INFORMATION_SCHEMA.PLUGINS	Provides the information about plug-ins.
INFORMATION_SCHEMA.PROCESSLIST	Provides the information about running threads.
INFORMATION_SCHEMA.PROFILING	Provides the information about statement profiling.
INFORMATION_SCHEMA.REFERENTIAL_CONSTRAINTS	Provides the information about foreign key constraints.
INFORMATION_SCHEMA.ROUTINES	Provides the information about stored subprograms: stored procedures and stored functions.
INFORMATION_SCHEMA.SCHEMATA	Provides the information about databases.
INFORMATION_SCHEMA.SCHEMA_PRIVILEGES	Provides the information about database permissions.
INFORMATION_SCHEMA.SESSION_STATUS	Provides the information about the status of local variables.
INFORMATION_SCHEMA.SESSION_VARIABLES	Provides the information about local variables.
INFORMATION_SCHEMA.STATISTICS	Provides the information about table indexes.
INFORMATION_SCHEMA.TABLES	Provides the information about database tables.

Table	Description
INFORMATION_SCHEMA.TABLESPACES	Provides the information about tablespaces.
INFORMATION_SCHEMA.TABLE_CONSTRAINTS	Describes the tables that have constraints.
INFORMATION_SCHEMA.TABLE_PRIVILEGES	Provides the information about table permissions.
INFORMATION_SCHEMA.TRIGGERS	Provides the information about triggers.
INFORMATION_SCHEMA.USER_PRIVILEGES	Provides the information about user permissions.
INFORMATION_SCHEMA.USER_RECYCLEBIN	-
INFORMATION_SCHEMA.VIEWS	Provides the information about views that are stored in databases.

This topic does not provide details about tables and columns in the INFORMATION_SCHEMA database. These details are provided in other topics. For each column of the tables in the INFORMATION_SCHEMA database, the following three types of information are provided:

- **Standard name:** specifies the name of the column in an INFORMATION_SCHEMA table. This column name is the standard name that is used in SQL statements.
- **SHOW name:** specifies the equivalent field name in the latest SHOW statement.
- **Remarks:** provides additional information about the column.

18.5.21.3. INFORMATION_SCHEMA.SCHEMATA table

This table provides the information about databases.

Standard name	SHOW name	Remarks
CATALOG_NAME	-	def
SCHEMA_NAME	Database	The name of the database.
DEFAULT_CHARACTER_SET_NAME	-	The default character set.
DEFAULT_COLLATION_NAME	-	The default collation name.
SQL_PATH	-	NULL

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
  FROM INFORMATION_SCHEMA.SCHEMATA
 [WHERE SCHEMA_NAME LIKE 'wild']

SHOW DATABASES
 [LIKE 'wild']
```

18.5.21.4. INFORMATION_SCHEMA.TABLES table

This table provides the information about database tables.

Table information

Standard name	SHOW name	Remarks
TABLE_CATALOG	-	def
TABLE_SCHEMA	Table_...	The name of the schema or database where the table is stored.
TABLE_NAME	Table_...	The name of the table.
TABLE_TYPE		The type of the table. The BASE TABLE value indicates a table, the VIEW value indicates a view, and the TEMPORARY value indicates a temporary table.
ENGINE	Engine	The storage engine.
VERSION	Version	The version number.
ROW_FORMAT	Row_format	-
TABLE_ROWS	Rows	-
AVG_ROW_LENGTH	Avg_row_length	The average row size.
DATA_LENGTH	Data_length	The size of the data file. Unit: bytes.
MAX_DATA_LENGTH	Max_data_length	The maximum size of the data file. Unit: bytes.
INDEX_LENGTH	Index_length	The size of the index file. Unit: bytes.
DATA_FREE	Data_free	-
AUTO_INCREMENT	Auto_increment	Specifies whether the values are auto-incremented.
CREATE_TIME	Create_time	The time when the table was created.
UPDATE_TIME	Update_time	The time when the table was last updated.
CHECK_TIME	Check_time	The time when the table was last checked.
TABLE_COLLATION	Collation	The table collation.
CHECKSUM	Checksum	The checksum value.
CREATE_OPTIONS	Create_options	The options that are used in the CREATE TABLE statement.
TABLE_COMMENT	Comment	The description.

Notes:

- In the outputs of SHOW statements, the values of the TABLE_SCHEMA and TABLE_NAME columns are included in the values of a single field.
- The valid values in the TABLE_TYPE column include BASE TABLE and VIEW. The BASE TABLE value indicates a table and the VIEW value indicates a view. If you are using a temporary table, set TABLE_TYPE to TEMPORARY: TABLE_TYPE = TEMPORARY .
- If the table is stored in the INFORMATION_SCHEMA database, the value in the TABLE_ROWS column is NULL.

- The outputs of query statements do not include the information about the default character set of the table. The TABLE_COLLATION column is disabled because the collation name starts with the character set name.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
  [WHERE table_schema = 'db_name']
  [WHERE|AND table_name LIKE 'wild']

SHOW TABLES
[FROM db_name]
[LIKE 'wild']
```

18.5.21.5. INFORMATION_SCHEMA.COLUMNS table

This table provides the information about table columns.

Table information

Standard name	SHOW name	Remarks
TABLE_CATALOG	-	def
TABLE_SCHEMA	-	The name of the database.
TABLE_NAME	-	The name of the table.
COLUMN_NAME	Field	The name of the column.
ORDINAL_POSITION	-	The position of the column. For more information, see the "Notes" section in this topic.
COLUMN_DEFAULT	Default	The default value for the column.
IS_NULLABLE	Null	Specifies whether NULL values can be stored in the column.
DATA_TYPE	Type	The data type of the column.
CHARACTER_MAXIMUM_LENGTH	Type	The maximum length of each string. The length is measured in characters.
CHARACTER_OCTET_LENGTH	-	The maximum length of each string. The length is measured in bytes. For more information, see the "Notes" section in this topic.
NUMERIC_PRECISION	Type	The numeric precision.
NUMERIC_SCALE	Type	The range of the numeric values.
DATETIME_PRECISION	Type	The date and time granularity.
CHARACTER_SET_NAME	-	The name of the character set.
COLLATION_NAME	Collation	The collation name.
COLUMN_TYPE	Type	The data type of the column.

Standard name	SHOW name	Remarks
COLUMN_KEY	Key	The column key.
EXTRA	Extra	The additional information about the column.
PRIVILEGES	Privileges	The permissions.
COLUMN_COMMENT	Comment	The description of the column.

Notes:

- In the outputs of SHOW statements, the Type column lists the data types of different columns that are stored in the COLUMNS table.
- ORDINAL_POSITION is required in some scenarios. For example, you may need to execute the ORDER BY ORDINAL_POSITION statement to sort data based on the ordinal positions of columns. Unlike SHOW statements, SELECT statements returns data that is not automatically sorted.
- If single-byte character sets are used, the CHARACTER_OCTET_LENGTH value is the same as the CHARACTER_MAXIMUM_LENGTH value. If multi-byte character sets are used, the values are different.
- You can obtain the CHARACTER_SET_NAME column value based on the COLLATION_NAME column value. For example, if you execute a SHOW FULL COLUMNS FROM `tbl_name` statement and the latin1_swedish_ci value is displayed in the COLLATION_NAME column, the name of the character set is latin1. The portion that is located before the first underscore (_) specifies the name of the character set.

The following statements are equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_KEY, COLUMN_DEFAULT, EXTRA
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']

SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE wild]
```

18.5.21.6. INFORMATION_SCHEMA.STATISTICS table

This table provides the information about table indexes.

Table information

Standard name	SHOW name	Remarks
TABLE_CATALOG	-	def
TABLE_SCHEMA	-	The name of the database.
TABLE_NAME	Table	The name of the table.
NON_UNIQUE	Non_unique	-

Standard name	SHOW name	Remarks
INDEX_SCHEMA	-	The name of the database.
INDEX_NAME	Key_name	The name of the index.
SEQ_IN_INDEX	Seq_in_index	-
COLUMN_NAME	Column_name	The name of the column.
COLLATION	Collation	-
CARDINALITY	Cardinality	-
SUB_PART	Sub_part	-
PACKED	Packed	-
NULLABLE	Null	-
INDEX_TYPE	Index_type	-
COMMENT	Comment	-
INDEX_COMMENT	-	-
IS_VISIBLE	-	-

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
  WHERE table_name = 'tbl_name'
  [AND table_schema = 'db_name']
```

```
SHOW INDEX
  FROM tbl_name
  [FROM db_name]
```

18.5.21.7. INFORMATION_SCHEMA.USER_PRIVILEGES table

This table provides the information about user permissions.

Table information

Standard name	SHOW name	Remarks
GRANTEE	-	The name of the account to which the permission is granted. For example, the value can be user'@'host.
TABLE_CATALOG	-	def
PRIVILEGE_TYPE	-	The permission type.
IS_GRANTABLE	-	Specifies whether the user has the permission to execute the GRANT OPTION statement.

18.5.21.8. INFORMATION_SCHEMA.SCHEMA_PRIVILEGES table

This table provides the information about database permissions.

Table information

Standard name	SHOW name	Remarks
GRANTEE	-	The name of the account to which the permission is granted. For example, the value can be user'@'host.
TABLE_CATALOG	-	def
TABLE_SCHEMA	-	-
PRIVILEGE_TYPE	-	The permission type.
IS_GRANTABLE	-	Specifies whether the user has the permission to execute the GRANT OPTION statement. If the user has the permission, the value is YES. If the user does not have the permission, the value is NO.

18.5.21.9. INFORMATION_SCHEMA.TABLE_PRIVILEGES table

This table provides the information about table permissions.

Standard name	SHOW name	Remarks
GRANTEE	-	The name of the account to which the permission is granted. For example, the value can be user'@'host.
TABLE_CATALOG	-	def
TABLE_SCHEMA	-	The name of the database where the table is stored.
TABLE_NAME	-	The name of the table.
PRIVILEGE_TYPE	-	The permission type.
IS_GRANTABLE	-	Specifies whether the user has the permission to execute the GRANT OPTION statement. If the user has the permission, the value is YES. If the user does not have the permission, the value is NO.

The following statements are not equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
```

```
SHOW GRANTS ...
```

The `PRIVILEGE_TYPE` column stores only one of the following values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`, `ALTER`, `INDEX`, `DROP`, and `CREATE VIEW`.

18.5.21.10. INFORMATION_SCHEMA.CHARACTER_SETS table

This table provides the information about available character sets.

Table information

Standard name	SHOW name	Remarks
<code>CHARACTER_SET_NAME</code>	Charset	The name of the character set.
<code>DEFAULT_COLLATE_NAME</code>	Default collation	The default collation for the character set.
<code>DESCRIPTION</code>	Description	The description of the character set.
<code>MAXLEN</code>	Maxlen	The maximum length.

 **Note** The `DESCRIPTION` and `MAXLEN` columns are not standard columns. These columns are added to align with the following columns that are displayed in the output of the `SHOW CHARACTER SET` statement: `Description` and `Maxlen`.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
  [WHERE name LIKE 'wild']

SHOW CHARACTER SET
  [LIKE 'wild']
```

18.5.21.11. INFORMATION_SCHEMA.COLLATIONS table

This table provides the information about collations for character sets.

Table information

Standard name	SHOW name	Remarks
<code>COLLATION_NAME</code>	Collation	The collation name.
<code>CHARACTER_SET_NAME</code>	Charset	The name of the character set.
<code>ID</code>	Id	The collation ID.
<code>IS_DEFAULT</code>	Default	Specifies whether the collation is the default collation for the character set.
<code>IS_COMPILED</code>	Compiled	Specifies whether the character set is compiled.
<code>SORTLEN</code>	Sortlen	The number of bytes in the strings when the strings are sorted in the memory. The strings are expressed based on the character set.

Note The CHARACTER_SET_NAME, ID, IS_DEFAULT, IS_COMPILED, and SORTLEN columns are not standard columns. These columns are added to align with the following columns that are displayed in the output of the `SHOW COLLATION` statement: Charset, Id, Default, Compiled, and Sortlen.

The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
[WHERE collation_name LIKE 'wild']

SHOW COLLATION
[LIKE 'wild']
```

18.5.21.12.

INFORMATION_SCHEMA.COLLATION_CHARACTER_SET_APPLICABILITY table

This table specifies the character set that is used for the collation. This table consists of two columns. The two columns correspond to the first two columns that are displayed in the output of the `SHOW COLLATION` statement.

Table information

Standard name	SHOW name	Remarks
COLLATION_NAME	Collation	The collation name.
CHARACTER_SET_NAME	Charset	The name of the character set.

18.5.21.13. INFORMATION_SCHEMA.TABLE_CONSTRAINTS table

This table provides the information about tables that have constraints.

Table information

Standard name	SHOW name	Remarks
CONSTRAINT_CATALOG	-	def
CONSTRAINT_SCHEMA	-	The name of the schema or database to which the constraint belongs.
CONSTRAINT_NAME	-	The name of the constraint.
TABLE_SCHEMA	-	The name of the schema or database where the table is stored.
TABLE_NAME	-	The name of the table.
CONSTRAINT_TYPE	-	The type of the constraint.

Notes:

- The valid values in the `CONSTRAINT_TYPE` column include `UNIQUE`, `PRIMARY KEY`, and `FOREIGN KEY`.
- If the value of the `Non_unique` field is 0, the `UNIQUE` and `PRIMARY KEY` information is the same as the

Key_name column values in the output of the SHOW INDEX statement.

- The CONSTRAINT_TYPE column stores only one of the following values: UNIQUE, PRIMARY KEY, FOREIGN KEY, and CHECK. The data type of the CONSTRAINT_TYPE column is CHAR instead of ENUM.

The CHECK value is unavailable before the CHECK constraint is supported by ApsaraDB for OceanBase.

18.5.21.14. INFORMATION_SCHEMA.REFERENTIAL_CONSTRAINTS

table

This table provides the information about foreign key constraint.

Standard name	SHOW name	Remarks
CONSTRAINT_CATALOG	-	def
CONSTRAINT_SCHEMA	-	The name of the schema or database to which the foreign key constraint belongs.
CONSTRAINT_NAME	-	The name of the foreign key constraint.
UNIQUE_CONSTRAINT_CATALOG	-	def
UNIQUE_CONSTRAINT_SCHEMA	-	The name of the database. The database contains the unique constraint or the primary key that the foreign key constraint references.
UNIQUE_CONSTRAINT_NAME	-	The name of the unique constraint or the primary key that the foreign key constraint references.
MATCH_OPTION	-	The match rule of the foreign key constraint. The value in the column can be FULL, PARTIAL, or NONE.
UPDATE_RULE	-	The update rule of the foreign key constraint. The value in the column can be CASCADE, SET NULL, SET DEFAULT, RESTRICT, or NO ACTION.
DELETE_RULE	-	The deletion rule of the foreign key constraint. The value in the column can be CASCADE, SET NULL, SET DEFAULT, RESTRICT, or NO ACTION.
TABLE_NAME	-	The name of the table.
REFERENCED_TABLE_NAME	-	The name of the table that is referenced by the foreign key constraint.

 **Note** The value in the TABLE_NAME column is the same as that in the TABLE_NAME column of the INFORMATION_SCHEMA.TABLE_CONSTRAINTS table. For more information, see [INFORMATION_SCHEMA.TABLE_CONSTRAINTS table](#).

18.5.21.15. INFORMATION_SCHEMA.KEY_COLUMN_USAGE table

This table describes the key columns that have constraints.

Table information

Standard name	SHOW name	Remarks
CONSTRAINT_CATALOG	-	def
CONSTRAINT_SCHEMA	-	The name of the database to which the constraint belongs.
CONSTRAINT_NAME	-	The name of the constraint.
TABLE_CATALOG	-	The name of the catalog to which the table belongs. The table contains the field on which the constraint is applied.
TABLE_SCHEMA	-	The name of the schema that stores the table. The table contains the field on which the constraint is applied.
TABLE_NAME	-	The name of the table that includes the constraint. The table contains the field on which the constraint is applied.
COLUMN_NAME	-	The name of the column on which the constraint is implemented.
ORDINAL_POSITION	-	The column position in the constraint. The column position is represented by the sequence number.
POSITION_IN_UNIQUE_CONSTRAINT	-	The ordinal position in the key of the table that is referenced.
REFERENCED_TABLE_SCHEMA	-	The name of the database that is referenced by the constraint.
REFERENCED_TABLE_NAME	-	The name of the table that is referenced by the constraint.
REFERENCED_COLUMN_NAME	-	The name of the column that is referenced by the constraint.

Notes:

- If the constraint is a foreign key, the value in the `COLUMN_NAME` column is the name of the foreign key. The value is not the name of the column that the foreign key references.
- The value in the `ORDINAL_POSITION` column specifies the column position in the constraint instead of the column position in the table. Column positions are represented by sequence numbers that start from 1.
- For unique and primary key constraints, the value in the `POSITION_IN_UNIQUE_CONSTRAINT` column is `NULL`. For foreign key constraints, the value in the `POSITION_IN_UNIQUE_CONSTRAINT` column is the ordinal position in the key of the table that is referenced.

For example, execute the following statements to create the t1 and t3 tables:

```

CREATE TABLE t1
(
s1 INT,
s2 INT,
s3 INT,
PRIMARY KEY(s3)
);

CREATE TABLE t3
(
s1 INT,
s2 INT,
s3 INT,
KEY(s1),
CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
);

```

The KEY_COLUMN_USAGE table stores two rows for the t1 and t3 tables:

- One row contains CONSTRAINT_NAME='PRIMARY ', TABLE_NAME='t1', COLUMN_NAME='s3 ', ORDINAL_POSITION=1, POSITION_IN_UNIQUE_CONSTRAINT=NULL.
- The other row contains CONSTRAINT_NAME='CO ', TABLE_NAME='t3', COLUMN_NAME='s2 ', ORDINAL_POSITION=1, POSITION_IN_UNIQUE_CONSTRAINT=1 .

18.5.21.16. INFORMATION_SCHEMA.ROUTINES table

This table provides the information about stored subprograms: stored procedures and stored functions.

Table information

Standard name	Description
SPECIFIC_NAME	The name of the function.
ROUTINE_CATALOG	def
ROUTINE_SCHEMA	The name of the schema or database to which the function belongs.
ROUTINE_NAME	The name of the function.
ROUTINE_TYPE	The type of the stored subprogram. Valid values: PROCEDURE and FUNCTION.
DATA_TYPE	The data type of the return value.
CHARACTER_MAXIMUM_LENGTH	The maximum length of the character set.
CHARACTER_OCTET_LENGTH	The maximum length of the value. If single-byte character sets are used, the CHARACTER_OCTET_LENGTH value is the same as the CHARACTER_MAXIMUM_LENGTH value. If multi-byte character sets are used, the values are different.

Standard name	Description
NUMERIC_PRECISION	The numerical precision.
NUMERIC_SCALE	The range of numeric values.
DATETIME_PRECISION	The date and time granularity.
CHARACTER_SET_NAME	The name of the character set.
COLLATION_NAME	The collation name for the character set.
DTD_IDENTIFIER	The identifier of the data type descriptor. The data type is returned by the function. The identifier is unique among the data type descriptors that are assigned to the function.
ROUTINE_BODY	The query language that is used to define the function. The value is always SQL.
ROUTINE_DEFINITION	The source code text of the function. If the function is not owned by the current user, the value is NULL.
EXTERNAL_NAME	NULL
EXTERNAL_LANGUAGE	NULL
PARAMETER_STYLE	SQL
IS_DETERMINISTIC	Specifies whether the function is declared as immutable. If the function is declared as immutable, the value is YES. In this scenario, the function is a deterministic function in SQL. If the function is not declared as immutable, the value is NO.
SQL_DATA_ACCESS	The setting of data access. The value is always MODIFIES. This means that the function may modify SQL data.
SQL_PATH	NULL
SECURITY_TYPE	If the function runs based on the permissions of the current user, the value is INVOKER. If the function runs based on the permissions of the user who defines the function, the value is DEFINER.
CREATED	The date and time when the function was created. The value is a TIMESTAMP value.
LAST_ALTERED	The date and time when the stored subprogram was last modified. The value is a TIMESTAMP value.
SQL_MODE	-
ROUTINE_COMMENT	The description.
DEFINER	The user who defines the function.
CHARACTER_SET_CLIENT	The session value of the character_set_client system variable when the function was created.
COLLATION_CONNECTION	The session value of the collation_connection system variable when the stored subprogram was created.

Standard name	Description
DATABASE_COLLATION	The collation of the database with which the stored subprogram is associated.

18.5.21.17. INFORMATION_SCHEMA.VIEWS table

This table provides the information about the views that are stored in databases.

Table information

Standard name	SHOW name	Remarks
TABLE_CATALOG	-	def
TABLE_SCHEMA	-	The name of the schema or database to which the view belongs.
TABLE_NAME	-	The name of the view.
VIEW_DEFINITION	-	The SELECT statement that defines the view. If the current user is not the owner of the view, the value is NULL.
CHECK_OPTION	-	NONE
IS_UPDATABLE	-	Specifies whether the view can be updated.
DEFINER	-	The user who created the view.
SECURITY_TYPE	-	Valid values: DEFINER and INVOKER.
CHARACTER_SET_CLIENT	-	The session value of the character_set_client system variable when the view was created.
COLLATION_CONNECTION	-	The session value of the collation_connection system variable when the view was created.

Notes:

- If you do not have the permission to execute the `SHOW VIEW` statement, you cannot access the `INFORMATION_SCHEMA.VIEWS` table. This permission is newly added.
- The `VIEW_DEFINITION` column stores most of the information about the fields that you use to create views. You can execute the `SHOW CREATE VIEW` statement to view the statement that creates the specified view. To obtain the `SELECT` statement that creates the specified view, skip the words that are located before the `SELECT` keyword and skip the `WITH CHECK OPTION` words in the SQL statement.

For example, you can execute the following SQL statement to create a view:

```
CREATE VIEW v AS
SELECT s2,s1 FROM t
WHERE s1 > 5
ORDER BY s1
WITH CHECK OPTION;
```

In this example, the view is created based on the following SELECT statement:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

Notes:

- The value in the CHECK_OPTION column is always NONE.
- If the view can be updated, the value in the IS_UPDATABLE column is YES. If the view cannot be updated, the value in the column is NO.
- The DEFINER column specifies the user who defined the view. The valid values in the SECURITY_TYPE column are DEFINER or INVOKER.

18.5.21.18. INFORMATION_SCHEMA.TRIGGERS table

This table provides the information about triggers.

You must have the SUPER permission to view the INFORMATION_SCHEMA.TRIGGERS table.

Table information

Standard name	SHOW name	Remarks
TRIGGER_CATALOG	-	def
TRIGGER_SCHEMA	-	The name of the database to which the trigger belongs.
TRIGGER_NAME	Trigger	The name of the trigger.
EVENT_MANIPULATION	Event	The event that activates the trigger. The value in the column is INSERT, UPDATE, or DELETE.
EVENT_OBJECT_CATALOG	-	def
EVENT_OBJECT_SCHEMA	-	The name of the database. The database stores the table with which the trigger is associated.
EVENT_OBJECT_TABLE	Table	The name of the table with which the trigger is associated.
ACTION_ORDER	-	-
ACTION_CONDITION	-	NULL
ACTION_STATEMENT	Statement	The statement that is executed if the trigger is activated. The value in the column is always EXECUTE PROCEDURE. <i>function(...)</i> .
ACTION_ORIENTATION	-	The value is always ROW. The value indicates that the trigger applies to each processed row.
ACTION_TIMING	Timing	Specifies whether the trigger is activated before or after the event. The valid values are BEFORE and AFTER.
ACTION_REFERENCE_OLD_TABLE	-	NULL
ACTION_REFERENCE_NEW_TABLE	-	NULL

Standard name	SHOW name	Remarks
ACTION_REFERENCE_OLD_ROW	-	OLD
ACTION_REFERENCE_NEW_ROW	-	NEW
CREATED	Created	NULL
SQL_MODE	sql_mode	
DEFINER	Definer	The user who created the trigger.
CHARACTER_SET_CLIENT	character_set_client	The session value of the character_set_client system variable when the trigger was created.
COLLATION_CONNECTION	collation_connection	The session value of the collation_connection system variable when the trigger was created.
DATABASE_COLLATION	Database Collation	The collation of the database with which the trigger is associated.

Notes:

- The TRIGGER_NAME column specifies the name of the trigger. The TRIGGER_SCHEMA column specifies the name of the database where the trigger occurs.
- The valid values in the EVENT_MANIPULATION column are INSERT, DELETE, and UPDATE.
- Each trigger is associated with only one table. The EVENT_OBJECT_SCHEMA column specifies the name of the database. The EVENT_OBJECT_TABLE column specifies the name of the table. The database stores the table with which the trigger is associated.
- The ACTION_ORDER column specifies the ordinal position of the trigger action in the list of similar triggers that are applied on the same table. The value in the ACTION_ORDER column is always 0. The system does not allow two or more triggers that have the same EVENT_MANIPULATION and ACTION_TIMING values to take effect on the same table.
- The ACTION_STATEMENT column specifies the statement that is executed if the trigger is activated. The text in this column is the same as the text in the Statement column that is displayed in the output of the `SHOW TRIGGERS` statement.

 **Note** SHOW The text in the Statement column in the output of SHOW TRIGGERS statement uses UTF-8 encoding.

- The value in the ACTION_ORIENTATION column is always ROW.
- The valid values in the ACTION_TIMING column are BEFORE and AFTER.
- The ACTION_REFERENCE_OLD_ROW column specifies the previous column identifier, and the ACTION_REFERENCE_NEW_ROW column specifies the new column identifier. Therefore, the value in the ACTION_REFERENCE_OLD_ROW column is always OLD, and the value in the ACTION_REFERENCE_NEW_ROW column is always NEW.
- The SQL_MODE column specifies the valid server SQL mode that was used when the trigger was created.

 **Note** The trigger remains valid after the trigger is activated, regardless of the current server SQL mode.

The value range for the SQL_MODE column is the same as that of the sql_mode system variable.

- The values in the following columns are always NULL: TRIGGER_CATALOG, EVENT_OBJECT_CATALOG, ACTION_CONDITION, ACTION_REFERENCE_OLD_TABLE, and CREATED.

18.5.21.19. INFORMATION_SCHEMA.TABLESPACE table

This table provides the information about tablespaces. However, ApsaraDB for OceanBase does not use tablespaces. Therefore, the INFORMATION_SCHEMA.TABLESPACE table is not required in ApsaraDB for OceanBase. The INFORMATION_SCHEMA.TABLESPACE table in ApsaraDB for OceanBase is an empty table.

Table information

Standard name	SHOW name	Remarks
TABLE_CATALOG	-	def
TABLESPACE_NAME	-	-
ENGINE	-	-
TABLESPACE_TYPE	-	-
LOGFILE_GROUP_NAME	-	-
EXTENT_SIZE	-	-
AUTOEXTEND_SIZE	-	-
MAXIMUM_SIZE	-	-
NODEGROUP_ID	-	-
TABLESPACE_COMMENT	-	-

18.5.21.20. INFORMATION_SCHEMA.PARTITIONS table

Table information

Standard name	SHOW name	Remarks
TABLE_CATALOG	-	def
TABLE_SCHEMA	-	The name of the database.
TABLE_NAME	-	The name of the table.
PARTITION_NAME	-	The name of the partition.
SUBPARTITION_NAME	-	The name of the subpartition.
PARTITION_ORDINAL_POSITION	-	The original ordinal position of the partition.
SUBPARTITION_ORDINAL_POSITION	-	The original ordinal position of the subpartition.
PARTITION_METHOD	-	The partitioning type. For example, hash partitioning or list partitioning is used. The default partitioning type is hash partitioning.

Standard name	SHOW name	Remarks
SUBPARTITION_METHOD	-	The subpartitioning type. The default subpartitioning type is hash partitioning.
PARTITION_EXPRESSION	-	The partition expression.
SUBPARTITION_EXPRESSION	-	The subpartition expression.
PARTITION_DESCRIPTION	-	The partition description.
TABLE_ROWS	-	The number of table rows in the partition.
AVG_ROW_LENGTH	-	The average length of the data in the table rows.
DATA_LENGTH	-	The data length. Unit: bytes.
MAX_DATA_LENGTH	-	The maximum length of the data in the table rows that are stored in the partition or subpartition. Unit: bytes.
INDEX_LENGTH	-	The size of the index file. Unit: bytes.
DATA_FREE	-	
CREATE_TIME	-	The time when the partition or subpartition was created.
UPDATE_TIME	-	The time when the partition or subpartition was last modified.
CHECK_TIME	-	The time when the table that includes the partition or subpartition was last checked.
CHECKSUM	-	The checksum value.
PARTITION_COMMENT	-	The additional information about the partition.
NODEGROUP	-	-
TABLESPACE_NAME	-	The name of the tablespace.

Notes:

- The PARTITIONS table is not a standard SQL table in the INFORMATION_SCHEMA database.
- One row is stored in the PARTITIONS table for each non-partitioned table. The values in the following columns are NULL: PARTITION_NAME, SUBPARTITION_NAME, PARTITION_ORDINAL_POSITION, SUBPARTITION_ORDINAL_POSITION, PARTITION_METHOD, SUBPARTITION_METHOD, PARTITION_EXPRESSION, SUBPARTITION_EXPRESSION, and PARTITION_DESCRIPTION. The columns store no data.

18.5.21.21. INFORMATION_SCHEMA.EVENTS table

This table provides the information about events.

Standard name	SHOW name	Remarks
EVENT_CATALOG	-	def

Standard name	SHOW name	Remarks
EVENT_SCHEMA	Db	The name of the database to which the event belongs.
EVENT_NAME	Name	The name of the event.
DEFINER	Definer	user_name!'@'host_name'
TIME_ZONE	Time zone	The time zone.
EVENT_BODY	-	The query language.
EVENT_DEFINITION	-	The statement that is executed if the event occurs.
EVENT_TYPE	Type	The repetition type of the event. Events are divided into one-time events and recurring events.
EXECUTE_AT	Execute at	The time when the event occurred.
INTERVAL_VALUE	Interval value	The time interval at which the event recurs.
INTERVAL_FIELD	Interval field	-
SQL_MODE	-	-
STARTS	Starts	The start date and time of a recurring event.
ENDS	Ends	The end date and time of a recurring event.
STATUS	Status	The event status. Valid values: ENABLED, DISABLED, and SLAVESIDE_DISABLED.
ON_COMPLETION	-	Valid values: PRESERVE and NOT PRESERVE.
CREATED	-	The date and time when the event was created. The value is a TIMESTAMP value.
LAST_ALTERED	-	The date and time when the event was last modified.
LAST_EXECUTED	-	The date and time when the event was last run.
EVENT_COMMENT	-	The description about the event.
ORIGINATOR	Originator	The ID of the server on which the event was created.
CHARACTER_SET_CLIENT	character_set_client	The session value of the character_set_client system variable when the event was created.

Standard name	SHOW name	Remarks
COLLATION_CONNECTION	collation_connection	The session value of the collation_connection system variable when the event was created.
DATABASE_COLLATION	Database Collation	The collation of the database with which the event is associated.

18.5.21.22. INFORMATION_SCHEMA.FILES table

This table provides the information about tablespace data.

Standard name	SHOW name	Remarks
FILE_ID	-	-
FILE_NAME	-	-
FILE_TYPE	-	-
TABLESPACE_NAME	-	-
TABLE_CATALOG	-	-
TABLE_SCHEMA	-	-
TABLE_NAME	-	-

MAXIMUM_SIZE	-	-
AUTOEXTEND_SIZE	-	-
CREATION_TIME	-	-
LAST_UPDATE_TIME	-	-
LAST_ACCESS_TIME	-	-
RECOVER_TIME	-	-

Standard name	SHOW name	Remarks
TRANSACTION_COUNTER	-	-
VERSION	-	-
ROW_FORMAT	-	-
TABLE_ROWS	-	-
AVG_ROW_LENGTH	-	-
DATA_LENGTH	-	-
MAX_DATA_LENGTH	-	-
INDEX_LENGTH	-	-
DATA_FREE	-	-
CREATE_TIME	-	-
UPDATE_TIME	-	-
CHECK_TIME	-	-
CHECKSUM	-	-
STATUS	-	-
EXTRA	-	-

Notes:

- The values in the FILE_ID column are auto-incremented.
- The FILE_NAME column specifies the name of the data file that is created by executing the `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.
- The FILE_TYPE column specifies the type of the tablespace file.
- The TABLESPACE_NAME column specifies the name of the tablespace.
- The value in the TABLESPACE_CATALOG column is always NULL.
- The TABLE_NAME column specifies the name of the table.
- The value in the EXTENT_SIZE column is always 0.
- You cannot execute SHOW statements to view the data that is stored in the INFORMATION_SCHEMA.FILES table.

18.5.21.23. INFORMATION_SCHEMA.GLOBAL_STATUS table

This table provides the information about the status of global variables. To view the global variables, execute the `SHOW GLOBAL STATUS` statement.

Standard name	SHOW name	Remarks
VARIABLE_NAME	Variable_name	The name of the variable.
VARIABLE_VALUE	Value	The value of the variable.

The data type of the VARIABLE_VALUE column is VARCHAR(1024).

18.5.21.24. INFORMATION_SCHEMA.GLOBAL_VARIABLES table

This table provides the information about global variables. To view the global variables, execute the `SHOW GLOBAL VARIABLES` statement.

Standard name	SHOW name	Remarks
VARIABLE_NAME	Variable_name	The name of the variable.
VARIABLE_VALUE	Value	The value of the variable.

The data type of the VARIABLE_VALUE column is VARCHAR(1024).

18.5.21.25. INFORMATION_SCHEMA.PROCESSLIST table

This table provides the information about running threads.

Standard name	SHOW name	Remarks
ID	Id	The ID of the thread.
USER	User	The user.
HOST	Host	The name of the host.
DB	db	The name of the database.
COMMAND	Command	The command.
TIME	Time	The time.
STATE	State	The current status of the thread.
INFO	Info	The statement that is being executed on the thread.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
```

```
SHOW FULL PROCESSLIST
```

18.5.21.26. INFORMATION_SCHEMA.SESSION_STATUS table

This table provides the information about local variables. To view the local variables, execute the `SHOW SESSION STATUS` statement.

Standard name	SHOW name	Remarks
VARIABLE_NAME	Variable_name	The name of the variable.
VARIABLE_VALUE	Value	The value of the variable.

The data type of the VARIABLE_VALUE column is VARCHAR(1024).

18.5.21.27. INFORMATION_SCHEMA.SESSION_VARIABLES table

This table provides the information about local variables. To view the local variables, execute the `SHOW SESSION VARIABLES` statement.

Standard name	SHOW name	Remarks
VARIABLE_NAME	Variable_name	The name of the variable.
VARIABLE_VALUE	Value	The value of the variable.

The data type of the VARIABLE_VALUE column is VARCHAR(1024).

18.5.21.28. INFORMATION_SCHEMA.PROFILING table

This table provides the information about statement profiling. The profiling information in this table is the same as that in the output of the SHOW PROFILES or SHOW PROFILE statement.

Standard name	SHOW name	Remarks
QUERY_ID	Query_ID	-
SEQ	-	-
STATE	Status	-
DURATION	Duration	-
CPU_USER	CPU_user	-
CPU_SYSTEM	CPU_system	-
CONTEXT_VOLUNTARY	Context_voluntary	-
CONTEXT_INVOLUNTARY	Context_involuntary	-
BLOCK_OPS_IN	Block_ops_in	-
BLOCK_OPS_OUT	Block_ops_out	-
MESSAGES_SENT	Messages_sent	-
MESSAGES_RECEIVED	Messages_received	-
PAGE_FAULTS_MAJOR	Page_faults_major	-
PAGE_FAULTS_MINOR	Page_faults_minor	-
SWAPS	Swaps	-
SOURCE_FUNCTION	Source_function	-
SOURCE_FILE	Source_file	-
SOURCE_LINE	Source_line	-

18.5.21.29. INFORMATION_SCHEMA.PARAMETERS table

This table provides the information about the parameters for functions and methods.

Standard name	SHOW name	Remarks
SPECIFIC_CATALOG	-	def
SPECIFIC_SCHEMA	db	The name of the database that stores the function.
SPECIFIC_NAME	name	The name of the function.
ORDINAL_POSITION	-	The ordinal position of the parameter in the parameter list of the function. For example, the value can be 1, 2, or 3. The value 0 indicates the ordinal position of the row that describes the return value of the function.
PARAMETER_MODE	-	The type of the parameter. Valid values: <ul style="list-style-type: none"> IN. OUT. INOUT. If the value of the parameter is returned by a function, the PARAMETER_MODE value is NULL.
PARAMETER_NAME	-	The name of the parameter. NULL is returned for a response parameter.
DATA_TYPE	-	The data type of the parameter.
CHARACTER_MAXIMUM_LENGTH	-	The maximum length of the parameter value. The length is measured in characters.
CHARACTER_OCTET_LENGTH	-	The maximum length of the value. If single-byte character sets are used, the CHARACTER_OCTET_LENGTH value is the same as the CHARACTER_MAXIMUM_LENGTH value. If multi-byte character sets are used, the values are different.
NUMERIC_PRECISION	-	The numeric precision.
NUMERIC_SCALE	-	The range of numeric values.
DATETIME_PRECISION	-	The time granularity.
CHARACTER_SET_NAME	-	The name of the character set.
COLLATION_NAME	-	The collation name.
DTD_IDENTIFIER	-	The identifier of the data type descriptor for the parameter.
ROUTINE_TYPE	type	{PROCEDURE FUNCTION}

18.5.21.30. INFORMATION_SCHEMA.OPTIMIZER_TRACE table

Standard name	SHOW name	Remarks
QUERY	-	The query statement.
TRACE	-	The trace record.
MISSING_BYTES_BEYOND_MAX_MEM_SIZE	-	Reserved.
MISSING_PRIVILEGES	-	Reserved.

18.5.21.31. INFORMATION_SCHEMA.ENGINES table

Standard name	SHOW name	Remarks

18.5.22. MySQL dictionary tables

To ensure compatibility with MySQL, ApsaraDB for OceanBase provides a MySQL database for each tenant. You can execute the `SHOW DATABASES` statement to view the MySQL database.

The MySQL database stores a set of dictionary tables that have the same schema as MySQL tables. [MySQL dictionary tables](#) describes these dictionary tables.

MySQL dictionary tables

Dictionary table	Description
db	Provides the information about databases and permissions.
user	Provides the information about users and permissions.
time_zone	Provides the information about time zones.
time_zone_name	Provides the information about time zones.
time_zone_name	
time_zone_transition_type	Provides the information about time zones.

18.5.23. Error codes

18.5.23.1. ApsaraDB for OceanBase error codes

18.5.24. Logs

Log levels

The following log levels in ApsaraDB for OceanBase are listed based on severity in descending order: ERROR, USER_ERROR, WARN, INFO, TRACE, and DEBUG.

[Log levels and descriptions](#) describes each of the log levels.

Log levels and descriptions

Log level	Description
ERROR	The unexpected errors that must be manually handled.
USER_ERROR	The errors that are caused by invalid input data.
WARN	The expected errors that can be resolved by applications.

Log level	Description
INFO	The messages that describe the changes of the system status.
TRACE	The fine-grained debugging messages that allow you to trace the details of each request. For example, the execution of an SQL statement is divided into different stages and a trace log entry is generated for each stage.
DEBUG	The detailed debugging messages.

Log print settings

Logs are displayed by program module. Program modules consist of parent modules and child modules.

Examples:

- `SQL_OPT_LOG` records the information about the `SQL.OPT` child module. The `SQL_OPT_LOG` log entries are generated based on the log level settings of the `SQL.OPT` child module.
- `SQL_LOG` records the information about the SQL module. The `SQL_LOG` log entries are generated based on the log level settings of the SQL module.
- `OB_LOG` records the information about all the modules. The `OB_LOG` log entries are generated based on global settings of log levels.

Program logs divided into statement, session, and system logs.

Program logs are generated based on priorities in the following descending order: statement logs, session logs, and system logs.

Use the following methods to specify log print settings:

- System logs

- Method 1: Execute the `ALTER SYSTEM SET OB_LOG_LEVEL` statement

Execute the `ALTER SYSTEM SET OB_LOG_LEVEL` statement to change the log level of system logs.

Example:

```
alter system set ob_log_level='sql. *:debug, common. *:error';
```

`alter SYSTEM SET` allows you to specify the server or zone. For more information, see the `ALTER SYSTEM SET` syntax.

- Method 2: Run the `kill -41` and `kill -42` commands

You can run the `kill -41` command to increase the log level. For example, if the previous log level is `INFO`, you can run the `kill -41` command to change the log level to `TRACE`.

`kill` You can run the `kill -42` command to decrease the log level. For example, if the previous log level is `INFO`, you can run the `kill -42` command to change the log level to `WARN`.

`kill` You can run the `kill -41` command to increase the log level to the highest level: `DEBUG`. You can run the `kill -42` command to decrease the log level to the lowest level: `ERROR`.

We recommend that you use the first method. If the server updates the configuration file, the `ob_log_level` configurations in the file are imported. In this scenario, the `kill` commands fail to be run.

- Session logs

Run the `set @@ob_log_level='par_mod.sub_mod:level, par_mod.sub_mod:level'` command.

Example:

```
set @@ob_log_level='sql.*:debug, common.*:info';
```

- Statement logs

Use hints to set the log levels of statement logs.

Example:

```
select /*+log_level('debug')*/ * from t;
```

```
select /*+log_level('sql.*:debug, common.*:info')*/ * from t;
```

To view the log details in an easy way when you debug OBServers, you can execute the `ALTER SYSTEM SET ob_log_level='error'` statement to set the log level to `error`. You can run the `set @@ob_log_level='debug'` command to specify the log level of the session log as `debug`. If you execute a statement to retrieve data from multiple OBServers, the global settings of log levels apply to each of the OBServers.

19.Data Transmission Service (DTS)

19.1. What is DTS?

Data Transmission Service (DTS) is a data service that is provided by Alibaba Cloud. DTS supports data transmission between various types of data sources, such as relational databases and big data systems.

Features

DTS has the following advantages over traditional data migration and synchronization tools: high compatibility, high performance, security, reliability, and ease of use. DTS allows you to simplify data transmission and focus on business development.

Feature	Description
Data migration	You can use DTS to migrate data between homogeneous and heterogeneous data sources. This feature applies to the following scenarios: data migration to Alibaba Cloud, data migration between instances within Alibaba Cloud, and database splitting and scale-out.
Data synchronization	You can use DTS to synchronize data between data sources. This feature applies to the following scenarios: disaster recovery, data backup, load balancing, cloud BI systems, and real-time data warehousing.
Change tracking	You can use DTS to track data changes from user-created MySQL databases, ApsaraDB RDS for MySQL instances, Cloud Native Distributed Database PolarDB-X instances (formerly known as DRDS), and user-created Oracle databases in real time. This feature applies to the following scenarios: cache updates, business decoupling, asynchronous data processing, synchronization of heterogeneous data, and synchronization of extract, transform, and load (ETL) operations.

19.2. Log on to the DTS console

This topic describes how to log on to the Data Transmission Service (DTS) console. Google Chrome is used in this example.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
2. Enter your username and password.

Obtain the username and password used to log on to the console from the operations administrator.

Note When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:

- Uppercase or lowercase letters.
- Digits.
- Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.

4. In the top navigation bar, choose **Products > Data Transmission Service**.
5. On the **DTS** page, select an **organization** and **region**, and then click **DTS**.

 **Note** If the top navigation bar is enabled for the DTS console, you can select the organization and resource set in the top navigation bar after you log on to the DTS console.

19.3. Data migration

19.3.1. Database and migration types

You can use Data Transmission Service (DTS) to migrate data between homogeneous and heterogeneous data sources. Typical scenarios include data migration to Alibaba Cloud, data migration between instances within Alibaba Cloud, and database splitting and scale-out. This topic describes the database types, database versions, and migration types that are supported by data migration.

Source database	Destination database	Migration type
<ul style="list-style-type: none"> • User-created MySQL database Versions 5.1, 5.5, 5.6, and 5.7 • RDS MySQL All versions 	User-created MySQL database Versions 5.1, 5.5, 5.6, and 5.7	<ul style="list-style-type: none"> • Schema migration • Full data migration • Incremental data migration
	RDS MySQL Versions 5.6 and 5.7	<ul style="list-style-type: none"> • Schema migration • Full data migration • Incremental data migration
	Cloud Native Distributed Database PolarDB-X (formerly known as DRDS) All versions	<ul style="list-style-type: none"> • Full data migration • Incremental data migration
	User-created Oracle database (RAC or non-RAC architecture) Versions 9i, 10g, 11g, and 12c	<ul style="list-style-type: none"> • Full data migration • Incremental data migration

Source database	Destination database	Migration type

	AnalyticDB for MySQL Versions 2.0 and 3.0	<ul style="list-style-type: none"> • Schema migration • Full data migration • Incremental data migration
<ul style="list-style-type: none"> • User-created PostgreSQL database Versions 9.4, 9.5, 9.6, and 10.x • RDS PostgreSQL Versions 9.4 and 10 	<ul style="list-style-type: none"> • User-created PostgreSQL database Versions 9.4, 9.5, 9.6, and 10.x • RDS PostgreSQL Versions 9.4 and 10 	<ul style="list-style-type: none"> • Schema migration • Full data migration • Incremental data migration

19.3.2. Create a data migration instance

Before you configure a task to migrate data, you must create a data migration instance. This topic describes how to create a data migration instance in the Data Transmission Service (DTS) console.

Procedure

1. [Log on to the DTS console.](#)
2. In the left-side navigation pane, click **Data Migration**.
3. In the upper-right corner, click **Create Migration Task**.
4. In the Create DTS Instances dialog box, select a region, and enter the number of data migration instances that you want to create.

 **Note** In the Create DTS Instances dialog box, you can view the total number of instances, the number of existing instances, and the number of instances that can be created.

5. Click **Create**.

19.3.3. Configure data migration tasks

19.3.3.1. Migrate data between ApsaraDB RDS for PostgreSQL instances

instances

This topic describes how to migrate data between ApsaraDB RDS for PostgreSQL instances by using Data Transmission Service (DTS). DTS supports schema migration, full data migration, and incremental data migration. You can select all of the supported migration types to ensure service continuity.

Prerequisites

The network type of both the source and destination ApsaraDB RDS for PostgreSQL instances is VPC.

Precautions

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the load of the database server. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise,

the destination database may contain duplicate data records.

- To ensure that the delay time of incremental data migration is accurate, DTS adds a heartbeat table named *dts_postgres_heartbeat* to the source database.
- During incremental data migration, DTS creates a replication slot for the source database. The replication slot is prefixed with *dts_sync_*. DTS automatically clears historical replication slots every 90 minutes to prevent them from occupying disk space.

 **Note** If a migration task is released or fails, DTS automatically clears the replication slot. After a switchover between primary and secondary ApsaraDB RDS for PostgreSQL databases, you must log on to the secondary database to clear the replication slot.

- If a data migration task fails, DTS automatically resumes the task. Before you switch your workloads to the destination instance, stop or release the data migration task. Otherwise, the data in the source instance will overwrite the data in the destination instance after the task is resumed.

Limits

- A single data migration task can migrate data from only one database. To migrate data from multiple databases, you must create a data migration task for each database.
- During incremental data migration, DTS synchronizes only data manipulation language (DML) operations. DML operations include INSERT, DELETE, and UPDATE.

Data migration process

The following table describes how DTS migrates the schemas and data of the source PostgreSQL database. The process avoids data migration failures that are caused by dependencies between objects.

Data migration process	Description
1. Schema migration	DTS migrates the schemas of tables, views, sequences, functions, user-defined types, rules, domains, operations, and aggregates to the destination database.  Note DTS does not migrate functions that are written in the C programming language.
2. Full data migration	DTS migrates historical data of the required objects to the destination database.
3. Schema migration	DTS migrates the schemas of triggers and foreign keys to the destination database.
4. Incremental data migration	DTS migrates incremental data of the required objects to the destination database.  Note Incremental data migration does not support the BIT data type.

Before you begin

If you need to perform incremental data migration, you must change the value of the *wal_level* parameter to *logical* for the source RDS instance.

Warning After you change the value of the `wal_level` parameter, you must restart the instance to apply the change. We recommend that you evaluate the impact on your business and change the parameter setting during off-peak hours.

Procedure

1. Create a data migration instance.
2. In the migration task list, find the migration task that you created, and click **Configure Migration Task** in the **Actions** column.
3. Configure the source and destination databases.

1. Configure Source and Destination
2. Configure Migration Types and
3. Advanced Settings
4. Precheck

* Task Name:

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select RDS instance.
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	RDS Instance ID	Select the ID of the source RDS instance.
	Database Name	Enter the name of the source database.

Section	Parameter	Description
	Database Account	Enter the database account of the source RDS instance. The account must have the read and write permissions on the source database.
	Database Password	Enter the password of the source database account.
Destination Database	Instance Type	Select RDS instance.
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	RDS Instance ID	Select the ID of the destination RDS instance.
	Database Name	Enter the name of the destination database. <div style="border: 1px solid #add8e6; padding: 5px; background-color: #e6f2ff;"> ? Note The name of the destination database can be different from the name of the source database. </div>
	Database Account	Enter the database account of the destination RDS instance. The account must have the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.

5. Select the migration types and the objects to be migrated.

1.Configure Source and Destination
2.Configure Migration Types and Objects
3.Map name modification
4.Precheck

*** Migration Types:** Schema Migration Full Data Migration Incremental Data Migration

Data migration applies to short-term migration scenarios. Typical scenarios include migrating data to the cloud, scaling and sharding databases, and migrating data between Apsara Stack databases.
For long-term data synchronization in real time, use the data synchronization feature.

Information:
 1. Data migration only copies the data and schema in the source database and saves the copy in the destination database. The process does not affect any data or schema in the source database.
 2. DDL operations are not supported during data migration because this can cause migration failures.

Cancel Previous Save Precheck

Parameter	Description
Migration Types	<ul style="list-style-type: none"> To perform only full data migration, select Schema Migration and Full Data Migration. To ensure service continuity during data migration, select Schema Migration, Full Data Migration, and Incremental Data Migration. <p> Note If Incremental Data Migration is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.</p>
Objects	<p>Select objects from the Available section and click the  icon to move the objects to the Selected section.</p> <p> Note</p> <ul style="list-style-type: none"> You can select columns, tables, or databases as the objects to be migrated. After an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.

6. In the lower-right corner of the page, click **Precheck**.

 **Note** You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

7. After the task passes the precheck, click **Next**.

 **Note** If **Incremental Data Migration** is not selected, wait until the migration task is completed. If **Incremental Data Migration** is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

19.3.3.2. Migrate incremental data from a user-created SQL Server database to an ApsaraDB RDS for SQL Server instance

This topic describes how to migrate incremental data from a user-created SQL Server database to an ApsaraDB RDS for SQL Server instance by using Data Transmission Service (DTS). DTS supports schema migration, full data migration, and incremental data migration. You can select all of the supported migration types to ensure service continuity.

Prerequisites

- The version of the user-created SQL Server database is 2005, 2008, 2008 R2, 2012, 2014, or 2016.

 Note

- DTS does not support SQL Server clusters or SQL Server Always On availability groups (AOAG).
- If the version of the source database is 2005, incremental data migration is not supported.
- If you migrate data between different versions of databases, make sure that the database versions are compatible.

- The tables to be migrated from the user-created SQL Server database must have primary keys or UNIQUE NOT NULL indexes.

Precautions

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the load of the database server. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- To ensure that the incremental data migration task runs as expected, do not frequently back up the source database. We recommend that you retain log files for more than three days. Otherwise, you cannot retrieve log files after they are truncated.
- To ensure that the delay time of incremental data migration is accurate, DTS adds a heartbeat table to the user-created SQL Server database. The name of the heartbeat table is `Source table name_dts_mysql_heartbeat`.
- DTS automatically creates a destination database in the ApsaraDB RDS for SQL Server instance. However, if the name of the source database is invalid, you must manually create a database in the ApsaraDB RDS for SQL Server instance before you configure the data migration task.
- If a data migration task fails, DTS automatically resumes the task. Before you switch your workloads to the destination instance, stop or release the data migration task. Otherwise, the data in the source database will overwrite the data in the destination instance after the task is resumed.

Limits

- A single data migration task can migrate incremental data from only one database. To migrate incremental data from multiple databases, you must create a data migration task for each database.
- DTS cannot migrate the schemas of assemblies, service brokers, full-text indexes, full-text catalogs, distributed schemas, distributed functions, CLR stored procedures, CLR scalar-valued functions, CLR table-valued functions, internal tables, systems, or aggregate functions.
- DTS cannot migrate data of the `sql_variant` type.
- DTS cannot migrate tables that contain computed columns.

Migration types

- Schema migration

DTS migrates the schemas of the required objects to the destination instance. DTS supports schema migration for the following types of objects: table, view, trigger, synonym, SQL stored procedure, SQL function, plan guide, user-defined type, rule, and default.

- Full data migration

DTS migrates historical data of the required objects from the user-created SQL Server database to the destination ApsaraDB RDS for SQL Server instance.

- Incremental data migration

After full data migration is complete, DTS migrates incremental data from the user-created SQL Server database to the destination ApsaraDB RDS for SQL Server instance. Incremental data migration allows you to ensure service continuity when you migrate data from a user-created SQL Server database to Alibaba Cloud.

SQL operations that can be synchronized during incremental data migration

- INSERT, UPDATE, and DELETE

 **Note** DTS cannot synchronize the UPDATE operations that update only the large fields.

- CREATE TABLE

 **Note** If a CREATE TABLE operation creates a partition table or a table that contains functions, DTS does not synchronize the CREATE TABLE operation.

- ALTER TABLE operations, including only ADD COLUMN, DROP COLUMN, and RENAME COLUMN
- DROP TABLE
- RENAME TABLE, TRUNCATE TABLE, and CREATE INDEX

Migration process

To avoid data migration failures caused by dependencies among objects, DTS migrates the schemas and data from the source SQL Server database in the following order:

1. Migrate the schemas of tables, views, synonyms, user-defined types, rules, defaults, and plan guides.
2. Perform full data migration.
3. Migrate the schemas of SQL stored procedures, SQL functions, triggers, and foreign keys.
4. Perform incremental data migration.

 **Note** During schema migration and full data migration, do not perform data definition language (DDL) operations on the required objects. Otherwise, the objects may fail to be migrated.

Before you begin

Before you configure a data migration task, configure log settings on the user-created SQL Server database.

 **Note** Skip this step if you do not need to perform incremental data migration.

1. Run the following command in the user-created SQL Server database to change the recovery mode to full mode:

```
use master;
GO
ALTER DATABASE <database_name> SET RECOVERY FULL WITH ROLLBACK IMMEDIATE;
GO
```

Parameters:

<database_name>: the name of the source database.

Example:

```
use master;
GO
ALTER DATABASE mytestdata SET RECOVERY FULL WITH ROLLBACK IMMEDIATE;
GO
```

2. Run the following command to create a logical backup for the source database. Skip this step if you have already created a logical backup.

```
BACKUP DATABASE <database_name> TO DISK='<physical_backup_device_name>';
GO
```

Parameters:

- <database_name>: the name of the source database.
- <physical_backup_device_name>: the storage path and file name of the backup file.

Example:

```
BACKUP DATABASE mytestdata TO DISK='D:\backup\dbdata.bak';  
GO
```

3. Run the following command to back up the log entries of the source database:

```
BACKUP LOG <database_name> to DISK='<physical_backup_device_name>' WITH init;  
GO
```

Parameters:

- <database_name>: the name of the source database.
- <physical_backup_device_name>: the storage path and file name of the backup file.

Example:

```
BACKUP LOG mytestdata TO DISK='D:\backup\dblog.bak' WITH init;  
GO
```

Procedure

1. Create a data migration instance.
2. In the migration task list, find the migration task that you created, and click **Configure Migration Task** in the **Actions** column.
3. Configure the source and destination databases.

The screenshot shows a configuration window for a data migration task. At the top, there are four tabs: "1. Configure Source and Destination" (active), "2. Configure Migration Types and Objects", "3. Map name modification", and "4. Precheck".

Task Name: SQL Server

Source Database:

- Instance Type: User-Created Database with Public IP Address
- Instance Region: cn-qingdao
- Database Type: SQLServer
- Hostname or IP Address: [Redacted]
- Port Number: 1433
- Database Account: dtstest
- Database Password: [Redacted]

Test Connectivity: Passed

Destination Database:

- Instance Type: RDS Instance
- Instance Region: cn-qingdao
- RDS Instance ID: [Redacted]
- Database Account: dtstest
- Database Password: [Redacted]

Test Connectivity: Passed

19.3.3.3. Migrate data from a user-created MySQL database to an ApsaraDB RDS for MySQL instance

This topic describes how to migrate data from a user-created MySQL database to an ApsaraDB RDS for MySQL instance by using Data Transmission Service (DTS). DTS supports schema migration, full data migration, and incremental data migration. You can select all of the supported migration types to ensure service continuity.

Prerequisites

- The version of the user-created MySQL database is 5.1, 5.5, 5.6, or 5.7.
- If you need to perform incremental data migration, you must enable the binary logging feature. The following requirements must be met:
 - The value of the `binlog_format` parameter is set to `row`.
 - The value of the `binlog_row_image` parameter is set to `full`.

Precautions

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the load of the database server. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- DTS uses the `ROUND(COLUMN,PRECISION)` function to retrieve values from columns of the FLOAT or DOUBLE data type. If you do not specify a precision, DTS sets the precision for the FLOAT data type to 38 digits and the precision for the DOUBLE data type to 308 digits. You must check whether the precision settings meet your business requirements.
- DTS automatically creates a destination database in the ApsaraDB RDS for MySQL instance. However, if the name of the source database is invalid, you must manually create a database in the ApsaraDB RDS for MySQL instance before you configure the data migration task.

Migration types

- Schema migration

DTS migrates the schemas of the required objects to the destination instance. DTS supports schema migration for the following types of objects: table, view, trigger, stored procedure, and function.

Note

- During schema migration, DTS changes the value of the SECURITY attribute in views, stored procedures, and functions from DEFINER to INVOKER.
- DTS does not migrate user information. Before a user can call views, stored procedures, and functions of the destination database, you must grant the read/write permissions to the user.

- Full data migration

DTS migrates historical data of the required objects from the user-created MySQL database to the destination database in the ApsaraDB RDS for MySQL instance.

Note

During full data migration, concurrent INSERT operations cause fragmentation in the tables of the destination instance. After full data migration is complete, the tablespace of the destination instance is larger than that of the source database.

- Incremental data migration

After full data migration is complete, DTS retrieves binary log files from the user-created MySQL database. Then, DTS synchronizes incremental data from the user-created MySQL database to the destination ApsaraDB RDS for MySQL instance. Incremental data migration allows you to ensure service continuity when you migrate data from a user-created MySQL database to Alibaba Cloud.

SQL operations that can be synchronized during incremental data migration

Operation type	SQL statements
DML	INSERT, UPDATE, DELETE, and REPLACE
DDL	<ul style="list-style-type: none"> • ALTER TABLE and ALTER VIEW • CREATE FUNCTION, CREATE INDEX, CREATE PROCEDURE, CREATE TABLE, and CREATE VIEW • DROP INDEX and DROP TABLE • RENAME TABLE • TRUNCATE TABLE

* Database Password: ✔ Passed

Parameter	Description

Parameter	Description
Migration Types	<ul style="list-style-type: none"> To perform only full data migration, select Schema Migration and Full Data Migration. To ensure service continuity during data migration, select Schema Migration, Full Data Migration, and Incremental Data Migration. <p>Note If Incremental Data Migration is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.</p>
Objects	<p>Select objects from the Available section and click the  icon to move the objects to the Selected section.</p> <p>Note</p> <ul style="list-style-type: none"> You can select columns, tables, or databases as the objects to be migrated. After an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.

6. In the lower-right corner of the page, click **Precheck**.

Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

7. After the task passes the precheck, click **Next**.

Note If **Incremental Data Migration** is not selected, wait until the migration task is completed. If **Incremental Data Migration** is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

19.3.3.4. Migrate data from a user-created MySQL database to a Cloud Native Distributed Database PolarDB-X instance

This topic describes how to migrate data from a user-created MySQL database to a Cloud Native Distributed Database PolarDB-X instance by using Data Transmission Service (DTS). Cloud Native Distributed Database PolarDB-X is formerly known as Distributed Relational Database Service (DRDS).

Precautions

- DTS cannot migrate schemas from a user-created MySQL database to a Cloud Native Distributed Database PolarDB-X instance.

 **Note** During schema migration, DTS migrates the schemas of the required objects, such as tables, from the source database to the destination database.

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the load of the database server. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- DTS uses the `ROUND(COLUMN,PRECISION)` function to retrieve values from columns of the FLOAT or DOUBLE data type. If you do not specify a precision, DTS sets the precision for the FLOAT data type to 38 digits and the precision for the DOUBLE data type to 308 digits. You must check whether the precision settings meet your business requirements.

SQL operations that can be synchronized during incremental data migration

INSERT, UPDATE, DELETE, and REPLACE

Permissions required for database accounts

Database	Full data migration	Incremental data migration
User-created MySQL database	The SELECT permission	The REPLICATION SLAVE, REPLICATION CLIENT, SHOW VIEW, and SELECT permissions
Cloud Native Distributed Database PolarDB-X	The read and write permissions	The read and write permissions

Procedure

1. Create databases and tables in the destination PolarDB-X instance based on the schemas of the source tables.
2. [Create a data migration instance.](#)
3. In the migration task list, find the migration task that you created, and click **Configure Migration Task** in the Actions column.
4. Configure the source and destination databases.

1. Configure Source and Destination Databases
2. Configure Migration Types and Objects
3. Map name modification
4. Precheck

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select User-Created Database with Public IP Address .
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	Database Type	Select MySQL .
	Hostname or IP Address	Enter the endpoint that is used to connect to the user-created MySQL database.
	Port Number	Enter the service port number of the user-created MySQL database. The default port number is 3306.
	Database Account	Enter the account of the user-created MySQL database. For more information about the permissions that are required for the account, see Permissions required for database accounts .
	Database Password	Enter the password of the source database account.
	Instance Type	Select DRDS Instance .
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	DRDS Instance ID	Select the ID of the Cloud Native Distributed Database PolarDB-X instance.

Destination Database	Parameter	Description
	Database Name	Enter the name of the destination database.
	Database Account	Enter the database account of the Cloud Native Distributed Database PolarDB-X instance. For more information about the permissions that are required for the account, see Permissions required for database accounts .
	Database Password	Enter the password of the destination database account.

5. In the lower-right corner of the page, click **Set Whitelist and Next**.

6. Select the migration types and the objects to be migrated.

* Migration Types: Full Data Migration Incremental Data Migration

Data migration applies to short-term migration scenarios. Typical scenarios include migrating data to the cloud, scaling and sharding databases, and migrating data between Apsara Stack databases.
For long-term data synchronization in real time, use the data synchronization feature.

19.3.3.5. Migrate data from an ApsaraDB RDS for MySQL instance to a user-created Oracle database

This topic describes how to migrate data from an ApsaraDB RDS for MySQL instance to a user-created Oracle database by using Data Transmission Service (DTS). DTS supports full data migration and incremental data migration. You can select these migration types to ensure service continuity of the source ApsaraDB RDS for MySQL instance during data migration.

Prerequisites

The destination Oracle database is created. The schema of the Oracle database is the same as the schema of the source database in the ApsaraDB RDS for MySQL instance. This is because DTS does not support schema migration from an ApsaraDB RDS for MySQL instance to a user-created Oracle database.

Permissions required for database accounts

Migration type	Full data migration	Incremental data migration
Source ApsaraDB RDS for MySQL instance	The read and write permissions	The read and write permissions
Destination Oracle database	The read and write permissions	The read and write permissions

Procedure

1. **Create a data migration instance.**
2. In the migration task list, find the instance that you created, and click **Configure Migration Task** in the Actions column.
3. **Optional.** Enter a name for the task.

DTS automatically generates a name for each task. Duplicate task names are allowed. You can edit the task name based on your needs. We recommend that you specify an informative name for easy identification.

4. **Configure the source and destination databases.** The following table describes the parameters.

* Task Name:

Source Database

* Instance Type:

* Instance Region:

* RDS Instance ID:

* Database Account:

* Database Password:

* Encryption: Non-encrypted SSL-encrypted

Destination Database

* Instance Type:

* Instance Region:

* Database Type:

* Hostname or IP Address:

* Port Number:

* Instance Type: Non-RAC Instance RAC or PDB Instance

* SID:

* Database Account:

* Database Password:

Section	Parameter	Description
Source Database	Instance Type	Select RDS Instance as the type of the source instance.
	Instance Region	The region where the source instance resides.
	RDS Instance ID	Select the ID of the source RDS instance.
	Database Account	Enter an account that has the read and write permissions on the source database.
	Database Password	Enter the password of the source database account.
	Instance Type	Select User-Created Database with Public IP Address as the type of the destination database.
	Instance Region	The region where the destination instance resides.
	Database Type	Select Oracle.

Section	Parameter	Description
Destination Database	Hostname or IP Address	Enter the endpoint that is used to connect to the Oracle database.
	Port Number	The default port number is 1521.
	Instance Type	<ul style="list-style-type: none"> ◦ Non-RAC Instance: If you select this option, you must specify the SID. ◦ RAC Instance: If you select this option, you must specify the Service Name.
	Database Account	Enter an account that has the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account.

5. Click **Test Connectivity** and confirm that the test results for both the source and destination databases are **Passed**.
6. In the lower-right corner of the page, click **Set Whitelist and Next**.
7. Select the migration types based on your needs. Select objects from the **Available** section and click the  icon to move the objects to the **Selected** section.
 - To ensure service continuity during data migration, select **Full Data Migration and Incremental Data Migration**.
 - To perform only full data migration, select **Full Data Migration**.
8. Click **Precheck** and wait until the precheck is complete.

 **Note** You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

9. Click **Next** to start the migration task.

 **Note** If **Incremental Data Migration** is not selected, wait until the migration task is completed. If **Incremental Data Migration** is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

19.3.3.6. Migrate data between user-created Oracle databases

This topic describes how to migrate data between user-created Oracle databases by using Data Transmission Service (DTS). DTS supports schema migration, full data migration, and incremental data migration. You can select all of the supported migration types to ensure service continuity.

Prerequisites

- The version of the source Oracle database is 9i, 10g, 11g, or 12c.

 **Note** To ensure compatibility, make sure the versions of the source and destination databases are the same.

- Supplemental logging, including `SUPPLEMENTAL_LOG_DATA_PK` and `SUPPLEMENTAL_LOG_DATA_UI`, is enabled for the source Oracle database. For more information, see [Supplemental Logging](#).
- The `ARCHIVELOG` mode is enabled for the source Oracle database. Archived log files are accessible and a

suitable retention period is set for archived log files. For more information, see [Managing Archived Redo Log Files](#).

- The available storage space of the destination Oracle database is larger than the total size of the data in the source Oracle database.

Migration types

Migration type	Description
Schema migration	<p>DTS migrates the schemas of the required objects to the destination Oracle database. DTS supports schema migration for the following types of objects: table, view, synonym, trigger, stored procedure, function, package, and user-defined type.</p> <p>Note If an object contains triggers, the data between the source and destination databases will become inconsistent.</p>
Full data migration	<p>DTS migrates historical data of the required objects from the source Oracle database to the destination Oracle database.</p> <p>Note During schema migration and full data migration, do not perform DDL operations on the objects to be migrated. Otherwise, the objects may fail to be migrated.</p>
Incremental data migration	<p>After full data migration, DTS retrieves redo log files from the source Oracle database. Then, DTS synchronizes incremental data from the source Oracle database to the destination Oracle database. Incremental data migration allows you to ensure service continuity when you migrate data between Oracle databases.</p>

SQL operations that can be synchronized during incremental data migration

- INSERT, UPDATE, and DELETE operations
- CREATE TABLE operations

Note The CREATE TABLE operations to create partition tables or tables that contain functions cannot be synchronized.

- ALTER TABLE, DROP TABLE, RENAME TABLE, CREATE INDEX, and ADD INDEX operations

Permissions required for database accounts

Database	Schema migration	Full data migration	Incremental data migration
Source Oracle database	The owner permission on schemas	The owner permission on schemas	SYSDBA
Destination Oracle database	The owner permission on schemas	The owner permission on schemas	The owner permission on schemas

Note For more information about how to create and authorize an Oracle database account, see [CREATE USER](#) and [GRANT](#).

Procedure

1. [Create a data migration instance](#).
2. In the migration task list, find the migration task that you created, and click **Configure Migration Task** in the

Actions column.

3. Configure the source and destination databases.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select User-Created Database with Public IP Address .
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	Database Type	Select Oracle .
	Hostname or IP Address	Enter the endpoint that is used to connect to the source Oracle database.
	Port Number	Enter the port number of the source Oracle database. The default port number is 1521.
	Instance Type	Select Non-RAC Instance or RAC Instance based on the architecture of the source Oracle database.
	SID	Enter the system ID (SID) of the destination Oracle database. <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px; margin-top: 5px;"> ? Note This parameter is required if you select Non-RAC Instance as the instance type. </div>
	Service Name	Enter the server name of the instance. <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px; margin-top: 5px;"> ? Note This parameter is required if you select RAC Instance as the instance type. </div>
	Database Account	Enter the account that is used to connect to the source Oracle database.
	Database Password	Enter the password of the source database account.
	Instance Type	Select User-Created Database with Public IP Address .
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	Database Type	Select Oracle .
	Hostname or IP Address	Enter the endpoint that is used to connect to the destination Oracle database.
	Port Number	Enter the port number of the destination Oracle database. The default port number is 1521.
	Instance Type	Select Non-RAC Instance or RAC Instance based on the architecture of the destination Oracle database.

Destination Section Database	Parameter	Description
	SID	Enter the SID of the destination Oracle database. Note This parameter is required if you select Non-RAC Instance as the instance type.
	Service Name	Enter the server name of the instance. Note This parameter is required if you select RAC Instance as the instance type.
	Database Account	Enter the account that is used to connect to the destination Oracle database.
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.

5. Select the migration types and the objects to be migrated.

1. Configure Source and Destination | **2. Configure Migration Types and Objects** | 3. Map name modification | 4. Precheck

Objects	<p>Select objects from the Available section and click the  icon to move the objects to the Selected section.</p> <p>Note</p> <ul style="list-style-type: none"> You can select columns, tables, or databases as the objects to be migrated. After an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.

6. In the lower-right corner of the page, click **Precheck**.

Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

7. After the task passes the precheck, click **Next**.

Note If **Incremental Data Migration** is not selected, wait until the migration task is completed. If **Incremental Data Migration** is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

19.3.3.7. Migrate data from a user-created Oracle database to an ApsaraDB RDS for MySQL instance

This topic describes how to migrate data from a user-created Oracle database to an ApsaraDB RDS for MySQL instance by using Data Transmission Service (DTS). DTS supports schema migration, full data migration, and incremental data migration. When you migrate data from a user-created Oracle database, you can select all of the supported migration types to ensure service continuity.

Prerequisites

- The version of the user-created Oracle database is 9i, 10g, 11g, or 12c.
- Supplemental logging, including `SUPPLEMENTAL_LOG_DATA_PK` and `SUPPLEMENTAL_LOG_DATA_UI`, is enabled for the user-created Oracle database. For more information, see [Supplemental Logging](#).

- The ARCHIVELOG mode is enabled for the user-created Oracle database. Archived log files are accessible and a suitable retention period is set for archived log files. For more information, see [Managing Archived Redo Log Files](#).

Precautions

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the load of the database server. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- Table names in the ApsaraDB RDS for MySQL instance are case-insensitive. If a table name in the user-created Oracle database contains uppercase letters, ApsaraDB RDS for MySQL converts all uppercase letters to lowercase letters before creating the table.

If the source Oracle database contains identical table names that differ only in capitalization, these table names are identified as duplicate. During schema migration, the following message is returned: The object already exists. To avoid name conflicts in the destination database, you can change the names of the migrated objects by using the object name mapping feature. For more information, see [Object name mapping](#).

Migration types

- Schema migration

DTS supports schema migration for tables and indexes. DTS does not support schema migration for the following types of objects: view, synonym, trigger, stored procedure, function, package, and user-defined type. DTS has the following limits on schema migration for tables and indexes:

- Schema migration of nested tables is not supported. Clustered tables and index-organized tables (IOTs) are converted into common tables in the destination database.
- Schema migration of function-based indexes, domain indexes, bitmap indexes, and reverse indexes is not supported.

- Full data migration

DTS migrates historical data of the required objects from the user-created Oracle database to the destination ApsaraDB RDS for MySQL instance.

- Incremental data migration

DTS retrieves redo log files from the user-created Oracle database. Then, DTS synchronizes incremental data from the user-created Oracle database to the destination database in the ApsaraDB RDS for MySQL instance. Incremental data migration allows you to ensure service continuity when you migrate data from the user-created Oracle database to the destination database.

SQL operations that can be synchronized during incremental data migration

- INSERT, DELETE, and UPDATE
- CREATE TABLE

 **Note** If a CREATE TABLE operation creates a table that contains functions, DTS does not synchronize the CREATE TABLE operation.

- ALTER TABLE, ADD COLUMN, DROP COLUMN, RENAME COLUMN, and ADD INDEX
- DROP TABLE
- RENAME TABLE, TRUNCATE TABLE, and CREATE INDEX

Data type mappings

For more information, see [Data type mappings between heterogeneous databases](#).

Procedure

1. Create a data migration instance.
2. In the migration task list, find the migration task that you created, and click **Configure Migration Task** in the Actions column.
3. Configure the source and destination databases.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select an instance type based on where the source database is deployed. In this example, select User-Created Database with Public IP Address .
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	Database Type	Select Oracle .
	Hostname or IP Address	Enter the endpoint that is used to connect to the user-created Oracle database.
	Port Number	Enter the service port number of the user-created Oracle database. The default port number is 1521.
	Instance Type	<ul style="list-style-type: none"> ◦ Non-RAC Instance: If you select this option, you must specify the SID. ◦ RAC Instance: If you select this option, you must specify the Service Name.
	Database Account	Enter the account of the user-created Oracle database. To perform incremental data migration, the account must have the database administrator (DBA) permission. To perform schema migration or full data migration, the account must have the owner permission on schemas.
	Database Password	Enter the password of the source database account.
Destination Database	Instance Type	Select RDS Instance .
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	RDS Instance ID	Select the ID of the destination RDS instance.
	Database Account	Enter the database account of the destination RDS instance. The account must have the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. Select the migration types and the objects to be migrated.

Parameter	Description
-----------	-------------

Parameter	Description
Migration Types	<ul style="list-style-type: none"> To perform only full data migration, select Schema Migration and Full Data Migration. To ensure service continuity during data migration, select Schema Migration, Full Data Migration, and Incremental Data Migration. <p> Note If Incremental Data Migration is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.</p>
Objects	<p>Select objects from the Available section and click the  icon to move the objects to the Selected section.</p> <p> Note</p> <ul style="list-style-type: none"> You can select columns, tables, or databases as the objects to be migrated. After an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.

6. In the lower-right corner of the page, click **Precheck**.

 **Note** You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

7. After the task passes the precheck, click **Next**.

 **Note** If **Incremental Data Migration** is not selected, wait until the migration task is completed. If **Incremental Data Migration** is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

19.3.3.8. Migrate data from a user-created Oracle database to a PolarDB cluster

This topic describes how to migrate data from a user-created Oracle database to a PolarDB cluster by using Data Transmission Service (DTS). PolarDB is formerly known as ApsaraDB RDS for PPAS. DTS supports schema migration, full data migration, and incremental data migration. You can select all of the supported migration types to ensure service continuity.

Prerequisites

- The version of the user-created Oracle database is 9i, 10g, 11g, or 12c.
- Supplemental logging, including `SUPPLEMENTAL_LOG_DATA_PK` and `SUPPLEMENTAL_LOG_DATA_UI`, is enabled for the user-created Oracle database. For more information, see [Supplemental Logging](#).
- The ARCHIVELOG mode is enabled for the user-created Oracle database. Archived log files are accessible and a suitable retention period is set for archived log files. For more information, see [Managing Archived Redo Log](#)

Files.**Precautions**

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the load of the database server. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- DTS supports schema migration for the following types of objects: table, view, synonym, trigger, stored procedure, function, package, and user-defined type.

Limits

- During schema migration, the reverse indexes and bitmap indexes of the source database are stored as common indexes in the PolarDB cluster.
- During schema migration, partitioned indexes are converted into independent indexes on each partition in the PolarDB cluster.
- Incremental data migration supports only tables that have primary keys or UNIQUE NOT NULL indexes.
- Incremental data migration does not support the LONG data type.
- Data definition language (DDL) operations that are performed during incremental data migration cannot be synchronized to the destination database.
- Materialized views cannot be migrated.

Data type mappings

For more information, see [Data type mappings between heterogeneous databases](#).

Procedure

1. [Create a data migration instance](#).
2. In the migration task list, find the migration task that you created, and click **Configure Migration Task** in the Actions column.
3. Configure the source and destination databases.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select an instance type based on where the source database is deployed. In this example, select User-Created Database with Public IP Address .
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	Database Type	Select Oracle .
	Hostname or IP Address	Enter the endpoint that is used to connect to the user-created Oracle database.
	Port Number	Enter the service port number of the user-created Oracle database. The default port number is 1521.
	Instance Type	<ul style="list-style-type: none"> ◦ Non-RAC Instance: If you select this option, you must specify the SID. ◦ RAC Instance: If you select this option, you must specify the Service Name.

Section	Parameter	Description
	Database Account	Enter the account of the user-created Oracle database. To perform incremental data migration, the account must have the database administrator (DBA) permission. To perform schema migration or full data migration, the account must have the owner permission on schemas.
	Database Password	Enter the password of the source database account.
Destination Database	Instance Type	Select RDS Instance.
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	RDS Instance ID	Select the ID of the destination RDS instance.
	Database Name	Enter the name of the destination database.
	Database Account	Enter the database account of the destination RDS instance. The account must have the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.

5. Select the migration types and the objects to be migrated.

Parameter	Description
Migration Types	<ul style="list-style-type: none"> To perform only full data migration, select Schema Migration and Full Data Migration. To ensure service continuity during data migration, select Schema Migration, Full Data Migration, and Incremental Data Migration. <p> Note If Incremental Data Migration is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.</p>
Objects	<p>Select objects from the Available section and click the  icon to move the objects to the Selected section.</p> <p> Note</p> <ul style="list-style-type: none"> You can select columns, tables, or databases as the objects to be migrated. After an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.

6. In the lower-right corner of the page, click **Precheck**.

 **Note** You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

7. After the task passes the precheck, click **Next**.

 **Note** If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

19.3.3.9. Migrate data from a user-created Oracle database to a Cloud Native Distributed Database PolarDB-X instance

This topic describes how to migrate data from a user-created Oracle database to a Cloud Native Distributed Database PolarDB-X instance by using Data Transmission Service (DTS). Cloud Native Distributed Database PolarDB-X is formerly known as Distributed Relational Database Service (DRDS). DTS allows you to ensure service continuity when you migrate both historical data and incremental data.

Prerequisites

- The version of the user-created Oracle database is 9i, 10g, 11g, or 12c.
- Supplemental logging, including `SUPPLEMENTAL_LOG_DATA_PK` and `SUPPLEMENTAL_LOG_DATA_UI`, is enabled for the user-created Oracle database. For more information, see [Supplemental Logging](#).
- The ARCHIVELOG mode is enabled for the user-created Oracle database. Archived log files are accessible and a suitable retention period is set for archived log files. For more information, see [Managing Archived Redo Log Files](#).

Precautions

- DTS cannot migrate schemas from a user-created Oracle database to a Cloud Native Distributed Database PolarDB-X instance.

 **Note** During schema migration, DTS migrates the schemas of the required objects, such as tables, from the source database to the destination database.

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the load of the database server. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.

Migration types

- Full data migration

DTS migrates historical data of the required objects from the source Oracle database to the destination database.

- Incremental data migration

After full data migration is complete, DTS retrieves redo log files from the source Oracle database. Then, DTS synchronizes incremental data from the source Oracle database to the destination database.

Note The following SQL operations can be synchronized during incremental data migration: INSERT, DELETE, and UPDATE operations. Data definition language (DDL) operations cannot be synchronized during incremental data migration.

Procedure

1. Create databases and tables in the destination PolarDB-X instance based on the schemas of the source tables.

Note The data types of Oracle databases and PolarDB-X instances do not have one-to-one correspondence. You must create the corresponding data types in PolarDB-X instances. For more information, see [Data type mappings between heterogeneous databases](#).

2. Create a data migration instance.
3. In the migration task list, find the migration task that you created, and click **Configure Migration Task** in the Actions column.
4. Configure the source and destination databases.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select User-Created Database with Public IP Address .
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	Database Type	Select Oracle .
	Hostname or IP Address	Enter the endpoint that is used to connect to the user-created Oracle database. In this example, enter the public IP address.
	Port Number	Enter the service port number of the user-created Oracle database. The default port number is 1521.
	Instance Type	<ul style="list-style-type: none"> ◦ Non-RAC Instance: If you select this option, you must specify the SID. ◦ RAC Instance: If you select this option, you must specify the Service Name.
	Database Account	Enter the account of the user-created Oracle database. To perform incremental data migration, the account must have the database administrator (DBA) permission. To perform schema migration or full data migration, the account must have the owner permission on schemas.
	Database Password	Enter the password of the source database account.
Destination Database	Instance Type	Select DRDS Instance .
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	DRDS Instance ID	Select the ID of the destination Cloud Native Distributed Database PolarDB-X instance.

Section	Parameter	Description
	Database Account	Enter the database account of the destination Cloud Native Distributed Database PolarDB-X instance. The account must have the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account.

5. In the lower-right corner of the page, click **Set Whitelist and Next**.

6. Select the migration types and the objects to be migrated.

The screenshot shows the '2. Configure Migration Types and Objects' step in the DTS console. At the top, there are four progress indicators: '1. Configure Source and Destination', '2. Configure Migration Types and Objects' (active), '3. Map name modification', and '4. Precheck'. Below the progress indicators, there are two checked options for 'Migration Types': 'Full Data Migration' and 'Incremental Data Migration'. A note explains that data migration applies to short-term scenarios and that long-term synchronization should use data synchronization. The main area is split into two panels: 'Available' on the left and 'Selected' on the right. The 'Available' panel shows a search bar and a list of databases: 'data123', 'mysqltest', 'mysqltestnew', and 'sys'. The 'Selected' panel shows a search bar and a list of objects: 'mysqltest (20Objects)', 'customer', and 'vipinfo'. There are navigation arrows between the panels and 'Select All'/'Remove All' buttons at the bottom of each. At the bottom of the interface, there are buttons for 'Cancel', 'Previous', 'Save', and 'Precheck'. A 'Name batch change' section has 'No' selected. An 'Information' section contains two points: 1. Data migration only copies data and schema. 2. DDL operations are not supported during data migration.

Parameter	Description
Migration Types	<ul style="list-style-type: none"> To perform only full data migration, select Full Data Migration. To ensure service continuity during data migration, select Full Data Migration and Incremental Data Migration. <p>Note If Incremental Data Migration is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.</p>

Parameter	Description
Objects	<p>Select objects from the Available section and click the  icon to move the objects to the Selected section.</p> <div style="background-color: #e0f2f7; padding: 10px;"> <p> Note</p> <ul style="list-style-type: none"> ○ You can select columns, tables, or databases as the objects to be migrated. ○ After an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. ○ If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated. </div>

7. In the lower-right corner of the page, click **Precheck**.

 **Note** You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

8. After the task passes the precheck, click **Next**.

 **Note** If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until The migration task is not delayed appears and manually stop the task.

19.3.4. Manage data migration tasks

19.3.4.1. Object name mapping

Data Transmission Service (DTS) provides the object name mapping feature. You can use this feature to change the names of one or more objects that are migrated to the destination instance. This topic describes how to use the object name mapping feature when you configure a data migration task.

Limits

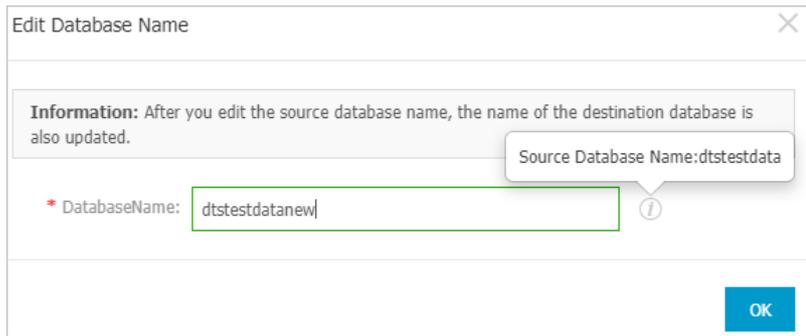

You can use the object name mapping feature only when a data migration task is configured and the current step is **Configure Migration Types and Objects**.

 **Note** Do not use the object name mapping feature after a data migration task is started. Otherwise, data may fail to be migrated.

Procedure

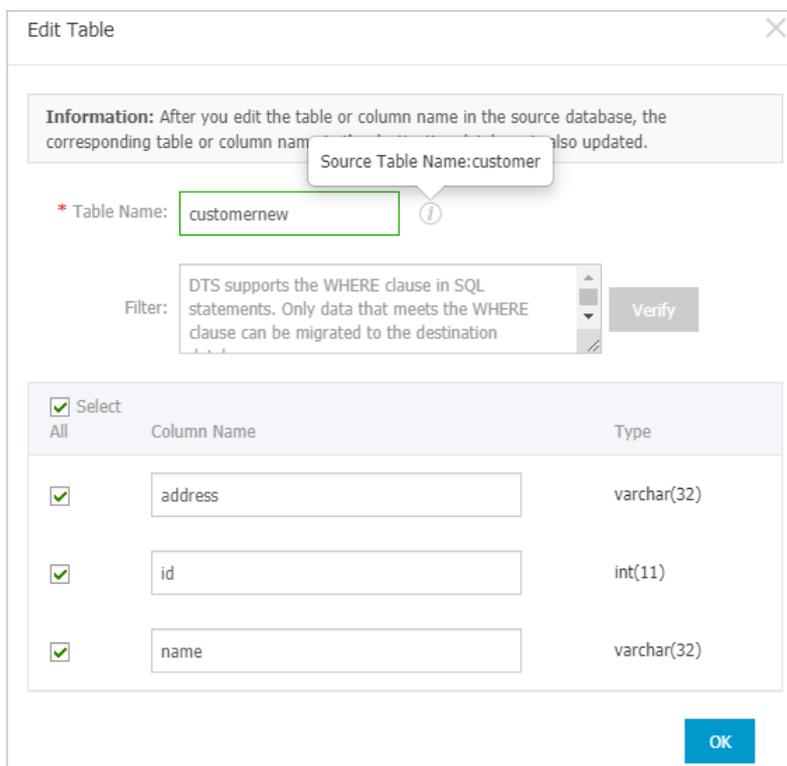

1. In the **Configure Migration Types and Objects** step, move the required objects to the **Selected** section, move the pointer over a database or table, and then click **Edit**.
2. In the dialog box that appears, specify a name for the object in the destination instance.
 - Database name mapping

In the **Edit Database Name** dialog box that appears, enter the database name that you want to use in the destination instance.

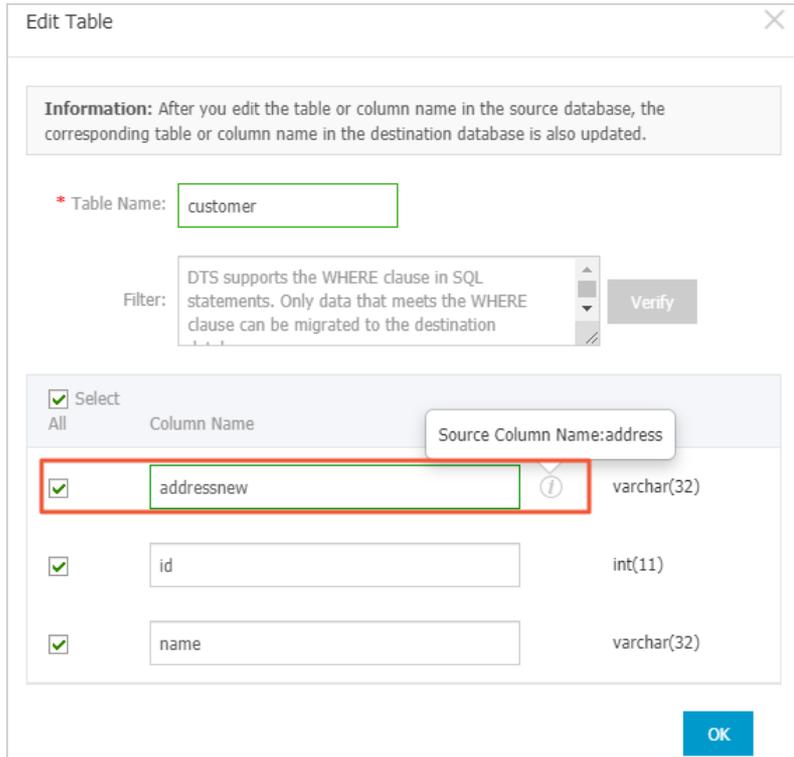

- **Table name mapping**

In the **Edit Table** dialog box that appears, enter the table name that you want to use in the destination instance.

- **Column name mapping**

In the **Edit Table** dialog box that appears, enter a new name for each column.

Note In this step, you can clear the options of columns that do not need to be synchronized.

3. Click **OK**.
4. Configure other parameters that are required for the data migration task.

19.3.4.2. Specify an SQL condition to filter data

This topic describes how to specify an SQL condition to filter the data of a specific table when you configure a data migration task.

The SQL condition takes effect only within the table that you select. DTS migrates only the data that meets the SQL condition to the destination database. This feature is applicable to scenarios such as regular data migration and table partitioning.

Limits

An SQL condition applies only to full data migration. If you select incremental data migration as the migration type, the SQL condition does not filter incremental data.

Specify an SQL condition

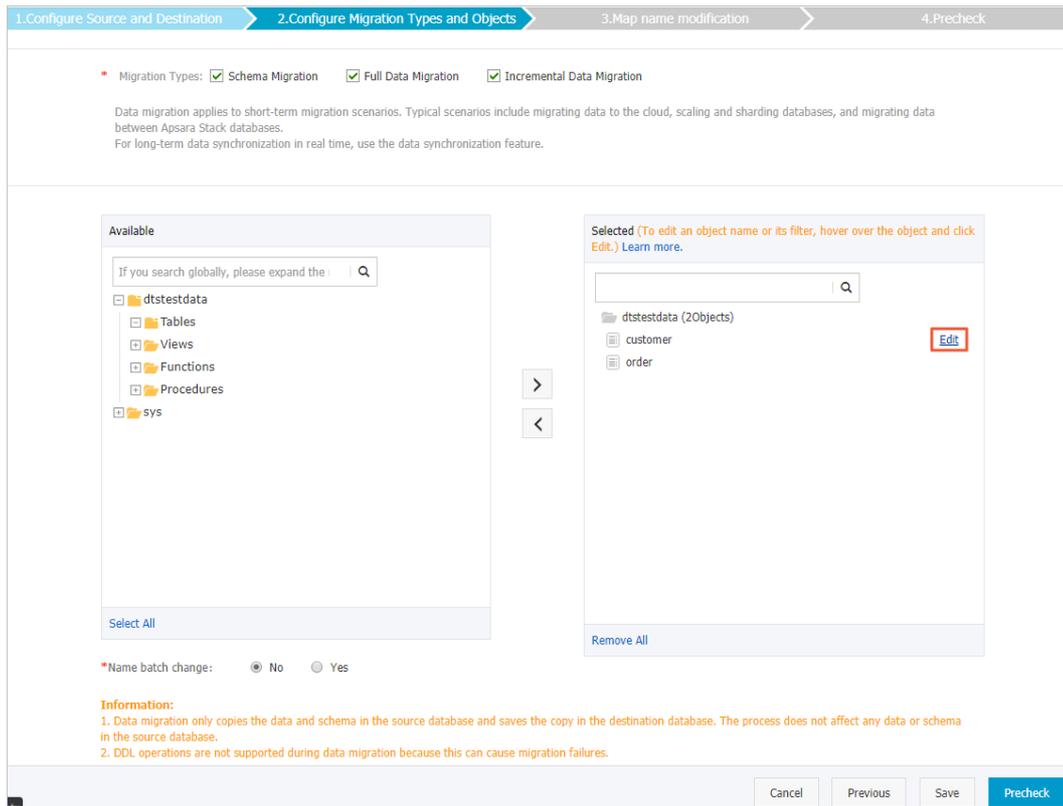

You can specify an SQL condition in the **Configure Migration Types and Objects** step when you configure a data migration task.

To filter the data of a specific table by using an SQL condition, you must select the table as the object that you want to migrate. You cannot select a database as the object. To specify an SQL condition, perform the following steps.

Procedure

1. In the **Configure Migration Types and Objects** step, move the pointer over a table in the **Selected** section. The **Edit** button appears, as shown in **Edit button**.

Edit button

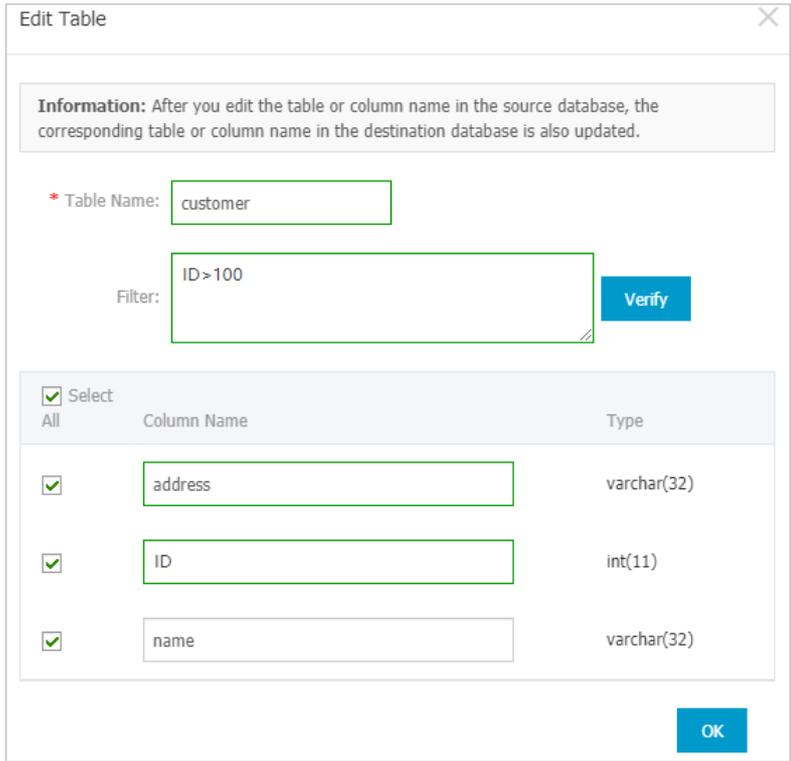

2. Click Edit. The Edit Table dialog box appears.

Modify an SQL condition

The SQL conditions in DTS are the same as the standard SQL WHERE conditions for databases. You can use SQL conditions to perform operations and run basic functions.

Enter an SQL condition in the text box. For example, you can enter `id>1000` to migrate the records whose IDs are greater than 1,000 to the destination instance, as shown in [Modify an SQL condition](#).

Modify an SQL condition

After the SQL condition is specified, click OK.

19.3.4.3. Troubleshoot a failed data migration task

This topic describes how to troubleshoot a failed data migration task. You can use this feature if your data migration task is in the Migration Failed state during schema migration or full data migration.

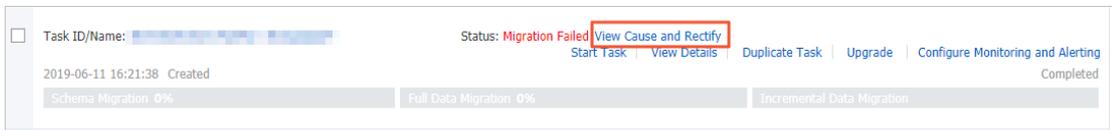

Troubleshoot a failed task during schema migration

DTS supports data migration between heterogeneous data sources. However, if you migrate data of unsupported types to the destination instance during schema migration, the task may fail.

1. [Log on to the DTS console.](#)
2. In the left-side navigation pane, click **Data Migration**.
3. Use one of the following methods to troubleshoot the failed task:

- o **Method 1**

- a. Find the task and click **View Cause and Rectify**.

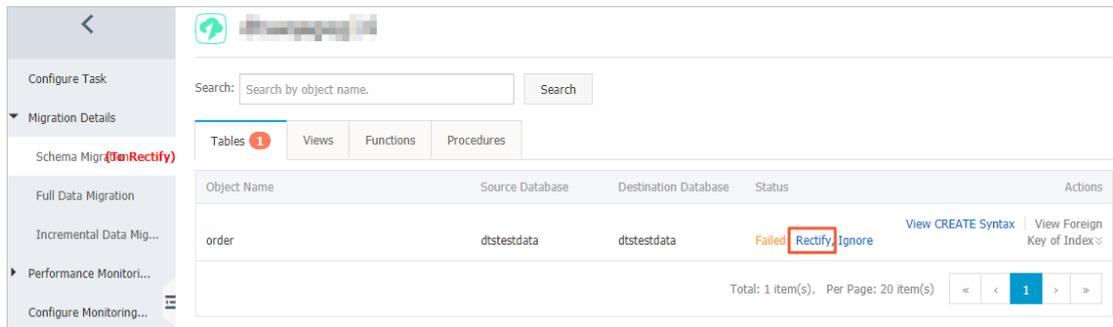

- b. Troubleshoot the issue based on the cause that is displayed in the View Cause and Rectify message. For example, you can troubleshoot an issue by modifying the schema syntax.

- c. Click **Restart Task**.

- o **Method 2**

- a. Click the instance ID or task name.
- b. In the left-side navigation pane, choose **Migration Details > Schema Migration**.

- c. On the **Schema Migration** page, find the object that causes the migration failure and click **Rectify** in the **Status** column.

- d. Troubleshoot the issue based on the cause that is displayed in the **Rectify** dialog box. For example, you can troubleshoot an issue by modifying the schema syntax.

- e. Click **Rectify**.

Note

- If the failure persists, the **Rectify** dialog box does not close and shows the failure cause. You must continue troubleshooting based on the failure cause until the troubleshooting is successful.
- If the troubleshooting is successful, the **Schema Migration** page appears and the status of the object changes to **Finished**.

4. If no objects are in the **Failed** state, DTS proceeds with the data migration task, for example, entering the full data migration process.

Troubleshoot a failed task during full data migration

1. **Log on to the DTS console.**
2. In the left-side navigation pane, click **Data Migration**.
3. Find the task and click **View Cause and Rectify**.

DTS allows you to troubleshoot a task that fails during full data migration due to the following reasons.

Note If a task fails during full data migration due to other reasons, DTS provides only the **Ignore** option. The object that causes the failure is not migrated to the destination database.

- The connection to the source or destination database failed or timed out.
Troubleshoot the issue, make sure that the connection is successful, and then click **Restart Task**.
 - The storage space of the destination instance is insufficient or the instance is locked.
Upgrade the specification of the destination instance or clear the log space, and then click **Restart Task**.
 - MyISAM tables in the source database are corrupted.
Troubleshoot the issue in the source database, and then click **Restart Task**.
4. In the dialog box that appears, troubleshoot the issue based on the failure cause.
 5. Click **Restart Task**.

19.3.5. Precheck items

19.3.5.1. Source database connectivity

DTS checks whether DTS servers can connect to the source database. DTS creates a connection to the source database by using the JDBC protocol. If the connection fails, the data migration task fails to pass the connectivity check.

The migration task may fail to pass the connectivity check because of the following reasons:

- The database account or password that is specified in the data migration task is invalid.

Troubleshooting:

Find a server that can connect to the source database. On the server, enter the database account and password that are specified in the data migration task to check whether the account and password are valid. If the database account or password is invalid, the following error message is displayed: Access deny.

Solution:

Log on to the DTS console, modify the database account and password, and then run a precheck again.

- The DTS servers are disallowed to access the source database.

Troubleshooting:

- Find a server that can connect to the source database. On the server, enter the database account and password that are specified in the data migration task to check whether the connection is successful. Only authorized DTS servers can connect to the source database. If the CIDR block of a DTS server is not included in the whitelist of the source database, the DTS server cannot connect to the source database.
- If the source database is a MySQL database, use a MySQL client to connect to the database and run the `SELECT HOST FROM mysql.user WHERE user='Account', password='Password';` command. If the CIDR blocks of DTS servers are not included in the whitelist of the source database, the query result of the preceding command is not %.

Solution:

- If the source database is a MySQL database, run the `GRANT ALL ON . TO 'Account'@'%' IDENTIFIED BY 'Password';` command to authorize the database account. Replace Account and Password in the preceding command with your database account and password. After the account is authorized, run a precheck again.
- A firewall is configured on the source database server.

Troubleshooting: If the server where the source database resides runs Linux, run the `iptables -L` command in the shell to check whether a firewall is configured for the server. If the server where the source database resides runs Windows, find Windows Defender Firewall from the Control Panel and check whether a firewall is configured for the server.

Solution:

Disable the firewall and run a precheck again.

- The network between DTS servers and the source database is unavailable.

If the failure persists, you can check whether the network between DTS servers and the source database is available. In this case, we recommend that you contact Alibaba Cloud engineers by submitting a ticket.

19.3.5.2. Check the destination database connectivity

This check item checks whether the DTS server can connect to the destination database for migration. DTS creates a connection to the destination database by using the JDBC protocol. If the connection fails, the check item fails.

The destination database connectivity precheck may fail for the following reasons:

- An incorrect account or password is provided when a migration task is created.

Diagnostics:

On any network-ready server that can connect to the destination database, use the account and password specified for creating the migration task to connect to the destination database through client software. Check whether the connection succeeds. If an error is reported for the connection and the error message contains Access deny, the account or password is incorrect.

Troubleshooting:

Modify the migration task in the DTS console, correct the account and password, and perform the precheck again.

- There is no connectivity between the DTS server and destination database.

If you check that the password and account are correct, the check item may fail because there is no connectivity between the DTS server and the destination database. In this case, contact the DTS engineers on duty.

19.3.5.3. Binary logging configurations of the source database

Whether binary logging is enabled in the source database

This item is checked only when you migrate incremental data between MySQL databases. DTS checks whether binary logging is enabled in the source database. If binary logging is disabled in the source database, the check result is Failed.

Troubleshooting: Run the `log_bin=mysql_bin` command to modify the configuration file of the source database. Restart the source database and run a precheck again.

Binary log format of the source database

This item is checked only when you migrate incremental data between MySQL databases. DTS checks whether the binary log format is set to ROW in the source database. If the binary log format is not set to ROW in the source database, the check result is Failed.

Troubleshooting: Run the `set global binlog_format=ROW` command in the source database and run a precheck again. We recommend that you restart the MySQL process. Otherwise, data loss may occur because sessions will continue to be written in a non-ROW mode.

Binary log files in the source database

This item is checked only when you migrate incremental data between MySQL databases. DTS checks whether specific binary log files are removed from the source database. If binary log files in the source database are incomplete, the check result is Failed.

Troubleshooting: Run the `PURGE BINARY LOGS TO 'The name of the first binary log file that is not deleted'` command in the source database and run a precheck again.

To find the binary log files that are removed from the source database, click the info icon next to the failed item. In the View Details dialog box, the names of deleted binary log files are displayed.

Parameter binlog_row_image of the source database

This item is checked only when you migrate incremental data between MySQL databases. DTS checks whether the value of the binlog_row_image parameter in the source database is set to FULL. This parameter indicates whether the full image is recorded. If the full image is not recorded in binary log files of the source database, the check result is Failed.

Troubleshooting: Run the `set global binlog_row_image=FULL` command in the source database and run a precheck again.

19.3.5.4. Integrity of the FOREIGN KEY constraints

DTS checks whether the parent table on which a child table depends is included in the selected objects. The precheck allows DTS to protect the integrity of the FOREIGN KEY constraints.

If the parent table on which a child table depends is not included in the selected objects, the check result is Failed.

Troubleshooting:

- Do not migrate the child tables that cause the check failure. To do this, remove these child tables from the selected objects and run a precheck again.

- Migrate the parent tables rather than the child tables. To do this, add the parent tables to the selected objects and run a precheck again.
- Delete the foreign key dependencies between the parent and child tables in the source database and run a precheck again.

19.3.5.5. Existence of FEDERATED tables

This item is checked only when you migrate incremental data between MySQL databases. DTS checks whether the source database contains storage engines that are not supported by incremental data migration. Incremental data migration does not support the FEDERATED and MRG_MyISAM storage engines.

If the FEDERATED storage engine is used by specific tables in the source database, the check result is Failed.

If the MRG_MyISAM storage engine is used by specific tables in the source database, the check result is Failed.

Solution:

Remove the tables that use the FEDERATED or MRG_MyISAM storage engine from the selected objects. Then, create a separate migration task to perform schema migration and full data migration for these tables.

19.3.5.6. Permissions

Source database permissions

DTS checks whether the account of the source database has the required permissions to perform data migration. For information about the permissions that are required by each type of database, see the topics about how to configure data migration tasks.

Destination database permissions

DTS checks whether the account of the destination database has the required permissions to perform data migration. For information about the permissions that are required by each type of database, see the topics about how to configure data migration tasks.

19.3.5.7. Object name conflict

This check item checks for duplicate object names in the destination and source database. If this check item fails, an object in the destination RDS instance has the same name as an object to be migrated. This causes the migration to fail.

When this check item fails, an error message is displayed indicating that an object in the destination database has the same name as an object to be migrated from the source database.

Troubleshooting:

- Use the database and table name mapping feature provided by DTS to migrate the object to be migrated to another object with a different name in the destination database.
- In the destination database, delete or rename the object that has the same name as the object to be migrated.
- Modify the migration task and delete that object to be migrated from the list of objects to be migrated. Do not migrate this object.

19.3.5.8. Schema existence

This check item checks whether the database to be migrated exists in the destination RDS instance. If no, DTS creates one automatically. However, under the following circumstances, the automatic database creation fails, and this check item prompts a failure:

- The database name contains characters other than lowercase letters, digits, underscores (_), and hyphens (-).

The cause of the precheck failure is that the name of the source database does not comply with the requirements of RDS.

Troubleshooting: On the database management page of the RDS console, create a database that complies with the requirements of RDS and grant the migration account the read and write permissions on the new database. Use the database name mapping feature provided by DTS to map the source database to the new database. Then, perform the precheck again.

- The character set of the database is not UTF8, GBK, Latin1, or UTF-8MB4.

The cause of the precheck failure is that the character set of the source database does not comply with the requirements of RDS.

Troubleshooting: On the database management page of the RDS console, create a database that complies with the requirements of RDS and grant the migration account the read and write permissions on the new database. If the new database and the database to be migrated have different names, you can use the database name mapping feature of DTS to map the database to be migrated to the new database. Then re-run the precheck.

- The migration account of the destination database has no read and write permissions on the database to be migrated.

The cause of the precheck failure is that you are not authorized to operate on the source database.

Troubleshooting: On the database management page of the RDS console, click the Account Management tab. Grant the migration account the read and write permissions on the source database. Then, perform the precheck again.

19.3.5.9. Value of server_id in the source database

This item is checked only when you migrate incremental data between MySQL databases. DTS checks whether the value of server-id in the source database is set to an integer greater than 1.

If the check result is Failed, run the `set global server_id='An integer greater than 1'` command in the source database and perform a precheck again.

19.3.5.10. Source database version

DTS checks whether the version of the source database is supported. The table [Source database types and versions](#) lists the source database versions that are supported by DTS.

Source database types and versions

Source database type	Supported version
MySQL	5.0, 5.1, 5.5, 5.6, and 5.7. Only 5.1, 5.5, 5.6, and 5.7 are supported for incremental data migration.

If the check result is Failed, you must upgrade or downgrade the source database to a supported version before you perform a precheck again.

19.3.6. Data type mappings between heterogeneous databases

Heterogeneous databases support different data types. During schema migration, Data Transmission Service (DTS) converts the data types of the source database into those of the destination database. This topic lists the data type mappings for you to evaluate the impact of data migration on your business.

Data migration from a user-created Oracle database to a user-created MySQL database or an ApsaraDB RDS for MySQL instance

Data type in the Oracle database	Data type in the MySQL database	Supported by DTS
varchar2(n [char/byte])	varchar(n)	Yes
nvarchar2[(n)]	national varchar[(n)]	Yes
char[(n [byte/char])]	char[(n)]	Yes
nchar[(n)]	national char[(n)]	Yes
number[(p[,s])]	decimal[(p[,s])]	Yes
float(p)	double	Yes
long	longtext	Yes
date	datetime	Yes
binary_float	decimal(65,8)	Yes
binary_double	double	Yes
timestamp[(fractional_seconds_precision)]	datetime[(fractional_seconds_precision)]	Yes
timestamp[(fractional_seconds_precision)]with localtimezone	datetime[(fractional_seconds_precision)]	Yes
timestamp[(fractional_seconds_precision)]with localtimezone	datetime[(fractional_seconds_precision)]	Yes
clob	longtext	Yes
nclob	longtext	Yes
blob	longblob	Yes
raw	varbinary(2000)	Yes
long raw	longblob	Yes
bfile	N/A	No
interval year(year_precision) to month	N/A	No
interval day(day_precision)to second[(fractional_seconds_precision)]	N/A	No

 Note

- A char column with a length greater than 255 bytes is converted to the varchar(n) type.
- Data types such as bfile, interval year to month, and interval day to second in Oracle databases are not supported in MySQL databases. They cannot be converted to data types supported by the destination database during schema migration.

The schema migration fails if the table to be migrated contains these three data types. You must make sure that columns with these three data types are excluded from the objects to be migrated.

- The timestamp data type of MySQL databases does not contain the time zone information. However, the timestamp with time zone and timestamp with local time zone data types in Oracle databases provide time zone information. Therefore, DTS converts the values of these data types based on the time zone to UTC time for storage in the destination instance.

Data migration from a user-created Oracle database to a PolarDB-X instance

Oracle data type	PolarDB-X data type	Supported by DTS
varchar2(n [char/byte])	varchar(n)	Yes
nvarchar2[(n)]	national varchar[(n)]	Yes
char[(n [byte/char])]	char[(n)]	Yes
nchar[(n)]	national char[(n)]	Yes
number[(p,s)]	decimal[(p,s)]	Yes
float(p)	double	Yes
long	longtext	Yes
date	datetime	Yes
binary_float	decimal(65,8)	Yes
binary_double	double	Yes
timestamp[(fractional_seconds_precision)]	datetime[(fractional_seconds_precision)]	Yes
timestamp[(fractional_seconds_precision)]with localtimezone	datetime[(fractional_seconds_precision)]	Yes
timestamp[(fractional_seconds_precision)]with localtimezone	datetime[(fractional_seconds_precision)]	Yes
clob	longtext	Yes
nclob	longtext	Yes
blob	longblob	Yes
raw	varbinary(2000)	Yes
long raw	longblob	Yes
bfile	None	No
interval year(year_precision) to month	None	No

Oracle data type	PolarDB-X data type	Supported by DTS
interval day(day_precision)to second[(fractional_seconds_precision)]	None	No

 Note

- If a char field in the Oracle database is greater than 255 bytes in length, DTS converts this field to the varchar(n) type in the PolarDB-X instance.
- The timestamp data type of PolarDB-X does not contain the time zone information. However, the timestamp with time zone and timestamp with local time zone data types in Oracle databases provide the time zone information. Therefore, DTS converts the values of these data types into UTC time in the destination PolarDB-X instance.

Data migration from a user-created Oracle database to a PolarDB cluster

Oracle data type	PolarDB data type	Supported by DTS
varchar2(n [char/byte])	varchar2[(n)]	Yes
nvarchar2[(n)]	nvarchar2[(n)]	Yes
char[(n [byte/char])]	char[(n)]	Yes
nchar[(n)]	nchar[(n)]	Yes
number[(p,s)]	number[(p,s)]	Yes
float(p)	double precision	Yes
long	long	Yes
date	date	Yes
binary_float	real	Yes
binary_double	double precision	Yes
timestamp[(fractional_seconds_precision)]	timestamp[(fractional_seconds_precision)]	Yes
timestamp[(fractional_seconds_precision)]with time zone	timestamp[(fractional_seconds_precision)]with time zone	Yes
timestamp[(fractional_seconds_precision)]with local time zone	timestamp[(fractional_seconds_precision)]with time zone	Yes
clob	clob	Yes
nclob	nclob	Yes
blob	blob	Yes
raw	raw(size)	Yes
long raw	long raw	Yes
bfile	None	No

Oracle data type	PolarDB data type	Supported by DTS
interval year(year_precision) to month	interval year to month	No
interval day(day_precision) to second[(fractional_seconds_precision)]	interval day to second[(fractional_seconds_precision)]	No

 **Note** PolarDB does not support the timestamp[(fractional_seconds_precision)]with local time zone data type. DTS converts the data of this type into UTC time and then stores the data in the destination PolarDB cluster by using the timestamp[(fractional_seconds_precision)]with time zone data type.

19.4. Data synchronization

19.4.1. Database types, initial synchronization types, and synchronization topologies

You can use Data Transmission Service (DTS) to synchronize data between various data sources. This topic describes the database types, initial synchronization types, and synchronization topologies that are supported by DTS.

Source database	Destination database	Initial synchronization type	Synchronization topology
<ul style="list-style-type: none"> • User-created MySQL database 5.1, 5.5, 5.6, and 5.7 • RDS MySQL 5.6 and 5.7 	User-created MySQL database 5.1, 5.5, 5.6, and 5.7	Initial schema synchronization Initial full data synchronization	One-way synchronization Two-way synchronization
	RDS MySQL 5.6 and 5.7	Initial schema synchronization Initial full data synchronization	One-way synchronization Two-way synchronization
	AnalyticDB for MySQL 2.0 and 3.0	Initial schema synchronization Initial full data synchronization	One-way synchronization
	AnalyticDB for PostgreSQL 4.3 and 6.0	Initial schema synchronization Initial full data synchronization	One-way synchronization
	Datahub	Initial schema synchronization	One-way synchronization

Source database	Destination database	Initial synchronization type	Synchronization topology
	MaxCompute	Initial schema synchronization Initial full data synchronization	One-way synchronization
Cloud Native Distributed Database PolarDB-X (formerly known as DRDS)	Cloud Native Distributed Database PolarDB-X	Initial full data synchronization	One-way synchronization
	Datahub	Initial schema synchronization	One-way synchronization
	AnalyticDB for MySQL 2.0 and 3.0	Initial schema synchronization Initial full data synchronization	One-way synchronization

19.4.2. Create a data synchronization instance

Before you configure a task to synchronize data, you must create a data synchronization instance. This topic describes how to create a data synchronization instance in the Data Transmission Service (DTS) console.

Procedure

1. [Log on to the DTS console.](#)
2. In the left-side navigation pane, click **Data Synchronization**.
3. In the upper-right corner of the page, click **Create Synchronization Task**.
4. In the Create DTS Instances dialog box, set the required parameters.

Parameter	Description
Source Instance Region	Select the region where the source instance resides.
Source Instance Type	Select the type of the source instance. <ul style="list-style-type: none"> ◦ MySQL: a user-created MySQL database or an ApsaraDB RDS for MySQL instance ◦ Drds: a Cloud Native Distributed Database PolarDB-X instance (formerly known as DRDS)
Destination Instance Region	Select the region where the destination instance resides.
Destination Instance Type	Select the type of the destination instance. <ul style="list-style-type: none"> ◦ MySQL: a user-created MySQL database or an ApsaraDB RDS for MySQL instance ◦ AnalyticDB: AnalyticDB for MySQL ◦ MaxCompute ◦ DataHub ◦ Drds: a Cloud Native Distributed Database PolarDB-X instance (formerly known as DRDS) ◦ AnalyticDB for PostgreSQL: AnalyticDB for PostgreSQL

Parameter	Description
Synchronization Mode	Two-way synchronization is available only when you select MySQL as the type of both the source and destination instances.
Instances to Create	Set the number of data synchronization instances that you want to create at a time. The default value is 1.

Note In the Create DTS Instances dialog box, you can view the total number of instances, the number of existing instances, and the number of instances that can be created.

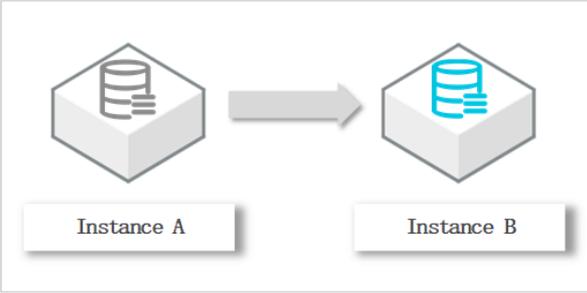

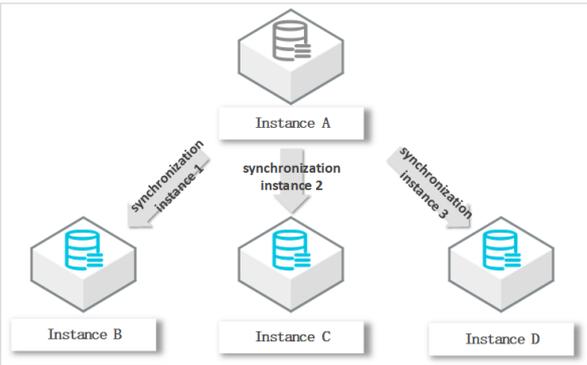

5. Click **Create**.

19.4.3. Synchronization topologies

The data synchronization feature supports multiple types of synchronization topologies. You can select a topology for your data synchronization instances based on your business requirements. This topic describes the synchronization topologies that are supported by DTS and how to use these topologies.

One-way synchronization

To ensure data consistency for one-way synchronization, we recommend that you perform only read operations on the objects in the destination instance. Do not modify the objects.

Topology type	Topology	Description
One-way one-to-one synchronization		None
One-way one-to-many synchronization		<p>You must purchase multiple synchronization instances to implement one-way one-to-many synchronization.</p> <p>For example, if you want to synchronize data from Instance A to Instance B, C, and D, you must purchase three synchronization instances.</p>

Topology type	Topology	Description
One-way cascade synchronization		<p>You must purchase multiple synchronization instances to implement one-way cascade synchronization.</p> <p>For example, if you want to synchronize data from Instance A to Instance B and then from Instance B to Instance C, you must purchase two synchronization instances.</p>
One-way many-to-one synchronization		<p>You must purchase multiple synchronization instances to implement one-way many-to-one synchronization.</p> <p>For example, if you want to synchronize data from Instance B, C, and D to Instance A, you must purchase three synchronization instances.</p> <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> <p>Note To ensure data consistency, you must select different objects for these synchronization instances.</p> </div>

Two-way synchronization

DTS supports two-way data synchronization only between two MySQL databases. DTS does not support two-way data synchronization between multiple MySQL databases.

Topology type	Topology	Description
Two-way one-to-one synchronization		<p>To ensure data consistency, make sure that records with the same primary key, business primary key, or unique key are updated only on one of the instances.</p>

19.4.4. Configure data synchronization tasks

19.4.4.1. Configure data synchronization between ApsaraDB RDS for MySQL instances

This topic describes how to configure one-way data synchronization between ApsaraDB RDS for MySQL instances.

Prerequisites

The source and destination ApsaraDB RDS for MySQL instances are created.

Precautions

- DTS uses the read and write resources of the source and destination databases during initial full data synchronization. This may increase the load of the database server. Before you synchronize data, evaluate the impact of data synchronization on the performance of the source and destination databases. We recommend that you synchronize data during off-peak hours.
- If you select one or more tables (not a database) as the required objects, do not use `gh-ost` or `pt-online-schema-change` to perform data definition language (DDL) operations on the tables during data synchronization. Otherwise, data may fail to be synchronized.
- The tables to be migrated in the source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- During initial full data synchronization, concurrent INSERT operations cause fragmentation in the tables of the destination instance. After initial full data synchronization, the tablespace of the destination instance is larger than that of the source instance.

Supported synchronization topologies

DTS supports one-way synchronization and two-way synchronization. For more information, see [Synchronization topologies](#).

SQL operations that can be synchronized

Operation type	SQL statements
DML	INSERT, UPDATE, DELETE, and REPLACE
DDL	<ul style="list-style-type: none"> • ALTER TABLE and ALTER VIEW • CREATE FUNCTION, CREATE INDEX, CREATE PROCEDURE, CREATE TABLE, and CREATE VIEW • DROP INDEX and DROP TABLE • RENAME TABLE • TRUNCATE TABLE

Limits

- Incompatibility with triggers

If you select a database as the object and the database contains a trigger that updates a table, data inconsistency may occur. To solve this issue, you must delete the trigger in the destination database.

- Limits on RENAME TABLE operations

RENAME TABLE operations may cause data inconsistency between the source and destination databases. For example, if you select a table as the object and rename the table during data synchronization, the data of this table is not synchronized to the destination database. To avoid this situation, you can select the database to which this table belongs as the object when you configure the data synchronization task.

Procedure

1. Create a data synchronization instance.

Note When you create the data synchronization instance, set both Source Instance Type and Destination Instance Type to MySQL, and set Synchronization Mode to One-Way Synchronization.

2. Find the data synchronization instance, and click **Configure Synchronization Channel** in the **Actions** column.

3. Configure the source and destination instances.

1.Configure Source and Destination
2.Select Objects to Synchronize
3.Advanced Settings
4.Precheck

Synchronization Task Name:

Source Instance Details

Instance Type:

Instance Region:

* Instance ID:

* Database Account:

* Database Password:

* Encryption: Non-encrypted SSL-encrypted

Destination Instance Details

Instance Type:

Instance Region:

* Instance ID:

* Database Account:

* Database Password:

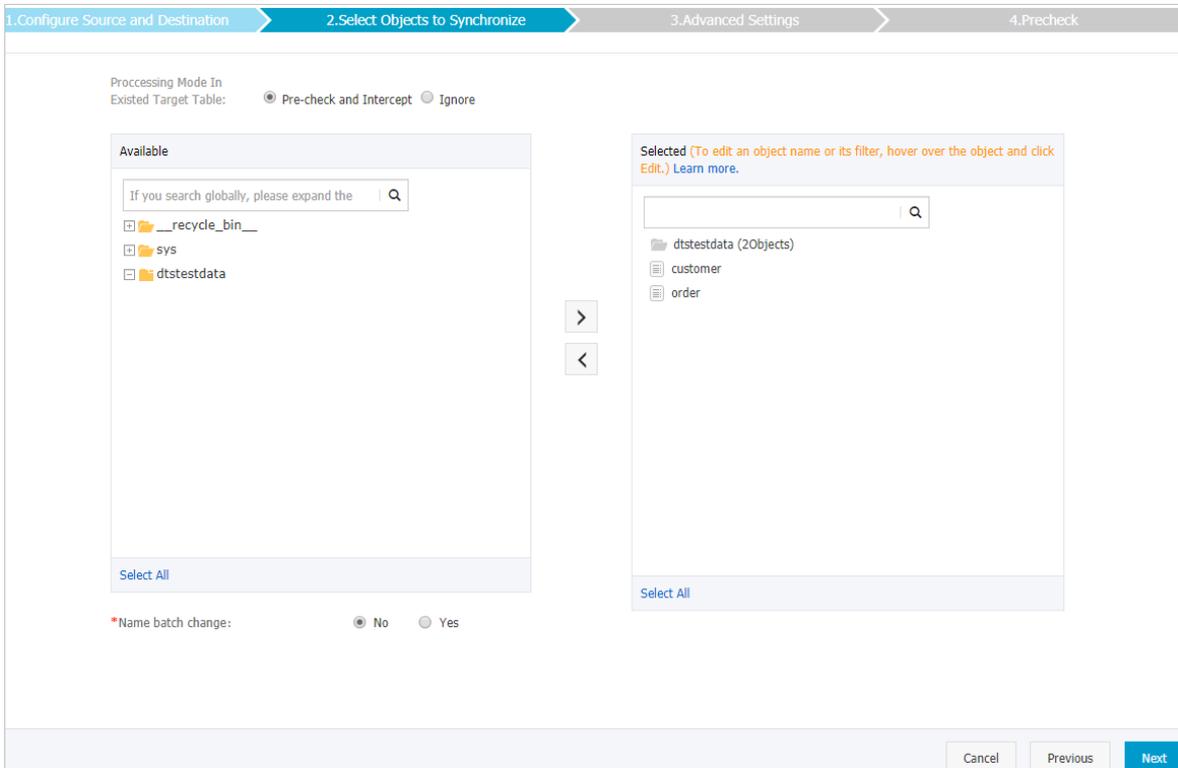

* Encryption: Non-encrypted SSL-encrypted

Section	Parameter	Description
N/A	Synchronization Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Instance Details	Instance Type	Select RDS Instance .
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Instance ID	Select the ID of the source RDS instance.
	Database Account	Enter the database account of the source RDS instance. <div style="background-color: #e0f2f7; padding: 5px; border: 1px solid #ccc; margin-top: 5px;"> <p>Note If the database engine of the source RDS instance is MySQL 5.6, you do not need to configure the database account or database password.</p> </div>
	Database Password	Enter the password of the source database account.

Section	Parameter	Description
	Encryption	Select an encryption method. If you select SSL-encrypted , you must enable SSL encryption for the RDS instance before you configure the data synchronization task.
Destination Instance Details	Instance Type	Select RDS Instance .
	Instance Region	The region of the source instance. The region is the same as the destination region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Instance ID	Select the ID of the destination RDS instance.
	Database Account	Enter the database account of the destination RDS instance. <div style="border: 1px solid #add8e6; padding: 5px; background-color: #e6f2ff;"> <p>? Note If the database engine of the destination RDS instance is MySQL 5.6, you do not need to configure the database account or database password.</p> </div>
	Database Password	Enter the password of the destination database account.
	Encryption	Select an encryption method. If you select SSL-encrypted , you must enable SSL encryption for the RDS instance before you configure the data synchronization task.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.

5. Select the processing mode of conflicting tables, and the objects that you want to synchronize.

Parameter	Description
Processing Mode In Existed Target Table	<ul style="list-style-type: none"> ◦ Pre-check and Intercept: checks whether the destination database contains tables that have the same names as tables in the source database. If the source and destination databases do not contain identical table names, the precheck is passed. Otherwise, an error is returned during precheck and the data synchronization task cannot be started. ◦ Ignore: skips the precheck for identical table names in the source and destination databases. <div style="background-color: #fff9c4; padding: 10px; border: 1px solid #ccc;"> <p> Warning If you select Ignore, data consistency is not guaranteed and your business may be exposed to potential risks.</p> <ul style="list-style-type: none"> ▪ DTS does not synchronize the data records that have the same primary keys as the data records in the destination database during initial data synchronization. This occurs if the source and destination databases have the same schema. However, DTS synchronizes these data records during incremental data synchronization. ▪ If the source and destination databases have different schemas, initial data synchronization may fail. In this case, only specific columns are synchronized or the data synchronization task fails. </div>
Select Objects	<p>Select objects (tables or a database) from the Available section and click the  icon to move the objects to the Selected section.</p> <div style="background-color: #e1f5fe; padding: 10px; border: 1px solid #ccc;"> <p> Note</p> <ul style="list-style-type: none"> ◦ If you select a database as the object to be synchronized, all schema changes in the database are synchronized to the destination database. ◦ After an object is synchronized to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are synchronized to the destination instance. For more information, see Specify the name of an object in the destination instance. </div>

6. In the lower-right corner of the page, click **Next**.

7. Configure initial synchronization.

1.Configure Source and Destination
2.Select Objects to Synchronize
3.Advanced Settings
4.Precheck

Initial Synchronization: Initial Schema Synchronization Initial Full Data Synchronization

 **Note** Initial synchronization includes initial schema synchronization and initial full data synchronization. If you select both **Initial Schema Synchronization** and **Initial Full Data Synchronization**, DTS synchronizes the schemas and historical data of the required objects before DTS synchronizes incremental data.

8. In the lower-right corner of the page, click **Precheck**.

 **Note** You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

9. Close the Precheck dialog box after the following message is displayed: The precheck is passed. Then, DTS performs initial synchronization.

19.4.4.2. Synchronize data from an ApsaraDB RDS for MySQL instance to a MaxCompute project

MaxCompute (formerly known as ODPS) is a fast and fully managed computing platform for large-scale data warehousing. MaxCompute can process exabytes of data. This topic describes how to synchronize data from an ApsaraDB RDS for MySQL instance to a MaxCompute project by using Data Transmission Service (DTS).

Precautions

- DTS uses the read and write resources of the source and destination databases during initial full data synchronization. This may increase the load of the database server. Before you synchronize data, evaluate the impact of data synchronization on the performance of the source and destination databases. We recommend that you synchronize data during off-peak hours.
- If you select one or more tables (not a database) as the required objects, do not use `gh-ost` or `pt-online-schema-change` to perform data definition language (DDL) operations on the tables during data synchronization. Otherwise, data may fail to be synchronized.
- You can select only tables as the objects to be synchronized.
- MaxCompute does not support the PRIMARY KEY constraint. If network errors occur, DTS may synchronize duplicate data records to MaxCompute.

SQL operations that can be synchronized

- Data definition language (DDL) operation: ADD COLUMN
- Data manipulation language (DML) operations: INSERT, UPDATE, and DELETE

Synchronization process

1. Initial schema synchronization DTS synchronizes the schemas of the required objects from the source database to MaxCompute. During initial schema synchronization, DTS adds the `_base` suffix to the end of the source table name. For example, if the name of the source table is `customer`, the name of the table in MaxCompute is `customer_base`.
2. Initial full data synchronization DTS synchronizes the historical data of the table from the source database to the destination table in MaxCompute. For example, the `customer` table in the source database is synchronized to the `customer_base` table in MaxCompute. The data is the basis for subsequent incremental synchronization.

 **Note** The destination table that is suffixed with `_base` is known as a full baseline table.

3. Incremental data synchronization DTS creates an incremental data table in MaxCompute. The name of the incremental data table is suffixed with `_log`, for example, `customer_log`. Then, DTS synchronizes the incremental data that was generated in the source database to the incremental data table.

 **Note** For more information, see [Schema of an incremental data table](#).

Procedure

1. [Create a data synchronization instance](#).

Note When you create the data synchronization instance, set Source Instance Type to MySQL, set Destination Instance Type to MaxCompute, and set Synchronization Mode to One-Way Synchronization.

- Find the data synchronization instance, and click **Configure Synchronization Channel** in the **Actions** column.
- Configure the source and destination instances.

Section	Parameter	Description
N/A	Synchronization Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Instance Details	Instance Type	Select RDS Instance.
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Instance ID	Select the ID of the source RDS instance.
	Database Account	Enter the database account of the source RDS instance. Note If the database engine of the source RDS instance is MySQL 5.5 or MySQL 5.6, you do not need to configure the database account or database password.
	Database Password	Enter the password of the source database account.
Destination Instance Details	Encryption	Select Non-encrypted or SSL-encrypted. If you select SSL-encrypted, you must enable SSL encryption for the RDS instance before you configure the data synchronization task.
	Instance Type	This parameter is set to MaxCompute and cannot be changed.
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Project	The name of the MaxCompute project.

- In the lower-right corner of the page, click **Set Whitelist and Next**.
- In the lower-right corner of the page, click **Next**. In this step, the permissions on the MaxCompute project are granted to the synchronization account.

1.Configure Source and Destination 2.Authorize MaxCompute Account 3.Select Objects to Synchronize 4.Precheck

To synchronize data to a MaxCompute instance, you must grant the following permissions of project dtstest to the synchronization account.

- CreateTable
- CreateInstance
- CreateResource
- CreateJob
- List

Cancel Previous **Next**

- Configure the synchronization policy and objects.

7. In the lower-right corner of the page, click **Precheck**.

Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

8. Close the **Precheck** dialog box after the following message is displayed: **The precheck is passed**. Then, DTS performs initial synchronization.

Schema of an incremental data table

DTS synchronizes incremental data that is generated in the source MySQL database to the incremental data table in MaxCompute. The incremental data table stores incremental data and specific metadata. The following figure shows the schema of an incremental data table.

	A	B	C	D	E	F	G	H	I	J	K	L
	id	register_time	address	record_id	operation_flag	utc_timestamp	before_flag	after_flag	modifytime_year	modifytime_month	modifytime_day	modifytime_hour
1	10000	2018-02-03 01:38:01		1560000333	U	156000655	Y	N	2019	08	16	16
2	10000	2018-02-03 01:38:01		1560000333	U	156000655	N	Y	2019	08	16	16
3	9999	2016-11-18 11:44:54		1560000419	D	156000845	Y	N	2019	08	16	16
4	10001	2018-12-23 05:11:59		1560000435	I	156000878	N	Y	2019	08	16	16

Note In the example, the `modifytime_year`, `modifytime_month`, `modifytime_day`, `modifytime_hour`, and `modifytime_minute` fields form the partition key.

The following table describes the schema of an incremental data table.

Field	Description
<code>record_id</code>	<p>The ID of the incremental log entry.</p> <div style="background-color: #e6f2ff; padding: 5px;"> <p>Note</p> <ul style="list-style-type: none"> The ID auto-increments for each new log entry. If an UPDATE operation is performed, DTS generates two incremental log entries for the operation. The two incremental log entries have the same record ID. </div>
<code>operation_flag</code>	<p>The operation type. Valid values:</p> <ul style="list-style-type: none"> I: an INSERT operation. D: a DELETE operation. U: an UPDATE operation.
<code>utc_timestamp</code>	The operation timestamp. It is also the timestamp of the binary log file. The timestamp is in the UTC format.
<code>before_flag</code>	Indicates whether the column values are pre-update values. Valid values: Y and N.
<code>after_flag</code>	Indicates whether the column values are post-update values. Valid values: Y and N.

Additional information about the `before_flag` and `after_flag` fields

For different operation types, the `before_flag` and `after_flag` fields of an incremental log entry are defined as follows:

- INSERT**

For an INSERT operation, the column values are the newly inserted record values (post-update values). The value of the `before_flag` field is N and the value of the `after_flag` field is Y.

	A	B	C	D	E	F	G	H	I	J	K	L
1	id	register_time	address	record_id	operation_flag	utc_timestamp	before_flag	after_flag	modifytime_year	modifytime_month	modifytime_day	modifytime_hour
5	10001	2018-12-23 05:11:59		156944878	I	15694878	N	Y	2019	08	16	16

• UPDATE

DTS generates two incremental log entries for an UPDATE operation. The two incremental log entries have the same values for the record_id, operation_flag, and dts_utc_timestamp fields.

The second log entry records the pre-update values, so the value of the before_flag field is Y and the value of the after_flag field is N. The second log entry records the post-update values, so the value of the before_flag field is N and the value of the after_flag field is Y.

	A	B	C	D	E	F	G	H	I	J	K	L
1	id	register_time	address	record_id	operation_flag	utc_timestamp	before_flag	after_flag	modifytime_year	modifytime_month	modifytime_day	modifytime_hour
2	10000	2018-02-03 01:38:01		156940333	U	15694655	Y	N	2019	08	16	16
3	10000	2018-02-03 01:38:01		156940333	U	15694655	N	Y	2019	08	16	16

• DELETE

For a DELETE operation, the column values are the deleted record values (pre-update values). The value of the before_flag field is Y and the value of the after_flag field is N.

	A	B	C	D	E	F	G	H	I	J	K	L
1	id	register_time	address	record_id	operation_flag	utc_timestamp	before_flag	after_flag	modifytime_year	modifytime_month	modifytime_day	modifytime_hour
4	9999	2016-11-18 11:44:54		1569400419	D	15694845	Y	N	2019	08	16	16

Merge a full baseline table and incremental data table

After a data synchronization task is started, DTS creates a full baseline table and an incremental data table in MaxCompute. You can use SQL statements to merge the two tables. This allows you to obtain the full data at a specific time point.

This section describes how to merge data for the customer table. The following figure shows the schema of the customer table.

	Field	Type	Null	Key	Default	Extra
1	id	int(11)	NO	PRI	null	
2	register_time	timestamp	YES		null	
3	address	varchar(32)	YES		null	

1. Create a table in MaxCompute based on the schema of the source table. The table is used to store the merged data.

For example, you can obtain full data of the customer table at the 1565944878 time point. Run the following SQL statements to create the required table:

```
CREATE TABLE `customer_1565944878` (
  `id` bigint NULL,
  `register_time` datetime NULL,
  `address` string);
```

Note For more information about the data types that are supported by MaxCompute, see MaxCompute User Guide.

2. Run the following SQL statements in MaxCompute to merge the full baseline table and incremental data table and obtain full data at a specific time point:

```
set odps.sql.allow.fullscan=true;
insert overwrite table <result_storage_table>
select <col1>,
       <col2>,
       <colN>
from(
select row_number() over(partition by t.<primary_key_column>
order by record_id desc, after_flag desc) as row_number, record_id, operation_flag, after_flag, <col1>, <col2>, <colN>
from(
select incr.record_id, incr.operation_flag, incr.after_flag, incr.<col1>, incr.<col2>,incr.<colN>
from <table_log> incr
where utc_timestamp< <timestamp>
union all
select 0 as record_id, 'I' as operation_flag, 'Y' as after_flag, base.<col1>, base.<col2>,base.<colN>
from <table_base> base) t) gt
where record_num=1
and after_flag='Y'
```

 Note

- <result_storage_table>: the name of the table that stores the merged data.
- <col1>/<col2>/<colN>: the names of the columns in the table to be merged.
- <primary_key_column>: the name of the primary key column in the table to be merged.
- <table_log>: the name of the incremental data table.
- <table_base>: the name of the full baseline table.
- <timestamp>: the timestamp that is generated when full data is obtained.

Run the following SQL statements to obtain full data of the customer table at the 1565944878 time point:

```

set odps.sql.allow.fullscan=true;
insert overwrite table customer_1565944878
select id,
       register_time,
       address
from(
select row_number() over(partition by t.id
order by record_id desc, after_flag desc) as row_number, record_id, operation_flag, after_flag, id, register_time, address
from(
select incr.record_id, incr.operation_flag, incr.after_flag, incr.id, incr.register_time, incr.address
from customer_log incr
where utc_timestamp< 1565944878
union all
select 0 as record_id, 'I' as operation_flag, 'Y' as after_flag, base.id, base.register_time, base.address
from customer_base base) t) gt
where gt.row_number= 1
and gt.after_flag= 'Y';
    
```

3. Query the merged data from the customer_1565944878 table.

	A	B	C
1	id	register_time	address
2	1	2017-12-09 14:00:12	
3	2	2017-11-16 21:17:39	
4	3	2019-01-29 07:56:20	

19.4.4.3. Synchronize data from an ApsaraDB RDS for MySQL instance to an AnalyticDB for MySQL cluster

AnalyticDB for MySQL is a real-time online analytical processing (RT-OLAP) service that is developed by Alibaba Cloud for online data analysis with high concurrency. This topic describes how to synchronize data from an ApsaraDB RDS for MySQL instance to an AnalyticDB for MySQL cluster by using Data Transmission Service (DTS). After you synchronize data, you can use AnalyticDB for MySQL to build internal business intelligence (BI) systems, interactive query systems, and real-time report systems.

Prerequisites

- The tables that you want to synchronize from the ApsaraDB RDS for MySQL instance contain primary keys.
- The destination AnalyticDB for MySQL cluster has sufficient storage space.

Precautions

- DTS uses the read and write resources of the source and destination databases during initial full data synchronization. This may increase the load of the database server. Before you synchronize data, evaluate the impact of data synchronization on the performance of the source and destination databases. We recommend that you synchronize data during off-peak hours.
- If you select one or more tables (not a database) as the required objects, do not use gh-ost or pt-online-schema-change to perform data definition language (DDL) operations on the tables during data synchronization. Otherwise, data may fail to be synchronized.
- If the disk space usage of nodes in an AnalyticDB for MySQL cluster reaches 80%, the cluster is locked. We recommend that you estimate the required disk space based on the objects to be synchronized. You must ensure that the destination cluster has sufficient storage space.

SQL operations that can be synchronized

- Data definition language (DDL) operations: CREATE TABLE, DROP TABLE, RENAME TABLE, TRUNCATE TABLE, ADD COLUMN, and DROP COLUMN
- Data manipulation language (DML) operations: INSERT, UPDATE, and DELETE

 **Note** We recommend that you do not change the data type of fields in the source table during data synchronization. Otherwise, DTS generates an error message and stops the data synchronization task.

Data type mappings

The data types of ApsaraDB RDS for MySQL and AnalyticDB for MySQL do not have one-to-one correspondence. During initial schema synchronization, DTS converts the data types of the source database into those of the destination database. The following table lists the data types that DTS can convert.

Data type of ApsaraDB RDS for MySQL	Data type of AnalyticDB for MySQL
BIGINT UNSIGNED	DECIMAL(20,0)
BINARY	VARBINARY
BIT	VARCHAR
BLOB	VARBINARY
CHAR	VARCHAR
DATE	DATE
DATETIME	DATETIME
DECIMAL	DECIMAL
DOUBLE	DOUBLE
ENUM	VARCHAR
FLOAT	FLOAT
GEOMETRY	VARBINARY
GEOMETRYCOLLECTION	VARBINARY
INT UNSIGNED	BIGINT
INTEGER	INT
JSON	JSON
LINestring	VARBINARY
LOBLOB	VARBINARY
LONGTEXT	VARCHAR
MEDIUMBLOB	VARBINARY
MEDIUMINT	INT
MEDIUMINT UNSIGNED	INT

Data type of ApsaraDB RDS for MySQL	Data type of AnalyticDB for MySQL
MEDIUMTEXT	VARCHAR
MULTILINESTRING	VARBINARY
MULTIPOINT	VARBINARY
MULTIPOLYGON	VARBINARY
NUMERIC	DECIMAL
POINT	VARBINARY
POLYGON	VARBINARY
SET	VARCHAR
SMALLINT UNSIGNED	INT
TEXT	VARCHAR
TIME	TIME
TIMESTAMP	TIMESTAMP
TINYBLOB	VARBINARY
TINYINT UNSIGNED	SMALLINT
TINYTEXT	VARCHAR
VARBINARY	VARBINARY
VARCHAR	VARCHAR
YEAR	INT

Procedure

1. **Create a data synchronization instance.**

 **Note** When you create the data synchronization instance, set Source Instance Type to **MySQL**, set Destination Instance Type to **AnalyticDB**, and set Synchronization Mode to **One-Way Synchronization**.

2. Find the data synchronization instance, and click **Configure Synchronization Channel** in the **Actions** column.
3. Configure the source and destination instances.

1. Select Source and Destination Instances for
2. Authorize AnalyticDB Account
3. Select Object to Be Synchronized
4. Precheck

Synchronization Task Name:

Source Instance Details

Instance Type:

Instance Region:

* Instance ID:

* Database Account:

* Database Password:

* Encryption: Non-encrypted SSL-encrypted

Destination Instance Details

Instance Type:

Instance Region:

* Version: 2.0 3.0

* Database:

* Database Account:

* Database Password:

Section	Parameter	Description
N/A	Synchronization Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Instance Details	Instance Type	Select RDS Instance.
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Instance ID	Select the ID of the source RDS instance.
	Database Account	Enter the database account of the source RDS instance. The account must have the REPLICATION CLIENT permission, the REPLICATION SLAVE permission, the SHOW VIEW permission, and the permission to perform SELECT operations on the required objects. 🔔 Note If the database engine of the source RDS instance is MySQL 5.5 or MySQL 5.6, you do not need to configure the database account or database password.
	Database Password	Enter the password of the source database account.
	Encryption	Select an encryption method. If you select SSL-encrypted, you must enable SSL encryption for the RDS instance before you configure the data synchronization task.
	Instance Type	This parameter is set to AnalyticDB and cannot be changed.

Section	Parameter	Description
Destination Instance Details	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Version	Select 3.0.
	Database	Select the ID of the destination AnalyticDB for MySQL cluster.
	Database Account	Enter the database account of the destination AnalyticDB for MySQL cluster. The account must have the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.

5. Configure the synchronization policy and objects.

Parameter	Description
Initial Synchronization	You must select both Initial Schema Synchronization and Initial Full Data Synchronization in most cases. After the precheck, DTS synchronizes the schemas and data of the required objects from the source instance to the destination cluster. The schemas and data are the basis for subsequent incremental synchronization.

Parameter	Description
Processing Mode In Existed Target Table	<ul style="list-style-type: none"> ◦ Pre-check and Intercept: checks whether the destination database contains tables that have the same names as tables in the source database. If the source and destination databases do not contain identical table names, the precheck is passed. Otherwise, an error is returned during precheck and the data synchronization task cannot be started. ◦ Ignore: skips the precheck for identical table names in the source and destination databases. <div style="background-color: #fff9c4; padding: 10px; margin-top: 10px;"> <p> Warning If you select Ignore, data consistency is not guaranteed and your business may be exposed to potential risks.</p> <ul style="list-style-type: none"> ▪ DTS does not synchronize the data records that have the same primary keys as the data records in the destination database during initial data synchronization. This occurs if the source and destination databases have the same schema. However, DTS synchronizes these data records during incremental data synchronization. ▪ If the source and destination databases have different schemas, initial data synchronization may fail. In this case, only specific columns are synchronized or the data synchronization task fails. </div>
Merge Multi Tables	<ul style="list-style-type: none"> ◦ If you select Yes, DTS adds the <code>__dts_data_source</code> column to each table to record data sources. In this case, DDL operations cannot be synchronized. ◦ No is selected by default. In this case, DDL operations can be synchronized. <div style="background-color: #e1f5fe; padding: 10px; margin-top: 10px;"> <p> Note You can merge the data source columns based on tasks rather than tables. To merge only the data source columns of specific tables, you can create two data synchronization tasks.</p> </div>
Synchronization Type	<p>Select the types of operations that you want to synchronize based on your business requirements. All operation types are selected by default.</p> <div style="background-color: #e1f5fe; padding: 10px; margin-top: 10px;"> <p> Note Only the INSERT, UPDATE, DELETE, and ADD COLUMN operations can be synchronized.</p> </div>
Select Objects	<p>Select objects (tables or a database) from the Available section and click the  icon to move the objects to the Selected section.</p> <div style="background-color: #e1f5fe; padding: 10px; margin-top: 10px;"> <p> Note</p> <ul style="list-style-type: none"> ◦ If you select a database as the object to be synchronized, all schema changes in the database are synchronized to the destination database. ◦ After an object is synchronized to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are synchronized to the destination instance. For more information, see Specify the name of an object in the destination instance. </div>

6. In the lower-right corner of the page, click **Next**.

7. Specify a type for the tables that you want to synchronize to the destination database.

1. Configure Source and Destination Instances		2. Authorize AnalyticDB Account		3. Select Objects to Synchronize		4. Precheck	
AnalyticDB Table Group	AnalyticDB Table Name	Type(All) ▾	Primary Key Column	Distribution Column	Definition Status(All) ▾		
dstestdata	customer	Partitioned 1 ▾	id	id ▾	Defined		
dstestdata	order	Partitioned 1 ▾	orderid	orderid ▾	Defined		

[Set All to Partitioned Table](#)
[Set All to Dimension Table](#)

Total: 2 item(s), Per Page: 20 ▾ item(s) << < 1 > >>

Note After you select Initial Schema Synchronization, you must specify the type, primary key column, and partition key column for the tables that you want to synchronize to AnalyticDB for MySQL.

8. In the lower-right corner of the page, click **Precheck**.

Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

9. Close the Precheck dialog box after the following message is displayed: **The precheck is passed.** Then, DTS performs initial synchronization.

19.4.4.4. Synchronize data from an ApsaraDB RDS for MySQL instance to an AnalyticDB for PostgreSQL instance

This topic describes how to synchronize data from an ApsaraDB RDS for MySQL instance to an AnalyticDB for PostgreSQL instance by using Data Transmission Service (DTS). The data synchronization feature allows you to transfer and analyze data with ease.

Prerequisites

- The tables that you want to synchronize contain primary keys.
- An AnalyticDB for PostgreSQL instance is created.

Precautions

- If you select one or more tables (not a database) as the required objects, do not use gh-ost or pt-online-schema-change to perform data definition language (DDL) operations on the tables during data synchronization. Otherwise, data may fail to be synchronized.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- Only one-way synchronization is supported.

Limits

- You can select only tables as the objects to be synchronized.
- DTS does not synchronize the schemas of the required objects from the source database to the destination database.
- DTS does not synchronize the following types of data: JSON, GEOMETRY, CURVE, SURFACE, MULTIPOINT, MULTILINESTRING, MULTIPOLYGON, GEOMETRYCOLLECTION, and BYTEA.

SQL operations that can be synchronized

- Data manipulation language (DML) operations: INSERT, UPDATE, and DELETE
- Data definition language (DDL) operations: ALTER TABLE, ADD COLUMN, DROP COLUMN, and RENAME COLUMN

 **Note** The CREATE TABLE and DROP TABLE operations are not supported. To synchronize data from a new table, you must add the table to the selected objects. For more information, see [Add objects to be synchronized](#).

Term mappings

Term in ApsaraDB RDS for MySQL	Term in AnalyticDB for PostgreSQL
Database	Schema
Table	Table

Create a data structure in the destination instance

Create a database, schema, and table in the destination AnalyticDB for PostgreSQL instance based on the data structure of the source RDS instance.

Configure a data synchronization task

1. [Create a data synchronization instance](#).

 **Note** When you create the data synchronization instance, set Source Instance Type to **MySQL**, set Destination Instance Type to **AnalyticDB for PostgreSQL**, and set Synchronization Mode to **One-Way Synchronization**.

2. Find the data synchronization instance, and click **Configure Synchronization Channel** in the **Actions** column.
3. Configure the source and destination instances.

Section	Parameter	Description
N/A	Synchronization Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Instance Details	Instance Type	Select RDS Instance .
	Instance Region	The region where the source RDS instance resides.
	Instance ID	Select the ID of the source RDS instance.
	Encryption	Select Non-encrypted or SSL-encrypted .  Note If you select SSL-encrypted , you must enable SSL encryption for the RDS instance before you configure the data synchronization task.
Destination Instance	Instance Type	This parameter is set to AnalyticDB for PostgreSQL and cannot be changed.
	Instance Region	The region where the destination instance resides.
	Instance ID	Select the ID of the destination AnalyticDB for PostgreSQL instance.
	Database Name	Enter the name of the destination database.

Destination Instance Details	Parameter	Description
	Database Account	<p>Enter the database account of the destination AnalyticDB for PostgreSQL instance.</p> <p>Note The database account must have the SELECT, INSERT, UPDATE, DELETE, COPY, TRUNCATE, and ALTER TABLE permissions.</p>
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. Wait until the synchronization account is created. Then, click **Next**.
6. Configure the synchronization policy and objects.

Section	Parameter	Description
Synchronization policy	Initial Synchronization	<p>Select Initial Full Data Synchronization.</p> <p>Note DTS synchronizes the historical data of the required objects from the source instance to the destination instance. The historical data is the basis for subsequent incremental synchronization.</p>
	Processing Mode In Existed Target Table	<ul style="list-style-type: none"> ◦ Pre-Check and intercept (Selected by default) Checks the Schema Name Conflict item and generates an error message if the destination table contains data. ◦ Clear Target Table Skips the Schema Name Conflict item during the precheck. Clears the data in the destination table before initial full data synchronization. If you want to synchronize your business data after testing the data synchronization task, you can select this mode. ◦ Ignore Skips the Schema Name Conflict item during the precheck. Adds data to the existing data during initial full data synchronization. If you want to synchronize data from multiple tables to one table, you can select this mode.
	Synchronization Type	<ul style="list-style-type: none"> ◦ Insert ◦ Update ◦ Delete ◦ AlterTable <p>Note Select the types of operations that you want to synchronize based on your business requirements.</p>

Section	Parameter	Description
Select Objects	N/A	<p>You can select only tables as the objects to be synchronized. You can use the object name mapping feature to change the names of the columns that are synchronized to the destination database. For more information, see Specify the name of an object in the destination instance.</p> <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px;"> <p> Note The CREATE TABLE operation is not supported. To synchronize data from a new table, you must add the table to the selected objects. For more information, see Add objects to be synchronized.</p> </div>

7. In the lower-right corner of the page, click **Precheck**.

 **Note** You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

8. Close the Precheck dialog box after the following message is displayed: **The precheck is passed**. Then, DTS performs initial synchronization.

19.4.4.5. Synchronize data between Cloud Native Distributed Database PolarDB-X instances

Cloud Native Distributed Database PolarDB-X is formerly known as Distributed Relational Database Service (DRDS). It is compatible with the MySQL protocol and syntax, and supports automatic sharding, online smooth scaling, auto scaling, and transparent read/write splitting. This topic describes how to synchronize data between Cloud Native Distributed Database PolarDB-X instances by using Data Transmission Service (DTS).

Prerequisites

The tables that you want to synchronize contain primary keys.

Precautions

- DTS uses the read and write resources of the source and destination databases during initial full data synchronization. This may increase the load of the database server. Before you synchronize data, evaluate the impact of data synchronization on the performance of the source and destination databases. We recommend that you synchronize data during off-peak hours.
- We recommend that you do not change the network type of the Cloud Native Distributed Database PolarDB-X instances during data synchronization.

 **Note** After you change the network type of a Cloud Native Distributed Database PolarDB-X instance during data synchronization, you must submit a ticket to resume the data synchronization instance.

- We recommend that you do not scale up or down the databases in the Cloud Native Distributed Database PolarDB-X instances. Otherwise, data may fail to be synchronized.

Supported synchronization topologies

DTS supports the following synchronization topologies: one-way one-to-one synchronization, one-way one-to-many synchronization, one-way cascade synchronization, and one-way many-to-one synchronization. For more information, see [Synchronization topologies](#).

SQL operations that can be synchronized

The INSERT, UPDATE, and DELETE operations can be synchronized.

Before you begin

Create a database and tables in the destination instance based on the schemas of the objects in the source instance. This is because DTS does not support initial schema synchronization between Cloud Native Distributed Database PolarDB-X instances.

Note During initial schema synchronization, DTS synchronizes the schemas of the required objects from the source database to the destination database.

Procedure

1. **Create a data synchronization instance.**

Note When you create the data synchronization instance, set both Source Instance Type and Destination Instance Type to **Drds**, and set Synchronization Mode to **One-Way Synchronization**.

2. Find the data synchronization instance, and click **Configure Synchronization Channel** in the **Actions** column.
3. Configure the source and destination instances.

1. Select Source and Destination
2. Select Object to Be Synchronized
3. Advanced Settings
4. Precheck

Synchronization Task Name:

Section	Parameter	Description
N/A	Synchronization Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Instance Details	Instance Type	This parameter is set to DRDS Instance and cannot be changed.
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	DRDS Instance ID	Select the ID of the source Cloud Native Distributed Database PolarDB-X instance.

Section	Parameter	Description
Destination Instance Details	Instance Type	This parameter is set to DRDS Instance and cannot be changed.
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	DRDS Instance ID	Select the ID of the destination Cloud Native Distributed Database PolarDB-X instance.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.

5. Configure the synchronization policy and objects.

Parameter	Description
-----------	-------------

Parameter	Description
Processing Mode In Existed Target Table	<ul style="list-style-type: none"> ◦ Pre-check and Intercept: checks whether the destination tables are empty. If the destination tables are empty, the precheck is passed. If the tables are not empty, an error is returned during the precheck and the data synchronization task cannot be started. ◦ Ignore: skips the check for empty destination tables. <div style="background-color: #fff9c4; padding: 10px; margin-top: 10px;"> <p> Warning If you select Ignore, data consistency is not guaranteed and your business may be exposed to potential risks.</p> <ul style="list-style-type: none"> ▪ If the source and destination databases have the same schema, DTS does not synchronize the data records that have the same primary keys as the data records in the destination database. ▪ If the source and destination databases have different schemas, initial data synchronization may fail. In this case, only specific columns are synchronized or the data synchronization task fails. </div>
Select Objects	<p>Select tables from the Available section and click the  icon to move the tables to the Selected section.</p> <div style="background-color: #e1f5fe; padding: 10px; margin-top: 10px;"> <p> Note</p> <ul style="list-style-type: none"> ◦ You can select only tables as the objects to be synchronized. ◦ After an object is synchronized to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are synchronized to the destination instance. For more information, see Specify the name of an object in the destination instance. </div>

6. Click **Next**.

7. Specify whether you want to perform initial full data synchronization.

 **Note** During initial full data synchronization, DTS synchronizes the historical data of the required objects from the source database to the destination database. If you do not select Initial Full Data Synchronization, DTS does not synchronize the historical data.

8. In the lower-right corner of the page, click **Precheck**.

 **Note** You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

9. Close the **Precheck** dialog box after the following message is displayed: **The precheck is passed**. Then, DTS

performs initial synchronization.

19.4.4.6. Synchronize data from a Cloud Native Distributed Database PolarDB-X instance to an AnalyticDB for MySQL cluster

This topic describes how to synchronize data from a Cloud Native Distributed Database PolarDB-X instance to an AnalyticDB for MySQL cluster by using Data Transmission Service (DTS).

Prerequisites

The tables that you want to synchronize contain primary keys.

Precautions

- If you select one or more tables (not a database) as the required objects, do not use gh-ost or pt-online-schema-change to perform data definition language (DDL) operations on the tables during data synchronization. Otherwise, data may fail to be synchronized.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- Only one-way synchronization is supported.

Supported synchronization topologies

DTS supports the following synchronization topologies: one-way one-to-one synchronization, one-way one-to-many synchronization, and one-way many-to-one synchronization. For more information, see [Synchronization topologies](#).

SQL operations that can be synchronized

The INSERT, UPDATE, and DELETE operations can be synchronized.

Data type mappings

The data types of ApsaraDB RDS for MySQL and AnalyticDB for MySQL do not have one-to-one correspondence. During initial schema synchronization, DTS converts the data types of the source database into those of the destination database. The following table lists the data types that DTS can convert.

Data type of ApsaraDB RDS for MySQL	Data type of AnalyticDB for MySQL
BIGINT UNSIGNED	DECIMAL(20,0)
BINARY	VARBINARY
BIT	VARCHAR
BLOB	VARBINARY
CHAR	VARCHAR
DATE	DATE
DATETIME	DATETIME
DECIMAL	DECIMAL
DOUBLE	DOUBLE
ENUM	VARCHAR
FLOAT	FLOAT

Data type of ApsaraDB RDS for MySQL	Data type of AnalyticDB for MySQL
GEOMETRY	VARBINARY
GEOMETRYCOLLECTION	VARBINARY
INT UNSIGNED	BIGINT
INTEGER	INT
JSON	JSON
LINESTRING	VARBINARY
LOB	VARBINARY
LONGTEXT	VARCHAR
MEDIUMBLOB	VARBINARY
MEDIUMINT	INT
MEDIUMINT UNSIGNED	INT
MEDIUMTEXT	VARCHAR
MULTILINESTRING	VARBINARY
MULTIPOINT	VARBINARY
MULTIPOLYGON	VARBINARY
NUMERIC	DECIMAL
POINT	VARBINARY
POLYGON	VARBINARY
SET	VARCHAR
SMALLINT UNSIGNED	INT
TEXT	VARCHAR
TIME	TIME
TIMESTAMP	TIMESTAMP
TINYBLOB	VARBINARY
TINYINT UNSIGNED	SMALLINT
TINYTEXT	VARCHAR
VARBINARY	VARBINARY
VARCHAR	VARCHAR
YEAR	INT

Procedure

1. Create a data synchronization instance.

Note When you create the data synchronization instance, set Source Instance Type to Drds, set Destination Instance Type to AnalyticDB, and set Synchronization Mode to One-Way Synchronization.

2. Find the data synchronization instance, and click **Configure Synchronization Channel** in the **Actions** column.

3. Configure the source and destination instances.

Section	Parameter	Description
N/A	Synchronization Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Instance Details	Instance Type	This parameter is set to DRDS Instance and cannot be changed.
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	DRDS Instance ID	Select the ID of the source Cloud Native Distributed Database PolarDB-X instance.
Destination Instance Details	Instance Type	This parameter is set to AnalyticDB and cannot be changed.
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Version	Select 3.0 .
	Database	Select the ID of the destination AnalyticDB for MySQL cluster.
	Database Account	Enter the database account of the destination AnalyticDB for MySQL cluster.
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.

5. Configure the synchronization policy and objects

Section	Parameter	Description
	Initial Synchronization	You must select both Initial Schema Synchronization and Initial Full Data Synchronization in most cases. After the precheck, DTS synchronizes the schemas and data of the required objects from the source instance to the destination cluster. The schemas and data are the basis for subsequent incremental synchronization.

Section	Parameter	Description
Synchronization policy	Processing Mode In Existed Target Table	<ul style="list-style-type: none"> ◦ Clear Target Table Skips the Schema Name Conflict item during the precheck. Clears the data in the destination table before initial full data synchronization. If you want to synchronize your business data after testing the data synchronization task, you can select this mode. ◦ Ignore Skips the Schema Name Conflict item during the precheck. Adds data to the existing data during initial full data synchronization. If you want to synchronize data from multiple tables to one table, you can select this mode.
	Synchronization Type	<p>Select the types of operations that you want to synchronize based on your business requirements.</p> <ul style="list-style-type: none"> ◦ Insert ◦ Update ◦ Delete
Select Objects	N/A	<p>Select tables from the Available section and click the  icon to move the tables to the Selected section.</p> <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 10px; margin-top: 10px;"> <p>Note</p> <ul style="list-style-type: none"> ◦ You can select only tables as the objects to be synchronized. ◦ You can use the object name mapping feature to change the names of the columns that are synchronized to the destination database. For more information, see Specify the name of an object in the destination instance. </div>

6. Click **Next**.

7. Specify a type for the tables that you want to synchronize to the destination database.

1. Configure Source and Destination Instances
2. Authorize AnalyticDB Account
3. Select Objects to Synchronize
4. Precheck

AnalyticDB Table Group	AnalyticDB Table Name	Type(All) ▼	Primary Key Column	Distribution Column	Definition Status(All) ▼
dtstestdata	customer	Partitioned 1 ▼	id	id ▼	Defined
dtstestdata	order	Partitioned 1 ▼	orderid	orderid ▼	Defined

[Set All to Partitioned Table](#)
[Set All to Dimension Table](#)

Total: 2 item(s), Per Page: 20 item(s) « < 1 > »

Note After you select **Initial Schema Synchronization**, you must specify the type, primary key column, and partition key column for the tables that you want to synchronize to AnalyticDB for MySQL.

8. In the lower-right corner of the page, click **Precheck**.

 **Note** You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

9. Close the Precheck dialog box after the following message is displayed: **The precheck is passed.** Then, DTS performs initial synchronization.

19.4.4.7. Synchronize data from a Cloud Native Distributed Database PolarDB-X instance to a DataHub instance

This topic describes how to synchronize data from a Cloud Native Distributed Database PolarDB-X instance to a DataHub instance by using Data Transmission Service (DTS). After you synchronize data, you can use big data services such as Realtime Compute to analyze data in real time.

Prerequisites

- The tables that you want to synchronize have PRIMARY KEY or UNIQUE constraints.
- A DataHub project is created to receive the synchronized data.

Precautions

- If you select one or more tables (not a database) as the required objects, do not use gh-ost or pt-online-schema-change to perform data definition language (DDL) operations on the tables during data synchronization. Otherwise, data may fail to be synchronized.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- Only one-way synchronization is supported.

Limits

- You can select only tables as the objects to be synchronized.
- Initial full data synchronization is not supported. DTS does not synchronize the historical data of the required objects from the source PolarDB-X instance to the destination DataHub instance.
- DTS does not synchronize data definition language (DDL) operations to the destination database. If you perform a DDL operation on the source PolarDB-X instance during data synchronization, data fails to be synchronized. To solve this issue, you must modify the related topic in the destination DataHub instance and then restart the data synchronization task.

SQL operations that can be synchronized

The INSERT, UPDATE, and DELETE operations can be synchronized.

Procedure

1. [Create a data synchronization instance.](#)

 **Note** When you create the data synchronization instance, set Source Instance Type to Drds, set Destination Instance Type to Datahub, and set Synchronization Mode to One-Way Synchronization.

2. Find the data synchronization instance, and click **Configure Synchronization Channel** in the **Actions** column.
3. Configure the source and destination instances.

Section	Parameter	Description
---------	-----------	-------------

Section	Parameter	Description
N/A	Synchronization Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Instance Details	Instance Type	This parameter is set to DRDS Instance and cannot be changed.
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	DRDS Instance ID	Select the ID of the source Cloud Native Distributed Database PolarDB-X instance.
Destination Instance Details	Instance Type	This parameter is set to DataHub and cannot be changed.
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Project	Select the name of the DataHub project.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.

5. Configure the synchronization policy and objects.

Parameter	Description
Initial Synchronization	<p>Select Initial Schema Synchronization.</p> <p> Note After you select Initial Schema Synchronization, DTS synchronizes the schemas of the required objects (such as tables) to the destination DataHub instance.</p>
Select Objects	<p>Select objects from the Available section and click the  icon to move the objects to the Selected section.</p> <p> Note</p> <ul style="list-style-type: none"> ◦ You can select only tables as the objects to be synchronized. ◦ You can use the object name mapping feature to change the names of the columns that are synchronized to the destination database. For more information, see Specify the name of an object in the destination instance.

6. In the lower-right corner of the page, click **Precheck**.

 **Note** You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

7. Close the **Precheck** dialog box after the following message is displayed: **The precheck is passed**. Then, DTS performs initial synchronization.

19.4.4.8. Configure two-way data synchronization between RDS instances

19.4.4.8.1. Overview

DTS supports two-way real-time data synchronization between RDS instances on any two clouds. This section describes how to use DTS to create a two-way synchronization task between two ApsaraDB RDS for MySQL instances for active geo-redundancy, geo-disaster recovery, and other scenarios.

19.4.4.8.2. Supported synchronization statements

Two-way synchronization between ApsaraDB RDS for MySQL instances supports all DML updates (including INSERT, UPDATE, and DELETE) and the following DDL updates:

- ALTER TABLE, ALTER VIEW, ALTER FUNCTION, and ALTER PROCEDURE
- CREATE DATABASE, CREATE SCHEMA, CREATE INDEX, CREATE TABLE, CREATE PROCEDURE, CREATE FUNCTION, CREATE TRIGGER, CREATE VIEW, and CREATE EVENT
- DROP FUNCTION, DROP EVENT, DROP INDEX, DROP PROCEDURE, DROP TABLE, DROP TRIGGER, and DROP VIEW
- RENAME TABLE and TRUNCATE TABLE

 **Note** To ensure the stability of a two-way synchronization channel, you can synchronize DDL updates on the same table in only one direction.

For example, for two-way synchronization, you must enable DDL synchronization in either the A-to-B or B-to-A direction. If DDL synchronization is configured in one direction, it is not supported in the reverse direction. You can only perform DML synchronization.

19.4.4.8.3. Detect and resolve conflicts

To ensure data consistency, for two-way synchronized instances, make sure that records with the same primary key, business primary key, or unique key are updated only on one of the instances. If you unexpectedly update a record with the same primary key, business primary key, or unique key on both instances that are two-way synchronized, a synchronization conflict occurs. To maximize the stability of two-way synchronized instances, DTS supports detecting and resolving data conflicts.

Considerations

During two-way synchronization, the system time of the source and destination instances may not be the same. Additionally, synchronization delays may occur. For these reasons, DTS cannot guarantee that its conflict detection mechanism can completely prevent data conflicts. You must refactor certain business logic to ensure that records of the same primary key, business primary key, or unique key are updated only on one of the instances that are two-way synchronized.

Supported conflict types

Currently, DTS supports detecting the following conflict types:

- Uniqueness conflicts caused by INSERT operations

A uniqueness conflict occurs when the synchronization of an inserted row violates the unique constraint. For example, if two instances in two-way synchronization insert a record with the same primary key value at almost the same time, one of the inserted records fails to be synchronized because a record with the same primary key value already exists in the destination instance.

- Inconsistent records caused by UPDATE operations

Update conflicts occur in the following scenarios:

- The records to be updated do not exist in the destination instance. If the records to be updated do not exist, DTS automatically changes the UPDATE operation to the INSERT operation and inserts these records to the destination instance. In this case, duplicate unique key values may occur.
- The primary keys or unique keys of the records to be updated conflict with each other.
- A DELETE operation is made on non-existent records
A delete conflict occurs when the records to be deleted do not exist in the destination instance.
In this case, DTS automatically ignores the DELETE operation regardless of the conflict resolution policy that you have configured.

Supported conflict resolution policies

For the preceding synchronization conflicts, DTS provides the following resolution policies. You can select a conflict resolution policy as required when configuring two-way synchronization.

- **TaskFailed:** The synchronization task reports an error and automatically exits the process in case of a conflict.
When the synchronization encounters a conflict of the preceding types, the synchronization task reports an error and automatically exits the process. The task enters a failed state and you must manually resolve the conflict. This method is the default conflict resolution policy.
- **Ignore:** The records in the destination instance are used in case of a conflict.
When the synchronization encounters a conflict of the preceding types, the synchronization task skips the current synchronization statement and continues the process. The records in the destination instance are used.
- **Overwrite:** The conflict records in the destination instance are overwritten in case of a conflict.
When the synchronization encounters a conflict of the preceding types, the conflict records in the destination instance are overwritten.

19.4.4.8.4. Synchronization restrictions

This section describes the restrictions in cross-cloud data synchronization using DTS.

Restrictions in data sources

Currently, only ApsaraDB RDS for MySQL instances support two-way synchronization. Other heterogeneous data sources do not support two-way synchronization.

The destination instance cannot be an RDS instance that runs in standard access mode and has only a public network address.

Restrictions in synchronization architecture

Currently, DTS only supports two-way synchronization between two ApsaraDB RDS for MySQL instances. Two-way synchronization between more than two instances is not supported.

Feature restrictions

- Incompatible with triggers

When you synchronize an entire database and the database contains a trigger that updates the synchronization table, the synchronized data may be inconsistent.

For example, the object to be synchronized is database A that contains table a and table b. Table a has a trigger that inserts a row to table b after the row is inserted to table a. In this case, if an INSERT operation is performed on table a in the source instance during synchronization, the data in table b is inconsistent between the source and destination instances.

To resolve this problem, you must delete the trigger in the destination instance, so that the data in table b is only synchronized from the source instance.

- Restrictions in the RENAME TABLE operation

The RENAME TABLE operation may result in inconsistent synchronization data. For example, if the object to be synchronized only includes table a and the rename a to b command is executed in the source instance during synchronization, subsequent operations to the renamed table b are not synchronized to the destination database. To solve this problem, you can synchronize the entire database where table a and table b are stored.

- Restrictions in DDL synchronization direction

To ensure the stability of a two-way synchronization channel, you can synchronize DDL updates on the same table in only one direction. For example, in A-to-B and B-to-A synchronization, you can implement DDL synchronization in either the A-to-B or B-to-A direction. If DDL synchronization is configured in one direction, it is not supported in the reverse direction.

19.4.4.8.5. Configure two-way data synchronization between ApsaraDB RDS for MySQL instances across regions

This topic describes how to configure two-way data synchronization between ApsaraDB RDS for MySQL instances across regions.

Prerequisites

The source and destination ApsaraDB RDS for MySQL instances are created.

Procedure

1. [Log on to the DTS console](#).
2. In the left-side navigation pane, click **Data Synchronization**.
3. On the **Synchronization Tasks** page, click **Create Synchronization Task** in the upper-right corner.

 **Note**

Source Instance Region: Select the region where the source RDS instance resides.

Source Instance Type: Select the type of the source instance. In this example, select MySQL.

Destination Instance Region: Select the region where the destination RDS instance resides.

Destination Instance Type: Select the type of the destination instance. In this example, select MySQL.

Synchronization Mode: Select the synchronization mode. In this example, select Two-Way Synchronization.

Instances to Create: Set the number of instances that you want to create.

4. After you configure the preceding information, click **Create**.

After you create a synchronization instance, go back to the **Synchronization Tasks** page. The new synchronization instance is in the Not Configured state and contains two synchronization tasks. You can configure two-way synchronization for the tasks.

5. Find one of the created synchronization tasks and click **Configure Synchronization Channel** in the Actions column.
6. Configure the parameters for the data synchronization task.
 - Synchronization Task Name

We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
 - RDS instance ID

You must specify the ID of the Apsara Stack tenant account to which the destination RDS instance belongs. You can then select an RDS instance ID from the Instance ID drop-down list.

After you complete the preceding configurations, click **Set Whitelist** and **Next** to configure the RDS instance whitelists.

7. Configure the RDS instance whitelists.

In this step, DTS adds the CIDR blocks of DTS servers to the whitelists of the source and destination RDS instances. This ensures that DTS servers can connect to the RDS instances and the data synchronization task can be created.

We recommend that you do not remove the CIDR blocks of DTS servers from the whitelists of the RDS instances. This ensures the stability of the data synchronization task.

Click **Next** to create a data synchronization account.

8. Create a data synchronization account in the destination RDS instance.

Create a data synchronization account named `dtssyncwriter` in the destination RDS instance. Do not delete the account during data synchronization. Otherwise, an interruption occurs.

9. Configure the synchronization policies and select the objects that you want to synchronize.

After you create a data synchronization account, you must configure the synchronization policies and select the objects that you want to synchronize.

- **Exclude DDL Statements**

Specify whether to synchronize DDL statements in a specific direction. To include DDL statements, select **No**. To exclude DDL statements, select **Yes**. If you select **No**, DTS does not synchronize the DDL operations that are performed on a table in the opposite direction.

- **DML Statements for Synchronization**

Select the types of DML operations that you want to synchronize. By default, **Insert**, **Update**, and **Delete** are selected.

- **Conflict Resolution Policy**

Select the resolution policy for synchronization conflicts. By default, **TaskFailed** is selected.

For example, if Node A is the primary business center and Node B is a secondary business center, you must give the priority to Node A. You must set the conflict resolution policy in the A-to-B direction to **Overwrite** and that in the B-to-A direction to **Ignore**.

- **Select Objects**

You can select databases and tables as the objects to be synchronized.

If you select an entire database, all schema changes such as the **CREATE TABLE** and **DROP VIEW** operations that performed on the objects in the database are synchronized to the destination database.

If you select a table, only the **DROP TABLE**, **ALTER TABLE**, **TRUNCATE TABLE**, **RENAME TABLE**, **CREATE INDEX**, and **DROP INDEX** operations that performed on this table are synchronized to the destination database.

10. Configure initial synchronization.

Initial synchronization is the first step to start the synchronization task. During initial synchronization, DTS synchronizes the schemas and data of the required objects from the source instance to the destination instance. The schemas and data are the basis for subsequent incremental synchronization.

Initial synchronization includes **initial schema synchronization** and **initial full data synchronization**. You must select both **Initial Schema Synchronization** and **Initial Full Data Synchronization** in most cases.

If the tables to be synchronized in one direction are also included in the objects to be synchronized in the opposite direction, DTS does not synchronize these tables during initial synchronization.

11. Run a precheck.

After the data synchronization task is configured, DTS performs a precheck. Close the **Precheck** dialog box after the task passes the precheck.

After the task is started, the task list appears. The task is in the **Performing Initial Sync** state. The duration of the initial synchronization depends on the data volume of the objects that you want to synchronize. After initial synchronization, the task status changes to **Synchronizing**. This indicates that the data synchronization task is created.

After the task is configured in one direction, the source and destination RDS instances of the task in the opposite direction cannot be changed.

12. Repeat steps 5 to 11 to configure the data synchronization task in the opposite direction.

19.4.5. Manage data synchronization instances

19.4.5.1. Specify the name of an object in the destination instance

After an object, such as a database or table, is synchronized from the source instance to the destination instance, the name of the object remains unchanged. You can use the object name mapping feature provided by DTS to specify a different name for the object in the destination instance.

Notes

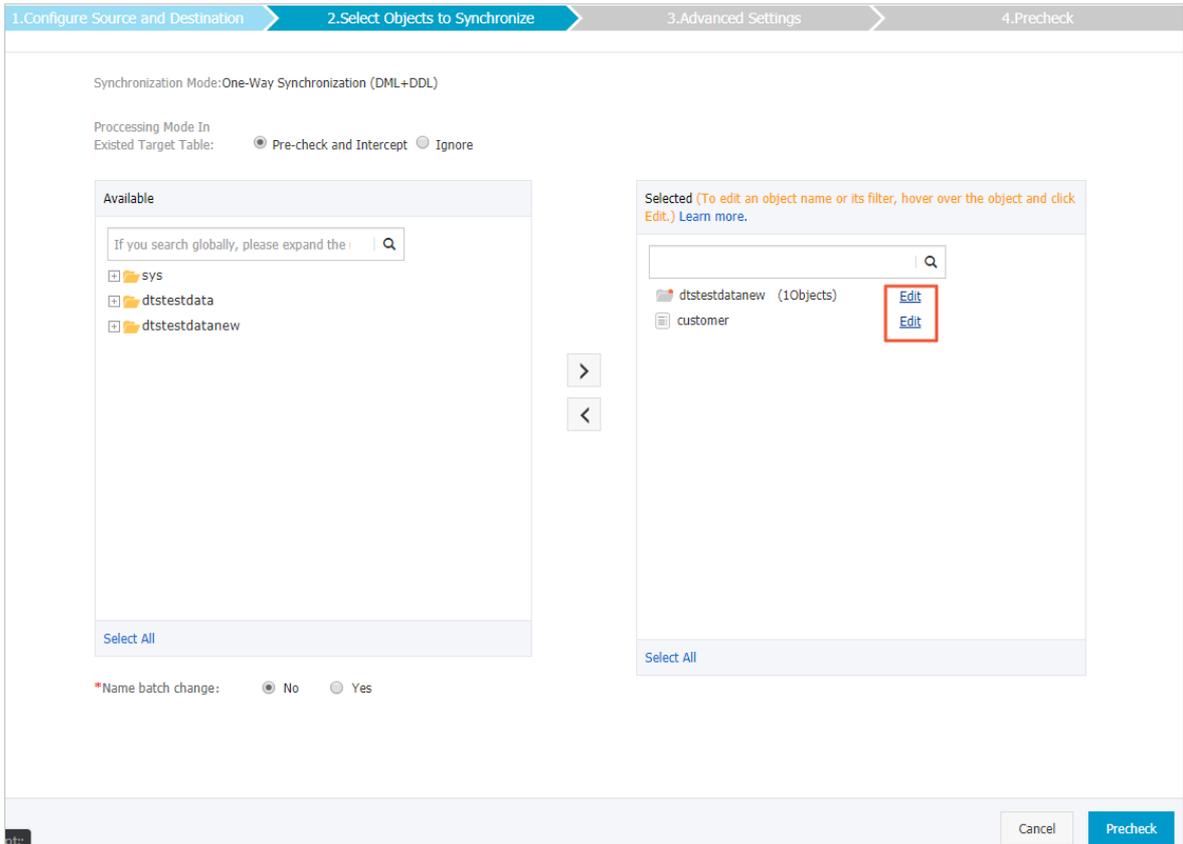

You can perform this operation only when a data synchronization task is configured and the current process is **Select Objects to Synchronize**.

 **Note** Do not perform this operation after the data synchronization task is started. Otherwise, the synchronization may fail.

Procedure

1. On the **Select Objects to Synchronize** page, move the required objects to the **Selected** section, move the pointer over a database or table, and then click **Edit**.

 **Note** Different database types support different objects. If **Edit** appears when you move the pointer over the target object, the operation is supported.

2. In the dialog box that appears, specify a name for the object in the destination instance.

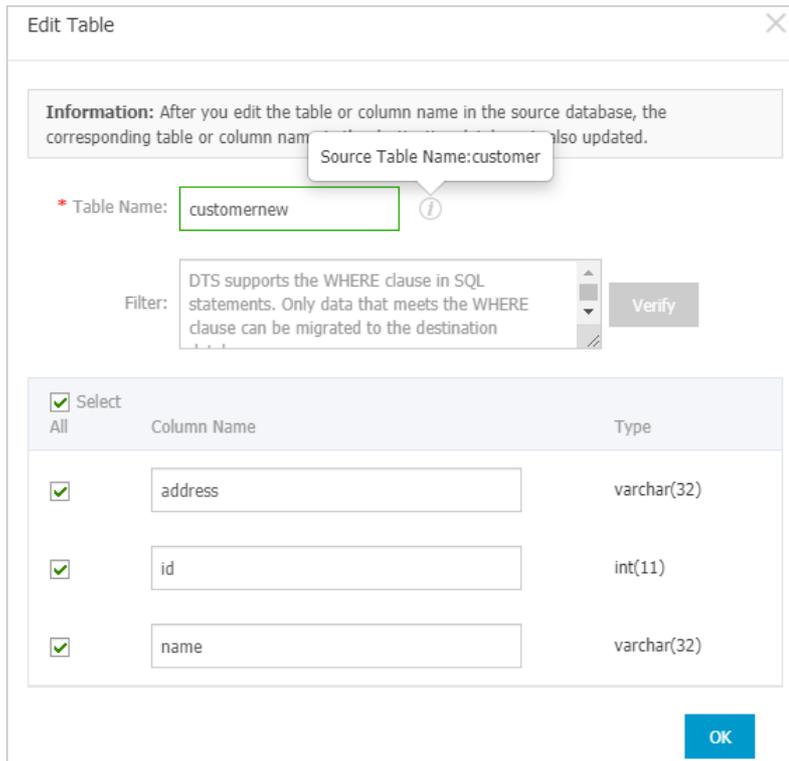

- o Database name mapping

In the **Edit Database Name** dialog box that appears, enter the database name that you want to use in the destination instance.

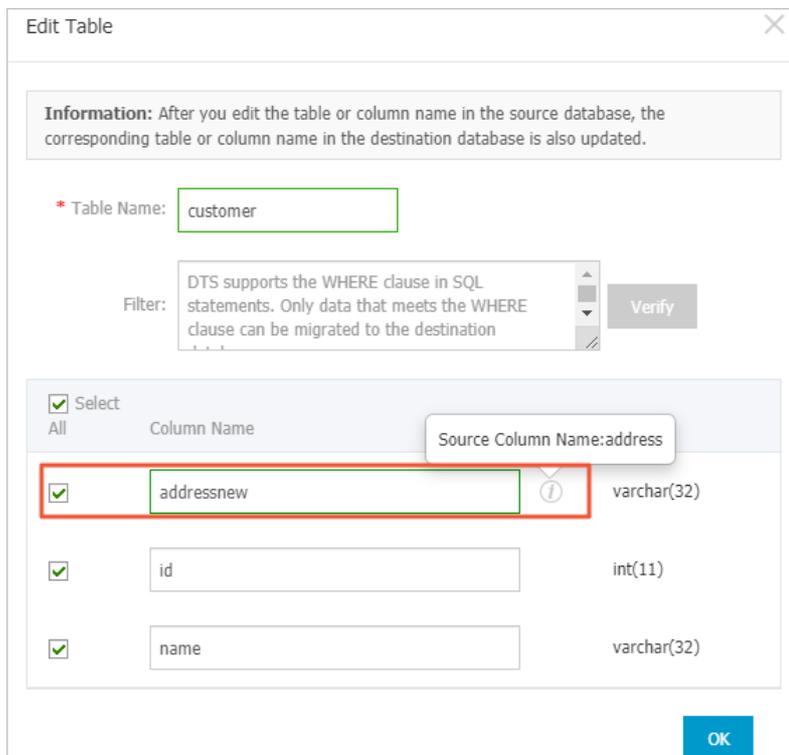

- o Table name mapping

In the **Edit Table** dialog box that appears, enter the table name that you want to use in the destination instance.

o Column name mapping

In the Edit Table dialog box that appears, enter a new name for each column.

Note In this step, you can deselect columns that do not need to be synchronized.

3. Click **OK**.

4. Configure other parameters that are required for the data synchronization task.

19.4.5.2. Check the synchronization performance

DTS provides the trend charts of data synchronization tasks based on three performance metrics: bandwidth, synchronization speed (TPS), and synchronization delay. You can view the running status of data synchronization tasks in the DTS console.

1. [Log on to the DTS console](#).
2. In the left-side navigation pane, click **Data Synchronization**.
3. On the Synchronization Tasks page, click the ID of the data synchronization task that you want to check.
The task details page appears.
4. On the task details page, click **Synchronization Performance** in the left-side navigation pane.
5. View the trend charts of synchronization performance.

DTS provides the trend charts of data synchronization tasks based on three performance metrics: bandwidth, synchronization speed (TPS), and synchronization delay.

- **Bandwidth:** the bandwidth of data that the data writing module pulls from the data pulling module per second. Unit: MB/s.
- **Synchronization speed (TPS):** the number of transactions that DTS synchronizes to the destination instance per second.
- **Synchronization delay:** the difference between the timestamp of the latest synchronized data in the destination instance and the current timestamp in the source instance. Unit: milliseconds.

19.4.5.3. Add objects to a data synchronization task

When a data synchronization task is running, you can add objects to the task or remove objects from the task. This topic describes how to add objects to a data synchronization task in the DTS console.

Limits

You can modify the required objects only when the data synchronization task is in the **Synchronizing** or **Synchronization Failed** state.

Start time of data synchronization

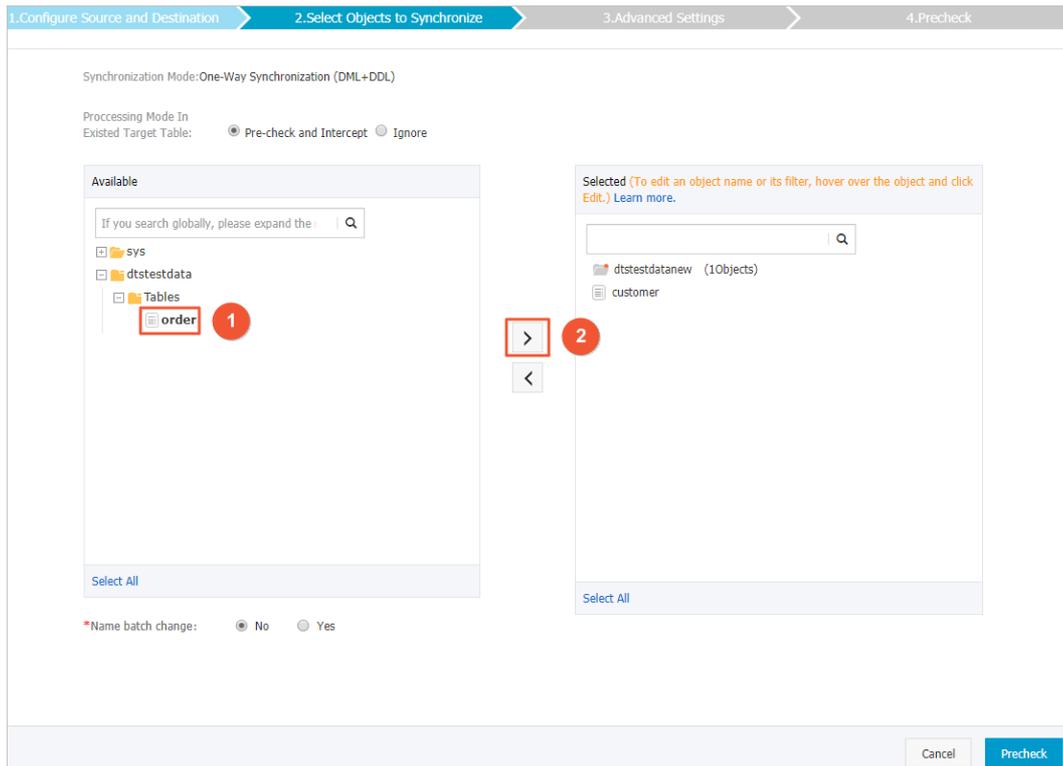

The time when DTS synchronizes data of new objects depends on whether initial synchronization is specified for the data synchronization task.

- If initial synchronization is specified, DTS synchronizes schemas and historical data, and then synchronizes incremental data.
- If initial synchronization is not specified, DTS synchronizes data after incremental data is generated on the source instance.

Procedure

1. [Log on to the DTS console](#).
2. In the left-side navigation pane, click **Data Synchronization**.
3. Find the data synchronization task and choose **More > Modify Objects to Synchronize** in the Actions column.
4. On the **Select Objects to Synchronize** tab, add objects based on your needs, as shown in [Add objects to a data synchronization task](#).

Add objects to a data synchronization task

5. Click Precheck.

After the task passes the precheck, the objects are added to the data synchronization task.

After the objects are added, if initial synchronization is specified for the data synchronization task, the task status changes from **Synchronizing** to **Synchronizing (The initial synchronization of the new objects is being performed.)**.

Note You can click **View More** to view the initial synchronization progress of the new objects. After the initial synchronization on the new objects is complete, the task status returns to **Synchronizing**.

19.4.5.4. Remove objects from a data synchronization task

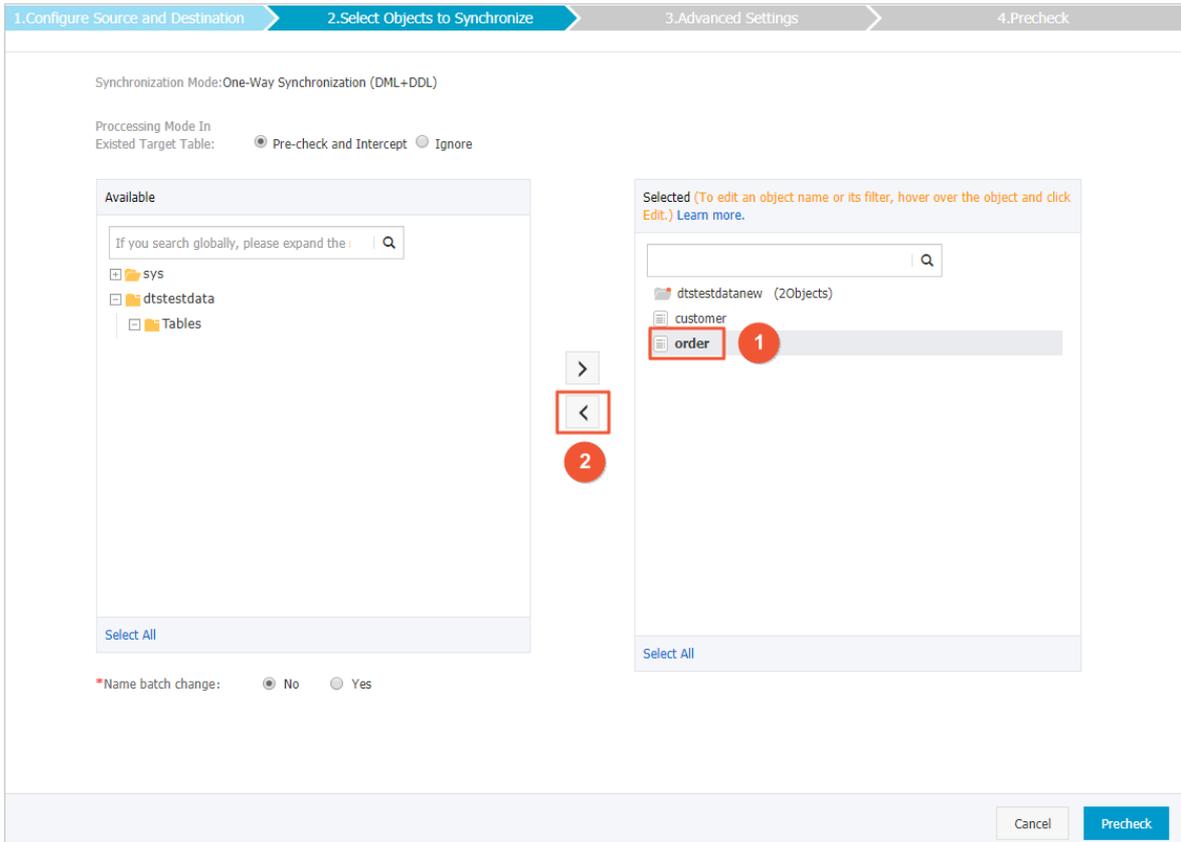

When a data synchronization task is running, you can add objects to the task or remove objects from the task. This topic describes how to remove objects from a data synchronization task in the DTS console.

Limits

You can modify the required objects only when the data synchronization task is in the **Synchronizing** or **Synchronization Failed** state.

Procedure

1. **Log on to the DTS console.**
2. In the left-side navigation pane, click **Data Synchronization**.
3. Find the data synchronization task and choose **More > Modify Objects to Synchronize** in the Actions column.
4. On the **Select Objects to Synchronize** tab, remove objects based on your needs.

5. Click **Precheck** to run a precheck.

19.4.5.5. Troubleshoot precheck failures

Before Data Transmission Service (DTS) runs a data synchronization task, DTS performs a precheck. This topic describes the precheck items and how to troubleshoot precheck failures.

Source database connectivity

- **Description**
DTS checks whether DTS servers can connect to the source RDS instance. DTS creates a connection to the source RDS instance by using the JDBC protocol. If the connection fails, the task fails to pass the precheck.
- **Cause of failure**
 - DTS does not support data synchronization between RDS instances in the region where the source instance resides.
 - The database account or password of the source instance is invalid.
- **Solution**
Submit a ticket and contact Alibaba Cloud technical support.

Destination database connectivity

- **Description**
DTS checks whether DTS servers can connect to the destination RDS instance. DTS creates a connection to the destination RDS instance by using the JDBC protocol. If the connection fails, the task fails to pass the precheck.
- **Cause of failure**
 - DTS does not support data synchronization between RDS instances in the region where the destination instance resides.

- The database account or password of the destination instance is invalid.

- **Solution**

Submit a ticket and contact Alibaba Cloud technical support.

Source database version

- **Description**

DTS checks whether:

- The database version of the source RDS instance is supported by the data synchronization feature.
- The database version of the destination RDS instance is the same as the database version of the source RDS instance.

- **Cause of failure**

- The database version of the source RDS instance is earlier than the supported database versions. The data synchronization feature supports the following database versions: MySQL 5.1, 5.5, 5.6, and 5.7.
- The database version of the destination RDS instance is earlier than the database version of the source RDS instance.

- **Solution**

- If the database version of the source RDS instance is earlier than the supported database versions, upgrade the source RDS instance to MySQL 5.6 or 5.7 in the RDS console. Then, create a data synchronization task again.
- If the database version of the destination RDS instance is earlier than the database version of the source RDS instance, upgrade the destination RDS instance to MySQL 5.6 or 5.7 in the RDS console. Then, create a data synchronization task again.

Database existence

DTS checks whether the destination database already exists in the destination instance. If the destination database does not exist in the destination instance, DTS automatically creates a database. However, DTS fails to create the database and reports a failure under the following circumstances:

- The database name contains characters other than lowercase letters, digits, underscores (_), and hyphens (-).
- The character set of the database is not UTF-8, GBK, Latin1, or UTF-8MB4.
- The account of the destination database does not have the read/write permissions on the source database.

If the data source is an RDS instance, the task passes the precheck.

Source database permissions

DTS checks whether the account of the source database has the required permissions. If the account does not have the required permissions, the task fails to pass the precheck. If the source database is an RDS instance, the task passes the precheck.

Destination database permissions

- **Description**

DTS checks whether the account of the destination database has the required permissions. If the account does not have the required permissions, the task fails to pass the precheck.

- **Cause of failure**

- DTS fails to create a database account in the destination RDS instance.
- DTS fails to grant the read/write permissions to the database account of the destination RDS instance.

- **Solution**

Submit a ticket and contact Alibaba Cloud technical support.

Object name conflict

- Description

DTS checks object names only if you select initial synchronization for a data synchronization task. DTS checks whether an object that you want to synchronize has the same name as an object in the destination RDS instance.

- Cause of failure

If an object in the destination RDS instance has the same name as the object that you want to synchronize, the task fails to pass the precheck.

- Solution

- Remove the conflicting object from the destination database.
- Then, create a data synchronization task again. Select both Initial Schema Synchronization and Initial Full Data Synchronization.

Value of server_id in the source database

DTS checks whether the value of the server_id parameter in the source database is set to an integer that is greater than or equal to 2. If the data source is an RDS instance, the task passes the precheck.

Whether binary logging is enabled for the source database

DTS checks whether the binary logging feature is enabled for the source database. If the binary logging feature is disabled for the source database, the task fails to pass the precheck. If the data source is an RDS instance, the task passes the precheck.

Binary log format of the source database

DTS checks whether the binary log format of the source database is set to ROW. If the binary log format of the source database is not set to ROW, the task fails to pass the precheck. If the data source is an RDS instance, the task passes the precheck.

Integrity of the FOREIGN KEY constraints

- Description

DTS checks whether the parent tables and child tables that have referential relationships with each other are all included in the required objects. The precheck allows DTS to protect the integrity of the FOREIGN KEY constraints.

- Cause of failure

One or more child tables are included in the required objects. However, the parent tables that are referenced by the child tables are not included in the required objects. This impairs the integrity of the FOREIGN KEY constraints.

- Solution

The following solutions are available:

- Create a data synchronization task again and do not synchronize the child tables that fail to pass the precheck.
- Create a data synchronization task again and add the parent tables to the required objects.
- Remove the FOREIGN KEY constraints from the child tables that fail to pass the precheck. Then, create a data synchronization task again.

Storage engine

- Description

DTS checks whether the required objects use the storage engines that are not supported by the data synchronization feature, such as FEDERATED, MRG_MyISAM, and TokuDB.

- Cause of failure

If the storage engine of a source table is FEDERATED, MRG_MyISAM, or TokuDB, the task fails to pass the precheck.

- Solution

Change the unsupported storage engine to InnoDB and create a data synchronization task again.

Character set

- Description

DTS checks whether the required objects use the character sets that are not supported by the data synchronization feature, such as the UCS-2 character set.

- Cause of failure

If the character sets used by the required objects are not supported by the data synchronization feature, the task fails to pass the precheck.

- Solution

Change the unsupported character sets to UTF-8, GBK, or Latin1. Then, create a data synchronization task again.

Complicated topologies

- Description

DTS checks whether the topology that you specify for the source and destination RDS instances is supported.

- Cause of failure

- The source RDS instance in the current task is being used as the destination instance of another task.
- The destination RDS instance in the current task is being used as the source or destination instance of another task.
- The objects that you want to synchronize in the current task are being synchronized by an existing task. The two tasks have the same source and destination RDS instances.

- Solution

- If the task that you want to create has the same source and destination RDS instances as an existing task, you can add the required objects to the existing task. You do not need to create another task to synchronize these objects.
- If the task that you want to create conflicts with an existing task, wait until the existing task is completed before you create a data synchronization task again.

Format of the MySQL database password

DTS checks whether the format of the password that is used to access the source database is no longer valid. If the data source is an RDS instance, the task passes the precheck.

19.5. Change tracking

19.5.1. Overview

You can use Data Transmission Service (DTS) to track data changes from ApsaraDB RDS for MySQL instances in real time. This feature applies to the following scenarios: lightweight cache updates, business decoupling, asynchronous data processing, and synchronization of extract, transform, and load (ETL) operations.

Supported databases

- User-created MySQL databases or ApsaraDB RDS for MySQL
- PolarDB-X (formerly known as DRDS)
- User-created Oracle database

Objects for change tracking

The objects for change tracking include tables and databases.

In change tracking, data changes include data manipulation language (DML) operations and data definition language (DDL) operations. When you configure change tracking, you must select operation types.

Change tracking tasks

A change tracking task is the basic unit of change tracking and data consumption. To track data changes from an RDS instance, you must create a change tracking task in the DTS console for the RDS instance. The change tracking task pulls data changes from the RDS instance in real time and locally stores the data changes. You can use the DTS SDK to consume the tracked data. You can also create, manage, or delete change tracking tasks in the DTS console.

19.5.2. Create a change tracking instance

Before you configure a task to track data changes, you must create a change tracking instance. This topic describes how to create a change tracking instance in the Data Transmission Service (DTS) console.

Procedure

1. [Log on to the DTS console](#).
2. In the left-side navigation pane, click **Change Tracking**.
3. In the upper-right corner, click **Create Change Tracking Task**.
4. In the **Create DTS Instances** dialog box, select a region, and enter the number of change tracking instances that you want to create.

 **Note** In the **Create DTS Instances** dialog box, you can view the total number of instances, the number of existing instances, and the number of instances that can be created.

5. Click **Create**.

19.5.3. Configure change tracking tasks

19.5.3.1. Track data changes from a user-created MySQL database or an ApsaraDB RDS for MySQL instance

You can use Data Transmission Service (DTS) to track data changes in real time. This feature applies to the following scenarios: lightweight cache updates, business decoupling, asynchronous data processing, and synchronization of extract, transform, and load (ETL) operations. This topic describes how to track data changes from a user-created MySQL database or an ApsaraDB RDS for MySQL instance.

Prerequisites

The version of the MySQL database is 5.1, 5.5, 5.6, or 5.7.

Precautions

- DTS does not track data definition language (DDL) operations that are performed by `gh-ost` or `pt-online-schema-change`. Therefore, the change tracking client may fail to write the consumed data to the destination tables due to schema conflict.
- If the source database is used in another task, for example, it is used in a running data migration task, DTS may track data changes of other objects. In this case, you must use the change tracking client to filter the tracked data.

Procedure

1. [Create a change tracking instance](#).
2. Find the change tracking instance that you created, and click **Configure Channel** in the **Actions** column.

3. Configure the source database.

1. Select Instance
2. Select Required Objects
3. Precheck

Task Name:

Source Database

* Version: Old New

* Instance Type:

Database Type: MySQL

Instance Region:

* RDS Instance ID:

Information: Currently, DTS does not support change tracking of read-only instances or temporary instances.

* Database Account:
The account must have the following permissions: REPLICATION SLAVE, REPLICATION CLIENT, and SELECT for all objects to synchronize.

* Database Password:

Consumer network type

* Network Type: Classic

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Version	Select a version based on your business requirements: <ul style="list-style-type: none"> ◦ If the source database is a user-created MySQL database, select Old. ◦ If the source database is ApsaraDB RDS for MySQL, select New. <div style="background-color: #e1f5fe; padding: 5px; border: 1px solid #cfe2f3; margin-top: 5px;"> Note You can follow the same procedure to configure change tracking tasks when you select Old or New. In this example, select New. </div>
	Instance Type	Select RDS Instance .
	Database Type	MySQL is selected by default.
	Instance Region	The region of the source instance. The region is the same as the region that you selected when you created the change tracking task. You cannot change the value of this parameter.
	RDS Instance ID	Select the ID of the RDS instance from which you want to track data changes. <div style="background-color: #e1f5fe; padding: 5px; border: 1px solid #cfe2f3; margin-top: 5px;"> Note A read-only instance or temporary instance cannot be used as the source instance for change tracking. </div>

Section	Parameter	Description
	Database Account	<p>Enter the database account of the source RDS instance.</p> <p>Note</p> <ul style="list-style-type: none"> The account must have the REPLICATION SLAVE permission, the REPLICATION CLIENT permission, and the permission to perform SELECT operations on the required objects. If the database engine of the source RDS instance is MySQL 5.5 or MySQL 5.6, you do not need to configure the database account or database password.
	Database Password	<p>Enter the password of the source database account.</p>
Consumer Network Type	Network Type	<p>Classic is selected by default.</p> <p>Note</p> <ul style="list-style-type: none"> This parameter is available only if the Version parameter is set to New. If you track data changes over internal networks, the network latency is minimal.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.

5. Select the data change types and objects.

1.Select Instance 2.Select Required Objects 3.Precheck

Information: If you select an entire database, DTS tracks all the data added to the database. If you only select some tables, you must modify the objects in the Available section to include other required objects in the task.

In this case, if you want to track data changes of another table, you must add the table to the required objects. For more information, see Modify the objects for change tracking. </div>
Required Objects	Select objects from the Required Objects section and click the icon to move the objects to the Selected section.

6. In the lower-right corner of the page, click **Save and Precheck**.

 **Note** You can start a change tracking task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

7. Close the Precheck dialog box after the following message is displayed: **The precheck is passed.** After the change tracking task is configured, DTS performs initial change tracking, which takes about 1 minute. After the initial change tracking is complete, you can consume the tracked data.

What's next

- Previous change tracking feature: [Run the SDK demo code](#)
- New change tracking feature: [Use a Kafka client to consume tracked data](#)

19.5.3.2. Track data changes from a PolarDB-X instance

You can use Data Transmission Service (DTS) to track data changes in real time. This feature applies to the following scenarios: lightweight cache updates, business decoupling, asynchronous data processing, and synchronization of extract, transform, and load (ETL) operations. This topic describes how to track data changes from a PolarDB-X instance. PolarDB-X is formerly known as Distributed Relational Database Service (DRDS).

Precautions

- DTS does not track data definition language (DDL) operations that are performed by gh-ost or pt-online-schema-change. Therefore, the change tracking client may fail to write the consumed data to the destination tables due to schema conflict.
- If the source database is used in another task, for example, it is used in a running data migration task, DTS may track data changes of other objects. In this case, you must use the change tracking client to filter the tracked data.

Procedure

1. [Create a change tracking instance.](#)
2. Find the change tracking instance that you created, and click **Configure Channel** in the **Actions** column.
3. Configure the source database.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	This parameter is set to DRDS Instance and cannot be changed.
	Database Type	This parameter is set to DRDS and cannot be changed.
	Instance Region	The region of the source instance. The region is the same as the region that you selected when you created the change tracking task. You cannot change the value of this parameter.
	DRDS Instance ID	Select the ID of the PolarDB-X instance.
	Database Name	Select the ID of the source database in the PolarDB-X instance.
	Database Account	Enter the database account of the PolarDB-X instance.
	Database Password	Enter the password of the source database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.

5. Select the data change types and objects.

1.Select Instance
2.Select Required Objects
3.Precheck

Information: If you select an entire database, DTS tracks all the data added to the database. If you only select some tables, you must modify the objects in the Available section to include other required objects in the task.

7. Close the **Precheck** dialog box after the following message is displayed: **The precheck is passed.**
After the change tracking task is configured, DTS performs initial change tracking, which takes about 1 minute. After the initial change tracking is complete, you can consume the tracked data.

19.5.3.3. Track data changes from a user-created Oracle database

You can use Data Transmission Service (DTS) to track data changes in real time. This feature applies to the following scenarios: lightweight cache updates, business decoupling, asynchronous data processing, and synchronization of extract, transform, and load (ETL) operations. This topic describes how to track data changes from a user-created Oracle database.

Prerequisites

- The version of the user-created Oracle database is 9i, 10g, 11g, or 12c.
- Supplemental logging, including SUPPLEMENTAL_LOG_DATA_PK and SUPPLEMENTAL_LOG_DATA_UI, is enabled for the user-created Oracle database. For more information, see [Supplemental Logging](#).
- The ARCHIVELOG mode is enabled for the user-created Oracle database. Archived log files are accessible and a suitable retention period is set for archived log files. For more information, see [Managing Archived Redo Log Files](#).

Precautions

- DTS does not track data definition language (DDL) operations that are performed by gh-ost or pt-online-schema-change. Therefore, the change tracking client may fail to write the consumed data to the destination tables due to schema conflict.
- If the source database is used in another task, for example, it is used in a running data migration task, DTS

may track data changes of other objects. In this case, you must use the change tracking client to filter the tracked data.

Procedure

1. **Create a change tracking instance.**
2. Find the change tracking instance that you created, and click **Configure Channel** in the **Actions** column.
3. Configure the source database and network type.

The screenshot shows a configuration wizard with three steps: 1. Select Instance, 2. Select Required Objects, and 3. Precheck. The 'Task Name' field is set to 'Oracle'. The 'Source Database' section includes a dropdown for 'Instance Type' (User-Created Database with Public IP Address), 'Database Type' (Oracle), 'Instance Region', and input fields for 'Hostname or IP Address', 'Port Number' (1521), 'SID' (testsid), 'Database Account' (dtstest), and 'Database Password' (masked). The 'Consumer network type' section has a radio button for 'Network Type' set to 'Classic'. At the bottom right are 'Cancel' and 'Set Whitelist and Next' buttons.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select an instance type based on where the source database is deployed. In this example, select User-Created Database with Public IP Address .
	Database Type	This parameter is set to Oracle and cannot be changed.
	Instance Region	The region of the source instance. The region is the same as the region that you selected when you created the change tracking task. You cannot change the value of this parameter.
	Hostname or IP Address	Enter the hostname or IP address of the user-created Oracle database.
	Port Number	Enter the service port number of the user-created Oracle database.
	SID	Enter the system ID (SID) of the user-created Oracle database.

Section	Parameter	Description
	Database Account	Enter the account of the user-created Oracle database. Note The account must have the database administrator (DBA) permission.
	Database Password	Enter the password of the source database account.
Consumer Network Type	N/A	Classic is selected by default. Note If you track data changes over internal networks, the network latency is minimal.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.

5. Select the data change types and objects.

Information: If you select an entire database, DTS tracks all the data added to the database. If you only select some tables, you must modify the objects in the Available section to include other required objects in the task.

* Required Data Types: Data Updates Schema Updates

Required Objects

- EOA_USER
- DTSTEST
 - Tables
 - GOOD_SALE
 - ORACLESTTABLE1216
- SCOTT
- OWBSYS_AUDIT
- OWBSYS
- APEX_030200
- APEX_PUBLIC_USER
- SPATIAL_CSW_ADMIN_USR
- SPATIAL_WFS_ADMIN_USR
- ORDDATA
- XS\$NULL

Selected

- DTSTEST(10objects)
 - ORACLESTTABLE

Buttons: Cancel, Previous, Save and Precheck

Parameter	Description
-----------	-------------

Parameter	Description
Required Data Types	<ul style="list-style-type: none"> ◦ Data Updates If you select Data Updates, DTS tracks data updates of the selected objects, including the INSERT, DELETE, and UPDATE operations. ◦ Schema Updates If you select Schema Updates, DTS tracks the create, delete, and modify operations that are performed on all object schemas of the source instance. You must use the change tracking client to filter the tracked data. <div style="background-color: #e6f2ff; padding: 10px; margin-top: 10px;"> <p> Note</p> <ul style="list-style-type: none"> ◦ If you select a database as the object, DTS tracks data changes of all objects, including new objects in the database. ◦ If you select a table as the object, DTS tracks only data changes of this table. In this case, if you want to track data changes of another table, you must add the table to the required objects. For more information, see Modify the objects for change tracking. </div>
Required Objects	Select objects from the Required Objects section and click the  icon to move the objects to the Selected section.

6. In the lower-right corner of the page, click **Save and Precheck**.

 **Note** You can start a change tracking task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

7. Close the Precheck dialog box after the following message is displayed: **The precheck is passed.** After the change tracking task is configured, DTS performs initial change tracking, which takes about 1 minute. After the initial change tracking is complete, you can consume the tracked data.

What's next

[Use a Kafka client to consume tracked data](#)

19.5.4. Manage change tracking tasks

19.5.4.1. Modify the consumption checkpoint

During data consumption, you can modify the consumption checkpoint of a change tracking task based on your business requirements. After you modify the consumption checkpoint, the downstream SDK client will consume the data that is generated after the specified time.

Prerequisites

A change tracking task is created. For more information, see [Track data changes from a user-created MySQL database or an ApsaraDB RDS for MySQL instance \(previous version\)](#) or [Track data changes from a PolarDB-X instance](#).

Procedure

1. Stop all downstream SDK consumption processes.

Note We recommend that you perform this operation during off-peak hours to avoid service interruption.

2. Log on to the DTS console.
3. In the left-side navigation pane, click Change Tracking.
4. Find the change tracking task, move the pointer over the Consumption Checkpoint column, and then click the  icon.

<input type="checkbox"/>	Task ID/Name	Status	Consumption Checkpoint	Data Range	Billing Method	Actions
<input type="checkbox"/>		Normal	2019-07-18 10:02:32 	2019-09-19 10:33:14 2019-09-26 11:13:56	Pay-As-You-Go	Modify Required Objects More
<input type="checkbox"/>	Delete					Total: 1 item(s) Per Page: 20 item(s) << < 1 > >>

5. In the Modify Consumption Checkpoint dialog box, specify a new consumption checkpoint.

Information: The time you select must be within the range[2019-09-19 10:33:14 - 2019-09-26 11:10:34]that is specified for the channel.

Consumption Checkpoint: 2019-07-18 

10 : 02 : 32

Close Edit

Note The selected time range must be within the time range of the tracked data. For more information, see the prompt in the dialog box.

6. Click Modify.
7. Restart the downstream SDK consumption processes.
The downstream SDK client tracks data changes from the new consumption checkpoint.

19.5.4.2. Modify the objects for change tracking

DTS allows you to add or remove the objects for change tracking in the consumption process. This topic describes how to modify the objects for change tracking.

Procedure

1. Log on to the DTS console.
2. In the left-side navigation pane, click Change Tracking.
3. Find the change tracking task, and click Modify Required Objects in the Actions column.
4. In the Select Required Objects step, add or remove the objects for change tracking.
 - o Add the objects for change tracking
In the Required Objects section, select one or more objects and click the  icon to add the objects to the Selected section.
 - o Remove the objects for change tracking
In the Selected section, select one or more objects and click the  icon to move the objects to the Required Objects section.

- In the lower-right corner of the page, click **Save and Precheck**.

 **Note** You can start a change tracking task only after the task passes the precheck. If the task fails to pass the precheck, click the  icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

19.5.4.3. Create a consumer group

You can manage consumer groups of a change tracking task in the DTS console. This topic describes how to create a consumer group.

Prerequisites

A change tracking task is created. For more information, see [Track data changes from a user-created MySQL database or an ApsaraDB RDS for MySQL instance \(new version\)](#) or [Track data changes from a PolarDB-X instance](#).

Note

- You can create multiple consumer groups (up to 20) in a change tracking instance to repeatedly consume data.
- A consumer group consumes each message only once, and only one consumer can consume data.

Procedure

- [Log on to the DTS console](#).
- In the left-side navigation pane, click **Change Tracking**.
- Find the change tracking task and click the task ID.
- In the left-side navigation pane, click **Consume Data**.
- On the **Consume Data** page, click **Add Consumer Group** in the upper-right corner.
- In the dialog box that appears, set the parameters for the consumer group.

Parameter	Description
Consumer Group Name	Enter a new name for the consumer group. We recommend that you use an informative name for easy identification.
Username	Enter the username of the consumer group. <ul style="list-style-type: none"> A username must contain one or more of the following character types: uppercase letters, lowercase letters, digits, and underscores (_). The username must be 1 to 16 characters in length.
Password	Enter the password that corresponds to the username of the consumer group. <ul style="list-style-type: none"> A password must contain two or more of the following character types: uppercase letters, lowercase letters, digits, and special characters. The password must be 8 to 32 characters in length.
Confirm Password	Enter the new password again.

- Click **Create**.

19.5.4.4. Manage consumer groups

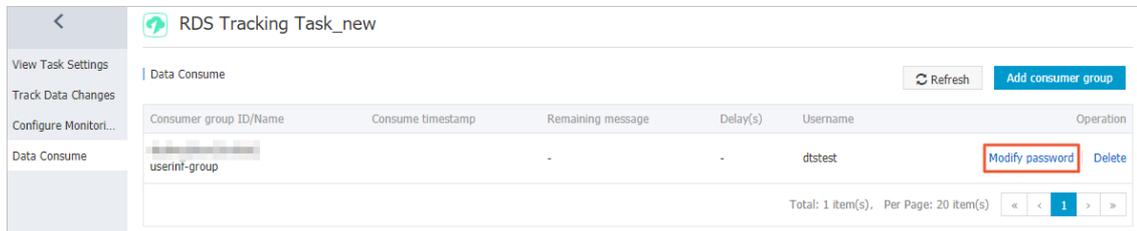

You can manage consumer groups of a change tracking task in the DTS console. This topic describes how to modify the password of a consumer group and how to delete a consumer group.

Prerequisites

[Create a consumer group](#)

Procedure

1. **Log on to the DTS console.**
2. In the left-side navigation pane, click **Change Tracking**.
3. Find the change tracking task and click the task ID.
4. In the left-side navigation pane, click **Consume Data**.
5. Modify the password of a consumer group or delete a consumer group. Modify the password of a consumer group
 - i. On the **Consume Data** page, find the target consumer group and click **Modify Password** in the **Actions** column.

- ii. In the **Modify Password** dialog box that appears, enter the **old password** and **new password**, and enter the **new password** again in the **Confirm Password** field.

Note

- A password must contain two or more of the following character types: uppercase letters, lowercase letters, digits, and special characters.
- The password must be 8 to 32 characters in length.

- iii. Click **Modify**.

Delete a consumer group

Note After a consumer group is deleted, the data in the group will be cleared and cannot be recovered. We recommend that you use caution when performing this operation.

- i. On the **Consume Data** page, find the target consumer group and click **Delete** in the **Actions** column.
 - ii. In the **Delete Consumer Group** message that appears, click **OK**.

19.5.5. Use the SDK to consume tracked data

19.5.5.1. Methods provided by SDK

You can use the SDK demo code that is provided by DTS to consume tracked data. This topic describes the methods that are available for the SDK classes.

Methods of the RegionContext class

Method	Description
--------	-------------

Method	Description
<code>setAccessKey(accessKey)</code>	Specifies the AccessKey ID of the Alibaba Cloud account to which the source instance belongs.
<code>setSecret(AccessKeySecret)</code>	Specifies the AccessKey secret of the Alibaba Cloud account to which the source instance belongs.
<code>setUsePublicIp(usePublicIp)</code>	Specifies whether to track data changes over the Internet. <div style="background-color: #e6f2ff; padding: 5px; border: 1px solid #d9e1f2;"> <p>? Note DTS can track data changes only over the Internet. Therefore, set the usePublicIp parameter to <code>true</code>.</p> </div>
<code>context.setUseBinary(boolean useBinary)</code>	Specifies whether to enable the binary packaging feature. Valid values: True and False. We recommend that you enable this feature to improve consumption performance.
<code>context.setUseDrcNet(boolean useDrcNet)</code>	Specifies whether to enable the network optimization feature. Valid values: True and False. We recommend that you enable this feature to improve consumption performance.

Methods of the ClusterClient class

Method	Description
<code>void addConcurrentListener(ClusterListener arg0)</code>	Adds a downstream listener to retrieve data changes from a change tracking instance. <div style="background-color: #e6f2ff; padding: 5px; border: 1px solid #d9e1f2;"> <p>? Note The <code>ClusterListener arg0</code> parameter specifies an object of the <code>ClusterListener</code> class.</p> </div>
<code>void askForGUID(String arg0)</code>	Retrieves data changes from a change tracking instance. Set the String arg0 parameter to the ID of the change tracking instance.
<code>List<ClusterListener> getConcurrentListeners()</code>	Queries the list of listeners in a ClusterClient object. The return type is <code>List<ClusterListener></code> .
<code>void start()</code>	Starts the SDK client to start change tracking.
<code>void stop()</code>	Stops the SDK client to stop change tracking. <div style="background-color: #e6f2ff; padding: 5px; border: 1px solid #d9e1f2;"> <p>? Note Data pulling and notification callback are performed in the same thread of the SDK client. If the consumption code of the notify() method contains a function that prevents signal interruptions, the stop() function may fail to terminate the SDK client.</p> </div>

Methods of the ClusterListener class

The `void notify(List<ClusterMessage> arg0)` method specifies the consumption mode of tracked data. When the DTS SDK receives the data, it uses the notify() function to notify a ClusterListener object to consume the data. Then, the SDK displays the data on the screen.

Methods of the ClusterMessage class

Note Each ClusterMessage object stores the data record of a transaction. Each data record in the transaction is stored by using a Record object.

Method	Description
<code>Record getRecord()</code>	Retrieves a change record from a ClusterMessage object. The change record contains an entry in the binary log file, such as a BEGIN, COMMIT, UPDATE, or INSERT operation.
<code>void ackAsConsumed</code>	<p>After the data consumption is complete, you must call this method to send an ACK packet to instruct the DTS server to update the consumer offset. This ensures the integrity of the consumed data after an abnormal SDK client restarts.</p> <p>Note If a downstream SDK client restarts after a breakdown, the client resumes change tracking from the last consumer offset.</p>

Methods of the Record class

The `String getAttribute(String key)` method retrieves the attribute values in a Record object. The following table describes the parameters that are available when you call this method.

Parameter	Description
<code>record_id</code>	<p>The ID of the record.</p> <p>Note The record ID may not increment during the change tracking process.</p>
<code>instance</code>	The endpoint that is used to connect to the database instance. The format is <IP address>:<Port number>.
<code>source_type</code>	The engine type of the database instance. The value is set to MySQL.
<code>source_category</code>	The type of the record. The value is set to full_recorded.
<code>timestamp</code>	The binlog timestamp that is generated when the SQL statement is executed in the source database.
<code>checkpoint</code>	<p>The checkpoint of the binary log file. The format is <code>binlog_offset@binlog_file</code> .</p> <p>Note The <code>binlog_offset</code> parameter indicates the offset of a record in the binary log file. The <code>binlog_file</code> parameter indicates the numerical suffix of the binary log file. For example, if the name of a binary log file is <code>mysql-bin.0008</code>, the value of the <code>binlog_file</code> parameter is 8.</p>

Parameter	Description
<code>record_type</code>	The operation type. Valid values: insert, update, delete, replace, ddl, begin, commit, and heartbeat. <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> ? Note A heartbeat record indicates the heartbeat table that is defined by DTS. The system generates one heartbeat record per second to detect whether the change tracking instance is running as expected. </div>
<code>db</code>	The name of the database.
<code>table_name</code>	The name of the table.
<code>record_recording</code>	The encoding format.
<code>primary</code>	The name of the primary key column. If the primary key is a composite key, separate column names with commas (,).
<code>fields_enc</code>	The encoding of each field value. Separate fields with commas (,). <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> ? Note If a field value is not of the character type, the encoding of this field value is null. </div>

The following table lists the methods that are preset in the SDK demo code. You can call these methods to retrieve the attribute values in a Record object.

Method	Description
Type <code>getOpt()</code>	Queries the operation type.
String <code>getCheckpoint()</code>	Queries the checkpoint of the binary log file.
String <code>getTimestamp()</code>	Queries the timestamp of the binary log file.
String <code>getDbname()</code>	Queries the database name.
String <code>getTablename()</code>	Queries the table name.
String <code>getPrimaryKeys()</code>	Queries the name of the primary key column.
DBType <code>getDbType()</code>	Queries the database type.
String <code>getServerId()</code>	Queries the endpoint that is used to connect to the database instance.
int <code>getFieldCount()</code>	Queries the number of fields.
List<Field> <code>getFieldList()</code>	Queries the definitions of all fields, the pre-change image values, and the post-change image values. For more information, see Methods of the Field class .
Boolean <code>isFirstInLogevent()</code>	Checks whether the record is the first transaction log in a large volume of data changes. The return value is True or False.

Methods of the Field class

Method	Description
<code>String getEncoding()</code>	Obtains the encoding format of the field value.
<code>String getFieldname()</code>	Queries the name of the field.
<code>Type getType()</code>	Queries the data type of the field.
<code>ByteString getValue()</code>	Queries the value of the field. The return type is <code>ByteString</code> . If the field is not specified, the method returns <code>NULL</code> .
<code>Boolean isPrimary()</code>	Checks whether the field is a primary key column. The return value is <code>True</code> or <code>False</code> .

19.5.5.2. Quick start

This section describes how to use the DTS Java SDK to perform some basic operations.

Initialize a RegionContext object

A `RegionContext` object stores the settings of authentication credentials and network access mode. The following code shows how to initialize a `RegionContext` object.

```
import java.util.List;
import com.aliyun.drc.clusterclient.ClusterClient;
import com.aliyun.drc.clusterclient.DefaultClusterClient;
import com.aliyun.drc.clusterclient.RegionContext;
public class MainClass
{
    public static void main(String[] args) throws Exception {
        // Create a RegionContext object.
        RegionContext context = new RegionContext();
        context.setAccessKey("<AccessKey>");
        context.setSecret("<AccessKeySecret>");
        context.setUsePublicIp(true);
        // Create a ClusterClient object.
        final ClusterClient client = new DefaultClusterClient(context);
        // Other invocation code.
        ...
    }
}
```

Initialize a Listener object

Data consumption is implemented by using an object of the `Listener` class. After you initialize the `ClusterClient` object, you must add a `Listener` object. The `Listener` object uses the `notify()` method to receive and consume the tracked data. The following code shows how to display the tracked data on the screen.

```
import com.aliyun.drc.clusterclient.ClusterClient;
import com.aliyun.drc.clusterclient.ClusterListener;
import com.aliyun.drc.clusterclient.DefaultClusterClient;
import com.aliyun.drc.clusterclient.RegionContext;
import com.aliyun.drc.clusterclient.message.ClusterMessage;
public class MainClass
{
    public static void main(String[] args) throws Exception {
        // Initialize the RegionContext object.
        ...
        //Initialize the ClusterClient object.
        ...
        ClusterListener listener = new ClusterListener(){
            @Override
            public void notify(List<ClusterMessage> messages) throws Exception {
                for (ClusterMessage message : messages) {
                    // Display the tracked data on the screen.
                    System.out.println(message.getRecord() + ":" + message.getRecord().getTablename() + ":"
                    + message.getRecord().getOpt());
                    // Call the following method to send an ACK packet to the DTS server.
                    message.ackAsConsumed();
                }
            }
        }
    }
}
```

DTS saves the consumption checkpoints of the SDK to the DTS server. This simplifies disaster recovery during the use of the SDK. The `ackAsConsumed()` method sends the checkpoint and timestamp of the latest data record that was consumed by the DTS SDK to the DTS server. If the SDK restarts due to an error, the SDK obtains the consumption checkpoint from the DTS server. The SDK resumes data consumption from the checkpoint. This ensures that the SDK does not consume duplicate data.

Start the ClusterClient object

Use the following code:

```

import java.util.List;
import com.aliyun.drc.clusterclient.ClusterClient;
import com.aliyun.drc.clusterclient.ClusterListener;
import com.aliyun.drc.clusterclient.DefaultClusterClient;
import com.aliyun.drc.clusterclient.RegionContext;
import com.aliyun.drc.clusterclient.message.ClusterMessage;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
public class MainClass
{
    public static void main(String[] args) throws Exception {
        // Initialize the RegionContext object.
        ...
        // Initialize the ClusterClient object.
        ...
        // Initialize the ClusterListener object.
        ...
        // Add a Listener class.
        client.addConcurrentListener(listener);
        // Specify the ID of the change tracking instance.
        client.askForGUID("dts_rdsrjiei2u2afnb_DSF");
        // Start a background thread. The main thread cannot exit.
        client.start();
    }
}

```

The `askForGUID()` method sets the ID of the change tracking instance. You can obtain the ID of the change tracking instance from the DTS console. After the ID of the change tracking instance is specified in the `askForGUID()` method, the SDK retrieves incremental data from this instance.

Before you can start a `ClusterClient` object, you must add a `Listener` class to the `ClusterClient` object. When the `ClusterClient` object pulls incremental data from the change tracking instance, it also calls the `notify()` method of the `Listener` class to consume data.

19.5.5.3. Parse tracked SQL statements

You can use the DTS SDK to track data changes. DTS records the tracked data changes in a custom format. This topic describes how to parse various types of SQL statements.

Parse a DDL statement

If a data definition language (DDL) operation is performed in the source database, the operation type of the data record is DDL. The DDL statement is stored in the value of the first column. You can use the following sample code to parse the DDL statement:

```

String ddl_string;
Record.Type type=record.getOpt();
if(type.equals(Record.Type.DDL)){
    List<DataMessage.Record.Field> fields = record.getFieldList();
    ddl_string = fields.get(0).getValue().toString();
}

```

Parse an INSERT statement

If an INSERT operation is performed in the source database, the operation type of the data record is INSERT. You can use the following sample code to parse the INSERT statement:

```
StringBuilder insert_string=new StringBuilder();
Record.Type type=record.getOpt();
DataMessage.Record.Field field;
StringBuilder fieldName=new StringBuilder();
StringBuilder fieldValue = new StringBuilder();
if(type.equals(Record.Type.INSERT)){
    int i=0;
    List<DataMessage.Record.Field> fields = record.getFieldList();
    for (; i < fields.size(); i++) {
        field = fields.get(i);           fieldName.append("`'+field.getFieldname().toLowerCase()+`'");
        fieldValue.append(""+field.getValue()+"");
        if (i != fields.size() - 1) {
            fieldName.append(',');
            fieldValue.append(',');
        }
    }
    insert_string.append("insert "+ record.getTablename()+"("+fieldName.toString()+") values("+fieldValue.toString()+");");
}
```

Parse an UPDATE statement

If an UPDATE operation is performed in the source database, the operation type of the data record is UPDATE. The field values prior to the UPDATE operation are stored in `Record.getFieldList()` entries with even indexes. The field values after the UPDATE operation are stored in `Record.getFieldList()` entries with odd indexes.

If the UPDATE operation is performed on a table that has a primary key, you can use the following sample code to parse the UPDATE statement:

```
StringBuilder update_string=new StringBuilder();
Record.Type type=record.getOpt();
DataMessage.Record.Field field;
StringBuilder SetValue = new StringBuilder();
StringBuilder WhereCondition = new StringBuilder();
String ConditionStr;
boolean hasPk=false;
boolean pkMode=false;
boolean hasSet=false;
if(type.equals(Record.Type.UPDATE)){
    int i=0;
    DataMessage.Record.Field OldField = null;
    DataMessage.Record.Field NewField = null;
    List<DataMessage.Record.Field> fields = record.getFieldList();
    for (; i < fields.size() ; i++) {
        if (i % 2 == 0) {
```

```

        OldField = fields.get(i);
        continue;
    }
    NewField = fields.get(i);
    field = NewField;
    if (field.isPrimary()) {
        if (hasPk) {
            WhereCondition.append(" and ");
        }
        //where old value
        ConditionStr = getFieldValue(OldField);
        if(ConditionStr==null){
            WhereCondition.append(""+field.getFieldname().toLowerCase()+" "+
+ " " + "is null");
        }else{
            WhereCondition.append(""+field.getFieldname().toLowerCase()+" "+" = " + ""+OldField.getValue()+"");
        }
        hasPk = true;
    }
    if (hasSet) {
        SetValue.append(",");
    }
    SetValue.append(""+field.getFieldname().toLowerCase()+" "+" = " + ""+field.getValue()+"");
    String setStr = getFieldValue(field);
    hasSet = true;
}
update_string.append("Update "+record.getTablename() +" Set " + SetValue + " Where "+WhereCondition +";");
}

protected String getFieldValue(Field field) throws Exception {
    ByteString byteString = field.getValue();
    if (byteString == null) {
        return null;
    }
    else {
        String value;
        if (field.getType() == com.aliyun.drc.client.message.DataMessage.Record.Field.Type.STRING && field.getEncoding()
!= null && field.getEncoding() != "ASCII") {
            value = field.getValue().toString(field.getEncoding());
        }
        else {
            value = byteString.toString();
        }
        return value;
    }
}
}

```

Parse a DELETE statement

If a DELETE operation is performed in the source database, the operation type of the data record is DELETE. If the DELETE operation is performed on a table that has a primary key, you can use the following sample code to parse the DELETE statement:

```
Stringbuilder delete_string=new StringBuilder();
Record.Type type=record.getOpt();
DataMessage.Record.Field field;
Stringbuilder FieldName=new StringBuilder();
Stringbuilder FieldValue = new StringBuilder();
Stringbuilder DeleteCondition = new StringBuilder();
boolean hasPk=false;
boolean pkMode=false;
if(type.equals(Record.Type.DELETE)){
    int i=0;
    List<DataMessage.Record.Field> fields = record.getFieldList();
    delete_string.append("Delete From" + record.getTablename() + "where");
    // Check whether the table has a primary key.
    if (record.getPrimaryKeys() != null) {
        pkMode = record.getPrimaryKeys().length() > 0 ? true : false;
    }
    for (; i < fields.size(); i++) {
        if ((pkMode && ! field.isPrimary())) {
            continue;
        }
        if (hasPk) {
            delete_string.append(" and ");
        }
        delete_string.append(field.getFieldname() + "=" + field.getValue());
        hasPk = true;
    }
    delete_string.append(";");
}
```

Parse a REPLACE statement

If a REPLACE operation is performed in the source database, the operation type of the data record is UPDATE or INSERT.

- If the value specified in the REPLACE statement does not exist, the operation type of the data record is INSERT.
- If the value specified in the REPLACE statement exists, the operation type of the data record is UPDATE.

Parse a BEGIN statement

If a BEGIN operation is performed in the source database, the operation type of the data record is BEGIN. You do not need to perform operations on fields because the BEGIN statement does not modify fields. You only need to check that the operation is a BEGIN operation. You can use the following sample code to parse the BEGIN statement:

```
StringBuilder sql_string = new StringBuilder();
Record.Type type = record.getOpt();
if(type.equals(Record.Type.BEGIN)){
    sql_string.append("Begin");
}
```

Parse a COMMIT statement

If a COMMIT operation is performed in the source database, the operation type for the data record is COMMIT. You do not need to perform operations on fields because the COMMIT statement does not modify fields. You only need to check that the operation is a COMMIT operation. You can use the following sample code to parse the COMMIT statement:

```
StringBuilder sql_string = new StringBuilder();
Record.Type type = record.getOpt();
if(type.equals(Record.Type.COMMIT)){
    sql_string.append("commit");
}
```

19.5.5.4. Run the SDK demo code

This section describes how to run the demo code provided by the DTS console.

1. Create an AccessKey.

Your account must pass the AccessKey authentication before you can use an SDK to connect to a subscription channel. Therefore, before using the SDK, you must obtain an AccessKey. For more information, see the "Obtain an AccessKey" section of the *DTS Developer Guide*.

2. Install the Java SDK.

The development environment supported by the DTS Java SDK is J2SE Development Kit (JDK) V1.5 or later.

For an Eclipse project, you can follow these steps to install the Java SDK:

- i. Click **View Example Code** and download the SDK package *consumer.jar*.
- ii. Import the JAR package to an Eclipse project as follows:

In Eclipse, right-click your project and choose **Properties > Java Build Path > Libraries > Add External JARs**. Select the path for storing the *consumer.jar* package *consumer.jar*.

- iii. Select the *consumer.jar* package and click **OK**.

Then you can use the DTS Java SDK in the project.

3. Run the demo code.

DTS provides the SDK demo code. You can copy the demo code by using the **View Demo Code** option in the DTS console. For an Eclipse project, you can follow these steps to run the demo code:

- i. Create a class named *MainClass* in the *src* directory of the Eclipse project.
- ii. Open the generated Java file *MainClass* and delete the code template.
- iii. Paste the demo code into the *MainClass* file.
- iv. Modify the *AccessKeyId*, *AccessKeySecret*, and subscription channel ID in the demo code.

Change the marked parts in the preceding demo code to the *AccessKeyId*, *AccessKeySecret*, and subscription channel ID of your account.

You can obtain the subscription channel ID from the [DTS console](#).

- v. In Eclipse, right-click the demo file and choose **Run as > Java Application** to run the demo code.

19.5.6. Use a Kafka client to consume tracked data

This topic describes how to use the demo code of a Kafka client to consume tracked data. The change tracking feature of the new version allows you to consume tracked data by using a Kafka client from V0.11 to V1.1.

Prerequisites

- A change tracking task is created. For more information, see [Track data changes from a user-created MySQL database or an ApsaraDB RDS for MySQL instance \(new version\)](#) or [Track data changes from a PolarDB-X instance](#).
- One or more consumer groups are created. For more information, see [Create a consumer group](#).

Precautions

- If you enable auto commit when you use the change tracking feature, some data may be committed before it is consumed. This results in data loss. We recommend that you manually commit data.

 **Note** If data fails to be committed due to a fault, you can restart the client to continue consuming data from the last recorded consumer offset. However, duplicate data may be generated during this period. You must manually filter out the duplicate data.

- Data is serialized and stored in the Avro format. For more information, see [Record.avsc](#).

 **Note** If the client that you use is not a Kafka client, you must parse the tracked data based on the Avro schema.

- Regarding the `offsetFotTimes` interface, the search unit of DTS is seconds, and the search unit of native Kafka is milliseconds.

Download and run the demo code of the Kafka client

Click [here](#) to download the demo code of the Kafka client. For more information about how to use the demo code, visit [Readme](#).

Download and run the demo code of the Kafka client

Step	File or directory
1. Use the native Kafka consumer to obtain incremental data from the change tracking instance.	subscribe_example-master/javaimpl/src/main/java/reco rdgenerator/
2. Deserialize the image of the incremental data, and obtain attributes such as the pre-image and post-image.	subscribe_example-master/javaimpl/src/main/java/boot /MysqlRecordPrinter.java
3. Convert the dataTypeNumber values in the deserialized data into MySQL or Oracle data types.	subscribe_example-master/javaimpl/src/main/java/reco rdprocessor/mysql/

 **Note** For more information, see [Mappings between MySQL data types and dataTypeNumber values](#) and [Mappings between Oracle data types and dataTypeNumber values](#).

Procedure

This procedure uses IntelliJ IDEA (Community Edition 2018.1.4 Windows) as an example.

1. Download the [demo code of the Kafka client](#), and then decompress the package.
2. Open IntelliJ IDEA. In the window that appears, click **Open**.

- In the dialog box that appears, go to the directory in which the downloaded demo code resides. Find the `pom.xml` file.
- In the dialog box that appears, select **Open as Project**.
- On the IntelliJ IDEA page, expand folders to find the demo file of the Kafka client, and double-click the file. The file name is `NotifyDemo.java`.

- Set the parameters in the `NotifyDemo.java` file.

Parameter	Description	Method to obtain
USER_NAME	<p>The username of the consumer group.</p> <p>Warning If you are not using the Kafka client that is described in this topic, you must specify the username in the following format: <code><Consumer group account>-<Consumer group ID></code>, for example, <code>dtstes-t-dtsae*****bpv</code>. Otherwise, the connection fails.</p>	<p>In the DTS console, click the instance ID, and then click Data Consume. You can obtain the Consumer Group ID and the corresponding Account information.</p> <p>Note The password of the consumer group account is specified when you create a consumer group.</p>
PASSWORD_NAME	The password of the account.	
SID_NAME	The ID of the consumer group.	
GROUP_NAME	The name of the consumer group. Set this parameter to the consumer group ID.	
KAFKA_TOPIC	The topic of the change tracking task.	
KAFKA_BROKER_URL_NAME	<p>The network address and port number of the change tracking task.</p> <p>Note If you track data changes over internal networks, the network latency is minimal. This is applicable if the ECS instance where you deploy the Kafka client belongs to the same VPC or classic network as the change tracking instance.</p>	<p>In the DTS console, click the instance ID. On the Track Data Changes page, you can obtain the tracked topic, network address, and port number.</p>

Parameter	Description	Method to obtain
INITIAL_CHECKPOINT_NAME	<p>The consumer offset of consumed data. The value is a UNIX timestamp.</p> <p>Note You must save the consumer offset. If the consumption process is interrupted, you can specify the consumer offset on the change tracking client to resume data consumption. This allows you to prevent against data loss. When you start the change tracking client, you can specify the consumer offset to consume data on demand.</p>	When you use the Kafka client to track data changes for the first time, convert the required time point into a UNIX timestamp.
USE_CONFIG_CHECKPOINT_NAME	<p>Default value: <i>true</i>. The default value indicates that the client is forced to consume data from the specified consumer offset. This allows you to retain the data that is received but not processed.</p>	None.

7. On the top of the IntelliJ IDEA page, choose **Run > Run** to run the client.

Note When you run IntelliJ IDEA for the first time, it loads and installs the relevant dependency.

Execution result

The following figure shows that the Kafka client can track data changes in the source database.

```

[2020-03-09 10:41:52.408] INFO [Consumer clientId=consumer-1, groupId=dts-...] Discovered coordinator [redacted] rack: null (org.apache.kafka.clients.consumer.internals.AbstractCoordinator)

20.Data Management (DMS)

20.1. What is Data Management?

Data Management (DMS) is an integrated database solution that provides data, schema, and server management, access control, business intelligence (BI) insights, data trend analysis, data tracking, and performance optimization.

Supported database types

- ApsaraDB RDS for MySQL
- ApsaraDB RDS for SQL Server
- PolarDB and ApsaraDB RDS for PostgreSQL

Supported database operations

- SQL operations
 - Use of SQL windows
 - Use of the command window
 - Saving of work environment settings
 - SQL statement execution
 - SQL statement optimization
 - SQL statement formatting and improvement
 - Viewing of execution plans
 - Smart SQL completion
- Operations on database objects
 - Operations on data tables
 - Operations on schemas: modify schemas by adding or deleting columns, indexes, foreign keys, and partitions
 - Changes to table data: insert, update, and delete
 - Table data query and visualized editing
- Operations on views and programmable objects such as functions, stored procedures, triggers, and events
 - Creation
 - Modification
 - Deletion
 - Enabling and disabling
- Data processing
 - Data import
 - Data export
- Performance and diagnosis
 - Lock wait analysis
- Use of data processing tools
 - Drawing of entity-relationship (ER) diagrams
 - Statistics on table data volume
 - Batch operations on tables

User-friendly interactions

DMS provides user-friendly tips. When an error occurs, DMS displays suggestions on how best to achieve your goal.

20.2. Log on to an ApsaraDB for RDS instance by using DMS

This topic describes how to log on to an ApsaraDB for RDS instance by using DMS.

Context

The ApsaraDB for RDS console allows you to log on to ApsaraDB for RDS instances by using DMS. You can use DMS to manage database data and schemas.

Procedure

1. Log on to the ApsaraDB for RDS console. For more information, see the *Log on to the ApsaraDB for RDS console* topic in *ApsaraDB for RDS User Guide*.
2. In the left-side navigation pane, click **Instances**. On the **Instances** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. On the page that appears, click **Log On to DB** to go to the logon page of the DMS console.
4. Enter the logon information.

Parameter	Description
IP address:Port	The internal or public endpoint and corresponding port number of the target ApsaraDB for RDS instance. Example: <code>rm-txxxxxxxxxxxxxxxxx.mysql.aliyun-inc.com:3306</code> . To obtain the internal or public endpoint and the port number, perform the following steps: <ol style="list-style-type: none"> Log on to the ApsaraDB for RDS console. Go to the Instances page, find the target instance, and then click the instance ID or click Manage in the Actions column. In the Basic Information section of the page that appears, obtain the endpoint and port number.
Database Username	The account used to connect to the ApsaraDB for RDS instance. <p> Note The account is created in the ApsaraDB for RDS instance.</p>
Enter your password	The password of the account used to connect to the ApsaraDB for RDS instance. <p> Note The password is that you specified when you create the account in the ApsaraDB for RDS instance.</p>

5. Click **Login**.

 **Note** If you want the browser to remember the password, select **Remember your password** and then click **Login**.

20.3. SQL operations

20.3.1. Use the command window

This topic describes how to use the command window in DMS.

Context

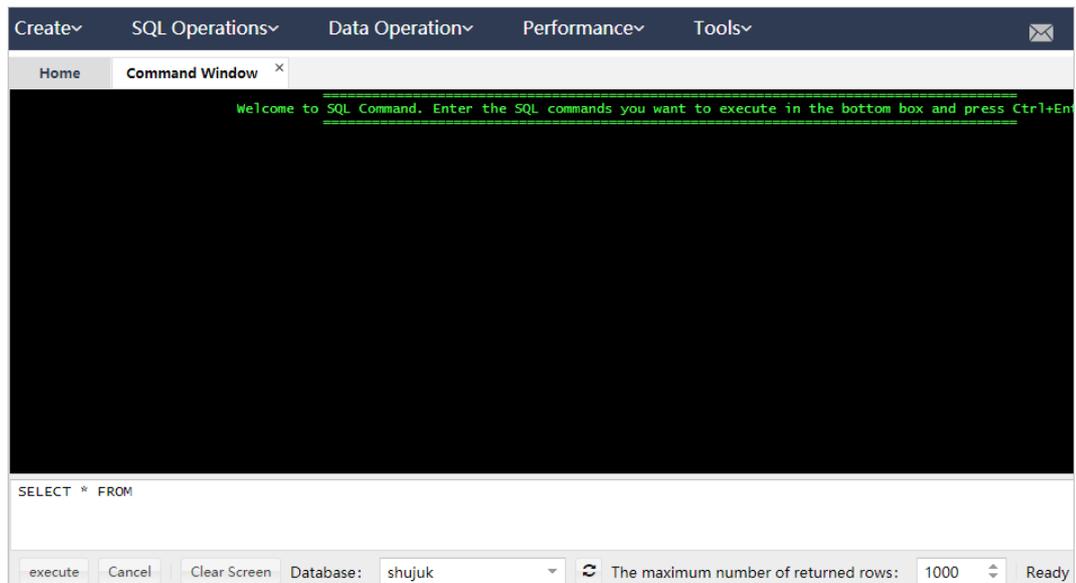

A MySQL database is used in this example.

Procedure

1. **Log on to an RDS instance through DMS.**
2. In the top navigation bar, choose **SQL Operations > Command Window**.

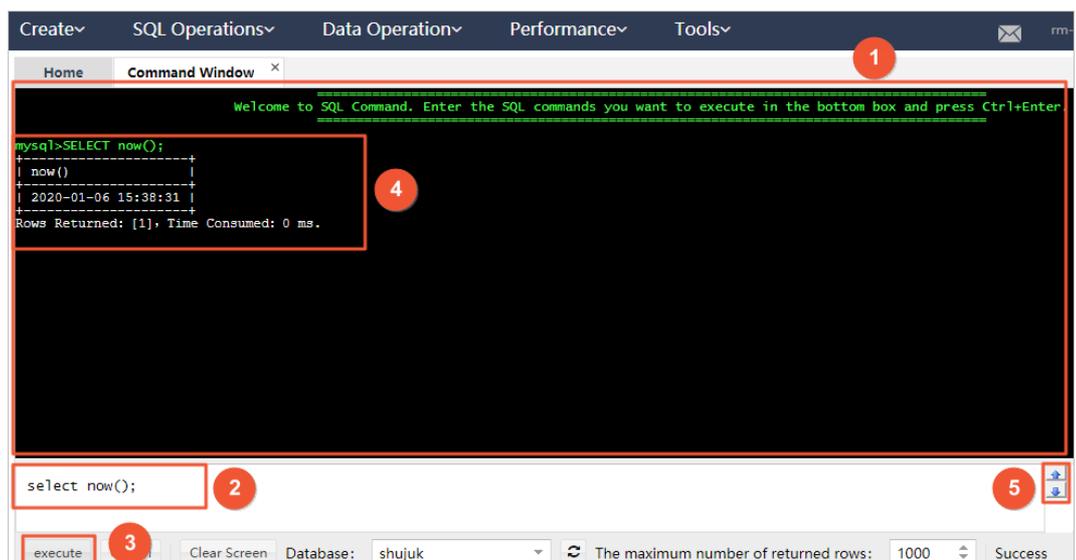

An empty command window appears, as shown in **Command window**.

Command window

3. Enter an SQL statement in the command window, and then click **execute**, as shown in **Execution of an SQL statement**.

Execution of an SQL statement

The following table describes the numbered items in the command window.

Numbered items in the command window

No.	Name	Description
1	Command window	The area displays execution results of SQL statements.
2	SQL statement input area	You can enter SQL statements in this area.
3	execute button	You can click this button to execute the entered SQL statements.
4	Result display area	DMS appends execution results to the result display area.
5	Up and down arrows	You can click the up or down arrow to view an executed SQL statement and execute it again.

- (Optional) If the execution process takes longer than expected, you can click **Cancel** to abort the execution.
- (Optional) Click **Clear Screen** to clear the results for proper display of subsequent results.

To switch to another database, select the new database from the Database drop-down list.

20.3.2. Use the SQL window

20.3.2.1. Open an empty SQL window

This topic describes how to use SQL windows.

Context

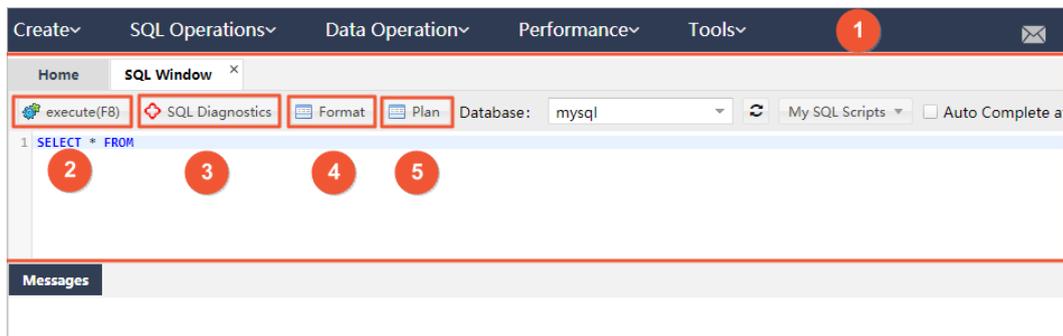

- A MySQL database is used in this example.
- A maximum of 20 SQL windows (including the homepage) can be opened in DMS. We recommend that you open no more than five SQL windows at a time.

Procedure

- Log on to an RDS instance through DMS.
- In the top navigation bar, choose **SQL Operations > SQL Window** to open the **SQL Window** tab.

Empty SQL window shows the empty SQL window you opened.

Empty SQL window

Numbered items in the SQL window describes the numbered items in the SQL window.

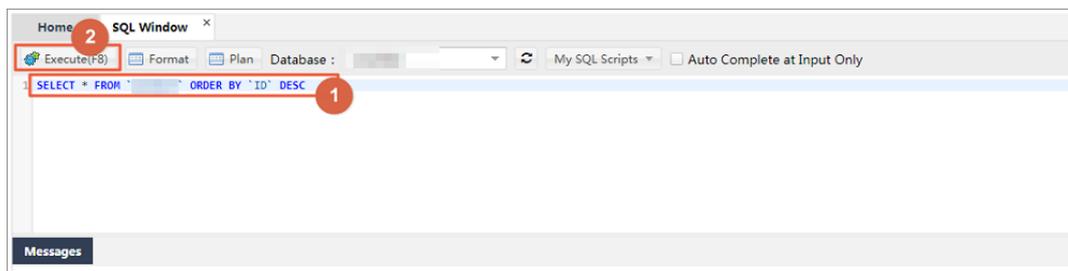

Numbered items in the SQL window

No.	Name	Description
-----	------	-------------

No.	Name	Description
1	SQL window	The green-framed area is the main body of the SQL window.
2	execute(F8) button	You can click this button to execute the entered SQL statements.
3	SQL Diagnostics button	You can click this button to diagnose the current SQL statements.
4	Format button	You can click this button to format the entered SQL statements for readability.
5	Plan button	You can click this button to display the execution plans of the selected SQL statements. You can optimize the SQL statements and improve SQL processing performance based on the execution plans.

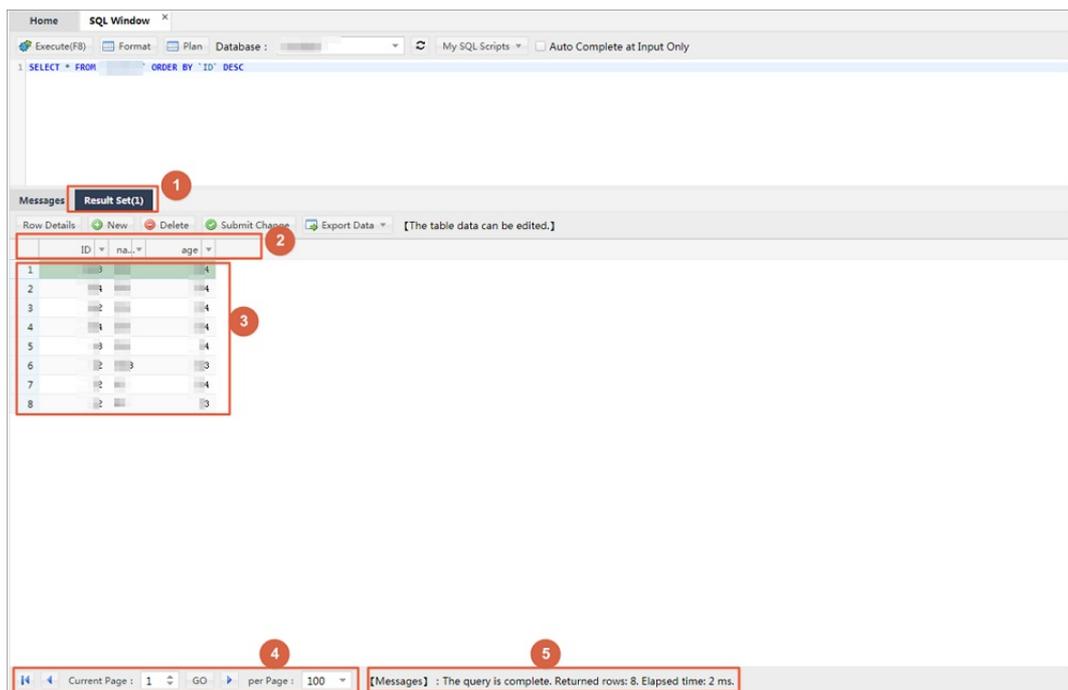

3. Enter the SQL statement that you want to execute and click execute(F8) to complete the SQL query or update, as shown in [Execute SQL statements.](#)

Execute SQL statements.

4. You can view the result set, as shown in [View the result set.](#)

View the result set

Numbered items in the result set

No.	Description
1	The Result Set tab displays the results returned by the SQL query statement.
2	The first row of the table shows the column names. If an alias has been specified for a column in the SQL statement, the alias is displayed in this table.
3	The data area of the table displays the queried data in rows. If the data area is not big enough to show all of the queried data, horizontal and vertical scroll bars will appear to help you navigate the result set.
4	<p>You can set Current Page or Per Page to view the result set.</p> <ul style="list-style-type: none"> Each page displays 100 data entries by default. Go to the next page to view more data. You can set the number of data entries displayed per page as needed. The obtained data entries on the next page are displayed in the data area numbered 3 in the figure.
5	You can view the progress of data acquisition and time elapsed.

5. View the SQL execution message.

Each time a data query (SELECT) or data correction (INSERT, UPDATE, or DELETE) statement is executed, DMS returns a message about the execution including the status and impact.

Data query shows the message returned for data query.

Data query

Data correction shows the message returned for data correction.

Data correction

Numbered items in the data correction window describes the numbered items in the data correction window.

Numbered items in the data correction window

No.	Description
1	After you execute an SQL statement, you can click the Messages tab to view the execution status. No result set is returned for data correction. DMS displays a message after data correction has been completed.
2	DMS executes the entered SQL statements step by step: <ul style="list-style-type: none"> ○ Analyzes the entered SQL statements. ○ Executes the SQL statements in the database. ○ Displays the queried data. ○ Displays statistics, including the number of data rows that are queried or affected.
3	DMS displays the SQL execution results: <ul style="list-style-type: none"> ○ Whether the execution is successful. ○ Number of queried rows, or number of rows affected by the Add, Delete, or Modify operation. ○ The amount of time consumed to execute the SQL statements.

6. Execute SQL statements in batches.

DMS supports batch execution of SQL statements, as shown in [Batch execution](#).

Batch execution

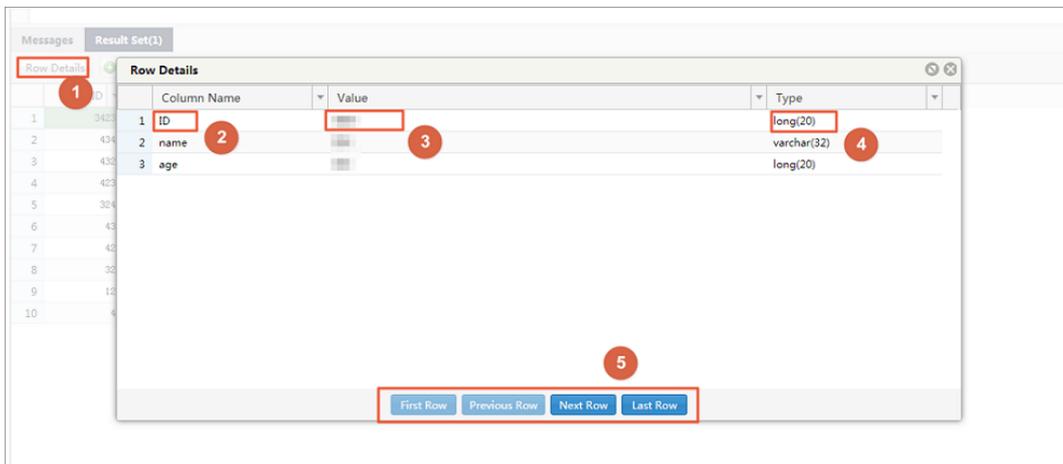

- o 1: Displays the execution result of the first SQL statement.
- o 2: Displays the execution result of the second SQL statement.
 - i. Separate each SQL statement with a semicolon (;) or another separator.
 - ii. To execute only some SQL statements, select the SQL statements that you want to execute. To execute all SQL statements, deselect or select all SQL statements, and click **execute(F8)**.
Wait until all SQL statements have been executed.
 - iii. View the execution results.

If you execute the SELECT statement, DMS displays the result set. If you execute other statements, DMS displays the execution results, such as the number of affected rows.

7. Click **Row Details** to view the details of a single entry in the result set, as shown in **Row details**.

Row details

The following table describes the numbered items in the **Row Details** dialog box.

Numbered items in the Row Details dialog box

No.	Description
1	On the Result Set tab, select a single data entry that you want to display, and click Row Details to view details of the entry. The Row Details dialog box displays the name, value, and type of each column of the data entry.

No.	Description
2	Column Name: If you have specified an alias for a column, the alias is displayed.
3	Value: DMS automatically parses and displays the column values. Data such as time and binary code is formatted as a string to ease reading.
4	Type: You can view the type and length of each column.
5	The navigation area. You can click Previous Row, Next Row, First Row, and Last Row to view the details of the corresponding data entry.

8. (Optional) Edit the queried data in the result set.

- Click **New** to add a row of data to the currently queried table.
- Click **Delete** to delete the selected row of data from the result set table.
- Select the row that you want to perform operations on.
- Update the column values in the selected row directly.

After you modify data, click **Submit Change** to save the modified data to the database.

After you click **Submit Change**, DMS displays the SQL statements required to save your changes. This allows you to confirm the changes and prevent misoperations that can result in data loss.

Click **OK** to apply the changes to the database as expected.

9. Click **Format** to format the selected SQL statements to make them easier to read and write.

- Only the selected SQL statements are formatted. If you do not select any SQL statements, all entered SQL statements will be formatted.
- This feature transforms your SQL statements into standard, easy-to-read statements without changing the SQL execution logic and syntax or affecting the execution.

Example:

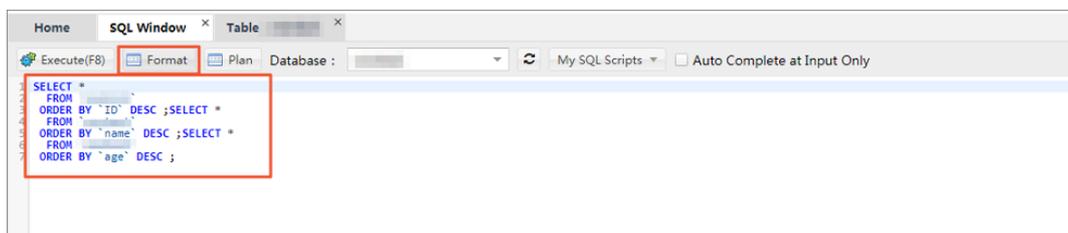

Original SQL statements shows the original SQL statements.

Original SQL statements

Formatted SQL statements shows the formatted SQL statements.

Formatted SQL statements

10. Click **Plan** to view the execution plan if you want to troubleshoot SQL-related problems or optimize SQL performance.

- After you click **Plan**, DMS displays the execution plan of the selected SQL statement. If no SQL statement is selected, DMS displays the execution plans of all SQL statements.

- DMS displays an execution plan in detail. You can view information such as the execution plan type and possible keys.
 - Different databases display execution plans in different ways and in varying levels of detail.
 - If you want to view the execution plans of several SQL statements, DMS displays the execution plan of each SQL statement in detail on different tabs, as shown in [Plan](#).

Plan

ID	SELECT_TYPE	TABLE	TYPE	POSSIBLE_KEYS	KEY	KEY_LEN	REF	ROWS
1	SIMPLE	index	PRIMARY			8		

- 1: Shows the execution plan of the first SQL statement in detail.
- 2: Shows the execution plan of the second SQL statement in detail.

20.3.2.2. Restore a saved SQL window

This topic describes how to restore a saved SQL window.

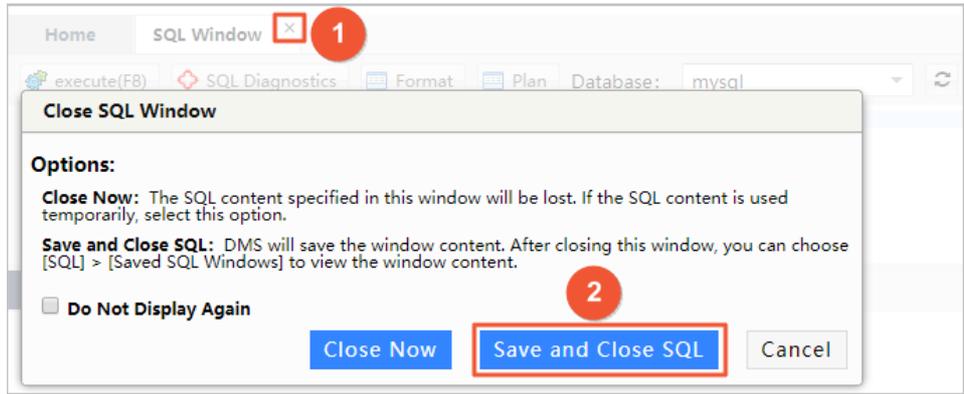

Context

- A MySQL database is used in this example.
- A maximum of 20 SQL windows (including the homepage) can be opened or stored in DMS. We recommend that you open no more than five SQL windows at a time.

Procedure

1. [Log on to an RDS instance through DMS.](#)
2. In the top navigation bar, choose **SQL Operations > SQL Window**.
3. Save the current SQL work environment.
 - DMS automatically saves the work environment when you close the operation page.
 - The next time that you log on to the DMS console, DMS automatically restores the last saved work environment, including the last used database, the open SQL windows, and the SQL statements entered in the SQL windows.
 - When you close a SQL window, DMS prompts you to confirm whether to save the content of the window, as shown in [Confirm to close a SQL window](#).

Confirm to close a SQL window

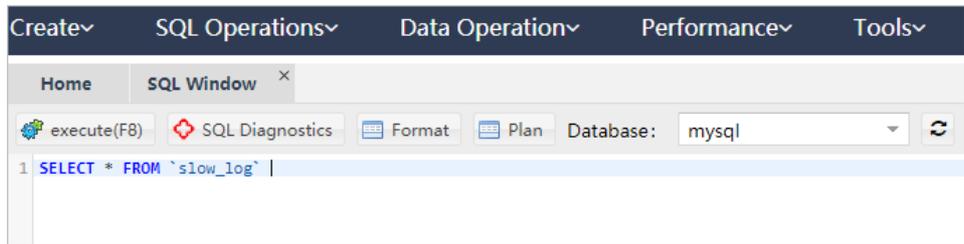

- 1: Click the Close icon in the upper-right corner of the SQL window to close the window.
- 2: DMS prompts you to confirm whether to save the content. Click **Save and Close SQL**. DMS saves the content of the SQL window before it is closed.

If you click **Close Now**, DMS does not save the content of the SQL window.

4. Restore a saved SQL window.
 - i. Choose **SQL Operations > Saved SQL Windows**.
DMS displays all saved SQL windows.
 - ii. Click **View SQL** next to a saved SQL window to restore the SQL window.
 - iii. When you log on to the database through DMS, DMS automatically restores the most recently saved content of the SQL window, as shown in [Restored SQL window](#).

Restored SQL window

20.3.2.3. Manage common SQL statements

This topic describes how to manage common SQL statements in DMS.

Context

A MySQL database is used in this example.

Procedure

1. [Log on to an RDS instance through DMS](#).
2. In the top navigation bar, choose **SQL Operations > SQL Window** to open the **SQL Window** tab.
3. Perform the following operations:
 - Add a common SQL statement.

Choose **My SQL Scripts > Add SQL** to add a common SQL statement.

The applicable scope is described as follows:

- **Current Instance:** You can only view the custom SQL statement through the instance (with the specified IP address and port number) that is currently connected to.

- **Current Database:** You can only view the custom SQL statement through the database that is currently connected to. If you switch the current database to another one, you cannot view the custom SQL statement by choosing **My SQL Scripts > Select SQL**.
- View saved SQL statements.
To view saved SQL statements, choose **My SQL Scripts > Select SQL**.
- Manage SQL statements.
To manage your SQL statements, choose **My SQL Scripts > Manage SQL**.
 - In the **Manage SQL** dialog box that appears, click **Edit** or **Delete** to edit or delete SQL statements.
 - In the **Manage SQL** dialog box, click **New** to add an SQL statement.
 - Double-click an SQL statement to insert the statement into **SQL Window**. The statement appears in the SQL window and is selected.

20.3.2.4. Use the SQL template

This topic describes how to use the SQL template in DMS.

Procedure

1. **Log on to an RDS instance through DMS.**
2. In the top navigation bar, choose **SQL Operations > SQL Window**. A SQL window appears.
The SQL template is displayed in the rightmost part of the SQL window.
3. Double-click an SQL command or drag it into the SQL window. Then you can use or reference the command.
You can directly modify the commands referenced from the template even if you are not familiar with the commands.

20.3.3. Table operations (based on the Table directory tree)

20.3.3.1. Open a table-based SQL window

This topic describes how to open a table-based SQL window in DMS.

Context

A MySQL database is used as an example.

Procedure

1. **Log on to an RDS instance through DMS.**
2. In the left-side directory tree, right-click a table and choose **SQL Operation Data** from the shortcut menu to open an SQL window. DMS automatically runs the SQL statement that queries top 50 records of the table.

20.3.3.2. Edit table data

This topic describes how to edit table data.

Context

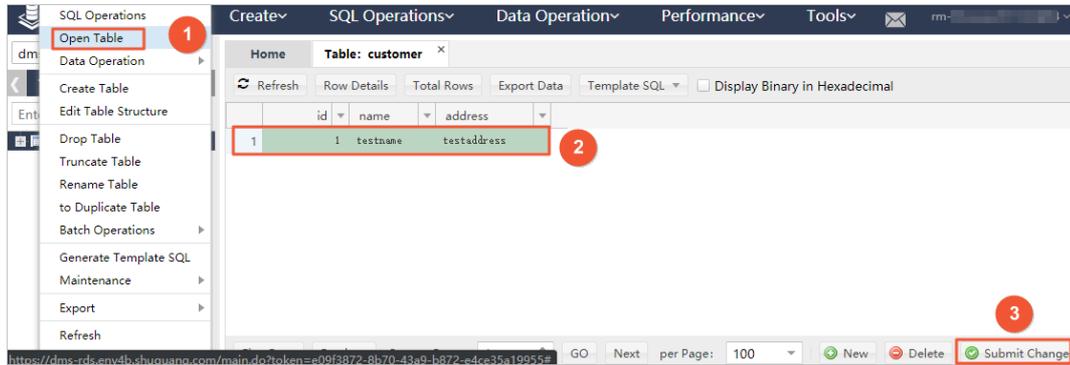

- An ApsaraDB RDS for MySQL database is used in this example.
- This feature applies to tables with a small volume of data. For tables containing a large volume of data, you must find the target data before you can edit the data. It may take time to find the data to be edited.

Procedure

1. **Log on to an RDS instance through DMS.**
2. In the left-side navigation pane, right-click a table and select **Open Table**. A tab appears on the right,

displaying the data of the selected table, as shown in **Table tab**.

Table tab

- 1: Right-click a table and select **Open Table**.
- 2: Modify the values of the columns in the table.
- 3: Click **Submit Change** to submit the modified data.

20.4. Database development

20.4.1. Overview

This topic describes how to add, modify, delete, and manage objects such as indexes, foreign keys, and stored procedures.

20.4.2. Table

20.4.2.1. Create a table

This topic describes how to create a table in DMS.

Procedure

1. **Log on to an RDS instance through DMS.**
2. You can create a table in one of the following ways:
 - In the top navigation bar, choose **Create > Table**.
 - In the left-side navigation pane, click **Table**, right-click a table, and then select **Create Table**.
3. **Edit columns.**

On the **New: Table** tab, the **Edit Column** tab appears by default.

You can edit the basic information and extended information about the fields as needed.

You can also click **Columns** to edit the table information.
4. **Click Index** to edit indexes.
 - Click **New** to add an index.
 - Click **Remove** to delete an index.
 - Click the index row to modify index information.
5. **Click Foreign Key** to go to the **Edit Foreign Key** tab.
 - Click **New** to add a foreign key. The new key is editable.
 - Click **Remove** to delete a foreign key.
 - To edit a foreign key, enter the key name, column name, and information about the referenced database, table, and column.

6. Click **Partition** to edit the partition information. The SQL statements of the partition must be configured.
7. Click **Basic** to edit the basic information about the table.
 - You can edit the table name, storage engine, character set, and description.
 - You can click **Advanced** to edit table parameters.
8. Click **Save**. DMS generates the SQL statements used to create a table.

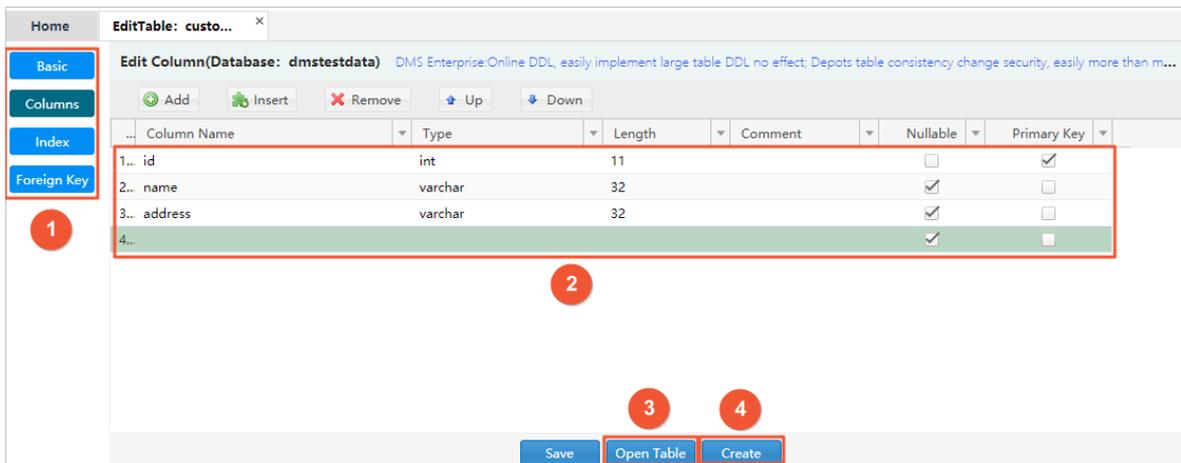

In the Submit Change dialog box, click **OK** after you confirm the SQL statements. DMS then adds the table to your database.

20.4.2.2. Edit a table

This topic describes how to edit a table in DMS.

Procedure

1. **Log on to an RDS instance through DMS.**
2. In the left-side Table directory tree, right-click a table and choose **Edit Table Structure** from the shortcut menu to edit the table structure.
3. The Edit Table window is similar to the Create Table window. DMS automatically loads the table structure into the window.

- 1: Select a table object type, such as Columns or Index.
 - 2: Click a specific operation on the table object, which is similar to the Create and Edit operations on tables.
 - 3: Click **Open Table** to view and modify table data.
 - 4: Click **Create** to view the statements used to create a table.
4. Click **Save**. DMS displays the SQL statements used to modify the table structure.
Click **OK** after you confirm the SQL statements. DMS then saves the modified table structure to your database.

20.4.2.3. Delete a table

This topic describes how to delete a table in DMS.

Procedure

1. **Log on to an RDS instance through DMS.**
2. In the left-side Table directory tree, right-click the table you want to delete and choose **Delete Table** from the shortcut menu.

Warning Deleting tables is a high-risk operation. Therefore, exercise caution when deleting tables.

3. Click Yes to delete the table.

20.4.2.4. Duplicate a table

This topic describes how to duplicate a table in DMS.

Procedure

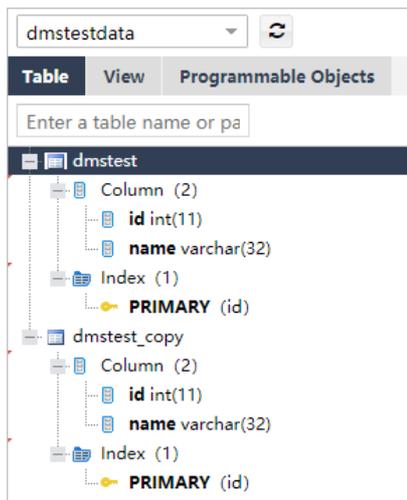

1. Log on to an RDS instance through DMS.
2. In the left-side navigation pane, click Table, right-click the table that you want to duplicate, and then choose To Duplicate Table from the shortcut menu.

The dialog box to enter the name of the destination table appears.

3. Enter the name of the destination table and then click OK. DMS duplicates the selected table.
4. The schema of the created destination table is the same as that of the selected source table.

A new table is created, as shown in Schema of the destination table.

Schema of the destination table

20.4.2.5. Generate SQL statement templates

This topic describes how to generate SQL templates in DMS.

Procedure

1. Log on to an RDS instance through DMS.
2. In the left-side Table directory tree, right-click the table you want to copy and choose Create SQL Template from the shortcut menu.
3. DMS generates SQL INSERT, UPDATE, SELECT and CREATE TABLE statement templates as a reference when you perform SQL operations.

20.4.2.6. Query table information

This topic describes how to query table information in DMS.

Procedure

1. Log on to an RDS instance through DMS.

2. In the left-side Table directory tree, right-click the table you want to query and choose **Object Info** from the shortcut menu.
3. DMS obtains information about the table object. Click the **Basic Info** tab to view basic information of the table.
4. Click the **Create Statement** tab to view the table creation statements.

20.4.2.7. Clear data

This topic describes how to clear table data in DMS.

Procedure

1. [Log on to an RDS instance through DMS.](#)
2. In the left-side Table directory tree, right-click the table that you want to clear data from and choose **Clear Table** from the shortcut menu.

 **Notice** Clearing table data is a high-risk operation and may affect your data usage. DMS prompts you to confirm whether to clear table data.

3. Click **Yes** if you want to clear table data. DMS then clears data of the selected table.
4. Open the table to check whether its data is cleared.

20.4.2.8. Perform operations on multiple tables

This topic describes how to perform operations on multiple tables in DMS.

Procedure

1. [Log on to an RDS instance through DMS.](#)
2. Delete multiple tables at a time.
 - i. In the left-side navigation pane, click **Table**, right-click a table name, and then choose **Batch Operations > Drop Batch Tables**.

The dialog box for you to select multiple tables to delete appears.
 - ii. Select the tables to be deleted.
 - iii. Click **OK**. DMS prompts you to confirm whether you want to perform the batch operation.
 - iv. Click **Drop**.

DMS deletes the selected tables at a time.
3. Perform other operations on multiple tables. You can clear data, delete or maintain tables, and modify table name prefixes in batches.
 - i. In the left-side navigation pane, click **Table**, right-click a table name, and then choose **Batch Operations > More**.
 - ii. Select multiple tables and then perform a batch operation. For example, click **Truncate Data**.
 - iii. In the **Information** dialog box that appears, click **Yes**.

DMS performs the batch operation.

20.4.2.9. Maintain a table

This topic describes how to maintain and optimize a table in DMS.

Procedure

1. [Log on to an RDS instance through DMS.](#)
2. In the left-side Table directory tree, right-click the table you want to maintain and choose **Maintain Table**

> **Optimize Table.**

3. Click **Yes**.

Click **Yes** if you want to optimize the table. Then DMS starts optimization.

Optimization allows you to reuse the table space in the database and organize file fragments.

 **Note** You can check, restore, and analyze tables in a way similar to optimizing tables.

20.4.3. Manage indexes

This topic describes how to add, modify, or delete indexes in DMS.

Procedure

1. **Log on to an RDS instance through DMS.**
2. In the left-side **Table** directory tree, expand the table you want to modify and choose **Index > Add Index**. The **Add Index** page appears.
3. Set index parameters.

- 1: Enter an index name and select an index type.
 - 2: Click **+** or **-** to add or delete a field to or from the index.
 - 3: Edit the fields of the index. You can enter or select values from the drop-down list. You can set a prefix length for a variable-length field (such as varchar) to save space occupied by the index.
4. Click **Save**.
DMS generates SQL statements used to add the index. Confirm the change.
 5. Click **Run**.
 6. After the index is added, check the indexes of the table to verify that the new index takes effect.
You can modify or delete the new index as needed.
 - In the left-side **Table** directory tree, right-click an index and choose **Modify Index** from the shortcut menu. The **Modify Index** window appears.
The method of modifying an index is similar to that of adding one, except that the SQL statements delete the old index before adding a new one.

- In the left-side Table directory tree, right-click an index and choose **Delete Index** from the shortcut menu. The **Delete Index** window appears. Click OK to delete the index.

20.4.4. Manage foreign keys

This topic describes how to add foreign keys in DMS.

Procedure

1. [Log on to an RDS instance through DMS.](#)
2. In the left-side Table directory tree, right-click the table to be modified and choose **Edit Table Structure** from the shortcut menu.
3. On the **Edit Table** page that appears, click the **Foreign Key** tab to edit foreign keys.
4. Enter the foreign key information, and set the fields of foreign keys and referenced tables.
5. Click **Save**.

20.4.5. Create a partition

This topic describes how to create partitions in DMS.

Procedure

1. [Log on to an RDS instance through DMS.](#)
2. In the left-side navigation page, click **Table**, right-click a table name, and then choose **Create Table** from the shortcut menu.
3. Enter the basic table information and set the table fields and partition information.
4. Click **Save** to save the created table schema.
A dialog box appears to prompt you to confirm the SQL statements used to create the table.
5. Click **OK**. DMS creates the partitioned table based on the configured partition fields and partitioning logic.
6. After you execute the SQL statements, check whether the partitioned table has been created.

20.4.6. Create a stored procedure

This topic describes how to create and manage stored procedures in DMS.

Context

A MySQL database is used as an example.

Stored procedures, functions, triggers, and events are considered programmable objects in DMS.

Procedure

1. [Log on to an RDS instance through DMS.](#)
2. Click the left-side **Programmable Object** directory tree, and choose **Stored Procedure > Create (Stored Procedure)**. The **Create Stored Procedure** tab is displayed.
3. Enter a name and a description for the stored procedure.
4. Click **OK**.
5. DMS provides a template for creating stored procedures. You only need to edit the stored procedure part.
6. Click **Save** to save the stored procedure to the database.
If a syntax error is found, DMS returns the cause of the error.
7. Click **Run** to run the stored procedure.
DMS displays a page for you to set the input parameters for the stored procedure.

Set the input parameters. In this example, set cnt to 80 to search for records that meet the Value=80 condition.

8. Click **Execute** to execute the stored procedure.

DMS displays output parameters or intermediate result set of the stored procedure, if any.

- The **Message** tab displays messages about the execution, such as output variables and intermediate result sets.
- The **Intermediate Result Set 1** tab displays the result set generated during the execution. If multiple intermediate result sets are available, DMS will generate multiple tabs, such as Intermediate Result Set 1, Intermediate Result Set 2, and Intermediate Result Set 3.

9. Click the **Intermediate Result Set 1** tab. DMS displays records with the value of 80.

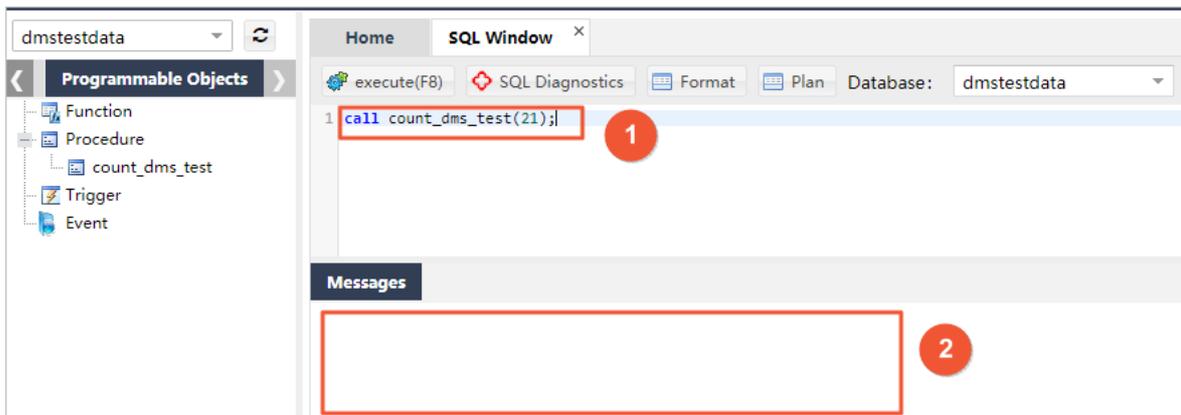

10. You can set the options when creating the stored procedure. Click **Option Settings** to set options for the stored procedure.

11. After a stored procedure is created, it is added to the Programmable Object directory tree.

You can perform other operations related to the stored procedure through the following menu options:

- **Create**
- **Edit**
- **Delete**
- **Execute**

12. You can run the stored procedure in the SQL window.

- 1: Run the call stored_procedure_name command to call a stored procedure.
- 2: The SQL window shows the result set of the stored procedure, if any.

20.4.7. Create a function

This topic describes how to create a function in DMS.

Context

Functions, stored procedures, triggers, and events are considered programmable objects in DMS.

Procedure

1. **Log on to an RDS instance through DMS.**
2. In the left-side **Programmable Object** directory tree, choose **Function > Create (Function)**.

The **Create Function** page is displayed.

3. Set basic information of the new function.
4. Click **OK**.

The **Edit Function** page appears. DMS generates a function creation template.

5. Enter information in the function part.
6. Click **Save**. DMS then checks whether the function is correctly defined. If not, DMS returns an error message.
DMS runs the correct function definition in your database, and returns a message, indicating that the function is saved.
7. Click **Execute** to execute the function.
8. Enter a parameter such as `wednesday` and click **Execute** to execute the function.
9. Click **Option Settings** to set different options for the function.
You can also run the function in the SQL window.

20.4.8. Create a view

This topic describes how to create and manage custom views in DMS.

Procedure

Create a view

1. **Log on to an RDS instance through DMS.**
2. Click the **View** directory tree on the left side to check the views of the current database.
3. Right-click the blank space and choose **New View** from the shortcut menu. The **Create: View** page is displayed.
4. Set basic information of the view.

The following example shows how to filter records in the `dmstest` table whose values are even numbers, and output the `id` and `name` fields.

5. Click **Save Changes**. DMS generates SQL statements used to create the view based on your settings.
6. Click **OK** after you confirm the SQL statements. DMS saves the defined view to your database.
7. The saved view is added to the **View** directory tree on the left side. You can click the view to display its definition.

Check the view

8. Right-click **View** and choose **Check View** from the shortcut menu to query data through the newly created view.
9. You can perform view-related operations in DMS.

The menu options include:

- View Data
- Create View
- Edit View
- Delete View
- Refresh Views

20.4.9. Create a trigger

This topic describes how to create and manage a trigger in DMS.

Context

Triggers, functions, stored procedures, and events are considered programmable objects in DMS.

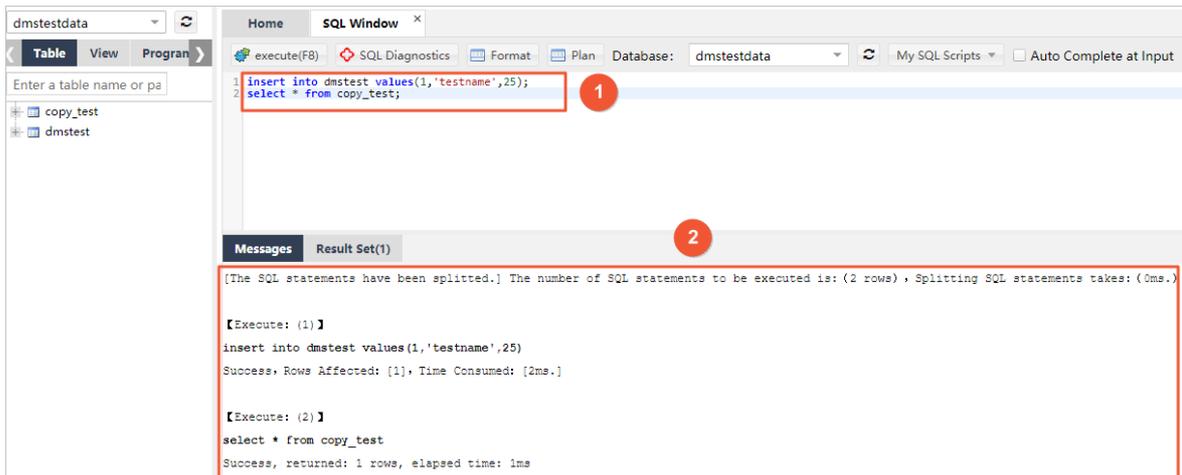

Procedure

1. **Log on to an RDS instance through DMS.**
2. Click the **Programmable Object** directory tree on the left side, and choose **Trigger > Create (Trigger)**.

The Create: Trigger tab is displayed.

- 1: Trigger table.
 - Enter a name for the trigger.
 - Select dmstest from the drop-down list as the trigger table.
 - Select AFTER from the drop-down list as the trigger time.
 - Select INSERT from the drop-down list as the trigger event.
- 2: Trigger settings.
 - Set the operations to be performed when the trigger event occurs.
 - When data is inserted into the dmstest table, the trigger in this example inserts data into the copy_test table and records the insertion time in copy_test.time.
- 3. Click Save after you finish the trigger settings. DMS then generates the SQL statement to be executed by the trigger based on your settings. Confirm the SQL statement.
- 4. Click OK. DMS then saves the trigger to your database. DMS returns a message, indicating that the trigger has been saved. In the left-side navigation pane, choose Programmable Object > Trigger to view the trigger you created.
- 5. You can insert data into the dmstest table to check whether the data is recorded in the copy_test table.

- 1: Insert data into the dmstest table and query the copy_test table for the inserted data.
- 2: The SQL window displays messages about the execution of the SQL statements. The messages indicate that a row is inserted into the dmstest table and that this row is also added to the copy_test table.
- 6. Check the result set in the SQL window to verify whether the insert operation is correctly performed by the trigger.
- 7. In the left-side navigation pane, choose Programmable Object > Trigger to perform trigger-related operations through the following menu options:

- Create (Trigger)
- Edit (Trigger)
- Delete (Trigger)

20.4.10. Create an event

This topic describes how to create and manage events in DMS.

Prerequisites

After you log on to a database, make sure that event support has been enabled for the database.

- Execute the `SELECT @@event_scheduler;` statement to check whether the database supports events. If ON is returned, event support is enabled.
- If OFF is returned, event support is disabled. You need to enable event support by modifying the configuration file or executing the `SET GLOBAL event_scheduler = ON;` statement.

Context

Events, triggers, functions, and stored procedures are considered programmable objects in DMS.

Procedure

1. Log on to an RDS instance through DMS.
2. Click the Programmable Object directory tree on the left side, and choose Event > Create (Event).

The Create Event page is displayed.

1: In the event setup area, set the event name, cycle, start time, end time, status, and comment, and choose whether to enable cyclic execution.

2: In the event execution Statement area, set the operations to be performed when a scheduled event is triggered.

3. Set an event trigger rule and the SQL statements for event execution.
4. Click Save. DMS generates the SQL statements used to create the event.
5. After you confirm that the SQL statements are correct, click OK. DMS then executes the edited event in your database.
 - If the event is created, DMS returns a message, indicating that the event is saved.
 - In the left-side navigation pane, choose Programmable Object > Event to view the event you created.
6. Check whether the event is properly executed in the SQL window.

In this example, the event executes SQL statements to insert a piece of data into the copy_testtable every minute. Check the copy_test table to see whether the data is inserted as programmed.

- 7. You can perform various event-related operations in DMS. The menu options include:
 - Create (Event)
 - Edit (Event)
 - Delete (Event)

20.5. Data processing

20.5.1. Import data

This topic describes how to use DMS to import data.

Context

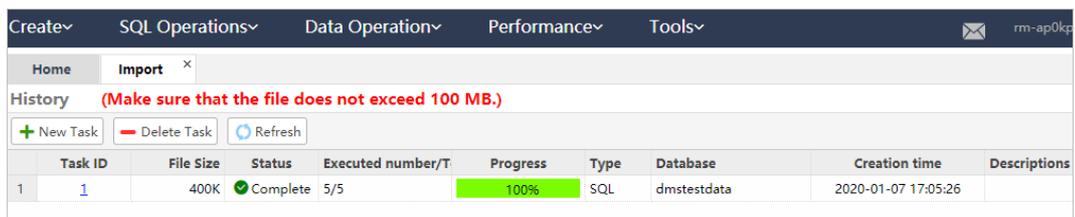

A MySQL database is used in this example.

Procedure

1. Log on to an RDS instance through DMS.
2. In the top navigation bar, choose Data Operation > Import.

The Import tab appears, as shown in [Import tab](#).

Import tab

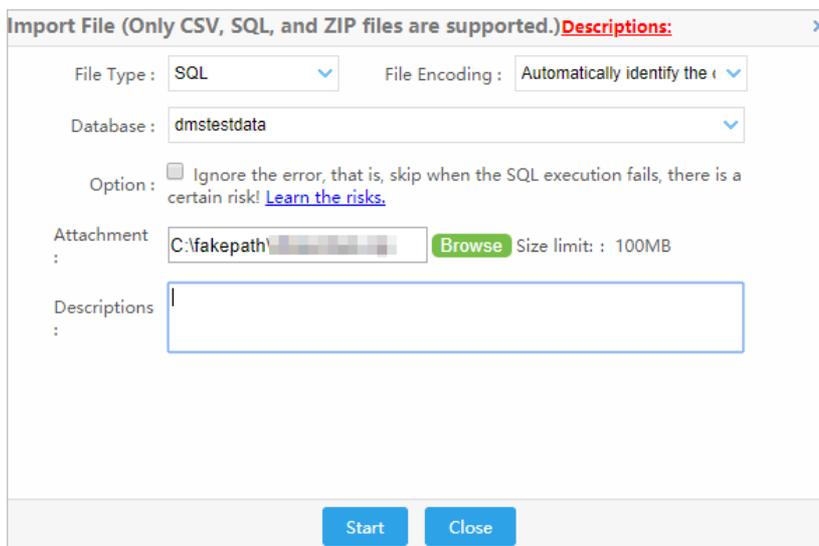

The Import tab contains the import toolbar and import history.

If you have imported data, you can view previous data import tasks in [History](#).

3. Click New Task.

The Import File dialog box appears, as shown in [Import File dialog box](#).

Import File dialog box

- Select the file type of the file to be imported. Currently, only SQL and CSV files are supported.

- If the data file uses a specific character set, you can manually specify the character set. By default, DMS detects the character sets used in a file.
 - If an error occurs while an SQL statement is being executed, DMS will terminate the import task. You can select Ignore Error to proceed. However, this operation may affect subsequent operations.
 - You can enter a brief description of the import task for later review.
4. Click **Start** to start the import task.
- If the imported data has any error, DMS terminates the import process and returns an error message. You can modify the data file to correct the error and import it again.
- If the imported data and SQL statements are correct, DMS displays the import progress, volume of imported data, and time elapsed.
- After the import is complete, you can view the import task in **History**.
- Click a task ID to view the execution details of the task.

20.5.2. Export data

20.5.2.1. Export a database

This topic describes how to use DMS to export a database.

Context

A MySQL database is used in this example.

Procedure

1. [Log on to an RDS instance through DMS.](#)
2. In the top navigation bar, choose **Data Operation > Export**. The **Export** tab appears.
3. On the **Export** tab, choose **New > Export Database**.
4. In the **New** dialog box that appears, select a database, a file type (SQL or CSV), and the content to be exported (schema and data, only data, or only schema). Select tables on the right side, and select additional information in the **Additional Information** section.
5. Click **OK**.
6. In the **Information** dialog box that appears, click **Yes**. DMS then starts executing the export task.

DMS refreshes the export progress every two seconds.

You can close the **Export** tab, and view and download the exported file in the export task list later.

After the export is complete, DMS automatically downloads the exported file to your local computer. You can also click **Download** to download the exported file.

You can view previously submitted export tasks in the export task list. You can click a task ID to view the task details, and can download the corresponding exported file.

20.5.2.2. Export an SQL result set

This topic describes how to use DMS to export an SQL result set.

Context

A MySQL database is used in this example.

Procedure

1. [Log on to an RDS instance through DMS.](#)
2. In the top navigation bar, choose **Data Operation > Export**. The **Export** tab appears.
3. On the **Export** tab, choose **New > Export SQL result sets**.

4. In the **New** dialog box that appears, complete the settings as needed.

Select a file type (CSV or SQL_Insert) and a database, set the maximum number of rows of the result set, and enter the SQL statements.

5. Click **OK**. DMS then executes the task of exporting the SQL result set in the background.

After the export task is complete, DMS automatically downloads the exported files to your local computer. You can also click **Download** to download the exported files.

DMS also summarizes the export results and automatically downloads the files of exported SQL result sets.

You can view the export tasks of SQL result sets that you submitted in the export task list and download SQL result set files.

20.6. Performance

20.6.1. Lock wait

20.6.1.1. View sessions in the lock wait state

When a session of an ApsaraDB RDS for MySQL instance is waiting for a row exclusive lock held by another session, an InnoDB lock wait will occur. This topic describes how to use DMS to view sessions in the lock wait state.

Context

A MySQL database is used in this example.

Procedure

1. [Log on to an RDS instance through DMS.](#)
2. In the top navigation bar, choose **Performance > InnoDB Lock Waits**.
If transactions of the current instance are waiting for locks, the Lock and Lock-Wait icons are displayed.
3. Move the pointer over the Lock or Lock-Wait icon to view the sessions that hold a lock or sessions that are waiting for a lock, and related session IDs.
4. Click  to reload the data.

20.6.1.2. Terminate a session in the lock wait state

This topic describes how to use DMS to terminate a session in the lock wait state.

Context

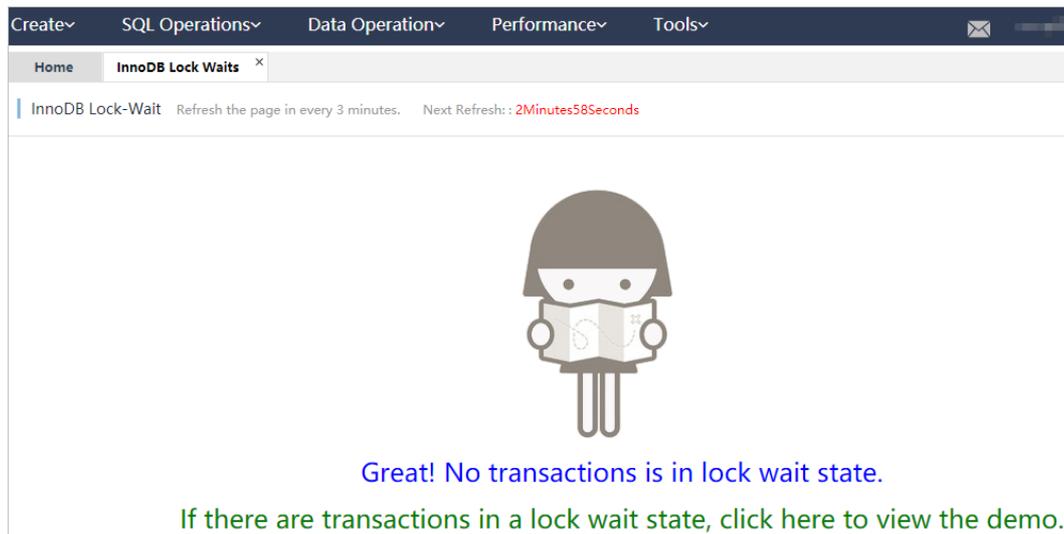

A MySQL database is used in this example.

Procedure

1. [Log on to an RDS instance through DMS.](#)
2. In the top navigation bar, choose **Performance > InnoDB Lock Waits**. If transactions of the current instance are waiting for locks, the Lock and Lock-Wait icons are displayed.
3. Move the pointer over the Lock or Lock-Wait icon to view the sessions that hold a lock or sessions that are waiting for a lock, and related session IDs.
4. Click the Lock or Lock-Wait icon.
The **Delete Session** message appears.
5. Click **Yes** to terminate the current session.

InnoDB Lock Waits tab shows the page when no transactions are waiting for locks.

InnoDB Lock Waits tab

20.7. Extended tools

20.7.1. View statistics on table data volumes

This topic describes how to view statistics on table data volumes in DMS.

Context

A MySQL database is used in this example.

Procedure

1. [Log on to an RDS instance through DMS.](#)
2. In the top navigation bar, choose **Tools > Table Data Amount**. The **Table Data Amount** tab appears, as shown in [Collection of statistics on table data volumes](#).

Collection of statistics on table data volumes

Database	Table Name	Storage	Rows	Row Leng.	Data	Index	All	Creation time	Collation Rules
d	customer	InnoDB	10137	156	1.52MB	0B	1.52MB	2020-01-07 17:05:27	utf8_general_ci
d	order	InnoDB	0	0	16KB	0B	16KB	2020-01-07 16:54:42	utf8_general_ci

3. This tab displays the information about all user tables of the current instance, including the database name, table name, storage engine, number of rows, row size (in bytes), data, index, total table size, creation time, and collation rules.

You can filter statistics on table data volumes based on a range of criteria such as database name, table name, total table size (in MB), number of table rows, global sorting, and storage engine. You can also perform the paging, refresh, and reset operations.

20.7.2. View ER diagrams

This topic describes how to view ER diagrams in DMS.

Context

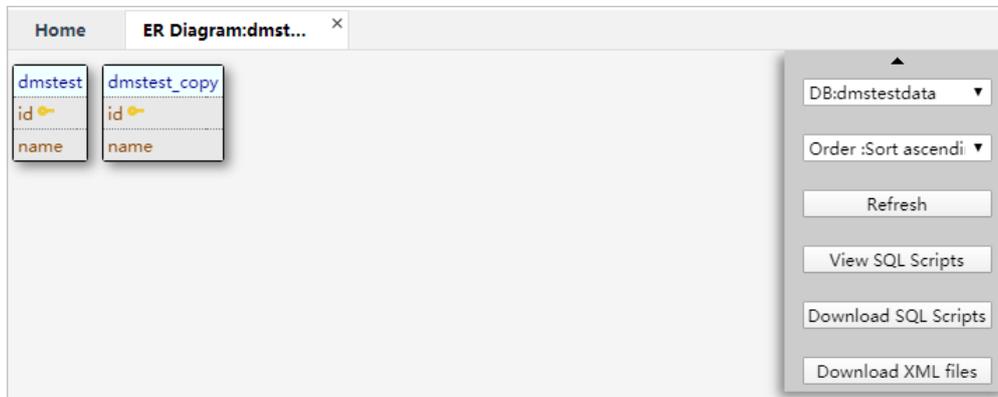

This topic uses a MySQL database as an example.

Procedure

1. Log on to an RDS instance through DMS.
2. In the top navigation bar, choose **Tools** > **ER Diagram**.

The ER Diagram tab appears, as shown in [ER Diagram tab](#).

ER Diagram tab

The ER Diagram tab displays the relationship between tables in the current database and provides methods for representing table names, column names, indexes, and relationships.

3. You can perform the following operations:
 - Select a database from the **DB:<Database name>** drop-down list to switch to the database.
 - Select a value from the **Order:<Sorting option>** drop-down list. Tables can be sorted by table name or column count in ascending or descending order.
 - Click **Refresh** to refresh the current ER Diagram tab.
 - Click **View SQL Scripts** to view the SQL statements used to create tables in the current database.
 - Click **Download SQL Scripts** to download the SQL statements used to create tables in the current database.
 - Click **Download XML files** to download the SQL statements used to create tables in the current database in XML format.
 - Double-click the name of a table column to view the column definition.
 - Double-click a table name to edit the table on a new tab.

21. Server Load Balancer (SLB)

21.1. What is SLB?

This topic provides an overview of Server Load Balancer (SLB). SLB distributes inbound network traffic across multiple Elastic Compute Service (ECS) instances that act as backend servers based on forwarding rules. You can use SLB to improve the responsiveness and availability of your applications.

Overview

After you add ECS instances that reside in the same region to an SLB instance, SLB uses virtual IP addresses (VIPs) to virtualize these ECS instances into backend servers in a high-performance server pool that ensures high availability. Client requests are distributed to the ECS instances based on forwarding rules.

SLB checks the health status of the ECS instances and automatically removes unhealthy ones from the server pool to eliminate single points of failure (SPOFs). This enhances the resilience of your applications.

Components

SLB consists of three components:

- SLB instances

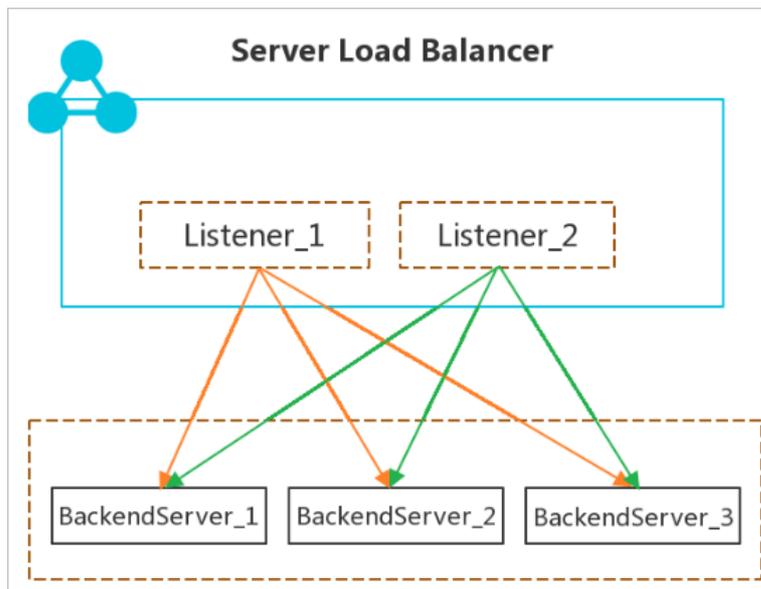

An SLB instance is a key load-balancing component in SLB. It receives traffic and distributes traffic to backend servers. To get started with SLB, you must create an SLB instance and add at least one listener and two ECS instances to the SLB instance.

- Listeners

A listener checks for connection requests from clients, forwards requests to backend servers, and performs health checks on backend servers.

- Backend servers

ECS instances are used as backend servers in SLB to receive and process distributed requests. ECS instances can be added to the default server group of an SLB instance. You can also add multiple ECS servers to VServer groups or primary/secondary server groups after the corresponding groups are created.

Benefits

- High availability

SLB features full redundancy that avoids SPOFs and supports zone-disaster recovery. You can use SLB with Apsara Stack DNS to achieve geo-disaster recovery with an availability of up to 99.95%.

SLB can be scaled based on network traffic to protect your services from outages caused by fluctuating traffic flows.

- **Strong scalability**

You can increase or decrease the number of backend servers to adjust the load balancing capacity for your applications.

- **Low costs**

SLB can save 60% of load balancing costs compared with using traditional hardware solutions.

- **Outstanding security**

You can use SLB with Apsara Stack Security to defend your applications against 5 Gbit/s distributed denial of service (DDoS) attacks.

- **High concurrency**

An SLB cluster supports hundreds of millions of concurrent connections, and a single SLB instance supports tens of millions of concurrent connections.

21.2. Log on to the SLB console

This topic provides an example of how to log on to the Server Load Balancer (SLB) console by using Google Chrome.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
2. Enter your username and password.

Obtain the username and password used to log on to the console from the operations administrator.

 **Note** When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:

- Uppercase or lowercase letters.
- Digits.
- Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Products > Networking > Server Load Balancer**.

21.3. Quick start

21.3.1. Overview

This quick start tutorial describes how to create a public-facing Server Load Balancer (SLB) instance and how to forward requests to two backend servers.

 **Note** Before creating an SLB instance, you must determine the region, type, and billing method of the SLB instance. For more information, see [Before you begin](#).

This tutorial includes the following content:

1. **Create an SLB instance**

Create an SLB instance. An SLB instance is a running entity of the SLB service.

2. **Add listeners and backend servers.**

Configure listening rules and backend servers for the SLB instance.

3. **Release an SLB instance**

If you no longer need the SLB instance, delete it to avoid extra fees.

21.3.2. Before you begin

This article presents the essential considerations for configuring an SLB instance. Before you create an SLB instance, you must determine the types of listeners and the network traffic you want to balance.

Instance region

When you select a region, note the following points:

- To reduce latency and increase the download speed, we recommend that you select a region closest to your end-users.
- SLB offers stable and reliable load balancing services by providing support for primary/secondary failovers in most regions. This implements disaster recovery across different zones within the same region. We recommend that you select a region that supports the primary/secondary SLB deployment.
- SLB instances cannot span across regions. Therefore, you must make sure that the SLB instance and its backend Elastic Compute Service (ECS) instances are located in the same region.

Network traffic

SLB provides load balancing services for both Internet and internal network traffic:

- If you need to use SLB to distribute requests from the Internet, you can create an Internet-facing SLB instance.

An Internet-facing SLB instance comes with a public IP address to receive requests from the Internet.

- If you need to use SLB to distribute requests from the internal network, you can create an internal SLB instance.

Internal SLB instances only have private IP addresses and are only accessible from the internal network and not from the Internet.

Listener protocol

SLB supports Layer-4 load balancing of Transmission Control Protocol (TCP) and User Datagram Protocol (UDP) traffic, and Layer-7 load balancing of HTTP and HTTPS traffic.

- A Layer-4 listener directly distributes requests to backend servers without modifying packet headers. After a client request reaches a Layer-4 listener, SLB uses the backend port configured for the listener to establish a TCP connection with an Elastic Compute Service (ECS) instance (backend server).
- A Layer-7 listener is implemented as a reverse proxy. After a client request reaches a Layer-7 listener, SLB establishes a new TCP connection over HTTP to a backend server, instead of directly forwarding the request to the backend server (ECS instance).

Compared with Layer-4 listeners, Layer-7 listeners require an additional step of engine processing. Therefore, Layer-4 listeners provide better performance than Layer-7 listeners. In addition, the performance of Layer-7 listeners can also be affected by factors such as insufficient client ports or excessive backend server connections. Therefore, we recommend that you use Layer-4 listeners for high-performance load-balancing services.

Backend servers

Before you use the SLB service, you must create ECS instances, deploy applications on them, and add the ECS instances to your SLB instance to process client requests.

When you create and configure an ECS instance, note the following points:

- Select a region and zone for the ECS instance

Make sure that the ECS instance resides in the same region and Virtual Private Cloud (VPC) as the SLB instance. We recommend that you deploy ECS instances in different zones to improve availability. For more information about how to create an ECS instance, see [Create an instance by using the provided wizard](#).

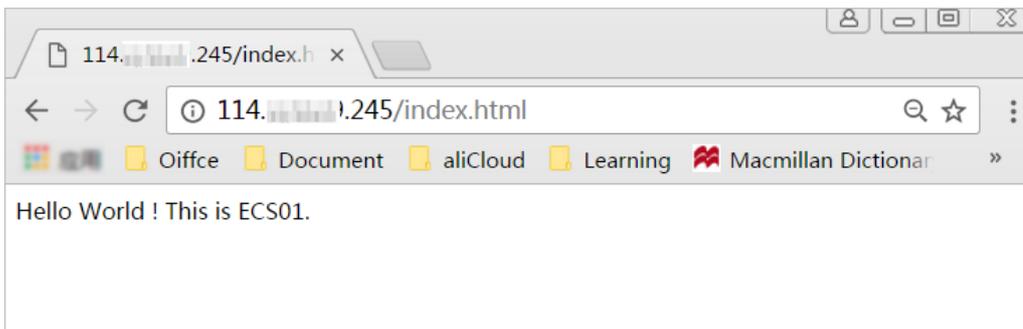

In this example, two ECS instances named ECS01 and ECS02 are created in the China (Hangzhou) region. The following figure shows their basic configurations.

Instance Name/ID	IP Address	Status	Monitoring	Health Check	Port/Health Check/Backend Server	Actions
ECS01	[Public IPv4 Address]	Active			HTTP:80 - VServer Group doctest	Configure Listener Add Backend Server
ECS02	[Public IPv4 Address]	Active			HTTP:80 (R) 443 - VServer Group test1	Configure Listener Add Backend Server

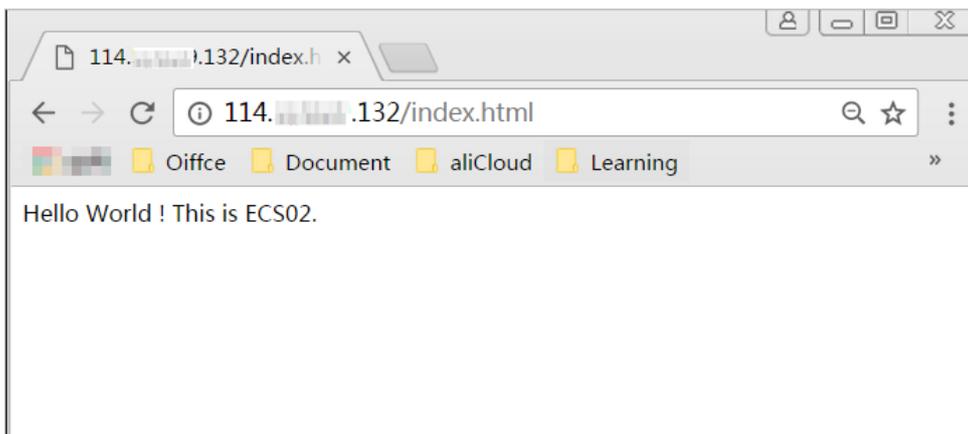

- Configure applications

In this example, two static web pages are built on ECS01 and ECS02 by using Apache.

- Enter the Elastic IP address (EIP) associated with ECS01 in the address box of your browser.

- Enter the EIP associated with ECS02 in the address box.

No additional configuration is required after you deploy applications on the ECS instances. However, if you need to use a Layer-4 (TCP or UDP) listener and the ECS instances run on Linux, make sure that the following parameters in the `net.ipv4.conf` file under `/etc/sysctl.conf` are set to 0:

```
net.ipv4.conf.default.rp_filter = 0
net.ipv4.conf.all.rp_filter = 0
net.ipv4.conf.eth0.rp_filter = 0
```

21.3.3. Create an SLB instance

This topic describes how to create an SLB instance. To get started with SLB, you must create an SLB instance. You can add multiple listeners and backend servers to an SLB instance.

Prerequisites

- You have created ECS instances and deployed applications on them.
- The ECS instances and the SLB instance belong to the same organization. In addition, the security group rules of the ECS instances permit traffic on HTTP port 80 and HTTPS port 443.

Procedure

1. [Log on to the SLB console](#).
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. On the **Server Load Balancers** page, click **Create Instance**.
 - **Organization:** Select the organization to which the SLB instance belongs.

 **Note** Make sure that the organization of the SLB instance is the same as the organization of its backend servers.

- **Resource Set:** Select the resource set to which the SLB instance belongs.
- **Region:** Select a region for the SLB instance.
- **Zone:** Select a zone for the SLB instance from the drop-down list.
- **Name:** Enter a name for the SLB instance.

The name must be 2 to 128 characters in length and can contain letters, digits, full-width characters, underscores (_), hyphens (-), periods (.), and colons (:). Line breaks and spaces are also supported. The name must start with a letter and cannot start with `http://` or `https://`.

- **Type:** Select the instance type of the SLB instance. Possible options are **Shared-Performance** and **Guaranteed-Performance**. Shared-performance instances share resources with each other, which means their performance cannot be guaranteed. The performance of a guaranteed-performance SLB instance varies by type.
- **Network Access:** Select the type of network traffic to balance. Possible options are **Internal Network** and **Public Network**. In this example, select **Internal Network**.
- **Network Type:** Select the network type of the SLB instance. Possible options are **Classic Network** and **VPC**. In this example, select **VPC**.
- **IP Version:** Select an IP version.
- **Service IP:** Enter the service IP address of the SLB instance. Make sure that the service IP address is valid. Otherwise, the SLB instance cannot be created. If you do not specify the service IP address, the system automatically allocates an IP address to the SLB instance.

4. Click **Submit**.

What's next

[Configure an SLB instance](#)

21.3.4. Configure an SLB instance

This topic describes how to configure an SLB instance. After you create an SLB instance, you must add at least one listener and a group of backend servers to this SLB instance so that it can forward traffic. The following example sets up a TCP listener and adds two ECS instances (ECS01 and ECS02) that host static web pages as backend servers to an SLB instance.

Procedure

1. **Log on to the SLB console**
2. On the **Server Load Balancers** page, find the target SLB instance and click **Configure Listener** in the **Actions** column.
3. In the **Protocol and Listener** step, complete the following information and use the default values for other fields to configure the listening rule.
 - **Select Listener Protocol:** Select a listener protocol. In this example, select **TCP**.
 - **Listening Port:** Set a frontend port to receive and forward requests to backend servers.

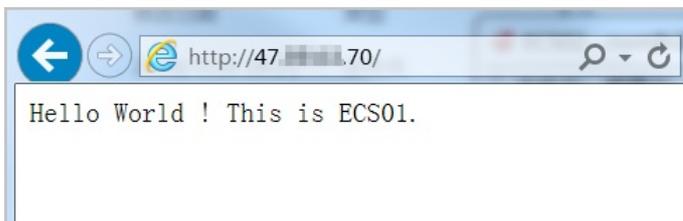

This port is configured for external load balancing. Generally, port 80 is used for HTTP and port 443 is used for HTTPS.

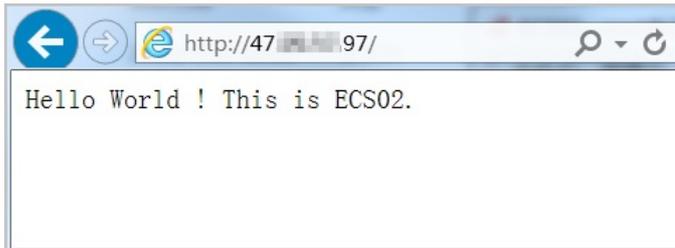

In this example, set the port number to **80**.
 - **Enable Peak Bandwidth Limit:** You can switch on this option and then set a bandwidth limit to control the bandwidth that is used by the applications running on backend servers to provide external services.
 - **Scheduling Algorithm:** Select a scheduling algorithm for distributing requests to backend servers. SLB supports the following scheduling algorithms. In this example, select **Round-Robin (RR)**.
 - **Weighted Round-Robin (WRR):** Requests are distributed proportionally based on the assigned weights of backend servers. Backend servers with higher weights receive more requests.
 - **Weighted Least Connections (WLC):** Requests are distributed based on the combination of the weights and active connections of backend servers. If multiple backend servers have the same weight, requests are routed to the backend server with the lowest number of active connections.
 - **Round-Robin (RR):** Requests are evenly and sequentially distributed to backend servers.
4. Click **Next**. In the **Backend Servers** step, select **Default Server Group** and click **Add More** to add backend servers.
 - i. In the **Select Servers** dialog box, select the previously created ECS01 and ECS02 instances and click **Next**.
 - ii. Configure the weights of the ECS instances. The higher the weight, the more requests a backend server receives. The default weight is 100. We recommend that you use the default value.
 - iii. Click **Add**.
 - iv. In the **Default Server Group** section, specify backend server ports. A backend server uses this port to receive requests. You can specify the same port for multiple backend servers of an SLB instance. In this example, set the port number to 80.
5. Click **Next** to configure the health check. The default health check settings are used in this example.

After you enable the health check feature, when a backend server is detected unhealthy, SLB bypasses requests from this backend server to other healthy backend servers. SLB will only send requests to this backend server when it has been restored and is considered healthy.
6. Click **Next**. In the **Submit** step, check the configuration and click **Submit**.
7. Click **OK** to go back to the **Server Load Balancers** page, and click  to refresh the page.

If the health check state of a backend ECS instance is **Active**, the backend server is working properly and is able to process requests.

8. In the web browser, enter the service IP address of the SLB instance in the address box to test network load balancing.

21.3.5. Release an SLB instance

This topic describes how to release an SLB instance. You can release an SLB instance when you no longer need it to avoid accumulating unnecessary charges. Releasing an SLB instance will not affect the operation of the backend ECS instances.

Procedure

1. [Log on to the SLB console](#)
2. Find and select the target SLB instance and click **Release** at the bottom of the list. You can also choose 
 - > **Release** in the Actions column.
3. In the Release dialog box, select **Release Now**.

 **Note** The system performs release operations at 30-minute and hour marks. However, billing for the SLB instance is stopped at the specified release time.

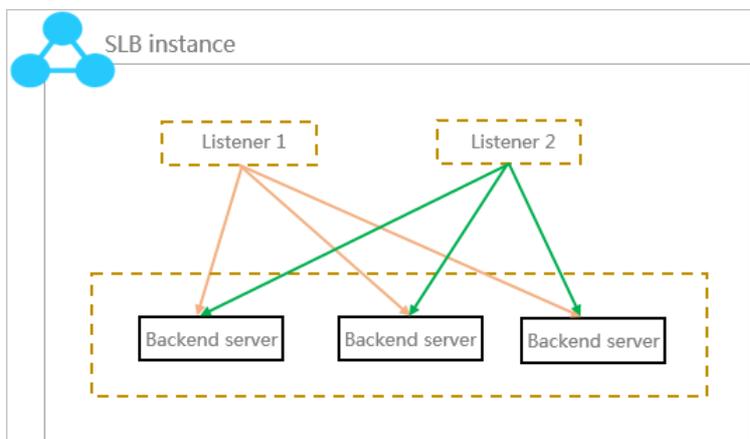

4. Click **Next**.
5. Click **OK**.

 **Note** Pay-as-you-go SLB instances cannot be restored once deleted. We recommend that you exercise caution when you release SLB instances.

21.4. SLB instances

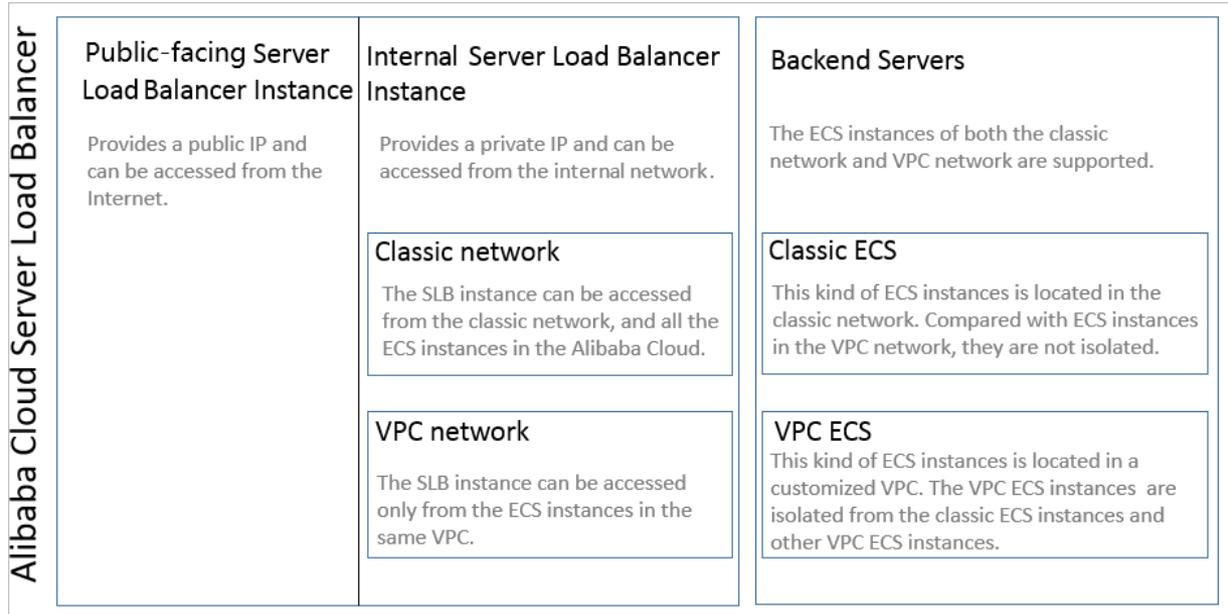

21.4.1. SLB instance overview

A Server Load Balancer (SLB) instance is a virtual machine in which the SLB service runs. To use the SLB service, you must create an SLB instance first, and then add listeners and backend servers to the SLB instance.

Instance network type

Alibaba Cloud provides public-facing and internal load balancing services. If you create a public-facing SLB instance, a public IP address is allocated to it. If you create an internal SLB instance, a private IP address is allocated.

- **Public-facing SLB instances**

A public-facing SLB instance distributes client requests over the Internet to backend servers according to configured forwarding rules.

When you create a public-facing SLB instance, the system allocates a public IP address to the instance. You can resolve a domain name to the public IP address to provide public services.

- **Internal SLB instances**

Internal SLB instances can only be used inside Alibaba Cloud and can only forward requests from clients that can access the internal network of SLB.

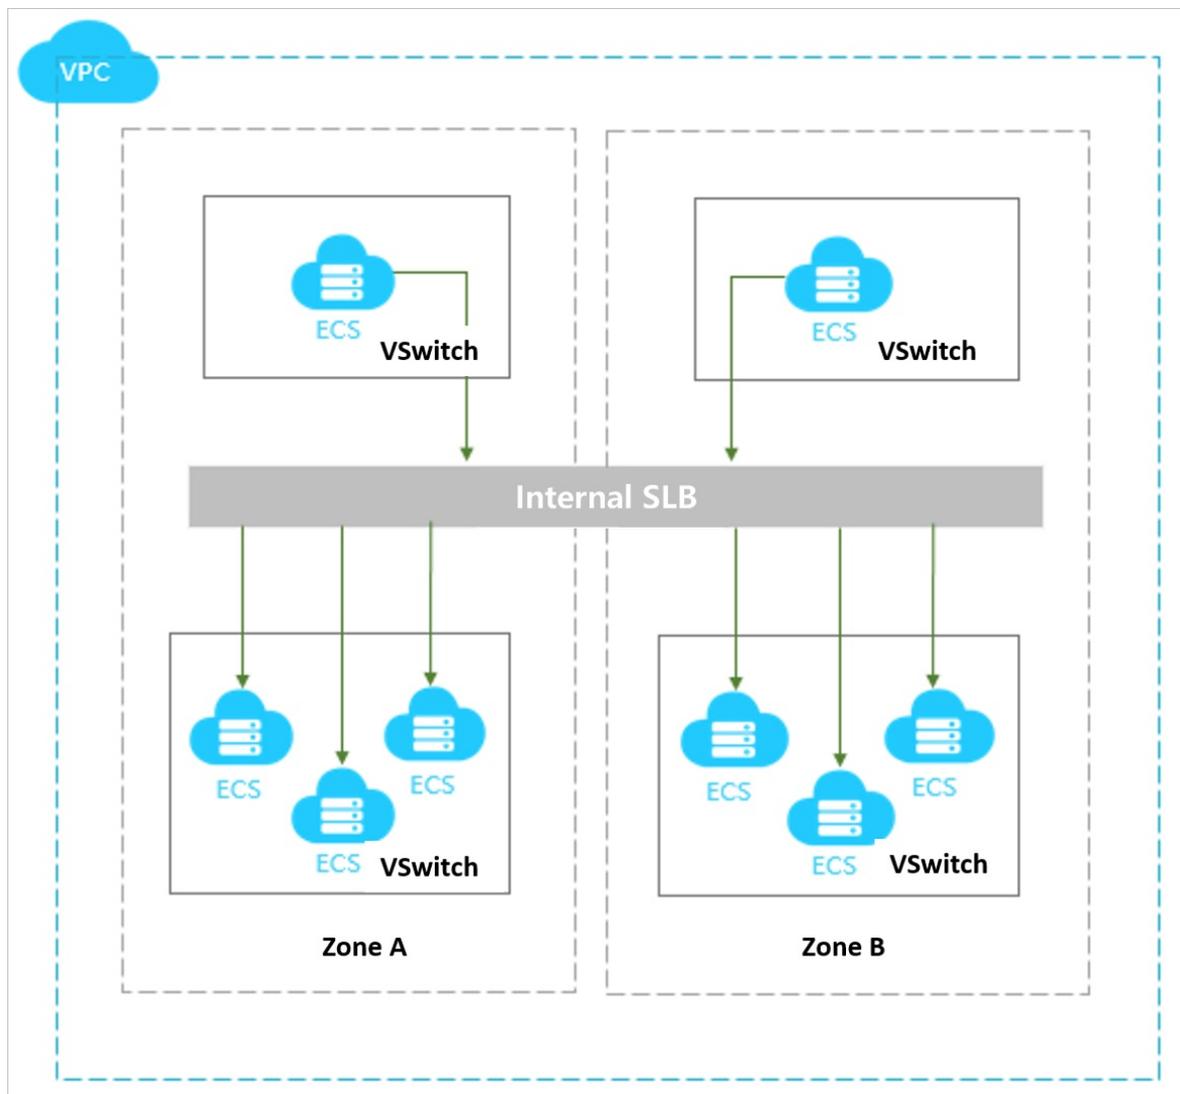

For an internal SLB instance, you can select the network type:

- **Classic network**

If you choose classic network for an internal SLB instance, the IP address of the SLB instance is allocated and maintained by Alibaba Cloud. The instance can only be accessed by classic-network ECS instances.

- VPC network

If you choose VPC network for an internal SLB instance, the IP address of the SLB instance is allocated from the CIDR block of the VSwitch that the instance belongs to. An SLB instance of the VPC-type network can only be accessed by ECS instances in the same VPC.

21.4.2. Create an SLB instance

This topic describes how to create an SLB instance. To get started with SLB, you must create an SLB instance. You can add multiple listeners and backend servers to an SLB instance.

Prerequisites

- You have created ECS instances and deployed applications on them.
- The ECS instances and the SLB instance belong to the same organization. In addition, the security group rules of the ECS instances permit traffic on HTTP port 80 and HTTPS port 443.

Procedure

1. [Log on to the SLB console](#).
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. On the **Server Load Balancers** page, click **Create Instance**.
 - **Organization:** Select the organization to which the SLB instance belongs.

 **Note** Make sure that the organization of the SLB instance is the same as the organization of its backend servers.

- **Resource Set:** Select the resource set to which the SLB instance belongs.
- **Region:** Select a region for the SLB instance.
- **Zone:** Select a zone for the SLB instance from the drop-down list.
- **Name:** Enter a name for the SLB instance.

The name must be 2 to 128 characters in length and can contain letters, digits, hyphens (-), colons (:), commas (,), periods (.), and underscores (_). It must start with a letter and cannot start with `http://` or `https://`.

- **Type:** Select the instance type of the SLB instance. Possible options are Shared-Performance and Guaranteed-Performance. Shared-performance instances share resources with each other, which means their performance cannot be guaranteed. The performance of a guaranteed-performance SLB instance varies by type.
 - **Maximum concurrent connections:** the maximum number of concurrent connections that an SLB instance can support. Connection requests that exceed this limit will be discarded.
 - **Connections per second (CPS):** the number of new connections per second. Connection requests that exceed this limit will be discarded.
 - **QPS:** the number of HTTP or HTTPS queries or requests that can be processed per second. This metric is specific to Layer-7 listeners. Connection requests that exceed this limit will be discarded.
- **Network Access:** Select the type of network traffic to balance. Possible options are Internal Network and Public Network.

If you select Public Network, you can choose an IP version between IPv6 and IPv4 for the SLB instance and specify a bandwidth for billing.
- **Network Type:** Select the network type of the SLB instance. Possible options are Classic Network and VPC.
- **IP Version:** Select an IP version. Internal SLB instances support only IPv4. Internet-facing SLB instances support IPv6 and IPv4.
- **Service IP:** Enter the service IP address of the SLB instance. Make sure that the service IP address is valid. Otherwise, the SLB instance cannot be created. If you do not specify the service IP address, the system automatically allocates an IP address to the SLB instance.

4. Click **Submit**.

What's next

[Configure an SLB instance](#)

21.4.3. Start and stop an SLB instance

This topic describes how to start and stop an SLB instance. SLB instances can be started or stopped at any time. A stopped SLB instance does not receive or forward client traffic.

Procedure

1. [Log on to the SLB console](#)
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. Find the target SLB instance. In the **Actions** column, choose  > **Start** or  > **Stop**.
4. To start or stop multiple instances at a time, select the instances and click **Start** or **Stop** at the bottom of the page.

21.4.4. Tags

21.4.4.1. Tag overview

This topic provides an overview of tags in SLB. SLB provides the tag management feature that allows you to classify SLB instances by using tags.

Each tag consists of a key and a value. Before you use tags, note the following limits:

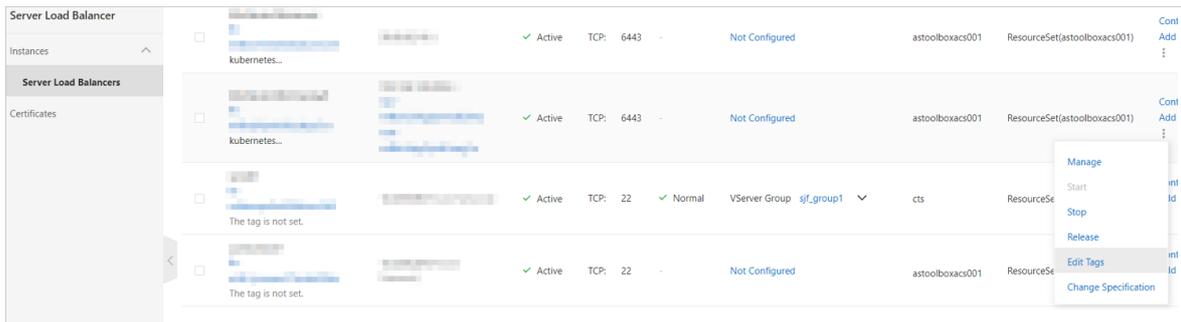

- Tags must be added to SLB instances.
- Each SLB instance can have a maximum of ten tags. You can add or remove a maximum of 5 tags at a time.
- The key of each tag added to an SLB instance must be unique. If a tag with the same key already exists, the tag is overwritten with the new value.

21.4.4.2. Add tags

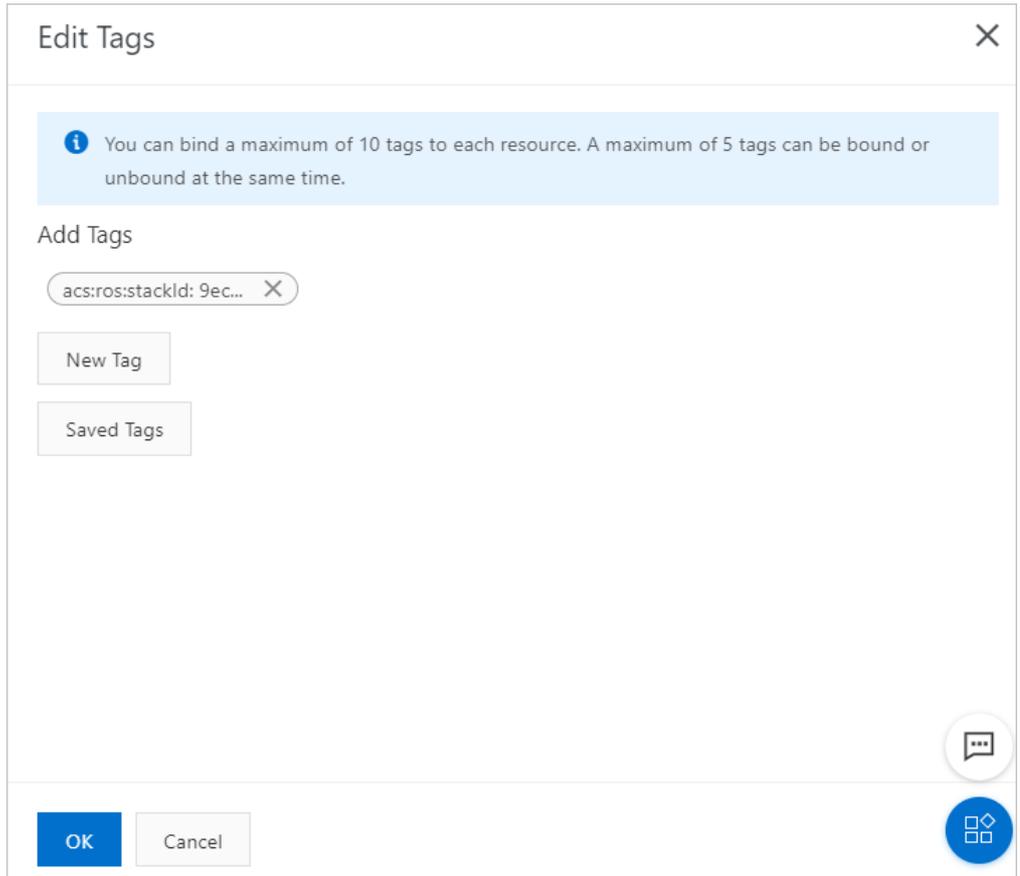

This topic describes how to add tags to an SLB instance.

Procedure

1. **Log on to the SLB console**
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. In the **Actions** column, choose  > **Edit Tags**.

4. Edit tags in the **Edit Tags** dialog box. To add a tag, perform the following operations:
 - To add an existing tag, click **Saved Tags** and then select a tag.
 - To create and add a new tag, click **New Tag** in the **Edit Tags** dialog box, enter the key and value of the new tag, and then click **OK** next to the value.

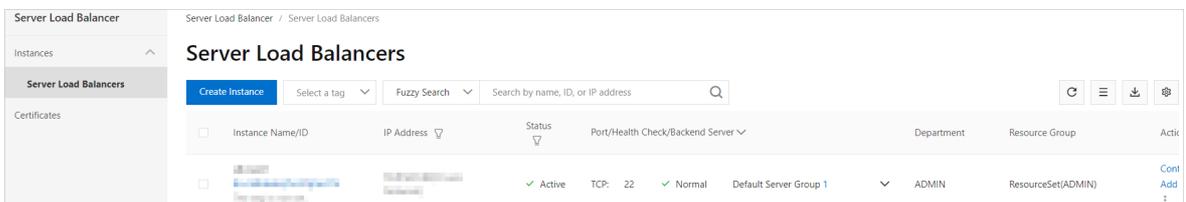

5. Click OK.

21.4.4.3. Query SLB instances by tag

This topic describes how to use tags to query SLB instances.

Procedure

1. [Log on to the SLB console](#).
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. Select a data from the **Select a tag** drip-down list to filter instances.

Note To clear the search condition, move the pointer over the selected tag and click the displayed deletion icon next to it.

21.4.4.4. Remove tags

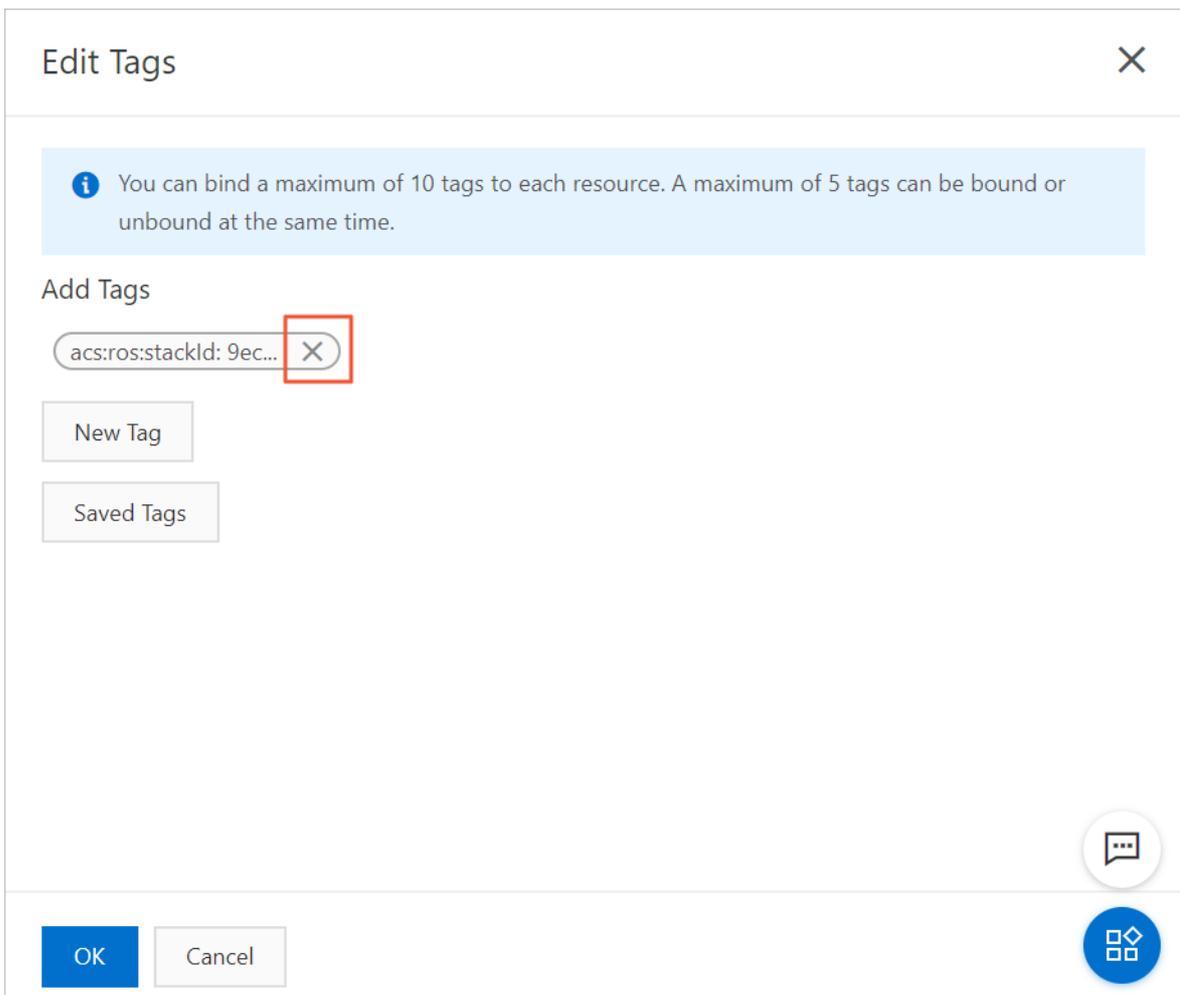

This topic describes how to remove tags from an SLB instance. You can only remove tags for one SLB instance at a time.

Procedure

1. [Log on to the SLB console.](#)
2. In the left-side navigation pane, choose **Instances > Server Load Balancers.**
3. In the **Actions** column, choose  > **Edit Tags.**

4. In the **Edit Tags** dialog box, click the deletion icon next to the tags to be removed, and then click **OK.**

 **Note** If a tag is removed from an SLB instance and is not added to any other instances, the tag is deleted from the system.

21.4.5. Release an SLB instance

This topic describes how to release an SLB instance. You can release SLB instances immediately.

Procedure

1. [Log on to the SLB console.](#)
2. In the left-side navigation pane, choose **Instances > Server Load Balancers.**
3. Find the target SLB instance and choose  > **Release.**

4. In the **Release** dialog box, select **Release Now.**
5. Click **Next.**

6. Confirm the displayed information and click **OK** to release the instance.

21.5. Listeners

21.5.1. Listener overview

This topic provides an overview of listeners. After you create an SLB instance, you must configure one or more listeners for it. A listener checks for connection requests and then distributes the requests to backend servers based on the forwarding rules that are defined by a specified scheduling algorithm.

SLB provides listeners for Layer-4 (TCP and UDP) and Layer-7 (HTTP and HTTPS) load balancing. The following table lists the features and use cases of these listeners.

Protocol	Feature	Use case
TCP	<ul style="list-style-type: none"> • A connection-oriented protocol that requires a logical connection to be established before any data can be transmitted • Source IP address-based session persistence • Source IP addresses readable at the network layer • Fast data transmission 	<ul style="list-style-type: none"> • Services that prioritize high reliability and data accuracy over high-speed data transmission, such as file transmission, email sending or receiving, and remote logon • Basic web applications <p>For more information, see Add a TCP listener.</p>
UDP	<ul style="list-style-type: none"> • A connectionless protocol that transmits data packets without implementing the three-way handshake and does not provide error recovery or data retransmission • Fast data transmission with relatively low reliability 	<p>Services that focus on real-time content delivery other than reliability, such as video chats and real-time quotes</p> <p>For more information, see Add a UDP listener.</p>
HTTP	<ul style="list-style-type: none"> • An application-layer protocol used to package data • Cookie-based session persistence • Support for using the X-Forwarded-For (XFF) header to identify original client IP addresses 	<p>Applications that need to identify data content, such as web applications and small-sized mobile games</p> <p>For more information, see Add an HTTP listener.</p>
HTTPS	<ul style="list-style-type: none"> • Encrypted data transmission that prevents unauthorized access • Centralized certificate management that allows certificate uploading and decryption on SLB 	<p>Applications that require encrypted transmission</p> <p>For more information, see Add an HTTPS listener.</p>

21.5.2. Add a TCP listener

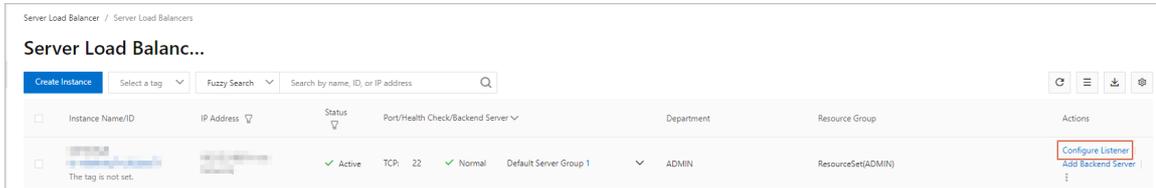

This topic describes how to add a TCP listener to an SLB instance. TCP provides reliable and accurate data delivery at relatively low connection speeds and therefore is applicable to services such as file transmission, email sending or receiving, and remote logon. You can add a TCP listener to forward TCP requests.

Step 1: Start the listener configuration wizard

To start the listener configuration wizard, perform the following operations:

1. [Log on to the SLB console](#).

2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. Use one of the following methods to start the listener configuration wizard:
 - On the **Server Load Balancers** page, find the target SLB instance and then click **Configure Listener** in the **Actions** column.

- On the **Server Load Balancers** page, click the ID of the target SLB instance. On the **Listener** tab, click **Add Listener**.

Step 2: Configure the TCP listener

Perform the following operations to configure the TCP listener.

1. Specify the following information:

Parameter	Description
Select Listener Protocol	Select the protocol of the listener. In this example, select TCP .
Listening Port	Set the listening port used to receive requests and forward them to backend servers. Valid values: 1 to 65535.
Advanced Settings	
Scheduling Algorithm	SLB supports three scheduling algorithms: round robin (RR), weighted round robin (WRR), and weighted least connections (WLC). <ul style="list-style-type: none"> ○ Weighted Round-Robin (WRR): Backend servers with higher weights receive more requests. ○ Round-Robin (RR): Requests are evenly and sequentially distributed to backend servers. ○ Weighted Least Connections (WLC): Requests are distributed based on the combination of the weights and active connections of backend servers. Requests are distributed to the backend server with the least number of active connections. If two backend servers have the same number of active connections, the backend server with a higher weight receives more requests.
Enable Session Persistence	Specify whether to enable session persistence. Unit: seconds. Valid values: 1 to 3600. After session persistence is enabled, the listener forwards all requests from the same client to a specific backend server for the duration of a session. For TCP listeners, session persistence is implemented based on IP addresses. Requests from the same IP address are forwarded to the same backend server.

Parameter	Description
Enable Peak Bandwidth Limit	<p>You can switch on this option and then set a bandwidth limit for the listener.</p> <p>If an SLB instance incurs fees based on the bandwidth, you can set different peak bandwidth values for different listeners to limit the amount of traffic that flows in each listener. The sum of the peak bandwidth values of all listeners added to an SLB instance cannot exceed the bandwidth of this SLB instance.</p> <p>By default, this feature is disabled and all listeners share the bandwidth of the SLB instance.</p>
Idle Timeout	Specify the idle timeout period of TCP connections. Unit: seconds. Valid values: 10 to 900.
Obtain Client Source IP Address	For Layer-4 listeners, backend servers can directly obtain the actual IP addresses of clients.
Automatically Enable Listener After Creation	Specify whether to start the listener after the listener is configured. By default, the listener is started after configuration.

2. Click **Next**.

Step 3: Add backend servers

After you configure the listener, you must add backend servers to process client requests. You can add backend servers to the default server group, or create VServer groups or primary/secondary server groups and then add servers to them. For more information, see [Backend server overview](#).

This example adds backend servers to the default server group.

1. Select **Default Server Group** and click **Add More**.
2. Select ECS instances (backend servers) that you want to add, and then click **Next**.
3. Configure weights for the added backend servers. A backend server with a higher weight receives more requests.

 **Note** If the weight of a backend server is set to 0, the backend server does not receive new requests.

4. Click **Add**. On the **Default Server Group** tab, configure ports for the backend servers. Set a port for each backend server to receive requests. Valid values: 1 to 65535. You can specify the same port for multiple backend servers of an SLB instance.
5. Click **Next**.

Step 4: Configure the health check

SLB checks the availability of backend servers by performing the health check. The health check feature improves the availability of frontend services by minimizing downtime caused by health issues of backend servers. Click **Modify** to configure advanced health check settings. For more information, see [Health check overview](#).

Click **Next**.

Step 5: Confirm the settings

Complete the following steps to confirm and apply the listener settings:

1. In the **Submit** step, check the configuration. You can click **Modify** to modify configuration settings.
2. Click **Submit**.
3. In the **Configure Successful** dialog box, click **OK**.

You can check the created listener on the Listener tab.

21.5.3. Add a UDP listener

This topic describes how to add a UDP listener to an SLB instance. UDP is applicable to services that prioritize real-time content delivery over reliability, such as video chats and real-time quotes. You can add a UDP listener to forward UDP requests.

Context

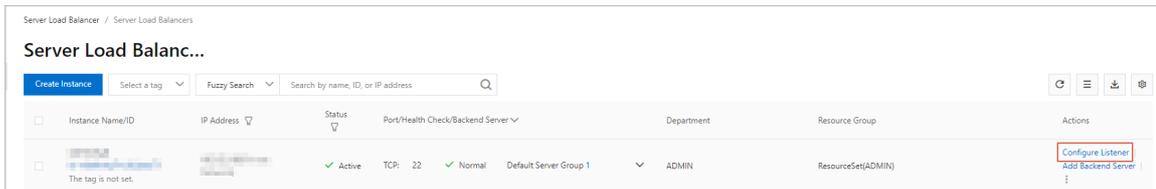

Before you configure a UDP listener, note the following limits:

- Ports 250, 4789, and 4790 of a UDP listener are reserved and therefore are unavailable for your configuration.
- Fragmented packets are not supported.
- The UDP listeners of an SLB instance in a classic network do not support the viewing of source IP addresses.
- The following operations take five minutes to take effect if they are performed for a UDP listener:
 - Remove backend servers
 - Set the weight of a backend server to 0 after it is detected unhealthy

Step 1: Start the listener configuration wizard

To start the listener configuration wizard, perform the following operations:

1. **Log on to the SLB console.**
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. Use one of the following methods to start the listener configuration wizard:
 - On the **Server Load Balancers** page, find the target SLB instance and then click **Configure Listener** in the **Actions** column.

- On the **Server Load Balancers** page, click the ID of the target SLB instance. On the **Listener** tab, click **Add Listener**.

Step 2: Configure the UDP listener

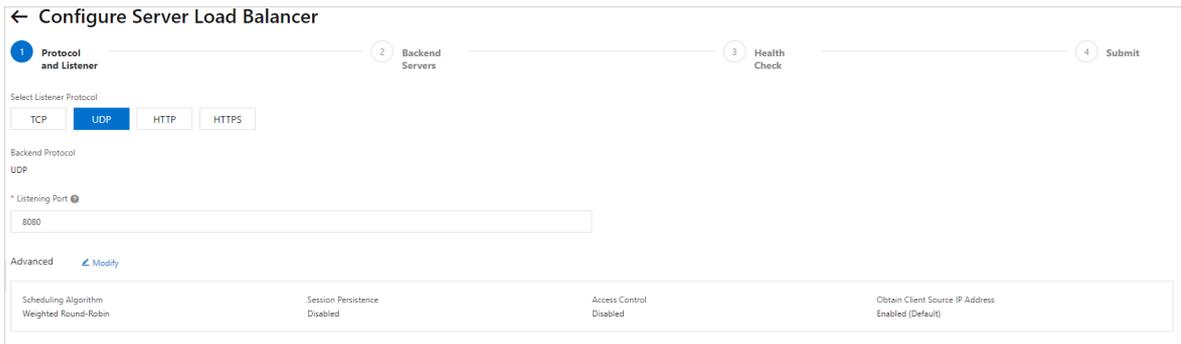

To configure the UDP listener, perform the following operations:

1. In the **Protocol and Listener** step, specify the following information:

Parameter	Description
Select Listener Protocol	Select the protocol of the listener. In this example, select UDP .
Listening Port	Set the listening port used to receive requests and forward them to backend servers. Valid values: 1 to 65535.
Advanced Settings	

Parameter	Description
Scheduling Algorithm	<p>SLB supports three scheduling algorithms: RR, WRR, and WLC.</p> <ul style="list-style-type: none"> ◦ Weighted Round-Robin (WRR): Backend servers with higher weights receive more requests. ◦ Round-Robin (RR): Requests are evenly and sequentially distributed to backend servers. ◦ Weighted Least Connections (WLC): Requests are distributed based on the combination of the weights and active connections of backend servers. Requests are distributed to the backend server with the least number of active connections. If two backend servers have the same number of active connections, the backend server with a higher weight receives more requests.
Enable Peak Bandwidth Limit	<p>You can switch on this option and then set a bandwidth limit for the listener.</p> <p>If an SLB instance incurs fees based on the bandwidth, you can set different peak bandwidth values for different listeners to limit the amount of traffic that flows in each listener. The sum of the peak bandwidth values of all listeners added to an SLB instance cannot exceed the bandwidth of this SLB instance.</p> <p>By default, this feature is disabled and all listeners share the bandwidth of the SLB instance.</p>
Obtain Client Source IP Address	<p>Backend servers of a UDP listener can directly obtain the actual IP addresses of clients.</p> <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> <p>? Note UDP listeners of an SLB instance in a classic network do not support the viewing of source IP addresses.</p> </div>
Automatically Enable Listener After Creation	<p>Specify whether to start the listener after the listener is configured. By default, the listener is started after configuration.</p>

2. Click Next.

Step 3: Add backend servers

After you configure the listener, you must add backend servers to process client requests. You can add backend servers to the default server group, or create VServer groups or primary/secondary server groups and then add servers to them. For more information, see [Backend server overview](#).

This example adds backend servers to the default server group.

1. Select **Default Server Group** and click **Add More**.
2. Select ECS instances (backend servers) that you want to add, and then click **Next**.

3. Configure weights for the added backend servers. A backend server with a higher weight receives more requests.

Note If the weight of a backend server is set to 0, the backend server does not receive new requests.

4. Click **Add**. On the **Default Server Group** tab, configure ports for the backend servers. Set a port for each backend server to receive requests. Valid values: 1 to 65535. You can specify the same port for multiple backend servers of an SLB instance.
5. Click **Next**.

Step 4: Configure the health check

SLB checks the availability of backend servers by performing the health check. The health check feature improves the availability of frontend services by minimizing downtime caused by health issues of backend servers. Click **Modify** to configure advanced health check settings. For more information, see [Health check overview](#).

Click **Next**.

Step 5: Confirm the settings

Complete the following steps to confirm and apply the listener settings:

1. In the **Submit** step, check the configuration. You can click **Modify** to modify configuration settings.
2. Click **Submit**.
3. In the **Configure Successful** dialog box, click **OK**.

You can check the created listener on the **Listener** tab.

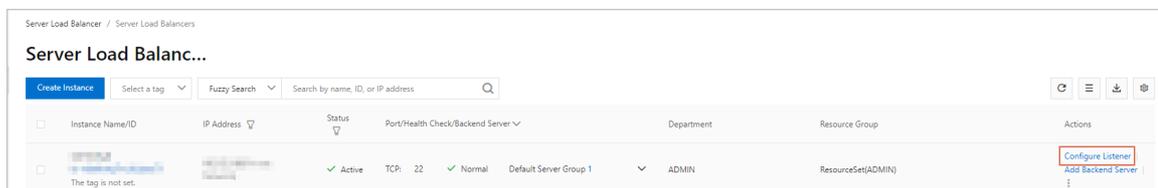

21.5.4. Add an HTTP listener

This topic describes how to add an HTTP listener to an SLB instance. HTTP is applicable to the applications that need to identify data content, such as web applications and small-sized mobile games. You can add an HTTP listener to forward HTTP requests.

Step 1: Start the listener configuration wizard

To start the listener configuration wizard, perform the following operations:

1. [Log on to the SLB console](#).
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. Use one of the following methods to start the listener configuration wizard:
 - On the **Server Load Balancers** page, find the target SLB instance and then click **Configure Listener** in the **Actions** column.
- On the **Server Load Balancers** page, click the ID of the target SLB instance. On the **Listener** tab, click **Add Listener**.

Step 2: Configure the HTTP listener

Perform the following operations to configure the HTTP listener.

1. In the **Protocol and Listener** step, specify the following information:

Parameter	Description
Select Listener Protocol	Select the protocol of the listener. In this example, select HTTP.
Listening Port	Set the listening port used to receive requests and forward them to backend servers. Valid values: 1 to 65535. Note The HTTP listening ports must be unique in an SLB instance.
Advanced Settings	
Scheduling Algorithm	SLB supports three scheduling algorithms: RR, WRR, and WLC. <ul style="list-style-type: none"> Weighted Round-Robin (WRR): Backend servers with higher weights receive more requests. Round-Robin (RR): Requests are evenly and sequentially distributed to backend servers. Weighted Least Connections (WLC): Requests are distributed based on the combination of the weights and active connections of backend servers. Requests are distributed to the backend server with the least number of active connections. If two backend servers have the same number of active connections, the backend server with a higher weight receives more requests.
Redirection	Specify whether to redirect traffic from the HTTP listener to an HTTPS listener. Note Before you enable redirection, make sure that you have created an HTTPS listener.
Enable Session Persistence	Specify whether to enable session persistence. After session persistence is enabled, the listener forwards all requests from the same client to a specific backend server for the duration of a session. HTTP implements cookie-based session persistence. You can choose from the following approaches to configure session persistence with cookies: <ul style="list-style-type: none"> Insert cookie: You only need to specify the cookie timeout period. SLB inserts a cookie (SERVERID) to the first HTTP or HTTPS response packet sent to a client. The next request from the client will contain this cookie, and the listener will distribute this request to the recorded backend server. Rewrite cookie: You can specify the cookie to be inserted into the HTTP or HTTPS response. You must specify the timeout period and lifecycle of this cookie on the backend server. SLB rewrites the original cookie when the new cookie is detected. The next request that contains the new cookie will be distributed to the recorded backend server.

Parameter	Description
Enable Peak Bandwidth Limit	<p>You can switch on this option and then set a bandwidth limit for the listener.</p> <p>If an SLB instance incurs fees based on the bandwidth, you can set different peak bandwidth values for different listeners to limit the amount of traffic that flows in each listener. The sum of the peak bandwidth values of all listeners added to an SLB instance cannot exceed the bandwidth of this SLB instance.</p> <p>By default, this feature is disabled and all listeners share the bandwidth of the SLB instance.</p>
Idle Timeout	<p>Specify the idle timeout period of connections. Unit: seconds. Valid values: 1 to 60.</p> <p>If no request is received during the idle timeout period, SLB closes the connection and will restart the connection when the next request is received.</p> <p>This feature is available in all regions.</p> <div style="background-color: #e6f2ff; padding: 5px; border: 1px solid #d9e1f2;"> <p> Note This feature is unavailable for HTTP/2 requests.</p> </div>
Request Timeout	<p>Specify the request timeout period. Unit: seconds. Valid values: 1 to 180.</p> <p>If no response is received from the backend server during the request timeout period, SLB sends an HTTP 504 error code to the client.</p> <p>This feature is available in all regions.</p>
Enable Gzip Compression	<p>Specify whether to enable compression for a specific file type.</p> <p>Gzip supports the following file types: text/xml, text/plain, text/css, application/javascript, application/x-javascript, application/rss+xml, application/atom+xml, and application/xml.</p>
Add HTTP Header Fields	<p>Select one or more custom HTTP header fields that you want to add:</p> <ul style="list-style-type: none"> ◦ Use the <code>X-Forwarded-For</code> header field to retrieve the IP addresses of clients. ◦ Use the <code>X-Forwarded-Proto</code> header field to retrieve the listener protocol used by the SLB instance. ◦ Use the <code>SLB-IP</code> header field to retrieve the public IP address of the SLB instance. ◦ Use the <code>SLB-ID</code> header field to retrieve the ID of the SLB instance.
Obtain Client Source IP Address	<p>HTTP listeners use the X-Forwarded-For header field to identify the originating IP addresses of clients.</p>
Automatically Enable Listener After Creation	<p>Specify whether to start the listener after the listener is configured. By default, the listener is started after configuration.</p>

2. Click **Next**.

Step 3: Add backend servers

After you configure the listener, you must add backend servers to process client requests. You can add backend servers to the default server group, or create VServer groups or primary/secondary server groups and then add servers to them. For more information, see [Backend server overview](#).

This example adds backend servers to the default server group.

1. Select **Default Server Group** and click **Add More**.
2. Select ECS instances (backend servers) that you want to add, and then click **Next**.
3. Configure weights for the added backend servers. A backend server with a higher weight receives more requests.

Note If the weight of a backend server is set to 0, the backend server does not receive new requests.

4. Click **Add**. On the **Default Server Group** tab, configure ports for the backend servers. Set a port for each backend server to receive requests. Valid values: 1 to 65535. You can specify the same port for multiple backend servers of an SLB instance.
5. Click **Next**.

Step 4: Configure the health check

SLB checks the availability of backend servers by performing the health check. The health check feature improves the availability of frontend services by minimizing downtime caused by health issues of backend servers. Click **Modify** to configure advanced health check settings. For more information, see [Health check overview](#).

Click **Next**.

Step 5: Confirm the settings

Complete the following steps to confirm and apply the listener settings:

1. In the **Submit** step, check the configuration. You can click **Modify** to modify configuration settings.
2. Click **Submit**.
3. In the **Configure Successful** dialog box, click **OK**.

You can check the created listener on the **Listener** tab.

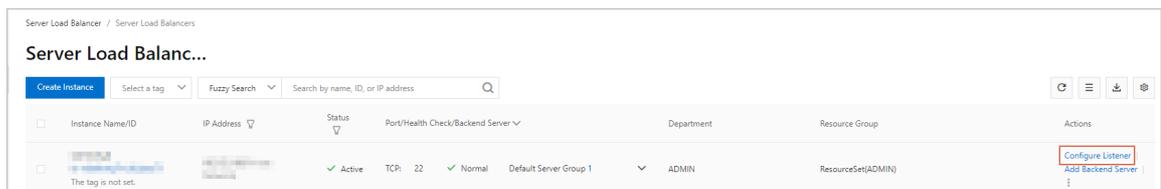

21.5.5. Add an HTTPS listener

HTTPS is applicable to applications that require encrypted data transmission. You can add an HTTPS listener to forward HTTPS requests.

Step 1: Start the listener configuration wizard

To start the listener configuration wizard, perform the following operations:

1. **Log on to the SLB console**.
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. Use one of the following methods to start the listener configuration wizard:
 - On the **Server Load Balancers** page, find the target SLB instance and then click **Configure Listener** in the **Actions** column.

- On the **Server Load Balancers** page, click the ID of the target SLB instance. On the **Listener** tab, click **Add**

Listener.

Step 2 Configure an HTTPS listener

To configure an HTTPS listener, perform the following operations:

1. In the **Protocol and Listener** step, configure the listener parameters listed in the following table.

Parameter	Description
Select Listener Protocol	Select the protocol type of the listener. In this example, select HTTPS.
Listening Port	The listening port used to receive requests and forward the requests to backend servers. Valid values: 1 to 65535. <div style="background-color: #e0f2f7; padding: 5px; border: 1px solid #ccc;"> <p> Note The listening port numbers must be unique in an SLB instance.</p> </div>
Advanced	
Scheduling Algorithm	SLB supports three scheduling algorithms: round robin, weighted round robin (WRR), and weighted least connections (WLC). <ul style="list-style-type: none"> ◦ Weighted Round-Robin (WRR): A backend server with a higher weight is more likely to be scheduled and receives more requests. ◦ Round-Robin (RR): Requests are evenly and sequentially distributed to backend servers. ◦ Weighted Least Connections (WLC): Requests are distributed to the backend server with the least number of connections. If two backend servers have the same number of connections, the backend server with a higher weight will receive more requests.
Enable Session Persistence	Specifies whether to enable session persistence. After session persistence is enabled, SLB forwards all requests from the same client to the same backend server. HTTP session persistence is implemented through cookies. SLB provides two methods to handle cookies: <ul style="list-style-type: none"> ◦ Insert cookie: You only need to specify the cookie timeout period. SLB inserts a cookie (SERVERID) to the first HTTP or HTTPS response packet sent to a client. The next request from the client will contain the cookie, and the listener will distribute the request to the recorded backend server. ◦ Rewrite cookie: You can specify the cookie to be inserted into the HTTP or HTTPS response to meet your specific needs. You must maintain the timeout period and lifecycle of the cookie on the backend server. SLB will overwrite the original cookie if it discovers that a new cookie has been specified. The next request will contain the new cookie, and the listener will distribute the request to the recorded backend server.

Parameter	Description
Enable Peak Bandwidth Limit	<p>Specifies whether to configure the bandwidth limit for the listener.</p> <p>If an SLB instance is billed based on bandwidth, you can set different peak bandwidth values for different listeners to limit the amount of traffic passing through each listener. The sum of the peak bandwidth values of all listeners for an SLB instance cannot exceed the bandwidth value of that SLB instance.</p> <p>By default, this feature is disabled, and all listeners share the bandwidth of the SLB instance.</p>
Enable Gzip Compression	<p>Specifies whether to enable compression for a specific file type.</p> <p>Gzip supports the following file types: text/xml, text/plain, text/css, application/javascript, application/x-javascript, application/rss+xml, application/atom+xml, and application/xml.</p>
Add HTTP Header Fields	<p>Select the custom HTTP header fields that you want to add:</p> <ul style="list-style-type: none"> ◦ Use the X-Forwarded-For header field to retrieve the IP addresses of clients. ◦ Use the X-Forwarded-Proto header field to retrieve the listener protocol used by the SLB instance. ◦ Use the SLB-IP header field to retrieve the public IP address of the SLB instance. ◦ Use the SLB-ID header field to retrieve the ID of the SLB instance.
Obtain Client Source IP Address	<p>HTTP listeners use the X-Forwarded-For header field to obtain the actual IP addresses of clients.</p>
Automatically Enable Listener After Creation	<p>Specifies whether to start the listener after the listener is configured. By default, the listener is started after configuration.</p>

2. Click Next.

Step 3 Configure an SSL certificate

To add an HTTPS listener, you must upload a server certificate or CA certificate.

 Notice SLB supports the following public key algorithms:

- RSA 1024
- RSA 2048
- RSA 4096
- ECDSA P-256
- ECDSA P-384
- ECDSA P-521

Certificate	Description	Required for one-way authentication	Required for mutual authentication

Certificate	Description	Required for one-way authentication	Required for mutual authentication
Server certificate	The certificate used to identify the server. The client checks whether the certificate sent by the server is issued by a trusted center.	Yes. You must upload the server certificate to the certificate management system of SLB.	Yes. You must upload the server certificate to the certificate management system of SLB.
Client certificate	The certificate that is used to identify the client. The server identifies the client by checking the certificate sent by the client. You can sign a client certificate with a self-signed CA certificate.	No.	Yes. You must install the client certificate on the client.
CA certificate	The server uses a CA certificate to verify the signature on the client certificate. If the certificate cannot be verified, the connection request is rejected.	No.	Yes. You must upload the CA certificate to the certificate management system of SLB.

Before you upload a certificate, take note of the following items:

- The uploaded certificate must be in the PEM format.
- After you upload the certificate to SLB, SLB can manage the certificate and you do not need to bind the certificate to backend servers.
- It may take some time to activate an HTTPS listener because the certificate must be uploaded, loaded, and verified. It can take up to three minutes for an HTTPS listener to be activated.
- The ECDHE cipher suites used by HTTPS listeners support forward secrecy but do not support the security enhancement parameters required by DHE cipher suites. As a result, strings that contain the `BEGIN DH PARAMETERS` field in a PEM certificate file cannot be uploaded. For more information, see [Certificate requirements](#).
- HTTPS listeners do not support Server Name Indication (SNI). You can use TCP listeners instead, and then configure SNI on backend servers.
- The session ticket timeout period of HTTPS listeners is 300 seconds.
- The actual amount of traffic generated on an HTTPS listener is larger than the billed traffic amount because some traffic is used for handshaking.
- If a large number of new connections are established, a large amount of traffic will be generated.
 1. Select an uploaded server certificate, or click **Create Server Certificate** to upload a server certificate. For more information, see [Certificate overview](#).
 2. To enable HTTPS mutual authentication, click **Modify** next to **Advanced**.
 3. Turn on **Enable Mutual Authentication**, and select an uploaded CA certificate or click **Create CA Certificate** to upload a CA certificate. You can use a self-signed CA certificate. For more information, see [Certificate overview](#).

Step 4 Add backend servers

After configuring the listener, you must add backend servers to process client requests. You can use the default server group configured for the SLB instance, or configure a VServer group or a primary/secondary server group. For more information, see [Backend server overview](#).

This example uses the default server group.

1. Select **Default Server Group** and click **Add More**.
2. Select ECS instances (backend servers) that you want to add, and then click **Next**.

3. Configure weights for the added backend servers. A backend server with a higher weight receives more requests.

Note If the weight of a backend server is set to 0, the backend server does not receive new requests.

4. Click **Add**. On the **Default Server Group** tab, configure ports for the backend servers. Set a port for each backend server to receive requests. Valid values: 1 to 65535. You can specify the same port for multiple backend servers of an SLB instance.
5. Click **Next**.

Step 5 Configure health checks

SLB checks the availability of backend servers by performing the health check. The health check feature improves the availability of frontend services by minimizing downtime caused by health issues of backend servers. Click **Modify** to configure advanced health check settings. For more information, see [Health check overview](#).

Step 6 Submit the configurations

Submit the configurations by performing the following operations:

1. In the **Submit** step, check the configuration. You can click **Modify** to modify configuration settings.
2. Click **Submit**.
3. In the **Configure Successful** dialog box, click **OK**.

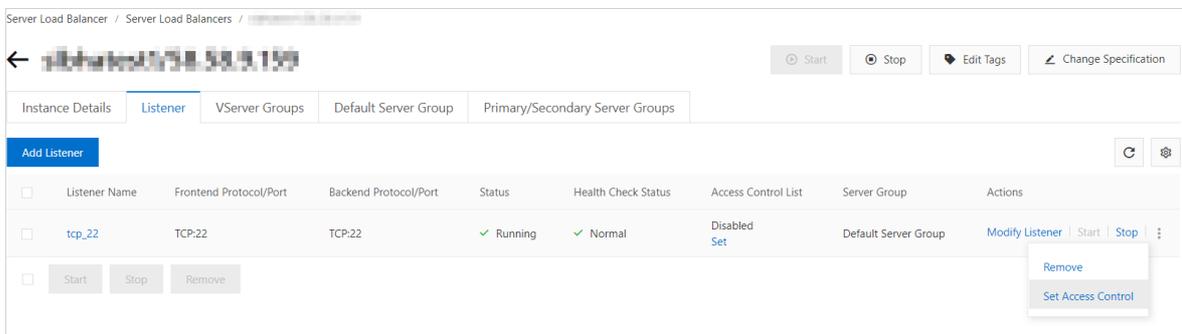

You can check the created listener on the **Listener** tab.

21.5.6. Enable access control

This topic describes how to enable access control for a listener. SLB provides listener-based access control. You can configure different whitelists for different listeners.

Procedure

1. [Log on to the SLB console](#).
2. Find the target SLB instance and click its instance ID.
3. On the page that appears, click the **Listener** tab.
4. Find the target listener and choose  > **Set Access Control** in the **Actions** column.

5. In the **Access Control Settings** dialog box, enable access control and configure the whitelist, and then click **OK**.

Whitelist: Only the requests from the IP addresses or CIDR blocks in the specified ACL are forwarded. You can use the whitelist feature when you want to allow access from specified IP addresses.

Using the whitelist feature may pose risks to your services. The whitelist allows only the traffic from the IP addresses in the specified ACL to access the SLB listener. If the whitelist is used while the corresponding ACL does not contain any IP addresses, the SLB listener forwards all access requests.

Separate multiple IP addresses with commas (,). Each IP address must be unique. You can add a maximum of 300 IP addresses.

- Supported formats: IP addresses (for example, 10.23.12.24) and CIDR blocks (for example, 10.23.12.0/24)
- 0.0.0.0 and x.x.x.x/0 are not supported.

 **Note** The access control feature works only for new connection requests and does not affect existing connections.

21.5.7. Disable access control

This topic describes how to disable access control for a listener.

Procedure

1. [Log on to the SLB console](#).
2. Find the target SLB instance and click its instance ID.
3. On the page that appears, click the **Listener** tab.
4. Find the target listener, and choose  > **Set Access Control** in the Actions column.
5. In the **Access Control Settings** dialog box, disable access control and then click **OK**.

21.6. Backend servers

21.6.1. Backend server overview

Before the Server Load Balancer (SLB) service can be used, you must add ECS instances as backend servers to an SLB instance to process client requests.

You can set virtual IP addresses for SLB instances. This way, the added ECS instances in the same region can be virtualized into an application service pool that provides high performance and availability. You can manage backend servers by using VServer groups. Each listener of an SLB instance can be associated with a specific VServer group so that different listeners can forward requests to their associated backend servers that use different ports.

 **Note** If you associate a VServer group with a listener, the listener will distribute requests to backend servers in the associated VServer group instead of those in the default server group.

You can increase or decrease the number of backend ECS instances at any time and switch ECS instances to receive client requests. However, we recommend that you enable the health check feature and make sure that at least one ECS instance is running properly to maintain service stability.

When you add ECS instances to an SLB instance, take note of the following items:

- You can use different operating systems for the backend ECS instances of an SLB instance. However, the applications deployed in the ECS instances must be the same and have consistent data. We recommend that you use the same operating system to facilitate management and maintenance.
- Up to 50 listeners can be added to a single SLB instance. Each listener corresponds to an application deployed on backend ECS instances. Listening ports of an SLB instance correspond to application service ports opened on backend ECS instances.
- You can specify a weight for each ECS instance in the application service pool. An ECS instance with a higher weight receives more requests.
- If session persistence is enabled, requests may not be evenly distributed to backend ECS instances. To solve

this problem, we recommend that you disable session persistence and check whether the problem persists.

If requests are not distributed evenly, troubleshoot as follows:

- i. Collect statistics on the access logs of the web service on backend ECS instances for a period of time.
 - ii. Check whether the numbers of access logs of backend ECS instances match SLB configurations. For example, if session persistence is enabled, you must differentiate the access logs for the same IP address. If different weights are configured for backend ECS instances, you must check whether the percentage of access logs is normal based on the percentage of weights.
- When an ECS instance is undergoing hot migration, persistent connections to SLB may be interrupted. You can solve this problem by reestablishing the connections.

Default server groups

A default server group contains ECS instances that are used to receive client requests. If a listener is not associated with a VServer group or a primary/secondary server group, the listener will forward requests to ECS instances in the default server group.

For more information about how to create a default server group, see [Add ECS instances to the default server group](#).

Primary/secondary server groups

A primary/secondary server group only contains two ECS instances. One ECS instance acts as the primary server and the other acts as the secondary server. Health checks are not performed on the secondary server. If the primary server is declared unhealthy, traffic is redirected to the secondary server. If the primary server is declared healthy, services will be restored and traffic will be forwarded to the primary server again.

For more information about how to create a primary/secondary server group, see [Add ECS instances to a primary/secondary server group](#).

 **Note** Only TCP and UDP listeners support configuring primary/secondary server groups.

VServer groups

If you want to distribute different requests to different backend servers or configure domain name- or URL-based forwarding rules, you can use VServer groups.

For more information about how to create a VServer group, see [Add ECS instances to a VServer group](#).

21.6.2. Default server groups

21.6.2.1. Add ECS instances to the default server group

This topic describes how to add ECS instances as default backend servers to the default server group of an SLB instance. Before you use the SLB service, you must add at least one default backend server to receive client requests forwarded by SLB.

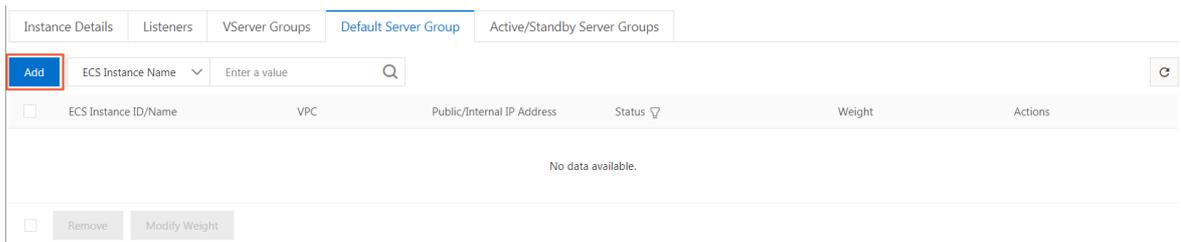

Prerequisites

Before you add ECS instances to the default server group, make sure that the following conditions are met:

- An SLB instance is created. For more information, see [Create an SLB instance](#).
- You have created ECS instances and deployed applications on these ECS instances to process requests.

Procedure

1. [Log on to the SLB console](#).
2. Find the target SLB instance and click its instance ID.
3. Click the **Default Server Group** tab.
4. Click **Add**.

5. In the **My Servers** dialog box, select ECS instances that you want to add.
6. Click **Next**.
7. In the **Configure Ports and Weights** dialog box, specify the weight of each added ECS instance. An ECS instance with a higher weight receives more requests.

You can change the weight of a server and then move the pointer over  to change the weights of multiple servers:

- **Click Replicate to Below:** The weights of all servers below the current server are set to the weight of the current server.
- **Click Replicate to Above:** The weights of all servers above the current server are set to the weight of the current server.
- **Click Replicate to All:** The weights of all servers in the default server group are set to the weight of the current server.
- **Click Reset:** The weight fields of all servers in the default server group are cleared.

 **Notice** If the weight of a backend server is set to 0, this backend server no longer receives new requests.

8. Click **Add**.
9. Click **OK**.

21.6.2.2. Add IDC servers to the default server group

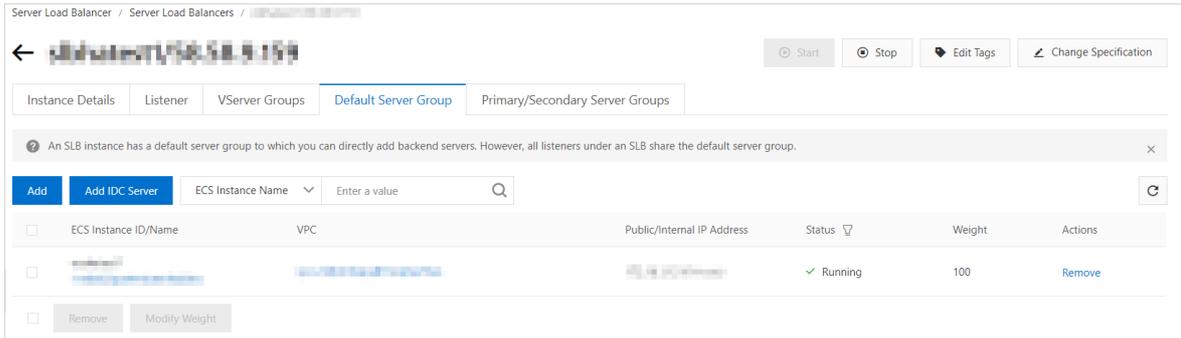

This topic describes how to add servers in on-premises Internet Data Centers (IDCs) as default backend servers to the default server group of an SLB instance. Before you use the SLB service, you must add at least one default backend server to receive client requests forwarded by SLB.

Prerequisites

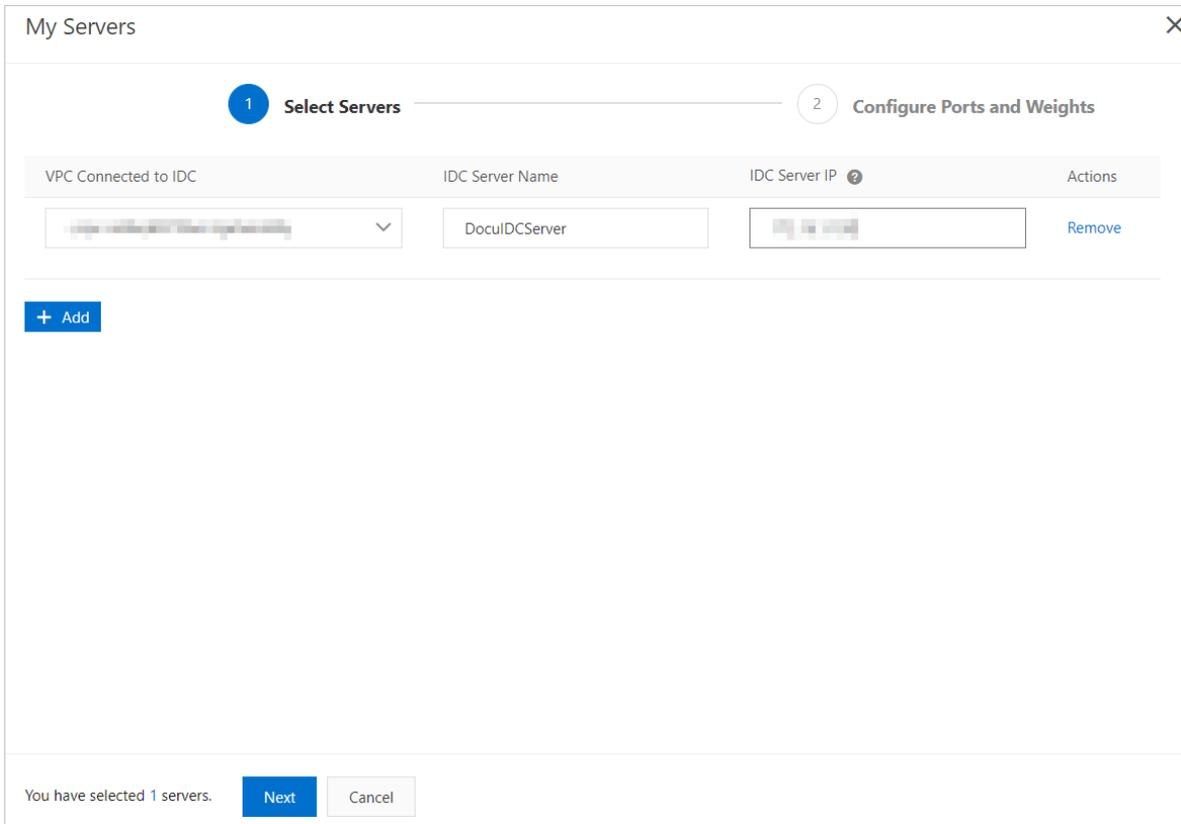

Applications are deployed on the IDC servers, and the IDC servers are ready to receive distributed requests.

Procedure

1. [Log on to the SLB console](#).
2. Find the target SLB instance and click its instance ID.
3. Click the **Default Server Group** tab.
4. Click **Add IDC Server**.

- In the **My Servers** dialog box, click **Add**.
- Select a VPC from the **VPC Connected to IDC** drop-down list, enter a name for the IDC server, and specify the IP address of the IDC server.

- Click **Next**.
- In the **Configure Ports and Weights** step, specify the weight of each added IDC server. An IDC server with a higher weight receives more requests.

You can change the weight of a server and then move the pointer over  to change the weights of multiple servers:

- Click **Replicate to Below**: The weights of all servers below the current server are set to the weight of the current server.
- Click **Replicate to Above**: The weights of all servers above the current server are set to the weight of the current server.
- Click **Replicate to All**: The weights of all servers in the default server group are set to the weight of the current server.
- Click **Reset**: The weight fields of all servers in the default server group are cleared.

 **Notice** If the weight of a backend server is set to 0, this backend server no longer receives new requests.

9. Click **Add**.
10. Click **OK**.

21.6.2.3. Change the weight of a backend server

This topic describes how to change the weight of a backend server to adjust the proportion of requests sent to the backend server.

Procedure

1. [Log on to the SLB console](#).
2. Find the target SLB instance and click its instance ID.
3. Click the **Default Server Group** tab.
4. Move the pointer over the weight value of the target backend server and click the  icon.
5. Change the weight and then click **OK**. A backend server (ECS instance or IDC server) with a higher weight receives more requests.

 **Notice** The weight value ranges from 0 to 100. If the weight of a backend server is set to 0, no requests are sent to the backend server.

21.6.2.4. Remove a backend server

This topic describes how to remove a backend server that is no longer needed.

Procedure

1. [Log on to the SLB console](#).
2. Find the target SLB instance and click its instance ID.
3. Click the **Default Server Group** tab.
4. Find the target backend server and click **Remove** in the **Actions** column.
5. In the dialog box that appears, click **OK**.

21.6.3. VServer groups

21.6.3.1. Add ECS instances to a VServer group

This topic describes how to create a VServer group and then add ECS instances as backend servers to the VServer group. If you associate a VServer group with a listener, the listener distributes requests only to the backend servers in the VServer group instead of other backend servers.

Prerequisites

Before you create a VServer group, make sure that the following conditions are met:

- An SLB instance is created. For more information, see [Create an SLB instance](#).
- You have created ECS instances and deployed applications on these ECS instances to process requests.

Context

Note the following items before you create a VServer group:

- An ECS instance can be added to multiple VServer groups.
- A VServer group can be associated with multiple listeners of an SLB instance.
- The settings of the VServer group include the settings of ECS instances and application ports.

Procedure

1. **Log on to the SLB console.**
2. Find the target SLB instance and click its instance ID.
3. Click the **VServer Groups** tab.
4. On the **VServer Groups** tab, click **Create VServer Group**.
5. On the **Create VServer Group** page, configure the VServer group.
 - i. In the **VServer Group Name** field, enter a name for the VServer group.
 - ii. Click **Add**. In the **My Servers** dialog box, select ECS instances that you want to add.
 - iii. Click **Next**.
 - iv. Specify a port and a weight for each ECS instance and then click **Add**. Set the ports and weights based on the following information:
 - **Port:** The backend port opened on an ECS instance to receive requests.
You can set the same port number for multiple backend servers of the same SLB instance. In addition, you can click **Add Port** to add multiple ports for a backend server.
 - **Weight:** An ECS instance with a higher weight receives more requests.

 **Notice** If the weight of an ECS instance is set to 0, the ECS instance no longer receives new requests.

You can change the weight of a server and then move the pointer over  to change the weights of multiple servers:

- **Click Replicate to Below:** The weights of all servers below the current server are set to the weight of the current server.
- **Click Replicate to Above:** The weights of all servers above the current server are set to the weight of the current server.
- **Click Replicate to All:** The weights of all servers in the VServer group are set to the weight of the current server.
- **Click Reset:** The weight fields of all servers in the VServer group are cleared.

 **Notice** If the weight of a backend server is set to 0, this backend server no longer receives new requests.

- v. Click **Add**.
6. Click **Create**.

21.6.3.2. Add IDC servers to a VServer group

This topic describes how to create a VServer group and then add IDC servers to the VServer group. You can add ECS instances and IDC servers as backend servers to a VServer group. If you associate a VServer group with a listener, the listener distributes requests only to the backend servers in the VServer group instead of other backend servers.

Prerequisites

Before you create a VServer group, make sure that applications are deployed on the IDC servers and the IDC servers are ready to receive distributed requests.

Context

Note the following items before you create a VServer group:

- An IDC server can be added to multiple VServer groups.
- A VServer group can be associated with multiple listeners of an SLB instance.
- The settings of the VServer group include the settings of IDC servers and application ports.

Procedure

1. **Log on to the SLB console.**
2. Find the target SLB instance and click its instance ID.
3. Click the **VServer Groups** tab.
4. On the **VServer Groups** tab, click **Create VServer Group**.
5. On the **Create VServer Group** page, configure the VServer group.
 - i. In the **VServer Group Name** field, enter a name for the VServer group.
 - ii. Click **Add IDC Server**.
 - iii. In the **My Servers** dialog box, click **Add**.
 - iv. Select a VPC from the **VPC Connected to IDC** drop-down list, enter a name for the IDC server, and specify the IP address of the IDC server. The IP address of the IDC server must be accessible to the VPC.
 - v. Click **Next**.
 - vi. Specify a port and weight for each IDC server, and then click **Add**. Set the ports and weights based on the following information:
 - **Port:** The backend port opened on an IDC server to receive requests. Multiple ports can be added to an IDC server.
You can set the same port number for multiple backend servers of the same SLB instance.
 - **Weight:** An IDC server with a higher weight receives more requests.

 **Notice** If the weight of an IDC server is set to 0, the IDC server no longer receives new requests.

You can change the weight of a server and then move the pointer over  to change the weights of multiple servers:

- **Click Replicate to Below:** The weights of all servers below the current server are set to the weight of the current server.
- **Click Replicate to Above:** The weights of all servers above the current server are set to the weight of the current server.
- **Click Replicate to All:** The weights of all servers in the VServer group are set to the weight of the current server.
- **Click Reset:** The weight fields of all servers in the VServer group are cleared.

 **Notice** If the weight of a backend server is set to 0, this backend server no longer receives new requests.

vii. Click **Add**.

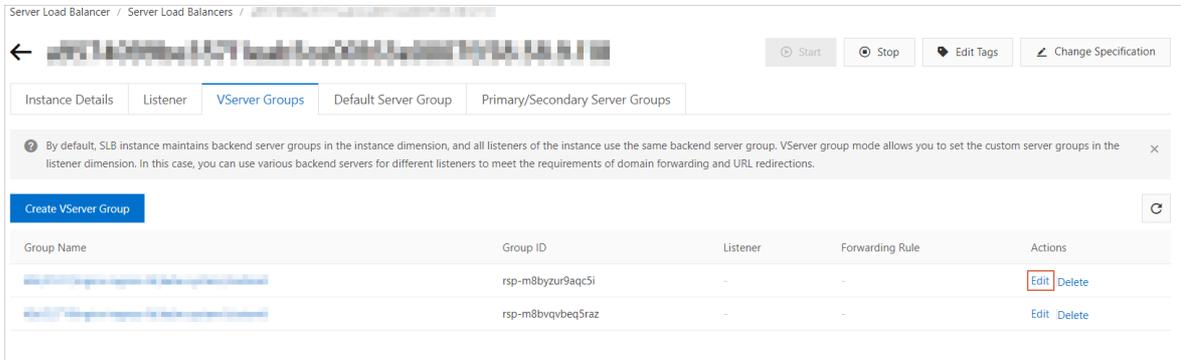

6. Click **Create**.

21.6.3.3. Modify a VServer group

This topic describes how to modify the settings of ECS instances or IDC servers in a VServer group.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the VServer Groups tab.
4. Find the target VServer group and then click Edit in the Actions column.

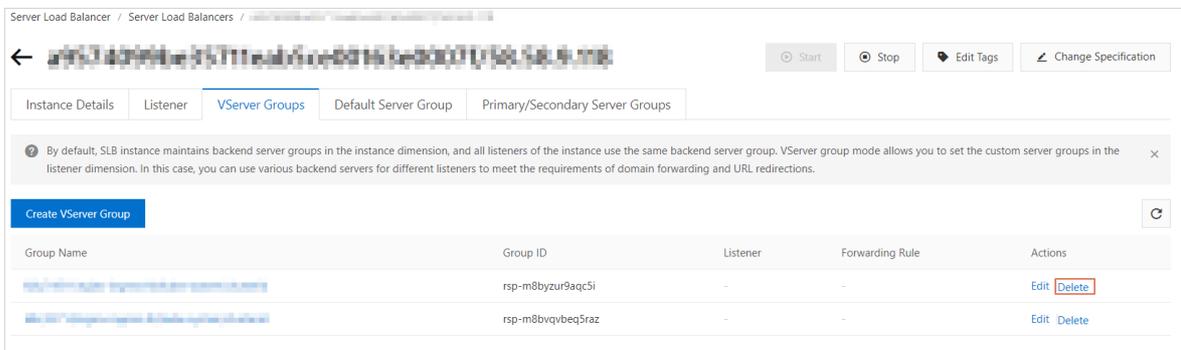

5. Modify the ports and weights of ECS instances or IDC servers, and then click Save.

21.6.3.4. Delete a VServer group

This topic describes how to delete a VServer group that is no longer needed for traffic distribution.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the VServer Groups tab.
4. Find the target VServer group, and then click Delete in the Actions column.

5. In the dialog box that appears, click OK.

21.6.4. Active/standby server groups

21.6.4.1. Add ECS instances to a primary/secondary server group

This topic describes how to create a primary/secondary server group and then add ECS instances to the primary/secondary server group. You can use a primary/secondary server group to implement failover between a primary server and a secondary server. By default, the primary server handles all distributed requests. When the primary server fails, traffic is redirected to the secondary server.

Prerequisites

Before you create a primary/secondary server group, make sure that the following conditions are met:

- An SLB instance is created. For more information, see [Create an SLB instance](#).
- You have created ECS instances and deployed applications on these ECS instances to process requests.

Procedure

1. **Log on to the SLB console.**
2. Find the target SLB instance and click its instance ID.
3. Click the **Primary/Secondary Server Groups** tab.
4. On the **Primary/Secondary Server Groups** tab, click **Create Primary/Secondary Server Group**.
5. On the **Create Primary/Secondary Server Group** page, configure the primary/secondary server group.
 - i. In the **Primary/Secondary Server Group Name** field, enter a name for the primary/secondary server group.

← Create Primary/Secondary Server Group

Note: The network type of the SLB instance is Classic Network, and the instance type is Private Network. You can add ECS instances in a classic or VPC network to the primary/secondary server group.

* Primary/Secondary Server Group Name

Enter a server group name

Added Servers

Add Add IDC Server Search by server name, ID, or IP

ECS Instance ID/Name	Region	VPC	Public/Private IP	Status	Port	Type	Actions
No data available.							

Create Cancel

- ii. Click Add. In the My Servers dialog box, select ECS instances that you want to add in the Select Servers step.

My Servers

1 Select Servers ————— 2 Configure Ports and Weights

ECS Instance Name Search by name, ID, or IP VPC Select

Show Available Instances Only Advanced Mode

<input type="checkbox"/>	ECS Instance ID/Name	Private IP	Public IP/VPC Property	Status	Number of SLB Associations
<input type="checkbox"/>	ecshatest1	192.168.1.1	192.168.1.1	Running	1
<input checked="" type="checkbox"/>	ecshatest2	192.168.1.2	192.168.1.2	Running	1
<input checked="" type="checkbox"/>	ecshatest3	192.168.1.3	192.168.1.3	Running	1

You have selected 2 servers.

You can add up to two ECS instances to a primary/secondary server group.

- iii. Click Next.

- iv. Configure the backend ports opened on ECS instances to receive requests, and then click Add.

My Servers

1 Select Servers ————— 2 Configure Ports and Weights

ECS Instance ID/Name	Private IP	Port	Reset	Actions
ecshatest3	[Redacted]	<input type="text"/>	Reset	Add Port Remove
ecshatest2	[Redacted]	<input type="text"/>	Reset	Add Port Remove

Previous Add Cancel

You can set multiple ports for an ECS instance.

- v. Set an ECS instance as the primary server.
vi. Click Create.

21.6.4.2. Add IDC servers to a primary/secondary server group

This topic describes how to create a primary/secondary server group and then add IDC servers to the primary/secondary server group. You can use a primary/secondary server group to implement failover between a primary server and a secondary server. By default, the primary server handles all distributed requests. When the primary server fails, traffic is redirected to the secondary server.

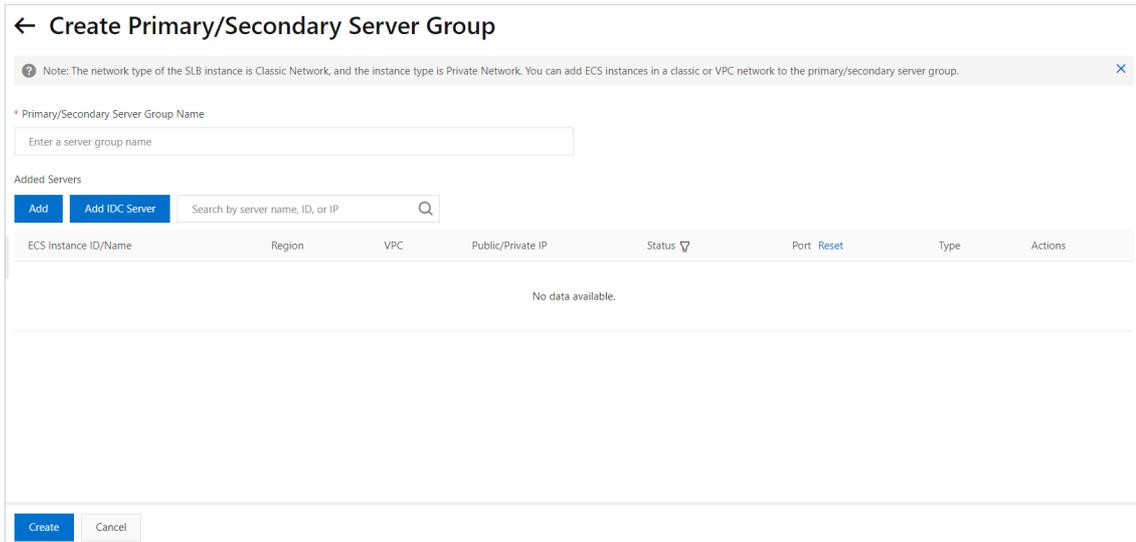

Prerequisites

The IDC servers are created, configured to deploy applications, and ready to receive distributed requests.

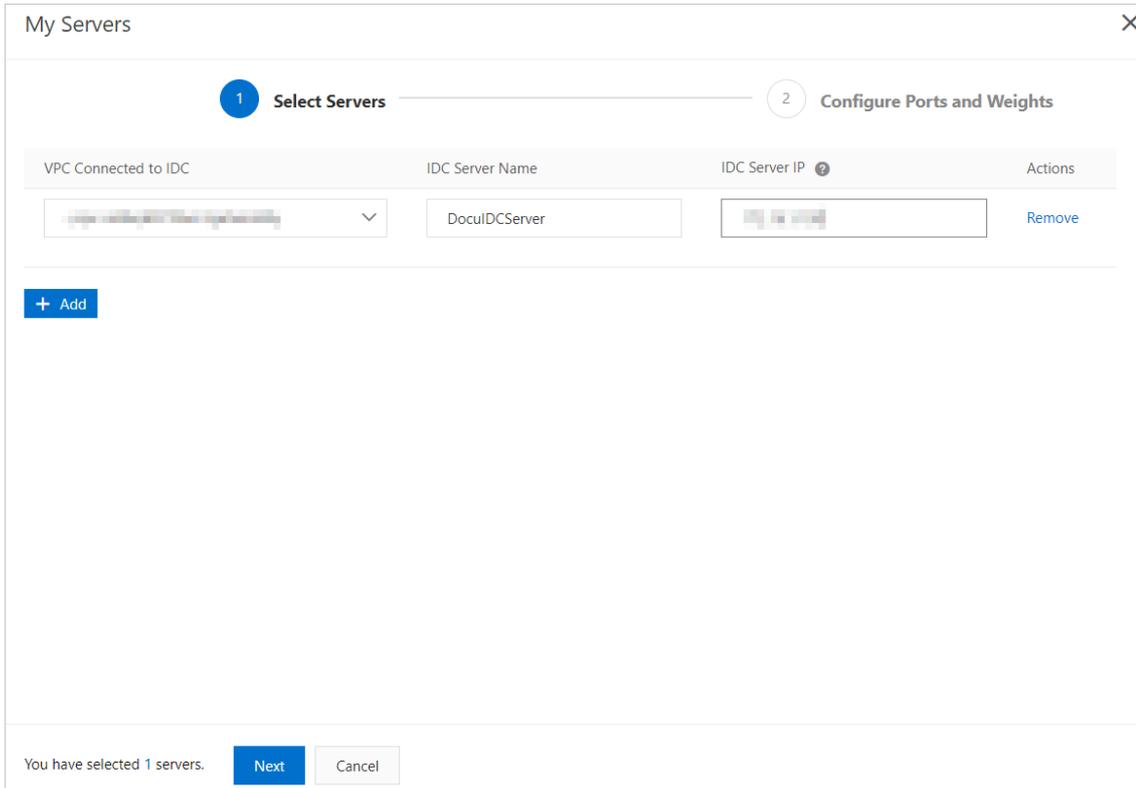

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the Primary/Secondary Server Groups tab.
4. On the Primary/Secondary Server Groups tab, click Create Primary/Secondary Server Group.
5. On the Create Primary/Secondary Server Group page, configure the primary/secondary server group.

- i. In the **Primary/Secondary Server Group Name** field, enter a name for the primary/secondary server group, and then click **Add IDC Server**.

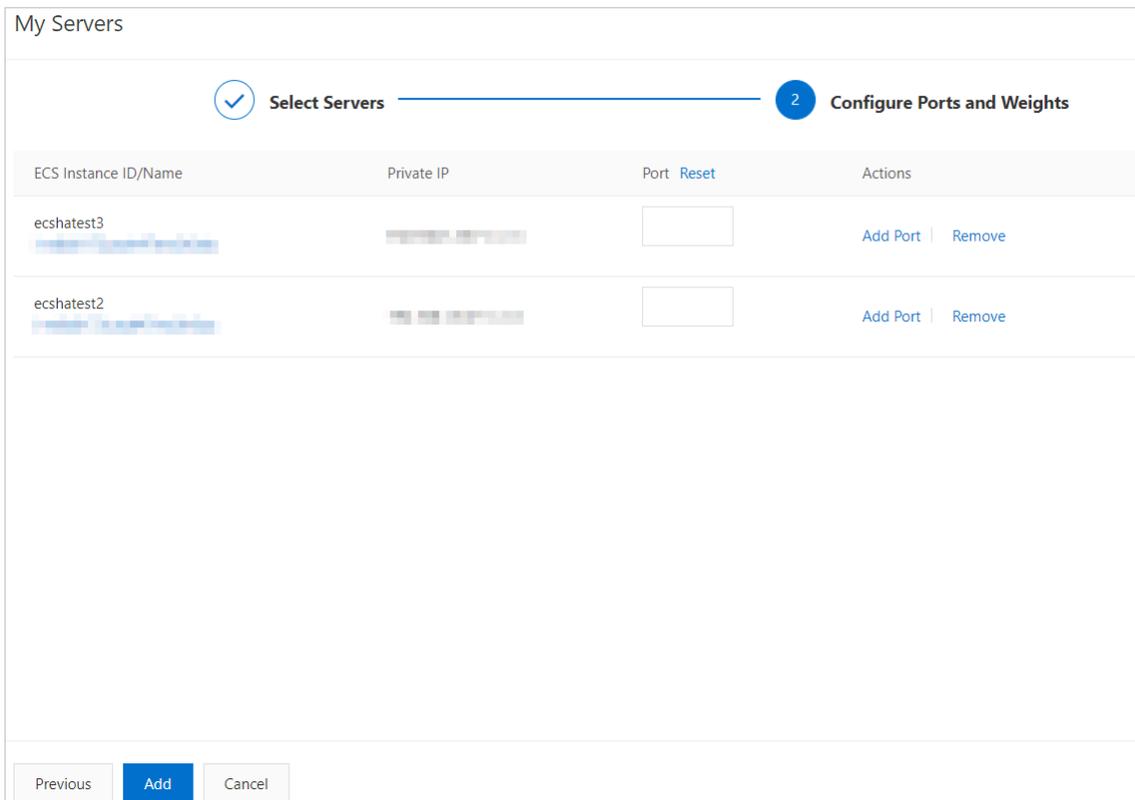

- ii. In the **My Servers** dialog box, click **Add**.

- iii. Select a VPC from the **VPC Connected to IDC** drop-down list, enter a name for the IDC server, and specify the IP address of the IDC server. The IP address of the IDC server must be accessible to the VPC.
- iv. Click **Next**.

v. Configure the backend ports opened on ECS instances to receive requests, and then click **Add**.

You can set multiple ports for an IDC server.

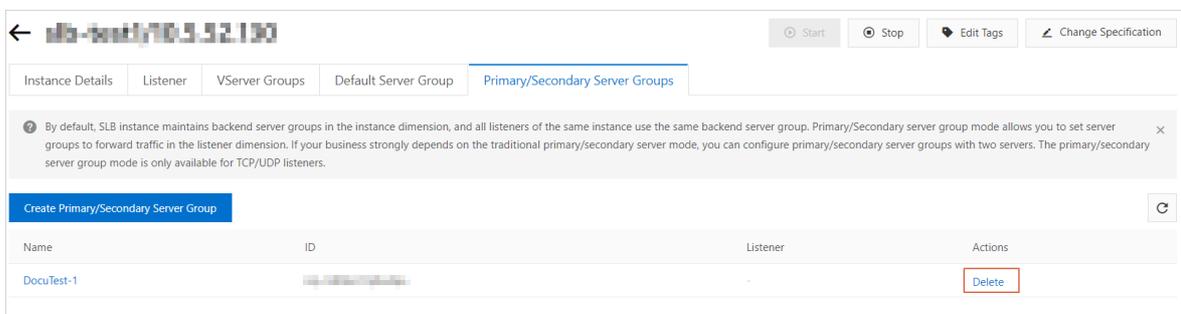

- vi. Set a backend server as the primary server.
- vii. Click **Create**.

21.6.4.3. Delete a primary/secondary server group

If a primary/secondary server group is no longer needed to forward traffic, you can delete the primary/secondary server group.

Procedure

1. **Log on to the SLB console.**
2. Find the target SLB instance and click its instance ID.
3. Click the **Primary/Secondary Server Groups** tab.
4. Find the target primary/secondary server group and click **Delete** in the Actions column.

5. In the dialog box that appears, click **OK**.

21.7. Health check

21.7.1. Health check overview

Server Load Balancer (SLB) checks the availability of backend servers (ECS instances) by performing health checks. The health check feature improves the overall availability of your frontend business and mitigates the impact of exceptions occurring on backend ECS instances.

After the health check feature has been enabled, SLB stops distributing requests to ECS instances that are declared unhealthy and distributes new requests to healthy ECS instances. When the unhealthy ECS instances have recovered, SLB begins forwarding requests to the ECS instances again.

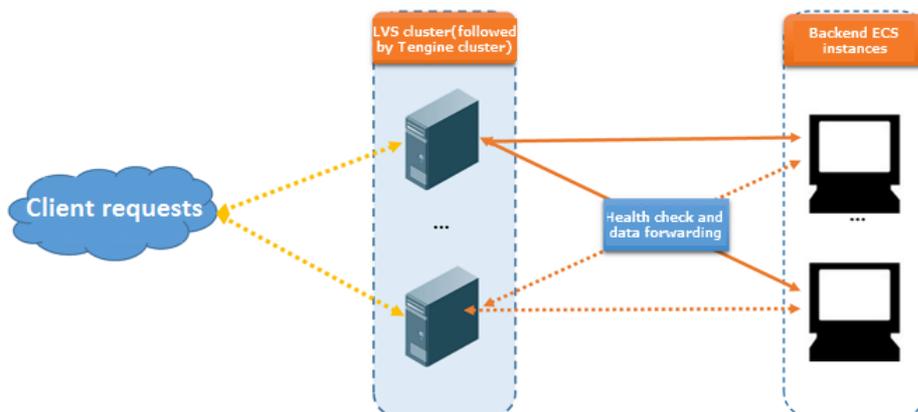

If your business is highly sensitive to traffic loads, frequent health checks may impact the availability of normal business. To reduce the impacts of health checks on your business, you can reduce the health check frequency, increase the health check interval, or change Layer 7 health checks to Layer 4 health checks to match business conditions. We recommend that you do not disable the health check feature to ensure business continuity.

Health check process

SLB is deployed in clusters. Node servers in the LVS or Tengine cluster forward data and perform health checks.

The node servers in the LVS cluster forward data and perform health checks independently and in parallel based on configured load balancing policies. If an LVS node server detects that a backend ECS instance is unhealthy, the node server no longer sends new client requests to the ECS instance.

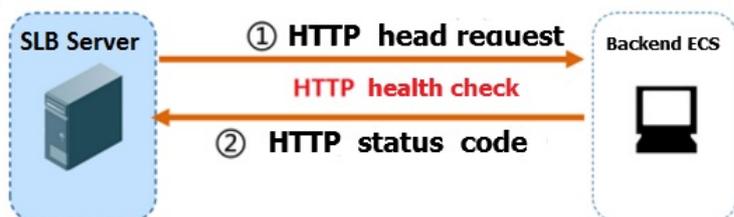

SLB uses the CIDR block of 100.64.0.0/10 for health checks. Make sure that backend ECS instances do not block this CIDR block. You do not need to configure a security group rule to allow access from this CIDR block. However, if you have configured security rules such as iptables, you must allow access from this CIDR block. 100.64.0.0/10 is reserved by Alibaba Cloud. Other users cannot use IP addresses within this CIDR block, and therefore there are no security risks associated with it.

Health checks of HTTP or HTTPS listeners

For Layer 7 (HTTP or HTTPS) listeners, SLB checks the status of backend ECS instances by sending HTTP HEAD requests.

For HTTPS listeners, certificates are managed in SLB. To improve system performance, HTTPS is not used for data exchange (including health check data and business interaction data) between SLB and backend ECS instances.

The health check process of a Layer 7 listener is as follows:

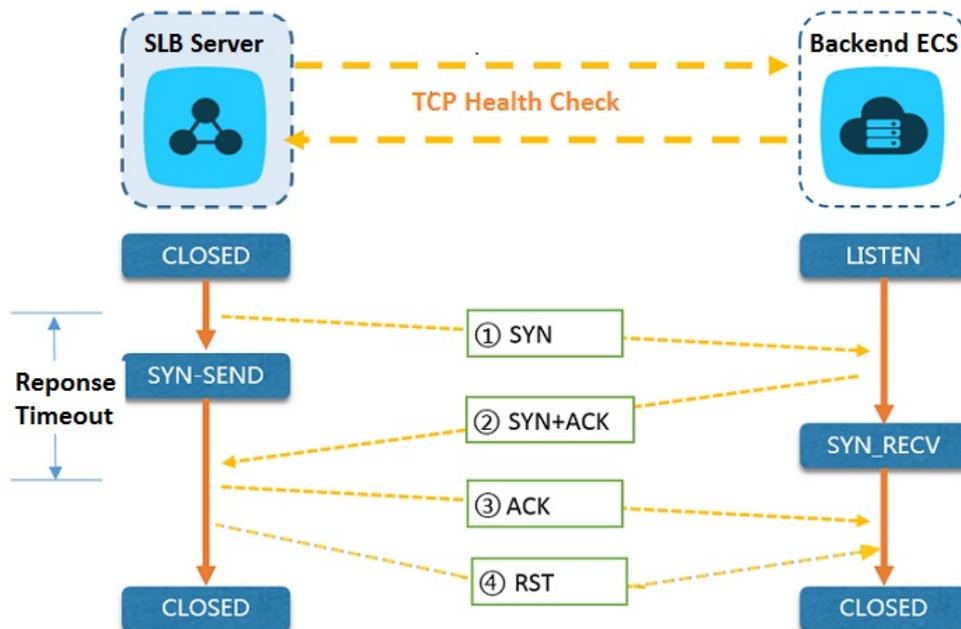

1. A Tengine node server sends an HTTP HEAD request containing the configured domain name to the internal

IP address, health check port, and health check path of a backend ECS instance based on health check settings.

2. After receiving the request, the backend ECS instance returns an HTTP status code based on the running status.
3. If the Engine node server does not receive a response from the backend ECS instance within the specified response timeout period, the node server determines that the service is unresponsive and the health check fails.
4. If the Engine node server receives a response from the backend ECS instance within the specified response timeout period, the node server compares the response information with the configured status code. If the status code in the response is the same as the configured one, the backend ECS instance is declared healthy. Otherwise, the backend ECS instance is declared unhealthy.

Health checks of TCP listeners

For TCP listeners, SLB checks the status of backend ECS instances by establishing TCP connections to improve health check efficiency.

The health check process of a TCP listener is as follows:

1. An LVS node server sends a TCP SYN packet to the internal IP address and health check port of a backend ECS instance.
2. After receiving the request, the backend ECS instance returns an SYN+ACK packet if listening on the corresponding port is normal.
3. If the LVS node server does not receive a packet from the backend ECS instance within the specified response timeout period, the node server determines that the service is unresponsive and the health check fails. Then, the node server sends an RST packet to the backend ECS instance to terminate the TCP connection.
4. If the LVS node server receives a packet from the backend ECS instance within the specified response timeout period, the node server determines that the service runs properly and the health check succeeds. Then, the node server sends an RST packet to the backend ECS instance to terminate the TCP connection.

Note Typically, a TCP three-way handshake is conducted to establish a TCP connection. After the LVS node server receives the SYN+ACK packet from the backend ECS instance, the node server sends an ACK packet, and then immediately sends an RST packet to terminate the TCP connection.

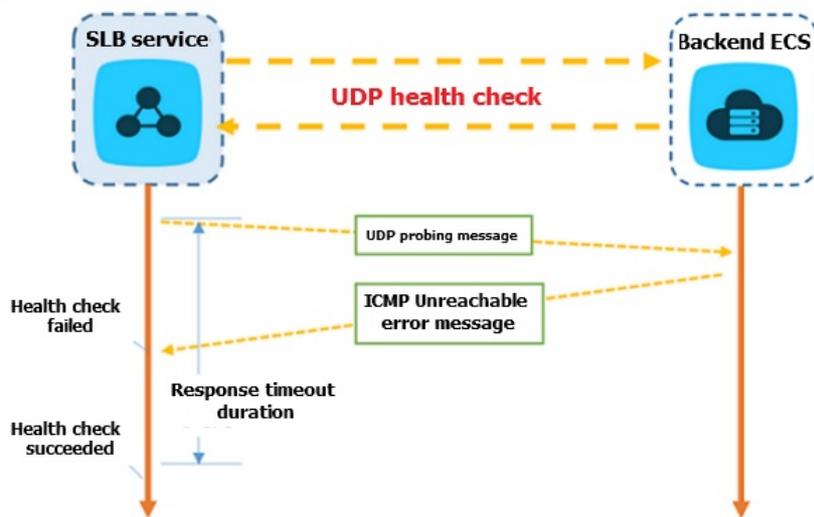

This process may cause the ECS instance to regard that an error such as an abnormal exit occurred in the TCP connection, and then report a corresponding error such as `Connection reset by peer`, for example, in Java connection pool logs.

Solution:

- You can implement HTTP health checks.
- If you have enabled the feature of obtaining actual client IP addresses on backend ECS instances, you can ignore connection errors caused by the access of the SLB CIDR block.

Health checks of UDP listeners

For UDP listeners, SLB checks the status of backend ECS instances by sending UDP packets.

The health check process of a UDP listener is as follows:

1. An LVS node server sends a UDP packet to the internal IP address and health check port of an ECS instance based on health check configurations.
2. If the listening on the corresponding port of the ECS instance is abnormal, the ECS instance returns an ICMP error message such as `port XX unreachable`. Otherwise, no message is returned.
3. If the LVS node server receives the ICMP error message within the response timeout period, the node server determines that the service is abnormal and the health check fails.
4. If the LVS node server does not receive any message within the response timeout period, the node server determines that the service is normal and the health check succeeds.

Note For UDP health checks, the health check result may not reflect the real status of a backend ECS instance in the following situation:

If the backend ECS instance uses a Linux operating system, the speed at which ICMP messages in high concurrency scenarios are sent is limited due to the ICMP attack prevention feature of Linux. In this case, even if a service exception occurs, SLB may declare the backend ECS instance healthy because the error message `port XX unreachable` is not returned. Consequently, the health check result deviates from the actual service status.

Solution:

You can specify a request and a response for UDP health checks. The ECS instance is considered healthy only when the specified response is returned. However, the client must be configured accordingly for returning responses.

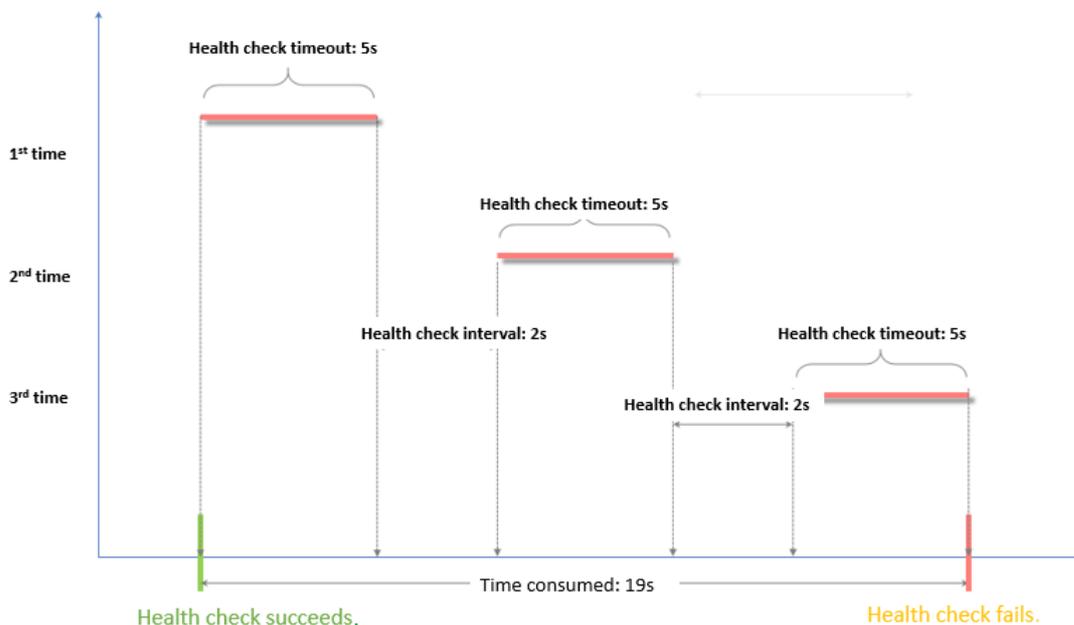

Health check time window

The health check feature effectively improves the availability of your services. However, to avoid impacts on system availability caused by frequent switching after failed health checks, the health check status only switches when health checks successively succeed or fail for a specified number of times within a certain time window. The health check time window is determined by the following three factors:

- Health check interval: how often health checks are performed
- Response timeout: the time to wait for a response
- Health check threshold: the number of times health checks succeed or fail successively

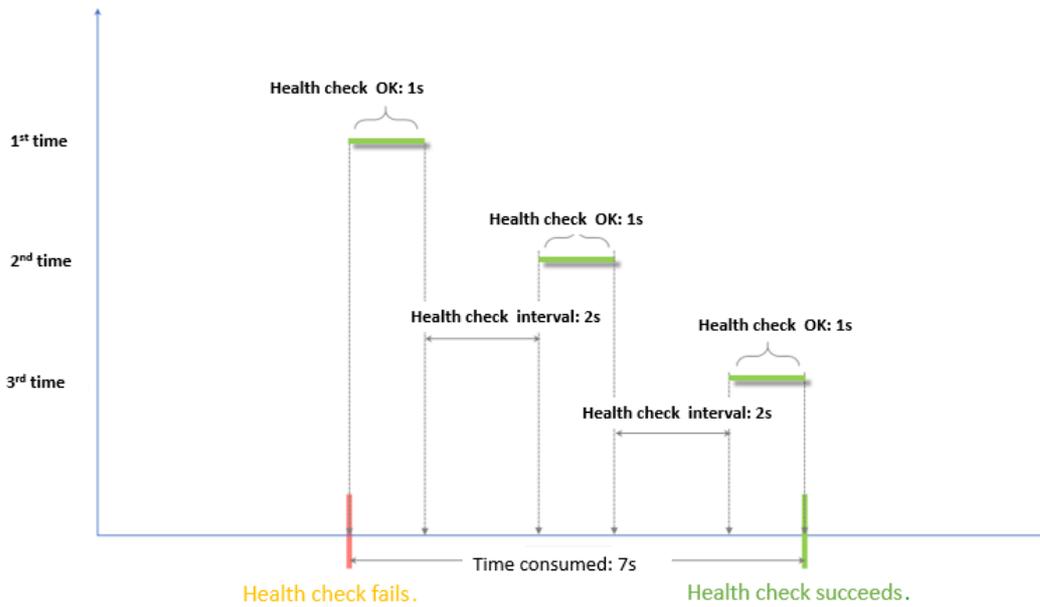

The health check time window is calculated as follows:

- Time window for health check failures = Response timeout × Unhealthy threshold + Health check interval × (Unhealthy threshold - 1)

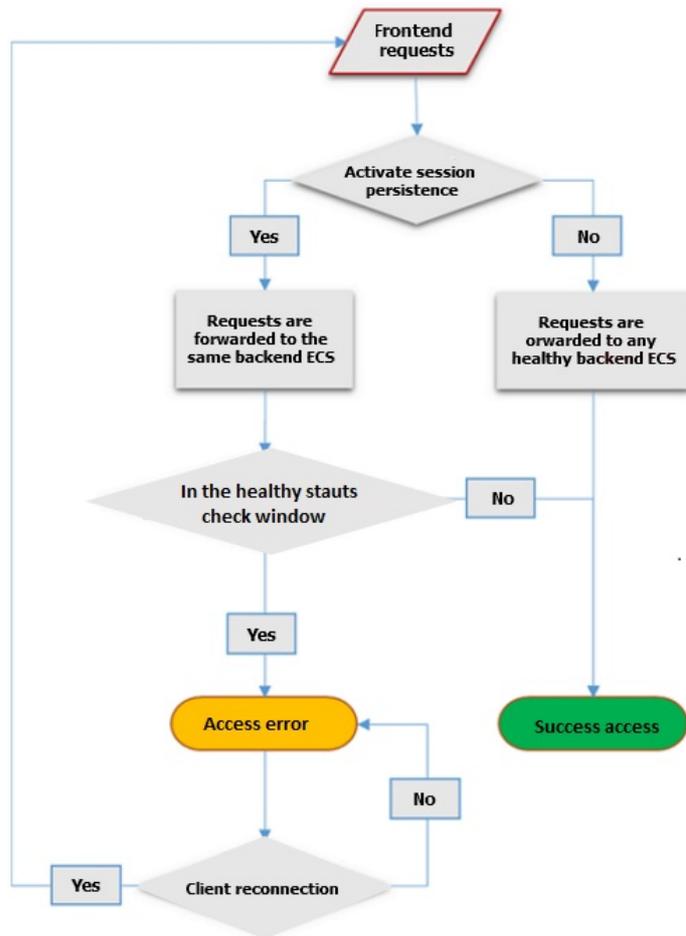

- Time window for health check successes = Response time of a successful health check × Healthy threshold + Health check interval × (Healthy threshold - 1)

Note The response time of a successful health check is the duration from the time when the health check request is sent to the time when the response is received. When TCP health checks are used, the response time is almost negligible because only whether the specific port is alive is checked. For HTTP health checks, the response time depends on the performance and load of the application server and is typically within a few seconds.

The health check result has the following impact on request forwarding:

- If the health check of the target ECS instance fails, new requests are distributed to other ECS instances. This does not affect client access.
- If the health check of the target ECS instance succeeds, new requests are distributed to the instance and client access is normal.
- If an exception occurs on the target ECS instance and a request arrives during a time window for health check failures, the request is still sent to the ECS instance because the number of failed health checks has not reached the unhealthy threshold (3 by default). In the case, client access fails.

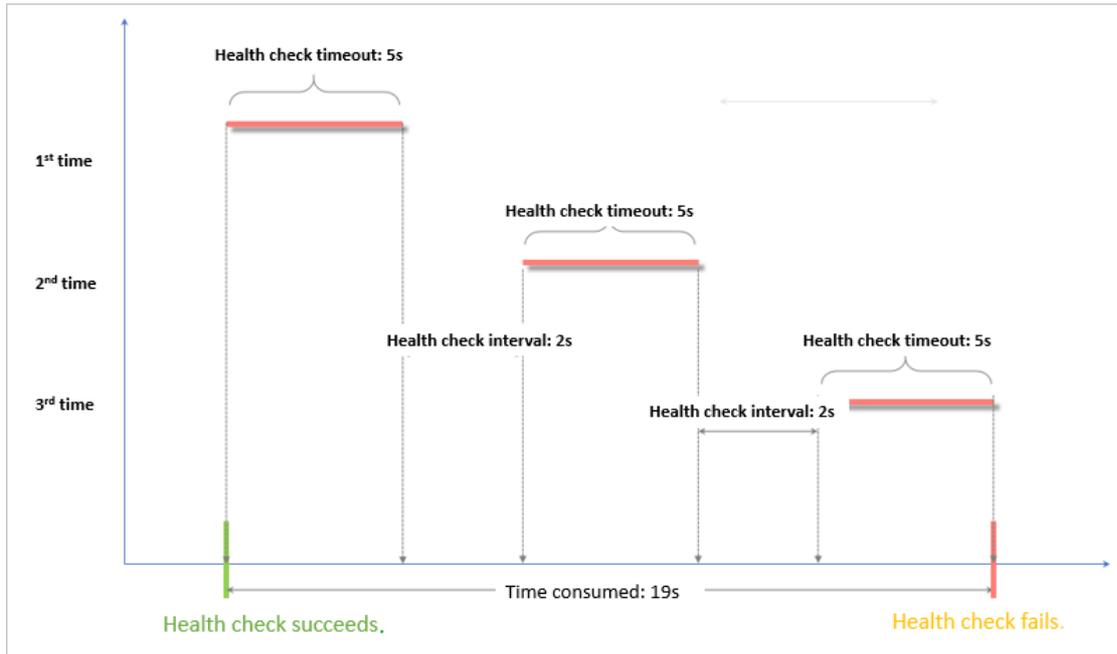

Examples of health check response timeout and health check interval

The examples use the following health check settings:

- Response timeout: 5s
- Health check interval: 2s
- Healthy threshold: 3
- Unhealthy threshold: 3

Time window for health check failures = Response timeout × Unhealthy threshold + Health check interval × (Unhealthy threshold - 1). That is, $5 \times 3 + 2 \times (3-1) = 19s$.

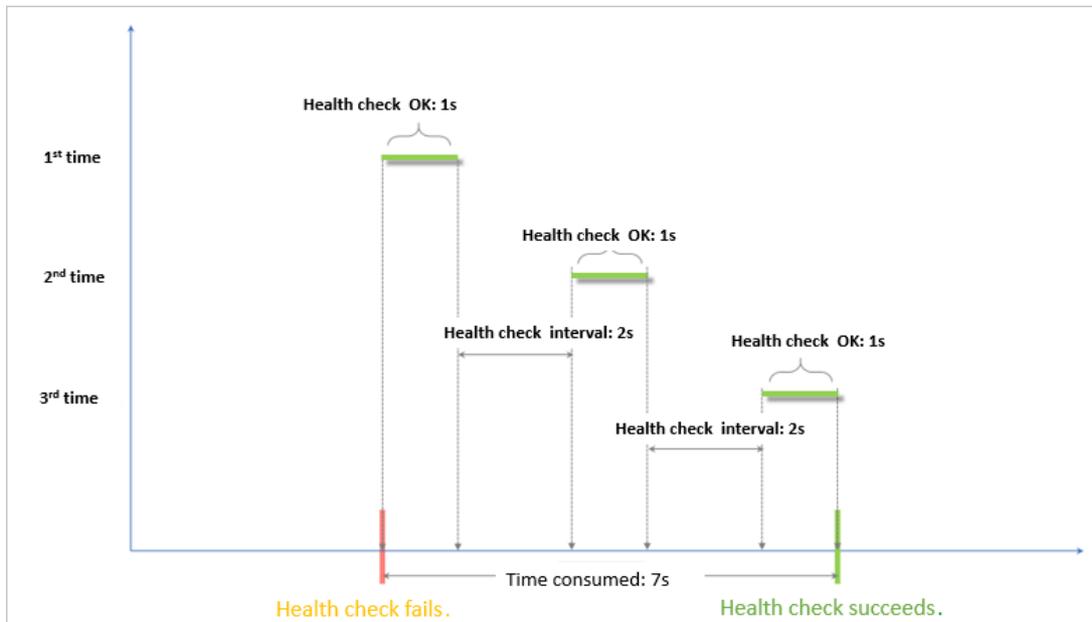

The following figure shows the process of a status change from healthy to unhealthy.

Time window for health check successes = Response time of a successful health check × Healthy threshold + Health check interval × (Healthy threshold - 1). That is, $(1 \times 3) + 2 \times (3-1) = 7s$ (assuming that the response time of a successful health check is 1s).

Note The response time of a successful health check is the duration from the time when the health check request is sent to the time when the response is received. When TCP health checks are used, the response time is almost negligible because only whether the specific port is alive is checked. For HTTP health checks, the response time depends on the performance and load of the application server and is typically within a few seconds.

The following figure shows the process of a status change from unhealthy to healthy.

Domain name setting in HTTP health checks

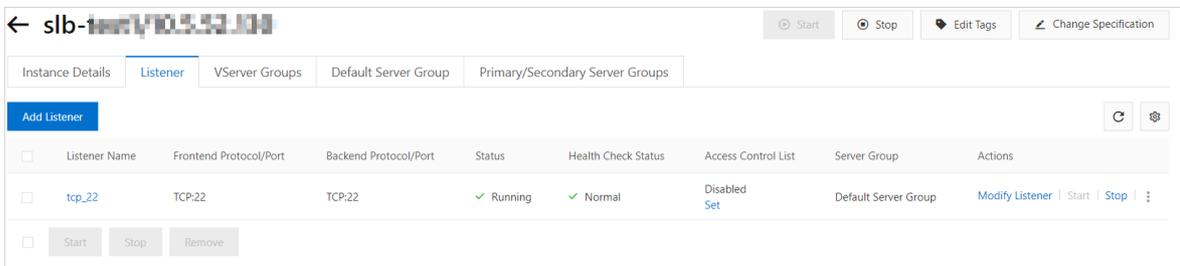

When HTTP health checks are used, you can set a domain name for health checks. The setting is optional. Some application servers verify the host field in requests. In this case, the request header must contain the host field. If a domain name is configured in the health check feature, SLB adds the domain name to the host field when forwarding a request to an application server. If no domain name is configured, the health check request will be denied by the application server because it does not contain a host field and the health check may fail. If your application server verifies the host field in requests, you must configure a domain name to make sure that the health check feature works.

21.7.2. Configure health check

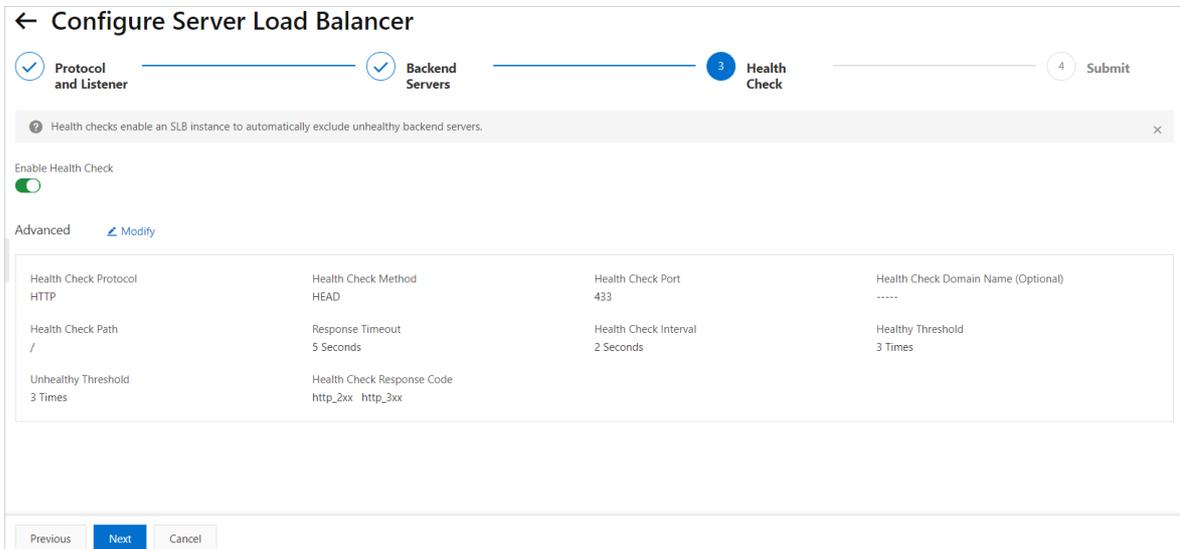

This topic describes how to configure health check. You can configure health check when you create a listener or for an existing listener. The default health check settings can meet your requirements in most cases.

Procedure

1. **Log on to the SLB console.**
2. Find the target SLB instance and click its instance ID.
3. Click the **Listener** tab.
4. Click **Add Listener**, or find the target listener and click **Modify Listener** in the **Actions** column.

5. Click **Next** to go to the **Health Check** step. Click **Modify** next to **Advanced**.

We recommend that you use the default settings when you configure the health check.

Health check configuration

Parameter	Description
-----------	-------------

Parameter	Description
Health Check Protocol	<p>Select the protocol for health check. For TCP listeners, both the TCP health check and HTTP health check are supported.</p> <ul style="list-style-type: none"> The TCP health check implements detection at the network layer by sending SYN packets to check if a port is open. The HTTP health check verifies the health of a backend server by sending HEAD/GET requests to simulate browser access.
Health Check Method (for the HTTP and HTTPS health checks only)	<p>The health check of Layer-7 (HTTP or HTTPS) listeners supports both the HEAD and GET methods. The HEAD method is used by default.</p> <p>If your backend applications do not support the HEAD method or if the HEAD method is disabled, the health check may fail. To resolve this issue, you can use the GET method instead.</p> <p>If the GET method is used and the response size exceeds 8 KB, the response is truncated. However, the health check result is not affected.</p>
Health Check Path and Health Check Domain Name (Optional) (for the HTTP health check only)	<p>By default, SLB performs the health check by sending HTTP HEAD requests to the default homepage of the application deployed on the ECS instance with the internal IP address of the ECS instance.</p> <p>If you need to use another web page other than the default homepage for the health check, you must specify a request path.</p> <p>Some application servers require the request header to contain the host field for verification. If a domain name is configured in health check settings, SLB adds this domain name to the host field when forwarding a health check request to one of the preceding application servers. If no domain name is configured, SLB does not include the host field in the request, which means that the request will be rejected by the application server and the health check may fail. Therefore, if your application server verifies the host field in requests, you must configure a domain name in health check settings to make sure that the health check can run properly.</p> <p>The URL path for the health check must be 1 to 80 characters in length and can contain letters, digits, hyphens (-), underscores (_), forward slashes (/), periods (.), percent signs (%), question marks (?), number signs (#), ampersands (&), and equals signs (=).</p> <p>The health check domain name can contain letters, digits, periods (.), and hyphens (-). The internal IP addresses of backend servers are used as domain names for the health check by default.</p>
Normal Status Code (for the HTTP health check only)	<p>Select the HTTP status code that indicates a successful health check.</p> <p>Default values: http_2xx and http_3xx.</p>
Health Check Port	<p>Set the detection port used by health check to access backend servers.</p> <p>By default, the backend port configured for the listener is used.</p> <p>Valid values: 1 to 65535.</p> <div style="background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> <p> Note If a VServer group or an active/standby server group is configured for the listener, and the ECS instances in the group use different ports, leave this parameter empty. SLB uses the backend ports of the ECS instances to perform the health check.</p> </div>

Parameter	Description
Response Timeout	Specify the amount of time to wait for a health check response. If the backend ECS instance does not send an expected response within the specified response timeout period, the health check fails. Valid values: 1 to 300. Unit: seconds. Default value for UDP listeners: 10. Default value for HTTP, HTTPS, and TCP listeners: 5.
Health Check Interval	Specify the interval between health checks. All nodes in the LVS cluster perform health checks independently and in parallel on backend ECS instances at the specified interval. The health check statistics of a single ECS instance cannot reflect the health check interval because the nodes perform health checks at different times. Valid values: 1 to 50. Unit: seconds. Default value for UDP listeners: 5. Default value for HTTP, HTTPS, and TCP listeners: 2.
Unhealthy Threshold	Specify the number of consecutive failed health checks that must occur before an ECS instance is declared unhealthy. Valid values: 2 to 10. Default value: 3.
Healthy Threshold	Specify the number of consecutive successful health checks that must occur before an ECS instance is declared healthy. Valid values: 2 to 10. Default value: 3.

6. Click **Next**.

21.7.3. Disable the health check feature

This topic describes how to disable the health check feature. If you disable the health check feature, requests may be distributed to unhealthy ECS instances and cause impacts on your business. We recommend that you enable the health check feature.

Context

 **Note** You can only disable the health check feature for HTTP and HTTPS listeners. The health check feature for UDP and TCP listeners cannot be disabled.

Procedure

1. [Log on to the SLB console](#).
2. On the **Server Load Balancer** page, find the target SLB instance and click its instance ID.
3. On the **Listeners** tab, find the target listener and click **Configure** in the **Actions** column.
4. On the **Configure Listener** page, click **Next** until the **Health Check** step appears.
5. Turn off **Enable Health Check**.
6. Click **Next**.
7. Click **Submit**, and then click **OK**.

21.8. Certificate management

21.8.1. Certificate overview

information, see [RFC 1421](#).

- The certificate must conform to the corresponding format requirements. Generally, the intermediate CA provides instructions about the certificate format when issuing the certificate. The certificate must conform to the format requirements.

A sample certificate chain is shown as follows.

```
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
```

Public keys of certificates

SLB supports the following public key algorithms:

- RSA 1024
- RSA 2048
- RSA 4096
- ECDSA P-256
- ECDSA P-384
- ECDSA P-521

RSA private keys

When you upload a server certificate, you must upload the private key of the certificate.

An RSA private key must meet the following format requirements:

- The private key must start with `-----BEGIN RSA PRIVATE KEY-----` and end with `-----END RSA PRIVATE KEY-----`, and these parts must also be uploaded.
- Blank lines are not allowed in the certificate content. Each line except the last line must contain 64 characters. The last line can contain 64 or fewer characters. For more information, see [RFC 1421](#).

You may use an encrypted private key. For example, the private key starts with `-----BEGIN PRIVATE KEY-----` and ends with `-----END PRIVATE KEY-----` or starts with `-----BEGIN ENCRYPTED PRIVATE KEY-----` and ends with `-----END ENCRYPTED PRIVATE KEY-----`. The private key may also contain `Proc-Type: 4,ENCRYPTED`. In this case, you must first run the following command to convert the private key:

```
openssl rsa -in old_server_key.pem -out new_server_key.pem
```

The following figure shows a sample RSA private key.

```
-----BEGIN RSA PRIVATE KEY-----

21.8.3. Upload a certificate

This topic describes how to create and upload a certificate. Before you create an HTTPS listener, you must upload the required server certificate and CA certificate to SLB. You do not need to configure certificates on backend servers after uploading the certificates to SLB.

Prerequisites

- A server certificate is purchased.
- A CA certificate and a client certificate are generated.

Context

Note that you can create up to 100 certificates per account.

Procedure

1. In the left-side navigation pane, click **Certificates**.
2. Click **Create Certificate**.
3. In the **Create Certificate** dialog box, set certificate parameters and then click **Create**.

Parameter	Description
Certificate Name	Enter a name for the certificate. The name must be 1 to 80 characters in length and can contain letters, digits, hyphens (-), forward slashes (/), periods (.), underscores (_), and asterisks (*).
Organization	Select the organization to which the certificate belongs.
Resource Group	Select the resource group to which the certificate belongs.
Certificate Type	Select Server Certificate . For HTTPS one-way authentication, only the server certificate and the private key are required.
Public Key Certificate	Copy and paste the contents of the server certificate into the field. Click Example to view the valid certificate format. For more information, see Certificate requirements .

Parameter	Description
Private Key	<p>Copy and paste the private key of the server certificate into the field.</p> <p>Click Example to view the valid certificate format. For more information, see Certificate requirements.</p> <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> <p> Notice A private key is required only when you upload a server certificate.</p> </div>
Region	Select one or more regions where the certificate will be deployed.

4. Click Create.

21.8.4. Generate a CA certificate

When you configure an HTTPS listener, you can use a self-signed CA certificate. This topic describes how to generate a CA certificate and use the CA certificate to sign a client certificate.

Generate a CA certificate by using Open SSL

1. Run the following commands to create a `ca` folder in the `/root` directory and then create four subfolders under the `ca` folder.

```
$ sudo mkdir ca
$ cd ca
$ sudo mkdir newcerts private conf server
```

- `newcerts` is used to store the digital certificate signed by the CA certificate.
 - `private` is used to store the private key of the CA certificate.
 - `conf` is used to store the configuration files used for simplifying parameters.
 - `server` is used to store the server certificate.
2. Create an `openssl.conf` file that contains the following information in the `conf` directory.

```
[ ca ]
default_ca = foo

[ foo ]
dir = /root/ca
database = /root/ca/index.txt
new_certs_dir = /root/ca/newcerts
certificate = /root/ca/private/ca.crt
serial = /root/ca/serial
private_key = /root/ca/private/ca.key
RANDFILE = /root/ca/private/.rand
default_days = 365
default_cr_l_days= 30
default_md = md5
unique_subject = no
policy = policy_any

[ policy_any ]
countryName = match
stateOrProvinceName = match
organizationName = match
organizationalUnitName = match
localityName = optional
commonName = supplied
emailAddress = optional
```

3. Run the following command to generate a private key.

```
$ cd /root/ca
$ sudo openssl genrsa -out private/ca.key
```

The following figure is an example of the key generation.

```
root@iZbp1hfvivcqx1jwbp31iZ:~/ca/conf# cd /root/ca
root@iZbp1hfvivcqx1jwbp31iZ:~/ca# sudo openssl genrsa -out private/ca.key
Generating RSA private key, 2048 bit long modulus
.....++++
....+++
..+++
e is 65537 (0x10001)
```

4. Run the following command and input the required information according to the prompts. Press Enter to generate a *csr* file.

```
$ sudo openssl req -new -key private/ca.key -out private/ca.csr
```

 **Note** Common Name is the domain name of the SLB instance.

```

root@iZbp1hfvivcqx1jwap3liZ:~/ca# sudo openssl req -new -key private/ca.key -out private/ca.csr
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:CN
State or Province Name (full name) [Some-State]:ZheJiang
Locality Name (eg, city) []:HangZhou
Organization Name (eg, company) [Internet Widgits Pty Ltd]:Alibaba
Organizational Unit Name (eg, section) []:Test
Common Name (e.g. server FQDN or YOUR name) []:mydomain
Email Address []:a@alibaba.com

Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []:
An optional company name []:
root@iZbp1hfvivcqx1jwap3liZ:~/ca#

```

5. Run the following command to generate a *crt* file:

```
$ sudo openssl x509 -req -days 365 -in private/ca.csr -signkey private/ca.key -out private/ca.crt
```

6. Run the following command to set the start sequence number for the private key, which can be any four characters.

```
$ sudo echo FACE > serial
```

7. Run the following command to create a CA key library:

```
$ sudo touch index.txt
```

8. Run the following command to create a certificate revocation list for removing the client certificate:

```
$ sudo openssl ca -gencrl -out /root/ca/private/ca.crl -crldays 7 -config "/root/ca/conf/openssl.conf"
```

The output is:

```
Using configuration from /root/ca/conf/openssl.conf
```

Sign the client certificate

1. Run the following command to generate a *users* folder under the *ca* directory to store the client key.

```
$ sudo mkdir users
```

2. Run the following command to create a key for the client certificate:

```
$ sudo openssl genrsa -des3 -out /root/ca/users/client.key 1024
```

 **Note** Enter a pass phrase when creating the key. It is the password to protect the private key from unauthorized access. Enter the same password twice.

3. Run the following command to create a *csr* file for the client key.

```
$ sudo openssl req -new -key /root/ca/users/client.key -out /root/ca/users/client.csr
```

Enter the pass phrase set in the previous step and other required information when prompted.

Note A challenge password is the password of the client certificate. Note that it is not the password of the client key.

- Run the following command to sign the client key.

```
$ sudo openssl ca -in /root/ca/users/client.csr -cert /root/ca/private/ca.crt -keyfile /root/ca/private/ca.key -out /root/ca/users/client.crt -config "/root/ca/conf/openssl.conf"
```

Enter *y* twice when prompted to confirm the operation.

```
root@izbplhfivvcqxljwv31iZ:~/ca# sudo openssl ca -in /root/ca/users/client.csr
-cert /root/ca/private/ca.crt -keyfile /root/ca/private/ca.key -out /root/ca/us
ers/client.crt -config "/root/ca/conf/openssl.conf"
Using configuration from /root/ca/conf/openssl.conf
Check that the request matches the signature
Signature ok
The Subject's Distinguished Name is as follows
countryName           :PRINTABLE:'CN'
stateOrProvinceName   :ASN.1 12:'ZheJiang'
localityName          :ASN.1 12:'HangZhou'
organizationName      :ASN.1 12:'Alibaba'
organizationalUnitName:ASN.1 12:'Test'
commonName            :ASN.1 12:'mydomain'
emailAddress          :IA5STRING:'a@alibaba.com'
Certificate is to be certified until Jun  4 15:28:55 2018 GMT (365 days)
Sign the certificate? [y/n]:y

1 out of 1 certificate requests certified, commit? [y/n]:y
Write out database with 1 new entries
Data Base Updated
root@izbplhfivvcqxljwv31iZ:~/ca#
```

- Run the following command to convert the certificate to a *PKCS12* file.

```
$ sudo openssl pkcs12 -export -clcerts -in /root/ca/users/client.crt -inkey /root/ca/users/client.key -out /root/ca/users/client.p12
```

Follow the prompts to enter the pass phrase of client key. Then enter the password used for exporting the client certificate. This password is used to protect the client certificate, which is required when you install the client certificate.

- Run the following commands to view the generated client certificate:

```
cd users
ls
```

21.8.5. Convert the certificate format

Server Load Balancer (SLB) supports PEM certificates only. Certificates in other formats must be converted to the PEM format before they can be uploaded to SLB. We recommend that you use Open SSL for conversion.

Convert DER to PEM

DER: This format is usually used on a Java platform. The certificate file suffix is generally *.der*, *.cer*, or *.crt*.

- Run the following command to convert the certificate format:

```
openssl x509 -inform der -in certificate.cer -out certificate.pem
```

- Run the following command to convert the private key:

```
openssl rsa -inform DER -outform PEM -in privatekey.der -out privatekey.pem
```

Convert P7B to PEM

P7B: This format is usually used in a Windows server and Tomcat.

Run the following command to convert the certificate format:

```
openssl pkcs7 -print_certs -in incertificate.p7b -out outcertificate.cer
```

Convert PFX to PEM

PFX: This format is usually used in a Windows server.

- Run the following command to extract the certificate:

```
openssl pkcs12 -in certname.pfx -nokeys -out cert.pem
```

- Run the following command to extract the private key:

```
openssl pkcs12 -in certname.pfx -nocerts -out key.pem -nodes
```

21.8.6. Replace a certificate

This topic describes how to replace a certificate with a new certificate. We recommend that you replace certificates before they expire to avoid impacts on your service.

Procedure

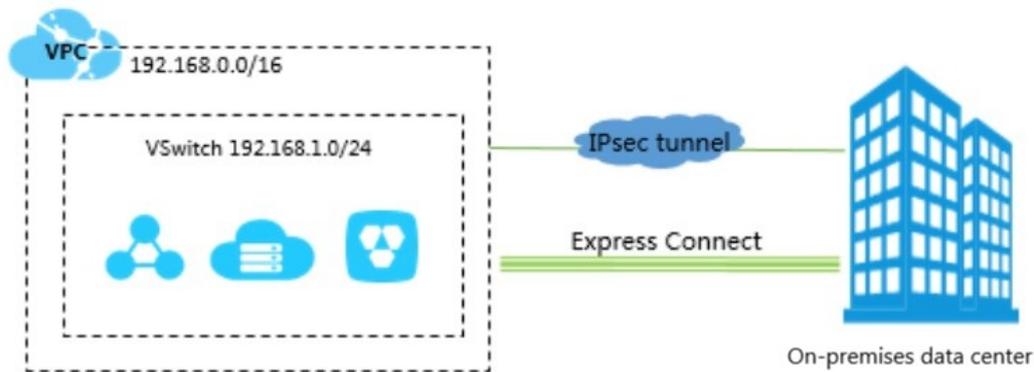

1. Create and upload a new certificate. For more information, see [Certificate overview](#).
2. Configure the certificate for the target HTTPS listener. For more information, see [Add an HTTPS listener](#).
3. On the **Certificates** page, find the certificate to be replaced and click **Delete** in the Actions column.
4. In the dialog box that appears, click **OK**.

22.Virtual Private Cloud (VPC)

22.1. What is a VPC?

A virtual private cloud (VPC) is a private network dedicated for your use. You have full control over your VPC, which you can define and customize by specifying the Classless Inter-domain Routing (CIDR) block, configuring route tables, and creating gateways. You can launch Apsara Stack resources such as Elastic Compute Service (ECS) instances, ApsaraDB for RDS (RDS) instances, and Server Load Balancer (SLB) instances in your VPC.

Furthermore, you can connect your VPC to other VPCs or on-premises networks to create a custom network environment. In this way, you can smoothly migrate applications and extend on-premises data centers to the cloud.

Components

Each VPC consists of one VRouter, at least one private CIDR block, and one or more VSwitches.

- Private CIDR block

When you create a VPC or a VSwitch, you must specify its private IP address range in the form of a CIDR block.

You can use the standard private CIDR blocks listed in the following table and their subsets as CIDR blocks for your VPCs. For more information, see the Plan and design a VPC section in this *User Guide*.

CIDR block	Number of available private IP addresses (excluding those reserved by the system)
192.168.0.0/16	65,532
172.16.0.0/12	1,048,572
10.0.0.0/8	16,777,212

- VRouter

A VRouter is a hub that connects all VSwitches in a VPC and serves as a gateway between the VPC and other networks. After a VPC is created, a VRouter is automatically created for the VPC. Each VRouter is associated with a route table.

For more information, see the Route table overview section in this *User Guide*.

- VSwitch

A VSwitch is a basic network component that connects different cloud resources in a VPC. After you create a VPC, you can create VSwitches to partition your VPC into multiple subnets. VSwitches within a VPC can communicate with each other over the private network. You can deploy your applications in VSwitches that belong to different zones to improve service availability.

For more information, see the Create a VSwitch section in this *User Guide*.

22.2. Log on to the VPC console

This topic provides an example of how to log on to the Virtual Private Cloud console by using Google Chrome.

Prerequisites

- Before logging on to the ASCM console, make sure that you have obtained the IP address or domain name of the ASCM console from the deployment personnel. The URL used to access the ASCM console is in the following format: `https://[IP address or domain name of the ASCM console]`.
- We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to access the ASCM console. Press the Enter key.
2. Enter your username and password.

Obtain the username and password for logging on to the console from the operations administrator.

 **Note** When you log on to the ASCM console for the first time, you must change the password of your username as prompted. Due to security concerns, your password must meet the minimum complexity requirements: The password must be 8 to 20 characters in length and must contain at least two of the following character types: uppercase letters, lowercase letters, digits, and special characters such as exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Products > Networking > Virtual Private Cloud**.

22.3. Quick start

22.3.1. Plan and design a VPC

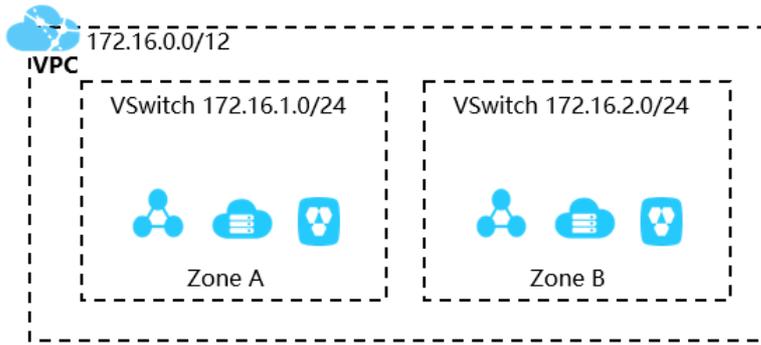

Before you create virtual private clouds (VPCs) and VSwitches, you need to plan the quantity and Classless Inter-domain Routing (CIDR) blocks of VPCs and VSwitches.

- [How many VPCs are required?](#)
- [How many VSwitches are required?](#)
- [How do I specify CIDR blocks?](#)
- [How do I specify CIDR blocks if I want to connect a VPC to other VPCs or on-premises data centers?](#)

How many VPCs are required?

- One VPC

We recommend that you create one VPC if you do not need to deploy systems in multiple regions or separate VPCs.

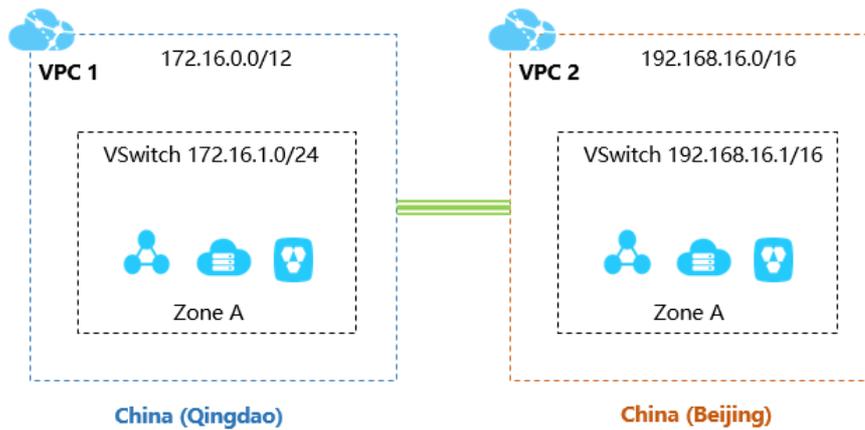

• Multiple VPCs

We recommend that you create multiple VPCs if you need to:

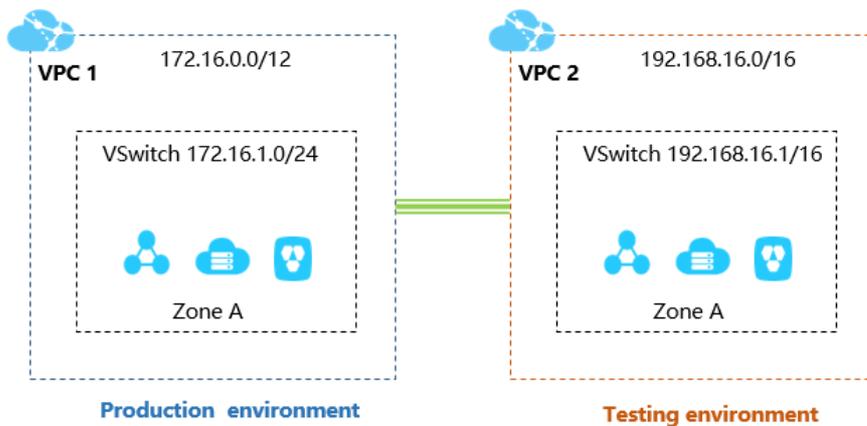

- Deploy application systems across regions.

A VPC cannot be deployed across regions. If you want to deploy your application systems in different regions, you must create multiple VPCs. You can use Express Connect and VPN Gateway to connect VPCs.

- Separate IT systems

To separate IT systems, you must create multiple VPCs. The following figure shows an example of isolating a production environment from a test environment by deploying them in separate VPCs.

How many VSwitches are required?

We recommend that you create at least two VSwitches for each VPC and deploy these VSwitches in different zones to achieve zone-disaster recovery.

After you deploy your applications in different zones within a region, you must measure the network latency between these applications. This is because the cross-zone network latency may be higher than expected due to complex data processing or cross-zone calls. An ideal approach is to optimize and adjust your systems to strike a balance between availability and latency.

In addition, the sizes and designs of your IT systems must also be taken into consideration when you create VSwitches. If you allow traffic from the Internet to be routed to and from the frontend systems, you can deploy the front-end systems in different VSwitches and the backend systems in other VSwitches to create a robust disaster recovery strategy.

How do I specify CIDR blocks?

When you create VPCs and VSwitches, you must specify their private IP address ranges in the form of CIDR blocks.

- VPC CIDR blocks

You can use 192.168.0.0/16, 172.16.0.0/12, 10.0.0.0/8, or their subsets as the CIDR blocks of your VPCs. To specify CIDR blocks for VPCs, follow these rules:

- If you have only one VPC and this VPC does not need to communicate with any on-premises data center, you can use one of the preceding CIDR blocks or one of their subsets as the CIDR block of the VPC.
- If you have multiple VPCs, or you need to build a hybrid cloud to integrate VPCs and on-premises data centers, we recommend that you use the subsets of the preceding CIDR blocks for your VPCs. In this case, the mask cannot be longer than 16 bits.

- VSwitch CIDR blocks

The CIDR block of a VSwitch must be a subset of the CIDR block of the VPC this VSwitch resides in. For example, if the CIDR block of a VPC is 192.168.0.0/16, the CIDR block of a VSwitch in the VPC must be a segment from 192.168.0.0/17 to 192.168.0.0/29.

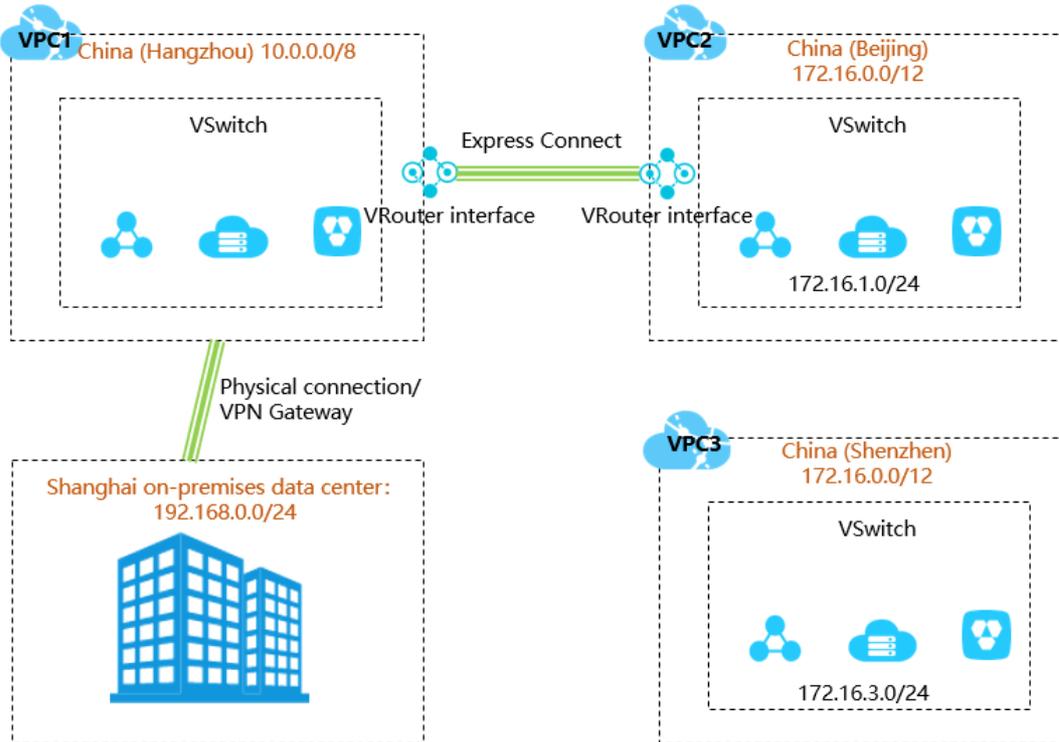

To specify CIDR blocks for VSwitches, follow these rules:

- The CIDR block size for a VSwitch is between a 16-bit mask and a 29-bit mask. It means that 8 to 65,536 IP addresses can be provided. This range is set because a 16-bit host address space provides addressing for 65,534 ECS instances, which can meet your needs in most cases, while a mask smaller than 29 bits can only allow very few usable host addresses.
- The first and the last three IP addresses in each VSwitch CIDR block are reserved by the system. For example, if the CIDR block of a VSwitch is 192.168.1.0/24, the IP addresses 192.168.1.0, 192.168.1.253, 192.168.1.254, and 192.168.1.255 are reserved.
- You must check the number of ECS instances in the VSwitch before you specify the CIDR block of a VSwitch.

How do I specify CIDR blocks if I want to connect a VPC to other VPCs or on-premises data centers?

Before you connect your VPC to another VPC or an on-premises data center, you must make sure that the CIDR block of your VPC does not conflict with that of the peer network.

For example, assume you have three VPCs: VPC1 in China (Hangzhou), VPC2 in China (Beijing), and VPC3 in China (Shenzhen), as shown in the following figure. Express Connect circuit is used for VPC1 and VPC2 to communicate with each other. VPC3 does not communicate with other VPCs, but may need to communicate with VPC2 in the future. Additionally, you have an on-premises data center in Shanghai, and you need to connect it to VPC1 by using an Express Connect circuit.

In this example, the CIDR block of VPC2 is different from the CIDR block of VPC1, but is the same with the CIDR block of VPC3. However, considering that VPC2 and VPC3 may need to communicate with each other later in the private network, the VSwitches in these VPCs are assigned with different CIDR blocks. This example demonstrates that VPCs communicating with each other can have identical CIDR blocks, but their VSwitches must have different CIDR blocks.

When you specify CIDR blocks for multiple VPCs that need to communicate with each other, follow these rules:

- The preferred practice is to specify different CIDR blocks for different VPCs. You can use the subsets of the standard CIDR blocks to increase the number of available CIDR blocks.
- If you cannot assign different CIDR blocks for VPCs, try to specify different CIDR blocks for the VSwitches in these VPCs.
- If you cannot assign different CIDR blocks for all VSwitches in these VPCs, make sure that different CIDR blocks are configured for the VSwitches communicating with each other.

22.3.2. Create an IPv4 VPC

This topic describes how to build a virtual private cloud (VPC) with an IPv4 Classless Inter-domain Routing (CIDR) block and create an Elastic Compute Service (ECS) instance in the VPC.

Prerequisites

Before you create a VPC, you must first plan and design the VPC. For more information, see [Set up network connections](#).

Step 1: Create a VPC

Perform the following steps to create a VPC:

1. Log on to the VPC console.
2. On the VPCs page, click **Create VPC**.
3. On the **Create VPC** page, configure the VPC and click **Submit**. The following table describes the parameters for creating a VPC.

Parameter	Description
Organization	Select the organization to which the VPC belongs.
Resource Set	Select the resource set to which the VPC belongs.
Region	Select a region to deploy the VPC.
Share with Sub-organizations	Specify whether to share the VPC. If you select Yes, the administrators of sub-organizations can create resources in the VPC. In this tutorial, select No.
VPC Name	Enter a name for the VPC. The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code> . In this tutorial, enter <code>VPCtest</code> .
IPv4 CIDR Block	Select an IPv4 CIDR block for the VPC. The following setting methods are supported: <ul style="list-style-type: none"> ◦ Recommended CIDR Block: Enter 192.168.0.0/16, 172.16.0.0/12, or 10.0.0.0/8. ◦ Custom CIDR Block: Enter 192.168.0.0/16, 172.16.0.0/12, 10.0.0.0/8, or a subset of these CIDR blocks. The subnet mask must be 8 to 28 bits in length. For example, enter 192.168.0.0/16. In this tutorial, select Recommended CIDR Block and then select 192.168.0.0/16. <div style="background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> ? Note After you create a VPC, you cannot change its IPv4 CIDR block. </div>
IPv6 CIDR Block	Specify whether to assign an IPv6 CIDR block to the VPC. <ul style="list-style-type: none"> ◦ Do Not Assign: No IPv6 CIDR block will be assigned to the VPC. ◦ Assign: An IPv6 CIDR block will be automatically assigned to the VPC. In this tutorial, select Do Not Assign .
Description	Enter a description for the VPC. The description must be 2 to 256 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code> .

Step 2: Create a VSwitch

Perform the following steps to create a VSwitch in a VPC:

1. In the left-side navigation pane, click **VSwitches**.
2. On the **VSwitches** page, click **Create VSwitch**.
3. On the **VSwitch** page, configure the VSwitch and click **Submit**. The following table describes the parameters for creating a VSwitch.

Parameter	Description
Organization	Select the organization to which the VSwitch belongs.
Resource Set	Select the resource set to which the VSwitch belongs.
Region	Select a region to deploy the VSwitch.
Zone	<p>Select a zone to deploy the VSwitch.</p> <p>Each VSwitch must reside entirely within one zone and cannot span multiple zones. However, you can deploy cloud resources in VSwitches that reside in different zones to achieve zone-disaster recovery.</p> <div style="background-color: #e0f2f1; padding: 5px; border: 1px solid #ccc;"> <p> Note Each cloud resource can be deployed in only one VSwitch.</p> </div>
VPC	<p>Select the VPC for which you want to create the VSwitch.</p> <p>In this tutorial, select VPCtest.</p>
Dedicated for Off-Cloud Servers	<p>Specify whether the VSwitch is dedicated for off-cloud servers.</p> <p>For more information, see the Features of off-cloud servers for VPC section in the <i>ECS Bare Metal Instance User Guide</i>.</p> <p>In this tutorial, select No.</p>
VSwitch Name	<p>Enter a name for the VSwitch.</p> <p>The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code>.</p>
IPv4 CIDR Block	<p>Enter an IPv4 CIDR block for the VSwitch.</p> <p>This tutorial uses the default IPv4 CIDR block.</p>
IPv6 CIDR Block	<p>Specify whether to assign an IPv6 CIDR block to the VSwitch.</p> <p>In this tutorial, select Do Not Assign.</p>
Description	<p>Enter a description for the VSwitch.</p> <p>The description must be 2 to 256 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code>.</p>

Step 3: Create a security group

Perform the following steps to create a security group:

1. In the top navigation bar, choose **Products > Elastic Computing > Elastic Compute Service**.
2. Choose **Networks and Security > Security Groups**.
3. On the **Security Groups** page, click **Create Security Group**.
4. On the **Create Security Group** page, configure the security group and click **Submit**. The following table describes the parameters for creating a security group.

Parameter	Description
Organization	Select the organization to which the security group belongs.
Resource Set	Select the resource set to which the security group belongs.
Region	Select the region that will use the security group. The security group and the VPC must belong to the same region.
Zone	Select the zone that will use the security group.
VPC	Select the VPC to which the security group belongs.
Security Group Name	Enter a name for the security group. The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code> .
Description	Enter a description for the security group. The description must be 2 to 256 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code> .

Step 4: Create an ECS instance

Perform the following steps to create an ECS instance in the specified VPC:

1. In the top navigation bar, choose **Products > Networking > Virtual Private Cloud**.
2. In the left-side navigation pane, click **VSwitches**.
3. In the top navigation bar, select the region of the target VSwitch.
4. On the **VSwitches** page, find the target VSwitch and choose **Purchase > ECS Instance** in the **Actions** column.
5. On the **Create ECS Instance** page, configure the ECS instance and click **Submit**. For more information about how to configure an ECS instance, see **Create an instance** under **Quick start** in the *Apsara Stack Elastic Compute Service User Guide*.

22.3.3. Create an IPv6 VPC

This topic describes how to build a virtual private cloud (VPC) with an IPv6 Classless Inter-domain Routing (CIDR) block and create an Elastic Compute Service (ECS) instance assigned with an IPv6 address in the VPC.

Step 1: Create a VPC and a VSwitch

Before you deploy cloud resources in a VPC, you must create a VPC and a VSwitch.

Perform the following steps to create a VPC and a VSwitch:

1. Log on to the VPC console.
2. On the **VPCs** page, click **Create VPC**.
3. On the **Create VPC** page, configure the VPC and click **Submit**. The following table describes the parameters for creating a VPC.

Parameter	Description
Organization	Select the organization to which the VPC belongs.

Parameter	Description
Resource Set	Select the resource set to which the VPC belongs.
Region	Select a region to deploy the VPC.
Share with Sub-organizations	Specify whether to share the VPC. If you select Yes, the administrators of sub-organizations can create resources in the VPC. In this tutorial, select No.
VPC Name	Enter a name for the VPC. The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code> . In this tutorial, enter <code>VPCtest</code> .
IPv4 CIDR Block	Select an IPv4 CIDR block for the VPC. The following setting methods are supported: <ul style="list-style-type: none"> ◦ Recommended CIDR Block: Enter 192.168.0.0/16, 172.16.0.0/12, or 10.0.0.0/8. ◦ Custom CIDR Block: Enter 192.168.0.0/16, 172.16.0.0/12, 10.0.0.0/8, or a subset of these CIDR blocks. The subnet mask must be 8 to 28 bits in length. For example, enter 192.168.0.0/16. In this tutorial, select Recommended CIDR Block and then select 192.168.0.0/16. <div style="background-color: #e0f2f7; padding: 5px; margin-top: 10px;"> ? Note After you create a VPC, you cannot change its IPv4 CIDR block. </div>
IPv6 CIDR Block	Specify whether to assign an IPv6 CIDR block to the VPC. <ul style="list-style-type: none"> ◦ Do Not Assign: No IPv6 CIDR block will be assigned to the VPC. ◦ Assign: An IPv6 CIDR block will be automatically assigned to the VPC. In this tutorial, select Assign.
Description	Enter a description for the VPC. The description must be 2 to 256 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code> .

4. Click **Back to Console**. In the left navigation pane, click **VSwitches**.
5. On the **VSwitches** page, click **Create VSwitch**.
6. On the **VSwitch** page, configure the VSwitch and click **Submit**. The following table describes the parameters for creating a VSwitch.

Parameter	Description
Organization	Select the organization to which the VSwitch belongs.
Resource Set	Select the resource set to which the VSwitch belongs.
Region	Select a region to deploy the VSwitch.

Parameter	Description
Zone	<p>Select a zone to deploy the VSwitch.</p> <p>Each VSwitch must reside entirely within one zone and cannot span multiple zones. However, you can deploy cloud resources in VSwitches that reside in different zones to achieve zone-disaster recovery.</p> <p> Note Each cloud resource can be deployed in only one VSwitch.</p>
VPC	<p>Select the VPC for which you want to create the VSwitch.</p> <p>In this tutorial, select VPCtest.</p>
Dedicated for Off-Cloud Servers	<p>Specify whether the VSwitch is dedicated for off-cloud servers.</p> <p>For more information, see the Features of off-cloud servers for VPC section in the <i>ECS Bare Metal Instance User Guide</i>.</p> <p>In this tutorial, select No.</p>
VSwitch Name	<p>Enter a name for the VSwitch.</p> <p>The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code>.</p>
IPv4 CIDR Block	<p>Enter an IPv4 CIDR block for the VSwitch.</p> <p>This tutorial uses the default IPv4 CIDR block.</p>
IPv6 CIDR Block	<p>Enter an IPv6 CIDR block for the VSwitch.</p> <p>This tutorial uses the default IPv6 CIDR block.</p>
Description	<p>Enter a description for the VSwitch.</p> <p>The description must be 2 to 256 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code>.</p>

Step 2: Create a security group

Perform the following steps to create a security group:

1. In the top navigation bar, choose **Products > Elastic Computing > Elastic Compute Service**.
2. Choose **Networks and Security > Security Groups**.
3. On the **Security Groups** page, click **Create Security Group**.
4. On the **Create Security Group** page, configure the security group and click **Submit**. The following table describes the parameters for creating a security group.

Parameter	Description
Organization	Select the organization to which the security group belongs.
Resource Set	Select the resource set to which the security group belongs.

Parameter	Description
Region	Select the region that will use the security group. The security group and the VPC must belong to the same region.
Zone	Select the zone that will use the security group.
VPC	Select the VPC to which the security group belongs.
Security Group Name	Enter a name for the security group. The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code> .
Description	Enter a description for the security group. The description must be 2 to 256 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code> .

Step 3: Create and configure an ECS instance

After you create a VPC and a VSwitch, you must create an ECS instance and assign an IPv6 address to the ECS instance, and then associate this IPv6 address with the network interface controller (NIC) of the ECS instance.

Perform the following steps to create and configure an ECS instance:

1. In the top navigation bar, choose **Products > Networking > Virtual Private Cloud**.
2. In the left-side navigation pane, click **VSwitches**.
3. Select the region where your VSwitch resides.
4. On the **VSwitches** page, find the target VSwitch and choose **Purchase > ECS Instance** in the **Actions** column.
5. On the **Create ECS Instance** page, configure the ECS instance and click **Submit**. In this tutorial, select **Assign** to assign an IPv6 address to the ECS instance. For more information about other parameters, see **Create an instance** under **Quick start** in the *Apsara Stack Elastic Compute Service User Guide*.
6. Return to the **Instances** page, and click the instance ID to view the assigned IPv6 address.
7. Configure a static IPv6 address.
 - If the image of your ECS instance supports DHCPv6, you do not need to manually configure the static IPv6 address. DHCPv6 enables automatic configuration of IPv6 addresses. Therefore, if your ECS instance image supports DHCPv6, the ECS instance can use the assigned IPv6 address to communicate in the private network directly after being created.

The following images support DHCPv6:

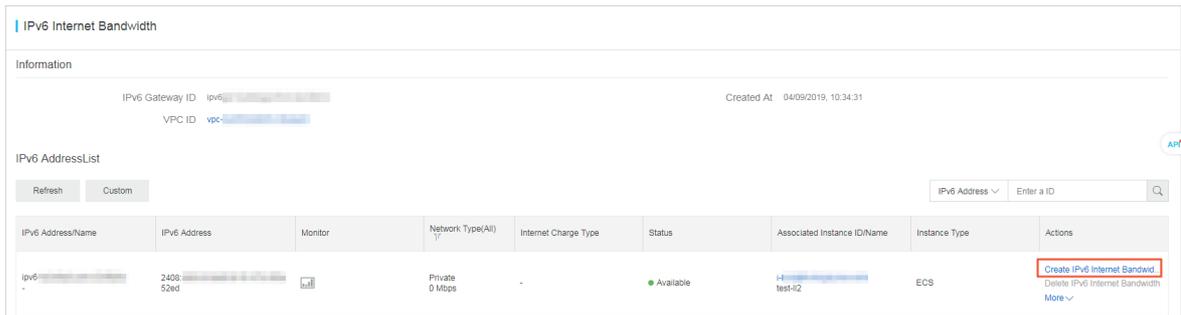

- Linux images:
 - CentOS 7.6 IPV6 64Bit
 - CentOS 6.10 64Bit
 - SUSE Linux Enterprise Server 12 SP4 64Bit
- Windows Server images
- If the image of your ECS instance does not support DHCPv6, you must manually configure an IPv6 address for the ECS instance. We recommend that you refer to the related documentation for each image for configuration guidance.

Step 4: Purchase an IPv6 Internet bandwidth plan

By default, IPv6 addresses are only used for communication inside private networks. If you want to allow an instance assigned with an IPv6 address to access the Internet or be accessed by IPv6 clients over the Internet, you must purchase an Internet bandwidth plan for the IPv6 address.

Perform the following steps to purchase an Internet bandwidth plan for the IPv6 address:

1. In the top navigation bar, choose **Products > Networking > IPv6 Gateway**.
2. Select the region where the IPv6 Gateway resides.
3. On the **IPv6 Gateway** page, find the target IPv6 Gateway and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **IPv6 Internet Bandwidth**.
5. On the **IPv6 Internet Bandwidth** page, find the target IPv6 address and click **Enable IPv6 Internet Bandwidth** in the **Actions** column.

6. Select a bandwidth plan and then click **Submit**. The maximum IPv6 Internet bandwidth for an IPv6 Gateway of the Free, Enterprise, or Enhanced Edition is 2 Gbit/s.

Step 5: Configure the security group rules

IPv4 and IPv6 addresses are independent of each other. If the current security group rules cannot serve your IPv6 services, you must configure security group rules for IPv6 traffic.

For more information, see *Add security group rules* under *Security groups* in the *Apsara Stack Elastic Compute Service User Guide*.

Step 6: Test the network connectivity

Log on to the ECS instance and run the ping command to test the network connectivity.

```
[root@iZhp3aehva ~]# ping6 ipv6.baidu.com
PING ipv6.baidu.com(2400:da00:2::29 (2400:da00:2::29)) 56 data bytes

22.4. VPCs and VSwitches

22.4.1. Overview

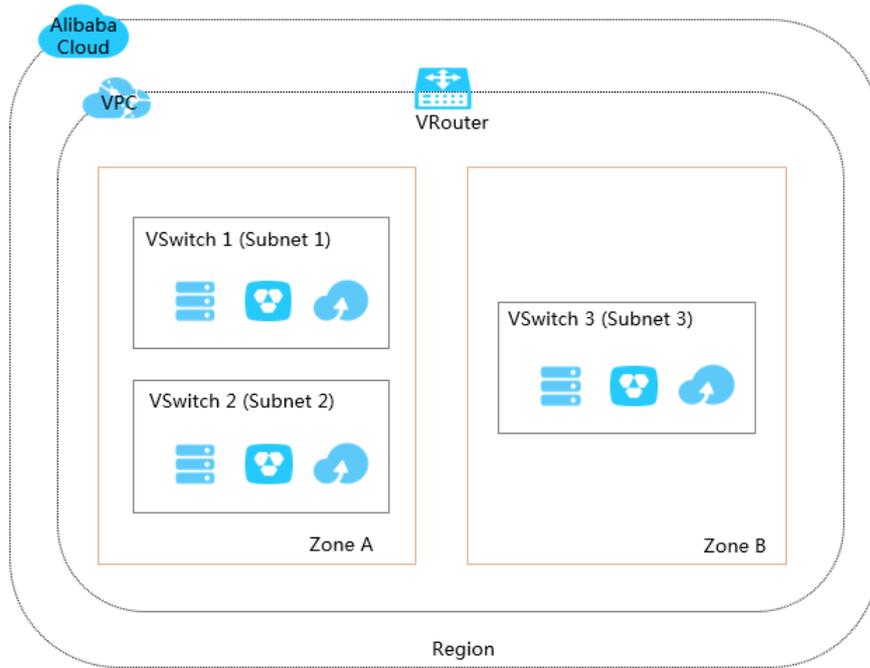

To get started with Virtual Private Cloud, you need to create at least one virtual private cloud (VPC) and one VSwitch. You can create VSwitches in a VPC to partition a VPC into multiple subnets. By default, subnets (VSwitches) within a VPC can communicate with each other over the private network.

VPCs and VSwitches

A VPC is a virtual network dedicated for your use. You can deploy cloud resources in VPCs that you define.

Note A cloud resource cannot be directly deployed in a VPC, but can be deployed in a VSwitch of the VPC.

A VSwitch is a basic network component in a VPC and is used to connect cloud resources. Each VPC must reside entirely within one region and cannot span multiple regions. However, a VPC spans all of the zones in a region, which means you can create one or more VSwitches in each zone to partition a VPC into subnets.

CIDR blocks and IP addresses

VPCs support both IPv4 and IPv6 addressing protocols. By default, VPCs use the IPv4 addressing protocol. You can enable the IPv6 addressing protocol as needed.

VPCs can operate in a dual-stack mode, which allows your resources to communicate over IPv4, or IPv6, or both. IPv4 and IPv6 addresses are independent of each other. Therefore, you must configure routing and security groups in your VPC separately for IPv4 and IPv6.

The following table summarizes the differences between IPv4 and IPv6 in Apsara Stack VPC.

IPv4 VPC	IPv6 VPC
The format is 32-bit, 4 groups of up to 3 decimal digits.	The format is 128-bit, 8 groups of 4 hexadecimal digits.
The IPv4 addressing protocol is enabled for all VPCs by default.	The IPv6 addressing protocol is optional for a VPC.
The VPC Classless Inter-domain Routing (CIDR) block size can be from /8 to /24.	The VPC CIDR block size is fixed at /61.
The VSwitch CIDR block size can be from /16 to /29.	The VSwitch CIDR block size is fixed at /64.
You can choose the private IPv4 CIDR block for your VPC.	Apsara Stack automatically assigns an IPv6 CIDR block for your VPC from its IPv6 address pool. You cannot select your own range.

IPv4 VPC	IPv6 VPC
Supported on all instance types.	Not supported on certain instance types. For more information, see <i>Instance types</i> under <i>What is ECS</i> in the <i>Apsara Stack Elastic Compute Service User Guide</i> .
Elastic IPv4 addresses are supported.	Elastic IPv6 addresses are not supported.
VPN gateways and NAT gateways are supported.	VPN gateways and NAT gateways are supported.

By default, the IPv4 and IPv6 addresses provided for VPCs can only be used for communication within the private network. Resources in different VSwitches within a VPC communicate with one another over private network connections. To connect a VPC to another VPC or an on-premises data center, you need to configure Express Connect or VPN Gateway. .

To enable cloud resources in a VPC to access the Internet, set the following configurations:

- IPv4 communication

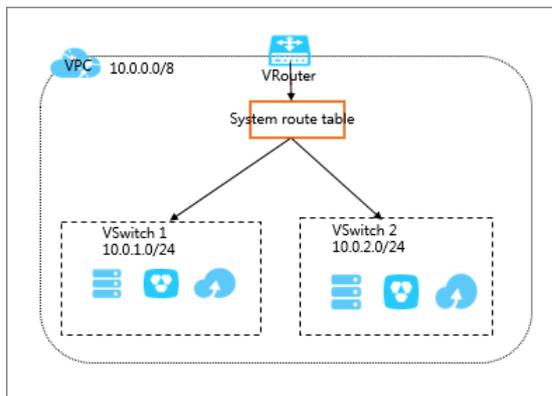

You can configure a NAT gateway or associate elastic IP addresses (EIPs) to the Elastic Compute Service (ECS) instances in a VPC to allow these ECS instances to access the Internet by using IPv4 addresses.

- IPv6 communication

To enable cloud resources in a VPC to access the Internet by using an IPv6 address, you must purchase public bandwidth for the IPv6 address. You can also configure an egress-only rule for an IPv6 address to allow outbound communication over IPv6 from instances in your VPC to the Internet, and prevent clients on the Internet from initiating IPv6 connections with your instances.

Routing

After a VPC is created, the system automatically creates a system route table and adds system routes to the route table for traffic management. Each VPC has only one system route table, which is generated automatically upon the creation of the VPC. You cannot create or delete system route tables.

If one destination address matches more than one route entry in a route table, the system selects an entry by implementing the longest prefix match algorithm, whereby the most specific of the matching entries, the one with the longest subnet mask, is used to route traffic. You can add a custom route entry to route traffic destined for a specific destination. For more information, see [Add a custom route entry](#).

22.4.2. VPC management

22.4.2.1. Create a VPC

A virtual private cloud (VPC) is a private network dedicated for your use. You have full control over your VPC. For example, you can specify Classless Inter-domain Routing (CIDR) blocks, configure route tables, and set network gateways for your VPC. You can deploy Apsara Stack resources in your VPC, such as Elastic Compute Service (ECS) instances, ApsaraDB for RDS (RDS) instances, and Server Load Balancer (SLB) instances.

Procedure

1. **Log on to the VPC console.**
2. In the top navigation bar, select a region to deploy your VPC.

 **Note** The VPC must be in the same region as the cloud resources that you want to deploy in this VPC.

3. On the VPC page, click **Create VPC**.
4. On the **Create VPC** page, configure the VPC and click **Submit**. The following table describes the parameters for creating a VPC.

Parameter	Description
Organization	Select the organization to which the VPC belongs.
Resource Set	Select the resource set to which the VPC belongs.
Region	Select a region to deploy the VPC.
Share with Sub-organizations	Specify whether to share the VPC. If you select Yes, the administrators of sub-organizations can create resources in the VPC.
VPC Name	Enter a name for the VPC. The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code> .
IPv4 CIDR Block	Select an IPv4 CIDR block for the VPC. The following setting methods are supported: <ul style="list-style-type: none"> ◦ Recommended CIDR Block: Enter 192.168.0.0/16, 172.16.0.0/12, or 10.0.0.0/8. ◦ Custom CIDR Block: Enter 192.168.0.0/16, 172.16.0.0/12, 10.0.0.0/8, or a subset of these CIDR blocks. The subnet mask must be 8 to 28 bits in length. For example, enter 192.168.0.0/16. <div style="background-color: #e6f2ff; padding: 5px; border: 1px solid #d9e1f2; margin-top: 10px;"> <p> Note After you create a VPC, you cannot change its IPv4 CIDR block.</p> </div>
IPv6 CIDR Block	Specify whether to assign an IPv6 CIDR block to the VPC. <ul style="list-style-type: none"> ◦ Do Not Assign: No IPv6 CIDR block will be assigned to the VPC. ◦ Assign: An IPv6 CIDR block will be automatically assigned to the VPC. <p>If you set this parameter to Assign, the system automatically creates a free IPv6 gateway for this VPC, and assigns an IPv6 CIDR block with the subnet mask /56, such as 2xx1: db8::/56. By default, IPv6 addresses are only used for communication inside private networks. If you want to allow an instance assigned with an IPv6 address to access the Internet or be accessed by IPv6 clients over the Internet, you must purchase an Internet bandwidth plan for the IPv6 address. For more information, see <i>Enable IPv6 Internet bandwidth</i> under <i>Manage IPv6 Internet bandwidth</i> in the <i>Apsara Stack Elastic Compute Service User Guide</i>.</p>

Parameter	Description
Description	<p>Enter a description for the VPC.</p> <p>The description must be 2 to 256 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code>.</p>

22.4.2.2. Modify the name and description of a VPC

This topic describes how to modify the name and description of a virtual private cloud (VPC).

Procedure

1. [Log on to the VPC console.](#)
2. In the top navigation bar, select the region where your VPC is deployed.
3. On the VPCs page, find the target VPC network and click **Manage** in the **Actions** column.
4. In the **VPC Details** section, click **Edit** next to **Name**. In the dialog box that appears, enter a new name for the VPC and click **OK**. The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), and hyphens (-). It must start with a letter or a Chinese character.
5. Click **Edit** next to **Description**. In the dialog box that appears, enter a new description, and click **OK**. The description must be 2 to 256 characters in length and cannot start with `http://` or `https://`.

22.4.2.3. Delete a VPC

This topic describes how to delete a virtual private cloud (VPC). After you delete a VPC, the VRouter and route tables associated with this VPC are also deleted.

Prerequisites

Before you delete a VPC, make sure that the following requirements are met:

- No VSwitch exists in the VPC. If the VPC has one or more VSwitches, we recommend that you delete the VSwitches first before deleting the VPC. For more information, see [Delete a VSwitch](#).
- No IPv6 gateway is associated with the VPC. If the VPC is associated with an IPv6 gateway, we recommend that you delete the IPv6 gateway first before deleting the VPC.

Procedure

1. [Log on to the VPC console.](#)
2. In the top navigation bar, select the region where your VPC is deployed.
3. On the VPCs page, find the target VPC and click **Delete** in the **Actions** column.
4. In the **Delete VPC** dialog box, click **OK**.

22.4.3. VSwitch management

22.4.3.1. Create a VSwitch

A VSwitch is a basic network component in a virtual private cloud (VPC) and is used to connect cloud resources.

Context

After you create a VPC, you can create VSwitches to partition your VPC into multiple subnets. VSwitches within a VPC can communicate with each other over the private network. Cloud resources are deployed in VSwitches. You can deploy your applications in VSwitches that belong to different zones to improve service availability.

 **Note** VSwitches do not support multicasting or broadcasting.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click VSwitches.
3. Select the region of the VPC in which you want to create a VSwitch.
4. On the VSwitches page, click Create VSwitch.
5. On the VSwitch page, configure the VSwitch and click Submit. The following table describes the parameters for creating a VSwitch.

Parameter	Description
Organization	Select the organization to which the VSwitch belongs.
Resource Set	Select the resource set to which the VSwitch belongs.
Region	Select a region to deploy the VSwitch.
Zone	<p>Select a zone to deploy the VSwitch.</p> <p>Each VSwitch must reside entirely within one zone and cannot span multiple zones. However, you can deploy cloud resources in VSwitches that reside in different zones to achieve zone-disaster recovery.</p> <div style="background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> <p> Note Each cloud resource can be deployed in only one VSwitch.</p> </div>
VPC	Select the VPC for which you want to create the VSwitch.
Dedicated for Off-Cloud Servers	<p>Specify whether the VSwitch is dedicated for off-cloud servers.</p> <p>For more information, see the Features of off-cloud servers for VPC section in the <i>ECS Bare Metal Instance User Guide</i>.</p>
VSwitch Name	<p>Enter a name for the VSwitch.</p> <p>The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (<code>_</code>), hyphens (<code>-</code>), periods (<code>.</code>), colons (<code>:</code>), and commas (<code>,</code>). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code>.</p>
IPv4 CIDR Block	<p>Enter an IPv4 CIDR block for the VSwitch.</p> <ul style="list-style-type: none"> ○ You must specify the IP address range for the VSwitch in the form of a CIDR block. The CIDR block size for a VSwitch is between a 16-bit mask and a 29-bit mask. It means that 8 to 65,536 IP addresses can be provided. ○ The CIDR block of a VSwitch must be a subset of the CIDR block of the VPC this VSwitch resides in. ○ The first and the last three IP addresses in each VSwitch CIDR block are reserved by the system. For example, if the CIDR block of a VSwitch is 192.168.1.0/24, the IP addresses 192.168.1.0, 192.168.1.253, 192.168.1.254, and 192.168.1.255 are reserved. ○ The CIDR block of a VSwitch must be more specific than the CIDR range of a route in any of the VPC route tables. ○ After you create a VSwitch, you cannot modify its CIDR block.

Parameter	Description
IPv6 CIDR Block	<p>Enter an IPv6 CIDR block for the VSwitch.</p> <ul style="list-style-type: none"> You must check whether IPv6 is enabled for the specified VPC. If not, you cannot assign an IPv6 CIDR block to the VSwitch. If yes, you can enter a decimal number ranging from 0 to 255 to define the last 8 bits of the IPv6 CIDR block of the VSwitch. <p>For example, if the IPv6 CIDR block of the VPC that contains the VSwitch is 2xx1:db8::/64, you can enter 255 (FF in the hexadecimal system) in this field to define the IPv6 CIDR block of the VSwitch as 2xx1:db8:ff::/64.</p>
Description	<p>Enter a description for the VSwitch.</p> <p>The description must be 2 to 256 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code>.</p>

22.4.3.2. Create cloud resources in a VSwitch

This topic describes how to create cloud resources in a VSwitch. Note that cloud resources are not directly deployed in a virtual private cloud (VPC), but are provisioned into VSwitches (subnets) of a VPC. You can create cloud resources in a VSwitch.

Procedure

1. [Log on to the VPC console.](#)
2. In the left-side navigation pane, click **VSwitches**.
3. Select the region of the VPC to which the VSwitch belongs.
4. On the **VSwitches** page, find the target VSwitch, click **Purchase** in the **Actions** column, and select the cloud resource you want to create. You can create Elastic Compute Service (ECS) instances, ApsaraDB for RDS (RDS) instances, and Server Load Balancer (SLB) instances in a VSwitch.
5. On the page that appears, set the parameters to create a cloud resource.

22.4.3.3. Modify the name and description of a VSwitch

This topic describes how to modify the name and description of a VSwitch.

Procedure

1. [Log on to the VPC console.](#)
2. In the left-side navigation pane, click **VSwitches**.
3. Select the region of the VPC to which the VSwitch belongs.
4. On the **VSwitches** page, find the target VSwitch and click **Manage** in the **Actions** column.
5. In the **VSwitch Basic Information** section, click **Edit** next to **Name**. In the dialog box that appears, enter a new name for the VSwitch and click **OK**. The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), and hyphens (-). It must start with a letter or a Chinese character.
6. Click **Edit** next to **Description**. In the dialog box that appears, enter a new description for the VSwitch and click **OK**. The description must be 2 to 256 characters in length and cannot start with `http://` or `https://`.

22.4.3.4. Delete a VSwitch

This topic describes how to delete a VSwitch that you no longer need. Cloud resources cannot be deployed in deleted VSwitches.

Prerequisites

Before you delete a VSwitch, make sure that the following conditions are met:

- You have deleted all of your cloud resources created under the VSwitch, such as Elastic Compute Service (ECS) instances, Server Load Balancer (SLB) instances, and ApsaraDB for RDS (RDS) instances.
- You have deleted or disabled all resources and actions associated with this VSwitch, such as high-availability virtual IP addresses (HAVIPs) and source network address translation (SNAT) entries.

Procedure

1. [Log on to the VPC console](#).
2. In the left-side navigation pane, click **VSwitches**.
3. Select the region of the VPC to which the VSwitch belongs.
4. On the **VSwitches** page, find the target VSwitch and click **Delete** in the **Actions** column.
5. In the **Delete VSwitch** dialog box that appears, click **OK**.

22.5. Route tables

22.5.1. Overview

Routes and route tables

Each virtual private cloud (VPC) comes with a default route table pre-configured with system route entries that direct traffic flowing in and out of the VPC. You cannot create or delete system route entries. However, you can create custom route entries to route traffic destined for specific Classless Inter-domain Routing (CIDR) blocks to the destinations that you define.

Route tables

When you create a VPC, it automatically has a system route table that controls the routing for all VSwitches (subnets) within the VPC by default. You cannot create or delete the system route table of a VPC.

Each *route entry* in the route table defines a route that is used to direct traffic, and consists of multiple fields, including the destination CIDR block, the next hop for the traffic, and the type of the next hop. Route entries are classified into system route entries and custom route entries.

System routes

After you create a VPC, the system automatically adds the following system routes to the route table:

- A route entry with a destination CIDR block of 100.64.0.0/10. This route is used for communication among cloud resources within the VPC.
- Route entries with destination CIDR blocks same as the CIDR blocks of the VSwitches in this VPC. Such routes are used for communication among cloud resources within VSwitches.

For example, if you create a VPC and specify 192.168.0.0/16 as its CIDR block, and then create two VSwitches whose CIDR blocks are 192.168.1.0/24 and 192.168.0.0/24, three system routes listed in the following table are automatically added to the route table of the VPC.

Destination CIDR block	Next hop	Route entry type
100.64.0.0/10	-	System route
192.168.1.0/24	-	System route
192.168.0.0/24	-	System route

Custom routes

You can add custom routes to replace system routes or route traffic to specified destinations. You can specify the following next hop types when you create a custom route:

- **ECS instance:** Traffic destined for the destination CIDR block is forwarded to a specified Elastic Compute Service (ECS) instance in the VPC.
You can select this type if you want to access the Internet or other applications through the applications deployed on an ECS instance.
- **VPN gateway:** Traffic destined for the destination CIDR block is forwarded to a specified VPN gateway.
You can select this type if you want to connect a VPC to another VPC or a local network through a VPN connection.
- **NAT gateway:** Traffic destined for the destination CIDR block is forwarded to a specified NAT gateway.
You can select this type if you want to connect a VPC to the Internet by using a NAT gateway.
- **Router interface (to VPC):** Traffic destined for the destination CIDR block is forwarded to a specified VPC.
You can select this type if you want to connect two VPCs by using Express Connect.
- **Router interface (to VBR):** Traffic destined for the destination CIDR block is forwarded to a specified Virtual Border Router (VBR).
You can select this type if you want to connect a VPC to an on-premises network by using Express Connect.
- **Secondary ENI:** Traffic destined for the destination CIDR block is forwarded to a specified secondary Elastic Network Interface (ENI).

IPv6 routes

If IPv6 is enabled for your VPC, the following route entries are automatically added to the system route table of the VPC:

- A custom route entry with a destination CIDR block of `::/0` and whose next hop is the IPv6 gateway. This route is used to direct traffic between the cloud resources deployed in the VPC and the Internet by using IPv6 addresses.
- System route entries whose destination CIDR blocks are the IPv6 CIDR blocks of the VSwitches in the VPC. Such routes are used for communication within the VSwitches.

Routing rules

If one destination address matches more than one route entry in a route table, the system selects an entry by implementing the longest prefix match algorithm, whereby the most specific of the matching entries, the one with the longest subnet mask, is used to route traffic.

The following table describes a route table of a VPC.

Destination CIDR block	Next hop type	Next hop	Route entry type
100.64.0.0/10	-	-	System route
192.168.0.0/24	-	-	System route
0.0.0.0/0	Instance	i-12345678	Custom route
10.0.0.0/24	Instance	i-87654321	Custom route

As shown in the preceding table, the route entries destined for `100.64.0.0/10` and `192.168.0.0/24` are system route entries, and the two destined for `0.0.0.0/0` and `10.0.0.0/24` are custom route entries. Traffic destined for `0.0.0.0/0` is forwarded to the ECS instance `i-12345678`, and traffic destined for `10.0.0.0/24` is forwarded to the ECS instance `i-87654321`. According to the longest prefix match algorithm, traffic destined for `10.0.0.1` is forwarded to the ECS instance `i-87654321`, and traffic destined for `10.0.1.1` is forwarded to the ECS instance `i-12345678`.

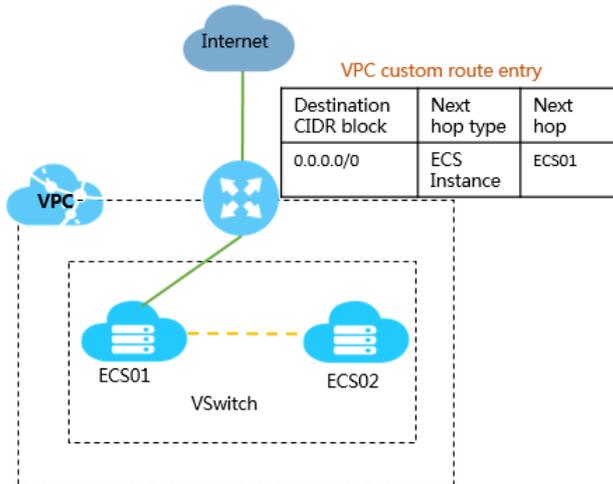

Routing examples

You can add custom route entries to a route table to control inbound and outbound traffic for a VPC.

- Routing within a VPC

As shown in the following figure, a NAT gateway is deployed on an ECS instance (ECS01) in a VPC. To enable the cloud resources in this VPC to access the Internet by this ECS instance, you can add the following route entry to the route table.

Destination CIDR block	Next hop type	Next hop
0.0.0.0/0	ECS instance	ECS01

- Connect two VPCs by using Express Connect

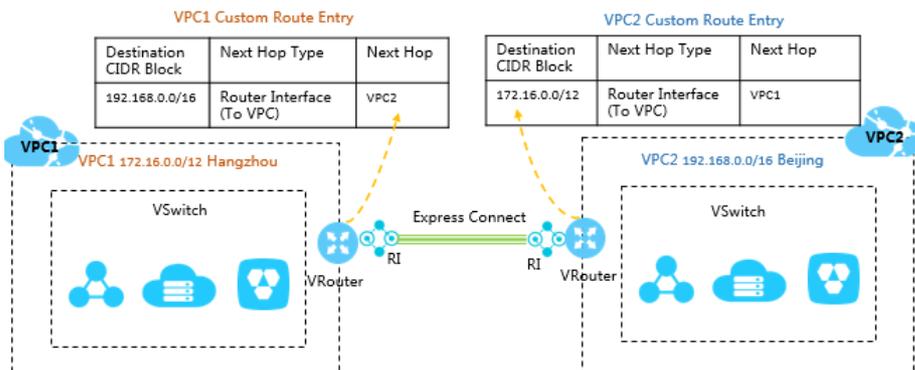

As shown in the following figure, VPC1 (172.16.0.0/12) needs to be connected to VPC2 (192.168.0.0/16) by using Express Connect. After you create router interfaces for interconnection, you must add the following route entries in the route table of each VPC respectively.

- VPC1

Destination CIDR block	Next hop type	Next hop
192.168.0.0/16	Router interface (to VPC)	VPC2

- VPC2

Destination CIDR block	Next hop type	Next hop
172.16.0.0/12	Router interface (to VPC)	VPC1

- Connect two VPCs by using VPN gateways

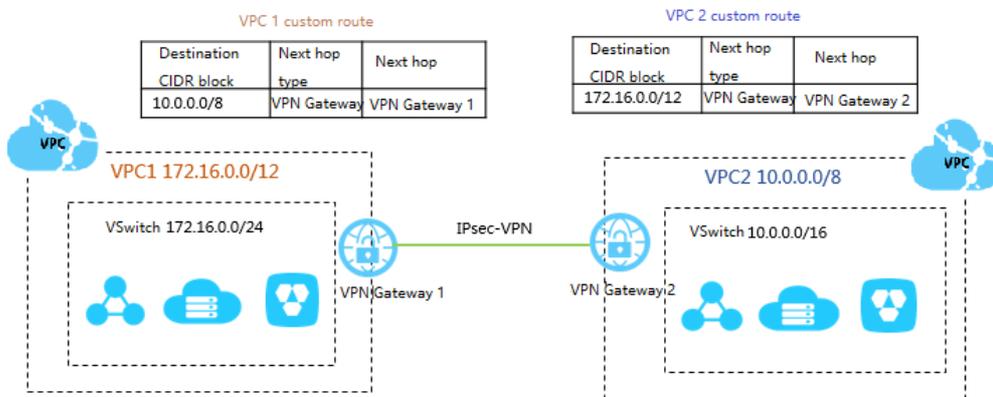

As shown in the following figure, VPC1 (172.16.0.0/12) needs to be connected to VPC2 (10.0.0.0/8) with VPN gateways. After you configure the VPN gateways, you must add the following route entries in the route table of each VPC respectively.

- VPC1

Destination CIDR block	Next hop type	Next hop
10.0.0.0/8	VPN gateway	VPN gateway 1

- VPC2

Destination CIDR block	Next hop type	Next hop
172.16.0.0/12	VPN gateway	VPN gateway 2

- Connect a VPC to an on-premises data center by using Express Connect

As shown in the following figure, a VPC needs to be connected to an on-premises data center by using Express Connect. After you configure an Express Connect circuit and a VBR, you must add the following route entries for related networks and devices:

- VPC

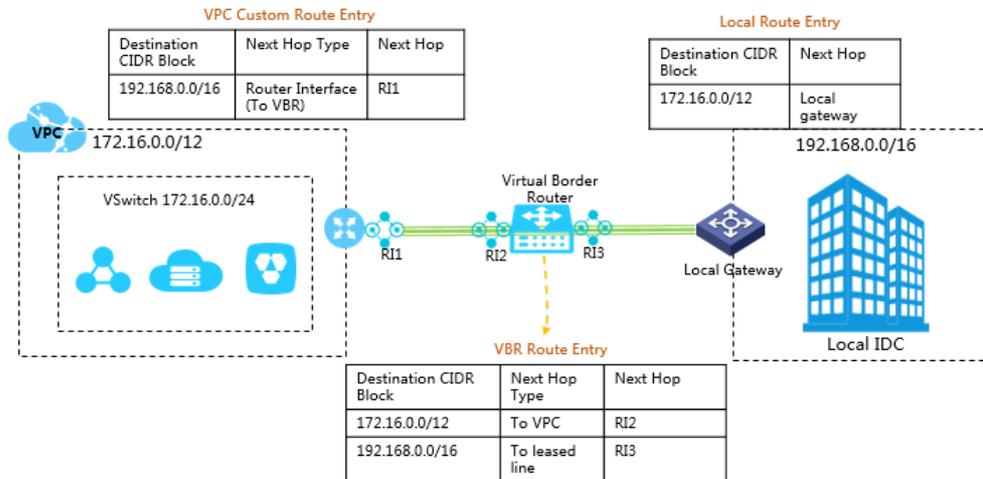

Destination CIDR block	Next hop type	Next hop
192.168.0.0/16	Router interface (general routing)	Router interface RI1

- VBR

Destination CIDR block	Next hop type	Next hop
192.168.0.0/16	To the Express Connect circuit	Router interface RI3
172.16.0.0/12	To VPC	Router interface RI2

○ On-premises network

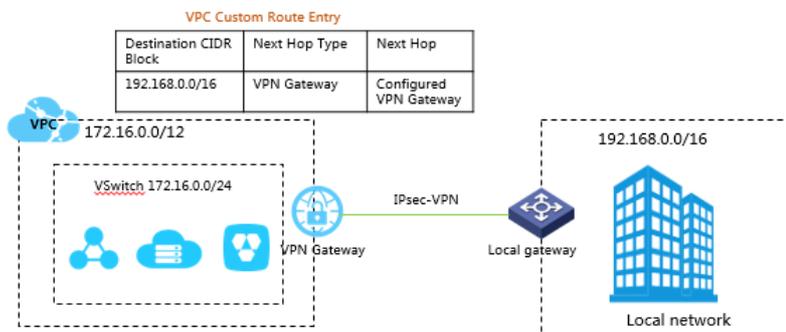

Destination CIDR block	Next hop type	Next hop
172.16.0.0/12	-	A specified local gateway device

● Connect a VPC to an on-premises data center by using VPN gateways

As shown in the following figure, a VPC (172.16.0.0/12) needs to be connected to an on-premises data center (192.168.0.0/16). After you configure the VPN gateway, you must add the following route entry to the route table of the VPC.

Destination CIDR block	Next hop type	Next hop
192.168.0.0/16	VPN gateway	A specified VPN gateway

22.5.2. Add a custom route entry

This topic describes how to add a custom route entry. After you create a Virtual Private Cloud (VPC) network, the system creates a default route table and adds system route entries to the route table for traffic management. You cannot create or delete system route entries. However, you can create custom route entries to route traffic from source CIDR blocks to specific destinations.

Context

Each entry in the route table is a route entry. A route entry, which specifies the destination for network traffic, consists of the destination CIDR block, next hop type, and next hop. Route entries are classified into system route entries and custom route entries.

Procedure

1. [Log on to the VPC console.](#)
2. In the left-side navigation pane, click **Route Tables**.
3. In the top navigation bar, select the region to which the route tables belong.
4. On the **Route Tables** page, find the route table and click **Manage** in the **Actions** column.
5. In the **Route Table Details** section, click the **Route Entry List** tab, and then click **Add Route Entry**.
6. On the **Add Route Entry** page, set the following parameters and click **OK**.

Parameter	Description
Name	The name of the route entry. The name must be 2 to 128 characters and can contain digits, underscores (_), and hyphens (-). The name must start with a letter or a Chinese character.
Destination CIDR Block	The destination CIDR block to which you want to route traffic.
Next Hop Type	<p>The type of the next hop. Valid values:</p> <ul style="list-style-type: none"> ◦ ECS Instance: Traffic destined for the specified CIDR block is routed to the Elastic Compute Service (ECS) instance you select. Select this type if you want to route traffic to an ECS instance for centralized traffic forwarding and management. For example, when an ECS instance is configured as the Internet-facing gateway to manage the traffic from other ECS instances to the Internet. ◦ VPN Gateway: Traffic destined for the specified CIDR block is routed to the VPN gateway you select. ◦ NAT Gateway: Traffic destined for the specified CIDR block is routed to the NAT gateway you select. ◦ Router Interface (To VPC): Traffic destined for the specified CIDR block is routed to the VPC network you select. Select this type if you want to connect VPC networks through Express Connect. ◦ Router Interface (To VBR): Traffic destined for the specified CIDR block is routed to the router interface that is associated with a Virtual Border Router (VBR). Select this type if you want to connect the VPC network to an on-premises data center through Express Connect. <p>If you select Router Interface (To VBR), you must also select a routing mode:</p> <ul style="list-style-type: none"> ▪ General Routing: Select an associated router interface. ▪ Active/Standby Routing: Select two instances as the next hop. The active route has a weight of 100 and the standby route has a weight of 0. The standby route takes over when the active route fails the health check. ▪ Load Balancing: Select two to four router interfaces as the next hop. The peer router of each router interface must be a VBR. Valid values of the instance weight: 1 to 255. The value must be an integer and the default value is 100. The weights of the selected instances must be the same. This way, traffic can be evenly distributed to the next-hop instances.
ECS Instance/VPN Gateway/NAT Gateway	Select the next-hop instance.

- [CreateRouteEntry](#)

22.5.3. Export route entries

This topic describes how to export route entries from a route table for backup.

Procedure

1. [Log on to the VPC console](#).
2. In the left-side navigation pane, click **Route Tables**.
3. In the top navigation bar, select the region to which the route tables belong.
4. On the **Route Tables** page, find the route table and click **Manage** in the **Actions** column.
5. In the **Route Table Details** section, click the **Route Entry List** tab, and then click **Export**. The route entries are exported to a `.csv` file in your local computer.

22.5.4. Modify a route table

This topic describes how to modify the name and description of a route table.

Procedure

1. [Log on to the VPC console](#).
2. In the left-side navigation pane, click **Route Tables**.
3. In the top navigation bar, select the region to which the route tables belong.
4. On the **Route Tables** page, find the route table and click **Manage** in the **Actions** column.
5. In the **Route Table Details** section, click **Edit** next to **Name**. In the dialog box that appears, enter a new name for the route table and click **OK**. The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (`_`), and hyphens (`-`). It must start with a letter or a Chinese character.
6. Click **Edit** next to **Description**. In the dialog box that appears, enter a new description of the route table, and click **OK**. The description must be 2 to 256 characters in length and cannot start with `http://` or `https://`.

22.5.5. Delete a custom route entry

This topic describes how to delete a custom route entry. A route table consists of one or more route entries that determine which way to forward traffic. Note that system route entries cannot be deleted.

Procedure

1. [Log on to the VPC console](#).
2. In the left-side navigation pane, click **Route Tables**.
3. In the top navigation bar, select the region to which the route tables belong.
4. On the **Route Tables** page, find the route table and click **Manage** in the **Actions** column.
5. On the **Route Entry List** tab, find the target route entry and then click **Delete** in the **Actions** column.
6. In the **Delete Route Entry** dialog box, click **OK**.

22.6. HAVIPs

22.6.1. Overview

A high-availability virtual IP address (HAVIP) is a private IP address that can be created and released as an independent resource. After you associate an HAVIP with an Elastic Compute Service (ECS) instance, the ECS instance can advertise this HAVIP by sending Address Resolution Protocol (ARP) messages.

Features

HAVIPs have the following features:

- Each HAVIP can be associated with a maximum of two ECS instances. After the association, the ECS instance can advertise the associated HAVIP by sending ARP messages.
- Each ECS instance can claim more than one private IP address by advertising multiple HAVIPs.
- By allowing ECS instances to advertise HAVIPs with ARP messages, a Virtual Router Redundancy Protocol (VRRP) configuration is implemented to ensure high availability of your services.
- Each HAVIP can be associated with an elastic IP address (EIP), which means that after an HAVIP is disassociated from the previous ECS instance and reassociated with a different ECS instance, the traffic sent to the EIP can also be delivered to the current ECS instance.

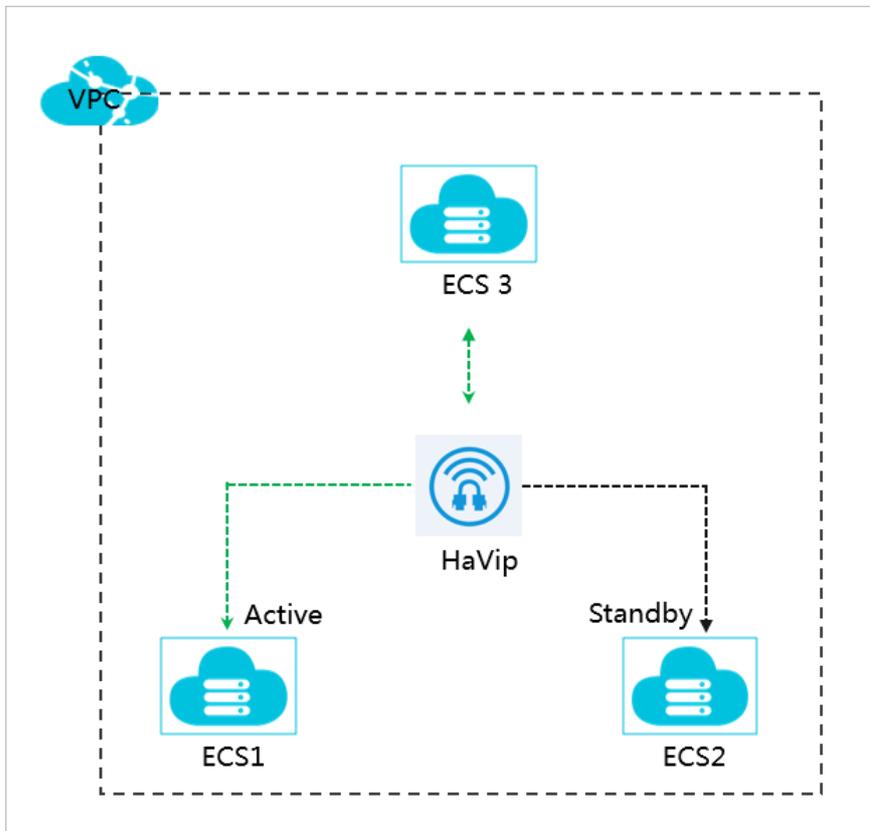

Scenarios

HAVIPs support flexible configurations in the following scenarios.

- Scenario 1: High availability services for private networks

High-availability solutions are provided by using open-source programs such as Keepalived and Heartbeat.

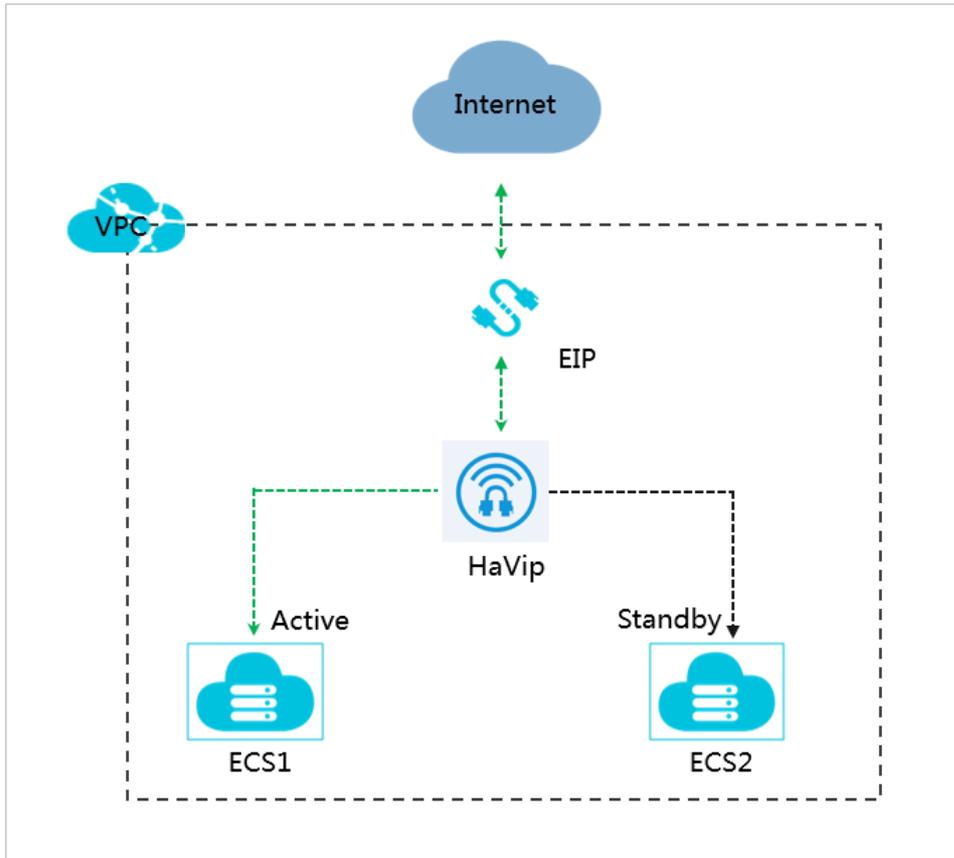

In the following figure, Keepalived integrates the HAVIP and two ECS instances (ECS 1 and ECS 2) into a highly available solution designed for the private network. The cloud instances in the same virtual private cloud (VPC) can access this service over the private network from the IP address of this HAVIP, which is also the endpoint. The high availability of this solution makes sure that ECS 2 is always ready to serve on the same IP address in case ECS 1 fails.

- Scenario 2: High availability services on the Internet

High-availability solutions are provided by using open-source programs such as Keepalived and Heartbeat.

In the following figure, ECS 1 and ECS 2 are associated with an HAVIP, which is configured with an EIP. In this case, the service can be accessed over the Internet from its endpoint, that is, the IP address of the HAVIP. Keepalived is used to implement failover, where ECS 2 takes over to keep the service available on the same IP address in case ECS 1 fails.

Limits

Before you use HAVIPs, note the following limits:

- HAVIPs can only be deployed in VPCs.
- HAVIPs do not support multicasting or broadcasting.
- Each account can hold a maximum of five HAVIPs.
- A maximum of five HAVIPs can exist in a VPC.
- Each ECS instance can be associated with a maximum of five HAVIPs.
- Each HAVIP can be associated with a maximum of two ECS instances.
- Each VPC can have a maximum of five route entries destined for HAVIPs.

22.6.2. Create an HAVIP

A high-availability virtual IP address (HAVIP) is a private IP address that can be created and released as an independent resource. This topic describes how to create an HAVIP in the console.

Procedure

1. [Log on to the VPC console.](#)
2. In the left-side navigation pane, click **HaVip Addresses**.
3. Click **Create HaVip Address**.
4. Configure the HAVIP and then click **Submit**. The following table describes the parameters for creating an HAVIP.

Parameter	Description
Organization	Select the organization to which the HAVIP belongs.

Parameter	Description
Resource Set	Select the resource set to which the HAVIP belongs.
Region	Select a region to deploy the HAVIP.
VPC	Select the VPC to which the HAVIP belongs.
VSwitch	Select the VSwitch to which the HAVIP belongs.
Private IP Address	Specify a private IP address for the HAVIP. <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 5px;"> 🔊 Notice You must select an available private IP address in the CIDR range of the VSwitch. </div>

22.6.3. Associate an HAVIP with an ECS instance

This topic describes how to associate a high-availability virtual IP address (HAVIP) with an Elastic Compute Service (ECS) instance deployed in a virtual private cloud (VPC). After the association, the ECS instance can advertise this HAVIP by sending Address Resolution Protocol (ARP) messages. Each HAVIP can be associated with a maximum of two ECS instances.

Prerequisites

An ECS instance is created and placed in the same region as the HAVIP to be associated.

For more information, see [Create an instance](#) under [Quick start](#) in the *Apsara Stack Elastic Compute Service User Guide*.

Procedure

1. [Log on to the VPC console](#).
2. In the left-side navigation pane, click **HaVip Addresses**.
3. Select the region of the HAVIP.
4. Find the target HAVIP and then click **Manage** in the **Actions** column.

5. In the **Resources** section, click the  icon.

6. On the page that appears, select the ECS instance to associate and click **OK**.
7. On the **HaVip Details** page, click **Refresh** to check the ECS associations of this HAVIP.

After you associate an HA VIP with an ECS instance, you must configure the HA VIP on the network interface of the ECS instance.

22.6.4. Associate an HA VIP with an EIP

This topic describes how to associate a high-availability virtual IP address (HA VIP) with an elastic IP address (EIP). After the association, you can use the HA VIP to provide your instances with public network access.

Prerequisites

You have purchased an EIP. For more information, see [Create an elastic IP address](#) under [Quick start](#) in the *Apsara Stack Elastic Compute Service User Guide*.

Procedure

1. **Log on to the VPC console.**
2. In the left-side navigation pane, click **HaVip Addresses**.
3. Select the region of the HA VIP.
4. Find the target HA VIP instance and choose **More > Bind EIP Address** in the **Actions** column.
5. On the page that appears, select the EIP to associate and click **OK**.

22.6.5. Disassociate an HA VIP from an ECS instance

This topic describes how to disassociate a high-availability virtual IP address (HA VIP) from an Elastic Compute Service (ECS) instance. After the disassociation, the ECS instance can no longer announce this HA VIP by sending Address Resolution Protocol (ARP) messages.

Procedure

1. **Log on to the VPC console.**
2. In the left-side navigation pane, click **HaVip Addresses**.
3. Select the region of the HA VIP.
4. On the **HaVip Addresses** page, find the target HA VIP and then click **Manage** in the **Actions** column.
5. In the **Resources** section, find the target ECS instance and then click **Unbind**.

6. In the dialog box that appears, click **OK**.

22.6.6. Disassociate an EIP from an HAVIP

This topic describes how to disassociate a high-availability virtual IP address (HAVIP) from an elastic IP address (EIP). After the disassociation, you can no longer use the HAVIP to provide your instances with Internet access.

Procedure

1. [Log on to the VPC console](#).
2. In the left-side navigation pane, click **HaVip Addresses**.
3. Select the region of the HAVIP.
4. On the **HaVip Addresses** page, find the target HAVIP and then choose **More > Unbind with EIP** in the **Actions** column.
5. In the dialog box that appears, click **OK**.

22.6.7. Delete an HAVIP

This topic describes how to delete a high-availability virtual IP address (HAVIP).

Prerequisites

- The HAVIP is not associated with any elastic IP address (EIP).
If the HAVIP is associated with an EIP, before you delete the HAVIP, you must disassociate it from the EIP. For more information, see [Disassociate an EIP from an HAVIP](#).
- The HAVIP is not associated with any Elastic Compute Service (ECS) instance.
If the HAVIP is associated with one or more ECS instances, before you delete the HAVIP, you must disassociate it from the ECS instances. For more information, see [Disassociate an HAVIP from an ECS instance](#).

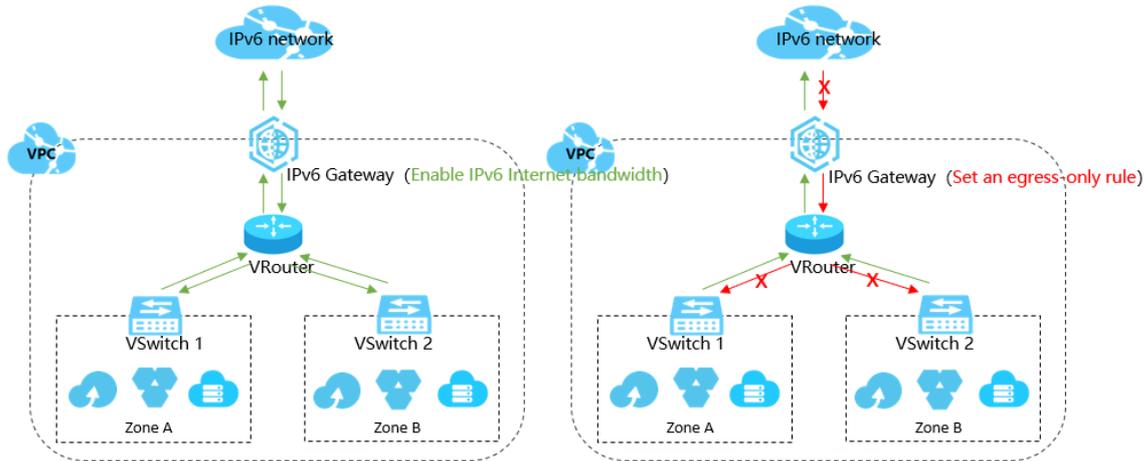

Procedure

1. [Log on to the VPC console](#).
2. In the left-side navigation pane, click **HaVip Addresses**.
3. Select the region of the HAVIP.
4. On the **HaVip Addresses** page, find the target HAVIP and then choose **More > Delete** in the **Actions** column.
5. In the dialog box that appears, click **OK**.

23. IPv6 Gateway

23.1. What is an IPv6 Gateway?

This topic provides an overview of the IPv6 Gateways of Virtual Private Cloud (VPC). An IPv6 Gateway functions as an IPv6 traffic gateway for a VPC. You can configure the IPv6 Internet bandwidth and egress-only rules to manage the inbound and outbound IPv6 traffic.

Functions

The functions of an IPv6 gateway are as follows:

- **IPv6 internal network communication**

By default, an IPv6 address in a VPC is allocated with an Internet bandwidth of 0 Mbit/s and only supports communication over the internal network. Specifically, the cloud instances in a VPC can only access other IPv6 addresses in the same VPC through the IPv6 address. The resources cannot access the Internet with these IPv6 addresses or be accessed by IPv6 clients over the Internet.

- **IPv6 public network communication**

You can purchase an Internet bandwidth for the IPv6 address for which you have applied. In this way, the resources in the VPC can access the Internet through the IPv6 address and be accessed by IPv6 clients over the Internet.

You can set the Internet bandwidth to 0 Mbit/s at any time to deny the IPv6 address Internet access. After this configuration, the IPv6 address can only communicate over the internal network.

- **IPv6 public network communication with an egress-only rule**

You can set an egress-only rule for an IPv6 Gateway. In this way, the IPv6 address can access the Internet, but IPv6 clients are denied access to your cloud resources in the VPC over the Internet.

You can delete the egress-only rule at any time. After the rule is deleted, your resources in the VPC can access the Internet through the IPv6 address for which you have purchased Internet bandwidth, and IPv6 clients can access the resources in the VPC over the Internet.

The network access capability of IPv6 addresses is dependent on the settings of the network type, Internet bandwidth, and egress-only rule, as shown in the following table.

IPv6 network type	Enable IPv6 Internet bandwidth?	Set an egress-only rule?	IPv6 network access capability
Internal network	No	No	Internal network communication

IPv6 network type	Enable IPv6 Internet bandwidth?	Set an egress-only rule?	IPv6 network access capability
Public network	Yes	No	Internal network communication Public network communication
		Yes	Internal network communication Public network communication when access is initiated by VPCs

Benefits

IPv6 Gateway provides the following benefits:

- **High availability**
IPv6 Gateways provide cross-zone high availability and stable IPv6 Internet gateway services.
- **High performance**
A single IPv6 Gateway provides a 10-gigabit level throughput.
- **Flexible management of public network communication**
You can manage the Internet communication capability of an IPv6 Gateway by adjusting its Internet bandwidth and setting an egress-only rule.

23.2. Log on to the IPv6 Gateway console

This topic provides an example of how to use Google Chrome to log on to the IPv6 Gateway console in the Apsara Stack Cloud Management (ASCM) console.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
2. Enter your username and password.

Obtain the username and password used to log on to the console from the operations administrator.

Note When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:

- Uppercase or lowercase letters.
- Digits.
- Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.

4. In the top navigation bar, choose **Products > Networking > IPv6 Gateway**.

23.3. Quick start

23.3.1. Create an IPv6 VPC

This topic describes how to build a virtual private cloud (VPC) with an IPv6 Classless Inter-domain Routing (CIDR) block and create an Elastic Compute Service (ECS) instance assigned with an IPv6 address in the VPC.

Step 1: Create a VPC and a VSwitch

Before you deploy cloud resources in a VPC, you must create a VPC and a VSwitch.

Perform the following steps to create a VPC and a VSwitch:

1. Log on to the VPC console.
2. On the VPCs page, click **Create VPC**.
3. On the **Create VPC** page, configure the VPC and click **Submit**. The following table describes the parameters for creating a VPC.

Parameter	Description
Organization	Select the organization to which the VPC belongs.
Resource Set	Select the resource set to which the VPC belongs.
Region	Select a region to deploy the VPC.
Share with Sub-organizations	Specify whether to share the VPC. If you select Yes, the administrators of sub-organizations can create resources in the VPC. In this tutorial, select No.
VPC Name	Enter a name for the VPC. The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code> . In this tutorial, enter <code>VPCTest</code> .
IPv4 CIDR Block	Select an IPv4 CIDR block for the VPC. The following setting methods are supported: <ul style="list-style-type: none"> ◦ Recommended CIDR Block: Enter 192.168.0.0/16, 172.16.0.0/12, or 10.0.0.0/8. ◦ Custom CIDR Block: Enter 192.168.0.0/16, 172.16.0.0/12, 10.0.0.0/8, or a subset of these CIDR blocks. The subnet mask must be 8 to 28 bits in length. For example, enter 192.168.0.0/16. In this tutorial, select Recommended CIDR Block and then select 192.168.0.0/16. <div style="background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> ? Note After you create a VPC, you cannot change its IPv4 CIDR block. </div>
IPv6 CIDR Block	Specify whether to assign an IPv6 CIDR block to the VPC. <ul style="list-style-type: none"> ◦ Do Not Assign: No IPv6 CIDR block will be assigned to the VPC. ◦ Assign: An IPv6 CIDR block will be automatically assigned to the VPC. In this tutorial, select Assign.

Parameter	Description
Description	<p>Enter a description for the VPC.</p> <p>The description must be 2 to 256 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code>.</p>

4. Click **Back to Console**. In the left navigation pane, click **VSwitches**.
5. On the **VSwitches** page, click **Create VSwitch**.
6. On the **VSwitch** page, configure the VSwitch and click **Submit**. The following table describes the parameters for creating a VSwitch.

Parameter	Description
Organization	Select the organization to which the VSwitch belongs.
Resource Set	Select the resource set to which the VSwitch belongs.
Region	Select a region to deploy the VSwitch.
Zone	<p>Select a zone to deploy the VSwitch.</p> <p>Each VSwitch must reside entirely within one zone and cannot span multiple zones. However, you can deploy cloud resources in VSwitches that reside in different zones to achieve zone-disaster recovery.</p> <p> Note Each cloud resource can be deployed in only one VSwitch.</p>
VPC	<p>Select the VPC for which you want to create the VSwitch.</p> <p>In this tutorial, select <code>VPCtest</code>.</p>
Dedicated for Off-Cloud Servers	<p>Specify whether the VSwitch is dedicated for off-cloud servers.</p> <p>For more information, see the Features of off-cloud servers for VPC section in the <i>ECS Bare Metal Instance User Guide</i>.</p> <p>In this tutorial, select <code>No</code>.</p>
VSwitch Name	<p>Enter a name for the VSwitch.</p> <p>The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code>.</p>
IPv4 CIDR Block	<p>Enter an IPv4 CIDR block for the VSwitch.</p> <p>This tutorial uses the default IPv4 CIDR block.</p>
IPv6 CIDR Block	<p>Enter an IPv6 CIDR block for the VSwitch.</p> <p>This tutorial uses the default IPv6 CIDR block.</p>

Parameter	Description
Description	<p>Enter a description for the VSwitch.</p> <p>The description must be 2 to 256 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code> or <code>/</code> or <code>.</code></p>

Step 2: Create a security group

Perform the following steps to create a security group:

1. In the top navigation bar, choose **Products > Elastic Computing > Elastic Compute Service**.
2. Choose **Networks and Security > Security Groups**.
3. On the **Security Groups** page, click **Create Security Group**.
4. On the **Create Security Group** page, configure the security group and click **Submit**. The following table describes the parameters for creating a security group.

Parameter	Description
Organization	Select the organization to which the security group belongs.
Resource Set	Select the resource set to which the security group belongs.
Region	<p>Select the region that will use the security group.</p> <p>The security group and the VPC must belong to the same region.</p>
Zone	Select the zone that will use the security group.
VPC	Select the VPC to which the security group belongs.
Security Group Name	<p>Enter a name for the security group.</p> <p>The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code> or <code>/</code> or <code>.</code></p>
Description	<p>Enter a description for the security group.</p> <p>The description must be 2 to 256 characters in length and can contain letters, Chinese characters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or a Chinese character and cannot start with <code>http://</code> or <code>https://</code> or <code>/</code> or <code>.</code></p>

Step 3: Create and configure an ECS instance

After you create a VPC and a VSwitch, you must create an ECS instance and assign an IPv6 address to the ECS instance, and then associate this IPv6 address with the network interface controller (NIC) of the ECS instance.

Perform the following steps to create and configure an ECS instance:

1. In the top navigation bar, choose **Products > Networking > Virtual Private Cloud**.
2. In the left-side navigation pane, click **VSwitches**.
3. Select the region where your VSwitch resides.
4. On the **VSwitches** page, find the target VSwitch and choose **Purchase > ECS Instance** in the **Actions** column.

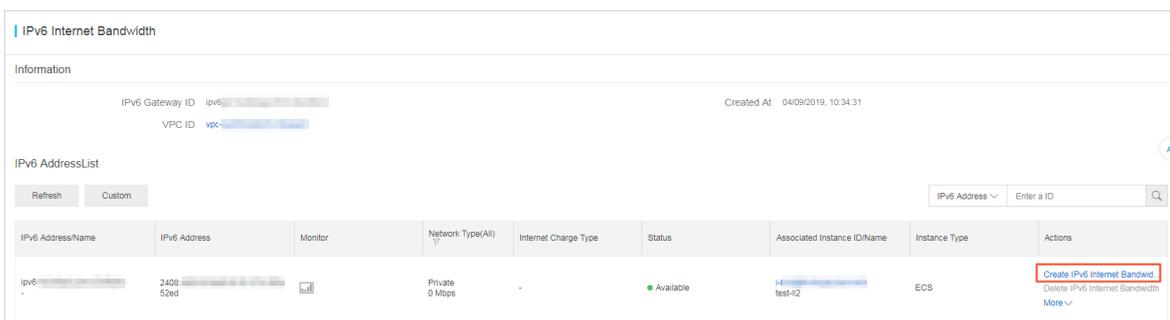

5. On the **Create ECS Instance** page, configure the ECS instance and click **Submit**. In this tutorial, select **Assign** to assign an IPv6 address to the ECS instance. For more information about other parameters, see **Create an instance** under **Quick start** in the *Apsara Stack Elastic Compute Service User Guide*.
6. Return to the **Instances** page, and click the instance ID to view the assigned IPv6 address.
7. Configure a static IPv6 address.
 - If the image of your ECS instance supports DHCPv6, you do not need to manually configure the static IPv6 address. DHCPv6 enables automatic configuration of IPv6 addresses. Therefore, if your ECS instance image supports DHCPv6, the ECS instance can use the assigned IPv6 address to communicate in the private network directly after being created.
The following images support DHCPv6:
 - Linux images:
 - CentOS 7.6 IPV6 64Bit
 - CentOS 6.10 64Bit
 - SUSE Linux Enterprise Server 12 SP4 64Bit
 - Windows Server images
 - If the image of your ECS instance does not support DHCPv6, you must manually configure an IPv6 address for the ECS instance. We recommend that you refer to the related documentation for each image for configuration guidance.

Step 4: Purchase an IPv6 Internet bandwidth plan

By default, IPv6 addresses are only used for communication inside private networks. If you want to allow an instance assigned with an IPv6 address to access the Internet or be accessed by IPv6 clients over the Internet, you must purchase an Internet bandwidth plan for the IPv6 address.

Perform the following steps to purchase an Internet bandwidth plan for the IPv6 address:

1. In the top navigation bar, choose **Products > Networking > IPv6 Gateway**.
2. Select the region where the IPv6 Gateway resides.
3. On the **IPv6 Gateway** page, find the target IPv6 Gateway and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **IPv6 Internet Bandwidth**.
5. On the **IPv6 Internet Bandwidth** page, find the target IPv6 address and click **Enable IPv6 Internet Bandwidth** in the **Actions** column.

6. Select a bandwidth plan and then click **Submit**. The maximum IPv6 Internet bandwidth for an IPv6 Gateway of the Free, Enterprise, or Enhanced Edition is 2 Gbit/s.

Step 5: Configure the security group rules

IPv4 and IPv6 addresses are independent of each other. If the current security group rules cannot serve your IPv6 services, you must configure security group rules for IPv6 traffic.

For more information, see **Add security group rules** under **Security groups** in the *Apsara Stack Elastic Compute Service User Guide*.

Step 6: Test the network connectivity

Log on to the ECS instance and run the ping command to test the network connectivity.

```
[root@iZhp3aehva ~]# ping6 ipv6.baidu.com
PING ipv6.baidu.com(2400:da00:2::29 (2400:da00:2::29)) 56 data bytes
64 bytes from 2400:da00:2::29 (2400:da00:2::29): icmp_seq=1 ttl=45 time=77.1 ms
64 bytes from 2400:da00:2::29 (2400:da00:2::29): icmp_seq=2 ttl=45 time=77.1 ms
64 bytes from 2400:da00:2::29 (2400:da00:2::29): icmp_seq=3 ttl=45 time=77.0 ms
^C
--- ipv6.baidu.com ping statistics ---
3 packets transmitted, 3 received, 0% packet loss, time 2002ms
rtt min/avg/max/mdev = 77.070/77.101/77.127/0.227 ms
[root@iZhp3aehva ~]#
```

23.4. Enable IPv6 for VPCs

23.4.1. Create an IPv4 and IPv6 dual-stack VPC

This topic describes how to configure both IPv4 and IPv6 CIDR blocks for a VPC when you create the VPC. By default, all VPCs are associated with IPv4 CIDR blocks which cannot be deleted. However, you can choose whether to allocate an IPv6 CIDR blocks to a VPC. After you choose to allocate an IPv6 CIDR block to a VPC, the system creates an IPv6 gateway of the Free Edition for the VPC for you to provision IPv6 bandwidth and manage IPv6 traffic.

Procedure

1. Log on to the VPC console.
2. On the top of the page, select a region to deploy your VPC.
3. On the VPCs page, click **Create VPC**.
4. On the **Create VPC** page, configure the VPC network and click **Submit**. The following table describes the configuration parameters.

Parameter	Description
Organization	Select the organization to which the VPC belongs.
Resource Set	Select the resource set to which the VPC belongs.
Region	Select a region to deploy the VPC.
Share with Sub-organizations	Specify whether to share the VPC. If you select Yes, administrators of sub-organizations can create resources in the VPC network.
VPC Name	Enter a name for the VPC. The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with <code>http://</code> or <code>https://</code> .

Parameter	Description
IPv4 CIDR Block	<p>Specify an IPv4 CIDR block for the VPC. The following setting methods are supported:</p> <ul style="list-style-type: none"> ◦ Recommended CIDR Block: Use 192.168.0.0/16, 172.16.0.0/12, or 10.0.0.0/8 as the IPv4 CIDR block of the VPC. ◦ Custom CIDR Block: Use 192.168.0.0/16, 172.16.0.0/12, 10.0.0.0/8, or one of their subnets as the IPv4 CIDR block of the VPC. The subnet mask must be 8 to 24 bits in length. For example, enter 192.168.0.0/16. <p>Note After you create a VPC, you cannot modify its IPv4 CIDR block.</p>
IPv6 CIDR Block	<p>Specify whether to assign an IPv6 CIDR block to the VPC. In this example, select Assign.</p> <p>If you set this parameter to Assign, the system automatically creates an IPv6 gateway of the Free Edition for your VPC and assigns an IPv6 CIDR block with the subnet mask /61, such as 2xx1:db8::/61. By default, IPv6 addresses can only be used for communication within private networks. If you need to enable an IPv6 address to access and be accessed over the Internet, you must purchase IPv6 Internet bandwidth for the IPv6 address. For more information, see Enable Internet connectivity for an IPv6 address.</p> <p>Note After you create a VPC, you cannot modify its IPv6 CIDR block.</p>
Description	<p>Enter a description for the VPC.</p> <p>The description must be 2 to 256 characters in length and can contain letters, digits, underscores (<code>_</code>), hyphens (<code>-</code>), periods (<code>.</code>), colons (<code>:</code>), and commas (<code>,</code>). It must start with a letter and cannot start with <code>http://</code> or <code>https://</code>.</p>

23.4.2. Enable an IPv6 CIDR block for a VPC network

This topic describes how to enable an IPv6 CIDR block for a Virtual Private Cloud (VPC) network. After the IPv6 CIDR block is enabled, the system automatically creates an IPv6 gateway free of charge for the VPC network. You can use the IPv6 Gateway to manage the IPv6 Internet bandwidth and set egress-only rules.

Procedure

1. Log on to the VPC console.
2. Select the region where your VPC network is deployed.
3. On the **VPCs** page, find the target VPC network and click **Enable IPv6 CIDR Block** in the **IPv6 CIDR Block** column.

Instance ID/Name	CIDR	IPv6 CIDR Block	Status	Default VPC	Route Tables	VSwitches	Organization	Resource Set	Actions
vpc-9dbr1	192.168.0.0/16	Enable IPv6 CIDR Block	Available	No	1	1	yundun	ResourceSet(yundun)	Manage Delete
vpc-9dbr1	172.16.0.0/16	Enable IPv6 CIDR Block	Available	No	1	1	yundun	ResourceSet(yundun)	Manage Delete

4. In the **Enable IPv6 CIDR Block** dialog box, select **Enable IPv6 CIDR Block of all VSwitches in VPC**, and then click **OK**. If you do not select **Enable IPv6 CIDR Block of all VSwitches in VPC**, you must enable IPv6 CIDR Block for each VSwitch. For more information, see [Enable an IPv6 CIDR block for a VSwitch](#).

23.5. Enable IPv6 for VSwitches

23.5.1. Create an IPv4 and IPv6 dual-stack VSwitch

This topic describes how to assign an IPv6 CIDR block to a VSwitch when you create the VSwitch.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **VSwitches**.
3. Select the region where you want to deploy the VSwitch.
4. On the **VSwitches** page, click **Create VSwitch**.
5. On the **VSwitch** page, configure the VSwitch and click **Submit**. The following table describes the configuration parameters.

Parameter	Description
Organization	Select the organization to which the VSwitch belongs.
Resource Set	Select the resource set to which the VSwitch belongs.
Region	Select a region to deploy the VSwitch.
Zone	<p>Select a zone to deploy the VSwitch.</p> <p>Each VSwitch must reside entirely within one zone and cannot span multiple zones. However, you can deploy cloud resources in VSwitches of different zones to achieve cross-zone disaster recovery.</p> <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> <p> Note Each cloud resource can be deployed in only one VSwitch.</p> </div>
VPC	Select the VPC for which you want to create the VSwitch.
Dedicated for Off-Cloud Servers	<p>Specify whether the VSwitch is dedicated for off-cloud servers.</p> <p>For more information, see <i>the Features of off-cloud servers for VPC</i> topic in the Apsara Stack Bare Metal Server User Guide.</p>
VSwitch Name	<p>Enter a name for the VSwitch.</p> <p>The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with <code>http://</code> or <code>https://</code>.</p>
IPv4 CIDR Block	<p>Specify an IPv4 CIDR block for the VSwitch.</p> <ul style="list-style-type: none"> ○ You must specify the IP address range for the VSwitch in the form of a CIDR block. The IPv4 CIDR block size for a VSwitch is between a 16-bit mask and a 29-bit mask. It means that 8 to 65,536 IP addresses can be provided. ○ The IPv4 CIDR block of a VSwitch must be a subset of the IPv4 CIDR block of the VPC this VSwitch resides in. ○ The first and the last three IP addresses of each VSwitch IPv4 CIDR block are reserved. For example, if the VSwitch IPv4 CIDR block is 192.168.1.0/24, the IP addresses 192.168.1.0, 192.168.1.253, 192.168.1.254, and 192.168.1.255 are reserved. ○ The IPv4 CIDR block of a VSwitch must be more specific than the CIDR range of a route in any of the VPC route tables. ○ After you create a VSwitch, you cannot modify its IPv4 CIDR block.

Parameter	Description
IPv6 CIDR Block	<p>Specify an IPv6 CIDR block for the VSwitch.</p> <p>The default subnet mask for the IPv6 CIDR block of a VSwitch is /64. You can enter a decimal number ranging from 0 to 255 to define the last 8 bits of the IPv6 CIDR block.</p> <p>For example, if the IPv6 CIDR block of the VPC that contains the VSwitch is 2xx1:db8::/64, you can enter 255 (FF in hexadecimal notation) in this field to define the IPv6 CIDR block of the VSwitch as 2xx1:db8:ff::/64.</p>
Description	<p>Enter a description for the VSwitch.</p> <p>The description must be 2 to 256 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with <code>http://</code> or <code>https://</code>.</p>

23.5.2. Enable IPv6 for a VSwitch

This topic describes how to allocate an IPv6 CIDR block to a VSwitch.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **VSwitches**.
3. Select the region where your VSwitch resides.
4. On the **VSwitches** page, find the target VSwitch, and click **Enable IPv6 CIDR Block** in the **IPv6 CIDR Block** column.

Instance ID/Name	VPC	Status	IPv4 CIDR Block	Number of Available Private IPs	IPv6 CIDR Block	Default VSwitch
vsw-2wff	vpc-9-szw	Available	172.31.0.0/16	65532	Enable IPv6 CIDR Block	No
vsw-iyay	vpc-9-ka	Available	172.16.0.0/26	59	1007:1100:0:58::/64	No

5. (Optional) In the **Enable IPv6 CIDR Block** dialog box, click **OK**.

Note This operation is required only when IPv6 is not enabled for the VPC to which the VSwitch belongs.

6. Specify an IPv6 CIDR block and click **OK**.

The default subnet mask for the IPv6 CIDR block of a VSwitch is /64. You can enter a decimal number ranging from 0 to 255 to define the last 8 bits of the IPv6 CIDR block.

For example, if the IPv6 CIDR block of the VPC that contains the VSwitch is 2xx1:db8::/64, you can enter 255 (FF in hexadecimal notation) in this field to define the IPv6 CIDR block of the VSwitch as 2xx1:db8:ff/64.

23.6. Manage IPv6 Gateways

23.6.1. Editions of IPv6 gateways

This topic describes the different editions of IPv6 gateways. Different quotas and limits apply to IPv6 gateways of different editions, such as the maximum forwarding bandwidth, maximum IPv6 bandwidth per IPv6 address, and maximum number of egress-only rules.

IPv6 gateway edition	Maximum forwarding bandwidth	Maximum IPv6 bandwidth per IPv6 address	Maximum number of egress-only rules
Free Edition	10 Gbit/s	2 Gbit/s	0
Enterprise Edition	20 Gbit/s	2 Gbit/s	50
Enhanced Enterprise Edition	50 Gbit/s	2 Gbit/s	200

23.6.2. Create an IPv6 gateway

This topic describes how to create an IPv6 gateway for a VPC. After you create an IPv6 gateway, you can purchase IPv6 Internet bandwidth and set egress-only rules for the IPv6 gateway.

Prerequisites

Make sure that IPv6 is enabled for the VPC before you create an IPv6 gateway for the VPC. For more information, see [Allocate an IPv6 CIDR block when you create a VPC](#) and [Enable an IPv6 CIDR block for a VPC network](#).

Procedure

1. [Log on to the IPv6 Gateway console](#).
2. On the IPv6 Gateway page, click **Create IPv6 Gateway**.
3. Configure the IPv6 gateway and click **Submit**. The following table describes the configuration parameters.

Parameter	Description
Organization	Select the organization to which the IPv6 gateway belongs.
Resource Set	Select the resource set to which the IPv6 gateway belongs.
Region	Select a region to deploy the IPv6 gateway. The IPv6 gateway must belong to the same region as the VPC for which you want to create the IPv6 gateway.
VPC	Select the VPC for which you want to create an IPv6 gateway. The target VPC may not be available due to the following reasons: <ul style="list-style-type: none"> ○ Only one IPv6 gateway can be created for each VPC. The VPC already has an IPv6 gateway. ○ The VPC has a custom route with the destination CIDR block set to <code>::/0</code>. If this happens, you must delete this custom route before you can create an IPv6 gateway for the VPC. <div style="background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> <p> Note After an IPv6 gateway is created, you cannot change the VPC that is associated with the IPv6 gateway.</p> </div>

Parameter	Description
Edition	<p>Select the edition of the IPv6 gateway. IPv6 gateways are available in the following editions:</p> <ul style="list-style-type: none"> ◦ Free Edition ◦ Enterprise Edition ◦ Enhanced Enterprise Edition <p>Different quotas and limits apply to IPv6 gateways of different editions, such as the maximum forwarding bandwidth, maximum IPv6 bandwidth per IPv6 address, and maximum number of egress-only rules. For more information, see Editions of IPv6 gateways.</p>

23.6.3. Modify an IPv6 gateway

This topic describes how to modify the name and description of an IPv6 gateway.

Procedure

1. [Log on to the IPv6 Gateway console](#).
2. Select the region where the IPv6 gateway resides.
3. On the IPv6 Gateway page, find the target IPv6 gateway, and click **Manage** in the **Actions** column.
4. On the IPv6 Gateway Details page, click **Edit** next to **Name**. In the dialog box that appears, enter a new name for the IPv6 gateway, and click **OK**. The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter.
5. Click **Edit** next to **Description**. In the dialog box that appears, enter a new description for the IPv6 gateway and click **OK**. The description must be 2 to 256 characters in length and cannot start with `http://` or `https://`.

23.6.4. Delete an IPv6 gateway

This topic describes how to delete an IPv6 gateway. If a VPC no longer needs to access or be accessed by IPv6 clients, you can delete the IPv6 gateway associated with the VPC.

Prerequisites

Before you delete an IPv6 gateway of the enterprise edition or enhanced enterprise edition, you must delete the egress-only rules of the IPv6 gateway. For more information, see [Delete an egress-only rule](#).

Procedure

1. [Log on to the IPv6 Gateway console](#).
2. Select the region where the IPv6 gateway resides.
3. On the IPv6 Gateway page, find the target IPv6 gateway, and click **Delete** in the **Actions** column.
4. In the dialog box that appears, click **OK**.

23.7. Manage IPv6 Internet bandwidth

23.7.1. Enable Internet connectivity for an IPv6 address

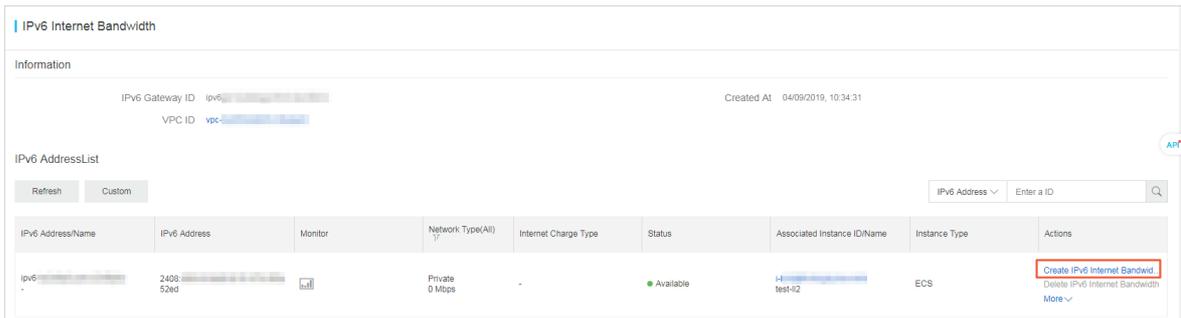

This topic describes how to enable Internet bandwidth for an IPv6 address. After Internet bandwidth is enabled for an IPv6 address, the IPv6 address can be used to communicate over the Internet.

Prerequisites

An ECS instance is created in the VPC associated with the corresponding IPv6 gateway and is configured with an IPv6 address.

Procedure

1. Log on to the IPv6 Gateway console.
2. Select the region where the IPv6 gateway resides.
3. On the IPv6 Gateway page, find the target IPv6 gateway, and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **IPv6 Internet Bandwidth**.
5. On the IPv6 Internet Bandwidth page, find the target IPv6 address, and click **Enable IPv6 Internet Bandwidth** in the **Actions** column.

6. Specify a bandwidth and click **Submit**. An IPv6 gateway of the Free Edition, Enterprise Edition, or Enhanced Enterprise Edition supports a 2 Gbit/s maximum bandwidth per IPv6 address.

23.7.2. Modify the maximum bandwidth of an IPv6 address

This topic describes how to modify the maximum bandwidth of an IPv6 address. The modification takes effect immediately.

Procedure

1. Log on to the IPv6 Gateway console.
2. Select the region where the IPv6 gateway resides.
3. On the IPv6 Gateway page, find the target IPv6 gateway, and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **IPv6 Internet Bandwidth**.
5. In the IPv6 AddressList section, find the target IPv6 address, and choose **More > Modify IPv6 Internet Bandwidth** in the **Actions** column.
6. Specify a bandwidth and click **Submit**.

23.7.3. Disable Internet connectivity for an IPv6 address

This topic describes how to delete the Internet bandwidth of an IPv6 address that is no longer needed for Internet communication.

Procedure

1. Log on to the IPv6 Gateway console.
2. Select the region where the IPv6 gateway resides.
3. On the IPv6 Gateway page, find the target IPv6 gateway, and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **IPv6 Internet Bandwidth**.
5. In the IPv6 AddressList section, find the target IPv6 address, and click **Delete IPv6 Internet Bandwidth** in the **Actions** column.
6. In the dialog box that appears, click **OK**.

23.8. Manage egress-only rules

23.8.1. Create an egress-only rule

This topic describes how to create an egress-only rule. If you want an instance in the VPC associated with an IPv6 gateway to be able to access the Internet with an IPv6 address, while resources on the Internet cannot initiate communication with this instance, you can create an egress-only rule for the instance.

Prerequisites

IPv6 Internet bandwidth is enabled for the IPv6 address configured for the instance. For more information, see [Enable Internet connectivity for an IPv6 address](#).

Context

IPv6 gateways of the Free Edition do not support egress-only rules. IPv6 gateways of the enterprise edition and enterprise enhanced edition support a maximum of 50 and 200 egress-only rules respectively.

Procedure

1. [Log on to the IPv6 Gateway console](#).
2. Select the region where the IPv6 gateway resides.
3. On the IPv6 Gateway page, find the target IPv6 gateway, and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **Egress-only Rule**.
5. On the Egress-only Rule page, click **Create Egress-only Rule**.
6. In the **Create Egress-only Rule** dialog box, select the ECS instance that uses the IPv6 address to communicate with the Internet, and click **OK**.

23.8.2. Delete an egress-only rule

This topic describes how to delete an egress-only rule. After the rule is deleted, the IPv6 address with Internet bandwidth can access the Internet, and the instance associated with the IPv6 address can be accessed over the Internet.

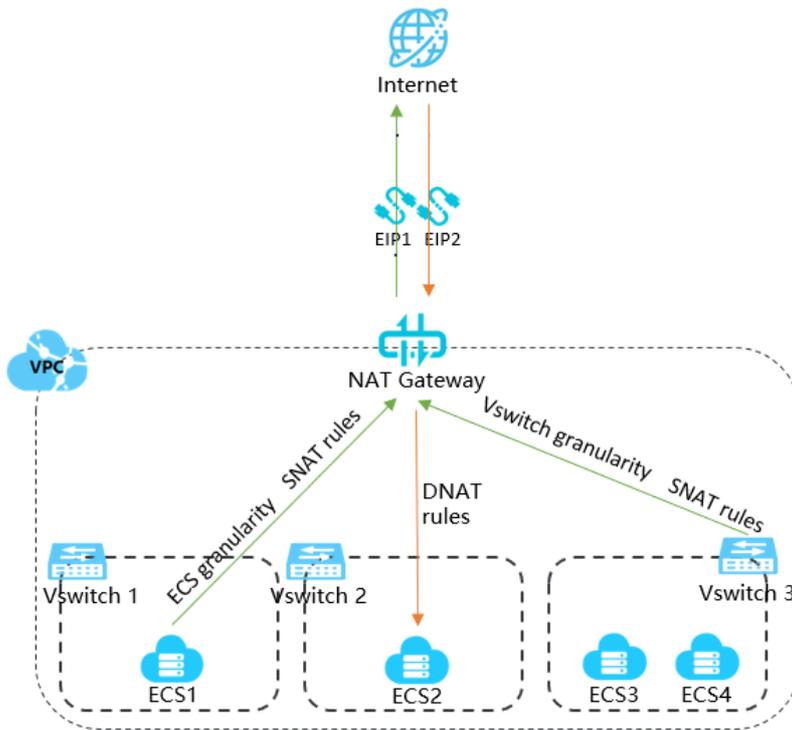

Procedure

1. [Log on to the IPv6 Gateway console](#).
2. Select the region where the IPv6 gateway resides.
3. On the IPv6 Gateway page, find the target IPv6 gateway, and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **Egress-only Rule**.
5. On the Egress-only Rule page, find the egress-only rule that you want to delete, and click **Delete** in the **Actions** column.
6. In the dialog box that appears, click **OK**.

24.NAT Gateway

24.1. What is NAT Gateway?

A NAT gateway is an enterprise-grade Internet gateway. NAT Gateway provides source network address translation (SNAT) and destination network address translation (DNAT) features, a maximum forwarding capacity of 10 Gbit/s, and support for cross-zone disaster recovery.

Features

NAT gateways must be associated with public IP addresses. After you create a NAT gateway, you can associate it with one or more elastic IP addresses (EIPs).

NAT Gateway supports SNAT and DNAT.

- SNAT allows Elastic Compute Service (ECS) instances that are deployed in a virtual private cloud (VPC) and not associated with public IP addresses to access the Internet.
- DNAT maps public IP addresses of a NAT gateway to ECS instances so that the ECS instances can be accessible from the Internet.

24.2. Log on to the NAT Gateway console

This topic describes how to use Google Chrome to log on to the NAT Gateway console in Apsara Stack Cloud Management (ASCM).

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
2. Enter your username and password.

Obtain the username and password used to log on to the console from the operations administrator.

Note When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:

- Uppercase or lowercase letters.
- Digits.
- Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Products > Network > NAT Gateway**.

24.3. Quick Start

24.3.1. Overview

This topic describes how to configure Source Network Address Translation (SNAT) and Destination Network Address Translation (DNAT). You can configure SNAT and DNAT to enable ECS instances in a Virtual Private Cloud (VPC) network to communicate with the Internet through a NAT gateway.

Prerequisites

Before you start, make sure that the following conditions are met:

- A VPC network is created. For more information, see *VPC User Guide Create a VPC network in the Quick Start chapter in the VPC User Guide*.
- An ECS instance is created in the VPC network. For more information, see *ECS User Guide Create an instance in the Quick Start chapter in the ECS User Guide*.
- An elastic IP address (EIP) is created. For more information, see *EIP User Guide Create an EIP in the Quick Start chapter in the EIP User Guide*.

Procedure

In this topic, an ECS instance that is not associated with any public IP addresses in a VPC network is used as an example. The following flowchart shows how to associate an EIP with a NAT gateway:

Create a NAT Gateway Associate an EIP Create a DNAT entry Create an SNAT entry

- Region
- VPC
- Specification
- Select an EIP
- Public IP address
- Private IP address
- Port settings
- VSwitch granularity
- ECS granularity

1. Create a NAT gateway

A NAT gateway is an enterprise-class gateway that provides NAT proxy services. Before you configure SNAT and DNAT entries, you must create a NAT gateway.

For more information, see [Create a NAT Gateway](#).

2. Associate an EIP to a NAT gateway

A NAT gateway functions as expected only after it is associated with a public IP address. After you create a NAT gateway, you can associate it with an EIP.

For more information, see [Associate an EIP with a NAT Gateway](#).

3. Create a DNAT entry

This topic describes how to create a Destination Network Address Translation (DNAT) entry. DNAT maps public IP addresses to Elastic Compute Service (ECS) instances in a Virtual Private Cloud (VPC) network. This way, the ECS instances can receive requests sent over the Internet. DNAT supports port mapping and IP mapping.

For more information, see [Create a DNAT entry](#).

4. Create an SNAT entry

This topic describes how to create a Source Network Address Translation (SNAT) entry. SNAT allows Elastic Compute Service (ECS) instances in a Virtual Private Cloud (VPC) network to access the Internet without using public IP addresses.

For more information, see [Create a SNAT entry](#).

24.3.2. Create a NAT gateway

A NAT gateway is an enterprise-class gateway that provides NAT proxy services. Before you configure SNAT and DNAT entries, you must create a NAT gateway.

Prerequisites

A VPC network is created. For more information, see *VPC User Guide* [Create a VPC network](#) in the **Quick Start** chapter in the VPC User Guide.

Procedure

1. [Log on to the NAT Gateway console](#).
2. On the **NAT Gateway** page, click **Create NAT Gateway**.
3. Set the parameters for the NAT gateway based on the following information, and then click **Submit**.

Parameter	Description
Organization	The organization to which the NAT gateway belongs.
Resource set	The resource set to which the NAT gateway belongs.
Region	The region where the NAT gateway is deployed.
VPC	<p>The VPC network to which the NAT gateway belongs.</p> <p>If you cannot find the target VPC network in the list, perform the following operations:</p> <ul style="list-style-type: none"> ◦ Check whether the VPC network is already associated with a NAT gateway. Each VPC network can be associated with only one NAT gateway. ◦ Check whether the VPC network has a custom route entry with the destination CIDR block set to 0.0.0.0/0. If such a custom route entry exists, delete it. ◦ Check whether the RAM user is authorized to access the VPC network. If the RAM user is not authorized, contact your Alibaba Cloud account owner to grant permissions.

Parameter	Description
Specification	<p>Select the size of the NAT gateway. Valid values:</p> <ul style="list-style-type: none"> ○ Small: supports up to 10,000 SNAT connections. ○ Medium: supports up to 50,000 SNAT connections. ○ Large: supports up to 200,000 SNAT connections. ○ Super Large: supports up to 1,000,000 SNAT connections. <p> Note The size of a NAT gateway determines the maximum number of SNAT connections, but it does not affect the maximum number of DNAT connections.</p>
Parameter	<p>Enter a name for the NAT gateway.</p> <p>The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character but cannot start with <code>http://</code> or <code>https://</code>.</p>

24.3.3. Associate an EIP with the a NAT gateway

A NAT gateway functions as expected only after it is associated with a public IP address. After you create a NAT gateway, you can associate it with an elastic IP address (EIP).

Context

You can associate an EIP or a NAT service plan with a NAT gateway. However, you can choose only one of them for the NAT gateway. If you want to associate a NAT service plan with a NAT gateway, you must purchase a NAT service plan first. Then, you can configure the SNAT or DNAT feature for the NAT gateway. For more information, see [Create a NAT service plan](#).

Procedure

1. [Log on to the NAT Gateway console](#).
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the NAT Gateways page, find the NAT gateway, and choose  > **Bind Elastic IP Address** in the Actions column.
4. In the **Bind Elastic IP Address** dialog box, set the following parameters, and then click **OK**.

Parameter	Description
Usable EIP list	Select the EIP that is used to access the Internet.
VSwitch	<p>Select the VSwitch for which you want to add SNAT entries.</p> <p>After a VSwitch is selected, the system automatically adds an SNAT entry so that Alibaba cloud services in the VSwitch can access the Internet. You can also skip this step and manually add SNAT entries after you associate an EIP with the NAT gateway. For more information, see Create a SNAT entry.</p>

24.3.4. Create a DNAT entry

This topic describes how to create a Destination Network Address Translation (DNAT) entry. DNAT maps public IP addresses to Elastic Compute Service (ECS) instances in a Virtual Private Cloud (VPC) network. This way, the ECS instances can receive requests sent over the Internet. DNAT supports port mapping and IP mapping.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the NAT Gateways page, find the target NAT gateway, and click **Configure DNAT** in the Actions column.
4. On the DNAT Table page, click **Create DNAT Entry**.
5. On the Create DNAT Entry page, set the following parameters, and then click **OK**.

Parameter	Description
Public IP address	<p>Select an available public IP address.</p> <p> Note If a public IP address is already used in a SNAT entry, it cannot be used to create a DNAT entry.</p>
Private IP address	<p>Select the ECS instance that uses the DNAT entry to receive requests from the Internet. You can specify the private IP address of the target ECS instance in the following ways:</p> <ul style="list-style-type: none"> ◦ Auto Fill: select an ECS instance from the ECS instance or Elastic Network Interface (ENI) list. ◦ Manually Input: enter the private IP address of the target ECS instance. <p> Note The private IP address that you enter must fall in the range of the CIDR block or belong to an in-use ECS instance.</p>
Port Settings	<p>Select a DNAT mapping method:</p> <ul style="list-style-type: none"> ◦ All: This method uses IP mapping. All requests destined for the public IP address are forwarded to the target ECS instance. ◦ Specific Port: This method uses port mapping. The NAT gateway forwards requests from the specified protocol and port to the specified port of the target ECS instance. <p>After you select a specific port, specify Public Port (the external port for port mapping), Private Port (the internal port for port mapping), and IP Protocol (the protocol of the ports).</p>
Entry Name	<p>Enter a name for the DNAT entry.</p> <p>The name must be 2 to 128 characters in length and can contain digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.</p>

24.3.5. Create an SNAT entry

This topic describes how to create a Source Network Address Translation (SNAT) entry. You can create SNAT entries on the NAT gateway of a Virtual Private Cloud (VPC) network. Then, the Elastic Compute Service (ECS) instances without public IP addresses assigned in the VPC network can use the SNAT entries to access the Internet.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the NAT Gateways page, find the target NAT gateway and click **Configure SNAT** in the Actions column.
4. On the SNAT Table page, click **Create SNAT Entry**.

5. In the Create SNAT Entry dialog box, set the following parameters, and then click OK.

Parameter	Description
VSwitch Granularity	
VSwitch	<p>Select the VSwitch for which you want to create the SNAT entry in the associated VPC network. All ECS instances attached to the specified VSwitch can access the Internet by using the SNAT entry.</p> <p> Note SNAT entries do not take effect on ECS instances that are assigned public IP addresses. For example, an ECS instance may be assigned static public IP address, associated with an elastic IP address (EIP) or has a Destination Network Address Translation (DNAT) IP mapping configured. These ECS instances use the public IP addresses instead of the SNAT entries to access the Internet.</p>
VSwitch CIDR block	The CIDR block of the selected VSwitch.
Public IP address	<p>Select the public IP address that is used to access the Internet.</p> <p>You can select multiple public IP addresses to create an SNAT IP address pool.</p> <p> Note A public IP address that is already used in a DNAT entry cannot be used to create an SNAT entry.</p>
Entry name	<p>Enter a name for the SNAT entry.</p> <p>The name must be 2 to 128 characters in length and can contain digits, underscores (_), and hyphens (-). It must start with a letter or a Chinese character.</p>
ECS Granularity	
Available ECS Instances	<p>Select the ECS instance for which you want to create the SNAT entry in the associated VPC network.</p> <p>The selected ECS instance can access the Internet by using the specified public IP address. Make sure that the following conditions are met:</p> <ul style="list-style-type: none"> ◦ The ECS instance is in the running state. ◦ The ECS instance is not associated with an EIP or assigned a static public IP address.
ECS CIDR Block	Displays the CIDR block of the ECS instance.

Parameter	Description
Public IP address	<p>Select the public IP address that is used to access the Internet.</p> <p>You can select multiple public IP addresses to create an SNAT IP address pool.</p> <p>The maximum bandwidth for each public IP address in an SNAT IP address pool is 200 Mbit/s. To fully utilize the EIP bandwidth plan and avoid port conflicts caused by insufficient public IP addresses, note the following limits when you add public IP addresses to an SNAT entry:</p> <ul style="list-style-type: none"> ◦ If the maximum bandwidth of the EIP bandwidth plan is 1024 Mbit/s, add at least five public IP addresses to the SNAT entry. ◦ For each additional 200 Mbit/s of the peak bandwidth to the EIP bandwidth plan, at least one public IP address must be added to the SNAT entry. <p> Note A public IP address that is used in a DNAT entry cannot be used to create an SNAT entry.</p>
Entry Name	<p>Enter a name for the SNAT entry.</p> <p>The name must be 2 to 128 characters in length and can contain numbers, underscores (_), and hyphens (-). The name must start with a letter or Chinese character.</p>

24.4. Manage a NAT gateway

24.4.1. Sizes of NAT gateways

This topic describes the available sizes of Network Address Translation (NAT) gateways. The available sizes are Small, Middle, Large, and Super Large. The maximum number of SNAT connections and the number of SNAT connections per second (CPS) supported by a NAT gateway are determined by the size of NAT gateway. However, the size of a NAT gateway does not affect the performance of Destination Network Address Translation (DNAT).

Compare NAT gateway sizes

The following table lists different sizes of NAT gateways.

Size	Maximum number of SNAT connections	Number of SNAT CPS
Small	10,000	1,000
Middle	50,000	5,000
Large	200,000	10,000
Super Large	1,000,000	30,000

Limits

When you select a size for a NAT gateway, note the following limits:

- Cloud Monitor monitors only the maximum number of SNAT connections for NAT gateways. It does not monitor the number of new SNAT connections per second.
- The timeout of SNAT connections in a NAT gateway is 900 seconds.
- To avoid the timeout of SNAT connections caused by network congestion and Internet instability, make sure

that your applications support automatic reconnection. This ensures higher availability.

- NAT gateways do not support packet fragmentation.
- For the same destination public IP address and port, the number of EIPs associated with a NAT gateway determines the maximum number of connections. Each EIP associated with a NAT gateway supports up to 55,000 connections. If N EIPs are associated with the NAT gateway, the maximum number of connections that the NAT gateway supports is $N \times 55,000$.

24.4.2. Create a NAT gateway

A NAT gateway is an enterprise-class gateway that provides NAT proxy services. Before you configure SNAT and DNAT entries, you must create a NAT gateway.

Prerequisites

A VPC network is created. For more information, see *VPC User Guide* Create a VPC network in the Quick Start chapter in the VPC User Guide.

Procedure

1. [Log on to the NAT Gateway console](#).
2. On the NAT Gateway page, click **Create NAT Gateway**.
3. Set the parameters for the NAT gateway based on the following information, and then click **Submit**.

Parameter	Description
Organization	The organization to which the NAT gateway belongs.
Resource set	The resource set to which the NAT gateway belongs.
Region	The region where the NAT gateway is deployed.
VPC	<p>The VPC network to which the NAT gateway belongs.</p> <p>If you cannot find the target VPC network in the list, perform the following operations:</p> <ul style="list-style-type: none"> ◦ Check whether the VPC network is already associated with a NAT gateway. Each VPC network can be associated with only one NAT gateway. ◦ Check whether the VPC network has a custom route entry with the destination CIDR block set to 0.0.0.0/0. If such a custom route entry exists, delete it. ◦ Check whether the RAM user is authorized to access the VPC network. If the RAM user is not authorized, contact your Alibaba Cloud account owner to grant permissions.
Specification	<p>Select the size of the NAT gateway. Valid values:</p> <ul style="list-style-type: none"> ◦ Small: supports up to 10,000 SNAT connections. ◦ Medium: supports up to 50,000 SNAT connections. ◦ Large: supports up to 200,000 SNAT connections. ◦ Super Large: supports up to 1,000,000 SNAT connections. <p> Note The size of a NAT gateway determines the maximum number of SNAT connections, but it does not affect the maximum number of DNAT connections.</p>

Parameter	Description
Parameter	<p>Enter a name for the NAT gateway.</p> <p>The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character but cannot start with <code>http://</code> or <code>https://</code>.</p>

24.4.3. Modify a NAT gateway

This topic describes how to modify the name and description of a NAT gateway.

Procedure

1. [Log on to the NAT Gateway console](#).
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the NAT Gateway page, find the NAT gateway that you want to manage, and then click **Manage** in the **Actions** column.
4. On the **NAT Gateway Details** tab, click **Edit** next to the name. In the dialog box that appears, enter a new name for the NAT gateway, and then click **OK**. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.
5. Click **Edit** next to the description. In the dialog box that appears, enter a new description, and then click **OK**. The description must be 2 to 256 characters in length. It cannot start with `http://` or `https://`.

24.4.4. Delete a NAT gateway

You can delete NAT gateways that are billed on a pay-as-you-go basis. You cannot delete subscription NAT gateways.

Prerequisites

Before you delete a NAT gateway, make sure that the following conditions are met:

- The NAT gateway is not associated with an EIP. If the NAT gateway is associated with an EIP, disassociate the EIP first. For more information, see [Disassociate EIPs from a NAT gateway](#).
- The DNAT table is empty. If the DNAT table contains DNAT entries, delete these entries first. For more information, see [Delete a DNAT entry](#).
- The SNAT table is empty. If the DNAT table contains SNAT entries, delete these entries first. For more information, see [Delete a SNAT entry](#).

Procedure

1. [Log on to the NAT Gateway console](#).
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateways** page, find the target NAT gateway, and click  > **Delete** in the **Actions** column.
4. In the dialog box that appears, click **OK**.

 **Note** If you select **Delete (Delete NAT gateway and resources)**, the DNAT and SNAT entries of the NAT gateway are deleted automatically. The EIP associated with the NAT gateway is also disassociated.

24.5. Manage EIPs

24.5.1. Associate an EIP with a NAT gateway

This topic describes how to associate an EIP with a NAT gateway. NAT gateways must be associated with EIPs so that they can work as expected. After you create a NAT gateway, you can associate it with an EIP.

Prerequisites

Before you associate an EIP with a NAT gateway, make sure that the following conditions are met:

- A NAT gateway is created. For more information, see [Create a NAT Gateway](#).
- An EIP is purchased. For more information, see the [Create an Elastic IP address](#) topic of the [Quick start](#) document in the *EIP user guide*.

Context

You can associate an EIP or a NAT service plan with a NAT gateway. However, you can choose only one of them for the NAT gateway. If you want to associate a NAT service plan with a NAT gateway, you must purchase a NAT service plan first. Then, you can configure the SNAT or DNAT feature for the NAT gateway. For more information, see [Create a NAT service plan](#).

Procedure

1. [Log on to the NAT Gateway console](#).
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateways** page, find the NAT gateway, and choose  > **Bind Elastic IP Address** in the **Actions** column.
4. In the **Bind Elastic IP Address** dialog box, set the following parameters, and then click **OK**.

Parameter	Description
Usable EIP list	Select the EIP that is used to access the Internet.
VSwitch	Select the VSwitch for which you want to add SNAT entries. After a VSwitch is selected, the system automatically adds an SNAT entry so that Alibaba cloud services in the VSwitch can access the Internet. You can also skip this step and manually add SNAT entries after you associate an EIP with the NAT gateway. For more information, see Create a SNAT entry .

24.5.2. Disassociate an EIP from a NAT gateway

If your NAT gateway does not need to communicate with the Internet, you can disassociate the EIP from the NAT gateway.

Prerequisites

The EIP that you want to disassociate is not used in any SNAT or DNAT entries.

Procedure

1. [Log on to the NAT Gateway console](#).
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateways** page, find the NAT gateway, and choose  > **Unbind Elastic IP Address** in the **Actions** column.
4. In the **Unbind Elastic IP Address** dialog box, select the EIP that you want to disassociate, and click **OK**.

24.6. Manage a DNAT table

24.6.1. DNAT table overview

NAT Gateway supports the Destination Network Address Translation (DNAT) feature. You can create DNAT entries to map public IP addresses to ECS instances in a Virtual Private Cloud (VPC) network. This way, the ECS instances can receive requests from the Internet.

DNAT entries

You can configure port mapping when you create a DNAT entry. After the DNAT entry is created, requests destined for the specified public IP address are forwarded to the ECS instances within a VPC network based on the port mapping rule.

Each DNAT entry consists of the following elements:

- **Public IP address:** the EIP associated with the NAT gateway.
- **Private IP address:** the private IP address assigned to the ECS instance in the VPC network.
- **Public Port:** the external port where requests from the Internet are received.
- **Private Port:** the internal port to which the requests received on the external port are forwarded.
- **Protocol Type:** the protocol used by the ports.

Port mapping and IP mapping

The DNAT feature supports port mapping and IP mapping:

- **Port mapping**

After port mapping is configured, a NAT gateway forwards requests destined for a public IP address to the specified ECS instance based on the specified protocol and ports.

DNAT entry	Public IP address	Public port	Private IP address	Private port	Protocol type
Entry 1	139.224.xx.xx	80	192.168.x.x	80	TCP
Entry 2	139.224.xx.xx	8080	192.168.x.x	8000	UDP

Entry 1: The NAT gateway forwards requests destined for TCP port 80 of ECS instance 139.244.xx.xx to TCP port 80 of ECS instance 192.168.x.x.

Entry 2: The NAT gateway forwards requests destined for UDP port 8080 of ECS instance 139.224.xx.xx to UDP port 8000 of ECS instance 192.168.x.x.

- **IP mapping**

After IP mapping is configured, a NAT gateway forwards all requests destined for a public IP address to the specified ECS instance.

DNAT entry	Public IP address	Public port	Private IP address	Private port	Protocol type
Entry 3	139.224.xx.xx	Any	192.168.x.x	Any	Any

Entry 3: The NAT gateway forwards requests destined for ECS instance 139.224.xx.xx to ECS instance 192.168.x.x.

24.6.2. Create a DNAT entry

This topic describes how to create a Destination Network Address Translation (DNAT) entry. DNAT maps a public IP address to an Elastic Compute Service (ECS) instance in a Virtual Private Cloud (VPC) network. This allows the ECS instance to receive requests sent over the Internet. DNAT supports port mapping and IP mapping.

Prerequisites

A NAT gateway is created and associated with an elastic IP address (EIP). For more information, see [Create a NAT Gateway](#) and [Associate an EIP with a NAT Gateway](#).

Procedure

1. [Log on to the NAT Gateway console](#).
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateways** page, find the target NAT gateway, and click **Configure DNAT** in the **Actions** column.
4. On the **DNAT Table** page, click **Create DNAT Entry**.
5. On the **Create DNAT Entry** page, set the following parameters, and then click **OK**.

Parameter	Description
Public IP address	<p>Select an available public IP address.</p> <p> Note If a public IP address is already used in a SNAT entry, it cannot be used to create a DNAT entry.</p>
Private IP address	<p>Select the ECS instance that uses the DNAT entry to receive requests from the Internet. You can specify the private IP address of the target ECS instance in the following ways:</p> <ul style="list-style-type: none"> ◦ Auto Fill: select an ECS instance from the ECS instance or Elastic Network Interface (ENI) list. ◦ Manually Input: enter the private IP address of the target ECS instance. <p> Note The private IP address that you enter must fall in the range of the CIDR block or belong to an in-use ECS instance.</p>
Port Settings	<p>Select a DNAT mapping method:</p> <ul style="list-style-type: none"> ◦ All: This method uses IP mapping. All requests destined for the public IP address are forwarded to the target ECS instance. ◦ Specific Port: This method uses port mapping. The NAT gateway forwards requests from the specified protocol and port to the specified port of the target ECS instance. <p>After you select a specific port, specify Public Port (the external port for port mapping), Private Port (the internal port for port mapping), and IP Protocol (the protocol of the ports).</p>
Entry Name	<p>Enter a name for the DNAT entry.</p> <p>The name must be 2 to 128 characters in length and can contain digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.</p>

24.6.3. Modify a DNAT entry

This topic describes how to modify a Destination Network Address Translation (DNAT) entry. After you create a DNAT entry, you can modify the public IP address, private IP address, ports, and name of the DNAT entry.

Procedure

1. [Log on to the NAT Gateway console](#).
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateways** page, find the target NAT gateway, and click **Configure DNAT** in the **Actions** column.
4. On the **DNAT table** page, find the target DNAT entry, and click **Edit** in the **Actions** column.

5. In the **Edit DNAT Entry** dialog box, change the public IP address, private IP address, ports, and name of the DNAT entry, and then click **OK**.

24.6.4. Delete a DNAT entry

This topic describes how to delete a Destination Network Address Translation (DNAT) entry. If you no longer need an Elastic Compute Service (ECS) instance to receive requests sent over the Internet, you can delete the DNAT entry of the ECS instance.

Procedure

1. [Log on to the NAT Gateway console](#).
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateways** page, find the target NAT gateway, and click **Configure DNAT** in the **Actions** column.
4. On the **DNAT** table page, find the target DNAT entry, and click **Remove** in the **Actions** column.
5. In the dialog box that appears, click **OK**.

24.7. Manage an SNAT table

24.7.1. SNAT table overview

NAT Gateway supports Source Network Address Translation (SNAT). SNAT allows Elastic Compute Service (ECS) instances in a Virtual Private Cloud (VPC) network to access the Internet without using public IP addresses.

SNAT entries

You can create SNAT entries in an SNAT table to allow ECS instances to access the Internet.

An SNAT entry consists of the following elements:

- **VSwitch or ECS instance:** the VSwitch or ECS instance that requires the SNAT proxy service.
- **Public IP address:** the public IP address used to access the Internet.

VSwitch granularity and ECS granularity

SNAT entries can be created based on the following granularity to enable ECS instances in a VPC network to access the Internet.

- **VSwitch granularity**

You can select the VSwitch granularity to create an SNAT entry. The NAT gateway provides proxy service for an ECS instance attached to the specified VSwitch by using a specified public IP address when the instance sends requests to the Internet. By default, all ECS instances attached to the VSwitch can use the specified public IP address to access the Internet.

 **Note** SNAT entries do not take effect on ECS instances that are assigned public IP addresses. For example, an ECS instance may be assigned static public IP address, associated with an elastic IP address (EIP) or has a Destination Network Address Translation (DNAT) IP mapping configured. These ECS instances use the public IP addresses instead of the SNAT entries to access the Internet.

- **ECS granularity**

If you select the ECS granularity to create an SNAT entry, the specified ECS instance uses the specified public IP address to access the Internet. The NAT gateway provides proxy service (SNAT) for a specified ECS instance by using a specified public IP address when the instance sends requests to the Internet.

24.7.2. Create an SNAT entry

This topic describes how to create a Source Network Address Translation (SNAT) entry. SNAT allows Elastic Compute Service (ECS) instances in a Virtual Private Cloud (VPC) network to access the Internet without using public IP addresses.

Prerequisites

Before you create an SNAT entry, make sure that the following requirements are met:

- A NAT gateway is created and associated with an elastic IP address (EIP). For more information, see [Create a NAT Gateway](#) and [Associate an EIP with a NAT Gateway](#).
- To create an SNAT entry with VSwitch granularity, make sure that the VSwitch is created and associated with the NAT gateway in a VPC network.
- To create an SNAT entry with ECS granularity, make sure that the ECS instance is created and associated with the NAT gateway in a VPC network.

Procedure

1. [Log on to the NAT Gateway console](#).
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the NAT Gateway page, find the target NAT gateway and click **Configure SNAT** in the **Actions** column.
4. On the **SNAT Table** page, click **Create SNAT Entry**.
5. In the **Create SNAT Entry** dialog box, set the following parameters, and click **OK**.

Parameter	Description
VSwitch Granularity	
VSwitch	<p>Select the VSwitch for which you want to create the SNAT entry in the associated VPC network. All ECS instances attached to the VSwitch can access the Internet by using the SNAT entry.</p> <p> Note SNAT entries do not take effect on ECS instances that are assigned public IP addresses. For example, an ECS instance may be assigned a static public IP address, associated with an EIP, or configured with a Destination Network Address Translation (DNAT) IP mapping. Such an ECS instance uses the public IP address instead of the SNAT entry to access the Internet.</p>
VSwitch CIDR Block	The CIDR block of the selected VSwitch.
Public IP Address	<p>Select the public IP address that is used to access the Internet.</p> <p>You can select more than one public IP address to form a SNAT IP address pool.</p> <p> Note A public IP address that is already used in a DNAT entry cannot be used to create a SNAT entry.</p>
Entry Name	<p>Enter a name for the SNAT entry.</p> <p>The name must be 2 to 128 characters in length, and can contain digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.</p>
ECS Granularity	

Parameter	Description
Available ECS Instances	<p>Select the ECS instance for which you want to create the SNAT entry in the associated VPC network.</p> <p>The selected ECS instance can access the Internet by using the specified public IP address. Make sure that the following conditions are met:</p> <ul style="list-style-type: none"> ◦ The ECS instance is in the Running state. ◦ The ECS instance is not associated with an EIP or assigned a static public IP address.
ECS CIDR Block	The CIDR block of the ECS instance.
Public IP Address	<p>Select the public IP address that is used to access the Internet.</p> <p>You can select more than one public IP address to form a SNAT IP address pool.</p> <p>The maximum bandwidth for each public IP address in a SNAT IP address pool is 200 Mbit/s. To fully utilize the EIP bandwidth plan and avoid port conflicts caused by insufficient public IP addresses, add public IP addresses to the SNAT IP address pool based on the following rules:</p> <ul style="list-style-type: none"> ◦ If the maximum bandwidth of the EIP bandwidth plan is 1,024 Mbit/s, add at least five public IP addresses to the SNAT IP address pool. ◦ For each additional 200 Mbit/s added to the maximum bandwidth of the EIP bandwidth plan, add at least one public IP address to the SNAT IP address pool. <div style="background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> <p> Note A public IP address that is already used in a DNAT entry cannot be used to create a SNAT entry.</p> </div>
Entry Name	<p>Enter a name for the SNAT entry.</p> <p>The name must be 2 to 128 characters in length, and can contain digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.</p>

24.7.3. Modify an SNAT entry

This topic describes how to modify a Source Network Address Translation (SNAT) entry. After you create an SNAT entry, you can modify the public IP address and name of the SNAT entry.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the NAT Gateway page, find the target NAT gateway and click **Configure SNAT** in the **Actions** column.
4. On the SNAT table page, find the target SNAT entry, and click **Edit** in the **Actions** column.
5. In the **Edit SNAT Entry** dialog box, change the public IP address and name of the SNAT entry, and then click **OK**.

24.7.4. Delete a SNAT entry

This topic describes how to delete a Source Network Address Translation (SNAT) entry. You can delete the SNAT entry if the Elastic Compute Service (ECS) instances without public IP addresses in a Virtual Private Cloud (VPC) network no longer need the SNAT service to access the Internet.

Procedure

1. Log on to the NAT Gateway console.

2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the NAT Gateway page, find the target NAT gateway and click **Configure SNAT** in the **Actions** column.
4. On the SNAT table page, find the target SNAT entry, and click **Remove** in the **Actions** column.
5. In the dialog box that appears, click **OK**.

24.8. NAT service plan

24.8.1. Create a NAT service plan

You can associate an elastic IP address (EIP) or a NAT service plan to a NAT gateway. However, you can choose only one of them for the NAT gateway. If you want to associate a NAT service plan with the NAT gateway, you must create a NAT service plan first. Then, you can configure SNAT or DNAT for the NAT gateway. A NAT service plan consists of public IP addresses and Internet bandwidth.

Procedure

1. [Log on to the NAT Gateway console](#).
2. On the **NAT Gateways** page, find the target NAT gateway and choose **Purchase NAT Bandwidth Package** in the **Internet Shared Bandwidth** column.
3. On the **Bandwidth Package Details** page, click **Purchase**.
4. On the **NAT Bandwidth Package** page, set the following parameters, and click **Submit**.

Parameter	Description
Region	Indicates the region for which the NAT service plan is purchased.
Billing methods	Select the billing method of the NAT service plan. Only By Bandwidth is supported.
Bandwidth (Mbit/s)	Enter a bandwidth value for the NAT service plan that you want to purchase. The maximum value is 5000 Mbit/s.
Name	Enter a name for the NAT service plan. The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.
Description	Enter a description for the NAT service plan. The description must be 2 to 256 characters in length and cannot start with <code>http://</code> or <code>https://</code> .
Quantity	Enter the number of NAT bandwidth plans that you want to purchase.

24.8.2. Modify the bandwidth of a NAT service plan

This topic describes how to modify the bandwidth of a NAT bandwidth plan. The modification takes effect immediately.

Procedure

1. [Log on to the NAT Gateway console](#).
2. On the **NAT Gateways** page, find the target NAT gateway and click the ID of the NAT service plan in the **Internet Shared Bandwidth** column.

3. On the **Bandwidth Package Details** page, click the target NAT service plan, and then choose **Modify Bandwidth**.
4. On the **Modify Bandwidth** page, modify the bandwidth, and then click **Submit**. Each NAT bandwidth plan supports a maximum of 5,000 Mbit/s in bandwidth.

24.8.3. Add an IP address

This topic describes how to add IP addresses to a NAT service plan. The added IP addresses can be used to create Source Network Address Translation (SNAT) and Destination Network Address Translation (DNAT) rules.

Procedure

1. [Log on to the NAT Gateway console](#).
2. On the **NAT Gateways** page, find the target NAT gateway and click the ID of the NAT service plan in the **Internet Shared Bandwidth** column.
3. On the **Bandwidth Package Details** page, click the target NAT service plan, and then choose **Add IP Address**.
4. On the **Modify IP Addresses** page, enter the number of IP addresses to be added, and then click **Submit**.

24.8.4. Release an IP address

This topic describes how to release IP addresses in a NAT service plan. The NAT service plan must contain at least one IP address.

Prerequisites

Before you release an IP address in the NAT service plan, make sure that the IP address is not used in Source Network Address Translation (SNAT) and Destination Network Address Translation (DNAT) entries. If the IP address is used in an SNAT or DNAT entry, delete the SNAT or DNAT entry first. For more information, see [Delete a DNAT entry](#) and [Delete a SNAT entry](#).

Procedure

1. [Log on to the NAT Gateway console](#).
2. On the **NAT Gateways** page, find the target NAT gateway and click the ID of the NAT service plan in the **Internet Shared Bandwidth** column.
3. On the **Bandwidth Package Details** page, click the target NAT service plan.
4. In the **Public IP List** section, find the target IP address, and click **Release** in the **Actions** column.
5. In the **Release IP** dialog box, click **OK**.

24.8.5. Delete a NAT service plan

This topic describes how to delete a service plan.

Prerequisites

Before you start, make sure that the following requirements are met:

- Delete the IP addresses that are used in Destination Network Address Translation (DNAT) entries. For more information, see [Delete a DNAT entry](#).
- Delete the IP addresses that are used for Source Network Address Translation (SNAT) entries. For more information, see [Delete a SNAT entry](#).

Procedure

1. [Log on to the NAT Gateway console](#).
2. On the **NAT Gateways** page, find the target NAT gateway and click the ID of the NAT service plan in the **Internet Shared Bandwidth** column.

3. On the **Bandwidth Package Details** page, find the target NAT service plan and click **Delete**.
4. In the **Delete Shared Internet Shared Bandwidth** dialog box, click **OK**.

24.9. Anti-DDoS Basic

Distributed Denial of Service (DDoS) attack is a malicious network attack against the target system, which can make the attacked network inaccessible. Alibaba Cloud provides up to 5 Gbit/s of basic anti-DDoS protection for NAT Gateway, which can efficiently prevent DDoS attack.

How Anti-DDoS Basic works

After you enable Anti-DDoS Basic, all traffic from the Internet must first pass through Alibaba Cloud Security before arriving at NAT Gateway. Anti-DDoS Basic scrubs and filters common DDoS attacks at Alibaba Cloud Security. Anti-DDoS Basic protects your services against attacks such as SYN flood, UDP flood, ACK flood, ICMP flood, and DNS Query flood.

Anti-DDoS Basic sets the scrubbing threshold and black hole triggering threshold based on the EIP bandwidth of NAT Gateway. When the inbound traffic reaches the threshold, scrubbing or blackholing is triggered:

- **Scrubbing:** When the attack traffic from the Internet exceeds the scrubbing threshold or matches certain attack traffic pattern, Alibaba Cloud Security starts scrubbing the attack traffic. The scrubbing includes packet filtering, bandwidth capping, and traffic throttling.
- **Blackholing:** When the attack traffic from the Internet exceeds the black hole triggering threshold, blackholing is triggered and all inbound traffic is dropped.

Scrubbing threshold

The thresholds for triggering traffic scrubbing and blackholing on NAT Gateway are calculated as described in the following table:

EIP bandwidth	Traffic scrubbing threshold (bits/s)	Traffic scrubbing threshold (packets/s)	Default black hole triggering threshold
Lower than or equal to 800 Mbit/s	800Mbps	120,000	1.5 Gbps
Higher than 800 Mbit/s	Predefined bandwidth	Predefined bandwidth × 150	Predefined bandwidth × 2

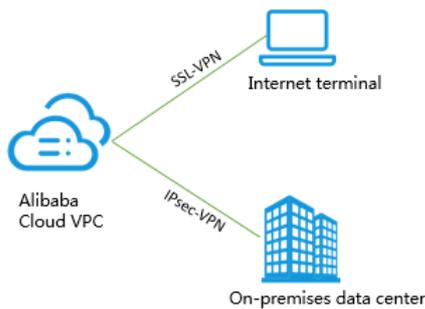

If the EIP bandwidth is 1,000 Mbit/s, the traffic scrubbing threshold (bits/s) is 1,000 Mbit/s, the traffic scrubbing threshold (packets/s) is 150,000 and the default blackholing threshold is 2 Gbit/s.

25.VPN Gateway

25.1. What is VPN Gateway?

VPN Gateway is an Internet-based service that allows you to connect enterprise data centers, office networks, or Internet-facing terminals to Alibaba Cloud Virtual Private Cloud (VPC) networks through secure and reliable connections. VPN Gateway supports both IPsec-VPN connections and SSL-VPN connections.

 **Note** The Alibaba Cloud VPN Gateway service complies with the local regulations and policies. VPN Gateway does not provide Internet access services.

Features

VPN Gateway supports the following features:

- IPsec-VPN

Route-based IPsec-VPN allows you to route network traffic in multiple ways, and also facilitates the configuration and maintenance of VPN policies.

You can use IPsec-VPN to connect an on-premises data center to a VPC network or connect two VPC networks. IPsec-VPN supports the IKEv1 and IKEv2 protocols. Any devices that support these two protocols can connect to Alibaba Cloud VPN Gateway, such as devices manufactured by Huawei, H3C, Hillstone, Sangfor, Cisco ASA, Juniper, SonicWall, Nokia, IBM, and Ixia.

- SSL-VPN

SSL-VPN is implemented based on the OpenVPN framework. You can create an SSL-VPN connection to connect a remote client to applications and services deployed in a VPC network. After you deploy your applications or services, you only need to import the certificate to the client to initiate a connection.

Benefits

VPN Gateway offers the following benefits:

- **High security:** You can use the IKE and IPsec protocols to encrypt data for secure and reliable data transmission.
- **High availability:** VPN Gateway adopts the hot-standby architecture to achieve failover within a few seconds, session persistence, and zero service downtime.
- **Cost-effectiveness:** The encrypted Internet connections provided by VPN Gateway are more cost-effective than leased lines.
- **Ease of use:** VPN Gateway is a ready-to-use service. VPN gateways start to work immediately after they are deployed.

25.2. Log on to the VPN Gateway console

This topic describes how to use Google Chrome to log on to the VPN Gateway console in Apsara Stack Cloud Management (ASCM).

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
2. Enter your username and password.

Obtain the username and password used to log on to the console from the operations administrator.

Note When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:

- Uppercase or lowercase letters.
- Digits.
- Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Products > Networking > VPN Gateway**.

25.3. Get started with IPsec-VPN

25.3.1. Connect on-premises data centers to VPC networks

This topic describes how to create IPsec-VPN connections on VPN gateways to connect an on-premises data center to a Virtual Private Cloud (VPC) network.

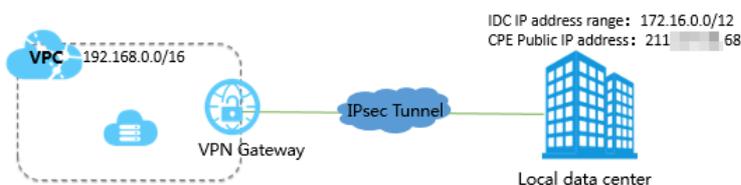

Prerequisites

Before you start, make sure that the following requirements are met:

- Check the gateway device in the on-premises data center. Alibaba Cloud VPN gateways support the standard IKEv1 and IKEv2 protocols. Any gateway device that supports these two protocols can connect to Alibaba Cloud VPN gateways, such as gateway devices manufactured by Huawei, H3C, Hillstone, Sangfor, Cisco ASA, Juniper, SonicWall, Nokia, IBM, and Ixia.
- Make sure that you have set a static public IP address for the gateway device in the on-premises data center.
- The CIDR block of the on-premises data center must not overlap with that of the VPC network.

Context

For example, a company creates a VPC network on Alibaba Cloud. The CIDR block of the VPC network is 192.168.0.0/16. The CIDR block of the on-premises data center is 172.16.0.0/12. The static public IP address for the gateway device in the on-premises data center is 211.xx.xx.68. To meet business requirements, the company needs to connect the on-premises data center to the VPC network.

The preceding figure displays that the on-premises data center is connected to the VPC network through IPsec-VPN. Cloud resources can be shared with on-premises data centers.

Step 1: Create a VPN gateway

Take the following steps to create a VPN gateway:

1. **Log on to the VPN Gateway console.**
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. On the **VPN Gateways** page, click **Create VPN Gateway**.
4. On the **Create VPN Gateway** page, set the following parameters for the VPN gateway, and then click **Submit**.
 - **Organization:** Select the organization to which the VPN gateway belongs.
 - **Resource Set:** Select the resource set to which the VPN gateway belongs.
 - **Region:** Select the region where you want to deploy the VPN gateway.

 **Note** Make sure that the VPC network and the VPN gateway associated with the VPC network are deployed in the same region.

- **Name:** Enter a name for the VPN gateway.
The name must be 2 to 128 characters in length, and can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter or Chinese character and cannot start with `http://` or `https://`.
- **VPC:** Select the VPC network to be associated with the VPN gateway.
- **Bandwidth:** Specify the maximum bandwidth of the VPN gateway. The bandwidth is provided for data transfer over the Internet.
- **IPsec-VPN:** Specify whether to enable IPsec-VPN for the VPN gateway. In this example, select **Enable**.
After IPsec-VPN is enabled, you can create IPsec-VPN connections between an on-premises data center and a VPC network, or between two VPC networks.
- **SSL-VPN:** Specify whether to enable SSL-VPN. In this example, select **Disable**.
SSL-VPN connections are point-to-site connections. SSL-VPN allows you to connect a client to Alibaba Cloud without configuring a customer gateway.
- **SSL Connections:** Specify the maximum number of concurrent SSL connections that the VPN gateway supports.

 **Note** This parameter is available only after SSL-VPN is enabled.

5. Go to the **VPN Gateways** page to view the newly created VPN gateway. The newly created VPN gateway is in the **Preparing** state. Its status changes to **Normal** after about two minutes. The **Normal** state indicates that the VPN gateway is initialized and ready for use.

 **Note** It takes about one to five minutes to create a VPN gateway.

Step 2: Create a customer gateway

Take the following steps to create a customer gateway.

1. In the left-side navigation pane, choose **VPN > Customer Gateways**.
2. Select the region where you want to deploy the customer gateway
3. On the **Customer Gateways** page, click **Create Customer Gateway**.
4. On the **Create Customer Gateway** page, set the following parameters, and click **Submit**.
 - **Organization:** Select the organization to which the customer gateway belongs.

- **Resource Set:** Select the resource set to which the customer gateway belongs.
- **Region:** Select the region where you want to deploy the customer gateway.

 **Note** Make sure that the customer gateway and the VPN gateway to be connected are deployed in the same region.

- **Zone:** Select the zone where you want to deploy the customer gateway.
- **Name:** Enter a name for the customer gateway.
The name must be 2 to 128 characters in length, and can contain letters, digits, hyphens (-), and underscores (_). It must start with a letter or Chinese character and cannot start with `http://` or `https://`.
- **IP Address:** Enter the public IP address of the gateway device in the on-premises data center that is to be connected to the VPC network. In this example, enter `211.xx.xx.68`.
- **Description:** Enter a description for the customer gateway.
The description must be 2 to 256 characters in length, and cannot start with `http://` or `https://`.

Step 3: Create an IPsec-VPN connection

Take the following steps to create an IPsec-VPN connection:

1. In the left-side navigation pane, choose **VPN > IPsec Connections**.
2. Select the region where you want to create an IPsec-VPN connection.
3. On the IPsec Connections page, click **Create IPsec Connection**.
4. On the **Create IPsec Connection** page, set the following parameters for the IPsec-VPN connection, and click **Submit**.
 - **Organization:** Select the organization to which the IPsec-VPN connection belongs.
 - **Resource Set:** Select the resource set to which the IPsec-VPN connection belongs.
 - **Region:** Select the region where the IPsec-VPN connection is established.
 - **Zone:** Select the zone where the IPsec-VPN connection is established.
 - **Name:** Enter a name for the IPsec-VPN connection.
 - **VPN Gateway:** Select a VPN gateway.
 - **Customer Gateway:** Select the customer gateway to be connected through the IPsec-VPN connection.
 - **Source CIDR Block:** Enter the CIDR block of the VPC network with which the selected VPN gateway is associated. In this example, enter `192.168.0.0/16`.
 - **Destination CIDR Block:** Enter the CIDR block of the on-premises data center. In this example, enter `172.16.0.0/12`.
 - **Immediate Effect:** Specify whether to start connection negotiations immediately.
 - **Yes:** negotiate immediately after the configuration is complete.
 - **No:** negotiate when traffic is detected in the IPsec-VPN connection.
 - **Pre-shared Key:** Enter the pre-shared key. The pre-shared key must be the same as that of the gateway device deployed in the on-premises data center.
Use the default settings for other parameters.

Step 4: Load the configurations of the IPsec-VPN connection to the customer gateway device

Take the following steps to load the configurations of the IPsec-VPN connection to the customer gateway device:

1. In the left-side navigation pane, choose **VPN > IPsec Connections**.

2. Select the region where the IPsec-VPN connection is established.
3. On the IPsec Connections page, find the target IPsec-VPN connection, and then choose **More > Download Configuration** in the **Actions** column.
4. Load the configurations of the IPsec-VPN connection to the customer gateway device by following the instructions described in . For more information about how to configure customer gateways, consult the manufacturers of the gateway devices. **RemotSubnet** and **LocalSubnet** in the downloaded configurations are opposite to **RemotSubnet** and **LocalSubnet** that you specify when you create an IPsec-VPN connection. For a VPN gateway, **RemotSubnet** refers to the CIDR block of the on-premises data center and **LocalSubnet** refers to the CIDR block of the VPC network. For a customer gateway, **LocalSubnet** refers to the CIDR block of the on-premises data center and **RemoteSubnet** refers to the CIDR block of the VPC network.

Step 5: Configure routes for the VPN gateway

Take the following steps to configure routes for the VPN gateway:

1. In the left-side navigation pane, choose **VPN > VPN Gateways**.
2. Select the region where the VPN gateway is deployed.
3. On the **VPN Gateways** page, find the target VPN gateway, and then click the instance ID in the **Instance ID/Name** column.
4. In the **Destination-based routing** tab, click **Add Route Entry**.
5. In the **Add Route Entry** dialog box, set the following parameters and click **OK**.
 - **Destination CIDR Block:** Enter the CIDR block of the on-premises data center. In this example, enter **172.16.0.0/12**.
 - **Next Hop Type:** Select **IPsec Connection**.
 - **Next Hop:** Select an IPsec instance.
 - **Publish to VPC:** Specify whether to automatically publish new route entries to the VPC route table. In this example, select **Yes**.
 - **Weight:** Select a weight. In this example, select **100**.

Step 6: Verify the settings

Log on to an Elastic Compute Service (ECS) instance that is not assigned a public IP address in the VPC network. Run the **ping** command to ping the private IP address of a server that resides in the on-premises data center, and test the connectivity.

25.4. Get started with SSL-VPN

25.4.1. Initiate a connection from a Linux client

This topic describes how to use SSL-VPN to connect a Linux client to a Virtual Private Cloud (VPC) network.

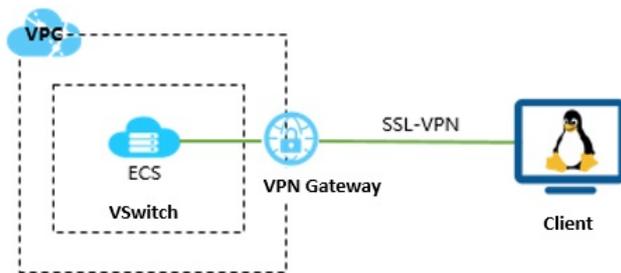

Prerequisites

Before you start, make sure that the following requirements are met:

- The CIDR block of the VPC network must not overlap with that of the client. Otherwise, the client cannot communicate with the VPC network.
- The client must be able to access the Internet.

Context

The following scenario is used as an example.

Step 1: Create a VPN gateway

Take the following steps to create a VPN gateway.

1. [Log on to the VPN Gateway console.](#)
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. On the **VPN Gateways** page, click **Create VPN Gateway**.
4. On the **Create VPN Gateway** page, specify the following parameters for the VPN gateway, and then click **Submit**.

- **Organization:** Select the organization to which the VPN gateway belongs.
- **Resource Set:** Select the resource set to which the VPN gateway belongs.
- **Region:** Select the region where the VPN gateway is deployed.

Note Make sure that the VPC network and the VPN gateway associated with the VPC network are deployed in the same region.

- **Instance Name:** Enter a name for the VPN gateway.
The name must be 2 to 128 characters in length, and can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter or Chinese character, and cannot start with `http://` or `https://`.
 - **VPC:** Select the VPC network to be associated with the VPN gateway.
 - **Bandwidth:** Specify the maximum bandwidth of the VPN gateway. The bandwidth is provided for data transfer over the Internet.
 - **IPsec-VPN:** Specify whether to enable IPsec-VPN for the VPN gateway. In this example, select **Disable**.
 - **SSL-VPN:** Specify whether to enable SSL-VPN for the VPN gateway. In this example, select **Enable**.
SSL-VPN connections are point-to-site connections. SSL-VPN allows you to connect a client to Alibaba Cloud without configuring a gateway for the client.
 - **SSL Connections:** Specify the maximum number of concurrent SSL connections that the VPN gateway supports.
5. Go to the **VPN Gateways** page to view the newly created VPN gateway. The newly created VPN gateway is in the **Preparing** state. Its status changes to **Normal** after about two minutes. The **Normal** status indicates that the VPN gateway is initialized and ready for use.

Note It takes about one to five minutes to create a VPN gateway.

Step 2: Create an SSL server

Take the following steps to create an SSL server.

1. In the left-side navigation pane, choose **VPN > SSL Servers**.
2. Select the region where you want to create the SSL server.

3. On the **SSL Servers** page, click **Create SSL Server**.
4. On the **Create SSL Server** page, set the following parameters for the SSL server, and then click **Submit**.
 - **Organization:** Select the organization to which the SSL server belongs.
 - **Resource Set:** Select the resource set to which the SSL server belongs.
 - **Region:** Select the region where you want to deploy the SSL server.
 - **Zone:** Select the zone where you want to deploy the SSL server.
 - **Name:** Enter a name for the SSL server.
 - **VPN Gateway:** Select a VPN gateway from the drop-down list.
 - **Source CIDR Block:** Enter the CIDR block of the VPC network. Click **+Add Local Network** to add more CIDR blocks. You can add the CIDR block of a VPC network, a VSwitch, and a local network.
 - **Client CIDR Block:** Enter the CIDR block of the client. The client connects to the SSL server from the specified CIDR block.
 - **Advanced Settings:** Specify whether to customize the advanced settings. In this topic, the default settings are used.

Step 3: Create and download an SSL client certificate

Take the following steps to create and download an SSL client certificate.

1. In the left-side navigation pane, choose **VPN > SSL Clients**.
2. Select the region where the client is created.
3. On the **SSL Clients** page, click **Create Client Certificate**.
4. On the **Create SSL Client Certificate** page, set the following parameters for the SSL client, and then click **Submit**.
 - **Organization:** Select the organization to which the SSL client certificate belongs.
 - **Resource Set:** Select the resource set to which the SSL client certificate belongs.
 - **Region:** Select the region where you want to create the SSL client certificate.
 - **Zone:** Select the zone where you want to create the SSL client certificate.
 - **Name:** Enter a name for the SSL client certificate.
 - **VPN Gateway:** Select the VPN gateway to be associated with the SSL client certificate.
 - **SSL Server:** Select the SSL server to which you want to import the SSL client certificate.
5. On the **SSL Clients** page, find the target SSL client certificate, and then click **Download** in the **Actions** column.

Step 4: Configure the client

Take the following steps to configure the Linux client:

1. Run the following command to install the OpenVPN:

```
yum install -y openvpn
```

2. Decompress the client certificate package that you downloaded in Step 3 and copy the client certificate file to the `/etc/openvpn/conf/` folder where OpenVPN is installed.
3. Run the following command to launch OpenVPN:

```
openvpn --config /etc/openvpn/conf/config.ovpn --daemon
```

Step 5: Test the connectivity

To test the connectivity, run the `ping` command to ping the connected ECS instance in the VPC network.

Note Make sure that the security group rules of the ECS instance allow remote access from Linux clients.

25.4.2. Initiate a connection from a Windows client

This topic describes how to use SSL-VPN to connect a Windows client to a Virtual Private Cloud (VPC) network.

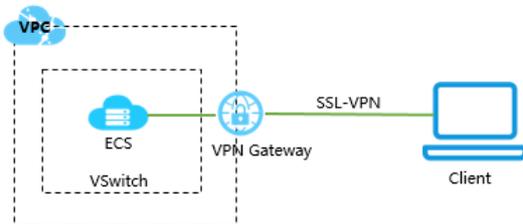

Prerequisites

Before you start, make sure that the following requirements are met:

- The CIDR block of the VPC network must not overlap with that of the client. Otherwise, the client cannot communicate with the VPC network.
- The client must be able to access the Internet.

Context

The following scenario is used as an example.

Step 1: Create a VPN gateway

Take the following steps to create a VPN gateway.

1. [Log on to the VPN Gateway console](#).
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. On the **VPN Gateways** page, click **Create VPN Gateway**.
4. On the **Create VPN Gateway** page, specify the following parameters for the VPN gateway, and then click **Submit**.
 - **Organization:** Select the organization to which the VPN gateway belongs.
 - **Resource Set:** Select the resource set to which the VPN gateway belongs.
 - **Region:** Select the region where the VPN gateway is deployed.

Note Make sure that the VPC network and the VPN gateway associated with the VPC network are deployed in the same region.

- **Instance Name:** Enter a name for the VPN gateway.

The name must be 2 to 128 characters in length, and can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter or Chinese character, and cannot start with `http://` or `https://`.

- **VPC:** Select the VPC network to be associated with the VPN gateway.
- **Bandwidth:** Specify the maximum bandwidth of the VPN gateway. The bandwidth is provided for data transfer over the Internet.
- **IPsec-VPN:** Specify whether to enable IPsec-VPN for the VPN gateway. In this example, select **Disable**.
- **SSL-VPN:** Specify whether to enable SSL-VPN for the VPN gateway. In this example, select **Enable**.

SSL-VPN connections are point-to-site connections. SSL-VPN allows you to connect a client to Alibaba Cloud without configuring a gateway for the client.

- **SSL Connections:** Specify the maximum number of concurrent SSL connections that the VPN gateway supports.
- 5. Go to the VPN Gateways page to view the newly created VPN gateway. The newly created VPN gateway is in the Preparing state. Its status changes to Normal after about two minutes. The Normal status indicates that the VPN gateway is initialized and ready for use.

 **Note** It takes about one to five minutes to create a VPN gateway.

Step 2: Create an SSL server

Take the following steps to create an SSL server.

1. In the left-side navigation pane, choose **VPN > SSL Servers**.
2. Select the region where you want to create the SSL server.
3. On the **SSL Servers** page, click **Create SSL Server**.
4. On the **Create SSL Server** page, set the following parameters for the SSL server, and then click **Submit**.
 - **Organization:** Select the organization to which the SSL server belongs.
 - **Resource Set:** Select the resource set to which the SSL server belongs.
 - **Region:** Select the region where you want to deploy the SSL server.
 - **Zone:** Select the zone where you want to deploy the SSL server.
 - **Name:** Enter a name for the SSL server.
 - **VPN Gateway:** Select a VPN gateway from the drop-down list.
 - **Source CIDR Block:** Enter the CIDR block of the VPC network. Click **+Add Local Network** to add more CIDR blocks. You can add the CIDR block of a VPC network, a VSwitch, and a local network.
 - **Client CIDR Block:** Enter the CIDR block of the client. The client connects to the SSL server from the specified CIDR block.
 - **Advanced Settings:** Specify whether to customize the advanced settings. In this topic, the default settings are used.

Step 3: Create and download an SSL client certificate

Take the following steps to create and download an SSL client certificate.

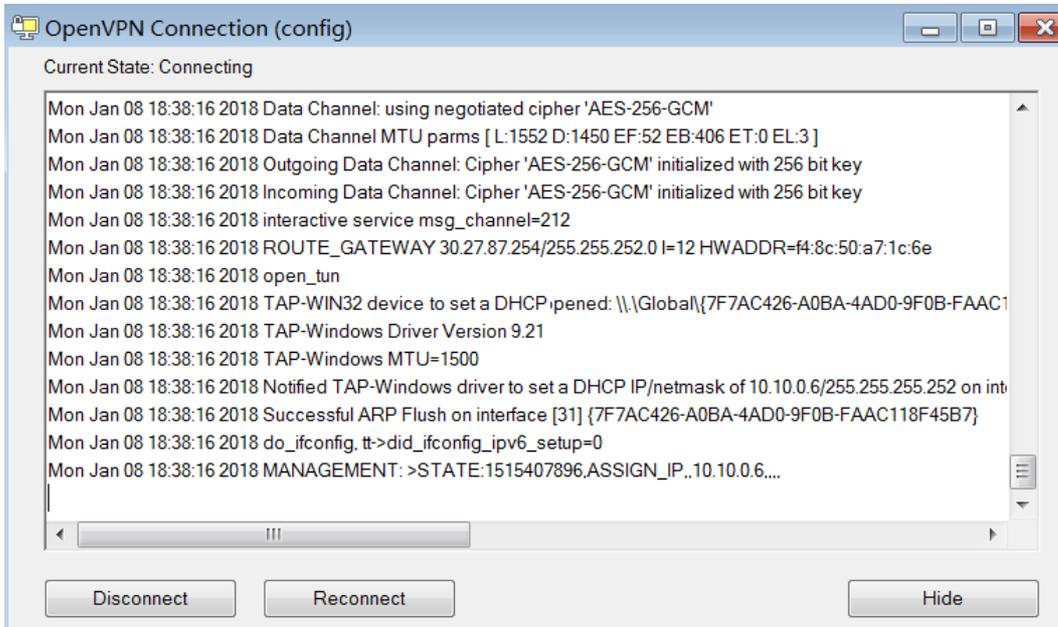

1. In the left-side navigation pane, choose **VPN > SSL Clients**.
2. Select the region where the client is created.
3. On the **SSL Clients** page, click **Create Client Certificate**.
4. On the **Create SSL Client Certificate** page, set the following parameters for the SSL client, and then click **Submit**.
 - **Organization:** Select the organization to which the SSL client certificate belongs.
 - **Resource Set:** Select the resource set to which the SSL client certificate belongs.
 - **Region:** Select the region where you want to create the SSL client certificate.
 - **Zone:** Select the zone where you want to create the SSL client certificate.
 - **Name:** Enter a name for the SSL client certificate.
 - **VPN Gateway:** Select the VPN gateway to be associated with the SSL client certificate.
 - **SSL Server:** Select the SSL server to which you want to import the SSL client certificate.
5. On the **SSL Clients** page, find the target SSL client certificate, and then click **Download** in the **Actions** column.

Step 4: Configure the client

Take the following steps to configure the Windows client:

Notice You must run the client as an administrator.

1. Download and install OpenVPN.
2. Decompress the client certificate package that you downloaded in Step 3 and copy the client certificate file to the *config* folder where OpenVPN is installed.
3. Click **Connect** to initiate a connection.

Step 5: Test the connectivity

To test the connectivity, run the ping command to ping the connected ECS instance in the VPC network.

Note Make sure that the security group rules of the ECS instance allow remote access from Linux clients.

25.4.3. Initiate a connection from a macOS client

This topic describes how to use SSL-VPN to connect a macOS client to a Virtual Private Cloud (VPC) network.

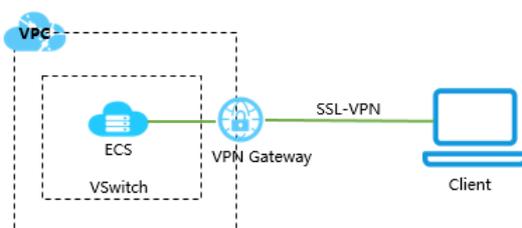

Prerequisites

Before you start, make sure that the following requirements are met:

- The CIDR block of the VPC network must not overlap with that of the client. Otherwise, the client cannot communicate with the VPC network.
- The client must be able to access the Internet.

Context

The following scenario is used as an example.

Step 1: Create a VPN gateway

Take the following steps to create a VPN gateway.

1. [Log on to the VPN Gateway console](#).
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. On the **VPN Gateways** page, click **Create VPN Gateway**.
4. On the **Create VPN Gateway** page, specify the following parameters for the VPN gateway, and then click **Submit**.
 - **Organization:** Select the organization to which the VPN gateway belongs.
 - **Resource Set:** Select the resource set to which the VPN gateway belongs.
 - **Region:** Select the region where the VPN gateway is deployed.

 **Note** Make sure that the VPC network and the VPN gateway associated with the VPC network are deployed in the same region.

- **Instance Name:** Enter a name for the VPN gateway.
The name must be 2 to 128 characters in length, and can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter or Chinese character, and cannot start with `http://` or `https://`.
 - **VPC:** Select the VPC network to be associated with the VPN gateway.
 - **Bandwidth:** Specify the maximum bandwidth of the VPN gateway. The bandwidth is provided for data transfer over the Internet.
 - **IPsec-VPN:** Specify whether to enable IPsec-VPN for the VPN gateway. In this example, select **Disable**.
 - **SSL-VPN:** Specify whether to enable SSL-VPN for the VPN gateway. In this example, select **Enable**.
SSL-VPN connections are point-to-site connections. SSL-VPN allows you to connect a client to Alibaba Cloud without configuring a gateway for the client.
 - **SSL Connections:** Specify the maximum number of concurrent SSL connections that the VPN gateway supports.
5. Go to the **VPN Gateways** page to view the newly created VPN gateway. The newly created VPN gateway is in the **Preparing** state. Its status changes to **Normal** after about two minutes. The **Normal** status indicates that the VPN gateway is initialized and ready for use.

 **Note** It takes about one to five minutes to create a VPN gateway.

Step 2: Create an SSL server

Take the following steps to create an SSL server.

1. In the left-side navigation pane, choose **VPN > SSL Servers**.
2. Select the region where you want to create the SSL server.
3. On the **SSL Servers** page, click **Create SSL Server**.
4. On the **Create SSL Server** page, set the following parameters for the SSL server, and then click **Submit**.
 - **Organization:** Select the organization to which the SSL server belongs.
 - **Resource Set:** Select the resource set to which the SSL server belongs.
 - **Region:** Select the region where you want to deploy the SSL server.
 - **Zone:** Select the zone where you want to deploy the SSL server.
 - **Name:** Enter a name for the SSL server.
 - **VPN Gateway:** Select a VPN gateway from the drop-down list.
 - **Source CIDR Block:** Enter the CIDR block of the VPC network. Click **+Add Local Network** to add more CIDR

blocks. You can add the CIDR block of a VPC network, a VSwitch, and a local network.

- **Client CIDR Block:** Enter the CIDR block of the client. The client connects to the SSL server from the specified CIDR block.
- **Advanced Settings:** Specify whether to customize the advanced settings. In this topic, the default settings are used.

Step 3: Create and download an SSL client certificate

Take the following steps to create and download an SSL client certificate.

1. In the left-side navigation pane, choose **VPN > SSL Clients**.
2. Select the region where the client is created.
3. On the **SSL Clients** page, click **Create Client Certificate**.
4. On the **Create SSL Client Certificate** page, set the following parameters for the SSL client, and then click **Submit**.
 - **Organization:** Select the organization to which the SSL client certificate belongs.
 - **Resource Set:** Select the resource set to which the SSL client certificate belongs.
 - **Region:** Select the region where you want to create the SSL client certificate.
 - **Zone:** Select the zone where you want to create the SSL client certificate.
 - **Name:** Enter a name for the SSL client certificate.
 - **VPN Gateway:** Select the VPN gateway to be associated with the SSL client certificate.
 - **SSL Server:** Select the SSL server to which you want to import the SSL client certificate.
5. On the **SSL Clients** page, find the target SSL client certificate, and then click **Download** in the **Actions** column.

Step 4: Configure the client

Take the following steps to configure the macOS client:

1. Run the following command to install OpenVPN:

```
brew install openvpn
```

 **Note** If Homebrew is not installed, install Homebrew first.

2. Decompress the client certificate package that you downloaded in Step 3, copy the client certificate file to the folder where OpenVPN is installed, and initiate a connection.

- i. Back up the default configuration file.
- ii. Run the following command to delete the default configuration file:

```
rm /usr/local/etc/openvpn/*
```

- iii. Run the following command to copy the file to the configuration directory:

```
cp cert_location /usr/local/etc/openvpn/
```

In the preceding command, `cert_location` represents the path that stores the certificate downloaded in Step 3, for example, `/Users/example/Downloads/certs6.zip`.

- iv. Run the following command to decompress the client certificate package:

```
cd /usr/local/certificates
unzip /usr/local/etc/openvpn/certs6.zip
```

v. Run the following command to initiate a connection:

```
sudo /usr/local/opt/openssh/sbin/ssh-keygen --config /usr/local/etc/ssh/sshd_config
```

Step 5: Test the connectivity

To test the connectivity, run the ping command to ping the connected ECS instance in the VPC network.

 **Note** Make sure that the security group rules of the ECS instance allow remote access from Linux clients.

25.5. Manage a VPN Gateway

25.5.1. Create a VPN gateway

This topic describes how to create a VPN gateway. You must create a VPN gateway before you can use the IPsec-VPN and SSL-VPN services. After the VPN gateway is created, a public IP address is assigned to the VPN gateway.

Procedure

1. [Log on to the VPN Gateway console](#).
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. On the **VPN Gateways** page, click **Create VPN Gateway**.
4. On the **Create VPN** page, specify the following parameters for the VPN gateway, and then click **Submit**.

Parameter	Description
Organization	Select the organization to which the VPN gateway belongs.
Resource Set	Select the resource set to which the VPN gateway belongs.
Region	Select the region where the VPN gateway is deployed. You can use IPsec-VPN to connect an on-premises data center to a VPC network or connect two VPC networks. Make sure that the VPC network and the VPN gateway associated with the VPC network are deployed in the same region.
Instance Name	Enter a name for the VPN gateway. The name must be 2 to 128 characters in length, and can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter or Chinese character and cannot start with <code>http://</code> or <code>https://</code> .
VPC	Select the VPC network to be associated with the VPN gateway.
Bandwidth	Specify the maximum bandwidth of the VPN gateway. The bandwidth is provided for data transfer over the Internet.
IPsec-VPN	Specify whether to enable IPsec-VPN for the VPN gateway. After IPsec-VPN is enabled, you can create IPsec-VPN connections between an on-premises data center and a VPC network, or between two VPC networks.
SSL-VPN	Specify whether to enable SSL-VPN for the VPN gateway. SSL-VPN connections are point-to-site connections. SSL-VPN allows you to connect a client to Alibaba Cloud without configuring a customer gateway.

Parameter	Description
SSL Connections	<p>Specify the maximum number of concurrent SSL connections that the VPN gateway supports.</p> <p> Note This parameter is available only after SSL-VPN is enabled.</p>

25.5.2. Modify a VPN gateway

This topic describes how to modify the name and description of a VPN gateway.

Prerequisites

A VPN gateway is created. For more information, see [Create a VPN gateway](#).

Procedure

1. [Log on to the VPN Gateway console](#).
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the target VPN gateway, and click the  icon in the **Instance ID/Name** column. In the dialog box that appears, enter a new name and click **OK**. The name must be 2 to 100 characters in length, and can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.
5. Click the  icon in the **Description** column. In the dialog box that appears, enter a new description and click **OK**. The description must be 2 to 256 characters in length, and cannot start with `http://` or `https://`.

25.5.3. Configure routes of a VPN Gateway

25.5.3.1. VPN Gateway route overview

After you create an IPsec-VPN connection, you must manually add a VPN Gateway route.

The route-based IPsec-VPN enables you to easily configure and maintain VPN policies, and provides flexible ways for routing traffic.

You can add the following two types of routes for a VPN Gateway:

- Policy-based routes.
- Destination-based routes.

Policy-based route

If a policy-based route is used, traffic is forwarded based on both the source IP address and the destination IP address.

For more information, see [Add policy-based routes](#).

 **Note** Policy-based routes take precedence over destination-based routes.

Destination-based route

If a destination-based route is used, traffic is forwarded based only on the destination IP address.

For more information, see [Add Destination-based routes](#).

25.5.3.2. Add a policy-based route entry

This topic describes how to add a policy-based route entry after an IPsec-VPN connection is created. Policy-based routing (PBR) is a technique that routes packets based on source and destination IP addresses.

Procedure

1. [Log on to the VPN Gateway console.](#)
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the target VPN gateway and click the instance ID in the **Instance ID/Name** column.
5. Click the **Policy-based Routing** tab, and then click **Add Route Entry**.
6. In the **Add Route Entry** dialog box, set the following parameters and click **OK**.

Parameter	Description
Destination CIDR Block	The CIDR block that you want to access.
Source CIDR Block	The CIDR block of the VPC network.
Next Hop Type	Select IPsec Connection.
Next Hop	Select an IPsec instance to create an IPsec-VPN connection.
Publish to VPC	<p>Specify whether to automatically publish new route entries to the VPC route table.</p> <ul style="list-style-type: none"> ◦ Yes (Recommended): automatically publishes new route entries to the VPC route table. ◦ No: does not automatically publish new route entries to the VPC route table. <p> Note If you select No, you must manually publish new route entries to the VPC route table.</p>
Weight	<p>Select a weight. Valid values:</p> <ul style="list-style-type: none"> ◦ 100: indicates that the priority of the route entry is high. ◦ 0: indicates that the priority of the route entry is low. <p> Note If two policy-based route entries are configured with the same destination CIDR block, you cannot set the weights of both route entries to 100.</p>

25.5.3.3. Add a destination-based route entry

This topic describes how to manually add a destination-based route entry after an IPsec-VPN connection is created. Destination-based routing is a technique that routes packets to specified destination IP addresses.

Procedure

1. [Log on to the VPN Gateway console.](#)
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the target VPN gateway and click the instance ID in the **Instance ID/Name** column.
5. In the **Destination-based routing** tab, click **Add Route Entry**.

6. In the Add Route Entry dialog box, set the following parameters and click **OK**.

Parameter	Description
Destination CIDR Block	The CIDR block that you want to access.
Next Hop Type	Select IPsec Connection.
Next Hop	Select an IPsec instance to create an IPsec-VPN connection.
Publish to VPC	Specify whether to automatically publish new route entries to the VPC route table. <ul style="list-style-type: none"> Yes (Recommended): automatically publishes new route entries to the VPC route table. No: does not automatically publish new route entries to the VPC route table. <p>Note If you select No, you must manually publish new route entries to the VPC route table.</p>
Weight	Select a weight. Valid values: <ul style="list-style-type: none"> 100: indicates that the priority of the route entry is high. 0: indicates that the priority of the route entry is low. <p>Note If two destination-based route entries are configure with the same destination CIDR block, you cannot set the weights of both route entries to 100.</p>

25.5.4. Delete a VPN gateway

This topic describes how to delete a VPN gateway. After you delete a VPN gateway, you can no longer use the VPN gateway to establish IPsec-VPN or SSL-VPN connections.

Context

Before you delete a VPN gateway, make sure that the following conditions are met:

- The IPsec-VPN connections on the VPN gateway are deleted. For more information, see [Delete an IPsec-VPN connection](#).
- The SSL server associated with the VPN gateway is deleted. For more information, see [Delete an SSL server](#).

Procedure

- Log on to the [VPN Gateway console](#).
- In the left-side navigation pane, choose **VPN > VPN Gateways**.
- Select the region where the VPN gateway is deployed.
- On the **VPN Gateways** page, find the target VPN gateway, and then click **Delete** in the **Actions** column.
- In the **Delete VPN Gateway** dialog box, click **OK**.

25.6. Manage a customer gateway

25.6.1. Create a customer gateway

This topic describes how to create a customer gateway when you use IPsec-VPN to connect a Virtual Private Cloud (VPC) network to an on-premises data center or connect two VPC networks. You can register and update the information of an on-premises gateway to Alibaba Cloud by creating a customer gateway, and then connect the customer gateway to the VPN gateway. A customer gateway can be connected to multiple VPN gateways.

Procedure

1. [Log on to the VPN Gateway console.](#)
2. In the left-side navigation pane, click **VPN > Customer Gateways**.
3. Select the region where you want to deploy the customer gateway.

 **Note** Make sure that the customer gateway and the VPN gateway to be connected are deployed in the same region.

4. On the **Customer Gateways** page, click **Create Customer Gateway**.
5. On the **Create Customer Gateway** page, set the following parameters, and click **Submit**.

Parameter	Description
Organization	Select the organization to which the customer gateway belongs.
Resource Set	Select the resource set to which the customer gateway belongs.
Region	Select the region where you want to deploy the customer gateway.  Note Make sure that the customer gateway and the VPN gateway to be connected are deployed in the same region.
Zone	Select the zone where you want to deploy the customer gateway
Name	Enter a name for the customer gateway. The name must be 2 to 128 characters in length, and can contain letters, digits, hyphens (-), and underscores (_). It must start with a letter or Chinese character and cannot start with <code>http://</code> or <code>https://</code> .
IP Address	Enter the static public IP address of the gateway device that is deployed in the on-premises data center.
Description	Enter a description for the customer gateway. The description must be 2 to 256 characters in length, and cannot start with <code>http://</code> / or <code>https://</code> .

25.6.2. Modify a customer gateway

This topic describes how to modify the name and description of a customer gateway.

Prerequisites

A customer gateway is created. For more information, see [Create a customer gateway](#).

Procedure

1. [Log on to the VPN Gateway console.](#)
2. In the left-side navigation pane, click **VPN > Customer Gateways**.

3. Select the region where the customer gateway is deployed.
4. On the **Customer Gateways** page, find the target customer gateway, click the  icon in the **Instance ID** column. In the dialog box that appears, enter a name and click **OK**. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.
5. Click the  icon in the **Description** column. In the dialog box that appears, enter a new description and click **OK**. The description must be 2 to 256 characters in length, and cannot start with `http://` or `https://`.

25.6.3. Delete a customer gateway

This topic describes how to delete a customer gateway.

Procedure

1. [Log on to the VPN Gateway console](#).
2. In the left-side navigation pane, click **VPN > Customer Gateways**.
3. Select the region where the customer gateway is deployed.
4. On the **Customer Gateways** page, find the target customer gateway, and then click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

25.7. Configure SSL-VPN

25.7.1. Configuration overview

This topic describes how to use the SSL-VPN function to connect a remote client to a VPC.

Prerequisites

The following conditions must be met before you deploy a VPN Gateway:

- The client and the VPC are not using the same private CIDR block.
- The client is able to access the Internet.

Procedure

The following figure illustrates the work flow of how to connect a client to a VPC by using the SSL-VPN function.

1. **Create a VPN Gateway**
Create a VPN Gateway and enable the SSL-VPN function.
2. **Create an SSL server**
Specify the IP address range of the SSL server and the IP address range used by the client.
3. **Create a client certificate**

Create the client certificate according to server configurations, and then download the client certificate and configurations.

4. Configure the client

Download and install client VPN software in the client, load the client certificate and configurations, and initiate the connection.

5. Configure security groups

Make sure that the security group rules of ECS instances in the VPC allow remote access.

25.7.2. Manage an SSL server

25.7.2.1. Create an SSL Server

This topic describes how to create an SSL server. Before you use SSL-VPN to establish point-to-site connections, you must create an SSL server.

Prerequisites

A VPN gateway is created and SSL-VPN is enabled. For more information, see [Create a VPN gateway](#).

Procedure

1. [Log on to the VPN Gateway console](#).
2. In the left-side navigation pane, choose **VPN > SSL Servers**.
3. In the top navigation bar, select the region where you want to create the SSL server.
4. On the **SSL Servers** page, click **Create SSL Server**.
5. On the **Create SSL Server** page, configure the SSL server based on the following information, and then click **Submit**.

Parameter	Description
Organization	Select the organization to which the SSL server belongs.
Resource Set	Select the resource set to which the SSL server belongs.
Region	Select the region where the SSL server is to be deployed.
Zone	Select the zone where the SSL server is to be deployed.
Name	Enter a name for the SSL server. The name must be 2 to 128 characters in length, and can contain letters, digits, hyphens (-), and underscores (_). It must start with a letter or Chinese character and cannot start with <code>http://</code> or <code>https://</code> .
VPN Gateway	Select the VPN gateway to be associated with the SSL server. Make sure that SSL-VPN is enabled for the VPN gateway.

Parameter	Description
Source CIDR Block	<p>Enter the CIDR block that the client needs to access through the SSL-VPN connection. It can be the CIDR block of a VPC network, a VSwitch, an on-premises data center connected to a VPC through a leased line, or a cloud service such as ApsaraDB for RDS or Object Storage Service (OSS).</p> <p>Click + to add more CIDR blocks.</p> <p> Note The subnet mask of the specified server CIDR block must be 16 to 29 bits in length.</p>
Client CIDR Block	<p>Enter the CIDR block to be allocated to the virtual network interface of the client. Do not enter the CIDR block where the client resides. When the client accesses the server through an SSL-VPN connection, the VPN gateway selects an IP address from the specified CIDR block and assigns it to the client.</p> <p> Note Make sure the server CIDR block and the client CIDR block do not overlap.</p>
Advanced Settings	<p>Specify whether to customize the advanced settings.</p> <ul style="list-style-type: none"> ◦ Default: Use the default settings. ◦ Configure: Use custom settings. You can customize the following settings: <ul style="list-style-type: none"> ▪ Protocol: Select the protocol over which the SSL-VPN connection is established. Supported protocols are UDP and TCP. ▪ Port: Specify the port to which the SSL-VPN connection is established. <p>The following ports are not supported: 22, 2222, 22222, 9000, 9001, 9002, 7505, 80, 443, 53, 68, 123, 4510, 4560, 500, and 4500.</p> ▪ Encryption Algorithm: Select the encryption algorithm used by the SSL connection. Valid values: AES-128-CBC, AES-192-CBC, AES-256-CBC, and none. ▪ Compress: Specify whether to enable data compression.

25.7.2.2. Modify an SSL server

This topic describes how to modify the name, server CIDR block, client CIDR block, and advanced settings of an SSL server.

Prerequisites

An SSL server is created. For more information, see [Create an SSL server](#).

Procedure

1. [Log on to the VPN Gateway console](#).
2. In the left-side navigation pane, choose **VPN > SSL Servers**.
3. In the top navigation bar, select the region where you want to create the SSL server.
4. On the **SSL Servers** page, find the target SSL server, and then click **Edit** in the **Actions** column.
5. On the **Edit SSL Server** page, modify the name, server CIDR block, client CIDR block, and advanced settings of the SSL server, and then click **OK**.

25.7.2.3. Configure a routing group

This topic describes how to configure a routing group to control the inbound and outbound traffic of an Elastic Compute Service (ECS) instance after you create an IPsec-VPN connection.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose VPN > SSL Servers.
3. Select the region where the SSL server is deployed.
4. On the SSL Servers page, find the target SSL server, and then click **Configure Routing Group** in the **Actions** column.
5. In the **Configure Routing Group** dialog box, set the following parameters, and then click **Submit**.

Parameter	Description
Routing Group	Select the routing group to which you want to add the routing group rule.
Rule Direction	Select the direction in which the rule is applied. <ul style="list-style-type: none"> ◦ Outbound: from the ECS instances in the current routing group to other ECS instances on Alibaba Cloud or resources on the Internet. ◦ Inbound: from other ECS instances on Alibaba Cloud or resources on the Internet to the ECS instances in the current routing group.
Authorization Policy	Select an authorization policy. <ul style="list-style-type: none"> ◦ Allow: accept requests received on the specified ports. ◦ Deny: discard requests received on the specified ports without returning messages. If you specify different authorization policies for two routing group rules but the other settings are the same, the Deny rule prevails over the Allow rule.
Protocol Type	Select a protocol type.
Port Range	Select a port range for the routing group rule. The port range depends on the protocol type: <ul style="list-style-type: none"> ◦ When you set Protocol to All, this parameter displays -1/-1, which indicates all ports. You cannot specify a port range if you select this protocol type. ◦ When you set Protocol to TCP, you can specify a port range in the <start port number>/<end port number> format. Valid port numbers: 1 to 65535. To specify a single port, set the start and end port numbers to the same value. For example, use 22/22 to indicate port 22. ◦ When Protocol is set to UDP, specify a port range in the <start port number>/<end port number> format. Valid port numbers: 1 to 65535. To specify a single port, set the start and end port numbers to the same value. For example, use 3389/3389 to indicate port 3389. ◦ When Protocol is set to ICMP, this parameter displays -1/-1, which indicates all ports. You cannot set a port range if you select this protocol type. ◦ When Protocol is set to GRE, this parameter displays -1/-1, which indicates all ports. You cannot set a port range if you select this protocol type.
Priority	Set the priority of the rule. Valid values: 1 to 100. The default value is 1, which indicates the highest priority.
Authorization Type	Select the authorization type of the routing group rule. You can select only Address .
NIC type	Select a NIC type. <ul style="list-style-type: none"> ◦ Internal: Control inbound and outbound traffic within Alibaba Cloud. ◦ External: Control inbound and outbound traffic over the Internet.

Parameter	Description
Authorized IP Addresses	Select the CIDR blocks to be authorized. You can specify up to 10 CIDR blocks at a time.
Automatically Configure Routers	Specify whether to automatically configure routers.
Description	The description of the routing group rule. The description must be 2 to 256 characters in length, and cannot start with <code>http://</code> or <code>https://</code> . You can left this parameter empty.

25.7.2.4. Delete an SSL server

This topic describes how to delete an SSL server.

Procedure

1. [Log on to the VPN Gateway console.](#)
2. In the left-side navigation pane, choose **VPN > SSL Servers**.
3. In the top navigation bar, select the region where you want to create the SSL server.
4. On the **SSL Servers** page, find the target SSL server, and then click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

25.7.3. Manage an SSL client certificate

25.7.3.1. Create an SSL client certificate

After you create an SSL server, you must create an SSL client certificate based on the configuration of the SSL server before you can establish an SSL-VPN connection.

Prerequisites

An SSL server is created. For more information, see [Create an SSL Server](#).

Procedure

1. [Log on to the VPN Gateway console.](#)
2. In the left-side navigation pane, choose **VPN > SSL Clients**.
3. Select the region where the SSL client is deployed.
4. On the **SSL Clients** page, click **Create Client Certificate**.
5. On the **Create SSL Client Certificate** page, configure the client certificate based on the following information, and then click **Submit**.

Parameter	Description
Organization	Select the organization to which the SSL client belongs.
Resource Set	Select the resource set to which the SSL client belongs.
Region	Select the region where the SSL client is deployed.
Zone	Select the zone where the SSL client is deployed.

Parameter	Description
Name	Enter a name for the SSL client certificate. The name must be 2 to 128 characters in length, and can contain letters, digits, hyphens (-), and underscores (_). It must start with a letter or Chinese character and cannot start with <code>http://</code> or <code>https://</code> .
VPN Gateway	Select the VPN gateway that is used to establish the SSL-VPN connection.
SSL Server	Select the SSL server to be associated with the SSL client.

25.7.3.2. Download an SSL client certificate

This topic describes how to download an SSL client certificate. Before you use an SSL client to initiate an SSL-VPN connection, you must import the SSL client certificate to the SSL client.

Prerequisites

An SSL client certificate is created. For information, see [Create an SSL client certificate](#).

Procedure

1. [Log on to the VPN Gateway console](#).
2. In the left-side navigation pane, choose **VPN > SSL Clients**.
3. Select the region where the SSL client is deployed.
4. On the **SSL Clients** page, find the target SSL client certificate, and then click **Download** in the **Actions** column.

25.7.3.3. Delete an SSL client certificate

This topic describes how to delete an SSL client certificate.

Procedure

1. [Log on to the VPN Gateway console](#).
2. In the left-side navigation pane, choose **VPN > SSL Clients**.
3. Select the region where the SSL client is deployed.
4. On the **SSL Clients** page, find the target SSL client certificate, and then click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

25.8. Configure IPsec-VPN connections

25.8.1. Configuration overview

This topic describes how to connect a VPC to an on-premises data center through IPsec-VPN.

Prerequisites

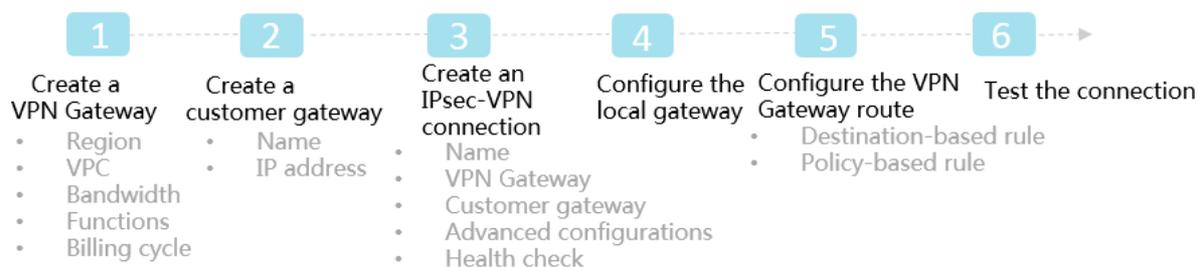

Before creating a site-to-site VPN connection, make sure the following conditions are met:

- The protocols IKEv1 and IKEv2 are supported by the gateway device of the on-premises data center.
IPsec-VPN supports IKEv1 and IKEv2 protocols. Devices that support these two protocols can connect to Alibaba Cloud VPN Gateway, including devices of Huawei, H3C, Hillstone, SANGFOR, Cisco ASA, Juniper, SonicWall, Nokia, IBM, and Ixia.
- A static public IP address is configured for the local gateway.

- The IP address ranges of the VPC and on-premises data center to be connected do not conflict with each other.

Procedure

The following figure shows the procedure of connecting a VPC to an on-premises data center through IPsec-VPN.

1. Create a VPN Gateway

Enable the IPsec-VPN function. Up to 10 IPsec-VPN connections can be established in a VPN Gateway.

2. Create a customer gateway

By creating a customer gateway, you can register the local gateway to Alibaba Cloud and connect the customer gateway to the VPN Gateway. A customer gateway can be connected to multiple VPN Gateways.

3. Create an IPsec connection

An IPsec connection is a VPN channel established between a VPN Gateway and a customer gateway. The encrypted communication between the VPN Gateway and the on-premises data center can be achieved only after the IPsec connection is established.

4. Configure the local gateway

You need to load the VPN Gateway configurations to the local gateway device. For more information, see [Local CPE configurations](#).

5. Configure the VPN Gateway route

You need to configure a route in the VPN Gateway and publish it to the VPC route table. For more information, see [VPN Gateway route overview](#).

6. Test the connection

Log on to an ECS instance (without a public IP address) in the connected VPC. ping the private IP address of a server in the on-premises data center to check whether the connection is established.

For more information, see [Establish a connection between a VPC and an on-premises data center](#).

25.8.2. Manage an IPsec-VPN connection

25.8.2.1. Create an IPsec-VPN connection

This topic describes how to create an IPsec-VPN connection. After you create a VPN gateway and a customer gateway, you can create an IPsec-VPN connection between the two gateways for encrypted data transmission.

Procedure

1. [Log on to the VPN Gateway console](#).
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. Select the region where you want to create the IPsec-VPN connection.
4. On the **IPsec Connections** page, click **Create IPsec Connection**.
5. On the **Create IPsec Connection** page, configure the IPsec-VPN connection based on the following

information and click **Submit**.

Parameter	Description
Organization	Select the organization to which the IPsec-VPN connection belongs.
Resource Set	Select the resource set to which the IPsec-VPN connection belongs.
Region	Select the region where the IPsec-VPN connection is established.
Zone	Select the zone where the IPsec-VPN connection is established.
Name	Enter a name for the IPsec-VPN connection. The name must be 2 to 128 characters in length, and can contain letters, digits, hyphens (-), and underscores (_). It must start with a letter or Chinese character and cannot start with <code>http://</code> or <code>https://</code> .
VPN Gateway	Select the VPN gateway to be connected through the IPsec-VPN connection.
Customer Gateway	Select the customer gateway to be connected through the IPsec-VPN connection.
Source CIDR Block	Enter the CIDR block of the VPC network to be connected to the on-premises data center. The CIDR block is used during phase 2 negotiation. You can add more than one CIDR blocks only if IKEv2 is used.
Destination CIDR Block	Enter the CIDR block of the on-premises data center to be connected to the VPC network. This CIDR block is used during phase 2 negotiation. You can add more than one CIDR blocks only if IKEv2 is used.
Immediate Effect	Specify whether to start connection negotiations immediately. <ul style="list-style-type: none"> ◦ Yes: Negotiate immediately after the configuration is complete. ◦ No: Negotiate when traffic is detected in the IPsec-VPN tunnel.
Advanced Settings	Specify whether to customize the advanced settings. <ul style="list-style-type: none"> ◦ Default: Use default settings. ◦ Configure: Use custom settings.
Advanced configuration: IKE configuration	
Pre-shared Key	Enter the pre-shared key used for authentication between the VPN gateway and customer gateway. You can specify a key, or use the default key that is randomly generated by the system.
Version	The version of the IKE protocol. Select an IKE version. Compared with IKEv1, IKEv2 simplifies the process of Security Association (SA) negotiation and provides better support for scenarios where an SSL-VPN connection is established with multiple subnets. We recommend that you select IKEv2.
Negotiation Mode	The negotiation mode of IKEv1. <ul style="list-style-type: none"> ◦ Main: This mode offers higher security. ◦ Aggressive: This mode is faster than the main mode. Negotiations are more likely to succeed in this mode. <p>Connections negotiated in both modes ensure the same security level of data transmission.</p>

Parameter	Description
Encryption Algorithm	Select the encryption algorithm used during phase 1 negotiation. Supported algorithms are aes, aes192, aes256, des, and 3des.
Authentication Algorithm	Select the authentication algorithm used during phase 1 negotiation. Supported algorithms are sha1, and md5.
DH Group	Select the Diffie-Hellman key exchange algorithm used during phase 1 negotiation.
SA Life Cycle (Seconds)	Specify the lifecycle of the SA after phase 1 negotiation succeeds. Default value: 86,400.
LocalId	The ID of the VPN gateway used during phase 1 negotiation. The default value is the public IP address of the VPN gateway. If you set LocalId to a FQDN, we recommend that you set Negotiation Mode to Aggressive.
Remoteld	The ID of the customer gateway used during phase 1 negotiation. The default value is the public IP address of the customer gateway. If you set Remoteld to a FQDN, we recommend that you select set Negotiation Mode to Aggressive.
Advanced configuration: IPsec configuration	
Encryption Algorithm	Select the encryption algorithm used during phase 2 negotiation. Supported algorithms are aes, aes192, aes256, des, and 3des.
Authentication Algorithm	Select the authentication algorithm used during phase 2 negotiation. Supported algorithms are sha1, and md5.
DH Group	Select the Diffie-Hellman key exchange algorithm for phase 2 negotiations. <ul style="list-style-type: none"> ◦ If you select a Diffie-Hellman group, the perfect forward secrecy (PFS) feature is enabled and each negotiation requires a new key. Therefore, you must also enable PFS for the client. ◦ For clients that do not support PFS, select disabled.
SA Life Cycle (Seconds)	Specify the lifecycle of the SA after phase 2 negotiation succeeds. Default value: 86,400.

25.8.2.2. Modify an IPsec-VPN connection

This topic describes how to modify the name, advanced settings, and health check for an IPsec-VPN connection.

Prerequisites

An IPsec-VPN connection is created. For more information, see [Create an IPsec-VPN connection](#).

Procedure

1. [Log on to the VPN Gateway console](#).
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. Select the region where you want to create the IPsec-VPN connection.
4. On the IPsec Connections page, find the target IPsec-VPN connection and then click **Edit** in the **Actions** column.
5. In the **Modify IPsec Connections** dialog box, modify the name, advanced settings, and health check, and click **Submit**.

25.8.2.3. Download the configuration file of an IPsec-VPN connection

This topic describes how to download the configurations of an IPsec-VPN connection, and load the configurations to the customer gateway device after an IPsec-VPN connection is configured.

Prerequisites

An IPsec-VPN connection is created. For more information, see [Create an IPsec-VPN connection](#).

Procedure

1. [Log on to the VPN Gateway console](#).
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. Select the region where you want to create the IPsec-VPN connection.
4. On the **IPsec Connections** page, find the target IPsec-VPN connection, and then choose **More > Download Configuration** in the **Actions** column.

 **Note** RemotSubnet and LocalSubnet in the downloaded configurations are opposite to RemotSubnet and LocalSubnet that you specify when you create an IPsec-VPN connection. For a VPN gateway, RemotSubnet refers to the CIDR block of the on-premises data center and LocalSubnet refers to the CIDR block of the VPC network. For a customer gateway, LocalSubnet refers to the CIDR block of the on-premises data center and RemoteSubnet refers to the CIDR block of the VPC network.

25.8.2.4. Configure a routing group

This topic describes how to configure routing groups to control the inbound and outbound traffic of ECS instances in a routing group after an IPsec-VPN connection is created.

Procedure

1. [Log on to the VPN Gateway console](#).
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. Select the region where you want to create the IPsec-VPN connection.
4. On the **IPsec Connections** page, find the target IPsec-VPN connection, and then choose **More > Configure Routing Group** in the **Actions** column.
5. In the **Configure Routing Group** dialog box, set the following parameters, and then click **Submit**.

Parameter	Description
Routing Group	Select the routing group to which you want to add the routing group rule.
Rule Direction	Select the direction in which the rule is applied. <ul style="list-style-type: none"> ◦ Outbound: from the ECS instances in the current routing group to other ECS instances on Alibaba Cloud or resources on the Internet. ◦ Inbound: from other ECS instances on Alibaba Cloud or resources on the Internet to the ECS instances in the current routing group.
Authorization Policy	Select an authorization policy. <ul style="list-style-type: none"> ◦ Allow: accept requests received on the specified ports. ◦ Deny: discard requests received on the specified ports without returning messages. If you specify different authorization policies for two routing group rules but the other settings are the same, the Deny rule prevails over the Allow rule.

Parameter	Description
Protocol Type	Select a protocol type.
Port Range	<p>Select a port range for the routing group rule. The port range depends on the protocol type:</p> <ul style="list-style-type: none"> When you set Protocol to All, this parameter displays -1/-1, which indicates all ports. You cannot specify a port range if you select this protocol type. When you set Protocol to TCP, you can specify a port range in the <start port number>/<end port number> format. Valid port numbers: 1 to 65535. To specify a single port, set the start and end port numbers to the same value. For example, use 22/22 to indicate port 22. When Protocol is set to UDP, specify a port range in the <start port number>/<end port number> format. Valid port numbers: 1 to 65535. To specify a single port, set the start and end port numbers to the same value. For example, use 3389/3389 to indicate port 3389. When Protocol is set to ICMP, this parameter displays -1/-1, which indicates all ports. You cannot set a port range if you select this protocol type. When Protocol is set to GRE, this parameter displays -1/-1, which indicates all ports. You cannot set a port range if you select this protocol type.
Priority	Set the priority of the rule. Valid values: 1 to 100. The default value is 1, which indicates the highest priority.
Authorization Type	Select the authorization type of the routing group rule. You can select only Address.
NIC type	Select a NIC type. <ul style="list-style-type: none"> Internal: Control inbound and outbound traffic within Alibaba Cloud. External: Control inbound and outbound traffic over the Internet.
Authorized IP Addresses	Select the CIDR blocks to be authorized. You can specify up to 10 CIDR blocks at a time.
Automatically Configure Routers	Specify whether to automatically configure routers.
Description	The description of the routing group rule. The description must be 2 to 256 characters in length, and cannot start with <code>http://</code> or <code>https://</code> . You can left this parameter empty.

25.8.2.5. View IPsec-VPN connection logs

This topic describes how to view IPsec-VPN connection logs that are generated within the last 30 days to troubleshoot connection errors. You can query log data generated within 10 minutes.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose VPN > IPsec Connections.
3. Select the region where you want to create the IPsec-VPN connection.
4. On the IPsec Connections page, find the target IPsec-VPN connection, and then choose More > View Logs in the Actions column.

5. In the IPsec Connection Logs dialog box, set the time range and query the logs.

25.8.2.6. Delete an IPsec-VPN connection

This topic describes how to delete an IPsec-VPN connection.

Procedure

1. [Log on to the VPN Gateway console.](#)
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. Select the region where you want to create the IPsec-VPN connection.
4. On the IPsec Connections page, find the target IPsec-VPN connection, and then click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

25.8.3. MTU notes

The maximum transmission unit (MTU) is the size (in bytes) of the largest packet supported by the network layer protocol (such as TCP), with headers and data included.

Network packets sent over IPsec tunnels are encrypted and then encapsulated in external packets for routing. Because an encapsulated internal packet itself must fit the MTU of the corresponding external packet, the MTU of the internal packet must be smaller.

Gateway MTU and system MTU

You must configure the MTU limit of the local VPN Gateway to not more than 1,400 bytes. We recommend that you set the MTU to 1,400 bytes.

For TCP traffic, the maximum length of data that can be carried by each packet segment can be negotiated by the sender and receiver when they communicate based on the maximum segment size (MSS).

26. Elastic IP Address

26.1. What is an EIP?

This topic provides an overview of Elastic IP Address. An elastic IP address (EIP) is a public IP address that you can purchase and hold as an independent resource. You can associate an EIP with an Elastic Compute Service (ECS) instance deployed in a virtual private cloud (VPC), an internal Server Load Balancer (SLB) instance deployed in a VPC, or a secondary elastic network interface (ENI) attached to a VPC. You can also associate an EIP with a NAT gateway, or a High-Availability Virtual IP Address (HAVIP).

An EIP is also a NAT IP address that is provisioned in a public-facing gateway of Alibaba Cloud and is mapped to the associated cloud resource with NAT. After an EIP is associated with a cloud resource, the cloud resource can connect to the Internet by using this EIP.

Differences between an EIP and a public IP address of an ECS instance

The following table compares the features of an EIP with those of a public IP address of an ECS instance.

Feature	EIP	ECS public IP address
Supported networks	VPC	VPC
Support for being held as an independent resource	Yes	No
Support for being associated with and disassociated from an ECS instance at any time	Yes	No
Support for being displayed in the ENI information of the associated ECS instance	The IP address is displayed in the ENI information if it is associated with the ENI in the cut-through mode	No

Benefits

EIPs have the following benefits:

- **Independent purchase and possession**
You can purchase and hold an EIP as an independent resource. EIPs are not bundled with other computing or storage resources.
- **Flexible association**
You can dissociate an EIP from a cloud resource and then release the EIP if the EIP is no longer needed.
- **Configurable network capabilities**
You can adjust the peak bandwidth of an EIP at any time. The bandwidth changes take effect immediately.

26.2. Log on to the EIP console

This topic provides an example of how to log on to the EIP console by using Google Chrome.

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.

2. Enter your username and password.

Obtain the username and password used to log on to the console from the operations administrator.

Note When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:

- Uppercase or lowercase letters.
- Digits.
- Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Products > Networking > Elastic IP Address**.

26.3. Quick start

26.3.1. Tutorial overview

This topic provides an overview of the tutorial that guides you in creating an EIP and associating an EIP with an ECS instance to allow the ECS instance to access the Internet.

This tutorial walks you through the following tasks:

1. **Create an Elastic IP address**

An EIP is a public IP address that you can purchase and hold as an independent resource. To get started, you must create an EIP.

2. **Bind an EIP to an ECS instance**

You can associate an EIP with an ECS instance deployed in a VPC to enable the ECS instance to connect to the Internet.

3. **Unbind an Elastic IP address from a cloud instance**

You can disassociate an ECS instance from an EIP when the ECS instance no longer requires access to the Internet.

4. **Release an Elastic IP address**

You can release an EIP if it is no longer needed.

26.3.2. Create a EIP

This topic describes how to create a EIP. An EIP is a public IP address that you can purchase and hold as an independent resource.

Procedure

1. **Log on to the EIP console.**
2. On the **Elastic IP Addresses** page, click **Create EIP**.
3. On the **Create Elastic IP Address** page, set the parameters and click **Submit**. The following table describes the configuration parameters.

Parameter	Description
Organization	Select the organization to which the EIP belongs.
Resource Set	Select the resource set to which the EIP belongs.

Parameter	Description
Region	Select a region for the EIP. Make sure that the EIP and the cloud resource to be associated with the EIP are located in the same region.
Zone	Select the zone to which the EIP belongs.
Line Type	Select the line type of the EIP.
Network Type	Select the network type of communication for which the EIP will be used. <ul style="list-style-type: none"> Public Network: Use the EIP to enable communication with the Internet. Hybrid Cloud: Use the EIP to enable communication within a hybrid cloud. For example, if you need to establish network connections from an on-premises data center to the Internet by using source network address translation (SNAT) and destination network address translation (DNAT), you must select this type for your EIP.
Service IP	Specify a specific EIP. Make sure that the specified IP address is an IPv4 address and is not taken by another account. Otherwise, the EIP cannot be allocated. <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px;"> <p> Note If you do not specify a service IP, a random EIP will be assigned to you by the system.</p> </div>
Peak Bandwidth	Specify the maximum bandwidth for the EIP. Unit: Mbit/s.

26.3.3. Associate an EIP with an ECS instance

This topic describes how to associate an EIP with an ECS instance deployed in a VPC. ECS instances that are associated with EIPs can communicate with the Internet.

Prerequisites

You have created an ECS instance. For more information, see the **Create an instance** topic of **Quick start** in the *Apsara Stack Elastic Compute Service User Guide*.

Procedure

1. [Log on to the EIP console](#).
2. Select the region of the EIP.
3. On the **Elastic IP Addresses** page, find the target EIP, and then click **Bind** in the **Actions** column.
4. In the **Bind Elastic IP Address** dialog box, set the following parameters and click **OK**.

Parameter	Description
Instance Type	Select ECS Instance.

Parameter	Description
ECS Instance	<p>Select the ECS instance to be associated with the EIP.</p> <p>When you select an ECS instance, note the following points:</p> <ul style="list-style-type: none"> ◦ The ECS instance must be deployed in a VPC. ◦ The ECS instance must be running or stopped. ◦ An ECS instance can be associated with only one EIP. ◦ The ECS instance and the EIP must reside in the same region. ◦ The ECS instance is not associated with a public IP address or another EIP.

26.3.4. Disassociate an EIP from a cloud resource

This topic describes how to dissociate an EIP from a cloud resource when this cloud resource no longer needs to communicate with the Internet.

Procedure

1. [Log on to the EIP console.](#)
2. In the upper-left corner, select the region where your EIP is created.
3. On the Elastic IP Addresses page, find the target EIP, and click **Unbind** in the **Actions** column.
4. In the **Unbind Elastic IP Address** dialog box, click **OK**.

26.3.5. Release an EIP

This topic describes how to release an Elastic IP address (EIP).

Prerequisites

The EIP is disassociated from all instances. For more information, see [Disassociate an EIP from a cloud resource.](#)

Procedure

1. [Log on to the EIP console.](#)
2. In the upper-left corner, select the region where your EIP is created.
3. On the Elastic IP Addresses page, find the target EIP, move the mouse pointer over **More operations** in the **Actions** column, and then click **Release**.
4. In the **Release an EIP** dialog box, click **OK**.

26.4. Manage EIPs

26.4.1. Create a EIP

This topic describes how to create a EIP. An EIP is a public IP address that you can purchase and hold as an independent resource.

Procedure

1. [Log on to the EIP console.](#)
2. On the Elastic IP Addresses page, click **Create EIP**.
3. On the **Create Elastic IP Address** page, set the parameters and click **Submit**. The following table describes the configuration parameters.

Parameter	Description
Organization	Select the organization to which the EIP belongs.
Resource Set	Select the resource set to which the EIP belongs.
Region	Select a region for the EIP. Make sure that the EIP and the cloud resource to be associated with the EIP are located in the same region.
Zone	Select the zone to which the EIP belongs.
Line Type	Select the line type of the EIP.
Network Type	Select the network type of communication for which the EIP will be used. <ul style="list-style-type: none"> Public Network: Use the EIP to enable communication with the Internet. Hybrid Cloud: Use the EIP to enable communication within a hybrid cloud. For example, if you need to establish network connections from an on-premises data center to the Internet by using source network address translation (SNAT) and destination network address translation (DNAT), you must select this type for your EIP.
Service IP	Specify a specific EIP. Make sure that the specified IP address is an IPv4 address and is not taken by another account. Otherwise, the EIP cannot be allocated. <div style="background-color: #e0f2f1; padding: 5px; border: 1px solid #ccc;"> <p> Note If you do not specify a service IP, a random EIP will be assigned to you by the system.</p> </div>
Peak Bandwidth	Specify the maximum bandwidth for the EIP. Unit: Mbit/s.

26.4.2. Bind an EIP to a cloud instance

26.4.2.1. Associate an EIP with an ECS instance

This topic describes how to associate an EIP with an ECS instance deployed in a VPC. ECS instances that are associated with EIPs can communicate with the Internet.

Prerequisites

You have created an ECS instance. For more information, see the [Create an instance](#) topic of *Quick start* in the *Apsara Stack Elastic Compute Service User Guide*.

Procedure

1. [Log on to the EIP console](#).
2. Select the region of the EIP.
3. On the **Elastic IP Addresses** page, find the target EIP, and then click **Bind** in the **Actions** column.
4. In the **Bind Elastic IP Address** dialog box, set the following parameters and click **OK**.

Parameter	Description
Instance Type	Select ECS Instance.

Parameter	Description
ECS Instance	<p>Select the ECS instance to be associated with the EIP.</p> <p>When you select an ECS instance, note the following points:</p> <ul style="list-style-type: none"> ◦ The ECS instance must be deployed in a VPC. ◦ The ECS instance must be running or stopped. ◦ An ECS instance can be associated with only one EIP. ◦ The ECS instance and the EIP must reside in the same region. ◦ The ECS instance is not associated with a public IP address or another EIP.

26.4.2.2. Associate an EIP with an SLB instance

This topic describes how to associate an EIP with an SLB instance. After the association, the SLB instance can distribute requests from the Internet.

Prerequisites

You have created an SLB instance. For more information, see the **Create an SLB instance** topic of **Quick start** in the *Apsara Stack Server Load Balancer User Guide*.

Procedure

1. Log on to the [EIP console](#) [EIP console](#).
2. [Log on to the EIP console](#).
3. In the upper-left corner, select the region where your EIP is created.
4. On the **Elastic IP Addresses** page, find the EIP that you want to manage, and click **Bind** in the **Actions** column.
5. In the **Bind Elastic IP Address** dialog box, set the following parameters and click **OK**.

Parameter	Description
Instance Type	Select SLB Instance.
SLB Instance	<p>Select the SLB instance to be associated with the EIP.</p> <p>When you select an SLB instance, note the following points:</p> <ul style="list-style-type: none"> ◦ The SLB instance must be deployed in a VPC. ◦ The SLB instance and the EIP must reside in the same region. ◦ An SLB instance can be associated with only one EIP.

26.4.2.3. Associate an EIP with an HAVIP

This topic describes how to associate an EIP with an HAVIP. After the association, the HAVIP can be used to connect to the Internet.

Prerequisites

You have created an HAVIP. For more information, see the **Create an HAVIP** topic of **HAVIPs** in the *Apsara Stack Virtual Private Cloud User Guide*.

Procedure

1. Log on to the [EIP console](#) [EIP console](#).
2. [Log on to the EIP console](#).

- In the upper-left corner, select the region where your EIP is created.
- On the **Elastic IP Addresses** page, find the EIP that you want to manage, and click **Bind** in the **Actions** column.
- In the **Bind Elastic IP Address** dialog box, set the following parameters and click **OK**.

Parameter	Description
Instance Type	Select HaVIP Address.
HaVIP Address	<p>Select the HAVIP to be associated with the EIP.</p> <p>When you select an HAVIP, note the following points:</p> <ul style="list-style-type: none"> The HAVIP and the EIP must reside in the same region. The HAVIP must be available or allocated. An HAVIP can be associated with only one EIP.

26.4.2.4. Associate an EIP with a NAT gateway

This topic describes how to associate an EIP with a NAT gateway. After the association, you can use the EIP to configure DNAT and SNAT entries.

Prerequisites

You have created a NAT gateway. For more information, see the **Create a NAT gateway** topic of **Quick start** in the *Apsara Stack NAT Gateway User Guide*.

Procedure

- Log on to the EIP console.**
- In the upper-left corner, select the region where your EIP is created.
- On the **Elastic IP Addresses** page, find the EIP that you want to manage, and click **Bind** in the **Actions** column.
- In the **Bind Elastic IP Address** dialog box, set the following parameters and click **OK**.

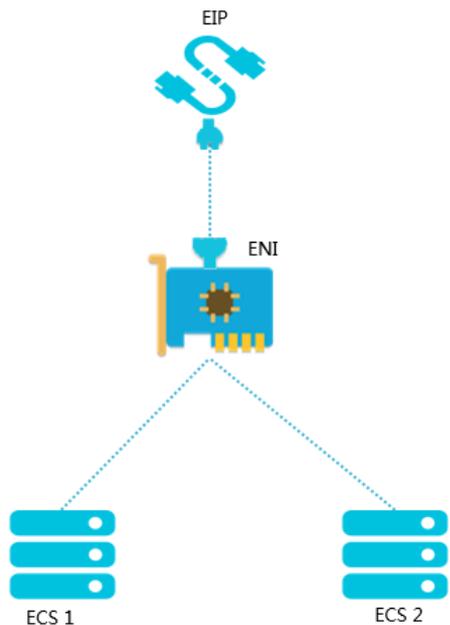

Parameter	Description
Instance Type	Select NAT Gateway.
NAT Gateway	<p>Select the NAT gateway to be associated with the EIP.</p> <p>When you select a NAT gateway, note the following points:</p> <ul style="list-style-type: none"> The NAT gateway and the EIP must reside in the same region. A NAT gateway can be associated with a maximum of 20 EIPs.

26.4.2.5. Bind an EIP to a secondary ENI

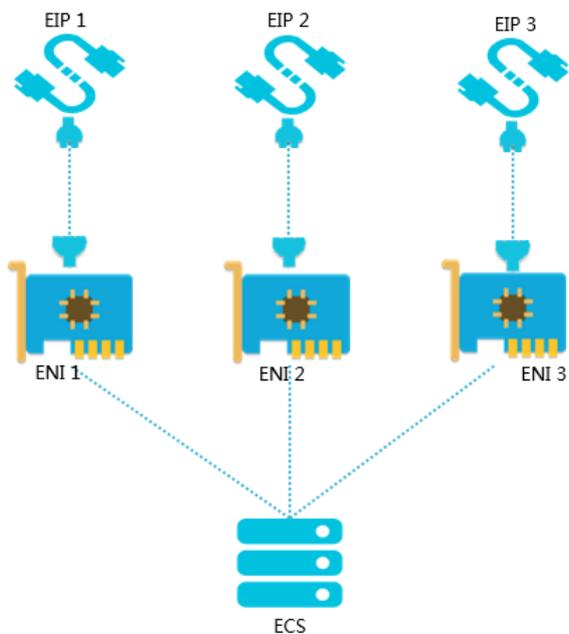

26.4.2.5.1. Overview

This topic provides an overview of EIP associations with ENIs. You can associate EIPs with ENIs to build a highly robust, flexible, and scalable IT solution. This also allows a cloud server to use multiple public IP addresses.

An ENI is assigned with a private IP address. After you associate an EIP with an ENI, the ENI has both a private IP address and a public IP address. When you migrate an ENI that is associated with an EIP from an ECS instance to another ECS instance, the public and private IP addresses are also migrated. This provides a highly reliable and available IP migration solution for cloud servers that use both public and private IP addresses.

To enable an ECS instance to use multiple public IP addresses, you can associate the ECS instance with multiple ENIs, and then associate each ENI with an EIP. You can use these public IP addresses along with security group rules to provide external services.

Association modes

You can associate an EIP with an ENI in one of the following two modes:

- NAT mode
- Cut-through mode

The following table lists the distinguishing features of each mode.

Feature	NAT mode	Cut-through mode
---------	----------	------------------

Feature	NAT mode	Cut-through mode
Support for displaying the associated EIPs in the ENI information	No	Yes  Note You can run the <code>ifconfig</code> or <code>ipconfig</code> command to query the EIP associated with the corresponding ENI.
Supported ENIs that can be associated with EIPs	Primary and secondary ENIs	Secondary ENIs
The maximum number of EIPs that can be associated with a primary ENI	1	EIP associations with primary ENIs are not supported.
The maximum number of EIPs that can be associated with a secondary ENI	Depends on the number of private IP addresses of the secondary ENI.  Note A one-to-one relationship is implemented between EIPs and the private IP addresses of a secondary ENI. For example, if a secondary ENI has 10 private IP addresses, a maximum of 10 EIPs can be associated with this ENI.	1  Note In the cut-through mode, an EIP can only be associated with the primary private IP address of a secondary ENI.
Support for the secondary ENI to deliver networking connectivity within the private network after the ENI is associated with an EIP	Yes	No
Supported protocols	EIPs that are associated in the NAT mode do not support the protocols that require connection management from NAT application-level gateway (ALG), such as H.323, Session Initiation Protocol (SIP), Domain Network System (DNS), and Real Time Streaming Protocol (RTSP).	All IP protocols, such as H.323, SIP, DNS, RTSP, File Transfer Protocol (FTP), and Trivial File Transfer Protocol (TFTP).

26.4.2.5.2. Associate an EIP with an ENI in the NAT mode

This topic describes how to associate an EIP with an ENI in the NAT mode. With this association, both the public and private IP addresses of the ENI can be used to provide networking connectivity. EIPs associated in the NAT mode cannot be displayed in the ENI information.

Prerequisites

Before you associate an EIP with an ENI in the NAT mode, make sure that the following conditions are met:

- You have created a secondary ENI that is attached to a VPC. The secondary ENI and the EIP to be associated reside in the same region. For more information, see the [Create an ENI](#) topic of *Elastic Network Interfaces in the Apsara Stack Elastic Compute Service User Guide*.
- The secondary ENI is not associated with an ECS instance.

If the secondary ENI is associated with an ECS instance, you must disassociate it from the ECS instance. You can re-associate the ENI with the ECS instance after you have associated the ENI with the intended EIP in the NAT mode. For more information, see the **Unbind a secondary ENI from an instance** topic of **Elastic Network Interfaces** in the *Apsara Stack Elastic Compute Service User Guide*.

Context

The NAT mode has the following characteristics:

- The number of EIPs with which a secondary ENI can be associated depends on the number of private IP addresses of this secondary ENI.
- When an EIP is associated with an ENI in the NAT mode, both the private and public IP addresses of this ENI are available.
- The EIP associated with an ENI cannot be viewed in the operating system. To query the EIP associated with an ENI, call the DescribeEipAddresses operation.
- EIPs that are associated in the NAT mode do not support the protocols that require connection management from NAT ALG, such as H.323, SIP, DNS, RTSP, and TFTP.

Procedure

1. **Log on to the EIP console.**
2. In the top navigation bar, select the region of the EIP.
3. On the **Elastic IP Addresses** page, find the target EIP and click **Bind** in the **Actions** column.
4. In the **Bind Elastic IP Address** dialog box, set the following parameters and click **OK**.

Parameter	Description
IP Address	Displays the target EIP.
Instance Type	Select Secondary ENI.
Mode	Select NAT Mode.
Secondary ENI	Select the secondary ENI to be associated with the EIP.

26.4.2.5.3. Associate an EIP with an ENI in the cut-through mode

This topic describes how to associate an EIP with an ENI in the cut-through mode. After the association, the EIP replaces the private IP address of the secondary ENI, which changes the secondary ENI to an Internet interface. You can view the EIP in the ENI information.

Prerequisites

Before you associate an EIP with an ENI in the cut-through mode, make sure that the following conditions are met:

- The secondary ENI is attached to a VPC.
- The secondary ENI and the EIP reside in the same region.
- The secondary ENI is not associated with an ECS instance.

If the secondary ENI is associated with an ECS instance, you must disassociate it from the ECS instance. You can re-associate the ENI with the ECS instance after you have associated the ENI with the intended EIP in the cut-through mode. For more information, see the **Unbind a secondary ENI from an instance** topic of **Elastic Network Interfaces** in the *Apsara Stack Elastic Compute Service User Guide*.

- A secondary ENI can be associated with only one EIP.

Context

An EIP is essentially a NAT IP address. After you associate an EIP with an ENI in the NAT mode, the public IP address of the ENI is provisioned in a gateway rather than the ENI of the associated ECS instance. Therefore, the public IP address cannot be displayed in the operating system of the ECS instance, which only shows the private IP address in the ENI information. This complicates operations and maintenance because you must keep track of the mappings between network interfaces or servers and public IP addresses. In addition, EIPs that are associated with ENIs in the NAT mode do not support protocols such as H.323, SIP, DNS, or RTSP.

To solve the preceding problems, you can associate an EIP with an ENI in cut-through mode. In the cut-through mode:

- The EIP replaces the private IP address of the secondary ENI. This changes the secondary ENI to an Internet interface which can no longer deliver networking connectivity within the private network.
- You can view the EIP in the ENI information. To query the EIP associated with the corresponding ENI, you can call the `theifconfig oripconfig` operation.
- EIPs that are associated in the cut-through mode support all Internet protocols, such as H.323, SIP, DNS, RTSP, FTP, and TFTP.

Procedure

1. [Log on to the EIP console](#).
2. Select the region of the EIP.
3. On the **Elastic IP Addresses** page, find the EIP that you want to manage, and click **Bind** in the **Actions** column.
4. In the **Bind Elastic IP Address** dialog box, set the following parameters and click **OK**.

Parameter	Description
Instance Type	Select Secondary ENI .
Binding mode	Select Cut-Through Mode .
Secondary ENI	Select the secondary ENI to be associated with the EIP.

 **Notice** Make sure that the selected secondary ENI is not associated with an ECS instance.

5. Return to the **Elastic IP Addresses** page and click the ID of the associated ENI.
6. Find the target ENI from the list of ENIs. In the **Actions** column, click **Bind** to associate the ENI with an ECS instance.

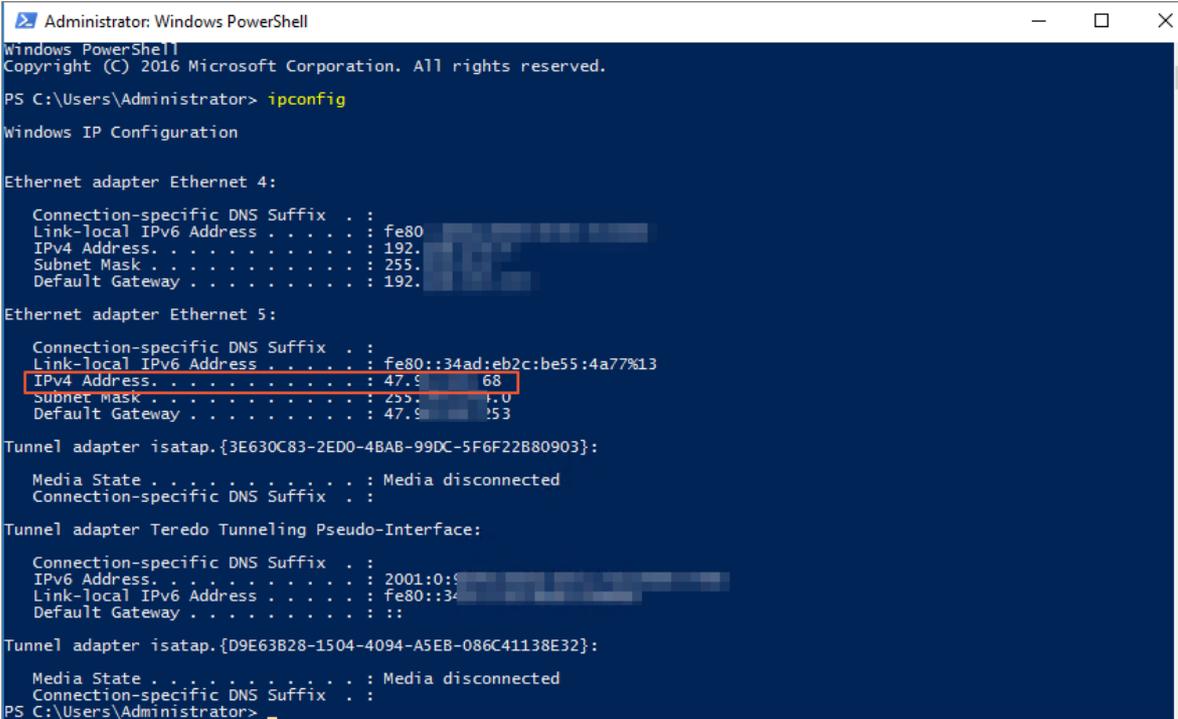

Note

- The maximum number of ENIs that can be associated with an ECS instance depends on the specification of the ECS instance. For more information, see the **Instance types** topic of *What is ECS* in the *Apsara Stack Elastic Compute Service User Guide*.
- After you associate a secondary ENI with an ECS instance, you must enable Dynamic Host Configuration Protocol (DHCP) for the secondary ENI and then restart the ENI. Otherwise, the configuration made for the cut-through mode will not take effect.
- After the configuration is complete, a route entry is automatically created for the ECS instance with the secondary ENI as the egress interface. The priority of this route entry is lower than that of the route with the primary ENI as the egress interface. Therefore, you can adjust the priority of these entries based on your service requirements.

7. Log on to the ECS instance by using the associated EIP to check the network configuration of the ECS instance.

Note Make sure that the security group rules of the ECS instance allow remote access.

As shown in the following figure, the IPv4 address of the ECS instance is changed to the associated EIP.

26.4.3. Upgrade a subscription EIP

This topic describes how to upgrade the bandwidth of EIP. Bandwidth upgrades take effect immediately.

Procedure

1. Log on to the EIP console.
2. In the upper-left corner, select the region where your EIP is created.
3. On the Elastic IP Addresses page, find the target EIP and choose More > Upgrade in the Actions column.
4. On the Change Specifications page, set a new peak bandwidth for the EIP, and then click Submit.

26.4.4. Disassociate an EIP from a cloud resource

This topic describes how to dissociate an EIP from a cloud resource when this cloud resource no longer needs to communicate with the Internet.

Procedure

1. Log on to the EIP console.
2. In the upper-left corner, select the region where your EIP is created.
3. On the Elastic IP Addresses page, find the target EIP, and click Unbind in the Actions column.
4. In the Unbind Elastic IP Address dialog box, click OK.

26.4.5. Release an EIP

This topic describes how to release an Elastic IP address (EIP).

Prerequisites

The EIP is disassociated from all instances. For more information, see [Disassociate an EIP from a cloud resource](#).

Procedure

1. [Log on to the EIP console](#).
2. In the upper-left corner, select the region where your EIP is created.
3. On the **Elastic IP Addresses** page, find the target EIP, move the mouse pointer over **More operations** in the **Actions** column, and then click **Release**.
4. In the **Release an EIP** dialog box, click **OK**.

27. Express Connect

27.1. What is Express Connect?

This topic provides an overview of Express Connect. Express Connect allows you to establish private connections to enable fast, stable, and secure communication between different networking environments. You can use Express Connect to ensure network stability and prevent data breaches.

Features

You can use a leased line provided by an Internet Service Provider (ISP) to establish a physical connection between your data center and an Alibaba Cloud access point. After the physical connection is established, you can create a virtual border router (VBR) to connect your data center with Alibaba Cloud to build a hybrid cloud.

The physical connections of Express Connect do not traverse the Internet, and therefore feature faster speeds, lower latency, greater security, and higher reliability compared with Internet connections.

Express Connect enables you to create a peering connection between two Virtual Private Clouds (VPCs) as a channel for private communication.

Benefits

Express Connect provides the following benefits:

- High-speed interconnections

Powered by the network virtualization technology of Alibaba Cloud, Express Connect allows networks to connect and exchange traffic at high speeds within internal networks without carrying traffic across the Internet. The impact of distance on network performance is minimized to ensure low-latency and high-bandwidth communication.

- Stability and reliability

Built on the state-of-the-art infrastructure of Alibaba Cloud, Express Connect guarantees stable and reliable communication between networks.

- Security

Express Connect implements cross-network communication at the network virtualization layer, where data is transmitted over separate and private channels within the infrastructure of Alibaba Cloud, mitigating the risks of data breaches.

- Buy-as-you-need service

Express Connect delivers connectivity with a wide range of bandwidth options. You can choose based on the needs of your business to get the best value for your purchase.

27.2. Log on to the Express Connect console

This topic provides an example of how to log on to the Apsara Stack Cloud Management (ASCM) console and then access Express Connect by using Google Chrome .

Prerequisites

- The domain name of the ASCM console is obtained from the deployment personnel before you log on to the ASCM console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to log on to the ASCM console. Press the Enter key.
2. Enter your username and password.

Obtain the username and password used to log on to the console from the operations administrator.

Note When you log on to the ASCM console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:

- Uppercase or lowercase letters.
- Digits.
- Special characters. Special characters include exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Products > Networking > Express Connect**.

27.3. Connect two VPCs

This topic describes how to create a peering connection to connect two VPCs.

Procedure

1. **Log on to the Express Connect console.**
2. In the left-side navigation pane, choose **VPC Peering Connections > VPC-to-VPC**.
3. On the **VPC Peering Connections** page, click **Create Peering Connection**.
4. Specify the following information to configure the peering connection.

Parameter	Description
Scenario	Select VPC-to-VPC to create a peering connection between two VPCs.
Source Configurations	
Organization	Select the organization to which the source VPC belongs.
Resource Set	Select the resource set to which the source VPC belongs.
Region	Select the region where the source VPC resides.

Parameter	Description
Router Type	Use the default VRouter setting.
Source VPC ID	Select the ID of the source VPC (initiator or acceptor of this peering connection).
Source Router	Select the router of the source VPC (initiator or acceptor of this peering connection).
Destination Configurations	
Organization	Select the organization to which the destination VPC belongs.
Resource Set	Select the resource set to which the destination VPC belongs.
Destination Region	Select the region where the destination VPC resides.
Destination Router Type	Use the default VRouter setting.
Destination VPC ID	Select the ID of the destination VPC (initiator or acceptor of this peering connection).
Destination Router	Select the router of the destination VPC (initiator or acceptor of this peering connection).
Basic Settings	
Bandwidth	Select a bandwidth for the peering connection.

5. Click **Submit**.

27.4. Delete a peering connection

This topic describes how to delete a peering connection.

Procedure

1. **Log on to the Express Connect console.**
2. In the left-side navigation pane, choose **VPC Peering Connections > VPC-to-VPC**.
3. Find the target peering connection and choose  > **Suspend Initiator** in the **Actions** column.
4. Find the target peering connection and choose  > **Suspend Acceptor** in the **Actions** column.
5. Find the target peering connection and choose  > **Delete** in the **Actions** column.
6. In the **Delete Peering Connection** dialog box, click **Confirm**.

28. Apsara Stack Security

28.1. What is Apsara Stack Security?

Apsara Stack Security is a solution that provides Apsara Stack with a full suite of security features, such as network security, server security, application security, data security, and security management.

Background

Traditional security solutions for IT services detect attacks on network perimeters. They use hardware products such as firewalls and intrusion prevention systems (IPSs) to protect networks against attacks.

However, with the development of cloud computing, an increasing number of enterprises and organizations now use cloud computing services instead of traditional IT services. Cloud computing features low costs, on-demand flexible configuration, and high resource utilization. Cloud computing environments do not have definite network perimeters. As a result, traditional security solutions cannot effectively secure cloud assets.

With the powerful data analysis capabilities and professional security operations team of Alibaba Cloud, Apsara Stack Security provides integrated security protection services at the network layer, application layer, and server layer.

Complete security solution

Apsara Stack Security consists of Apsara Stack Security Standard Edition and optional security services, and provides users with a comprehensive security solution.

Security domain	Service	Description
Security management	Threat Detection Service	Monitors traffic and overall security status to audit and centrally manage security.
Server security	Server Guard	Protects Elastic Compute Service (ECS) instances against intrusions and malicious code.
Application security	Web Application Firewall	Protects web applications against attacks and ensures that mobile and PC users can securely access web applications over the Internet.
Network security	Anti-DDoS	Ensures the availability of network links and improves business continuity.
Data security	Sensitive Data Discovery and Protection	Prevents data leaks and helps your business systems meet compliance requirements.
Security O&M service	On-premises security services	Help you establish and optimize your cloud security system to protect your business system against attacks by making full use of the security features of Apsara Stack Security and other Apsara Stack services.

28.2. Precautions

Before you log on to the Apsara Stack Security console, you must verify that your local PC meets the configuration requirements.

The configuration requirements for the local PC are listed in [Configuration requirements](#).

Configuration requirements

Item	Requirement
------	-------------

Item	Requirement
Browser	<ul style="list-style-type: none"> • Internet Explorer: V11 or later • Chrome (recommended): V42.0.0 or later • Firefox: V30 or later • Safari: V9.0.2 or later
Operating system	<ul style="list-style-type: none"> • Windows XP, Windows 7, or later • macOS

28.3. Quick start

28.3.1. User roles and permissions

This topic describes the user roles involved in Apsara Stack Security.

All roles in Apsara Stack Security Center are provided by default. You cannot add custom roles. Before you log on to Apsara Stack Security Center, make sure that your account is assigned the required role. For more information, see [Default roles in Apsara Stack Security](#).

Default roles in Apsara Stack Security

Role	Permission
System administrator of Apsara Stack Security Center	Manages and configures system settings for Apsara Stack Security Center. The system administrator has permissions to manage Apsara Stack accounts, synchronize data, configure alerts, and configure global settings.
Security administrator of Apsara Stack Security Center	<p>Monitors the security status across Apsara Stack and configures security policies for each functional module of Apsara Stack Security. The security administrator has permissions on all functions under Threat Detection, Network Security, Application Security, Server Security, PM Security, and Asset Management.</p> <p> Note The permissions on WAF and Cloud Firewall must be separately assigned.</p>
Department security administrator	<p>Monitors the security status of cloud product resources in the specified department and configures security policies for each functional module of Apsara Stack Security for this department. The department security administrator has permissions on all functions under Threat Detection, Network Security, Application Security, Server Security, PM Security, and Asset Management. In addition, the department security administrator can specify alert notification methods and alert recipients in the department.</p> <p> Note The permissions on WAF and Cloud Firewall must be separately assigned.</p>
Auditor of Apsara Stack Security Center	Conducts security audits across Apsara Stack. The auditor can view audit events and original logs, configure audit policies, and access all functions under Security Audit.

If you do not have a user that assume the required role, contact the administrator to create the account. For more information, see the [Create a user](#) topic in the *ASCM Console User Guide*

28.3.2. Log on to Apsara Stack Security Center

This topic describes how to log on to Apsara Stack Security Center.

Prerequisites

- Before logging on to the ASCM console, make sure that you have obtained the IP address or domain name of the ASCM console from the deployment personnel. The URL used to access the ASCM console is in the following format: `http://IP address or domain name of the ASCM console/manage`.
- We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL used to access the ASCM console. Press Enter.
2. Enter your username and password.

The system has a default super administrator, whose username is `super`. The super administrator can create system administrators. A system administrator can create system users and notify the users of the default passwords by SMS or email.

 **Note** When you log on to the ASCM console for the first time, you must modify the password of your username as instructed. For security concerns, your password must meet the minimum complexity requirements: The password must be 8 to 20 characters in length and must contain at least two types of the following characters: letters, digits, and special characters such as exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click **Login** to go to the ASCM console homepage.
4. In the top navigation bar, choose **Security > Apsara Stack Security**.
5. On the **Apsara Stack Security Center** page, select **Region**.
6. Click **YD** to go to Apsara Stack Security Center.

28.4. Threat Detection Service

28.4.1. Threat Detection Service overview

This topic describes the basic concepts of Threat Detection Service (TDS).

TDS provides comprehensive protection for enterprises. It can monitor vulnerabilities, intrusions, web attacks, DDoS attacks, threat intelligence, and public opinions. TDS uses modeling and analysis to obtain key information based on traffic characteristics, host processes, and host operations logs. In addition, TDS identifies intrusions that cannot be detected by traffic inspection or file scan. You can use the input of cloud analysis models and intelligence data to discover sources and behavior of attacks and assess threats.

TDS provides the following features:

- **Overview:** provides a security situation overview and information about security screens.
- **Security Alerts:** displays security alerts that occur in the business system.
- **Attack Analysis:** displays application attacks and brute-force attacks that occur in the system.
- **Cloud Service Check:** checks whether the security configuration for cloud services has risks.
- **Application Whitelist:** provides information about application processes on servers that require protection based on intelligent learning. The application processes are identified as trusted, suspicious, or malicious. This prevents unauthorized processes.
- **Assets:** manages servers and cloud services on Apsara Stack.
- **Security Reports:** allows you to configure security report tasks on Apsara Stack.

28.4.2. Security overview

28.4.2.1. View security overview information

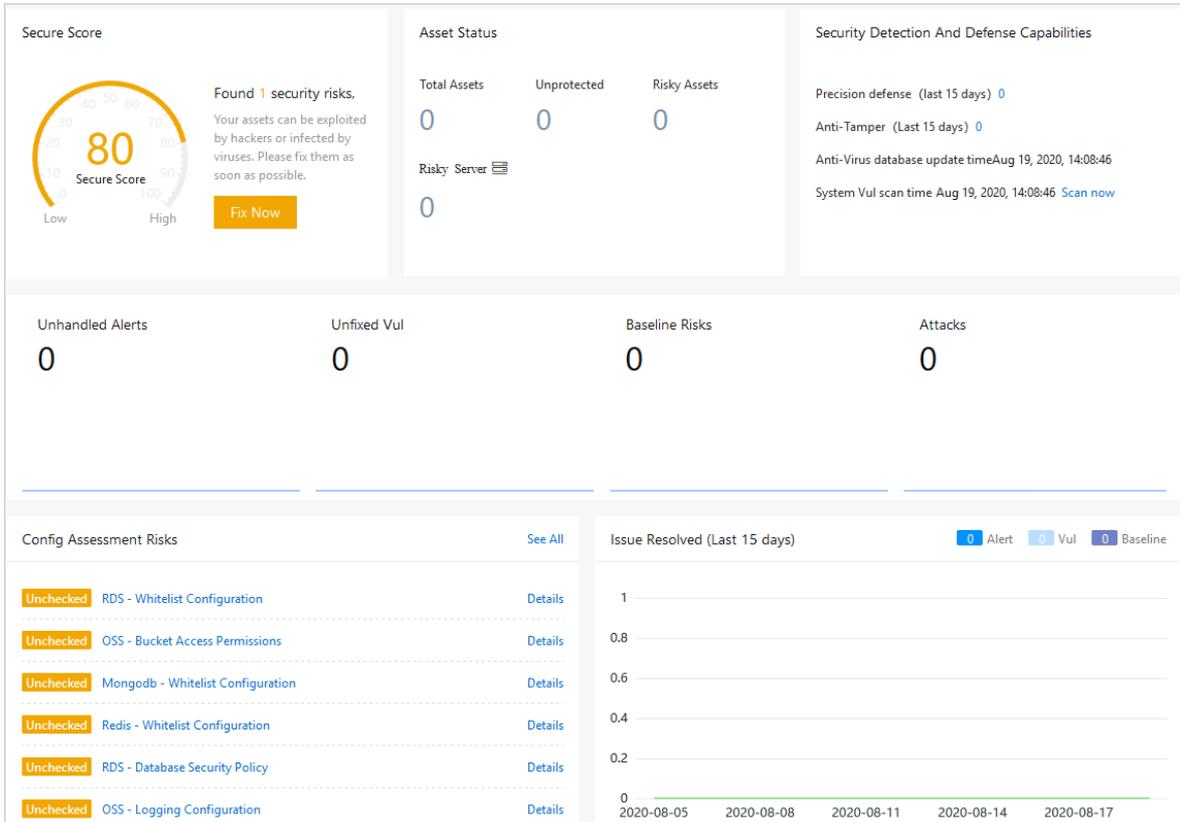

This topic describes how to view security statistics, attack trends, and network traffic information on Apsara Stack.

Context

The **Security Overview** tab provides an overview of detected security events, the latest threats, and inherent vulnerabilities in the system. A security administrator can view information on the **Security Overview** tab to have a comprehensive understanding of the system security situation.

Procedure

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Threat Detection > Overview > Security Overview.**
3. View the security situation of Apsara Stack.

Sections on the Security Overview tab

Section	Description
Security Score	The security score of assets and the number of detected security risks.
Asset Status	The total number of assets and the numbers of servers that are not protected, servers that are stopped, and servers that are at risk.
Security Detection And Defense Capabilities	The numbers of precise defense events and anti-tampering events in the last 15 days, the time when the anti-virus database was updated, and the time of vulnerability scanning. This allows you to obtain information about the defense situation and security status of your assets in real time.
Threat statistics	The numbers of alerts that are not handled, vulnerabilities that are not fixed, baseline risks, and attacks.
Config Assessment Risks	Risks in the baseline configurations of cloud services.
Issue Resolved	Statistics of alerts, vulnerabilities, and baseline risks that have been processed in the last 15 days. The statistics are displayed in a bar and trend chart.

28.4.3. Security alerts

28.4.3.1. View security alerts

This topic describes how to view security alerts on the Security Alerts page.

Procedure

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Threat Detection > Security Alerts**.
3. (Optional)Set filter conditions for security alerts.

 **Note** If you want to view all alerts, do not set the conditions.

Ur... X No... X War... X ▼ Unhandle... ▼ All ▼ Asset Group ▼ Alert/Asset Q

Filter condition	Description
Severity	The severity level. You can select one or more levels. Valid values: <ul style="list-style-type: none"> ○ Urgent ○ Warning ○ Notice
Alert status	The status of alerts. Valid values: <ul style="list-style-type: none"> ○ Unhandled Alerts ○ Handled
Alert type	The type of alerts. Select All or a specific type.
Affected asset group	The affected asset group. Select Asset Group or a specific group.
Search for alerts by name or asset	Enter an alert name or a keyword of affected assets to search for alerts.

4. View security alerts and their details in the list.

28.4.3.2. Manage quarantined files

This topic describes how to manage threat files that are quarantined by the system. The system deletes a quarantined file 30 days after the file is quarantined. You can restore the file before it is deleted.

Procedure

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Threat Detection > Security Alerts**.
3. In the upper-right corner of the **Alerts** page, click **Quarantine**.
4. On the **Quarantine** page, view information about a quarantined file, such as the host, path, status, and operation time.
5. (Optional)If a file is incorrectly quarantined, click **Restore** in the **Actions** to restore the file.

 **Notice** Before you restore a quarantined file, make sure that the file is normal and does not bring risks.

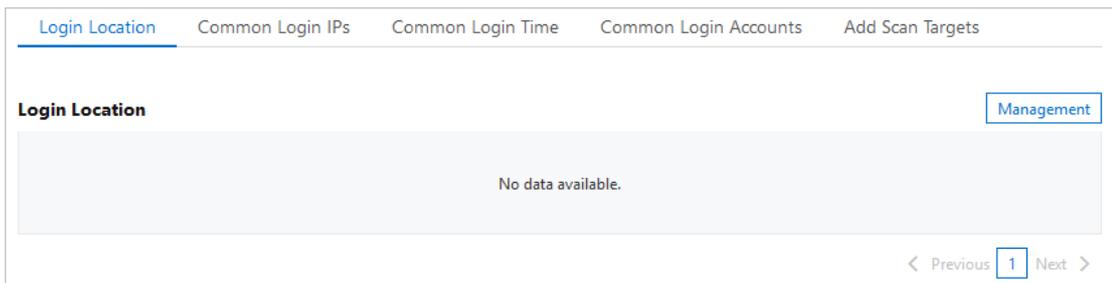

The restored file is removed from the quarantine and is displayed in the security alert list again.

28.4.3.3. Configure security alerts

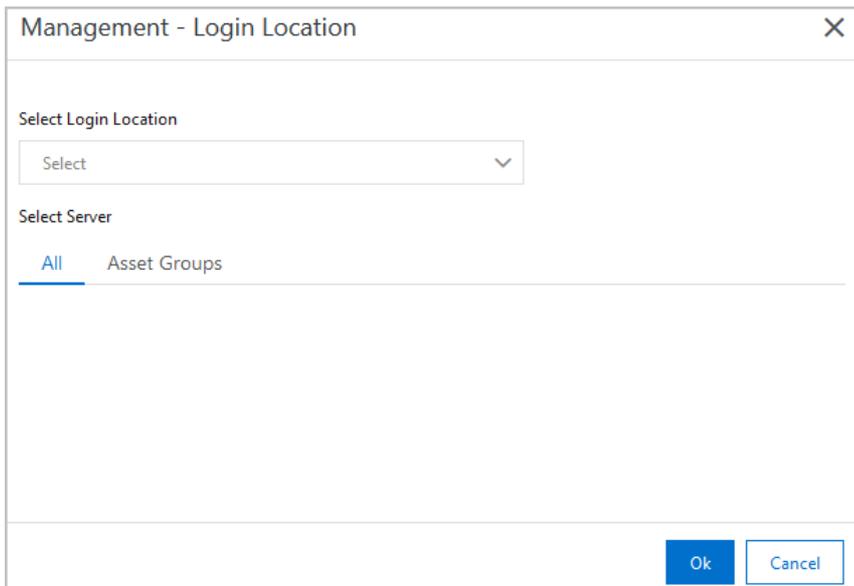

This topic describes how to configure logon settings and web directories that are scanned.

Procedure

1. **Log on to Apsara Stack Security Center.**
2. In the left-side navigation pane, choose **Threat Detection > Security Alerts.**
3. In the upper-right corner of the page, click **Settings**. You can perform the following operations:
 - o **Manage a common logon location.**
 - a. On the right side of **Login Location**, click **Add**.

- b. Select a logon location and the servers that are allowed to be logged on to from the location.

- c. Click **OK**.

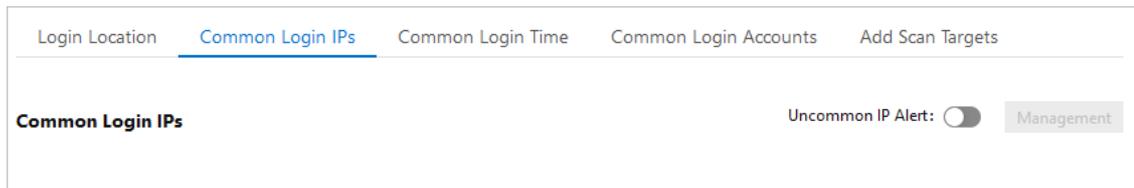

Threat Detection Service (TDS) allows you to edit and delete added logon locations.

- Find the target logon location and click **Edit** on the right side to change the servers that are allowed to be logged on to from this location.
- Find the target logon location and click **Delete** on the right side to delete the logon location.

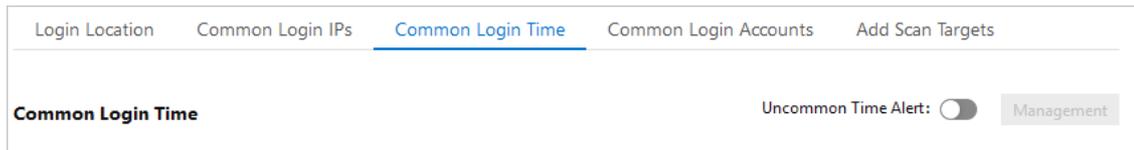

- o **Configure advanced logon settings.**

Note You can specify the IP addresses, accounts, and time periods that are allowed to log on to your assets. After you configure these settings, alerts are triggered if your assets receive logon requests that do not meet the requirements. The procedure to configure advanced logon settings is similar to that to configure common logon locations. You can follow the preceding procedure to add, edit, and delete advanced logon settings.

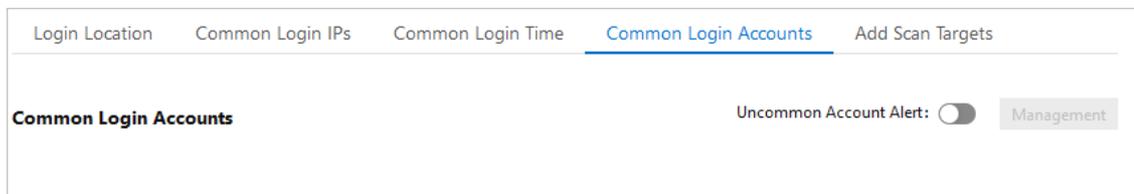

- On the right side of **Common Login IPs**, enable or disable **Uncommon IP Alert**. After this function is enabled, alerts are triggered if your assets receive logon requests from unauthorized IP addresses.

- On the right side of **Common Logon Time**, enable or disable **Uncommon Time Alert**. After this function is enabled, alerts are triggered if your assets receive logon requests at unauthorized time.

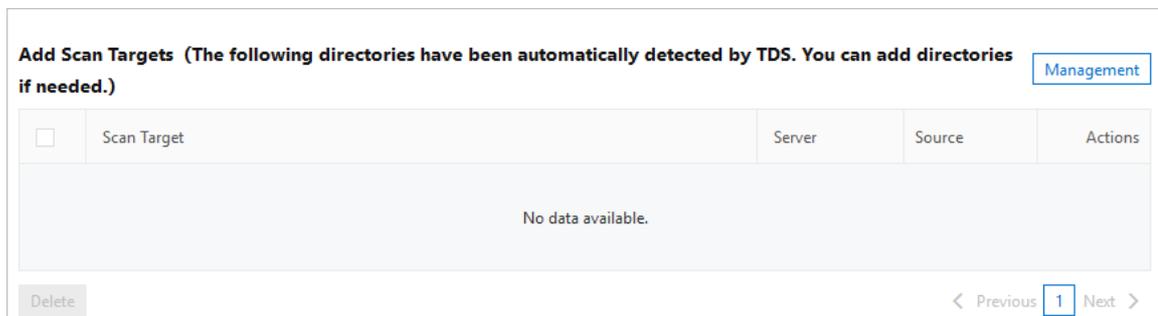

- On the right side of **Common Login Accounts**, enable or disable **Uncommon Account Alert**. After this function is enabled, alerts are triggered if your assets receive logon requests from unauthorized accounts.

- **Add a web directory as the scan target.**

TDS automatically detects web directories on your servers.

It performs dynamic and static scans on these directories. You can also manually add web directories for scanning.

- On the right side of **Add Scan Targets**, click **Add**.
- Enter a valid web directory and select the servers on which the directory is scanned. The web directory is added to the scan list.

Note To ensure performance and efficiency, do not enter a root directory.

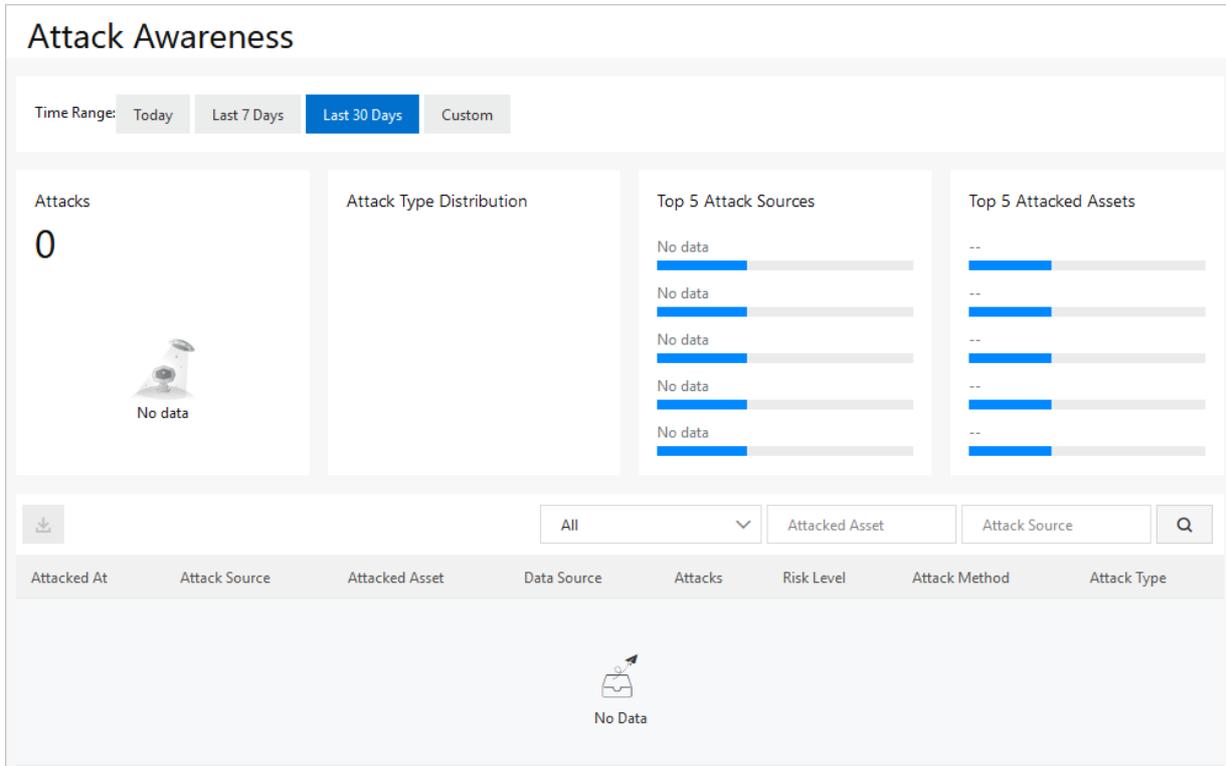

- Click **OK**.

28.4.4. Attack analysis

This topic describes the statistics provided by the attack analysis feature. These statistics include the total number of attacks, the distribution of attack types, top five attack sources, top five attacked assets, and the attack list.

Background information

The attack analysis feature provides basic attack detection and prevention capabilities in the Apsara Stack Security console. We recommend that you develop a more refined and in-depth defense system by optimizing firewalls and enhancing business security.

On the **Attack Awareness** page, you can specify a time period to view the following attack analysis statistics. You can view the attack analysis statistics of the current day, last 7 days, or last 30 days. You can also select **Custom** to view the statistics of a time period within the last 30 days.

- **Attacks**
- **Attack Type Distribution:** the attack types and the number of attacks of each type.
- **Top 5 Attack Sources:** the top five IP addresses where most attacks are initiated.
- **Top 5 Attacked Assets:** the top five assets that have encountered the most attacks.
- **Attack list:** The details of all attacks. These details include the attack time, source IP address, attacked asset, attack type, and attack status.

Note The attack list displays a maximum of 10,000 entries. You can specify **Time Range** to view details about attacks that occur over a specified time range.

Parameters in the attack list

Parameter	Description
Attacked At	The time when an attack is detected.
Attack Source	The source IP address of an attack.
Attacked Asset	The name, public IP address, and private IP address of an attacked asset.
Attack Method	The HTTP request method used to initiate an attack. Valid values: POST and GET.

Parameter	Description
Attack Type	The type of an attack. Supported attack types include SSH brute-force attacks and remote code execution attacks.

- **Search for an attack**

To view the details of a specific attack, you can specify search conditions in the upper-right corner of the attack list. Search conditions include the attack type, attacked asset, and source IP address.

- **View the details of an attacked asset**

To view the details of an attacked asset, you can place the pointer over the name of the **Attacked Asset**.

- **Export the attack list**

To export and save the attack list to your computer, you can click the  icon in the upper-left corner of the attack list. The asset records are exported to an Excel file.

28.4.5. Cloud service check

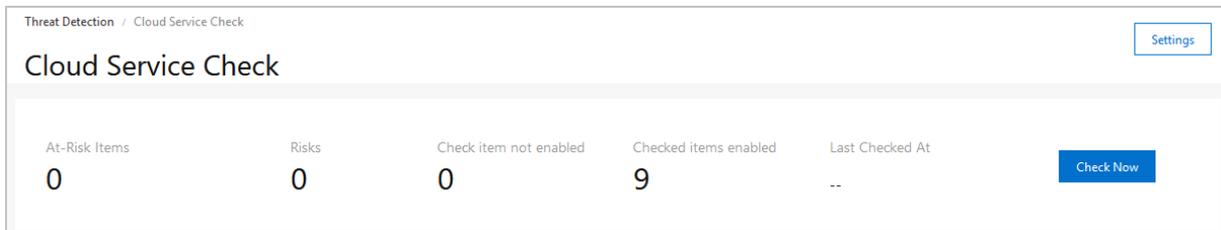

28.4.5.1. Overview

Threat Detection Service (TDS) provides the cloud service check feature. This feature allows you to check for security risks in the configurations of your Alibaba Cloud services. This topic describes the functions and check items that are supported by the cloud service check feature.

Background information

The cloud service check feature allows you to perform network access control and data security checks. The checks help you detect configuration risks of your Alibaba Cloud services and provide repair solutions.

You can view the number of **Checked items** enabled on the **Cloud Service Check** page.

At-Risk Items	Risks	Check item not enabled	Checked items enabled	Last Checked At
0	0	0	9	--

Cloud service check list

The following table lists the check items.

Type	Supported item	Description
	PolarDB - Backup configurations	Checks whether the automatic backup feature is enabled for PolarDB. Regular backups help you improve database security. You can restore data if an error occurs in your database. PolarDB supports automatic backup. We recommend that you enable automatic backup to create a backup on a daily basis.
	Container Registry - Repository permission configurations	Checks whether the status of Container Registry warehouses is set to private. Container Registry warehouses include public warehouses and private warehouses. Public warehouses allow all Internet users to anonymously download information. If an image contains sensitive information, we recommend that you set the value to private. Otherwise, ignore relevant alerts.

Type	Supported item	Description
Data security	OSS - Bucket server-side encryption	Checks whether the data encryption feature of Object Storage Service (OSS) buckets is enabled. OSS supports server-side encryption to secure data that is persistently stored in OSS. We recommend that you enable server-side encryption to protect sensitive data.
	OSS - Sensitive information leakage scans	Checks whether OSS sensitive files require access permissions.
	ApsaraDB for RDS - Cross-region backup configurations	Checks whether cross-region backup is enabled for ApsaraDB for RDS instances. ApsaraDB RDS for MySQL provides the cross-region backup feature that automatically synchronizes local backup files to OSS in another region. We recommend that you enable the cross-region backup feature.
	KVStore for Redis - Backup configurations	Checks whether the data backup feature is enabled for ApsaraDB for Redis instances.
	ApsaraDB for MongoDB - SSL encryption	Checks whether SSL encryption is enabled for ApsaraDB for MongoDB databases. We recommend that you enable the SSL encryption feature to improve the security of data links in ApsaraDB for MongoDB databases.
	ApsaraDB for MongoDB - Backup configurations	Checks whether the automatic backup feature is enabled for ApsaraDB for MongoDB databases. Regular backups help you improve database security. You can restore data if an error occurs in your database. ApsaraDB for MongoDB provides automatic backup policies. We recommend that you enable automatic backup to create a backup on a daily basis.
	ECS - Disk encryption	Checks whether encryption is enabled for disks on Elastic Compute Service (ECS) instances.
	ECS - Automatic snapshot policies	Checks whether the automatic snapshot feature is enabled for the disks on ECS instances. The automatic snapshot feature improves the security of ECS data and supports disaster recovery.
	OSS - Bucket permissions	Checks whether the OSS bucket permission is set to <i>private</i> .
	OSS - Logging configuration	Checks whether the logging feature is enabled for OSS.
	OSS - Cross-region replication configurations	Checks whether the cross-region replication feature is enabled for OSS.
	ApsaraDB for RDS - Database security policies	Checks whether the SQL audit, SSL encryption, and Transparent Data Encryption features are enabled for ApsaraDB for RDS databases.
	ApsaraDB for RDS - Backup configurations	Checks whether the data backup feature is enabled for ApsaraDB for RDS instances.
	SSL Certificates Service - Validity check	Checks whether your SSL certificate is expired. If your SSL certificate is expired, you are not allowed to use SSL Certificates Service.

Type	Supported item	Description
Network access control	ECS - Security group policies	Checks ECS security group policies. We recommend that you grant minimum permissions to users. If you set 0.0.0.0/0 for a service, it indicates that access from all IP addresses is allowed. For example, you can set 0.0.0.0/0 for ports 80, 443, 22, and 3389.
	OSS - Bucket hotlinking protection	Checks whether hotlinking protection is enabled for OSS buckets. The OSS hotlinking protection feature checks the Referer header to deny access from unauthorized users. We recommend that you enable this feature.
	VPC - DNAT management port mapping	Checks whether a port is mapped to the Internet. When you create a Destination Network Address Translation (DNAT) rule for a NAT Gateway that is deployed in a virtual private cloud (VPC), we recommend that you do not map internal management ports to the Internet. Do not map all ports or an important port, for example, ports 22, 3389, 1433, or 3306.
	Apsara Stack Security - Back-to-origin configuration checks	Checks whether Anti-DDoS Pro or Anti-DDoS Premium is configured to allow only Web Application Firewall (WAF) back-to-origin IP addresses. After you set up Anti-DDoS Pro, Anti-DDoS Premium, or WAF, you must hide the IP addresses of the backend servers to prevent attacks on the cloud assets.
	Apsara Stack Security - WAF back-to-origin configurations	Checks whether WAF only allows requests from WAF back-to-origin IP addresses. After you set up Anti-DDoS Pro, Anti-DDoS Premium, or WAF, you must hide the IP addresses of the backend servers to prevent attacks on the cloud assets.
	SLB - IP address whitelist configurations	Checks the access control configurations of Server Load Balancer (SLB) instances. Checks whether access control is enabled for HTTP and HTTPS services and checks whether 0.0.0.0/0 is added to the IP address whitelist.
	SLB - High-risk ports	Checks whether SLB opens ports to the Internet for forwarding unnecessary public services.
	ApsaraDB for RDS - IP address whitelist configurations	Checks whether the ApsaraDB for RDS access control policy is set to 0.0.0.0/0 (all IP addresses), which allows requests from all IP addresses. We recommend that you restrict the access scope to a specific range of IP addresses rather than expose database services to the Internet.
	KVStore for Redis - IP address whitelist configurations	Checks whether the KVStore for Redis access control policy is set to 0.0.0.0/0 (all IP addresses), which allows requests from all IP addresses. We recommend that you restrict the access scope to a specific range of IP addresses rather than expose database services to the Internet.
	AnalyticDB for PostgreSQL - IP address whitelist configurations	Checks whether the AnalyticDB for PostgreSQL access control policy is set to 0.0.0.0/0 (all IP addresses), which allows requests from all IP addresses. We recommend that you restrict the access scope to a specific range of IP addresses rather than expose database services to the Internet.
PolarDB - IP address whitelist configurations	Checks whether IP address whitelists of PolarDB are configured to allow requests from 0.0.0.0/0 (all IP addresses). To prevent security risks, we recommend that you configure IP address whitelists to allow only requests from specific IP addresses.	

Type	Supported item	Description
	ApsaraDB for MongoDB - IP address whitelist configurations	Checks whether the ApsaraDB for MongoDB access control policy is set to 0.0.0.0/0 (all IP addresses), which allows requests from all IP addresses. We recommend that you restrict the access scope to a specific range of IP addresses rather than expose database services to the Internet.

28.4.5.2. Run cloud service checks

Threat Detection Service (TDS) provides the cloud service check feature. This feature allows you to check for security risks in the configurations of your Alibaba Cloud services. This topic describes how to manually run cloud service checks on your Alibaba Cloud services. This topic also describes how to specify a detection interval to automate periodic checks.

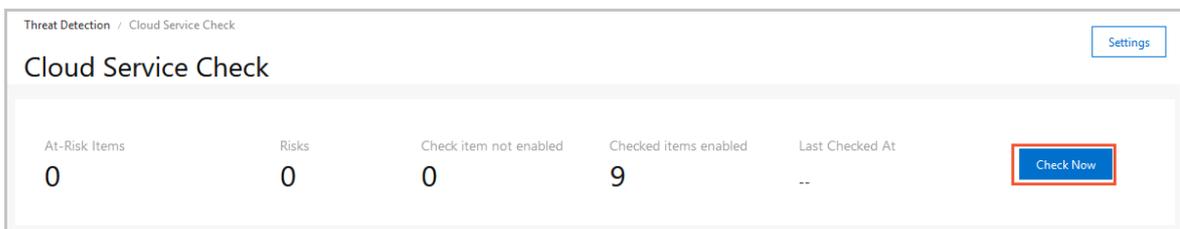

Context

Apsara Stack Security Center supports manual and automated periodic checks to scan for configuration risks in cloud services.

- **Manual checks:** On the **Cloud Service Check** page, click **Check Now** to check for security risks in the configurations of your Alibaba Cloud services
- **Automated periodic checks:** By default, Apsara Stack Security Center automatically runs configuration checks during the 00:00:00-06:00:00 time range every other day. You can also set a custom time period to automatically check whether the configurations of your Alibaba Cloud services contain risks. This helps you detect and manage configuration risks at the earliest opportunity.

Manual checks

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Threat Detection > Cloud Service Check**.
3. On the **Cloud Service Check** page, click **Check Now** to check whether the configurations of all your Alibaba Cloud services contain risks. After you run a check, the number of affected assets is displayed on this page.

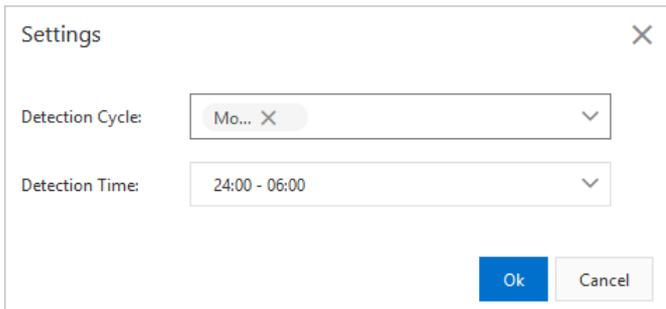

Note Do not perform other operations until the check is complete.

After the check is complete, the detected risks are listed based on their risk levels.

Automated checks

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Threat Detection > Cloud Service Check**.
3. In the upper-right corner of the **Config Assessment** page, click **Settings**.
4. In the **Settings** dialog box, specify **Detection Cycle** and **Detection Time**.

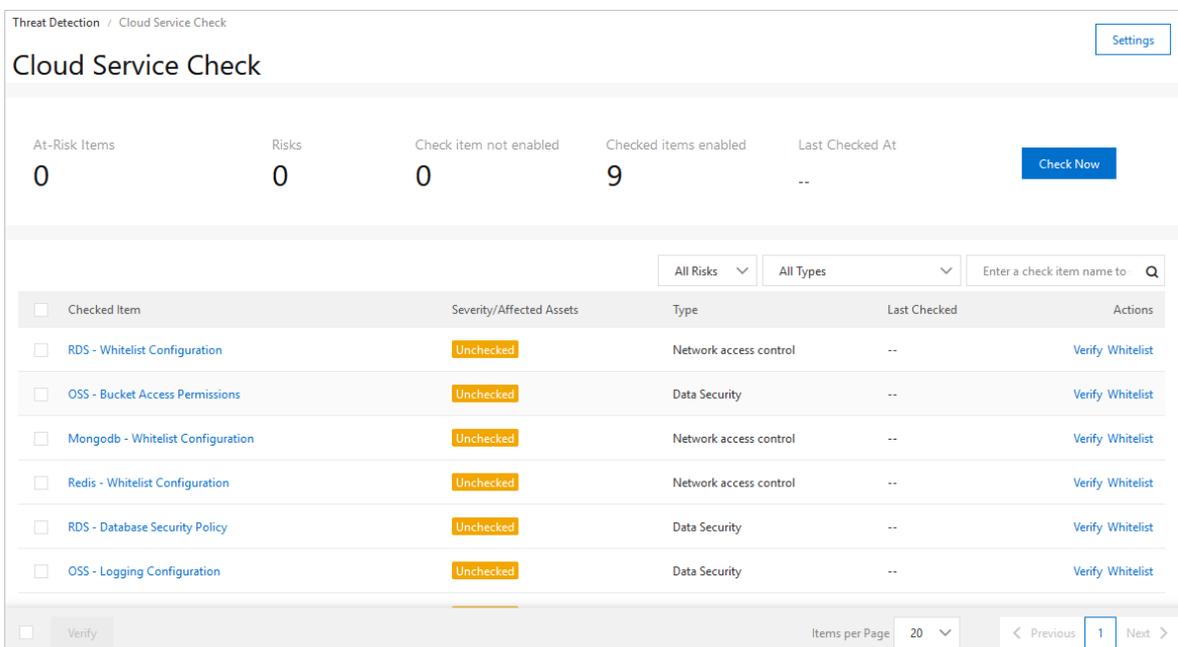

- **Detection Cycle:** supports Monday to Sunday. You can select multiple days.
 - **Detection Time:** Select 24:00:00 - 06:00:00 , 06:00:00 - 12:00:00 , 12:00:00 - 18:00:00 , or 18:00:00 - 24:00:00 .
5. Click **OK**.
During the selected period, Apsara Stack Security Center automatically runs checks based on all check items.

28.4.5.3. View and manage check results of Alibaba Cloud services

This topic describes how to view check results and manage configuration risks in Apsara Stack Security Center. Check results include check items, details of check items, potential impacts, and suggestions on how to manage configuration risks. You can manage configuration risks on the Cloud Service Check page.

View check results

1. **Log on to Apsara Stack Security Center.**
2. In the left-side navigation pane, choose **Threat Detection > Cloud Service Check**.
3. On the **Cloud Service Check** page, you can view the check results and details of the last configuration check.

- **View statistics on the result of the last check.**
Above the check item list, you can view the number of **At-Risk Items** (including the total number of items and the number of items at each risk level), the number of assets with risks (**Risks**), the number of enabled check items, the number of disabled check items, and the last check time.
- **View the check items.**

In the check item list, you can view information about the check items. The check items include the risk level, the type and number of assets affected by each check item, the type of each check item, and the time of the last check.

- View the check result details of a check item.

Click the name of the target checked item in the **Checked Item** column to go to the details page. You can view the check description, potential risks, and suggestions on how to manage the risks on this page.

Manage configuration risks

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Cloud Service Check**.
3. On the **Cloud Service Check** page, manage the configuration risks.
 - Check whether the new settings contain risks.

If you have changed the configuration settings of an item, find the item on the check item list on the **Cloud Service Check** page and click **Verify** in the **Actions** column to check whether the new settings contain risks.

Threat Detection / Cloud Service Check

Cloud Service Check Settings

At-Risk Items: 0 Risks: 0 Check item not enabled: 0 Checked items enabled: 9 Last Checked At: -- Check Now

All Risks All Types Enter a check item name to:

<input type="checkbox"/> Checked Item	Severity/Affected Assets	Type	Last Checked	Actions
<input type="checkbox"/> RDS - Whitelist Configuration	Unchecked	Network access control	--	<input type="button" value="Verify"/> Whitelist
<input type="checkbox"/> OSS - Bucket Access Permissions	Unchecked	Data Security	--	Verify Whitelist
<input type="checkbox"/> MongoDB - Whitelist Configuration	Unchecked	Network access control	--	Verify Whitelist
<input type="checkbox"/> Redis - Whitelist Configuration	Unchecked	Network access control	--	Verify Whitelist
<input type="checkbox"/> RDS - Database Security Policy	Unchecked	Data Security	--	Verify Whitelist
<input type="checkbox"/> OSS - Logging Configuration	Unchecked	Data Security	--	Verify Whitelist

Verify Items per Page: 20 < Previous 1 Next >

- Add a check item to the whitelist.

If you want to ignore the detected risks of a checked item, find the item on the check item list and click **Whitelist** to add the item to the whitelist. The status of the item will change to **Ignored**. Ignored items are not counted as **At-Risk** items.

In the check item list, you can also click **Remove** to remove the **Ignored** items from the whitelist.

Note After you click **Whitelist**, the risk is ignored for this time only. If the risk is detected in the future, Apsara Stack Security Center will continue to report it.

28.4.6. Application whitelist

Application whitelists can prevent unauthorized programs from running on your servers and provide a trusted running environment for your assets.

Context

The application whitelist feature allows you to add servers and trusted applications to a whitelist. Applications that are not specified in the whitelist cannot run on your servers. This feature protects your servers from untrusted or malicious programs and improves resource utilization.

After you apply a whitelist policy to a server, Apsara Stack Security Center detects suspicious or malicious processes and generates alerts on the processes that are not specified in the whitelist.

Note An alert is triggered if a process that is not specified in the whitelist is detected. The detected process may be a normal process or a malicious process. If you trust the process that triggers an alert, we recommend that you add the process to the whitelist. A process that is added to the whitelist no longer triggers alerts when it restarts. If the process is malicious, we recommend that you remove this process immediately and check whether configuration files of scheduled tasks have been modified.

Step 1: Create an application whitelist policy

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Threat Detection > Application Whitelists**.
3. On the **App Control** page, click the **Policies** tab.
4. On the **App Control** page, click the **Policies** tab. Then click **Create Policy** in the upper-left corner.
5. In the **Create Policy** step of the **Create Whitelist Policy** pane, configure the following parameters:
 - **Policy Name:** Enter a whitelist policy name.
 - **Intelligent Learning Duration:** Select a duration for intelligent learning. Valid values: 1 Day, 3 Days, 7 Days, and 15 Days. The intelligent learning feature uses machine learning to automatically collect and categorize large amounts of alert data. Apsara Stack Security Center can identify suspicious or malicious processes based on the collected data.
 - **Servers for Intelligent Learning:** Select the servers that you want to add to the whitelist.
6. Click **Next** to create the whitelist policy.
After the whitelist policy is created, its details are automatically displayed in the policy list on the **Policies** tab.

The following table lists the parameters in the policy list.

Parameter	Description
Policy Name	The name of the created whitelist policy.
Servers	The number of servers to which the whitelist policy is applied.
Status	<p>The status of the policy. Valid values:</p> <ul style="list-style-type: none"> ○ Applied: Intelligent learning is completed. The policy is applied to servers. ○ Pending Confirmation: Intelligent learning is completed. The policy must be confirmed and enabled. After intelligent learning is completed, you also need to turn on the switch in the Policy Status column to enable this policy. The policy takes effect only after it is enabled. Apsara Stack Security Center automatically identifies the processes on your servers as trusted, suspicious, or malicious processes. ○ Paused: Intelligent learning is manually paused. You can click Continue in the Actions column to resume intelligent learning. ○ Progress: Intelligent learning is in progress. After a whitelist policy is created, Apsara Stack Security Center automatically performs intelligent learning based on the policy. The status of a newly created policy is Progress.
Applications	The numbers of processes, including Trusted , Suspicious , and Malicious processes, on all servers to which the policy is applied.

Parameter	Description
Actions	<p>The operations that you can perform on a policy. Valid values:</p> <ul style="list-style-type: none"> ○ Apply: Add or remove servers to which the policy is applied on the Apply Whitelist Policy pane. ○ Modify: Modify the policy on the Modify Whitelist Policy pane. You can change the values of Policy Name and Intelligent Learning Duration, and modify the servers that need to automatically perform intelligent learning. ○ Pause Learning: Pause intelligent learning. ○ Continue: Resume intelligent learning. <p>After you click Continue, the status of the policy changes to Progress. You can view the learning progress of the policy in the Status column.</p> <ul style="list-style-type: none"> ○ Delete: Delete the policy. <p>After the policy is deleted, the corresponding servers and processes are no longer protected by the policy.</p>

Step 2: Add servers to the application whitelist

1. **Log on to Apsara Stack Security Center.**
 2. In the left-side navigation pane, choose **Threat Detection > Application Whitelists**.
 3. On the **Servers** tab of the **App Control** page, click **Add Server** in the upper-left corner.
 4. In the **Add Server** pane, configure the following parameters:
 - **Whitelist Policy:** Select an existing whitelist policy from the drop-down list.
 - **Event Handling:** The default value is **Alert**, which indicates that Apsara Stack Security Center generates alerts when a suspicious process is detected.

When an unauthorized process starts on a server protected by the whitelist, an alert is automatically triggered. You can click the number in the **Suspicious Events** column to go to the **Alerts** tab and view the alert details.

 - **Servers:** Select the servers that you want to add to the whitelist. You can select multiple servers.

To search for a server, enter the server name in the search box of **Servers** and click the search icon. Fuzzy match is supported.
 5. Click **OK**.
- After you create an application whitelist, you can view the protected servers and the name of the whitelist policy applied to the servers in the server list on the **Servers** tab.

The following information of the added servers is displayed on the **Servers** tab:

- **Server Name/IP:** the name and IP address of the server to which the whitelist policy is applied.
- **Whitelist Policy:** the whitelist policy that is applied to the server.
- **Suspicious Events:** the number of unauthorized processes that are detected on the server. Apsara Stack Security Center generates alerts immediately when a suspicious process is detected.
- **Event Handling:** The default value is **Alert**, which indicates that Apsara Stack Security Center generates alerts when a suspicious process is detected.

When an unauthorized process starts on a server protected by the whitelist, an alert is automatically triggered. You can click the number in the **Suspicious Events** column to go to the **Alerts** tab and view the alert details.

- **Actions:** You can click **Delete** in the **Actions** column to remove a server from the application whitelist.
- After the server is removed from the whitelist, the application whitelist policy no longer protects the server. Apsara Stack Security Center generates alerts when a process starts on that server.

Add or remove a process to or from an application whitelist

After an application whitelist is configured for your servers, you can view the protected servers and the names of the whitelist policies applied to the servers in the server list on the Servers tab. You can click a policy name in the **Whitelist Policy** column to view the processes running on the required server. You can also view the trusted, suspicious, and malicious processes and their detailed information.

The following information about each process on the server is displayed:

- **Type:** the type of the process. Processes are classified as trusted, suspicious, or malicious processes.
- **Process Name:** the name of the process.
- **Hash:** the Hash function of the process. The Hash function is used to ensure that the process is unique and has not been forged.
- **Path:** the file path of the process on the server.
- **Degree of Trustability:** the degree of trustability for the process determined by Apsara Stack Security Center. Valid values: 0% (malicious process), 60% (suspicious process), and 100% (trusted process).

 **Note** We recommend that you focus on the processes of 0% trustability.

- **Actions:** the operations that can be performed on the process. You can determine whether to add the process to the whitelist based on the services deployed on your server. You can perform the following operations:
 - **Add to Whitelist:** If a process is trusted, add it to the whitelist.
 - **Remove from Whitelist:** After a process is removed from the whitelist, Apsara Stack Security Center identifies the process as untrusted and generates an alert when this process starts.

28.4.7. Assets

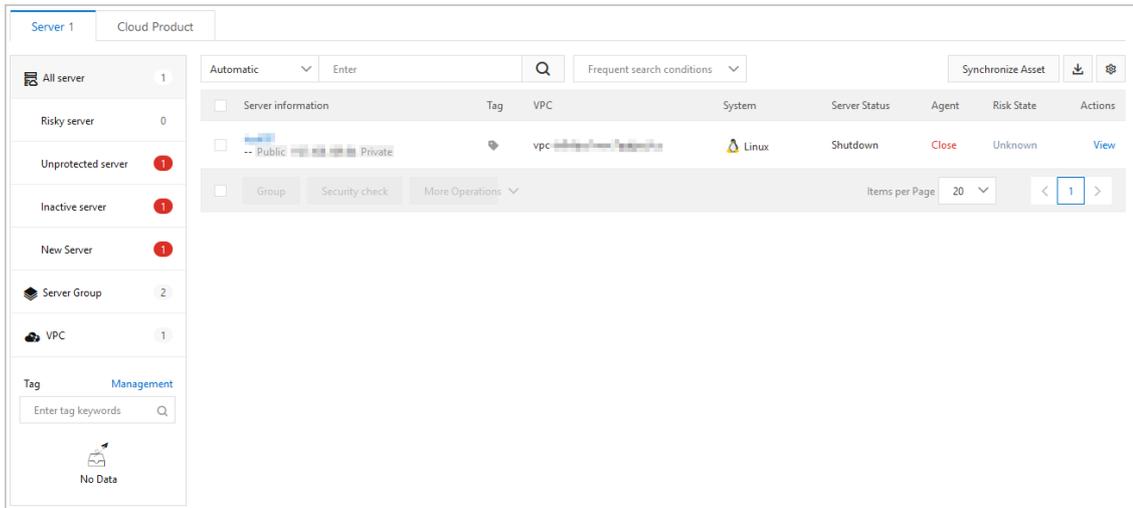

28.4.7.1. View the security status of a server

The Assets page displays security information about each protected server, including the virtual private cloud (VPC) that each server resides, server status, and risk status. This topic describes how to filter assets based on search conditions to view the security status of specific servers. This topic also describes how to specify search conditions and select the items that you want to display on the Assets page.

Procedure

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Server** tab, view the security status of each server. To view the security status of each server, perform one of the following operations:
 - **Filter by server status**

- The All server section displays the numbers of all servers, risky servers, unprotected servers, inactive servers, and new servers.

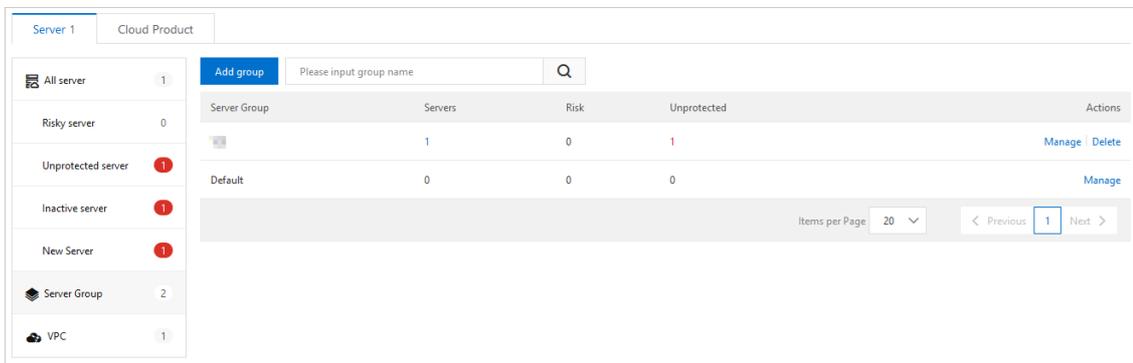

To view the details of a server, click the name of the server, or click Fix in the Actions column. For more information, see [View the details of a single asset](#).

- You can click Risky server, Unprotected server, Inactive server, or New server to view the security status of target servers.

○ Filter by server group

- You can click Server Group to view the total number of server groups and the numbers of servers, servers that are at risk, and unprotected servers in each server group.

You can Manage or Delete to manage a server group in Threat Detection Service (TDS). For more information, see [Manage asset groups](#).

- Find the target server group, click the number in the Servers, Risk, or Unprotected column to view the security status of specified servers in this group.

○ Filter by VPC instance ID

- You can click **VPC** to view the total number of VPCs and the numbers of servers, servers that are at risk, and unprotected servers that are deployed in each VPC.

VPC	Servers	Risk	Unprotected
vpc- <i>id</i>	1	0	1

- Find the target VPC, and click the number in the **Servers**, **Risk**, or **Unprotected** column to view the security status of specified servers in this VPC.

- **Filter by tag**

You can click a tag to the left of the asset list to view the security status of the servers to which this tag is bound.

- **Filter by search condition**

You can click **All server**, **Server Group**, **VPC**, or a **Tag**, and use the search bar on the **Assets** page to filter specific servers.

- Use multiple subconditions to search for specific assets:

Above the asset list of the **Assets** page, you can select a search condition, and select or enter a keyword in the search bar to filter specific servers. Supported search conditions include **Internet IP**, **Private IP**, **Instance name**, **System**, **Baseline problems**, **Vul problems**, **Alert problems**, **Risk Status**, **Online or Offline**, **Tag**, **Group name**, and **OS**.

Note

You can select multiple search conditions at a time and specify the Boolean operator between each search condition. The following content describes Boolean operators:

- Boolean operators:
 - **AND**: specifies the **AND** logical relation for the search conditions.
 - **OR**: specifies the **OR** logical relation for the search conditions.
- If you need to use one search condition and multiple keywords to search for specific servers, set the Boolean operator to **OR**.
- If the search condition requires you to enter a keyword, enter a keyword and then click the Search icon. Results are displayed only after you click the Search icon.

- Use multiple search conditions to search for specific assets:

Apply multiple search conditions to search for specific assets.

You can also select **Server Group**, **Region**, **VPC**, or a **Tag**, and use the search bar on the **Assets** page to filter specific servers.

- **Specify frequently used search conditions**

You can save applied search conditions as frequently used search conditions. Click **Save** and enter a name in the **Save condition** dialog box. Then, you can select the saved search conditions from the **Frequent search conditions** drop-down list on the right of the search bar.

- **Customize displayed items**

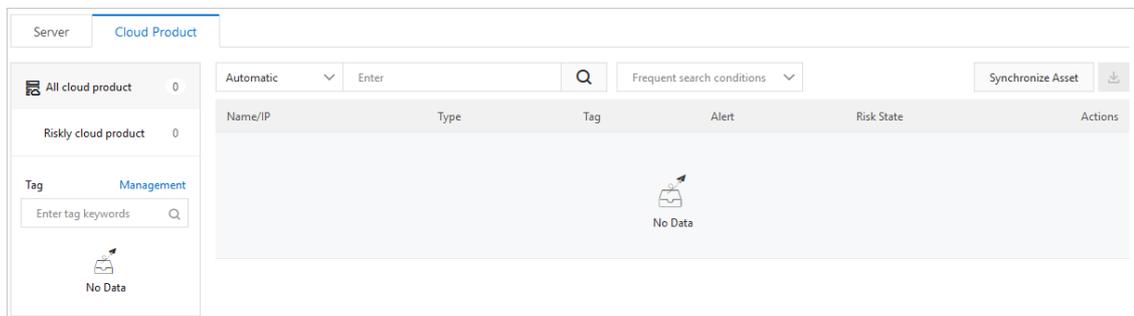

On the Assets page, click the  icon in the upper-right corner. You can then select the items that you want to display on the Assets page.

28.4.7.2. View the security status of cloud services

The Assets page displays the security information about each protected cloud service. The information includes the at-risk services and the types of services, for example, SLB and NAT Gateway. This topic describes how to configure search conditions to view the security status of cloud services.

Procedure

1. **Log on to Apsara Stack Security Center.**
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. Click the **Cloud Product** tab to view the security status of cloud services. You can perform the following operations based on your business requirements:
 - **Search by asset status**
 - In the left-side pane on the **Cloud Product** tab, you can view the numbers of **All cloud product** and **Risky cloud product**. You can also view the security status of all cloud services.

- You can click **Risky cloud product** to view the cloud services that are at risk.

You can click the name of the target cloud service or click **View** in the **Actions** column that corresponds to a service to view detailed information. For more information, see [View the details of a single asset](#).

- **Search by asset type**

Cloud services are classified into two asset types:

- **SLB**
- **NAT Gateway**

In the left-side pane on the **Cloud Product** tab, you can view the number of cloud services of each asset type. You can click **SLB** or **NAT** to view the security status of the target cloud service.

- **Search by tag**

In the **Tag** section in the left-side pane of the **Cloud Product** tab, you can view the number of assets bound to each tag. You can click a tag on the left of the asset list to view the security status of the cloud services to which this tag is bound.

- **Filter by search condition**

You can click **All cloud product**, **SLB**, or **NAT** in the left-side pane of the **Cloud Product** tab and configure search conditions in the search box to search for specific assets.

For example, you can click **All cloud product** and configure search conditions to search for specific assets.

- Use multiple subconditions to search for specific assets:

Select a condition from the drop-down list of the search box on the **Cloud Product** tab, and select a subcondition or enter a keyword into the search box to search for specific assets. Supported search conditions are **Internet IP**, **Instance name**, **Alert problems**, **Risk Status**, **Tag**, and **Group name**.

 **Note**

You can select multiple search conditions at a time and specify the Boolean operator between each search condition. The following content describes Boolean operators:

- Boolean operators:
 - **AND**: specifies the **AND** logical relation for the search conditions.
 - **OR**: specifies the **OR** logical relation for the search conditions.
- If you need to use one search condition and multiple keywords to search for specific servers, set the Boolean operator to **OR**.
- If the search condition requires you to enter a keyword, enter a keyword and click the **Search** icon. Results are displayed only after you click the **Search** icon.

- Use multiple search conditions to search for specific assets:

Apply multiple search conditions.

- You can click **SLB**, **NAT**, or a tag specified in the **Tag** section and configure conditions in the search box on the **Cloud Product** tab to search for specific assets.
- You can also click **All cloud product**, **SLB**, or **NAT** and select a tag specified in the **Tag** section to search for specific assets.

- **Set frequently used search conditions**

You can save applied search conditions as frequently used search conditions. Click **Save** below the search box and enter a name in the **Save condition** dialog box. Then, you can select the saved search condition from the **Frequent search conditions** drop-down list on the right of the search box.

28.4.7.3. View the details of a single asset

The **Assets** page provides details about all assets. These details include basic information, alert management status, baseline check analysis, and asset fingerprints. This topic describes how to view details of a single server or Alibaba Cloud service.

Context

The basic information about assets is displayed on the **Assets** page. Based on the types of assets, servers or Alibaba Cloud services can be managed in different ways.

The following table lists the features that are supported by servers and Alibaba Cloud services on the **Assets** page. The following content describes the marks that are used to indicate whether a feature is supported by servers or Alibaba Cloud services:

- x: not supported by this edition.
- √: supported by this edition.

Feature	Description	Server	Cloud service
	Risk state: displays the number of risks of an asset. Risks can be divided into the following types: <ul style="list-style-type: none"> ● Vulnerability ● Alert ● Baseline risk 	√	√ (Only alerts can be processed.)

Feature	Description	Server	Cloud service
Basic information	Detail: displays the configuration and protection status of an asset. You can specify a group and a tag for the asset.	√	√ (You cannot specify a group for the asset.)
	Asset investigation: displays asset fingerprints, including ports, software, processes, and accounts.	√	X
	Vulnerability check: displays the supported types of vulnerability checks. You can enable or disable different types of vulnerability checks for an asset.	√	X
	Logon security setting: displays the common logon locations, IP addresses, time, and accounts of an asset. You can also enable or disable alerts for the asset.	√	X
Vulnerabilities	Displays the vulnerability check results of an asset.	√	X
Alerts	Displays the security alerts of an asset.	√	√
Baseline Risks	Displays the baseline check results of an asset.	√	X
Asset Fingerprints	Displays the fingerprints of an asset.	√	X

Procedure

1. **Log on to Apsara Stack Security Center.**
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Assets** page, click the **Server** or the **Cloud Product** tab.
4. On the **Server** or **Cloud Product** tab, find the target asset and click its name.
5. View the details of the target asset.

On the asset details page, click the **Basic Information**, **Vulnerabilities**, **Alerts**, **Baseline Risks**, or **Asset Fingerprints** tab to view relevant details.

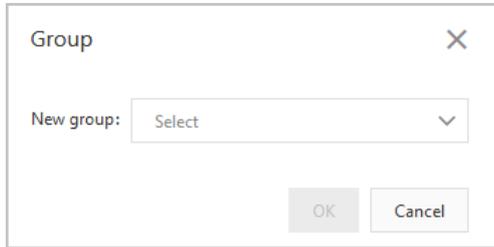

The following content displays the details of the target asset:

- **Basic Information:** This tab consists of sections where you can view asset details and manage an asset.
 - **Risk State:** This section displays information about vulnerabilities, alerts, and baseline risks of an asset. You can click the number under **Vulnerabilities**, **Alerts**, or **Baseline Risks** to view the details.

- **Detail:** This section displays information about the asset configuration and security protection settings, and allows you to manage asset tags and groups.

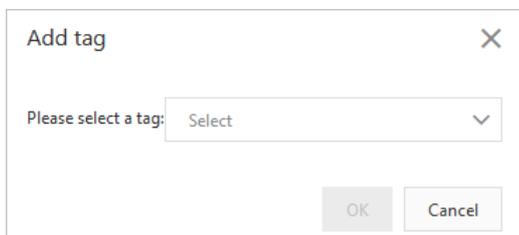

- **Change asset groups**

Click **Group**. In the **Group** dialog box, select a new group and click **OK**.

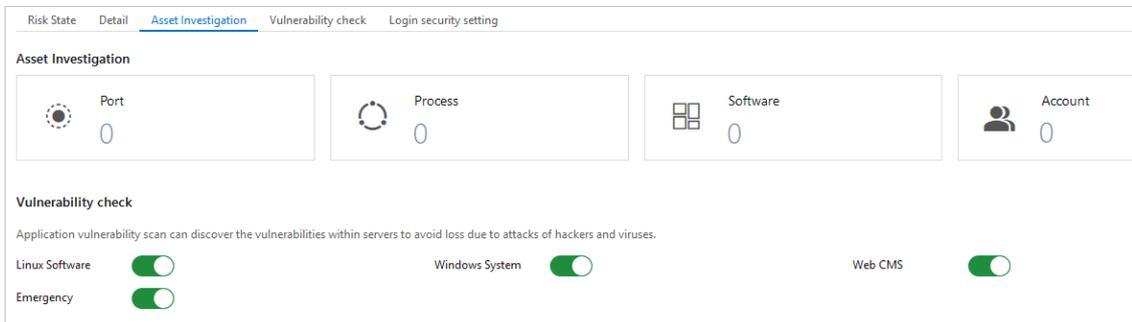

- **Modify tags**

Click the  icon. In the **Add tag** dialog box, select a tag and click **OK**.

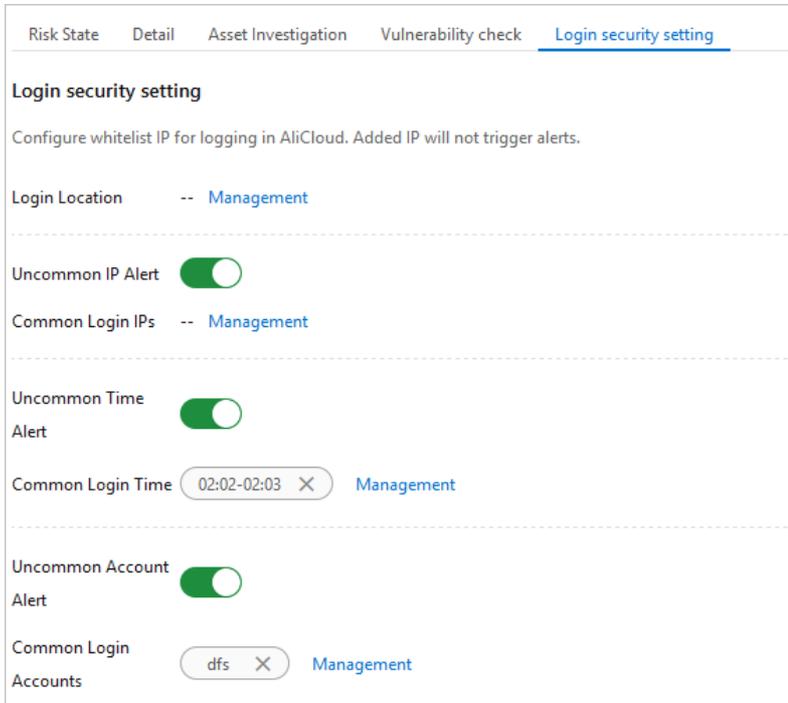

To remove the tag of an asset, click the  icon to the right of the tag.

- **Asset Investigation:** This section displays the fingerprints of an asset. You can click the number under an item to go to the **Asset Fingerprints** tab to view the details.

- **Vulnerability check:** This section displays vulnerability check items that are enabled or disabled for an asset. You can enable or disable different types of vulnerability checks for the asset. The vulnerabilities include Linux software vulnerabilities, Windows system vulnerabilities, Web CMS vulnerabilities, and emergency vulnerabilities.

- Login security setting:** This section allows you to add approved logon locations, configure advanced logon settings, turn on or turn off the unapproved IP address, time, and account alert function. The advanced logon settings include approved IP addresses or Classless Inter-Domain Routing (CIDR) blocks, time periods, and accounts. You can also add approved IP addresses, time periods, and accounts that are allowed to log on to a specific asset.

- Vulnerabilities:** This tab displays vulnerabilities of an asset.

Priority	Disclosure Time	Vulnerability	Related process	Vul (cve)	Status	Actions
High	Aug 10, 2020	RHSA-2018:1062-Important: kernel security, bug fix, and enhancement update		CVE-2016-3672 Total 30	Unfixed	Fix Verify Details
High	Aug 10, 2020	RHSA-2018:1453-Critical: dhcp security update		CVE-2018-1111	Unfixed	Fix Verify Details
High	Aug 10, 2020	RHSA-2018:3665-Important: NetworkManager security update		CVE-2018-15688	Unfixed	Fix Verify Details
High	Aug 10, 2020	RHSA-2017:3263-Moderate: curl security update		CVE-2017-1000257	Unfixed	Fix Verify Details

- Alerts:** This tab displays security alerts of an asset.

- Baseline Risks:** This tab displays baseline risks of an asset.

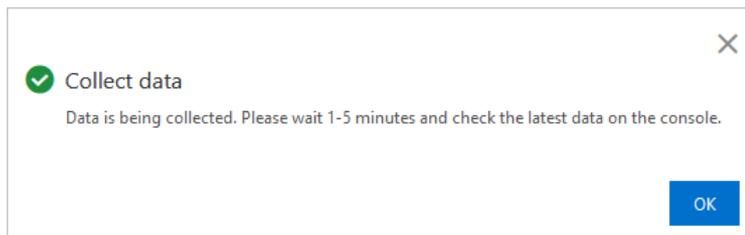

Severity	Baseline	Checked Item	Failed Items/Affected Servers	Category	Last Check
High	Alibaba Cloud Standard - CentOS Linux 7/8 Security Baseline Check	15	5 / 1	Best security practices	Aug 13, 2020, 00:35:11
High	Weak password - Linux system login weak password baseline	1	Risk free	Weak password	Aug 13, 2020, 00:35:11

- Asset Fingerprints:** This tab displays the fingerprints, including ports, processes, software, and accounts of an asset.

You can manually collect the latest fingerprints of an asset.

- You can click the **Port, Software, Process, Account, or Scheduled Tasks** tab. In the upper-right corner, click **Collect data now**.

b. In the **Collect data** dialog box, click **OK**.

After the data collection task is submitted, it takes one to five minutes to collect the fingerprints of the target asset. After the data collection task is complete, you can view the latest fingerprints of the target asset.

28.4.7.4. Enable and disable server protection

This topic describes how to enable and disable server protection.

Procedure

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Server** tab, enable or disable server protection for specified servers.

- o **Enable server protection**

Select one or more servers where the agent is in the **Close** state, and choose **More operations > Turn on protection**.

After server protection is enabled, the status of the agent on the servers changes to **Enable**.

- o **Disable server protection**

You can disable server protection for specified servers. Select one or more servers where the agent is in the **Enable** state, and choose **More operations > Suspend Protection**.

Note After server protection is disabled, Apsara Stack Security Center stops providing protection for your servers. The protection mechanisms that are stopped include vulnerability detection and security event alerting. We recommend that you proceed with caution.

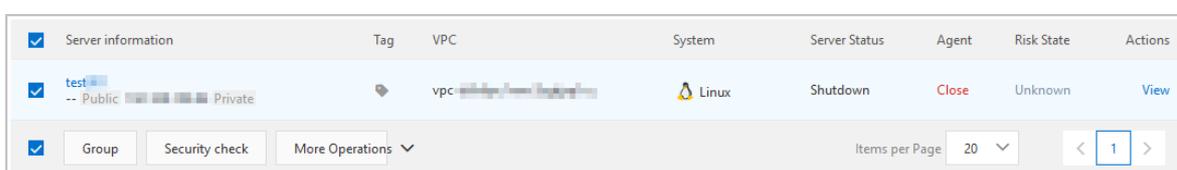

After server protection is disabled, the status of the agent on your servers changes to **Close**.

28.4.7.5. Perform a one-click security check

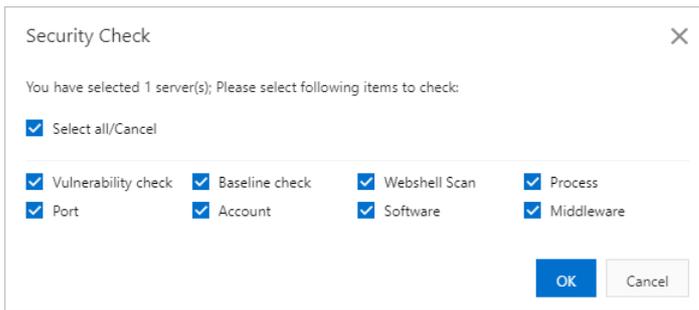

The **Server** tab of the **Assets** page allows you to run security checks. You can dispatch security check tasks to scan for vulnerabilities, baseline risks, and webshells, and collect asset fingerprints on a specific server. The asset fingerprints are ports, software, processes, and accounts. This topic describes how to perform security checks on servers.

Procedure

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Server** tab, select one or more servers on which you want to perform security checks.
4. In the lower part of the page, click **Security check**.

5. In the Security Check dialog box, select check items.

6. Click OK to start the check.

7. In the dialog box that appears, click OK.

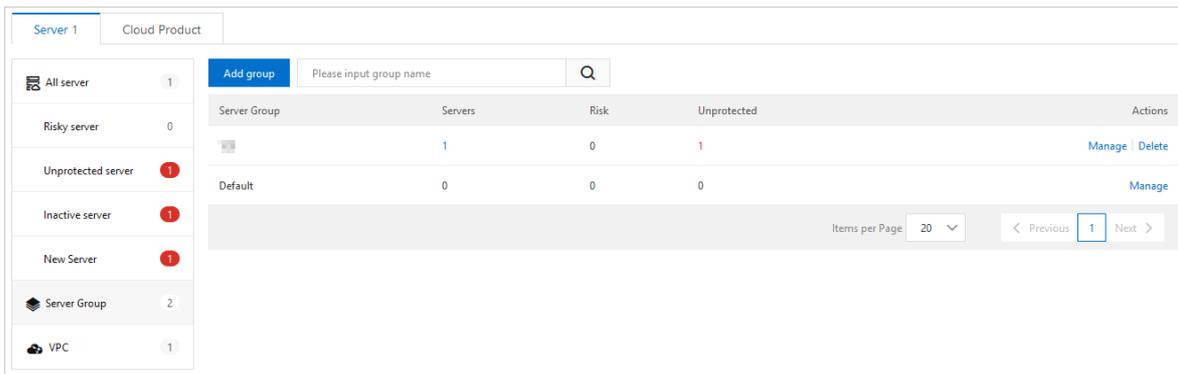

After the one-click security check is complete, the check results are automatically displayed on the Basic Information tab of the target asset.

28.4.7.6. Manage asset groups

This topic describes how to create, modify, delete, and replace server groups.

Add a group

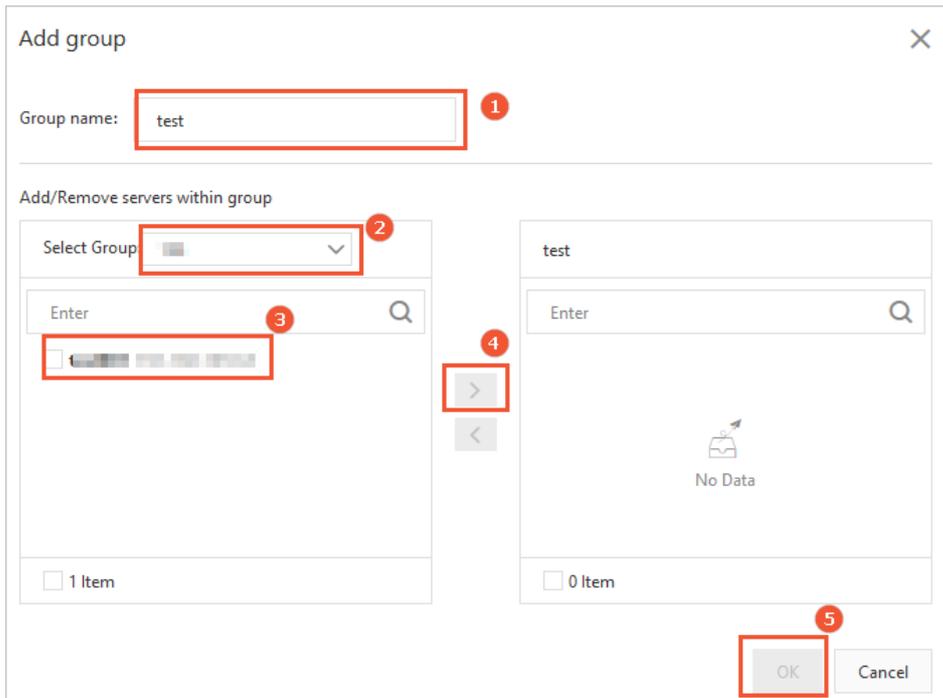

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose Threat Detection > Assets.
3. On the page that appears, click the Server tab. In the servers list on the left, click Server Group.

Note Ungrouped assets are in the Default group.

4. Click Add Group.

5. In the Add Group dialog box, configure the parameters.

You can perform the following steps to configure the parameters:

- i. Enter a group name in the **Group name** field.
- ii. Add assets to the new group.

You can add assets from the **Default** group to the new group. You can also move assets from another group to the new group. Select **Default** or other groups from the **Select Group** drop-down list, select assets in the group, and click the  icon to add the selected groups to the new group.

6. Click **OK**.

In the server group list, you can view the new group.

Modify or delete a server group

The following procedure shows how to modify a server group. You can rename a group, add assets to a group, or remove assets from a group.

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the page that appears, click the **Server** tab. In the servers list on the left, click **Server Group**.
4. Find the target group. In the **Actions** column, click **Manage** or **Delete**. Perform the following operations based on your business requirements:
 - **Modify a group**
 - a. In the **Actions** column, click **Manage** to open the **Group** dialog box.
 - b. In the **Group** dialog box, select a group from the **Select Group** drop-down list, select assets in the current group on the right, and click the  icon to add the selected groups to the new group on the left. You can also select assets in the group on the left and click the  icon to add the selected assets to the current group on the right.
 - c. Click **OK**.
 - **Delete a group**

To delete a group, click **Delete** in the **Actions** column. In the message that appears, click **OK**.

 **Note** After you delete a group, assets in this group are moved to the Default group.

Change server groups

You can add assets to an asset group to manage multiple assets at a time. We recommend that you add the same types of assets to an asset group. For example, when you configure a baseline check policy template, you can specify an asset group to apply the policy to all assets in the group. You can also filter and view assets based on asset groups in the assets list.

To add assets to a specific server group, perform the following steps:

1. **Log on to Apsara Stack Security Center.**
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Server** tab, select one or more assets and click **Group**.
4. In the **Group** dialog box, select a new server group.
5. Click **OK**.

28.4.7.7. Manage asset tags

This topic describes how to add asset importance tags, and add, modify, and remove custom tags for a server.

Context

Apsara Stack Security Center provides the following asset importance tags to classify the assets. You can select appropriate importance tags for your assets.

An asset importance tag is transformed to the target asset importance score that is used to calculate the score of the urgency to fix a vulnerability. Asset importance score affects the score of the urgency to fix a vulnerability. You can determine whether to prioritize the repair of a vulnerability based on the score of the urgency to fix a vulnerability. If you add importance asset tags for core assets, Apsara Stack Security Center prompts you to fix vulnerabilities as soon as possible. The following table shows the relation between asset importance tags and asset importance scores.

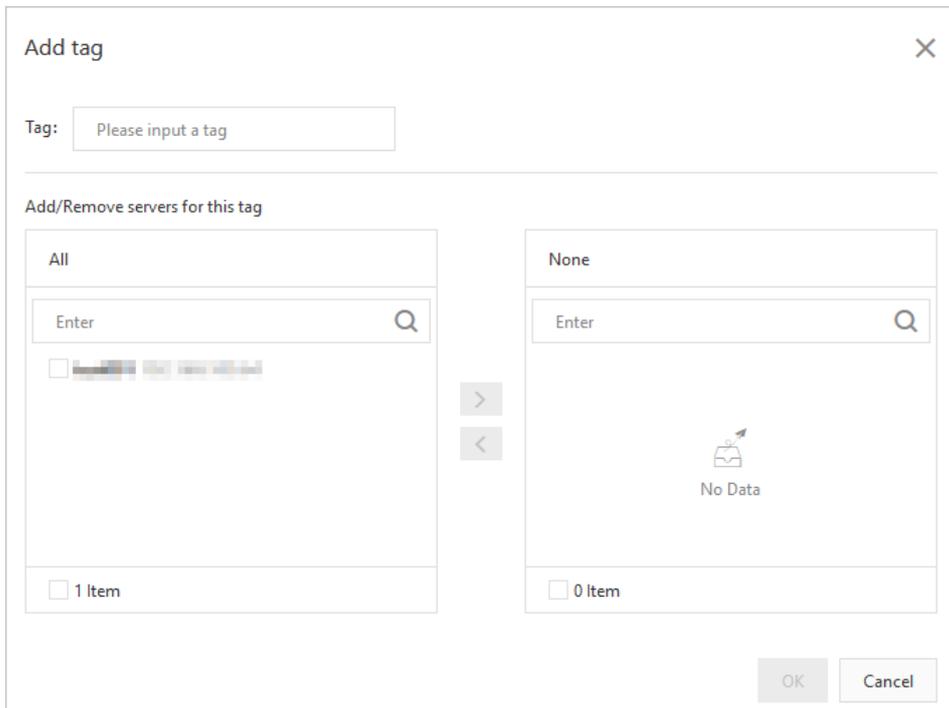

Type	Asset importance score	Recommendation
Important Assets	1.5	Assets that are related to crucial businesses and store core business data. Virus intrusion adversely affects the business system and causes major losses.
General Assets	1	Assets that are related to non-core businesses and are highly replaceable. Virus intrusion causes less impact on the system.
Test Assets	0.5	Assets for performance test, or assets that cause less impact on the system.

 **Note** If you do not add asset importance tags, the tag for each asset is set to **General Assets** by default, which specifies the asset importance score to 1.

Add a custom tag

1. **Log on to Apsara Stack Security Center.**
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. Click **Server** or **Cloud Product**.
4. Click **Server** or **Cloud Product**. In the assets list on the left, click **Management** to the right of the **Tag** column.
5. In the **Add Tag** dialog box, enter the tag name. In the servers list on the left, select target servers, and

click the  icon to add the tag to the selected servers.

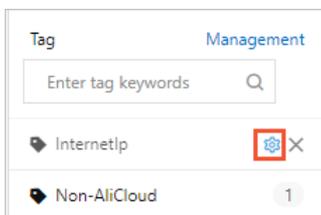

6. Click **OK**. In the left-side assets list, click the  icon in the **Tag** column to add a tag to the asset.

 **Note** You can add multiple tags to one asset. All tags of an asset are displayed in the **Tag** column.

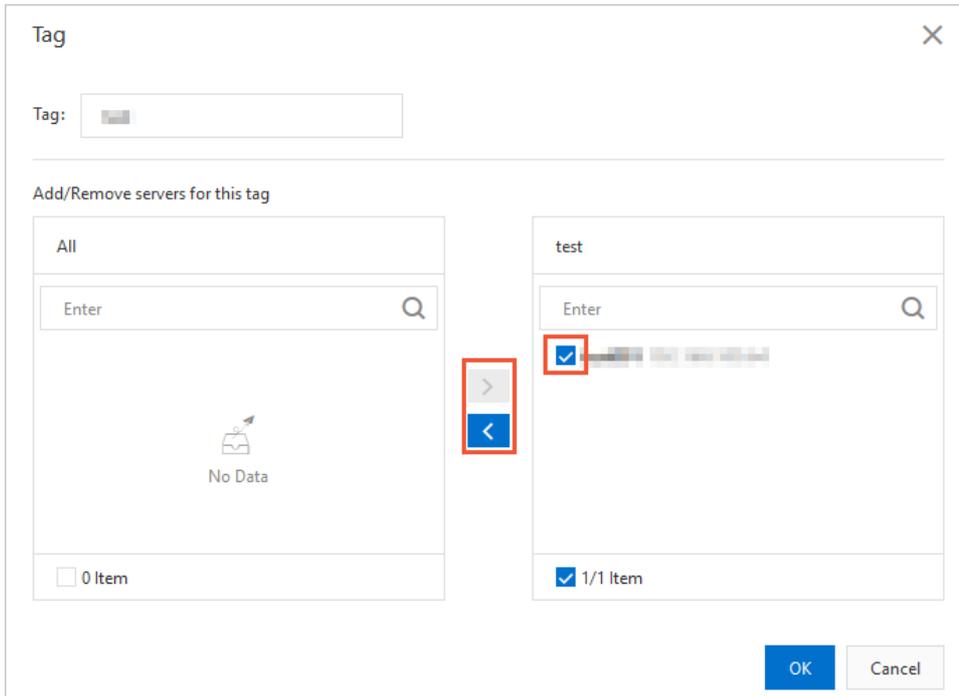

Modify and delete custom tags

Perform the following steps to modify or delete a tag:

1. **Log on to Apsara Stack Security Center.**
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. Click **Server** or **Cloud Product**.
4. On the **Server** or **Cloud Product** tab, modify or delete a tag. Perform the following steps to modify or delete a tag:
 - o **Modify a tag**
 - a. If you want to modify a tag, move the pointer over the  icon to the right of the tag.

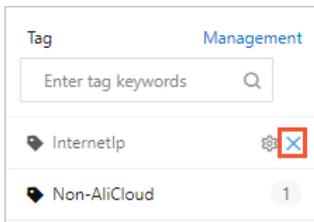

- b. In the Tag dialog box, enter a new name in the Tag field, add the tag to more servers, or remove the tag from servers.

- c. Click OK.

- o **Delete a tag**

Click the  icon in the Tag column. Click OK to delete a tag.

28.4.8. Create a security report

You can specify the report content, statistics types, and recipient email addresses. This way, you can view the security statistics of your assets. This topic describes how to create a security report.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose Threat Detection > Security Reports.
3. On the Reports page, click Create Report.

 **Notice** In addition to the default security report created by Apsara Stack Security Center, you can also create a maximum of nine security reports.

4. On the Specify Basic Information tab, configure the parameters.

Threat Detection / Reports

← Reports

Specify Basic Information
Specify Reported Data

* Report Name:

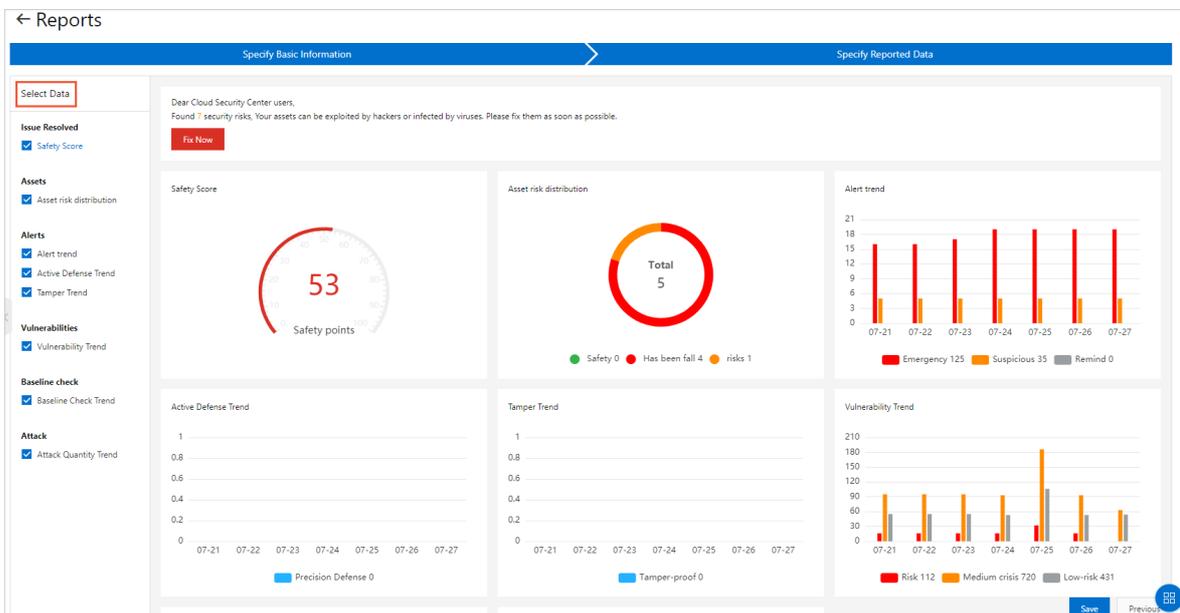

* Report Type: Daily ▼
Data Collection Period: Yesterday 00:00:00 to 24:00:00

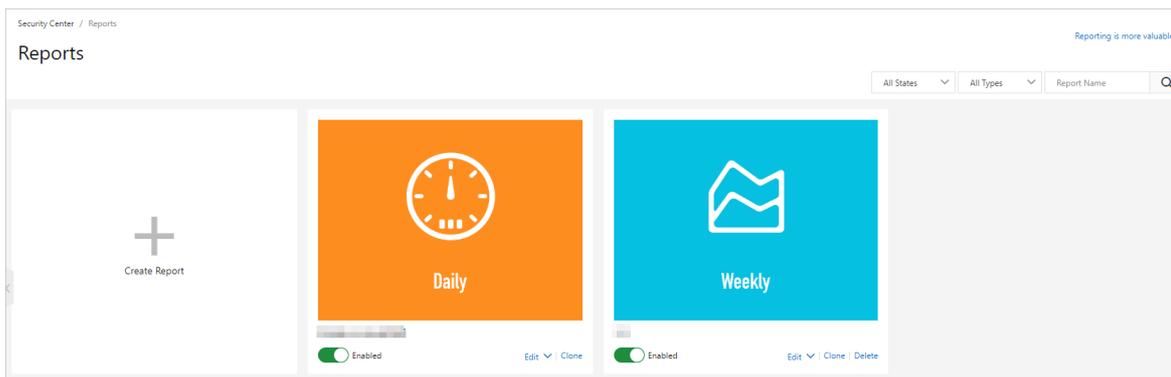

* Language: English ▼

Next

Configure the following parameters:

- **Report Name:** Enter a name for the security report.
 - **Report Type:** Select a report type from the drop-down list. Supported types are *Daily*, *Weekly*, *Monthly*, and *Custom*.
 If you select *Custom*, you must set the **Data Collection Period** parameter to specify the cycle when data is collected.
 - **Language:** Select a language for the security report.
5. Click **Next**.
6. On the **Specify Reported Data** tab, select the types of data that you want to view in the security report. You can select assets, alerts, vulnerabilities, baseline checks, attacks, and other data related to security operations.

28.5. Network Traffic Monitoring System

28.5.1. View traffic trends

This topic describes how to view the network traffic trends, inbound traffic statistics, and outbound traffic statistics.

Context

By analyzing traffic trends, the security administrator can obtain the throughput and the peaks and troughs of traffic periods. In addition, the security administrator can block traffic from malicious IP addresses by viewing the top five IP addresses with the most traffic.

Procedure

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Network Security > Traffic Analysis > Traffic Trend**.
3. In the upper-right corner of the Traffic Trends page, select the time range, which can be **Last 1 Hour**, **Last 24 Hours**, or **Last 7 Days**.
4. View network traffic information.
 - **Network traffic trends**
View the network traffic trends from the selected time range. The network traffic trends include inbound and outbound traffic measured in bit/s.
 - **Inbound Traffic**
View the information of Inbound Sessions, Inbound Applications, and Destination IPs with Most Requests.
 - **Outbound Traffic**
View the information of Outbound Sessions, Outbound Applications, and Source IPs with Most Requests.
5. (Optional) Click the  icon to export traffic trends as a PDF file.

28.5.2. View traffic at the Internet border

This topic describes how to view traffic at the Internet border. You can obtain up-to-date information about network security.

Prerequisites

The Network Traffic Monitoring System module is purchased and deployed at the egress (ISW) of Apsara Stack. This module audits, analyzes, and manages both inbound and outbound traffic at Internet borders.

Context

You can use traffic information to identify abnormal Internet traffic and block malicious traffic.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose Network Security > Traffic Analysis > Internet Border.
3. Specify traffic filter conditions.

Item	Description
1	Specify the traffic direction. Valid values: <i>Inbound</i> and <i>Outbound</i> . <ul style="list-style-type: none"> ◦ <i>Inbound</i>: The traffic flows from the Internet to the internal network. ◦ <i>Outbound</i>: The traffic flows from the internal network to the Internet.
2	Specify whether you want to view the traffic from the IP address or application dimension. Valid values: <i>By IP</i> and <i>By Application</i> .
3	Specify the time range. Valid values: <i>Last 1 Hour</i> , <i>Last 24 Hours</i> , and <i>Last 7 Days</i> .

4. View details about the traffic at the Internet border.

o Traffic Statistics

- The Visits to IP section includes Source IPs, Destination IPs, Applications, and Traffic Risk.
- In the traffic chart on the right, you can view Average Traffic, Peak Traffic, and traffic trends.

o Traffic List

The Traffic List section features two tabs: 'By Source IP' (selected) and 'By Destination IP'. Below the tabs is a search bar with an 'Enter' field and a 'Search' button. The main area contains a table with the following columns: Source IP, Direction, Traffic Volume, Visited Destination IPs, Applications, Destination Ports, Sessions, and Actions. The table is currently empty, displaying a 'No Data' message.

In the Traffic List section, you can view traffic details.

5. In the Traffic List section, view abnormal traffic of the specified IP address.
 - o If *Inbound* is specified, you can view abnormal traffic on the **By Destination IP** tab of the Traffic List section.
 - o If *Outbound* is specified, you can view abnormal traffic in the Traffic List section.

28.5.3. View traffic at the internal network border

This topic describes how to view the traffic at the internal network border. You can obtain up-to-date information about network security based on the traffic.

Prerequisites

The Network Traffic Monitoring System module is purchased and deployed at the ingress (CSW) of Apsara Stack. This module is used to audit, analyze, and control both inbound and outbound traffic routed over leased lines between on-premises data centers and virtual private clouds (VPCs).

Context

You can use traffic information to identify suspicious traffic from the internal network and block malicious requests.

Procedure

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Network Security > Traffic Analysis > Internal Network Border**.
3. Specify traffic filter conditions.

Item	Description
1	Select a VPC name from the drop-down list.
2	Specify the traffic direction. Valid values: <i>Inbound</i> and <i>Outbound</i> . <ul style="list-style-type: none"> ◦ <i>Inbound</i>: The traffic flows from the Internet to the internal network. ◦ <i>Outbound</i>: The traffic flows from the internal network to the Internet.
3	Specify whether you want to view the traffic that flows through the internal network border from the IP address or application dimensions. Valid values: <i>By IP</i> and <i>By Application</i> .
4	Specify the time range. Valid values: <i>Last 1 Hour</i> , <i>Last 24 Hours</i> , and <i>Last 7 Days</i> .

4. View details about the traffic at the internal network border.
 - **Traffic Statistics**
 - The **Visits to IP** section includes **Source IPs**, **Destination IPs**, **Applications**, and **Traffic Risk**.
 - In the traffic chart on the right, you can view **Average Traffic**, **Peak Traffic**, and traffic trends.
 - **Traffic List**

In the **Traffic List** section, you can view traffic details.

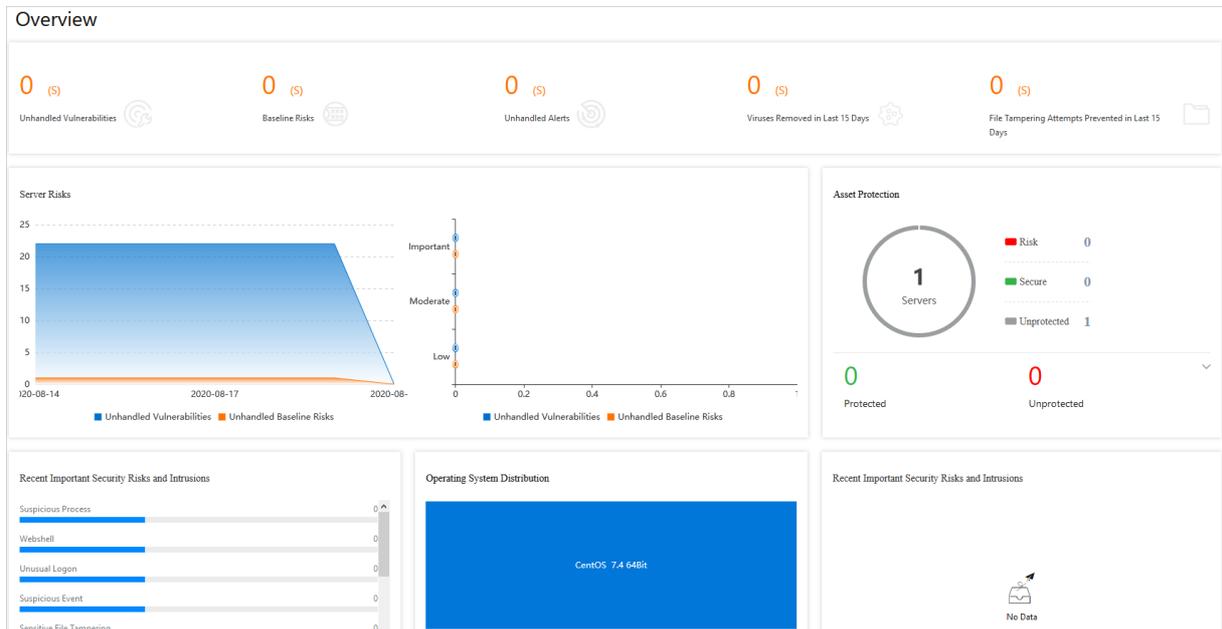

If **By IP** is specified, you can view the suspicious traffic of the specified IP address in the **Traffic List** section.

28.6. Server security

28.6.1. Server security overview

The security administrator can view the current security status of all servers on the server security overview page of Apsara Stack Security Center.

In the left-side navigation pane, choose **Server Security > Overview**. On the page that appears, you can view detailed information in the Overview, Server Risks, Asset Protection, Operating System Distribution, and Recent Important Security Risks and Intrusions sections.

- **Overview:** This section displays the number of security vulnerabilities of each type (including **Unhandled Vulnerabilities** and **Baseline Risks**) and the number of security events of each type (including **Unhandled Alerts**, **Viruses Removed in Last 15 Days**, and **File Tampering Attempts Prevented in Last 15 Days**) on servers.
- **Server Risks:** This section displays the number of unhandled vulnerabilities, the number of baseline risks, and the distribution of risk levels.
- **Asset Protection:** This section displays the number of protected servers and the number of offline servers.
- **Recent Important Security Risks and Intrusions:** This section displays the recent important risks and events on your servers. You can click a risk or event to view the details.

28.6.2. Server fingerprints

28.6.2.1. Manage listener ports

This topic describes how to regularly collect information from listener ports on a server, and record and view the port changes and historical port information. This allows you to locate suspicious listening behavior.

Context

This task is suitable to the following scenarios:

- Check for servers that listen on a specific port.
- Check for ports that are open on a specific server.

Procedure

1. **Log on to Apsara Stack Security Center.**
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. On the page that appears, click the **Port** tab.
3. **View Port, Protocol, and Server.** You can search for a port by using its port number, process name, server name, or IP address.
4. Click a port number to view the details, such as the assets and protocol.

28.6.2.2. Manage software versions

This topic describes how to regularly collect software version information of a server and record the changes. This helps to check your software assets.

Context

This task is suitable to the following scenarios:

- Check for software assets that are installed without authorization.
- Check for software of outdated versions.
- Locate the affected assets when vulnerabilities are detected.

Procedure

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. On the page that appears, click the **Software** tab.
3. View all software in use and the number of servers that use such software. You can search for a piece of software by using its software name, version, installation directory, server name, or IP address.
4. Click a software name to view the details, such as the assets and software version.

28.6.2.3. Manage processes

This topic describes how to regularly collect the process information on a server and record changes. This helps check for processes and view historical process changes.

Context

This task is suitable to the following scenarios:

- Checks for servers that run a specified process.
- Checks for processes that run on a server.

Procedure

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. On the page that appears, click the **Process** tab.
3. View all running processes and the number of servers that run these processes. You can search for a process by using its process name, running user, startup parameter, or server name or IP address.
4. Click a process name to view the details, such as the assets, path, and startup parameters.

28.6.2.4. Manage account information

This topic describes how to regularly collect the account information on a server and record changes. This helps check for accounts and view historical account changes.

Context

This task is suitable to the following scenarios:

- Check for servers where the specified account is created.
- Check for accounts that are created on a server.

Procedure

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. On the page that appears, click the **Account** tab.
3. View all logged-on accounts and the number of servers that use these accounts. You can search for an account by using its account name, root permissions, server name, or IP address.

4. Click an account name to view the details, such as the assets, root permissions, and user group.

28.6.2.5. Manage scheduled tasks

This topic describes how to regularly collect information of scheduled tasks on a server. This allows you to check your tasks.

Procedure

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. On the page that appears, click the **Scheduled Tasks** tab.
3. View the paths of all tasks and the number of servers that run these tasks. You can search for a task by using its path, server name, or IP address.
4. Click a task path to view the details, such as the assets, executed command, and task cycle.

28.6.2.6. Set the server fingerprint collection frequency

You can set the frequency at which the data of running processes, system accounts, listening ports, and software versions is collected.

Procedure

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. In the upper-right corner of the page that appears, click **Settings**.
3. Select the collection frequency from each drop-down list.
4. Click **OK** to complete the configuration.

28.6.3. Threat protection

28.6.3.1. Vulnerability management

28.6.3.1.1. Manage Linux software vulnerabilities

This topic describes how to manage Linux software vulnerabilities.

Context

Apsara Stack Security automatically scans the software that are installed on your servers based on the vulnerabilities provided in the Common Vulnerabilities and Exposures (CVE) list. It also sends you alerts about the detected vulnerabilities. In addition, Apsara Stack Security provides commands that are used to fix vulnerabilities and allows you to verify these vulnerability fixes.

Procedure

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**. On the page that appears, click the **Linux Software** tab.
3. View the detected Linux vulnerabilities.

 **Note** You can locate a vulnerability by using the search and filter functions.

4. Click a vulnerability to go to the vulnerability details page. You can view details about the vulnerability and affected assets on this page.

 **Note** You can locate specific affected assets by using the search and filter functions.

- **Basic Information:** the basic information of the vulnerability, including the name, Common Vulnerability Scoring System (CVSS) score, description, and resolution.
 - **Affected Assets:** the servers that are affected by the vulnerability.
5. Select an action based on the impact of the vulnerability.

Actions on vulnerabilities

Option	Description
Generate Fix Command	Select this option to generate the commands that are used fix the vulnerability. You can then log on to the server to run these commands.
Fix Now	Select this option to fix the vulnerability.
Restarted and Verified	If a vulnerability fix takes effect only after a server reboot, you must reboot the server after the status of the vulnerability changes to Fixed (To Be Restarted). After the reboot, click Restarted and Verified.
Ignore	Select this option to ignore a vulnerability. The system does not send you an alert about an ignored vulnerability.
Verify	Click Verify to verify the vulnerability fix. If you do not manually verify a fix, the system automatically verifies the fix within 48 hours after the vulnerability fix is complete.

You can fix a vulnerability for one or more affected assets at a time.

- To fix a vulnerability for one affected asset, select an action from the **Actions** column of the asset.
- To fix a vulnerability for one or more affected assets, select the target servers, and select an action in the lower-left corner.

28.6.3.1.2. Manage Windows vulnerabilities

This topic describes how to manage Window vulnerabilities.

Context

Apsara Stack Security automatically checks if your servers have the latest Microsoft updates installed, and notifies you of the detected vulnerabilities. Apsara Stack Security also automatically detects and fixes major vulnerabilities on your servers.

Procedure

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**. On the page that appears, click the **Window System** tab.
3. Check the detected Windows vulnerabilities.

 **Note** You can find a vulnerability by using the search and filter functions.

4. Click a vulnerability to go to the vulnerability details page. You can view details about the vulnerability and affected assets on this page.

 **Note** You can find specific affected assets by using the search and filter functions.

- **Basic Information:** the basic information of the vulnerability, including the name, Common Vulnerability Scoring System (CVSS) score, description, and resolution.
 - **Affected Assets:** the servers that are affected by the vulnerability.
5. Select an action based on the impact of the vulnerability. [Actions on vulnerabilities](#) describes the actions.

Actions on vulnerabilities

Option	Description
Rectify	Select this option to fix the vulnerability. The system caches an official Windows patch in the cloud for your server to download and update.
Ignore	Select this option to ignore a vulnerability. The system does not send you an alert about an ignored vulnerability.
Verify	Click Verify to verify the vulnerability fix.
Restarted and Verified	If a vulnerability fix takes effect only after a server reboot, you must reboot the server after the status of the vulnerability changes to Fixed (To Be Restarted) . After the reboot, click Restarted and Verified .

You can fix a vulnerability for one or more affected assets at a time.

- To fix a vulnerability for one affected asset, select an action from the **Actions** column of the asset.
- To fix a vulnerability for one or more affected assets, select the target servers, and select an action in the lower-left corner.

28.6.3.1.3. Manage Web CMS vulnerabilities

This topic describes how to manage Web CMS vulnerabilities.

Context

The Web CMS vulnerability detection feature obtains the information of the latest vulnerabilities and provides patches in the cloud. This helps you detect and fix vulnerabilities.

Procedure

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**. On the page that appears, click the **Web CMS** tab.
3. View all vulnerabilities.

 **Note** You can find a vulnerability by using the search and filter functions.

4. Click a vulnerability to go to the vulnerability details page. You can view details about the vulnerability and affected assets on this page.

 **Note** You can find specific affected assets by using the search and filter functions.

5. Select an action based on the impact of the vulnerability. [Actions on vulnerabilities](#) describes the actions.

Actions on vulnerabilities

Option	Description
--------	-------------

Option	Description
Rectify	<p>Select this option to fix the Web CMS vulnerability by replacing the web files that contain the vulnerability on your server.</p> <div style="background-color: #e0f2f1; padding: 5px; border: 1px solid #ccc;"> <p> Note Before you fix the vulnerability, we recommend that you back up the web files affected by this vulnerability. For more information about the paths of the web files, see the paths specified in the vulnerability remarks.</p> </div>
Ignore	Select this option to ignore a vulnerability. The system does not send you an alert about an ignored vulnerability.
Verify	<p>Click Verify to verify the vulnerability fix.</p> <p>If you do not manually verify a fix, the system automatically verifies the fix within 48 hours after the vulnerability fix is complete.</p>
Undo Fix	For vulnerabilities that have been fixed, click Undo Fix to restore the web files that have been replaced.

You can fix a vulnerability for one or more affected assets at a time.

- To fix a vulnerability for one affected asset, select an action from the **Actions** column of the asset.
- To fix a vulnerability for one or more affected assets, select the target servers, and select an action in the lower-left corner.

28.6.3.1.4. Manage emergency vulnerabilities

This topic describes how to manage emergency vulnerabilities.

Context

Apsara Stack Security automatically detects vulnerabilities on servers, such as the unauthorized Redis access vulnerability and Struts S2-052 vulnerability, and sends vulnerability alerts. After you fix a vulnerability, you can also check whether the fix is successful.

Procedure

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**. On the page that appears, click the **Emergency** tab.
3. **View all vulnerabilities.** You can quickly locate a vulnerability by using the search and filter functions.
4. Click a vulnerability to go to the vulnerability details page. You can view detailed vulnerability information and affected assets on this page. You can quickly locate specific affected assets by using the search and filter functions.
5. Select an action based on the impact of the vulnerability. [Actions on vulnerabilities](#) describes the actions.

Follow the instructions to manually fix the vulnerabilities on the **Emergency** tab.

Actions on vulnerabilities

Action	Description
Ignore	Ignore a vulnerability. The system does not alert you about an ignored vulnerability.
Verify	<p>Verify the fix after you manually fix a vulnerability.</p> <p>If you do not manually verify a fix, the system automatically verifies the fix within 48 hours after the vulnerability fix is complete.</p>

You can fix a vulnerability for one or more affected assets at a time.

- To fix a vulnerability for one affected asset, select an action from the **Actions** column of the asset.
- To fix a vulnerability for one or more affected assets, select the target servers, and select an action in the lower-left corner.

28.6.3.1.5. Configure vulnerability management policies

You can enable or disable automatic detection for different types of vulnerabilities, and enable vulnerability detection for specific servers. You can also set a time duration for which invalid vulnerabilities are retained, and configure a vulnerability whitelist.

Context

A vulnerability whitelist allows you to exclude vulnerabilities from the detection list. You can add multiple vulnerabilities in the vulnerability list to the whitelist. The system does not detect vulnerabilities in the whitelist. You can manage the vulnerability whitelist on the vulnerability settings page.

Procedure

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**.
3. In the upper-right corner, click **Settings** to configure vulnerability management policies.

Settings

Linux Software:	<input checked="" type="checkbox"/>	Total : 1, Scan-Disabled : 0	Manage
Windows System:	<input checked="" type="checkbox"/>	Total : 1, Scan-Disabled : 0	Manage
Web CMS:	<input checked="" type="checkbox"/>	Total : 1, Scan-Disabled : 0	Manage
Emergency:	<input checked="" type="checkbox"/>	Total : 1, Scan-Disabled : 0	Manage

Retain Invalid Vul for:

Vul scan level: High Medium Low

Vul Whitelist:

Vulnerability	Actions
No Data	

- Select a vulnerability type and enable or disable detection for vulnerabilities of this type.
- Click **Manage** next to a vulnerability type and specify the servers on which vulnerabilities of this type are detected.
- Select a time duration for which invalid vulnerabilities are retained: 7 days, 30 days, or 90 days.

Note If you do not take any action on a detected vulnerability, the system determines that the alert is invalid. The system deletes the vulnerability after the specified duration.

- Select the vulnerability severities for scanning.
 - **High:** Vulnerabilities of this severity must be fixed as soon as possible.

- **Medium:** Vulnerabilities of this severity can be fixed later.
- **Low:** Vulnerabilities of this severity do not need to be fixed for now.
- Select vulnerabilities in the whitelist and click **Remove** to enable the system to detect these vulnerabilities and send alerts again.

28.6.3.2. Baseline check

28.6.3.2.1. Baseline check overview

The baseline check feature automatically checks the security configurations on servers and provides the detailed check results and suggestions for baseline reinforcement.

Description

After you enable the baseline check feature, Apsara Stack Security automatically checks for risks related to the operating systems, accounts, databases, passwords, and security compliance configurations of your servers, and provides reinforcement suggestions. For more information, see [Baseline check items](#).

By default, a full baseline check is automatically performed from 00:00 to 06:00 every day. You can create and manage scan policies for baseline checks. When you create or modify a policy, you can customize the check items, interval, and time period of a baseline check, and select the servers to which you want to apply this policy. For more information, see [Add a custom baseline check policy](#).

Precautions

The following check items are disabled by default. To check these items, make sure that these items do not affect your business and select them when you customize a scan policy.

- Check items related to weak passwords for specific applications such as MySQL, PostgreSQL, and SQL Server

 **Note** If these check items are enabled, the system attempts to log on to servers with weak passwords. The logon attempts consume server resources and generate many logon failure records.

- Check items related to China classified protection of cybersecurity
- Check items related to the Center for Internet Security (CIS) standard

Baseline check items

Category	Check item
Database	Alibaba Cloud Standard - MongoDB Security Baseline Check
	Alibaba Cloud Standard - Redis Security Baseline Check
	Alibaba Cloud Standard - Oracle 11g Security Baseline Check
	Alibaba Cloud Standard - Memcached Security Baseline Check
	Alibaba Cloud Standard - Mysql Security Baseline Check

Category	Check item
Operating system	<p>Security baseline check against the Alibaba Cloud standard:</p> <ul style="list-style-type: none"> • Alibaba Cloud Aliyun Linux 2 Benchmark • Alibaba Cloud Standard - CentOS Linux 6 Security Baseline Check • Alibaba Cloud Standard - CentOS Linux 7/8 Security Baseline Check • Alibaba Cloud Standard - Debian Linux 8 Security Baseline • Alibaba Cloud Standard - Red Hat Enterprise Linux 6 Security Baseline Check • Alibaba Cloud Standard - Red Hat Enterprise Linux 7 Security Baseline Check • Alibaba Cloud Standard - Ubuntu Security Baseline • Alibaba Cloud Standard - Windows Server 2008 R2 Security Baseline Check • Alibaba Cloud Standard - Windows 2012 R2 Security Baseline • Alibaba Cloud Standard - Windows 2016/2019 R2 Security Baseline

	Alibaba Cloud Standard - Nginx Security Baseline Check

28.6.3.2.2. Configure baseline check policies

This topic describes how to add, modify, and delete baseline check policies and how to set baseline check levels.

Context

By default, the baseline check feature uses the **default policy** to check the baseline security of assets. You can also customize baseline check policies based on your business requirements, for example, to check the compliance with China classified protection of cybersecurity-Level II.

Procedure

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Baseline Check**.
3. In the upper-right corner of the page that appears, click **Manage Policies**. In the **Manage Policies** pane, add, modify, or delete a baseline check policy, or modify the default policy.

- In the upper-right corner of the pane, click **Create Policy** to customize a baseline check policy. Then, click **Ok**.

Parameter	Description
Policy Name	Enter a policy name.
Schedule	Select a time interval for scheduled scan tasks from: 1 Day(s), 3 Day(s), 7 Day(s), and 30 Day(s), which represent every second day, every fourth day, every eighth day, and every thirty-first day. You can also select a time period for scheduled scan tasks from: 00:00 to 06:00, 06:00 to 12:00, 12:00 to 18:00, and 18:00 to 24:00.
Check Items	Select the baseline items that need to be checked under these categories: High risk exploit, CIS and China's Protection of Cybersecurity, Best security practices, and Weak password.
Servers	Select the asset groups to which you want to apply this policy. <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px;"> <p> Note Newly purchased servers belong to Default under Asset Groups. To apply this policy to new servers, select Default.</p> </div>

- Click **Edit** or **Delete** next to the target policy to modify or delete it.

 **Note** You cannot restore a policy after it is deleted.

- Click **Edit** in the **Actions** column next to the **Default** policy to modify the asset groups to which the default policy is applied.

 **Note** You cannot delete the default policy or modify the check items of the default policy. You can only modify the asset groups to which the default policy is applied.

- In the lower part of the **Manage Policies** pane, set the baseline check level to High, Medium, and Low.

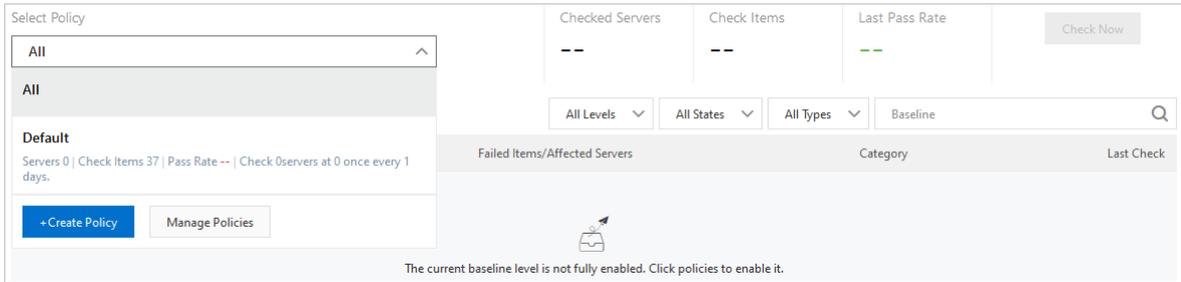

4. Click **Ok**.

28.6.3.2.3. View baseline check results and manage failed check items

The Apsara Stack Security console provides detailed baseline check results and suggestions on how to manage failed check items. This topic describes how to view baseline check results and manage failed check items in the Apsara Stack Security console. The check results include affected assets, checked items, and the suggestions.

View the summary of baseline check results

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Baseline Check**.
3. In the upper part of the **Baseline Check** page, view the summary of baseline check results. You can filter data by policy.

You can select a policy from the **Select Policy** drop-down list to view the following information:

- **Checked Servers:** The number of servers on which the baseline check runs. These servers are specified in the selected baseline check policy.
- **Check Items:** The number of Check Items specified in the selected baseline check policy.
- **Last Pass Rate:** The pass rate of the last baseline check.

If the number under **Last Pass Rate** is green, the pass rate of the checked servers is high. If this number is red, a large number of failed check items have been detected on the checked servers. We recommend that you view the check result details and manage the failed check items.

View all check items

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Baseline Check**.
3. Select **All** from the **Select Policy** drop-down list.
The **Baseline Check** page displays check result details, including **Baseline**, **Checked Item**, **Failed Items/Affected Servers**, **Category**, and **Last Check**.

Note You can also select a baseline check policy from the **Select Policy** drop-down list to view the check items specified in this policy.

View details of a check item

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Baseline Check**.
3. In the **Baseline** column, click the target check item to view its details.
Baseline details include the affected assets and numbers of **Passed Items** and **At-Risk Items**.
4. On the details page, manage the failed check items.
 - Find the target asset and click **View** in the **Actions** column to open the **At-Risk Items** pane.
 - You can click **Verify** in the **Actions** column to check whether the baseline risks of an asset have been managed. If the verification is passed, the number of **At-Risk Items** is reduced, and the status of the check items change to **Passed**.

View failed check items

1. Open the check item details page. Find the target asset and click **View** in the **Actions** column to view failed check items.
You can view the check items of the asset and the statuses of the check items (**Passed** or **Failed**).
2. You can click **Details** in the **Actions** column to view the description, result, and suggestion for this check item.

High Ensure password expiration period is set. | Identity authentication ✕

Description

Set password expiration time, force regular modification of password, reduce password leakage and guess risk. Use non-password login (e.g. key pair) please ignore this item.

Result

--

Suggestion

Use non-password login (e.g. key pair) please ignore this item. Set the PASS_MAX_DAYS parameter between 60 and 180 in the /etc/login.defs file:

```
PASS_MAX_DAYS 90
```

Meanwhile, execute the following commands to modify the root user settings:

```
chage --maxdays 90 root
```

Record the security enhancement operations, or back up the related data before the operation.

Ok

? **Note** We recommend that you follow the suggestions to manage Failed check items at the earliest opportunity, especially the high-risk check items.

Manage failed check items

In the At-Risk Items pane, manage failed check items as required.

- **Add a check item to the whitelist**

If you want to disable alerts for a check item, click **Whitelist** to add the check item to the whitelist. Check items in the whitelist do not trigger alerts.

? **Note** You can also select multiple check items and click **Whitelist** in the lower-left corner to add the check items to the whitelist at a time.

- **Remove a check item from the whitelist**

If you want to enable alerts for a check item in the whitelist, you can click **Remove** to remove the check item from the whitelist. You can remove one or more check items from the whitelist at a time. After a check item is removed from the whitelist, the check item triggers alerts again.

- **Verify a fixed check item**

After you fix a baseline risk, you can click **Verify** to check whether the risk has been fixed. After you click **Verify**, the status of the check item changes to **Verifying**.

If you do not manually perform the verification, Apsara Stack Security automatically verifies the check item based on the detection interval specified in the policies.

If the verification is passed, the **Status** of the check item changes to **Passed**.

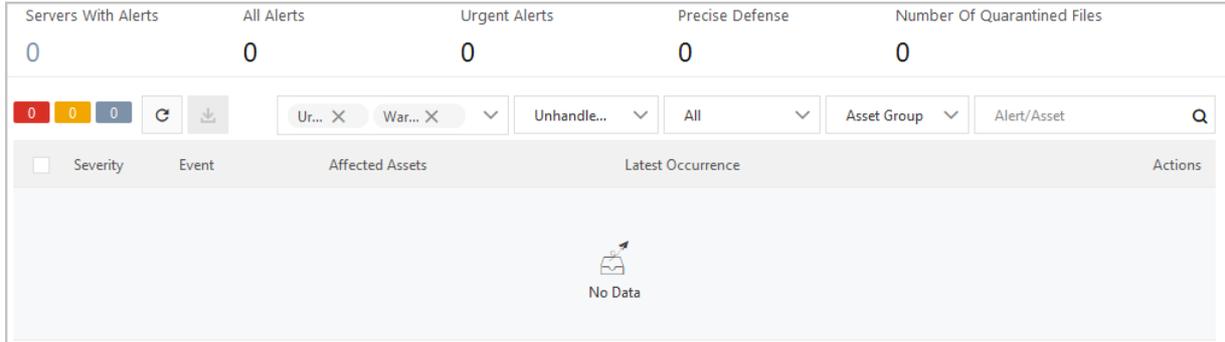

28.6.4. Intrusion detection

28.6.4.1. Intrusion events

28.6.4.1.1. Intrusion event types

If the Server Security feature detects sensitive file tampering, webshells, unusual logons, suspicious processes, and malicious processes, it generates alerts. Based on these alerts, you can monitor the security status of your assets and handle potential threats at the earliest opportunity.

Apsara Stack Security Center provides statistics based on enabled alerts and defense items. This allows you to understand enabled and disabled defense items. You can view statistics on alerts and information about defense items. To achieve this purpose, choose **Server Security > Intrusion Prevention > Intrusions**.

Alert types

The following table describes the defense items.

Alert	Description
Suspicious Process	Detects whether suspicious processes exist.
Webshell	<p>Uses engines developed by Alibaba Cloud to scan common webshell files. Apsara Stack Security Center supports scheduled scan tasks, provides real-time protection, and quarantines webshell files.</p> <ul style="list-style-type: none"> Apsara Stack Security Center scans the entire web directory early in the morning on a daily basis. A change made to files under the web directory triggers dynamic detection. You can specify the assets on which Apsara Stack Security Center scans for webshells. You can quarantine, restore, and ignore detected Trojan files.
Unusual Logon	<p>Detects unusual logons to your servers. You can specify approved logon IP addresses, time periods, and accounts. Logons from unapproved IP addresses, accounts, or time periods trigger alerts. You can manually add approved logon locations or configure the system to automatically update approved logon locations. You can also specify assets on which alerts are triggered when unusual logon locations are detected.</p> <p>Apsara Stack Security Center can detect the following logon events:</p> <ul style="list-style-type: none"> Logons to Elastic Compute Service (ECS) instances from unapproved IP addresses Logons to ECS instances from unapproved locations Execution of unusual commands after logons to ECS instances by using Secure Shell (SSH) ECS instances passwords cracked due to brute-force attacks based on the SSH protocol
Sensitive File Tampering	Checks whether sensitive files on your servers are maliciously modified, such as tampering of pre-loaded configuration files in Linux shared libraries.

Alert	Description
Malicious Process	<p>Dynamically scans your servers based on the anti-virus mechanism of Alibaba Cloud and Apsara Stack Security Center, and generates alerts if viruses are detected. Process information is collected by Apsara Stack Security Center and uploaded to Alibaba Cloud. You can manage detected viruses in the Apsara Stack Security Center console.</p> <p>Apsara Stack Security Center can detect the following malicious activities and processes:</p> <ul style="list-style-type: none"> • Visiting malicious IP addresses • Mining programs • Self-mutating Trojans • Malicious programs • Trojans
Unusual Network Connection	Detects disconnections or unusual network connections.
Suspicious Account	Detects logons to your assets from unapproved accounts.
Application intrusion event	Detects intrusion activities that use system application components.
Precision defense	The Virus Removal feature provides precise defenses against a majority of ransomware, distributed denial-of-service (DDoS) Trojans, mining programs, Trojan programs, malicious processes, webshells, and worms.
Cloud threat detection	Detects threats in other Alibaba Cloud services.
Persistence	Detects suspicious scheduled tasks on servers and generates alerts when persistent threats against the servers are detected.
Web Application Threat Detection	Detects server intrusions that use web applications.
Malicious scripts	Checks whether the system services of your assets are attacked or modified by malicious scripts. Alerts are generated if potential script attacks are detected.
Other	Detects other types of attacks, such as DDoS attacks.

28.6.4.1.2. View and handle intrusion events

This topic describes how to view and handle detected alert events on the Intrusions page.

Background information

After alert events are detected, they are displayed on the Intrusions page. You can choose **Server Security > Intrusion Prevention > Intrusions** to go to the Intrusions page.

If the alert events are not handled, they are displayed in the **Unhandled Alerts** list on the Intrusions page. After the alert events are handled, the status changes from **Unhandled Alerts** to **Handled**.

 **Note** Apsara Stack Security Center retains the records of **Unhandled Alerts** and **Handled** on the Intrusions page. By default, the records of **Unhandled Alerts** are displayed.

View alert events

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions**.
3. In the intrusions list, you can view or search for detected intrusions, alert events, and relevant details.

Handle alert events

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions.**
3. On the **Intrusions** page, find the target alert event. In the **Actions** column, click **Processing**. In the dialog box that appears, configure parameters and click **Process Now**.

 **Note** If the alert event contains multiple related exceptions, click **Processing** and the details page appears. You can handle different exception events.

- **Ignore:** If you ignore this alert, the status of this alert changes to **Handled**. This alert event no longer triggers alerts if Server Guide detects it.
- **Whitelist:** If the alert is a false positive, you can add the alert event to the whitelist. After you add the alert event to the whitelist, the status of the alert changes to **Handled**. This event no longer triggers alerts if Server Guide detects it. In the **Handled** alert list, you can click **Cancel whitelist** to remove the target alert event from the whitelist.

 **Note** A false positive represents that Apsara Stack Security Center generates false alerts on a normal process. Common false positives include suspicious processes that send TCP packets. Common false positives notify you that suspicious scan activities on other devices are detected on your servers.

4. (Optional) If you confirm that one or more alert events are false positives or need to be ignored, go to the **Intrusions** page, select the target alert events, and then click **Ignore** or **Whitelist**.

Export alert events

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions.**
3. In the upper-left corner of the **Intrusions** page, click the  icon to export the alert list. After the alert list is exported, the **Done** dialog box appears in the upper-right corner.
4. In the **Done** dialog box, click **Download**.
The alert list is downloaded as an Excel file.

28.6.4.1.3. View exceptions related to an alert

Server Guide supports automatic analysis of exceptions related to an alert. You can click an alert name on the alert list to view and manage all exceptions related to this alert and view the results of automatic attack tracing.

Context

- Security Center automatically associates alerts with exceptions in real time to detect potential threats.
- The related exceptions of an alert are listed by time. This allows you to easily analyze and manage the exceptions to improve the emergency response mechanism.

Procedure

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions.**
3. On the **Intrusions** page, click the target alert name. The alert details page appears.
4. On the alert details page, view the details and related exceptions of the alert and manage the exceptions.
 - View alert details

You can view the assets affected by this alert, the first and latest occurrence time of the alert, and the details of the related exceptions.

- View affected assets

Click the name of an affected asset to view the details of the asset. These details include alerts, vulnerabilities, baseline risks, and asset fingerprints.

- View and manage related exceptions

In the **Related Exceptions** section, you can view the details and recommended solutions of all exceptions related to this alert.

- Click **Note** to the right of an exception name to add notes for the exception.
- Click the  icon to the right of a note to delete the note.

28.6.4.1.4. Use the file quarantine function

Server Guard can quarantine malicious files. Quarantined files are listed in the quarantine box on the Intrusions page. The system automatically deletes a quarantined file 30 days after it is quarantined. You can restore a quarantined file with a few clicks before it is deleted. This topic describes how to view quarantined files and remove files from the quarantine box.

Procedure

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions**.
3. In the upper-right corner of the **Intrusions** page, click **Quarantine**.

You can perform the following operations in the **Quarantine** pane:

- View information about quarantined files. The information includes server IP addresses, directories that store the files, file status, and time of the last modification.
- Click **Restore** in the **Actions** column to remove a file from the quarantine box. The restored file appears in the alert list again.

28.6.4.1.5. Configure security alerts

This topic describes how to configure security alerts in Server Guard to specify common logon locations, customize scan targets, and manage advanced logon settings and security alerts.

Context

Server Guard supports advanced logon settings and security alerts. You can configure more fine-grained logon detection rules. For example, you can specify valid logon IP addresses, logon time, and logon accounts to block unauthorized requests sent to your assets.

Procedure

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions**.
3. In the upper-right corner, click **Settings**. Select the target tab and configure the following parameters:

- **Add a common logon location**
 - a. Click **Management** to the right of **Login Location**.
 - b. Select the logon location that you want to approve, and select the servers that are allowed to be logged on to from the approved location.
 - c.

Server Guard allows you to edit and delete common logon locations.

- **Configure advanced logon settings**

 **Note** After you configure advanced logon settings, alerts are triggered if your assets receive requests from unapproved locations. You can specify the IP addresses, accounts, and time periods that are allowed for logons to your assets. After the advanced logon settings are configured, Server Guard sends you alerts if your assets receive unauthorized logon requests. The procedure of configuring advanced logon settings is similar to configuring common logon locations. You can follow the preceding procedure to add, edit, and delete advanced logon settings.

- Turn on or turn off **Uncommon IP Alert** to the right of **Common Login IPs**. Alerts are triggered if your assets receive requests from unauthorized IP addresses.
- On the right of **Common Login Time**, turn on or turn off **Uncommon Time Alert**. Alerts are triggered if your assets receive requests at unauthorized times.
- On the right of **Common Login Accounts**, turn on or turn off **Uncommon Account Alert**. Alerts are triggered if your assets receive requests from unauthorized accounts.

- **Add a scan target**

Server Guard automatically scans directories of your servers and runs dynamic and static scan tasks. You can also manually add directories of servers.

- a. On the right of **Add Scan Targets**, click **Management**.
- b. Specify a valid directory, and select the servers on which the specified directory is scanned.

 **Note** To ensure the performance and efficiency, do not specify a root directory.

- c.

28.6.4.1.6. Virus removal

The virus removal feature provided by Server Guard is integrated with major antivirus engines worldwide. It detects viruses against large amounts of threat intelligence data provided by Alibaba Cloud. Virus removal also provides an exception detection module designed by Alibaba Cloud to detect viruses based on machine learning and deep learning. This way, virus removal can provide full-scale and dynamic antivirus protection to safeguard your servers.

The cloud threat detection feature can scan millions of files on a daily basis and is currently protecting millions of assets on the cloud.

Detection capabilities

The virus removal feature uses the Server Guard client to collect process information, and then scans the retrieved data for viruses in the cloud. If a malicious process is detected, you can stop the process and quarantine the related files.

- **Deep learning engine (developed by Alibaba Cloud):** The deep learning engine is built on deep learning technology and a large amount of attack samples. The engine specializes in detecting malicious files in the cloud and automatically identifies potential threats. It provides additional detection capabilities compared to traditional antivirus engines.
- **Cloud sandbox (developed by Alibaba Cloud):** It allows you to simulate cloud environments and monitor attacks launched by malicious samples. Based on big data analytics and machine learning modeling techniques, cloud sandbox automatically detects threats and offers dynamic analysis and detection capabilities.
- **Integration with major antivirus engines:** The cloud threat detection feature is integrated with major antivirus engines worldwide. Its virus library is updated in real time.
- **Threat intelligence detection:** Based on the threat intelligence data provided by Alibaba Cloud Security, cloud threat detection works with the exception detection module to detect malicious processes and operations.

Detectable virus types

Cloud threat detection is one of the best practices tested by Alibaba Cloud Security technologies and specialists. It provides end-to-end security services, including threat intelligence collection, data masking, threat identification, threat analysis, and malicious file quarantine and restoration. You can quarantine and restore data that has viruses in the Security Center console.

Cloud threat detection can detect the following types of viruses:

Virus	Description
Mining programs	A mining program consumes server resources without authorization to mine virtual currencies.
Computer worms	A computer worm uses computer networks to replicate itself and spread to a large number of computers within a short period of time.
Ransomware	Ransomware, such as WannaCry, uses encryption algorithms to encrypt files and prevent users from accessing the files.
Trojans	A Trojan is a program that allows the attacker to access information about the server and users, to gain control of the server, and to consume system resources.
DDoS Trojans	A DDoS Trojan hijacks servers and uses zombie servers to launch DDoS attacks, which can interrupt your workloads.
Backdoors	A backdoor is a malicious program injected by an attacker, who uses the backdoor to control the server or launch attacks.
Computer viruses	A computer virus inserts malicious code into other programs, and may replicate and infect the whole system.
Malicious programs	Programs that may pose a threat to the system and data security.

Benefits

- **Independent development and controllability:** Cloud threat detection is based on deep learning, machine learning, and big data analytics with a large amount of attack and defense practices. It uses multiple detection engines to protect your assets against viruses without delay.
- **Lightweight:** Cloud threat detection only takes 1% CPU usage and 50 MB of memory.
- **Dynamic:** Cloud threat detection dynamically retrieves log data to monitor the launches of malicious programs.
- **Easy to manage:** You can manage all servers and view their status at any time in the Security Center console.

Threat detection limits

Apsara Stack Security Center allows you to process security alerts, scan for vulnerabilities, analyze attacks, and check security settings in the Security Center console. Apsara Stack Security Center can analyze alerts and automatically trace attacks. This allows you to protect your assets. Apsara Stack Security Center supports a wide range of protection features. We recommend that you also install the latest system patches on your server. We also recommend you to use security services, such as Cloud Firewall and Web Application Firewall (WAF), to better protect your assets against attacks.

 **Note** Attacks and viruses are evolving, and your business environments vary. Security breaches may occur. We recommend that you use the alerting, vulnerability detection, baseline check, and configuration assessment features provided by Apsara Stack Security Center to better protect your assets against attacks.

28.6.4.2. Website tamper-proofing

28.6.4.2.1. Overview

Tamper protection monitors website directories in real time, restores modified files or directories, and protects websites from trojans, hidden links, and uploads of violent and illicit content.

Background information

To make illegal profits or conduct business attacks, attackers exploit vulnerabilities in websites to insert illegal hidden links and tamper with the websites. Defaced web pages affect normal user access and may lead to serious economic losses, damaged brand reputation, or political risks.

Tamper protection allows you to add Linux and Windows processes to the whitelist and update protected files in real time.

How tamper protection works

The Security Center agent automatically collects the list of processes that attempt to modify files in the protected directories of the protected servers. It identifies unusual processes and file changes in real time and blocks unusual processes.

The alert list is displayed on the Tamper Protection page. You can view unusual file changes, the corresponding processes, and the number of attempts made by each process in the alert list. If a file is modified by a trusted process, you can add the process to the whitelist. After the process is added to the whitelist, tamper protection no longer blocks the process. In scenarios where the content of websites, such as news and education websites, is frequently modified, the whitelist saves you the effort of frequently enabling and disabling tamper protection.

Versions of operating systems and kernels supported by tamper protection

OS	Supported operating system version	Supported kernel version
Windows	Windows Server 2008 and later	All versions
CentOS	6.5, 6.6, 6.7, 6.8, 6.9, 6.10, 7.0, 7.1, 7.2, 7.3, 7.4, 7.5, and 7.6	<ul style="list-style-type: none"> • 2.6.32-x • 3.10.0-x
Ubuntu	14, 16, and 18	<ul style="list-style-type: none"> • 3.13.0-32-generic • 3.13.0-86-generic • 4.4.0-62-generic • 4.4.0-63-generic • 4.4.0-93-generic • 4.4.0-151-generic • 4.4.0-117-generic • 4.15.0-23-generic • 4.15.0-42-generic • 4.15.0-45-generic • 4.15.0-52-generic

 **Note**

- The preceding table lists kernel versions supported by tamper protection. Servers that use an unsupported kernel version cannot use tamper protection. Make sure that your server uses a supported kernel version. If a kernel version is not supported, you must upgrade it to a supported version. Otherwise, you cannot add processes to the whitelist.
- Before you upgrade the server kernel, back up your asset data.

28.6.4.2.2. Configure tamper protection

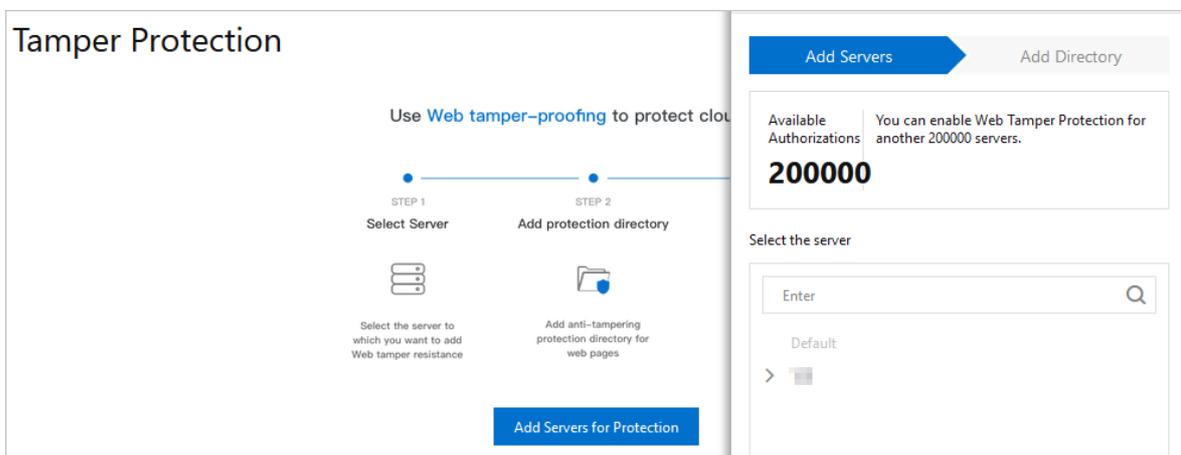

The Server Security feature allows you to configure tamper protection for web pages.

Limits

- For each server, you can add a maximum of 10 directories for protection.
- The protected directories of a Windows server must meet the following requirements: The maximum size of each directory is no more than 20 GB. Each directory contains a maximum of 2,000 folders. The maximum directory level is 20. The maximum size of each file is 3 MB.
- The protected directories of a Linux server must meet the following requirements: The maximum size of each directory is no more than 20 GB. Each directory contains a maximum of 3,000 folders. The maximum directory level is 20. The maximum size of each file is 3 MB.
- Before you add a directory for protection, make sure that the directory level, the number of folders, and the directory size meet the preceding requirements.
- We recommend that you exclude file formats that do not require protection, such as *.log*, *.png*, *.jpg*, *.mp4*, *.avi*, and *.mp3*. Separate multiple file formats with semicolons (;).

Procedure

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, click **Server Security** and choose **Intrusion Prevention > File Tamper Protection**.
3. On the **Tamper Protection** page, click the **Management** tab.
4. On the **Tamper Protection** page, click **Add Servers for Protection**.
5. In the **Add Servers for Protection** dialog box, select a server that you want to protect.

6. Click **Next** to go to the **Add Directory** step.
7. In the **Add Directory** step, configure the following parameters:

Add Servers for Protection
✕

Add Servers
Add Directory

We recommend that you use the whitelist mode. In this mode, the file formats that usually require protection have been added to the protection list by default. You can add more directories and file formats for protection. [Blacklist Mode >](#)

* Protected Directory ⓘ

Enter or select the directory to be protected. the directory currer

* Protected File Formats ⓘ

php ✕
jsp ✕
asp ✕
aspx ✕

cgi ✕
html ✕
htm ✕

xml ✕
shtml ✕
shtm ✕
jpg ✕

gif ✕
png ✕

* Local Backup Directory ⓘ

/usr/local/aegis/bak

Enable Protection
Cancel

Select the protection mode. You can select the **Whitelist Mode** or **Blacklist Mode**. In whitelist mode, tamper protection is enabled for the specified directories and file formats. In blacklist mode, tamper protection is enabled for the subdirectories, file formats, and files that are not specified. The whitelist mode is selected by default.

- o In whitelist mode, configure the following parameters.

Parameter	Description
Protected Directory	Enter the path of the directory that you want to protect. <div style="background-color: #e0f2f1; padding: 5px; margin-top: 5px;"> ⓘ Note Servers that run Linux and Windows operating systems use different path formats. Enter a valid directory path based on your operating system type. </div>
Protected File Formats	Select file formats from the drop-down list, such as <i>.js</i> , <i>.html</i> , <i>.xml</i> , and <i>.jpg</i> .
Local Backup Directory	The default path where backup files of the protected directories are stored. By default, Security Center assigns <i>/usr/local/aegis/bak</i> to servers that run the Linux operating system and <i>C:\Program Files (x86)\Alibaba\Aegis\bak</i> to servers that run the Windows operating system. You can change the default path as needed.

- o In blacklist mode, configure the following parameters.

Parameter	Description
Protected Directory	Enter the path of the directory that you want to protect.

Parameter	Description
Excluded Sub-Directories	<p>Enter the subdirectories that do not require tamper protection.</p> <p>Click Add Sub-Directory to enter more subdirectories.</p> <p>Security Center does not provide tamper protection for files under the excluded sub-directories.</p>
Excluded File Formats	<p>Select the formats of files that do not require tamper protection.</p> <p>Supported formats include log, txt, and ldb.</p> <p>Security Center does not provide tamper protection for the files in the excluded formats.</p>
Excluded Files	<p>Enter the path of the file that does not require tamper protection.</p> <p>You can click Add File to add more files.</p> <p>Security Center does not provide tamper protection for the excluded files.</p>
Local Backup Directory	<p>The default path where backup files of the protected directories are stored.</p> <p>By default, Security Center assigns <code>/usr/local/aegis/bak</code> to servers that run the Linux operating system and <code>C:\Program Files (x86)\Alibaba\Aegis\bak</code> to servers that run the Windows operating system. You can change the default path as needed.</p>

8. Click **Enable Protection**.

After you enable tamper protection for a server, it is displayed in the server list on the **Tamper Protection** page.

 **Note** By default, tamper protection is in the **Not Initiated** state for newly added servers. To enable tamper protection, you must turn on the **On** switch on the **Tamper Protection** page for the target server.

9. In the server list on the **Tamper Protection** page, find the target server and turn on the switch in the **Protection** column to enable tamper protection for the server.

 **Note** By default, tamper protection is in the **Not Initiated** state for newly added servers. You must enable tamper protection on the **Tamper Protection** page for the target server.

After tamper protection is enabled, the protection state changes to **Running**.

 **Note** If the protection state of a server is **Exception**, click **Exception** in the **Status** column. A message that indicates the causes appears. Click **Retry** in the message.

What to do next

After you enable tamper protection for a server, you can go to the **Overview** page, and select tamper protection in the event type drop-down list to view the alerts on tampering events.

Note

Tamper protection does not take effect immediately after you configure the protected directory, and you can still write files to the directory. In this case, you must go to the **Management** page, disable **Protection** for the server where the directory is located, and then enable **Protection** again.

Handle abnormal protection states

Protection state	Description	Suggestion
Initializing	Web tamper protection is being initialized.	If this is your first time enabling tamper protection for a server, the protection status becomes Initializing . It takes a few seconds to enable tamper protection.
Running	Tamper protection is enabled and running as expected.	-
Exception	An error occurred when tamper protection was enabled.	Click Exception in the Status column to view the exception cause and click Retry .
Not Initiated	Tamper protection is disabled.	You must turn on the On switch to enable tamper protection.

28.6.4.2.3. View the protection status

This topic describes how to view the status of tamper protection for your assets.

Context

The tamper protection feature monitors changes of directories and files in real time and blocks suspicious file changes. To view the status and details of tamper protection in the Apsara Stack Security console, click **Server Security** and choose **Intrusion Prevention > File Tamper Protection**. The details include:

- Overview

On the Overview page, you can view the total number of changed files, protected servers, and protected directories on the current day and during the last 15 days.

- Distribution of protected file types

Protected file types include .txt, .png, .msi, and .zip. You can also add more types of files for protection as needed.

 **Note** All types of files can be added for tamper protection.

- Top five files with the largest number of changes

This module shows the names and paths of the five files with the largest number of changes in the last 15 days.

- Details of tamper protection alerts

The tamper protection feature helps you block all suspicious changes to directories and files on your assets. On the alert details page, you can view the alerts of these changes, including the severity, alert name, affected assets, paths of files with suspicious changes, and protection status.

 **Note**

- If the number of alerts exceeds 100, we recommend that you process these alerts at your earliest opportunity.
- Only the alerts at the **Warning** level are displayed in the console.
- Only alerts in the **Isolation successful** state are displayed. This indicates that the tamper protection feature has blocked the suspicious processes that attempted to make unauthorized file changes.

28.6.4.3. Configure the Virus Removal feature

The Virus Removal feature of Server Guard allows you to customize virus and webshell detection settings.

Virus detection

The Virus Removal feature can automatically quarantine common Internet viruses, such as mainstream trojans, ransomware, mining programs, and DDoS trojans. Apsara Stack Security experts test and verify all automatically quarantined viruses to ensure a minimum false positive rate.

If automatic quarantine is disabled, Server Guard generates alerts when viruses are detected. You must manually manage detected viruses in the console. We recommend that you enable automatic quarantine to better safeguard your servers.

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, click **Server Security** and choose **Intrusion Prevention > Virus Removal**.
3. In the **Anti-virus** section, click **Manage**.
4. In the **Configure Servers for Virus Detection** dialog box, select the servers for which you want to enable the Virus Removal feature.

Select servers from the **Detection Disabled** list on the left side of the tab and click the right arrow to move them to the **Detection Enabled** list on the right side. The anti-virus feature is enabled for the servers in the **Detection Enabled** list. To disable the anti-virus feature for a server, move the server from the **Detection Enabled** list to the **Detection Disabled** list.

5. Click **OK**.
6. In the **Anti-virus** section, turn on **Virus Blocking** to enable virus blocking. After virus blocking is enabled, Server Guard automatically quarantines detected viruses. Quarantined viruses are listed on the **Overview** page. You can select the **Precision Defense** type to filter quarantined viruses.

Webshell detection

1. [Log on to Apsara Stack Security Center](#).
2. In the left-side navigation pane, click **Server Security** and choose **Intrusion Prevention > Virus Removal**.
3. Configure servers for webshell detection.
 - i. In the **Webshell Detection** section, click **Manage**.
 - ii. Select the servers for which you want to enable webshell detection.
 - iii. Click **OK** to complete the configuration.

28.6.5. Log retrieval

28.6.5.1. Log retrieval overview

The log retrieval function provided by Server Security allows you to manage logs scattered in various systems of Apsara Stack in a centralized manner, so that you can easily identify the causes of issues that occur on your servers.

The log retrieval function supports storage of logs for 180 days and query of logs generated within 30 days.

Benefits

The log retrieval function provides the following benefits:

- **End-to-end log retrieval platform:** Allows you to retrieve logs of various Apsara Stack services in a centralized manner and trace issues easily.
- **Cloud-based SaaS service:** Allows you to query logs on all servers in Apsara Stack without additional installment and deployment.
- Supports TB-level data retrieval. It also allows you to add a maximum of 50 inference rules (Boolean expressions) in a search condition and obtain full-text search results within several seconds.
- Supports a wide range of log sources.
- Supports log shipping, which allows you to import security logs to Log Service for further analysis.

Scenarios

You can use log retrieval to meet the following requirements:

- **Security event analysis:** When a security event is detected on a server, you can retrieve the logs to identify the cause and assess the damage and affected assets.
- **Operation audit:** You can audit the operation logs on a server to identify high-risk operations and serious issues in a meticulous way.

Supported log types

Log types

Log type	Description
Logon history	Log entries about successful system logons
Brute-force attack	Log entries about system logon failures that are generated during brute-force attacks
Process snapshot	Log entries about processes on a server at a specific time
Listening port snapshot	Log entries about listening ports on a server at a specific time
Account snapshot	Log entries about account logon information on a server at a specific time
Process initiation	Log entries about process initiation on a server
Network connection	Log entries about active connections from a server to external networks

28.6.5.2. Log retrieval

This topic describes how to search for and view server logs.

Procedure

1. [Log on to Apsara Stack Security Center.](#)
2. In the left-side navigation pane, choose **Server Security > Log Retrieval.**
3. Configure search conditions.

Search condition	Description
Log source	Select a supported log source. For more information, see Log sources.
Field	Select a field that is supported by the specified log source. For more information, see Log sources.
Keyword	Enter the keyword of the field that you want to search for.
Logical operator	Select a logical operator from AND, OR, and NOT. For more information, see Logical operators.
+	Add inference rules in a search condition for a log source.
Add conditions	Add search conditions for different log sources.

4. Click **Search** and view the search result.
 - **Reset:** Click **Reset** to clear the search condition configuration.

- **Save Search:** Click **Save Search** to save the search condition configuration for future use.
- **Saved Searches:** Click **Saved Searches** to select and apply a search condition configuration that has been saved.

28.6.5.3. Supported log sources and fields

This topic describes log source types and fields that are supported by the log retrieval feature.

Log retrieval allows you to query the following types of logs. You can click a log source to view the fields that can be retrieved.

Log sources

Log source	Description
Account log	Log entries of successful system logons.
Brute Force log	Log entries of system logon failures generated during brute-force attacks.
Process Snapshot log	Log entries about processes on a server at a specific time.
Network Snapshot log	Log entries of listening ports on a server at a specific time.
Account Snapshot log	Log entries of account logon information on a server at a specific time.
Process log	Log entries of process startup on a server.
