3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure MySQL Writer by using the code editor

In the following code, a node is configured to write data to a MySQL database. For more information about the parameters, see the preceding parameter description.

```

{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"mysql",// The writer type.
      "parameter":{
        "postSql":[// The SQL statement to execute after the sync node is run.
          "datasource":"","// The connection name.
          "column":[// The columns to which data is written.
            "id",
            "value"
          ],
          "writeMode":"insert",// The write mode.
          "batchSize":1024,// The number of data records to write at a time.
          "table":"","// The name of the destination table.
          "preSql":[// The SQL statement to execute before the sync node is run.
        ],
        "name":"Writer",
        "category":"writer"
      }
    }
  ],
  "setting":{
    "errorLimit":{// The maximum number of dirty data records allowed.
      "record":"0"
    },
    "speed":{
      "throttle":false,// Specifies whether to enable bandwidth throttling.
      "concurrent":1 // The maximum number of concurrent threads.
    }
  },
  "order":{
    "hops":[
      {
        "from":"Reader",
        "to":"Writer"
      }
    ]
  }
}

```

2.4.5.4.13. Configure Oracle Writer

This topic describes the data types and parameters supported by Oracle Writer and how to configure it by using the codeless UI and code editor.

Oracle Writer allows you to write data to tables stored in primary Oracle databases. Oracle Writer connects to a remote Oracle database by using JDBC, and executes an `INSERT INTO` statement to write data to the Oracle database.

 **Note** You must configure a connection before you configure Oracle Writer.

Oracle Writer is designed for ETL developers to import data from data warehouses to Oracle databases. Oracle Writer can also be used as a data migration tool by users such as DBAs.

Oracle Writer obtains data from a Data Integration reader, connects to a remote Oracle database by using JDBC, and then executes an SQL statement to write data to the Oracle database.

Data types

Oracle Writer supports most Oracle data types. Make sure that your data types are supported.

The following table lists the data types supported by Oracle Writer.

Category	Oracle data type
Integer	NUMBER, ROWID, INTEGER, INT, and SMALLINT
Floating point	NUMERIC, DECIMAL, FLOAT, DOUBLE PRECISION, and REAL
String	LONG, CHAR, NCHAR, VARCHAR, VARCHAR2, NVARCHAR2, CLOB, NCLOB, CHARACTER, CHARACTER VARYING, CHAR VARYING, NATIONAL CHARACTER, NATIONAL CHAR, NATIONAL CHARACTER VARYING, NATIONAL CHAR VARYING, and NCHAR VARYING
Date and time	TIMESTAMP and DATE
Boolean	BIT and BOOLEAN
Binary	BLOB, BFILE, RAW, and LONG RAW

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the destination table.	Yes	None
writeMode	<p>The write mode. Valid values: <i>insert into</i>, <i>on duplicate key update</i>, and <i>replace into</i>.</p> <ul style="list-style-type: none"> <i>insert into</i>: If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows and is regarded as dirty data. <i>on duplicate key update</i>: If no primary key conflict or unique index conflict occurs, the action is the same as that of insert into. If a conflict occurs, specified fields in original rows are updated. <i>replace into</i>: If no primary key conflict or unique index conflict occurs, the action is the same as that of insert into. If a conflict occurs, original rows are deleted and new rows are inserted. This means that all the field values of the original rows are replaced. 	No	<i>insert</i>

Parameter	Description	Required	Default value
column	The columns in the destination table to which data is written. Separate the columns with commas (,), for example, <code>"column": ["id","name","age"]</code> . To write data to all the columns in the destination table, set the value to an asterisk (*), for example, <code>"column":["*"]</code> .	Yes	None
preSql	The SQL statement to execute before the sync node is run. For example, you can clear outdated data before data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	None
postSql	The SQL statement to execute after the sync node is run. For example, you can add a timestamp after data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the Oracle database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	1,024

Configure Oracle Writer by using the codeless UI

1. Configure the connections.

Configure the connections to the source and destination data stores for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Statement Run Before Writing	The preSql parameter in the preceding parameter description. Enter an SQL statement to execute before the sync node is run.
Statement Run After Writing	The postSql parameter in the preceding parameter description. Enter an SQL statement to execute after the sync node is run.

2. Configure field mapping. It is equivalent to setting the column parameter in the preceding parameter description. Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right.

GUI element	Description
Map Fields with the Same Name	Click Map Fields with the Same Name to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click Map Fields in the Same Line to establish a mapping for fields in the same row. Note that the data types of the fields must match.

GUI element	Description
Delete All Mappings	Click Delete All Mappings to remove mappings that have been established.
Auto Layout	Click Auto Layout to sort the fields based on specified rules.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure Oracle Writer by using the code editor

In the following code, a node is configured to write data to an Oracle database.

```

{
  "type": "job",
  "version": "2.0", // The version number.
  "steps": [
    {
      "stepType": "stream",
      "parameter": {},
      "name": "Reader",
      "category": "reader"
    },
    {
      "stepType": "oracle", // The writer type.
      "parameter": {
        "postSql": [], // The SQL statement to execute after the sync node is run.
        "datasource": "",
        "session": [], // The settings of the session to the database.
        "column": [], // The columns to which data is written.
          "id",
          "name"
        ],
        "encoding": "UTF-8", // The encoding format.
        "batchSize": 1024, // The number of data records to write at a time.
        "table": "", // The name of the destination table.
        "preSql": [] // The SQL statement to execute before the sync node is run.
      },
      "name": "Writer",
      "category": "writer"
    }
  ],
  "setting": {
    "errorLimit": {
      "record": "0" // The maximum number of dirty data records allowed.
    },
    "speed": {
      "throttle": false, // Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
      "concurrent": 1 // The maximum number of concurrent threads.
    }
  },
  "order": {
    "hops": [
      {
        "from": "Reader",
        "to": "Writer"
      }
    ]
  }
}

```

2.4.5.4.14. Configure OSS Writer

This topic describes the data types and parameters supported by OSS Writer and how to configure it by using the codeless UI and code editor.

OSS Writer allows you to write one or more CSV-like files to OSS.

 **Note** You must configure a connection before you configure OSS Writer.

OSS Writer can write files that store logical two-dimensional tables, such as CSV files that store text data, to OSS.

OSS Writer allows you to convert data obtained from a Data Integration reader to files and write the files to OSS. The OSS files store unstructured data only. OSS Writer supports the following features:

- Writes only files that store text data. The text data must be logical two-dimensional tables.
- Writes CSV-like files with custom delimiters.
- Uses concurrent threads to write files. Each thread writes a file.
- Supports file rotation. OSS Writer can write data to another file when the size of the current file exceeds a specific value. OSS Writer can also write data to another file when the number of rows in the current file exceeds a specific value.

OSS Writer does not support the following features:

- Uses concurrent threads to write a single file.
- Distinguishes between data types. OSS does not distinguish between data types. Therefore, OSS Writer writes all data as strings to files in OSS.

The following table lists the data types supported by OSS Writer.

Category	OSS data type
Integer	LONG
Floating point	DOUBLE
String	STRING
Boolean	BOOLEAN
Date and time	DATE

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
object	<p>The name prefix of the files to be written to OSS as objects. OSS simulates the directory effect by adding separators to object names. You can set the object parameter based on the following rules:</p> <ul style="list-style-type: none"> • <code>"object": "datax"</code> : The names of the files start with datax, which is followed by a random string as the suffix. • <code>"object": "cdo/datax"</code> : The names of the files start with /cdo/datax, which is followed by a random string as the suffix. OSS uses backslashes (/) in objects to simulate the directory effect. <p>If you do not want to add a random universally unique identifier (UUID) as the suffix, we recommend that you set the writeSingleObject parameter to <code>true</code>.</p>	Yes	None

Parameter	Description	Required	Default value
writeMode	<p>The mode in which OSS Writer writes the files. Valid values:</p> <ul style="list-style-type: none"> <i>truncate</i>: deletes all existing objects with the specified object name prefix before writing files to OSS. For example, if you set the object parameter to <code>abc</code>, all objects whose names start with <code>abc</code> are deleted. <i>append</i>: writes all files and ensures that the actual file names do not conflict with those of existing objects by suffixing the file names with random UUIDs. For example, if you set the object parameter to <code>DI</code>, the actual names of the files written to OSS are in the following format: <code>DI_****_****_****</code>. <i>nonConflict</i>: returns an error message if an object with the specified object name exists. For example, if you set the <code>object</code> parameter to <code>abc</code> and the object named <code>abc123</code> exists, an error message is returned. 	Yes	None
fileFormat	<p>The format in which the files are written to OSS. Valid values: <code>csv</code> and <code>text</code>.</p> <ul style="list-style-type: none"> If a file is written as a CSV file, the file strictly follows CSV specifications. If the data in the file contains the column delimiter, the column delimiter is escaped by using double quotation marks ("<code>"</code>"). If a file is written as a text file, the data in the file is separated with the column delimiter. If the data in the file contains the column delimiter, the column delimiter is not escaped. 	No	<i>text</i>
fieldDelimiter	The column delimiter that is used in the files to be written to OSS.	No	,
encoding	The encoding format of the files to be written to OSS.	No	<i>utf-8</i>
nullFormat	The string that represents null. No standard strings can represent null in text files. Therefore, Data Integration provides the <code>nullFormat</code> parameter to define which string represents a null pointer. For example, if you specify <code>nullFormat="null"</code> , Data Integration considers null as a null pointer.	No	None
header (advanced parameter, which cannot be set on the codeless UI)	The table header in the files to be written to OSS, for example, <code>['id','name','age']</code> .	No	None

Parameter	Description	Required	Default value
maxFileSize (advanced parameter, which cannot be set on the codeless UI)	<p>The maximum size of a single file that can be written to OSS. Default value: 100000. Unit: MB. File rotation based on this maximum size is similar to log rotation of Log4j. When a file is uploaded to OSS in multiple parts, the minimum size of a part is 10 MB. This size is the minimum granularity for file rotation. That is, if you set the maxFileSize parameter to less than 10 MB, the minimum size of a file is still 10 MB. Each call of the InitiateMultipartUploadRequest operation supports writing up to 10,000 parts.</p> <p>If file rotation occurs, suffixes, such as <code>_1</code>, <code>_2</code>, and <code>_3</code>, are appended to the new file names that consist of file name prefixes and random UUIDs.</p>	No	100,000MB
suffix (advanced parameter, which cannot be set on the codeless UI)	<p>The file name extension of the files to be written to OSS. For example, if you set the suffix parameter to <code>.csv</code>, the final name of a file written to OSS is in the format <code>fileName****.csv</code>.</p>	No	None

Configure OSS Writer by using the codeless UI

1. Configure the connections.

Configure the connections to the source and destination data stores for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Object Name Prefix	The object parameter in the preceding parameter description. Enter the path of the directory for storing the files. Do not include the name of the OSS bucket in the path.
File Type	The fileFormat parameter in the preceding parameter description. Valid values: <code>csv</code> and <code>text</code> .
Field Delimiter	The fieldDelimiter parameter in the preceding parameter description. The default delimiter is comma (<code>,</code>).
Encoding	The encoding parameter in the preceding parameter description. Default value: <code>UTF-8</code> .
Null String	The nullFormat parameter in the preceding parameter description. Enter a string that represents null. If the data in the source data store contains the string, the string is replaced with null.

Parameter	Description
Time Format	The format in which the data of the DATE type is serialized in an object, for example, <code>"dateFormat": "yyyy-MM-dd"</code> .
Solution to Duplicate Prefixes	The solution to take when a prefix conflict occurs. If an object with the specified name prefix exists, replace the object with the new object, insert the new object, or return an error message.

2. Configure field mapping. Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right.

GUI element	Description
Map Fields with the Same Name	Click Map Fields with the Same Name to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click Map Fields in the Same Line to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click Delete All Mappings to remove mappings that have been established.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure OSS Writer by using the code editor

In the following code, a node is configured to write files to OSS. For more information about the parameters, see the preceding parameter description.

```
{
  "type": "job",
  "version": "2.0",
  "steps": [
    {
      "stepType": "stream",
      "parameter": {},
      "name": "Reader",
      "category": "reader"
    },
    {
      "stepType": "oss", // The writer type.
      "parameter": {
        "nullFormat": "", // The string that represents null.
        "dateFormat": "", // The format in which the data of the DATE type is serialized in an object.
        "datasource": "", // The connection name.
        "writeMode": "", // The write mode.
        "encoding": "", // The encoding format.
        "fieldDelimiter": ",", // The column delimiter.
        "fileFormat": "", // The format in which the files are written to OSS.
        "object": "" // The name prefix of the files to be written to OSS as objects.
      },
      "name": "Writer",
      "category": "writer"
    }
  ],
  "setting": {
    "errorLimit": {
      "record": "0" // The maximum number of dirty data records allowed.
    },
    "speed": {
      "throttle": false, // Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
      "concurrent": 1 // The maximum number of concurrent threads.
    }
  },
  "order": {
    "hops": [
      {
        "from": "Reader",
        "to": "Writer"
      }
    ]
  }
}
```

2.4.5.4.15. Configure PostgreSQL Writer

This topic describes the data types and parameters supported by PostgreSQL Writer and how to configure it by using the codeless UI and code editor.

PostgreSQL Writer allows you to write data to a PostgreSQL database. PostgreSQL Writer connects to a remote PostgreSQL database by using JDBC, and executes an SQL statement to write data to the PostgreSQL database.

 **Note** You must configure a connection before you configure PostgreSQL Writer.

- PostgreSQL Writer generates the SQL statement based on the table, column, and where parameters that you specified, and sends the generated SQL statement to the PostgreSQL database.
- If you specify the querySql parameter, PostgreSQL Writer directly sends the value of this parameter to the PostgreSQL database.

Data types

PostgreSQL Writer supports most PostgreSQL data types. Make sure that your data types are supported.

The following table lists the data types supported by PostgreSQL Writer.

Data Integration data type	PostgreSQL data type
LONG	BIGINT, BIGSERIAL, INTEGER, SMALLINT, and SERIAL
DOUBLE	DOUBLE, PRECISION, MONEY, NUMERIC, and REAL
STRING	VARCHAR, CHAR, TEXT, BIT, and INET
DATE	DATE, TIME, and TIMESTAMP
BOOLEAN	BOOL
BYTES	BYTEA

 **Note**

- Data types that are not listed in the table are not supported.
- You can convert the MONEY, INET, and BIT types by using syntax such as `a_inet::varchar`.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the destination table.	Yes	None
writeMode	<p>The write mode. Valid values: insert and copy.</p> <ul style="list-style-type: none"> • <i>insert</i>: executes the <code>INSERT INTO</code> statement to write data to the PostgreSQL database. If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows and is regarded as dirty data. We recommend that you select the insert mode. • <i>copy</i>: copies data between tables and the standard input or output file. Data Integration supports the <code>COPY FROM</code> command, which allows you to copy data from files to tables. We recommend that you try this mode when performance issues occur. 	No	<i>insert</i>

Parameter	Description	Required	Default value
column	The columns in the destination table to which data is written. Separate the columns with commas (,), for example, <code>"column": ["id","name","age"]</code> . To write data to all the columns in the destination table, set the value to an asterisk (*), for example, <code>"column":["*"]</code> .	Yes	None
preSql	The SQL statement to execute before the sync node is run. For example, you can clear outdated data before data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	None
postSql	The SQL statement to execute after the sync node is run. For example, you can add a timestamp after data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the PostgreSQL database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	1,024

Parameter	Description	Required	Default value
pgType	<p>The PostgreSQL configuration for converting data types. Valid values: bigint[], double[], text[], jsonb, and json. Example:</p> <pre> { "job": { "content": { "reader": {...}, "writer": { "parameter": { "column": [// The columns in the destination table to which data is written. "bigint_arr", "double_arr", "text_arr", "jsonb_obj", "json_obj"], "pgType": { // The PostgreSQL configuration for converting data types. In each key-value pair, the key specifies the name of a field in the destination table, and the value specifies the data type of the field. "bigint_arr": "bigint[]", "double_arr": "double[]", "text_arr": "text[]", "jsonb_obj": "jsonb", "json_obj": "json" } } } } } } </pre>	No	None

Configure PostgreSQL Writer by using the codeless UI

1. Configure the connections.

Configure the connections to the source and destination data stores for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.

Parameter	Description
Table	The table parameter in the preceding parameter description.
Statement Run Before Writing	The preSql parameter in the preceding parameter description. Enter an SQL statement to execute before the sync node is run.
Statement Run After Writing	The postSql parameter in the preceding parameter description. Enter an SQL statement to execute after the sync node is run.
Write Method	The writeMode parameter in the preceding parameter description. Valid values: <i>Insert</i> and <i>Copy</i> .

2. Configure field mapping. It is equivalent to setting the column parameter in the preceding parameter description. Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right.

Button	Description
Map Fields with the Same Name	Click Map Fields with the Same Name to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click Map Fields in the Same Line to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click Delete All Mappings to remove mappings that have been established.
Auto Layout	Click Auto Layout to sort the fields based on specified rules.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure PostgreSQL Writer by using the code editor

In the following code, a node is configured to write data to a PostgreSQL database. For more information about the parameters, see the preceding parameter description.

```

{
  "type": "job",
  "version": "2.0", // The version number.
  "steps": [
    {
      "stepType": "stream",
      "parameter": {},
      "name": "Reader",
      "category": "reader"
    },
    {
      "stepType": "postgresql", // The writer type.
      "parameter": {
        "postSql": [], // The SQL statement to execute after the sync node is run.
        "datasource": "", // The connection name.
        "col1",
        "col2"
      },
      "table": "", // The name of the destination table.
      "preSql": [] // The SQL statement to execute before the sync node is run.
    },
    {
      "name": "Writer",
      "category": "writer"
    }
  ],
  "setting": {
    "errorLimit": {
      "record": "0" // The maximum number of dirty data records allowed.
    },
    "speed": {
      "throttle": false, // Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
      "concurrent": "1" // The maximum number of concurrent threads.
    }
  },
  "order": {
    "hops": [
      {
        "from": "Reader",
        "to": "Writer"
      }
    ]
  }
}

```

2.4.5.4.16. Configure Redis Writer

Redis Writer is a writer that is developed based on the Data Integration framework. It can be used to import data from data stores such as data warehouses to Redis databases.

Redis is a network-enabled key-value storage system that is either in-memory or permanent. It supports logs and delivers high performance. It can be used as a database, cache, and message broker. Redis supports diverse data types for values, including STRING, LIST, SET, ZSET (sorted set), and HASH.

Redis Writer interacts with a Redis server by using Jedis. As a preferred Java client development kit provided by Redis, Jedis supports almost all the features of Redis.

Note

- You must configure a connection before you configure Redis Writer.
- If you write values of the LIST type to Redis by using Redis Writer, the result of rerunning a sync node is not idempotent. If the data type of the values is LIST, you must manually clear the corresponding data on Redis when you rerun a sync node.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
keyIndexes	The columns used as the key. The index of the first column is 0. For example, if you want to set the first and second columns of the source data as the key, set the keyIndexes parameter to [0,1]. Note After you specify the keyIndexes parameter, Redis Writer specifies the remaining columns as the value. If you do not want to synchronize all the columns, filter columns when you configure the reader.	Yes	None
keyFieldDelimiter	The delimiter used to separate keys when data is written to Redis. Example: key=key1\u0001id. If multiple keys need to be concatenated, this parameter is required. If only one key exists, this parameter is not required.	No	\u0001
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the Redis database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	1,000
expireTime	The expiration time of the values to be cached in Redis. Unit: seconds. The data is valid permanently if you do not specify this parameter. <ul style="list-style-type: none"> • <i>seconds</i>: the relative time in seconds starting from the current time point. It specifies the time range during which data is valid. • <i>unixtime</i>: the UNIX timestamp, indicating that data is invalid at a specific time point in the future. The UNIX timestamp represents the number of seconds that have elapsed since 00:00:00 on January 1, 1970. Note If the specified expiration time is larger than 30 days, the server identifies the time as the UNIX timestamp.	No	0, indicating that the values never expire
timeout	The timeout period to connect to Redis when data is written to Redis. Unit: milliseconds.	No	30,000

Parameter	Description	Required	Default value
dateFormat	The format in which the data of the DATE type is written to Redis. Set the value to yyyy-MM-dd HH:mm:ss.	No	None
writeMode	<p>The write mode. Redis supports diverse data types for values, including STRING, LIST, SET, ZSET (sorted set), and HASH. Redis Writer allows you to write values of the preceding types to Redis. The value of the writeMode parameter varies based on the specified data type of the values.</p> <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> <p> Note When you configure Redis Writer, you can choose only one of the five data types described in the following table. If you do not specify a data type, the data type is STRING by default.</p> </div>	No	<i>string</i>

The following table lists the data types supported by Redis Writer.

Type	Parameter	Description	Required
String	type	The data type of the values is STRING.	Yes
	mode	The mode in which data of the STRING type is written to Redis.	Yes. Valid value: set (overwrites the existing data).
	valueFieldDelimiter	<p>This parameter is required if two or more columns are specified as the values. This parameter is not required if only one column is specified as the values.</p> <p>The delimiter used to separate values if the data is of the STRING type. Example: value1\u0001value2\u0001value3.</p>	No. Default value: \u0001.
LIST	type	The data type of the values is LIST.	Yes
	mode	The mode in which data of the LIST type is written to Redis.	Yes. Valid values: lpush (stores the data at the leftmost of the list) and rpush (stores the data at the rightmost of the list).

Type	Parameter	Description	Required
<pre> writeMode":{ "type": "list", "mode": " push rpush", "valueFieldDelimiter" : "\u0001" } </pre>	valueFieldDelimiter	The delimiter used to separate values if the data is of the STRING type. Example: value1\u0001value2\u0001value3.	No. Default value: \u0001.
	type	The data type of the values is SET.	Yes
	mode	The mode in which data of the SET type is written to Redis.	Yes. Valid value: sadd (stores the data to a set, or overwrites the existing data).
<pre> writeMode":{ "type": "set", "mode": "sadd", "valueFieldDelimiter" : "\u0001" } </pre>	valueFieldDelimiter	The delimiter used to separate values if the data is of the STRING type. Example: value1\u0001value2\u0001value3.	No. Default value: \u0001.
	type	The data type of the values is ZSET.	Yes
	mode	The mode in which data of the ZSET type is written to Redis.	Yes. Valid value: zadd (stores data to a sorted set, or overwrites the existing data).
<pre> writeMode":{ "type": "zset", "mode": "zadd" } </pre>	type	<p>The data type of the values is ZSET.</p> <div style="border: 1px solid #add8e6; padding: 5px; background-color: #e6f2ff;"> <p>Note If the data type of the values is ZSET, each data record must follow the following standard: Except for the key, a data record can contain only one score and one value. The score must be placed before the value. In this way, Redis Writer can identify which column is the score and which column is the value.</p> </div>	Yes
	mode	The mode in which data of the ZSET type is written to Redis.	Yes. Valid value: zadd (stores data to a sorted set, or overwrites the existing data).

Type	Parameter	Description	Required
HASH	type	<p>The data type of the values is HASH.</p> <div style="background-color: #e0f2f1; padding: 5px;"> <p> Note If the data type of the values is HASH, each data record must follow the following standards: Except for the key, a data record can contain only one attribute and one value. The attribute must be placed before the value. In this way, Redis Writer can identify which column is the attribute and which column is the value.</p> </div>	Yes
	mode	<p>The mode in which data of the HASH type is written to Redis.</p>	<p>Yes. Valid value: hmset (stores data to a hash sorted set, or overwrites the existing data).</p> <p>If you do not specify a data type, the data type is STRING by default.</p>

```

"writeMode":{
  "type": "hash",
  "mode": "hset"
}

```

Configure Redis Writer by using the codeless UI

The codeless UI is not supported for Redis Reader.

Configure Redis Writer by using the code editor

In the following code, a node is configured to write data to Redis. For more information about parameters, see the preceding parameter description.

```

{
  "type": "job",
  "version": "2.0", // The version number.
  "steps": [
    {
      "stepType": "stream",
      "parameter": {},
      "name": "Reader",
      "category": "reader"
    },
    {
      "stepType": "redis", // The writer type.
      "parameter": {
        "expireTime": { // The expiration time of the values to be cached in Redis.
          "seconds": "1000"
        }
      }
    }
  ]
}

```

```
    },
    "keyFieldDelimiter": "u0001", // The delimiter used to separate keys when data is written to Redis.
    "dateFormat": "yyyy-MM-dd HH:mm:ss", // The format in which the data of the DATE type is written to Redis.
    "datasource": "", // The connection name.
    "writeMode": {}, // The write mode.
    "mode": "", // The write mode used to write data of a specified data type.
    "valueFieldDelimiter": "", // The delimiter used to separate values.
    "type": "" // The data type of the values.
  },
  "keyIndexes": [ // The columns used as the key.
    0,
    1
  ],
  "batchSize": "1000" // The number of data records to write at a time.
},
"name": "Writer",
"category": "writer"
}
],
"setting": {
  "errorLimit": {
    "record": "0" // The maximum number of dirty data records allowed.
  },
  "speed": {
    "throttle": false, // Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
    "concurrent": 1 // The maximum number of concurrent threads.
  }
},
"order": {
  "hops": [
    {
      "from": "Reader",
      "to": "Writer"
    }
  ]
}
}Writer"
}
]
}
}
```

2.4.5.4.17. Configure SQL Server Writer

This topic describes the data types and parameters supported by SQL Server Writer and how to configure it by using the codeless UI and code editor.

SQL Server Writer allows you to write data to tables stored in primary SQL Server databases. SQL Server Writer connects to a remote SQL Server database by using JDBC, and executes an `INSERT INTO` statement to write data to the SQL Server database. Internally, data is submitted to the database in batches.

SQL Server Writer is designed for ETL developers to import data from data warehouses to SQL Server databases. SQL Server Writer can also be used as a data migration tool by users such as DBAs.

SQL Server Writer obtains data from a Data Integration reader, and generates the `INSERT INTO` statement. If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows. To improve performance, SQL Server Writer makes batch updates with the `PreparedStatement` method and sets `rewriteBatchedStatements` to true. In this way, SQL Server Writer buffers data, and submits a write request when the amount of data in the buffer reaches a specific threshold.

 **Note**

- Data can be written only to tables stored in the primary SQL Server database.
- A sync node that uses SQL Server Writer must have at least the permission to execute the `INSERT INTO` statement. Whether other permissions are required depends on the SQL statements specified in the `preSql` and `postSql` parameters when you configure the node.

Data types

SQL Server Writer supports most SQL Server data types. Make sure that your data types are supported.

The following table lists the data types supported by SQL Server Writer.

Category	SQL Server data type
Integer	BIGINT, INT, SMALLINT, and TINYINT
Floating point	FLOAT, DECIMAL, REAL, and NUMERIC
String	CHAR, NCHAR, NTEXT, NVARCHAR, TEXT, VARCHAR, NVARCHAR (MAX), and VARCHAR (MAX)
Date and time	DATE, TIME, and DATETIME
Boolean	BIT
Binary	BINARY, VARBINARY, VARBINARY (MAX), and TIMESTAMP

Parameters

Parameter	Description	Required	Default value
<code>datasource</code>	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
<code>table</code>	The name of the destination table.	Yes	None
<code>column</code>	The columns in the destination table to which data is written. Separate the columns with commas (.). Example: <code>"column": ["id","name","age"]</code> . To write data to all the columns in the destination table, set the value to an asterisk (*), for example, <code>"column":["*"]</code> .	Yes	None
<code>preSql</code>	The SQL statement to execute before the sync node is run. For example, you can clear outdated data before data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	None

Parameter	Description	Required	Default value
postSql	The SQL statement to execute after the sync node is run. For example, you can add a timestamp after data synchronization. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	None
writeMode	The write mode. Valid value: <i>insert</i> . When a data record violates the primary key constraint or unique index constraint, Data Integration considers it dirty and retains the original data.	No	<i>insert</i>
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the SQL Server database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	1,024

Configure SQL Serve Writer by using the codeless UI

1. Configure the connections.

Configure the connections to the source and destination data stores for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Statement Run Before Writing	The preSql parameter in the preceding parameter description. Enter an SQL statement to execute before the sync node is run.
Statement Run After Writing	The postSql parameter in the preceding parameter description. Enter an SQL statement to execute after the sync node is run.
Solution to Primary Key Violation	The writeMode parameter in the preceding parameter description. Select the required write mode.

2. Configure field mapping. It is equivalent to setting the column parameter in the preceding parameter description.

Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right. You can click **Add** to add a field, or move the pointer over a field and click the **Delete** icon to delete the field.

GUI element	Description
Map Fields with the Same Name	Click Map Fields with the Same Name to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click Map Fields in the Same Line to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click Delete All Mappings to remove mappings that have been established.

GUI element	Description
Auto Layout	Click Auto Layout to sort the fields based on specified rules.
Change Fields	Click the Change Fields icon. In the Change Fields dialog box, you can manually edit fields in the source table. Each field occupies a row. The first and the last blank rows are included, whereas other blank rows are ignored.
Add	<ul style="list-style-type: none"> ◦ Click Add to add a field. You can enter constants. Each constant must be enclosed in single quotation marks (' '), for example, 'abc' and '123'. ◦ You can use scheduling parameters such as \${bizdate}. ◦ You can enter functions supported by relational databases, for example, now() and count(1). ◦ If the value you entered cannot be parsed, the type is displayed as Unidentified.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure SQL Server Writer by using the code editor

In the following code, a node is configured to write data to an SQL Server database. For more information about the parameters, see the preceding parameter description.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"sqlserver",// The writer type.
      "parameter":{
        "postSql":[// The SQL statement to execute after the sync node is run.
          "datasource":"","// The connection name.
          "column":[// The columns to which data is written.
            "id",
            "name"
          ],
          "table":"","// The name of the destination table.
          "preSql":[// The SQL statement to execute before the sync node is run.
        ],
        "name":"Writer",
        "category":"writer"
      }
    },
    ],
    "setting":{
      "errorLimit":{
        "record":"0"// The maximum number of dirty data records allowed.
      },
      "speed":{
        "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
        "concurrent":1 // The maximum number of concurrent threads.
      }
    },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
        }
      ]
    }
  }
}
```

2.4.5.4.18. Configure Elasticsearch Writer

This topic describes the data types and parameters supported by Elasticsearch Writer and how to configure it by using the code editor.

Elasticsearch is an open-source product that complies with the Apache open standards. It is the mainstream search engine for enterprise data. Elasticsearch is a Lucene-based data search and analysis tool that provides distributed services. The mappings between Elasticsearch core concepts and database core concepts are as follows:

Relational database (instance) -> database -> table -> row -> column
 Elasticsearch -> index -> type -> document -> field

Elasticsearch can contain multiple indexes (databases). Each index can contain multiple types (tables). Each type can contain multiple documents (rows). Each document can contain multiple fields (columns). Elasticsearch Writer uses the RESTful API of Elasticsearch to write multiple data records retrieved by a reader to Elasticsearch at a time.

Parameters

Parameter	Description	Required	Default value
endpoint	The endpoint for accessing Elasticsearch, in the format of <code>http://xxx.com:9999</code> .	No	None
accessId	The AccessKey ID for accessing Elasticsearch, which is used for authorization when a connection with Elasticsearch is established. <div style="border: 1px solid #add8e6; padding: 5px; background-color: #e6f2ff;"> <p> Note The accessId and accessKey parameters are required. If you do not set the parameters, an error is returned. If you use on-premises Elasticsearch for which basic authentication is not configured, the AccessKey ID and AccessKey secret are not required. In this case, you can set the accessId and accessKey parameters to random values.</p> </div>	No	None
accessKey	The AccessKey secret for accessing Elasticsearch.	No	None
index	The index name in Elasticsearch.	No	None
indexType	The type name in the index of Elasticsearch.	No	<i>Elasticsearch</i>
cleanup	Specifies whether to clear existing data in the index. The method used to clear the data is to delete and rebuild the corresponding index. The default value false indicates that the existing data in the index is retained.	No	<i>false</i>
batchSize	The number of data records to write at a time.	No	<i>1000</i>
trySize	The number of retries after a failure.	No	<i>30</i>
timeout	The connection timeout of the client. Unit: milliseconds.	No	<i>600000</i>
discovery	Specifies whether to enable Node Discovery. When Node Discovery is enabled, the server list in the client is polled and regularly updated.	No	<i>false</i>

Parameter	Description	Required	Default value
compression	Specifies whether to enable compression for an HTTP request.	No	<i>true</i>
multiThread	Specifies whether to use multiple threads for an HTTP request.	No	<i>true</i>
ignoreWriteError	Specifies whether to ignore write errors and proceed with writing without retries.	No	<i>false</i>
ignoreParseError	Specifies whether to ignore format parsing errors and proceed with writing.	No	<i>true</i>
alias	<p>The alias of the index. The alias feature of Elasticsearch is similar to the view feature of a traditional database. For example, if you create an alias named <code>my_index_alias</code> for the index <code>my_index</code>, the operations on <code>my_index_alias</code> also take effect on <code>my_index</code>.</p> <p>Configuring alias means that after the data import is completed, an alias is created for the specified index.</p>	No	None
aliasMode	The mode in which an alias is added after the data is imported. Valid values: <i>append</i> and <i>exclusive</i> .	No	append
settings	<p>The delimiter (-,-) for splitting the source data if you are inserting an array to Elasticsearch. Example:</p> <p>The source column stores data <code>a,-,b,-,c,-,d</code> of the String type. Elasticsearch Writer uses the delimiter (-,-) to split the source data and obtains the array <code>["a", "b", "c", "d"]</code>. Then, Elasticsearch Writer writes the array to the corresponding field in Elasticsearch.</p>	No	-,-
	<p>The fields of the document. The parameters for each field include basic parameters such as name and type and advanced parameters such as analyzer, format, and array.</p> <p>The field types supported by Elasticsearch are as follows:</p>		

Parameter	Description	Required	Default value
column	<p>- id // The id type corresponds to the _id type in Elasticsearch, and can be considered as the unique primary key. Data with the same ID will be overwritten and not indexed.</p> <ul style="list-style-type: none"> - string - text - keyword - long - integer - short - byte - double - float - date - boolean - binary - integer_range - float_range - long_range - double_range - date_range - geo_point - geo_shape - ip - token_count - array - object - nested <ul style="list-style-type: none"> When the field type is Text, you can specify the analyzer, norms, and index_options parameters. Example: <pre data-bbox="475 1234 1050 1413" style="background-color: #f0f0f0; padding: 5px;"> { "name": "col_text", "type": "text", "analyzer": "ik_max_word" } </pre> When the field type is date, you can specify the format and timezone parameters, indicating the date serialization format and the time zone, respectively. Example: <pre data-bbox="475 1559 1050 1765" style="background-color: #f0f0f0; padding: 5px;"> { "name": "col_date", "type": "date", "format": "yyyy-MM-dd HH:mm:ss", "timezone": "UTC" } </pre> When the field type is ge_shape, you can specify the tree (geohash or quadtree) and precision parameters. Example: 	Yes	None

Parameter	Description	Required	Default value
	<pre>{ "name": "col_geo_shape", "type": "geo_shape", "tree": "quadtree", "precision": "10m" }</pre> <p>If you specify the array parameter for a field and set the array parameter to <i>true</i>, the field is an array column. Elasticsearch Writer uses the delimiter specified by the splitter to split the source data, converts the data to an array of strings, and writes the array to the destination. Only one delimiter is supported for one node. Example:</p> <pre>{ "name": "col_integer_array", "type": "integer", "array": true }</pre>		
dynamic	Specifies whether to use the mapping configuration of Elasticsearch. A value of <i>true</i> indicates that the mapping configuration of Elasticsearch, instead of the mapping configuration of Data Integration, is used.	No	<i>false</i>
actionType	<p>The type of the action for writing data to Elasticsearch. Currently, Data Integration supports only the following action types: <i>index</i> and <i>update</i>. Default value: <i>index</i>.</p> <ul style="list-style-type: none"> • <i>index</i>: Data Integration uses Index.Builder of the Elasticsearch SDK to construct a request for writing multiple data records at a time. In <i>index</i> mode, Elasticsearch first checks whether an ID is specified for the document to be inserted. <ul style="list-style-type: none"> ◦ If the ID is not specified, Elasticsearch generates a unique ID by default. In this case, the document is directly inserted to Elasticsearch. ◦ If the ID is specified, Elasticsearch replaces the existing document with the document to be inserted. <div style="border: 1px solid #add8e6; padding: 5px; margin: 10px 0;"> <p> Note In this case, you cannot modify specific fields in the document.</p> </div> • <i>update</i>: Data Integration uses Update.Builder of the Elasticsearch SDK to construct a request for writing multiple data records at a time. In <i>update</i> mode, Elasticsearch calls the get method of InternalEngine to obtain the information of the original document for each update. In this way, you can modify specific fields. In update mode, you must obtain the information of the original document for each update, which greatly affects the performance. However, you can modify specific fields in this mode. If the original document does not exist, the new document is directly inserted. 	No	<i>index</i>

Configure Elasticsearch Writer by using the code editor

In the following code, a node is configured to write data to Elasticsearch. For more information about the parameters, see the preceding parameter description.

```
{
  "order": {
    "hops": [
      {
        "from": "Reader",
        "to": "Writer"
      }
    ]
  },
  "setting": {
    "errorLimit": {

      "type": "geo_shape",
      "tree": "quadtree",
      "precision": "10m"
    }
  ]
}
```

```

    }
  ]
},
"stepType": "elasticsearch"
}
],
"type": "job",
"version": "2.0"
}

```

Note Currently, Elasticsearch that is deployed in a Virtual Private Cloud (VPC) supports only custom resource groups. A sync node that is run on the default resource group may fail to connect to Elasticsearch.

2.4.5.4.19. Configure LogHub Writer

This topic describes the data types and parameters supported by LogHub Writer and how to configure it by using the code editor.

LogHub Writer allows you to transfer data from a Data Integration reader to LogHub through Log Service Java SDK.

Note LogHub does not guarantee idempotence. Rerunning a node after the node fails may result in redundant data.

LogHub Writer obtains data from a Data Integration reader and converts the data types supported by Data Integration to String. When the number of the data records reaches the value specified for the batchSize parameter, LogHub Writer sends the data records to LogHub at a time through Log Service Java SDK. LogHub Writer sends 1,024 data records at a time by default. The batchSize parameter can be set to 4096 at most.

Data types

The following table lists the data types supported by LogHub Writer.

Data Integration data type	LogHub data type
LONG	STRING
DOUBLE	STRING
STRING	STRING
DATE	STRING
BOOLEAN	STRING
BYTES	STRING

Parameters

Parameter	Description	Required	Default value
endpoint	The endpoint for accessing Log Service.	Yes	None

Parameter	Description	Required	Default value
accessKeyId	The AccessKey ID for accessing Log Service.	Yes	None
accessKeySecret	The AccessKey secret for accessing Log Service.	Yes	None
project	The name of the destination Log Service project.	Yes	None
logstore	The name of the destination Logstore.	Yes	None
topic	The name of the destination topic.	No	Empty string
batchSize	The number of data records to write at a time.	No	1024
column	The columns in each data record.	Yes	None

Configure LogHub Writer by using the codeless UI

Currently, the codeless user interface (UI) is not supported for LogHub Writer.

Configure LogHub Writer by using the code editor

In the following code, a node is configured to write data to LogHub. For more information about the parameters, see the preceding parameter description.

```

{
  "type": "job",
  "version": "2.0", // The version number.
  "steps": [
    { //
      "stepType": "stream",
      "parameter": {},
      "name": "Reader",
      "category": "reader"
    },
    {
      "stepType": "loghub", // The writer type.
      "parameter": {
        "datasource": "", // The connection name.
        "column": [ // The columns in each data record.
          "col0",
          "col1",
          "col2",
          "col3",
          "col4",
          "col5"
        ],
        "topic": "", // The name of the destination topic.
        "batchSize": "1024", // The number of data records to write at a time.
        "logstore": "" // The name of the destination Logstore.
      },
      "name": "Writer",
      "category": "writer"
    }
  ],
  "setting": {
    "errorLimit": {
      "record": "" // The maximum number of dirty data records allowed.
    },
    "speed": {
      "concurrent": 3, // The maximum number of concurrent threads.
      "throttle": false, // Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
    }
  },
  "order": {
    "hops": [
      {
        "from": "Reader",
        "to": "Writer"
      }
    ]
  }
}

```

2.4.5.4.20. Configure Open Search Writer

This topic describes the data types and parameters supported by Open Search Writer and how to configure it by using the code editor.

How it works

Open Search Writer allows you to insert data to or update data in Open Search. Open Search Writer is designed for developers to import data to Open Search so that the data can be searched.

Specifically, Open Search Writer uses the search API provided by Open Search to import data.

Note

- Open Search V3 uses internal dependent databases, with POM of `com.aliyun.opensearch:aliyun-sdk-opensearch:2.1.3`.
- To use Open Search Writer, you must install JDK 1.6-32 or later. You can run the `java-version` command to view the JDK version.

Features

The columns in Open Search are unordered. Open Search Writer writes data strictly in accordance with the order of the specified columns. If the number of specified columns is less than that in Open Search, redundant columns in Open Search are set to the default value or null.

Assume that an Open Search table contains columns a, b, and c, and you only need to write data to columns b and c. You can set the column parameter to ["c","b"]. In this case, Open Search Writer imports the first and second columns of the source data obtained from a reader to columns c and b in the Open Search table respectively. Column a in the Open Search table is set to the default value or null.

Additional instructions:

- Handling of column configuration errors

To avoid losing the data of redundant columns and ensure high data reliability, Open Search Writer returns an error message if the number of columns to be written is more than that in the destination Open Search table. For example, if an Open Search table contains columns a, b, and c, Open Search Writer returns an error if more than three columns are to be written to the table.

- Table configuration

Open Search Writer can write data to only one table at a time.

- Node rerunning

After a node is rerun, data is automatically overwritten based on IDs. Therefore, the data written to Open Search must contain one ID column. An ID is a unique identifier of a row in Open Search. The existing data with the same ID as the new data will be overwritten.

- Node rerunning

After a node is rerun, data is automatically overwritten based on IDs.

Data types

Open Search Writer supports most Open Search data types. Make sure that your data types are supported.

The following table lists the data types supported by Open Search Writer.

Category	Open Search data type
Integer	INT
Floating point	DOUBLE and FLOAT
String	TEXT, LITERAL, and SHORT_TEXT

Category	Open Search data type
Date and time	INT
Boolean	LITERAL

Parameters

Parameter	Description	Required	Default value
accessId	The AccessKey ID for connecting to the Open Search database.	Yes	None
accessKey	The AccessKey secret for connecting to the Open Search database.	Yes	None
host	The endpoint for connecting to Open Search. You can view the endpoint in the Apsara Stack console.	Yes	None
indexName	The name of the Open Search project.	Yes	None
table	The name of the table to which data is written. You can specify only one table name because Data Integration does not support importing data to multiple tables at a time.	Yes	None
column	<p>The columns in the destination table to which data is written. To write data to all the columns in the destination table, set the value to an asterisk (*), for example, <code>"column":["*"]</code>. Separate the columns with a comma (,) if data is written to some of the columns in the destination table. Example: <code>"column":["id","name"]</code>.</p> <p>Open Search Writer supports filtering columns and changing the order of columns. Assume that an Open Search table has three columns: a, b, and c. If you want to write data only to columns c and b, you can set the column parameter in the format <code>"column":["c","b"]</code>. During data synchronization, column a is automatically set to null.</p>	Yes	None
batchSize	<p>The number of data records to write at a time. Data is written to Open Search in batches. The advantage of Open Search is data query. The transactions per second (TPS) of Open Search is generally not high. Set this parameter based on the resources available for the account that is used to connect to Open Search.</p> <p>Generally, the size of a data record must be less than 1 MB, and the size of the data records to write at a time must be less than 2 MB.</p>	Required only for writing data to a partitioned table	300

Parameter	Description	Required	Default value
writeMode	<p>The write mode. To ensure the idempotence of write operations, set the writeMode parameter to add/update when you configure Open Search Writer.</p> <ul style="list-style-type: none"> • add: deletes the existing data record and inserts the new data record to Open Search, which is an atomic operation. • update: updates the existing data record based on the new data record, which is an atomic operation. <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> <p> Note Writing data to Open Search in batches is not an atomic operation. Part of the data may fail to be written. Exercise caution when you set the writeMode parameter. Open Search V3 does not support the update mode.</p> </div>	Yes	None
ignoreWriteError	<p>Specifies whether to ignore failed write operations.</p> <p>Example: <code>"ignoreWriteError":true</code> . If data is written to Open Search in batches, this parameter specifies whether to ignore failed write operations in the current batch. If you set the parameter to true, Open Search Writer continues to perform other write operations. If you set the parameter to false, the sync node ends and an error message is returned. We recommend that you use the default value.</p>	No	<i>false</i>
version	<p>The version of Open Search, for example, <code>"version":"v3"</code> . We recommend that you use Open Search V3 because the push operation faces many constraints in Open Search V2.</p>	No	v2

Configure Open Search Writer by using the code editor

In the following code, a node is configured to write data to Open Search.

```

{
  "type": "job",
  "version": "1.0",
  "configuration": {
    "reader": {},
    "writer": {
      "plugin": "opensearch",
      "parameter": {
        "accessId": "*****",
        "accessKey": "*****",
        "host": "http://yyyy.aliyuncs.com",
        "indexName": "datax_xxx",
        "table": "datax_yyy",
        "column": [
          "appkey",
          "id",
          "title",
          "gmt_create",
          "pic_default"
        ],
        "batchSize": 500,
        "writeMode": add,
        "version": "v2",
        "ignoreWriteError": false
      }
    }
  }
}

```

2.4.5.4.21. Configure Tablestore Writer

This topic describes the data types and parameters supported by Tablestore Writer and how to configure it by using the code editor.

Tablestore is a NoSQL database service that is built on the Apsara distributed operating system. The service allows you to store and access large volumes of structured data in real time. Tablestore organizes data into instances and tables. It uses data sharding and load balancing technologies to seamlessly expand the data scale.

Tablestore Writer connects to the Tablestore server by using Tablestore SDK for Java and writes data to the server by using the SDK. Tablestore Writer greatly optimizes the write process, including retry after write timeouts, retry after exceptions, and batch submission.

Tablestore Writer writes data to Tablestore in one of the following modes:

- **PutRow**: the PutRow API operation for Tablestore, which is used to insert data to a specified row. If this row does not exist, a new row is added. Otherwise, the original row is overwritten.
- **UpdateRow**: the UpdateRow API operation for Tablestore, which is used to update the data of a specified row. If this row does not exist, a new row is added. Otherwise, the values of the specified columns are added, modified, or removed as requested.

Tablestore Writer supports all Tablestore data types. The following table lists the data types.

Category	Tablestore data type
Integer	INTEGER

Category	Tablestore data type
Floating point	DOUBLE
String	STRING
Boolean	BOOLEAN
Binary	BINARY

 **Note** To write INTEGER-type data, set the data type to INT in the code editor. Then, DataWorks converts the INT type into the INTEGER type. If you directly set the data type to INTEGER, an error is reported in the log, and the node fails.

Parameters

Parameter	Description	Required	Default value
datasource	The name of the data source. It must be the same as the name of the added data source. You can add data sources by using the code editor.	Yes	None
endPoint	The endpoint of the Tablestore server.	Yes	None
accessId	The AccessKey ID of the account that is used to access Tablestore.	Yes	None
accessKey	The AccessKey secret of the account that is used to access Tablestore.	Yes	None
instanceName	The name of the Tablestore instance. The instance is an entity for you to use and manage Tablestore. After you activate the Tablestore service, you must create an instance in the Tablestore console before you can create and manage tables. Instances are the basic units that you can use to manage Tablestore resources. Access control and resource measurement for applications are implemented at the instance level.	Yes	None
table	The name of the destination table. You can specify only one table as the destination table. Multi-table synchronization is not required for Tablestore.	Yes	None

Parameter	Description	Required	Default value
primaryKey	<p>The primary key of the destination table in Tablestore. The primary keys are described in a JSON array. Tablestore is a NoSQL database service. You must specify the primary key of the destination table for Tablestore Writer to write data.</p> <div style="background-color: #e6f2ff; padding: 5px; border: 1px solid #d9e1f2;"> <p> Note The primary keys in Tablestore must be of the STRING or INT type. Therefore, you must set the data type of a primary key to STRING or INT in the code editor.</p> </div> <p>Data Integration supports data type conversion. Tablestore Writer can convert data that is not of the STRING or INT type to the STRING or INT type. The following code provides a configuration example:</p> <pre style="background-color: #f0f0f0; padding: 5px;">"primaryKey": [{"name": "pk1", "type": "string"}, {"name": "pk2", "type": "int"}],</pre>	Yes	None
column	<p>The columns that you want to synchronize to the destination table. The columns are described in a JSON array.</p> <p>Specify this parameter in the following format:</p> <pre style="background-color: #f0f0f0; padding: 5px;">{"name": "col2", "type": "INT"},</pre> <p>The name parameter specifies the name of the column to which data is written. The type parameter specifies the data type of the column. Data types supported by Tablestore include STRING, INT, DOUBLE, BOOLEAN, and BINARY.</p>	Yes	None
writeMode	<p>The write mode. Constants, functions, or custom statements are not supported during the write process. The following three modes are supported:</p> <ul style="list-style-type: none"> PutRow: the PutRow API operation for Tablestore, which is used to insert data to a specified row. If this row does not exist, a new row is added. Otherwise, the original row is overwritten. UpdateRow: the UpdateRow API operation for Tablestore, which is used to update the data of a specified row. If this row does not exist, a new row is added. Otherwise, the values of the specified columns are added, modified, or removed as requested. DeleteRow: deletes a row. 	Yes	None

Configure Tablestore Writer by using the codeless UI

This method is not supported.

Configure Tablestore Writer by using the code editor

In the following code, a node is configured to write data to Tablestore:

```
{
```

```
"type":"job",
"version":"2.0",// The version number.
"steps":[
  {
    "stepType":"stream",
    "parameter":{},
    "name":"Reader",
    "category":"reader"
  },
  {
    "stepType":"ots",// The writer type.
    "parameter":{
      "datasource":"","// The data source.
      "column":[// The columns to which data is written.
        {
          "name":"columnName1",// The name of the column.
          "type":"INT",// The data type of the column.
        },
        {
          "name":"columnName2",
          "type":"STRING"
        },
        {
          "name":"columnName3",
          "type":"DOUBLE"
        },
        {
          "name":"columnName4",
          "type":"BOOLEAN"
        },
        {
          "name":"columnName5",
          "type":"BINARY"
        }
      ],
      "writeMode":"","// The write mode.
      "table":"","// The name of the destination table.
      "primaryKey":[// The primary key of the destination table in Tablestore.
        {
          "name":"pk1",
          "type":"STRING"
        },
        {
          "name":"pk2",
          "type":"INT"
        }
      ]
    },
    "name":"Writer",
    "category":"writer"
  }
],
"setting":{
  "errorLimit":{
    "record":"0",// The maximum number of dirty data records allowed.
  },
  "speed":{
```

```
"throttle":false,// Specifies whether to enable bandwidth throttling. The value false indicates that bandwidth throttling is disabled, and the value true indicates that bandwidth throttling is enabled. The concurrent parameter takes effect only when the throttle parameter is set to true.
```

```
    "concurrent":1,// The maximum number of concurrent threads.
  }
},
"order":{
  "hops":[
    {
      "from":"Reader",
      "to":"Writer"
    }
  ]
}
}
```

2.4.5.4.22. Configure RDBMS Writer

This topic describes the data types and parameters supported by RDBMS Writer and how to configure it by using the code editor.

RDBMS Writer allows you to write data to tables stored in primary relational database management system (RDBMS) databases. Specifically, RDBMS Writer obtains data from a Data Integration reader, connects to a remote RDBMS database through Java Database Connectivity (JDBC), and then runs an `INSERT INTO` statement to write data to the RDBMS database. RDBMS Writer is a common writer for relational databases. To enable RDBMS Writer to support a new relational database, register the driver for the relational database.

RDBMS Writer is designed for extract-transform-load (ETL) developers to import data from data warehouses to RDBMS databases. RDBMS Writer can also be used as a data migration tool by users such as database administrators (DBAs).

Data types

RDBMS Writer supports most data types in relational databases, such as numbers and characters. Make sure that your data types are supported.

Parameters

Parameter	Description	Required	Default value
jdbcUrl	<p>The JDBC URL for connecting to the database. The format must be in accordance with official specifications. You can also specify the information of the attachment facility. The format varies with the database type. Data Integration selects an appropriate driver for data reading based on the format.</p> <ul style="list-style-type: none"> Format for DM databases: <code>jdbc:dm://ip:port/database</code> Format for Db2 databases: <code>jdbc:db2://ip:port/database</code> Format for PPAS databases: <code>jdbc:edb://ip:port/database</code> 	Yes	None
username	The username for connecting to the database.	Yes	None

Parameter	Description	Required	Default value
password	The password for connecting to the database.	Yes	None
table	The name of the destination table.	Yes	None
column	<p>The columns in the destination table to which data is written. Separate the columns with a comma (,).</p> <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> <p>? Note We recommend that you do not use the default setting.</p> </div>	Yes	None
preSql	<p>The SQL statement to run before the sync node is run. For example, you can clear outdated data before data synchronization. Currently, you can run only one SQL statement.</p> <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> <p>? Note If you specify multiple SQL statements in the code editor, the system does not guarantee that they are run in the same transaction.</p> </div>	No	None
postSql	<p>The SQL statement to run after the sync node is run. For example, you can add a timestamp after data synchronization. Currently, you can run only one SQL statement.</p> <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> <p>? Note If you specify multiple SQL statements in the code editor, the system does not guarantee that they are run in the same transaction.</p> </div>	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the RDBMS database over the network, and increase the throughput. However, an excessively large value may lead to the out of memory (OOM) error during the data synchronization process.	No	1024

Configure RDBMS Writer by using the code editor

In the following code, a node is configured to write data to an RDBMS database.

```
{
  "job": {
    "setting": {
      "speed": {
        "channel": 1
      }
    }
  },
  "content": [
    {
      "reader": {
```

```

    "name": "streamreader",
    "parameter": {
      "column": [
        {
          "value": "DataX",
          "type": "string"
        },
        {
          "value": 19880808,
          "type": "long"
        },
        {
          "value": "1988-08-08 08:08:08",
          "type": "date"
        },
        {
          "value": true,
          "type": "bool"
        },
        {
          "value": "test",
          "type": "bytes"
        }
      ],
      "sliceRecordCount": 1000
    }
  },
  "writer": {
    "name": "RDBMS Writer",
    "parameter": {
      "connection": [
        {
          "jdbcUrl": "jdbc:dm://ip:port/database",
          "table": [
            "table"
          ]
        }
      ],
      "username": "username",
      "password": "password",
      "table": "table",
      "column": [
        "*"
      ],
      "preSql": [
        "delete from XXX;"
      ]
    }
  }
}
]
}
}

```

You can enable RDBMS Writer to support a new database as follows:

1. Go to the directory of RDBMS Writer, `#{DATA_HOME}/plugin/writer/RDBMS Writer`. In the preceding

directory, `$(DATA_HOME)` indicates the main directory of Data Integration.

2. Add the driver of your database to the `drivers` array in the `plugin.json` file in the RDBMS Writer directory. RDBMS Writer automatically selects an appropriate driver for connecting to a database.

```
{
  "name": "RDBMS Writer",
  "class": "com.alibaba.datax.plugin.reader.RDBMS Writer.RDBMS Writer",
  "description": "useScene: prod. mechanism: Jdbc connection using the database, execute select sql, retrieve data from the ResultSet. warn: The more you know about the database, the less problems you encounter.",
  "developer": "alibaba",
  "drivers": [
    "dm.jdbc.driver.DmDriver",
    "com.ibm.db2.jcc.DB2Driver",
    "com.sybase.jdbc3.jdbc.SybDriver",
    "com.edb.Driver"
  ]
}
```

3. Add the package of the driver to the `libs` directory in the RDBMS Writer directory.

```
$tree
.
|-- libs
| |-- Dm7JdbcDriver16.jar
| |-- commons-collections-3.0.jar
| |-- commons-io-2.4.jar
| |-- commons-lang3-3.3.2.jar

```

2.4.5.4.23. Configure Stream Writer

This topic describes the data types and parameters supported by Stream Writer and how to configure it by using the code editor.

Stream Writer allows you to display the data obtained from a Data Integration reader on the screen or discard the data. Stream Writer is mainly applicable to performance testing for data synchronization and basic functional testing.

Parameters

print

- Description: specifies whether to display the data obtained from the reader on the screen.
- Required: No
- Default value: true

Configure Stream Writer by using the codeless UI

Currently, the codeless user interface (UI) is not supported for Stream Writer.

Configure Stream Writer by using the code editor

In the following code, a node is configured to display the data obtained from a Data Integration reader on the screen.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"stream",// The writer type.
      "parameter":{
        "print": false, // Specifies whether to display data on the screen.
        "fieldDelimiter":",",// The column delimiter.
      },
      "name":"Writer",
      "category":"writer"
    }
  ],
  "setting":{
    "errorLimit":{
      "record":"0",// The maximum number of dirty data records allowed.
    },
    "speed":{
      "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
      "concurrent":1,// The maximum number of concurrent threads.
    }
  },
  "order":{
    "hops":[
      {
        "from":"Reader",
        "to":"Writer"
      }
    ]
  }
}
```

2.4.5.4.24. Configure Hive Writer

Hive Writer allows you to write data to HDFS and load the data to Hive. This topic describes how Hive Writer works, its parameters, and how to configure it by using the codeless UI and code editor.

Background information

Hive is a Hadoop-based data warehouse tool that is used to process large amounts of structured logs. Hive maps structured data files to a table and allows you to execute SQL statements to query data in the table.

Essentially, Hive converts Hive Query Language (HQL) or SQL statements to MapReduce programs.

- Hive stores processed data in HDFS.
- Hive uses MapReduce programs to analyze data at the underlying layer.
- Hive runs MapReduce programs on Yarn.

How it works

Hive Writer accesses a Hive metastore, parses the configuration to obtain the file storage path, file format, and column delimiter of the file to which data is written, and then writes data to the HDFS file. Hive Writer loads data in the HDFS file to the destination Hive table by using JDBC.

The underlying logic of Hive Writer is the same as that of HDFS Writer. You can configure parameters of HDFS Writer in the parameters of Hive Writer. Data Integration transparently transmits the configured parameters to HDFS Writer.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection.	Yes	None
column	<p>The columns to which data is written. Example: <code>"column": ["id", "name"]</code>.</p> <ul style="list-style-type: none"> • Column pruning is supported. You can select specific columns to export. • The column parameter must explicitly specify a set of columns to which data is written. The parameter cannot be left empty. • The column order cannot be changed. 	Yes	None
table	<p>The name of the Hive table to which data is written.</p> <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px; margin-top: 5px;"> ? Note The name is case-sensitive. </div>	Yes	None
partition	<p>The partition in the Hive table to which data is written.</p> <ul style="list-style-type: none"> • This parameter is required for a partitioned Hive table. The sync node writes data to the partition specified by the partition parameter. • This parameter is not required for a non-partitioned table. 	No	None

Parameter	Description	Required	Default value
writeMode	<p>The mode in which data is loaded to the Hive table. After data is written to the HDFS file, Hive Writer executes the <code>LOAD DATA INPATH (overwrite) INTO TABLE</code> statement to load data to the Hive table.</p> <p>The writeMode parameter specifies the data loading mode.</p> <ul style="list-style-type: none"> • <i>truncate</i>: deletes existing data before loading the data to the Hive table. • <i>append</i>: retains the existing data and appends the data to the Hive table. • If the writeMode parameter is set to Other, the data is written to the HDFS file but not loaded to the Hive table. <div style="background-color: #e1f5fe; padding: 10px; margin-top: 10px;"> <p> Note Setting the writeMode parameter is a high-risk operation. Pay attention to the destination directory and the value of this parameter to avoid deleting data incorrectly.</p> <p>This parameter must be used together with the hiveConfig parameter.</p> </div>	Yes	None

Parameter	Description	Required	Default value
hiveConfig	<p>The extended parameters for Hive, including hiveCommand, jdbcUrl, username, and password.</p> <ul style="list-style-type: none"> hiveCommand: the full path of the Hive client. After you run the <code>hive -e</code> command, the <code>LOAD DATA INPATH</code> statement is executed to load data based on the mode specified by the writeMode parameter. <p>The client specified by the hiveCommand parameter provides access information about Hive.</p> <ul style="list-style-type: none"> jdbcUrl, username, and password: the information that is required to connect to Hive by using JDBC. After Hive Writer connects to Hive by using JDBC, Hive Writer executes the <code>LOAD DATA INPATH</code> statement to load data based on the mode specified by the writeMode parameter. <pre>"hiveConfig": { "hiveCommand": "", "jdbcUrl": "", "username": "", "password": "" }</pre> <ul style="list-style-type: none"> Hive Writer allows you to write data to HDFS files by using an HDFS client. You can use the hiveConfig parameter to specify advanced settings for the HDFS client. 	Yes	None

Configure Hive Writer by using the codeless UI

On the DataStudio page, double-click a data sync node, and perform the following operations on the node configuration tab that appears:

1. Configure the connections.

Configure the connections to the source and destination data stores for the sync node.

Parameter	Description
Connection	The datasource parameter in the preceding parameter description. Select a connection type, and then select a connection name that you have configured in DataWorks.
Table	The table parameter in the preceding parameter description.
Partition Key Column	The partition to which data is written. The last-level partition must be specified. Hive Writer can write data to only one partition.
Writing Rule	The writeMode parameter in the preceding parameter description.

2. Configure field mapping. It is equivalent to setting the column parameter in the preceding parameter description. Fields in the source table on the left have a one-to-one mapping with fields in the destination table on the right.

GUI Element	Description
Map Fields with the Same Name	Click Map Fields with the Same Name to establish a mapping between fields with the same name. Note that the data types of the fields must match.
Map Fields in the Same Line	Click Map Fields in the Same Line to establish a mapping for fields in the same row. Note that the data types of the fields must match.
Delete All Mappings	Click Delete All Mappings to remove mappings that have been established.
Auto Layout	Click Auto Layout to sort the fields based on specified rules.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of concurrent threads to read data from and write data to data storage within the sync node. You can configure the concurrency for a node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workload of the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to a proper value.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.
Resource Group	The resource group used for running the sync node. By default, the node runs on the default resource group. If resources are insufficient, you can add a custom resource group and run the sync node on the custom resource group. Set the resource group properly based on network conditions of the connections, resource group usage, and business importance.

Configure Hive Writer by using the code editor

In the following code, a node is configured to write data to Hive in JSON format.

```
{
  "type": "job",
  "steps": [
    {
      "stepType": "hive",
      "parameter": {
      },
      "name": "Reader",
      "category": "reader"
    },
    {
      "stepType": "hive",
      "parameter": {
        "partition": "year=a,month=b,day=c", // The partition to which data is written.
        "datasource": "hive_ha_shanghai", // The connection name.
        "table": "partitiontable2", // The name of the destination table.
        "column": [ // The columns in the destination table to which data is written.
          "id",
          "name",
          "age"
        ],
        "writeMode": "append" // The write mode.
      },
      "name": "Writer",
      "category": "writer"
    }
  ],
  "version": "2.0",
  "order": {
    "hops": [
      {
        "from": "Reader",
        "to": "Writer"
      }
    ]
  },
  "setting": {
    "errorLimit": {
      "record": ""
    },
    "speed": {
      "throttle": false,
      "concurrent": 2
    }
  }
}
```

2.4.5.4.25. Configure Vertica Writer

Vertica is a column-oriented database using the MPP architecture. Vertica Writer allows you to write data to tables stored in Vertica databases. This topic describes how Vertica Writer works, its parameters, and how to configure it by using the code editor.

How it works

Vertica Writer connects to a remote Vertica database by using JDBC, and executes an `INSERT INTO` statement to write data to the Vertica database. Internally, data is submitted to the Vertica database in batches.

Vertica Writer is designed for ETL developers to import data from data warehouses to Vertica databases. Vertica Writer can also be used as a data migration tool by users such as DBAs.

Vertica Writer obtains data from a Data Integration reader, and generates the `INSERT INTO` statement based on your configurations.

- `INSERT INTO` : If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows.
- Data can be written only to tables stored in the primary Vertica database.

 **Note** A sync node that uses Vertica Writer must have at least the permission to execute the `INSERT INTO` statement. Whether other permissions are required depends on the SQL statements specified in the `preSql` and `postSql` parameters when you configure the node.

- Vertica Writer does not support the `writeMode` parameter.
- Vertica Writer accesses a Vertica database by using the Vertica database driver. Confirm the compatibility between the driver version and your Vertica database. Vertica Writer uses the following version of the Vertica database driver:

```
<dependency>
  <groupId>com.vertica</groupId>
  <artifactId>vertica-jdbc</artifactId>
  <version>7.1.2</version>
</dependency>
```

Parameters

Parameter	Description	Required	Default value
<code>datasource</code>	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
<code>jdbcUrl</code>	<p>The JDBC URL for connecting to the Vertica database. You do not need to set this parameter because the system automatically obtains the value from the connection parameter.</p> <ul style="list-style-type: none"> • You can configure only one JDBC URL for a database. Vertica Writer cannot write data to a database with multiple primary databases. • The format must be in accordance with Vertica official specifications. You can also specify the information of the attachment facility. Example: <code>jdbc:vertica://127.0.0.1:3306/database</code>. 	Yes	None
<code>username</code>	The username that you can use to connect to the database.	Yes	None
<code>password</code>	The password that you can use to connect to the database.	Yes	None

Parameter	Description	Required	Default value
table	The names of the destination tables, which are described in a JSON array. <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> ? Note You do not need to set this parameter because the system automatically obtains the value from the connection parameter. </div>	Yes	None
column	The columns in the destination table to which data is written. Separate the columns with a comma (,), for example, <code>"column": ["id","name","age"]</code> .	Yes	None
preSql	The SQL statement to execute before the sync node is run. Use <code>@table</code> to specify the name of the destination table in the SQL statement. When you execute this SQL statement, DataWorks replaces <code>@table</code> with the name of the destination table.	No	None
postSql	The SQL statement to execute after the sync node is run.	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the Vertica database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	1,024

Configure Vertica Writer by using the codeless UI

The codeless UI is not supported for Vertica Writer.

Configure Vertica Writer by using the code editor

In the following code, a node is configured to write data to a Vertica database.

```
{
  "type": "job",
  "version": "2.0", // The version number.
  "steps": [
    {
      "stepType": "stream",
      "parameter": {},
      "name": "Reader",
      "category": "reader"
    },
    {
      "stepType": "vertica", // The writer type.
      "parameter": {
        "datasource": "The connection name.",
        "username": "",
        "password": "",
        "column": [ // The columns to which data is written.
          "id",
          "name"
        ],
        "connection": [
```

```

    {
      "table": [// The name of the destination table.
        "vertica_table"
      ],
      "jdbcUrl": "jdbc:vertica://ip:port/database"
    }
  ],
  "preSql": [// The SQL statement to execute before the sync node is run.
    "delete from @table where db_id = -1"
  ],
  "postSql": [// The SQL statement to execute after the sync node is run.
    "update @table set db_modify_time = now() where db_id = 1"
  ]
},
"name": "Writer",
"category": "writer"
}
],
"setting": {
  "errorLimit": {
    "record": "0" // The maximum number of dirty data records allowed.
  },
  "speed": {
    "throttle": false, // Specifies whether to enable bandwidth throttling. A value of false indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throttled. The maximum transmission rate takes effect only if you set this parameter to true.
    "concurrent": 1 // The maximum number of concurrent threads.
  }
},
"order": {
  "hops": [
    {
      "from": "Reader",
      "to": "Writer"
    }
  ]
}
}
}

```

2.4.5.4.26. Configure Gbase8a Writer

This topic describes the implementation principle and parameter configurations of Gbase8a Writer.

Gbase8a Writer allows you to write data to tables stored in Gbase8a databases. At the underlying implementation level, Gbase8a Writer connects to a remote Gbase8a database through the JDBC Driver and runs the relevant SQL statements to write data to the Gbase8a database.

 **Note** You must configure a connection before configuring Gbase8a Writer.

Parameters

Parameter	Description	Required	Default value
-----------	-------------	----------	---------------

Parameter	Description	Required	Default value
datasource	The connection name. It must be identical to the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the table to be synchronized.	Yes	None
writeMode	<p>The write mode. Valid values: <i>insert into</i>, <i>on duplicate key update</i>, and <i>replace into</i>.</p> <ul style="list-style-type: none"> <i>insert into</i>: If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows and is regarded as dirty data. <i>on duplicate key update</i>: If no primary key conflict or unique index conflict occurs, the action is the same as that of insert into. If a conflict occurs, specified fields in original rows are updated. <i>replace into</i>: If no primary key conflict or unique index conflict occurs, the action is the same as that of insert into. If a conflict occurs, original rows are deleted and new rows are inserted. That is, all fields of original rows are replaced. 	No	<i>insert</i>
column	The columns in the destination table to which data is written. Separate the columns with a comma (.). Example: <code>"column":["id", "name", "age"]</code> . Set the value to an asterisk (*) if data is written to all the columns in the destination table. That is, set the column parameter as follows: <code>"column":["*"]</code> .	Yes	None
preSql	<p>The SQL statement to run before the sync node is run. For example, you can clear outdated data before data synchronization. Currently, you can run only one SQL statement on the codeless user interface (UI), and multiple SQL statements in the code editor.</p> <div style="background-color: #e0f2f1; padding: 5px;"> <p> Note If you specify multiple SQL statements in the code editor, the system does not guarantee that they are run in the same transaction.</p> </div>	No	None
postSql	<p>The SQL statement to run after the sync node is run. For example, you can add a timestamp after data synchronization. Currently, you can run only one SQL statement on the codeless UI, and multiple SQL statements in the code editor.</p> <div style="background-color: #e0f2f1; padding: 5px;"> <p> Note If you specify multiple SQL statements in the code editor, the system does not guarantee that they are run in the same transaction.</p> </div>	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the Gbase8a database over the network, and increase the throughput. However, an excessively large value may lead to the out of memory (OOM) error during the data synchronization process.	No	1024

Configure Gbase8a Writer by using the codeless UI

Currently, the codeless UI is not supported for Gbase8a Writer.

Configure Gbase8a Writer by using the code editor

In the following code, a node is configured to write data to the Gbase8a database. For more information about the parameters, see the preceding parameter description.

```
{
  "type":"job",
  "version":"2.0",// The version number.
  "steps":[
    {
      "stepType":"stream",
      "parameter":{},
      "name":"Reader",
      "category":"reader"
    },
    {
      "stepType":"gbase8a",// The writer type.
      "parameter":{
        "postSql":[// The SQL statement to run after the sync node is run.
          "datasource":"","// The connection name.
          "column":[// The columns to be synchronized.
            "id",
            "value"
          ],
          "writeMode":"insert",// The write mode.
          "batchSize":1024,// The number of data records to write at a time.
          "table":"","// The name of the table to be synchronized.
          "preSql":[// The SQL statement to run before the sync node is run.
        ],
        "name":"Writer",
        "category":"writer"
      }
    },
    "setting":{
      "errorLimit":{// The maximum number of dirty data records allowed.
        "record":"0"
      },
      "speed":{
        "throttle":false,// Specifies whether to enable bandwidth throttling.
        "concurrent":1,// The maximum number of concurrent threads.
      }
    },
    "order":{
      "hops":[
        {
          "from":"Reader",
          "to":"Writer"
        }
      ]
    }
  ]
}
```

2.4.5.5. Optimize synchronization performance

This topic describes how to maximize the synchronization speed by adjusting the concurrency configuration, the difference between nodes that are configured with bandwidth throttling and those that are not, and precautions for custom resource groups.

Data Integration is a one-stop platform that supports real-time and offline data synchronization between any connections in any location and in any network environment. You can synchronize 10 TB of data between various types of cloud storage and local storage each day.

DataWorks provides excellent data transmission performance and supports data exchanges between more than 400 pairs of disparate connections. These features allow you to focus on the key issues on constructing big data solutions.

Factors affecting the speed of data synchronization

The factors that affect the speed of data synchronization are listed as follows:

- Source
 - Database performance: the performance of the CPU, memory module, SSD, network, and hard disk.
 - Concurrency: A high concurrency results in a heavy database workload.
 - Network: the bandwidth (throughput) and speed of the network. Generally, a database with better performance can support more concurrent nodes and a larger concurrency value can be set for sync nodes.
- Sync node
 - Synchronization speed: whether an upper limit is set for the synchronization speed.
 - Concurrency: a maximum number of concurrent threads to read data from the source and write data to destination data storage within a single sync node.
 - Nodes that are waiting for resources.
 - Bandwidth throttling: The bandwidth of a single thread is 1,048,576 bit/s. Timeout occurs when the business is sensitive to the network speed. We recommend that you set a smaller value.
 - Whether to create an index for query statements.
- Destination
 - Performance: the performance of the CPU, memory module, SSD, network, and hard disk.
 - Load: Excessive load in the destination database affects the write efficiency within the sync nodes.
 - Network: the bandwidth (throughput) and speed of the network.

You need to monitor and optimize the performance, load, and network of the source and destination databases. The following describes the optimal settings of a sync node.

Concurrency

You can configure the concurrency for a node on the codeless user interface (UI). The following is an example of how to configure the concurrency in the code editor:

```
"setting": {  
  "speed": {  
    "concurrent": 10  
  }  
}
```

Bandwidth throttling

By default, bandwidth throttling is disabled. In a sync node, data is synchronized at the maximum speed given the concurrency configured for the node. Considering that excessively fast synchronization may overstress the database and thus affect the production, Data Integration allows you to limit the synchronization speed and optimize the configuration as required. If bandwidth throttling is enabled, we recommend that you limit the maximum speed to 30 Mbit/s. The following is an example for configuring an upper limit for synchronization speed in the code editor, in which the transmission bandwidth is 1 Mbit/s:

```
"setting": {
  "speed": {
    "throttle": true // The bandwidth throttling is enabled.
    "mbps": 1, // The synchronization speed.
  }
}
```

Note

- When the throttle parameter is set to false, throttling is disabled, and you do not need to configure the mbps parameter.
- The bandwidth value is a Data Integration metric and does not represent the actual network interface card (NIC) traffic. Generally, the NIC traffic is two to three times of the channel traffic, which depends on the serialization of the data storage system.
- A semi-structured file does not have shard keys. If multiple files exist, you can set the maximum job speed to increase the synchronization speed. However, the maximum job speed is limited by the number of files. For example, the maximum job speed limit is set to n Mbit/s for n files. If you set the limit to n+1 Mbit/s, the synchronization speed remains at n Mbit/s. If you set the limit to n-1 Mbit/s, the synchronization is performed at n-1 Mbit/s.
- A table can be partitioned according to the preset maximum job speed only when a maximum job speed and a shard key are configured for a relational database. Relational databases only support numeric shard keys, while Oracle databases support both numeric and string shard keys.

Scenarios of slow data synchronization

- Scenario 1: Resolve the issue that sync nodes to be run on the default resource group remain waiting for resources.
 - Example

When you test a sync node in DataWorks, the node remains waiting for resources and an internal system error occurs.

For example, a sync node is configured to synchronize data from RDS to MaxCompute. The node has waited for about 800 seconds before it is run successfully. However, the log shows that the node runs for only 18 seconds and then stops. The sync node uses the default resource group. When you run other sync nodes, they also remain in the waiting state.

The log is displayed as follows:

```
2017-01-03 07:16:54 : State: 2(WAIT) | Total: 0R 0B | Speed: 0R/s 0B/s | Error: 0R 0B | Stage: 0.0%
```

- Solution

The default resource group is not exclusively used by a single user. It is used by many projects concurrently, not just two or three nodes for a single user. If such resources are insufficient after you start to run a node, the node needs to wait for resources. In this case, the node is completed 800 seconds after you start running the node, but it only takes 10 seconds for the node to be executed.

To improve the synchronization speed and reduce the waiting time, we recommend that you run sync nodes during off-peak hours. Typically, most sync nodes are run between 00:00 and 03:00.

- Scenario 2:

Accelerate nodes that synchronize data from multiple source tables to the same destination table.

- Example

To synchronize data from tables of multiple data stores to a table, you configure multiple sync nodes to run in sequence. However, the synchronization takes a long time.

- Solution

To launch multiple concurrent nodes that write data to the same destination database, pay attention to the following points:

- Ensure that the destination database can support the execution of all the concurrent nodes.
- You can configure a sync node that synchronizes multiple source tables to the same destination table. Alternatively, you can configure multiple nodes to run concurrently in the same workflow.
- If resources are insufficient, you can configure sync nodes to run during off-peak hours.

- Scenario 3:

If no index is added when the WHERE clause is used, a full table scan slows down the data synchronization.

- Example

SQL statement:

```
select bid,inviter,uid,createTime from `relatives` where createTime>='2016-10-23 00:00:00'and reateTime<'2016-10-24 00:00:00';
```

Assume that the sync node started to run the preceding statement at 2016-10-25 11:01:24 and started to return results from 2016-10-25 11:11:05. It took a long time to finish the sync node.

- Cause

When the WHERE clause is used for a query, the createTime column is not indexed, resulting in a full table scan.

- Solution

We recommend that you use an indexed column or add an index to the column that you want to scan if you use the WHERE clause.

2.4.6. Real-time synchronization

2.4.6.1. Overview

This topic describes the definition, highlights, supported data sources, and architecture of the real-time synchronization feature. This topic also describes how to use this feature.

Definition

The real-time synchronization feature allows you to synchronize the data changes in a source database to a destination database in real time. For example, after you add, modify, or delete the data in a source database, the real-time synchronization feature synchronizes these changes to a destination database in real time. If a real-time synchronization is performed during a batch synchronization for full historical data, all the data in your source database is synchronized to your destination database. The real-time synchronization feature helps ensure that the data in your destination database is updated in real time and consistent with that in your source database.

Highlights

- Diverse data sources
 - Star-shaped combination is supported. Each supported source can be combined with a supported destination to synchronize data.
 - The feature will soon allow you to synchronize data from a single source to multiple destinations at the same time.
- Comprehensive synchronization solutions
 - You can configure a synchronization solution to synchronize the full data or incremental data from a database to MaxCompute or Hologres.
 - The feature synchronizes full data first and then continuously synchronizes incremental data to the destination database based on the synchronization solution that you configure.
- Real-time data extraction

The feature can extract data from the table shards, a single table, and multiple tables in a database, and extract the data definition language (DDL) statements of tables.
- Data processing

The feature can filter data and replace strings during synchronization.
- Monitoring and alerting
 - The feature monitors the service latency, failovers, dirty data, heartbeats, and failures during synchronization.
 - Alert notifications can be sent by email, phone call, and DingTalk message.
- Small impact on the source

The feature is optimized to have a small impact on the source.
- Graphical development
 - You can develop real-time synchronization nodes in a graphical user interface (GUI) without the need to write code.
 - The feature is easy to use even for beginners.

Supported data sources

- Source: MySQL Binlog, Oracle CDC, Kafka, DataHub, LogHub, and PolarDB.
- Destination: MaxCompute, Hologres, Kafka, and DataHub.
- The feature can filter data and replace strings during synchronization.

How to use the feature

You can use the real-time synchronization feature to create real-time synchronization solutions or synchronization nodes.

- For more information about how to create a real-time synchronization node, see [Create a real-time synchronization node](#).

- For more information about how to create a synchronization solution, see [Go to the Sync Solutions page](#).

2.4.6.2. Data sources supported by real-time synchronization

Real-time synchronization supports reader, writer, and conversion plug-ins. The following table lists the plug-ins.

Category	Plug-in	References
Reader	MySQL Binlog Reader	MySQL binlogs
	Oracle Change Data Capture (CDC) Reader	Oracle CDC
	DataHub Reader	DataHub
	LogHub Reader	LogHub
	Kafka Reader	Kafka
Writer	Hologres Writer	Hologres
	DataHub Writer	DataHub
	Kafka Writer	Kafka
	MaxCompute Writer	Configure MaxCompute Writer
Conversion	Data filtering	Data filter
	Groovy	Groovy
	String replacement	String replacement

 **Note** A real-time synchronization node cannot be directly run on the node configuration tab. Instead, you must save and commit the node before the real-time synchronization node is run in the production environment.

Basic configuration

After you configure the reader, writer, and conversion plug-ins, you can click the **Basic configuration** panel in the right-side navigation pane to configure the synchronization node.

Parameter	Description
Description	The description of the real-time synchronization node.
JVM parameters	The Java virtual machine (JVM) memory allocated for the real-time synchronization node. If this parameter is not specified, Data Integration automatically allocates JVM memory based on your node configurations.

2.4.6.3. Create, configure, commit, and manage real-time synchronization nodes

DataWorks allows you to synchronize data in real time. This topic describes how to create, configure, commit, and manage real-time synchronization nodes.

Create a real-time synchronization node

1. [Log on to the DataWorks console.](#)
2. On the DataStudio page, move the pointer over the  icon and choose **Data Integration > Real-time synchronization**. Alternatively, you can find the required workflow, right-click the workflow name, and then choose **Create > Data Integration > Real-time synchronization**.
3. In the **Create Node** dialog box, configure the parameters.

Parameter	Description
Node Type	The type of the node. Default value: Real-time synchronization .
Sync Method	The method used to synchronize data. Valid values: <ul style="list-style-type: none"> ◦ End-to-end ETL: synchronizes data in one table to one or more tables. Data type conversion is supported during the synchronization. ◦ Migration to Hologres: synchronizes all or some tables in a database to Hologres. Destination tables can be automatically created in Hologres. ◦ Migration to MaxCompute: synchronizes all or some tables in a database to MaxCompute. ◦ Migration to DataHub: synchronizes all or some tables in a database to DataHub.
Node Name	The name of the node. The name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).
Location	The directory in which the real-time synchronization node is stored.

4. Click **Commit**.

Configure the real-time synchronization node

The operations that you can perform on the configuration tab of the real-time synchronization node vary based on the synchronization method that you selected.

- To configure the real-time synchronization node for which **Sync Method** is set to **End-to-end ETL**, perform the following steps:
 - i. Click **Basic configuration** in the right-side navigation pane. In the Basic configuration panel, select the required resource group from the **Resource Group** drop-down list.

No.	Description
1	The left-side navigation tree, which consists of the Input , Output , and Conversion sections.
2	The configuration canvas of the real-time synchronization node. You can drag a component from the navigation tree to the canvas and configure the component.

No.	Description
3	The property configuration panel of the real-time synchronization node. This panel appears after you click Basic configuration in the right-side navigation pane.

- ii. Drag components from the navigation tree to the canvas, and draw lines to connect the components. This way, the components synchronize data based on the connections.
 - iii. Click each component on the canvas. In the panel that appears, configure the parameters.
 - iv. Click the  icon in the top toolbar.
- To configure the real-time synchronization node for which **Sync Method** is set to **Migration to Hologres**, perform the following steps:
 - i. Click **Basic configuration** in the right-side navigation pane. In the Basic configuration panel, select the required resource group from the **Resource Group** drop-down list.

 **Notice** You must select a resource group before you commit the node. Otherwise, the system returns an error when you commit the node.

- ii. In the **Data source** section, specify **Type** and **Data source**.
- iii. In the **Select the source table for synchronization** section, select the tables that you want to synchronize in the **SOURCE Table** list and click the  icon to move the tables to the **Selected Source table** list.

The **SOURCE Table** list displays all the tables in the source. You can select all or some tables to synchronize them at a time.

 **Notice** If a selected table does not have a primary key, the table cannot be synchronized in real time.

- iv. (Optional) In the **Set synchronization rules** section, click **Add rule** and select an option to configure naming rules for destination tables.

Supported options include **Table name conversion rules** and **Target table name rule**.

- **Table name conversion rules:** the rule for converting the names of source tables to those of destination tables.
- **Target table name rule:** the rule for adding a prefix and suffix to the converted names of destination tables.

- v. Click **Next Step**.
- vi. In the **Set target table** step, specify **Target Hologres data source** and **Schema**.
- vii. Click **Reload source table and Hologres Table mapping** to configure the mappings between the source tables and destination Hologres tables.
- viii. View the mapping progress, source tables, and mapped destination tables, and click **Next Step**.

You can view the mapping progress between the source tables and destination tables. The mapping may take a long period of time if you want to synchronize a large number of tables.

An error message appears if the selected source table does not have a primary key. The synchronization can be performed if one of the selected source tables has a primary key. Source tables without primary keys are ignored during the synchronization.

You can set Table creation method to **Create tables automatically** or **Use existing Table**. The name of the destination table that appears in the **Hologres Table name** column varies based on the setting of Table creation method.

- If you set **Table creation method** to **Create tables automatically**, the name of the destination table that is automatically created appears. You can click the table name to view and modify the table creation statements.
 - If you set **Table creation method** to **Use existing Table**, you must select a table from the drop-down list in the **Hologres Table name** column.
- ix. In the **Run resource settings** step, specify **Maximum number of connections supported by source read** and **Number of concurrent writes on the target side**. Then, click the  icon in the top toolbar.
- To configure the real-time synchronization node for which **Sync Method** is set to **Migration to MaxCompute**, perform the following steps:
 - i. Click **Basic configuration** in the right-side navigation pane. In the Basic configuration panel, select the required resource group from the **Resource Group** drop-down list.
 - ii. In the **Data source** section, specify **Type** and **Data source**.
 - iii. In the **Select the source table for synchronization** section, select the tables that you want to synchronize in the **SOURCE Table** list and click the  icon to move the tables to the **Selected Source table** list.

The **SOURCE Table** list displays all the tables in the source. You can select all or some tables to synchronize them at a time.

 **Notice** If a selected table does not have a primary key, the table cannot be synchronized in real time.

- iv. In the **Set synchronization rules** section, click **Add rule** and select an option to configure naming rules for destination tables.
- Supported options include **Table name conversion rules** and **Target table name rule**.
- **Table name conversion rules**: the rule for converting the names of source tables to those of destination tables.
 - **Target table name rule**: the rule for adding a prefix and suffix to the converted names of destination tables.
- v. Click **Next Step**.
- vi. In the **Set target table** step, select a data source from the **Target MaxCompute data source** drop-down list and click the  icon next to **MaxCompute time automatic partition settings**. In the **Edit** dialog box, set the partition interval of tables in MaxCompute to day or hour.
- vii. Click **Reload source table and MaxCompute Table mapping** to configure the mappings between the source tables and destination MaxCompute tables.
- viii. View the mapping progress, source tables, and destination tables. Then, click **Next Step**.

You can view the mapping progress between the source tables and destination tables. The mapping may take a long period of time if you want to synchronize a large number of tables.

An error message appears if the selected source table does not have a primary key. The synchronization can be performed if one of the selected source tables has a primary key. Source tables without primary keys are ignored during the synchronization.

You can set Table creation method to **Create tables automatically** or **Use existing Table**. The name of the destination table that appears in the **MaxCompute Table name** column varies based on the setting of Table creation method.

- If you set **Table creation method** to **Create tables automatically**, the name of the destination table that is automatically created appears. You can click the table name to view and modify the table creation statements.
 - If you set **Table creation method** to **Use existing Table**, you must select a table name from the drop-down list in the **MaxCompute Table name** column.
- ix. In the **Run resource settings** step, specify **Maximum number of connections supported by source read** and **Number of concurrent writes on the target side**. Then, click the  icon in the top toolbar.
- To configure the real-time synchronization node for which **Sync Method** is set to **Migration to DataHub**, perform the following steps:
 - i. On the node configuration tab that appears, click **Basic configuration** in the right-side navigation pane. In the Basic configuration panel, select the required resource group from the **Resource Group** drop-down list.
 - ii. In the **Data source** section, specify **Type** and **Data source**.
 - iii. In the **Select the source table for synchronization** section, select the tables that you want to synchronize in the **SOURCE Table** list and click the  icon to move the tables to the **Selected Source table** list.

The **SOURCE Table** list displays all the tables in the source. You can select all or some tables to synchronize them at a time.

 **Notice** If a selected table does not have a primary key, the table cannot be synchronized in real time.

- iv. In the **Set synchronization rules** section, click **Add rule** and then select an option to configure naming rules for destination DataHub topics.
- Supported options include **SOURCE table name and Topic conversion rules** and **Target Topic rules**.
- v. Click **Next Step**.
- vi. In the **Set target table** step, select a data source from the **Target DataHub data source** drop-down list and then click **Reload source table and DataHub Topic mapping** to configure the mappings between the source tables and destination DataHub topics.
- vii. View the mapping progress, source tables, and destination topics. Then, click **Next Step**.

You can view the mapping progress between the source tables and destination topics. The mapping may take a long period of time if you want to synchronize a large number of tables.

You can set Topic creation method to **Create tables automatically** or **Use existing Topic**. The message that appears in the **DataHub Topic** column varies based on the setting of Topic creation method.

- If you set Topic creation method to **Create tables automatically**, the **Create tables automatically** dialog box appears after you click **Next Step**. Click **Start table building** in the dialog box, and then click **Close** after the topic is created.
 - If you set Topic creation method to **Use existing Topic**, you must select a topic from the drop-down list in the **DataHub Topic** column.
- viii. In the **Run resource settings** step, specify **Maximum number of connections supported by**

source read and **Number of concurrent writes on the target side**. Then, click the  icon in the top toolbar.

Commit the real-time synchronization node

1. On the configuration tab of the real-time synchronization node, click the  icon in the top toolbar.
2. In the **Commit Node** dialog box, enter your comments in the **Change description** field.
3. Click **OK**. If the workspace that you use is in standard mode, you must click **Deploy** in the upper-right corner after you commit the real-time synchronization node.

Manage the real-time synchronization node

1. After you commit or deploy the real-time synchronization node, click **Operation Center** in the upper-right corner of the DataStudio page to manage the node on the **Real Time DI** page.
2. On the **Real Time DI** page, find the real-time synchronization node, click the node name, and then view the O&M details about the node. On the Real Time DI page, you can start, stop, undeploy, or configure alert settings for the real-time synchronization node.
 - o To start a node that is not running, perform the following steps:
 - a. Find the node and click **Start** in the Operation column.
 - b. In the **Start** dialog box, configure the parameters.

Parameter	Description
Whether to reset the site	Specifies whether to set the time point for the next startup. If you select Reset site , the Start time point and Time zone parameters are required.
Start time point	The date and time for starting the real-time synchronization node.
Time zone	The time zone where the source resides. Select a time zone from the Time zone drop-down list.
Failover	<ul style="list-style-type: none"> ■ The condition for automatically terminating the real-time synchronization node. You can specify the maximum number of dirty data records allowed. If you set this parameter to 0, no dirty data records are allowed. If this parameter is not specified, the node continues to run no matter whether dirty data records exist. ■ You can also specify the maximum number of failover times. If you do not specify the times, the node is automatically terminated if the node fails 100 times within 5 minutes. This prevents resource occupation caused by frequent startups.

- c. Click **OK**.
- o To stop a running node, perform the following steps:
 - a. Find the node and click **Stop** in the Operation column.
 - b. In the message that appears, click **Stop**.
- o To undeploy a node that is not running, perform the following steps:
 - a. Find the node and click **Offline** in the Operation column.
 - b. In the message that appears, click **Offline**.

- Find the node and click **Alarm settings** in the Operation column. Then, you can view alert event information and alert rules on the **Alert event** and **Alarm rules** tabs.
- To configure alert settings for a node, perform the following steps:
 - a. Select the node and click **New Alarm** in the lower part of the page.
 - b. In the **New rule** dialog box, configure the parameters.

Parameter	Description
Name	Required. The name of the rule that you want to create.
Description	The description of the rule.
Indicators	The metrics in the rule that you want to create. Valid values: Task Status , Business latency , Failover , Dirty Data , and DDL error .
Threshold	The threshold for reporting an alert. The default value is 5 minutes for both WARNING and CRITICAL alerts.
Alarm interval	The interval at which an alert is reported. The default value is 5 minutes.
WARNING	The method used to send alert notifications. The value of this parameter can be only Mail .
CRITICAL	
Recipient	The alert recipient. Select a recipient from the Receiver drop-down list.

- c. Click **OK**.
- To modify alert settings for a node, perform the following steps:
 - a. Select the node whose alarm settings you want to modify and click **Operation alarm** in the lower part of the page.
 - b. In the **Operation alarm** dialog box, specify **Operation type** and **Alarm indicators**.
DataWorks automatically modifies all the rules for the selected alert types at a time.
 - c. Click **OK**.

2.4.6.4. Reader

2.4.6.4.1. MySQL binlogs

The MySQL binlog reader reads data from the tables of MySQL databases in real time.

The MySQL binlog reader reads data from the MySQL database in real time by using Canal, which parses incremental MySQL binlogs and subscribes to data changes.

Parameters

Parameter	Description	Required	Default value
-----------	-------------	----------	---------------

Parameter	Description	Required	Default value
dbHost	The endpoint of the database. You can set this parameter to the domain name or the IP address.	Yes	None
dbName	The name of the database.	Yes	None
port	The port number of the database.	Yes	None
table	The name of the table to be synchronized.	Yes	None
username	The username used to access the database.	Yes	None
password	The password used to access the database.	Yes	None
startTimestampMills	<p>The start time of data synchronization. The value of this parameter is a 13-bit timestamp.</p> <div style="background-color: #e6f2ff; padding: 5px;"> <p>Note If the start time you specify is later than the last data change time of MySQL binlogs, data synchronization starts from the last data change time of MySQL binlogs.</p> <p>If the start time you specify is earlier than the earliest data change time of MySQL binlogs, no data is synchronized.</p> </div>	No	None

Example

In the following code, a node is configured to read data from a MySQL database and write data to DataHub in real time:

```
{
  "order": {
    "hops": [
      {
        "from": "mysqlbinlog_01",
        "to": "datahub_01"
      }
    ]
  }
}
```

```
}
]
},
"setting": {
  "errorLimit": {
    "record": 0
  },
},
"steps": [
  {
    "category": "reader",
    "name": "mysqlbinlog_01",
    "parameter": {
      "password": "xxx",
      "column": [
        "_log_file_name_offset_",
        "_operation_type_",
        "_execute_time_",
        "_before_image_",
        "_after_image_",
        "id",
        "pipeline_name",
        "execute_name",
        "context"
      ],
      "dbHost": "127.0.0.1",
      "dbName": "xxx",
      "port": 3306,
      "startTimestampMills": 1555689600000,
      "table": "xxx",
      "username": "xxx"
    },
    "stepType": "mysqlbinlog"
  },
  {
    "category": "writer",
    "name": "datahub_01",
    "parameter": {
      "accessKey": "xxx",
      "accessId": "xxx",
      "batchSize": 1000,
      "column": [
        "_log_file_name_offset_",
        "_execute_time_",
        "_before_image_",
        "_after_image_",
        "id",
        "pipeline_name",
        "execute_name",
        "context"
      ],
      "columnMapping": [
        {
          "dstColName": "_log_file_name_offset_",
          "sourceColName": "_log_file_name_offset_"
        },
        {
          "dstColName": "_execute_time_"
        }
      ]
    }
  }
]
```

```

      "dstColName": "_execute_time_",
      "sourceColName": "_execute_time_"
    },
    {
      "dstColName": "_before_image_",
      "sourceColName": "_before_image_"
    },
    {
      "dstColName": "_after_image_",
      "sourceColName": "_after_image_"
    },
    {
      "dstColName": "id",
      "sourceColName": "id"
    },

      "dstColName": "pipeline_name",
      "sourceColName": "pipeline_name"
    },
    {
      "dstColName": "execute_name",
      "sourceColName": "execute_name"
    },
    {
      "dstColName": "context",
      "sourceColName": "context"
    }
  ],
  "endpoint": "xxx",
  "project": "xxx",
  "topic": "xxx"
},
"stepType": "datahub"
}
]
}

```

2.4.6.4.2. Oracle CDC

StreamX uses Change Data Capture (CDC) to synchronize data of Oracle databases in real time. This synchronization mode uses triggers on the source database to capture change data. When the CDC synchronization mode is enabled, the performance of the database may be deteriorated.

Before synchronizing data from an Oracle database, you need to perform a series of operations in the database. Take data synchronization between two Oracle tables as an example.

Synchronize data from the source table named `synctest.trade` to the destination table named `cdcuser.trade_target`.

The source and destination tables are created by using the `CREATE TABLE` statement. StreamX obtains changes of the incremental data and synchronizes the changed data to the destination table. The changed incremental data that StreamX reads includes the specific information about the action types. The `UPDATE` statements are divided into the before image and after image. The before image contains the data before the update. The after image contains the updated data.

Procedure

1. Create a table. You can also select an existing table.

```
create tablespace ts_cdcpub  
logging datafile '/u01/app/oracle/oradata/mydb/cdcpub01.dbf'  
size 5000M autoextend off;
```

2. Create a user named cdcuser to store incremental data and grant permissions to the user.

```
CREATE USER cdcuser IDENTIFIED BY cdcuser DEFAULT TABLESPACE ts_cdcpub QUOTA UNLIMITED ON ts_cdcpub;  
GRANT CREATE SESSION TO cdcuser;  
GRANT CREATE TABLE TO cdcuser;  
GRANT SELECT_CATALOG_ROLE TO cdcuser;  
GRANT EXECUTE_CATALOG_ROLE TO cdcuser;  
GRANT CONNECT, RESOURCE TO cdcuser;
```

3. Grant the SELECT permission on the table to be synchronized to the cdcuser user.

```
grant select on syntest.trade to cdcuser;
```

4. Create a change set and a change table.

- o Create a change set

```
DBMS_CDC_PUBLISH.CREATE_CHANGE_SET(  
change_set_name => 'tradetest',  
description => 'Change set for syntest.trade info',  
change_source_name => 'SYNC_SOURCE');
```

- o Create a change table

```
DBMS_CDC_PUBLISH.CREATE_CHANGE_TABLE(  
owner => 'cdcuser',  
change_table_name => 'trade_ct',  
change_set_name => 'tradetest',  
source_schema => 'syntest',  
source_table => 'trade',  
column_type_list => 'id number,money number,op_user varchar(100)',  
capture_values => 'both',  
rs_id => 'y',  
row_id => 'n',  
user_id => 'n',  
timestamp => 'n',  
object_id => 'n',  
source_colmap => 'y',  
target_colmap => 'y',  
DDL_MARKERS => 'N',  
options_string => 'TABLESPACE ts_cdcpub');
```

5. After the change set and change table are created, add an Oracle CDC connection and an Oracle connection.
6. Go to the **Data Integration** page. In the left-side navigation pane, choose **Nodes > Real-Time Sync**.
 - o Configure the reader. The reader currently supports four connection types including MySQL Binlog, Oracle CDC, DataHub, and LogHub. Configure the corresponding connection before configuring the reader.

Parameter	Description
Connection	The name of the connection.

Parameter	Description
Table	By default, four data records in the selected table are available for preview.
Start Offset	The time when the data synchronization node runs.
Time Zone	The time zone of the data synchronization node. The time zone can be determined based on the time zone of the connection.

- Configure the writer. The writer currently supports three connection types including MySQL, Oracle, and DataHub. Configure the corresponding connection before configuring the writer.

Specify and map the fields in the source and destination.

2.4.6.4.3. DataHub

The DataHub stream reader reads data from DataHub in real time by using the DataHub SDK.

The reader keeps running after it is started and reads data from DataHub when DataHub stores new data. The DataHub stream reader has the following two features:

- Reads data in real time.
- Reads data concurrently based on the number of shards in DataHub.

Parameters

Parameter	Description	Required
endpoint	The endpoint used to access DataHub.	Yes
accessId	The AccessKey ID used to access DataHub.	Yes
project	The destination project of DataHub. A project is the resource management unit in DataHub for resource isolation and control.	Yes
topic	The destination topic of DataHub.	Yes
batchSize	The size of data read at a time.	No. Default value: 1024.
startTimestampMills	The start time of data consumption. The time is an integer accurate to milliseconds. Example: 1554739200000.	No. You must specify either the startTimestampMills parameter or the position parameter.
position	The start time of data consumption for each shard. You can specify this parameter for each shard. Example: <code>{"allShardTimestampMills": {"0":1549098048000,"1":1549098048000,"2":1549098048000,"3":1549098048000,"4":1549098048000}}</code> .	No. You must specify either the startTimestampMills parameter or the position parameter.

Example

In the following code, a node is configured to read data from DataHub and write data to a MySQL database in real time:

```
{
  "connections": [],
  "name": "yj_datahub2datahub4",
  "order": {
    "hops": [
      {
        "from": "datahubstreamreader",
        "to": "mysqloutput001"
      }
    ]
  },
  "params": [],
  "setting": {
    "performance": {}
  },
  "steps": [
    {
      "name": "datahubstreamreader",
      "category": "reader",
      "parameter": {
        "endpoint": "http://dh-cn-hangzhou.aliyuncs.com",
        "accessId": "*****",
        "accessKey": "*****",
        "project": "streamx_datahub",
        "topic": "mysqlbinlog_to_datahub_topic2",
        "batchSize": 512,
        "startTimestampMills": 1554739200000,
        "position": "{\"allShardTimestampMills\": {\"0\":1549098048000,\"1\":1549098048000,\"2\":1549098048000,\"3\":1549098048000,\"4\":1549098048000}}",
        "column": [
          "cdc_record_id",
          "cdc_operation",
          "cdc_timestamp",
          "cdc_before_image",
          "cdc_after_image",
          "id",
          "name",
          "age"
        ]
      },
      "stepType": "datahubstream"
    },
    {
      "name": "mysqloutput001",
      "category": "writer",
      "parameter": {
        "batchSize": 100,
        "writeMode": "insert",
        "username": "*****",
        "password": "*****",
        "column": [
          "cdc_record_id",
          "cdc_operation"
        ]
      }
    }
  ]
}
```

```

]
},
"stepType": "mysql"
}
],
"type": "job",
"version": "2.0"
}

```

2.4.6.4.4. LogHub

The LogHub stream reader reads data from LogHub in real time by using the LogHub SDK.

The reader reads data from LogHub topics you specified in real time and supports shard merge and split.

 **Note** When shard merge or split is enabled, duplicate data records may exist. However, data missing is avoided.

Parameters

Parameter	Description	Required	Default value
endpoint	The endpoint used to access LogHub.	Yes	None
project	The name of the LogHub project.	Yes	None
logstore	The Logstore of LogHub.	Yes	None
table	The name of the table to be synchronized.	Yes	None
accessId	The AccessKey ID used to access LogHub.	Yes	None
accessKey	The AccessKey secret used to access LogHub.	Yes	None

Parameter	Description	Required	Default value
startTimestampMills	<p>The start time of data synchronization. The value of this parameter is a 13-bit timestamp.</p> <div style="background-color: #e0f2f7; padding: 5px; border: 1px solid #ccc;"> <p> Note If the start time you specify is later than the last data change time of MySQL binlogs, data synchronization starts from the last data change time of MySQL binlogs. If the start time you specify is earlier than the earliest data change time of MySQL binlogs, no data is synchronized.</p> </div>	No	None

Example

In the following code, a node is configured to read data from LogHub and write data to DataHub in real time:

```
{
  "order": {
    "hops": [
      {
        "from": "loghubstream_01",
        "to": "datahub_01"
      }
    ]
  },
  "steps": [
    {
      "category": "reader",
      "name": "loghubstream_01",
      "parameter": {
        "accessKey": "<yourAccessKey>",
        "accessId": "<yourAccessId>",
        "column": [
          "col1",
          "col2",
          "col3"
        ],
        "endpoint": "<yourEndpoint>",
        "logstore": "<yourLogstore>",
        "project": "<yourProject>",
        "startTimestampMills": 1555050358000,
      },
      "stepType": "loghubstream"
    }
  ],
}
```

```

{
  "category": "writer",
  "name": "datahub_01",
  "parameter": {
    "accessKey": "<yourAccessKey>",
    "batchSize": 1000,
    "column": [
      "col1",
      "col2",
      "col3"
    ],
    "columnMapping": [
      {
        "dstColName": "col1",
        "sourceColName": "col1"
      },
      {
        "dstColName": "col2",
        "sourceColName": "col2"
      },
      {
        "dstColName": "col3",
        "sourceColName": "col3"
      }
    ],
    "endpoint": "<yourEndpoint>",
    "project": "<yourProject>",
    "topic": "<yourTopic>"
  },
  "stepType": "datahub"
}
]
}

```

2.4.6.4.5. Kafka

Create a real-time sync node

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration** to go to the **Data Integration** page.
3. In the left-side navigation pane, choose **Nodes > Real-Time Sync**. Click **Create Node** in the upper-right corner.
4. In the **Create Node** dialog box that appears, set **Node Name** and **Description**.
5. Click **OK**.

Configure an input node of the Kafka type

Drag **Kafka** under **Reader** to the canvas. Click the node and then configure the node in the **Node Settings** dialog box that appears.

Parameter	Description
server	The broker server address of Kafka in the format of <code>ip:port</code> .

Parameter	Description
topic	The name of the Kafka topic.
keyType	The type of the Kafka key.
valueType	The type of the Kafka value.
Consumer Offset	The consumer offset from which Kafka starts to consume data.
Parameters	The JSON-formatted parameters for specifying additional Kafka configurations. Example: group_id.
Start Offset	The date and time of the start offset.
Time Zone	The time zone.
Output Fields	The output fields of the node. You can customize the output fields.

Take the following Kafka configuration script as an example.

```
"parameter": {
  "server": "100.81.127.26:9092",
  "topic": "xin_001",
  "keyType": "long",
  "valueType": "string",
  "startupMode": "earliestOffset", -- Consume data from the earliest consumer offset.
  "discoveryIntervalMillis": 10000, -- The interval between partitions. The value is automatically discovered by the
system.
  "kafkaConfig": {
    "group.id": "xin_group_001"
  }
}
```

2.4.6.4.6. Configure PolarDB Reader

PolarDB Reader can read data only from PolarDB for MySQL databases. It cannot read data from PolarDB for PostgreSQL databases.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the  icon and choose **Data Integration > Real-time synchronization**. Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

 **Notice** The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **PolarDB** in the **Input** section to the canvas on the right.

- Click the **PolarDB** node. In the panel that appears, configure the parameters.

Parameter	Description
Data source	The PolarDB for MySQL data source that you have added. You can select only a PolarDB for MySQL data source. If no data source is available, click New data source to add one on the Data Source page.
Table	The name of the table from which you want to read data. You can click Data preview on the right to preview the selected table.
Output field	The fields from which you want to read data.

- Click the  icon in the toolbar.

2.4.6.5. Writer

2.4.6.5.1. Configure MaxCompute Writer

MaxCompute offers a comprehensive data import solution to support fast computing for large amounts of data.

Prerequisites

A reader or conversion node is configured.

Procedure

- Log on to the DataWorks console.
- Move the pointer over the  icon and choose **Data Integration > Real-time synchronization**. Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
- In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

 **Notice** The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).

- Click **Commit**.
- On the configuration tab of the real-time synchronization node, drag **MaxCompute** in the **Output** section to the canvas on the right. Connect the MaxCompute node to the configured reader or conversion node.
- Click the **MaxCompute** node. In the panel that appears, configure the parameters.

Parameter	Description
Data source	The MaxCompute data source that you have configured. You can select only a MaxCompute data source. If no data source is available, click New data source on the right to add one on the Data Source page.

Parameter	Description
Table	<p>The name of the MaxCompute table to which you want to write data.</p> <p>You can click One-Click table creation on the right to create a table, or click Data preview to preview the selected table.</p> <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px;"> <p> Notice Before you create a table, connect the MaxCompute node to a reader node, and make sure that the output field parameters are specified for the reader node.</p> </div>
Partition message	The information about the partitioned MaxCompute table.
Field Mapping	The field mappings between the source and destination. Click Field Mapping and configure field mappings. The synchronization node synchronizes data based on the field mappings.

If you want to create a table, click **One-Click table creation** next to Table. In the **New data table** dialog box, configure the parameters.

Parameter	Description
Table name	The name of the MaxCompute table.
Life cycle	The lifecycle of the MaxCompute table.
Data field structure	The field structure of the MaxCompute table. To add a field, click Add .
Partition settings	<p>The partitions of the MaxCompute table.</p> <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px;"> <p> Notice You must configure at least two levels of partitions, which are yearly and monthly partitions. You can configure a maximum of five levels of partitions, which are yearly, monthly, daily, hourly, and minutely partitions.</p> </div>

7. Click the  icon in the toolbar.

2.4.6.5.2. Configure Hologres Writer

You can build a real-time data warehouse by using the real-time write capability of Hologres.

Prerequisites

A reader or conversion node is configured.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the  icon and choose **Data Integration > Real-time synchronization**. Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

 **Notice** The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **Hologres** in the **Output** section to the canvas on the right. Then, draw a line to connect it to the configured reader or conversion node.
6. Click the **Hologres** node. In the panel that appears, configure the parameters.

Parameter	Description
Data source	<p>The Hologres data source that you configured. You can select only a Hologres data source.</p> <p>If no data source is available, click New data source to add one on the Data Source page.</p>
Table	<p>The name of the Hologres table to which you want to write data.</p> <p>You can click One-Click table creation on the right to create a table, or click Data preview to preview the selected table.</p>
Dynamic Time Partition	<p>If the Hologres table is a partitioned table, you must specify a dynamic time-based partition.</p> <p>The dynamic time-based partition parses the value of a source field in the <code>yyyymmddhhmmss</code> format. After the value is parsed, you can use the dynamic partition whose name is a string of variables in the destination table. The destination partition varies based on the value of the source field.</p> <p>For example, the value of the source field is <code>20200816</code>, and the name of the destination partition is in the <code>{yyyy}-{mm}-{dd}</code> format. In this case, the value is written to the <code>2020-08-16</code> partition.</p>
Job type	<p>The type of the data write operation. Valid values: Replay (replay operation log to restore data) and Insert (direct archive save).</p> <ul style="list-style-type: none"> ◦ Replay (replay operation log to restore data): indicates that Hologres Writer performs the same operation on the Hologres destination as that performed on the source. For example, if the <code>INSERT</code> statement is executed to add a record to the source, Hologres Writer executes the <code>INSERT</code> statement to add the same record to the Hologres destination. If the <code>UPDATE</code> or <code>DELETE</code> statement is executed in the source, Hologres Writer executes the <code>UPDATE</code> or <code>DELETE</code> statement in the Hologres destination. ◦ Insert (direct archive save): indicates that Hologres Writer uses the Hologres destination as streaming data storage. Data is synchronized from the source to the Hologres destination by using the <code>INSERT</code> statement.

Parameter	Description
Writer conflict policy	The solution to data write conflicts. Valid values: <ul style="list-style-type: none">◦ Cover (Overwrite): indicates that Hologres Writer uses the new data synchronized from the source to overwrite the existing data in the Hologres destination.◦ Ignore (Ignore): indicates that Hologres Writer ignores the new data synchronized from the source and retains the existing data in the Hologres destination.
Field Mapping	The field mappings between the source and destination. Click Field Mapping and configure field mappings between the source and destination. The synchronization node synchronizes data based on the field mappings.

7. Click the  icon in the toolbar.

2.4.6.5.3. Configure DataHub Writer

DataHub is a platform that is designed to process streaming data. You can publish and subscribe to streaming data in DataHub and distribute the data to other platforms. DataHub allows you to analyze streaming data and build applications based on the streaming data.

Prerequisites

A reader or conversion node is configured.

Context

DataHub Writer writes data to DataHub by using DataHub SDK for Java. The following code provides an example of DataHub SDK for Java:

```
<dependency>
  <groupId>com.aliyun.datahub</groupId>
  <artifactId>aliyun-sdk-datahub</artifactId>
  <version>2.5.1</version>
</dependency>
```

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the  icon and choose **Data Integration > Real-time synchronization**. Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

 **Notice** The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **DataHub** in the **Output** section to the canvas on the right. Connect the new node to the configured reader or conversion node.
6. Click the new **DataHub** node. In the configuration panel that appears, set the parameters.

Parameter	Description
Data source	The configured DataHub data source. In this example, you can select only a DataHub data source. If no data source is available, click New data source on the right to add one on the Data Source page.
Topic	The name of the DataHub topic to which you want to write data. You can click Data preview on the right to preview the selected topic.
Batch number	The number of records to write at a time.
Field Mapping	The mappings between fields in the source and destination. DataWorks synchronizes data based on the field mappings.

7. Click the  icon in the toolbar.

2.4.6.5.4. Kafka

Create a real-time sync node

1. Log on to the DataWorks console.
2. Move the pointer over the DataWorks icon in the upper-left corner and select **Data Integration**.
3. In the left-side navigation pane, choose **Nodes > Real-Time Sync**. Click **Create Task** in the upper-right corner.
4. In the **Create Node** dialog box that appears, set **Node Name** and **Description**.
5. Click **OK**.

Configure an output node of the Kafka type

Drag **Kafka** under **Writer** to the canvas. Click the node and then configure the node in the **Node Settings** dialog box that appears.

Parameter	Description
server	The broker server address of Kafka in the format of <code>ip:port</code> .
topic	The name of the Kafka topic.
keyColumn	The column for storing the key.
keyType	The type of the Kafka key.
valueColumn	The column for storing the value. If this parameter is not specified, all columns are concatenated by using the delimiter specified by fieldDelimiter to form the value.
valueType	The type of the Kafka value.
batchSize	The amount of data written at a time. Default value: 1024.

Parameter	Description
Parameters	The extended parameters specified when KafkaConsumer is created, such as bootstrap.servers, auto.commit.interval.ms, and session.timeout.ms. By setting parameters in kafkaConfig, you can control the data consumption behaviors of KafkaConsumer.

Take the following Kafka configuration script as an example.

```
"parameter": {
  "server": "100.81.127.26:9092",
  "keyIndex": 0,
  "valueIndex": 1,
  "keyType": "long",
  "valueType": "string",
  "topic": "xin_002",
  "batchSize": 1,
}
```

2.4.6.6. Transform

2.4.6.6.1. Data filter

The data filter plug-in is used to filter data.

Parameters

Parameter	Description	Required
category	The category of the plug-in. Set this parameter to filter for the data filter plug-in.	Yes
stepType	The type of the step. Set this parameter to filter rows for the data filter plug-in.	Yes
name	The name of the step.	Yes
condition	The filter condition in the expression format. The expression can contain the columns of the reader. In this example, the id and age columns in the filter condition are two columns specified in the reader. An expression that does not contain any column names can also be valid, such as 1==1.	Yes

Example

```
{
  "connections": [],
  "transform": {
    "name": "Data Filter",
    "category": "Data Filter",
    "stepType": "Data Filter",
    "name": "Data Filter",
    "condition": "id > 100"
  }
}
```

```
name : yj_mysql_2_mysql ,
"order":{
  "hops":[
    {
      "from": "J3Bji***NPLn",
      "to": "rYCN***VxmIK0"
    },
    {
      "from": "rYCNF***mIK0",
      "to": "nD***JWPh0YJI0X"
    }
  ]
},
"params": [],
"setting": {
  "keyVersion": "201412091312",
  "metric": {
    "transMetric": {
      ...
    }
  },
},
"steps": [
  {
    "category": "reader",
    "name": "J3BjiG***QNPLn",
    "parameter": {
      "password": "<yourPassWord>",
      "access": "Native",
      "column": [
        "id",
        "name",
        "age"
      ],
      "dbHost": "10.101.83.3",
      "dbName": "test",
      "port": 3306,
      "startTimestampMills": 1551801600000,
      "table": "streamx_test_real_time",
      "type": "MYSQLBINLOG",
      "username": "<yourUserName>"
    },
    "stepType": "mysqlbinlog"
  },
  {
    "category": "filter",
    "name": "rYCNFINr38VxmIK0",
    "parameter": {
      "condition": "(id > 10) &&(age > 30)",
    },
    "stepType": "filterrows"
  },
  ... // The writer configuration is omitted here.
]
```

2.4.6.6.2. String replacement

The string replacement plug-in is used to replace the field values of the String type.

Parameter	Description
Field	The input fields read in the previous step.
Regular Expression Match	Specifies whether to perform regular expression match on the fields. For more information about regular expressions, see the relevant Java documentation.
Original String	The string to be replaced.
New String	The string used to replace the original string.
Case Sensitive	Specifies whether the query of the original string is case-sensitive.

2.4.7. Data synchronization solutions

2.4.7.1. Go to the Sync Solutions page

The Data Integration service of DataWorks allows you to create and configure a synchronization solution to synchronize data from a source to a destination in real time. You can use a synchronization solution to synchronize multiple tables at a time or synchronize both full and incremental data. If you want to synchronize both full and incremental data, you can synchronize the incremental data after the full data is synchronized.

Procedure

1. [Log on to the DataWorks console.](#)
2. On the DataStudio page, click the  icon in the upper-left corner and choose **All Products > Data Aggregation > Data Integration.**
3. In the left-side navigation pane, click **Sync Solutions.** The **Solution Task list** page appears. You can create synchronization solutions and view the details and statuses of the created synchronization solutions on this page. A synchronization solution has the following states:
 - **Not running:** The synchronization solution is not run. You can click **Start execution** in the Operation column that corresponds to the synchronization solution to run the synchronization solution.

 **Note** You can click **Task configuration** in the Operation column that corresponds to a synchronization solution in the **Not running** state to edit the synchronization solution. If you click **Task configuration** in the Operation column that corresponds to a synchronization solution in another state, you can only view the information about the synchronization solution.

- **Running:** The synchronization solution is running and cannot be terminated. You must wait until the synchronization solution is completed.
- **Exception:** An error occurred during the running of the synchronization solution. You can click **Execution details** in the Operation column that corresponds to the synchronization solution to troubleshoot the error.
- **Success:** The synchronization solution is completed. You can click **Execution details** in the Operation

column that corresponds to the synchronization solution to view the running results of the synchronization solution.

2.4.7.2. Synchronize data to Hologres in real time

You can create and configure a data synchronization solution to synchronize data in a specified data source to Hologres in real time. This topic describes how to synchronize data to Hologres in real time.

Procedure

1. Go to the **Solution Task list** page.
 - i. [Log on to the DataWorks console](#).
 - ii. Click the  icon in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
 - iii. In the left-side navigation pane, click **Sync Solutions**.
2. On the **Solution Task list** page, click **New Task** in the upper-right corner.
3. In the **New resolution task** dialog box, click **One-click real-time synchronization to Hologres**.
4. In the **Set synchronization sources and rules** step, configure the parameters.
 - i. In the **Basic configuration** section, configure the relevant parameters.

Parameter	Description
Scheme name	The name of the synchronization solution. The name can be a maximum of 50 characters in length.
Description	The description of the synchronization solution. The description can be a maximum of 50 characters in length.
Destination task storage location	<p>If you select Automatically establish workflow, DataWorks automatically creates a workflow named in the format of <code>clone_database_Source name+to+Destination name</code> in the Data Integration directory. All synchronization nodes generated by the synchronization solution are placed in the directory of this workflow.</p> <p>If you do not select Automatically establish workflow, you must select a directory from the Select Location drop-down list. All synchronization nodes generated by the synchronization solution are placed in the specified directory.</p>

- ii. In the **Data source** section, specify **Type** and **Data source**.
- iii. In the **Select the source table for synchronization** section, select the tables that you want to synchronize in the **SOURCE Table** list and click **>** to move the tables to the **Selected Source table** list. The **SOURCE Table** list displays all the tables in the source. You can select all or some tables to synchronize them at a time.

 **Notice** If a selected table does not have a primary key, the table cannot be synchronized in real time.

- iv. In the **Set synchronization rules** section, click **Add rule** and select an option to configure naming rules for destination tables. Supported options include **Table name conversion rules** and **Target table name rule**.
 - **Table name conversion rules**: the rule for converting the names of source tables to those of destination tables.
 - **Target table name rule**: the rule for adding a prefix and suffix to the converted names of destination tables.
 - v. Click **Next Step**.
5. In the **Set target table** step, configure the parameters.
- i. Specify **Target Hologres data source** and **Schema**. **Write Hologres policy** is set to **Replay (replay operation log to restore data)** by default and cannot be changed.
 - ii. Click **Reload source table and Hologres Table mapping** to configure the mappings between the source tables and destination Hologres tables.
 - iii. View the mapping progress, source tables, and mapped destination tables. You can view the mapping progress between the source tables and destination tables. The mapping may take a long period of time if you want to synchronize a large number of tables.
- An error message appears if the selected source table does not have a primary key. The synchronization can be performed if one of the selected source tables has a primary key. Source tables without primary keys are ignored during the synchronization.
- You can set **Table creation method** to **Create tables automatically** or **Use existing Table**. The name of the destination table that appears in the **Hologres Table name** column varies based on the setting of **Table creation method**.
- If you set **Table creation method** to **Create tables automatically**, the name of the destination table that is automatically created appears. You can click the table name to view and modify the table creation statements.
 - If you set **Table creation method** to **Use existing Table**, you must select a table from the drop-down list in the **Hologres Table name** column.
- iv. Click **Next Step**.

6. In the **Run resource settings** step, configure the parameters.

Parameter	Description
Realtime task resource group	The resource group used for running the batch synchronization node and real-time synchronization nodes generated by the synchronization solution.
Offline task resource group	
Select scheduling Resource Group	The resource group for scheduling used for running the nodes generated by the synchronization solution.
Maximum number of connections supported by source read	The maximum number of Java Database Connectivity (JDBC) connections that are allowed for the source. Specify an appropriate number based on the resources of the source.
Offline task name rules	The name of the batch synchronization node that is used to synchronize the full data of the source. After a synchronization solution is created, a batch synchronization node is generated first to synchronize full data, and then real-time synchronization nodes are generated to synchronize incremental data.

7. Click **Complete configuration**.

8. On the **Solution Task list** page, find the newly created synchronization solution and click **Start execution** in the Operation column. After the running of the synchronization solution is successful, you can perform the following operations on the synchronization solution:
 - Click **Task configuration** in the Operation column to view the information about or edit the synchronization solution.

 **Note** You can click **Task configuration** in the Operation column that corresponds to the data synchronization solution in the **Not running** state to edit the data synchronization solution. If you click **Task configuration** in the Operation column of a synchronization solution in another state, you can only view information about the synchronization solution.

- Click **Execution details** in the Operation column to view the points in time at which the synchronization solution was started and ended and the status of each node.
- Click **Delete** in the Operation column to delete the synchronization solution. In the **Delete** message, click **Confirm**.

 **Note** After you click **Confirm**, only the configuration record of the data synchronization solution is deleted. The generated synchronization nodes and tables are not affected.

2.4.7.3. Synchronize data to MaxCompute in real time

You can create a synchronization solution to synchronize data from a specified data source to MaxCompute in real time.

Procedure

1. Go to the **Solution Task list** page.
 - i. [Log on to the DataWorks console](#).
 - ii. Click the  icon in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
 - iii. In the left-side navigation pane, click **Sync Solutions**.
2. On the **Solution Task list** page, click **New Task** in the upper-right corner.
3. In the **New resolution task** dialog box, click **One-click real-time synchronization to MaxCompute**.
4. In the **Set synchronization sources and rules** step, configure the parameters.

i. In the **Basic configuration** section, configure the relevant parameters.

Parameter	Description
Scheme name	The name of the synchronization solution. The name can be a maximum of 50 characters in length.
Description	The description of the synchronization solution. The description can be a maximum of 50 characters in length.
Destination task storage location	<p>If you select Automatically establish workflow, DataWorks automatically creates a workflow named in the format of <code>clone_database_Source name+to+Destination name</code> in the Data Integration directory. All synchronization nodes generated by the synchronization solution are placed in the directory of this workflow.</p> <p>If you do not select Automatically establish workflow, you must select a directory from the Select Location drop-down list. All synchronization nodes generated by the synchronization solution are placed in the specified directory.</p>

ii. In the **Data source** section, specify **Type** and **Data source**.

iii. In the **Select the source table for synchronization** section, select the tables that you want to synchronize in the **SOURCE Table** list and click **>** to move the tables to the **Selected Source table** list. The **SOURCE Table** list displays all the tables in the source. You can select all or some tables to synchronize them at a time.

 **Notice** If a selected table does not have a primary key, the table cannot be synchronized in real time.

iv. In the **Set synchronization rules** section, click **Add rule** and select an option to configure naming rules for destination tables. Supported options include **Table name conversion rules** and **Target table name rule**.

- **Table name conversion rules:** the rule for converting the names of source tables to those of destination tables.
- **Target table name rule:** the rule for adding a prefix and suffix to the converted names of destination tables.

v. Click **Next Step**.

5. In the **Set target table** step, configure the parameters.

- i. Select a data source from the **Target MaxCompute data source** drop-down list and specify **Write mode**.
- ii. Click  next to **MaxCompute time automatic partition settings**. In the **Edit** dialog box, modify the partition settings for the destination tables. You can configure daily and hourly partitions.
- iii. Click **Reload source table and MaxCompute Table mapping** to configure the mappings between the source tables and destination MaxCompute tables.

- iv. View the mapping progress, source tables, and mapped destination tables. You can view the mapping progress between the source tables and destination tables. The mapping may take a long period of time if you want to synchronize a large number of tables.

An error message appears if the selected source table does not have a primary key. The synchronization can be performed if one of the selected source tables has a primary key. Source tables without primary keys are ignored during the synchronization.

You can set Table creation method to **Create tables automatically** or **Use existing Table**. The name of the destination table that appears in the MaxCompute Table name column varies based on the setting of Table creation method.

- If you set **Table creation method** to **Create tables automatically**, the name of the destination table that is automatically created appears. You can click the table name to view and modify the table creation statements.
- If you set **Table creation method** to **Use existing Table**, you must select a table name from the drop-down list in the MaxCompute Table name column.

v.

6. In the **Run resource settings** step, configure the parameters.

Parameter	Description
Synchronization engine	Default value: Default embedded engine .
Realtime task resource group	The resource group that is used to run the nodes generated by the real-time synchronization solution.
Real-time synchronization task name	The name of the real-time synchronization solution.
Select scheduling Resource Group	The resource group that is used to run the real-time synchronization nodes and batch synchronization node generated by the synchronization solution. Synchronization solutions can run on shared resource groups and custom resource groups for Data Integration.
Offline task resource group	
Maximum number of connections supported by source read	The maximum number of Java Database Connectivity (JDBC) connections that are allowed for the source database. Specify an appropriate number based on the resources of the source database.
Offline task name rules	The name of the batch synchronization node that is used to synchronize the full data of the source database. After a data synchronization solution is created, DataWorks first generates a batch synchronization node to synchronize full data, and then generates real-time synchronization nodes to synchronize incremental data.

7. Click **Complete configuration**.
8. On the **Solution Task list** page, find the newly created synchronization solution and click **Start execution** in the Operation column. After the synchronization solution is run, you can perform the following operations on the synchronization solution:
 - Click **Task configuration** in the Operation column to view information about or configure the synchronization solution.

Note You can configure a synchronization solution only when it is in the **Not running** state. If you click Task configuration in the Operation column of a synchronization solution that is in another state, you can only view information about the synchronization solution.

- Click **Execution details** in the Operation column to view the time at which the synchronization solution was started and ended and the status of each node.
- Click **Delete** in the Operation column to delete the synchronization solution. In the **Delete** message, click **Confirm**.

Note After you click Confirm, only the configuration record of the data synchronization solution is deleted. The generated synchronization nodes and tables are not affected.

2.4.8. Resource groups

2.4.8.1. Overview

This topic introduces the definition of resource groups. It also describes how the connectivity and performance of resource groups affect data synchronization.

Definition

A resource group is a collection of computing resources on which synchronization nodes of Data Integration are run. In most cases, a resource group is one or more servers that consist of CPU, memory, and network resources.

In the process of running a synchronization node, the resource group pulls data from the source and pushes the data to the destination.

Connectivity and performance

When you use resource groups, you must pay attention to their connectivity and performance.

- Connectivity

To ensure that data can be synchronized, a resource group must be connected to the source and destination. Connectivity is the most important factor that affects data synchronization.

Data Integration cannot build networks. Before you use Data Integration to synchronize data, you must make sure that the resource group is connected to the data sources. If the resource group is disconnected from the data sources, synchronization nodes cannot be run.

- Performance

Synchronization nodes consume the CPU, memory, and network resources on the servers where the nodes are run. Insufficient resources may lead to various issues. For example, the nodes fail to be started, wait for resources for a long period of time after startup, transmit data at a low rate, or fail to generate data. To ensure the smooth running of synchronization nodes, you must allocate adequate resources for them.

2.4.8.2. Shared resource groups

Data Integration of DataWorks provides shared resource groups for you to create and run synchronization nodes.

Shared resource groups for Data Integration are created and maintained by Data Integration. Shared resource groups compose a public resource pool. Nodes that use resources in the public resource pool may not be run as scheduled due to insufficient resources. We recommend that you prepare sufficient resources to ensure the efficient running of synchronization nodes.

Note

- You can run a maximum of 25 parallel nodes on a shared resource group for Data Integration when the shared resource group is not in use.
- You cannot change the memory size of a shared resource group. Instead, you can change the number of parallel nodes that can be run on the shared resource group.

The following formula is used to calculate the memory size: $\text{Memory size} = \text{Number of parallel nodes} \times 512 \text{ MB}$.

2.4.9. Full-database migration

2.4.9.1. Overview

This section describes the full-database migration feature in terms of its functions and limits.

Full-database migration is an easy-to-use tool that helps you to improve cost-efficiency. It can quickly upload all the tables in a MySQL database to MaxCompute at a time, saving time that is spent on creating batch tasks for initial data migration to the cloud.

For example, if a database contains 100 tables, you must configure 100 data synchronization tasks in a traditional way. With the full-database migration, you can upload all the tables at a time. However, an upload failure might occur due to the issues that involve the principles of designing database tables.

Task generation rules

After the configuration is completed, MaxCompute tables are created and data synchronization tasks are generated based on the selected tables to be synchronized.

The table names, field names, and field types of the MaxCompute tables are generated according to the advanced settings. If no advanced settings are configured, the structure of MaxCompute tables is identical to that of MySQL tables. The partition of these tables is pt, and its format is yyyyymmdd.

The generated data synchronization tasks are daily scheduled tasks and run automatically on the early morning of the next day. The typical transmission rate is 1 Mbit/s, but it varies depending on the synchronization method and concurrency configurations. **To customize a data synchronization task, locate the task by choosing clone_database > Data Source Name > mysql2odps_table name, and then specify its settings.**

 **Note** We recommend that you perform smoke testing on a data synchronization task on the day when it is generated. **To perform smoke testing, choose Administration Center > Task Management > project_etl_start > Upload Database > Data Source Name, find the synchronization task, right-click the task, and then test the task.**

Limits

Full-database migration has the following limits due to the issues that involve the principles of designing database tables.

- Currently, only the full-database migration from a MySQL data source to MaxCompute is supported. We are working on support for full-database migration from a Hadoop or Hive data source to Oracle.
- Only the daily incremental and daily full upload modes are available.

If you want to synchronize historical data at a time, this feature cannot meet your needs. We recommend that:

- You configure daily tasks instead of synchronizing historical data at a time. You trace the historical data with the provided retrospective data import feature. This eliminates the need to run temporary SQL tasks to split data after all the historical data is synchronized.
- To synchronize historical data at a time, configure a task on the task development page and click **Run**. Then, data is converted by using SQL statements. They are both one-time operations.

If your daily incremental upload task uses a special business logic and cannot be identified by a date field, this feature cannot meet your needs. We provide the following suggestions:

- The incremental data upload can be achieved by using two methods: binlog provided by the DTS product and the date field for data changes provided by databases.

Currently, Data Integration supports the second method. Therefore, your database must contain the date field for data changes. The system determines whether your data is changed on the same day as the business date by using this field. If yes, all the changed data is synchronized.

- To facilitate the incremental data uploading, we recommend that you include the `gmt_create` and `gmt_modify` fields when creating any database tables. Additionally, you can set the `id` field as the primary key to improve efficiency.
- Full-database migration supports batch upload and full upload modes.

Batch upload is configured with time intervals. Currently, the connection pool protection feature for data sources is not supported, but will be available later.

- To prevent overloads on the database, the full-database migration feature provides the batch upload mode. This mode enables you to upload tables in batches at a specified time interval and prevents compromised service functionality. We provide the following suggestions:
 - If you have master and slave databases, we recommend that you synchronize the data of the slave database.
 - In a batch upload task, each table has a database connection with a maximum transmission rate of 1 Mbit/s. For example, if you run a synchronization task for 100 tables at a time, 100 database connections are established. We recommend that you specify proper concurrency settings based on your business needs.
- If you have special requirements for transmission efficiency, this feature cannot meet your needs. The maximum transmission of each generated task is 1 Mbit/s.
- Only the mapping of all table names, field names, and field types are supported.

During the full-database migration process, MaxCompute tables are created automatically, where the partition field is `pt`, the field type is `string`, and the format is `yyyymmdd`.

 **Note** When you select tables for synchronization, all fields must be synchronized and none of these fields can be edited.

2.4.9.2. Migrate a MySQL database

This topic describes how to migrate a MySQL database to MaxCompute.

The database migration feature improves efficiency and reduces costs. It can quickly upload all tables in a MySQL database to MaxCompute. For more information, see [Overview](#).

Procedure

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration** to go to the **Data Integration** page.
3. In the left-side navigation pane, choose **Sync Resources > Connections**. On the page that appears, click **Add Connection**.
4. In the **Add Connection** dialog box that appears, select **MySQL**.
5. Add a MySQL connection named `clone_database` for database migration.
6. Click **Test Connection** and verify that the database can be accessed. Click **Complete**.
7. The added MySQL connection named `clone_database` appears in the connection list. Find the added connection and click **Migrate Database** in the Actions column.

The database migration settings page consists of three functional modules.

Functional module	Description
Tables to migrate	This module lists all the tables in the MySQL connection named <code>clone_database</code> . Selected tables will be migrated.
Advanced Settings	You can configure the rules for converting the table name, column names, and data types.
Basic settings	You can select whether to synchronize full or incremental data, whether to upload data in one or more batches, and the synchronization efficiency. You can also view the migration progress and results.

8. Click **Advanced Settings** and configure conversion rules based on your needs. For example, you can add an `ods_` prefix to the name of each MaxCompute table.
9. Specify basic settings. Set Sync Method to Synchronize Incremental Data Daily, and configure the incremental data to be determined based on the `gmt_modified` column. Data Integration will generate WHERE clauses based on the specified column and DataWorks scheduling parameters such as `#{bdp.system.bizdate}`.

Data Integration reads data from MySQL tables by connecting to a remote MySQL database over JDBC and running SELECT statements. Data Integration uses standard SQL statements, and therefore you can configure WHERE clauses to filter data. The WHERE clause used in this example is provided as follows:

```
STR_TO_DATE("#{bdp.system.bizdate}', '%Y%m%d') <= gmt_modified AND gmt_modified < DATE_ADD(STR_TO_DATE("#{bdp.system.bizdate}', '%Y%m%d'), interval 1 day)
```

Select data upload in batches to protect the MySQL database from being overloaded. Let Data Integration start data synchronization for three tables every one hour from 00:00 each day.

Click **Commit**. Then, you can view the migration progress and results of each table.

10. Find table `a1` and click **View Node** to view the migration results.

You have configured a node for migrating a MySQL connection named clone_database to MaxCompute. This node is run based on the specified schedule, daily by default. You can also create retroactive node instances to transmit historical data. The database migration feature of **Data Integration** significantly simplifies the initial configurations for migrating your data to the cloud and reduces data migration costs.

You can view the migration success logs of table a1.

2.4.9.3. Migrate Oracle databases

This topic describes how to migrate an Oracle database to MaxCompute.

The database migration feature improves efficiency and reduces costs. It can quickly upload all tables in an Oracle database to MaxCompute. For more information, see [Overview](#).

Procedure

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration** to go to the **Data Integration** page.
3. In the left-side navigation pane, choose **Sync Resources > Connections**. On the page that appears, click **Add Connection** in the upper-right corner.
4. In the **Add Connection** dialog box that appears, select **Oracle**.
5. Add an Oracle connection named clone_database for database migration.
6. Click **Test Connection** and verify that the database can be accessed. Click **Complete**.
7. The added Oracle connection named clone_database appears in the connection list. Find the added connection and click **Migrate Database** in the Actions column.

The database migration settings page consists of three functional modules.

Functional module	Description
Tables to migrate	This module lists all the tables in the Oracle connection named clone_database. Selected tables will be migrated.
Advanced Settings	You can configure the rules for converting the table name, column names, and data types.
Basic settings	You can select whether to synchronize full or incremental data, whether to upload data in one or more batches, and the synchronization efficiency. You can also view the migration progress and results.

8. Click **Advanced Settings** and configure conversion rules based on your needs.
9. Set Sync Method to Synchronize All Data Daily.

 **Note** If a date column exists in your table, you can select incremental migration and configure the incremental data to be determined based on the date column. Data Integration will generate WHERE clauses based on the specified column and DataWorks scheduling parameters such as \${bdp.system.bizdate}.

Select data upload in batches to protect the Oracle database from being overloaded. Let Data Integration start data synchronization for three tables every one hour from 00:00 each day.

Click **Commit**. Then, you can view the migration progress and results of each table.

10. Find a related table and click **View Node** to view the node details.

You have configured a node for migrating an Oracle connection named clone_databae to MaxCompute. This node is run based on the specified schedule, daily by default. You can also create retroactive node instances to transmit historical data. The database migration feature of **Data Integration** significantly simplifies the initial configurations for migrating your data to the cloud and reduces data migration costs.

2.5. Data Analytics

2.5.1. Solution

The data analytics mode of DataWorks is upgraded so that you can group multiple workflows in a solution of a workspace.

Overview

DataWorks upgrades the data analytics mode to organize various types of nodes based on the business category. You can organize workflows to analyze data by business.

By using the data analytics mode that involves the **workspace**, **solution**, and **workflow**, DataWorks defines a new development process and improves user experience.

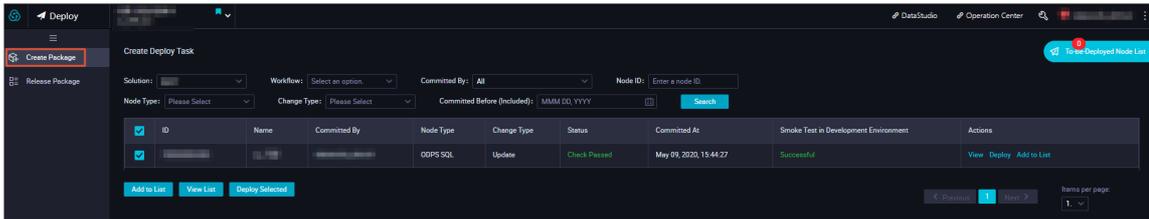

- A workspace is the basic organizational unit that manages the development and O&M permissions of users. The code of all nodes in a workspace can be collaboratively developed and managed by workspace members.
- A solution contains one or more workflows. It has the following advantages:
 - A solution can contain multiple workflows.
 - A workflow can be added to multiple solutions.
 - All solutions in a workspace can be collaboratively developed and managed by workspace members.
- A workflow is an abstract entity of business that enables you to develop data analytics code from a business perspective. A workflow can be added to multiple solutions. It has the following advantages:
 - Workflows facilitate business-oriented code development. Nodes in a workflow are organized by type. A hierarchical directory structure is supported. We recommend that you create a maximum of four levels of sub-directories. To create a sub-directory, right-click the target node type and select **Create Folder**.
 - You can view and optimize each workflow from a business perspective.
 - You can view each workflow on a dashboard to develop code with improved efficiency.
 - You can deploy and manage each workflow as a whole.

Develop a solution

If you double-click a solution in the left-side navigation pane, the left-side navigation pane only displays workflows in the solution. This prevents the development process from being affected by the code that is not related to the current solution in the workspace. To develop a solution, perform the following steps:

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, move the pointer over  and select **Solution**.
3. In the **Create Solution** dialog box, set **Solution Name** and **Description**, select a workflow from the **Workflows** drop-down list, and then click **Create**.
4. In the solution list, right-click the created solution and select **Solution Kanban**. On the solution dashboard that appears, you can view the selected workflows or modify the solution.
5. Move the pointer over the solution name. The  and  icons appear.

- Click the  icon. The **Deploy** page appears. You can view the nodes to be deployed in the current solution.

 **Note** This icon is available only when the workspace is in standard mode.

- Click the  icon to go to the **Cycle Instance** page under **Cycle Task Maintenance** in **Operation Center**. You can view recurring instances of all nodes in the current solution.

In the left-side navigation pane, double-click the created solution. All the created workflows in the solution appear. You can click a workflow name to show the created nodes in it and perform operations on the nodes and the workflow.

A workflow can be added to multiple solutions. After you develop a solution and add a workflow to the solution, other users can edit the workflow you referenced in their solutions for collaborative development.

2.5.2. SQL coding guidelines and specifications

This topic describes the basic guidelines and detailed specifications of SQL coding.

SQL coding guidelines

The SQL coding guidelines are as follows:

- Make sure that the code is comprehensive.
- Make sure that code lines are clear, neat, well-organized, and structured.
- Consider the optimal execution speed during SQL coding.
- Provide comments whenever necessary to enhance the readability of your code.
- The guidelines impose non-mandatory constraints on the coding behavior of developers. In practice, understandable deviations are allowed when developers obey general rules.
- Use lowercase letters for all keywords and reserved words. Keywords and reserved words include select, from, where, and, or, union, insert, delete, group, having, and count.
- In addition to keywords and reserved words, other code such as field names and table alias must be in lowercase.
- A unit of indentation contains four spaces. All indentations must be the integral multiple of an indentation unit. The code is aligned according to its hierarchy.
- The `select *` operation is prohibited. The column name must be specified for all operations.
- Matching opening and closing parentheses must be placed in the same column.

SQL coding specifications

The SQL coding specifications are as follows:

- Code header

The code header contains information such as the subject, description, author, and date. Reserve a line for change log and a title line so that later users can add change records. Each line can contain a maximum of 80 characters. The template is as follows:

```
-- MaxCompute(ODPS) SQL
_*****
-- ** Subject: Transaction
-- ** Description: Transaction refund analysis
-- ** Author: Youma
-- ** Created on: 20170616
-- ** Change log:
-- ** Modified on Modified by Content
-- yyyyymmdd name comment
-- 20170831 Wuma Add a comment on the biz_type=1234 transaction
_*****
```

- Field arrangement
 - Use a line for each field that is selected for the SELECT statement.
 - Separate the first field from SELECT by one indentation unit.
 - Enter another field name in a separate line after two indentation units.
 - Place the comma (,) between two fields right before the second field.
 - Place the AS statement in the same line as the corresponding field. We recommend that you keep the AS statements of multiple fields in the same column.

```
select  channel_id          as channel_id
        , trade_channel_desc as trade_channel_desc
        , trade_channel_edesc as trade_channel_edesc
        , inst_date         as inst_date
        , trade_iswap       as trade_iswap
        , channel_type      as channel_type
        , channel_second_desc as channel_second_desc
from    (
```

- Clause arrangement for an INSERT statement

Arrange the clauses of an INSERT statement in the same line.
- Clause arrangement for a SELECT statement

The clauses such as FROM, WHERE, GROUP BY, HAVING, ORDER BY, JOIN, and UNION in a SELECT statement must be arranged according to the following requirements:

 - Use a line for each clause.
 - Make sure that the clauses are left aligned with the SELECT statement.
 - Add two indentation units between the first word and the other code in a clause.
 - Keep the logical operators such as AND and OR in a WHERE clause left aligned with WHERE.

- If the length of a clause name exceeds two indentation units such as ORDER BY and GROUP BY, add a space between the clause name and its content.

```
select      trim(channel) channel
            ,min(id)      id
from        ods_trd_trade_base_dd
where       channel is not null
and         dt = ${tmp_uuuummdd}
and         trim(channel) <> ''
group by    trim(channel)
order by    trim(channel)
```

- Spacing before and after operators

Keep one space before and one space after the arithmetic and logical operators and keep the operators in the same line, unless the clause contains more than 80 characters.

```
select      trim(channel) channel
            ,min(id)      id
from        ods_trd_trade_base_dd
where       channel is not null
and         dt = ${tmp_uuuummdd}
and         trim(channel) <> ''
group by    trim(channel)
order by    trim(channel)
```

- CASE statement

The CASE statement can be used to determine the value of a field in a SELECT statement. Rules for writing CASE statements are as follows:

- Place the WHEN clause in the same line as the CASE statement, with one indentation unit between them.
- Keep a WHEN clause in one line whenever possible. If the statement is long, line breaks can be made.
- A CASE statement must contain an ELSE clause. The ELSE clause must be aligned with the WHEN clause.

```
, case      when p1.trade_from = '3008' and p1.trade_email is null then 2
            when p1.trade_from = '4000' and p1.trade_email is null then 1
            when p9.trade_from_id is not null then p9.trade_from_id
end
,p1.trade_email as trade_from_id
               as partner_id
```

- Nested query

Nested queries are often used in extract-transform-load (ETL) development of data warehouse systems. The following figure shows an example of a nested query.

```

select      p.channel
           ,rownumber() order_id
from        (
           select  s1.channel
                ,s1.id
           from      (
                   select  trim(channel)      as channel
                        ,min(id)             as id
                   from    ods_trd_trade_base_dd
                   where   channel is not null
                   and     dt = ${tmp_yyyymmdd}
                   and     trim(channel) <> ''
                   group  by trim(channel)
                ) s1
           left outer join
                dim_trade_channel s2
           on    s1.channel = s2.trade_channel_edesc
           where s2.trade_channel_edesc is null
           order by id
        ) p
;

```

- Table alias

- Once an alias is defined for a table in a SELECT statement, use the alias whenever you reference the table in the statement. Therefore, you must specify an alias for each table.
- We recommend that you define the table aliases with simple characters, such as a, b, c, and d in sequence, and avoid using keywords.

- In the nested query, levels 1 to 4 of SQL statements are named part, segment, unit, and detail, which are abbreviated as P, S, U, and D. You can also use a, b, c, and d to represent levels 1 to 4.

To differentiate multiple clauses at the same level, add numbers such as 1, 2, 3, and 4 next to the letters. Add comments to the table aliases as needed.

```

select      p.channel
            ,rownumber() order_id
from        (
            select  s1.channel
                ,s1.id
            from    (
                    select  trim(channel)      as channel
                        ,min(id)              as id
                    from    ods_trd_trade_base_dd
                    where   channel is not null
                    and     dt = ${tmp_yyyymmdd}
                    and     trim(channel) <> ''
                    group by trim(channel)
                ) s1
            left outer join
                dim_trade_channel s2
            on   s1.channel = s2.trade_channel_edesc
            where s2.trade_channel_edesc is null
            order by id
        ) p
;

```

- SQL comments
 - Add a comment for each SQL statement.
 - Use a separate line for the comment of each SQL statement and place the comment in front of the SQL statement.
 - Place the comment of a field right after the field.
 - Add comments for clauses that are difficult to understand.
 - Add comments for important code.
 - If a statement is long, we recommend that you add comments based on the purposes of each segment.
 - The description for a constant or variable is required. The comment on the valid value range is optional.

2.5.3. GUI elements

2.5.3.1. Overview

This topic describes the graphical user interface (GUI) elements on the DataStudio page and the configuration tab of an ODPS SQL node.

Log on to the DataWorks console. The **Data Analytics** page appears. You can double-click a created node to perform operations on the node configuration tab.

The following table describes the GUI elements.

No.	GUI element	Description
1	Show My Nodes Only icon	Click the icon to view your own nodes.

No.	GUI element	Description
2	Search Code icon	Click the icon to search for a node or a code segment.
3	Create icon	Click the icon to create a solution, workflow, folder, node, table, resource, or function.
4	Refresh icon	Click the icon to refresh the directory tree in the left-side navigation pane.
5	Locate icon	Click the icon to find the current node in the left-side navigation pane.
6	Import icon	<p>Click the icon to import local data to an online table. You must specify the encoding format.</p> <div style="background-color: #e0f2f1; padding: 5px; border: 1px solid #ccc;"> <p> Note In a workspace of the standard mode, the local data is imported to a table in the development environment.</p> </div>
7	Filter icon	Click the icon to query nodes based on the specified filter conditions.
8	Save icon	Click the icon to save the code of the current node.
9	Save as Ad-Hoc Query Node icon	Click the icon to save the code of the current node in an ad-hoc query node. You can find the node on the Ad-Hoc Query tab.
10	Commit icon	Click the icon to commit the current node.
11	Commit and Unlock icon	Click the icon to commit and unlock the current node for editing.
12	Steal Lock icon	Click the icon to steal the lock of the current node and then edit it if you are not the owner of the node.
13	Run icon	Click the icon to run the code of the current node. You only need to assign values to variables in SQL statements once. The initial values are retained even if the node code changes.
14	Run with Arguments icon	<p>Click the icon to run the code of the current node with the configured parameters. You must manually assign values to variables in SQL statements each time you click this icon. The initial values are passed to the Run with Arguments feature, which replaces the initial values with the assigned values.</p> <p>For example, if the run date of a node is set to April 2, the node always runs on April 2 when you click the Run icon. After you click Run with Arguments icon and change the run date to April 3, the run date is updated. When you click the Run icon again, the node is run on April 3.</p>
15	Stop icon	Click the icon to stop running the code of the current node.
16	Reload icon	Click the icon to reload the code of the current node. The code will be restored to the version last saved. Unsaved changes will be lost.

No.	GUI element	Description
17	Run Smoke Test icon	<p>Click the icon to test the code of the current node. A smoke test allows you to replace the values of scheduling parameters in the specified data timestamp with your simulated ones. This feature tests the effect of value changes for scheduling parameters.</p> <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> <p> Note Each time after you modify the values of scheduling parameters, you must save and commit the modification before running the smoke test. Otherwise, the new values of scheduling parameters do not take effect.</p> </div>
18	View Smoke Test Log icon	Click the icon to view the runtime logs of the current script template.
19	Format Code icon	Click the icon to format the code to avoid excessively long code in a single line.
20	Operation Center button	Click the icon to go to Operation Center.
21	Properties tab	Click the tab to configure the properties such as the scheduling properties, parameters, and resource group for the current node.
22	Lineage tab	Click the tab to view the relationships between the current node and other nodes.
23	Versions tab	Click the tab to view the committed and deployed versions of the current node.
24	Code Structure tab	Click the tab to view the code structure of the current node. If the code is excessively long, you can quickly find a code segment based on the key information in the structure.

2.5.3.2. Workflow Parameters

On the Workflow Parameters tab, you can assign a value to a variable or replace the value of a parameter for all nodes in the current workflow. This topic describes how to configure a workflow parameter by assuming that you want to replace the value of the ReplaceMe parameter with ReplaceMe123 in a manually triggered workflow.

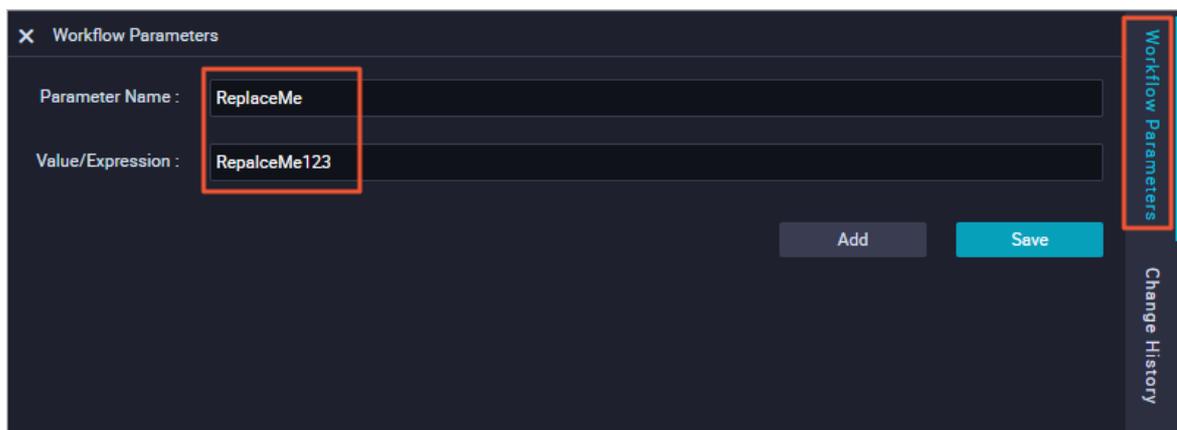

Limits

- In manually triggered workflows, ODPS SQL nodes, Shell nodes, and sync nodes support global parameters. The format for specifying a global parameter varies based on the node type. For example, a global workflow parameter is specified as `x=y1`.
 - To configure the workflow parameter for an ODPS SQL node, double-click the target node and click the **General** tab in the right-side navigation pane. On the **General** tab, enter `x=aaa` in the Arguments field. When the node is run, `x=aaa` specified in the Arguments field is replaced with `x=y1`. You can use `$x` to reference the workflow parameter in the code.
 - To configure the workflow parameter for a Shell node, double-click the target node and click the **General** tab in the right-side navigation pane. On the **General** tab, enter `$x` in the Arguments field. When the node is run, `x=aaa` specified in the Arguments field is replaced with `y1`. You can use `$1` to reference the workflow parameter in the code.

- To configure the workflow parameter for a sync node, double-click the target node and click the **General** tab in the right-side navigation pane. On the **General** tab, enter `-p"-Dx=aaa"` in the Arguments field. When the node is run, `x=aaa` specified in the Arguments field is replaced with `-p"-Dx=y1`. You can use `$x` to reference the workflow parameter in the code.
- In auto triggered workflows, only ODPS SQL nodes support global parameters.
- Parameter names and values are case-sensitive.

Configure a workflow parameter

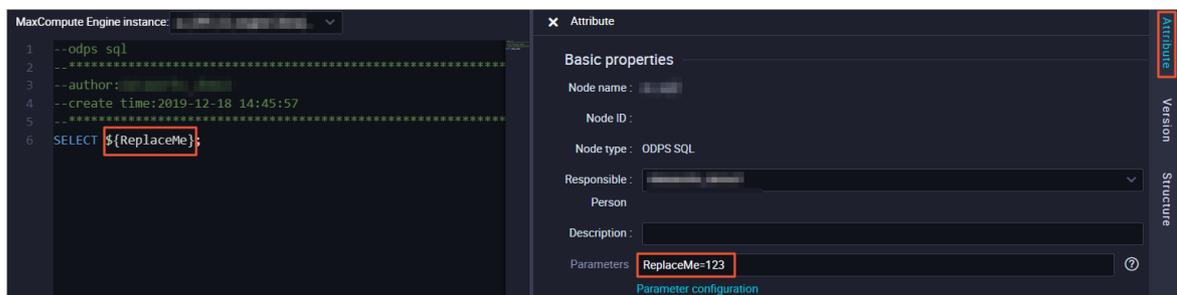

1. Log on to the DataWorks console.
2. In the left-side navigation pane, click **Manually Triggered Workflows**.
3. Double-click the target workflow to go to the workflow configuration tab.
4. In the right-side navigation pane, click the **Workflow Parameters** tab. In the Workflow Parameters pane, enter `ReplaceMe` in the **Parameter Name** field and `ReplaceMe123` in the **Value/Expression** field.

5. Click  in the toolbar.

Configure the workflow parameter for an ODPS SQL node

1. On the DataStudio page, click **Manually Triggered Workflows** in the left-side navigation pane.
2. Find the target workflow and choose **MaxCompute > Data Analytics** to show all the existing data analytics nodes. Double-click the target ODPS SQL node to go to the node configuration tab.
3. In the right-side navigation pane, click the **General** tab. In the General pane, enter `ReplaceMe=123` in the **Arguments** field.

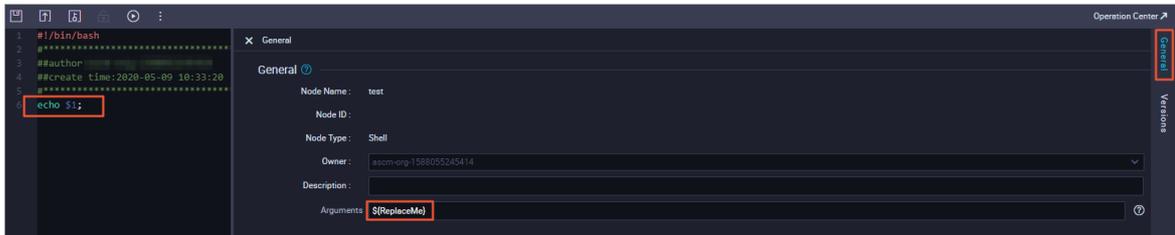

The workflow parameter is specified as `ReplaceMe=ReplaceMe123`. Therefore, the workflow parameter `ReplaceMe` is assigned the value `ReplaceMe123` for this node when the workflow is run.

4. Click  in the toolbar.

Configure the workflow parameter for a Shell node

1. On the **DataStudio** page, click **Manually Triggered Workflows** in the left-side navigation pane.
2. Find the target workflow and click **General** to show all the existing data analytics nodes. Double-click the target Shell node to go to the node configuration tab.
3. In the right-side navigation pane, click the **General** tab. In the General pane, enter `${ReplaceMe}` in the **Arguments** field.

Note Make sure that you enter the parameter in the correct format.

4. Click  in the toolbar.

Configure the workflow parameter for a sync node

1. On the **DataStudio** page, click **Manually Triggered Workflows** in the left-side navigation pane.
2. Find the target workflow and click **Data Integration** to show all the existing data integration nodes. Double-click the target sync node to go to the node configuration tab.
3. In the right-side navigation pane, click the **General** tab. In the General pane, enter `-p"ReplaceMe=abc"` in the **Arguments** field.

Note Make sure that you enter the parameter in the correct format, namely, `-p"-DParameter name=Parameter value"`.

4. Click  in the toolbar.

Run the workflow to view the result

On the configuration tab of the workflow, click  in the toolbar. In the Warning dialog box, click **Settings**. In the **Runtime Parameters** dialog box, set **Arguments** to `ReplaceMe`. The value of the workflow parameter is replaced when the workflow is run.

You can use the following methods to view the value assigned to the workflow parameter for different types of nodes:

- Right-click the ODPS SQL node and select **View Log**. Then, you can view the value assigned to the workflow parameter for the ODPS SQL node.
- Right-click the Shell node and select **View Log**. Then, you can view the value assigned to the workflow parameter for the Shell node.
- Right-click the sync node and select **View Log**. Then, you can view the value assigned to the workflow parameter for the sync node.

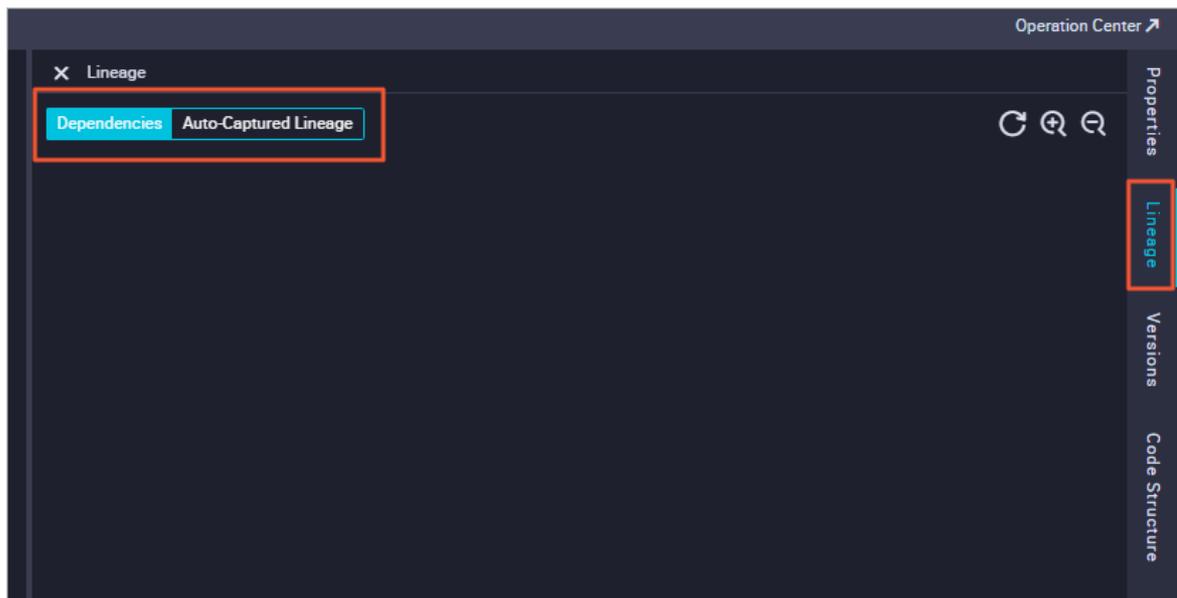

If you have not assigned a value to a workflow parameter on the **Workflow Parameters** tab for a manually triggered workflow, you must assign a value to the workflow parameter every time you run the workflow in the production environment.

2.5.3.3. Lineage

The Lineage tab displays the relationships between a node and other nodes. You can view the node dependencies and the lineage parsed from the code of the node.

Go to the Lineage tab

1. Log on to the DataWorks console.
2. Double-click the target node. For more information about how to create a node, see [Create an ODPS SQL node](#).
3. On the node configuration tab that appears, click the **Lineage** tab in the right-side navigation pane.

On the **Lineage** tab, you can click **Dependencies** to view the dependencies or click **Auto-Captured Lineage** to view the lineage.

View the dependencies

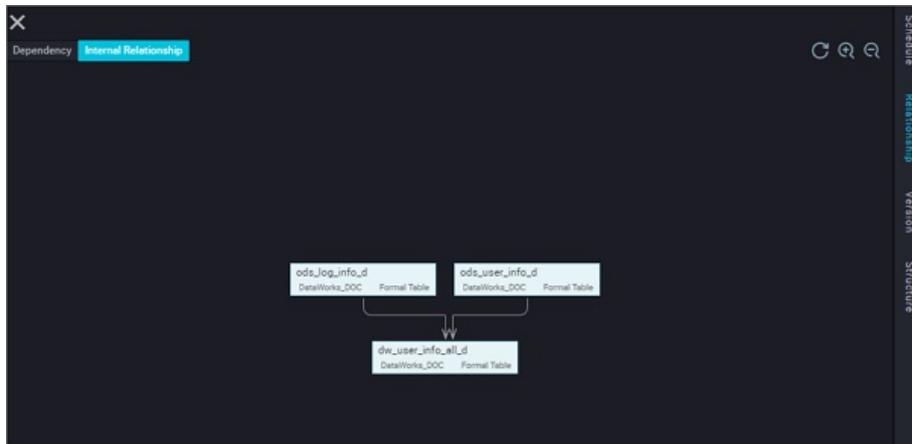

You can check the node dependencies presented based on the current configuration. If the node dependencies fail to meet your expectations, you can reconfigure the node dependencies on the Properties tab.

View the auto-captured lineage

The lineage is parsed based on the code of the current node. For example, an ODPS SQL node contains the following SQL statements:

```
INSERT OVERWRITE TABLE dw_user_info_all_d PARTITION (dt='${bdp.system.bizdate}')
SELECT COALESCE(a.uid, b.uid) AS uid
, b.gender
, b.age_range
, b.zodiac
, a.region
, a.device
, a.identity
, a.method
, a.url
, a.referer
, a.time
FROM (
  SELECT *
  FROM ods_log_info_d
  WHERE dt = ${bdp.system.bizdate}
) a
LEFT OUTER JOIN (
  SELECT *
  FROM ods_user_info_d
  WHERE dt = ${bdp.system.bizdate}
) b
ON a.uid = b.uid;
```

The following figure shows the lineage parsed from the preceding SQL statements. The results queried from the ods_log_info_d and ods_user_info_d tables are joined and then inserted into the dw_user_info_all_d table.

2.5.3.4. Versions

The Versions tab displays all committed and deployed versions of a node. You can view the historical versions and information about each version, including the user who committed the version, time when the version was committed, change type, status, and description.

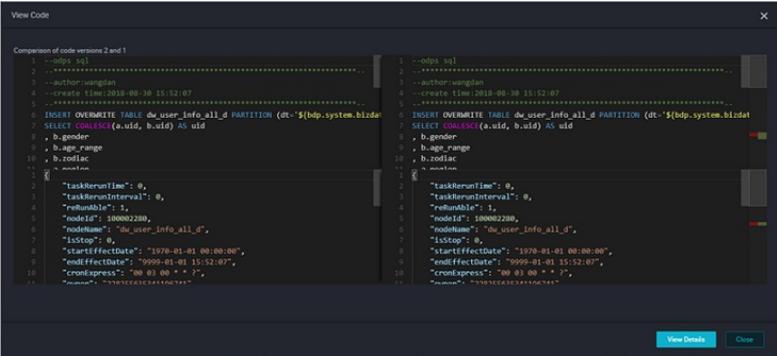

Note Only a committed node has the version information. Every time a node is committed, a version is generated and added to the Versions tab.

1. Log on to the DataWorks console.
2. On the **DataStudio** page, double-click the target node.
3. On the node configuration tab that appears, click the **Versions** tab in the right-side navigation pane. In

the Versions pane, view the committed and deployed versions of the current node.

Module	Relationship	Version	Structure					
<input type="checkbox"/>	5000118 87	V7	dataworks_demo2	2018-09-02 10:3 9:57	Edit	Published	test	View Code Roll Back
<input type="checkbox"/>	5000118 87	V6	dataworks_demo2	2018-09-02 10:3 7:47	Edit	Published	123	View Code Roll Back
<input type="checkbox"/>	5000118 87	V5	dataworks_demo2	2018-09-02 10:3 6:28	Edit	Published	test	View Code Roll Back
<input type="checkbox"/>	5000118 87	V4	dataworks_demo2	2018-09-02 10:3 3:54	Edit	Published	test	View Code Roll Back
<input type="checkbox"/>	5000118 87	V3	dataworks_demo2	2018-09-02 10:3 0:19	Edit	Published	test	View Code Roll Back
<input type="checkbox"/>	5000118 87	V2	wangdan	2018-08-31 10:2 1:19	Edit	Published	workshop user portrait part is written logically.	View Code Roll Back
<input type="checkbox"/>	5000118 87	V1	wangdan	2018-08-30 17:3 7:55	Add	Published	workshop user portrait part is written logically.	View Code Roll Back

GUI element	Description
File ID	The ID of the node.
Versions	The version of the node. A version is generated each time the node is committed and deployed. V1 indicates version 1 and V2 indicates version 2. The version number is incremented by 1 each time.
Committed By	The user who committed the version.
Committed At	The time when the version was committed. If a version is committed and then deployed at a later time point, the value of this parameter is updated to the time when the version is deployed. By default, this column records the time when the version is last operated.
Change Type	The operation on the node. The value of this parameter is Create if the node is committed and deployed for the first time or Change if the node is modified, committed, and then deployed.
Status	The status of the version. Valid values: <ul style="list-style-type: none"> ◦ Yes: The version is committed to the development environment but the related deployment task has not been created. The version has not been deployed in the production environment. ◦ Not Deployed: The version is committed to the development environment and the deployment task is created. The version is pending for deployment. ◦ Deployed: The version is committed to the development environment and deployed in the production environment.
Description	The change description of the version when it is committed. This description helps other users find the relevant version when they manage the node.

GUI element	Description
<p>Actions</p>	<p>The actions that you can perform on the version. Two actions are available: View Code and Roll Back.</p> <ul style="list-style-type: none"> ◦ View Code: Click the button to view the code of the current version. ◦ Roll Back: Click the button to roll back the node from the current version to the required version. After you roll back a node, you must commit and deploy it again.
<p>Compare</p>	<p>Click the button to compare the code and properties between two selected versions.</p>  <p>Click View Details. On the details page that appears, you can view the changes in code and properties.</p> <p>Note You can only compare two versions and cannot compare one or more than two versions at a time.</p>

2.5.3.5. Code Structure

The Code Structure tab displays the SQL code structure parsed from the code of a node. The code structure helps you view and modify the code.

1. Log on to the DataWorks console.
2. Double-click the ODPS SQL node whose code structure you want to view. For more information about how to create a node, see [Create an ODPS SQL node](#).
3. On the node configuration tab that appears, click the **Code Structure** tab in the right-side navigation pane.

```

1  --odps sql
2  .....
3  --author: .....
4  --create time:2020-05-09 11:16:53
5  .....
6  INSERT OVERWRITE TABLE dw_user_info_all_d PARTITION (dt='${bdp.system.bizdate}')
7  SELECT COALESCE(a.uid, b.uid) AS uid
8     , b.gender
9     , b.age_range
10    , b.zodiac
11    , a.region
12    , a.device
13    , a.identity
14    , a.method
15    , a.url
16    , a.referer
17    , a.time
18  FROM (
19     SELECT *
20     FROM ods_log_info_d
21     WHERE dt = '${bdp.system.bizdate}')
22     ) a
23  LEFT OUTER JOIN (
24     SELECT *
25     FROM ods_user_info_d
26     WHERE dt = '${bdp.system.bizdate}')
27     ) b
28  ON a.uid = b.uid;

```

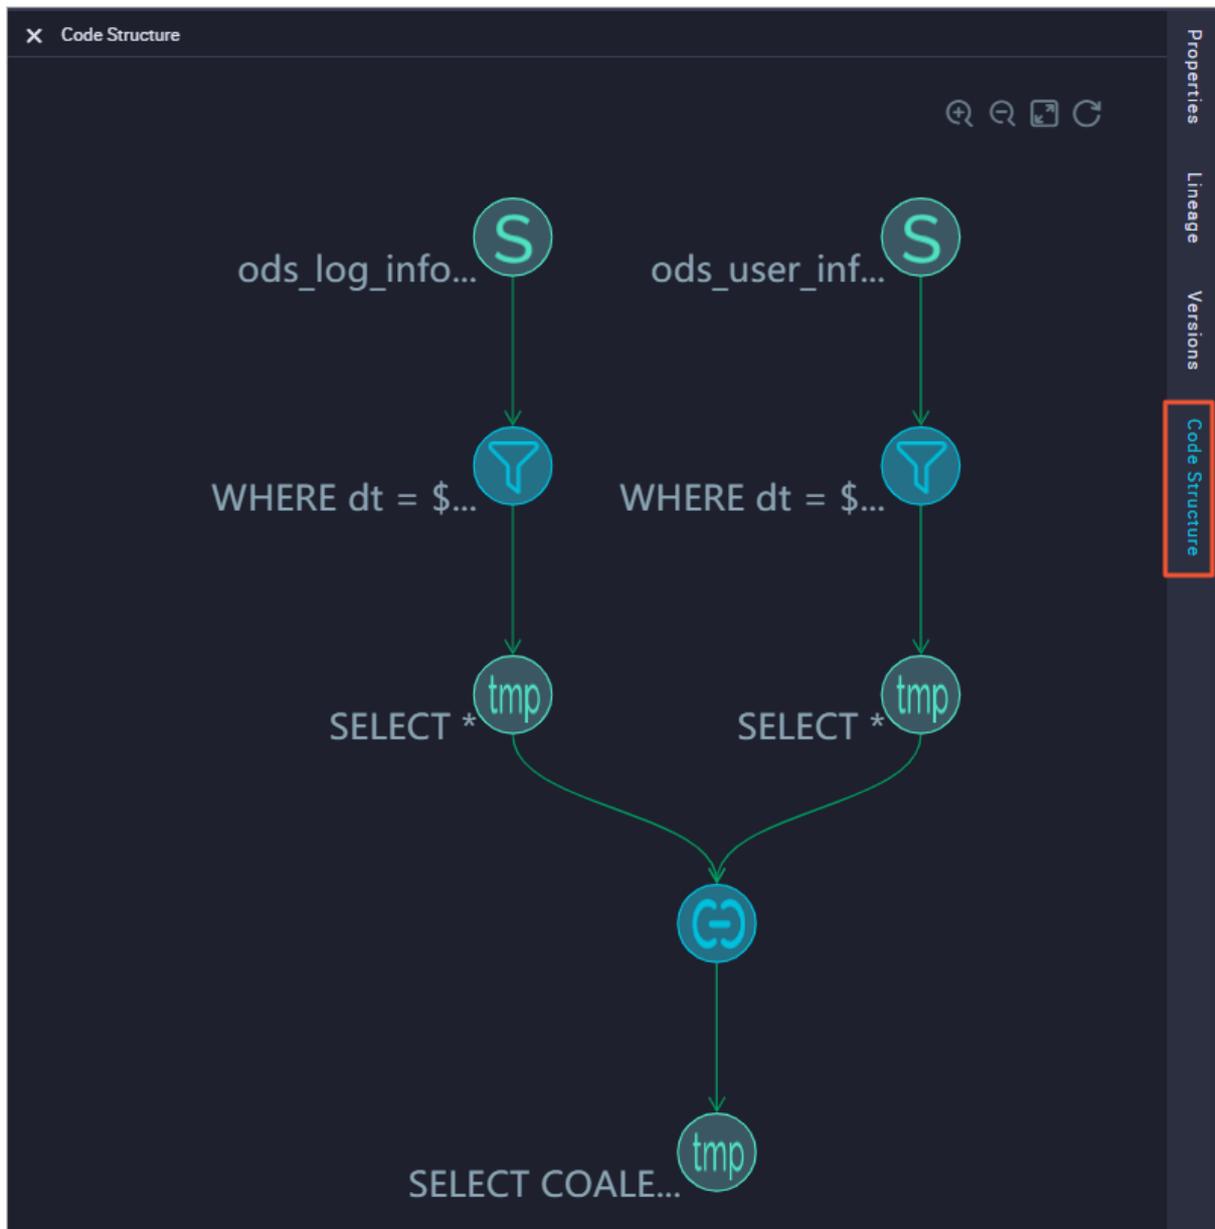

In this example, the ODPs SQL node contains the following SQL statement:

```

INSERT OVERWRITE TABLE dw_user_info_all_d PARTITION (dt='${bdp.system.bizdate}')
SELECT COALESCE(a.uid, b.uid) AS uid
, b.gender
, b.age_range
, b.zodiac
, a.region
, a.device
, a.identity
, a.method
, a.url
, a.referer
, a.time
FROM (
  SELECT *
  FROM ods_log_info_d
  WHERE dt = '${bdp.system.bizdate}')
) a
LEFT OUTER JOIN (
  SELECT *
  FROM ods_user_info_d
  WHERE dt = '${bdp.system.bizdate}')
) b
ON a.uid = b.uid;

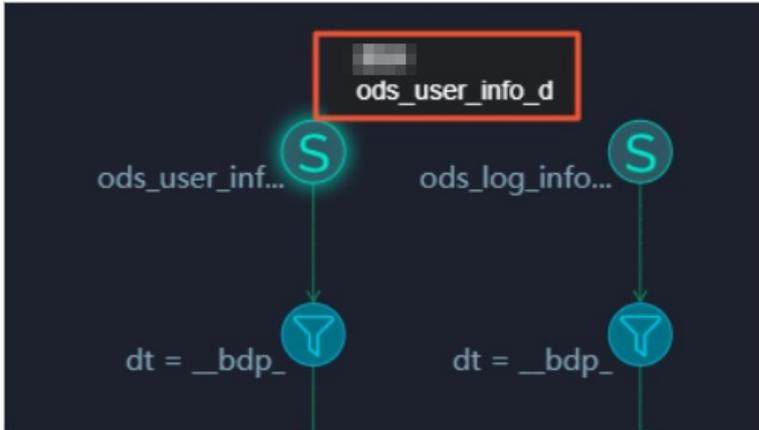

```

The following figure shows the code structure parsed from the preceding SQL statement.

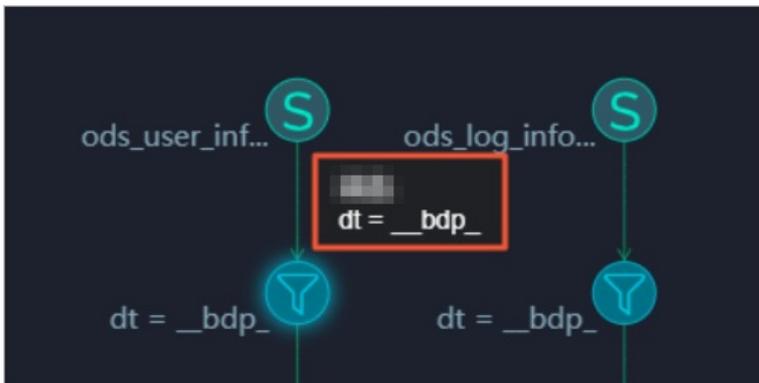

Move the pointer over a circle to view the description.

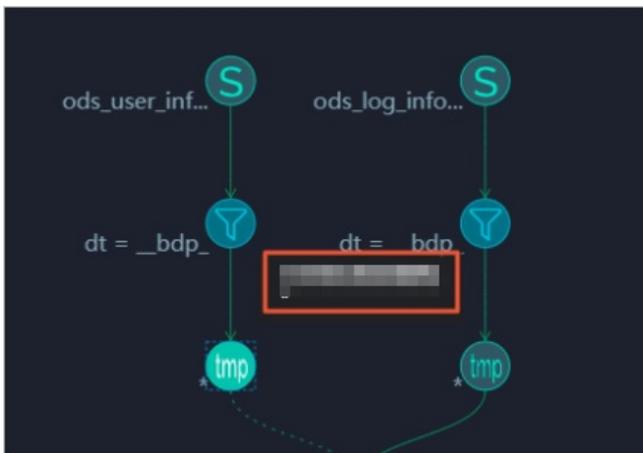

- **Source table:** the table to be queried.

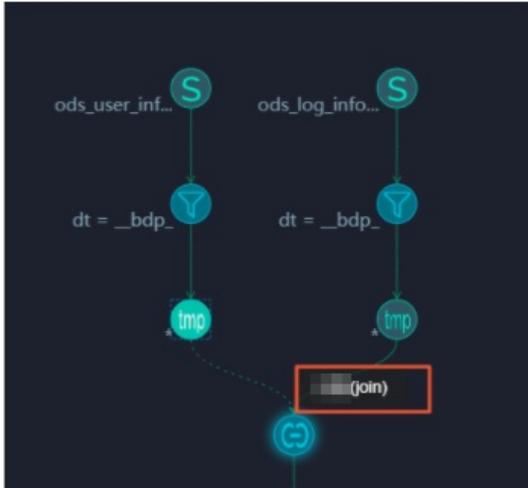

- **Filter:** the condition for filtering the partitions in the table to be queried.

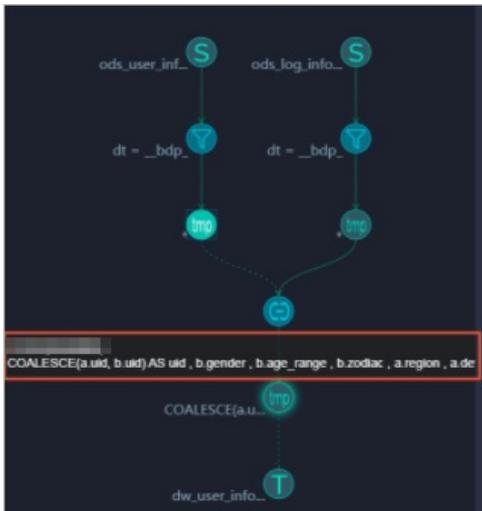

- **First intermediate table (view):** the temporary table that stores the query results.

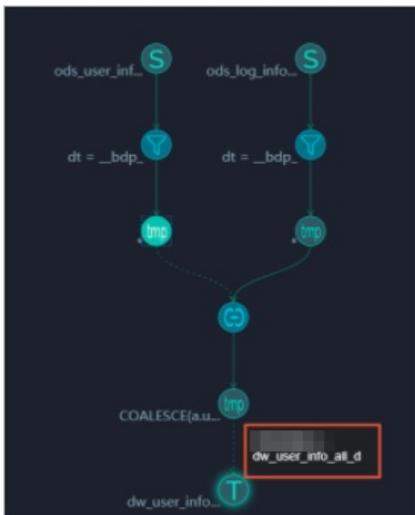

- **Join:** the operation for joining the query results.

- **Second intermediate table (view):** the temporary table that stores the results of the JOIN operation. This temporary table can be stored for three days. After three days, this table is automatically deleted.

- **Destination table (insert):** the destination table to which the query results are inserted by using an **INSERT OVERWRITE** statement.

2.5.4. Business flows

2.5.4.1. Overview

DataWorks organizes different types of nodes in a workflow by business category. This allows you to develop code by business.

DataWorks provides you with a dashboard for different types of nodes in each workflow. DataWorks also provides tools for you to optimize and manage nodes in each workflow. This promotes easy and intelligent development and management.

Workflow structure

A workspace supports multiple types of compute engines and multiple workflows. A workflow is a collection of various types of nodes that are closely associated with each other. DataWorks automatically generates a DAG so that you can view the workflow. A workflow supports the following types of nodes: data integration, data analytics, table, resource, function, and algorithm.

Each type of node has an independent folder. You can also create subfolders in each folder. To facilitate management, we recommend that you create a maximum of four levels of subfolders. If more than four subfolder levels are required, your workflow is too complex. We recommend that you split the workflow into two or more workflows and add the split workflows to one solution.

Create a workflow

1. Log on to the DataWorks console.
2. In the left-side navigation pane, click **Data Analytics**.
3. On the **Data Analytics** tab, right-click **Business Flow** and select **Create Workflow**.
4. In the **Create Workflow** dialog box, set **Workflow Name** and **Description**.

 **Notice** The name of the workflow, which cannot exceed 128 characters in length.

5. Click **Create**.

Workflow nodes

A workflow consists of the following types of nodes:

- **Data integration**

Click the target workflow and double-click **Data Integration** to view all data integration nodes of the workflow.

- **MaxCompute**

The MaxCompute engine supports various data analytics nodes, such as ODPS SQL, SQL Snippet, ODPS Spark, PyODPS, ODPS Script, and ODPS MR nodes. You can also view and create tables, resources, and functions.

- **Data analytics**

Right-click **Data Analytics** under **MaxCompute** in the target workflow and select **Create** to create a data analytics node of a specific type.

- **Table**

Click the target workflow and choose **Create > Table** under **MaxCompute** to create a table. You can also view all the tables that are created in the current MaxCompute project.

- **Resource**

Click the target workflow, choose **Create > Resource** under **MaxCompute**, and then click a specific resource type to create a resource. You can also view all the resources that are created in the current MaxCompute project.

- **Function**

Click the target workflow and choose **Create > Function** under **MaxCompute** to create a function. You can also view all the functions that are created in the current MaxCompute project.

- **EMR**

The E-MapReduce compute engine supports the following types of data analytics nodes: EMR Hive, EMR MR, EMR Spark, and EMR Spark SQL. You can also view and create E-MapReduce resources.

Note The EMR folder is available only after you create an E-MapReduce compute engine on the Project Management page.

- **Data analytics**

Click the target workflow, right-click **Data Analytics** under **EMR**, and then select **Create** to create a data analytics node of a specific type.

- **Resource**

Click the target workflow, right-click **Resource** under **EMR**, and then select **Create** to create a resource of a specific type. You can also view all the resources that are created in the current E-MapReduce compute engine.

- **Algorithm**

Click the target workflow, right-click **Algorithm**, and then choose **Create > PAI Experiment** to create a PAI Experiment node. You can also view all the PAI Experiment nodes that are created in the current workflow.

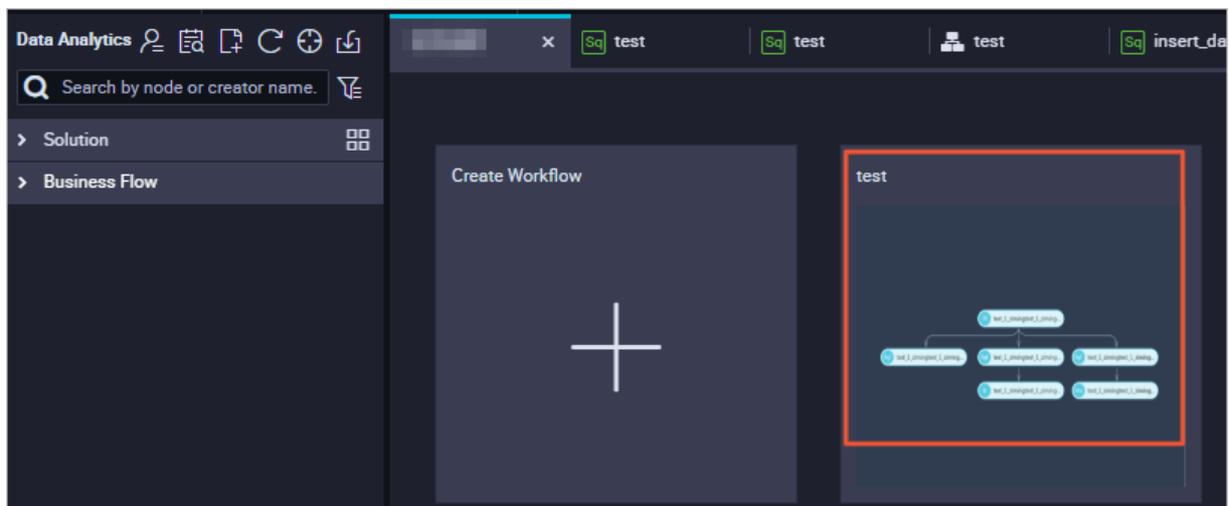

- **General**

Click the target workflow, right-click **General**, and then select **Create** to create a node of a specific type.

View all workflows

On the **Data Analytics** tab, right-click **Business Flow** and select **All Workflows** to view all workflows that are created in the current workspace.

Click a workflow. The dashboard of the workflow appears.

View the dashboard for each node type

DataWorks provides a dashboard for each type of nodes in a workflow. On the dashboard, each node is presented by a card that offers operation and optimization suggestions, so that you can intelligently manage nodes.

For example, the card of each data analytics node provides two indicators to show whether baseline-based monitoring and event notification are enabled for the node. This allows you to understand the status of each node.

You can double-click a folder in a workflow to view the dashboard of the selected node type.

Commit a workflow

1. Go to the dashboard of a workflow and click  in the toolbar.
2. In the **Commit** dialog box, select the nodes to be committed, set **Description**, and then select **Ignore I/O Inconsistency Alerts**.
3. Click **Commit**.

 **Note** If a node has been committed but the node code is not modified, the node cannot be selected again. In this case, you can enter your comments on the node and click **Commit**. The property changes of the node are automatically committed.

2.5.4.2. Create and reference a node group

This topic describes how to create and reference a node group.

Context

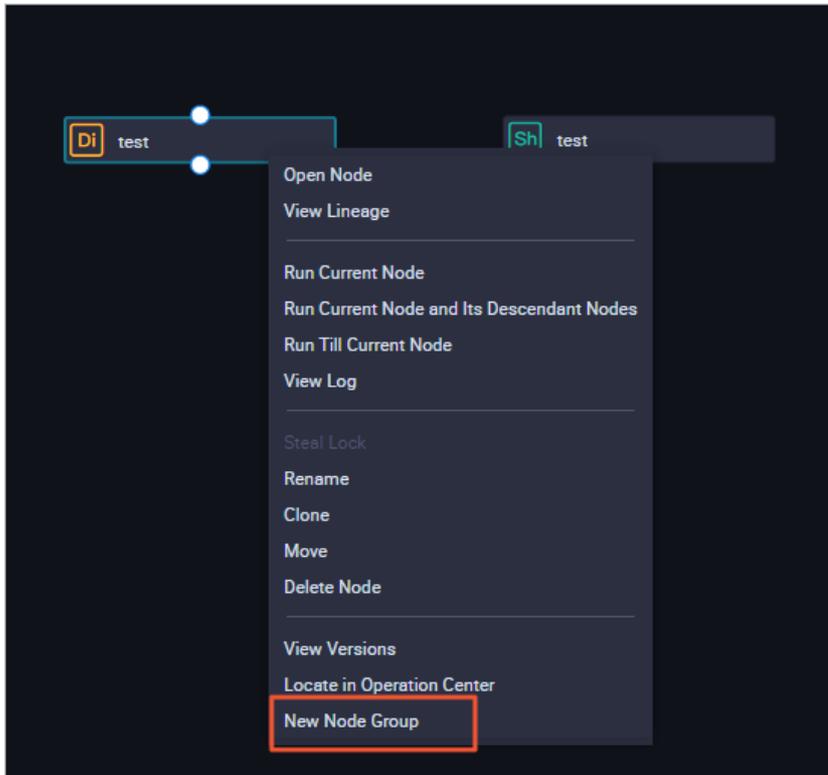

You can group several nodes that are frequently reused together as a node group. The configuration of each node remains unchanged after the nodes are added to a node group. Later, you can directly reference the node group to reuse these nodes.

Create a node group

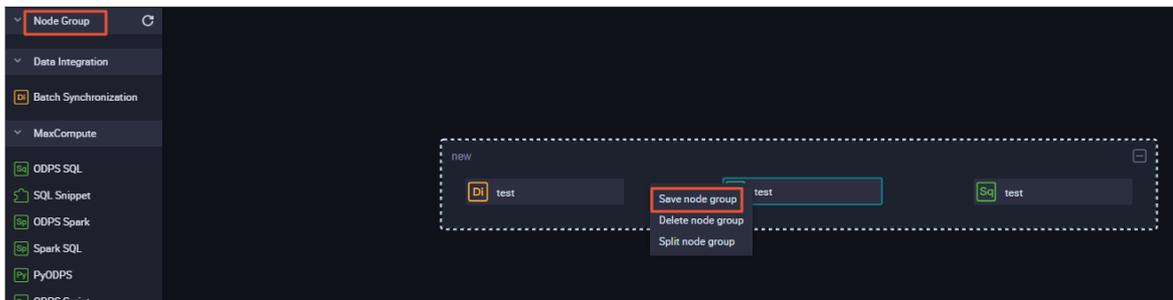

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, create a workflow. For more information, see [Create a workflow](#).
3. Go to the dashboard of the created workflow. Click  in the upper-right corner and drag a box to select the target nodes to be included in a node group.

4. Right-click any node among the selected nodes and select **New Node Group**.

5. In the **New Node Group** dialog box, enter a name in the **Name** field and click **OK**.
6. Right-click the node group and select **Save node group**. In the dialog box that appears, click **OK**. Then, you can view the created node group in the **Node Group** section.

Menu item	Description
Save node group	Save the node group. The node group that you have created appears in the Node Group section only after you click Save node group . A node group that is not saved cannot be referenced in other workflows.
Delete node group	Delete the node group. Click Delete node group to delete all nodes in the selected node group.
Split node group	Dismiss the node group. After the node group is dismissed, the selected nodes no longer form a node group in the workflow. However, the node group still exists in the Node Group section.

Note If the created node group contains a PAI Experiment node, create a PAI experiment in another workflow to reference the node group. If the created node group contains a branch node, add digits to the value in the **Associated Node Output** parameter.

Reference a node group

You can directly drag a node group to another workflow to reference the node group in the workflow. The dependencies among the nodes in the node group remain unchanged.

You can run the workflow or commit and deploy the workflow. Then, go to **Operation Center** to view the running result.

2.5.5. Node types

2.5.5.1. Data Integration

2.5.5.1.1. Create a batch sync node

Batch sync nodes support various types of data stores, including MaxCompute, MySQL, DRDS, SQL Server, PostgreSQL, Oracle, MongoDB, Db2, Table Store, OSS, FTP, HBase, LogHub, HDFS, and Stream.

Context

When you enter a table name, a drop-down list appears, displaying all matched tables. Only exact match is supported. Therefore, you must enter a complete table name. Tables are labeled as unsupported if they are not supported by batch sync nodes.

If you move the pointer over a table in the list, the details of the table appear, including the database, IP address, and owner of the table. After you select a table, the column information is automatically entered. You can add, move, and delete columns.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **Data Integration > Batch Synchronization**. Alternatively, you can click a workflow in the Business Flow section, right-click **Data Integration**, and then choose **Create > Batch Synchronization**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. Click **Commit**.
5. Configure the batch sync node. For more information, see [Overview](#).
6. On the configuration tab of the batch sync node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see [Basic properties](#).
7. Commit the node.

 **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

- i. Click  in the toolbar.
- ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
- iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the

batch sync node. For more information, see [Publish nodes](#).

8. Test the batch sync node. For more information, see [Manage auto triggered nodes](#).

2.5.5.2. MaxCompute

2.5.5.2.1. Create an ODPS SQL node

Using the SQL-like syntax, ODPS SQL nodes can process terabytes of data in distributed processing scenarios that do not require real-time processing.

Context

Generally, it takes a long time from preparing to committing a job. You can use ODPS SQL nodes to process thousands to tens of thousands of transactions. ODPS SQL nodes are online analytical processing (OLAP) applications designed to deal with large amounts of data.

Limits

- You cannot use SET statements, USE statements, or SQL alias statements independently in the code of an ODPS SQL node. They must be executed together with other SQL statements. For example, you can use a SET statement together with a CREATE TABLE statement.

```
set a=b;
create table name(id string);
```

- You cannot add comments to statements containing keywords, including SET statements, USE statements, and SQL alias statements, in the code of an ODPS SQL node. For example, the following comment is not allowed:

```
create table name(id string);
set a=b; // Comment.
create table name1(id string);
```

- The running of an ODPS SQL node during workflow development and the scheduled running of an ODPS SQL node have the following differences:
 - Running during workflow development: combines all the statements containing keywords, including SET statements, USE statements, and SQL alias statements, in the node code and executes them before executing other SQL statements.
 - Scheduled running: executes all SQL statements in sequence.

```
set a=b;
create table name1(id string);
set c=d;
create table name2(id string);
```

The following table shows the differences between the two running modes for the preceding SQL statements.

SQL statement	Running during workflow development	Scheduled running
First SQL statement	<pre>set a=b; set c=d; create table name1(id string);</pre>	<pre>set a=b; create table name1(id string);</pre>

SQL statement	Running during workflow development	Scheduled running
Second SQL statement	<pre>set a=b; set c=d; create table name2(id string);</pre>	<pre>set c=d; create table name2(id string);</pre>

- You must specify a scheduling parameter in the format of key=value. Do not add any spaces before or after the equation mark (=). Examples:

```
time = {yyyymmdd hh:mm:ss} // Incorrect format.
a =b // Incorrect format.
```

- If you use keywords such as bizdate and date as scheduling parameters, you must specify the values in the format of yyyymmdd. If you want to use other time formats, do not use the preceding keywords as scheduling parameters. Example:

```
bizdate=201908 // Incorrect format.
```

- You can only use statements starting with SELECT, READ, or WITH to query the result data for a node during the workflow development. Otherwise, no results are returned.
- Separate multiple SQL statements with semicolons (;) and place them in different lines.

- Incorrect example

```
create table1;create table2
```

- Correct example

```
create table1;
create table2;
```

Create an ODPS SQL node

- Log on to the DataWorks console.
- On the Data Analytics tab, move the pointer over  and choose **MaxCompute > ODPS SQL**.
Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > ODPS SQL**.

 **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

- In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

- Click **Commit**.
- Edit the code of the ODPS SQL node. Edit the code of the ODPS SQL node. The code must conform to the syntax. The following example creates a table, inserts data to the table, and queries data in the table:

- i. Create a table named test1.

```
CREATE TABLE IF NOT EXISTS test1
(id BIGINT COMMENT "",
name STRING COMMENT "",
age BIGINT COMMENT "",
sex STRING COMMENT "");
```

- ii. Insert data to the table.

```
INSERT INTO test1 VALUES (1,'Zhang San',43,'Male');
INSERT INTO test1 VALUES (1,'Li Si',32,'Male');
INSERT INTO test1 VALUES (1,'Chen Xia',27,'Female');
INSERT INTO test1 VALUES (1,'Wang Wu',24,'Male');
INSERT INTO test1 VALUES (1,'Ma Jing',35,'Female');
INSERT INTO test1 VALUES (1,'Zhao Qian',22,'Female');
INSERT INTO test1 VALUES (1,'Zhou Zhuang',55,'Male');
```

- iii. Query data in the table.

```
select * from test1;
```

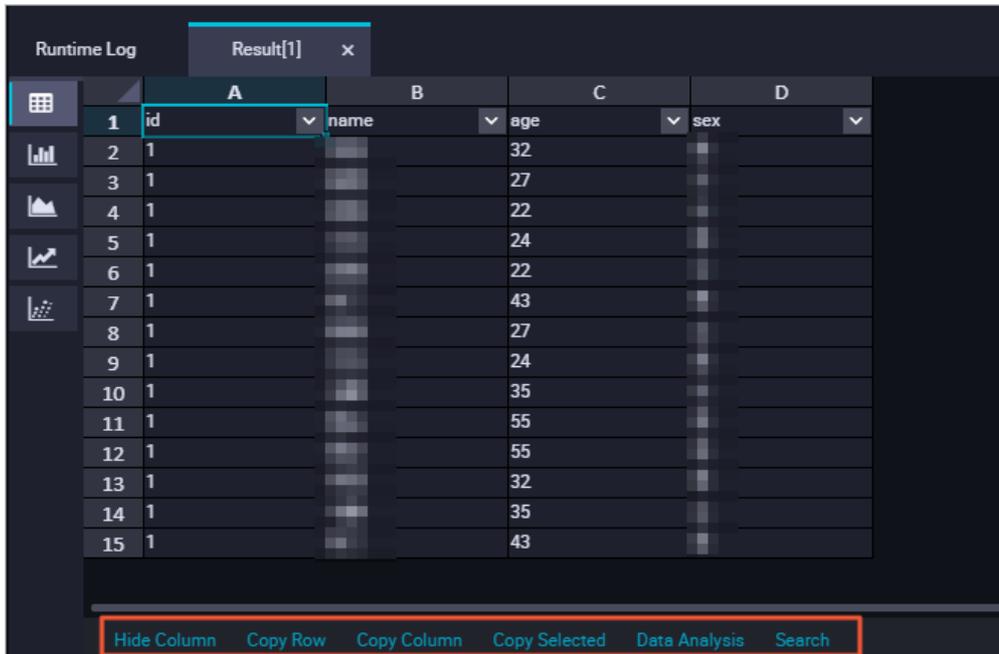

- iv. After you enter the preceding SQL statements in the code editor, click  in the toolbar. DataWorks executes your SQL statements from top to bottom and displays logs. The `INSERT INTO` statement may result in unexpected data duplication. Although DataWorks does not re-execute the `INSERT INTO` statement, it may rerun corresponding nodes. We recommend that you avoid using the `INSERT INTO` statement. When DataWorks executes the `INSERT INTO` statement, the following information appears in logs:

The `INSERT INTO` statement in SQL may cause repeated data insertion. Although SQL-level retries have been revoked for the `INSERT INTO` statement, task level retries may still happen. We recommend that you avoid the use of the `INSERT INTO` statement.

If you continue to use `INSERT INTO` statements, we deem that you are aware of the associated risks and are willing to take the consequences of potential data duplication.

- v. View the query result. DataWorks displays the query result in a workbook.

You can view or manage the query result in the workbook, or copy the query result to a local Excel file.

Action	Description
Hide Column	Select one or more columns and click Hide Column at the bottom to hide the selected columns.
Copy Row	Select one or more rows and click Copy Row at the bottom to copy the selected rows.
Copy Column	Select one or more columns and click Copy Column at the bottom to copy the selected columns.
Copy Selected	Select one or more cells in the workbook and click Copy Selected at the bottom to copy the selected cells.
Data Analysis	Click Data Analysis at the bottom to go to the workbook editing page.
Search	Click Search at the bottom to search for data in the workbook. After you click the button, a search box appears in the upper-right corner of the Results tab.

6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see [Basic properties](#).
7. Commit the node.

Notice You must set **Rerun** and **Parent Nodes** before you can commit the node.

- i. Click  in the toolbar.

- ii. In the **Commit Node** dialog box, ignore the alert on mismatch between the input and output that you set with those detected in code lineage analysis, enter your comments in the **Description** field, and then select **I confirm to proceed with the commission**.
- iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the ODPS SQL node. For more information, see [Publish nodes](#).

8. Test the node. For more information, see [Manage auto triggered nodes](#).

2.5.5.2.2. Create an SQL Snippet node

SQL script templates are SQL templates that involve multiple input and output parameters. Each SQL script template involves one or more source tables. You can use an SQL script template to filter, join, or aggregate data in source tables.

Context

When a new version is released for a script template, you can decide whether to upgrade the version of the script template used in your nodes to the latest version.

The script template upgrade mechanism allows developers to continuously upgrade script template versions. This mechanism enhances the process execution efficiency and optimizes the business performance.

For example, User A uses V1.0 of a script template that belongs to User B. Then, User B releases V2.0 for the script template. User A receives a notification of the new version. After User A compares the code of the two versions, User A can decide whether to upgrade the script template to the latest version.

To upgrade an SQL script template, click **Update Code** and check whether the parameter configuration of the SQL script template is valid in the new version. Set parameters for the SQL script template of the new version based on the version description. Then, save the node and commit it for deployment.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **MaxCompute > SQL Snippet**.
Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > SQL Snippet**.

 **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the node configuration tab, select a script template from the **Snippet** drop-down list. To improve development efficiency, you can create data analytics nodes by using the script templates provided by workspace members and tenants.
 - o The script templates provided by members of the current workspace are available on the **Workspace-Specific** tab.
 - o The script templates provided by tenants are available on the **Public** tab.
6. Click the **Parameters** tab in the right-side navigation pane and set parameters for the SQL script

template.

7. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see [Basic properties](#).
8. Commit the node.

 **Notice** You can commit the node only after you specify the Rerun and Parent Nodes parameters.

- i. Click the  icon in the toolbar.
- ii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.
- iii. Click **OK**.

In a workspace in standard mode, you must click **Publish** in the upper-right corner after you commit the node. For more information, see [Publish nodes](#).

9. Test the node. For more information, see [Recurring tasks](#).

2.5.5.2.3. Create an ODPS Spark node

DataWorks supports ODPS Spark nodes. This topic uses the JAR resource type as an example to describe how to create and configure an ODPS Spark node.

Create and upload a resource

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **MaxCompute > Resource > JAR**.
Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Resource > JAR**.

 **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

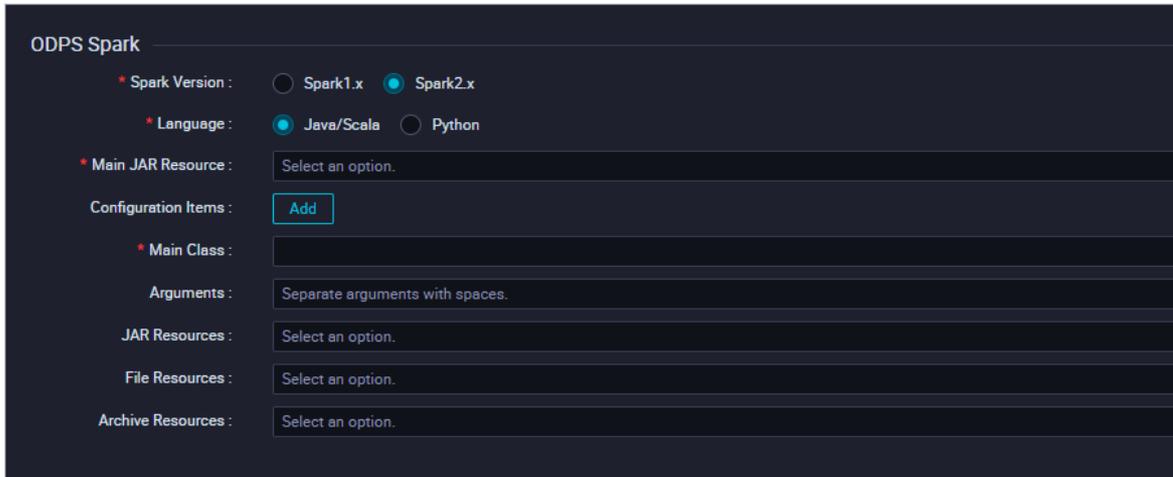

3. In the **Create Resource** dialog box, set **Resource Name** and **Location**.
4. Click **Upload** and select the target file to upload.
5. Click **OK**.

Create an ODPS Spark node

1. On the **Data Analytics** tab, move the pointer over  and choose **MaxCompute > ODPS Spark**.
Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > ODPS Spark**.
2. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (`_`), and periods (`.`).

3. Click **Commit**.
4. On the node configuration tab, set the parameters.

You can set **Spark Version** and **Language** as needed. The parameters vary with the value of the **Language** parameter. You can set the parameters as prompted.

The following table describes the parameters that appear after you set the Language parameter to **Java/Scala**.

Parameter	Description
Spark Version	The Spark version of the node. Valid values: Spark1.x and Spark2.x .
Language	The programming language of the node. Valid values: Java/Scala and Python . Select Java/Scala .
Main JAR Resource	The main JAR resource referenced by the node. Select a JAR resource that you uploaded from the drop-down list.
Configuration Items	The configuration items of the node. Click Add and set key and value to add a configuration item.
Main Class	The class name of the node.
Arguments	The parameter used to assign a value to a variable in the code during node scheduling. Separate multiple parameters with spaces.
JAR Resources	The JAR resource referenced by the node. Select a JAR resource that you uploaded from the drop-down list. The ODPS Spark node automatically finds the uploaded JAR resources based on the resource type.
File Resources	The file resource referenced by the node. Select a file resource that you uploaded from the drop-down list. The ODPS Spark node automatically finds the uploaded file resources based on the resource type.
Archive Resources	The archive resource referenced by the node. Select an archive resource that you uploaded from the drop-down list. The ODPS Spark node automatically finds the uploaded archive resources based on the resource type. Only compressed resources appear.

- On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see [Basic properties](#).
- Commit the node.

 **Notice** You can commit the node only after you specify the **Rerun** and **Parent Nodes** parameters.

- i. Click the  icon in the toolbar.
- ii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.
- iii. Click **OK**.

In a workspace in standard mode, you must click **Publish** in the upper-right corner after you commit the node. For more information, see [Publish nodes](#).

7. Test the node. For more information, see [Recurring tasks](#).

2.5.5.2.4. Create a PyODPS node

DataWorks supports PyODPS nodes, which are integrated with the Python SDK of MaxCompute. You can edit Python code in PyODPS nodes of DataWorks to process data in MaxCompute.

Context

You can also use the Python SDK of MaxCompute to process data in MaxCompute.

Note

- The Python version of PyODPS nodes is 2.7.
- Each PyODPS node can process a maximum of 50 MB data and can occupy a maximum of 1 GB memory. Otherwise, DataWorks terminates the PyODPS node. Avoid writing too much data processing code for a PyODPS node.

PyODPS nodes are designed to use the Python SDK of MaxCompute. If you want to run pure Python code, you can create a Shell node to run the Python scripts uploaded to DataWorks.

Create a PyODPS node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **MaxCompute > PyODPS**. Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > PyODPS**.

 **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (`_`), and periods (`.`).

4. Click **Commit**.
5. Edit the code of the PyODPS node on the node configuration tab.
 - i. Use the MaxCompute entry. Each PyODPS node includes the global variable `odps` or `o`, which is the MaxCompute entry. Therefore, you do not need to manually specify the MaxCompute entry.

```
print(odps.exist_table('PyODPS_iris'))
```

- ii. Run SQL statements. In PyODPS nodes, you can execute MaxCompute SQL statements to query data and obtain the query results. You can use the `execute_sql` or `run_sql` method to run MaxCompute job instances.

To execute statements that are not directly compatible with the MaxCompute console, you can use some methods. For example, you cannot directly execute statements other than DDL and DML in the MaxCompute console.

To execute a GRANT or REVOKE statement, use the `run_security_query` method. To run a PAI command, use the `run_xflow` or `execute_xflow` method.

```
o.execute_sql('select * from dual') # Execute the statement in synchronous mode. Other nodes are blocked until the SQL statement is executed.
instance = o.run_sql('select * from dual') # Execute the statement in asynchronous mode.
print(instance.get_logview_address()) # Obtain the Logview URL of an instance.
instance.wait_for_success() # Other nodes are blocked until the SQL statement is executed.
```

- iii. Set runtime parameters. You can use the `hints` parameter to set the runtime parameters. The type of the `hints` parameter is DICT.

```
o.execute_sql('select * from PyODPS_iris', hints={'odps.sql.mapper.split.size': 16})
```

If you set the `sql.settings` parameter for the global configuration, you must set the runtime parameters each time you run the code.

```
from odps import options
options.sql.settings = {'odps.sql.mapper.split.size': 16}
o.execute_sql('select * from PyODPS_iris') # The hints parameter is automatically set based on the global configuration.
```

- iv. Obtain SQL query results. You can use the `open_reader` method to obtain query results in the following scenarios:

- The SQL statement returns structured data.

```
with o.execute_sql('select * from dual').open_reader() as reader:
    for record in reader: # Process each record.
```

- SQL statements such as DESC are executed. In this case, you can use the `reader.raw` property to obtain raw query results.

```
with o.execute_sql('desc dual').open_reader() as reader:
    print(reader.raw)
```

 **Note** If you use a custom time variable, you must fix the variable to a time. PyODPS nodes do not support relative time variables.

6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see [Basic properties](#).

7. Commit the node.

 **Notice** You can commit the node only after you specify the **Rerun** and **Parent Nodes** parameters.

- i. Click the  icon in the toolbar.

- ii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.
- iii. Click **OK**.

In a workspace in standard mode, you must click **Publish** in the upper-right corner after you commit the node. For more information, see [Publish nodes](#).

8. Test the node. For more information, see [Recurring tasks](#).

Built-in modules for PyODPS nodes

A PyODPS node contains the following built-in modules:

- setuptools
- cython
- psutil
- pytz
- dateutil
- requests
- pyDes
- numpy
- pandas
- scipy
- scikit_learn
- greenlet
- six
- Other built-in modules in Python 2.7, such as smtplib

2.5.5.2.5. Create an ODPS Script node

You can create an ODPS Script node to develop an SQL script by using the SQL engine provided by MaxCompute V2.0.

Context

The ODPS Script node allows DataWorks to compile the SQL script as a whole, instead of compiling the SQL statements in the script one by one. In this way, the SQL script is committed and run as a whole. This guarantees that an execution plan is only queued and executed once, making full use of MaxCompute computing resources.

Create an ODPS Script node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **MaxCompute > ODPS Script**.
Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > ODPS Script**.

 **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. Edit the SQL script of the ODPS Script node as required.
6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see [Basic properties](#).
7. Commit the node.

 **Notice** You can commit the node only after you specify the **Rerun** and **Parent Nodes** parameters.

- i. Click the  icon in the toolbar.
- ii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.
- iii. Click **OK**.

In a workspace in standard mode, you must click **Publish** in the upper-right corner after you commit the node. For more information, see [Publish nodes](#).

8. Test the node. For more information, see [Recurring tasks](#).

SQL syntax and limits for ODPS Script nodes

Write SQL statements based on your business logic in a way similar to that of using a common programming language. You do not need to consider how to organize the SQL statements.

```
-- SET statements
set odps.sql.type.system.odps2=true;
[set odps.stage.reducer.num=***;]
[...]
-- DDL statements
create table table1 xxx;
[create table table2 xxx;]
[...]
-- DML statements
@var1 := SELECT [ALL | DISTINCT] select_expr, select_expr, ...
  FROM table3
  [WHERE where_condition];
@var2 := SELECT [ALL | DISTINCT] select_expr, select_expr, ...
  FROM table4
  [WHERE where_condition];
@var3 := SELECT [ALL | DISTINCT] var1.select_expr, var2.select_expr, ...
  FROM @var1 join @var2 on ...;
INSERT OVERWRITE|INTO TABLE [PARTITION (partcol1=val1, partcol2=val2 ...)]
  SELECT [ALL | DISTINCT] select_expr, select_expr, ...
  FROM @var3;
[@var4 := SELECT [ALL | DISTINCT] var1.select_expr, var.select_expr, ... FROM @var1
  UNION ALL | UNION
  SELECT [ALL | DISTINCT] var1.select_expr, var.select_expr, ... FROM @var2;
CREATE [EXTERNAL] TABLE [IF NOT EXISTS] table_name
  AS
  SELECT [ALL | DISTINCT] select_expr, select_expr, ...
  FROM var4;]
```

SQL syntax and limits for ODPS Script nodes

- ODPS Script nodes support SET statements, DML statements, and some DDL statements. The DDL statements used to return data, such as DESC and SHOW statements, are not supported.
- A complete script consists of SET statements, DDL statements, and DML statements in sequence. You can write one or more statements of each type, or even skip a type without writing any statements of that type. However, you cannot mix different types of statements together. You must strictly follow the sequence of SET statements > DDL statements > DML statements.
- The at signs (@) residing before some statements indicate that these statements are connected by using variables.
- A script supports only one statement that returns data, such as an independent SELECT statement. If multiple such statements are provided, an error occurs. We recommend that you do not use SELECT statements in a script.
- A script supports only one CREATE TABLE AS statement, which must be the last statement. We recommend that you put CREATE TABLE statements and INSERT statements in different sections to separate them.
- If one statement in a script fails, the whole script fails.
- A job is generated to process data only after all the input data is prepared for a script.
- If a script writes data to a table and then reads the table, an error occurs. For example, an error occurs for the following statements:

```
insert overwrite table src2 select * from src where key > 0;
@a := select * from src2;
select * from @a;
```

To avoid the error, modify the statements to the following:

```
@a := select * from src where key > 0;
insert overwrite table src2 select * from @a;
select * from @a;
```

Sample script:

```
create table if not exists dest(key string , value bigint) partitioned by (d string);
create table if not exists dest2(key string,value bigint ) partitioned by (d string);
@a := select * from src where value >0;
@b := select * from src2 where key is not null;
@c := select * from src3 where value is not null;
@d := select a.key,b.value from @a left outer join @b on a.key=b.key and b.value>0;
@e := select a.key,c.value from @a inner join @c on a.key=c.key;
@f := select * from @d union select * from @e union select * from @a;
insert overwrite table dest partition (d='20171111') select * from @f;
@g := select e.key,c.value from @e join @c on e.key=c.key;
insert overwrite table dest2 partition (d='20171111') SELECT * from @g;
```

Scenarios of ODPS Script nodes

- You can use an ODPS Script node to rewrite a single statement with nested subqueries, or a script that must be split into multiple statements due to its complexity.
- Data from different data stores may be prepared at different time points, and the time difference may be large. For example, the data from one data store can be prepared at 01:00, whereas that from another data store can be prepared at 07:00. In this case, table variables are not suitable for connecting statements. You can use an ODPS Script node to combine the statements to a script.

2.5.5.2.6. Create an ODPS MR node

MaxCompute supports the MapReduce API. You can create and commit ODPS MR nodes that call the Java API operations of MapReduce to develop MapReduce programs for processing data in MaxCompute.

Context

Before you create ODPS MR nodes, you must upload, commit, and then deploy required resources.

Create a resource

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **MaxCompute > Resource > JAR**.
Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Resource > JAR**.

 **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Resource** dialog box, set **Resource Name** and **Location**.

 **Note**

- The resource name can be different from the name of the uploaded file.
- Convention for naming resources: A resource name can contain letters, digits, underscores (`_`), and periods (`.`). It is not case-sensitive and must be 1 to 128 characters in length. A JAR resource name must end with `.jar`. A Python resource name must end with `.py`.

4. Click **Upload** and select the target file to upload.
5. Click **OK**.
6. Click  in the toolbar to commit the resource to the development environment.

Create an ODPS MR node

1. On the Data Analytics tab, find the target workflow, right-click **MaxCompute**, and then choose **Create > ODPS MR**.
2. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (`_`), and periods (`.`).

3. Click **Commit**.
4. Edit the ODPS MR node.

```

-- Create an input table.
CREATE TABLE if not exists jingyan_wc_in (key STRING, value STRING);
-- Create an output table.
CREATE TABLE if not exists jingyan_wc_out (key STRING, cnt BIGINT);
--- Create the dual table.
drop table if exists dual;
create table dual(id bigint); -- Create the dual table if no dual table exists in the current workspace and initialize the table.
--- Initialize the dual table.
insert overwrite table dual select count(*) from dual;
--- Insert the sample data to the wc_in table.
insert overwrite table jingyan_wc_in select * from (
select 'project','val_pro' from dual
union all
select 'problem','val_pro' from dual
union all
select 'package','val_a' from dual
union all
select 'pad','val_a' from dual
) b;
-- Reference the uploaded JAR package. You can find the JAR package in the resource list, right-click the JAR resource, and select Insert Resource Path.
--@resource_reference{"mapreduce-examples.jar"}
jar -resources mapreduce-examples.jar -classpath ./mapreduce-examples.jar com.aliyun.odps.mapred.open.example.WordCount jingyan_wc_in jingyan_wc_out

```

Pay attention to the following information when you write the code:

- `--@resource_reference` : references a resource. Find the target resource, right-click it, and then select **Insert Resource Path** to generate the reference statement.
 - `-resources` : the name of the referenced JAR resource.
 - `-classpath` : the path of the JAR resource. You can enter `./Resource name` because the resource has been referenced.
 - `com.aliyun.odps.mapred.open.example.WordCount` : the main class in the JAR resource to be called during node running. It must be the same as the main class name in the JAR resource.
 - `jingyan_wc_in` : the name of the input table of the ODPS MR node. The input table is created in the preceding code.
 - `jingyan_wc_out` : the name of the output table of the ODPS MR node. The output table is created in the preceding code.
 - If you use multiple JAR resources in a single ODPS MR node, separate the resource paths with commas (,), for example, `-classpath ./xxx1.jar,./xxx2.jar`.
5. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see [Basic properties](#).
 6. Commit the node.

 **Notice** You can commit the node only after you specify the **Rerun** and **Parent Nodes** parameters.

- i. Click the  icon in the toolbar.
- ii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.

iii. Click **OK**.

In a workspace in standard mode, you must click **Publish** in the upper-right corner after you commit the node. For more information, see [Publish nodes](#).

7. Test the node. For more information, see [Recurring tasks](#).

2.5.5.2.7. Create a MaxCompute table

This topic describes how to create a MaxCompute table.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **MaxCompute > Table**. Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Table**.

 **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Table** dialog box, set **Table Name** and click **Commit**.

 **Notice** A table name can be up to 64 characters in length. The table name must start with a letter and cannot contain Chinese or special characters.

4. On the table configuration tab that appears, set the parameters in the **General** section.

Parameter or button	Description
Display Name	The display name of the table.
Level 1 Folder	The name of the level-1 folder where the table resides.  Note Level-1 and level-2 folders only show the table locations in DataWorks so that you can better manage tables.
Level 2 Folder	The name of the level-2 folder where the table resides.
Create Folder	Goes to the Folder Management tab. On this tab, you can create level-1 and level-2 folders for tables.
Description	The description of the table.

5. Create a table. Use one of the following methods to create a table:

- o Create a table by using DDL statements.

Click **DDL Statement** in the top navigation bar. In the dialog box that appears, enter the statements for creating a table.

After you finish editing the statements, click **Generate Table Schema**. Information is automatically entered in the General, Physical Model, and Schema sections.

- Create a table on the graphical user interface (GUI).

If DDL statements are inappropriate for you to create a table, try to use the GUI. The following table describes the relevant parameters for creating a table on the GUI.

Section	Parameter or button	Description
Physical Model	Partitioning	Specifies whether the table is partitioned. Valid values: Partitioned Table and Non-Partitioned Table .
	Time-to-Live	The time-to-live of data in MaxCompute. If you select this check box, you must enter a number in the TTL field. If the table or partition is stored for more than the specified number of days, data that has not been updated is cleared.
	Table Level	The level of the table. Generally, tables are divided into operation data store (ODS), common data model (CDM), and application data service (ADS) levels. You can specify a custom level name.
	Categories	<p>The category of the table. Tables are categorized into basic services, advanced services, and other services. You can specify a custom category name.</p> <p>If you want to create a table category or level, click Create Level to go to the Level Management tab.</p> <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> <p> Note Categories are designed only for your management convenience and do not involve underlying implementation.</p> </div>
	Table Type	The type of the table. Default value: Internal Table .
	Field Name	The name of the field. The name can contain letters, digits, and underscores (_).
	Display Name	The display name of the field.
	Data Type	The data type of the field.
	Definition or Maximum Value Length	The maximum value length of a field. You can set a maximum value length only for fields of the DECIMAL, VARCHAR, ARRAY, MAP, and STRUCT types.
	Description	The description of the field.
	Primary Key Field	Specifies whether the field serves as the primary key or part of a composite primary key.
	Create Field	Adds a field to the table.

Section	Parameter or button	Description
Schema	Delete Field	Deletes a field from the table.  Note If you delete a field from an existing table, DataWorks requests you to delete the table and create another table with the same name. This operation is forbidden in the production environment.
	Move Up	Adjusts the field sequence of the table. If you adjust the sequence of fields in an existing table, DataWorks requests you to delete the table and create another table with the same name. This operation is forbidden in the production environment.
	Move Down	The description is the same as that of the Move Up operation.
	Add	Adds a partition to the table. If you add a partition to an existing table, DataWorks requests you to delete the table and create another table with the same name. This operation is forbidden in the production environment.
	Delete	Deletes a partition from the table. If you delete a partition from an existing table, DataWorks requests you to delete the table and create another table with the same name. This operation is forbidden in the production environment.
	Actions	Commits a partition or deletes a field.
Partition Field Design	Add	Adds a partition field.
	Data Type	The data type of the partition field. We recommend that you use the STRING type for all partition fields.
	Length	The maximum length of the partition field. You can set the maximum length only for fields of the VARCHAR-type.
	Description	The description of the partition field.
	Partition Column Date Format	The format of the date partition. If the partition field is a date, although the data type may be STRING, select or enter a date format, such as <i>yyyymmdd</i> or <i>yyyy-mm-dd</i> .
	Partition Column Date Granularity	The granularity of the date partition. The granularities can be second, minute, hour, day, month, quarter, and year. You can enter a partition granularity as required. If you want to specify multiple partition granularities, note that a greater granularity corresponds to a higher partition level. For example, three partitions whose granularities are day, hour, and month, respectively, are available. Multi-level partitions are in the hierarchical order of level-1 partition (month), level-2 partition (day), and level-3 partition (hour).

 **Note** This section is available only when Partitioning under Physical Model is set to Partitioned Table.

- Click **Commit in Development Environment** and **Commit to Production Environment** in sequence. If you are using a workspace in basic mode, you only need to click **Commit to Production Environment**.

Button	Description
Load from Development Environment	<p>If the table has been committed to the development environment, the button is clickable. After you click the button, the information about the table you create in the development environment overwrites the table information on the current page.</p> <p> Note This feature is supported only for MaxCompute tables.</p>
Commit in Development Environment	<p>Before you click the button, make sure that you have filled in all required parameters on the table configuration tab. Do not click the button if any parameters are not specified.</p>
Load from Production Environment	<p>After you click the button, the information about the table that is committed to the production environment overwrites the table information on the current page.</p> <p> Note This feature is supported only for MaxCompute tables.</p>
Commit to Production Environment	<p>After you click the button, the table is created in the workspace of the production environment.</p>

What's next

After the table is created, you can query the table data and modify or delete the table. For more information, see [Manage tables](#).

2.5.5.2.8. Create, reference, and download resources

This topic describes how to create, reference, and download JAR and Python resources.

Context

If your code or function requires resource files such as .jar files, you can upload resources to your workspace and reference them.

If the existing built-in functions do not meet your requirements, DataWorks allows you to create user-defined functions (UDFs) and customize processing logic. You can upload the required JAR packages to your workspace so that you can reference them when you create UDFs.

Note

- You can view built-in functions on the **Built-In Functions** tab. For more information, see [View built-in functions](#).
- You can view the UDFs that you have committed or deployed on the **MaxCompute Functions** tab.

The resources that you can upload to MaxCompute include text files, MaxCompute tables, Python code, and compressed packages in the .zip, .tgz, .tar.gz, .tar, and .jar formats. You can read or use these resources when you run UDFs or MapReduce.

MaxCompute provides API operations for you to read and use resources. The following types of MaxCompute resources are available:

- Python:** the Python code you have written. You can use Python code to register Python UDFs.

- **JAR**: the compiled Java JAR packages.
- **Archive**: the compressed files that can be identified by the file name extension. Supported file types include .zip, .tgz, .tar.gz, .tar, and .jar.
- **File**: files in the .zip, .so, or .jar format.

JAR resources and file resources have the following differences:

- To create a JAR resource, write Java code in the offline Java environment, compress the code to a JAR package, and upload the package as a JAR resource to DataWorks.
- To create a file resource that is smaller than or equal to 500 KB in size, you can create and edit it in the DataWorks console.
- To create a file resource that is larger than 500 KB in size, select **Large File (more than 500 KB)** and click Upload to upload the file.

 **Note** Each resource file to be uploaded in the DataWorks console cannot exceed 30 MB.

Create a JAR resource

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **MaxCompute > Resource > JAR**.
Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Resource > Python**.

 **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Resource** dialog box, set **Resource Name** and **Location**.

 **Note**

- The resource name can be different from the name of the uploaded file.
- A resource name can contain letters, digits, underscores (_), and periods (.), and is not case-sensitive. It must be 1 to 128 characters in length. A JAR resource name must end with .jar, and a Python resource name must end with .py.

4. Click **Upload** and select the target file to upload.
5. Click **OK**.
6. Click  in the toolbar to commit the resource to the development environment.

Create a Python resource and register a UDF

1. Create a Python resource.
 - i. On the **Data Analytics** tab, move the pointer over  and choose **MaxCompute > Resource > Python**. Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Resource > Python**.
 - ii. In the **Create Resource** dialog box, set **Resource Name** and **Location**.
 - iii. Click **OK**.

- iv. On the configuration tab that appears, edit the code of the created resource. Sample code:

```
from odps.udf import annotate
@annotate("string->bigint")
class ipint(object):
    def evaluate(self, ip):
        try:
            return reduce(lambda x, y: (x << 8) + y, map(int, ip.split('.')))
        except:
            return 0
```

- v. Click  in the toolbar.

2. Register a UDF.

- i. On the **Data Analytics** tab, move the pointer over  and choose **MaxCompute > Function**. Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Function**.
- ii. In the **Create Function** dialog box, set **Function Name** and **Location**.
- iii. Click **Commit**.
- iv. In the **Register Function** section of the configuration tab that appears, enter the class name and the name of the Python resource that has been created, and then click  in the toolbar. In this example, the class name is `ipint.ipint`.
- v. Check whether the ipint function is valid and meets your expectation. For example, you can create an ODPS SQL node to test the ipint function by running an SQL statement.

Reference and download resources

- For more information about how to reference resources for functions, see [Register a UDF](#).
- For more information about how to reference resources for nodes, see [Create an ODPS MR node](#).

To download a resource, double-click **Resource** under the target workflow. In the resource list that appears, move the pointer over the required resource and click **Download**.

2.5.5.2.9. Register a UDF

DataWorks allows you to develop UDFs in Python and Java. This topic describes how to register a UDF.

Prerequisites

Before you register a UDF, you must upload the related resource.

Procedure

1. Log on to the DataWorks console.
2. Create a workflow. For more information, see [Create a workflow](#).
3. Write Java code in the offline Java environment, compress the code to a JAR package, and upload the package as a JAR resource to DataWorks. For more information, see [Create a JAR resource](#).
4. Create a UDF.
 - i. Find the target workflow, right-click **MaxCompute**, and then choose **Create > Function**.
 - ii. In the **Create Function** dialog box, set **Function Name** and **Location** and click **OK**.

iii. In the **Register Function** section of the configuration tab that appears, set the parameters.

Parameter	Description
Function Type	The type of the function. Valid values: Mathematical Function, Aggregate Function, String Function, Date Function, Analytic Function, and Other.
Engine Instance MaxCompute	The MaxCompute engine instance bound to the current workspace. By default, you cannot change the engine instance.
Function Name	The name of the function, which is used to reference the function in SQL. The function name must be globally unique and cannot be modified after the function is registered.
Owner	The owner of the function. By default, this parameter is automatically set.
Class Name	Required. The name of the class for implementing the function. <div style="border: 1px solid #add8e6; padding: 5px; background-color: #e6f2ff;"> <p> Note If the resource type is Python, enter the class name in the Python resource name. Class name format. Do not include the .py extension in the resource name.</p> </div>
Resources	Required. The list of resources. You can search for existing resources in the current workspace in fuzzy match mode.
Description	The description of the function.
Expression Syntax	The instructions on how to use the function, for example, <code>test</code> .
Parameter Description	The description of supported input and output parameter types.
Return Value	Optional. The value to return. Example: 1.
Example	Optional. An example of the function.

5. Click  in the toolbar.

6. Commit the function.

i. Click  in the toolbar.

ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

iii. Click **OK**.

2.5.5.3. EMR

2.5.5.3.1. Create an EMR MR node

You can create an EMR MR node to compute a large-scale dataset by using multiple Map tasks in a parallel manner.

Prerequisites

The EMR folder is available on the DataStudio page only after you bind an E-MapReduce compute engine to the current workspace on the **Project Management** page.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **EMR > EMR MR**. Alternatively, you can click a workflow in the Business Flow section, right-click **EMR**, and then choose **Create > EMR MR**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the node configuration tab, select an E-MapReduce compute engine from the **Engine Instance EMR** drop-down list and edit the code of the node.
6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see [Basic properties](#).
7. Commit the node.
 - i. Click  in the toolbar.
 - ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
 - iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see [Publish nodes](#).

8. Test the node. For more information, see [Recurring tasks](#).

2.5.5.3.2. Create an EMR Spark SQL node

You can create an EMR Spark SQL node to use the distributed SQL query engine to process structured data, improving the task execution efficiency.

Prerequisites

The EMR folder is available on the DataStudio page only after you bind an E-MapReduce compute engine to the current workspace on the **Project Management** page.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **EMR > EMR Spark SQL**. Alternatively, you can click a workflow in the Business Flow section, right-click **EMR**, and then choose **Create > EMR Spark SQL**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.

5. On the node configuration tab, select an E-MapReduce compute engine from the **Engine Instance EMR** drop-down list and edit the code of the node.
6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see [Basic properties](#).
7. Commit the node.
 - i. Click  in the toolbar.
 - ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
 - iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see [Publish nodes](#).
8. Test the node. For more information, see [Recurring tasks](#).

2.5.5.3.3. Create an EMR Spark node

You can create an EMR Spark node to perform complex memory analysis and build large and low-latency data analysis applications.

Prerequisites

The EMR folder is available on the DataStudio page only after you bind an E-MapReduce compute engine to the current workspace on the **Project Management** page.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **EMR > EMR Spark**. Alternatively, you can click a workflow in the Business Flow section, right-click **EMR**, and then choose **Create > EMR Spark**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the node configuration tab, select an E-MapReduce compute engine from the **Engine Instance EMR** drop-down list and edit the code of the node.
6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see [Basic properties](#).
7. Commit the node.
 - i. Click  in the toolbar.
 - ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
 - iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see [Publish nodes](#).
8. Test the node. For more information, see [Recurring tasks](#).

2.5.5.3.4. Create an EMR Hive node

This topic describes how to create an EMR Hive node. This type of node allows you to use SQL-like statements to read data from, write data to, and manage data warehouses with a large amount of data stored in a distributed storage system. By using this type of node, you can efficiently analyze a large amount of log data.

Prerequisites

The EMR folder is available on the DataStudio page only after you bind an E-MapReduce compute engine to the current workspace on the **Project Management** page.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **EMR > EMR Hive**. Alternatively, you can click a workflow in the Business Flow section, right-click **EMR**, and then choose **Create > EMR Hive**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the node configuration tab, select an E-MapReduce compute engine from the **Engine Instance EMR** drop-down list and edit the code of the node.
6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see [Basic properties](#).
7. Commit the node.
 - i. Click  in the toolbar.
 - ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
 - iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see [Publish nodes](#).
8. Test the node. For more information, see [Recurring tasks](#).

2.5.5.4. Hologres

2.5.5.4.1. Create a Hologres SQL node

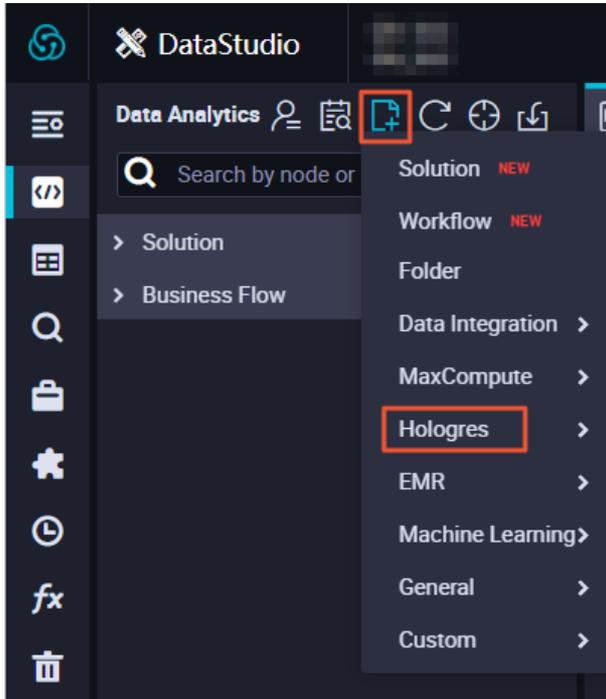

This topic describes how to create a Hologres SQL node. Hologres seamlessly integrates with MaxCompute at the underlying layer. This integration allows you to use standard PostgreSQL statements to query and analyze large volumes of data stored in MaxCompute. In this case, you do not need to transfer data. This allows you to quickly obtain query results.

Prerequisites

A **Hologres** compute engine instance is added on the **Project Management** page. This ensures that the **Hologres** folder is displayed on the page on which you want to create a Hologres SQL node.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the  icon and choose **Hologres > Hologres SQL**.

3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

 **Note** The name of the node must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the tab that appears, edit and run the code in the code editor. After the Hologres SQL node is created, edit the code in compliance with the required SQL syntax.
6. On the configuration tab of the node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure properties for the node. For more information, see [Basic properties](#).
7. Save and commit the node.

 **Notice** You must set the **Rerun** and **Parent Nodes** parameters before you commit the node.

- i. Click the  icon in the top toolbar to save the node.
- ii. Click the  icon in the top toolbar.
- iii. (Optional) In the **Commit Node** dialog box, enter your comments in the **Change description** field.
- iv. Click **OK**.

If the workspace that you use is in standard mode, you must click **Deploy** in the top navigation bar after you commit the node. For more information, see [Deploy nodes](#).

8. Test the node. For more information, see [Manage auto triggered nodes](#).

2.5.5.5. AnalyticDB for PostgreSQL

2.5.5.5.1. Create an AnalyticDB for PostgreSQL node

You can create AnalyticDB for PostgreSQL nodes in the DataWorks console to build an online extract, transform, load (ETL) process.

Prerequisites

The AnalyticDB for PostgreSQL compute engine is associated with the workspace in which you want to create an AnalyticDB for PostgreSQL node. The AnalyticDB for PostgreSQL folder is displayed in a workspace only after you associate an AnalyticDB for PostgreSQL compute engine instance with the workspace on the **Workspace Management** page. For more information, see [Create an AnalyticDB for PostgreSQL node](#).

Procedure

1. [Log on to the DataWorks console](#).
2. On the **DataStudio** page, move the pointer over the  icon and choose **AnalyticDB > ADB for PostgreSQL**. Alternatively, you can find the required workflow, right-click the workflow name, and then choose **Create > AnalyticDB for PostgreSQL > ADB for PostgreSQL**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The name of the node must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. Configure the AnalyticDB for PostgreSQL node.
 - i. Select a data source from the **Select a connection** drop-down list.

Notice

- When you associate the AnalyticDB for PostgreSQL compute engine with the workspace, DataWorks automatically creates an AnalyticDB for PostgreSQL data source.
- You can select a data source that is added only by using the connection string mode.

- ii. Compile SQL statements. After you select a data source, compile SQL statements based on the syntax that is supported by AnalyticDB for PostgreSQL.
 - iii. Click the  icon in the top toolbar to save the SQL statements.
 - iv. Click the  icon in the top toolbar to execute the SQL statements.
6. Click **Properties** in the right-side navigation pane. In the Properties panel, configure scheduling properties for the node. For more information, see [Basic properties](#).
 7. Save and commit the node.

 **Notice** You must specify the **Rerun** and **Parent Nodes** parameters in the Properties panel before you commit the node.

- i. Click  in the top toolbar to save the node.
- ii. Click the  icon in the top toolbar.
- iii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.

iv. Click **OK**.

If the workspace that you use is in standard mode, you must click **Deploy** in the upper-right corner after you commit the AnalyticDB for PostgreSQL node. For more information, see [Deploy nodes](#).

8. Test the node. For more information, see [Manage auto triggered nodes](#).

2.5.5.5.2. Create an AnalyticDB for PostgreSQL table

This topic describes how to create an AnalyticDB for PostgreSQL table.

Prerequisites

- An AnalyticDB for PostgreSQL instance is associated with the workspace in which you want to create an AnalyticDB for PostgreSQL table. The AnalyticDB for PostgreSQL folder is displayed on the DataStudio page of a workspace only after you associate an AnalyticDB for PostgreSQL instance with the workspace on the **Project Management** page. For more information, see [Create an AnalyticDB for PostgreSQL table](#).
- The metadata of the associated AnalyticDB for PostgreSQL instance is collected on the **Data Map** page. For more information, see [Collect metadata from an AnalyticDB for PostgreSQL data source](#).

Procedure

1. [Log on to the DataWorks console](#).
2. On the **DataStudio** page, move the pointer over the  icon and choose **AnalyticDB > table**.
Alternatively, you can find your workflow in the Business Flow section, right-click **AnalyticDB for PostgreSQL**, and then choose **Create > ADB visual table creation**.
3. In the **Create Table** dialog box, set **Table Name**.

Notice

- The table name must be in the format of `schema_name.table_name`.
- The values of `schema_name` and `table_name` must be 1 to 63 characters in length and can contain letters, digits, and underscores (`_`). The values must start with a letter or underscore (`_`).
- If you associate multiple AnalyticDB for PostgreSQL instances with the current workspace, you must select one based on your business requirements.

4. Click **Commit**. The table configuration tab appears. The upper part of the table configuration tab displays the table name and AnalyticDB for PostgreSQL instance name.
5. In the **General** section, set the parameters.

Parameter	Description
Level 1 theme	The name of the level-1 folder where the table resides.  Note Level-1 and level-2 folders show the table locations in DataWorks for you to manage tables more conveniently.
Level 2 theme	The name of the level-2 folder where the table resides.

Parameter	Description
Create a theme	<p>Click Create a theme to go to the Folder Management tab. On this tab, you can create level-1 and level-2 folders for tables.</p> <p>After you create a folder, click the  icon next to Create Folder to synchronize the folder.</p>
Description	The description of the table.

6. In the **Physical model design** section, set the parameters.

Parameter	Description
Level selection	The layer where the table data is stored or processed. A data warehouse consists of the operational data store (ODS), common data model (CDM), and application data store (ADS) layers. You can customize a name for each layer.
Physical classification	<p>The category of the table. Tables are categorized into basic services, advanced services, and other services. You can customize a name for each category.</p> <div style="border: 1px solid #add8e6; padding: 5px; background-color: #e6f2ff;"> <p> Note Categories are designed only for your management convenience and do not involve underlying implementation.</p> </div>
New Level	The levels and categories that you want to create. To add levels and categories, click New Level to go to the Hierarchical management tab. After levels and categories are created, click the  icon.

7. In the **AnalyticDB for PostgreSQL table design** section, set the parameters. You can configure the schema of an AnalyticDB for PostgreSQL table on the following tabs: **Column information settings**, **Index settings**, **Sub-table design**, and **Partition settings (optional)**.

Tab	Parameter	Description
Column information settings	New columns	Allows you to click the button and set the relevant parameters to create a field.
	Name	The name of the field.
	Field type	The data type of the field.
	Field length	The length of the field. You can specify the length for fields only of some specific data types.
	Default value	The default value of the field.
	Allow to be empty	Specifies whether the field can be empty.
	Is it the primary key?	Specifies whether the field serves as the primary key.
	Foreign key	Specifies whether the field serves as a foreign key.

Tab	Parameter	Description
	Operation	<ul style="list-style-type: none"> You can perform the following operations on a new field: save, cancel, delete, move up, and move down. You can perform the following operations on an existing field: modify, delete, move up, and move down.
Index settings	New columns	Allows you to click the button and set the relevant parameters to create an index.
	Index name	The name of the index. Make sure that you specify a unique name.
	Include columns	<p>The field on which the index will be created. To select a field, click Edit. In the Select at least one index dialog box, click the + icon. All the created fields appear in the Column information drop-down list.</p> <p>Select the field from the Column information drop-down list and click Save.</p>
	Index type	The type of the index. Valid values: Normal , Primary Key , and Unique .
	Index mode	The mode for indexing data in the fields. Valid values: B-tree , Bitmap , and GiST .
	Operation	<ul style="list-style-type: none"> You can perform the following operations on a new index: save, cancel, delete, move up, and move down. You can perform the following operations on an existing index: modify, delete, move up, and move down.
Sub-table design	Hash (Recommended) , Copy Schema , and Random (Not Recommended)	<p>The way in which the partition key is generated. Take Hash (Recommended) as an example. Click New columns and select the target field from the Name drop-down list. The information about the selected field appears. Click Save.</p> <p>For more information, see the Column information settings section of this table.</p>
Partition settings (optional)	Partition settings (optional)	The partitions of the table. You can configure the partitions based on your business requirements.

- Click **Submit to development environment** and **Submit to production environment** in sequence. If you are using a workspace in basic mode, you need only to click **Submit to production environment**.
- In the **Submit changes** dialog box, confirm that the table creation statements are correct, select a resource group from the **Select a resource group** drop-down list, and then click **Confirm execution**.

What's next

After the AnalyticDB for PostgreSQL table is created, you can query the table data, modify the table, or delete the table. For more information, see [Manage tables](#).

2.5.5.6. Algorithm

2.5.5.6.1. Create a PAI node

PAI nodes are used to call tasks that are created on PAI and schedule production activities based on the node configuration.

Prerequisites

To create a PAI node in DataWorks, you must first create a PAI experiment in PAI.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **Machine Learning > PAI Experiment**.
Alternatively, you can click a workflow in the Business Flow section, right-click **Algorithm**, and then choose **Create > PAI Experiment**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. Select the PAI experiment that you have created from the **Experiment** drop-down list and load it. If you want to modify the PAI experiment, click **Edit in PAI Console**.
6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see [Basic properties](#).
7. Commit the node.
 - i. Click  in the toolbar.
 - ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
 - iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see [Publish nodes](#).
8. Test the node. For more information, see [Recurring tasks](#).

2.5.5.7. General

2.5.5.7.1. Create a for-each node

This topic describes how to use a for-each node to repeat a loop twice and display the loop count.

Prerequisites

The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

Context

You can use a for-each node to repeat a loop for a maximum of 128 times. If the loop count exceeds this limit, an error occurs.

If the for-each node needs to perform logic judgment and result traversal, you can use the branch node. However, the branch node must be used with the merge node for result traversal.

Procedure

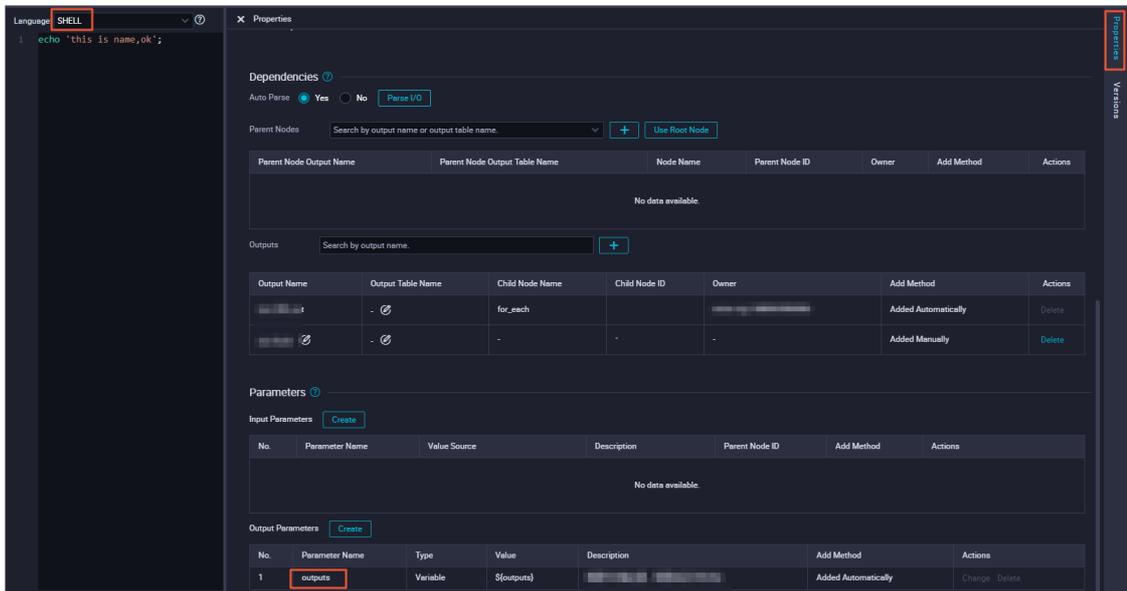

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **General > for-each**. Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > for-each**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. Create a workflow with an assignment node as the parent node and a for-each node as the child node.
For more information, see [Create a workflow](#).
 - i. Double-click the created assignment node. Set the language of the assignment node to SHELL, and enter the following code:

```
echo 'this is name,ok';
```

On the node configuration tab, click the **Properties** tab in the right-side navigation pane. By default, the **outputs** parameter appears in the **Output Parameters** section.

- ii. Double-click the created for-each node. Enter the following code for the for-each node:

```
echo ${dag.loopTimes} ----Display the loop count.
```

Note

- The start and end nodes of the for-each node have fixed logic and cannot be edited.
- After you modify the code of the Shell node, save the modification. No message will appear to remind you to save the modification when you commit the node. If you do not save the modification, the code cannot be updated to the latest version in time.

A for-each node supports the following environment variables:

- `${dag.foreach.current}`: the current data row.
- `${dag.loopDataArray}`: the input dataset.
- `${dag.offset}`: the offset of the loop count to 1.
- `${dag.loopTimes}`: the loop count, whose value equals to the value of `${dag.offset}` plus 1.

```
// Compare the code of the Shell node with that of a common for loop.
data=[] // It is equivalent to ${dag.loopDataArray}.
// i is equivalent to ${dag.offset}.
for(int i=0;i<data.length;i++) {
    print(data[i]); // data[i] is equivalent to ${dag.foreach.current}.
}
```

The `${dag.loopDataArray}` parameter is the default input parameter of the for-each node. Set this parameter to the value of the outputs parameter of the parent node. If you do not set this parameter, an error occurs when you commit the node.

6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see [Basic properties](#).
7. Commit the node.

 **Notice** You can commit the node only after you specify the **Rerun** and **Parent Nodes** parameters.

- i. Click the  icon in the toolbar.
- ii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.
- iii. Click **OK**.

In a workspace in standard mode, you must click **Publish** in the upper-right corner after you commit the node. For more information, see [Publish nodes](#).

8. Test the node. For more information, see [Recurring tasks](#).

2.5.5.7.2. Create a do-while node

You can define mutually dependent nodes, including a loop decision node named end, in a do-while node. DataWorks repeatedly runs the nodes and exits the loop only when the end node returns False.

Context

Note A loop can be repeated for a maximum of 128 times. If the loop count exceeds this limit, an error occurs.

The do-while node supports the MaxCompute SQL, SHELL, and Python languages. If you use MaxCompute SQL, you can use a **CASE WHEN** statement to evaluate whether the specified condition for exiting the loop is met.

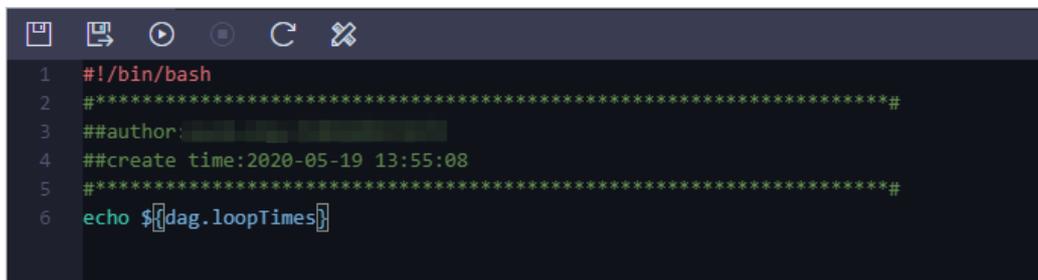

Simple example

This section describes how to use a do-while node to repeat a loop five times and display the loop count each time the loop runs.

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **General > do-while**. Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > do-while**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

Note The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (**_**), and periods (**.**).

4. Click **Commit**.
5. Define the loop body. By default, the do-while node consists of the start, SQL, and end nodes.
 - o The start node marks the start up of a loop and does not have any business effect.
 - o DataWorks provides the SQL node as a sample business processing node. You must replace the SQL node with your own business processing node, for example, a Shell node named Display loop count.

```
1 #!/bin/bash
2 #*****#
3 ##author: *****#
4 ##create time:2020-05-19 13:55:08
5 #*****#
6 echo ${dag.loopTimes}
```

- o The end node marks the end of a loop and determines whether to start the loop again. In this example, it defines the condition for exiting the loop for the do-while node.

The end node is an assignment node. It generates only True or False, indicating whether to start the loop again or exit the loop.

The `${dag.loopTimes}` variable is used in both the Display loop count node and the end node. It is a reserved variable of DataWorks. This variable indicates the loop count and the value increments from 1. All internal nodes of the do-while node can reference this variable.

In the code shown in the preceding figure, the value of the `dag.loopTimes` variable is compared with 5 to limit the loop count. The value of the `dag.loopTimes` variable is 1 when the loop runs for the first time and is incremented by 1 each time, for example, 2 for the second time. In the fifth loop, the value is 5. In this case, the result of `${dag.loopTimes}<5` is False, and the do-while node exits the loop.

6. Run the do-while node. You can configure the scheduling properties for the do-while node as needed and commit it to **Operation Center** for running.
 - o do-while node: The do-while node appears as a whole node in Operation Center. To view the loop details about the do-while node, right-click the node in the DAG and select **View Internal Nodes**.

- Internal loop body: This view is divided into three parts.
 - The left pane of the view lists the rerun history of the do-while node. A record is generated each time a do-while node instance is run.
 - The middle pane of the view shows a loop record list. A record is generated each time the loop of the do-while node is run. The running status of each loop also appears.
 - The right pane of the view shows the details about the do-while node each time the loop is run. You can click a record in the loop record list to view the running details.
7. View the running result. View the internal loop body. In the loop record list, click the record corresponding to the third loop. The loop count is 3 in the runtime logs.

You can also view the runtime logs of the end node that are generated when the loop runs for the third time and for the fifth time, respectively.

Based on the preceding simple example, the do-while node works in the following way:

- i. Run from the start node.
- ii. Run nodes in sequence based on the defined node dependencies.
- iii. Define the condition for exiting the loop in the end node.
- iv. Run the conditional statement of the end node after the loop ends for the first time.
- v. Record the loop count as 1 and start the loop again if the conditional statement returns True in the runtime logs of the end node.
- vi. Exit the loop if the conditional statement returns False in the runtime logs of the end node.

Complex example

In addition to simple scenarios, do-while nodes can also be used in complex scenarios where each row of data is processed in sequence by using a loop. Before you process data in such scenarios, make sure that:

- You have deployed a parent node that can export queried data to the do-while node. You can use an assignment node to meet this condition.
- The do-while node can obtain the output of the parent node. You can configure the node context and dependencies to meet this condition.
- The internal nodes of the do-while node can reference each row of data. In this example, the existing node context is enhanced and the system variable `#{dag.offset}` is used to reference the context of the do-while node.

This section describes how to use the do-while node to display the data entries in a table in sequence until all data entries in the table are displayed. Each time the loop runs, a data entry is displayed.

1. On the **Data Analytics** tab, double-click the created do-while node.
2. Define the loop body.
 - i. Create an assignment node named Initialize dataset and add it as the parent node of the do-while node. The parent node generates a test dataset.
 - ii. On the Properties tab of the do-while node, define an input parameter in the **Parameters** section. Set Parameter Name to input and Value Source to the output of the parent node.

- iii. Write code for the business processing node named Print each data row.
 - `${dag.offset}` : a reserved variable of DataWorks. This variable indicates the offset of the loop count to 1. For example, the offset is 0 when the loop runs for the first time and 1 for the second time. The offset equals to the loop count minus 1.

- `${dag.input}` : the context that you configure for the do-while node. In the preceding steps, the input parameter is defined for the do-while node and the value of the input parameter is the output of the parent node named Initialize dataset.

The internal nodes of the do-while node can directly use `${dag.${ctxKey}}` to reference the context. In this example, `ctxKey` is set to input. Therefore, you can use `${dag.input}` to reference the context.

- `${dag.input[${dag.offset}]}` : the data obtained from the table generated by the Initialize dataset node. DataWorks can obtain a row of data from the table based on the specified offset. The value of the `${dag.offset}` variable increments from 0. Therefore, the data entries such as `${dag.input[0]}` and `${dag.input[1]}` are returned until all data entries in the dataset are returned.

- iv. Define the condition for exiting the loop for the end node. The values of the `${dag.loopTimes}` and `${dag.input.length}` variables are compared, as shown in the following figure. If the value of the former is less than that of the latter, the end node returns True and the do-while node continues the loop. Otherwise, the end node returns False and the do-while node exits the loop.

```
Language: Python
1 if ${dag.loopTimes}<${dag.input.length}:
2     print True;
3 else
4     print False;
```

Note The system automatically sets the `${dag.input.length}` variable to the number of rows in the array specified by the input parameter based on the context configured for the do-while node.

- 3. Run the do-while node and view the running result.

Summary

- Compared with the while, foreach, and do...while statements, a do-while node has the following characteristics:
 - A do-while node contains a loop body that runs a loop before evaluating the conditional statement. This node functions the same as the do...while statement. A do-while node can also use the system variable `${dag.offset}` and the node context to implement the feature of the foreach statement.
 - A do-while node cannot achieve the feature of the while statement because a do-while node runs a loop before evaluating the conditional statement.
- A do-while node works in the following way:
 - i. Run nodes in the loop body starting from the start node based on node dependencies.
 - ii. Run the code defined for the end node.
 - Run the loop again if the end node returns True.
 - Exit the loop if the end node returns False.
- How to use the node context: The internal nodes of a do-while node can use `${dag.${ctxKey}}` to reference the context defined for the do-while node.
- System parameters: DataWorks provides the following system variables for the internal nodes of the do-

while node:

- $\{\text{dag.loopTimes}\}$: the loop count, starting from 1.
- $\{\text{dag.offset}\}$: the offset of the loop count to 1, starting from 0.

2.5.5.7.3. Create a merge node

This topic describes the definition of merge nodes and how to create a merge node and define the merging logic. It also provides an example to show the scheduling configuration and running details of a merge node.

A merge node is a logical control node in DataStudio. It can merge the running results of its parent nodes, regardless of their running statuses. It aims at facilitating the running of nodes that depend on the output of the child nodes of a branch node.

You cannot change the running status of a merge node. A merge node merges the running results of multiple child nodes of a branch node and sets the running status to Successful. To guarantee the proper running of a node that depends on the output of the child nodes of a branch node, you can configure the node to directly depend on the merge node.

For example, Branch node C has two logically exclusive branches C1 and C2. These two branches use different logic to write data to the same MaxCompute table. Assume that Node B depends on the output of this MaxCompute table. To make sure that Node B can run properly, you must use Merge node J to merge the running results of branches C1 and C2, and then configure Merge node J as the parent node of Node B. If Node B directly depends on branches C1 and C2, one of the branches will fail to run because only one branch meets the branch condition each time Branch node C runs. In this case, Node B cannot be triggered as scheduled.

Create a merge node

1. [Log on to the DataWorks console.](#)
2. On the Data Analytics tab, move the pointer over  and choose **General > MERGE Nodes**.

Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > MERGE Nodes**.

3. In the **Create Node** dialog box, set **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (`_`), and periods (`.`). It is not case-sensitive.

4. Click **Commit**.

Define the merging logic

After the merge node is created, the node configuration tab appears. Specify the branches to be merged for the node. Enter the output name or output table name of the parent node, and click the **Add** icon. You can view the running status in the **Result** section. The available running statuses are **Successful** and **Branch Not Running**.

Click the **Properties** tab in the right-side navigation pane and configure the scheduling properties of the merge node.

Run the merge node

If a branch meets the specified condition, the branch is run. You can select the branch and view the running details on the **Runtime Logs** tab.

If a branch does not meet the specified condition, the branch is skipped. You can select the branch and view related information on the **Runtime Logs** tab.

2.5.5.7.4. Create a branch node

A branch node is a logical control node in DataStudio. It can define the branch logic and the direction of branches under different logical conditions.

Prerequisites

Generally, branch nodes need to be used with assignment nodes.

Create a branch node

1. [Log on to the DataWorks console.](#)
2. On the Data Analytics tab, move the pointer over  and choose **General > Branch Node**. Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Branch Node**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (`_`), and periods (`.`). It is not case-sensitive.

4. Click **Commit**.
5. Define the branch logic
 - i. In the **Definition** section, click **Add Branch**.
 - ii. In the **Branch Definition** dialog box, set the parameters.

Parameter	Description
Condition	<p>The condition of the branch.</p> <ul style="list-style-type: none">■ You can only use Python comparison operators to define logical conditions for the branch node.■ If the result of the expression is <i>true</i> when the node is running, the corresponding branch condition is met.■ If the expression fails to be parsed when the node is running, the whole branch node fails.■ To define branch conditions, you can use global variables and parameters defined in the node context. For example, the <code>#{input}</code> variable can be used as an input parameter of the branch node.
Associated Node Output	<p>The associated node output of the branch.</p> <ul style="list-style-type: none">■ The node output is used to configure dependencies for the child nodes of the branch node.■ If the branch condition is met, the child node corresponding to the node output is run. If the child node also depends on the output of other nodes, the status of these nodes is considered.■ If the branch condition is not met, the child node corresponding to the node output is not run. The child node is set to the Not Running state.
Description	<p>The description of the branch. For example, the branches <code>#{input}==1</code> and <code>#{input}>2</code> are defined.</p>

- iii. Click **OK**. After you add a branch, you can click **Change** or **Delete** in the Actions column of the branch to modify or delete it.
 - Click **Change** to modify the branch and related dependencies.
 - Click **Delete** to delete the branch and related dependencies.
6. On the configuration tab of the branch node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. After the branch conditions are defined, the output names are automatically added to the **Outputs** section on the **Properties** tab. Then, you can associate child nodes with the branch node based on the output names.

 **Note**

- Child nodes inherit dry-run properties of the parent node. Therefore, we recommend that you do not create a node depending on its last-cycle instance as the branch.
- The dependencies established by drawing lines between nodes on the dashboard of a workflow are not recorded on the Properties tab. You must manually enter these dependencies.

7. Commit the node.

 **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

- i. Click  in the toolbar.
- ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
- iii. Click **OK**.

In a workspace in standard mode, you need to click **Deploy** in the upper-right corner after you commit the branch node.

8. Test the node.

Supported Python comparison operators

In the following table, assume that the value of the a variable is 10 and that of the b variable is 20.

Comparison operator	Description	Example
==	Equal: checks whether two objects are equal.	(a==b) returns false.
!=	Not equal: checks whether two objects are not equal.	(a!=b) returns true.
<>	Not equal: checks whether two objects are not equal.	(a<>b) returns true. This operator is similar to !=.
>	Greater than: checks whether the variable on the left side of the operator is greater than that on the right side.	(a>b) returns false.

Comparison operator	Description	Example
<	Less than: checks whether the variable on the left side of the operator is less than that on the right side. If the return result is 0 or 1, 0 indicates false and 1 indicates true. These two results are equivalent to the special variables true and false, respectively.	(a<b) returns true.
>=	Greater than or equal to: checks whether the variable on the left side of the operator is greater than or equal to that on the right side.	(a>=b) returns false.
<=	Less than or equal to: checks whether the variable on the left side of the operator is less than or equal to that on the right side.	(a<=b) returns true.

2.5.5.7.5. Create an assignment node

An assignment node uses one of the three value assignment languages MaxCompute SQL, SHELL, and Python to assign values by using the outputs parameter. This node is used to transmit data between a parent node and a child node based on context-based parameters.

Context

The outputs parameter has the following limits:

- The value of the outputs parameter is taken only from the output of the last line of the code.
 - If you use MaxCompute SQL, the output of the SELECT statement in the last line is used.
 - If you use SHELL, the output of the ECHO statement in the last line is used.
 - If you use Python, the output of the PRINT statement in the last line is used.
- The passed value of the outputs parameter is limited to 2 MB in size. If the output of the assignment statement exceeds this limit, the assignment node fails to run.

 **Note** If you use Python or SHELL, the value of the outputs parameter is a one-dimensional array where elements are separated with commas (.). If you use MaxCompute SQL, the value of the outputs parameter is passed to child nodes as a two-dimensional array.

Create an assignment node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **General > Assignment Node**.
Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Assignment Node**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

 **Notice** A node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

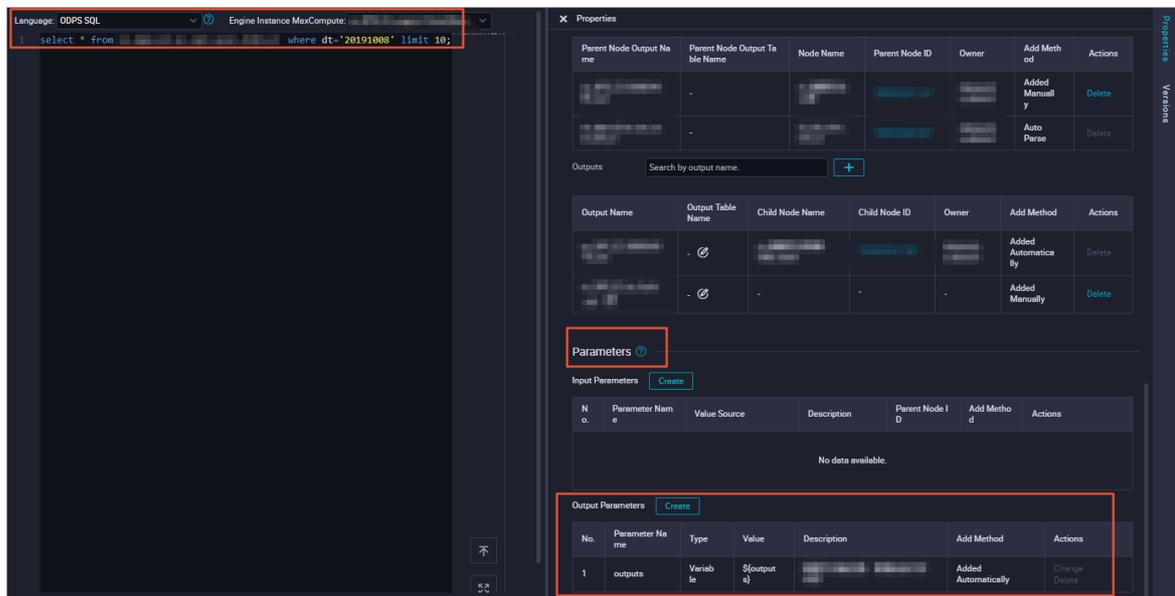

This following sections describe how to use assignment nodes that use the Python, MaxCompute SQL, and SHELL languages respectively to pass data between a parent node and a child node named Assignment node value comparison_shell by using context-based parameters.

After the assignment nodes that use the Python, MaxCompute SQL, and SHELL languages are created, you must set the dependencies so that the child node can reference the parameter values passed by these nodes.

4. Click **Commit**.

Configure the child node to reference the output values of the assignment node that uses MaxCompute SQL

1. Find the target workflow and double-click the assignment node `fuzhi_sql` that uses MaxCompute SQL.
2. On the configuration tab of the `fuzhi_sql` node that appears, click **Properties** in the right-side navigation pane.
3. Configure the `fuzhi_sql` node. The `fuzhi_sql` node assigns the results queried from a specified table to the outputs parameter.

4. Double-click the Assignment node `value comparison_shell` node, which is the child node of the `fuzhi_sql` node.
5. On the configuration tab of the Assignment node `value comparison_shell` node that appears, click **Properties** in the right-side navigation pane and configure the node. The Assignment node `value comparison_shell` node depends on the `fuzhi_sql` node and uses the value of the `outputs` parameter of the `fuzhi_sql` node as the value of its input parameter `sql_inputs`.

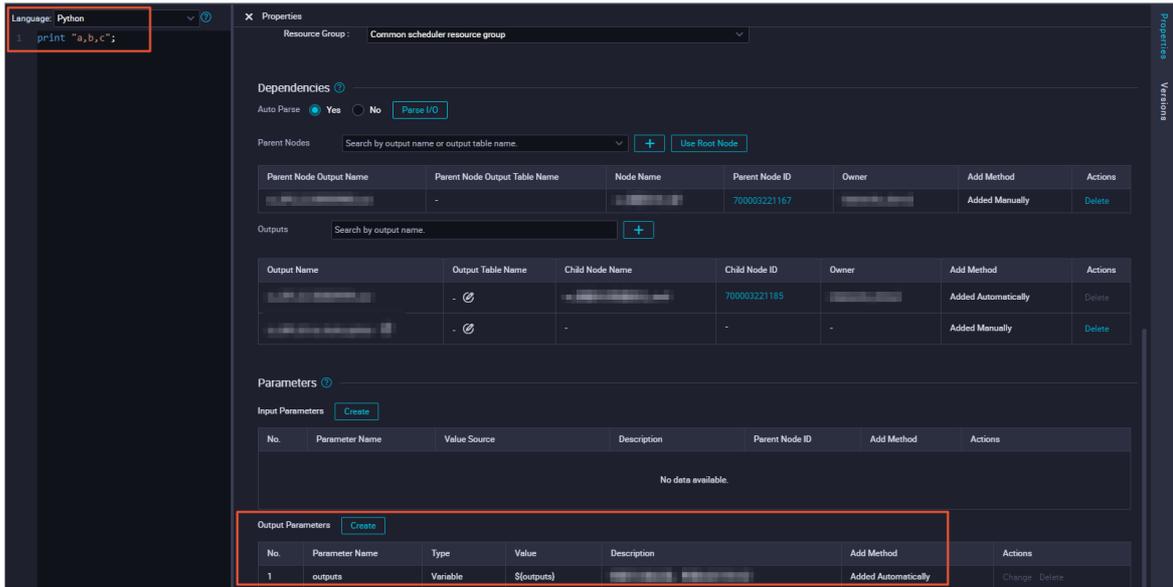

```
echo '${sql_inputs}';
echo 'Use the value in the first line in the output of the fuzhi_sql node as the input'${sql_inputs[0]};
echo 'Use the value in the second line in the output of the fuzhi_sql node as the input'${sql_inputs[1]};
echo 'Use the value of the second field in the first line in the output of the fuzhi_sql node as the input'${sql_inputs[0][1]};
echo 'Use the value of the third field in the second line in the output of the fuzhi_sql node as the input'${sql_inputs[1][2]};
```

6. Click  in the toolbar.
7. In the **Warning** message, click **Continue to Run**.

8. View the result.

Configure the child node to reference the output values of the assignment node that uses Python

1. Find the target workflow and double-click the assignment node `fuzhi_python` that uses Python.
2. On the configuration tab of the `fuzhi_python` node that appears, click **Properties** in the right-side navigation pane.
3. Configure the `fuzhi_python` node. The `fuzhi_python` node assigns the values `a,b,c` to the outputs parameter.

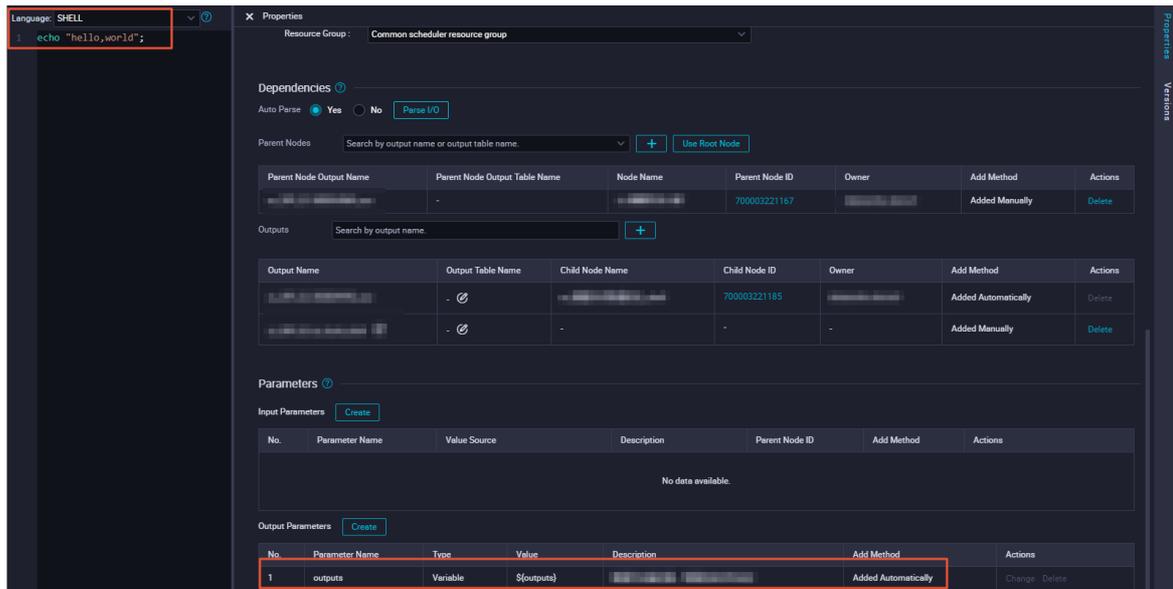

4. Double-click the Assignment node value `comparison_shell` node, which is the child node of the `fuzhi_python` node.
5. On the configuration tab of the Assignment node value `comparison_shell` node that appears, click **Properties** in the right-side navigation pane and configure the node. The Assignment node value `comparison_shell` node depends on the `fuzhi_python` node and uses the value of the outputs parameter of the `fuzhi_python` node as the value of its input parameter `python_inputs`.

```
echo 'The output of the fuzhi_python node'${python_inputs};
echo 'Use the first value in the output of the fuzhi_python node as the input'${python_inputs[0]};
echo 'Use the second value in the output of the fuzhi_python node as the input'${python_inputs[1]};[1]
```

6. Click  in the toolbar.
7. In the **Warning** message, click **Continue to Run**.
8. View the result.

Configure the child node to reference the output values of the assignment node that uses SHELL

1. Find the target workflow and double-click the assignment node `fuzhi_shell` that uses SHELL.
2. On the configuration tab of the `fuzhi_shell` node that appears, click **Properties** in the right-side navigation pane.
3. Configure the `fuzhi_shell` node. The `fuzhi_shell` node assigns the values `hello,world` to the outputs parameter.

4. Double-click the Assignment node value comparison_shell node, which is the child node of the fuzhi_shell node.
5. On the configuration tab of the Assignment node value comparison_shell node that appears, click **Properties** in the right-side navigation pane and configure the node. The Assignment node value comparison_shell node depends on the fuzhi_shell node and uses the value of the outputs parameter of the fuzhi_shell node as the value of its input parameter shell_inputs.

```
echo 'The output of the fuzhi_shell node'${shell_inputs};
echo 'Use the first value in the output of the fuzhi_shell node as the input'${shell_inputs[0]};
echo 'Use the second value in the output of the fuzhi_shell node as the input'${shell_inputs[1]};
```

6. Click  in the toolbar.
7. In the **Warning** message, click **Continue to Run**.
8. View the result.

2.5.5.7.6. Create a Shell node

Shell nodes support standard shell syntax but not interactive syntax.

Procedure

1. [Log on to the DataWorks console](#).
2. On the Data Analytics tab, move the pointer over  and choose **General > Shell**. Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Shell**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. Click **Commit**.
5. Edit the Shell node.

- i. Edit the code on the configuration tab of the Shell node. To call the system scheduling parameters for the Shell node, execute the following statement:

```
echo "$1 $2 $3"
```

 **Note** Separate multiple parameters with spaces.

- i. Click  in the toolbar to save the SQL statement to the server.
 - ii. Click  in the toolbar to execute the SQL statement you have saved. If you need to change the resource group used to test the Shell node on the **DataStudio** page, click  in the toolbar and select your desired exclusive resource group.
6. On the configuration tab of the Shell node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section.
 7. Commit the node.

 **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

- i. Click  in the toolbar.
- ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
- iii. Click **OK**.

In a workspace in standard mode, you need to click **Deploy** in the upper-right corner after you commit the branch node.

8. Test the node.

2.5.5.7.7. Create a zero-load node

A zero-load node is a control node, which only supports dry-run scheduling and does not generate any data. It usually serves as the root node of a workflow.

Context

You can configure an output table for a zero-load node so that the output table can be used as an input table of another node. However, the zero-load node does not process the table data.

Procedure

1. [Log on to the DataWorks console.](#)
2. On the **Data Analytics** tab, move the pointer over  and choose **General > Zero-Load Node**.
Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Zero-Load Node**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (`_`), and periods (`.`). It is not case-sensitive.

4. Click **Commit**.
5. On the configuration tab of the zero-load node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see [Basic](#)

properties.

6. Commit the node.

 **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

- i. Click  in the toolbar.
- ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
- iii. Click **OK**.

In a workspace in standard mode, you need to click **Deploy** in the upper-right corner after you commit the branch node.

7. Test the node.

2.5.5.7.8. Create a cross-tenant collaboration node

Cross-tenant collaboration nodes are used to associate nodes from different tenants. Cross-tenant collaboration nodes are classified into sender nodes and receiver nodes.

Prerequisites

A sender node and its receiver node use the same CRON expression. You can click the **Properties** tab in the right-side navigation pane of a node configuration tab and view the CRON expression in the **Schedule** section.

Create a cross-tenant collaboration node

1. [Log on to the DataWorks console](#).
2. On the Data Analytics tab, move the pointer over  and choose **General > Cross-Tenant Collaboration**.

Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Cross-Tenant Collaboration**.

3. In the **Create Node** dialog box, set **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (`_`), and periods (`.`). It is not case-sensitive.

4. On the node configuration tab, set the parameters in the **Cross-Tenant Collaboration** section.

Parameter	Description
Type	The type of the cross-tenant collaboration node. Valid values: Sender and Receiver .
Location	The path of the cross-tenant collaboration node. The node path cannot be modified.
Collaborative Workspaces	The workspace name and Apsara Stack tenant account of the peer node. This example sets the node type to Sender . Therefore, you must enter the workspace name and Apsara Stack tenant account of the receiver node.

5. After the sender node is created, follow the same procedure to create the receiver node under the Apsara Stack tenant account and workspace to which the receiver node belongs.

Set the node type to **Receiver**. The information about available sender nodes appears. You must also set **Timeout**. This parameter indicates the timeout period of the receiver node after it starts running.

The sender node first sends a message to the message center. After the message is delivered, the status of the sender node is set to successful. The receiver node continuously pulls messages from the message center. If a message is received within the timeout period, the status of the receiver node is set to successful.

If the receiver node does not receive any messages within the timeout period, the receiver node fails. The lifecycle of a message is 24 hours.

Assume that an auto triggered instance was run on October 8, 2018. A message indicating the completion of the instance was then sent to the message center. If you create a retroactive instance for the receiver node with the data timestamp set to October 7, 2018, the status of the generated receiver node instance is set to successful.

6. After the configuration is completed, save and commit the node.

2.5.5.7.9. Create a data analysis report node

A data analysis report node is used to associate a report in the DataAnalysis module with the parent nodes on which the report depends and update the report as scheduled.

Prerequisites

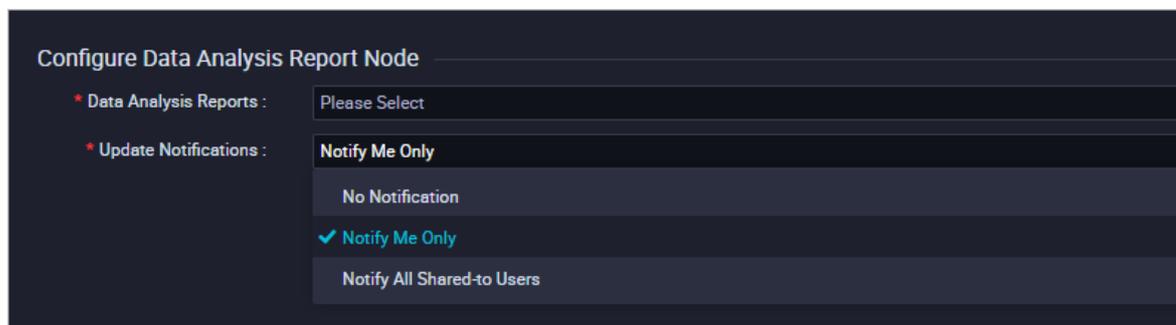

A table is created on the **Report** page of the **DataAnalysis** module.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **General > Data Analysis Reports**.
Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Data Analysis Reports**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the node configuration tab, set the parameters in the **Configure Data Analysis Report Node** section.

Parameter	Description
-----------	-------------

Parameter	Description
Data Analysis Reports	The report for which you want to receive the notifications about the updates. Select a report created on the Report page of the DataAnalysis module.
Update Notifications	Specifies the users who can receive the notifications when the report is updated. Valid values: No Notification , Notify Me Only , and Notify All Shared to Users .

6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see [Basic properties](#).
7. Commit the node.
 - i. Click  in the toolbar.
 - ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
 - iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see [Publish nodes](#).

8. Test the data analysis report node. For more information, see [Recurring tasks](#). After the node is run in the production environment, you can view updates of the report on the Report page of the **DataAnalysis** module.

2.5.5.7.10. Create a real-time sync node check node

This topic describes how to create and configure a real-time sync node check node.

Context

DataWorks provides the real-time sync node check node for you to associate the status of the current node with scheduling of its child node, which is a batch sync node. After you set dependencies in the workflow, the scheduling of the child node is determined by the status of the current node. This node allows you to schedule real-time sync nodes and batch sync nodes in a unified manner.

Create a real-time sync node check node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **General > Check Realtime Compute Node**. Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Check Realtime Compute Node**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the node configuration tab that appears, set the parameters in the **Check Realtime Compute Node** section.

Parameter	Description
StreamCompute Node	<p>The real-time sync node in Stream Studio.</p> <div style="background-color: #e0f2f7; padding: 5px; border: 1px solid #ccc;"> <p> Note The node must be deployed in Stream Studio.</p> </div>
Control rule	<p>The control rule that determines whether to schedule or block the child node based on the status of the current node.</p> <ul style="list-style-type: none"> ○ The status of the current node can be Normal or Paused. <ul style="list-style-type: none"> ■ Normal: The node is running and no error is reported. ■ Paused: The node is stopped or paused manually, or the node stops or cannot be restarted due to an exception. ○ The control method for the child node can be Scheduled or Blocked. <ul style="list-style-type: none"> ■ Scheduled: The child node can be run as scheduled. ■ Blocked: The child node cannot be scheduled, regardless of the settings.

6. Commit the node.

- i. Click  in the toolbar.
- ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
- iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the real-time sync node check node. For more information, see [Publish nodes](#).

2.5.5.8. Custom

2.5.5.8.1. Create a Hologres development node

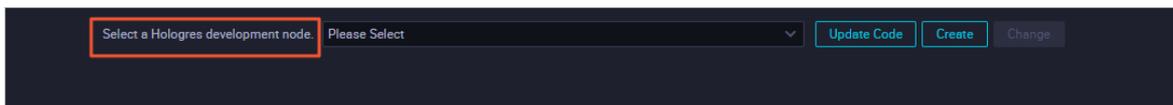

This topic describes how to create and modify a Hologres development node and update the node version.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **Custom > Hologres Development**.
Alternatively, you can click a workflow in the Business Flow section, right-click **UserDefined**, and then choose **Create > Hologres Development**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (`_`), and periods (`.`).

4. Click **Commit**.
5. On the node configuration tab that appears, select a Hologres development node.

If no Hologres node is available, click **Create** to create one. You can also click **Change** to modify an existing node.

6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see [Basic properties](#).
7. Commit the node.
 - i. Click  in the toolbar.
 - ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
 - iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see [Publish nodes](#).

8. Test the node. For more information, see [Recurring tasks](#).

2.5.6. Schedule

2.5.6.1. Basic properties

On the Properties tab of a node, you can set parameters of the node in the General, Schedule, Dependencies, and Parameters sections. The General section allows you to set the basic properties of the node.

On the **Data Analytics** tab of the DataStudio page, double-click a node. On the node configuration tab that appears, click the **Properties** tab in the right-side navigation pane and set the parameters in the **General** section.

Parameter	Description
Node Name	The name of the node that you set when creating the node. To modify the name, right-click the node in the left-side navigation pane and select Rename .
Node ID	The unique ID of the node. The node ID is generated when the node is committed at the first time. The node ID cannot be modified.
Node Type	The type of the node that you set when creating the node. The node type cannot be modified.
Owner	<p>The owner of the node. By default, the owner of a newly created node is the current logon user. You can change the owner.</p> <div style="background-color: #e6f2ff; padding: 5px; border: 1px solid #d9e1f2;"> <p> Note Only a member in the workspace where the node resides can be selected as the owner.</p> </div>
Description	The description of the node, such as the business and usage.
Arguments	The parameter used to assign a value to a variable in the code during node scheduling. You can enter multiple parameters. Separate multiple parameters with spaces.

Parameter value assignment formats for various node types

- Format for ODPS SQL and ODPS MR nodes: `Variable name 1=Parameter 1 Variable name 2=Parameter 2 .`
Separate multiple parameters with spaces.

- Format for Shell nodes: `Parameter 1 Parameter 2` . Separate multiple parameters with spaces.

For more information about the built-in scheduling parameters, see [Parameter configuration](#).

2.5.6.2. Scheduling parameters

In common data development scenarios, the code of different types of nodes may be subject to change from time to time. You must dynamically modify the values of some parameters, such as the date and time, based on the requirement changes and time changes.

In this case, you can use the scheduling parameter configuration feature of DataWorks. After relevant parameters are set, auto triggered nodes can automatically parse the code to obtain required data. Configurable parameters in DataWorks are classified into system parameters and custom parameters. We recommend that you use custom parameters.

```
{
  "data":[
    {
      "beginRunningTime":"1564019679966",
      "beginWaitResTime":"1564019679966",
      "beginWaitTimeTime":"1564019679506",
      "bizdate":"1559318400000",

```

Auto-completion is supported when you specify a data type for a parameter.

Parameter types

Parameter type	Configuration method	Applicable to	Example
----------------	----------------------	---------------	---------

Parameter type	Configuration method	Applicable to	Example
System parameters: including bdp.system.bizdate and bdp.system.cyctime	To use the system parameters in the scheduling system, reference <code>\${bdp.system.bizdate}</code> and <code>\${bdp.system.cyctime}</code> in the code, instead of setting them in the Arguments field. The system can automatically replace the values of the parameters that reference the system parameters in the code.	All nodes	N/A
Non-system parameters: custom parameters (recommended)	Reference <code>#{key1}</code> and <code>#{key2}</code> in the code and set them in the Arguments field, for example, <code>"key1=value1 key2=value2"</code> .	Non-Shell nodes	<ul style="list-style-type: none"> • Constant parameters: <code>param1="abc"param2=1234</code>. • Variables: <code>param1=\${yyyyymmdd}</code>, the value of which is calculated based on the value of <code>bdp.system.cyctime</code>.
	Reference <code>\$1</code> , <code>\$2</code> , and <code>\$3</code> in the code and set them in the Arguments field, for example, <code>"value1 value2 value3"</code> .	Shell nodes	<ul style="list-style-type: none"> • Constant parameters: <code>"abc" 1234</code>. • Variables: <code>#{yyyyymmdd}</code>, the value of which is calculated based on the value of <code>bdp.system.cyctime</code>.

As described in the preceding table, the values of custom variables are calculated based on the values of system parameters. You can use custom variables to flexibly define the data to be obtained and the data format. For custom parameters, the following types of brackets are used:

- Braces { } define the data timestamp. For example, the value of `{yyyyymmdd}` is calculated based on the value of `bdp.system.bizdate`.
- Brackets [] define the running time. For example, the value of `[yyyyymmddhh]` is calculated based on the value of `bdp.system.cyctime`.

Note Nodes can be scheduled only in the production environment. Therefore, the values of scheduling variables are replaced only after nodes are run in the production environment.

After you set the scheduling variables for a node, you can click the **Run Smoke Test in Development Environment** icon on the node configuration tab to test whether the values of scheduling variables can be replaced as expected during node scheduling.

You can click the **Properties** tab in the right-side navigation pane, and assign values to scheduling variables in the **Arguments** field in the **General** section. Note the following issues when you set parameters:

- Do not add spaces on either side of the equal sign (=) for a parameter. For example, enter `bizdate=$bizdate`.
- Separate multiple parameters (if any) with spaces. For example, enter `bizdate=$bizdate datetime=${yyyymmdd}`.

System parameters

DataWorks provides the following system parameters:

- `${bdp.system.cyctime}`: the scheduled time to run an instance. Default format: `yyyymmddhh24miss`. This parameter can specify the hour and minutes of the scheduled time.
- `${bdp.system.bizdate}`: the timestamp of data to be analyzed by an instance. Default format: `yyyymmdd`. The default data timestamp is one day before the scheduled time.

Use the following formula to calculate the running time based on the data timestamp: `Running time = Data timestamp + 1`.

To use the system parameters, you can reference them in the code, instead of setting them in the **Arguments** field. The system can automatically replace the values of the parameters that reference the system parameters in the code.

Note The scheduling properties of an auto triggered node are configured to define the scheduling rules of the running time. Therefore, you can calculate the data timestamp based on the scheduled time to run an instance and obtain the values of system parameters for the instance.

Example of system parameters

For example, to set an ODPS SQL node to run once per hour from 00:00 to 23:59 every day, perform the following steps if you want to use system parameters in the code:

1. Reference system parameters in the code.

```
insert overwrite table tb1 partition(ds='20150304') select
c1,c2,c3
from (
select * from tb2
where ds='${bdp.system.cyctime}') t
full outer join(
select * from tb3
where ds='${bdp.system.bizdate}') y
on t.c1=y.c1;
```

2. After the preceding step, your node is partitioned by using the system parameters. Set the scheduling properties and dependencies. For more information, see [Schedule](#) and [Dependencies](#). In this example, the node is scheduled by hour.
3. After you set the recurrence and dependencies, commit and deploy the node. Then, you can check the

node in **Manage auto triggered nodes**. The scheduling system generates instances for the auto triggered node from the second day. You can right-click an instance in the directed acyclic graph (DAG) and select **View Runtime Log** to view the parsed values of the system parameters.

For example, the scheduling system generated 24 running instances for the node on January 14, 2019. The data timestamp is January 13, 2019 for all instances. Therefore, the value of `bdp.system.bizdate` is 20190113. The running time is the running date appended with the scheduled time. Therefore, the value of `bdp.system.cyctime` is 20190114000000 plus the scheduled time of each instance.

Open the runtime logs of each instance and search for the replaced values of the system parameters in the code:

- The scheduled time for the first instance is January 14, 2019 00:00:00. Therefore, `bdp.system.bizdate` is replaced with 20190113 and `bdp.system.cyctime` is replaced with 20190114000000.
- The scheduled time for the second instance is January 14, 2019 01:00:00. Therefore, `bdp.system.bizdate` is replaced with 20190113 and `bdp.system.cyctime` is replaced with 20190114010000.
- Similarly, the scheduled time for the twenty-fourth instance is January 14, 2019 23:00:00. Therefore, `bdp.system.bizdate` is replaced with 20190113 and `bdp.system.cyctime` is replaced with 20190114230000.

Custom parameters for non-Shell nodes

To set scheduling variables for a non-Shell node, add `#{Variable name}` in the code to reference the function and assign a value to the scheduling variable.

Note The name of a variable in the SQL code can contain only letters, digits, and underscores (`_`). If the variable name is `date`, the value of `bizdate` is automatically assigned to this variable. For more information, see the "Built-in scheduling parameters" section in this topic. You do not need to assign a value in the Arguments field. Even if another value is assigned, it is not used in the code because the value of `bizdate` is automatically assigned in the code.

Example of custom parameters for non-Shell nodes

For example, to set an ODPS SQL node to run once per hour from 00:00 to 23:59 every day, perform the following steps if you want to use the hour-related custom variables `thishour` and `lasthour` in the code:

1. Reference the parameters in the code.

```
insert overwrite table tb1 partition(ds='20150304') select
c1,c2,c3
from (
select * from tb2
where ds='#{thishour}') t
full outer join(
select * from tb3
where ds = '#{lasthour}') y
on t.c1=y.c1;
```

2. Click the **Properties** tab in the right-side navigation pane of the node configuration tab. Assign values to the custom parameters referenced in the code in the **Arguments** field in the **General** section.

Set the custom parameters in the following formats:

- `thishour=${yyyy-mm-dd/hh24:mi:ss}`
- `lasthour=${yyyy-mm-dd/hh24:mi:ss-1/24}`

 **Note** The value of yyyy-mm-dd/hh24:mi:ss corresponds to that of cyctime. For more information, see the "Custom parameters" section in this topic.

You can enter `thishour=${yyyy-mm-dd/hh24:mi:ss} lasthour=${yyyy-mm-dd/hh24:mi:ss-1/24}` in the **Arguments** field.

3. Set the node to run once per hour.
4. After you set the recurrence and dependencies, commit and deploy the node. Then, you can check the node in **Operation Center**. The scheduling system generates instances for the auto triggered node from the second day. You can right-click an instance in the DAG and select **View Runtime Log** to view the parsed values of the custom parameters. The value of cyctime is 20190114010000. Therefore, the value of thishour is 2019-01-14/01:00:00 and the value of lasthour, which indicates the last hour, is 2019-01-14/00:00:00.

Custom parameters for Shell nodes

The parameter configuration procedure of a Shell node is similar to that of a non-Shell node, except that the variable naming rules are different. Variable names for a Shell node cannot be customized, but must follow the \$1,\$2,\$3... format. For example, add \$1 in the code of a Shell node and enter the built-in scheduling parameter \$xxx in the **Arguments** field. Then, the value of \$xxx can replace that of \$1 in the code.

 **Note** If the number of parameters in a Shell node reaches 10, use \${10} to declare the tenth variable.

Example of custom parameters for Shell nodes

For example, set a Shell node to run at 01:00 every day. To use the custom constant parameter myname and the custom variable ct in the code, perform the following steps:

1. Reference the parameters in the code.

```
echo "hello $1, two days ago is $2, the system param is ${bdp.system.cyctime}";
```

2. Click the **Properties** tab in the right-side navigation pane of the node configuration tab. Assign values to the custom parameters referenced in the code in the **Arguments** field in the **General** section. Separate multiple parameters with spaces, for example, enter Parameter 1 Parameter 2 Parameter 3. The custom parameters are parsed based on the parameter sequence. For example, \$1 is replaced with the value of Parameter 1. In this example, enter abcd \${yyyy-mm-dd-2} in the **Arguments** field to set \$1 and \$2 to abcd and \${yyyy-mm-dd-2}, respectively.
3. Set the node to run at 01:00 every day.
4. After you set the recurrence and dependencies, commit and deploy the node. Then, you can check the node in **Operation Center**. The scheduling system generates instances for the auto triggered node from the second day. Right-click an instance in the DAG and select **View Runtime Log**. The logs show that \$1 in the code is replaced with abcd, \$2 is replaced with 2019-01-12 (two days before the running date), and \${bdp.system.cyctime} is replaced with 20190114010000.

Custom parameters

Custom parameters are divided into constant parameters and variables based on the value type. DataWorks provides some built-in scheduling parameters as variables.

- Constant parameters

For example, for an SQL node, add \${Variable name} in the code and set the following parameter for the node: Variable name=Fixed value.

- Code: `select xxxxxx type='${type}'`

- Value assigned to the scheduling variable: type='aaa'. When the node is run, the variable in the code is replaced with type='aaa'.

- Variables

Variables are built-in scheduling parameters whose values depend on the system parameters `#{bdp.system.bizdate}` and `#{bdp.system.cycetime}`.

For example, for an SQL node, add `#{Variable name}` in the code and set the following parameter for the node: Variable name=Scheduling parameter.

- Code: `select xxxxxx dt=#{datetime}`
- Value assigned to the scheduling variable: `datetime=$bizdate`

If the node is run on July 22, 2017, the variable in the code is replaced with `dt=20170721`.

Built-in scheduling parameters

- `$bizdate`

- Parameter description: the data timestamp in the format of `yyyymmdd`. By default, the value of this parameter is one day before the scheduled time to run a node.
- For example, the code of an ODPS SQL node includes `pt=#{datetime}`, and the parameter configured for the node is `datetime=$bizdate`. If the node is run on July 22, 2017, `$bizdate` is replaced with `pt=20170721`.

- `$cycetime`

- Parameter description: the scheduled time to run a node. If no scheduled time is configured for a node scheduled by day, `$cycetime` is set to 00:00 of the day. The time is accurate to seconds. This parameter is usually used for nodes scheduled by hour or minute.

Note

- Pay attention to the difference between the time parameters configured by using `#{}` and `#{}`. `$bizdate` specifies the data timestamp, which is one day before the current day by default.
- `$cycetime` specifies the scheduled time to run a node. If no scheduled time is configured for a node scheduled by day, `$cycetime` is set to 00:00 of the day. The time is accurate to seconds. This parameter is usually used for nodes scheduled by hour or minute.

For example, if a node is scheduled to run at 00:30 on the current day, `$cycetime` is set to `yyyy-mm-dd 00:30:00`.

- If a time parameter is configured by using `#{}`, `$bizdate` is used as the benchmark for running nodes. The time parameter is replaced with the data timestamp selected for retroactive data generation.
- If a time parameter is configured by using `#{}`, `$cycetime` is used as the benchmark for running nodes. The time is calculated in the same way as the time in Oracle. The time parameter is replaced with the data timestamp selected for retroactive data generation plus one day.

For example, if the data timestamp is set to 20140510 for retroactive data generation, `$cycetime` is replaced with 20140511.

- The following examples show the values of custom parameters when `$cycetime` is set to 20140515103000:
 - `${yyyy} = 2014`, `${yy} = 14`, `${mm} = 05`, `${dd} = 15`, `${yyyy-mm-dd} = 2014-05-15`, `${hh24:mi:ss} = 10:30:00`, `${yyyy-mm-dd hh24:mi:ss} = 2014-05-15 10:30:00`
 - `${hh24:mi:ss - 1/24} = 09:30:00`
 - `${yyyy-mm-dd hh24:mi:ss - 1/24/60} = 2014-05-15 10:29:00`
 - `${yyyy-mm-dd hh24:mi:ss - 1/24} = 2014-05-15 09:30:00`
 - `${add_months(yyyymmdd,-1)} = 20140415`
 - `${add_months(yyyymmdd,-12*1)} = 20130515`
 - `${hh24} = 10`
 - `${mi} = 30`

- Method for testing the `$cycetime` parameter:

After an instance starts to run, right-click the instance in the DAG and select **More**. Check whether the scheduled time is the time at which the instance is run.

- `$jobid`
 - Parameter description: the ID of the workflow to which a node belongs.
 - Example: `jobid=$jobid`.
- `$nodeid`
 - Parameter description: the ID of a node.
 - Example: `nodeid=$nodeid`.
- `$taskid`
 - Parameter description: the instance ID of a node.
 - Example: `taskid=$taskid`.
- `$bizmonth`
 - Parameter description: the month of the data timestamp in the format of `yyyymm`. If the month of a data timestamp is the current month, the value of `$bizmonth` is the month of the data timestamp minus 1. Otherwise, the value of `$bizmonth` is the month of the data timestamp.
 - For example, the code of an ODPS SQL node includes `pt=${datetime}`, and the parameter configured for the node is `datetime=$bizmonth`.

Assume that the current day is July 22, 2017. If the node is run on July 22, 2017, `$bizmonth` is replaced with `pt=201706`.
- `${...}` custom parameters
 - You can customize a time format based on the value of `$bizdate`, where `yyyy` indicates the four-digit year, `yy` indicates the two-digit year, `mm` indicates the month, and `dd` indicates the day. You can use any combination of these parameters, for example, `${yyyy}`, `${yyyymm}`, `${yyyymmdd}`, and `${yyyy-mm-dd}`.
 - `$bizdate` is accurate to the day. Therefore, `${...}` can specify only the year, month, or day.

- The following table describes how to specify other intervals based on \$bizdate.

Interval	Expression
N years later	`\${yyyy+N}`
N years before	`\${yyyy-N}`
N months later	`\${yyyymm+N}`
N months before	`\${yyyymm-N}`
N weeks later	`\${yyyymmdd+7*N}`
N weeks before	`\${yyyymmdd-7*N}`
N days later	`\${yyyymmdd+N}`
N days before	`\${yyyymmdd-N}`

- \$gmtdate
 - Parameter description: the current date in the format of yyyymmdd. By default, the value of this parameter is the current date. During retroactive data generation, the input value is the data timestamp plus one day.
 - For example, the code of an ODPS SQL node includes pt=\${datetime}, and the parameter configured for the node is datetime=\$gmtdate. Assume that the current day is July 22, 2017. If the node is run on July 22, 2017, \$gmtdate is replaced with pt=20170722.
- \${yyyymmdd}
 - Parameter description: the data timestamp in the format of yyyymmdd. The value of this parameter is the same as that of \$bizdate. This parameter supports delimiters, for example, yyyy-mm-dd.
By default, the value of this parameter is one day before the scheduled time to run a node. You can customize a time format for this parameter, for example, yyyy-mm-dd for \${yyyy-mm-dd}.
 - Examples:
 - The code of an ODPS SQL node includes pt=\${datetime}, and the parameter configured for the node is datetime=\${yyyy-mm-dd}. If the node is run on July 22, 2018, \${yyyy-mm-dd} is replaced with pt=2018-07-21.
 - The code of an ODPS SQL node includes pt=\${datetime}, and the parameter configured for the node is datetime=\${yyyymmdd-2}. If the node is run on July 22, 2018, \${yyyymmdd-2} is replaced with pt=20180719.
 - The code of an ODPS SQL node includes pt=\${datetime}, and the parameter configured for the node is datetime=\${yyyymm-2}. If the node is run on July 22, 2018, \${yyyymm-2} is replaced with pt=201805.
 - The code of an ODPS SQL node includes pt=\${datetime}, and the parameter configured for the node is datetime=\${yyyy-2}. If the node is run on July 22, 2018, \${yyyy-2} is replaced with pt=2016.
 - You can assign values to multiple parameters when configuring an ODPS SQL node. For example, set startdatetime=\$bizdate enddatetime=\${yyyymmdd+1} starttime=\${yyyy-mm-dd} endtime=\${yyyy-mm-dd+1}.

FAQ

- Q: The table partition format is pt=yyyy-mm-dd hh24:mi:ss, but spaces are not allowed in scheduling parameters. How can I configure the format of \${yyyy-mm-dd hh24:mi:ss}?

A: Use the custom variables `datetime=${yyyy-mm-dd}` and `hour=${hh24:mi:ss}` to obtain the date and time. Then, join them together to form `pt="${datetime} ${hour}"` in the code. Separate the two variables with a space.

- Q: The table partition is `pt="${datetime} ${hour}"` in the code. To obtain the data for the last hour when the node is run, the custom variables `datetime=${yyyymmdd}` and `hour=${hh24-1/24}` can be used to obtain the date and time, respectively. However, for an instance running at 00:00, it analyzes data for 23:00 of the current day, instead of 23:00 of the previous day. What measures can I take in this case?

A: Modify the formula of `datetime` to `${yyyymmdd-1/24}` and keep the formula of `hour` unchanged at `${hh24-1/24}`. Then, the node can be run properly.

- For an instance that is scheduled to run at 2015-10-27 00:00:00, the values of `${yyyymmdd-1/24}` and `${hh24-1/24}` are 20151026 and 23, respectively. This is because the scheduled time minus 1 hour is a time value that belongs to yesterday.
- For an instance that is scheduled to run at 2015-10-27 01:00:00, the values of `${yyyymmdd-1/24}` and `${hh24-1/24}` are 20151027 and 00, respectively. This is because the scheduled time minus 1 hour is a time value that belongs to the current day.

DataWorks offers the following node running modes:

- Manually run a node in DataStudio: You must assign temporary values to parameters in the code to ensure proper running of the node. The assigned values are not saved as node properties and do not take effect in other node running modes.
- Automatically run a node at specified intervals: No configuration is needed in the Arguments field. The scheduling system automatically replaces the values of parameters based on the scheduled time of the current instance.
- Test a node or generate retroactive data: You must specify the data timestamp. The scheduled time of each instance can be calculated based on the formula described earlier in this topic.

2.5.6.3. Scheduling properties

This topic describes how to configure the scheduling properties of a node, including the recurrence and dependencies.

You can click the **Properties** tab in the right-side navigation pane of the node configuration tab and set the parameters in the **Schedule** section.

Node status

- **Normal**: If you select this option, the node is run based on the recurrence. By default, this option is selected for a node.
- **Dry Run**: If you select this option, the node is run based on the recurrence. However, the scheduling system does not actually run the code but directly returns a success response.
- **Retry Upon Error**: If you select this check box, the node is rerun when it encounters an error. By default, a node can be automatically rerun for a maximum of three times at an interval of 2 minutes.
- **Skip Execution**: If you select this check box, the node is run based on the recurrence. However, the scheduling system does not actually run the code but directly returns a failure response. You can select this check box if you want to suspend a node and run it later.

Recurrence

After a node is committed and deployed, the scheduling system generates instances every day from the next day based on the scheduling properties of the node. Then, the scheduling system runs the instances based on the running results of ancestor instances and the scheduled time. If a node is committed and deployed after 23:30, the scheduling system generates instances for it from the third day.

Note

If you schedule a node to run every Monday, the node is run only on Mondays. On the other days, the scheduling system does not actually run the code but directly returns a success response. When you test a node scheduled by week or generate retroactive data for the node, you must set the data timestamp to one day earlier than the scheduled time to run the node.

For an auto triggered node, its dependencies take priority over other scheduling properties. That is, when the scheduled time arrives, the scheduling system does not immediately run a node instance but first checks whether all the ancestor instances are run.

- The node instance is in the Not Running state if any ancestor instances are not run when the scheduled time arrives.
- The node instance is in the Pending (Schedule) state if the scheduled time does not arrive but all the ancestor instances are run.
- The node instance is in the Pending (Resources) state if all the ancestor instances are run and the scheduled time arrives.

Cross-cycle dependencies

DataWorks supports the following three types of cross-cycle dependencies:

- Dependency on instances of child nodes
 - Node dependency: The current node depends on the last-cycle instances of its child nodes. For example, Node A has three child nodes B, C, and D. If you select this node dependency, Node A depends on the last-cycle instances of nodes B, C, and D.
 - Business scenario: The current node depends on instances of child nodes in the last cycle to cleanse the output tables of the current node and check whether the final result is generated properly.
- Dependency on instances of the current node
 - Node dependency: The current node depends on its last-cycle instances.
 - Business scenario: The current node depends on the data output result of its last-cycle instances.
- Dependency on instances of custom nodes: If you select this node dependency, enter the IDs of the nodes on which the current node depends. You can specify multiple nodes and separate their IDs with commas (,). For example, enter 12345,23456.
 - Node dependency: The current node depends on the last-cycle instances of custom nodes.
 - Business scenario: In the business logic, the current node depends on the proper output of other business data that is not processed by the current node.

Note The difference between cross-cycle dependencies and dependencies in the current cycle lies in that cross-cycle dependencies are displayed as dotted lines in Operation Center.

Before deleting a node from Operation Center, you must delete all dependencies of the node so that other nodes can run properly.

Scheduled by day

Nodes scheduled by day are automatically run once per day. When you create an auto triggered node, the node is set to run at 00:00 every day by default. You can specify another time as needed. In the example shown in the following figure, the time is specified as 13:00.

- If you select Customize Runtime, the node is run at the specified time every day. The time format is YYYY-MM-DD HH:MM:SS.

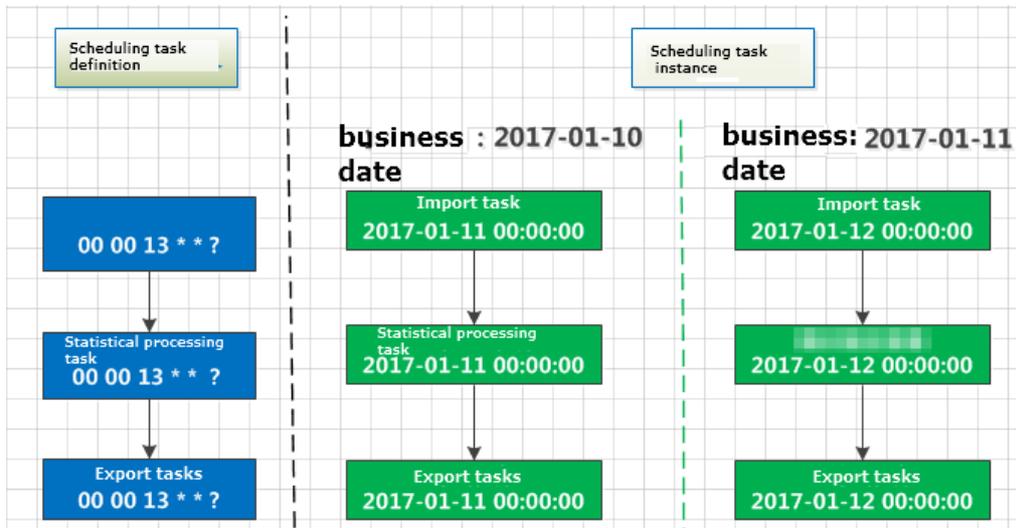

Note An auto triggered node can be run only when all the ancestor instances are run and the scheduled time arrives. Both prerequisites are indispensable and have no specific chronological order.

- If you clear Customize Runtime, the scheduled time of the node is randomly set in the range of 00:00 to 00:30.

Scenarios:

For example, you have created an import node, an analytics node, and an export node. They are all scheduled to run at 13:00 every day. The analytics node depends on the import node, and the export node depends on the analytics node. The following figure shows that the analytics node is configured to depend on the import node.

Based on the preceding node scheduling properties, the scheduling system automatically generates and runs instances for the nodes, as shown in the following figure.

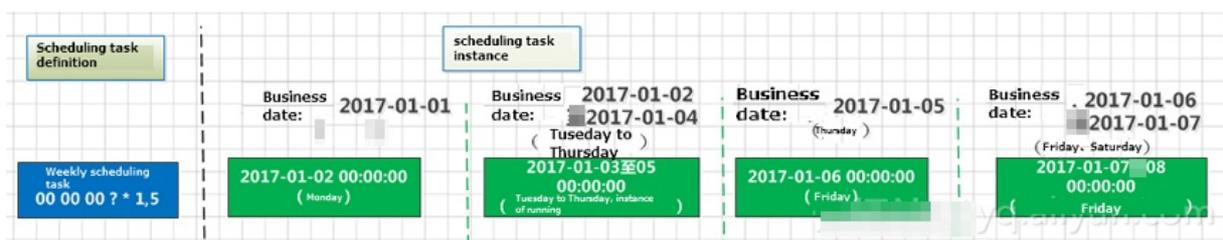

Scheduled by week

Nodes scheduled by week are automatically run at a specified time of specified days every week. On the other days, the scheduling system still generates instances to make sure the proper running of descendant instances. However, the system does not actually run the code or consume resources but directly returns a success response.

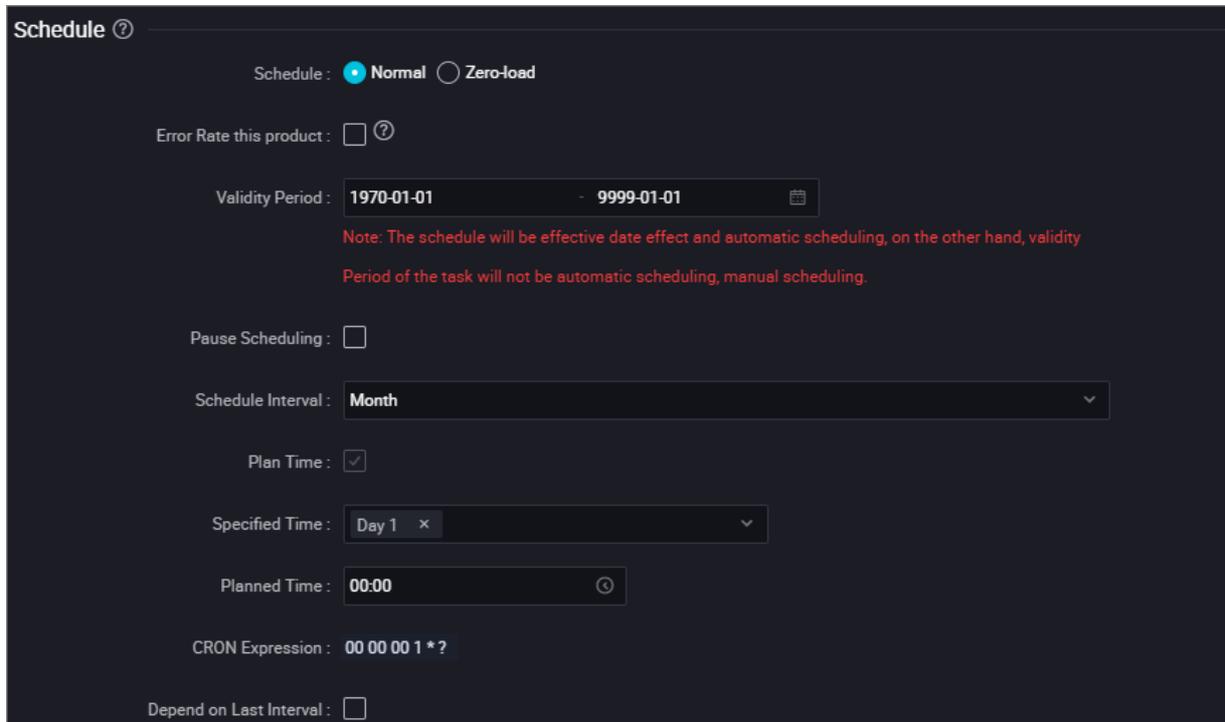

For example, you have created a node. As shown in the preceding figure, the scheduling system runs instances generated on Mondays and Fridays, but returns success responses without running the code for instances generated on Tuesdays, Wednesdays, Thursdays, Saturdays, and Sundays.

Based on the preceding node scheduling properties, the scheduling system automatically generates and runs instances for the node, as shown in the following figure.

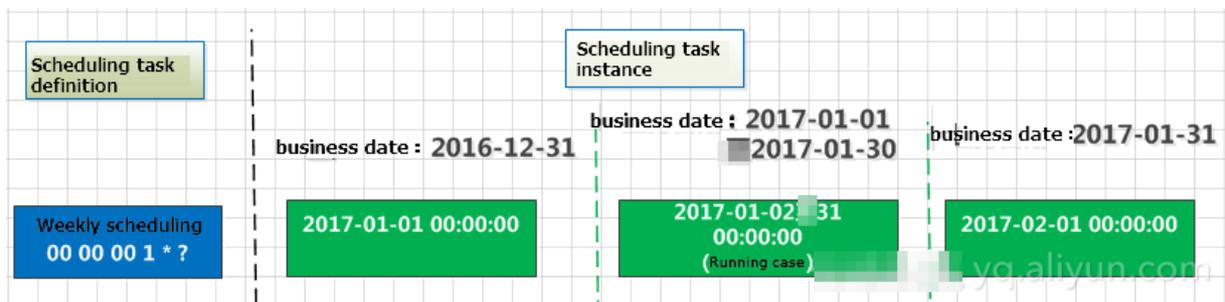

Scheduled by month

Nodes scheduled by month are automatically run at a specified time of specified days every month. On the other days, the scheduling system still generates instances to make sure the proper running of descendant instances. However, the system does not actually run the code or consume resources but directly returns a success response.

For example, you have created a node. As shown in the preceding figure, the scheduling system runs the instance generated on the first day of each month, but returns success responses without running the code for instances generated on the other days.

Based on the preceding node scheduling properties, the scheduling system automatically generates and runs instances for the node, as shown in the following figure.

Scheduled by hour

Nodes scheduled by hour are automatically run once every N hours in a specific time period every day. For example, a node is run once per hour from 01:00 to 04:00 every day.

Note The time period is a closed interval. For example, if a node is scheduled to run once per hour in the period from 00:00 to 03:00, the scheduling system generates four instances every day, which are run at 00:00, 01:00, 02:00, and 03:00, respectively.

Error Rate this product : ?

Validity Period : 1970-01-01 - 9999-01-01

Note: The schedule will be effective date effect and automatic scheduling, on the other hand, validity Period of the task will not be automatic scheduling, manual scheduling.

Pause Scheduling :

Schedule Interval : **Hour**

Plan Time :

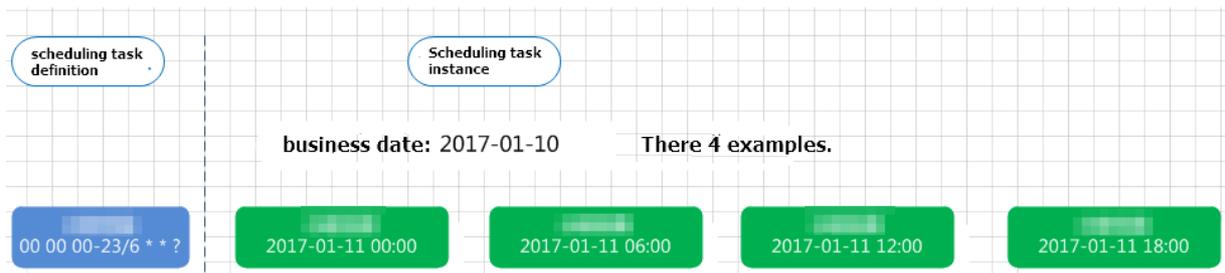

Start Time : 00:00 Interval : 1 h End Time : 23:59

Specified Time : 0:00

CRON Expression : 00 00 00-23/6 ** ?

Depend on Last Interval :

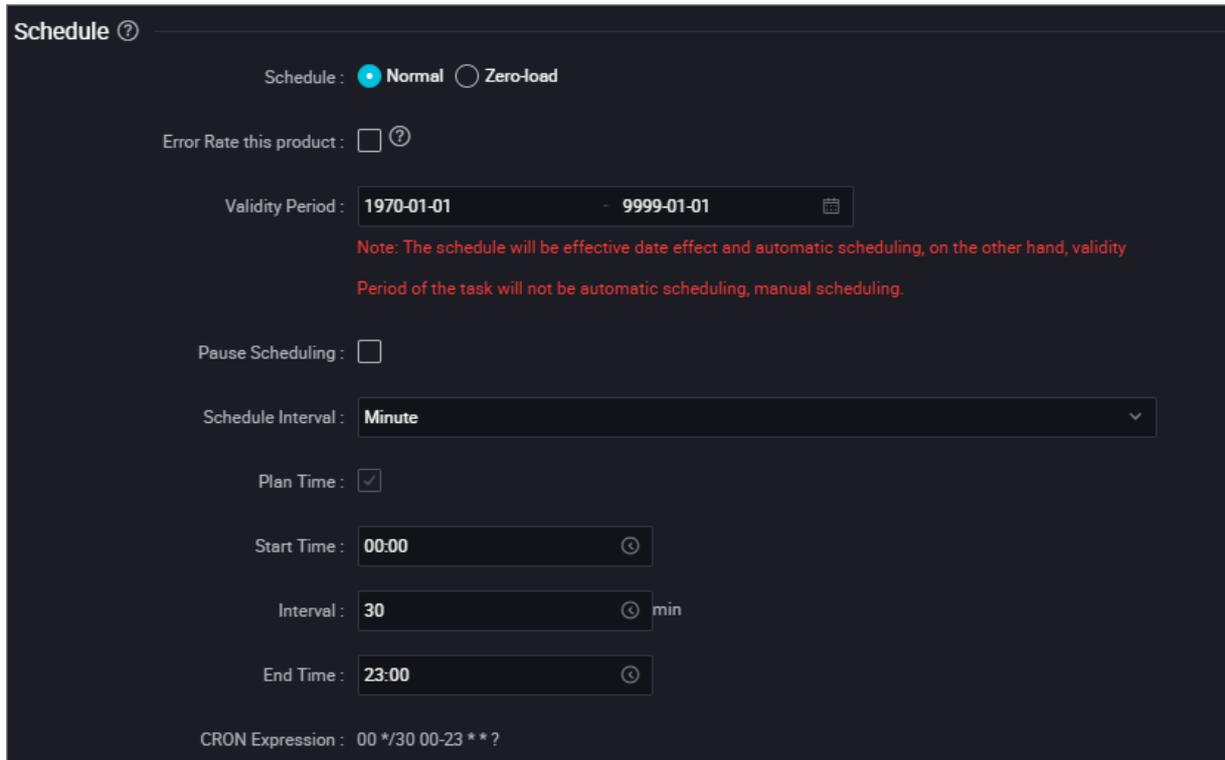

For example, you have created a node. As shown in the preceding figure, the node is automatically run every 6 hours in the period from 00:00 to 23:59 every day. In this case, the scheduling system automatically generates and runs instances for the node, as shown in the following figure.

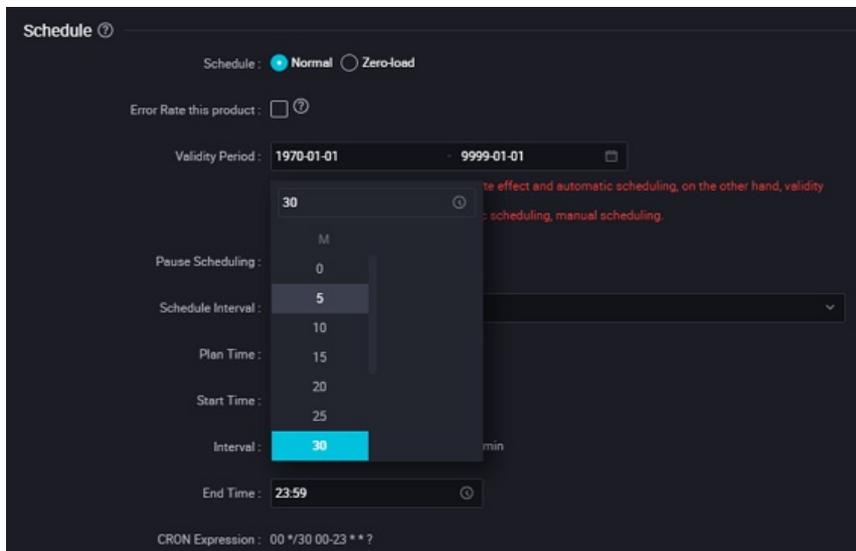

Scheduled by minute

Nodes scheduled by minute are automatically run once every N minutes in a specific time period every day.

For example, you have created a node. As shown in the following figure, the node is run every 30 minutes in the period from 00:00 to 23:00 every day.

Currently, a minimum interval of 5 minutes is supported. The time expression is automatically generated based on the time you select and cannot be modified.

FAQ

- Q: Node A is scheduled by hour and Node B is scheduled by day. How do I enable Node B to automatically run every day after all instances of Node A are run?

A: A node scheduled by day can depend on a node scheduled by hour. To enable Node B to automatically run every day after all 24 instances of Node A are run, do not specify the time to run Node B every day. Then, configure Node A as an ancestor of Node B. For more information, see the Dependencies topic. A node can depend on any other node, regardless of the recurrence. The recurrence of each node is specified in its scheduling properties.

- Q: Node A is run once per hour on the hour every day and Node B is run once per day. How do I enable Node B to automatically run after Node A is run for the first time every day?

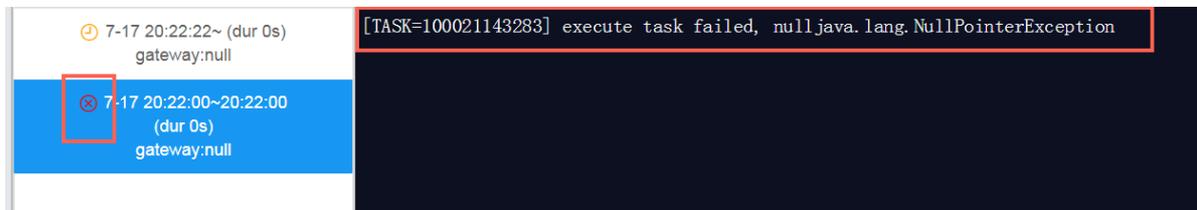

A: When configuring the scheduling properties of Node A, select **Cross-Cycle Dependencies** and select **Instances of Current Node** from the Depend On drop-down list. When configuring the scheduling properties of Node B, configure Node B to depend on Node A and set the scheduled time of Node B to 00:00 every day. In this way, instances of Node B only depend on the instance of Node A generated at 00:00 every day, that is, the first instance of Node A.

- Q: Node A is run once every Monday and Node B depends on Node A. How do I enable Node B to run once every Monday?

A: Set the scheduling properties of Node B to be the same as those of Node A. That is, select **Week** as the instance recurrence and select **Monday**.

- Q: How are the instances of a node affected when the node is deleted?

A: When a node is deleted, its instances are retained because the scheduling system still generates one or more instances for the node based on the scheduling properties. However, when the scheduling system runs such instances after the node is deleted, an error message appears because the required code is unavailable, as shown in the following figure.

- Q: Can I enable a node to process monthly data on the last day of each month?

A: No, DataWorks does not support setting a node to run on the last day of each month. If you enable a node to run on the thirty-first day of each month, the scheduling system runs a node instance in each month that has 31 days and returns a success response without running the code in any other month.

We recommend that you configure a node to process the data of the past month on the first day of each month.

- Q: If a node scheduled by day depends on a node scheduled by hour, how do I enable the node scheduled by day to run at 00:00 every day?

A: You can configure the node scheduled by day to depend on the data generated on the day before for the node scheduled by hour. If the node scheduled by day depends on the data generated on the current day for the node scheduled by hour, the instances of the node scheduled by day can be run only on the next day.

In the Schedule section of the node scheduled by day, select **Cross-Cycle Dependencies**, select **Instances of Custom Nodes** from the Depend On drop-down list, and then enter the ID of the node scheduled by hour on which the node scheduled by day depends. Commit and deploy the node scheduled by day.

- Q: What can I do if I do not know when the output data of the ancestor node is generated?

A: You can set the cross-cycle dependency for the current node to depend on the last-cycle instances of the ancestor node.

- Q: After a modified node is committed and deployed to the production environment, will the node instances that were originally faulty in the production environment be overwritten?

A: No, the node instances that have been generated will not be overwritten. The updated code is used to run the node instances that are newly generated and have not been run. If the scheduling properties are modified, the modified configuration also applies to the newly generated node instances.

2.5.6.4. Dependencies

Scheduling dependencies are the foundation for building orderly workflows. You must configure correct dependencies between nodes to make sure that business data is produced effectively and in a timely manner. This helps standardize data development activities.

DataWorks allows you to automatically parse node dependencies from the code or manually customize node dependencies. You can configure correct relationships between ancestor and descendant nodes and monitor the running status of nodes to make sure the orderly production of business data.

The purpose of configuring node dependencies is to check the data output time of the table queried by SQL statements and check whether data is properly produced from an ancestor node based on the node status.

You can set the output of an ancestor node as the input of a descendant node to configure a dependency between the two nodes.

Regardless of the dependency configuration mode, the overall scheduling logic is that descendant nodes can be run only after ancestor nodes are run. Therefore, each node in a workflow must have at least one parent node. The dependencies between the parent nodes and child nodes are the core of scheduling dependencies. The following sections describe the principles and configuration methods of scheduling dependencies in detail.

Differences between automatic parsing and custom dependencies

DataWorks can automatically parse the input and output of a node based on the lineage parsed from the code.

If the lineage parsed from the code is inaccurate, you can add custom dependencies as needed. We recommend that you write the code correctly to parse the lineage from the code and reduce custom dependencies. The following example shows how to configure the input and output of a node.

Auto Parse: If you select Yes, node dependencies are automatically parsed from the code.

For example, the code of an ODPS SQL node is as follows:

```
insert overwrite table table_a as select * from project_b_name.table_b;
```

From the code, DataWorks determines that the current node depends on the node that generates table_b and the current node generates table_a. Therefore, the output name of the parent node is project_b_name.table_b and the output name of the current node is project_name.table_a.

- If you do not want to parse node dependencies from the code, select **No** for Auto Parse.
- If a table in an SQL statement is both an output table and a referenced table on which another node depends, the table is parsed only as an output table.
- If a table in an SQL statement is used as an output table or a referenced table multiple times, only one scheduling dependency is parsed.
- If the SQL code contains a temporary table, the table is not involved in a scheduling dependency. Temporary tables are prefixed with t_. For more information, see [Project Configuration](#).

Parent nodes

In the Dependencies section of a node, you must specify an ancestor node as the parent node on which the current node depends. You must enter the output name of the ancestor node, rather than the ancestor node name. A node may have multiple output names. Enter an output name as needed. You can search for an output name of the ancestor node to be added, or click Parse I/O to parse the output name based on the lineage parsed from the code.

 **Note** You must enter an output name or output table name to search for the ancestor node.

If you enter an output name to search for the ancestor node, DataWorks searches for the output name among the output names of nodes that have been committed to the scheduling system.

- Search by entering an output name

You can enter an output name to search for the ancestor node and configure the node as the parent node of the current node to create a dependency.

- Search by entering an output table name

When using this method, make sure that the entered output table name of the ancestor node is the table name used in the INSERT or CREATE statement of the current node, such as Project name.Table name . Such output names can be automatically parsed.

After you click the **Submit** icon, the output table name of the parent node configured for the current node can be found when you enter an output table name to search for the ancestor node for other nodes.

Outputs

You can click the **Properties** tab in the right-side navigation pane to view and configure the output of the current node.

DataWorks assigns a default output name that ends with .out to each node. You can also customize an output name or click Parse I/O to parse the output name based on the lineage parsed from the code.

 **Note** The output name of each node must be globally unique.

FAQ

- Q: After DataWorks automatically parses the input and output of a node, the node fails to be committed. An error message appears to indicate that the parsed output name workshop_yanshi.tb_2 of the parent node does not exist and you must commit the parent node before committing the current node. Why does this error occur?

A: The possible causes are as follows:

- The ancestor node is not committed. Commit the ancestor node and try again.
- The ancestor node is committed, but workshop_yanshi.tb_2 is not an output name of the ancestor node.

 **Note** Usually, the output names of the parent node and the current node are automatically parsed based on the table name that is used in the INSERT or CREATE statement or follows the FROM keyword. Make sure that you follow the principles of automatic parsing in the Differences between automatic parsing and custom dependencies section.

- Q: In the output of the current node, the descendant node name and ID are empty and cannot be specified. Why does this happen?

A: If the current node does not have a descendant node, the descendant node name and ID are empty. After a descendant node is configured for the current node, the corresponding content can be automatically parsed.

- Q: What is the output name of a node used for?

A: The output name of a node is used to establish dependencies between nodes. For example, if the output name of Node A is ABC and Node B uses ABC as its input, a dependency is established between nodes A and B.

- Q: Can a node have multiple output names?

A: Yes, a node can have multiple output names. If a descendant node references an output name of the current node as the output name of the parent node, a dependency is established between the descendant node and the current node.

- Q: Can multiple nodes have the same output name?

A: No, the output name of each node must be unique under your Apsara Stack tenant account. If multiple nodes export data to the same MaxCompute table, we recommend that you use Table name_Partition ID as the output name format of these nodes.

- Q: How can I avoid intermediate tables when I enable DataWorks to automatically parse node dependencies?

A: Right-click an intermediate table name in the SQL code and select **Delete Input** or **Delete Output**. Then, click Parse I/O to parse the input and output of the node.

- Q: How do I configure dependencies for the upmost node in a workflow?

A: You can set the node to depend on the root node of the current workspace.

- Q: Why do I find a non-existent output name of Node B when I enter an output name to search for the ancestor node for Node A?

A: DataWorks searches for the output name among the output names of nodes that have been committed to the scheduling system. After Node B is committed, if you delete the output name of Node B and does not commit Node B to the scheduling system again, the deleted output name of Node B can still be found.

- Q: How do I enable nodes A, B, and C to run in sequence once per hour?

A: Set the output of Node A as the input of Node B and the output of Node B as the input of Node C. Also, set nodes A, B, and C to run once per hour.

- Q: An error message is returned to indicate that the parent node ID fails to be automatically parsed based on an output table name. Why does this error occur?

A: This error does not indicate that the table does not exist. Instead, it indicates that the table is not the output of a specific node. Therefore, the table name cannot be used to find the node that generates the table data. In this case, the dependency on the node cannot be created.

According to the principles of automatic parsing described in this topic, a dependency is created after the output of an ancestor node is set as the input of a descendant node. If no ancestor node can be parsed based on the xc_demo_partition table referenced in SQL statements, no node uses the xc_demo_partition table as its output.

You can resolve this problem in the following way:

- i. Find the node that generates the table data and view the node output.

If you do not know which the target node is, you can enter keywords to search the code for the node in fuzzy match mode.

- ii. If the table data is uploaded from a local server or you do not need to depend on the node, you can right-click the table name in the code and select **Delete Input**.

 **Note** We recommend that you write the code correctly to parse the lineage from the code and reduce custom dependencies.

2.5.7. Components

2.5.7.1. Create a script template

This topic describes the definition and composition of script templates and how to create a script template.

Definition

A script template defines an SQL code process that involves multiple input and output parameters. Each SQL code process references one or more source tables. You can filter source table data, join source tables, and aggregate them to generate a result table required for new business.

Value

In actual business, many SQL code processes are similar. The input and output tables in these processes may have the same or compatible schema but different names. In this case, developers can abstract an SQL code process as a script template to reuse the SQL code. The script template extracts input parameters from input tables and generates output parameters in output tables.

To create SQL script templates, you can select script templates from the script template list based on your business process and configure specific input and output tables in your business for the selected script templates, without repeatedly copying the code. This greatly improves the development efficiency and avoids repeated development. You can deploy and run the created SQL script templates in the same way as other SQL nodes.

Composition

Similar to a function, a script template consists of input parameters, output parameters, and an SQL code process.

Input parameters

The input parameters of a script template have the properties such as the parameter name, parameter type, parameter description, and parameter definition. The parameter type can be table or string.

- A table-type parameter specifies the table to be referenced in an SQL code process. When you use a script template, you can specify the input table required for the specific business.
- A string-type parameter specifies the variable control parameter in an SQL code process. For example, to export only the sales amount of the top N cities in each region in a result table of an SQL code process, you can use a string-type parameter to specify the value of N.

To export the total sales amount of a province in a result table of an SQL code process, you can set a string-type parameter to specify the province and obtain the sales data of the specified province.

- The parameter description specifies the role of a parameter in an SQL code process.
- The parameter definition is a text definition of the table schema, which is required only for table-type parameters. When you specify the parameter definition for a table-type parameter, you must provide an input table that contains the same field names and compatible types defined by the table-type parameter so that the SQL code process can run properly. Otherwise, an error is returned when the SQL code process runs because the specified field name cannot be found in the input table. The input table must contain the field names and types defined by the table-type parameter. The input table can also contain other fields. The field names and types in the input table can be in any order. The parameter definition is for reference only.
- We recommend that you enter the parameter definition in the following format:

```
Name of field 1 Type of field 1 Description of field 1  
Name of field 2 Type of field 2 Description of field 2  
Name of field n Type of field n Description of field n
```

Examples:

```
area_id string 'Region ID'  
city_id string 'City ID'  
order_amt double 'Order amount'
```

Output parameters

- The output parameters of a script template have the properties such as the parameter name, parameter type, parameter description, and parameter definition. The parameter type must be table. A string-type output parameter has no logical meaning.
- A table-type parameter specifies the table to be generated in an SQL code process. When you use a script template, you can specify the result table that the SQL code process generates for the specific business.
- The parameter description specifies the role of a parameter in an SQL code process.
- The parameter definition is a text definition of the table schema. When you specify the parameter definition for a table-type parameter, you must provide an output table that contains the same number of fields and compatible types defined by the table-type parameter so that the SQL code process can run properly. Otherwise, an error is returned when the SQL code process runs because the number of fields does not match or the field type is incompatible. The field names of the output table do not need to be consistent with those defined by the table-type parameter. The parameter definition is for reference only.
- We recommend that you enter the parameter definition in the following format:

```
Name of field 1 Type of field 1 Description of field 1  
Name of field 2 Type of field 2 Description of field 2  
Name of field n Type of field n Description of field n
```

Examples:

```
area_id string 'Region ID'  
city_id string 'City ID'  
order_amt double 'Order amount'  
rank bigint 'Ranking'
```

SQL code process

The parameters in an SQL code process are referenced in the following format: `@@{Parameter name}`.

By containing an abstract SQL code process, a script template controls and processes an input table based on input parameters to generate an output table with business value.

To develop an SQL code process, you must use input and output parameters in the code properly to make sure that they can be set as needed and correct SQL code can be generated and run during the process.

Create a script template

1. [Log on to the DataWorks console](#).
2. On the left-side navigation submenu, click the **Snippets** icon.
3. On the Snippets tab, move the pointer over  and choose **Create > Snippet**.
4. In the **Create Snippet** dialog box, set **Snippet Name**, **Description**, and **Location**.
5. Click **Commit**.

Source table schema

The following table describes the schema of a source MySQL table that contains sales data.

Field	Data type	Description
order_id	varchar	The ID of the order.
report_date	datetime	The date of the order.
customer_name	varchar	The name of the customer.
order_level	varchar	The level of the order.
order_number	double	The number of orders.
order_amt	double	The amount of the order.
back_point	double	The discount.
shipping_type	varchar	The transportation method.
profit_amt	double	The amount of the profit.
price	double	The unit price.
shipping_cost	double	The transportation cost.
area	varchar	The region.
province	varchar	The province.
city	varchar	The city.
product_type	varchar	The type of the product.
product_sub_type	varchar	The subtype of the product.
product_name	varchar	The name of the product.
product_box	varchar	The packaging of the product.
shipping_date	datetime	The shipping date.

Business implication

Script template name: get_top_n

This script template uses the specified sales data table as the table-type input parameter, the number of the top cities as the string-type input parameter, and the total sales amount of the cities for ranking. By using this SQL code process, you can obtain the rankings of the specified top cities in each region with ease.

Script template parameters

Input parameter 1

- Parameter name: myinputtable
- Type: table

Input parameter 2

- Parameter name: topn
- Type: string

Output parameter 3

- Parameter name: myoutput
- Type: table

Parameter definition:

- area_id string
- city_id string
- order_amt double
- rank bigint

You can execute the following statement to create a table for storing the sales data of a specified number of top cities:

```
CREATE TABLE IF NOT EXISTS company_sales_top_n
(
  area STRING COMMENT 'Region',
  city STRING COMMENT 'City',
  sales_amount DOUBLE COMMENT 'Sales amount',
  rank BIGINT COMMENT 'Ranking'
)
COMMENT 'Company sales rankings'
PARTITIONED BY (pt STRING COMMENT '')
LIFECYCLE 365;
```

Example of defining an SQL code process

```

INSERT OVERWRITE TABLE @@{myoutput} PARTITION (pt='${bizdate}')
  SELECT r3.area_id,
  r3.city_id,
  r3.order_amt,
  r3.rank
from (
SELECT
  area_id,
  city_id,
  rank,
  order_amt_1505468133993_sum as order_amt ,
  order_number_15054681****_sum,
  profit_amt_15054681****_sum
FROM
  (SELECT
  area_id,
  city_id,
  ROW_NUMBER() OVER (PARTITION BY r1.area_id ORDER BY r1.order_amt_1505468133993_sum DESC)
AS rank,
  order_amt_15054681****_sum,
  order_number_15054681****sum,
  profit_amt_1505468****_sum
FROM
  (SELECT area AS area_id,
  city AS city_id,
  SUM(order_amt) AS order_amt_1505468****_sum,
  SUM(order_number) AS order_number_15054681****_sum,
  SUM(profit_amt) AS profit_amt_1505468****_sum
FROM
  @@{myinputtable}
WHERE
  SUBSTR(pt, 1, 8) IN ( '${bizdate}' )
GROUP BY
  area,
  city )
r1 ) r2
WHERE
  r2.rank >= 1 AND r2.rank <= @@{topn}
ORDER BY
  area_id,
  rank limit 10000) r3;

```

Sharing scope

Script templates can be shared within a workspace or made public.

By default, a deployed script template is visible and available to users within the current workspace. The developer of a script template can click the **Publish Snippet** icon to make the general-purpose script template public to the current tenant account so that all users under the account can view and use the script template.

You can view the **Publish Snippet** icon in the toolbar of the configuration tab of a script template. If the icon is clickable, the script template is made public.

Use of script templates

For more information about how to use a developed script template, see [Use components](#).

Reference records

In the script template list, double-click a script template. On the configuration tab that appears, click the **Snippet Nodes** tab in the right-side navigation pane to view the reference records of the script template.

2.5.7.2. Use a script template

To improve development efficiency, you can create data analytics nodes by using the script templates provided by workspace members and tenants.

Note the following points when you use script templates:

- The script templates provided by members of the current workspace are available on the **Workspace-Specific** tab.
- The script templates provided by tenants are available on the **Public** tab.

GUI elements

Icon or tab	Description
Save icon	Saves the settings of the current script template.
Steal Lock icon	Allows you to steal the lock of the current script template and then edit it if you are not the owner of the script template.
Submit icon	Commits the current script template to the development environment.
Publish Snippet icon	Makes the current general-purpose script template public to the current tenant account so that all users under the account can view and use the script template.
Parse I/O Parameters icon	Parses input and output parameters from the code. <div style="background-color: #e0f2f7; padding: 5px;"><p> Note Typically, the parameters entered here are table names instead of scheduling parameters.</p></div>
Run icon	Runs the current script template in the development environment.
Stop icon	Stops running the current script template.
Format icon	Formats the code based on keywords.
Parameters tab	Allows you to view the basic information and set input and output parameters for the current script template.
Versions tab	Allows you to view the deployed versions of the current script template.
Snippet Nodes tab	Lists the reference records of the current script template.

2.5.8. Custom node type

2.5.8.1. Overview

DataStudio supports default node types such as ODPS SQL and Shell nodes. You can also create custom node types to meet your requirements.

To create a custom node type, you need to create a custom wrapper and use it to define a custom node type.

Entry

1. Log on to the DataWorks console.
2. Click **Node Market** in the upper-right corner to go to the node configuration page.

 **Note** Only the workspace owner and administrators can access this page.

View the list of wrappers

The Wrappers page displays all the wrappers you have created. You can click **Create** in the upper-right corner to create a custom wrapper.

The values displayed in the Latest Version, Version in Development, and Version in Production Environment columns for the created wrappers follow these rules:

- If a created wrapper has not been deployed, the values of both the Version in Development and Version in Production Environment columns are **Not Deployed**.
- If a wrapper has been deployed, the version and the deployment time appear in these columns.
- If a wrapper is under deployment, the values of both the Version in Development and Version in Production Environment columns are **Deploying**.

You can click **Settings**, **View Versions**, or **Delete** in the Actions column of each wrapper.

Action	Description
Settings	You can click Settings to configure the wrapper. The page that appears depends on the wrapper status. The Deploy in Production Environment page appears if the wrapper has been deployed in the production environment.
View Versions	<p>You can click View Versions to view all historical versions of the wrapper.</p> <ul style="list-style-type: none"> • View: You can click this button to view the settings of the selected version. • Roll Back: You can click this button to roll back to the selected version. After you click this button, the system creates a new version for the wrapper. In the new version, the wrapper uses the basic settings and the resource file of the selected version. The new version number equals the latest version number among all the versions plus 1. • Download: You can click Download to download the resource file of the selected version.
Delete	<p>If an error occurs while a node type is using the wrapper, you need to delete the node type.</p> <p> Note Before deleting a wrapper, ensure that no node type is associated with the wrapper.</p>

Create a custom wrapper

A wrapper is the core processing logic of a node type. For example, after you compile an SQL statement in the editor for an ODPS SQL node and submit the statement, the system calls the corresponding wrapper to parse and run the statement. You need to create a wrapper before creating a custom node type. Currently, only the Java programming language is supported.

The procedure of creating a wrapper includes four steps: specify settings for the wrapper, deploy the wrapper in the development environment, test the wrapper in the development environment, and deploy the wrapper in the production environment. For more information, see [Create a custom wrapper](#).

View the list of custom node types

The Custom Node Types page displays all custom node types in the workspace. You can click **Create** in the upper-right corner to create a custom node type. For more information, see [Create a custom node type](#).

Currently, you can only create custom node types in DataStudio.

The workspace owner or node type creator can **change** or **delete** existing node types.

- **Change:** You can click **Change** to edit the settings for the node type as needed.
- **Delete:** You can click this button to delete the node type that no node uses. If any node uses the node type, a message appears, indicating that you need to disable the node first before deleting the node type.

Use a custom node type

After creating a custom node type, go to the **Data Analytics** page.

Move the pointer over the **Create** icon and click **Data Analytics**. In the list that appears, select the created node type to create a node.

2.5.8.2. Create a custom wrapper

The procedure of creating a wrapper includes four steps: specify settings for a wrapper, deploy the wrapper in the development environment, test the wrapper in the development environment, and deploy the wrapper in the production environment.

Specify settings for a wrapper

1. Click **Wrappers** in the left-side navigation pane. On the page that appears, click **Create** in the upper-right corner.
2. Specify the parameters in the **Settings** step.

Parameter	Description
Name	The name of the wrapper. It must start with a letter and can only contain letters, digits, and underscores (_).
Owner	The owner of the wrapper. You can select an owner from the workspace members. You are not allowed to edit wrappers owned by other members even if you are an administrator. Only the workspace owner can edit the wrappers of other members.
Resource Type	The type of the resource package for configuring the wrapper. Valid values: JAR and Archive . The size of the resource package can be up to 50 MB.

Parameter	Description
Resource File	The local resource file or OSS object for configuring the wrapper. <div style="background-color: #e1f5fe; padding: 5px;"> <p> Note The size of a local file can be up to 50 MB, and the size of a file that is stored in an OSS bucket can be up to 200 MB.</p> </div>
Class Name	The full path of the class for implementing the user wrapper.
Parameter Example	The parameters designed based on the JAR package you upload.
Version	The version of the configured wrapper. Select Create Version if you are creating a new wrapper. Select Overwrite Version if you are editing and rolling back a version. <div style="background-color: #e1f5fe; padding: 5px;"> <p> Note The version number is automatically generated.</p> </div>
Description	The description of the wrapper version.

3. Click **Save** and then click **Next**.

-  **Note** The settings are updated to the database after you click **Save**.

 - If you only modify basic settings of a wrapper without changing the resource file, the modification takes immediate effect after you click **Save**.
 - If you change the resource file, the change only applies after deployment.

Deploy the wrapper in the development environment

After you specify the parameters in the **Settings** step and click **Next**, the information in the **Deploy in Development Environment** step is updated accordingly. You can identify the changes by checking the file name and MD5 checksum.

Click **Deploy in Development Environment**. You can view the **deployment progress** in real time. After the wrapper is deployed, click **Next**.

Test the wrapper in the development environment

Specify the parameters for testing and click **Test** to send the parameters to the wrapper. This step is to validate the deployment and logic of the wrapper. You can also locally test the wrapper before uploading it for deployment.

After the test, review the output logs in the **Test Results** section on the right to determine whether the test is passed. If the test is passed, select **Test Passed** and click **Next**.

-  **Note** The **Next** button is operable only after you select **Test Passed**.

Deploy the wrapper in the production environment

Click **Deploy in Production Environment**. In the **Confirm** dialog box that appears, click **OK**. The wrapper is deployed in the production environment. You can view the deployment progress in real time.

 **Note** The wrapper to be deployed in the production environment must be of the latest version, have been deployed in the development environment, and have passed the test. Otherwise, a message appears, indicating that the deployment in the production environment fails.

Click **Complete**. You can view and edit the created wrapper on the **Wrappers** page.

2.5.8.3. Create a custom node type

The Configure Custom Node Type page consists of three sections: Basic Information, Interaction, and Wrapper.

1. On the DataStudio page, click **Node Market** in the top navigation bar. On the page that appears, click **Custom Node Types** in the left-side navigation pane.
2. Click **Create** in the upper-right corner.
3. Specify the parameters in the **Basic Information** section.

Parameter	Description
Name	The name of the node type, which cannot be changed after being saved. Each node type has a unique name within the workspace. The name can be up to 20 characters in length, and can only contain letters, spaces, and underscores (_).
Icon	The icon of the node type.
Tabs	The template of the node type. Currently, only Data Analytics is available.
Folder	The folder where the node type belongs. You can select Data Integration or Data Analytics .

4. Specify the parameters in the **Interaction** section.

Parameter	Description
Shortcut Menu	<ul style="list-style-type: none"> ◦ The options to appear in the shortcut menu. The following options are selected by default: Rename, Move, Clone, Steal Lock, View Versions, Locate in Operation Center, Delete, and Submit for Review. ◦ More options include Edit, Copy Resource Name, and Send to DataWorks Desktop (Shortcut).
Tool Bar	<ul style="list-style-type: none"> ◦ The options to appear in the top navigation bar. The following options are selected by default: Save, Commit, Commit and Unlock, Steal Lock, Run, Show/Hide, Run with Arguments, Stop, Reload, Run Smoke Test in Development Environment, View Smoke Test Log in Development Environment, Run Smoke Test, View Smoke Test Log, Go to Operation Center of Development Environment, and Format. ◦ More options include Operation Center, Deploy, and Precompile.
Editor Type	The type of the editor. Currently, only Editor Only is available.
Right-Side Bar	<ul style="list-style-type: none"> ◦ The options to appear in the right-side bar. The following options are selected by default: Code Structure and Properties. ◦ More options include Version, Lineage, and Parameters.

Parameter	Description
Auto Parse Option	Specifies whether to display the Auto Parse option for this type of node. If you turn on this switch, the Auto Parse option is displayed on the Properties tab. Otherwise, it is not displayed. In an automatic parsing process, the system parses the input and output of a node based on the lineage specified in the code.

5. Specify the parameters in the **Wrapper** section.

Parameter	Description
Wrapper	The wrapper used for running the type of node. Select a wrapper that has been deployed.
Editor Language	The language used for writing the code in the editor. Currently, only ODPS SQL is available.
Use MaxCompute as Engine	Specifies whether to use MaxCompute as the compute engine. If your wrapper uses MaxCompute as the compute engine, select Yes. Otherwise, select No. Default value: Yes.

6. Click **Save and Exit**. Then, go to the **Data Analytics** page to use the custom node type that is created.

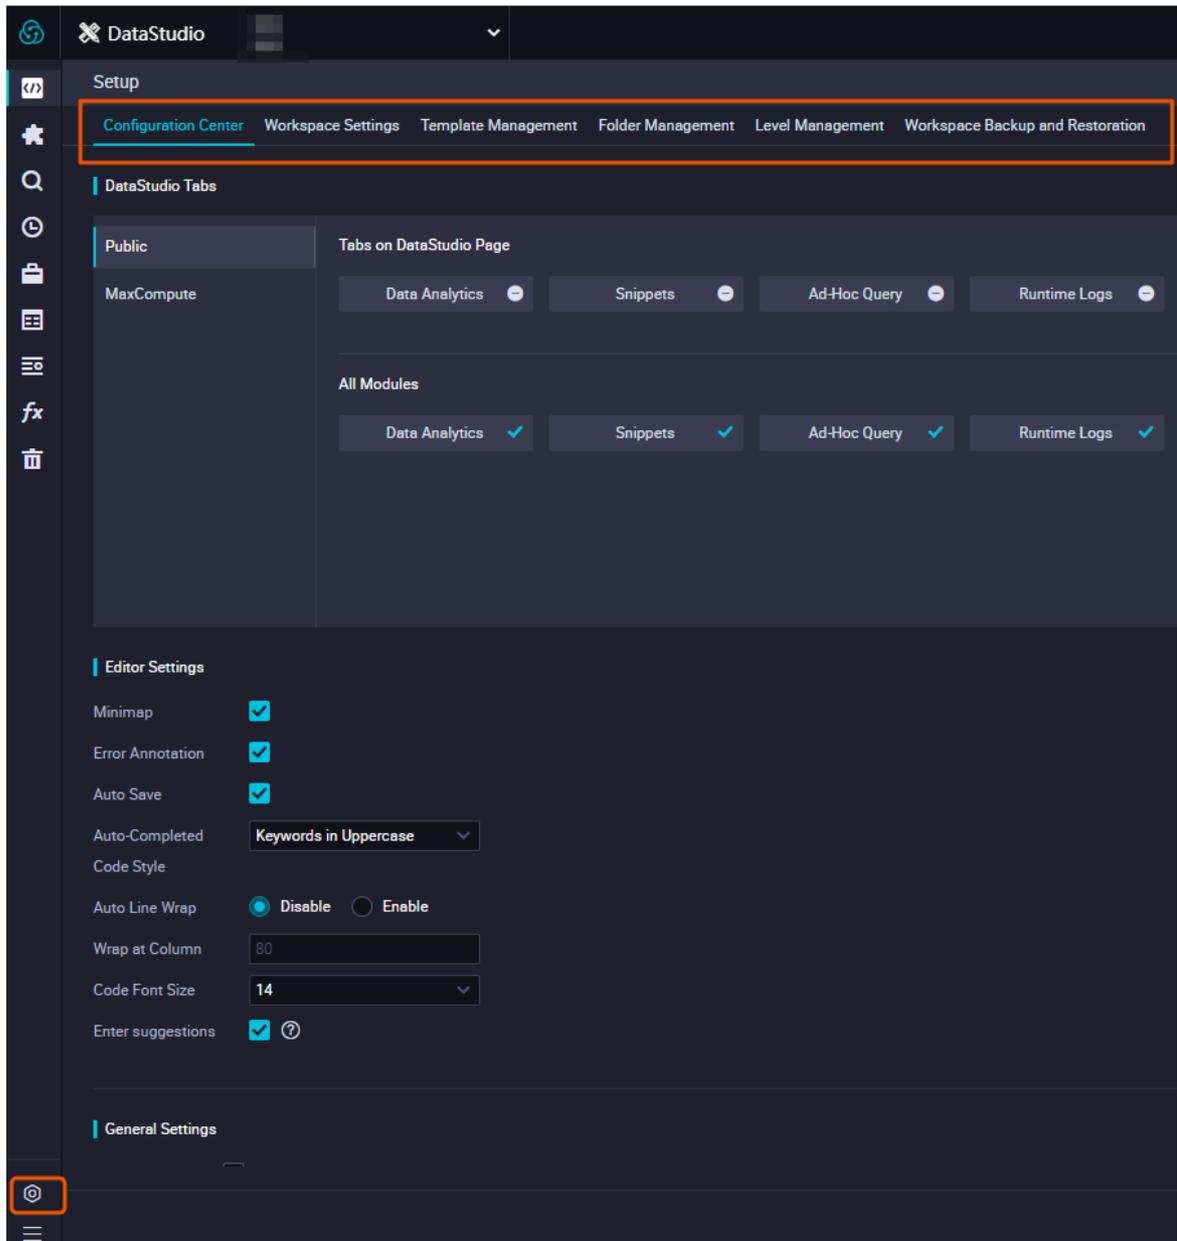

2.5.9. Manage configurations

2.5.9.1. Setup

On the Setup page, you can add and delete modules. You can also configure code templates, folders, and table levels on this page.

Procedure

1. [Log on to the DataWorks console](#).
2. Click  in the lower-left corner of the **Data Studio** page to go to the **Setup** page.

You can perform operations on the following tabs:

- [Configuration Center](#)
- [Project Configuration](#)
- [Template management](#)
- [Folder management](#)
- [Level management](#)

2.5.9.2. Configuration center

You can combine your DataStudio modules and specify editor settings on the Configuration Center tab.

Go to Configuration Center

1. [Log on to the DataWorks console.](#)

- Click  in the lower-left corner of the **DataStudio** page. The **Configuration Center** tab appears.

The Configuration Center tab includes three sections: **DataStudio Tabs**, **Editor Settings**, and **General Settings**. After the configurations are completed, you can click **Apply to All Workspaces** in the lower-right corner of the page to apply the settings to all existing workspaces.

DataStudio tabs

On the **DataStudio Tabs** tab, you can add and delete public and MaxCompute functional modules, and drag modules to change their orders.

- Under **Tabs on DataStudio Page**, click  next to a module to delete it. Deleted modules will not appear in the left-side navigation pane of the **DataStudio** page.
- Under **All Modules**, click the desired module to add it. Added modules will appear in the left-side navigation pane of the **DataStudio** page.

 **Note** The module settings take effect immediately for the current workspace. To make the module settings effective for all workspaces, click **Apply to All Workspaces** in the lower-right corner of the page.

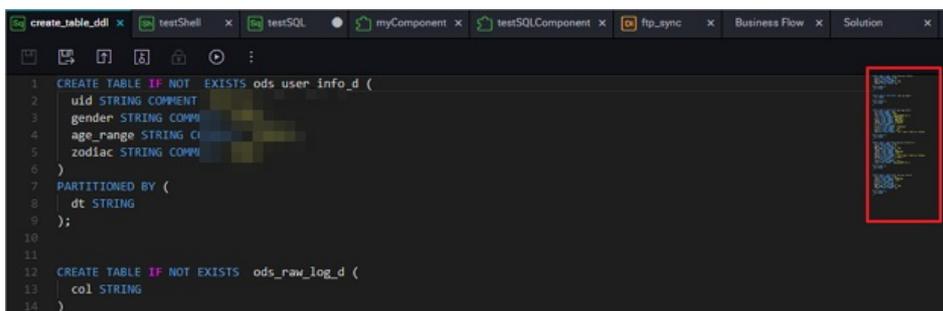

Editor settings

You can configure the code editor in the Editor Settings section. The editor settings take effect immediately for the current workspace without requiring you to refresh the page.

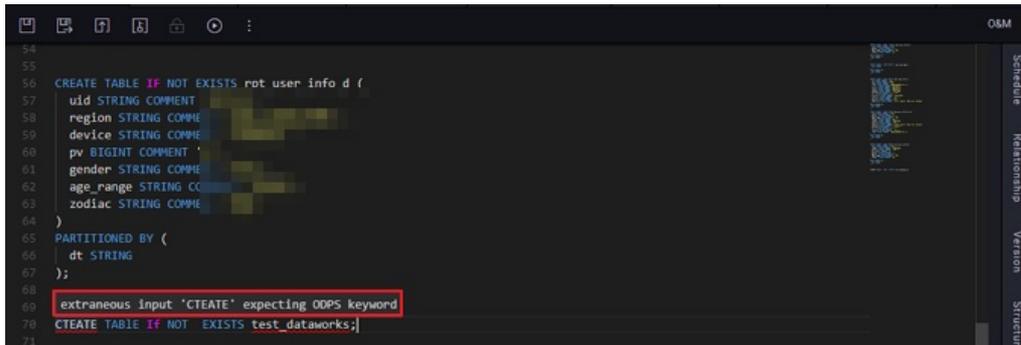

- Minimap**

The masked code in the current interface is displayed in the minimap in the upper-right corner of the page. When the code is long, you can move the pointer to specify the code block to be displayed in the minimap.

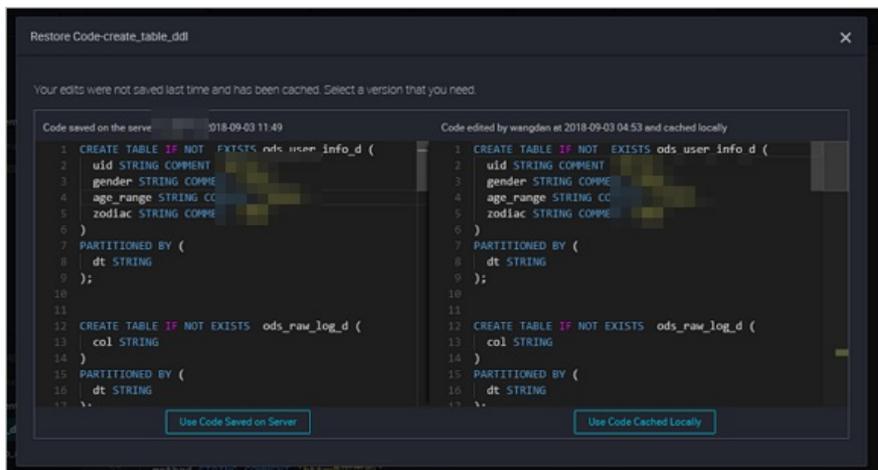

- Error Annotation**

If you select this check box, DataWorks marks potential syntax errors with a red squiggly line. When you see a syntax error, you can move the pointer over the underlined code to view the error message.

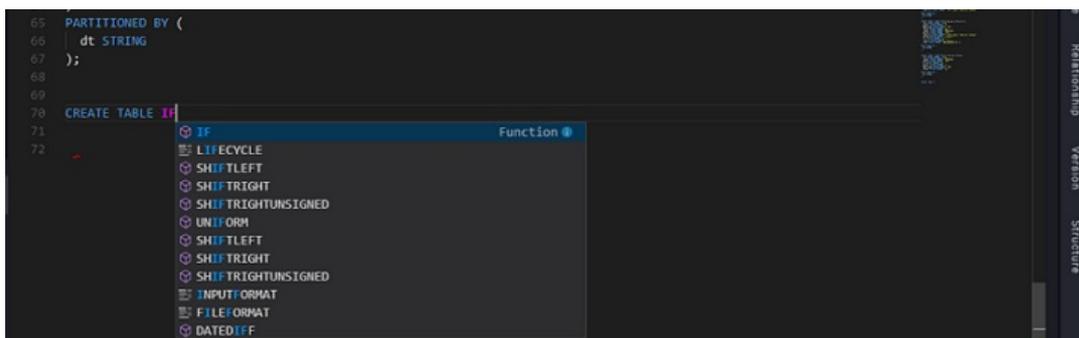

- **Auto Save**

If you select this check box, DataWorks automatically saves the code being edited at a specific interval. In this way, if the code editor of a node is closed unexpectedly, you can click **Use Version Saved on Server** or **Use Version Saved in Local Cache** to re-open the node.

- **Auto-Completed Code Style**

You can set the code style to uppercase or lowercase as required.

- **Auto Line Wrap**

You can set Auto Line Wrap to **Disable** or **Enable**.

- **Wrap at Column**

- If Auto Line Wrap is set to **Disable**, the value of Wrap at Column is 80 by default, which cannot be modified.
- If Auto Line Wrap is set to **Enable**, you can set a value for Wrap at Column as required.

- **Code Font Size**

Valid values: 12 to 18. You can change the font size based on your habits and code size.

- **Enter suggestions**

If you select this check box, the system automatically displays suggestions on how to set a field when you press Enter. If you clear this check box, a new line is started after you press Enter. In addition to the Enter key, you can also use the Tab key to enter prompted suggestions.

- **Auto Completion**

You can specify whether to enable the following code hints when you enter the code:

- **Continuous Smart Tips**: specifies whether to automatically add a space after each auto-completed term such as a keyword, table name, or field name.
- **Keyword**: specifies whether to enable keyword hints.
- **Syntax Template**: specifies whether to enable syntax template hints.
- **Project**: specifies whether to enable project name hints.
- **Table Name**: specifies whether to enable table name hints. When this feature is enabled, the system gives higher priority to tables used recently.
- **Field**: specifies whether to enable field name hints.

General settings

- **Display Node Engine Information on DAG**

You can specify whether to display node engine information on the DAG.

- **Theme**

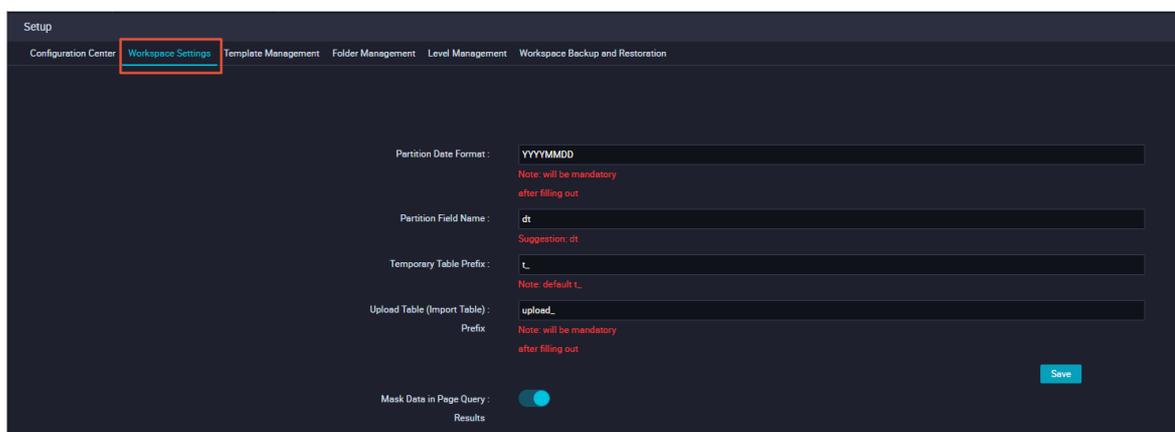

You can set the DataStudio theme to black or white.

2.5.9.3. Workspace settings

The Workspace Settings tab displays five parameters: Partition Date Format, Partition Field Name, Temporary Table Prefix, Upload Table (Import Table) Prefix, and Mask Data in Page Query Results.

Go to the Workspace Settings tab

1. [Log on to the DataWorks console.](#)
2. On the **Data Analytics** tab, click  in the lower-left corner.
3. On the **Setup** page, click the **Workspace Settings** tab.

Parameter	Description
Partition Date Format	The default date format of partition field values. You can modify the format as required.
Partition Field Name	The default name of a partition field.
Temporary Table Prefix	The prefix of temporary table names. By default, tables with the prefix t_ in their names are identified as temporary tables.
Upload Table (Import Table) Prefix	The prefix of the names of tables uploaded on the DataStudio page.
Mask Data in Page Query Results	Specifies whether to de-identify data in the query results. When the switch is turned on, the result returned for an ad hoc query node in the current workspace will be de-identified.

Enable de-identification for DataWorks workspaces

Data de-identification for DataWorks needs to be enabled in workspaces one by one. After data de-identification is enabled, the result returned for an ad hoc query node in the current workspace will be de-identified. The underlying storage data is not affected because only dynamic de-identification is performed.

Note For example, data de-identification is enabled in workspace A but not workspace B. If you initiate a request in workspace B to query tables in workspace A, the query result is displayed in plaintext.

On the **Workspace Settings** tab, turn on **Mask Data in Page Query Results**. After you click **Save**, the result returned for an ad hoc query node in the current workspace will be de-identified.

Note By default, the **Mask Data in Page Query Results** switch is turned off and you are not allowed to download de-identified data.

After data de-identification is enabled for DataWorks workspaces, the data types listed in the following table are de-identified by default.

Type	Data de-identification rule	Raw data	De-identified data
ID card number	Only the first and last digits in a 15-digit or an 18-digit ID card number are displayed in plaintext. All the other digits are displayed as asterisks (*).	512345678943215678	5*****8
Mobile number	Only the first three and last two digits in a mobile number in mainland China are displayed in plaintext. All the other digits are displayed as asterisks (*).	18112345678	181*****78

Type	Data de-identification rule	Raw data	De-identified data
Email address	If the string before the at sign (@) in an email address contains three or more characters, only the leftmost three characters are displayed in plaintext, followed by three asterisks (*). If the string before the at sign (@) contains only one or two characters, the entire string is displayed in plaintext, followed by three asterisks (*).	<ul style="list-style-type: none"> eftry.abc@gmail.com af@abc.com 	<ul style="list-style-type: none"> eft***@gmail.com af***@abc.com
Bank card number	Only the last four digits in a credit card number or deposit card number are displayed in plaintext. All the other digits are displayed as asterisks (*).	<ul style="list-style-type: none"> 1234576834509782 643257829145430986 	<ul style="list-style-type: none"> *****9782 *****0986
IP address or MAC address	Only the first segment in an IP address or a MAC address is displayed in plaintext. All the other characters are displayed as asterisks (*).	<ul style="list-style-type: none"> 192.000.0.0 ab:cd:11:a3:a0:50 	<ul style="list-style-type: none"> 192.***.*.* ab:*.*.*.*.*.*.*
License plate number	Only the one-character provincial abbreviation and the last three characters in a license plate number in mainland China are displayed in plaintext. All the other characters are displayed as asterisks (*).	<ul style="list-style-type: none"> (One-character provincial abbreviation)AP555B (One-character provincial abbreviation)ADP555T 	<ul style="list-style-type: none"> (One-character provincial abbreviation)A**55B (One-character provincial abbreviation)A***55T

 **Note** If you want to de-identify more data types or have special requirements on the de-identified data formats, complete your de-identification settings in Data Security Guard. The feature of de-identifying data for DataWorks workspaces must work with Data Security Guard. For more information, see [Data security guard](#).

2.5.9.4. Template management

The Template Management page displays code templates. Workspace administrators can change the display formats of the templates as required.

Procedure

1. [Log on to the DataWorks console](#).
2. On the **Data Analytics** tab, click  in the lower-left corner.
3. On the **Setup** page, click the **Template Management** tab.

Note Templates are only available for ODPS SQL, ODPS MR, and Shell nodes.

4. Find the target template and click **Change** in the Actions column.
5. In the **Node Template** dialog box, enter the template as required.
6. Click **Save**.

2.5.9.5. Folder management

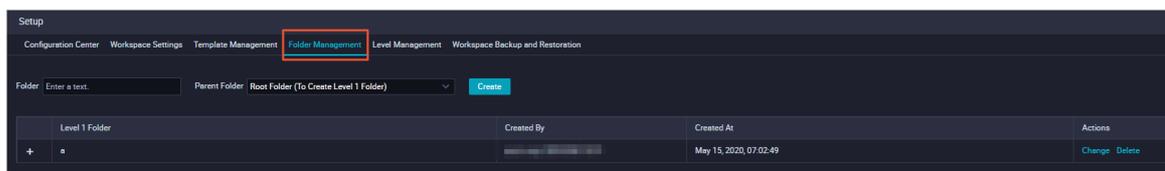

Each workspace can hold a great number of tables. For easy management, you can organize tables in two levels of folders.

Context

Folders are used to store tables. A workspace administrator can add multiple folders and classify tables by purpose and name.

Procedure

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, click  in the lower-left corner.
3. On the **Setup** page, click the **Folder Management** tab.

On the page that appears, you can add, modify, and delete folders.

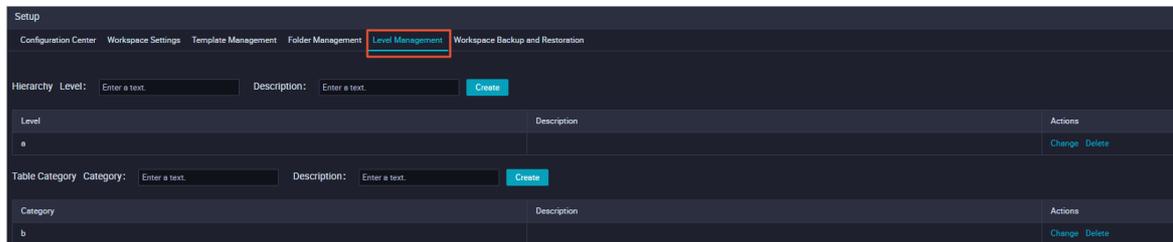

- o Add a folder
Enter a custom folder name in the **Folder** field, select a parent folder from the **Parent Folder** drop-down list, and then click **Create**.
- o Modify a folder
Find the target folder and click **Change** in the Actions column. In the **Change Folder** dialog box, enter a new folder name and click **OK**.
- o Delete a folder
Find the target folder and click **Delete** in the Actions column. In the **Delete Folder** message, click **OK**.

2.5.9.6. Level management

On the Level Management tab, you can design physical levels of tables.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, click  in the lower-left corner.
3. On the Setup page, click the **Level Management** tab.

You can classify tables based on their importance. Level management allows you to precisely locate incorrectly organized tables and ensures normal running of published jobs.

If a workspace does not contain default table levels, the workspace owner or workspace administrator must add them as required.

On the **Level Management** tab, you can add, modify, and delete table levels.

- o To add a table level, perform the following steps:
 - a. In the **Hierarchy** section, set **Level** and **Description**.
 - b. Click **Create**.
- o To modify a table level, perform the following steps:
 - a. Find the target table level and click **Change** in the **Actions** column.
 - b. In the **Change Level** dialog box, modify **Level** and **Description** as needed.
 - c. Click **OK**.
- o To delete a table level, perform the following steps:
 - a. Find the target table level and click **Delete** in the **Actions** column.
 - b. In the **Delete Level** message, click **OK**.

On the **Level Management** tab, you can also add, modify, and delete table categories.

- o To add a table category, perform the following steps:
 - a. In the **Table Category** section, set **Category** and **Description**.
 - b. Click **Create**.
- o To modify a table category, perform the following steps:
 - a. Find the target table category and click **Change** in the **Actions** column.
 - b. In the **Change Category** dialog box, modify **Category** and **Description** as needed.
 - c. Click **OK**.
- o To delete a table category, perform the following steps:
 - a. Find the target table category and click **Delete** in the **Actions** column.
 - b. In the **Delete Category** message, click **OK**.

2.5.9.7. Workspace backup and restore

On the Workspace Backup and Restoration tab, you can migrate code between workspaces. This topic describes how to back up and restore a workspace.

Prerequisites

Workspaces are created. For more information, see [Create a workspace](#).

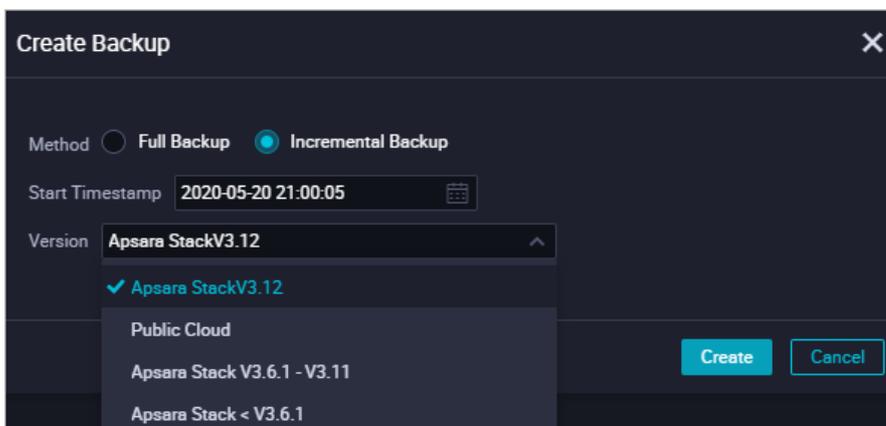

Go to the Workspace Backup and Restoration tab

1. [Log on to the DataWorks console](#).
2. On the **Data Analytics** tab, click  in the lower-left corner.
3. On the **Setup** page, click the **Workspace Backup and Restoration** tab. On the page that appears, you can back up and restore workspaces.
 - On the **Backup** tab, you can compress the node code, node dependencies, resources, and functions in a workspace into one package.
 - On the **Restore** tab, you can restore a workspace to its original scheduling settings. After the workspace is restored, all nodes in the workspace are saved but not committed.

Back up a workspace

A workspace backup is a compressed package containing the node code, node dependencies, resources, and functions in the workspace.

- Only workspace administrators can export backups and restore data from backups.
 - Workflows and node groups of earlier versions cannot be backed up. We recommend that you use the latest version for data analytics.
 - A node backed up to a path in the workspace will override the original node with the same name in the path. We recommend that you create another workspace to restore data.
 - Data in tables is not backed up when you back up a workspace. You can synchronize the table data in the following ways:
 - Click the **Workspace Manage** icon in the upper-right corner. On the page that appears, click **Data Source** and configure a MaxCompute connection. Then, create a sync node to back up the data.
 - In workspace A, run the data definition language (DDL) statement `create table select * from workspace B. Table name` to migrate data.
1. On the **Workspace Backup and Restoration** tab, click **Backup**.
 2. Click **Create Backup** in the upper-right corner.
 3. In the **Create Backup** dialog box, set the parameters as required.

Parameter	Description
-----------	-------------

Parameter	Description
Method	<p>The method used to back up the workspace. Valid values:</p> <ul style="list-style-type: none"> ◦ Full Backup: Back up all the node code, node dependencies, resources, and functions in the workspace. ◦ Incremental Backup: Back up all the new or modified nodes from the timestamp specified by the Start Timestamp parameter to the current time. <p>Note If you use the incremental backup method, make sure that the dependencies between incremental sync nodes are correct. Otherwise, the workspace may fail to be restored. We recommend that you set this parameter to Full Backup.</p>
Start Timestamp	The start time point at which data in the workspace is backed up. This parameter is available only when you set Method to Incremental Backup .
Version	The version of the workspace to be backed up. Valid values: Apsara Stack V3.12 , Public Cloud , Apsara Stack V3.6.1 - V3.11 , and Apsara Stack < V3.6.1 .

4. Click **Create**. After the data is backed up, click **Download** to download the backup data to a local device.

Restore a workspace

1. On the **Workspace Backup and Restoration** tab, click **Restore**.
2. Click **Restore** in the upper-right corner.
3. In the **Restore** dialog box, click **Select File**.

Note You can upload the compressed package that you previously backed up to the workspace.

4. Click **Restore**.
5. Click **Set Compute Engine Mapping**. In the dialog box that appears, set the mapping between the compute engines of the current workspace and the destination workspace.
6. Click **OK**. If the workspace that you backed up contains multiple compute engines, the system scans all compute engine instances during restoration. The system only restores nodes of the existing compute engines in the workspace to be restored. In this case, you must configure the mappings between the compute engines before restoring the destination workspace.

Note

- If the workspace to be restored does not contain a compute engine type such as E-MapReduce, or no instance is available for the compute engine type, nodes of this engine type are not restored.
- Compute engine mappings must be configured for custom node types.

2.5.10. Deploy

2.5.10.1. Deploy nodes

In a rigorous data development process, developers develop and debug code and configure dependencies and scheduling properties for nodes in the development environment. Then, developers commit and deploy the nodes to run them in the production environment.

DataWorks workspaces in standard mode can process data seamlessly from the development environment to the production environment within a single workspace. We recommend that you use workspaces in standard mode to develop and produce data.

Deploy nodes in a workspace in standard mode

Each DataWorks workspace in standard mode is linked with two MaxCompute projects, one as the development environment and the other as the production environment. You can directly commit and deploy nodes from the development environment to the production environment.

Follow these steps:

1. On the **DataStudio** page, configure and debug the code of nodes. Then, double-click the target workflow in the left-side navigation pane. On the dashboard of the workflow that appears, click the **Submit** icon to check whether the dependencies between nodes are correct and commit the nodes.
2. After the nodes are committed, click the **Deploy** icon.
3. On the **Create Deploy Task** page that appears, select the target nodes and click **Add to List**. The nodes are added to the to-be-deployed node list.

You can search for nodes by condition, such as the committer, node type, change type, time when a node is committed, node name, and node ID. If you click **Deploy Selected**, the selected nodes are deployed to the production environment.

4. Click **View List**. In the **Nodes to Deploy** dialog box that appears, click **Deploy All**. All nodes in the list are deployed to the production environment.

 **Note** Workspaces in standard mode protect tables in the production environment from being manipulated, and therefore provide the stable, secure, and reliable production environment. We recommend that you use workspaces in standard mode to deploy and run nodes.

Clone nodes between workspaces in basic mode

You cannot deploy nodes in workspaces in basic mode. If you want to isolate the development environment from the production environment for workspaces in basic mode, create two workspaces, one for development and the other for production. You can clone nodes from the development workspace to the production workspace.

As shown in the following figure, two workspaces in basic mode are created, one for development and the other for production. You can use the cross-workspace cloning feature to clone nodes from Workspace A to Workspace B, and then commit the cloned nodes to the scheduler for scheduling.

-  **Note**
- **Permission requirement:** Only workspace administrators and Resource Access Management (RAM) users who have the O&M permissions can clone nodes.
 - **Workspace type:** You can only clone nodes in workspaces in basic mode, but cannot clone those in workspaces in standard mode.
 - **Prerequisites:** The source workspace in basic mode and the destination workspace in basic mode are created.

1. Commit nodes.

After you create and configure nodes in the source workspace, commit the nodes on the dashboard of the target workflow.

2. Click **Cross-Workspace Cloning**.

3. On the Create Clone Task page that appears, select the target nodes and the destination workspace, and then click **Add to List**.

4. Clone the nodes. Click **View List**. In the To-Be-Cloned Nodes dialog box that appears, check the nodes to be cloned and click **Clone All**.

In the Create Clone Task dialog box that appears, click **Clone**.

5. View the cloned nodes.

You can view the successfully cloned nodes on the View Clone Tasks page of the source workspace.

Switch to the destination workspace. You can find that the nodes are cloned from the source workspace.

2.5.10.2. Overview of cross-workspace cloning

For workspaces under the same Apsara Stack tenant account, you can use the cross-workspace cloning feature to clone and deploy workflows across these workspaces. You can also use this feature to clone nodes, such as computing or sync nodes, across workspaces. This topic describes how to process the dependencies between nodes during cross-workspace cloning.

If you clone nodes across workspaces by using the **cross-workspace cloning** feature, DataWorks automatically changes the output names of the cloned nodes in the destination workspace to distinguish nodes in different workspaces under the same Apsara Stack tenant account. This allows you to successfully clone node dependencies.

 **Note** Cross-workspace cloning cannot be used to clone nodes across workspaces in different regions.

You can set the owner of cloned nodes in the destination workspace to **Default** or **Clone Task Creator**.

- If you clone nodes owned by the workspace administrator:

After the nodes are cloned to the destination workspace, their owner is set to the original owner preferentially. If the original owner is not added to the destination workspace, you will become the owner.

- If you clone nodes owned by yourself:

After the nodes are cloned to the destination workspace, their owner is set to you preferentially. If you are not added to the destination workspace, you are asked whether to change the owner. If you agree to change the owner, you will be added to the destination workspace and become the owner of the cloned nodes. If you do not agree to change the owner, the clone task is canceled.

Clone a workflow

Assume that the output of the task_A node in the project_1 workspace is project_1.task_A_out. If you clone a workflow that contains the task_A node to the destination workspace project_2, the node output name changes to project_2.task_A_out in the destination workspace.

Clone node dependencies

Assume that the task_B node in the project_1 workspace depends on the task_A node in the project_3 workspace. If you clone the task_B node in the project_1 workspace to the destination workspace project_2, the dependency between the task_A and task_B nodes is also cloned. The task_B node in the project_2 workspace also depends on the task_A node in the project_3 workspace.

2.5.10.3. Clone nodes across workspaces

This topic describes how to clone nodes across workspaces with an example of cloning a workflow from one workspace to another.

Prerequisites

Two workspaces named `Weisong_dataworks_test` and `Weisong_dataworks_test2` respectively are created. For more information about how to create a workspace, see [Create a workspace](#).

Context

You can clone nodes across workspaces in the following scenarios:

- Clone nodes from a workspace in the basic mode to another workspace in the basic mode.
- Clone nodes from a workspace in the basic mode to another workspace in the standard mode.

After you clone a node, the folder and workflow to which the node belongs are cloned to the destination workspace. Any change to the node, folder, or workflow can also be cloned to the destination workspace.

Procedure

1. Log on to the DataWorks console. On the DataStudio page that appears, switch to the `Weisong_dataworks_test` workspace in the top navigation bar.
2. Select the target workflow. In the Data Analytics section, double-click the target workflow. On the workflow configuration page that appears, click **Cross-Workspace Cloning** in the upper-right corner. The Create Clone Task page appears.
3. Select the destination workspace, node type, and change type. On the **Create Clone Task** page, set **Target Workspace** to `Weisong_dataworks_test2`. Select the node type and change type of the node for the clone task as required, and select one or more target nodes that appear in the list. Then, click **Clone Selected**.
4. In the **Create Clone Task** dialog box that appears, check the destination workspace, target node, and change type, and then click **Clone**.
5. After the system message that indicates the target node is cloned successfully and is being committed to the destination workspace appears, switch to the `Weisong_dataworks_test2` workspace. In the **Data Analytics** section, view the workflow that has been successfully cloned to the current workspace.

2.5.11. Create an ad hoc query node

The Ad-Hoc Query tab allows you to test your code in the development environment. You can check for errors and check whether your code works as expected.

Context

You do not need to commit and deploy ad hoc query nodes or configure scheduling policies for ad hoc query nodes. You can configure scheduling policies only for nodes created under **Business Flow** on the **Data Analytics** tab.

Create a folder

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Ad-Hoc Query** icon. Click  in the lower-left corner to show or hide the left-side navigation pane.
3. On the Ad-Hoc Query tab, move the pointer over  and select **Folder**.

4. In the **Create Folder** dialog box, set **Folder Name** and **Location**.

 **Note**

- The folder name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
- DataWorks supports multi-level folders. You can save a newly created folder under another folder that already exists.

5. Click **Commit**.

Create an ad hoc query node

You can create **ODPS SQL** and **Shell** nodes on the **Ad-Hoc Query** tab. This topic describes how to create an ODPS SQL node.

1. On the **Ad-Hoc Query** tab, right-click the target folder and choose **Create Node > ODPS SQL**.
2. In the **Create Node** dialog box, set **Node Name** and **Location**.

 **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

3. Click **Commit**.
4. On the node configuration tab that appears, enter an SQL statement.
5. Click  in the toolbar.

2.5.12. View runtime logs

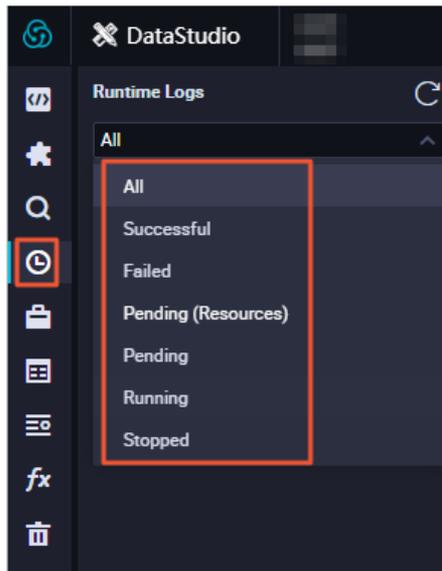

The **Runtime Logs** tab displays the records of all nodes that have been run in the last three days. You can click a node to view its runtime logs.

Context

The runtime logs are retained for only three days.

Procedure

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Runtime Logs** icon. Click  in the lower-left corner to show or hide the left-side navigation pane.
3. Select a node state from the drop-down list to view the runtime logs of nodes in the specified state.

4. Click a record to view the runtime log on the right. If you need to save the SQL statements in the runtime log, click  in the toolbar. In the **Create Node** dialog box, set the parameters and click **Commit** to save the SQL statements that have been run as an ad hoc query node.

2.5.13. View tenant tables

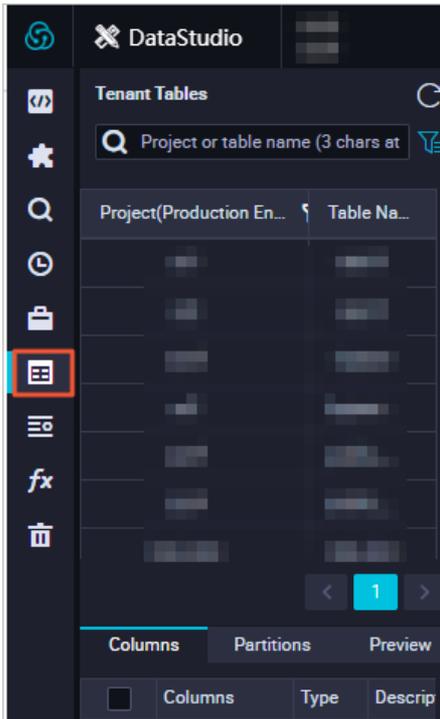

On the Tenant Tables tab, you can view tables of all workspaces of the current tenant account.

Prerequisites

The **Tenant Tables** tab appears only after you bind a MaxCompute compute engine on the **Project Management** page. For more information, see [Configure a workspace](#).

Procedure

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Tenant Tables** icon. Click  in the lower-left corner to show or hide the left-side navigation pane.
3. View MaxCompute tenant tables.

Parameter or tab	Description
Project Name	<p>The name of the workspace in the corresponding environment.</p> <p>Click  next to the search box and select the target environment to switch to the environment.</p> <div style="background-color: #e0f2f1; padding: 10px;"> <p> Note</p> <ul style="list-style-type: none"> ◦ For a workspace in standard mode, the Tenant Tables tab displays tables in both the development environment and the production environment. For a workspace in basic mode, the Tenant Tables tab displays only the tables in the production environment. ◦ The current environment is marked in blue. </div>
Table Name	The name of the table in the corresponding workspace.
Columns tab	Displays the name, data type, and description of fields in the table.
Partitions tab	<p>Displays the partition information of the current table. A maximum of 60,000 partitions are supported. If you have specified the TTL for partitions, the number of partitions depends on the TTL.</p> <div style="background-color: #e0f2f1; padding: 10px;"> <p> Notice The partition information is displayed only for MaxCompute tenant tables.</p> </div>

Parameter or tab	Description
Preview tab	<p>Displays the data of the current table.</p> <div style="border: 1px solid #ccc; background-color: #e0f2f1; padding: 5px;"> <p> Notice You can preview only the data of MaxCompute tenant tables.</p> </div>

2.5.14. Manage tables

This topic describes how to view, modify, and delete MaxCompute tables, and the basic knowledge about data hierarchy.

Prerequisites

The **Workspace Tables** tab appears only after you bind a MaxCompute compute engine on the **Project Management** page. For more information, see [Configure a workspace](#).

Manage tables

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Workspace Tables** icon. Click  in the lower-left corner to show or hide the left-side navigation pane.
3. View and manage tables. The following section describes how to view, modify, and delete a MaxCompute table. For more information about how to create a table, see [Create a MaxCompute table](#).

Operation	Description
View a table	<p>Click  next to the search box and select the target environment to switch to the environment.</p> <div style="border: 1px solid #ccc; background-color: #e0f2f1; padding: 5px;"> <p> Note</p> <ul style="list-style-type: none"> ○ For a workspace in standard mode, the Workspace Tables tab displays tables in both the development environment and the production environment. ○ For a workspace in basic mode, the Workspace Tables tab displays only the tables in the production environment. ○ The current environment is marked in blue. </div> <p>Double-click a table to view its details on the table configuration tab.</p>
Import data to a table	<p>On the Workspace Tables tab, click  to import data to a table. For more information, see Create tables and import data.</p>

Divide a data warehouse into layers

In the **Physical Model** section of the configuration tab of a table, you can define table layers for a data warehouse. This allows you to have better planning and control over your data.

Typically, a data warehouse consists of the following layers:

- ODS: The ODS layer stores raw data of the source system based on the original data structure. The ODS

layer serves as the data staging area of the data warehouse. It imports basic data to MaxCompute and records historical changes of basic data.

- CDM: The CDM layer consists of the dimension data (DIM), data warehouse detail (DWD), and data warehouse service (DWS) layers. The CDM layer processes and integrates the data of the ODS layer to define conformed dimensions, create reusable detailed fact tables for data analysis and statistics collection, and aggregate common metrics.
 - The DIM layer defines conformed dimensions for an enterprise based on the concepts of dimensional modeling. It reduces the risk of inconsistent statistical criteria and algorithms.

Tables at the DIM layer are also called logical dimension tables. Generally, each dimension corresponds to a logical dimension table.
 - The DWS layer is driven by analyzed subjects during data modeling. Based on the metric requirements of upper-layer applications and products, the DWS layer creates fact tables to aggregate common metrics and builds a physical data model by using wide tables. The DWS layer creates statistical metrics in compliance with uniform naming conventions and statistical criteria, provides common metrics for the upper layer, and generates aggregate wide tables and detailed fact tables.

Tables at the DWS layer are also called logical aggregate tables, which are used to store derived metrics.
 - The DWD layer is driven by business processes during data modeling. It creates detailed fact tables at the finest granularity based on each specific business process. In combination with the data usage habits of an enterprise, you can duplicate some key attribute fields of dimensions in detailed fact tables to create wide tables.

Tables at the DWD layer are also called logical fact tables.
- ADS: The ADS layer stores personalized statistical metrics of data products. It processes the data of the CDM and ODS layers.

2.5.15. View built-in functions

The Built-In Functions tab displays functions built in MaxCompute. You can view the types, description, and examples of functions on this tab.

Procedure

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Built-In Functions** icon. Click  in the lower-left corner to show or hide the left-side navigation pane.
3. View the types, description, and examples of the built-in functions. Functions are categorized into aggregate functions, analytic functions, date functions, mathematical functions, string functions, and other functions. The preceding functions are built in MaxCompute. You can click a function to view its description.

2.5.16. Manage deleted nodes

DataWorks provides a recycle bin to store all deleted nodes in the current workspace. You can restore or permanently delete the nodes.

Go to the Recycle Bin tab

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Recycle Bin** icon. Click  in the lower-left corner to show or hide the left-side navigation pane.

3. View all the deleted nodes in the current workspace. On this tab, you can delete or restore a deleted node.

 **Notice**

- The recycle bin displays only 100 nodes. If more than 100 nodes are deleted, the nodes deleted earlier are deleted permanently from the recycle bin.
- Deleted node groups are not displayed in the recycle bin.

Restore a node in the recycle bin

1. On the **Recycle Bin** tab, right-click a deleted node.
2. Select **Restore**.
3. In the **Restore Node** message, click **OK**.

 **Note** After you restore a node, a new node ID is generated for scheduling and all the information about the node is restored.

Permanently delete a node from the recycle bin

1. On the **Recycle Bin** tab, right-click a deleted node.
2. Select **Delete**.
3. In the **Delete** message, click **OK**.

 **Note** Nodes permanently deleted from the recycle bin cannot be restored. The recycle bin displays only deleted nodes.

2.5.17. Create a manually triggered workflow

In a manually triggered workflow, all nodes must be manually triggered, and cannot be automatically scheduled by DataWorks. Therefore, you do not need to specify parent nodes or outputs for nodes in manually triggered workflows.

Create a manually triggered workflow

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Manually Triggered Workflows** icon.

Click  in the lower-left corner to show or hide the left-side navigation pane.

3. Right-click **Manually Triggered Workflows** and select **Create Workflow**.
4. In the **Create Workflow** dialog box, set **Workflow Name** and **Description**.

 **Notice** The workflow name must be 1 to 128 characters in length and can contain letters, digits, underscores (`_`), and periods (`.`). It is not case-sensitive.

5. Click **Create**.

Composition of a manually triggered workflow

 **Note** We recommend that you create a maximum of 100 nodes in a manually triggered workflow.

A manually triggered workflow consists of the nodes of the following modules. After you create a manually triggered workflow, open this workflow and create nodes of various types for each module. For more information, see [Node types](#).

- **Data Integration**

Double-click **Data Integration** under the created workflow to view all the data integration nodes.

Right-click **Data Integration** and choose **Create > Batch Synchronization** to create a batch sync node. For more information, see [Create a batch sync node](#).

- **MaxCompute**

The MaxCompute compute engine consists of data analytics nodes, such as ODPS SQL, SQL Snippet, ODPS Spark, PyODPS, ODPS Script, and ODPS MR nodes. You can also view and create tables, resources, and functions.

- **Data Analytics**

Show **MaxCompute** under the created workflow and right-click **Data Analytics** to create a data analytics node. For more information, see [Create an ODPS SQL node](#), [Create an SQL Snippet node](#), [Create an ODPS Spark node](#), [Create a PyODPS node](#), [Create an ODPS Script node](#), and [Create an ODPS MR node](#).

- **Table**

Show **MaxCompute** under the created workflow and right-click **Table** to create a table. You can also view all the tables created for the current MaxCompute compute engine. For more information, see [Create a MaxCompute table](#).

- **Resource**

Show **MaxCompute** under the created workflow and right-click **Resource** to create a resource. You can also view all the resources created for the current MaxCompute compute engine. For more information, see [Create, reference, and download resources](#).

- **Function**

Show **MaxCompute** under the created workflow and right-click **Function** to create a function. You can also view all the functions created for the current MaxCompute compute engine. For more information, see [Register a UDF](#).

- **Algorithm**

Click the created workflow and right-click **Algorithm** to create an algorithm. You can also view all the PAI nodes created in the current manually triggered workflow. For more information, see [Create a PAI node](#).

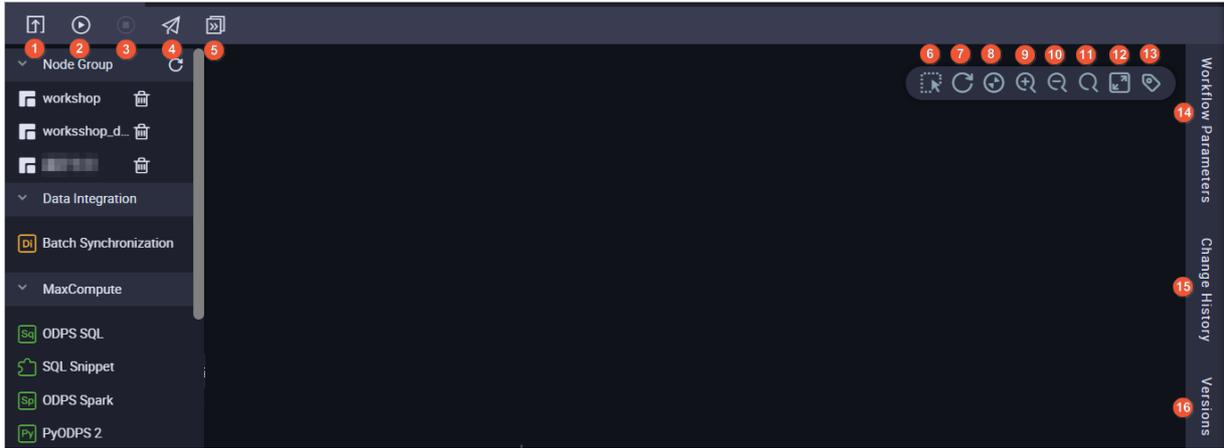

- **General**

Click the created workflow and right-click **General** to create relevant nodes. For more information, see [Create a Shell node](#) and [Create a zero-load node](#).

- **UserDefined**

Click the created workflow and right-click **UserDefined** to create relevant nodes. For more information, see [Create a Hologres development node](#).

GUI elements

The following table describes the icons and tabs on the Manually Triggered Workflows page.

No.	Icon or tab	Description
1	Submit icon	Commits all nodes in the current manually triggered workflow.
2	Run icon	Runs all nodes in the current manually triggered workflow. Nodes in this workflow do not have dependencies, and therefore they can run at a time.
3	Stop icon	Stops all running nodes in the current manually triggered workflow.
4	Deploy icon	Navigates to the Deploy page. On this page, you can deploy some or all nodes that are committed but not deployed to the production environment. <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> <p>Note This icon is available only when the workspace is in standard mode.</p> </div>
5	Go to Operation Center icon	Navigates to the Operation Center page.
6	Box. icon	Box-selects a node group consisting of required nodes.
7	Refresh icon	Refreshes the page of the current manually triggered workflow.
8	Auto Layout icon	Sorts the nodes in the current manually triggered workflow.
9	Zoom In icon	Zooms in the current page.
10	Zoom Out icon	Zooms out the current page.
11	Search icon	Searches for a node in the current manually triggered workflow.
12	Toggle Full Screen View icon	Displays nodes in the current manually triggered workflow in the full screen.
13	Show Engine Information/Hide Engine Information icon	Shows or hides engine information.

No.	Icon or tab	Description
14	Workflow Parameters tab	Allows you to set parameters. Parameters set on this tab have a higher priority than those specified on the corresponding node configuration tab. If two values are set separately, the value set on the Workflow Parameters tab takes effect.
15	Change History tab	Allows you to view the operation records of all nodes in the current manually triggered workflow.
16	Versions tab	Allows you to view the deployment records of all nodes in the current manually triggered workflow.

2.5.18. Editor keyboard shortcuts

This section describes keyboard shortcuts available for the code editor.

Google Chrome in Windows OS

Ctrl + S : Save changes to a node.

Ctrl + Z : Undo an action.

Ctrl + Y : Redo an action.

Ctrl + D : Select occurrences.

Ctrl + X : Cut a line.

Ctrl + Shift + K : Delete a line.

Ctrl + C : Copy a line.

Ctrl + I : Select a line.

Alt + Shift + Drag : Select a block.

Alt + Click : Insert an additional cursor.

Ctrl + Shift + L : Select all occurrences.

Ctrl + F : Search for text in a node.

Ctrl + H : Replace text in a node.

Ctrl + G : Locate a line.

Alt + Enter : Select all matched strings.

Alt + Up or down arrow : Move a line up or down.

Alt + Shift + Up or down arrow : Duplicate a line.

Ctrl + Shift + K : Delete a line.

Ctrl + Enter or Ctrl + Shift + Enter : Insert a line break downwards or upwards.

Ctrl + Shift + Back slash (\) : Jump to the parenthesis, bracket, or brace that matches the adjacent one.

Ctrl + Left bracket ([) or right bracket (]) : Increase or decrease the indent of a line.

Home or End : Move the cursor to the beginning or end of a line.

Ctrl + Home or End : Move the cursor to the top or bottom of a node.

Ctrl + Left or Right arrow : Move the cursor one word to left or right.

Ctrl + Shift + Left bracket (]) or right bracket ([) : Hide or show a block.

Ctrl + K + Left bracket (]) or right bracket ([) : Hide or show sub-blocks in a block.

Ctrl + K + 0 or J : Hide or show all blocks.

Ctrl + Slash (/) : Comment out or uncomment the selected lines or blocks.

Google Chrome in Mac OS

Command-S : Save changes to a node.

Command-Z : Undo an action.

Command-Y : Redo an action.

Command-D : Select occurrences.

Command-X : Cut a line.

Shift-Command-K : Delete a line.

Command-C : Copy a line.

Command-I : Select a line.

Command-F : Search for text in a node.

Option-Command-F : Replace text in a node.

Option-Up or down arrow : Move a line up or down.

Option-Shift-Up or down arrow : Duplicate a line.

Shift-Command-K : Delete a line.

Command-Enter or Shift-Command-Enter : Insert a line break downwards or upwards.

Shift-Command-Back slash (\) : Jump to the parenthesis, bracket, or brace that matches the adjacent one.

Command-Left bracket (]) or right bracket ([) : Increase or decrease the indent of a line.

Command-Left or right arrow : Move the cursor to the beginning or end of a line.

Command-Up or down arrow : Move the cursor to the top or bottom of a node.

Option-Left or right arrow : Move the cursor one word to left or right.

Option-Command-Left bracket (]) or right bracket ([) : Hide or show a block.

Command-K-Left bracket (]) or right bracket ([) : Hide or show sub-blocks in a block.

Command-K-0 or J : Hide or show all blocks.

Command-Slash (/) : Comment out or uncomment the selected lines or blocks.

Insert multiple cursors and select multiple occurrences or lines

Option-Click : Insert an additional cursor.

Option-Command-Up or down arrow : Insert an additional cursor to the previous or next line.

Command-U : Undo a cursor-related operation.

Option-Shift-I : Insert a cursor at the end of each selected line.

Command-G or Shift-Command-G : Select the next or previous matched string.

Command-F2 : Select the nearest character of each cursor.

Shift-Command-L : Select the nearest word of each cursor.

Option-Enter : Select all the matched strings.

Option-Shift-Drag : Multi-select lines

Option-Shift-Command-Up or down arrow : Extend a selection one line up or down.

Option-Shift-Command-Left or right arrow : Extend a selection one character to the left or right.

2.5.19. Use E-MapReduce in DataWorks

This topic describes how to use E-MapReduce in DataWorks.

Bind an E-MapReduce project to a DataWorks workspace

Note Before you bind an E-MapReduce project to a DataWorks workspace, you must obtain the information about the E-MapReduce project.

1. Log on to the DataWorks console.
2. On the DataStudio page, click  in the upper-right corner. The **Project Management** page appears.
3. Click the **E-MapReduce** tab in the **Computing Engine Information** section. On this tab, you can view the information about all available E-MapReduce compute engines in the current workspace.
4. Click **Add instances**.
5. In the **New EMR cluster** dialog box, set the parameters as required.

Parameter	Description
Instance display name	The name of the E-MapReduce compute engine instance.
Region	The region of the workspace.
Access ID	The AccessKey ID of the account authorized to access the E-MapReduce cluster.
Access Key	The AccessKey secret of the account authorized to access the E-MapReduce cluster.

Parameter	Description
EmrClusterID	The ID of the E-MapReduce cluster.
Cluster ID	The ID of the user who created the E-MapReduce cluster.
Project ID	The ID of the project in the E-MapReduce cluster.
YARN resource queue	The name of the resource queue in the E-MapReduce cluster. Unless otherwise specified, set the value to <i>default</i> .
Endpoint	The endpoint of the E-MapReduce cluster. You can obtain the endpoint in the Apsara Stack Operations console. For more information, see Obtain an endpoint .

6. Click **Confirm**. After the E-MapReduce cluster is bound to your workspace, you can create E-MapReduce nodes on the **DataStudio** page.

-  **Note** If the binding fails, check whether the failure is caused by one of the following reasons:
- The E-MapReduce user ID is bound to another tenant account.
 - The specified cluster name already exists.

Create an E-MapReduce node

E-MapReduce nodes are categorized into four types: EMR Hive, EMR Spark SQL, EMR Spark, and EMR MR. For more information, see [Create an EMR MR node](#).

Reference resource files

E-MapReduce resource files are categorized into two resource types: EMR JAR and EMR File.

Reference E-MapReduce resource files by using the following methods:

- For EMR Hive and EMR MR nodes, add `--@resource_reference{"Resource name"}` at the first line of the code.
- For EMR Spark nodes, add `##@resource_reference{"Resource name"}` at the first line of the code.

Manage data

DataWorks allows you to query E-MapReduce metadata and synchronize the data for data development.

2.6. HoloStudio

2.6.1. Overview

This topic describes what is HoloStudio and the features of HoloStudio.

HoloStudio, which is developed based on Hologres, is an all-in-one online analytical processing (OLAP) development platform deeply integrated with DataWorks. HoloStudio provides Hologres users with standardized and easy-to-use development services and one-stop real-time data warehouse building services by using a visualized and wizard-based user interface. In addition to standard management available in PostgreSQL, HoloStudio provides more interactive analytics features. HoloStudio supports the following features:

- Table management

HoloStudio allows you to create a PostgreSQL table on a visualized user interface or by using SQL statements. HoloStudio also allows you to create a foreign table sourced from MaxCompute by synchronize the schema with one click and preview and analyze MaxCompute data.

- **SQL Console**

The SQL Console module of HoloStudio allows you to use an SQL editor to obtain query results in seconds.

- **Data analytics**

Based on the underlying capabilities of DataWorks, HoloStudio allows you to create multiple foreign tables at a time and synchronize data with one click and provides you with the one-stop, stable, and efficient extract-transform-load (ETL) service.

- **Seamless connection to the Hologres console**

HoloStudio is seamlessly connected to the Hologres console. In the Hologres console, you can manage Hologres instances, users, and databases on a visualized user interface.

2.6.2. Bind a Hologres database to the current workspace

This topic describes how to bind a Hologres database to the current workspace.

If you need to use HoloStudio for data development, bind a Hologres database to the current workspace. Perform the following steps:

1. Log on to HoloStudio.

On the left-side navigation submenu, click **PG management**. On the PG management tab, move the pointer over the Create icon and select **Database**.

2. In the Create Database dialog box, set relevant parameters.

In the **Create Database** dialog box, set relevant parameters and click **Test connectivity**. If the system message indicating that the connectivity test is passed appears, the specified database is connected. Then, click **Complete**.

Parameter	Description	Remarks
Connect To	The type of the data store.	The value is automatically generated and cannot be changed.
Server	The endpoint of the Hologres instance.	You can view the endpoint on the Basic Information page of the Hologres instance in the Hologres console.
Port	The port number of the Hologres instance.	You can view the port number on the Basic Information page of the Hologres instance in the Hologres console.
Database Name	The name of the Hologres database to be bound to the current workspace.	In actual scenarios, create a Hologres database and set this parameter to the name of the database to bind the database to the current workspace.

Parameter	Description	Remarks
User name	The AccessKey ID of your Apsara Stack tenant account.	You can click the username in the upper-right corner to view the AccessKey ID.
Password	The AccessKey secret of your Apsara Stack tenant account.	You can click the username in the upper-right corner to view the AccessKey secret.
JDBC Extension	The extension parameters used to establish a Java Database Connectivity (JDBC) connection to Hologres.	Example: <code>?preferOuervMode=simple&tcpKeepAlive=true</code>
Test connectivity	Tests whether the database is connected.	N/A

3. Use the Hologres database in HoloStudio.

After the Hologres database is bound to the current workspace, click the Refresh icon on the **PG management** tab. After the database appears, you can use the database in HoloStudio.

2.6.3. SQL Console

The SQL Console in HoloStudio is an editor for executing SQL statements. In the SQL Console, you can execute SQL statements to analyze data in Hologres and obtain the query results. This topic describes the basic features and usage of the SQL Console in HoloStudio.

Folder

The Folder module stores new ad hoc queries, which helps you manage ad hoc queries.

In the left-side navigation pane, click **SQL Console**. Move the pointer over the Create icon and select **Folder**. In the Create Folder dialog box, enter a folder name and click Commit to create a folder. You can create an ad hoc query in the folder and execute standard SQL statements on tables. You can also right-click a table in the folder and select the relevant menu item to move, rename, or delete the table.

SQL Console

The SQL Console module allows you to create ad hoc queries and execute standard SQL statements.

1. Create an ad hoc query.

In the left-side navigation pane, click **SQL Console**. Move the pointer over the Create icon and select **SQL Console**. In the Create Node dialog box, set relevant parameters.

The following table describes the parameters for creating an ad hoc query.

Parameter	Description
Node Name	The name of the ad hoc query. The name can contain letters, digits, underscores (_), and periods (.).
Location	The folder where the ad hoc query is stored.
Database	The target database in which the ad hoc query is run.

2. Run the ad hoc query.

Write the SQL statements used in the ad hoc query and click the **Run** icon to run the query. Then, you can check the query result. The following example shows how to create a table, import data to the table, and then query the table:

```
CREATE TABLE supplier (
  s_suppkey bigint NOT NULL,
  s_name text NOT NULL,
  s_address text NOT NULL,
  s_nationkey bigint NOT NULL,
  s_phone text NOT NULL,
  s_acctbal bigint NOT NULL,
  s_comment text NOT NULL,
  PRIMARY KEY (s_suppkey)
);
INSERT INTO supplier VALUES
(1, 'Supplier#000000001', 'gf0JBoQDd7tgrzrddZ', 17, '27-918-335-1736', 575594, 'each slyly above the car
eful'),
(6, 'Supplier#000000006', 'tQxuVm7s7CnK', 14, '24-696-997-4969', 136579, 'final accounts. regular dolph
ins use against the furiously ironic decoys. '),
(10, 'Supplier#000000010', 'Saygah3gYWmp72i PY', 24, '34-852-489-8585', 389191, 'ing waters. regular request
s ar'),
(18, 'Supplier#000000001', 'PGGVE5PWAMwKDZw', 16, '26-729-551-1115', 704082, 'accounts snooze slyly furiou
sly bold'),
(39, 'Supplier#000000039', 'SYpEPWr1yAFHaC91qjFcijjeU5eH', 8, '18-851-856-5633 611565', 88990, 'le slyly re
quests. special packages shall are blithely. slyly unusual packages sleep'),
(48, 'Supplier#000000048', 'FNPMQDuyuKvTnLXXaLf3Wl6OtONA6mQlWJ', 14, '24-722-551-9498', 563062, 'xp
ress instructions affix. fluffily even requests boos');
SELECT * FROM supplier;
```

The following table describes the GUI elements on the node editing tab.

GUI element	Description
SQL editor	You can write SQL statements in the SQL editor.
Save icon	You can click this icon to save all statements in the SQL editor.
Run icon	You can click this icon to execute all statements in the SQL editor. The result appears on the Result tab. You can also select an SQL statement to be executed. In this case, the system only executes this statement.
Refresh icon	You can click this icon to refresh the content in the SQL editor. The system retains only the saved content after the refresh.
Stop icon	You can click this icon to stop executing SQL statements.
Runtime Log	You can check the execution results and, if any, error messages.
Result	You can check the table content after the SQL statements are executed.

GUI element	Description
Steal Lock icon	You can click this icon to unlock the locked SQL Console.

HoloStudio also allows you to directly manage the queried data. For example, you can hide columns, copy data, and search for data.

 **Note** For statements without results returned, such as the `CREATE TABLE` statement, only operational logs are generated after the statements are executed.

2.6.4. PostgreSQL management

2.6.4.1. Manage databases

The PG management module of HoloStudio allows you to manage databases and tables with one click in a visualized manner. In addition, HoloStudio supports interactive queries with a response time within seconds. This topic describes how to use the PG management module to manage databases.

Create a database

The PG management module allows you to connect databases to HoloStudio and manage the connected databases in a visualized manner. Before you connect a database to HoloStudio, create the database in the Hologres console or by executing SQL statements in the SQL Console. The following example demonstrates how to create a database by executing SQL statements in the SQL Console and connect the database to HoloStudio:

1. Create an ad hoc query.

Log on to the DataWorks console as a superuser and go to the HoloStudio page. In the SQL Console, execute the following SQL statement:

```
create database dbname;
create database testdb; // Create a database named testdb.
```

2. Bind the Hologres database to the current workspace.

On the HoloStudio page, click **PG management** on the left-side navigation submenu. On the PG management tab, move the pointer over the Create icon and select **Database**.

3. In the Create Database dialog box, set relevant parameters.

In the **Create Database** dialog box, set relevant parameters and click **Test connectivity**. If the system message indicating that the connectivity test is passed appears, the specified database is connected. Then, click **Complete**.

Parameter	Description	Remarks
Connect To	The type of the data store. Default value: Hologres.	The value is automatically generated and cannot be changed.
Server	The endpoint of the Hologres instance.	You can view the endpoint on the Basic Information page of the Hologres instance in the Hologres console.

Parameter	Description	Remarks
Port	The port number of the Hologres instance.	You can view the port number on the Basic Information page of the Hologres instance in the Hologres console.
Database Name	The name of the database to be bound to the current workspace.	The value must be the same as the database name in the CREATE DATABASE statement, for example, <code>testdb</code> .
User name	The AccessKey ID of your Apsara Stack tenant account.	You can click the username in the upper-right corner to view the AccessKey ID.
Password	The AccessKey secret of your Apsara Stack tenant account.	You can click the username in the upper-right corner to view the AccessKey secret.
JDBC Extension	The extension parameters used to establish a JDBC connection to Hologres.	Example: <code>?preferQueryMode=simple&tcpKeepAlive=true</code>
Test connectivity	Tests whether the database is connected.	If the system message indicating that the connectivity test is passed appears, the specified database is connected.

Delete a database

The PG management module of HoloStudio allows you to delete databases. On the left-side navigation submenu, click **PG management**. On the PG management tab, right-click the database you want to delete and select **Delete Database**.

In the Delete Database message, click **Ok** to delete the database.

 **Note** Only a superuser of a database or the database owner configured by a superuser can delete the database.

View database details

On the left-side navigation submenu, click **PG management**. On the PG management tab, right-click the database for which you want to view details and select **Database details**.

2.6.4.2. Manage tables

Similar to PostgreSQL, Hologres manages data by using tables. The PG management module of HoloStudio allows you to manage tables in a visualized manner. You can create, check, or delete a table with one click. This topic describes how to use the PG management module of HoloStudio to manage tables.

Create a table

1. Create a table.

On the homepage of HoloStudio, click **Create Table**. Alternatively, click **PG management** on the left-side navigation submenu. On the PG management tab, move the pointer over the Create icon and select **Table**.

2. Edit the table content and attributes.

On the tab that appears, edit the table content and attributes, and click **Commit**. The following figure shows an example of a column-oriented table with primary keys.

Section or tab	Parameter	Description
General	Interactive Analytics Database	The database where the table resides.
	Table Name	The name of the table.
	Description	The description of the table.
Field	Field Name	The name of the field in the table.
	Data Type	The data type of the field.
	Primary Key Field	Specifies whether to use the field as the primary key for the table.
	Optional	Specifies whether the field can be null.
	Array	Specifies whether the field is an ordered array of elements.
	Description	The description of the field.
	Actions	The actions that you can perform on the field. For example, you can delete the field from the table, or move up or down the position of the field in the table.
Properties	Storage Mode	The storage mode of the table. Valid values: Row Store and Column Store. Default value: Column Store.
	Lifecycle (Seconds)	The lifecycle of the table. Default value: Permanent.
	Clustered Index	The index used for sorting.
	Dictionary Code Columns	The column based on whose values a dictionary mapping is built.
	Bitmap Column	The column on which bit code is built.
Partitioned Table	PARTITION BY LIST	The partition field.

Check a table

1. View the DDL statement used to create the table.

On the left-side navigation submenu, click **PG management**. Double-click the table you want to check and click **Generate DDL Statement** to check the SQL statement used to create the table.

2. Preview data.

On the left-side navigation submenu, click **PG management**. Double-click the table you want to check and click **Data Preview** to check the content of the table. If the table contains no data, you can only view the fields of the table.

Delete a table

On the left-side navigation submenu, click **PG management**. On the PG management tab, right-click the table you want to delete and select **Delete Table**.

In the Delete message, click **Ok**.

2.6.4.3. Manage foreign tables

In Hologres, a foreign table does not store data but maps the table from the external data source. The PG management module of HoloStudio allows you to create, query, or delete foreign tables. You can only analyze foreign tables sourced from MaxCompute. This helps you obtain the query results.

This topic describes how to use the PG management module of HoloStudio to manage foreign tables.

Create a foreign table

On the left-side navigation submenu, click **PG management**. On the PG management tab, move the pointer over the Create icon and select **External Table**. On the tab that appears, set parameters for creating a foreign table and click **Commit**. An existing MaxCompute table is used in the following example. After you search for a MaxCompute table by entering its name, HoloStudio automatically generates a foreign table based on the fields of the MaxCompute table after you click **Commit**.

Note

1. Before you create a foreign table in Hologres, make sure that its source table exists in a MaxCompute project.
2. The fields of a foreign table in Hologres have a one-to-one mapping with those of the source table in MaxCompute. You can query specific fields or all fields.

Section or icon	Parameter	Description
General	Interactive Analytics Database	The database where the foreign table to be created resides.
	Table Name	The name of the foreign table.
External Service	Types	The service type of the external table. You can only set this parameter to MaxCompute.
Table	Table	The source table in MaxCompute to be mapped.
Commit	Commit	You can click this button to commit the foreign table that you create.

Check a foreign table

1. Preview data.

On the left-side navigation submenu, click **PG management**. On the PG management tab, double-click the foreign table you want to check, and click **Data Preview** to check the content of the foreign table.

2. View the DDL statement used to create the table.

On the left-side navigation submenu, click **PG management**. On the PG management tab, double-click the foreign table you want to check, and click **Generate DDL Statement** to check the SQL statement used to create the foreign table.

Delete a foreign table

On the left-side navigation submenu, click **PG management**. On the PG management tab, right-click the foreign table you want to delete and select **Delete Table**. In the Delete message, click **Ok** to delete the foreign table.

2.6.5. Data analytics

2.6.5.1. Overview

The Data Analytics module of HoloStudio is seamlessly integrated with DataWorks for node scheduling and provides all-in-one, stable, and efficient extract, transform, load (ETL) services. It can also synchronize MaxCompute table schemas and data and allows you to upload local files for data analytics.

The Data Analytics module consists of the following submodules:

1. Folder: stores data analytics nodes, helping you manage data analytics nodes of each database.
2. Interactive Analytics Development: is integrated with DataWorks to schedule ETL nodes.
3. One-click MaxCompute table structure synchronization: allows you to create multiple foreign tables sourced from MaxCompute at a time.
4. One-click MaxCompute data synchronization: provides a visualized user interface for you to synchronize MaxCompute data to Hologres.
5. One-click local file Upload: allows you to upload local files to Hologres.

Folder

Folders store data analytics nodes, helping you manage data analytics nodes of each database.

On the left-side navigation submenu, click **Data Analytics**. On the Data Analytics tab, move the pointer over the Create icon and select **Folder**. In the Create Folder dialog box, enter a folder name and click **Commit**.

2.6.5.2. Use the Interactive Analytics Development submodule

The Interactive Analytics Development submodule is seamlessly integrated with DataWorks. You can use HoloStudio to import data from MaxCompute to Hologres. You can also use DataWorks to schedule nodes to periodically import data to Hologres. This topic describes how to use HoloStudio to map the source data stored in a MaxCompute table to Hologres for periodic scheduling.

1. Prepare a MaxCompute table.

Create a table in MaxCompute and import data to the table. You can also select a table with data from Data Map. In this example, an existing table in Data Map is used. The following Data Definition Language (DDL) statement is used to create the table:

```
CREATE TABLE IF NOT EXISTS bank_data_odps
(
  age      BIGINT COMMENT 'age',
  job      STRING COMMENT 'job type',
  marital  STRING COMMENT 'marital status',
  education STRING COMMENT 'education level',
  card     STRING COMMENT 'credit card available or not',
  housing  STRING COMMENT 'mortgage',
  loan     STRING COMMENT 'loan',
  contact  STRING COMMENT 'contact',
  month    STRING COMMENT 'month',
  day_of_week STRING COMMENT 'day in a week',
  duration STRING COMMENT 'duration',
  campaign BIGINT COMMENT 'number of contacts during the campaign',
  pdays    DOUBLE COMMENT 'interval from the last contact',
  previous DOUBLE COMMENT 'number of contacts with the customer',
  poutcome STRING COMMENT 'result of the previous marketing campaign',
  emp_var_rate DOUBLE COMMENT 'employment change rate',
  cons_price_idx DOUBLE COMMENT 'consumer price index',
  cons_conf_idx DOUBLE COMMENT 'consumer confidence index',
  euribor3m DOUBLE COMMENT 'euro deposit rate',
  nr_employed DOUBLE COMMENT 'number of employees',
  y        BIGINT COMMENT 'fixed time deposit available or not'
);
```

2. Create a foreign table.

Go to the HoloStudio page. On the left-side navigation submenu, click **PG management** or **SQL Console**. On the tab that appears, create a foreign table for mapping data in the MaxCompute source table. In this example, use the following SQL statements to create a foreign table:

```
BEGIN;
CREATE FOREIGN TABLE if not EXISTS bank_data_foreign_holo (
  age int8,
  job text,
  marital text,
  education text,
  card text,
  housing text,
  loan text,
  contact text,
  month text,
  day_of_week text,
  duration text,
  campaign int8,
  pdays float8,
  previous float8,
  poutcome text,
  emp_var_rate float8,
  cons_price_idx float8,
  cons_conf_idx float8,
  euribor3m float8,
  nr_employed float8,
  y int8
)
SERVER odps_server
OPTIONS (project_name 'projectname', table_name 'bank_data_odps');
GRANT SELECT ON bank_data_foreign_holo TO PUBLIC;
COMMIT;
```

 **Note** The OPTIONS parameter contains two fields: project_name, which is the name of the MaxCompute project, and table_name, which is the name of the MaxCompute table.

3. Create a data storage table.

Create a table in HoloStudio to receive and store data. The fields in this table must be of the same data types as those in the foreign table. In this example, use the following SQL statements to create the storage table:

```
BEGIN;
CREATE TABLE if not EXISTS bank_data_holo (
  age int8,
  job text,
  marital text,
  education text,
  card text,
  housing text,
  loan text,
  contact text,
  month text,
  day_of_week text,
  duration text,
  campaign int8,
  pdays float8,
  previous float8,
  poutcome text,
  emp_var_rate float8,
  cons_price_idx float8,
  cons_conf_idx float8,
  euribor3m float8,
  nr_employed float8,
  y int8,
  ds text NOT NULL
)
PARTITION BY LIST(ds);
CALL SET_TABLE_PROPERTY('bank_data_holo', 'orientation', 'column');
CALL SET_TABLE_PROPERTY('bank_data_holo', 'time_to_live_in_seconds', '700000');
COMMIT;
```

4. Create a partitioned table.

On the HoloStudio page, click **Data Analytics** on the left-side navigation submenu. On the Data Analytics tab, move the pointer over the Create icon and select **Interactive Analytics Development** to create a Hologres development node. Then, go to the SQL editor of the node and enter SQL statements to create a partitioned table for obtaining the required data. After you enter the SQL statements, click the **Run** icon. In the Field dialog box, set a value for the `${bizdate}` parameter. After the SQL statements are executed, click the **Save** icon and then **Go to DataStudio for Scheduling** to schedule the node. You can enter the following sample SQL statements:

```
create table if not exists bank_data_holo_1_${bizdate} partition of bank_data_holo
for values in ('${bizdate}');
insert into bank_data_holo_1_${bizdate}
select
  age as age,
  job as job,
  marital as marital,
  education as education,
  card as card,
  housing as housing,
  loan as loan,
  contact as contact,
  month as month,
  day_of_week as day_of_week,
  duration as duration,
  campaign as campaign,
  pdays as pdays,
  previous as previous,
  poutcome as poutcome,
  emp_var_rate as emp_var_rate,
  cons_price_idx as cons_price_idx,
  cons_conf_idx as cons_conf_idx,
  euribor3m as euribor3m,
  nr_employed as nr_employed,
  y as y,
  '${bizdate}' as ds
from bank_data_foreign_holo;
```

5. Schedule the partitioned table.

Go to the DataStudio page and create a Hologres development node. In the SQL editor of the node, enter SQL statements to synchronize the partitioned table information to the node and click **Update Code**. Before you create the node, make sure that a workflow is created.

6. Set parameters for scheduling the data analytics node.

On the editing tab of the Hologres development node, click the **Properties** tab in the right-side navigation pane to set parameters for scheduling the node.

i. Set parameters in the General section.

In the **Arguments** field, specify a value for the `${bizdate}` variable.

ii. Set parameters in the Schedule section.

Select **Normal** for **Execution Mode** and set other parameters as required.

iii. Set parameters in the Dependencies section.

Select **Yes** for **Auto Parse** and click **Use Root Node**. After DataStudio automatically parses and displays the root node as a parent node, change the value of **Auto Parse** to **No**. You can also select a table that is scheduled as a parent node.

7. Save and deploy the node for scheduling.

After you set the scheduling parameters for the node, click the **Save** icon and then the **Submit** icon. After that, click **Deploy** in the upper-right corner.

8. Deploy the node in Operation Center.

On the **Create Package** page, find the target node and click **Publish** in the **Actions** column. After the node is deployed, click **Operation Center** in the top navigation bar to generate retroactive data for the node.

In **Operation Center**, right-click the published node and choose **Run > Current Node Retroactively**. Configure the node based on your business requirements.

9. Check the content of the table in HoloStudio.

After the retroactive data generation node is run, go back to HoloStudio. On the left-side navigation submenu, click **PG management**. On the PG management tab, click a database and choose **Mode > public > Table**. Double-click the partitioned table that is scheduled and click **Data Preview** to check whether the data is imported to the table.

2.6.5.3. Create multiple foreign tables at a time

Seamlessly integrated with MaxCompute at the underlying layer, Hologres allows you to create foreign tables to query MaxCompute data in an accelerated manner. You can create multiple foreign tables at a time by using the `IMPORT FOREIGN TABLE` statement. To free you from SQL operations, HoloStudio provides the following submodule for you to create foreign tables in a visualized manner: **One-click MaxCompute table structure synchronization**.

1. Create a schema sync node.

On the HoloStudio page, click **Data Analytics** on the left-side navigation submenu. On the Data Analytics tab, move the pointer over the **Create** icon and select **One-click MaxCompute table structure synchronization**. In the **Create Node** dialog box, set relevant parameters and click **Commit**. The schema sync node is created.

2. Set parameters for synchronizing the table schema.

After the schema sync node is created, you must set parameters for synchronizing the table schema based on your needs.

Parameter	Description	Remarks
Target Library	The name of the Hologres database where the foreign tables are to be created.	N/A
Target Schema	The name of the schema in the specified Hologres database.	The default value is public. If you have created a schema, you can select the created schema.
Remote Service type	The type of the external service. You can create only foreign tables sourced from MaxCompute.	The default value is odps.
Remote server	The external server. The default value is odps_server.	After you purchase a Hologres instance, the system automatically creates a server named odps_server. You can directly use it.
Remote library	The name of the MaxCompute project where the tables mapping the foreign tables to be created reside.	N/A

Parameter	Description	Remarks
Table name rules	The regular expression for specifying the tables whose schema is to be synchronized. By default, the schema of all tables in the specified MaxCompute project will be synchronized.	<ul style="list-style-type: none"> ◦ If a foreign table to be created is named the same as an existing foreign table in Hologres, the foreign table is not created. ◦ If a MaxCompute table whose schema is to be synchronized contains data types that Hologres does not support, an error is thrown. In this case, exclude this MaxCompute table in the regular expression. ◦ For more information, see <code>IMPORT FOREIGN SCHEMA</code>.
Regular preview	The execution result of the regular expression.	N/A

3. Run the schema sync node.

Click the **Save** icon and then click the **Run** icon to run the schema sync node. After the schema sync node is run, click PG management on the left-side navigation submenu. The created foreign tables appear. You can query the table data.

2.6.5.4. Import MaxCompute data

To improve the efficiency of querying MaxCompute data, Hologres allows you to import MaxCompute data to Hologres for queries. HoloStudio provides the following submodule for you to directly import MaxCompute data in a visualized manner: One-click MaxCompute data synchronization.

1. Create a data sync node.

On the HoloStudio page, click Data Analytics on the left-side navigation submenu. On the Data Analytics tab, move the pointer over the Create icon and select **One-click MaxCompute data synchronization**. In the Create Node dialog box, enter the node information and click Commit. The data sync node is created.

2. Set parameters for synchronizing data.

After the data sync node is created, you must set parameters for synchronizing data.

Section	Parameter	Description	Remarks
MaxCompute Source table selection	External table source	The source of the foreign table. Valid values: External table already exists and New external table.	<ul style="list-style-type: none"> ◦ If you select External table already exists, the existing foreign table mapping the MaxCompute table will be used. ◦ If you select New external table, you must create a foreign table mapping the MaxCompute table.

Section	Parameter	Description	Remarks
	External table name	The name of the existing foreign table.	The foreign table must map the MaxCompute table whose data will be synchronized.
Target table settings	Target Library	The name of the Hologres database to which the MaxCompute data will be synchronized.	N/A
	Target schema	The name of the schema in the specified Hologres database.	The default value is public. If you have created a schema, you can select the created schema.
	Destination Table Name	The name of the target table to which the MaxCompute data will be synchronized.	The table name can be customized.
	Target table description	The description of the target table.	N/A
Synchronization settings	Synchronization field	The fields to be synchronized from the specified MaxCompute table.	You can select specific or all fields in the MaxCompute table.
	Partition configuration	The partition fields to be synchronized.	Hologres supports a maximum of one level of partitions.
	Index configuration	The index to be built for the target table.	N/A
SQL Script	SQL Script	The SQL statements that are executed when the data sync node is run.	N/A

3. Run the data sync node.

Click the **Save** icon and then click the **Run** icon to run the data sync node. After the node is run, you can query the imported data in SQL Console or PG management.

2.6.5.5. Upload local files

This topic describes how to upload local files in HoloStudio in a visualized manner.

Hologres allows you to use the COPY statement to import data from the standard input of a client to a specified table. For more information, see COPY. HoloStudio allows you to import data in a local file to a specified table by uploading the local file in a visualized manner. To upload a local file in HoloStudio, perform the following steps:

1. Create a table.

In SQL Console or PG management, create a table to which data in the local file will be imported. In this example, use the following SQL statements to create a table:

```
BEGIN;
CREATE TABLE if not EXISTS holo_bank (
  age int8,
  job text,
  marital text,
  education text,
  card text,
  housing text,
  loan text,
  contact text,
  month text,
  day_of_week text,
  duration text,
  campaign int8,
  pdays float8,
  previous float8,
  poutcome text,
  emp_var_rate float8,
  cons_price_idx float8,
  cons_conf_idx float8,
  euribor3m float8,
  nr_employed float8,
  y int8
);
COMMIT;
```

2. Create a node for uploading the local file.

Go to the HoloStudio page. On the left-side navigation submenu, click Data Analytics. On the Data Analytics tab, move the pointer over the Create icon and select **Upload files locally with one click**.

3. Enter the node information.

In the **One-click local file Upload** dialog box, set the parameters based on your business needs and click Next Step.

Parameter	Description	Remarks
Target Library	The name of the Hologres database where the target table resides.	N/A
Target Schema	The name of the schema where the target table resides.	The default value is public. If you have created a schema, you can select the created schema.
Select the data table to import	The name of the target table to which data in the local file will be imported.	N/A

4. Select the local file to upload and set other required parameters.

After you click Next Step, select the local file to upload, set other required parameters, and then click Commit.

Parameter	Description	Remarks
-----------	-------------	---------

Select File	The local file to upload.	You can select a local file only in the .txt, .csv, or .log format.
Select separator	The delimiter of fields in the file. Select Comma (,) or Space ().	N/A
Original character set	The character set of the file.	<ul style="list-style-type: none"> ◦ GBK ◦ UTF-8 ◦ CP936 ◦ ISO-8859
First behavior title	Specifies whether to use the first line as the header line.	N/A

5. View the imported data.

After you click **Commit**, data in the selected local file is imported to the specified table. You can go to SQL Console or PG management to view the imported data.

2.6.6. Hologres console

2.6.6.1. Overview

Hologres is a real-time interactive analytics service that is fully compatible with PostgreSQL and seamlessly integrated with the big data ecosystem. Hologres delivers high-concurrency and low-latency performance in analyzing terabyte-scale data. Hologres allows you to use mainstream Business Intelligence (BI) tools to get an analytical insight into data from multiple dimensions and explore business data in an efficient and cost-effective manner.

For convenience of business, Apsara Stack provides the Hologres console independent from the DataWorks console for different users to managing Hologres instances, users, and databases.

Log on to the Apsara Stack console. In the top navigation bar, choose **Products > Interactive Analytics** to go to the Hologres console. The following figure shows the Overview page in the Hologres console.

2.6.6.2. View the instance list

The Instances page lists all Hologres instances purchased by your Apsara Stack tenant account. On this page, you can view the instance status, change instance configurations, and create instances. You can also click an instance name to go to the instance details page where you can manage objects in the instance, including databases and users.

Instances

Log on to the Apsara Stack console. In the top navigation bar, choose **Products > Interactive Analytics** to go to the Hologres console. In the Hologres console, click **Instance List** in the left-side navigation pane. The following figure shows the Instance List page.

1. New engine instance button

On the Instance List page, click **New engine instance**. In the New engine instance dialog box, enter an instance name and select the instance specifications to create a Hologres instance.

2. Search box

If you have purchased multiple Hologres instances, you can enter a keyword of an instance name in the search box to find the target instance.

3. Running status column

The Running status column displays the running status of each Hologres instance. An instance can be in one of the following states:

- Normal operation: The instance is running as expected.
- Creating: The payment is successful, and Hologres is creating the instance. You must wait for 3 to 5 minutes.
- Shutdown: The instance has been suspended and you cannot connect to it.

Operation column

The Operation column provides the following buttons for you to manage a Hologres instance:

1. Management

Find the target instance and click **Management** in the Operation column. On the page that appears, you can view and manage objects in the instance, including databases and users.

2. Change configuration

If your instance cannot meet your business needs or your instance has a large amount of surplus resources, you can click **Change configuration** in the Operation column. In the **Change configuration** dialog box, upgrade or downgrade your instance configurations based on your business needs.

3. Shutdown

Find the target instance and click **Shutdown** in the Operation column to suspend the instance. You cannot connect to the suspended instance.

2.6.6.3. Manage instances

This topic describes how to view and change instance configurations, select a network type, and select a connection method on the Basic information page in the Hologres console.

View and change instance configurations

In the Hologres console, click **Instance List** in the left-side navigation pane. In the instance list, find the target instance and click **Management** in the Operation column. The Basic information page displays basic information about a Hologres instance, including the instance name, instance ID, region, instance version, billing method, instance specification, and creation time.

If you need to change the instance specifications, click **Change configuration**. In the Change configuration dialog box, upgrade or downgrade the instance specifications based on your business needs.

Select a network type

The following table lists the supported network type.

Network type	Domain name	Scenario
Internal network	<instancename>-cn-<region>-internal.hologres.aliyuncs.com:80	Select this network type when you want to connect to the Hologres instance by using the classic network, without charges on the Internet traffic.

Select a connection method

Hologres is compatible with PostgreSQL. You can connect to a Hologres instance from the PostgreSQL client or over JDBC interfaces by using ETL or BI tools.

The Connection Methods section offers methods for you to use common development tools to connect to a Hologres instance. You can select a development tool and connection method based on your business needs and preference.

1. Connect from the PostgreSQL client

To connect to a Hologres instance from the PostgreSQL client, use the following connection string:

```
PGUSER=<AccessId> PGPASSWORD=<AccessKey> psql -p <Port> -h <Endpoint> -d <Database>
```

2. Connect over JDBC

To connect to a Hologres instance over JDBC, use the following connection string:

```
postgres://<AccessId>:<AccessKey>@<Endpoint>:<Port>/<database>?preferQueryMode=simple&tcpKeepAlive=true
```

2.6.6.4. Manage users

This topic describes how to manage users on the User Management page in the Hologres console.

Overview

In the Hologres console, click **Instance List** in the left-side navigation pane. In the instance list, find the target instance and click **Management** in the **Operation** column. On the page that appears, click **User Management**. On the User Management page, you can manage users on a Hologres instance without executing cumbersome SQL statements. For example, you can add and delete users and grant permissions to users on this page.

After you create a Hologres instance with your Apsara Stack tenant account, this account becomes a superuser of the instance. A superuser has all permissions on the Hologres instance. By default, the User Management page displays only the information of the Apsara Stack tenant account that creates the Hologres instance. The information of a Resource Access Management (RAM) user appears on this page only after you use the Apsara Stack tenant account to add it to the instance.

Column	Description	Remarks
Members	Displays the usernames of the Apsara Stack tenant account and RAM users on the Hologres instance.	Generally, a username appears in the xxx format.
Cloud account	Displays the account IDs of users on the Hologres instance.	N/A
Type	Displays the roles assigned to users on the Hologres instance.	The user can be a superuser or normal user.

Add a user

On the User Management page, you can create RAM users on a Hologres instance without executing the SQL CREATE statement.

Click **Add new user**. In the Add new user dialog box, select existing RAM users under your Apsara Stack tenant account to add them to the Hologres instance. If no RAM user exists under your Apsara Stack tenant account, create a RAM user first.

When you add a RAM user, you can assign the superuser or normal user role to the user.

- **Superuser:** A superuser has all permissions on the Hologres instance without the need for additional authorization.
- **Normal user:** A normal user cannot view or manage any objects on the Hologres instance, including databases, schemas, and tables. A normal user must be authorized before it can view and manage objects in the instance. We recommend that you go to the DB management page to grant permissions to RAM users as required. Alternatively, you can use SQL statements to grant permissions to RAM users.

Delete a user

Find the target user on the User Management page and click **Delete** in the Operation column to delete the user from the Hologres instance. A deleted user has no access to the Hologres instance.

2.6.6.5. Manage databases

This topic describes how to manage databases on the DB management page in the Hologres console.

Overview

In the Hologres console, click **Instance List** in the left-side navigation pane. In the instance list, find the target instance and click **Management** in the **Operation** column. On the page that appears, click **DB management**. On the DB management page, you can manage all databases on the current Hologres instance. You can create databases, select a permission management mode for the databases, and view database information.

 **Note** A default database named `postgres` is automatically created after you create a Hologres instance. This database is provided for management purposes only and does not appear on the DB management page. This database is allocated with limited resources. Create databases on this page based on your business needs.

Create a database

Hologres allows you to create a database with one click on the graphical user interface (GUI), eliminating the need for SQL operations.

Click **New Database**. In the New Database dialog box, enter a name for the database and set the Simple permissions model parameter to Open or Close. To simplify authorization, we recommend that you set the Simple permissions model parameter to Open.

Hologres provides two permission models for you to authorize users in a convenient way.

- **Standard PostgreSQL authorization:** Compatible with PostgreSQL, Hologres provides a permission model that is exactly the same as the standard PostgreSQL authorization model. You can authorize RAM users by using the standard PostgreSQL GRANT statement.
- **SPM:** Backed by the understanding of customers' business and its practical experience, Alibaba Cloud introduced a simple permission model (SPM) to Hologres to simplify the management of user permissions. The SPM is a coarse-grained model that authorizes users by user group.

After a database is created, you can use a development tool to connect to the database to analyze data.

Authorize a user

After the SPM is enabled for a new database, you can authorize RAM users with one click in the Hologres console. Perform the following steps:

1. **Open the Permission management right-side pane.**

Find the target RAM user and click **User authorization** in the Operation column. You can grant permissions to a RAM user by adding the user to the desired user group.

2. Add a RAM user to a user group.

In the Permission management right-side pane, click **Add authorization**. In the Add authorization dialog box, select the account to which you want to grant permissions, select the desired user group below Permissions policy, and then click **OK**.

Revoke permissions

If the SPM is enabled for your database, you can revoke the permissions of a RAM user with one click in the Hologres console.

On the instance details page, click **DB management**. On the DB management page, find the target database and click **User authorization** in the Operation column. In the Permission management right-side pane, find the target RAM user and click **Delete authorization** in the Operation column.

Delete a database

On the DB management page, find the database no longer required and click **Delete** in the Operation column to delete the database. After a database is deleted, data in the database is also deleted and cannot be recovered.

2.7. Realtime Analysis

2.7.1. Overview

Integrated with DataWorks, DataAnalysis supports creating MaxCompute tables in tabular mode, collaboratively editing workbooks and performing statistical analysis, and generating and sharing visual reports. These features enable data developers and business staff to quickly analyze data.

Go to DataAnalysis

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > DataAnalysis**.
3. On the **Home** page of DataAnalysis, click **Experience now** to go to the Web Excel page.

Features

- **Workbook**

You can create and edit workbooks. Workbooks support basic operations such as addition, subtraction, multiplication, and division, and multiple data processing methods, including functions, classification, and aggregation. In addition, you can edit workbooks collaboratively with other users online and create pivot tables for further analysis.

- **Visual report**

You can create and design visual reports by dragging, dropping, and configuring controls without running SQL statements.

- **Dimension table**

You can create MaxCompute tables in tabular mode by one click without running SQL statements and edit MaxCompute tables collaboratively with other users online.

- You can create a MaxCompute table in tabular mode.
- You can import data into a MaxCompute table by one click.

2.7.2. Workbook

2.7.2.1. Create a workbook

This topic describes how to create a workbook. After a workbook is created, you can rename, clone, delete, or change the owner of the workbook.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page, click  in the upper-left corner and choose **All Products > DataAnalysis**.
3. On the DataAnalysis homepage, click **Experience Now**.
4. On the **Web Excel** page, click  in the **New Spreadsheet** section.

 **Note** If you have created workbooks, you can search for a workbook by entering its name in the search box in the **All Spreadsheets** section. Then, click the workbook name in the **File Name** column to go to the workbook editing page.

5. In the **New spreadsheet** dialog box, enter a name in the **File Name** field.
6. Click **OK**.

Result

After the workbook is created, it appears in the **All Spreadsheets** section. In this section, you can view all created workbooks. In addition, you can rename, clone, delete, or change the owner of a workbook.

- Find the target workbook and click **Rename** in the Operation column. In the **Rename** dialog box, enter the new name in the **File Name** field and click **OK**.
- Find the target workbook and click **Change Owner** in the Operation column. In the **Change Owner** dialog box, select an owner from the New Owner drop-down list and click **OK**.
- Find the target workbook and click **Clone** in the Operation column. The cloned workbook appears in the workbook list. The name of the cloned workbook contains the **_copy** suffix.
- Find the target workbook and click **Delete** in the Operation column. In the **Delete** message, click **OK**.

2.7.2.2. Edit a workbook

This topic describes how to edit a workbook. For example, you can import data to, export data from, and share a workbook, create a pivot table in a workbook, and use the data profiling feature.

Go to the workbook editing page

1. [Log on to the DataWorks console](#).
2. On the DataStudio page, click  in the upper-left corner and choose **All Products > DataAnalysis**.
3. On the DataAnalysis homepage, click **Experience Now**. The **Web Excel** page appears.
4. In the **All Spreadsheets** section of the **Web Excel** page, click the name of the target workbook in the **File Name** column. After you create a workbook, the workbook editing page appears.

Apply a template to a workbook or save a workbook as a template

You can apply an existing template to the current workbook by performing the following steps:

1. In the upper-right corner of the workbook editing page, choose **Template > Import Template**.
2. In the **Import Template** dialog box, select a file to be used as a template for the current workbook.

Note The data of the selected template will overwrite that of the current workbook.

3. Click **OK**.

You can save the current workbook as a template by performing the following steps:

1. In the upper-right corner of the workbook editing page, choose **Template > Save as Template**.
2. In the **Template settings** dialog box, set the **Type**, **Name**, and **Description** parameters.

Notice The template name can be up to 256 characters in length and the template description can be up to 1,024 characters in length.

3. Click **OK**.

Import data to a workbook

1. In the upper-right corner of the workbook editing page, click **Import**.
2. In the Open dialog box, find and select a local file to be imported and click **Open**. The data in the local file is imported to the current workbook.

Note You can only import data from Excel files.

Export data from a workbook to a MaxCompute table

1. In the upper-right corner of the workbook editing page, choose **Export > Generate MaxCompute Build Table Statement**.
2. In the **Export as MaxCompute Table** dialog box, set relevant parameters.

Insert mode	Parameter	Description
Insert Data into MaxCompute Table (INSERT OVERWRITE)	Workspace	The workspace to which the MaxCompute table belongs.

TABLE (INSERT OVERWRITE) (insertoverwrite)	Parameter	Description
	Table	The MaxCompute table to which you want to insert data.
Create MaxCompute Table and Insert Data (INSERT OVERWRITE)	Workspace	The workspace to which the MaxCompute table belongs.
	Table Name	The name of the MaxCompute table. Make sure that the table name has not been used. You can click Check Duplicate Names to check whether the table name exists.

3. After the parameters are set, click **Copy SQL Statement**.

 **Notice** Only non-partitioned tables are supported.

Create a pivot table

1. On the workbook editing page, select the data for which you want to create a pivot table and click **Pivot** in the upper-right corner.
2. In the **Create Pivot Table** dialog box, set relevant parameters.

Specify the range of the data to be analyzed. You can set the **Choose Data** parameter to **Select Range** or **Use External Data Store** as needed.

- If you select **Select Range**, select the cells in the workbook for which you want to create a pivot table. The value of the **Range** field changes based on the selected cells.

 **Note** This parameter is available only when you select **Select Range**.

- If you select **Use External Data Store**, set the **Type** parameter first. You can set the **Type** parameter to **Mysql** or **Data Services**.

- If you select **MySQL**, set the parameters described in the following table.

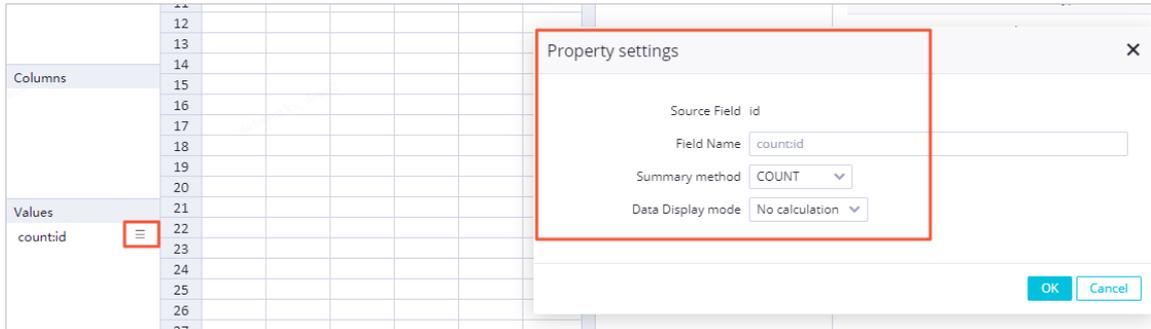

Parameter	Description
Choose Data	The range of the data to be analyzed. Select Use External Data Store .
Type	The type of the data source. Select MySQL .
Workspace	The workspace where the MySQL data store resides.
Data Store	The name of the connection to the data store. To create a connection to a data store, perform the following steps: Click the Workspace Manage icon in the upper-right corner. On the page that appears, click Data Source in the left-side navigation pane. On the Data Source page, create a connection to a data store.
Table	The table for which you want to create a pivot table.

- If you select **Data Services**, set the parameters described in the following table.

Parameter	Description
Choose Data	The range of the data to be analyzed. Select Use External Data Store .
Type	The type of the data source. Select Data Services .
Workspace	The workspace where the API of DataService Studio resides.
API Group	The API group to which the API belongs.
API	The API to be used as the data source.

3. Click **OK**. The pivot table editing page appears. This topic takes the pivot table for a selected range of data as an example.

- **Data Source**: the range that you specified in the previous step.
- **Pivot Table Fields**: the names of the fields that you selected in the previous step.
- **Rows**: Drag fields from the Pivot Table Fields section to the **Rows** section. Each value of the field added to the **Rows** section occupies a row in the pivot table.
- **Columns**: Drag fields from the Pivot Table Fields section to the **Columns** section. Each value of the field added to the **Columns** section occupies a column in the pivot table.
- **Values**: Click the property setting icon for a field in the **Values** section. In the Property settings dialog box, set the **Summary method** and **Data Display mode** parameters. By default, the **Field Name** parameter cannot be modified.

Parameter	Description
Source Field	The name of the selected source field.
Field Name	The name of the field that appears in the pivot table. The name is in the format of Aggregation method:Source field name .
Summary method	The aggregation method. Valid values: SUM, COUNT, MAX, MIN, and AVG .
Data Display mode	The mode for displaying the data. Valid values: No calculation and Percentage of Total .

- **Filters:** Drag fields from the Pivot Table Fields section to the Filters section. In the right-side pivot table display area, you can select the fields to filter data.

Download a workbook

In the upper-right corner of the workbook editing page, click **Download** to download the workbook to a local directory.

Share a workbook

In the upper-right corner of the workbook editing page, click **Share**. In the dialog box that appears, set the sharing mode.

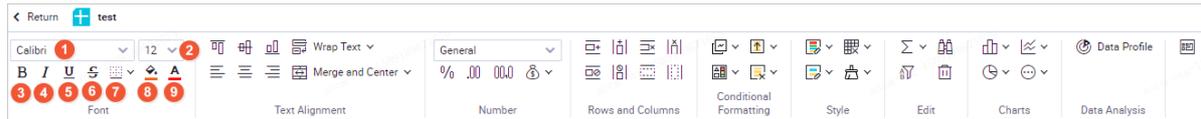

You can share the workbook in the following ways:

- **Link:** Click **Copy Link** and send the copied URL to other users as needed.
- **Users with Edit Access:** Click **Add** in the **Users with Edit Access** section. In the dialog box that appears, select the users to whom you want to grant the edit permission and click **OK**.
- **Visible to All:** To allow all users to view the workbook, turn on the **Visible to All** switch.
- **Users with Read Access:** To allow only specific users to view the workbook, turn off the **Visible to All** switch and click **Add** in the **Users with Read Access** section. In the dialog box that appears, select the users to whom you want to grant the read-only permission and click **OK**.

Note If the system notifies you that the number of users to whom you want to grant the read-only permission reaches the upper limit, you can upgrade the DataWorks edition.

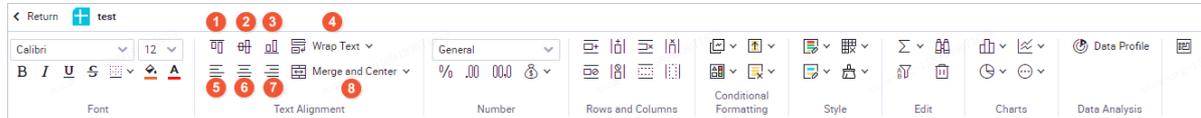

Menu bar

- **Font**

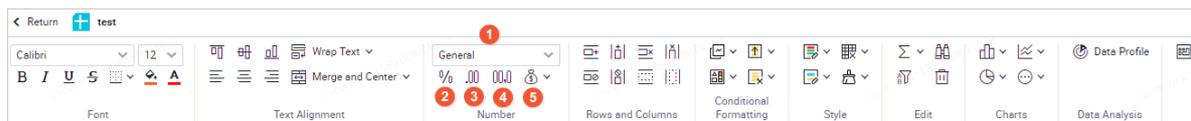

No.	Feature	Description
①	Font	Select a font type from the drop-down list as needed.
②	Font Size	Select a font size from the drop-down list as needed.
③	Bold	Set text in bold.
④	Italic	Set text in italic.
⑤	Underline	Underline text.
⑥	Strikethrough	Add a strikethrough to text.
⑦	Borders	Add borders to cells.
⑧	Background Color	Specify the background color of cells.
⑨	Text Color	Change the text color.

● **Text Alignment**

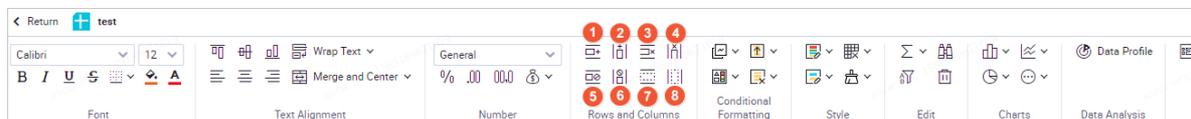

No.	Feature	Description
①	Top Align	Align text vertically to the top.
②	Middle Align	Align text vertically to the center.
③	Bottom Align	Align text vertically to the bottom.
④	Wrap Text	Display long text in multiple lines in a cell.
⑤	Align Left	Align text horizontally to the left.
⑥	Center	Align text horizontally to the center.
⑦	Align Right	Align text horizontally to the right.
⑧	Merge and Center	Merge multiple cells to one cell and center the content in the cell.

● **Number**

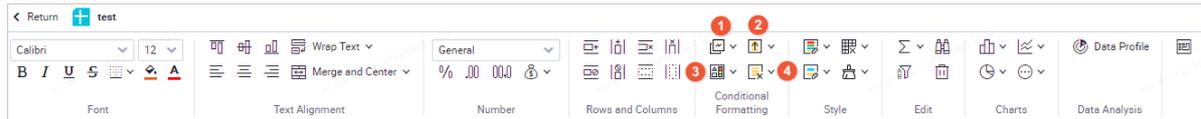

No.	Feature	Description
①	Data Type	Specify the type of data held in cells. You can select General, Number, Currency, Short Date, Long Date, Time, Percentage, Fraction, Scientific, and Text from the drop-down list.
②	Percentage	Apply the percentage format to numbers.
③	Two Decimal Places	Round numbers to two decimal places.
④	1000 Separator	Display numbers with thousands separators, for example, 1,005.
⑤	Currency	Add a currency sign to numbers. The following currency signs are supported: yuan sign (¥), dollar sign (\$), pound sign (£), euro sign (€), and franc sign (Fr).

• **Rows and Columns**

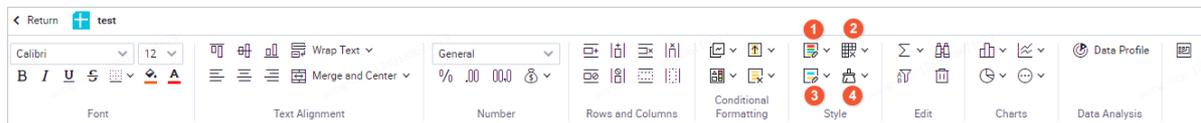

No.	Feature	Description
①	Insert Row	Insert a row to the workbook.
②	Insert Column	Insert a column to the workbook.
③	Delete Row	Delete rows from the workbook.
④	Delete Column	Delete columns from the workbook.
⑤	Lock Row	Lock the rows before the selected row in the workbook.
⑥	Lock Column	Lock the columns before the selected column in the workbook.
⑦	Hide Row	Hide rows in the workbook.
⑧	Hide Column	Hide columns in the workbook.

• **Conditional Formatting**

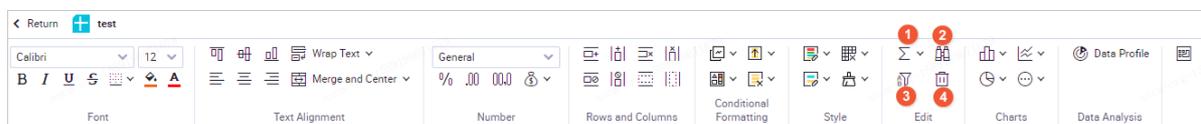

No.	Feature	Description
①	Highlight cell rules	Specify the rules for highlighting cells.
②	Data Bar/Color Scale	Format cells by using data bars and color scales.
③	Icon Set	Format cells by using icon sets. The icon sets include directional icons, shapes, indicators, and rating icons.
④	Clear Rule	Clear the formatting. You can select Clear Rules from Selected Cells or Clear Rules from Entire Sheet from the drop-down list.

• **Style**

No.	Feature	Description
①	Apply table style	Apply a predefined table style to cells.
②	Delete	Remove the applied table style.
③	Cell Style	Apply a cell style to cells.
④	Clear	Clear the content or style in cells. You can select Clear All , Clear Content , or Clear Style from the drop-down list.

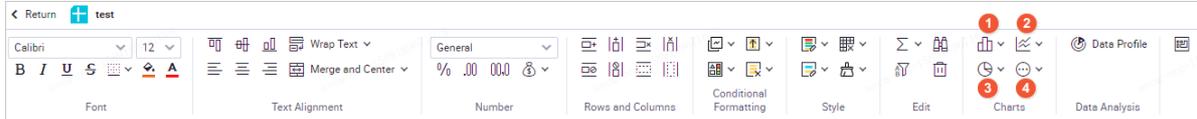

• **Edit**

No.	Feature	Description
①	AutoSum	Select an aggregation method. You can select Sum , Average , Count Numbers , Max , or Min from the drop-down list.
②	Search	Click Search or press Ctrl+F to open the search box.
③	Sort and Filter	Filter data and sort data in ascending or descending order.

No.	Feature	Description
④	Clear	Clear the content in cells.

• **Charts**

- **Column Chart** : After you click the **Column Chart** icon, you can select **Column Chart** , **Stacked Column Chart** , or **100% Stacked Column Chart** .
- **Line Chart** : After you click the **Line Chart** icon, you can select **Line Chart** , **Stacked Line Chart** , **100% Stacked Line Chart** , **Line Chart with Markers** , **Stacked Line Chart with Markers** , or **100% Stacked Line Chart with Markers** .
- **Pie Chart** : After you click the **Pie Chart** icon, you can select **Pie Chart** or **Doughnut Chart** .
- **More** : After you click the **More** icon, you can view more chart types, including area charts, bar charts, scatter charts, and stock charts.

• **Data Profile**

The data profiling feature allows you to analyze the quality, structure, distribution, and statistics of the data. It also allows you to preview, profile, process, analyze, and visualize data. The data profiling feature analyzes data by column and allows you to view the distribution of data types and values of each column.

Select the data to be analyzed and click **Data Profile**. The data profiling feature displays the data type and value distribution of each column above the editing area in the form of charts and rich text.

	A	B	C	D	E	F
unique values	13			12		
string		77%	100%		100%	
bigint		23%				

Simple mode:

- For a column whose values are of the **STRING** or **DATE** type: The simple mode displays the values ranking top 2 based on frequency and their respective percentages, and the percentage of other values in the form of rich text. If the number of value types exceeds 50% of the total number of values, the simple mode displays the number of unique values.
- For a column whose values are of the **INTEGER** or **FLOAT** type: The simple mode displays the value distribution in the form of a histogram.
- For a column whose values are of the **BOOLEAN** type: The simple mode displays the proportions of different values in the form of pie charts.
- For a column whose values are of two or more data types: The simple mode displays the proportions of different data types in the form of pie charts. In addition, the system reminds you that the current column has dirty data. After the dirty data is cleared, the simple mode displays the data in one of the preceding forms based on the data type.
- For a column whose values are null values: The simple mode displays the percentage of null values in red.

Click **Detailed Mode** in the upper-right corner. In the **Data Profile** dialog box, you can view the profiling result of each column.

Detailed mode:

- For a column whose values are of the STRING or DATE type: The detailed mode displays the number of fields, the numbers and percentages of unique values, valid values, and null values, and the numbers of occurrences of the values ranking top 5 based on frequency.
- For a column whose values are of the INTEGER or FLOAT type: The detailed mode displays the number of fields, the numbers and percentages of unique values, valid values, zeros, and null values, the numbers of occurrences of the values ranking top 5 based on frequency, the statistics, and a histogram.
- For a column whose values are of the BOOLEAN type: The detailed mode displays the number of fields, the numbers and percentages of unique values, zeros, and null values, the numbers of occurrences of the values ranking top 5 based on frequency, and a pie chart.

 **Note** The system considers the true and false strings and the 0 and 1 integers as values of the BOOLEAN type.

- **List of Shortcut Keys**

Click  to view the shortcut keys for different features.

2.7.3. Dimension tables

2.7.3.1. Create and manage dimension tables

The dimension table feature allows you to create MaxCompute tables, import local data to MaxCompute tables, and edit MaxCompute tables in a visualized manner.

Prerequisites

1. A MaxCompute compute engine instance is bound to a DataWorks workspace.
2. A MaxCompute table is created. For more information about how to create a MaxCompute table, see [Create a MaxCompute table](#).

Limits

- To create a dimension table in DataAnalysis, you must be an administrator, a project owner, or a developer of a DataWorks workspace.
- For a MaxCompute table that is created by using the dimension table feature, all fields in the MaxCompute table are of the STRING type. If you want to use fields of other data types, execute data definition language (DDL) statements to create a MaxCompute table on the **DataStudio** page.

Create a dimension table

1. [Log on to the DataWorks console](#).
2. On the DataStudio page, click the  icon in the upper-left corner and choose **All Products > Data Development > DataAnalysis**.
3. On the DataAnalysis homepage, click **Experience Now**. The **Web Excel** page appears.
4. In the top navigation bar, click **Dimension**.
5. On the **Dimension** page, click the  icon in the **New Dimension Table** section.
6. In the **New Dimension Table** dialog box, configure the parameters as required.

Parameter	Description
-----------	-------------

Parameter	Description
Target Workspace	The DataWorks workspace to which the MaxCompute table belongs.
Table Name	<p>The name of the dimension table. A MaxCompute table will be used in the production environment.</p> <p> Note The table name can contain only letters, digits, and underscores (_), and must start with a letter.</p>
Table Description	The description of the table, such as the purpose or features.
Field	The fields in the table. Only fields of the STRING type can be added.
Lifecycle	The lifecycle of the table. The table occupies storage resources in MaxCompute. To make sure that the resources can be recycled, select a proper lifecycle for the table from the drop-down list. If the specified lifecycle is exceeded, the table is deleted.

7. Select **I have known this risk and confirmed that as owner of this table, I am responsible for the subsequent changes to this table.** and click **OK** to go to the dimension table editing page to view and modify information about the table. For more information about how to edit a dimension table, see [Edit a dimension table](#). The MaxCompute table created in DataAnalysis is maintained in the production environment. The creator of the table is responsible for the creation and maintenance of the table.

View and manage dimension tables

1. On the dimension table editing page, click **Return** in the upper-left corner or **Dimension** in the top navigation bar to go back to the Dimension page.
2. In the **All Dimension Tables** section, select **I created** or **Share it with me** from the drop-down list in the upper-right corner to view the tables in the corresponding category. You can also share dimension tables with specific members. For more information about how to share a dimension table, see [Share a dimension table](#).
3. Click the file name of a required table or click **Edit** in the Operation column of the table to go to the dimension table editing page. On the Dimension page, you can also perform the following operations to manage a dimension table:
 - o To change the owner of a dimension table, find the table and click **Change Owner** in the Operation column. In the **Change Owner** dialog box, select an owner from the New Owner drop-down list and click **OK**.
 - o To delete a dimension table, find the table and click **Delete** in the Operation column. In the **Delete** message, click **OK**.

What's next

After you create a dimension table, go to the dimension table editing page and import data to this table. For more information about how to import data to a dimension table, see [Import data to a dimension table](#).

2.7.3.2. Import data to a dimension table

After you create a dimension table, you can write data to the table for data analysis. You can also import data from a workbook, local CSV file, or local Excel file to the table for data analysis. This topic describes how to import data to a dimension table.

Prerequisites

A dimension table is created. For more information about how to create a dimension table, see [Create a dimension table](#).

Procedure

1. [Log on to the DataWorks console](#).
2. On the DataStudio page, click the  icon in the upper-left corner and choose **All Products > Data Development > DataAnalysis**.
3. On the DataAnalysis homepage, click **Experience Now**. The **Web Excel** page appears.
4. In the top navigation bar, click **Dimension**.
5. In the **All Dimension Tables** section of the **Dimension** page, click the name of the table that you want to edit in the **File Name** column to go to the dimension table editing page. If no dimension table exists and you created one, the table editing page appears after the table is created. For more information about how to edit a dimension table, see [Edit a dimension table](#).
6. On the dimension table editing page, click **Import** in the upper-right corner.
7. In the **Import** dialog box, select the type of the file that contains the data to be imported and configure parameters.

 **Note** Only data of the STRING type can be imported to a dimension table. Data that is not of the STRING type will be automatically converted to the STRING type when it is imported.

o Workbook

Parameter	Description
Spreadsheet	The workbook from which the data is to be imported. Select a workbook from the Spreadsheet drop-down list.
Sheet	The sheet from which the data is to be imported. Select a sheet from the Sheet drop-down list.
Data Preview	Displays the data in the selected sheet. When you preview the data in the selected sheet, you can determine whether to use the values in the first row as the column names by selecting or clearing First Row as Field Names .
Field Mapping	The mappings between the columns in the selected sheet and the fields in the dimension table.
Import Data Mode	The mode used to import data. Valid values: Append and Overlay .

o Local CSV file

Parameter	Description
File	The CSV file from which the data is to be imported. Click Select File(.csv) , select a CSV file from the on-premises machine, and then click Open .
Original Character Set	The character set that is used by the selected CSV file. Valid values: UTF-8 and GBK . If garbled characters appear, you can change the character set.

Parameter	Description
Separator	<p>The row delimiter and column delimiter.</p> <ul style="list-style-type: none"> Valid values of row delimiters: \r\n, \n, and \r. Valid values of column delimiters: commas (,), semicolons (;), and \t. <p>If the cell data cannot be correctly separated, you can change the delimiters.</p>
Data Preview	<p>Displays the data in the selected sheet. When you preview the data in the selected sheet, you can determine whether to use the values in the first row as the column names by selecting or clearing First Row as Field Names.</p>
Field Mapping	<p>The mappings between the columns in the selected sheet and the fields in the dimension table.</p>
Import Data Mode	<p>The mode used to import data. Valid values: Append and Overlay.</p>

o **Local Excel file**

Parameter	Description
File	<p>The Excel file from which the data is to be imported. Click Select File(.xlsx), select an Excel file from the on-premises machine, and then click Open.</p>
Sheet	<p>The sheet from which the data is to be imported. Select a sheet from the Sheet drop-down list.</p>
Data Preview	<p>Displays the data in the selected sheet. When you preview the data in the selected sheet, you can determine whether to use the values in the first row as the column names by selecting or clearing First Row as Field Names.</p>
Field Mapping	<p>The mappings between the columns in the selected sheet and the fields in the dimension table.</p>
Import Data Mode	<p>The mode used to import data. Valid values: Append and Overlay.</p>

- Click **OK**.
- Click **Save** in the upper-right corner of the page. After you save the dimension table, you can click **Diff** in the upper-right corner of the page to check whether the changes meet expectations to prevent misoperations.

2.7.3.3. Edit a dimension table

This topic describes how to edit a dimension table in a visualized manner to modify the information of a MaxCompute table that you created. You do not need to write SQL code.

Prerequisites

A dimension table is created. For more information, see [Create a dimension table](#).

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page, click the  icon in the upper-left corner and choose **All Products > Data Development > DataAnalysis**.
3. On the DataAnalysis homepage, click **Experience Now**. The **Web Excel** page appears.
4. In the top navigation bar, click **Dimension**.
5. In the **All Dimension Tables** section of the **Dimension** page, click the name of the table that you want to edit in the **File Name** column to go to the dimension table editing page.

6. On the dimension table editing page, view and modify the information about the dimension table. In the left-side pane of the dimension table editing page, you can view the table information, such as the workspace, table name, table description, lifecycle, and field description. To view the details of the dimension table, click the link below **Table Details** to go to the **Data Map** page. For more information, see [View the details of a table](#).

To modify the settings of the dimension table, perform the following steps: Click **Modify field settings**. In the **Modify the field settings dimension table** dialog box, change the values of **Table Description** and **Lifecycle** and click OK. You can also add fields to the table in this dialog box.

The right side of the dimension table editing page displays all the data in the MaxCompute table as a workbook. The values in the first row are field names. You can double-click a cell to modify the content of a field in the corresponding row.

7. Click **Save** in the upper-right corner of the page to save the changes. After you save the dimension table, you can view all the data in the table. You can also click **Diff** in the upper-right corner of the page to view all the data in the **Diff Results** dialog box.

2.7.3.4. Share a dimension table

If you want to collaboratively edit a dimension table with multiple members, you can share the dimension table and grant the members the permissions to edit the table. This topic describes how to share a dimension table and grant edit or read permissions to specified members.

Prerequisites

The **Allow Sharing** switch is turned on on the **Management** page.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page, click the  icon in the upper-left corner and choose **All Products > Data Development > DataAnalysis**.
3. On the DataAnalysis homepage, click **Experience Now**. The **Web Excel** page appears.
4. In the top navigation bar, click **Dimension**.
5. In the **All Dimension Tables** section of the **Dimension** page, click the name of the table that you want to edit in the **File Name** column to go to the dimension table editing page. If no dimension table exists and you created one, the table editing page appears after the table is created. For more information about how to edit a dimension table, see [Edit a dimension table](#).
6. In the upper-right corner of the dimension table editing page, click **Share**. In the dialog box that appears, configure the sharing method as required. You must configure the following information before you can share a dimension table with other members:
 - o **Link**: After you specify Users with Edit Access and Users with Read Access, click **Copy Link** and send the copied URL to specified members.

- **Users with Edit Access:** To specify members with permissions to edit the dimension table, click **Add** in the **Users with Edit Access** section. In the **Share File with These Users** dialog box, enter and select the names of the members to be granted the edit permissions, and click **OK**.

 **Note** You can grant the edit permissions to a maximum of 10 members.

- **Users with Read Access:** To specify members with permissions to read the dimension table, click **Add** in the **Users with Read Access** section. In the **Share File with These Users** dialog box, enter and select the names of the members to be granted the read permissions, and click **OK**.

 **Note** You can grant the read permissions to a maximum of 30 members.

After the sharing method is configured, you can send the URL to specified members. The members can use the URL to access the dimension table. You can go back to the **Dimension** page to view shared dimension tables.

2.7.4. Report

2.7.4.1. Create a report

This topic describes how to create a report. After a report is created, you can rename or delete the report.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page, click  in the upper-left corner and choose **All Products > DataAnalysis**.
3. On the DataAnalysis homepage, click **Experience Now**.
4. On the **Web Excel** page, click **Report** in the top navigation bar.
5. Click  in the **New Report** section. Alternatively, click a template in the **New Report** section to create a report.

 **Note** If you have created reports, you can search for a report by entering its name in the search box in the **All Reports** section. Then, click the report name in the **File Name** column to go to the report editing page.

6. In the **New Report** dialog box, set the **Report Name** and **Report Description** parameters.
7. Click **OK**.

Result

After the report is created, it appears in the **All Reports** section. In this section, you can view all created reports. In addition, you can rename or delete a report.

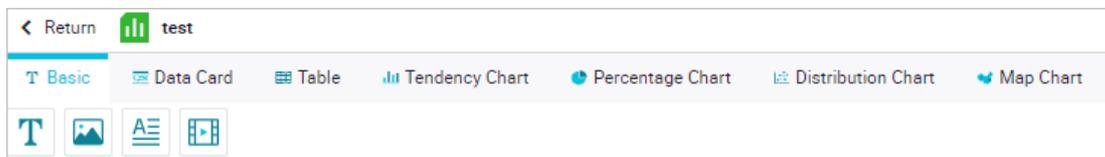

- To rename a report, perform the following steps: Find the target report and click **Rename** in the **Operation** column. In the **Rename** dialog box, enter the new name in the **File Name** field and click **OK**.
- To delete a report, perform the following steps: Find the target report and click **Delete** in the **Operation** column. In the **Delete** message, click **OK**.

2.7.4.2. Edit a report

This topic describes how to edit, preview, save, share, and release a report, and save a report as a template.

Procedure

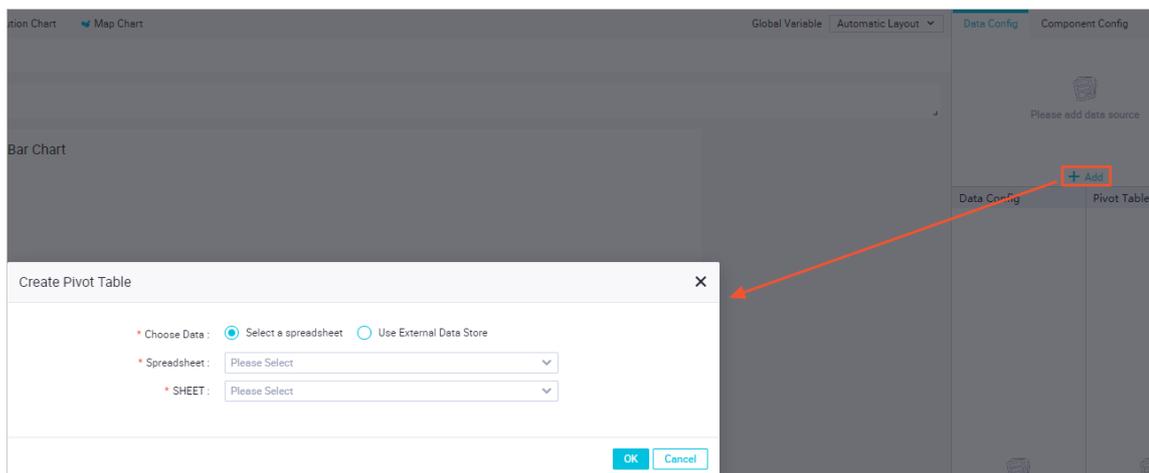

1. Go to the Report page.
 - i. Log on to the DataWorks console.
 - ii. On the DataStudio page, click  in the upper-left corner and choose **All Products > DataAnalysis**.
 - iii. On the DataAnalysis homepage, click **Experience Now**.
 - iv. On the **Web Excel** page, click **Report** in the top navigation bar.
2. Go to the report editing page. Use one of the following methods to go to the report editing page:
 - o After you create a report, the report editing page appears.
 - o In the **All Reports** section of the Report page, click the name of the target report in the **File Name** column.
3. Drag controls from the menu bar to the canvas. In this topic, the **Bar Chart** control on the **Tendency Chart** tab is dragged to the current report. You can drag a control from the menu bar to the canvas to use the control as a component in the report.

4. Click the **Bar Chart** component. Then, select a data store on the **Data Config** tab of the configuration section. If the required data store is added, click the name of the data store on the **Data Config** tab. If you need to add a data store, click **Add** on the **Data Config** tab. In the **Create Pivot Table** dialog box, set relevant parameters and click **OK**.

You can set the Choose Data parameter to Select a spreadsheet or Use External Data Store.

- o **Select a spreadsheet**: You can select an editable worksheet in a workbook of the current user as the data store.

Parameter	Description
Choose Data	The range of the data to be analyzed. Select Select a spreadsheet .
Spreadsheet	The workbook from which the data is analyzed. Select a workbook from the Spreadsheet drop-down list.

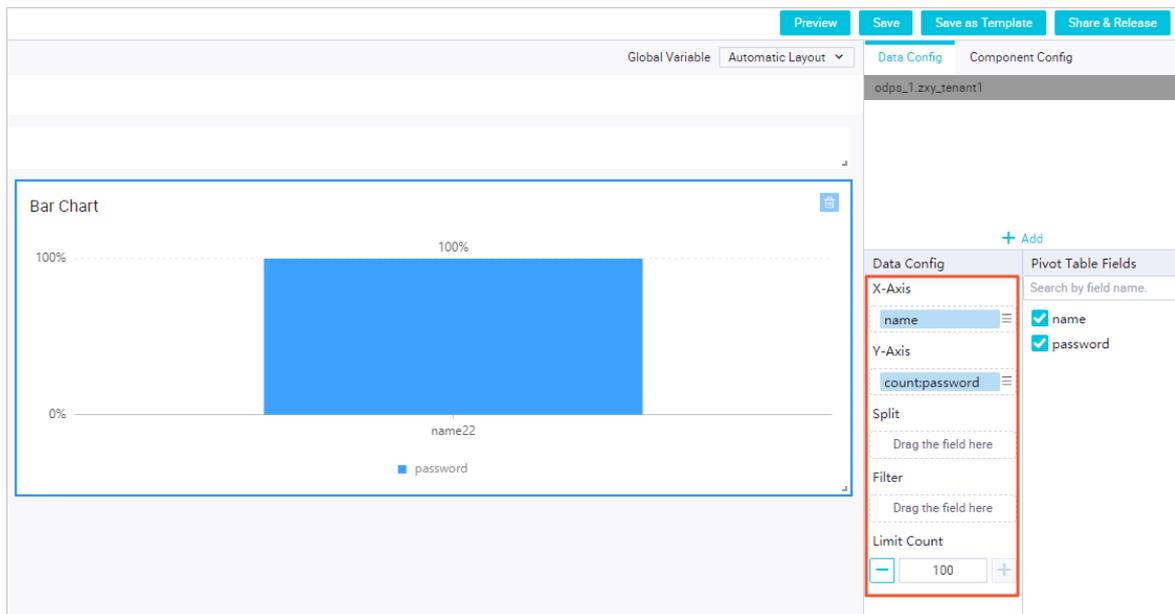

Parameter	Description
SHEET	The worksheet of which the data is analyzed. Select a worksheet from the SHEET drop-down list.

- o **Use External Data Store:** You can select a MySQL data store or the API of DataService Studio.

Parameter	Description
Choose Data	The range of the data to be analyzed. Select Use External Data Store .
Type	The type of the data source. Valid values: Mysql and Data Services .
Workspace	The workspace where the MySQL data store resides.
Data Store	The name of the connection to the data store. To create a connection to a data store, perform the following steps: Click the Workspace Manage icon in the upper-right corner. On the page that appears, click Data Source in the left-side navigation pane. On the Data Source page, create a connection to a data store. <div style="border: 1px solid #add8e6; padding: 5px; background-color: #e6f2ff;"> <p>Note This parameter is available only when you set the Type parameter to Mysql.</p> </div>
Table	The table of which the data is analyzed. <div style="border: 1px solid #add8e6; padding: 5px; background-color: #e6f2ff;"> <p>Note This parameter is available only when you set the Type parameter to Mysql.</p> </div>
API Group	The API group to which the API belongs. <div style="border: 1px solid #add8e6; padding: 5px; background-color: #e6f2ff;"> <p>Note This parameter is available only when you set the Type parameter to Data Services.</p> </div>

Parameter	Description
API	<p>The API to be used as the data source.</p> <p>Note This parameter is available only when you set the Type parameter to Data Services.</p>

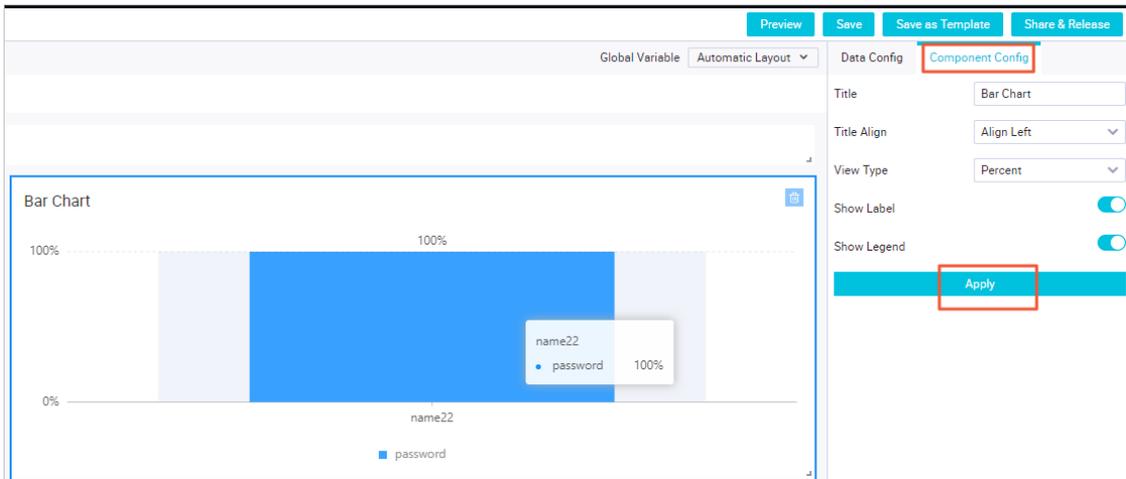

5. Select fields as statistical items. The fields that are required vary with the chart type. For example, you must specify the X-axis, Y-axis, split, and filter fields for a column chart by dragging fields from the **Pivot Table Fields** section to the **Data Config** section. You can also specify the number of vertical columns that can appear in the column chart.

Multiple charts can use the same data store. They can use the data store in different ways without affecting each other. A chart can use only one data store. When you click a chart and drag fields from the Pivot Table Fields section to the Data Config section, the chart is associated with the data store.

6. Configure the information about the column chart.
 - i. On the canvas, click the **Bar Chart** component.
 - ii. Click the **Component Config** tab in the right-side configuration section.

iii. On the **Component Config** tab, set relevant parameters.

Parameter	Description
Title	The title of the component.
Title Align	The alignment of the chart title. Valid values: Align Left , Align Center , and Align Right .
View Type	The display mode of vertical columns. Valid values: Stack , Parallel , and Percent .
Show Label	Specifies whether to display labels for the component.
Show Legend	Specifies whether to display legends for the component.

7. Click **Apply**.

8. Return to the **Report** page or preview, save, share, or release the report as needed.

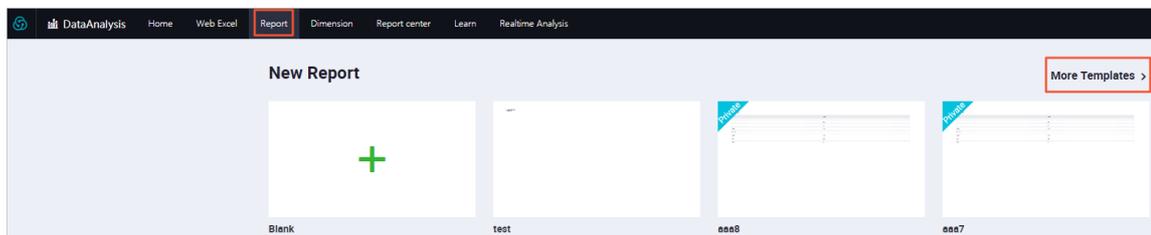

- **Return:** You can click **Return** in the upper-left corner to return to the **Report** page. On the Report page, you can view other reports and go to the report editing page of other reports.
- **Preview:** You can click **Preview** in the upper-right corner to preview the report.
- **Save:** You can click **Save** in the upper-right corner to save the report, so that you can open and edit the saved report next time.
- **Save as Template:** You can save a report as a template, so that you can create a report based on the template. Perform the following steps to save a report as a template:
 - a. On the report editing page, click **Save as Template** in the upper-right corner.
 - b. On the **Preview** page, click **Next Step (Template setup)**.

c. In the **Template settings** dialog box, set relevant parameters.

Parameter	Description
Type	Specifies whether to show or hide the template for other users. Valid values: Private and Open .
Name	The name of the template. The name can be up to 256 characters in length.
Description	The description of the template. The description can be up to 1,024 characters in length.

d. Click **OK**.

After you save the report as a template, you can click the template in the **New Report** section of the **Report** page to create a report.

- o **Share & Release**: You can click **Share & Release** in the upper-right corner to share and release the report. You can share the report with specified users or all users. If you need to share the report to specific users, click **Add** to specify the users.

2.7.5. Go to the report center

On the Data analysis report center page, you can view the visualized report solution that DataAnalysis provides.

Procedure

1. [Log on to the DataWorks console.](#)
2. On the **DataStudio** page, click  in the upper-left corner and choose **All Products > DataAnalysis**.
3. In the top navigation bar of the **DataAnalysis** page, click **Report center** to go to the **Data analysis report center** page.

2.7.6. Go to the learning center

On the Data analytics Learning Center page, you can view relevant materials and learn about DataAnalysis.

Procedure

1. [Log on to the DataWorks console.](#)
2. On the DataStudio page, click  in the upper-left corner and choose **All Products > DataAnalysis**.
3. In the top navigation bar of the DataAnalysis page, click **Learn** to go to the **Data analytics Learning Center** page.

2.8. Administration

2.8.1. Overview

Generally, developers need to test workflows and nodes on the Operation Center page.

As a key tool for routine O&M, Operation Center enables you to manage and maintain the workflows and nodes that you have committed. The Operation Center service consists of four modules: Dashboard, Nodes, Node Instances, and Monitor.

- **Dashboard:** enables you to view and manage all global nodes of DataWorks. It displays various information, including **Instances**, **Instances Run Today**, **Node Runtime**, **Instances Run in the Last Month**, **Nodes with Errors in the Last Month**, and **Node Types** of the current workspace.
- **Nodes:** provides **Recurring** and **Manually Triggered**.
- **Node Instances:** provides **Recurring**, **Manually Triggered**, **Smoke Test** and **Retroactive**. You can manage them in a list view or DAG.
 - The list view displays the running status of nodes in a list. You can add multiple alerts at a time, change owners, and add nodes to baselines.
 - In the DAG, you can maintain and manage the running status of nodes and their dependencies on ancestor and descendant nodes. You can also perform operations, such as retroactive data generation and rerun, for a single node.
- **Monitor:** provides **Baseline Instances**, **Baselines**, **Events**, **Alert Triggers**, and **Alerts**.

2.8.2. Dashboard

The Dashboard page provides information about the node running status, the trend of the number of nodes that were run, the node running time, and the nodes with errors.

Go to the Dashboard page

1. [Log on to the DataWorks console.](#)
2. Click  in the upper-left corner and choose **All Products > Operation Center**. By default, the **Dashboard** page appears.

The **Dashboard** page consists of the following sections: **Instances**, **Instances Run Today**, **Node Runtime**, **Nodes with Errors In the Last Month**, **Instances Run In the Last Month**, and **Node Types**.

Note

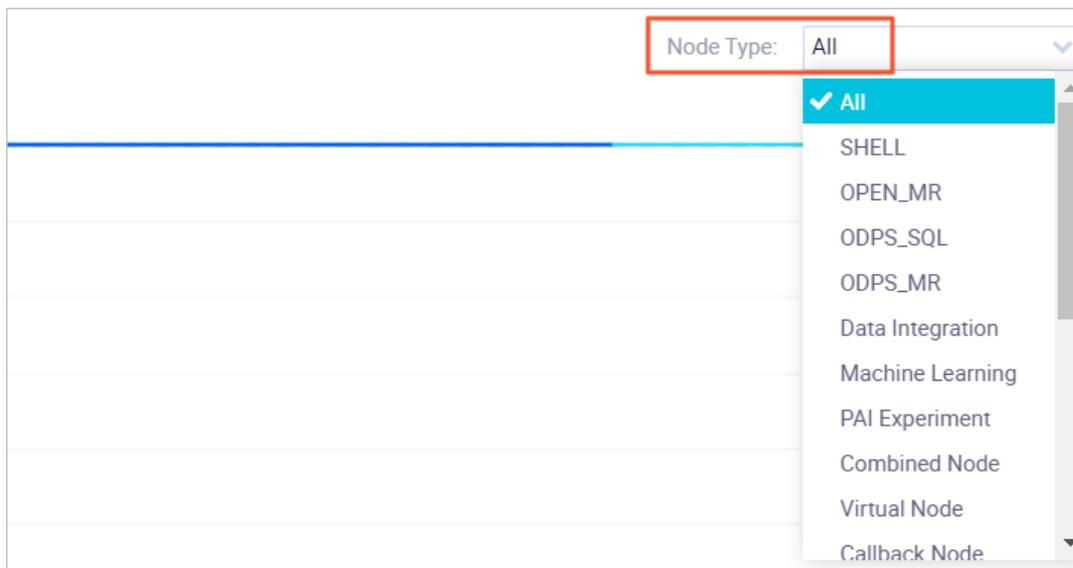

- Pending (Schedule): the instances whose scheduled time has not arrived. These instances will be automatically run when their scheduled time arrives.
- Pending (Resources): the instances whose scheduled time has arrived. These instances are waiting for scheduling resources.

View the summary of instance running

The **Instances** section displays the numbers of auto triggered node instances that were run today and yesterday, as well as the historical average. If the deviations among the three numbers are large, an exception occurred during a specific period of time. Further check and analysis are required.

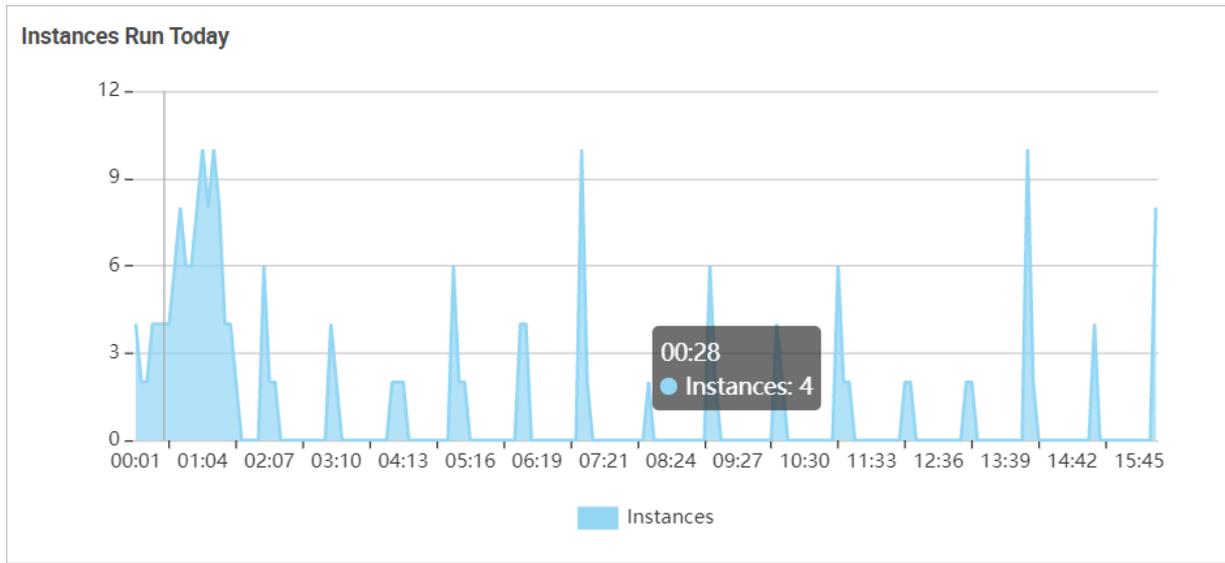

The statistical chart on the right of the Instances section shows three lines in different colors, representing the numbers of instances completed between 00:00 and 23:00 of today and yesterday, as well as the historical average. You can also view the number and proportion of instances in the pie chart on the left.

In the upper-right corner of the statistics chart, you can select a node type from the **Node Type** drop-down list to view statistics on the specified type of nodes.

View the statistics on instances run today

The **Instances Run Today** section displays the numbers of node instances that were running at different time points of the current day. In the chart, you can find the time point when peak concurrency occurred and the maximum number of concurrent nodes. Based on the information, you can determine whether to avoid node scheduling at the peak hours and adjust the scheduling time of nodes.

View the rankings of nodes based on their running time

The **Node Runtime** section displays nodes with a specified timestamp in the current workspace by their running time. By default, this section displays the top 10 nodes in descending order of their running time. You can view **Node ID**, **Node Name**, **Owner**, and **Runtime** of each node.

Node Runtime			
Node ID	Node Name	Owner	Runtime
[Node ID]	[Node Name]	[Owner]	1Hours19Min...
[Node ID]	[Node Name]	[Owner]	1Hours45Sec...

View the rankings of nodes with errors in the last month

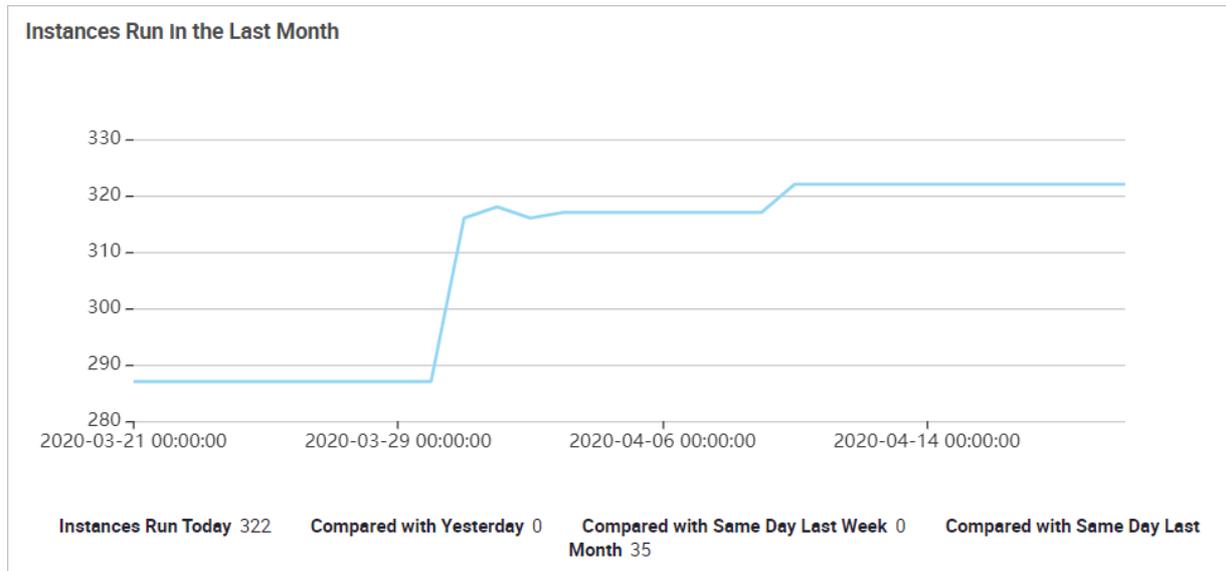

The **Nodes with Errors In the Last Month** section displays the top 10 nodes with the most errors in the last month. You can view **Node ID**, **Node Name**, **Owner**, and **Errors** of each node.

Nodes with Errors In the Last Month			
Node ID	Node Name	Owner	Errors
[Node ID]	[Node Name]	[Owner]	360
[Node ID]	[Node Name]	[Owner]	360
[Node ID]	[Node Name]	[Owner]	360
[Node ID]	[Node Name]	[Owner]	360

You can click a node ID to go to the node details page.

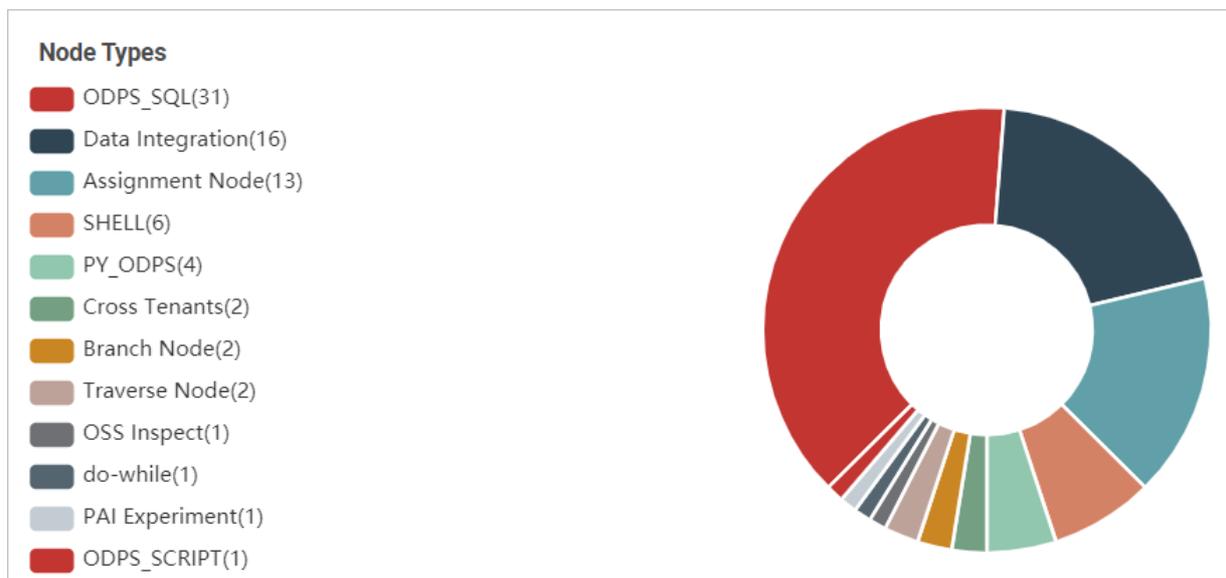

View the trend of the number of instances that were run

The **Instances Run In the Last Month** section displays the number of instances that were run today, comparison with yesterday, comparison with the same day last week, and comparison with the same day last month.

View the node distribution by node type

In the Node Types section, you can move the pointer over a sector of the pie chart to view the number and proportion of nodes of the specific type.

2.8.3. Manage real-time synchronization nodes

This topic describes how to manage real-time synchronization nodes on the Operation Center page.

Procedure

1. [Log on to the DataWorks console.](#)
2. On the **DataStudio** page, click the  icon in the upper-left corner and choose **All Products > Operation Center**.

3. In the left-side navigation pane of the Operation Center page, choose **RealTime Task Maintenance > Real Time DI**.
4. On the **Real Time DI** page, find your desired real-time synchronization node, click the node name, and then view the operations and maintenance (O&M) details about the node. On this page, you can **start**, **stop**, **undeploy**, or **configure alerting** for the real-time synchronization node.
 - o To start a node that is not running, perform the following steps:
 - a. Find the node and click **Start** in the Operation column.
 - b. In the **Start** dialog box, configure the parameters.

Parameter	Description
Whether to reset the site	Specifies whether to set the time point for the next startup. If you select Reset site , the Start time point and Time zone parameters are required.
Start time point	The date and time for starting the real-time synchronization node.
Time zone	The time zone where the source resides. Select a time zone from the Time zone drop-down list.
Failover	<ul style="list-style-type: none"> ■ The condition for automatically terminating the real-time synchronization node. You can specify the maximum number of dirty data records allowed. If you set the value to 0, no dirty data records are allowed. If the value is empty, the running of the node continues no matter whether dirty data records exist. ■ You can also specify the maximum number of failover times. If you do not specify Failover, the node is automatically terminated if the node fails 100 times within 5 minutes. This avoids resource occupation caused by frequent startup.

- c. Click **OK**.
- o To stop a running node, perform the following steps:
 - a. Find the node and click **Stop** in the Operation column.
 - b. In the message that appears, click **Stop**.
- o To undeploy a node that is not running, perform the following steps:
 - a. Find the node and click **Offline** in the Operation column.
 - b. In the message that appears, click **Offline**.
- o Find the node and click **Alarm settings** in the Operation column. On the page that appears, you can view alert event information and alert rules on the **Alert event** and **Alarm rules** tabs.
- o To configure alert settings for a node, perform the following steps:
 - a. Select your desired node and click **New Alarm** in the lower part of the page.

b. In the **New rule** dialog box, configure the parameters.

Parameter	Description
Name	Required. The name of the rule that you want to create.
Description	The description of the rule.
Indicators	The metrics in the rule that you want to create. Valid values: Task Status , Business latency , Failover , Dirty Data , and DDL error .
Threshold	The threshold for reporting an alert. The default value is 5 minutes for both WARNING and CRITICAL alerts.
Alarm interval	The interval at which an alert is reported. The default value is 5 minutes.
WARNING	The methods used to send alert notifications. Set the value to Mail .
CRITICAL	
Receiver	The alert recipient. Select a recipient from the Receiver drop-down list.

- c. Click **OK**.
- o To modify alert settings for a node, perform the following steps:
 - a. Select your desired node and click **Operation alarm** in the lower part of the page.
 - b. In the **Operation alarm** dialog box, specify the **Operation type** and **Alarm indicators** parameters.
DataWorks automatically modifies all the rules for the selected alert types at a time.
 - c. Click **OK**.

2.8.4. Auto triggered node O&M

2.8.4.1. Manage auto triggered nodes

Auto triggered nodes are automatically run as scheduled after they are committed to the scheduling system.

Note

- By default, the auto triggered node list displays nodes in all the workflows created by the current account.
- After you commit a node, the scheduling system automatically generates and runs an instance of the node at 23:30 the next day. If you commit a node after 23:30, the scheduling system generates and runs an instance of the node on the third day.
- Do not perform any operations on the **Workspace name_root** node, which is the root node of the workspace. All instances of auto triggered nodes depend on this node. If this node is frozen, instances of auto triggered nodes cannot be run.

Manage auto triggered nodes in the node list

The **Cycle Task** page displays auto triggered nodes that are committed to the scheduling system in a list.

Operation	Description
Filter	<p>Find required nodes by setting parameters in the red box marked with 1 in the preceding figure. You can search for nodes by node name or node ID and set the Node Type, Owner, My Nodes, Modified Today, and Frozen parameters to filter nodes.</p> <p> Note When you search for nodes by node name, the search result is affected by other filter conditions you specified. Only the nodes that meet both the specified search condition and other filter conditions are returned in the search result.</p>
DAG	Click DAG in the Actions column of a node to view the directed acyclic graph (DAG) of the node. You can view the node information, such as properties, operations logs, and code, in the DAG.
Test	Click Test in the Actions column of a node to test the node. For more information, see Manage test instances .
Patch Data	Click Patch Data in the Actions column of a node and select an item from the drop-down list to generate retroactive data for the node. For more information, see Manage retroactive instances .
More operations	<p>Click More in the Actions column of a node to perform more operations on the node. You can perform the following operations on the node:</p> <ul style="list-style-type: none"> • Select Freeze to freeze the node. After the node is frozen, DataWorks can still generate instances of the node, but does not run the instances of the node and its descendant instances. • Select Unfreeze to unfreeze the node. After the node is unfrozen, DataWorks can normally run the instances of the node and its descendant instances. • Select View Instances to view the instances of the node. • Select Configure Alert Trigger to configure alert triggers for the node. • Select Change Owner to change the owner of the node. • Select Add to Baseline to add the node to a baseline. • Select Change Resource Group to change the resource group used to run the node if multiple resource groups exist in the workspace. • Select Configure Data Quality Rules to configure rules for monitoring the data quality of the node. • Select View Lineage to view the lineage of the node. • Select View Ancestor and Descendant Nodes to go to the Node Information page, where you can view node information on the Ancestor Nodes and Descendant Nodes tabs.
Batch operations	Select multiple nodes and click a button in the red box marked with 3 in the preceding figure to perform batch operations. The buttons include Configure Alert Trigger , Change Owner , Change Resource Group , Add to Baseline , Freeze , Unfreeze , and Delete .

Manage auto triggered nodes in a DAG

Click the name of a node or **DAG** in the Actions column to view the DAG of the node. In the DAG, you can right-click the node to perform related operations.

Operation	Description
Show Ancestor Nodes or Show Descendant Nodes	View ancestor or descendant nodes at one or more levels. If the workflow contains three or more nodes, the DAG displays only the current node and hides its ancestor and descendant nodes.

Operation	Description
View Node Details	Go to the Node Information page to view the node information, including the input table, output table, ancestor nodes, and descendant nodes.
View Code	View the code of the node.
Edit Node	Go to the DataStudio page to modify the node.
View Instances	View the instances of the node.
View Lineage	View the lineage of the node.
Test	Go to the Smoke Test dialog box. Set the Smoke Test Instance Name and Data Timestamp parameters and click OK . Then, the Test Instance page appears.
Run	Select Current Node Retroactively , Current and Descendant Nodes Retroactively , or Mass Nodes Retroactively .
Freeze	Pause the scheduling of the node.
Unfreeze	Resume the scheduling of the node after it is frozen.
Configure Data Quality Rules	Configure rules for monitoring the data quality of the node.

2.8.4.2. Manage auto triggered node instances

Auto triggered node instances are snapshots taken for auto triggered nodes that are run.

An instance is generated each time when an auto triggered node is run as scheduled. You can manage auto triggered node instances. For example, you can view the running status of instances, and stop, rerun, and unfreeze instances.

 **Note** DataWorks regularly generates instances for auto triggered nodes. Each generated instance runs the latest code. If you modify and recommit the node code after instances are generated, the instances that have not been run will run the latest code.

Manage auto triggered node instances in the instance list

You can manage auto triggered node instances in the instance list. For example, you can check operational logs, rerun instances, and stop running instances.

Operation	Description
Filter	<p>Find required instances by setting parameters in the red box marked with 1 in the preceding figure.</p> <p>You can search for instances by node name or node ID and set the following parameters to filter instances: Data Timestamp, Node Type, Run At, Solution, Workflow, Region, Engine type, Engine instance, Baseline, Owner, Recurrence, Status, My Nodes, My Nodes with Errors, My Incomplete Nodes, and Re-run node.</p> <p> Note By default, the data timestamp is set to the previous day of the current day.</p>

Operation	Description
Stop	Stop the instance. You can stop instances only when they are in the Pending (Resource) or Running state. After you perform this operation, the instance enters the Failed state.
Rerun	Rerun the instance. After the instance is rerun, its descendant instances will be run as scheduled. Perform this operation if an instance fails or it is not run as scheduled. <div style="background-color: #e6f2ff; padding: 5px;"> <p> Note This operation applies only to instances in the Pending (Ancestor), Successful, or Failed state.</p> </div>
Rerun Descendant Nodes	Rerun the instance and its descendant instances. You must specify the instances to rerun. After they are run, their descendant instances will be run as scheduled. This operation applies to data recovery. <div style="background-color: #e6f2ff; padding: 5px;"> <p> Note You can select instances only in the Pending (Ancestor), Successful, or Failed state. The value No appears in the Meet Rerun Condition column of instances in other states, and you cannot select the instances.</p> </div>
Set Status to Successful	Set the status of the instance to Successful and run its descendant instances as scheduled. You can perform this operation if an instance fails. <div style="background-color: #e6f2ff; padding: 5px;"> <p> Note This operation applies only to failed instances but not workflows.</p> </div>
Freeze	Freeze the instance if it is in the Running state.
Unfreeze	Unfreeze the instance after it is frozen. <ul style="list-style-type: none"> • If the instance is not run, DataWorks automatically runs this instance after its ancestor instances are run. • If all the ancestor instances have been run, the instance is directly set to Failed. You must manually rerun the instance.
Batch operations	Select multiple instances and click a button in the red box marked with 3 in the preceding figure to perform batch operations. The buttons include Stop , Rerun , Set Status to Successful , Freeze , and Unfreeze .

Manage auto triggered node instances in a DAG

Click the name of an instance or **DAG** in the **Actions** column to view the directed acyclic graph (DAG) of the instance. In the DAG, you can right-click the instance to perform related operations.

Operation	Description
Show Ancestor Nodes or Show Descendant Nodes	View ancestor or descendant instances at one or more levels. If a workflow contains three or more instances, the DAG displays only the current instance and hides its ancestor and descendant instances.
View Runtime Log	View the operational logs of the instance if it is in the Running , Successful , or Failed state.
View Code	View the code of the instance.

Operation	Description
Edit Node	Go to the DataStudio page to modify the node to which the instance belongs.
View Lineage	View the lineage of the instance.
More operations	View more instance information on the General, Context, Runtime Log, Operation Log, and Code tabs.
Stop	Stop the instance if it is in the Pending (Resource) or Running state. After you perform this operation, the instance enters the Failed state.
Rerun	<p>Rerun the instance. After the instance is rerun, its descendant instances will be run as scheduled. Perform this operation if an instance fails or it is not run as scheduled.</p> <p> Note This operation applies only to instances in the Pending (Ancestor), Successful, or Failed state.</p>
Rerun Descendant Nodes	<p>Rerun the instance and its descendant instances. You must specify the instances to rerun. After they are run, their descendant instances will be run as scheduled. This operation applies to data recovery.</p> <p> Note You can select instances only in the Pending (Ancestor), Successful, or Failed state. The value No appears in the Meet Rerun Condition column of instances in other states, and you cannot select the instances.</p>
Set Status to Successful	<p>Set the status of the instance to Successful and run its descendant instances as scheduled. You can perform this operation if an instance fails.</p> <p> Note This operation applies only to failed instances but not workflows.</p>
Resume	Continue to run the instance after it fails.
Emergency Operations	<p>Perform emergency operations, including Delete Dependencies, Change Priority, and Force Rerun. Perform these operations in emergency only. These operations take effect only on the current instance for one time.</p> <p>Select Delete Dependencies to delete dependencies of the current instance. You can perform this operation so that you can start the current instance when the ancestor instances fail and the current instance does not depend on the data of the ancestor instances.</p>
Freeze	Freeze the instance if it is in the Running state.
Unfreeze	<p>Unfreeze the instance after it is frozen.</p> <ul style="list-style-type: none"> • If the instance is not run, DataWorks automatically runs this instance after its ancestor instances are run. • If all the ancestor instances have been run, the instance is directly set to Failed. You must manually rerun the instance.

2.8.4.3. Manage retroactive instances

DataWorks runs retroactive instances to generate retroactive data for auto triggered nodes. You can manage retroactive instances. For example, you can view the running status of instances, and stop, rerun, or unfreeze instances.

Limits

- When DataWorks generates retroactive data in a period of time for a node, if one instance of the node fails on a day, the retroactive instance for that day is also set to Failed. DataWorks will not run instances of this node for the next day. To sum up, DataWorks runs instances of a node on a day only when all its instances of the previous day are successful.
- For a self-dependent auto triggered node, if the first instance for which retroactive data needs to be generated has a last-cycle instance on the previous day but the last-cycle instance is not run, the retroactive instance cannot be triggered. If the first instance for which retroactive data needs to be generated does not have a last-cycle instance on the previous day, the retroactive instance is directly triggered.
- DataWorks generates alerts only for auto triggered node instances.
- If an auto triggered node has an instance in the Running state, its retroactive or test instance can start to run only after this auto triggered node instance is run.
- If both an auto triggered node instance and a retroactive instance are running for a node at the same time, you must stop the retroactive instance to ensure proper running of the auto triggered node instance.

Go to the page for configuring retroactive instances

1. [Log on to the DataWorks console.](#)
2. Click  in the upper-left corner and choose **All Products > Operation Center**.
3. In the left-side navigation pane, choose **Cycle Task Maintenance > Cycle Task**.
4. On the page that appears, click the rightward arrow in the middle to show the Actions column in the node list. Find the target node, click **Patch Data** in the Actions column, and then select a mode for generating retroactive data.

You can also right-click the target node in the directed acyclic graph (DAG), move the pointer over **Run**, and then select a mode for generating retroactive data.

Generate retroactive data for the current node

1. Find the target node, click **Patch Data** in the Actions column, and then select **Current Node Retroactively**.
2. In the **Patch Data** dialog box, set the parameters.

Parameter	Description
Retroactive Instance Name	The name of the retroactive instance. DataWorks automatically generates a name, which can be changed.
Data Timestamp	The data timestamp of the retroactive instance.
Node	The name of the node for which you want to generate retroactive data. You cannot change the name.

Parameter	Description
Parallelism	<p>Specifies whether to generate multiple retroactive instances at a time.</p> <ul style="list-style-type: none"> ◦ If you select Disable, only one retroactive instance is generated. The retroactive instance is run multiple times based on the data timestamp in sequence. ◦ If you select 2 Parallel Groups, 3 Parallel Groups, 4 Parallel Groups, or 5 Parallel Groups, multiple retroactive instances are generated. The retroactive instances are run based on the data timestamp in parallel or in sequence. <ul style="list-style-type: none"> ▪ If the number of days in the data timestamp is smaller than the number of parallel groups, the retroactive instances are run in parallel. For example, the data timestamp is from January 11 to January 13, and you select 4 Parallel Groups. In this case, three retroactive instances are generated for each day in the data timestamp, and the three retroactive instances are run in parallel. ▪ If the number of days in the data timestamp is greater than the number of parallel groups, some instances must be run multiple times in sequence while others are run in parallel. For example, the data timestamp is from January 11 to January 13, and you select 2 Parallel Groups. In this case, two retroactive instances are generated. They are run in parallel for once, and one of them must be run for a second time.

3. Click **OK**.

Generate retroactive data for the current and descendant nodes

1. Find the target node, click **Patch Data** in the Actions column, and then select **Current and Descendant Nodes Retroactively**.
2. In the **Patch Data** dialog box, set the parameters, including **Nodes**.

Parameter	Description
Retroactive Instance Name	The name of the retroactive instance. DataWorks automatically generates a name, which can be changed.
Data Timestamp	The data timestamp of the retroactive instance.
Parallelism	<p>Specifies whether to generate multiple retroactive instances at a time.</p> <ul style="list-style-type: none"> ◦ If you select Disable, only one retroactive instance is generated. ◦ If you select 2 Parallel Groups, 3 Parallel Groups, 4 Parallel Groups, or 5 Parallel Groups, multiple retroactive instances are generated.
Nodes	The nodes for which you want to generate retroactive data. You can set Node Name and Node Type to filter nodes.

3. Click **OK**.

Generate retroactive data for a large number of nodes

1. Find the target node, click **Patch Data** in the Actions column, and then select **Mass Nodes Retroactively**.

2. In the **Patch Data** dialog box, set the parameters. The following table describes the parameters for generating retroactive data for a large number of nodes.

Parameter	Description
Retroactive Instance Name	The name of the retroactive instance. DataWorks automatically generates a name, which can be changed.
Data Timestamp	<p>The data timestamp of the retroactive instance.</p> <p> Note We recommend that you do not set this parameter to a long range. Otherwise, the retroactive instance may be delayed due to insufficient resources.</p>
Parallelism	<p>Specifies whether to generate multiple retroactive instances at a time.</p> <ul style="list-style-type: none"> ◦ If you select Disable, only one retroactive instance is generated. ◦ If you select 2 Parallel Groups, 3 Parallel Groups, 4 Parallel Groups, or 5 Parallel Groups, multiple retroactive instances are generated.
Nodes	<ul style="list-style-type: none"> ◦ If you select the Current Node check box, retroactive instances are generated for the current node and its descendant nodes. ◦ If you clear the Current Node check box, the current node is dry-run and retroactive instances are generated for its descendant nodes.
Workspaces	The workspaces of the nodes for which DataWorks needs to generate retroactive data. Select workspaces under Available Workspaces and add them to Selected Workspaces . Fuzzy match is supported when you search for workspaces under Available Workspaces.
Node Whitelist	<p>The nodes outside the selected workspaces, for which DataWorks needs to generate retroactive data.</p> <p> Note You can search for nodes by node ID.</p>
Node Blacklist	<p>The nodes inside the selected workspaces, for which DataWorks does not need to generate retroactive data.</p> <p> Note You can search for nodes by node ID.</p>

3. Click **OK**.

Manage retroactive instances in the instance list

Operation	Description
-----------	-------------

Operation	Description
Filter	<p>Find required instances by specifying filter conditions.</p> <p>You can search for instances by node name or node ID and set the following parameters to filter instances: Retroactive Instance Name, Node Type, Owner, Run At, Data Timestamp, Engine type, Engine instance, Baseline, and My Nodes.</p> <div style="background-color: #e0f2f7; padding: 5px; border: 1px solid #ccc;"> <p> Note By default, the data timestamp is set to the previous day of the current day.</p> </div>
DAG	View the DAG of the instance. You can view the running result of the instance in the DAG.
Stop	Stop the instance. You can stop instances only when they are in the Pending (Resource) or Running state. After you perform this operation, the instance enters the Failed state.
Rerun	Rerun the instance.
Rerun Descendant Nodes	Rerun the descendant instances of the instance.
Freeze	Pause the scheduling of the instance.
Recover	Resume the scheduling of the instance after it is paused.
View Lineage	View the lineage of the instance.

Manage retroactive instances in a DAG

Click the name of an instance or **DAG** in the Actions column to view the DAG of the instance. In the DAG, you can right-click the instance to perform related operations.

 **Note** After you click **Refresh** in the upper-right corner, the DAG of the instance is refreshed, but the operational logs are not.

Operation	Description
Show Ancestor Nodes or Show Descendant Nodes	Show ancestor or descendant instances at one or more levels. If a workflow contains three or more instances, the DAG displays only the current instance and hides its ancestor and descendant instances.
View Runtime Log	View the operational logs of the instance if it is in the Running, Successful, or Failed state.
View Code	View the code of the instance.
Edit Node	Go to the DataStudio page to modify the node to which the instance belongs.
View Lineage	View the lineage of the instance.

Operation	Description
Stop	Stop the instance. You can stop instances only when they are in the Pending (Resource) or Running state. After you perform this operation, the instance enters the Failed state.
Rerun	Rerun the instance if it is in the Failed or an abnormal state.
Rerun Descendant Nodes	Rerun all the descendant instances of the instance.
Set Status to Successful	Set the status of the instance to Successful and run its descendant instances as scheduled. You can perform this operation if an instance fails. <div style="background-color: #e0f2f7; padding: 5px; border: 1px solid #ccc;"> ? Note This operation applies only to failed instances but not workflows. </div>
Emergency Operations	Perform emergency operations in emergency only. Emergency operations take effect only on the current instance for one time. Select Delete Dependencies to delete dependencies of the current instance. You can perform this operation so that you can start the current instance when the ancestor instances fail and the current instance does not depend on the data of the ancestor instances.
Freeze	Pause the scheduling of the instance.
Unfreeze	Resume the scheduling of the instance after it is paused.

2.8.4.4. Manage test instances

Test instances are generated when you test auto triggered nodes. You can manage test instances.

Go to the Test Instance page

1. [Log on to the DataWorks console.](#)
2. Click  in the upper-left corner and choose **All Products > Operation Center**.
3. In the left-side navigation pane, choose **Cycle Task > Test Instance**. The Test Instance page appears, where you can view the list and directed acyclic graphs (DAGs) of test instances.

Manage test instances in the instance list

You can manage test instances in the instance list. For example, you can rerun, freeze, or unfreeze instances, set the status of instances to Successful, view the lineage of instances, and check operational logs.

Operation	Description
Filter	Find required instances by specifying filter conditions. You can search for instances by node name or node ID and set the following parameters to filter instances: Node Type , Owner , Run At , Data Timestamp , Status , Region , Engine type , Engine instance , Baseline , My Nodes , Tested by Me Today , and Frozen .
Stop	Stop the instance. You can stop instances only when they are in the Pending (Resource) or Running state. After you perform this operation, the instance enters the Failed state.

Operation	Description
Rerun	<p>Rerun the instance. After the instance is rerun, its descendant instances will be run as scheduled. Perform this operation if an instance fails or it is not run as scheduled.</p> <p> Note This operation applies only to instances in the Pending (Ancestor), Successful, or Failed state.</p>
More operations	Click More in the Actions column and then select an operation. The operations include Set Status to Successful , Freeze , Unfreeze , View Lineage , and View Runtime Log .
Batch operations	Select multiple instances and click a button in the lower part of the instance list to perform batch operations. The buttons include Stop , Rerun , Set Status to Successful , Freeze , and Unfreeze .

Manage test instances in a DAG

Click the name of an instance or **DAG** in the Actions column to view the DAG of the instance. In the DAG, you can right-click the instance to perform related operations.

Operation	Description
View Runtime Log	View the operational logs of the instance if it is in the Running , Successful , or Failed state.
View Code	View the code of the instance.
Edit Node	Go to the DataStudio page to modify the node to which the instance belongs.
View Lineage	View the lineage of the instance.
Stop	Stop the instance. You can stop instances only when they are in the Pending (Resource) or Running state. After you perform this operation, the instance enters the Failed state.
Rerun	<p>Rerun the instance. After the instance is rerun, its descendant instances will be run as scheduled. Perform this operation if an instance fails or it is not run as scheduled.</p> <p> Note This operation applies only to instances in the Pending (Ancestor), Successful, or Failed state.</p>
Set Status to Successful	<p>Set the status of the instance to Successful and run its descendant instances as scheduled. You can perform this operation if an instance fails.</p> <p> Note This operation applies only to failed instances but not workflows.</p>
Freeze	Pause the scheduling of the instance.

Operation	Description
Unfreeze	<p>Resume the scheduling of the instance after it is frozen.</p> <ul style="list-style-type: none"> • If the instance is not run, DataWorks automatically runs this instance after its ancestor instances are run. • If all the ancestor instances have been run, the instance is directly set to Failed. You must manually rerun the instance.

2.8.5. Manually triggered node O&M

2.8.5.1. Manage manually triggered nodes

Manually triggered nodes are nodes whose scheduling type is set to manual before they are committed to the scheduling system.

 **Note** After a manually triggered node is committed to the scheduling system, it will run only after it is manually triggered.

Manage manually triggered nodes in the node list

The manually triggered node list displays manually triggered nodes that are committed.

Operation	Description
Filter	<p>Find required nodes by specifying filter conditions.</p> <p>You can search for nodes by node name and set the Owner, My Nodes, and Modified Today parameters to filter nodes.</p> <p> Note When you search for nodes by node name, the search result is affected by other filter conditions you specified. Only nodes that meet both the specified search condition and other filter conditions are returned in the search result.</p>
DAG	Click DAG in the Actions column of a node to view the directed acyclic graph (DAG) of the node. You can view the node information, such as the code and lineage, in the DAG.
Run	Click Run in the Actions column of a node to run the node. Manually triggered node instances are generated.
View Instances	Click View Instances in the Actions column of a node to go to the Manual Instance page, where you can view the instances of the node.
More operations	Choose More > Change Owner in the Actions column of a node to change the owner of the node.
Batch operations	Select multiple nodes and click Change Owner in the lower part of the page to change the owner of the nodes.

Manage manually triggered nodes in a DAG

Click the name of a node or **DAG** in the Actions column to view the DAG of the node. In the DAG, you can right-click the node to perform related operations.

Operation	Description
View Code	View the code of the node.
Edit Node	Go to the DataStudio page to modify the node.
View Instances	View the instances of the node.
View Lineage	View the lineage of the node.
Run	Run the node. After you click Run, manually triggered node instances are generated.
Change Resource Group	Change the resource group where the node is run.

2.8.5.2. Manage manually triggered node instances

DataWorks generates manually triggered node instances from manually triggered nodes. Manually triggered nodes do not have node dependencies. They must be run manually.

 **Notice** DataWorks generates alerts only for auto triggered node instances when they fail to be run.

Go to the page for managing manually triggered node instances

1. [Log on to the DataWorks console.](#)
2. Click  in the upper-left corner and choose **All Products > Operation Center**.
3. In the left-side navigation pane, choose **Trigger Task Maintenance > Trigger Instance**. The Trigger Instance page appears, where you can view the list and directed acyclic graphs (DAGs) of manually triggered instances.

Manage manually triggered node instances in the instance list

Operation	Description
Filter	Find required instances by specifying filter conditions. You can search for instances by instance name and set the Owner , Data Timestamp , and Run At parameters to filter instances.
DAG	Click DAG in the Actions column to view the DAG of the instance. You can view the running result of the instance in the DAG.
Stop	Click Stop to stop the instance if it is in the Running state.
Rerun	Rerun the instance.
Batch stop	Select multiple instances and click Stop to stop the selected instances at a time.

Manage manually triggered node instances in a DAG

Click the name of an instance or DAG in the Actions column to view the DAG of the instance. In the DAG, you can right-click the instance to perform related operations.

 **Note** A manually triggered node instance does not have dependencies, so only the current instance appears in the DAG.

Operation	Description
View Runtime Log	View the operational logs of the instance if it is in the Running, Successful, or Failed state.
View Code	View the code of the instance.
Edit Node	Go to the DataStudio page to modify the node to which the instance belongs.
View Lineage	View the lineage of the instance.
Stop	Stop the instance.
Rerun	Rerun the instance if it is in the Failed or an abnormal state.

2.8.6. MaxCompute engine O&M

DataWorks Operation Center allows you to view the jobs, quota groups, and projects of MaxCompute.

Prerequisites

A MaxCompute engine is added on the **Project Management** page.

Go to the MaxCompute page

1. Log on to the DataWorks console.
2. Click  in the upper-left corner and choose **All Products > Operation Center**.
3. In the left-side navigation pane, choose **Engine Maintenance > MaxCompute**. The **Job Queue** tab appears by default. You can view the jobs, quota groups, and projects of MaxCompute.

View jobs

On the **Job Queue** tab, you can view the total number of jobs and numbers of jobs in the **Running**, **Waiting for Resources**, and **Initializing** states.

You can set the **Quota Group** and **Project** parameters to filter jobs. You can view the following parameters of each job: **Instance**, **Execution Time**, **CPU Usage (Minimum/Maximum)**, **Memory Usage (Minimum/Maximum)**, **Priority**, **Node**, **Submitted By**, **Project**, **Type**, **Quota Group**, **Cluster**, **Status**, and **Start Time**.

View quota groups

On the **MaxCompute** page, click the **Quotas** tab.

On the **Quotas** tab, you can view the following parameters of each quota group: **Project**, **Quota Group**, **Default**, **Cluster**, **Minimum CPU (cores)**, **Maximum CPU (cores)**, **Minimum Memory (bytes)**, **Maximum Memory (bytes)**, and **Projects**.

You can click the name of a quota group to view the resource usage information about the quota group.

View projects

On the **MaxCompute** page, click the **Projects** tab.

On the **Projects** tab, you can view the following parameters of each project: **Project**, **Owner**, **Cluster**, **Quota Group**, **Storage Used**, **Storage Quota**, **Storage Usage**, and **Files**.

2.8.7. Monitor

2.8.7.1. Overview

The Monitor module is a node monitoring and analysis system of DataWorks. Based on monitoring rules and node running status, the Monitor module determines whether, when, and how to trigger an alert, and whom an alert is sent to. It automatically selects the most appropriate alerting time, notification methods, and recipients.

The Monitor module provides you with the following benefits:

- Improves your efficiency on configuring monitoring rules.
- Prevents invalid alerts from bothering you.
- Automatically covers all important nodes for you.

General monitoring systems cannot meet the requirement of DataWorks. The reasons are as follows:

- DataWorks has numerous nodes, so it is difficult for you to find out the nodes to be monitored. Some DataWorks businesses have a large number of nodes, and dependencies between the nodes are complex. Even if you know the most important node, it is difficult to find all ancestor nodes of the node and monitor them all. In this case, if you simply monitor all nodes, a large number of invalid alerts may be generated. In consequence, you may miss those useful alerts.
- The alerting method varies with nodes. For example, some monitoring tasks require the relevant nodes to run for more than one hour before triggering alerts, while other monitoring tasks require the relevant nodes to run for more than two hours. It is extremely complex to set a monitoring node for each node, and it is difficult to predict the alert threshold value for each node.
- The alerting time varies with nodes. For example, an alert for an unimportant node can be sent after you start working in the morning. An alert for an important node needs to be sent immediately when an error occurs. General monitoring systems cannot tell the importance of each node.
- Different alerts require different operations to turn off.

The Monitor module provides comprehensive monitoring and alerting logic. You only need to provide the node name of your business. Then, the Monitor module automatically monitors the entire process of your node and creates standard alert triggers for the node. In addition, you can customize alerting triggers by completing basic settings.

Currently, the Monitor module has been used for monitoring all important businesses of Alibaba Group. Its full-path monitoring function guarantees the overall data output of all important businesses of Alibaba Group. In addition, it supports analyzing ancestor and descendant node paths to promptly detect risks and provide O&M advice for business departments. These functions of the Monitor module have guaranteed the long-term high stability of businesses in Alibaba Group.

2.8.7.2. Feature description

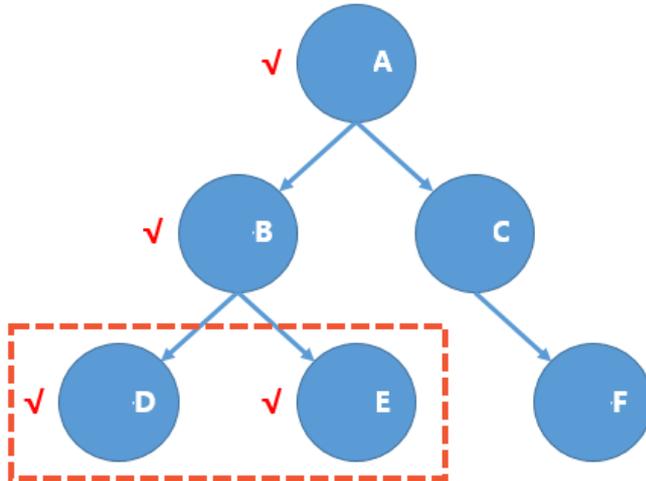

2.8.7.2.1. Baseline alert and event alert

This topic describes the functional logic of baseline alerts and event alerts from the aspects of monitoring scope, node capturing, alert object judgment, alerting time judgment, notification methods, and alert escalation.

Monitoring scope

A baseline is a management unit of a group of nodes, that is, a node group. You can specify nodes to monitor in a baseline.

After a baseline is monitored, all nodes of the baseline and its ancestor nodes are monitored. The Monitor module does not monitor all nodes by default. A node is monitored only when it has descendant nodes that are added to a monitoring baseline. If no descendant nodes are added to a monitoring baseline, the Monitor module does not report any alert even if the node fails.

As shown in the preceding figure, assume that DataWorks has only six nodes, and nodes D and E belong to a monitoring baseline. Nodes D and E and all their ancestor nodes are monitored by the Monitor module. That is, any error or slowdown on node A, B, D, or E will be detected by the Monitor module. However, nodes C and F are not monitored by the Monitor module.

Node capturing

After the nodes to be monitored are specified, if a monitored node incurs an exception, the Monitor module generates an event. All alert decisions are based on the analysis of this event. Two types of node exceptions are available. You can choose **Events > Event Type** to view them.

- **Error:** indicates that a node fails to run.
- **Slow:** indicates that the running time of a node is significantly longer than the average running time of the node in the past periods.

Note If a node times out and then encounters an error, two events are generated.

Alerting time judgment

Buffer, an important concept in the Monitor module, refers to the maximum time period that a node can be delayed. The latest start time of a node is obtained by subtracting the average uptime from the baseline time.

The baseline time of baseline A is 05:00, you must set the latest start time of node E to 04:10. This time is calculated by subtracting the average uptime of node F (20 minutes) and node E (30 minutes) from the baseline time 05:00. This time is also the latest completion time of node B in baseline A.

To ensure that the baseline time of baseline B is 06:00, you must set the latest completion time of node B to 04:00. This time, which is earlier than 04:10, is calculated by subtracting the average uptime of node D (2 hours) from the baseline time 06:00. To meet the baseline time of both baseline A and baseline B, you must set the latest completion time of node B to 04:00.

The latest completion time of node A is 02:00, which is calculated by subtracting the average uptime of node B (2 hours) from 04:00. The latest start time of node A is 01:50, which is calculated by subtracting the average uptime of node A (10 minutes) from 02:00. If node A fails to run before 01:50, it is probable that baseline A is broken.

If node A fails to run at 01:00, its buffer is 50 minutes, which is the difference between 01:00 and 01:50. As demonstrated in this example, buffer reflects the degree of caution for a node exception.

Baseline alert

Baseline alerting is an additional feature developed for baselines that are enabled. Each baseline must provide an alert buffer and committed time. Baseline alerting is the action of notifying the preset alert recipient three times at the interval of 30 minutes when the baseline completion time estimated by the Monitor module exceeds the alert buffer.

Notification method

Currently, baseline alerts are sent to the baseline owner by default. On the **Alert Triggers** page, you can find **Global Baseline Alert Trigger**, click **View Details**, and change the alert trigger method and the alerting action.

Gantt chart function

The Gantt chart function reflects the key path of a node. The function is provided by the **Baseline Instances** module of Monitor.

 **Note** The key path is the slowest upstream link that causes the node to be completed at this time point.

2.8.7.2.2. Custom alert trigger

Alert trigger customization is a lightweight monitoring function of the Monitor module.

You can customize all monitoring alert triggers by setting the following parameters:

- **Objects:** You can specify nodes, baselines, and workspaces as objects.
- **Trigger Condition:** Valid values include Completed, Uncompleted, Error, Uncompleted Cycle, and Overtime.
- **Notification Method:** Valid values include SMS and Email.
- **Maximum Alerts:** This parameter indicates the maximum number of alert reporting times. If the number of alerting times exceeds the preset threshold, no alerts are generated.
- **Minimum Alert Interval:** This parameter indicates the minimum time interval at which DataWorks reports alerts.
- **Quiet Hours:** This parameter indicates the specified period during which no alerts are reported.
- **Recipient:** This parameter indicates the person who receives alerts. You can set this parameter to the node owner or another recipient.

A monitoring rule uses the following five alert trigger conditions: Completed, Uncompleted, Error, Uncompleted Cycle, and Overtime.

- **Completed**

A completion alert can be set for nodes, baselines, and workspaces. Once all nodes of the preset objects are completed, the completion alert is reported. If you set a completion alert for a baseline, the alert is reported when all nodes of the baseline are completed.

- **Uncompleted**

You can set alerts for nodes, baselines, or workspaces that are not completed at a certain time point. For example, if you require that a baseline be completed at 10:00, an alert containing a list of uncompleted nodes is reported once a node in the baseline is not completed at the specified time.

- **Error**

An error alert can be set for nodes, baselines, and workspaces. Once a node has an error, an alert containing detailed node error information is sent to the recipient.

- **Uncompleted Cycle**

For the monitoring rules of hourly scheduled nodes, you can separately specify the uncompleted time points in different periods.

- **Overtime**

An overtime alert can be set for nodes, baselines, and workspaces. Once a monitored node of the preset object is not completed within the specified time, an alert is reported.

2.8.7.3. Instructions

2.8.7.3.1. Baseline instances

On the Baseline Instances page, you can view the information about a baseline.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Operation Center**. The **Operation Center** page appears.
3. On the Operation Center page, choose **Monitor > Baselines** in the left-side navigation pane. On the **Baselines** page, create a baseline. For more information about how to create a baseline, see [Create a baseline](#).

 **Note** If you have created a baseline, skip this step and directly go to the **Baseline Instances** page to perform subsequent operations.

4. In the left-side navigation pane, choose **Monitor > Baseline Instances**. The **Baseline Instances** page appears. On this page, you can search for baseline instances by condition, such as the data timestamp, owner name or ID, event ID, workspace, and baseline name. You can also click **View Details**, **Handle**, and **View Gantt Chart** in the Actions column to perform corresponding operations on a baseline.

 **Note** After creating a baseline, you must enable the baseline so that a baseline instance can be generated.

A baseline can be in the one of the following four states:

- **Normal**: All nodes in the baseline are completed before the alerting time.
- **Alerting**: One or more nodes in the baseline are not completed at the alerting time but the committed completion time has not arrived.
- **Overtime**: One or more nodes in the baseline are not completed at the committed completion time.
- **Others**: All nodes in the baseline are paused or the baseline is not associated with any node.

You can click **View Details**, **Handle**, and **View Gantt Chart** in the Actions column to perform corresponding operations on a baseline.

- **View Details**: Click **View Details** to go to the **Baseline Instance Details** page.

On the **Baseline Instance Details** page, you can view the general information, critical path, baseline instance information, history graph, and relevant events.

 **Note**

- In the preceding figure, the data timestamp is **one day before the system time**.
- When you create a baseline, you can select **By the Day Interval** or **By the Hour Interval**. The **Cycle** parameter appears as the advanced settings of the **Committed Time** parameter only when you select **By the Hour Interval**.

- **Handle**: Click **Handle** to pause the alert generated by the baseline when the baseline is being handled.
- **View Gantt Chart**: Click **View Gantt Chart** to view the critical paths of nodes.

2.8.7.3.2. Baselines

You can create and define baselines on the Baselines page.

Create a baseline

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Operation Center**. The **Operation Center** page appears.
3. On the Operation Center page, choose **Monitor > Baselines** in the left-side navigation pane.
4. On the **Baselines** page, click **Create Baseline** in the upper-right corner.

 **Note** Currently, only workspace administrators can create baselines.

5. In the **Create Baseline** dialog box that appears, set the parameters and click **OK**.

Parameter	Description
Baseline Name	The name of the baseline.
Workspace	The workspace of the node associated with the baseline.
Owner	The name or ID of the owner.
Recurrence	Specifies whether the baseline detects nodes by day or hour. <ul style="list-style-type: none"> ○ By the Day Interval: Select this option for nodes scheduled by day. ○ By the Hour Interval: Select this option for nodes scheduled by hour.
Nodes	<ul style="list-style-type: none"> ○ Node: the node associated with the baseline. Enter the name or ID of a node, and then click the icon on the right to add the node. You can add multiple nodes. ○ Workflow: the workflow associated with the baseline. Enter the name or ID of a workflow, and then click the icon on the right to add the workflow. We recommend that you only add the last node of a workflow instead of all nodes.
Priority	The priority of the baseline. A baseline with a higher priority is scheduled first. Currently, the only available priority value is 1.

Parameter	Description
Estimated Completion Time	The completion time of the node estimated based on the average running time of the node during previous scheduling. If no historical data is available, the message The completion time cannot be estimated due to a lack of historical data appears.
Committed Time	The time point when a node should be completed. An alert is triggered if the node is not completed until the time point obtained by subtracting the alert margin threshold from the committed completion time.
Margin Threshold	<p>The interval before an alert is triggered. For example, set Committed Time to 3:30 and Margin Threshold to 10 minutes. An alert is triggered if the node is not completed at 3:20. Assume that the average running time of the node is 30 minutes. If the node is not started at 2:50, an alert is triggered.</p> <div style="background-color: #e6f2ff; padding: 5px; border: 1px solid #d9e1f2;"> <p> Note The average running time of a node can be calculated based on the data of the last 15 days.</p> </div>

6. After a baseline is created, click **Enable** in the Actions column to enable the baseline.

You can click **View Details**, **Change**, **Enable**, **Disable**, or **Delete** in the Actions column to perform the corresponding operation on a baseline.

- **View Details:** Click **View Details** to view the basic information about the baseline.
- **Change:** Click **Change** to modify the baseline.
- **Enable** or **Disable:** Click **Enable** or **Disable** to enable or disable the baseline. A baseline instance can be generated only when the corresponding baseline is enabled.
- **Delete:** Click **Delete** to delete the baseline.

Add a node to a baseline

By default, all nodes in the production environment are in the default baseline of each workspace. When you create a baseline, you actually move nodes from the default baseline to the baseline that you create.

 **Note** A node must belong to a baseline, so you cannot directly remove nodes from the default baseline. Instead, you can create a baseline to move nodes from the default baseline to the new baseline. When you delete a baseline that you create, you actually move the nodes in the baseline to the default baseline.

To change the baseline of a node, perform one of the following operations:

- On the **Baselines** page, click **Create Baseline** in the upper-right corner. Then, create a baseline by following the instructions in the **Create a baseline** section.
- In the left-side navigation pane, choose **Nodes > Recurring**. On the page that appears, find the node and choose **More > Add to Baseline** in the Actions column.

2.8.7.3.3. Events

On the Events page, you can view all events related to slowdown or errors.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Operation Center**.

3. On the Operation Center page, choose **Monitor > Events** in the left-side navigation pane. The **Events** page appears.

You can search for events by condition, such as the event owner, time when an event was detected, event status, event type, and name or ID of a node or node instance.

In the search results, each event is displayed in a row and associated with a node that encounters errors. The worst baseline indicates a baseline with the minimum margin among the baselines affected by an event.

- Click **View Details** in the Actions column of an event. You can view the event occurrence time, alert time, clearance time, historical runtime logs of the node, and detailed node logs.

You can assign an alert recipient. After you click **View Alerts**, the alert details page corresponding to the event appears. Affected baselines are all descendant baselines affected by the node associated with the event. You can observe descendant baselines and the impact on these baselines and analyze node logs to identify the causes of the event.

- If you click **Handle**, DataWorks records the event handling operation and pauses the alert for the event when the event is being handled.
- If you click **Ignore**, DataWorks keeps the event ignorance record and permanently stops the alert for the event.

2.8.7.3.4. Alert triggers

This topic describes how to customize alert triggers on the Alert Triggers page.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Operation Center**.
3. On the Operation Center page, choose **Monitor > Alert Triggers** in the left-side navigation pane. The **Alert Triggers** page appears.
4. On the Alert Triggers page, click **Create Custom Trigger** in the upper-right corner.
5. In the **Create Custom Trigger** dialog box that appears, set relevant parameters.

Parameter	Description
Trigger Name	The name of the custom alert trigger.
Object Type	The granularity of monitored objects. Valid values: Node and Workflow .
Objects	The monitored object. Enter the name or ID of a node or workflow and click the icon on the right to add the object.
Trigger Condition	The condition for triggering an alert. Valid values: Completed , Uncompleted , Error , Uncompleted Cycle , and Overtime .
Maximum Alerts	The maximum number of alert reporting times. If the number of alert reporting times exceeds the preset threshold, no alerts are reported.
Minimum Alert Interval	The minimum time interval at which DataWorks reports an alert.
Quiet Hours	The specified period during which no alerts are reported.
Notification Method	The method of reporting alerts. Valid values: Email and SMS .

Parameter	Description
Recipient	The person who receives alerts. You can set this parameter to the node owner or another recipient.
DingTalk Chatbot	The DingTalk chatbot to receive alerts.

6. Click **OK** to create the alert trigger.

On the **Alert Triggers** page, you can click **View Details** in the Actions column of an alert trigger to view the details of the alert trigger.

2.8.7.3.5. Alert information

You can view all alerts on the Alerts page.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Operation Center**.
3. On the Operation Center page, choose **Monitor > Alerts** in the left-side navigation pane. The **Alerts** page appears.

You can search for alerts by condition, such as the alert trigger ID or name, recipient, alert time, notification method, and alert trigger type.

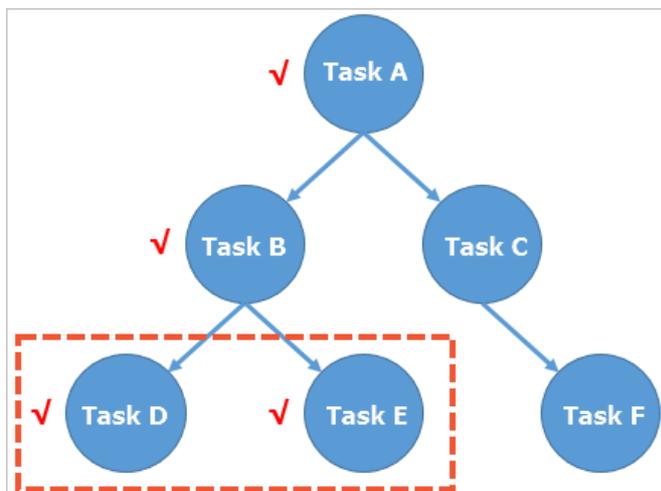

You can also view alert details such as the notification method and status. To view more alert details, find the target alert and click **View Details** in the Actions column.

2.8.7.4. FAQ

This topic describes the FAQ about the Monitor service.

What can I do if I do not need to receive alerts for a node?

After you create and enable a monitoring baseline, the Monitor service monitors all nodes in the baseline and their ancestor nodes. If a node in the baseline or an ancestor node of the baseline affects data generation of the monitored nodes in the baseline, the Monitor service reports an alert to the node owner.

As shown in the preceding figure, assume that DataWorks has only six nodes, and Nodes D and E belong to a monitoring baseline. The Monitor service monitors Nodes D and E and all their ancestor nodes. Namely, the Monitor service will detect any error or slowdown on Node A, B, D, or E. Nodes C and F are not monitored by the Monitor service.

Nodes A and B are ancestor nodes of Nodes D and E and may affect data generation of the monitored nodes in the baseline. When an error or slowdown occurs on Node A or B, the Monitor service reports an alert to the node owner.

If you do not need to receive alerts for a node, use the following methods:

- If the owners of Nodes D and E do not need to receive alerts, contact the baseline owner to remove Nodes D and E from the baseline.
- If the owner of Node A or B does not need to receive alerts, contact the owners of Nodes D and E to delete the dependency of Nodes D and E on Node A or B.

Why is no alert reported for a baseline in the Overtime state?

Baseline monitoring is controlled by the baseline switch and enabled for nodes. If all nodes are running properly, no alert will be triggered even in the Overtime state. This is because all the nodes are running properly and the Monitor service cannot determine which node has an error. Overtime is a baseline state, indicating that a node is still not completed after the committed time.

If the baseline still enters the Overtime state when all nodes are running properly, consider the following reasons:

- The baseline time is not properly set.
- The node dependency is not properly configured.

Can I disable the Monitor service from reporting an alert for a node that slows down?

The Monitor service reports a node slowdown alert only when a node meets both of the following conditions:

- The node is an ancestor node of an important baseline.
- Compared with its historical performance, the node does slow down.

You can view the descendant baseline affected by the node on the **Event Management** page. Then, you can confirm the impact with the party whose monitoring baseline contains descendant nodes of your node.

- If the node slowdown has a minor impact, you can ignore the alert.
- If the node slowdown has a major impact, maintain your node properly.

Why do I fail to receive an alert for an error node?

The Monitor service reports an alert only for specified nodes when an error occurs. An alert is reported for an error node only when the node meets one of the following conditions:

- The node is an ancestor node of a baseline that has been enabled.
- An alert trigger has been customized.

What can I do if I receive an alert at night?

1. [Log on to the DataWorks console.](#)
2. On the **DataStudio** page, click  in the upper-left corner and choose **All Products > Operation Center**.
3. In the left-side navigation pane, choose **Alarm > Event Management**.
4. On the **Event Management** page, disable the event alert. Disable the event alert in one of the following

ways:

- o Handle the event that triggers an alert.
 - a. Find the target event and click **Handle** in the Actions column.
 - b. In the **Handle Event** dialog box, set the **Handling Time** parameter.
 - c. Click **OK**.

 **Note** DataWorks records the event handling operation and pauses alerting for the event when the event is being handled.

- o Ignore the event that triggers an alert.
 - a. Find the target event and click **Ignore** in the Actions column.
 - b. In the **Ignore Event** message, click **OK**.

 **Note** DataWorks records the event ignoring operation and permanently stops alerting for the event.

2.9. Security Center

2.9.1. Overview

Security Center provides flexible permission management features. It allows you to request permissions and handle permission requests on the graphical user interface (GUI), and view and manage permissions. Security Center not only improves data security but also facilitates data permission management.

Log on to the DataWorks console. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Security Center**. The **Security Center** page appears.

Security Center consists of the following modules: **My Permissions**, **Authorizations**, and **Approval Center**.

Currently, Security Center provides the following features:

- **Self-service permission request:** Users can select the required tables to quickly initiate a permission request online. This online request mode is more efficient than the original mode in which users need to contact administrators offline.
- **Permission management:** Administrators can view the users who have permissions on database tables and revoke permissions as required. Users can also revoke unnecessary permissions themselves.
- **Permission request approval:** Before granting permissions to users, administrators approve permission requests initiated by users. This implements a visual and process-based permission management system, and supports reviewing the approval process.

In Security Center, you can view permissions on all the tables in an organization, request and revoke table permissions, and approve or reject permission requests.

Each operation in Security Center applies to all the workspaces of a tenant in standard mode and basic mode.

2.9.2. My Permissions

On the My Permissions page, you can view your table and field permissions in a workspace, and request or revoke table and field permissions.

View table and field permissions

1. Move the pointer over the DataWorks icon in the upper-left corner, and click **Security Center**. In the left-side navigation pane, click **My Permissions**. The **Table** tab appears.

- On this tab, you can select a workspace and specify the environment (for a workspace in standard mode) to view all the tables of the workspace in the specified environment. You can also enter a table name in the search box to search for required tables in fuzzy match mode.

You can view the names and owners of tables in the workspace, view your permissions on the tables, and request or revoke table and field permissions.

Request table and field permissions

- Select the tables and fields on which you want to request permissions.

- Request permissions on a table or some fields in the table

Select the required fields on which you have no permissions in a table and choose **More > Request Permission** in the Actions column.

Alternatively, choose **More > Request Permission** in the Actions column for a table without selecting any fields to request permissions on all the fields in the table.

Note You can request permissions on fields only in a workspace with LabelSecurity enabled. If LabelSecurity is disabled for a workspace, you can request permissions only on tables in this workspace.

- Request permissions on multiple tables and fields

Select all the required tables and fields and click **Request Permission**.

Note You can also click **Request Permission** without selecting any tables or fields, and then select the required tables and fields in the **Table Permission Request** dialog box.

- Set the parameters in the **Table Permission Request** dialog box.

Parameter	Description
Workspace	The name of the workspace, which is automatically entered based on the information you specified on the My Permissions page. You can change the workspace as required.
Environment	The environment of the workspace.
MaxCompute Project	The name of the MaxCompute project.
Grant To	The account for which you request permissions. You can request permissions for the current account or a production account of another workspace you joined.
Reason for Request	The reason why you request permissions.
Objects Requested	The tables on which you request permissions. The tables that you select on the previous page are displayed. You can add tables or delete existing tables as required.

- After the configuration is completed, click **Submit**. If you do not want to request the permissions, click **Cancel**.

Revoke permissions

You can revoke table and field permissions.

- Revoke field permissions

 **Note**

- You can revoke permissions on fields only in a workspace with LabelSecurity enabled.
- To revoke permissions on all the fields in a table, you can directly revoke the permissions on the table.

- Choose **More > Revoke Field Permission** in the **Actions** column for the table on which you want to revoke permissions.
 - In the **Revoke Field Permission** dialog box, select the fields on which you want to revoke permissions.
 - Click **OK**.
- Revoke table permissions
 - Choose **More > Revoke Permission** in the **Actions** column for the table on which you want to revoke permissions.
 - In the **Revoke Permission** dialog box, select the permissions you want to revoke.
 - Click **OK**.

2.9.3. Authorizations

On the Authorizations page, a workspace administrator can view the accounts that have permissions on tables and fields in each workspace, and revoke unnecessary table and field permissions.

You can move the pointer over the DataWorks icon in the upper-left corner, and click **Security Center**. In the left-side navigation pane, click **Authorizations**. On the **Table** tab that appears, you can view and search for tables in workspaces of the current organization.

On the Table tab, you can select a workspace and specify the environment (for a workspace in standard mode) to view all the tables of the workspace in the specified environment. You can also enter a table name in the search box to search for required tables in fuzzy match mode.

View accounts that have permissions on a table

On the **Table** tab of the **Authorizations** page, click the plus sign (+) in front of a table to view all the accounts that have permissions on the table.

Revoke table permissions

Click **Revoke Permission** in the **Actions** column for an account to revoke the permissions of the account on the current table.

View field permissions

Click **View Field Permissions** in the **Actions** column for an account to view the permissions of the account on the fields in the current table.

Revoke field permissions

If LabelSecurity is enabled for the workspace, select fields on the Field Permissions page and click **Revoke Field Permissions** to revoke the permissions on the fields.

2.9.4. Approval Center

On the Approval Center page, you can view your requests and their status, view and handle the requests pending your approval, and view the requests that you have handled.

My Requests

1. Move the pointer over the DataWorks icon in the upper-left corner, and click **Security Center**. In the left-side navigation pane, click **Approval Center**. On the Approval Center page, click the **My Requests** tab.

On this tab, you can view the information about each of your requests, including **Object Type**, **Workspace**, **Status**, **MaxCompute Project**, **Request Time**, and **Table**.

 **Note** If a request contains permission requests for tables that belong to different owners, Security Center automatically splits the request into multiple requests by table owner.

2. Click **View** in the Actions column to view the details about a request.

Pending My Approval

1. On the **Approval Center** page, click the **Pending My Approval** tab.

On this tab, you can view the requests pending your approval. If a request is pending your approval, a red dot appears next to Approval Center and Pending My Approval to remind you.

You can view the information about each of requests pending your approval, including **Object Type**, **Grant To**, **Request Time**, **Workspace**, **MaxCompute Project**, and **Table**.

2. Click **Handle** in the Actions column to view the details about a request and handle it on the Request Details page. The request details include the progress and objects requested.
3. Enter your comments and click Approve or Reject as required.

Handled by Me

1. On the **Approval Center** page, click the **Handled by Me** tab.

On this tab, you can view the information about each request that you have handled, including **Object Type**, **Grant To**, **Result**, **Workspace**, **MaxCompute Project**, **Table**, and **Request Time**.

2. Click **View** in the Actions column to view the details about a request. The request details include the progress and objects requested.

2.9.5. FAQ

This topic describes the frequently asked questions (FAQs) about the Security Center service of DataWorks.

- Q: What permissions can I request in Security Center?

A: In Security Center, you can request permissions on tables in DataWorks workspaces in the development environment and production environment.

- Q: What is the relationship between Data Management and Security Center?

A: Security Center is a product that upgrades and replaces the permission and security features in Data Management. You can choose **Security Center > My Permissions** to view the permissions requested or granted by using the `odpscmd grant` command in **Data Management**.

If you want to request other permissions and handle permission requests on the GUI, go to **Security Center** and perform operations as required. The **Data Management** service does not support permission request and approval any more.

- Q: Why cannot I select fields when I request permissions?

A: If LabelSecurity is enabled for a workspace, you can request permissions on fields in this workspace. If LabelSecurity is disabled for a workspace, you can request permissions only on tables in this workspace.

- Q: Who will handle my request?

A: Your request is handled by a workspace administrator or a table owner. After either of them approves or rejects your request, the request is closed.

- Q: Why do I find two requests on the **My Requests** page after I submit only one request?

A: The tables in your request belong to two owners. In this case, Security Center automatically splits your request into two by table owner.

- Q: I request permissions on a field for one month only. Why does the validity period of the permissions become permanent after my request is approved?

A: The security level of this field is zero or not higher than the security level of your account.

- Q: Why do I obtain permissions on some tables and fields on which I have not requested any permissions?

A: The possible causes are as follows:

- An administrator has granted the permissions to you by running commands in the DataWorks console.
- After your request is approved in Security Center, Security Center also grants you the permissions on fields whose security level is zero or not higher than the security level of your account, even though you have not requested the permissions.

- Q: Why does a request disappear from the **Pending My Approval** tab before I handle it?

A: Another workspace administrator or the table owner has approved or rejected the request. The request is closed and no longer needs to be handled.

- Q: What can I do if the message "An error occurred in the MaxCompute project" appears when I specify the workspace and environment?

A: Send the error message and error code to a workspace administrator for troubleshooting.

- Q: Why do I fail to revoke permissions on a field?

A: You can revoke permissions only on the fields whose security level is higher than the security level of your account.

- Q: Why do I fail to request permissions by using my tenant account?

A: By default, a tenant account has all permissions. Therefore, you do not need to request permissions for your tenant account. The tenant account hides unnecessary operations such as permission request. This does not affect the use of the tenant account.

- Q: In **Security Center**, can I view the permission request and approval records of **Data Management**?

A: Security Center and Data Management have not synchronized permission request and approval records yet. You need to go to **Data Management** to view the permission request and approval records of Data Management.

- Q: Can I revoke permissions based on the request records in Security Center?

A: Currently, Security Center is not the only service that provides authorization. To facilitate permission revocation, the Authorizations page in Security Center provides an access control list (ACL) of all users, regardless of the authorization channel. You can revoke any granted permissions without using the request records.

- Q: A permission request submitted in **Data Management** has not been approved yet. Do I need to submit it again in Security Center?

A: Security Center and Data Management have not synchronized permission request and approval records yet. You need to submit the permission request again in Security Center.

- Q: How do I specify the LabelSecurity parameter for fields?

A: You need to go to **Data Map** to set the LabelSecurity parameter for fields.

2.10. Data Quality

2.10.1. Overview

DataWorks provides a Data Quality service for you to control the data quality of disparate connections. In Data Quality, you can check data quality, configure alert notifications, and manage connections.

Relying on DataWorks, Data Quality provides a comprehensive data quality solution that has various features. For example, you can detect data, compare data, monitor data quality, and use intelligent alerting.

Data Quality monitors data in datasets. Currently, it allows you to monitor MaxCompute tables and DataHub topics. When offline MaxCompute data changes, Data Quality checks data and blocks nodes if it detects exceptions. This prevents nodes from being affected. In addition, Data Quality allows you to manage the check result history so that you can analyze and evaluate the data quality.

For streaming data, Data Quality uses DataHub to monitor data streams and sends alert notifications to subscribers if it detects stream discontinuity. You can also set the alert severity such as warning and error alerts, and the alert frequency to minimize repeated alerts.

The following figure shows the monitoring flowchart in Data Quality.

 **Note** Data Quality monitors the quality of data from MaxCompute and DataHub datasets. To use Data Quality features, you need to create tables and write data to the tables.

You can create MaxCompute tables and write data to the tables in the MaxCompute console or in the DataWorks console.

Log on to the DataWorks console. Click the DataWorks icon in the upper-left corner and choose **All Products > Data Quality** to go to the **Data Quality** page.

2.10.2. Features

2.10.2.1. Dashboard

As the homepage of Data Quality, the Dashboard page displays an overview of alerts and blocks for subscribed nodes. You can set filter conditions to view the required alerts and blocks.

Card	Description
My MaxCompute Partition Subscriptions	Displays the number of MaxCompute partitions with alerts or blocks and the number of normal MaxCompute partitions on the current day. You can click this card to go to the Search by Node page for the MaxCompute connection and view alert details.
My DataHub Topic Subscriptions	Displays the number of DataHub topics with alerts and the number of normal DataHub topics on the current day. You can click this card to go to the Search by Node page for the DataHub connection and view alert details.
Current task alarm condition	Displays alerts for MaxCompute and DataHub connections of the current workspace on the current day.
Current task blocking situation	Displays blocks for the MaxCompute connection of the current workspace on the current day.

Card	Description
Task Alarm Situation Trend	Displays the trend chart of alerts for MaxCompute and DataHub connections. You can view the alert trend in the past 7 or 30 days, or a custom time period within the past three months.
Task Blocking Situation Trend Graph	Displays the trend chart of blocks for MaxCompute and DataHub connections. You can view the block trend in the past 7 or 30 days, or a custom time period within the past three months.

2.10.2.2. My Subscriptions

The My Subscriptions page displays all nodes subscribed by your account.

Go to the My Subscriptions page

Currently, Data Quality allows you to monitor MaxCompute tables and DataHub topics. You can select a connection on the **My Subscriptions** page and search for subscribed nodes of the connection.

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Data Quality**.
3. In the left-side navigation pane, click **My Subscriptions**. The **My Subscriptions** page appears.

Subscribed MaxCompute connections

On the **My Subscriptions** page, select **MaxCompute** from the connection drop-down list in the upper-left corner. All the subscribed MaxCompute connections appear.

- You can click a partition expression on the right to go to the **Rules** page.
- You can click **View Check Results** in the Actions column for a partition expression to go to the Search by Node page.
- Data Quality supports the following four notification methods: **Email**, **Email and SMS**, **DingTalk Chatbot**, and **DingTalk Chatbot @ALL**.
- You can click **Cancel Subscription** to unsubscribe from the connection.

Subscribed DataHub connections

On the **My Subscriptions** page, select **DataHub** from the connection drop-down list in the upper-left corner. All the subscribed DataHub connections appear.

- After you click **Alerts** for a topic, the **Alerts** page appears, allowing you to view detailed information about the rule alert.
- You can click **Notification Method** for a topic to change the notification method of the rule alert.
- You can click **Cancel Subscription** in the Actions column for a topic to unsubscribe from the topic.

2.10.2.3. Configure monitoring rules

Data Quality can monitor data in the MaxCompute, DataHub, and E-MapReduce data stores. This topic describes how to configure a rule for monitoring a table or topic.

Go to the Monitoring Rules page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Quality**.

3. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane. On the Monitoring Rules page, you can select ODPS, Datahub, or EMR from the Engine/Data Source drop-down list.
 - If you select ODPS or EMR, all tables in the current MaxCompute or E-MapReduce data store appear. You can also switch to another data store or enter a keyword in the search box to search for topics or tables.
 - If you select Datahub, all topics and dimension tables in the current DataHub data store appear. You can also switch to another data store or enter a keyword in the search box to search for topics or tables.
4. Find the target table or topic and click **View Monitoring Rules** in the Actions column. The rule configuration page for the table or topic appears.

Data Quality allows you to configure template rules and custom rules for a table or topic.

 **Note** Before you configure a template rule for a table, you must configure a partition filter expression.

Create a template rule

1. Click **View Monitoring Rules** in the Actions column of a table or topic.
2. On the rule configuration page that appears, click the partition filter expression for which you want to configure a template rule. Then, click **Create rules**. In the Create rules right-side pane, the **Template Rules** tab appears.

On the **Template Rules** tab, click **Add Monitoring Rule** or **Quick Create** to create a template rule.

- **Click Add Monitoring Rule.**

Set parameters in the rule configuration section that appears, as described in the following table.

Parameter	Description
Rule Name	The name of the rule.
Rule Type	The type of the rule. Valid values: Rule Type and Soft. <ul style="list-style-type: none"> ■ If you select Rule Type, error alerts are reported and descendant nodes are blocked, whereas warning alerts are reported but descendant nodes are not blocked. ■ If you select Soft, error alerts are reported but descendant nodes are not blocked, whereas warning alerts are not reported and descendant nodes are not blocked.
Field	The fields to be monitored. You can select All Fields in Table or select a field of a numeric type or non-numeric type.
Template	The template to apply to the rule. Data Quality supports 37 rule templates. <div style="background-color: #e6f2ff; padding: 5px; margin-top: 5px;"> <p> Note You can set field-specific rules of the average value, accumulated value, minimum value, and maximum value only for numeric fields.</p> </div>
Comparison Method	The comparison method of the rule. Valid values: Absolute Value , Raise , and Drop .

Parameter	Description
Thresholds	<ul style="list-style-type: none"> You can calculate the fluctuation by using the following formula: $\text{Fluctuation} = (\text{Sample} - \text{Baseline}) / \text{Baseline}$ You can calculate the fluctuation variance only for numeric fields such as BIGINT and DOUBLE fields by using the following formula: $\text{Fluctuation variance} = (\text{Sample} - \text{Baseline}) / \text{Standard deviation}$ <div style="background-color: #e1f5fe; padding: 10px; margin: 10px 0;"> <p>Note The sample and baseline are defined in the following way:</p> <ul style="list-style-type: none"> Sample: the sample value for the current day. For example, if you need to check the fluctuation of table rows on an SQL node in a day, the sample is the number of table rows on the current day. Baseline: the comparison value from the previous N days. Examples: <ul style="list-style-type: none"> If you need to check the fluctuation of table rows on an SQL node in a day, the baseline is the number of table rows on the previous day. If you need to check the fluctuation of the average number of table rows on an SQL node in seven days, the baseline is the average number of table rows in the last seven days. </div> <p>You can set Warning Threshold and Error Threshold to monitor data at different severities:</p> <ul style="list-style-type: none"> If the fluctuation does not exceed the warning threshold, Data Quality determines that data is normal. If the fluctuation exceeds the warning threshold but does not exceed the error threshold, Data Quality reports a warning alert. If the fluctuation exceeds the error threshold, Data Quality reports an error alert. If you do not specify the warning threshold, Data Quality reports error alerts or normal based on the monitoring result. If you do not specify the error threshold, Data Quality reports warning alerts or normal based on the monitoring result. If you specify neither the warning threshold nor the error threshold, Data Quality reports error alerts if it detects anomalies. However, you must specify at least one of the two thresholds. If you specify neither of them, Data Quality applies default values, namely, 10% for the warning threshold and 50% for the error threshold.

o **Click Quick Create.**

Set parameters in the rule configuration section that appears, as described in the following table.

Parameter	Description
Rule Name	The name of the rule.
Field	The fields to be monitored. You can select All Fields in Table or a specific field of a numeric type or non-numeric type.

Parameter	Description
Trigger	The trigger condition of the rule. If you select All Fields in Table for the Field parameter, The number of rows is greater than 0 is selected by default.

3. Click **Batch Create**.

Create a custom rule

If template rules do not meet your requirements for monitoring the data quality, you can create custom rules.

1. Click **View Monitoring Rules** in the Actions column of a table or topic.
2. On the rule configuration page that appears, click the partition filter expression for which you want to configure a custom rule. Then, click **Create rules**. In the Create rules right-side pane, the **Template Rules** tab appears.
3. Click the **Custom Rules** tab. On the **Custom Rules** tab, click **Add Monitoring Rule** or **Quick Create** to create a custom rule.
 - o **Click Add Monitoring Rule.**

Set parameters in the rule configuration section that appears, as described in the following table.

Parameter	Description
Rule Name	The name of the rule.
Field	The fields to be monitored. You can select All Fields in Table , SQL Statement , or a specific field. <ul style="list-style-type: none"> ▪ If you select All Fields in Table or a specific field, you can specify the WHERE clause to customize filter conditions based on business requirements. ▪ If you select SQL Statement, you can customize the SQL logic to set a rule. The return value is the value in a row of a column.
Rule Type	The type of the rule. Valid values: Rule Type and Soft. <ul style="list-style-type: none"> ▪ If you select Rule Type, error alerts are reported and descendant nodes are blocked, whereas warning alerts are reported but descendant nodes are not blocked. ▪ If you select Soft, error alerts are reported but descendant nodes are not blocked, whereas warning alerts are not reported and descendant nodes are not blocked.
Sampling Method	The statistical function. Valid values: count and count/table_count .
Filter	The filter condition of the rule. For example, if you need to query partitions of the table based on a specific data timestamp, you can specify <code>pt=\${yyyymmdd-1}</code> as the filter condition.
Check type	The threshold type of the rule. Valid values: Numeric type and Fluctuation .
Comparison Method	The comparison method of the rule. If you set Check type to Numeric type, the values that are optional for this parameter include Greater Than , Greater Than or Equal To , Equal To , Unequal To , Less Than , and Less Than or Equal To .

Parameter	Description
Verification Method	The verification method of the rule. If you set Check type to Numeric type, you can only set this parameter to Compare with a specified value .
Expected Value	The expected value of the rule.
Description	The description of the rule.

o **Click Quick Create.**

Set parameters in the rule configuration section that appears, as described in the following table.

Parameter	Description
Rule Name	The name of the rule.
Trigger	The type of the rule. You can select only Values Duplicated in Multiple Fields .
Field	The fields to be monitored.

Associate a custom node with Data Quality monitoring rules

Before you associate a custom node with Data Quality monitoring rules, make sure that the custom node is created and committed to the production environment. For more information, see [Create a custom node type](#).

You can use one of the following methods to associate a custom node with Data Quality monitoring rules:

- Associate a custom node with Data Quality monitoring rules on the Data Quality page.
 - i. Log on to the DataWorks console.
 - ii. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Quality**.
 - iii. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane.
 - iv. Select the target data store from the Engine/Data Source drop-down list, find the target table or topic, and then click **View Monitoring Rules** in the Actions column.
 - v. On the rule configuration page that appears, click the partition filter expression for which monitoring rules are configured.
 - vi. Click **Manage Linked Nodes**.
 - vii. In the **Manage Linked Nodes** dialog box, select the target workspace, enter the ID or name of the custom node, and then click **Create**.
- Associate a custom node with Data Quality monitoring rules on the Operation Center page.
 - i. Log on to the DataWorks console.
 - ii. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Operation Center**.
 - iii. In the left-side navigation pane, choose **Cycle Task Maintenance > Cycle Task**.
 - iv. Find the target node and choose **More > Configure Data Quality Rules** in the Actions column.
 - v. In the **Configure Data Quality Rules** dialog box, set the **Workspace**, **Table Name**, **Engine type**, **Engine instance**, and **Partition Expression** parameters, and click **Add**.

2.10.2.4. View monitoring results

The Node Query page displays the monitoring results of rules. After monitoring rules are triggered, you can go to the Node Query page to view the monitoring results of the rules.

Go to the Node Query page

1. Log on to the DataWorks console.
2. On the DataStudio page, click  in the upper-left corner and choose **All Products > DataAnalysis**.
3. On the Data Quality page, click **Node Query** in the left-side navigation pane. On the **Node Query** page, you can set parameters, such as the **Engine/Data Source**, **Status**, and **My Subscriptions** parameters, to filter nodes and view the monitoring results.

View the monitoring results of E-MapReduce and MaxCompute tables

GUI element	Description
Engine/Data Source	The name of the compute engine. In this example, select EMR or ODPS .
Engine/Database Instance	The E-MapReduce instance or MaxCompute project where the desired tables reside.
Status	The monitoring result of rules. Pay attention to partitions that trigger alerts or blocks.
Data Timestamp	The data timestamp.
My Subscriptions	Specifies whether to display only monitoring results of tables that you subscribed to.
Run At	The time when rules were triggered.
Table Name	The name of the table whose monitoring results you want to view.
Node	The node that triggered rules.
Details	<p>Click Details in the Actions column of a table. On the page that appears, you can perform the following operations on each rule configured for the table:</p> <ul style="list-style-type: none"> • Click View History Check Results in the Actions column of a rule to view the monitoring result history of the rule. • Enter comments on a rule based on the execution status of the rule. Perform the following steps to enter comments on a rule: <ul style="list-style-type: none"> i. Click Problem Handling in the Actions column of the rule. ii. In the Problem Handling dialog box, set the Handling Method and Comments parameters. iii. Click OK. <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px; margin: 10px 0;"> <p> Notice You can only use the problem handling feature in DataWorks Enterprise Edition or higher.</p> </div> <ul style="list-style-type: none"> • Click Handling Logs in the Actions column of a rule to view the processing history of the rule.
Rules	<p>Click Rules in the Actions column of a table to go to the rule configuration page for the table. On this page, you can view partition filter expressions and rules configured for the table, and modify the rules as required. For more information, see MaxCompute monitoring.</p>

GUI element	Description
View Log	Click View Log in the Actions column of a table to view the operational logs of rules configured for the table.
View Statistics	Click View Statistics in the Actions column of a table to view rule execution information about the table, including the number of rows and the table size.

View the monitoring results of DataHub topics

GUI element	Description
Engine/Data Source	The name of the compute engine. In this example, select Datahub .
Configure a data source	The name of the DataHub connection.
Status	The monitoring result of rules. Pay attention to topics that trigger alerts or blocks.
Topic	The name of the topic whose monitoring results you want to view.
My Subscriptions	Specifies whether to display only monitoring results of topics that you subscribed to.
Clear	Click Clear to clear the filter conditions you specified.
View Log	Click View Log in the Actions column of a topic to view the operational logs of rules configured for the topic.
Alerts	Click Alerts in the Actions column of a topic. On the Alerts page, you can view details about alerts triggered by the topic. On the Alerts page, you can click Close in the Actions column of an alert. In the message that appears, click OK to disable the alert.

2.10.2.5. Report Template Management

On the **Report Template Management** page, you can create a template of data quality reports. DataWorks can periodically generate and send data quality reports based on the template.

Create a report template

1. Log on to the DataWorks console. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Quality**.
2. On the Data Quality page that appears, choose **Configuration > Report Template Management** in the left-side navigation pane. The Report Template Management page appears.
3. Click **Create Report Template**. On the **Create Report Template** page that appears, set required parameters.

Section	Parameter	Description
	Name	The name of the report template.

Section	Parameter	Description
Basic settings	Sending Cycle	The interval at which reports are sent. Valid values: Every Day , Every Week , Every Month , and Do Not Send . If you set Sending Cycle to Every Week or Every Month, you also need to specify the specific day on which reports are sent.
	Timespan	The number of days before the current day. DataWorks generates reports based on the data of those days. The maximum value of this parameter is 30.
Statistics of Rule Configuration The Statistics of Rule Configuration section displays metrics about rule configuration for offline data and real-time data. You can select metrics based on your needs.	Offline data	The metrics about rule configuration for tables in the workspace. The metrics include Table count , Partition expression count , Count of rule on offline data , and Rule coverage on tables . The Rule coverage on tables metric indicates the ratio of tables for which quality monitoring rules are configured.
	Realtime data	The metrics about rule configuration for topics in the workspace. The metrics include Topic count , Count of rule on realtime data , Count of rule on cut off data , Rule coverage on topic , Count of rule on delayed data , and Count of customized rule . The Rule coverage on topic metric indicates the ratio of topics for which quality monitoring rules are configured.
Statistics of Rule Execution The Statistics of Rule Execution section displays metrics about rule running for offline data and real-time data. You can select metrics based on your needs. Quality reports display the selected metrics in charts.	Offline data	The metrics about rule running for tables in the workspace. The metrics are classified into the following types: About rules , About partitions , and About tables .
	Realtime data	The metrics about rule running for topics in the workspace. The metrics are classified into the following types: About messages , About alarms , and About cut-offs .

Section	Parameter	Description
Manage Subscriptions	Subscription Method	The method used to notify report subscribers of new reports. Currently, DataWorks sends emails to notify report subscribers of new reports.
	Recipient	The recipient of report notifications. You can add multiple recipients.
	Actions	The operations that you can perform on the subscription. You can click Save or Cancel in the Actions column of a subscription to save or cancel the subscription.
	Add Subscription	The button that allows you to add a subscription.

- Click **Save** in the upper-right corner. A template of data quality reports is generated.

Preview a report template

After creating a report template, you can click **Preview** in the upper-right corner of the Create Report Template page to view the display format of reports generated based on this template.

 **Note** If report subscribers view reports through email notifications, they can only view the reports in tables. If they view reports on the Data Quality page, they can view reports in tables or charts.

2.10.2.6. Manage rule templates

In Data Quality, you can manage a set of custom rule templates and use the rule templates to improve the efficiency of rule configuration.

Context

You can create a rule template on the **Rule Templates** and **Monitoring Rules** pages. After the rule template is created, you can manage and use it.

Create a rule template on the Rule Template Management page

- Log on to the DataWorks console.
- On the DataStudio page, click  in the upper-left corner and choose **All Products > Data Quality**.
- On the Data Quality page, choose **Configuration > Rule Templates** in the left-side navigation pane.
- On the Rule Templates page, click  and select **Create Folder**.
- In the **Create Folder** dialog box, set the **Name** and **Location** parameters and click **OK**.
- Right-click the folder name and select **Create Rule Template**. You can also rename or delete a folder.
- In the **Create Rule Template** dialog box, set relevant parameters.

New rule Template
✕

* Template name :

* Field :

* Sampling Method :

Set Flag :

Please enter the pre-set statement of SQL. \r\nNote: Write the contents of the set directly, separated by an English comma between multiple statements, with no need for a bonus sign at the end of the statement.

* Check type :

* Verification Method :

* Custom SQL ? :

* Destination folder ? :

Parameter	Description
Template Name	The name of the rule template.
Field	The fields to be monitored and the statistical function. You can only set the two parameters to Custom SQL .
Sampling Method	
Set Flag	The SET clause of the SQL statement for querying the field to be monitored. <div style="background-color: #e0f2f7; padding: 5px; border: 1px solid #ccc; font-size: small;"> ? Note Separate multiple statements with commas (,). You do not need to add a semicolon (;) at the end of each statement. </div>
Check type	The threshold type of the rule. Valid values: Numeric type and Fluctuation .

Parameter	Description
Verification Method	<p>The verification method of the rule template. The verification methods that can be selected vary with the threshold type.</p> <ul style="list-style-type: none"> If you set the Check type parameter to Numeric type, you can only set this parameter to Compare with a specified value. If you set the Check type parameter to Fluctuation, the values that are optional for this parameter include Compare the current value with the average value of the last 7 days, Compare the current value with the average value of the last 30 days, Compare the current value with the value 1 day before, Compare the current value with the value 7 days before, Compare the current value with the value 30 days before, The variance between the current value and the value 7 days before, The variance between the current value and the value 30 days before, Compare with the value 1, 7, and 30 days before and Compare with the value of the previous cycle.
Custom SQL	The custom SQL statement. You can use <code>\${tableName}</code> as the table name.
Location	The name of the folder to which you want to store the custom rule template.

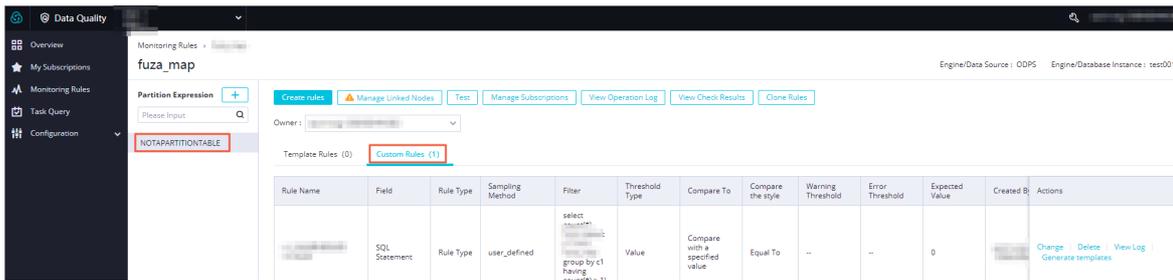

8. Click **OK**.

Create a rule template on the Monitoring Rules page

- Go to the **Data Quality** page.
- On the **Data Quality** page, click **Monitoring Rules** in the left-side navigation pane.
- On the **Monitoring Rules** page, select the compute engine or data store, find the target table or topic, and then click **View Monitoring Rules** in the **Actions** column.

Note This topic uses a MaxCompute table as an example.

- Click a partition filter expression and then click the **Custom Rules** tab.

Note For more information about how to create custom rules, see [Custom rules](#).

- On the **Custom Rules** tab, find the target custom rule and click **Generate Template** in the **Actions** column.
- In the **Create Template** dialog box, set relevant parameters.

If you set the Check type parameter to Fluctuation, the values that are optional for this parameter include Compare the current value with the average value of the last 7 days, Compare the current value with the average value of the last 30 days, Compare the current value with the value 1 day before, Compare the current value with the value 7 days before, Compare the current value with the value 30 days before, The variance between the current value and the value 7 days before, The variance between the current value and the value 30 days before, Compare with the value 1, 7, and 30 days before and Compare with the value of the previous cycle.
Custom SQL	The custom SQL statement. You can use <code>\$(tableName)</code> as the table name.
Location	The name of the folder to which you want to store the custom rule template.

- Click **OK**.
- In the left-side navigation pane, choose **Configuration > Rule Templates** to view the created rule template.

Manage an existing rule template

On the Rule Templates page, you can click the name of a rule template to go to the template details page. On this page, you can view, edit, delete, or copy the rule template.

Action	Description
View	<p>You can view the parameter configuration, the rules that use the rule template, and logs of the rule template:</p> <ul style="list-style-type: none"> The Application List tab displays the rules that use the rule template. The View Log tab displays the logs of operations performed on the rule template, including the user who performed each operation, the time when each operation was performed, and the operation details.
Edit	Click Edit in the upper-right corner. In the Edit Rule Template dialog box, modify the required parameters, and click OK .
Delete	Click Delete in the upper-right corner. In the Delete Template message, click OK .
Copy	Click Copy in the upper-right corner. In the Copy Rule Template dialog box, set the Template Name and Location parameters and click OK .

Use a rule template

When you create a monitoring rule, you can select a custom rule template to create the rule based on the rule template.

1. Go to the **Data Quality** page.
2. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane.
3. On the Monitoring Rules page, select the compute engine or data store, find the target table or topic, and then click **View Monitoring Rules** in the Actions column.

 **Note** This topic uses a MaxCompute table as an example.

4. Click a partition filter expression and click the **Custom Rules** tab.
5. On the **Template Rules** tab of the **Create rules** right-side pane, click **Add Monitoring Rule**.
6. Set the parameters for the rule. Specifically, set the **Rule Source** parameter to **Rule Templates** and select a rule template. For more information about the parameter description, see [Rules](#).

Create rules

Template rules Custom rules

Add Monitoring Rule Quick add

* Rule Name : Enter a rule name. Delete

* Rule Type : Rule Type Soft

* Rule source : Rule Template Library

* Field : SQL Statement(user_defined)

* Template :

* Sampling Method : Custom SQL

Set Flag : Please enter the pre-set statement of SQL. \n\nNote: Write the contents of the set directly, separated by an English comma between multiple statements, with no need for a bonus sign at the end of the statement.

* Check type :

* Verification Method : Compare with a specified value

* Custom SQL : tableName

* Comparison Method : Greater Than

* Expected Value : 0

Description :

Batch add Cancel

7. Click **Batch Create**.

2.10.3. User guide

2.10.3.1. Configure monitoring rules for MaxCompute

The Monitoring Rules page is the most important part of Data Quality, where you can configure rules to monitor data in E-MapReduce, MaxCompute, and DataHub. This topic describes how to configure monitoring rules for MaxCompute.

Add a MaxCompute connection

1. Log on to the DataWorks console.
2. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration**.
3. On the Data Integration page, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
4. Click **Add Connection** in the upper-right corner to add a MaxCompute connection.

Select the MaxCompute connection

1. On the current page, click  in the upper-left corner and choose **All Products > Data Quality**.
2. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane.
3. Select **ODPS** from the **Engine/Data Source** drop-down list to display all tables in the MaxCompute data store. You can search for a table by table name. Fuzzy search based on the initial letters of a table name is supported.
4. Find the target table and click **View Monitoring Rules** in the Actions column.

Configure a partition filter expression

In Data Quality, you must configure rules based on a partition filter expression:

- To configure rules for a non-partitioned table, you can specify **NOTAPARTITIONABLE** as the partition filter expression.
- To configure rules for a partitioned table, you can specify a data timestamp expression, such as `#{yyyymmdd}`, or a regular expression as the partition filter expression.

On the rule configuration page of a table, click **+** next to **Partition Expression** to add a partition filter expression.

You can create a partition filter expression or select a recommended partition filter expression.

- Create a partition filter expression

In the **Add Partition** dialog box, enter a partition filter expression that conforms to the syntax as required. For a non-partitioned table, select **NOTAPARTITIONABLE** from the recommended partition filter expressions.

- For a table with only one partition, follow the format: `Partition key=Partition value`. The partition value can be either a constant or a system parameter. You must configure partition expressions by using the last partition.
- For a table with multiple partitions, follow the format: `Partition key 1\=Partition value/Partition key 2=Partition value/Partition key N=Partition value`. Each partition value can be either a constant or a system parameter. You must use brackets [] to indicate a parameter, such as `#{yyyymmdd-N}`.

The data timestamp configured in a partition filter expression also determines the recurrence of the partition filter expression. For example, if the data timestamp is the date of five days ago, the partition filter expression is triggered every five days. The following table describes supported partition filter expressions.

Partition filter expression	Description
<code>dt=#{yyyymmdd-N}</code>	Indicates N days before.
<code>dt=#{yyyymm01-1}</code>	Indicates the first day of each month.

Partition filter expression	Description
dt=\${yyyyymm01-Nm}	Indicates the first day of the month that is N months before the current month.
dt=\${yyyymmld-1}	Indicates the last day of each month.
dt=\${yyyymmld-1m}	Indicates the last day of the month that is N months before the current month.
dt=\${hh24miss-1/24}	Indicates one hour before the hour specified by the data timestamp.
dt=\${hh24miss-30/24/60}	Indicates half an hour before the hour specified by the data timestamp.
\${yyyymmdd}	Indicates the data timestamp.
\${yyyymmdd-1}	Indicates one day before the data timestamp of the current instance.
\${yyyymmddhh24miss}	Indicates the data timestamp of the current instance. Follow the <code>yyyymmddhh24miss</code> format by understanding the following format description: <ul style="list-style-type: none"> ◦ yyyy indicates a four-digit year. ◦ mm indicates a two-digit month. ◦ dd indicates a two-digit day. ◦ hh24 indicates a two-digit hour (24-hour clock). ◦ mi indicates two-digit minutes. ◦ ss indicates two-digit seconds.
NOTAPARTITIONTABLE	Indicates the partition filter expression of a non-partitioned table.

- Select a recommended partition filter expression

This section uses the `dt partition` as an example to describe how to select a recommended partition filter expression. We recommend that you specify a regular expression as the partition filter expression for a dynamic partitioned table.

- i. In the **Add Partition** dialog box, click the **Partition Expression** field. A drop-down list appears to show you the partition filter expressions recommended by Data Quality.
 - Select a recommended partition filter expression if it meets your expectation.
 - Specify a custom partition filter expression if no recommended partition filter expressions meet your expectation.
- ii. After you enter a partition expression, click **Verify**. Data Quality uses the current time, that is, the data timestamp, to calculate data and verify the partition filter expression.
- iii. Click **OK**.

If you need to delete a partition filter expression, move the pointer over the partition filter expression and click the **Delete** icon to delete the partition filter expression. When you delete a partition filter expression, all rules configured based on the partition filter expression are also deleted.

Link a partition filter expression to a node

To monitor the quality of data involved in a node, you need to link a partition filter expression to the node.

- The Manage Linked Nodes dialog box lists all committed nodes. Data Quality allows you to link a partition filter expression to a node in another workspace.
- Before you link a partition filter expression to a node in another workspace, make sure that you are an administrator, a developer, or an administration expert in the two workspaces.

You can link a partition filter expression to one or more nodes. After nodes are linked, Data Quality can automatically monitor linked nodes.

 **Note** Data Quality allows you to flexibly link a partition filter expression to a node. You can select a node that is not related to your table.

1. On the rule configuration page of a table, click **Manage Linked Nodes**.
2. In **Manage Linked Nodes** dialog box, enter the name of the node that you want to link to the partition filter expression.
3. Click **Create**.

Create a rule

The Monitoring Rules page is the most important part of Data Quality, where you can create rules for your tables.

Data Quality allows you to create template rules and custom rules as needed. If you need to create a template rule or a custom rule, you can click **Add Monitoring Rule** or **Quick Create**. For more information, see [Rules](#).

After rules are configured, you can click **Batch Create** to save all the configured rules for the current partition filter expression.

Creation method	Parameter	Description
Add Monitoring	Rule Name	The name of the rule.
	Rule Type	The type of the rule. Valid values: <ul style="list-style-type: none"> • Rule Type: If a node reaches the error threshold, Data Quality reports an error alert and determines that the node fails. If a node reaches the warning threshold, Data Quality reports a warning alert and determines that the node is successful. • Soft: If a node reaches the error threshold, Data Quality reports an error alert and determines that the node is successful. If a node reaches the warning threshold, Data Quality does not report a warning alert and determines that the node is successful.
	Auto-Generated Threshold	You can use the dynamic threshold feature only in DataWorks Enterprise Edition or higher.
	Rule Source	The source of the rule. Valid values: Built-in Template and Rule Templates .

Rule Creation method	Parameter	Description
	Field	<p>The fields to be monitored. You can select All Fields in Table or a specific field. If you select a field, you can apply the rule to the specified field in the table.</p> <div style="background-color: #e0f2f7; padding: 5px; border: 1px solid #ccc;"> <p> Note In this example, select All Fields in Table and set other parameters for the table-specific rule.</p> </div>
	Template	<ul style="list-style-type: none"> • If you set Rule Source to Built-in Template, the built-in table-specific rules appear. • If you set Rule Source to Rule Templates, you must set parameters, such as Sampling Method and Set Flag.
	Comparison Method	The comparison method of the rule. Valid values: Absolute Value , Raise , and Drop .
	Thresholds	The warning threshold and error threshold of the fluctuation. You can adjust the slider to specify thresholds or directly enter thresholds.
	Description	The description of the rule.
Quick Create	Rule Name	The name of the rule.
	Field	The fields to be monitored. You can select All Fields in Table or a specific field. If you select a field, you can apply the rule to the specified field in the table.

Creation method	Parameter	Description
	Trigger	<ul style="list-style-type: none"> The trigger condition of the rule. If you select All Fields in Table for the Field parameter, you can set this parameter to The number of columns is greater than 0 or Table row number dynamic threshold. <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px; margin: 5px 0;"> <p> Notice You can use the dynamic threshold feature only in DataWorks Enterprise Edition or higher.</p> </div> <ul style="list-style-type: none"> If you select a field for the Field parameter, you can select The field value already exists, Null Field, or Unique value dynamic threshold. <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px; margin: 5px 0;"> <p> Notice You can use the dynamic threshold feature only in DataWorks Enterprise Edition or higher.</p> </div>

Test rules

After rules are configured for a partition filter expression, you can test all these rules and view the test results.

 **Note** You can manually run these rules to test their configuration and notification methods. We recommend that you test rules as required.

- On the rule configuration page of a table, click **Test**.
- In the **Test** dialog box, set the **Data Timestamp** parameter.

Parameter	Description
Partition	The partition filter expression for which rules are run. The actual partition key varies with the data timestamp. For a non-partitioned table, use <code>NOPARTITIONTABLE</code> as the partition filter expression.
Data Timestamp	The data timestamp for testing rules. The default value is the current time.

- Click **Test**.
- In the **Test** dialog box, click **The test is complete. Click to view the results** to view the test results on the **Node Query** page.

Manage subscriptions

By default, Data Quality sends notifications to the user who created a partition filter expression. You can add other users so that Data Quality sends notifications to them.

- On the rule configuration page of a table, click **Manage Subscriptions**.
- In the **Manage Subscriptions** dialog box, specify the notification method and notification receiver.

Quality supports the following four methods: **Email**, **Email and SMS**, **DingTalk Chatbot**, and **DingTalk Chatbot @ALL**.

 **Note** Add a DingTalk chatbot and obtain a webhook URL. Then, copy the webhook URL to the Manage Subscriptions dialog box.

3. Click **Save**.

View operational logs

On the rule configuration page of a table, click **View Operation Log**. In the **Operations Logs** right-side pane, you can view the information about each operation, including the user who performed the operation, the time when the operation was performed, and the operation details.

The **Details** column displays the details of each operation performed on the current partition filter expression, including the rule configuration details.

View check results

On the rule configuration page of a table, click **View Check Results** to go to the **Node Query** page. On this page, you can view the check results for all rules under the current partition filter expression.

Clone rules

1. On the rule configuration page of a table, click **Clone Rules**.
2. In **Clone Rules** dialog box, set the **Target Expression** parameter.
3. Select **Clone Subscribers** or **Change Table Names in Custom Rules** as required.
4. Click **Clone**.

2.10.3.2. Configure monitoring rules for DataHub

The Monitoring Rules page is the most important part of Data Quality, where you can configure rules to monitor data in E-MapReduce (EMR), MaxCompute, and DataHub. This topic describes how to configure monitoring rules for DataHub.

Context

DataHub monitoring supports the following features:

- Templates for monitoring stream discontinuity and data latency
- Stream processing features, such as custom Flink SQL, dimension table JOIN, multi-stream JOIN, and window functions

Procedure

1. Add a DataHub data source.
 - i. Log on to the DataWorks console.
 - ii. On the **DataStudio** page, click the icon in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
 - iii. On the Data Integration page, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
 - iv. Click **New data source** in the upper-right corner to add a DataHub data source. For more information, see [Configure a DataHub connection](#).
2. Select the DataHub data source.

- i. On the current page, click the icon in the upper-left corner and choose **All Products > Data Quality**.
- ii. On the page that appears, click **Monitoring Rules** in the left-side navigation pane.
- iii. On the Monitoring Rules page, select **Datahub** from the **Engine/Data Source** drop-down list and select the newly added DataHub data source from the Engine/Database Instance drop-down list. All the topics in the selected DataHub data source are displayed.

Parameter	Description
Configure Flink/SLS Resources	After you add a data source, click Configure Flink/SLS Resources to configure Realtime Compute and Log Service resources related to the data source.
Topics	<p>The Topics tab lists all the topics in the DataHub data source. You can click the following buttons in the Actions column for a topic:</p> <ul style="list-style-type: none"> ▪ View Monitoring Rules: Click it to create rules for the topic. You can create template rules and custom rules. ▪ Manage Subscriptions: Click it to view and modify subscribers to the topic, and change the notification method. You can use a DingTalk chatbot to receive notifications. The changed notification method takes effect for all subscribers to the topic.
Dimension Tables	<p>When you create custom rules for a topic, you can create and join dimension tables. If the collected data streams lack some fields for a dimension table, you must supplement fields to data streams before data analysis and declare the dimension table in Data Quality.</p> <p>DataHub supports the dimension tables of ApsaraDB for HBase, Lindorm, ApsaraDB RDS, Tablestore, Taobao Distributed Data Layer (TDDL), and MaxCompute.</p> <p>Flink SQL does not design the data definition language (DDL) syntax for dimension tables. You can use the standard CREATE TABLE statement. However, you must add <code>period for system_time</code> to specify the period of a dimension table and declare that the dimension table stores time-varying data.</p> <div style="background-color: #e6f2ff; padding: 5px; border: 1px solid #d9e1f2;"> <p> Note When you declare a dimension table, you must specify the primary key. When you join a dimension table with another table, the ON condition must contain an equivalence condition for each primary key of the tables.</p> </div>

- iv. Click the **Topics** tab. Find the topic for which you want to configure monitoring rules and click **View Monitoring Rules** in the Actions column.
3. On the rule configuration page of the topic, click **Create Rule**.
 4. Create a monitoring rule. In Data Quality, you can create template rules and custom rules.
 - o On the Template Rules tab of the Create rules panel, click **Create Template Rule**. Two templates are available: **Data Delay** and **Stream Discontinuity**.

For example, you can select **Data Delay** for the Template Type parameter.

Parameter	Description
-----------	-------------

Parameter	Description
Rule Name	The name of the rule. The name can be a maximum of 255 characters in length.
Field Type	The fields to be monitored. By default, this parameter is set to All Fields in Table.
Template Type	<ul style="list-style-type: none"> Data Delay: monitors the interval between the time when data is generated and the time when data is written to DataHub based on the data timestamp field. If the interval exceeds a specified threshold, an alert is generated. <div style="background-color: #e6f2ff; padding: 10px; margin: 10px 0;"> <p> Note</p> <ul style="list-style-type: none"> Before you configure a stream discontinuity rule, you must activate Realtime Compute in Flink and create a project. The data timestamp field supports two data types: <code>TIMESTAMP</code> and <code>STRING (yyyy-MM-dd HH:mm:ss)</code>. </div> <ul style="list-style-type: none"> Stream Discontinuity: monitors the period during which no data is written to DataHub. If the period exceeds a specified threshold, an alert is generated.
Alerts Threshold	The maximum number of alerts generated for data latency. Data Quality reports an alert when the number of alerts generated for data latency exceeds this threshold. This parameter is displayed only when you select Data Delay for the Template Type parameter.
Data Timestamp Field	The data timestamp field of the topic for which the rule is created. This field supports two data types: <code>TIMESTAMP</code> and <code>STRING (yyyy-MM-dd HH:mm:ss)</code> . This parameter is displayed only when you select Data Delay for the Template Type parameter.
Alert Frequency	The interval at which alerts are reported. You can set the alert interval to 10 minutes, 30 minutes, 1 hour, or 2 hours.
Warning Threshold	The warning threshold, in seconds. The value must be an integer and less than the error threshold.
Error Threshold	The error threshold, in seconds. The value must be an integer and greater than the warning threshold.

- If template rules do not meet your requirements for monitoring the data quality of DataHub topics, you can create a custom rule. On the Custom Rules tab of the Create rules panel, click **Create Custom Rule**.

 **Note**

- The field in the `SELECT` clause must be a column. Make sure that you can compare the field values with the warning threshold and error threshold.
- The `FROM` clause must include the current topic and all its columns.

Parameter	Description
Rule Name	The name of the rule. The name must be unique in the topic and can be a maximum of 20 characters in length.
Script	<p>The custom SQL script that is used to set a rule. The return value of the SELECT clause must be unique. You can refer to the following sample statements:</p> <ul style="list-style-type: none"> Use a simple SQL statement. <pre>select id as a from zmr_tst02;</pre> Join the topic and a dimension table named test_dim. <pre>select e.id as eid from zmr_test02 as e join test_dim for system_time as of proctime() as w on e.id=w.id</pre> Join the topic and another topic named dp1test_zmr01. <pre>select count(newtab.biz_date) as aa from (select o.* from zmr_test02 as o join dp1test_zmr01 as p on o.id=p.id)newtab group by id.biz_date,biz_date_str,total_price,'timestamp'</pre>
Warning Threshold	The warning threshold, in minutes. The value must be an integer and less than the error threshold.
Error Threshold	The error threshold, in minutes. The value must be an integer and greater than the warning threshold.
Minimum Alert Interval	The minimum interval at which alerts are reported, in minutes.
Description	The description of the rule.

- Click **Batch Create**. After rules are created for the topic, you can perform the following operations:
 - View Log**: Click it to view the operational logs of the rules.
 - Manage Subscriptions**: Click it to view and modify subscribers to the rules, and change the notification method. The changed notification method takes effect for all the subscribers of the rules.

Data Quality supports the following methods: **Email**, **Email and SMS**, **DingTalk Chatbot**, and **DingTalk Chatbot @ALL**.

 **Note** Add a DingTalk chatbot and obtain the webhook address of the chatbot. Then, copy the webhook address to the Manage Subscriptions dialog box.

2.11. Data Map

2.11.1. Overview

Developed based on Data Management, Data Map uses roles to control the permissions for using different features, such as the permissions for creating and previewing data. Data Map helps you build a better enterprise-level knowledge base.

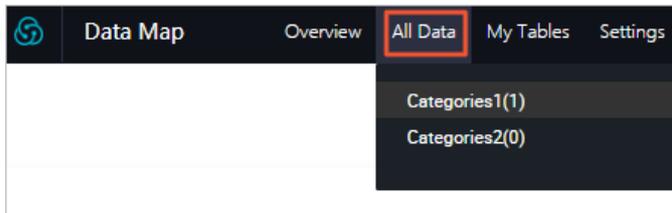

On the homepage of Data Map, you can enter keywords to search for tables by name. You can also click a table in any of the following sections to view the table data: **Recently Viewed Tables**, **Recently Read Tables**, **Most Viewed Tables**, and **Most Read Tables**.

- If you prefer a powerful search engine, go to the homepage to search for data.

Note The homepage appears by default when you access Data Map. To return to the homepage from other pages, click Data Map in the upper-left corner.

- If you need to find tables by project or cluster, click **All Data** in the top navigation bar. On the All Data page, you can view tables on the **MaxCompute** and **E-MapReduce** tabs. On the MaxCompute tab, you can perform the following operations on a table: **Add to Favorites**, **Apply for Permission**, **View Lineage**, and **View DDL Statement**.

If you have added tables to categories, move the pointer over **All Data** in the top navigation bar and select a category. Tables in the category appear. For more information, see [Manage categories and configure workspace permissions](#).

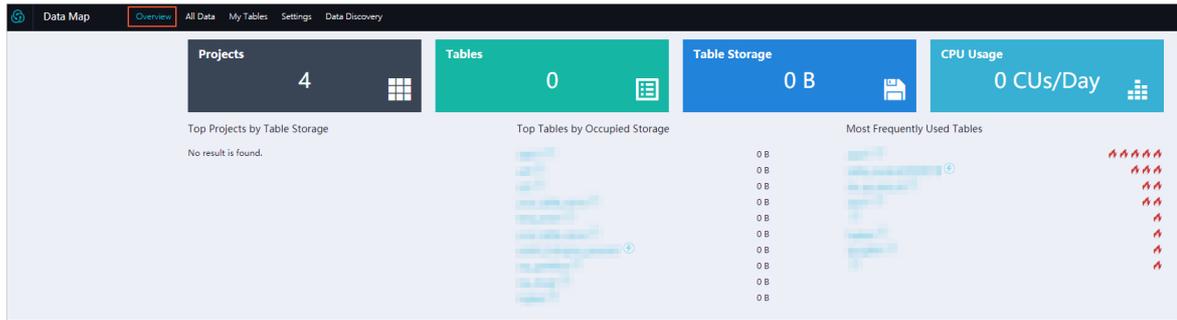

- If you need to view the overall data of the current tenant, click **Overview** in the top navigation bar. For more information, see [View overall data](#).
- If you need to modify tables owned by yourself, click **My Tables** in the top navigation bar. For more information, see [View and manage data and data permissions](#).
- If you are a category administrator or workspace administrator and need to modify the workspace configuration or global categories, click **Settings**. For more information, see [Manage categories and configure workspace permissions](#).

2.11.2. View overall data

This topic describes how to view the overall data of a tenant on the Overview page.

Procedure

1. Log on to the DataWorks console.
2. Click  in the upper-left corner and choose **All Products > Data Map(Data Management)**. The homepage of Data Map appears.
3. Click **Overview** in the top navigation bar. The **Overview** page displays offline statistics of the tenant.

Note The Overview page displays statistics of the previous day.

Section	Description
Projects	The total number of projects of the tenant.
Tables	The total number of tables of the tenant.
Table Storage	The total storage occupied by all tables of the tenant.
CPU Usage	The number of compute units (CUs) consumed by the tenant in one day. One CU is equivalent to the computing resources consumed by one fully loaded CPU core in one day.
Top Projects by Table Storage	The top projects that occupy the most storage space under the tenant.
Top Tables by Occupied Storage	<p>The top tables that occupy the most storage space under the tenant. You can click a table name to go to the details page of the table.</p> <p>Note The logical storage space occupied by projects and tables is collected in a T+1 manner. The numbers next to the project and table names indicate the sizes of the occupied logical storage space. The project storage volume includes the table storage volume, storage volumes of resources, data in the recycle bin, and other system files. Therefore, the project storage volume is larger than the table storage volume.</p> <p>The table storage volume is charged based on the logical storage rather than the physical storage.</p>
Most Frequently Used Tables	The most frequently referenced tables of the tenant. You can click a table name to go to the details page of the table.

2.11.3. View and manage data and data permissions

You can view and manage data on the Owned by Me, Managed by Me as Workspace Administrator, Managed by Tenant Account, and My Favorites pages. This topic describes how to view and manage data and data permissions.

Context

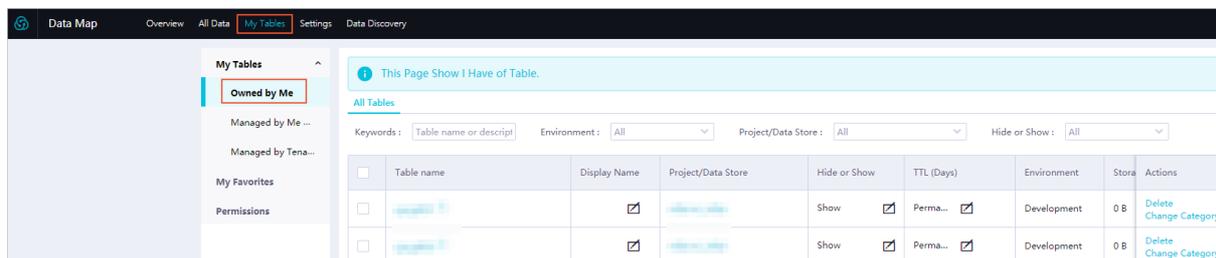

Data Map updates data one day after the data is generated. If you need to query real-time data, we recommend that you use SQL statements.

Go to the My Tables page

1. Log on to the DataWorks console.
2. Click  in the upper-left corner and choose **All Products > Data Map(Data Management)**. The homepage of Data Map appears.
3. In the top navigation bar, click **My Tables**. By default, the **My Tables > Owned by Me** page appears.

View and manage data on the Owned by Me page

On the **Owned by Me** page, you can search for data by keyword, environment, project or data store, and visibility. You can also view the details about a table and perform relevant operations on the table.

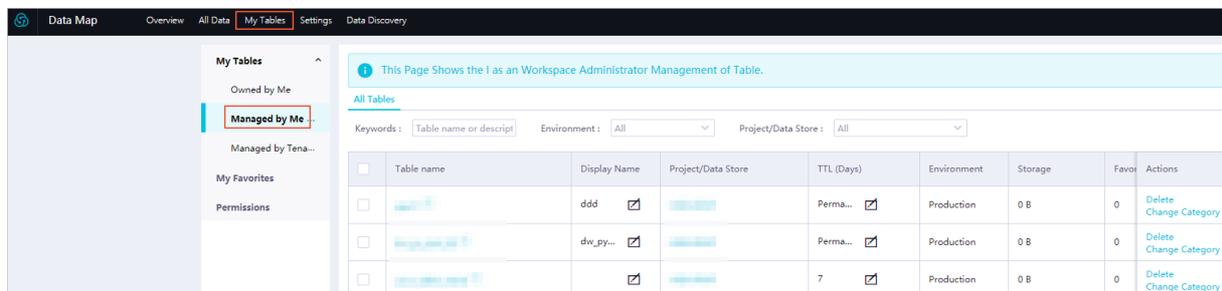

GUI element	Description
Table name	The name of the table. You can click a table name to go to the table details page.
Display Name	The display name of the table. You can click  in the Display Name column of a table to change the display name of the table.
Project/Data Store	The project or data store where the table resides.
Hide or Show	Indicates whether the table is hidden. You can click  in the Hide or Show column of a table to hide or show the table. <div style="border: 1px solid #add8e6; padding: 5px; background-color: #e6f2ff;"> <p> Note If you hide a table, the Apply for Permissions button does not appear on the details page of the table.</p> </div>
TTL (Days)	The TTL of the table, which is the same as that you set when you create the table.
Environment	The environment to which the table belongs. Valid values: Development and Production .
Storage	The amount of data that is stored in the table.
Favorites	The number of times that users add the table to favorites.
Views in Last 30 Days	The number of times that users view the table in the last 30 days.
Created At	The time when the table was created.

GUI element	Description
Actions	The operations that you can perform on the table. You can click Delete or Change Category in the Actions column of a table to delete the table or change the category of the table.
Edit, Change Owner, Delete, and Change Category	The operations that you can perform on multiple tables at a time. You can select tables and then click Edit , Change Owner , Delete , or Change Category to modify the tables, change the table owners, delete the tables, or change the categories of the tables.

View and manage data on the Managed by Me as Workspace Administrator page

In the left-side navigation pane, click **Managed by Me as Workspace Administrator**. On the page that appears, you can search for data by keyword, project or data store, and environment. You can also view the details about a table and perform relevant operations on the table.

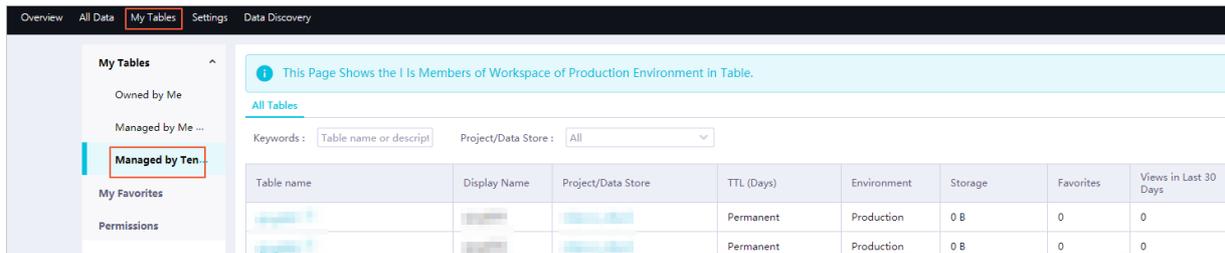

GUI element	Description
Table name	The name of the table. You can click a table name to go to the table details page.
Display Name	The display name of the table. You can click <input checked="" type="checkbox"/> in the Display Name column of a table to change the display name of the table.
Project/Data Store	The project or data store where the table resides.
TTL (Days)	The TTL of the table, which is the same as that you set when you create the table.
Environment	The environment to which the table belongs. Valid values: Development and Production .
Storage	The amount of data that is stored in the table.
Favorites	The number of times that users add the table to favorites.
Views in Last 30 Days	The number of times that users view the table in the last 30 days.
Created At	The time when the table was created.
Actions	The operations that you can perform on the table. You can click Delete or Change Category in the Actions column of a table to delete the table or change the category of the table.

GUI element	Description
Edit, Change Owner, Delete, and Change Category	The operations that you can perform on multiple tables at a time. You can select tables and then click Edit , Change Owner , Delete , or Change Category to modify the tables, change the table owners, delete the tables, or change the categories of the tables.

View data on the Managed by Tenant Account page

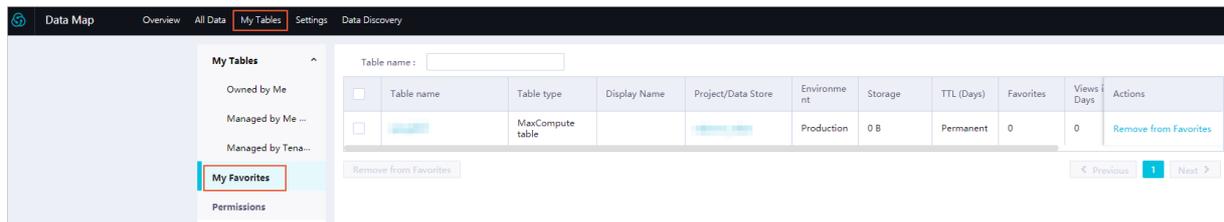

In the left-side navigation pane, click **Managed by Tenant Account**. On the page that appears, you can search for data by keyword and project or data store. You can also view the details about a table and perform relevant operations on the table.

GUI element	Description
Table name	The name of the table. You can click a table name to go to the table details page.
Display Name	The display name of the table. You can click  in the Display Name column of a table to change the display name of the table.
Project/Data Store	The project or data store where the table resides. Tables have different suffixes when they are deployed in different environments. For example, _dev indicates the development environment.
TTL (Days)	The TTL of the table, which is the same as that you set when you create the table.
Environment	The environment to which the table belongs. Valid values: Development and Production .
Storage	The amount of data that is stored in the table.
Favorites	The number of times that users add the table to favorites.
Views in Last 30 Days	The number of times that users view the table in the last 30 days.
Created At	The time when the table was created.

View data on the My Favorites page

In the left-side navigation pane, click **My Favorites**. On the page that appears, you can view the tables that you have added to favorites.

You can click **Remove from Favorites** in the Actions column of a table to remove the table from your favorites.

View and manage data permissions

In the left-side navigation pane, click **Permissions**. On the Permissions page, you can view and manage data permissions.

You can click **Apply function and resource permissions** in the upper-right corner of the **Permissions** page to request permissions. You can also view permission requests on the **To Be Approved**, **Submitted by Me**, and **Handled by Me** tabs.

- **Apply function and resource permissions**

- On the Permissions page, click **Apply function and resource permissions** in the upper-right corner.
- In the **Request Permission** dialog box, set the parameters as required. The following table describes the parameters for requesting permissions.

Request Permission ✕

* **Object Type** : Select an object type.

* **Grant To** : **Current Account** **Specified Account** Specify the account to which you want to grant the permission.

* **Project Name** : Specify a project name.

* **Function Name** : Specify a function name.

Validity Period : If this field is not specified, the permission is permanently valid by default.

* **Reason** : Enter a reason.

Parameter	Description
Object Type	The type of object on which you want to request permissions. Valid values: Function and Resources .

Parameter	Description
Grant To	The account to which the permissions will be granted. Valid values: Current Account and Specified Account . <ul style="list-style-type: none">▪ If you select Current Account, the permissions will be granted to you after the request is approved.▪ If you select Specified Account, you must also specify the Account parameter. The permissions will be granted to the specified account after the request is approved.
Project Name	The name of the MaxCompute project that contains the target function or resource.
Function Name or Resource Name	The full name of the function or resource in the project. If the resource is a file, enter the full name of the file, including the file name extension. Example: my_mr.jar.
Validity Period	The validity period of the permissions, in days. If this parameter is not specified, the permissions are permanently valid. After the validity period expires, the system automatically revokes the permissions.
Reason	The reason why you request the permissions.

- **To Be Approved**

If you are the workspace administrator, you can go to the **To Be Approved** tab. On the tab, you can view and approve the requests for permissions on all objects such as tables, resources, and functions in the workspace.

- **Submitted by Me**

Click the **Submitted by Me** tab on the **Permissions** page.

You can view the permission requests that you have submitted on this tab.

- **Handled by Me**

If you are the workspace administrator, you can go to the **Handled by Me** tab on the **Permissions** page.

On the **Handled by Me** tab, you can view the permission requests that you have handled for all objects such as tables, resources, and functions in the workspace.

2.11.4. Manage categories and configure workspace permissions

This topic describes how to manage categories and configure workspace permissions on the Configuration Management page.

Go to the Configuration Management page

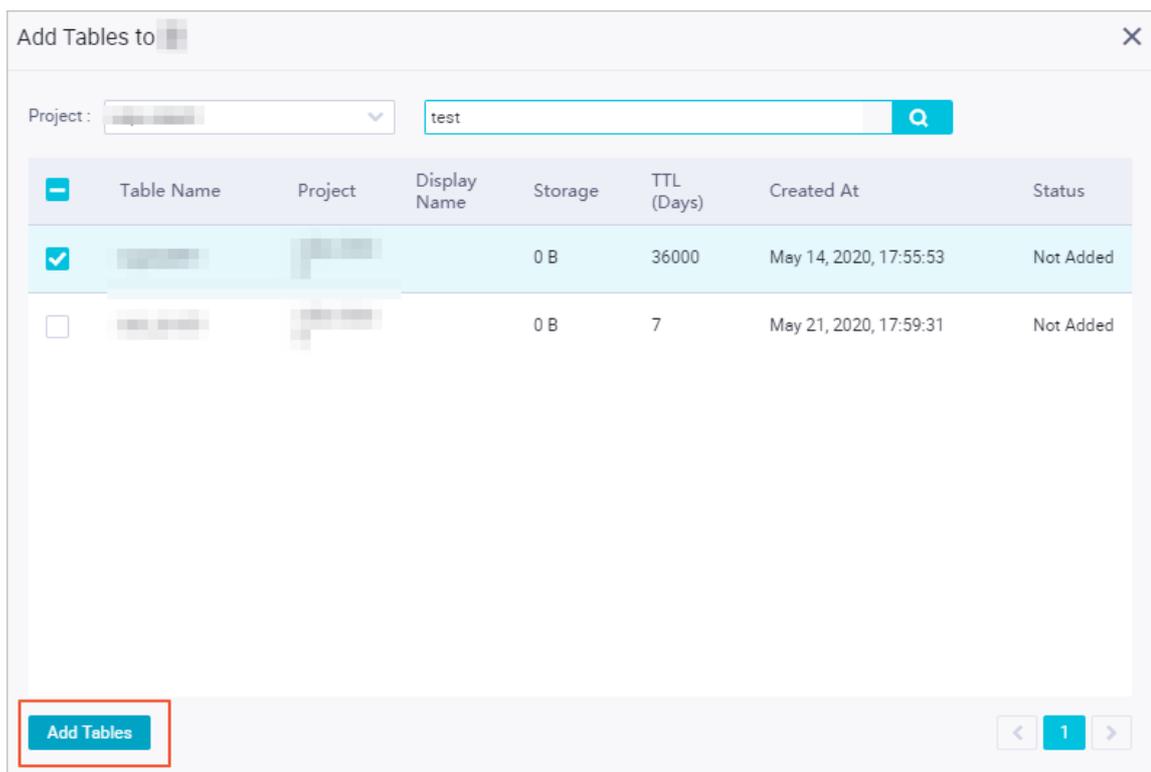

1. Log on to the DataWorks console.
2. Click the  icon in the upper-left corner and choose **All Products > Data Map(Data Management)**.
3. On the Data Map page, click **Configuration Management** in the top navigation bar. The **Manage Categories** tab is automatically opened.

Manage categories

Only tenant administrators have the permissions to create categories and add tables to the categories on the **Manage Categories** page. For more information about how to assign the tenant administrator role to a user, see [Member management](#).

To manage categories as a tenant administrator, perform the following steps:

1. On the **Manage Categories** page, move the pointer over **Categories** and click the **+** icon next to **Categories** to create a level-1 category.
2. Move the pointer over the name of the level-1 category and click the **+** icon next to the level-1 category to create a level-2 category. Use the same method to create more categories. DataWorks allows you to create categories at a maximum of four levels. You can change category names and delete categories.
 - To change the name of a category, move the pointer over the category name, click the **✎** icon, enter a new name, and then press Enter.
 - To delete a category, move the pointer over the category name and click the **🗑** icon. In the **Delete Category** message, click **OK**.
3. Add tables to or remove tables from a category.
 - To add tables to a category, click the name of the category and click **Add Tables** in the upper-right corner. In the Add Tables dialog box, select the tables that you want to add and click **Batch Add**.

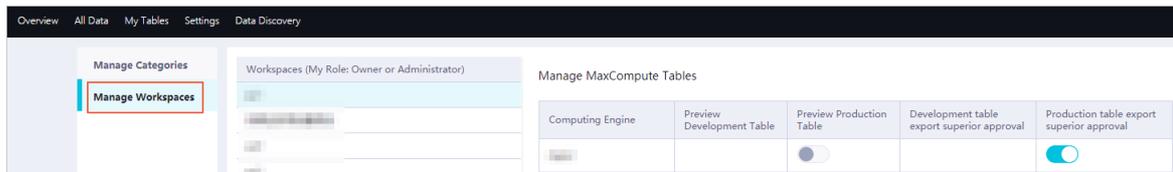

- To remove a table from a category, click the name of the category, find the table that you want to remove, and then click **Remove from Category** in the Actions column. In the message that appears, click **OK**.

Note To remove multiple tables from a category, click the name of the category, select the tables that you want to remove, and then click **Remove from Category** below the table list.

Configure workspace permissions

To configure workspace permissions on the Configuration Management page, perform the following steps:

1. In the left-side navigation pane, click **Manage Workspaces**.
2. Click the name of the required workspace.
3. In the **Manage MaxCompute Tables** section, configure the permissions on the workspace. You can turn on **Preview Tables in Development Environment** and **Preview Tables in Production Environment** as required.

Note If the workspace is in basic mode, you can turn on only **Preview Tables in Production Environment**.

Import and export a category tree

You can import or export a category tree on the **Manage Categories** page.

Note You can export and then import a category tree. You are not allowed to export a category tree, modify it, and then import it.

- Import a category tree
 - i. In the **Manage Categories** section, click **Import**.
 - ii. In the dialog box that appears, select a file that you want to import.
 - iii. Click **Open**.
- Export a category tree

In the **Manage Categories** section, click **Export**.

2.11.5. View table details

2.11.5.1. View the details of a table

This topic describes how to go to the details page of a table and view the details about the table, such as the basic information, output information, and lineage information.

Go to the details page of a table

1. Log on to the DataWorks console.
2. Click  in the upper-left corner and choose **All Products > Data Map(Data Management)**. The homepage of Data Map appears.
3. In the top navigation bar, click **All Data**.
4. On the All Data page, click a tab as required.
5. On the tab that appears, click the name of the table you want to view. On the details page that appears, you can view the basic information, business information, permission information, technical information, detailed information (including the fields, partitions, and change history), output information, lineage

information, reference records, and usage notes of the table. You can also preview data in the table.

View basic information

In the **Basic Information** section, you can view the numbers of reads, favorites, and views. You can also check the output nodes, MaxCompute project name, region to which the current workspace belongs, region to which the engine belongs, owner, creation time, time-to-live (TTL), storage capacity, description, and tags of the table, and whether the table is partitioned.

You can perform the following operations in this section:

- View the code of the output node of the table: Click **View Code** next to **Output Node**. On the **Operation Center** page, view the node code.
- View the details about the MaxCompute project: Click the MaxCompute project name. On the page that appears, view the details about the MaxCompute project to which the table belongs.
- Edit the description of the table: Click  next to **Description**, enter a description in the field that appears, and then click .
- Add a tag to or remove a tag from the table: Click  next to **Label**, enter a tag name in the field that appears, and then press **Enter**.

To remove a tag from the table, move the pointer over the tag and click the **Remove** icon.

View business information

In the **Business Information** section, you can view the DataWorks workspace name, environment type, and category of the table.

In this section, you can click the workspace name next to **DataWorks Workspace** to view the details about the workspace to which the table belongs.

View permission information

In the **Permission Information** section, you can view your permissions on the table.

To modify your permissions on the table, perform the following steps:

1. Click **More** in the upper-right corner of the **Permission Information** section.
2. In the **Apply for Data Permissions** dialog box, set the **Grant To**, **Validity Period**, and **Reason** parameters as required.

 **Note** If you do not set the **Validity Period** parameter, the permissions that you request will be permanently valid after your request is approved.

3. Click **Commit**.

View technical information

In the **Technical Information** section, you can view the technical type, last time when the DDL statement was modified, last time when the data was modified, last time when the data was viewed, and compute engine information.

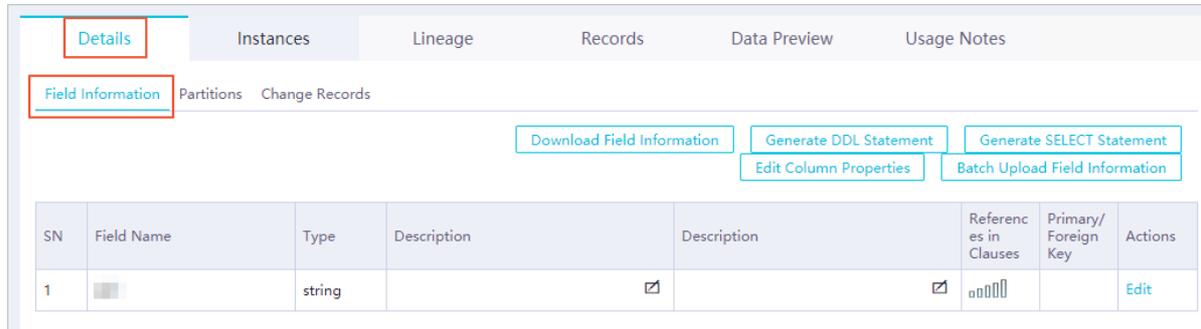

In this section, you can click **Click to View** next to **Compute Engine Information**. In the **Compute Engine Information** dialog box, you can view or copy the information about the compute engine.

View detailed information

The **Details** tab contains the following tabs: **Field Information**, **Partitions**, and **Change Records**.

• **Field Information tab**

On the **Field Information** tab, you can view the name, data type, description, business description, and popularity of fields. You can also check whether a field is a primary key or foreign key.

Button	Description
Edit Column Properties	Click this button, modify the field description and business description, and then click Save or Cancel as needed.
Batch Upload Field Information	Click this button and drag the local file to be uploaded to the Batch Upload Field Information dialog box.
Download Field Information	Click this button to download the field information of the current table.
Generate DDL Statement	Click this button. In the Generate DDL Statement dialog box, view or copy the DDL statement used to create the current table.
Generate SELECT Statement	Click this button. In the Generate SELECT Statement dialog box, view or copy the SELECT statement for querying data in the current table.

• **Partitions tab**

On the **Partitions** tab, you can view the name, number of records, storage capacity, creation time, and last update time of each partition in the current table.

• **Change Records tab**

On the **Change Records** tab, you can view the description, type, granularity, time, and operator of changes performed on the current table.

On this tab, you can also select a change type from the drop-down list in the upper-left corner to filter the table changes.

Change types include **Create Table**, **Modify Table**, **Delete Table**, **Add Partition**, **Delete Partition**, **Change Owner**, and **Modify Lifecycle**.

View output information

If the table data periodically changes with the corresponding node, you can view the change status and data that is continuously updated on the **Instances** tab.

On this tab, you can also click **Code** or **Logs** in the **Actions** column of a node to view the code or logs of the node.

View lineage information

On the **Lineage** tab, you can view the source and destination of data and manage the lineage information with ease.

The **Lineage** tab contains the following tabs: **Table Lineage**, **Field Lineage**, and **Impact Analysis**.

- **Table Lineage** tab: On this tab, you can search for the ancestor and descendant tables of the current table based on the globally unique identifier (GUID).
- **Field Lineage** tab: On this tab, you can select a field from the **Field Name** drop-down list to view the lineage information of the field.
- **Impact Analysis** tab: On this tab, you can query the node that generates a lineage and the full link of the lineage based on information such as the field, node type, table name, project name, and table owner.

You can perform the following operations on the query result:

- Click **Download** to download the query result to your local computer.
- Click **Email**. In the **Notify by Email** dialog box, set the required parameters and click **OK**. In this way, you can configure DataWorks to send email notifications to owners of the descendant tables of the current table.

View reference records

The **Records** tab contains the following tabs: **Foreign Key References** and **Access Statistics**.

- **Foreign Key References** tab: On this tab, you can check the number of users who reference the current table.
- **Access Statistics** tab: On this tab, you can view the reference records in a line chart.

Preview data

On the **Data Preview** tab, you can preview the data of the current table.

 **Notice** Only authorized users can preview tables in the production environment. If you do not have the required permissions, click **Apply Now**.

View usage notes

On the **Instructions** tab, you can edit usage notes, check the historical versions of the usage notes, and view the business description of data.

2.11.5.2. Request table permissions

This topic describes how to request table permissions on the Data Map or Security Center page.

Go to the details page of a table

1. Log on to the DataWorks console.
2. Click  in the upper-left corner and choose **All Products > Data Map(Data Management)**. The homepage of Data Map appears.
3. In the top navigation bar, click **All Data**.
4. On the All Data page, click a tab as required.
5. On the tab that appears, click the name of the table on which you want to request permissions.

Request table permissions

1. On the table details page, click **Apply for Permission**.

 **Note** If a table is hidden, the **Apply for Permissions** button does not appear on the details page of the table.

- In the **Apply for Permission** dialog box, set the parameters as required. The following table describes the parameters for requesting table permissions.

Apply for Permission ✕

Table : odps.data1.aaa11

* Grant To : Current Account Specified Account
Specify the account to which you want to grant the permission.

Validity Period : Days
If this field is not specified, the permission is permanently valid by default.

* Reason :
Enter a reason.

Parameter	Description
Table	The table on which you want to request permissions. You cannot change the default value.
Grant To	The type of the account to which the permissions will be granted. Valid values: Current Account and Specified Account .
Username	The username of the account to which the permissions will be granted. <div style="background-color: #e0f2f1; padding: 5px; border: 1px solid #ccc;"> ? Note This parameter is available only when you set the Grant To parameter to Specified Account. </div>
Validity Period	The validity period of the permissions. If you do not set this parameter, the permissions are permanently valid.
Reason	The reason why you request the permissions. Enter a reason for faster approval.

- Click **Commit**.

View the request status

- Click  in the upper-left corner and choose **All Products > Data Map(Data Management)**. The homepage of Data Map appears.
- In the top navigation bar, click **My Tables**.
- On the My Tables page, click **Permissions** in the left-side navigation pane.
- On the page that appears, click the **Submitted by Me** tab.
- Find the target request record and click **View** in the Actions column. The request details appear.

2.11.5.3. Add a table to favorites

This topic describes how to add a table to or remove it from favorites, and view the tables added to favorites.

Procedure

1. Log on to the DataWorks console.
2. Go to the details page of a table and click **Add to Favorites** in the upper-left corner.
3. In the top navigation bar, click **My Tables**.
4. On the **My Tables** page, click **My Favorites** in the left-side navigation pane. On the page that appears, you can view all the tables that you have added to favorites and remove tables from favorites. To remove a table from favorites, find the table in the table list and click **Remove from Favorites** in the Actions column.

2.11.6. Data discovery

2.11.6.1. Collect metadata from an E-MapReduce data source

source

This topic describes how to create a crawler to collect metadata from an E-MapReduce (EMR) data source to DataWorks. You can view the collected metadata on the Data Map page.

Prerequisites

An EMR cluster is bound.

Procedure

1. Go to the **Data Discovery** page.
 - i. [Log on to the DataWorks console](#).
 - ii. On the DataStudio page, click the  icon in the upper-left corner and choose **All Products > Data governance > Data Map(Data Management)**. The homepage of Data Map appears.
 - iii. In the top navigation bar, click **Data Discovery**.
2. On the **Obtain Metadata from E-MapReduce** page, click **Create Crawler**.
3. In the **Create Crawler** dialog box, specify **Select Engine Instance** and click **Commit** to enable metadata collection.
4. On the **Obtain Metadata from E-MapReduce** page, find the created crawler and click **Obtain All** in the Actions column. Click **Refresh** in the upper-right corner of the page and verify that the value in the **Running Status** column of the created crawler changes to **The data has been collected**.

 **Note** After full metadata from the EMR data source is collected, the system automatically synchronizes new metadata from the data source.

If you want to delete the created crawler, click **Delete** in the Actions column. In the **Delete Instance** message, click **OK**.

5. View the metadata collected from the EMR data source.
 - i. In the top navigation bar, click **All Data**.
 - ii. Click the **E-MapReduce** tab.
 - iii. On the **E-MapReduce** tab, click the name of the table that stores the collected metadata and view the table details.

2.11.6.2. Collect metadata from a MySQL data source

This topic describes how to create a crawler to collect metadata from a MySQL data source to DataWorks. You can view the collected metadata on the Data Map page.

Procedure

1. Log on to the DataWorks console.
2. In the left-side navigation pane, click **MySQL**.
3. On the **MySQL Metadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, perform the following steps:
 - i. In the **Basic Information** step, configure the basic parameters as required.

Parameter	Description
Crawler Name	Required. The name of the crawler. You must specify a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Connection Type	The type of the data source from which you want to collect metadata. The default value is MySQL .

- ii. Click **Next**.
 - iii. In the **Select Collection Object** step, select a data source from the **Connection** drop-down list. If the required data source does not exist, click **Create Connection** to go to the **Data Source** page in **Workspace Management** and create a data source. For more information, see [Configure a MySQL connection](#).
-  **Note** You can select an ApsaraDB RDS for MySQL instance or a MySQL data source that is accessible from the Internet by using a Java Database Connectivity (JDBC) connection string.
- iv. Click **Test Crawler Connectivity**.
 - v. When the message **The connectivity test has been passed.** appears, click **Next**.
 - vi. In the **Configure Execution Plan** step, specify an execution plan. Valid values of the **Execution Plan** parameter: **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**.
 - vii. Click **Next**.
 - viii. In the **Confirm Information** step, verify that the configuration of the crawler is correct and click **OK**.
5. On the **MySQL Metadata Crawler** page, find the created crawler and click **Run** in the **Actions** column. After the crawler is run, click the number in the **Updated Tables in Last Run** or **Added Tables in Last Run** column to view the details about the updated or added tables.

You can also perform the following operations on the **MySQL Metadata Crawler** page:

- Click **Details** in the **Actions** column of a crawler. In the **Crawler Details** dialog box, view the detailed information about the crawler.
- Click **Edit** in the **Actions** column of a crawler. In the **Edit Crawler** dialog box, modify the configuration of the crawler.
- Click **Delete** in the **Actions** column of a crawler. In the **Confirm** message, click **Ok** to delete the crawler.
- Click **Stop** in the **Actions** column of a running crawler to stop the crawler.

Result

After the crawler is run, you can go to the **MySQL** tab of the **All Data** page to view the table that stores the collected metadata.

2.11.6.3. Collect metadata from a PostgreSQL data source

This topic describes how to create a crawler to collect metadata from a PostgreSQL data source to DataWorks. You can view the collected metadata on the Data Map page.

Procedure

1. Go to the **Data Discovery** page.
 - i. [Log on to the DataWorks console](#).
 - ii. On the DataStudio page, click the  icon in the upper-left corner and choose **All Products > Data governance > Data Map(Data Management)**. The homepage of Data Map appears.
 - iii. In the top navigation bar, click **Data Discovery**.
2. In the left-side navigation pane, click **PostgreSQL**.
3. On the **PostgreSQL Metadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, perform the following steps:
 - i. In the **Basic Information** step, configure the basic parameters as required.

Parameter	Description
Crawler Name	Required. The name of the crawler. You must specify a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Connection Type	The type of the data source from which you want to collect metadata. The default value is PostgreSQL .

- ii. Click **Next**.
 - iii. In the **Select Collection Object** step, select a data source from the **Connection** drop-down list. If the required data source does not exist, click **Create Connection** to go to the **Data Source** page in **Workspace Management** and create a data source. For more information, see [Configure a PostgreSQL connection](#).
 - iv. Click **Test Crawler Connectivity**.
 - v. When the message **The connectivity test has been passed.** appears, click **Next**.
 - vi. In the **Configure Execution Plan** step, specify an execution plan. Valid values of the **Execution Plan** parameter: **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**.
 - vii. Click **Next**.
 - viii. In the **Confirm Information** step, verify that the configuration of the crawler is correct and click **OK**.
5. On the **PostgreSQL Metadata Crawler** page, find the created crawler and click **Run** in the **Actions** column. After the crawler is run, click the number in the **Updated Tables in Last Run** or **Added Tables in Last Run** column to view the details about the updated or added tables.

You can also perform the following operations on the **MySQL Metadata Crawler** page:

- Click **Details** in the Actions column of a crawler. In the **Crawler Details** dialog box, view the detailed information about the crawler.
- Click **Edit** in the Actions column of a crawler. In the **Edit Crawler** dialog box, modify the configuration of the crawler.
- Click **Delete** in the Actions column of a crawler. In the **Confirm** message, click **Ok** to delete the crawler.
- Click **Stop** in the **Actions** column of a running crawler to stop the crawler.

2.11.6.4. Collect metadata from an SQL Server data source

This topic describes how to create a crawler to collect metadata from an SQL Server data source to DataWorks. You can view the collected metadata on the Data Map page.

Procedure

1. Log on to the DataWorks console.
2. In the left-side navigation pane, click **SQL Server**.
3. On the **SQL Server Metadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, perform the following steps:
 - i. In the **Basic Information** step, configure the basic parameters as required.

Parameter	Description
Crawler Name	Required. The name of the crawler. You must specify a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Connection Type	The type of the data source from which you want to collect metadata. The default value is SQL Server .

- ii. Click **Next**.
 - iii. In the **Select Collection Object** step, select a data source from the **Connection** drop-down list. If the required data source does not exist, click **Create Connection** to go to the **Data Source** page in **Workspace Management** and create a data source. For more information, see [Configure an SQL Server connection](#).
 - iv. Click **Test Crawler Connectivity**.
 - v. When the message **The connectivity test has been passed.** appears, click **Next**.
 - vi. In the **Configure Execution Plan** step, specify an execution plan. Valid values of the **Execution Plan** parameter: **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**.
 - vii. Click **Next**.
 - viii. In the **Confirm Information** step, verify that the configuration of the crawler is correct and click **OK**.
5. On the **SQL Server Metadata Crawler** page, find the created crawler and click **Run** in the Actions column. After the crawler is run, click the number in the **Updated Tables in Last Run** or **Added Tables in Last Run** column to view the details about the updated or added tables.

You can also perform the following operations on the **OSS Metadata Crawler** page:

- Click **Details** in the Actions column of a crawler. In the **Crawler Details** dialog box, view the detailed information about the crawler.

- Click **Edit** in the Actions column of a crawler. In the **Edit Crawler** dialog box, modify the configuration of the crawler.
- Click **Delete** in the Actions column of a crawler. In the **Confirm** message, click **OK** to delete the crawler.
- Click **Stop** in the **Actions** column of a running crawler to stop the crawler.

2.11.6.5. Collect metadata from an Oracle data source

This topic describes how to create a crawler to collect metadata from an Oracle data source to DataWorks. You can view the collected metadata on the Data Map page.

Procedure

1. Log on to the DataWorks console.
2. In the left-side navigation pane, click **Oracle**.
3. On the **OracleMetadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, perform the following steps:
 - i. In the **Basic Information** step, configure the basic parameters as required.

Parameter	Description
Crawler Name	Required. The name of the crawler. You must specify a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Connection Type	The type of the data source from which you want to collect metadata. The default value is Oracle .

- ii. Click **Next**.
 - iii. In the **Select Collection Object** step, select a data source from the **Connection** drop-down list. If the required data source does not exist, click **Create Connection** to go to the **Data Source** page in **Workspace Management** and create a data source. For more information, see [Configure an Oracle connection](#).
 - iv. Click **Test Crawler Connectivity**.
 - v. When the message **The connectivity test has been passed.** appears, click **Next**.
 - vi. In the **Configure Execution Plan** step, specify an execution plan. Valid values of the **Execution Plan** parameter: **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**.
 - vii. Click **Next**.
 - viii. In the **Confirm Information** step, verify that the configuration of the crawler is correct and click **OK**.
5. On the **OracleMetadata Crawler** page, find the created crawler and click **Run** in the Actions column. After the crawler is run, click the number in the **Updated Tables in Last Run** or **Added Tables in Last Run** column to view the details about the updated or added tables.

You can also perform the following operations on the **OSSMetadata Crawler** page:

- Click **Details** in the Actions column of a crawler. In the **Crawler Details** dialog box, view the detailed information about the crawler.
- Click **Edit** in the Actions column of a crawler. In the **Edit Crawler** dialog box, modify the configuration of the crawler.

- Click **Delete** in the **Actions** column of a crawler. In the **Confirm** message, click **OK** to delete the crawler.
- Click **Stop** in the **Actions** column of a running crawler to stop the crawler.

2.11.6.6. Collect metadata from an AnalyticDB for PostgreSQL data source

This topic describes how to create a crawler to collect metadata from an AnalyticDB for PostgreSQL data source to DataWorks. After the metadata is collected, you can manage tables in the AnalyticDB for PostgreSQL data source on the Data Map page.

Procedure

1. Log on to the DataWorks console.
2. In the left-side navigation pane, click **AnalyticDB for PostgreSQL**.
3. On the **AnalyticDB for PostgreSQL Metadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, perform the following steps:
 - i. In the **Basic Information** step, configure the basic parameters as required.

Parameter	Description
Crawler Name	Required. The name of the crawler. You must specify a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Connection Type	The type of the data source from which you want to collect metadata. The default value is AnalyticDB for PostgreSQL .

- ii. Click **Next**.
 - iii. In the **Select Collection Object** step, select a data source from the **Connection** drop-down list. If the required data source does not exist, click **Create Connection** to go to the **Data Source** page in **Workspace Management** and create a data source.
 - iv. Click **Test Crawler Connectivity**.
 - v. When the message **The connectivity test has been passed.** appears, click **Next**.
 - vi. In the **Configure Execution Plan** step, specify an execution plan. Valid values of the **Execution Plan** parameter: **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**.
 - vii. Click **Next**.
 - viii. In the **Confirm Information** step, verify that the configuration of the crawler is correct and click **OK**.
5. On the **AnalyticDB for PostgreSQL Metadata Crawler** page, find the created crawler and click **Run** in the **Actions** column.

After the crawler is run, click the number in the **Updated Tables in Last Run** or **Added Tables in Last Run** column to view the details about the updated or added tables.

 **Notice** The **Run** button is displayed only in the **Actions** column of a crawler that needs to be manually triggered.

You can also perform the following operations on the AnalyticDB for PostgreSQL Metadata Crawler page:

- Click **Details** in the Actions column of a crawler. In the **Crawler Details** dialog box, view the detailed information about the crawler.
- Click **Edit** in the Actions column of a crawler. In the **Edit Crawler** dialog box, modify the configuration of the crawler.
- Click **Delete** in the Actions column of a crawler. In the **Confirm** message, click **Ok** to delete the crawler.
- Click **Stop** in the Actions column of a running crawler to stop the crawler.

2.11.6.7. Collect metadata from an AnalyticDB for MySQL 2.0 data source

This topic describes how to create a crawler to collect metadata from an AnalyticDB for MySQL 2.0 data source to DataWorks. You can view the collected metadata on the Data Map page.

Procedure

1. Log on to the DataWorks console.
2. In the left-side navigation pane, click **AnalyticDB for MySQL 2.0**.
3. On the **AnalyticDB for MySQL 2.0 Metadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, perform the following steps:
 - i. In the **Basic Information** step, configure the basic parameters as required.

Parameter	Description
Crawler Name	Required. The name of the crawler. You must specify a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Connection Type	The type of the data source from which you want to collect metadata. The default value is AnalyticDB for MySQL 2.0 .

- ii. Click **Next**.
 - iii. In the **Select Collection Object** step, select a data source from the **Connection** drop-down list. If the required data source does not exist, click **Create Connection** to go to the **Data Source** page in **Workspace Management** and create a data source.
 - iv. Click **Test Crawler Connectivity**.
 - v. When the message **The connectivity test has been passed.** appears, click **Next**.
 - vi. In the **Configure Execution Plan** step, specify an execution plan. Valid values of the **Execution Plan** parameter: **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**.
 - vii. Click **Next**.
 - viii. In the **Confirm Information** step, verify that the configuration of the crawler is correct and click **OK**.
5. On the **AnalyticDB for MySQL 2.0 Metadata Crawler** page, find the created crawler and click **Run** in the Actions column. After the crawler is run, click the number in the **Updated Tables in Last Run** or **Added Tables in Last Run** column to view the details about the updated or added tables.

You can also perform the following operations on the MySQLMetadata Crawler page:

- Click **Details** in the Actions column of a crawler. In the **Crawler Details** dialog box, view the detailed information about the crawler.
- Click **Edit** in the Actions column of a crawler. In the **Edit Crawler** dialog box, modify the configuration of the crawler.
- Click **Delete** in the Actions column of a crawler. In the **Confirm** message, click **Ok** to delete the crawler.
- Click **Stop** in the Actions column of a running crawler to stop the crawler.

2.11.6.8. Collect metadata from an AnalyticDB for MySQL 3.0 data source

This topic describes how to create a crawler to collect metadata from an AnalyticDB for MySQL 3.0 data source to DataWorks. You can view the collected metadata on the Data Map page.

Procedure

1. Log on to the DataWorks console.
2. In the left-side navigation pane, click **AnalyticDB for MySQL 3.0**.
3. On the **AnalyticDB for MySQL 3.0 Metadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, perform the following steps:
 - i. In the **Basic Information** step, configure the basic parameters as required.

Parameter	Description
Crawler Name	Required. The name of the crawler. You must specify a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Connection Type	The type of the data source from which you want to collect metadata. The default value is AnalyticDB for MySQL 3.0 .

- ii. Click **Next**.
 - iii. In the **Select Collection Object** step, select a data source from the **Connection** drop-down list. If the required data source does not exist, click **Create Connection** to go to the **Data Source** page in **Workspace Management** and create a data source.
 - iv. Click **Test Crawler Connectivity**.
 - v. When the message **The connectivity test has been passed.** appears, click **Next**.
 - vi. In the **Configure Execution Plan** step, specify an execution plan. Valid values of the **Execution Plan** parameter: **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**.
 - vii. Click **Next**.
 - viii. In the **Confirm Information** step, verify that the configuration of the crawler is correct and click **OK**.
5. On the **AnalyticDB for MySQL 3.0 Metadata Crawler** page, find the created crawler and click **Run** in the Actions column. After the crawler is run, click the number in the **Updated Tables in Last Run** or **Added Tables in Last Run** column to view the details about the updated or added tables.

You can also perform the following operations on the MySQLMetadata Crawler page:

- Click **Details** in the Actions column of a crawler. In the **Crawler Details** dialog box, view the detailed information about the crawler.
- Click **Edit** in the Actions column of a crawler. In the **Edit Crawler** dialog box, modify the configuration of the crawler.
- Click **Delete** in the Actions column of a crawler. In the **Confirm** message, click **Ok** to delete the crawler.
- Click **Stop** in the Actions column of a running crawler to stop the crawler.

2.11.6.9. Collect metadata from a Hologres data source

This topic describes how to create a crawler to collect metadata from a Hologres data source to DataWorks. You can view collected metadata on the Data Map page.

Procedure

1. Log on to the DataWorks console.
2. In the left-side navigation pane, click **Hologres**.
3. On the **HologresMetadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, perform the following steps:
 - i. In the **Basic Information** step, configure the basic parameters as required.

Parameter	Description
Crawler Name	Required. The name of the crawler. You must specify a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Connection Type	The type of the data source from which you want to collect metadata. The default value is Hologres .

- ii. Click **Next**.
 - iii. In the **Select Collection Object** step, select a data source from the **Connection** drop-down list.
 - iv. Click **Test Crawler Connectivity**.
 - v. When the message **The connectivity test has been passed.** appears, click **Next**.
 - vi. In the **Configure Execution Plan** step, specify an execution plan. Valid values of the **Execution Plan** parameter: **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**.
 - vii. Click **Next**.
 - viii. In the **Confirm Information** step, verify that the configuration of the crawler is correct and click **OK**.
5. On the **HologresMetadata Crawler** page, find the created crawler and click **Run** in the Actions column. After the crawler is run, click the number in the **Updated Tables in Last Run** or **Added Tables in Last Run** column to view the details about the updated or added tables.

You can also perform the following operations on the MySQLMetadata Crawler page:

- Click **Details** in the Actions column of a crawler. In the **Crawler Details** dialog box, view the detailed information about the crawler.

- Click **Edit** in the Actions column of a crawler. In the **Edit Crawler** dialog box, modify the configuration of the crawler.
- Click **Delete** in the Actions column of a crawler. In the **Confirm** message, click **Ok** to delete the crawler.
- Click **Stop** in the Actions column of a running crawler to stop the crawler.

2.12. Data Asset Management

2.12.1. Go to the Data Asset Management page

Data Asset Management provides you with an overview of your data assets. Data Asset Management requires that data be synchronized by using Data Integration and processed by using DataStudio before you manage your tables and APIs stored in your business system and DataWorks.

Context

Data Asset Management controls the permissions of users independently. You must grant the permissions on the Project Management page because Data Asset Management is a tenant-level feature.

Data Asset Management allows you to view the metadata collected in Data Map. You can also perform basic management operations on the metadata. For example, you can change the business classes and add business descriptions for metadata tables.

Procedure

1. Log on to the DataWorks console.
2. Click  in the upper-left corner and choose **All Products > Project Management**. The Project Management page appears.
3. In the left-side navigation pane, click **Member Management**. On the Member Management page, you can assign the following roles to members: **Data Asset Management-Asset Manager**, **Data Asset Management-Class Manager**, and **Data Asset Management-Home Visitor**.
4. Click  in the upper-left corner and choose **All Products > Data Asset Management** to manage data assets in Data Asset Management. The following table describes the permissions of each role.

Role	Permission
Data Asset Management-Asset Manager	In the top navigation bar of the Data Asset Management page, click the Assets tab. On the Assets tab, you can manage data assets, such as adding business units and classes. You can also add data assets to a class.
Data Asset Management-Class Manager	In the top navigation bar of the Data Asset Management page, click the Classes tab. On the Classes tab, you can view the data assets of each class.
Data Asset Management-Home Visitor	In the top navigation bar of the Data Asset Management page, click the Home tab. On the Home tab, you can view the statistics of data assets of different classes and business units.

2.12.2. Asset manager

Asset managers can view the information about data assets.

Procedure

1. Log on to the DataWorks console.

2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Asset Management**.
3. On the **Home** page that appears, enter keywords in the search box and click **Search**.
4. On the search results page that appears, click the **Tables**, **File**, or **API** tab to view details and apply for permissions.

You can click the **Classes** tab in the top navigation bar to filter data assets by class.

2.12.3. Asset user

Asset users can access Data Asset Management to perform operations such as searching for assets, applying for permissions, and using assets.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Asset Management**.
3. On the **Home** page that appears, enter keywords in the search box and click **Search**.
4. On the search results page that appears, click the **Tables**, **File**, or **API** tab to view details and apply for permissions.

You can click the **Classes** tab in the top navigation bar to filter data assets by class.

2.12.4. Asset administrator

Asset administrators can manage assets and authorizations in Data Asset Management.

 **Note** You can submit a ticket to apply for the asset administrator role.

An administrator can grant the administrator role to common users. An administrator can perform any operations in Data Asset Management, and no approval is required.

Go to the Assets tab

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Asset Management**.
3. In the top navigation bar, click the **Assets** tab.

Under the **Assets** tab, you can click **Data Management**, **Classes**, or **Business Management** in the left-side navigation pane to manage your data assets accordingly.

Manage data

In the left-side navigation pane, you can click **Data Management** and then **Tables**, **Files**, or **APIs** to manage tables, files, or APIs.

• Manage tables

In the left-side navigation pane, choose **Data Management > Tables** to go to the **Tables** page.

On the **Tables** page, you can view, edit, publish, or delete a table.

- Click the name of a table to view table details.
- Click **Edit** in the Actions column of a table. In the Edit dialog box that appears, you can edit the configuration of the table.

- Move the pointer over **Publish** in the Actions column of a table. In the dialog box that appears, click **Publish**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

 **Note** You can search for a published table in Data Asset Management.

- Move the pointer over **Delete** in the Actions column of a table. In the dialog box that appears, click **Delete**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

 **Note** You cannot search for a deleted table in Data Asset Management.

• Manage files

In the left-side navigation pane, choose **Data Management > Files** to go to the **Files** page.

On the **File Management** page that appears, you can upload a file. Then, you can view, edit, download, or delete the file.

- In the upper-right corner, click **Upload File**. In the **Upload File** dialog box that appears, click **Add File**. In the Add dialog box that appears, select the file to be uploaded and click **Open**. Alternatively, you can drag and drop a file to the **Upload File** dialog box. Then, click **Next**.

Note

- To upload a file, make sure that the size of the file does not exceed 50 MB.
- You can only upload a file with one of the following file name extensions:
3DX, 7Z, A3D, ATX, AVI, BMP, SV, DBF, DOC, DOCX, DWG, EPS, ESP, FREELIST, GDB, GDBINDEXES, GDBTABLE, GDBTABLX, GIF, GZ, HTM, HTML, IVE, JPEG, JPG, LOCK, LSP, LST, MP3, MP4, MPJ, OSG, OSGB, PDF, PNG, PPT, PPTX, PRJ, PSD, RAR, S3C, SBN, SBX, SCP, SHP, SPX, TFW, TIF, TIFF, TTF, TXT, WAV, WL, WP, WT, XLS, XLSX, ZIP, XML, SHX, and SKP

- Click the name of a file to view file details.
- Click **Edit** in the Actions column of a file. In the Edit dialog box that appears, you can edit the configuration of the file.
- Move the pointer over **Publish** in the Actions column of a file. In the dialog box that appears, click **Publish**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

 **Note** You can search for a published file in Data Asset Management.

- Move the pointer over **Delete** in the Actions column of a file. In the dialog box that appears, click **Delete**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

 **Note** You cannot search for a deleted file in Data Asset Management.

- Click **Download** in the Actions column of a file to download the file.

 **Note** Before downloading a file, apply for the download permission.

• Manage APIs

In the left-side navigation pane, choose **Data Management > APIs** to go to the **APIs** page.

On the **APIs** page, you can edit, publish, or delete an API.

- Click **Edit** in the Actions column of an API. In the **Edit** dialog box that appears, you can edit the configuration of the API. Then, click **Submit**.
- Move the pointer over **Publish** in the Actions column of an API. In the dialog box that appears, click **Publish**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

 **Note** You can search for a published API in Data Asset Management.

- Move the pointer over **Delete** in the Actions column of an API. In the dialog box that appears, click **Delete**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

 **Note** You cannot search for a deleted API in Data Asset Management.

Manage classes

1. In the left-side navigation pane, click **Classes** to go to the **Classes** page.

On the **Classes** page, you can import or export a class.

2. Click the  icon. In the **Add Class** dialog box that appears, set relevant parameters and click **OK** to add a level-1 class

Parameter	Description
Name	The name of the class, which can be up to 128 characters in length.
Code	The code of the class. This parameter cannot be left empty.
Description	The description of the class.
Confidential	Specifies whether the class is confidential. Valid values: Yes and No .
Share	Specifies whether to share the class. Valid values: Yes , Conditional , and No .

To create a subclass under a class, click the  icon next to the class.

3. Click a class. On the page that appears, click the **Tables** tab.
4. Click **Add Table**. In the **Add Table** dialog box that appears, select the tables to be added to the class and click **OK**.

You can add files and APIs to a class in the same way.

To change the class of a table, click **Modify Class** in the Actions column. In the **Change Class** dialog box that appears, change the class as needed.

Manage business

In the left-side navigation pane, you can click **Business Management** and then **Business Units**, **Business Systems**, or **Connections** to manage business units, business systems, or connections.

-  **Note** Connections belong to a business system, and business systems belong to a business unit.
- A business system with connections cannot be deleted.
 - A business unit with business systems cannot be deleted.

• Manage business units

In the left-side navigation pane, choose **Business Management > Business Units** to go to the **Business Units** page.

Click the  icon. In the **Add Business Unit** dialog box that appears, set relevant parameters and click **OK** to add a business unit.

Parameter	Description
Name	The name of the business unit. This parameter cannot be left empty.
Code	The code of the business unit. By default, the code cannot be modified.
Description	The description of the business unit.
Confidential	Specifies whether the business unit is confidential. Valid values: Yes and No .
Share	Specifies whether to share the business unit. Valid values: Yes , Conditional , and No .
Business system included	Select the business systems to be added to the business unit and click the > icon.

To create a sub-business unit under a business unit, click the  icon next to the business unit.

• Manage business systems

In the left-side navigation pane, choose **Business Management > Business Systems** to go to the **Business Systems** page.

On the **Business Systems** page, you can add a business system. Then, you can view, edit, or delete the business system.

- Click **Add Business System**. In the **Basic information** dialog box that appears, set relevant parameters and click **Submit**.
- Click **View** in the **Actions** column of a business system to view its details.
- Click **Edit** in the **Actions** column of a business system. In the **Business System Properties** dialog box that appears, you can edit the configuration of the business system.
- Click **Delete** in the **Actions** column of a business system. In the **Delete business system** dialog box that appears, click **OK** to delete the business system.

• Manage connections

In the left-side navigation pane, choose **Business Management > Connections** to go to the **Connections** page.

On the **Connections** page, you can view the information of connections. The connection information includes the connection name, the number of tables, the owner, the business system to which the connection belongs, the data type, and the update time. You can also edit the configuration of a connection.

2.12.5. Manage authorizations

Under the **Permissions** tab, you can view permissions in different states on the **Submitted by Me**, **To Be Handled**, **Handled by Me**, and **My Permissions** pages respectively.

Go to the Permissions tab

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Asset Management**.
3. In the top navigation bar, click the **Permissions** tab.

Under the **Permissions** tab, you can view permissions in different states on the **Submitted by Me**, **To Be Handled**, **Handled by Me**, and **My Permissions** pages respectively.

Submitted by Me

In the left-side navigation pane, click **Submitted by Me**.

On the **Submitted by Me** page, you can view request details or cancel requests submitted by you. To resubmit a request that was not approved, find the target request and click **Reapply**.

To Be Handled

In the left-side navigation pane, click **To Be Handled**. On the **To Be Handled** page, you can view request details and approve or reject requests.

Handled by Me

In the left-side navigation pane, click **Handled by Me** to view requests handled by you.

My Permissions

In the left-side navigation pane, click **My Permissions**. On the **My Permissions** page, you can view your permissions on tables, files, and APIs respectively.

2.12.6. Perform cross-tenant authorization

Authorization logic

The logic of authorization within a tenant and that of cross-tenant authorization are as follows:

- **Authorization within a tenant:** An access control list (ACL) is used for authorization. You need to add the applicant to the corresponding workspace and then grant permissions to the applicant as requested.
- **Cross-tenant authorization:** A package is used for authorization. First, check whether the workspace where the requested resources reside has a package.
 - If the workspace does not have a package, create a package and add the requested resources to the package. Then, install the package in the workspace where the requested resources are used.
After that, use an ACL to grant permissions to the applicant as requested.
 - If the workspace has a package, add the requested resources to the package.

If the requested resources need to be shared with multiple workspaces, install the package in all these workspaces. If the workspace where the requested resources reside has multiple packages, install all of them in the workspaces where the requested resources are used.

Procedure

1. Log on to the DataWorks console. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Asset Management**.
2. On the **Asset Portal** tab, enter the name of the table that belongs to another tenant in the search box and click **Search**.
3. On the **Asset Category** tab that appears, click the name of the found table on the **Tables** tab. The details page of the table appears.

On the details page, you can view details about the table, including the basic information, business information, physical information, and field information.

4. Click **Request Permission** in the upper-right corner. The **Table Permission Request** page appears.
5. Set parameters on the **Table Permission Request** page.

Parameter	Description
Target Workspace	The workspace where the table is to be used.
Environment	The type of the environment where the table is to be used. If the selected workspace is in standard mode, you need to set this parameter to Development or Production .
Home Workspace	The workspace where the table resides. This parameter is automatically set.
Home Tenant	The tenant to which the table belongs. This parameter is automatically set.
Grant To	The account for which permissions on the table are requested. Valid values: Current Account and System Account for Production Environment .
Requested Period	The period in which the requested permissions are valid.
Reason for Request	The reason why you request the permissions. To improve the review efficiency, we recommend that you describe the reason in detail.
Objects Requested	The tables you want to use. By default, the current table is selected. You can select other tables.

6. After the configuration is completed, click **Submit**.

After you submit the request, click **Approval Management** in the top navigation bar and then click **Submitted by Me**. You can view the review progress on the page that appears.

- If you want to revoke a request, click **Revoke** in the Actions column of the request.
- If you want to submit a revoked or rejected request again, click **Reapply** in the Actions column of the request.

7. Log on to the DataWorks console as the table owner, go to the **Approval Management** tab and click

To Be Handled. On the page that appears, review the request information and click **Agree**.

After clicking **Agree**, click **Approval Management** in the top navigation bar and click **Handled by Me**. On the page that appears, you can view your authorization records and revoke specific authorizations.

2.13. Organization management

2.13.1. Member management

1. [Log on to the DataWorks console](#) as a workspace administrator.
2. Move your pointer over the DataWorks icon in the upper-left corner, and click **Project Management**.
3. Click **Member Management** in the left-side navigation bar. The **Members** page appears.
4. You can enter a member name or logon name in the search box to search for a member to be added or removed from the current organization.
 - Assign a role
To assign a role to a member, click the **Roles** drop-down list next to the member, and select the role to be assigned.
To unassign a role from a member, click **x** next to the role.
 - Remove a member from an organization
Click **Delete** next to the member, and click **OK** in the **Remove from Tenant** dialog box that appears.

2.13.2. Resource groups

2.13.2.1. Go to the page for managing scheduling resources

Scheduling resources are managed at the tenant level. An exclusive scheduling resource can consist of multiple physical machines for running nodes.

1. [Log on to the DataWorks console](#).
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Project Management**.
3. In the left-side navigation pane, click **Schedule Resources**. On the Schedule Resources page, manage scheduling resources as required.

 **Note** If you are the tenant administrator, you can modify existing scheduling resources on the Schedule Resources page.

2.13.2.2. Change the workspace to which a scheduling resource belongs

After you create and configure an exclusive scheduling resource, you can change the workspace to which the resource belongs.

Procedure

1. [Log on to the DataWorks console](#) as the tenant administrator.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Project Management**.
3. On the page that appears, click **Schedule Resources** in the left-side navigation pane. On the **Schedule Resources** page, enter a keyword in the search box in the upper-left corner. DataWorks searches for the

scheduling resources whose names contain the keyword in fuzzy match mode.

4. Find the target scheduling resource and click **Modify attribution**.
5. In the **Modify attribution** dialog box, select the workspace to which the exclusive scheduling resource will be bound.
6. Click **OK**.

2.13.3. Configure the compute engine

Currently, DataWorks only supports MaxCompute as its compute engine. All business flows and nodes in a workspace are run on the MaxCompute project associated to the workspace.

Example

 **Note** Tenant administrators can modify the settings for MaxCompute projects. The following settings are changeable: the project description, whether to use the MaxCompute project owner account to run MaxCompute jobs, the account used for running MaxCompute jobs, and the AccessKey of the account.

Assume that the account used for running MaxCompute jobs is no longer available, for example, because the account owner has resigned. If **Run MaxCompute Task Using MaxCompute Owner Account** is not selected, the tenant administrator needs to immediately modify the account used for running MaxCompute jobs and its AccessKey so that tasks can properly run in the workspace that uses the corresponding MaxCompute project.

Procedure

You can modify the account used for running MaxCompute jobs and its AccessKey as follows:

1. Log on to the DataWorks console as a tenant administrator. For more information, see [Log on to the DataWorks console](#).
2. Choose **Project Management > Compute Engine**.
3. In the search box on the **Project Management > Compute Engine** page, enter the compute engine name. Fuzzy search is supported.
4. Find the target compute engine, and click **Configure** in the Actions column.
5. In the **Configure Compute Engine** dialog box, specify the Alibaba Cloud Account and the AccessKey.

 **Note** You can also select **Run MaxCompute Task Using MaxCompute Owner Account** or create a new Alibaba Cloud account.

6. Click **Submit**.

2.14. Data Service

2.14.1. Overview

With Data Service, you can manage all your table APIs after you create new APIs or register existing APIs. You can also easily publish your APIs to API Gateway. Together with API Gateway, Data Service provides a secure, stable, low-cost, and easy-to-use data sharing service.

Data Service adopts a serverless architecture and allows you to develop table APIs without thinking about infrastructure such as compute resources. Data Service supports automatic scaling for compute resources, which significantly reduces your OPEX.

Create an API

In Data Service, you can quickly create APIs based on tables in relational databases or NoSQL databases using a visual wizard. It takes only a few minutes to configure a data API, and coding is not required. You can also create APIs by specifying SQL scripts. The script mode supports advanced functions such as associative tables, complex criteria, and aggregate functions.

Register an API

You can register existing RESTful APIs to Data Service for unified API management. Four request methods and three data formats are supported. The four request methods are GET, POST, PUT, and DELETE. The three data formats are tables, JSON, and XML.

API Gateway

API Gateway provides API lifecycle management services, including API publishing, management, maintenance, and monetization. It enables low-risk, simple, cost-effective, and fast microservice integration, front and back end separation, and system integration. You can use API Gateway to share functions and data with your partners and third-party developers.

API Gateway supports authorization, authentication, flow control, and billing for Data Service.

2.14.2. Terms

This section introduces terms of Data Service.

Name	Description
Data source	Indicates database links. Data Service accesses data through data sources. Data sources are configured in Data Integration.
Create an API	Creates APIs based on data tables.
Register an API	Registers existing APIs to Data Service for unified management.
Wizard mode	Guides you through the procedure of API creation. This method is suitable for beginners who want to create simple APIs. You do not need to write any code.
Script mode	Allows you to create APIs by writing SQL scripts. This method supports associative tables, complex queries, and aggregate functions. This method is suitable for experienced developers who want to create complex APIs.
API group	Indicates a set of APIs for a specific scenario or for consuming a specific service. An API group is the smallest group unit in Data Service, and the smallest unit for API Gateway management. API groups are published in Alibaba Cloud API Marketplace as API products.
API Gateway	Indicates a hosted service provided by Alibaba Cloud to manage APIs. API Gateway supports API lifecycle management, permission management, access management, and traffic control.

2.14.3. Manage tags

This topic describes how to create, add, view, and remove tags for an API.

DataService Studio allows you to add tags to APIs when you manage workflows and create, register, and deploy APIs. This topic uses the scenario of creating an API in the codeless UI as an example. Tags allow you to efficiently classify and search for APIs. You can maintain only one tag list in a workspace, and cannot use the tag list of a workspace in another workspace.

 **Note**

- Each API supports zero to five tags. That is, you can add no tags to an API at all or add a maximum of five tags to an API.
- The name of a tag can contain letters, digits, and underscores (_), and cannot exceed 20 characters in length.

Create a tag for an API

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All Products > Data Service**.
2. On the Service Development tab, move the pointer over  and choose **API > Generate API**.
3. In the **Generate API** dialog box, set the API mode parameter to Wizard Mode and enter a tag in the **Label** field.
If the tag you entered does not exist in the current workspace, Add <Tag> appears in the drop-down list. Click Add <Tag> to create the tag for the API.
4. Set other parameters and click **OK**. The tag is created for the API and appears in the tag list of the current workspace.

Add an existing tag to an API

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All Products > Data Service**.
2. On the Service Development tab, move the pointer over  and choose **API > Generate API**.
3. In the **Generate API** dialog box, set the API mode parameter to Wizard Mode and click a blank area or the downward arrow in the **Label** field. Tags in the current workspace appear in a drop-down list.
4. Click the required tag, set other parameters, and then click **OK**. The tag is added to the API.

View tags of an API

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All Products > Data Service**.
2. On the **Service Development** tab, double-click the name of the target API in the API list.
3. In the right-side navigation pane, click **Properties**. Then you can view the tags of the API in the **Label** column.

 **Note** You can also create, add, and remove tags for the API in the Properties pane.

If an API is published, you can also perform the following steps to view the tags of the API:

- i. In DataService Studio, click **Service Management** in the upper-right corner.
- ii. Click **Manage APIs** in the left-side navigation pane. On the page that appears, click the **APIs of Published** tab and click the name of the target API. The **API Details** page appears.
- iii. View the tags of the API under **Label** in the **API Basic Information** section.

Remove a tag from an API

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All Products > Data Service**.

2. On the **Service Development** tab, double-click the name of the target API in the API list.
3. In the right-side navigation pane, click **Properties**. Then, you can view the tags of the API in the **Label** column.
4. Click  next to the tag to remove.
5. Click **Publish** in the upper-right corner. The tag is removed from the API.

Search for APIs by tag

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All Products > Data Service**.
2. On the **Service Development** tab, click **Service Management** in the upper-right corner.
3. Click **Manage APIs** in the left-side navigation pane. On the page that appears, click the **APIs of Published** tab and view the tags of each API in the **Label** column.
If an API has multiple tags and some of them are hidden, click ... to show all the tags.
4. On the **APIs of Published** tab, click **Advanced Search**.
5. Enter a tag in the **Label** field to search for all APIs associated with the tag.

 **Note** You can search for APIs based on multiple tags.

2.14.4. Manage business processes and objects under business processes

2.14.4.1. Manage business processes

This topic describes how to create, modify, and delete a business process.

Context

DataWorks allows you to organize different types of resources in a business process. This helps you analyze data by business. Each business process contains APIs, functions, and workflows.

Create a business process

1. [Log on to the DataWorks console](#).
2. Click  in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, move the pointer over  and select **Business process**.
4. In the **New business process** dialog box, set the parameters as required.

New business process ✕

i An API Group is an API Gateway unit that manages APIs. All APIs under a business process belong to the API Group specified by the business process.

* Business Name : 0/50

The business name must be unique. It can contain 4 to 50 characters, including Chinese characters, English letters, numbers, and underscores in English format. It must start with an English letter or Chinese character.

* API grouping : Please Select ▾

To create a new group, you can jump [API Gateway](#) Create new grouping

Business Description : 0/180

Business Description, no more than 180 characters

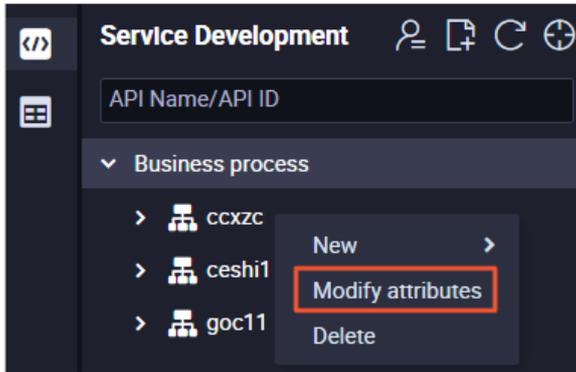

OK
Cancel

Parameter	Description
Business Name	<p>The name of the business process.</p> <ul style="list-style-type: none"> ◦ The name can contain letters, digits, and underscores (_). ◦ The name must start with a letter. ◦ The name must be 4 to 50 characters in length. ◦ The name must be unique in the workspace to which the business process belongs.
API Group	<p>The API group to which the APIs under the business process belong. An API group is the API management unit of API Gateway.</p> <p>You can select an API group from the drop-down list.</p> <p>DataService Studio creates a default API group named in the Workspace name_default format for each user. If you need to create an API group, click API Gateway in the note to go to the API Gateway console and create an API group.</p>
Business Description	<p>The description of the business process. The description can be up to 180 characters in length.</p>

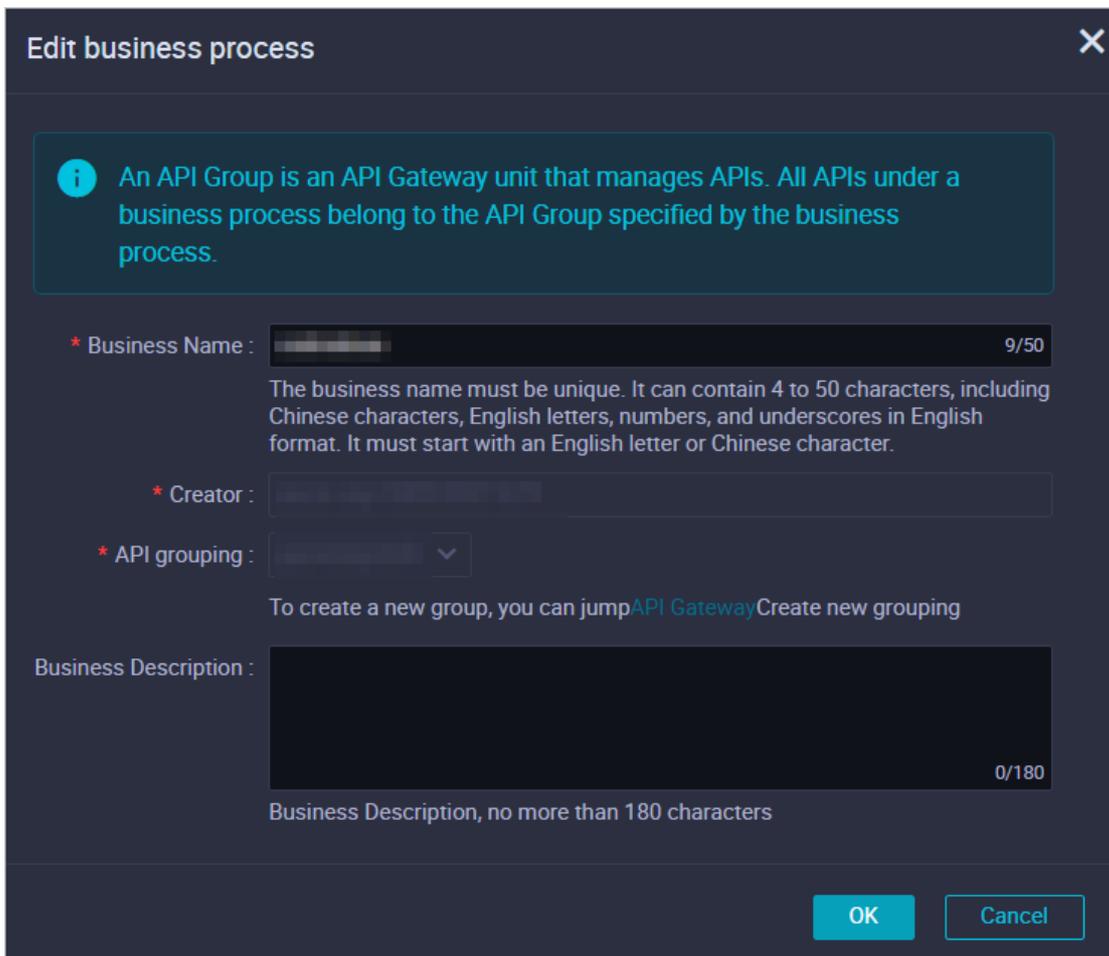

5. Click **OK**. After the business process is created, you can view it in the business process list.

Modify a business process

1. On the **Service Development** tab, right-click the name of the target business process and select **Modify attributes**.

2. In the **Edit business process** dialog box, modify the **Business Name** and **Business Description** parameters as required.

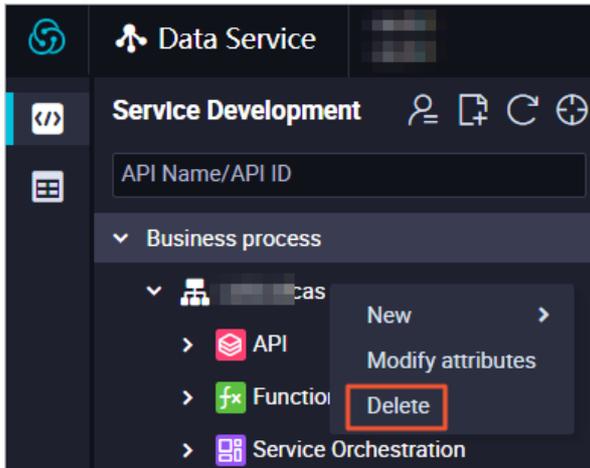

Note You cannot modify the **Creator** or **API Group** parameter of a business process.

3. Click **OK**.

Delete a business process

1. On the **Service Development** tab, right-click the name of the target business process and select **Delete**.

2. In the message that appears, click OK.

Note

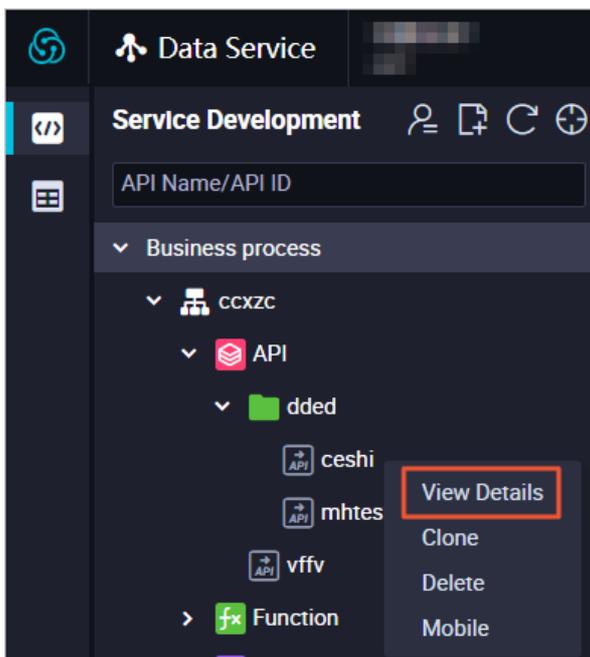

- You can delete only business processes that do not contain any objects such as APIs, functions, or workflows.
- If you need to delete a business process that contains such objects, delete the objects before you delete the business process.

2.14.4.2. Manage APIs

This topic describes how to view, clone, delete, and move APIs.

View an API

1. [Log on to the DataWorks console.](#)
2. Click  in the upper-left corner and choose **All Products > Data Service.**
3. On the **Service Development** tab, right-click the name of the target API and select **View Details.**

Note The **View Details** option appears only in the shortcut menu of an API that has been published. If an API has not been published, double-click the API to go to the configuration tab of the API. Then, click **Properties** in the right-side navigation pane to view its basic information.

Clone an API

You can clone an API to a specified directory in the directory tree.

1. On the **Service Development** tab, right-click the name of the target API and select **Clone**.
2. In the **Clone API** dialog box, set the parameters as required.

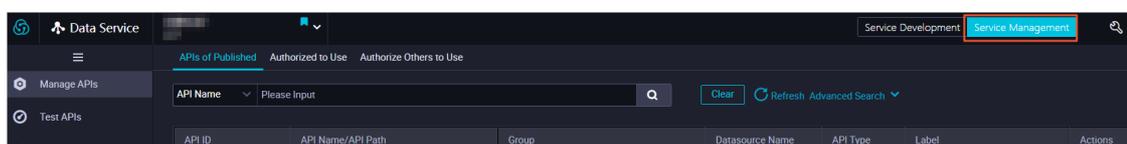

Parameter	Description
API Name	The name of the cloned API. It must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.
API Path	The path for storing the cloned API, for example, <i>/user</i> . The path can contain letters, digits, underscores (_), and hyphens (-). It must start with a forward slash (/) and can be up to 200 characters in length.
Target Folder	The directory for storing the cloned API.

3. Click **OK**.

Delete an API

You can delete only APIs that have not been published. To delete APIs that have been published, you must unpublish them first.

1. Optional. Unpublish the target API. If the API to be deleted is in the Unpublished state, skip this step.
 - i. Go to the **Service Development** tab and click **Service Management** in the upper-right corner.

- ii. On the page that appears, click the **APIs of Published** tab, find the target API, and then click **Unpublish** in the Actions column.
 - iii. In the **Unpublish API** message, click **OK**.
 - iv. Click **Service Development** in the upper-right corner to return to the **Service Development** tab.
2. On the **Service Development** tab, right-click the name of the target API and select **Delete**.
 3. In the **Delete API** message, click **OK**.

Note Deleted APIs cannot be recovered. Use caution when you delete an API.

Move an API to another directory

You can move only APIs that have not been published. To move APIs that have been published, you must unpublish them first.

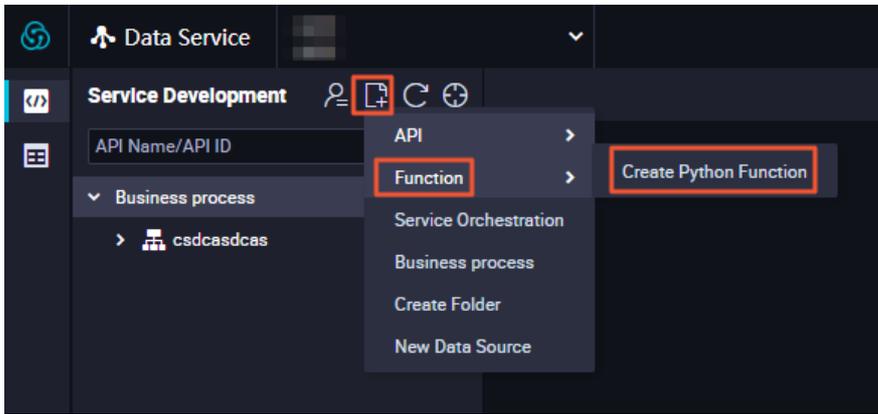

1. On the **Service Development** tab, right-click the name of the target API and select **Mobile**.
2. In the **Modify file path** dialog box, set the **Target Folder** parameter.
3. Click **OK**.

2.14.4.3. Manage functions

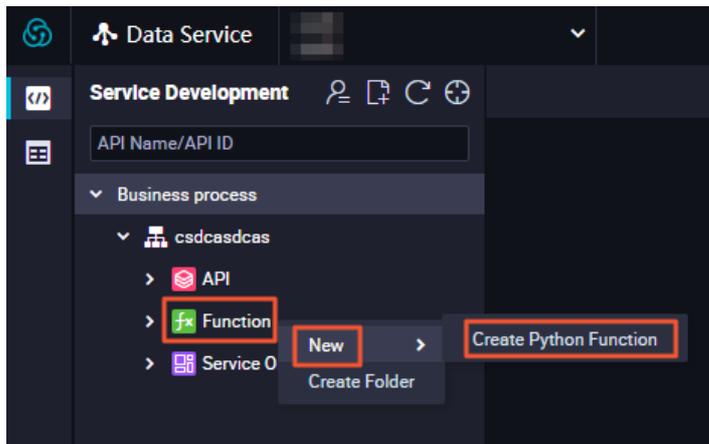

This topic describes how to create, clone, delete, and move Python functions.

Create a function

1. [Log on to the DataWorks console](#).
2. Click  in the upper-left corner and choose **All Products > Data Service**.
3. Move the pointer over  and choose **Function > Create Python Function**.

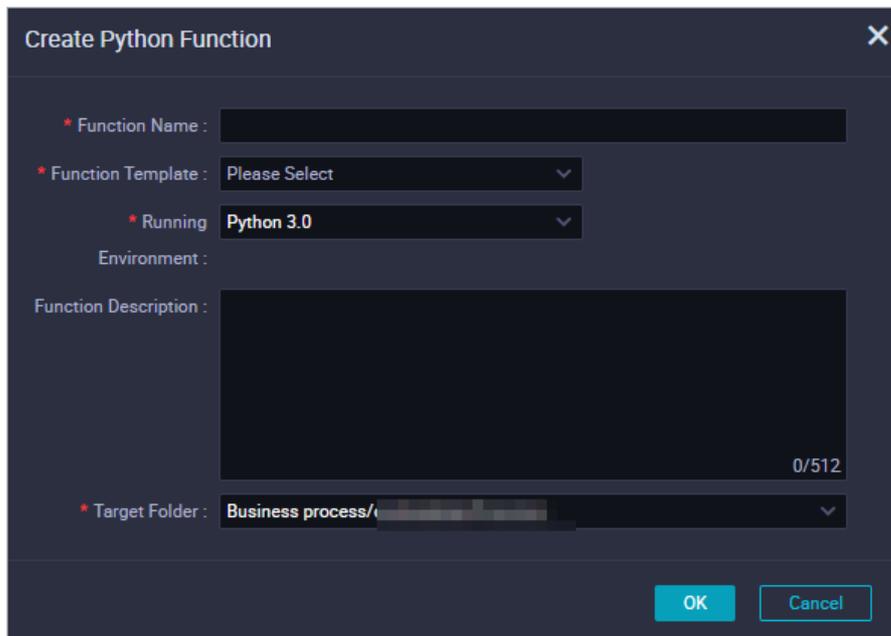

You can also click a business process, right-click **Function**, and then choose **New > Create Python Function**.

Notice DataService Studio allows you to create only Python functions.

4. In the **Create Python Function** dialog box, set the parameters as required.

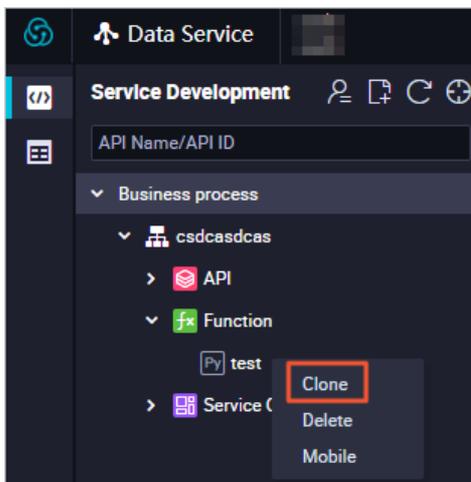

Parameter	Description
Function Name	The name of the function to create, which can be up to 256 characters in length.
Function Template	The template used to create the function. Set the value to Python3 Standard v1.
Running Environment	The runtime environment of the function. Set the value to Python 3.0.
Function Description	The description of the function. The description can be up to 512 characters in length.

Parameter	Description
Target Folder	The directory for storing the function.

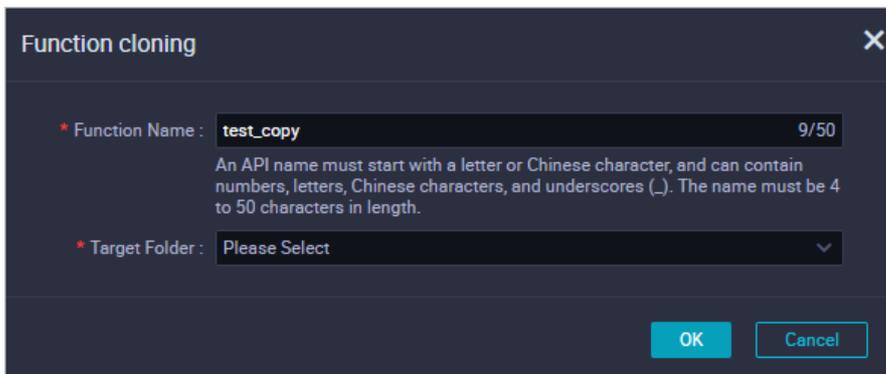

5. Click OK.
6. On the configuration tab of the function, configure the function.
 - i. In the **Edit Code** section, enter the function code.
 - ii. In the **Environment Configuration** section, set the **Memory** and **Function Timeout** parameters.
7. Click Save icon in the toolbar.

Clone a function

1. On the **Service Development** tab, right-click the name of the target function and select **Clone**.

2. In the **Function cloning** dialog box, set the **Function Name** and **Target Folder** parameters.

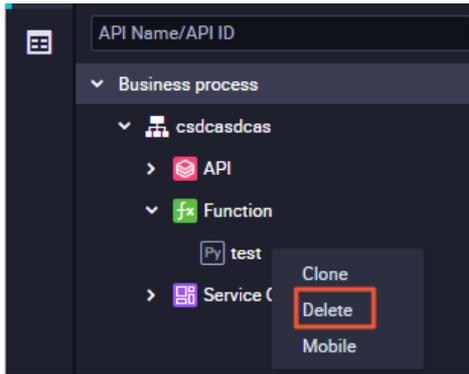

Note The name of the function must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.

3. Click OK.

Delete a function

1. On the **Service Development** tab, right-click the name of the target function and select **Delete**.

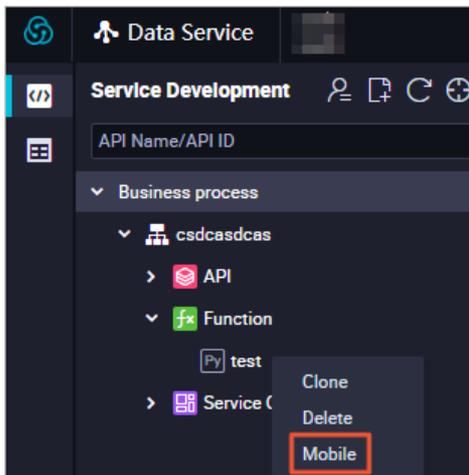

2. In the message that appears, click OK.

Note You can delete only functions that are not referenced by APIs. You must remove the function from the filters of the APIs that reference the function before you can delete the function.

Move a function to another directory

1. On the **Service Development** tab, right-click the name of the target function and select **Mobile**.

2. In the **Modify file path** dialog box, set the **Target Folder** parameter.
3. Click OK.

2.14.4.4. Manage workflows

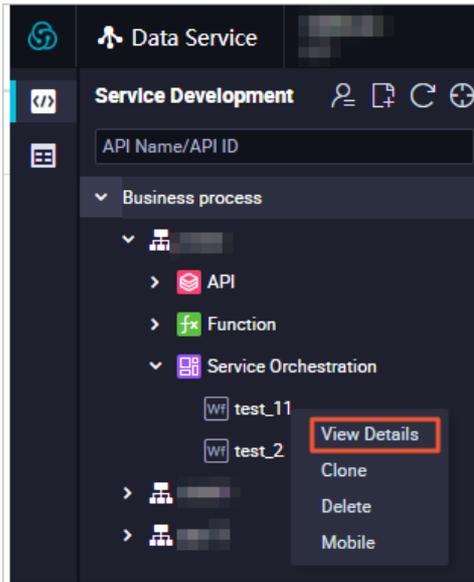

This topic describes how to view, clone, delete, and move a workflow.

Prerequisites

Workflows are created and published. For more information, see [Use workflows](#).

View a workflow

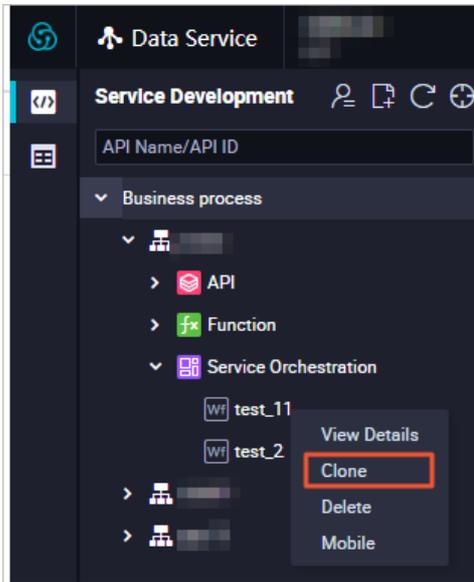

1. [Log on to the DataWorks console](#).
2. Click  in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, right-click the name of the target workflow and select **View Details**.

Note The View Details option appears only in the shortcut menu of a workflow that has been published. If a workflow has not been published, double-click the workflow to go to the configuration tab of the workflow. Then, click **Properties** in the right-side navigation pane to view its basic information.

Clone a workflow

1. On the **Service Development** tab, right-click the name of the target workflow and select **Clone**.

2. In the **Clone API** dialog box, set the parameters as required.

Parameter	Description
API Name	The name of the cloned workflow. It must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.

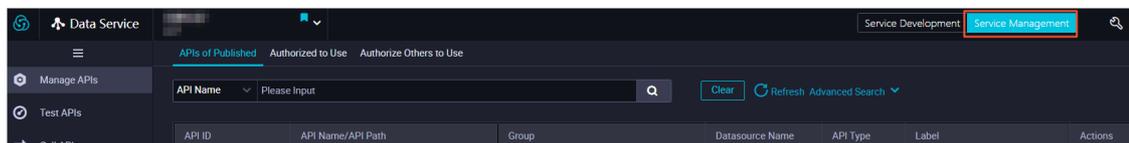

Parameter	Description
API Path	The path for storing the cloned workflow, for example, <i>/user</i> . The path can contain letters, digits, underscores (_), and hyphens (-). It must start with a forward slash (/) and can be up to 200 characters in length.
Target Folder	The directory for storing the cloned workflow.

3. Click **OK**.

Delete a workflow

You can delete only workflows that have not been published. To delete workflows that have been published, you must unpublish them first.

1. Optional. Unpublish the target workflow. If the workflow to be deleted is in the Unpublished state, skip this step.
 - i. Go to the **Service Development** tab and click **Service Management** in the upper-right corner.

- ii. On the page that appears, click the **APIs of Published** tab, find the target API, and then click **Unpublish** in the Actions column.
 - iii. In the **Unpublish API** message, click **OK**.
 - iv. Click **Service Development** in the upper-right corner to return to the **Service Development** tab.
2. On the **Service Development** tab, right-click the name of the target workflow and select **Delete**.
 3. In the **Delete API** message, click **OK**.

Note Deleted workflows cannot be recovered. Use caution when you delete a workflow.

Move a workflow to another directory

You can move only workflows that have not been published. To move workflows that have been published, you must unpublish them first.

1. On the **Service Development** tab, right-click the name of the target workflow and select **Mobile**.
2. In the **Modify file path** dialog box, set the **Target Folder** parameter.
3. Click **OK**.

2.14.5. Create an API

In Data Service, you can quickly create APIs based on tables in relational databases or NoSQL databases using a visual wizard. It takes only a few minutes to configure a data API, and coding is not required.

You can also create APIs by specifying SQL scripts. The script mode supports advanced functions such as associative tables, complex criteria, and aggregate functions.

The differences between the wizard mode and script mode are described as follows:

Differences between the wizard mode and script mode

Category	Description	Wizard mode	Script mode
Query object	Queries a single table from one data source	Supported	Supported
	Queries associative tables from one data source	Not supported	Supported
Search condition	Searches for an exact number	Supported	Supported
	Searches for a range of numbers	Not supported	Supported
	Matches an exact string	Supported	Supported
	Performs fuzzy search for strings	Supported	Supported
	Sets required and optional parameters	Supported	Supported
Query result	Returns the field value	Supported	Supported
	Performs a mathematical calculation for field values	Not supported	Supported
	Performs an aggregate operation on field values	Not supported	Supported
	Displays results with pagination	Supported	Supported

2.14.5.1. Configure connections

DataService Studio allows you to obtain table schemas and query data through APIs from connections.

 **Note** Before generating an API, make sure that you have configured the relevant connections.

You can click **Connections** on the **Data Integration** page to configure connections. The following table lists the available connection types and supported configuration modes.

Connection name	Create an API in the codeless UI	Create an API in the code editor
ApsaraDB for RDS	Supported	Supported
DRDS	Supported	Supported
ApsaraDB for MySQL	Supported	Supported
ApsaraDB for PostgreSQL	Supported	Supported
ApsaraDB for SQL Server	Supported	Supported
Oracle	Supported	Supported

Connection name	Create an API in the codeless UI	Create an API in the code editor
AnalyticDB	Supported	Supported
Table Store	Supported	Not supported
MongoDB	Supported	Not supported

2.14.5.2. Create an API in the codeless UI

DataWorks allows you to create APIs by setting parameters in the codeless UI without the need to write code. This topic describes how to create an API in the codeless UI.

Prerequisites

Connections are configured on the **Data Source** page. For more information, see [Configure data sources](#).

Create an API

1. Log on to the DataWorks console.
2. Click  in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, move the pointer over  and choose **API > Generate API**. You can also click a business process, right-click **API**, and then choose **New > Generate API**.
4. In the **Generate API** dialog box, set the parameters as required.

Parameter	Description
API mode	The mode for creating the API. Valid values: Wizard Mode and Script Mode . In this example, select Wizard Mode .
API Name	The name of the API. The name must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.
API Path	The path for storing the API, for example, <i>/user</i> .
Call Mode	The mode for calling the API. Valid values: Synchronous Call and Asynchronous Call . <ul style="list-style-type: none"> ◦ If you set this parameter to Synchronous Mode, the API returns results immediately after it is called. The synchronous mode is most commonly used. ◦ If you set this parameter to Asynchronous Mode, the API returns the RequestID parameter immediately after it is called. The API caller can then obtain the call result from a message queue based on the request ID.
Protocol	The protocol used by the API. Valid values: HTTP and HTTPS .
Request Method	The request method used by the API. Valid values: GET and POST .

Parameter	Description
Response Content Type	The return type of the API. Set the value to JSON .
Visible Range	<p>The visibility of the API. Valid values:</p> <ul style="list-style-type: none"> ◦ Work Space: The API is visible to all members in the current workspace. ◦ Private: The API is visible only to its owner and permissions on the API cannot be granted to other users. <p>Note If you set the Visible Range parameter to Private, the API is visible only to you in the directory tree. It is hidden to other members of the workspace.</p>
Label	<p>The tag of the API. Select one or more tags from the drop-down list. For more information, see Manage tags.</p> <p>Note You can set at most five tags for an API.</p>
Description	The description of the API, which can be up to 2,000 characters in length.
Target Folder	The directory for storing the API.

5. Click **OK**.

Configure the API

1. Double-click the API in the directory tree. On the configuration tab that appears, set the **DataSource Type**, **DataSource Name**, and **Table Name** parameters in the **Select Table** section.

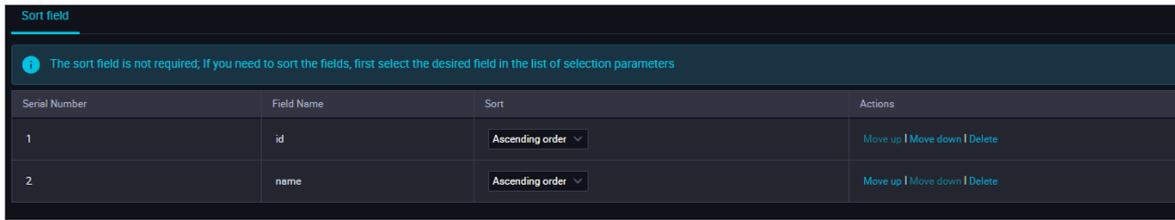

Note

- Before you select a table for an API, you must configure a connection in Data Integration. You can enter a table name in the Table Name field to search for the desired table.
- After you create an API, the table configuration tab automatically appears for you to select a table for the API.

2. In the **Environment Configuration** section, set the **Memory** and **Function Timeout** parameters.
3. In the **Select Parameters** section, set the request and response parameters for the API. After you select a table in the **Select Table** section, all fields in the table appear in the **Select Parameters** section. Select the required fields and select the check boxes in the **Set as Req Param** and **Set as Resp Param** columns as required.

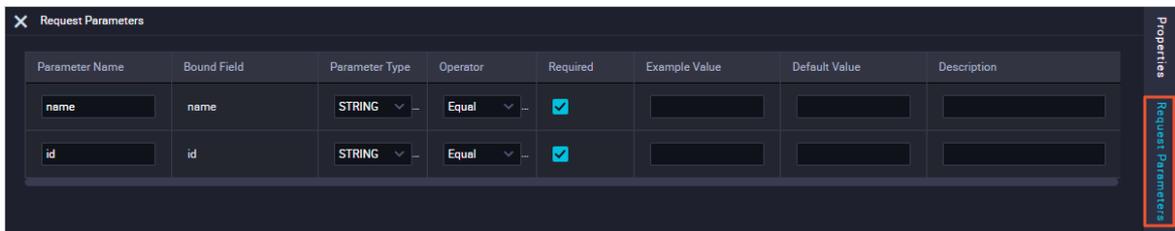

<input type="checkbox"/> Set as Req Param	<input type="checkbox"/> Set as Resp Param	Field Name	Field Type	Field Description	Field sorting
<input checked="" type="checkbox"/>	<input type="checkbox"/>	id	BIGINT UNSIGNED		Add to field sort
<input type="checkbox"/>	<input checked="" type="checkbox"/>	gmt_create	DATETIME		Add to field sort

To sort the data returned by the API based on a field, click **Add to field sort** in the Actions column of the field to add it to the **Sort field** section.

The sorting feature allows you to specify the fields based on which the parameters returned by the API are sorted. A field with a smaller sequence number in the Sort field section has a higher priority in sorting. You can click **Move up** or **Move down** to adjust the sequence of a field. You can specify the sorting mode for each field by selecting **Ascending order** or **Descending order** in the Sort column.

- In the right-side navigation pane, click **Request Parameters**. In the Request Parameters pane, set the parameters as required.

Parameter	Description
Parameter Name	The name of the request parameter. The name can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter and can be up to 64 characters in length.
Bound Field	The field to be bound to the request parameter. You cannot change the value.
Parameter Type	The type of the request parameter. Valid values: STRING , INT , LONG , FLOAT , DOUBLE , and BOOLEAN .

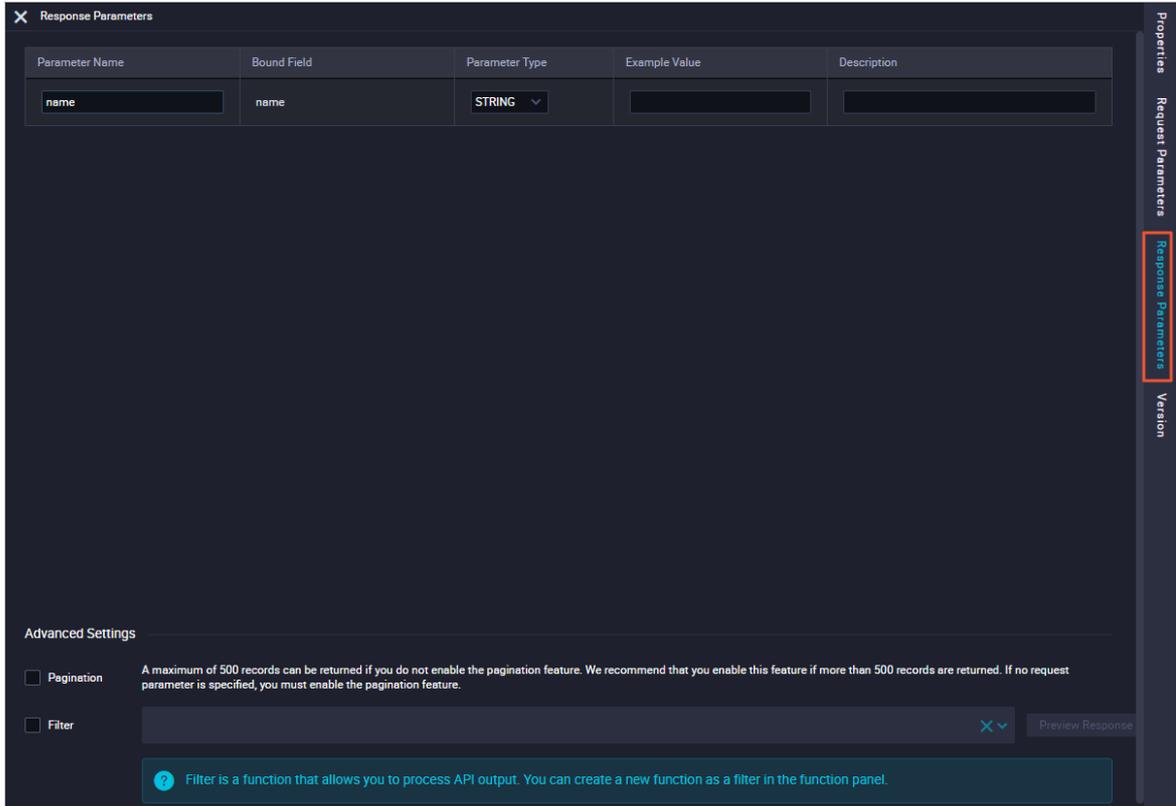

Parameter	Description
Operator	<p>The operator that is used to associate or compare the value of the request parameter with the specified value. You can select one of the following operators:</p> <ul style="list-style-type: none"> ◦ Equal: The value of the request parameter is equal to the specified value. ◦ LIKE: The value of the request parameter matches the specified pattern. ◦ IN: The value of the request parameter is in the specified range. ◦ NOT IN: The value of the request parameter is out of the specified range. ◦ NOT LIKE: The value of the request parameter does not match the specified pattern. ◦ ! =: The value of the request parameter is not equal to the specified value. ◦ >: The value of the request parameter is greater than the specified value. ◦ <: The value of the request parameter is less than the specified value. ◦ >=: The value of the request parameter is greater than or equal to the specified value. ◦ <=: The value of the request parameter is less than or equal to the specified value.
Required	Specifies whether the request parameter is required.
Example Value	The sample value of the request parameter.
Default Value	The default value of the request parameter.
Description	The description of the request parameter.

To preprocess the request parameters of the API, select **Use prefilter** in the **Advanced Settings** section. For more information, see [Use prefilters](#).

 **Note**

- To enhance the matching efficiency, set an indexed field as a request parameter.
- To make it easier for API callers to know the details about the API, we recommend that you specify information such as the sample value, default value, and description for each parameter of the API.

5. In the right-side navigation pane, click **Response Parameters**. In the Response Parameters pane, set the parameters as required.

Parameter	Description
Parameter Name	The name of the response parameter. The name can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter and can be up to 64 characters in length.
Bound Field	The field to be bound to the response parameter. You cannot change the value.
Parameter Type	The type of the response parameter. Valid values: STRING , INT , LONG , FLOAT , DOUBLE , and BOOLEAN .
Example Value	The sample value of the response parameter.
Description	The description of the response parameter.

You can select **Pagination** and **Filter** in the **Advanced Settings** section.

Select **Pagination** based on your needs.

- If you do not select **Pagination**, the API returns a maximum of 2,000 records by default.
- If the API may return more than 2,000 records, we recommend that you select **Pagination**.

The following common parameters are available when **Pagination** is selected:

- Common request parameters
 - **pageNum**: the number of the page to return.
 - **pageSize**: the number of entries to return on each page.
- Common response parameters
 - **pageNum**: the page number of the returned page.

- `pageSize`: the number of entries returned per page.
- `totalNum`: the total number of returned entries.

If you need to process the query results returned by the API, select **Filter**.

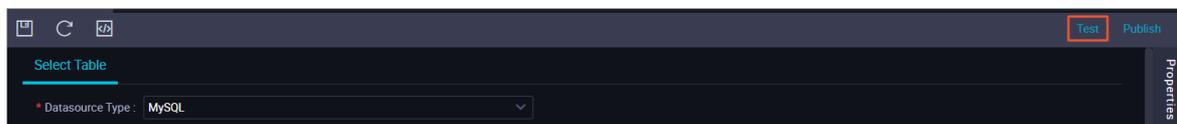

Note

- Field values are returned in the response as they are in the table.
- Request parameters are optional for an API. If you do not specify any request parameters for an API, you must select **Pagination**.

6. Click **Save** icon in the toolbar.

Test the API

1. After you save the settings of the API, click **Test** in the upper-right corner.

2. In the **Test APIs** dialog box, click **Test** to send an API request. The request and response details appear on the right. If the API fails the test, check the error message, modify the API settings accordingly, and test the API again.

You can select **Save the correct response example automatically** as required.

Note

- The system automatically generates sample failure responses and error codes when it tests an API. However, the system does not automatically generate sample success responses. To allow the system to save the success test result as a sample success response, you must select **Save the correct response example automatically** before you perform the test. If the response contains sensitive data that must be de-identified, you can manually edit the response.
- The sample success response is an important reference for API callers, and therefore must be configured.
- The Call Latency value is the latency of the current API request, which is used to evaluate the API performance. If the latency is long, consider optimizing the database.

3. After the API is tested, close the **Test APIs** dialog box and click **Publish** in the upper-right corner of the configuration tab.

Switch from the codeless UI to the code editor

On the configuration tab of an API, you can switch from the codeless UI to the code editor.

1. Go to the **Service Development** tab and double-click the target API. The configuration tab of the API appears.
2. Click  in the toolbar.
3. In the message that appears, click **OK**. Then, you can view the SQL statements of the API in the **Edit query SQL** section.

 Notice

- DataService Studio allows you to switch only from the codeless UI to the code editor.
- After you switch from the codeless UI to the code editor, you cannot switch back to the codeless UI.

2.14.5.3. Create an API in the code editor

To meet the requirements of advanced data query, DataService Studio allows you to create an API by writing an SQL script in the code editor. DataService Studio supports table join queries, complex queries, and aggregate functions. This topic describes how to create an API in the code editor.

Prerequisites

Connections are configured on the **Data Source** page. For more information, see [Configure data sources](#).

Create an API

1. [Log on to the DataWorks console](#).
2. Click  in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, move the pointer over  and choose **API > Generate API**. You can also click a workflow, right-click **API**, and then choose **New > Generate API**.
4. In the **Generate API** dialog box, set the parameters as required.

Parameter	Description
API mode	The mode for creating the API. Valid values: Wizard Mode and Script Mode . In this example, select Script Mode .
API Name	The name of the API. The name must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.
API Path	The path for storing the API, for example, <i>/user</i> .
Call Mode	The mode for calling the API. Valid values: Synchronous Call and Asynchronous Call . <ul style="list-style-type: none">◦ If you set this parameter to Synchronous Mode, the API returns results immediately after it is called. The synchronous mode is most commonly used.◦ If you set this parameter to Asynchronous Mode, the API returns the RequestID parameter immediately after it is called. The API caller can then obtain the call result from a message queue based on the request ID.
Protocol	The protocol used by the API. Valid values: HTTP and HTTPS .
Request Method	The request method used by the API. Valid values: GET and POST .
Response Content Type	The return type of the API. Set the value to JSON .

Parameter	Description
Visible Range	<p>The visibility of the API. Valid values:</p> <ul style="list-style-type: none"> ◦ Work Space: The API is visible to all members in the current workspace. ◦ Private: The API is visible only to its owner and permissions on the API cannot be granted to other users. <div style="border: 1px solid #ccc; background-color: #e0f2f1; padding: 5px; margin-top: 10px;"> <p>? Note If you set the Visible Range parameter to Private, the API is visible only to you in the directory tree. It is hidden to other members of the workspace.</p> </div>
Label	<p>The tag of the API. Select one or more tags from the drop-down list. For more information, see Manage tags.</p> <div style="border: 1px solid #ccc; background-color: #e0f2f1; padding: 5px; margin-top: 10px;"> <p>? Note You can set at most five tags for an API.</p> </div>
Description	The description of the API, which can be up to 2,000 characters in length.
Target Folder	The directory for storing the API.

5. Click OK.

Configure the API

1. Double-click the API. On the configuration tab that appears, set the **Datasource Type** and **Datasource Name** parameters in the **Select Table** section.

Select Table

* Datasource Type : Select data source type ▼

* Datasource Name : Select data source ▼ ?

? **Note** You must configure a connection in Data Integration in advance. You can enter a keyword in the Table Name field to search for the desired table.

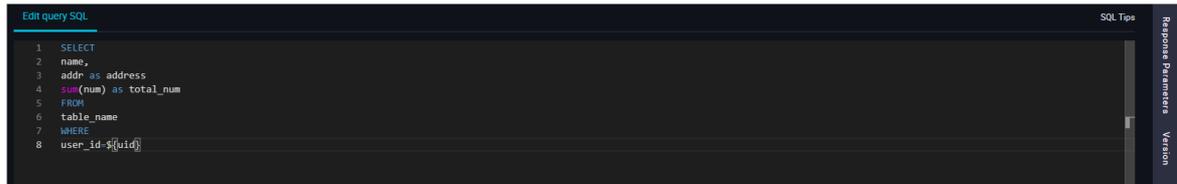

2. In the **Environment Configuration** section, set the **Memory** and **Function Timeout** parameters.

Environment Configuration

* Memory : 4096M ▼

Function Timeout : 10000 ms

3. In the **Edit query SQL** section, enter the SQL statement for querying data.

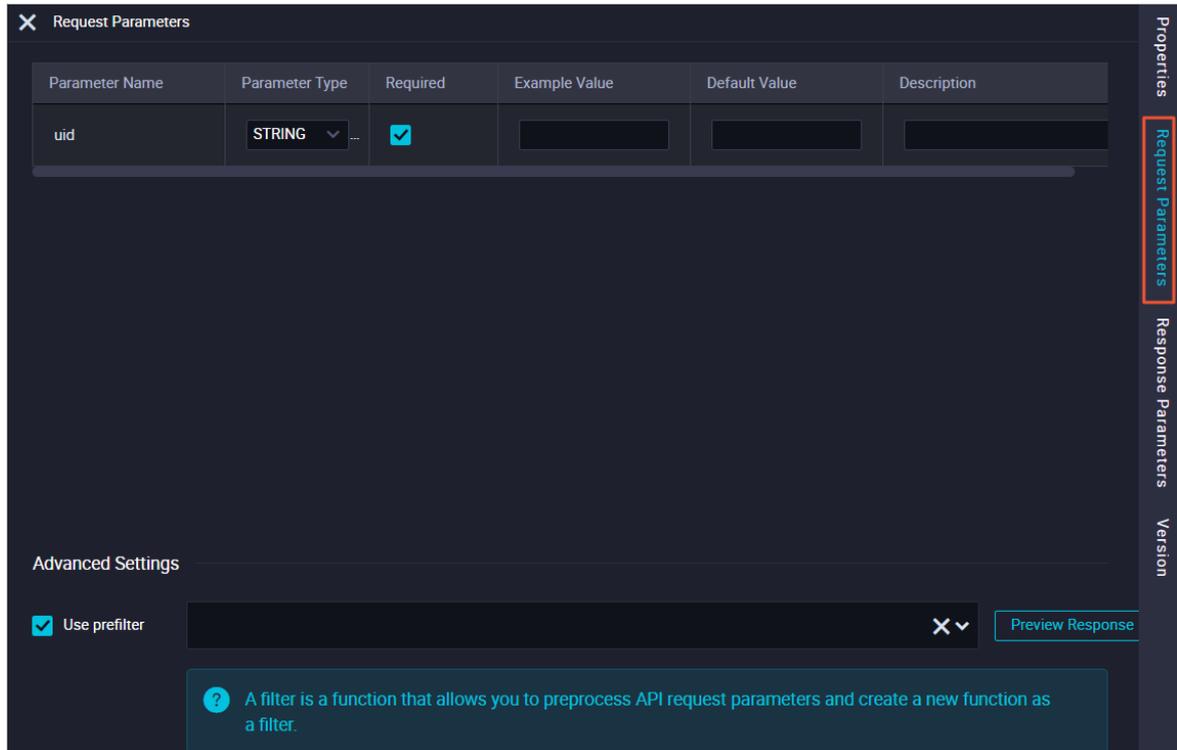

```
1 SELECT
2 name,
3 addr as address
4 sum(num) as total_num
5 FROM
6 table_name
7 WHERE
8 user_id=${uid}
```

Note The SELECT clause specifies the parameters that the API returns. The WHERE clause specifies the request parameters of the API. You must use `${}` to interpolate a request parameter.

Follow these rules when you enter the SQL statement :

- You can enter only one SQL statement in the script editor.
 - Only the SELECT clause is supported. Other clauses such as INSERT , UPDATE, and DELETE are not supported.
 - The clause `SELECT *` is not supported. You must specify the columns to be queried.
 - Single-table queries, table join queries, and nested queries under the same connection are supported.
 - If the name of the column that the SELECT clause specifies has a table prefix, for example, `t.name`, you must create an alias for the corresponding response parameter, for example, `t.name as name`.
 - If you use an aggregate function, such as `min`, `max`, `sum`, or `count`, you must create an alias for the corresponding response parameter, for example, `sum(num) as total_num`.
 - `${param}` in the SQL statement and that in character strings are regarded as request parameters and replaced. If an escape character `\` is placed before `${param}`, `${param}` is processed as a common string.
 - `${param}` cannot be enclosed in single quotation marks (`' '`). For example, `'${id}'` and `'abc${xyz}123'` are not allowed. If necessary, you can use `concat('abc', ${xyz}, '123')` instead.
 - Parameters cannot be configured as optional.
 - `${param}` is not allowed in comments. For example, `--${id}` is not allowed.
4. In the right-side navigation pane, click **Request Parameters**. In the Request Parameters pane, set the parameters as required.

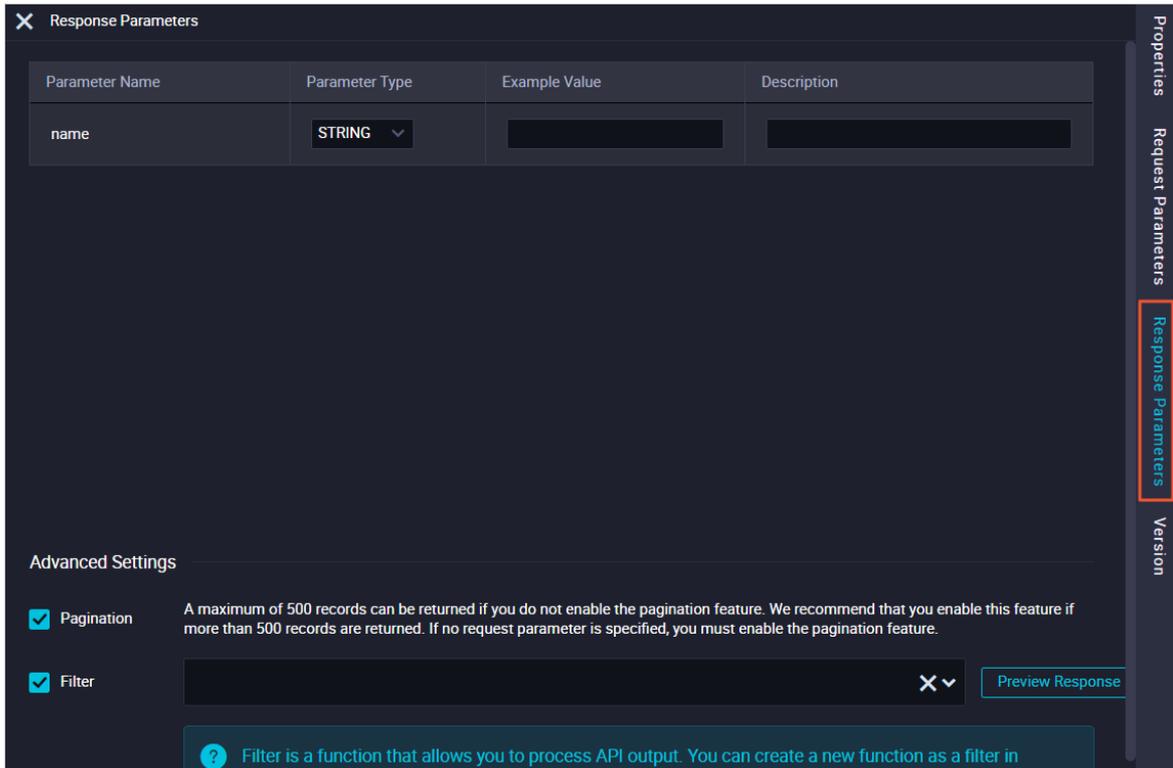

Parameter	Description
Parameter Name	The name of the request parameter. The name can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter and can be up to 64 characters in length.
Parameter Type	The type of the request parameter. Valid values: STRING , INT , LONG , FLOAT , DOUBLE , and BOOLEAN .
Required	Specifies whether the request parameter is required.
Example Value	The sample value of the request parameter.
Default Value	The default value of the request parameter.
Description	The description of the request parameter.

To preprocess the request parameters of the API, select **Use prefilter** in the **Advanced Settings** section. For more information, see [Use prefilters](#).

Note

- To enhance the matching efficiency, set an indexed field as a request parameter.
- To make it easier for API callers to know the details about the API, we recommend that you specify information such as the sample value, default value, and description for each parameter of the API.

- In the right-side navigation pane, click **Response Parameters**. In the Response Parameters pane, set the parameters as required.

Parameter	Description
Parameter Name	The name of the response parameter. The name can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter and can be up to 64 characters in length.
Parameter Type	The type of the response parameter. Valid values: STRING , INT , LONG , FLOAT , DOUBLE , and BOOLEAN .
Example Value	The sample value of the response parameter.
Description	The description of the response parameter.

You can select **Pagination** and **Filter** in the **Advanced Settings** section.

Select **Pagination** based on your needs.

- If you do not select **Pagination**, the API returns a maximum of 2,000 records by default.
- If the API may return more than 2,000 records, we recommend that you select **Pagination**.

The following common parameters are available when **Pagination** is selected:

- Common request parameters
 - **pageNum**: the number of the page to return.
 - **pageSize**: the number of entries to return on each page.
- Common response parameters
 - **pageNum**: the page number of the returned page.
 - **pageSize**: the number of entries returned per page.
 - **totalNum**: the total number of returned entries.

If you need to process the query results returned by the API, select **Filter**.

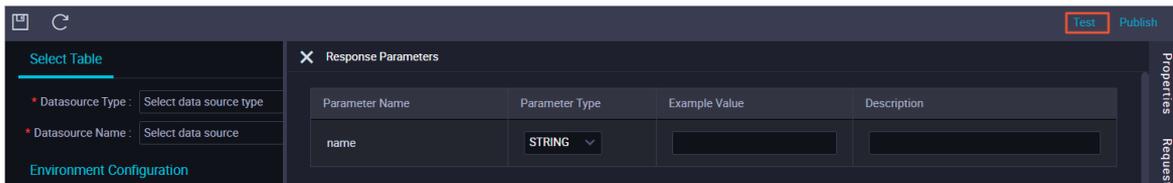

Note

- Field values are returned in the response as they are in the table.
- Request parameters are optional for an API. If you do not specify any request parameters for an API, you must select **Pagination**.

6. Click Save icon in the toolbar.

Test the API

1. After you save the settings of the API, click **Test** in the upper-right corner.

2. In the **Test APIs** dialog box, click **Test** to send an API request. The request and response details appear on the right. If the API fails the test, check the error message, modify the API settings accordingly, and test the API again.

You can select **Save the correct response example automatically** as required.

Note

- The system automatically generates sample failure responses and error codes when it tests an API. However, the system does not automatically generate sample success responses. To allow the system to save the success test result as a sample success response, you must select **Save the correct response example automatically** before you perform the test. If the response contains sensitive data that must be de-identified, you can manually edit the response.
- The sample success response is an important reference for API callers, and therefore must be configured.
- The Call Latency value is the latency of the current API request, which is used to evaluate the API performance. If the latency is long, consider optimizing the database.

3. After the API is tested, close the **Test APIs** dialog box and click **Publish** in the upper-right corner of the configuration tab.

2.14.5.4. Use filters

2.14.5.4.1. Use prefilters

A prefilter is a function that is used to process request parameters of APIs. You can specify one or more prefilters to customize the request content for APIs. This topic describes the limits of prefilters, the built-in function template provided by the system, and how to create functions and use them as prefilters.

Context

Prefilters have the following limits:

- Only Python 3.0 functions can be used as prefilters.
- Prefilters support importing only the following modules: json, time, random, pickle, re, and math.

- The function name of a prefilter must be `def handler(event,context):` .

Function template

The system provides the following built-in function template:

```
# -*- coding: utf-8 -*-
# event (str) : in filter it is the API result, in other cases, it is your param
# context : some environment information, temporarily useless
# import module limit: json,time,random,pickle,re,math
# do not modify function name
import json
def handler(event,context):
# load str to json object
obj = json.loads(event) # Convert the string specified by the event parameter to a JSON object.
# add your code here
# end add
return obj
```

You can modify the function template to write your own function. You can modify the names of the input parameters as needed.

```
Parameter 1 [context]: the context of calling APIs. The value is of the STRING type. This parameter is not in use and is left empty.
Parameter 2 [event]: the result data returned by APIs or the preceding filter. The value is of the STRING type.
```

Create a Python function

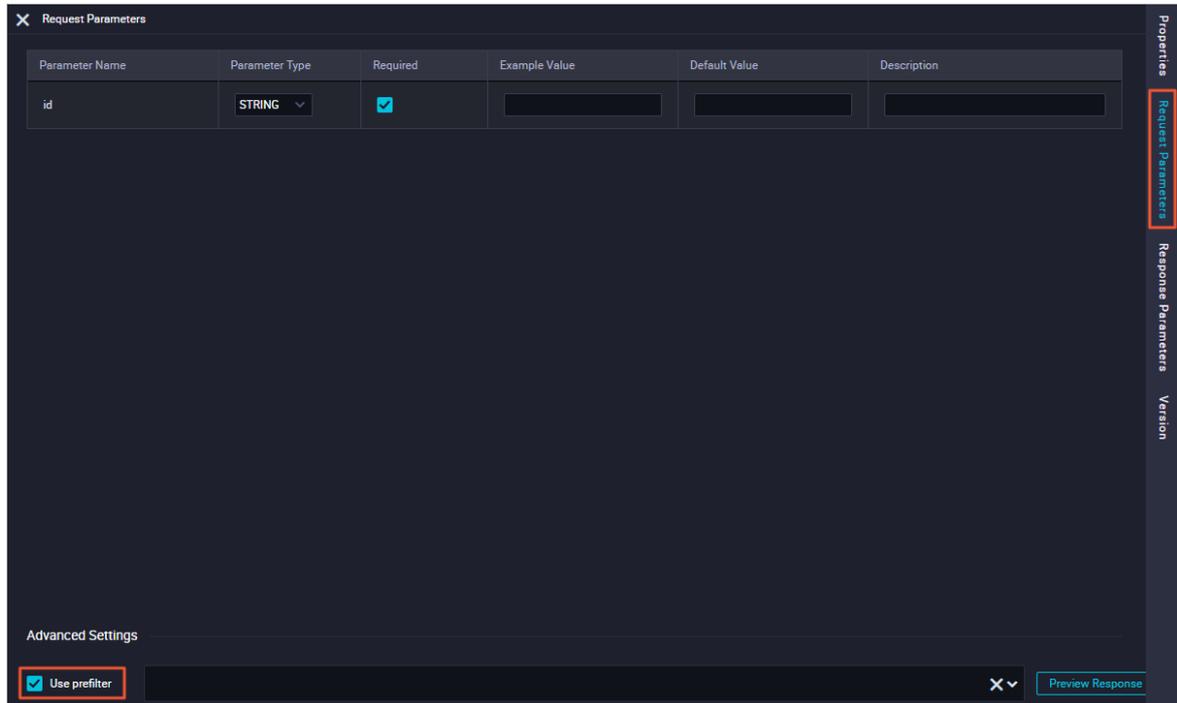

1. Log on to the DataWorks console.
2. Click  in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, move the pointer over  and choose **Function > Create Python Function**. You can also click a workflow, right-click **Function**, and then choose **New > Create Python Function**.
4. In the **Create Python Function** dialog box, set the parameters as required.

Parameter	Description
Function Name	The name of the function to create, which can be up to 256 characters in length.
Function Template	The template used to create the function. Set the value to Python3 Standard v1.
Running Environment	The runtime environment of the function. Set the value to Python 3.0.
Function Description	The description of the function.
Target Folder	The directory for storing the function.

5. Click **OK**.

Use prefilters

1. On the **Service Development** tab, double-click the target API.
2. On the configuration tab that appears, click **Request Parameters** in the right-side navigation pane.
3. In the **Request Parameters** pane, select **Use prefilter** in the **Advanced Settings** section.

4. Select functions from the **Use prefilter** drop-down list.

Note A prefilter is a function that is used to process request parameters of APIs. You can create a function and use it as a prefilter.

5. Click **Preview Response** to view the processing results of the prefilters.

2.14.5.4.2. Use post filters

A post filter is a function that is used to process the results returned by APIs. You can specify one or more post filters to process the results returned by APIs. This topic describes the limits of post filters, the built-in function template provided by the system, and how to create functions and use them as post filters.

Context

Post filters have the following limits:

- Only Python 3.0 functions can be used as post filters.
- Post filters support importing only the following modules: json, time, random, pickle, re, and math.
- The function name of a post filter must be `def handler(event,context):`.

Function template

The system provides the following built-in function template:

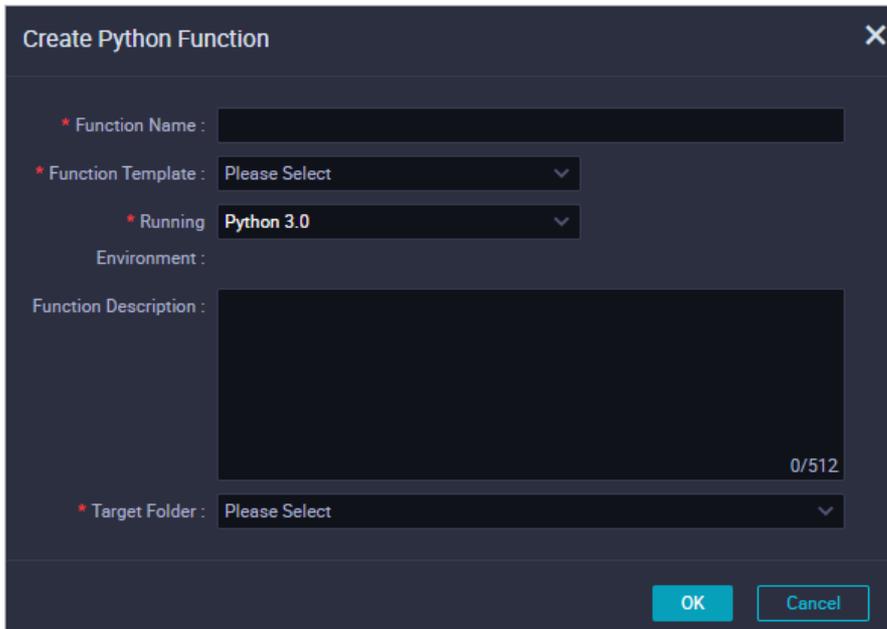

```
# -*- coding: utf-8 -*-
# event (str) : in filter it is the API result, in other cases, it is your param
# context : some environment information, temporarily useless
# import module limit: json,time,random,pickle,re,math
# do not modify function name
import json
def handler(event,context):
# load str to json object
obj= json.loads(event) # Convert the string specified by the event parameter to a JSON object.
# add your code here
# end add
return obj
```

You can modify the function template to write your own function. You can modify the names of the input parameters as needed.

Parameter 1 [context]: the context of calling APIs. The value is of the STRING type. This parameter is not in use and is left empty.
 Parameter 2 [event]: the result data returned by APIs or the preceding filter. The value is of the STRING type.

Create a Python function

1. Log on to the DataWorks console.
2. Click  in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, move the pointer over  and choose **Function > Create Python Function**. You can also click a workflow, right-click **Function**, and then choose **New > Create Python Function**.
4. In the **Create Python Function** dialog box, set the parameters as required.

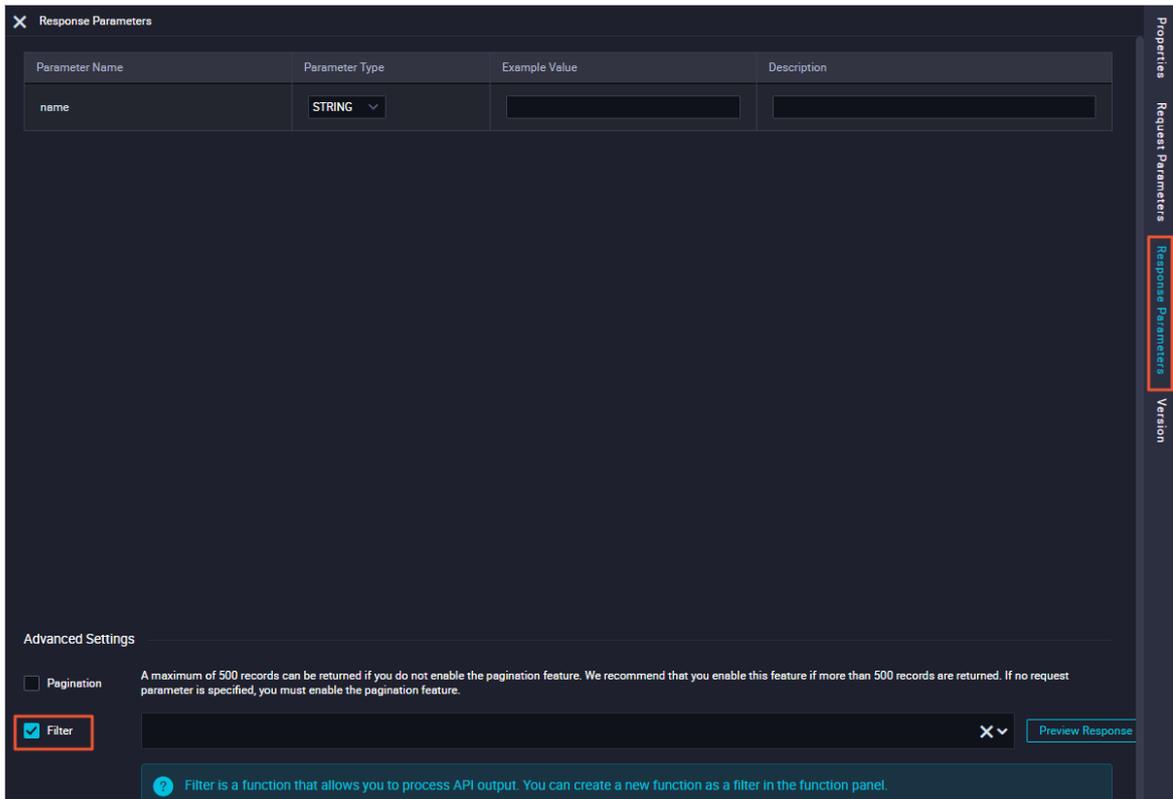

Parameter	Description
-----------	-------------

Parameter	Description
Function Name	The name of the function to create, which can be up to 256 characters in length.
Function Template	The template used to create the function. Set the value to Python3 Standard v1.
Running Environment	The runtime environment of the function. Set the value to Python 3.0.
Function Description	The description of the function.
Target Folder	The directory for storing the function.

5. Click **OK**.

Use post filters

1. On the **Service Development** tab, double-click the target API.
2. On the configuration tab that appears, click **Response Parameters** in the right-side navigation pane.
3. In the **Response Parameters** pane, select **Filter** in the **Advanced Settings** section.

4. Select functions from the **Filter** drop-down list.

Note A post filter is a function that is used to process the results returned by APIs. You can create a function and use it as a post filter.

5. Click **Preview Response** to view the processing results of the post filters.

2.14.6. Register APIs

This topic describes how to register APIs and manage and publish them to API Gateway together with APIs created based on data tables.

Currently, DataService Studio allows you to register only RESTful APIs. Supported request methods include GET, POST, PUT, and DELETE. Supported data types include forms, JSON data, and XML data.

Create a group

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > DataService Studio**.
3. Go to the **Service Development** page, right-click **Service List**, and then select **New API Group**.
4. In the **Create API Group** dialog box that appears, enter values for **Group Name** and **Description**.
5. Click **OK**.

Configure basic API information

1. Right-click the new group and select **Register API**.
2. In the **Create API** dialog box that appears, set each parameter.

Configuration item	Description
API Name	The name must be 4 to 50 characters in length. It must start with a letter and can contain letters, digits, and underscores (_).
API Group	An API group is a collection of APIs for a specific feature or scenario. It is also the minimum API management unit of API Gateway. To create an API group, move the pointer over the Create icon and select New API Group .
API Path	API Path is the alias of Backend Service Path. APIs with different API paths can share the same backend service path and backend service host. Parameters defined in Backend Service Path must also be defined in brackets in API Path.
Protocol	Currently, HTTP and HTTPS are supported.
Request Method	You can select GET, POST, PUT, or DELETE as the request method. The parameters to be configured vary with the request method.
Return Type	Currently, JSON and XML return types are supported.
Description	The description of the API.

3. After configuring the basic API information, click **OK** to go to the API parameter configuration page.

Configure API parameters

On the API parameter configuration page, you need to define the backend service, request parameters, response content, and error codes.

Configuration item	Description
Define the back-end Service	<ul style="list-style-type: none"> • Backend Service Host: Enter the host of the API. The host must start with http:// or https://, and cannot contain the path. • Backend Service Path: Enter the path of the API. Place parameter names in brackets, for example, /user/[userid]. In the next step, parameters defined in Backend Service Path are automatically added to the request parameter list. • Backend timeout: Set the backend timeout period.
Define Request Parameters	<ul style="list-style-type: none"> • Parameter Type: The available request parameter locations (Path, Header, Query, or Body) vary with the request method. • Constant Parameters: A constant parameter is fixed and is invisible to the caller. You do not have to specify the constant parameters when calling an API. Instead, the constant parameters and their values are automatically sent to the backend service. This is useful when you want to set a parameter to a fixed value and hide the parameter value from the caller. • Request Body Definition: This configuration item is available only when the request method is POST or PUT. You can enter the body description in Request Body Definition. It is equivalent to an example of the request body so that API callers can refer to the format of the request body. The content type of the request body can be JSON or XML. <p> Note If a parameter has been defined in both the request body and the request parameter list, the parameter value in the request body takes priority.</p>
Define Response Content	You can enter a successful response example or an error response example for API callers to refer to when writing the return parse code.
Error Codes	<p>Enter the common errors and solutions in API calling. This enables API callers to troubleshoot and solve these errors.</p> <p> Note To ensure that the API is easily used by the callers, provide complete API parameter information if possible, especially the parameter sample values, default values, and sample responses.</p>

Test the API

After you have configured and saved the API parameters, click **Test** in the upper-right corner to go to the API test page.

Set the parameters and click **Test** to send an API request. The request and response details are displayed on the right. If the test fails, check carefully the error message, make modifications accordingly, and test the API again.

Pay attention to the settings of the successful response example in the configuration process. When testing an API, the system automatically generates error response examples and error codes. However, successful response examples are not automatically generated. To enable the system to save the test result as the successful response example, you need to select **Save as Successful Response Example** before performing the test. If the response contains sensitive data that must be masked, you can manually edit the response.

Note

- The successful response example is an important reference for API callers, and therefore must be configured.
- The Call Latency value is the latency of the current API request, which is used to evaluate the API performance. If the latency is long, consider optimizing the database.

After the API test is passed, return to the **Service Development** page, and click **Publish** to generate an API.

2.14.7. Test APIs

This topic describes how to test APIs.

When creating and registering an API, you can test the API. The system also provides an independent API test feature, which allows you to test APIs online.

1. Go to the **DataService Studio** page and click **Service Management** in the upper-right corner.
2. Click **Test API** in the left-side navigation pane.
3. Select the API to be tested, set the parameters, and then click **Test**.

Note

- The API Test page provides only online API testing. You cannot update or save the successful response example for an API on this page. To update the successful response example for an API, click the API name in the API list to enter the API edit mode. Then, update the successful response example for the API in the API testing step.
- You must test an API before publishing it.

2.14.8. Publish APIs

API Gateway provides API lifecycle management services, including API publishing, management, maintenance, and monetization. It helps you easily and quickly aggregate microservices, separate the front end from the backend, and integrate systems at low costs and low risks, making features and data available to partners and developers.

API Gateway provides permission management, traffic control, access control, and metering services. The services make it easy for you to create, monitor, and secure APIs. Therefore, we recommend that you publish the APIs that have been created and registered in DataService Studio to API Gateway. DataService Studio and API Gateway are interconnected, which allows you to publish APIs to API Gateway easily.

Publish APIs to API Gateway

Before publishing an API, you must activate API Gateway and register and test the API.

After the API passes the test, click **Publish** in the upper-right corner to publish the API to API Gateway.

The system automatically registers the API with API Gateway during the publish process. The system also creates a group in API Gateway with the same name as the API group to which the API belongs in DataService Studio and publishes the API in this group. After the API is published, you can access the API Gateway console to view API details or configure bandwidth throttling, access control, and other features.

If you generate an API to be called by your own application, you need to create an application in API Gateway, authorize the application to use the API, and enable the application to call the API by using AppKey and AppSecret. For more information, see *API Gateway documentation*. API Gateway also provides SDKs for mainstream programming languages to help you quickly integrate the API into your own application.

2.14.9. Call APIs

This topic describes how to call an API after this API is published on API Gateway.

API Gateway provides the SDKs for authorizing and calling APIs. You can authorize yourself, your associates, or third parties to use APIs. If you want to call an API, perform the following operations.

Three conditions for calling an API

The following three conditions must be met to call an API:

- **API:** The API that you call is clearly defined by API parameters.
- **App:** The app that you use to call the API has a key pair that uniquely identifies you. The key pair consists of the AppKey and AppSecret.
- **Relationship between the API and app:** If you want to call an API by using an app, the app must have the permission to call this API. This permission is granted through authorization.

Procedure

1. Obtain the API documentation.

The method of obtaining the API documentation varies depending on how you obtain the API. You can obtain the API by purchasing it from the marketplace, or you are authorized to use the API for free.

2. Create an app.

The app identifies you when you call the API. Each app has a key pair: AppKey and AppSecret, which are equivalent to an account and the corresponding password.

3. Obtain the permission to call the API.

Authorization means granting the app the permission to call an API. Your app must be authorized to call the API. The authorization method varies depending on how you obtain the API.

4. Call the API.

You can edit an HTTP or HTTPS request to call the API. Before calling the API, you can use examples of calling APIs in multiple languages in the API Gateway console to test the call.

You can call APIs after you passed the quick authentication or encrypted signature authentication.

Click **API call**. The AppCode and AppKey that are synchronized from API Gateway are available on the page that appears. You can perform **copy** and **reset** operations on them. For more information about API Gateway, see *API Gateway documentation*.

2.14.10. Use workflows

The workflow feature, also called service orchestration, provides a composite API service. This topic describes the benefits of workflows and how to use workflows.

In DataService Studio, a workflow is represented as a directed acyclic graph (DAG). By dragging and dropping nodes to a DAG, you can arrange APIs and functions in a serial, parallel, or branch structure based on the business logic.

When you run a workflow to call APIs, DataWorks runs the nodes in the workflow in sequence, passes parameters among the nodes, and automatically changes the status of each node. The workflow feature simplifies the process of calling multiple APIs or functions and reduces the cost of development and maintenance. This allows you to focus on business development.

Benefits

- Reduced cost of combining multiple APIs

By dragging and dropping nodes to a DAG, you can arrange APIs and functions in a serial, parallel, or branch structure without writing code. This reduces the cost of developing APIs.

- Higher performance in calling APIs and functions

A workflow allows you to call multiple APIs and functions in a container. Compared with writing code to call APIs and functions, the workflow feature reduces the latency of calling APIs and functions.

- Serverless architecture

The workflow feature adopts a serverless architecture. A serverless architecture supports automatic resource scaling based on business needs. You can focus on the business logic, without worrying about the runtime environment.

Obtain values of request and response parameters

DataService Studio uses JSONPath to obtain parameter values. JSONPath is a query language that allows you to extract data from JSON files.

For example, three nodes are run in the following order: A, B, and then C. Node C needs to use the response parameters of nodes A and B.

- Response parameter of node A: {"namea": "valuea"}

Expression for obtaining the value of the response parameter of node A: `${A.namea}`

- Response parameter of node B: {"nameb": "valueb"}

Expression for obtaining the value of the response parameter of node B: `$.nameb` or `${B.nameb}`

The built-in start node provides request parameters for the whole workflow. Assume that a request parameter of a workflow is {"namewf": "valuewf"}. All nodes of the workflow can obtain the value of the request parameter by using the `${START.namewf}` expression.

Set parameters

Request parameters:

- If you do not specify a value for a request parameter of a node, DataService Studio obtains the value of the same parameter in the first layer of the JSON string returned by the parent node, and assigns the value to the request parameter. If no value is specified for a request parameter of the first node, DataService Studio obtains the value of the same parameter in the request parameters of the workflow.
- If you specify a value for a request parameter, DataService Studio uses the value that you set.
- If you need to use the value of the specified parameter returned by a specified ancestor node, obtain the value by using a JSONPath expression.

Common JSONPath expressions for obtaining parameter values:

- `$.:` obtains response parameters of the parent node.
- `$.param:` obtains the value of the param parameter returned by the parent node. To allow you to obtain response parameters of any ancestor nodes, DataService Studio enhances JSONPath expressions.
- `${NODEID1}:` obtains response parameters of the node whose ID is NODEID1.
- `${START}:` obtains request parameters of the workflow, which are response parameters of the start node.
- `${NODEID1.param}:` obtains the value of the param parameter returned by the node whose ID is NODEID1.

JSONPath expressions for setting response parameters of a node:

- `$.:` sets response parameters of the current node.
- `$.param:` sets the param parameter to be returned by the current node.
- `${NODEID1.param}:` sets the param parameter returned by the node whose ID is NODEID1.

Example

Add a connection before you create and use a workflow. In this example, a MySQL connection is used.

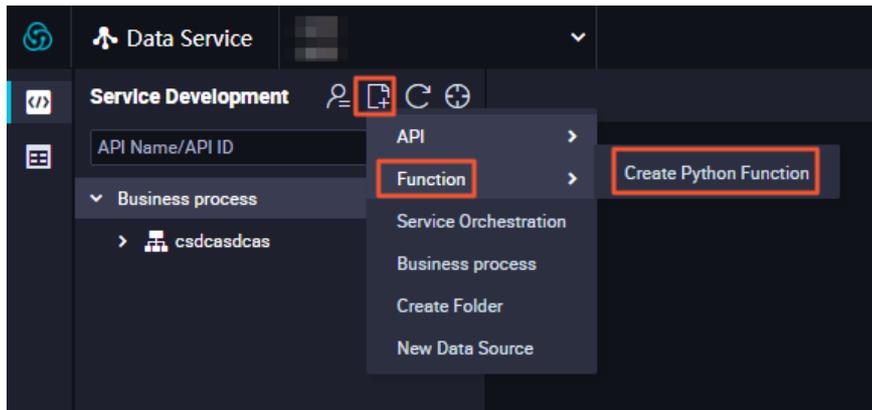

1. Register an API.

In this example, create an API by using the registration method. For more information, see [Register an API](#).

2. Register a function. For more information, see [Create a function](#).

In this example, create a Python function as a branch node to process the result data of the parent node.

- i. Go to the **Service Development** tab, move the pointer over  and choose **Function > Create Python Function**.

- ii. In the **Create Python Function** dialog box, set the parameters as required.

Parameter	Description
Function Name	The name of the function to create, which can be up to 256 characters in length.
Function Template	The template used to create the function. Set the value to Python3 Standard v1.
Running Environment	The runtime environment of the function. Set the value to Python 3.0.
Function Description	The description of the function. The description can be up to 512 characters in length.
Target Folder	The directory for storing the function.

- iii. Click **OK**.
- iv. On the configuration tab of the function, configure the function.
- a. In the **Edit Code** section, enter the function code.

```
# -*- coding: utf-8 -*-
# event (str) : in filter it is the API result, in other cases, it is your param
# context : some environment information, temporarily useless
# import module limit: json,time,random,pickle,re,math
import json
def handler(event,context):
    # load str to json object
    obj = json.loads(event)
    # add your code here
    # end add
    return obj
```

- b. In the **Environment Configuration** section, set the **Memory** and **Function Timeout** parameters.

- v. Click Save icon in the toolbar.
3. Create a workflow.
- i. On the **Service Development** tab, move the pointer over  and select **Service Orchestration**.
 - ii. In the **Service Orchestration** dialog box, set the parameters as required.

Parameter	Description
API Name	The name of the workflow. The name must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.
API Path	The path for storing the workflow, for example, <i>/user</i> .
Call Mode	The mode for calling the API to be arranged in the workflow. Valid values: Synchronous Call and Asynchronous Call . <ul style="list-style-type: none"> ▪ If you set this parameter to Synchronous Mode, the API returns results immediately after it is called. The synchronous mode is most commonly used. ▪ If you set this parameter to Asynchronous Mode, the API returns the RequestID parameter immediately after it is called. The API caller can then obtain the call result from a message queue based on the request ID.
Protocol	The protocol used by the API. Valid values: HTTP and HTTPS .

Parameter	Description
Request Method	The request method used by the API. Valid values: GET and POST .
Response Content Type	The return type of the API. Set the value to JSON .
Visible Range	<p>The visibility of the workflow. Valid values:</p> <ul style="list-style-type: none"> ▪ Work Space: The workflow is visible to all members in the current workspace. ▪ Private: The workflow is visible only to its owner and permissions on the workflow cannot be granted to other users. <p>Note If you set the Visible Range parameter to Private, the workflow is visible only to you in the directory tree. It is hidden to other members of the workspace.</p>
Label	<p>The tag of the workflow. Select one or more tags from the drop-down list. For more information, see Manage tags.</p> <p>Note You can set at most five tags for a workflow.</p>
Description	The description of the workflow, which can be up to 2,000 characters in length.
Target Folder	The directory for storing the workflow.

iii. Click **OK**.

4. Configure the workflow.

- i. On the configuration tab of the workflow, drag and drop nodes and connect them as required.
- ii. Double-click the **API1** node to edit the node. Select the API that you registered earlier as the API to be called in the node.

Select **set output results** and enter `{"user_id": "$.data[0].id"}`.

Use JSONPath expressions to set response parameters. The syntax for obtaining the value of a parameter is `$(NodeA.namea)`, which is the same as that for setting request parameters. `{"user_id": "$.data[0].id"}` assigns the value of the id parameter of the first element in the data array to the user_id parameter. Then, the API1 node returns `{"user_id": "value"}` in JSON format.

- iii. Double-click the **PYTHON1** node to edit the node. Select the function that you created earlier as the function to be called in the node.

- iv. Double-click the **SWITCH2** node to edit the node. In the right-side pane that appears, click **Set branch conditions**. In the Set branch conditions dialog box, enter conditional expressions based on the response parameter of the parent node. For example, you can enter expressions in the `{Node ID}.Parameter>1` or `$.Parameter>1` format. Conditional expressions support the following operators: `==`, `!=`, `>=`, `>`, `<=`, `<`, `&&`, `!`, `()`, `+`, `-`, `*`, `/`, and `%`.

In this example, the `user_id` parameter is the response parameter of the API1 node and is used as the request parameter of the SWITCH2 node.

Branch node 1: `$.user_id != 1`, indicating that the branch node 1 is run if the value of the `user_id` parameter is not 1.
Branch node 2: `$.user_id == 1`, indicating that the branch node 2 is run if the value of the `user_id` parameter is 1.

- v. Double-click the end node and then click the **Response Parameters** tab on the right side to set response parameters.
5. Click **Test** in the upper-right corner.
 6. In the **Test APIs** dialog box, set the parameters as required and click **OK**.

You can view the test result after the workflow is tested.

2.14.11. Manage versions

This topic describes how to manage versions of APIs, workflows, and functions in Data Service.

You can view and compare historical versions of APIs, workflows, and functions. Data Service generates a version record each time an API, a workflow, or a function is published.

View historical versions

1. Log on to the DataWorks console. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > DataService Studio**.
2. On the **Service Development** page that appears, double-click the name of the target API in the API list.

 **Note** You can also click **Function** or **Table** in the left-side navigation pane and double-click the name of a workflow or function to manage its versions.

3. In the right-side navigation pane, click **Version**. In the **Version** dialog box that appears, view historical versions of the API.

Parameter	Description
API ID	The ID of the API. Each API ID is unique.
Version	The version of the API. A version is generated each time the API is published. V1 indicates version 1 and V2 indicates version 2. The version number is incremented by 1 each time.
The Author	The user who published the version.
Submitted Date	The time when the version was published. The time is accurate to second.

Parameter	Description
Status	<p>The status of the version. Value values:</p> <ul style="list-style-type: none"> ◦ Release: indicates that the version of the API is the latest version. ◦ Off-Line: indicates that the version of the API is a historical version.
Actions	<p>The operations that you can perform on the version. The Actions column is only available for API and workflow versions. You can click API Details of a version to go to the details page of the version. The Actions column is unavailable for function versions.</p>

Compare historical versions

In the **Version** dialog box, select two versions to compare, and click **Contrast**. In the **History Version Contrast** dialog box that appears, compare the code and parameters of the two versions.

2.14.12. FAQ

This topic provides answers to commonly asked questions about DataService Studio.

- Q: Do I need to activate the API Gateway service?

A: API Gateway provides you with high-performance and highly available API hosting services. If you need to make your APIs available to others, activate the API Gateway service first.

- Q: Where can I add and change connections?

A: After you log on to the DataWorks console, click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration** to go to the **Data Integration** page. In the left-side navigation pane, choose **Sync Resources > Connections**. On the page that appears, perform the relevant configuration. DataService Studio automatically reads data from the connections that you have configured.

- Q: What is the role of an API group in DataService Studio? What is the relationship between an API group in DataService Studio and an API group in API Gateway?

A: An API group is a set of APIs specific to a feature or scenario. It is the smallest organization unit in DataService Studio, which is similar to an API group in API Gateway. An API group in DataService Studio is equivalent to an API group in API Gateway. After you publish an API from DataService Studio to API Gateway, API Gateway automatically creates an API group with the same name.

- Q: How can I configure an API group appropriately?

A: Typically, an API group includes APIs that provide similar features or resolve a specific issue. For example, a weather API group can include APIs that are used to check the weather by city and by longitude and latitude.

- Q: How many API groups can I create?

A: An Alibaba Cloud account can create up to 100 API groups.

- Q: When do I need to enable the pagination feature for an API call so that its return results can be displayed on multiple pages?

A: By default, an API call returns a maximum of 2,000 records. If an API call may return more than 2,000 records, enable the pagination feature. If you do not specify any request parameters, the API call usually returns a large number of records and the pagination feature is automatically enabled.

- Q: Do APIs created by DataService Studio support POST requests?

A: APIs created by DataService Studio support GET and POST requests.

- Q: Do APIs created by DataService Studio support the HTTPS protocol?

A: APIs created by DataService Studio support both HTTP and HTTPS protocols.

2.15. Stream Studio

2.15.1. Overview

Built on Alibaba Cloud Realtime Compute, which is based on Apache Flink, Stream Studio allows you to develop real-time computing nodes in directed acyclic graph (DAG) mode or SQL mode. You can switch between the two modes to edit the code or drag and drop components and configure them in a visual way.

As an ideal platform for developing real-time computing nodes, Stream Studio has the following features:

- Supports developing nodes in DAG mode. You can perform drag and drop components to configure real-time computing nodes.
- Supports developing nodes in SQL mode. You can edit the code to configure real-time computing nodes.
- Supports switching between the DAG mode and the SQL mode for you to easily check SQL operators.
- Supports using Function Studio to create and publish user-defined functions (UDFs) online in exclusive mode.
- Supports smart diagnosis for real-time computing nodes to facilitate online troubleshooting.

2.15.2. Bind a Realtime Compute project

1. Log on to the DataWorks console.
2. Click the **Project Manage** icon in the upper-right corner. The **Project Management** page appears.
3. On the **Project Management** page, click **Add Compute Engine** in the **Compute Engine** section, and select **Add engine service**.
4. Enter the name of the Blink engine to be added and click **Bind**.

2.15.3. Create a real-time computing node

This topic describes how to create a real-time computing node and develop data in Stream Studio.

Prerequisites

A workflow is created. You can create real-time computing nodes and develop data under an existing workflow.

Procedure

After a workflow is created, you can create real-time computing nodes under the workflow. By default, data is developed for a real-time computing node in directed acyclic graph (DAG) mode.

1. Right-click the workflow that you have created and select **Create task**.
2. In the **Create Node** dialog box that appears, set the parameters and click **Submit**.
3. Develop data in DAG mode on the **Components** page.

The Components page includes the following four sections:

- **Component list** section: In this section, you can view the list of available components. You can click **Components** on the left-side navigation submenu to go to the Components page and view the list.
- **DAG** section: In this section, you can drag and drop components to the DAG and connect them. To configure the dependency between two components, click and hold the highlighted dot at the

bottom of a component and move the pointer to link this component with a descendant component. A DAG corresponds to a real-time computing node.

- Parameter configuration section: Double-click a component in the DAG. Then, you can set the related parameters in this section.
- Toolbar section: In this section, you can click the icons to perform the save, submit, steal lock, pre-compilation, test, stop, reload, and format operations respectively.

When you configure the DAG, you can right-click a component and select an operation from the menu that appears to perform it on the selected component. Available operations include **Rename**, **View schema**, **Delete node**, **View error message**, **New component group**, and **Copy**.

2.15.4. Get started with Stream Studio

This topic uses an example to describe how to use Stream Studio to develop and manage a real-time computing node. Stream Studio allows you to create, configure, publish, run, stop, and unpublish a real-time computing node.

Prerequisites

A Realtime Compute project is bound to the current DataWorks workspace.

Context

- Data store: a Datahub table with a created topic, which contains the `m_name`, `id`, `m_type`, and `tag` fields.

 **Note** The Datahub topic must be created in advance.

- Data processing: splits the tag field by using the `semicolon (;)` as the delimiter to the color, mode, and weight fields.
- Output data: writes the `id`, `m_type`, and `weight` fields to a Log Service table.

 **Note** The Log Service project and Logstore must be created in advance.

Procedure

1. Log on to the DataWorks console. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Stream Studio**.
2. Create a workflow.
 - i. On the Stream Studio homepage, click **New business process**.
You can also move the pointer over the **Create** icon and click **Business process**.
 - ii. In the **Create business process** dialog box that appears, set the **Business Name** and **Description** parameters.
 - iii. Click **New**.
3. Create a real-time computing node.
 - i. Right-click the workflow that you have created and select **Create task**.
 - ii. In the **Create node** dialog box that appears, set the relevant parameters.
 - iii. Click **Submit**. The **Components** page appears.

- iv. On the left-side navigation submenu, click **Resource Reference** and select **PUBLIC_COMMON**.

 **Note** If this option is not selected, the message shown when you use the `FixedFieldsSplit` component.

You can also go to the Resource Reference page to configure the reference resources after this message appears.

- 4. Configure the created real-time computing node.

On the left-side navigation submenu, click **Components**. The **Components** page appears.

- i. Configure the data store of the node on the **Components** page.
 - a. Drag and drop the Datahub component in the Data Source section to the directed acyclic graph (DAG).
 - b. Click the Datahub component and set the parameters as needed on the **Parameter configuration** tab that appears.

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name. If this parameter is not specified, the real table name is used.
table schema	The custom fields and attribute fields to be returned. Click Custom . In the Select field dialog box that appears, click + Add and enter the name and type of the output field. Then, click OK .
endPoint	The endpoint used to access Datahub. It corresponds to the <code>endPoint</code> parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to read data from Datahub. It corresponds to the <code>accessId</code> parameter in the WITH clause of the CREATE TABLE statement.
accessKey	The AccessKey secret used to read data from Datahub. It corresponds to the <code>accessKey</code> parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the Datahub project from which data is to be read. It corresponds to the <code>project</code> parameter in the WITH clause of the CREATE TABLE statement.
topic	The name of the Datahub topic from which data is to be read. It corresponds to the <code>topic</code> parameter in the WITH clause of the CREATE TABLE statement.
startTime	The beginning of the time range when data is read. It corresponds to the <code>startTime</code> parameter in the WITH clause of the CREATE TABLE statement.
maxRetryTimes	The maximum number of retries for reading data from Datahub. It corresponds to the <code>maxRetryTimes</code> parameter in the WITH clause of the CREATE TABLE statement. Default value: 20.

Parameter	Description
retryIntervalMs	The retry interval at which data is read. It corresponds to the <code>retryIntervalMs</code> parameter in the <code>WITH</code> clause of the <code>CREATE TABLE</code> statement. Unit: milliseconds. Default value: <code>1,000</code> .
batchReadSize	The number of data records that are read at a time. It corresponds to the <code>batchReadSize</code> parameter in the <code>WITH</code> clause of the <code>CREATE TABLE</code> statement. Default value: <code>10</code> .
lengthCheck	The rule for checking the number of fields parsed from a row of data. It corresponds to the <code>lengthCheck</code> parameter in the <code>WITH</code> clause of the <code>CREATE TABLE</code> statement. Default value: <code>NONE</code> .
columnErrorDebug	Specifies whether to enable debugging. It corresponds to the <code>columnErrorDebug</code> parameter in the <code>WITH</code> clause of the <code>CREATE TABLE</code> statement. If you turn on this switch, logs about parsing errors are returned. You can view the node details Operation Center.

ii. Configure the data operator.

- a. Drag and drop the **FixedFieldsSplit** component to the DAG to split the tag field.
- b. Click and hold the highlighted dot at the bottom of the **Datahub** component and move the pointer to link this component with the **FixedFieldsSplit** component.
- c. Click the **FixedFieldsSplit** component and set the field to tag and the column separator to semicolon (;) on the **Parameter configuration** tab that appears.
- d. Click **Custom** for the Add column parameter. In the **Select field** dialog box that appears, click **+** Add and enter the name and type of the output field. Then, click **OK**.
- e. Drag and drop the **Select** component to the DAG. Click and hold the highlighted dot at the bottom of the **FixedFieldsSplit** component and move the pointer to link this component with the **Select** component.
- f. Click the **Select** component and click **0 Field has been selected** on the **Parameter configuration** tab that appears.
- g. In the dialog box that appears, select the fields to be returned and click **OK**.

iii. Configure the result table.

This example uses the **LogService** component as the destination.

- a. Drag and drop the **LogService** component to the DAG. Click and hold the highlighted dot at the bottom of the **Select** component and move the pointer to link this component with the **LogService** component.

- b. Click the **LogService** component and set the parameters as needed on the **Parameter configuration** tab that appears.

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name. If this parameter is not specified, the real table name is used.
Output Field	The fields to be returned. Click 0 Field has been selected for the Output Field parameter. In the dialog box that appears, select the fields to be returned and click OK .
endPoint	The endpoint used to access Log Service. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the Log Service project to which data is to be written. It corresponds to the project parameter in the WITH clause of the CREATE TABLE statement.
topic	The name of the Log Service topic to which data is to be written. It corresponds to the topic parameter in the WITH clause of the CREATE TABLE statement.
source	The name of the Log Service table to which data is to be written. It corresponds to the source parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to access Log Service. It corresponds to the accessId parameter in the WITH clause of the CREATE TABLE statement.
accessKey	The AccessKey secret used to access Log Service. It corresponds to the accessKey parameter in the WITH clause of the CREATE TABLE statement.
mode	The mode of data writing. It corresponds to the mode parameter in the WITH clause of the CREATE TABLE statement. Default value: <i>random</i> .
logStore	The name of the Logstore in the Log Service project to which the data is to be written. It corresponds to the logStore parameter in the WITH clause of the CREATE TABLE statement.

- iv. Switch between the DAG mode and SQL mode.

Stream Studio allows you to configure a real-time computing node in both DAG mode and SQL mode. You can switch between these two modes.

By default, you configure a node in DAG mode. You can click **Switch to SQL mode** in the upper-right corner to switch to the SQL mode.

In SQL mode, you can click **Switch to DAG mode** in the upper-right corner to switch back to the DAG mode.

- v. Configure the execution plan.

- a. Click **Execution Plan** on the right-side navigation submenu to generate an execution plan.
- b. Click **Save execution plan**.

5. Publish the real-time computing node.

You can publish the real-time computing node that you have configured. Click **Save** and then click **Submit** to publish the node.

- i. Click **Save** and then click **Submit**. If you have not saved the node, a message appears, indicating that you must save it.
- ii. In the **Submit New version** dialog box that appears, enter the remarks for the node and click **OK**.
- iii. After you publish the node, you can go to the **OAM** page to view the node status and manage the node.

6. Perform O&M on the real-time computing node.

Click **OAM** in the upper-right corner to perform O&M on the real-time computing node.

i. Start the real-time computing node.

Find the real-time computing node that you have created in the node list and click **Start** to start the node.

You can set a custom start time for the real-time computing node based on your business requirement.

After starting the real-time computing node, you can click the node name to view its running status. If the real-time computing node is started properly, it enters the **Run** state.

ii. Stop and unpublish the real-time computing node.

- a. Click **Stop** to stop the real-time computing node.
- b. After the real-time computing node is stopped, click **Offline** to unpublish it.

Result

Now you have created, configured, published, run, stopped, and unpublished a real-time streaming node.

2.15.5. Configure components

2.15.5.1. Source tables

2.15.5.1.1. Datahub

Datahub is a real-time data distribution platform that is designed to process streaming data. It provides a channel for the Apsara Stack DTplus platform to process big data.

Realtime Compute typically uses Datahub to store source and result tables for streaming data processing. Data Transmission Services (DTS) and the Internet of Things (IoT) also use Datahub to access big data platforms. Datahub stores streaming data that can be used as input data for Realtime Compute.

Parameter configuration

Parameter	Description	Remarks
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.	None
table schema	The custom fields and attribute fields to be read from Datahub.	None
endPoint	The consumer endpoint.	None

Parameter	Description	Remarks
accessId	The AccessKey ID used to read data from Datahub.	None
accessKey	The AccessKey secret used to read data from Datahub.	None
project	The name of the Datahub project from which data is to be read.	None
topic	The name of the Datahub topic from which data is to be read.	None
startTime	The beginning of the time range when data is read.	The format is <code>yyyy-MM-dd hh:mm:ss</code> .
maxRetryTimes	The maximum number of retries for reading data from Datahub.	None
retryIntervalMs	The retry interval at which data is read. Unit: milliseconds.	None
batchReadSize	The number of data records that are read at a time.	None
lengthCheck	The rule for checking the number of fields parsed from a row of data.	<p>Valid values: <i>SKIP</i>, <i>EXCEPTION</i>, and <i>PAD</i>. Default value: <i>SKIP</i>.</p> <ul style="list-style-type: none"> • <i>SKIP</i>: skips a data record when the number of fields in the data record is not the specified one. • <i>EXCEPTION</i>: throws an exception when the number of fields in the data record is not the specified one. • <i>PAD</i>: pads fields in sequence. Pad a field with null when the field does not exist.
columnErrorDebug	Specifies whether to enable debugging. If you turn on this switch, logs about parsing errors are returned.	None
BLOB	Specifies whether the type of data read from Datahub is BLOB.	None
Data Quality	Specifies whether to open the Data Quality page to view related monitoring nodes.	None

Field type mapping

The following table lists the mapping between Datahub and Realtime Compute data types. We recommend that you declare the type mapping in the DDL statement.

Datahub data type	Realtime Compute data type
BIGINT	BIGINT
DOUBLE	DOUBLE
TIMESTAMP	BIGINT
BOOLEAN	BOOLEAN
DECIMAL	DECIMAL

Attribute fields

You can obtain the attribute field indicating the system time at which each data record is written to Datahub.

Field	Description
System Time	The system time at which each data record is written to Datahub.

2.15.5.1.2. Log Service

As an all-in-one real-time data logging service, Log Service allows you to quickly finish tasks such as data ingestion, consumption, delivery, query, and analysis without any extra development work. This can help you improve O&M and operational efficiency, and build up the capability to process large amounts of logs in the data technology era.

Log Service stores streaming data that can be used as input data for Realtime Compute.

The data format of Log Service is consistent with JSON. Example:

```
{
  "a": 1000,
  "b": 1234,
  "c": "li"
}
```

Parameter configuration

Parameter	Description	Remarks
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.	None
table schema	The custom fields and attribute fields to be read from Log Service.	None
endPoint	The consumer endpoint.	Log Service endpoints
accessId	The AccessKey ID used to read data from Log Service.	None
accessKey	The AccessKey secret used to read data from Log Service.	None

Parameter	Description	Remarks
project	The name of the Log Service project from which data is to be read.	None
logStore	The name of the Logstore under the Log Service project.	None
consumerGroup	The name of the consumer group.	You can specify a custom consumer group name. The format of the name is not fixed.
startTime	The beginning of the time range when the log data is consumed.	None
heartBeatIntervalMills	Optional. The heartbeat interval at which the client sends heartbeat messages. Unit: milliseconds.	None
maxRetryTimes	The maximum number of retries for reading data from Log Service.	None
columnErrorDebug	Specifies whether to enable debugging. If you turn on this switch, logs about parsing errors are returned.	None

Field type mapping

The following table lists the mapping between Log Service and Realtime Compute data types. We recommend that you declare the type mapping in the DDL statement.

Log Service data type	Realtime Compute data type
STRING	VARCHAR

Attribute fields

Currently, Log Service supports the following three attribute fields by default. You can also specify other custom fields.

Field	Description
<code>__source__</code>	Specifies a log source.
<code>__topic__</code>	Specifies a log topic.
<code>__timestamp__</code>	Specifies the time when a logged event occurs.

Note

- Currently, Log Service does not support the MAP type.
- We recommend that you define the fields in the same order as the fields in the preceding table. Unordered fields are also supported.
- If the input data is in JSON format, define the delimiter and use the built-in function JSON_VALUE to parse the JSON value. Otherwise, the parsing fails and the following error is returned:

```
2017-12-25 15:24:43,467 WARN [Topology-0 (1/1)] com.alibaba.blink.streaming.connectors.common.source.parse.DefaultSourceCollector - Field missing error, table column number: 3, data column number: 3, data field number: 1, data: [{"lg_order_code":"LP00000005","activity_code":"TEST_CODE1","occur_time":"2017-12-10 00:00:01"}]
```

- The batchSize value must not exceed 1,000. Otherwise, an error occurs.
- The batchSize parameter specifies the number of log items read at a time in a log group. If both the size of a single log item and the batchSize value are too large, frequent garbage collection (GC) may be triggered. To avoid this, you must set batchSize parameter to a smaller value.

2.15.5.2. Dimension tables

2.15.5.2.1. ApsaraDB RDS

ApsaraDB RDS is a stable, reliable, and scalable cloud database service.

Parameter configuration

Parameter	Description	Remarks
-----------	-------------	---------

Parameter	Description	Remarks
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.	None
url	The URL of your ApsaraDB RDS instance.	None
tableName	The name of the table in your database.	None
userName	The username that is used to connect to the database.	None
password	The password that is used to connect to the database.	None
Output Field	The fields that you want to return to the descendant component.	None
maxRetryTimes	The maximum number of retries for reading data from the table.	None
Cache Policy	The policy that is used to cache data.	Valid values: <i>None</i> , <i>LRU</i> , and <i>ALL</i> .
primaryKey	The primary key field in the output fields.	<ul style="list-style-type: none"> You must specify a primary key when you declare a dimension table. When you join a dimension table with another table, the ON clause must contain the equivalent (=) conditions for all the primary key fields. The primary key in ApsaraDB RDS or PolarDB-X is the primary key or unique index column of an ApsaraDB RDS or PolarDB-X dimension table.

Additional information

- ApsaraDB RDS and PolarDB-X provide the following cache policies:

- None:** indicates that data is not cached.
- LRU:** indicates that only the recently used data is cached.

If this cache policy is selected, you must specify the `cacheSize` and `cacheTTLms` parameters.

- ALL:** indicates that all data is cached.

Before the system runs a node, it loads all the data in the remote table to the memory. Then, the system searches the cache for data in all dimension table queries. If a cache miss occurs, all data is cached again after the cache times out. The ALL cache policy applies to scenarios where the remote table is small but a large number of missing keys exist. If this cache policy is selected, you must specify the `cacheTTLms` and `cacheReloadTimeBlackList` parameters.

- If the ALL cache policy is used, the system reloads data asynchronously. Therefore, you must increase the memory of the JOIN operator. The size of the increased memory is twice the data size of the remote table.
- If the ALL cache policy is used, pay special attention to the memory of the JOIN operator to prevent out of memory (OOM) errors.

2.15.5.2.2. Tablestore

Tablestore is a distributed NoSQL database service that is developed based on the Apsara distributed operating system. It features high availability and data reliability.

Parameter configuration

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
instanceName	The name of the instance.
tableName	The name of the table.
Output Field	The fields that you want to return to the descendant component.
endPoint	The endpoint of the instance. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID of the account that you use to read data from the table.
accessKey	The AccessKey secret of the account that you use to read data from the table.

Parameter	Description
Cache Policy	The policy used to cache data. Valid values: None and LRU .
primaryKey	The primary key field in the output fields.

2.15.5.2.3. MaxCompute

This topic describes the parameter configuration, field type mapping, and metrics of a MaxCompute dimension table.

Parameter configuration

Parameter	Description	Remarks
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.	None
endPoint	The endpoint used to access MaxCompute. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.	None
tunnelEndPoint	The endpoint of the Tunnel service. It corresponds to the tunnelEndPoint parameter in the WITH clause of the CREATE TABLE statement.	This parameter is required for a MaxCompute dimension table deployed in a Virtual Private Cloud (VPC).
project	The name of the MaxCompute project to which the dimension table belongs.	None
accessId	The AccessKey ID used to read data from MaxCompute.	None
accessKey	The AccessKey secret used to read data from MaxCompute.	None
Output Field	The fields to be returned to the descendant component.	None
partition	The partition name of the MaxCompute dimension table.	None
maxRowCount	The maximum number of data records that can be read from the MaxCompute dimension table	None
Cache Policy	The policy for caching data.	Default value: ALL .

Parameter	Description	Remarks
cacheSize	The maximum number of data records that can be cached.	This parameter is required if you set the Cache Policy parameter to LRU . Default value: 100,000.
cacheTTLms	The time interval at which the cache is refreshed. It corresponds to the cacheTTLms parameter in the WITH clause of the CREATE TABLE statement. Units: milliseconds.	This parameter specifies the cache refresh interval when the Cache Policy parameter is set to ALL . The cache is not refreshed by default.
cacheReloadTimeBlackList	Optional. The time period during which the cache is not refreshed. This parameter is valid when the Cache Policy parameter is set to ALL . During the time period specified by this parameter, for example, the Double 11 Shopping Festival, the cache is not refreshed.	This parameter is left empty by default. If you want to set this parameter, specify the time period in the format shown in the following example: 2017-10-24 14:00 -> 2017-10-24 15:00, 2017-11-10 23:30 -> 2017-11-11 08:00 Separate multiple time periods with commas (.). Separate the start and end time for a time period with the string "->".
primaryKey	The primary key field of the output fields.	None

Field type mapping

MaxCompute data type	Realtime Compute data type
TINYINT	TINYINT
SMALLINT	SMALLINT
INT	INT
BIGINT	BIGINT
FLOAT	FLOAT
DOUBLE	DOUBLE
BOOLEAN	BOOLEAN
DATETIME	TIMESTAMP
TIMESTAMP	TIMESTAMP
VARCHAR	VARCHAR
STRING	STRING
DECIMAL	DECIMAL

MaxCompute data type	Realtime Compute data type
BINARY	VARBINARY

Metrics

When you join the dimension table to another table, you can view metrics such as the correlation degree and cache hit ratio. You can use K-Monitor to view the metrics.

Query statement	Description
fetch qps	Queries the total number of queries per second (QPS) against the dimension table, including hits and misses. The metric name is <code>blink.projectName.jobName.dimJoin.fetchQPS</code> .
fetchHitQPS	Queries the number of hits (in QPS) against the dimension table, including cache hits and hits against the physical dimension table. The metric name is <code>blink.projectName.jobName.dimJoin.fetchHitQPS</code> .
cacheHitQPS	Queries the number of cache hits (in OPS) against the dimension table. The metric name is <code>blink.projectName.jobName.dimJoin.cacheHitQPS</code> .
dimJoin.fetchHit	Queries the correlation degree of the dimension table and the table to which the dimension table is joined. The metric name is <code>blink.projectName.jobName.dimJoin.fetchHit</code> .
dimJoin.cacheHit	Queries the cache hit ratio of the dimension table. The metric name is <code>blink.projectName.jobName.dimJoin.cacheHit</code> .

Note

- We recommend that you use Realtime Compute V2.1.1 and later.
- To use a MaxCompute dimension table, you must grant the read permission to the account for accessing MaxCompute.
- When you declare a dimension table, you must specify the primary key. When you join a dimension table with another table, the ON condition must contain an equivalent condition that includes the primary key of either table.
- The primary key value for each row of a MaxCompute dimension table must be unique. Otherwise, the duplicate records are removed.
- If the dimension table is a partitioned table, Realtime Compute does not currently support writing the partition key column to the schema.
- When the cache policy is set to ALL, Realtime Compute reloads data asynchronously. Therefore, you must increase the memory of the JOIN operator. The size of the increased memory is twice the data size of the remote table.
- The following failover message may appear when you run a node:

```
RejectedExecutionException: Task
java.util.concurrent.ScheduledThreadPoolExecutor$ScheduledFutureTask,
```

Generally, this message appears because dimension table joining in Realtime Compute V1.x has certain issues. We recommend that you upgrade Realtime Compute to V2.1.1 or later. If you want to continue using the existing version, we recommend that you pause the node and resume it after troubleshooting. To troubleshoot the failover, check the specific error information that was generated for the first failover record in the failover history.

2.15.5.3. Data operators

2.15.5.3.1. Filter

The Filter component allows you to configure filter conditions. It corresponds to the WHERE clause in SQL statements.

Parameter configuration

Enter the filter expression to configure this component. The filter expression supports functions and operators (=, <>, >, >=, <, and <=), for example, `city = 'Beijing'`.

2.15.5.3.2. GroupBy

The GroupBy component corresponds to the GROUP BY clause in SQL statements.

Parameter configuration

Parameter	Description
Select grouping field	The fields based on which data is grouped. You can specify multiple fields.
Output Field	The fields to be returned, that is, the fields to be selected. You can specify the fields in the same way that you configure the Select component.

2.15.5.3.3. Join

The Join component corresponds to the JOIN clause in SQL statements.

Parameter configuration

Parameter	Description
JoinMode	The JOIN mode to be used. Valid values: INNER JOIN, LEFT OUTER JOIN, RIGHT OUTER JOIN, and FULL OUTER JOIN.
expression	The JOIN expression. An equijoin is supported, for example, <code>leftId = rightId AND limit = 0</code> , whereas a non-equijoin is not supported.
Select Field	The fields to be returned, that is, the fields to be selected.

2.15.5.3.4. Select

The Select component allows you to configure the fields to be returned and supports field expressions. It corresponds to SELECT statements.

Parameter configuration

Select or configure the output fields in the Select field dialog box.

You can select fields to be returned in the **Field list** section and set an alias for a field in the **Field alias** column. To set a field expression, click the Edit icon next to the target field name. In the Edit dialog box that appears, enter the required SQL statement.

2.15.5.3.5. UDTF

The UDTF component allows you to configure custom functions. It corresponds to the UDTF clause in SQL statements.

Parameter configuration

Parameter	Description
JoinMode	The JOIN mode for the custom function. Only <i>INNER JOIN</i> and <i>LEFT OUTER JOIN</i> are supported. <ul style="list-style-type: none">• <i>INNER JOIN</i>: returns an empty result set when the UDTF clause returns no result.• <i>LEFT OUTER JOIN</i>: returns the NULL string when the UDTF clause returns no result.
Select function	The name of the function that the current node references. To reference a function for the current node, upload the related resources on the Resource Reference page and select the target resource.
parameter expression	The input parameters and output parameters of the referenced function.
Output Field	The fields to be returned. You can configure the name, alias, and expression of each field.

2.15.5.3.6. UnionAll

The UnionAll component corresponds to the UNION ALL clause in SQL statements.

Parameter configuration

No parameter configuration is required.

2.15.5.3.7. Dynamic column splitting

Dynamic column splitting allows you to split data records with a dynamic number of columns.

Example

Input data:

```
k1=v1,k2=v2,k3=v3,k4=v4
```

In the preceding example, the data is stored in key-value pairs in the format of key=value. Different data records may have different numbers of key-value pairs, that is, they may have different numbers of columns. In this case, you can use the first-level delimiter, which is comma (,) in the preceding example, to split the data to different key-value pairs. Then, you can use the secondary-level delimiter, which is equal sign (=) in the preceding example, to split each key-value pair to the key and value.

Parameter configuration

Parameter	Description
Select Field	The name of the field to split.
first level column delimiter	The delimiter used to split the field at the first level. Default value: \u0001.
secondary level column delimiter	The delimiter used to split the field at the secondary level. Default value: \u0002.
Add column	The fields that store the split data. Specify a key for each field. An alias is allowed.

2.15.5.3.8. Static column splitting

Static column splitting allows you to split data records with fixed columns that are separated by a fixed delimiter.

Example

You can use commas (,) as the delimiter to split the following data to four new columns, that is, 1111, 2222, 3333, and 4444.

```
1111,2222,3333,4444
```

The static column splitting method is applicable to data records with fixed columns that are separated by a fixed delimiter.

Parameter configuration

Parameter	Description
Select Field	The name of the field to split.
column separator	The delimiter used to split the field. You can use full-width characters or half-width characters as needed.
Add column	The fields that store the split data. Specify a key and a sequence number for each field. An alias is allowed.

2.15.5.3.9. Row splitting

Row splitting allows you to split a row to multiple rows based on a field by using the specified delimiter.

Example

The following table lists the input data.

id	num
1	1,2

Split the row to multiple rows based on the num field by using the comma (,) as the delimiter, and place the split data in the new field new_num. The following table lists the output data.

id	num	new_num
1	1,2	1
1	1,2	2

Parameter configuration

Parameter	Description	Remarks
Select Field	The name of the field to split.	This parameter is set to num in the preceding example.
Field separator	The delimiter used to split the field. Default value: (\n).	This parameter is set to comma (,) in the preceding example.
Define new column name	The name of the new field that stores the split data.	This parameter is set to new_num in the preceding example.

2.15.5.4. Result tables

2.15.5.4.1. Datahub

Datahub is a real-time data distribution platform that is designed to process streaming data. It provides a channel for the Apsara Stack DTplus platform to process big data. Datahub works with multiple Apsara Stack services to provide an end-to-end data processing solution. Realtime Compute typically uses Datahub to store source and result tables for streaming data processing.

Parameter configuration

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
Output Field	The fields to be returned.
endPoint	The endpoint used to access DataHub. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the Datahub project to which data is to be written. It corresponds to the project parameter in the WITH clause of the CREATE TABLE statement.
topic	The name of the Datahub topic to which data is to be written. It corresponds to the topic parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to access Datahub. It corresponds to the accessId parameter in the WITH clause of the CREATE TABLE statement.

Parameter	Description
<code>accessKey</code>	The AccessKey secret used to access Datahub. It corresponds to the <code>accessKey</code> parameter in the WITH clause of the CREATE TABLE statement.
<code>maxRetryTimes</code>	The maximum number of retries for writing data to DataHub. It corresponds to the <code>maxRetryTimes</code> parameter in the WITH clause of the CREATE TABLE statement.
<code>batchSize</code>	The number of data records that are written at a time. It corresponds to the <code>batchSize</code> parameter in the WITH clause of the CREATE TABLE statement.
<code>batchWriteTimeoutMs</code>	The interval at which the cache is cleared. It corresponds to the <code>batchWriteTimeoutMs</code> parameter in the WITH clause of the CREATE TABLE statement.
<code>maxBlockMessages</code>	The maximum number of data blocks that are written at a time. It corresponds to the <code>maxBlockMessages</code> parameter in the WITH clause of the CREATE TABLE statement.

Field type mapping

The following table lists the mapping between Datahub and Realtime Compute data types. We recommend that you declare the type mapping in the DDL statement.

Datahub data type	Realtime Compute data type
BIGINT	BIGINT
DOUBLE	DOUBLE
TIMESTAMP	BIGINT
BOOLEAN	BOOLEAN
DECIMAL	DECIMAL

2.15.5.4.2. Log Service

As an all-in-one real-time data logging service, Log Service allows you to quickly finish tasks such as data ingestion, consumption, delivery, query, and analysis without any extra development work. This can help you improve O&M and operational efficiency, and build up the capability to process large amounts of logs in the data technology era.

Parameter configuration

Parameter	Description
<code>oriTableName</code>	The table name used in the CREATE TABLE statement. It must be a globally unique name.
Output Field	The fields to be returned.

Parameter	Description
endPoint	The endpoint used to access Log Service. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the Log Service project to which the data is to be written. It corresponds to the project parameter in the WITH clause of the CREATE TABLE statement.
primaryKey	The primary key field of the output fields.
source	The name of the log source. It corresponds to the source parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to access Log Service.
accessKey	The AccessKey secret used to access Log Service.
mode	The mode of data writing. It corresponds to the mode parameter in the WITH clause of the CREATE TABLE statement. Default value: <code>random</code> . If you set this parameter to <code>partition</code> , data is written by partition.
logStore	The name of the Logstore in the Log Service project to which the data is to be written.

2.15.5.4.3. ApsaraDB RDS

ApsaraDB RDS is a stable, reliable, and scalable cloud database service.

Parameter configuration

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
Output Field	The fields that you want to write to the table in your ApsaraDB RDS database.
url	The URL used to access your ApsaraDB RDS instance. This parameter corresponds to the url parameter in the WITH clause of the CREATE TABLE statement.
tableName	The name of the table to which you want to write data. This parameter corresponds to the tableName parameter in the WITH clause of the CREATE TABLE statement.
userName	The username that is used to access your ApsaraDB RDS database. This parameter corresponds to the userName parameter in the WITH clause of the CREATE TABLE statement.
password	The password that is used to access your ApsaraDB RDS database. This parameter corresponds to the password parameter in the WITH clause of the CREATE TABLE statement.
maxRetryTimes	The maximum number of retries for writing data to the table. This parameter corresponds to the maxRetryTimes parameter in the WITH clause of the CREATE TABLE statement.

Parameter	Description
batchSize	The number of data records that can be written at a time. This parameter corresponds to the batchSize parameter in the WITH clause of the CREATE TABLE statement.
bufferSize	The maximum number of data records that can be stored in the buffer before deduplication is triggered. This parameter corresponds to the bufferSize parameter in the WITH clause of the CREATE TABLE statement. You can use this parameter only after the primaryKey parameter is specified.
flushIntervalMs	The time interval at which the buffer is cleared. Unit: milliseconds. This parameter corresponds to the flushIntervalMs parameter in the WITH clause of the CREATE TABLE statement.
excludeUpdateColumns	The fields that are not updated when Realtime Compute updates data records with the same primary key value. This parameter corresponds to the excludeUpdateColumns parameter in the WITH clause of the CREATE TABLE statement.
ignoreDelete	Specifies whether to skip delete operations. This parameter corresponds to the ignoreDelete parameter in the WITH clause of the CREATE TABLE statement.
partitionBy	Specifies the partitioning rule for the result table. Before Realtime Compute writes data to the sink node, Realtime Compute performs hash partitioning based on the value of this parameter. The data then flows to the relevant hash node. This parameter corresponds to the partitionBy parameter in the WITH clause of the CREATE TABLE statement.
primaryKey	The primary key field in the output fields.

Data type mapping

ApsaraDB RDS data type	Realtime Compute data type
TEXT	VARCHAR
BYTE	VARCHAR
INTEGER	INT
LONG	BIGINT
DOUBLE	DOUBLE
DATE	VARCHAR
DATETIME	VARCHAR

ApsaraDB RDS data type	Realtime Compute data type
TIMESTAMP	VARCHAR
TIME	VARCHAR
YEAR	VARCHAR
FLOAT	FLOAT
DECIMAL	DECIMAL
CHAR	VARCHAR

JDBC parameters

Parameter	Description	Default value	Required JDBC version
useUnicode	Specifies whether to use the Unicode character set. This parameter must be set to true if you set the characterEncoding parameter to gb2312 or gbk.	<i>false</i>	1.1g
characterEncoding	The character encoding format. This parameter must be set if the useUnicode parameter is set to true. You can set this parameter to gb2312 or gbk.	<i>false</i>	1.1g
autoReconnect	Specifies whether to automatically re-establish a connection if the connection to the database is unexpectedly interrupted.	<i>false</i>	1.1
autoReconnectForPools	Specifies whether to apply the reconnection policy to a database connection pool.	<i>false</i>	3.1.3
failOverReadOnly	Specifies whether to set the connection to read-only after the database is automatically reconnected.	<i>true</i>	3.0.12

Parameter	Description	Default value	Required JDBC version
maxReconnects	The maximum number of reconnection attempts allowed. This parameter must be set if the autoReconnect parameter is set to true.	3	1.1
initialTimeout	The interval between two reconnection attempts. Unit: seconds. This parameter must be set if the autoReconnect parameter is set to true.	2	1.1
connectTimeout	The timeout period when you use a socket connection to access the database server. Unit: milliseconds. Default value: 0. This value indicates that the connection never times out. This parameter applies to JDK 1.4 and later.	0	3.0.1
socketTimeout	The timeout period for read and write operations on a socket connection. Unit: milliseconds. Default value: 0. This value indicates that read or write operations never time out.	0	3.0.1

FAQ

- Q:** When the output data of Realtime Compute is written to an ApsaraDB RDS table, is the result table updated based on the primary key or is a new data record generated in the table?

A: The processing method depends on whether the primary key is defined in the DDL statement.

 - If a primary key is defined in the DDL statement, the result table is updated by using `insert into on duplicate key update`. For a data record, if the primary key does not exist, the record is inserted into the table as a new row. If the value of the primary key field exists, the original row in the table is updated.
 - If no primary key is defined in the DDL statement, new data records are inserted into the table by using `insert into`.
- Q:** What do I need to pay attention to when I perform GROUP BY operations based on the unique index of an ApsaraDB RDS table?

A: An ApsaraDB RDS table has only one auto-increment primary key. Therefore, this auto-increment primary key cannot be declared as the primary key in a Realtime Compute job. If you want to perform GROUP BY operations based on the unique index of the table, declare the unique index as the primary key in the job.

2.15.5.4.4. Tablestore

Tablestore is a NoSQL database service that is built on the Apsara distributed operating system. Tablestore adopts data sharding and load balancing technologies to scale out and handle concurrent transactions. You can use Tablestore to store and access large volumes of structured data in real time.

Parameter configuration

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
Output Field	The fields that you want to write to the Tablestore table.
instanceName	The name of the Tablestore instance. This parameter corresponds to the instanceName parameter in the WITH clause of the CREATE TABLE statement.
tableName	The name of the table to which you want to write data. This parameter corresponds to the tableName parameter in the WITH clause of the CREATE TABLE statement.
endPoint	The endpoint of the Tablestore instance. This parameter corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID of the account that is used to access the Tablestore instance. This parameter corresponds to the accessId parameter in the WITH clause of the CREATE TABLE statement.

Parameter	Description
accessKey	The AccessKey secret of the account that is used to access the Tablestore instance. This parameter corresponds to the accessKey parameter in the WITH clause of the CREATE TABLE statement.
valueColumns	The names of the fields that you want to insert into the result table. Separate multiple names with commas (,).
bufferSize	The maximum number of data records that can be stored in the buffer before deduplication is triggered. This parameter corresponds to the bufferSize parameter in the WITH clause of the CREATE TABLE statement.
batchWriteTimeoutMs	The write timeout period. This parameter corresponds to the batchWriteTimeoutMs parameter in the WITH clause of the CREATE TABLE statement.
maxRetryTimes	The maximum number of retries for writing data to the table. This parameter corresponds to the maxRetryTimes parameter in the WITH clause of the CREATE TABLE statement.
retryIntervalMs	The retry interval. This parameter corresponds to the retryIntervalMs parameter in the WITH clause of the CREATE TABLE statement.
ignoreDelete	Specifies whether to skip delete operations. This parameter corresponds to the ignoreDelete parameter in the WITH clause of the CREATE TABLE statement.
primaryKey	The primary key field in the output fields.

Data type mapping

Tablestore data type	Realtime Compute data type
INTEGER	BIGINT
STRING	VARCHAR
BOOLEAN	BOOLEAN
DOUBLE	DOUBLE

2.15.5.4.5. MaxCompute

Realtime Compute supports creating a MaxCompute table as the result table.

Parameter configuration

Parameter	Description
-----------	-------------

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
tableName	The name of the MaxCompute table to which data is to be written.
Output Field	The fields to be written to the MaxCompute table.
endPoint	The endpoint used to access MaxCompute. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
tunnelEndPoint	The endpoint of the Tunnel service, which is required for a MaxCompute project deployed in a Virtual Private Cloud (VPC). It corresponds to the tunnelEndPoint parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the MaxCompute project to which data is to be written. It corresponds to the project parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to access MaxCompute. It corresponds to the accessId parameter in the WITH clause of the CREATE TABLE statement.
accessKey	The AccessKey secret used to access MaxCompute. It corresponds to the accessKey parameter in the WITH clause of the CREATE TABLE statement.
partition	<p>The partitions to which the data is to be written. It corresponds to the partition parameter in the WITH clause of the CREATE TABLE statement.</p> <p>This parameter must be specified for a partitioned table. For example, if the partition name of a table is <code>ds=20180905</code>, you can specify the parameter as <code>`partition` = 'ds=20180905'</code>. Separate multiple levels of partitions with commas (.), for example, <code>`partition` = 'ds=20180912,dt=xxxyyy'</code>.</p>

 **Note** Realtime Compute writes cached data to a MaxCompute table every time when a checkpoint is reached.

Field type mapping

MaxCompute data type	Realtime Compute data type
TINYINT	TINYINT
SMALLINT	SMALLINT
INT	INT

MaxCompute data type	Realtime Compute data type
BIGINT	BIGINT
FLOAT	FLOAT
DOUBLE	DOUBLE
BOOLEAN	BOOLEAN
DATETIME	TIMESTAMP
TIMESTAMP	TIMESTAMP
VARCHAR	VARCHAR
STRING	STRING
DECIMAL	DECIMAL
BINARY	VARBINARY

FAQ

Q: Does a real-time computing node clear the result table before it writes data to the MaxCompute sink that is in Stream mode when `isOverwrite` is set to `true` ?

A: The `isOverwrite` parameter is set to `true` by default. That is, a real-time computing node clears the result table and result data before it writes data to the sink. Every time a real-time computing node starts or resumes after being paused, it clears data of the existing result table or the result partition before it writes data. Certain data may be lost when data is cleared after a paused real-time computing node is resumed.

2.15.5.5. FAQ

This topic describes the frequently asked questions (FAQs) about Stream Studio.

Q: What computing engine do I need to activate before using Stream Studio?

A: You must first activate Realtime Compute because Stream Studio is a development platform based on Realtime Compute.

Q: Where can I create a Realtime Compute project? How do I bind the project to Stream Studio?

A: You can create a Realtime Compute project in the Realtime Compute console. After a project is created, you can bind it to an existing DataWorks workspace in the DataWorks console or directly create a workspace and bind the project to it. After the Realtime Compute project is bound to your workspace, you can develop real-time computing nodes in Stream Studio.

Q: What are the advantages of the directed acyclic graph (DAG) mode in Stream Studio? What are the similarities and differences between the DAG mode and SQL mode?

A: Stream Studio supports both the DAG mode and the SQL mode to develop real-time computing nodes. In DAG mode, you can perform drag-and-drop operations on components to configure real-time computing nodes without writing code. In this mode, what you see is what you get. You can also switch to the SQL mode to configure nodes by writing SQL statements.

Q: What types of SQL does Stream Studio support?

A: Realtime Compute is based on Apache Flink. Therefore, Stream Studio supports Flink SQL.

2.16. Data Protection

2.16.1. Overview

Data Protection is a data security management platform. It can be used to detect data assets, detect sensitive data, classify data, de-identify data, monitor data access behavior, report alerts, and audit risks.

Data Protection provides security management services for MaxCompute.

Access Data Protection

1. Log on to the DataWorks console.
2. On the DataWorks page that appears, click the icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now** to go to the Data Protection page.

Features

Data Protection provides the following features:

- **Intelligent sensitive data detection**
Data Protection automatically detects an enterprise's sensitive data based on self-training models and algorithms, and clearly displays statistics on data types, volume, and visitors. It also recognizes custom data types.
- **Accurate data classification:** Data Protection allows you to classify data and create custom levels for better data management.
- **Flexible data de-identification**
Data Protection provides diverse and configurable methods for dynamic data de-identification.
- **Risky behavior monitoring and auditing**
Data Protection uses various correlation analysis algorithms to detect risky behavior. It also provides alerts and supports visualized auditing for detected risks.

2.16.2. Configure rules for defining sensitive data

This topic describes how to configure rules for defining sensitive data.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now** to go to the **Data Security Guard** page.
4. In the left-side navigation pane, choose **Management > Data Definition**. On the Data Recognition Rules page that appears, click **Create Rule**.
5. In the dialog box that appears, set parameters in the **Set Basic Info** step.

You can create a template-based identification rule or a custom identification rule.

Parameter	Description
Data Type	<p>The category of the rule. You can select Template or Custom from the Data Type drop-down list.</p> <ul style="list-style-type: none"> ◦ If you select Template, you can select Personal Information, Merchant Information, or Company Information from the right drop-down list. ◦ If you select Custom, you can enter a data type.
Data Name	<ul style="list-style-type: none"> ◦ If you select Template from the drop-down list, you can select a built-in identification rule template from the right drop-down list. You can select Email, SeatNumber, MobilePhoneNumber, IP, MacAddress, CarNo, PostCode, IdCard, or BankCard. ◦ If you select Custom, you can enter a data name.
Owner	The owner of the rule.
Description	The description of the rule.

6. Click **Next**. Set the **Level** and **Data Definition** parameters.

Parameter	Description
Level	The security level of the sensitive data to which the rule is applied. If the existing security levels cannot meet your needs, click Levels in the left-side navigation pane to change the level settings.

Parameter	Description
Content Scanning	<p>Specifies whether to enable content scanning. This option is selected by default for all the built-in data identification templates.</p> <ul style="list-style-type: none"> ◦ If you select a template, you cannot modify the identification rule, but you can verify the accuracy of the identification rule. ◦ If you select regular expression matching, you can customize the identification rule.
Field Scanning	<p>Specifies whether to enable field scanning. This approach provides two matching methods: exact matching and fuzzy matching of field names. Multiple-field matching is supported, and the relationship between the fields is OR.</p>

7. Click **Next**. After you confirm the configuration, click **Save and Apply**.

-  **Note** When you create a rule to define sensitive data, note the following:
- The rule name must be unique.
 - The content scanning and field scanning configuration must be unique.
 - You can only view the sensitive data that is detected based on the data identification rule one day after the rule takes effect.

2.16.3. View the distribution of sensitive data

On the next day after you configure and activate sensitive data identification rules as a data security administrator, you can access Data Recognition to view the distribution of sensitive data.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. In the left-side navigation pane, click **Data Recognition**. On the Data Recognition page that appears, you can view the overall data distribution and field details.

2.16.4. View the information about data activities

On the next day after you configure and activate sensitive data identification rules as a data security administrator, you can access Data Activities to view related activity statistics, trend, and details.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. In the left-side navigation pane, click **Data Activities** to go to the **Data Activities** page.

The Data Activities page allows you to view the information of each activity that involves sensitive data. On the Manipulations and Queries tab, you can view the statistics, trend, user, and details of data access activities. On the Export tab, you can view the statistics and details of data export.

2.16.5. View the data audited as risky

Data activities are audited manually or based on the risk identification rules and AI-based identification rules. The Data Risks page displays data activities that are audited as risky. You can comment audit results as required.

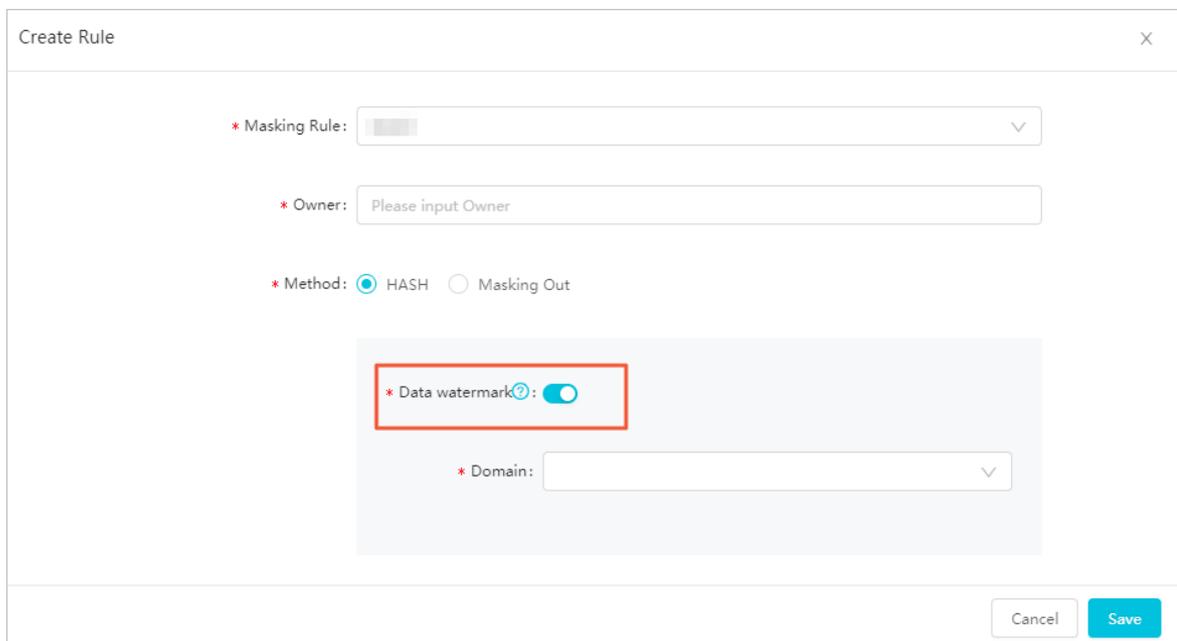

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now** to go to the **Data Security Guard** page.
4. In the left-side navigation pane, click **Data Risks** to filter and view the data audited as risky as needed.

2.16.6. Track data

You can create a data tracking task to track the source of leaked data. You can also download a data tracking file and delete a data tracking task.

Configure a data watermark

1. [Log on to the DataWorks console](#).
2. On the DataStudio page, click the  icon in the upper-left corner and choose **All Products > Data governance > Data Protection**.
3. On the page that appears, click **Try now**.
4. On the Data Protection page, choose **Rule Change > Data Masking** in the left-side navigation pane.
5. On the Data Masking page, click **Create Rule** to create a data masking rule. For more information, see [Customize de-identification rules](#). When you configure a data masking rule, you can turn on **Data watermark**. This way, a data watermark can be embedded into data when data masking is performed on the data, which facilitates the tracking of the leaked data.

 **Note** A data watermark cannot be added to Chinese data.

Create a data tracking task

1. In the left-side navigation pane, click **Data traceability**.

2. On the **Data traceability** page, click **New data tracing task**.
3. Drag the file in which data is leaked to the middle part of the **Traceability tasks** dialog box or click **Upload** to upload the file.

 **Note** You can upload a CSV file whose size is no more than 200 MB.

4. Click **Start tracing** to track the source of the leaked data.

 **Note** After the tracking computing starts, you can close the dialog box, and the computing is not affected.

5. After the computing is complete, click the  icon that corresponds to your data tracking task and view the tracking result. You can also enter a file name in the search box of the **Data traceability** page to view the historical data tracking task.

 **Note** Tracking results are for reference only. A data tracking task may not generate results or generate one or more results.

Download a data tracking file

On the **Data traceability** page, find a data tracking file that you want to download in the **Traceability file** column and click the  icon to download the file.

Delete a data tracking task

1. On the **Data traceability** page, find a data tracking task that you want to delete and click the  icon.
2. In the message that appears, click **Confirm**.

2.16.7. Manage a self-generated data recognition model

This topic describes how to train a model that can be used to summarize the data characteristics of specific columns in a table based on these columns. It also describes how to use the trained model to identify sensitive data.

Go to the Self Generated Data Recognition Model tab

1. [Log on to the DataWorks console](#).
2. On the **DataStudio** page, click the  icon in the upper-left corner and choose **All Products > Data governance > Data Protection**.
3. On the page that appears, click **Try now**.
4. On the **Data Protection** page, choose **Rule Change > Data Recognition Rules** in the left-side navigation pane.
5. Then, click **Self Generated Data Recognition Model**.

Create a self-generated data recognition model

1. On the **Self Generated Data Recognition Model** tab, click **Add Model**.
2. In the **Add Model** dialog box, configure the parameters.

Parameter	Description
Model Name	The name of the model that you want to create. The name can contain letters, digits, and underscores (_).
Owner	The name of the owner for the model. The name of the model can contain letters, digits, spaces, and underscores (_).
Selected Samples	You can select one or more columns from an existing MaxCompute table.

3. Click **Next** to go to the **Model Training** step.
4. Select **I accept data umbrella sampling for model training** and click **Start Training**.

 **Note** The column that you select must contain more than 10 rows. Otherwise, the system cannot start to train the model.

After the training starts, you can close the dialog box and view the training progress in the recognition model list.

5. View the status of the model in the recognition model list. After the training is complete, the status of the model becomes **Training Completed**. Click the  icon in the Actions column. Then, the Assess step of the Edit Model dialog box appears.
6. View the recognition results in the Assess step. In this step, a maximum of 10 results are displayed. You can also adjust the results based on your business requirements. If the accuracy of the recognition can meet your requirements, click **Create**. Then, the model is created. If excessive mismatches exist, you can click **Retrain** to retrain the model after you adjust the recognition results.

 **Note** In most cases, you must perform two to three training to optimize the model.

Retrain the self-generated data recognition model

1. Click **Retrain** to retrain the model if the recognition effect presented by the recognition results in the Assess step is not satisfactory.
2. Navigate to the Select Samples step. The system automatically places the recognition results in the Assess step into the Sample Field and Exclude Field sections based on the recognition results. Click **Next** to continue the training.
3. View the recognition results after the training process is complete.
4. Click **Create** if the recognition results are satisfactory to finish creating the model. If the recognition results are still not satisfactory, click **Retrain** to continue retraining the model.

Use the self-generated data recognition model

1. After the model is created, click **Go To Data Recognition Rules Online Page**.
2. In the **Create Rule** dialog box, Configure the parameters.

Parameter	Description
Data Type	You can set this parameter to Custom or Add By Template .

Parameter	Description
Rule Name	The value cannot be changed.
Owner	The value cannot be changed.
Description	The description of the data recognition rule. The description can be a maximum of 120 characters in length and cannot contain special characters.

3. In the **Specify Details** step, specify **Level** and select **Field Scanning**. Select a trained model from the **Data Recognition Rules** drop-down list and click **Next**.
4. In the **Complete** step, click **Save**.

Stop training a self-generated data recognition model

1. Find a model that is being trained and click the  icon in the **Actions** column to stop training the model.
2. Find the model whose training is stopped and click the  icon to continue the training.

Delete a self-generated data recognition model

Find a model that is not being trained and click the **Delete** icon in the **Actions** column to delete the model.

Note

- A model that is being trained cannot be deleted. If you want to delete such a model, you can stop training the model and delete it.
- A model that is in use cannot be deleted. If you want to delete such a model, you can delete the data recognition rules configured for the model and delete the model.

2.16.8. Manage the data security levels

When creating a rule, you can specify a security level for the data to which the rule applies. On the **Levels** page, you can create and delete security levels. You can also modify the priority of each security level and manage rules by security level.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now** to go to the **Data Security Guard** page.
4. In the left-side navigation pane, choose **Management > Levels**.

On the **Levels** page, you can create and delete security levels. You can also modify the priority of each security level and manage rules by security level.

Operation	Description
Create a security level	Click Create Level . Specify the security level name and operator.

Operation	Description
Manage rules by security level	Find the target security level and click the  icon in the Actions column. In the Manage Rules by Level dialog box that appears, you can select a rule and adjust its security level.
Delete a security level	Find the target security level and click the  icon in the Actions column. In the dialog box that appears, click Delete .
Modify the priority of a security level	Find the target security level. Drag and drop the  icon in the Actions column.

2.16.9. Manage data that is incorrectly detected

On the Manual Check page, you can manually correct the sensitive data that is incorrectly detected by rules. For example, you can delete incorrectly detected data, change the type of the detected data, and delete or recover data in batches.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now** to go to the **Data Security Guard** page.
4. In the left-side navigation pane, choose **Management > Manual Check**.

On the Manual Check page, you can delete incorrectly detected data, change the type of the detected data, and delete or recover data in batches.

- To delete a data record that is incorrectly detected, turn off the switch in the Status column of the data record.

 **Note** You can recover data records that you have deleted.

- To change the type of a data record, click the edit icon next to the name of the target rule and select a rule.

 **Note** You can only select a rule that has been configured in DataWorks.

- To delete or recover multiple data records at the same time, you can select the data records and click **Remove** or **Recover**.

2.16.10. Customize de-identification rules

This topic describes how to customize de-identification rules in Data Security Guard so that DataWorks can dynamically de-identify the results of ad hoc queries.

Prerequisites

Sensitive data detection rules are created and data security levels are specified. For more information, see [Configure rules for defining sensitive data](#) and [Manage the data security levels](#).

Go to the Data Masking page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now**.
4. In the left-side navigation pane, choose **Management > Data Masking**.

The **Data Masking** page has two tabs: **Data Masking** and **Whitelist**.

Customize de-identification rules in Data Security Guard

1. Set the **Masking Scene** parameter to **Global Config (_default_scene_code)** and click **Create Rule** in the upper-right corner.
2. In the **Create Rule** dialog box, set the **Rule**, **Owner**, and **Method** parameters.

 **Note** Data Security Guard provides three methods for de-identifying ID card numbers and email addresses, including **Pseudonymisation**, **Hashing**, and **Masking Out**. For other types of data, Data Security Guard only provides the **Hashing** and **Masking Out** methods.

o Pseudonymisation

This method replaces the text of a data record with an artificial pseudonym of the same data type. If you select this method, specify a security domain. Rules with different security domains generate different pseudonyms for the same data record.

o Hashing

If you select this method, specify a security domain. Rules with different security domains generate different hash values for the same data record.

o Masking Out

This method uses asterisks (*) to mask specified parts of a data record. It is commonly used.

Parameter	Description
Recommended	You can select recommended policies to mask data of common types such as ID card numbers and bank card numbers.
Custom	You can flexibly specify whether to mask the specified number of characters at the first, middle, or last part of a data record.

3. Click **OK**.
4. On the **Data Masking** tab of the **Data Masking** page, set the status of the de-identification rule to **Active** or **Inactive**.
You can click the **Test** icon in the **Actions** column of the rule to test whether it works.
5. Click the **Whitelist** tab. On the **Whitelist** tab, click **Add Account**.
6. In the **Add Account** dialog box, set the **Rule**, **Account**, **Effective From**, and **To** parameters. For more information about user groups, see [Manage user groups](#).

 **Note** If you query data beyond the time range specified for the whitelist, the query results will be de-identified.

7. Click **Save**.

Verify the de-identification effect in DataWorks

After you create and configure de-identification rules, DataWorks dynamically de-identifies the results of queries in your workspace based on the rules.

 **Note** You must first turn on Mask Data in Page Query Results for your workspace in the DataWorks console.

2.16.11. Manage user groups

You can create a user group on the GroupManagement page and reference it in a de-identification whitelist. You can also copy, edit, and delete user groups on the GroupManagement page.

Go to the GroupManagement page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now**.
4. In the left-side navigation pane, choose **Management > GroupManagement**. The GroupManagement page appears.

Create a user group

1. On the GroupManagement page, click **Create Group** in the upper-right corner.
2. In the **Create Group** dialog box that appears, set the parameters described in the following table.

Parameter	Description
Name	Enter the name of the user group.  Note The name of the user group must be unique.
Owner	Enter the owner of the user group.
Source Type	Specify the source of accounts in the user group. Valid values: <ul style="list-style-type: none">◦ Text: If you select this option, click Upload File next to Source File, select a local file to upload, and then click Open.◦ Select Existing Accounts: If you select this option, select the accounts to add next to Add Members and click >.

3. Click **Save**.

Copy a user group

On the GroupManagement page, find the target user group and click  in the Actions column. An identical user group is generated.

Note

- The name of the generated user group contains the -copy suffix. You can click  to change the name.
- You can only copy the content but not the dependencies of a user group.

Edit a user group

To edit an existing user group, follow these steps:

1. On the **GroupManagement** page, find the target user group and click  in the Actions column.
2. In the **Edit Group** dialog box that appears, modify parameters such as **Name**, **Owner**, and **Source Type**.
3. Verify the settings and click **Save**.

Delete a user group

To delete a user group, find the user group on the GroupManagement page and click **Delete** in the Actions column. In the dialog box that appears, click **Delete**.

Note You cannot delete a user group that is referenced in a de-identification whitelist.

If you still want to delete the user group, delete the user group from the corresponding de-identification whitelist first.

2.17. App Studio

2.17.1. Overview

App Studio is a tool designed to help you develop data products. It comes with a rich set of front-end components that you can drag and drop to simply and quickly build front-end apps.

With App Studio, you do not need to download and install a local integrated development environment (IDE) or configure and maintain environment variables. Instead, you can use a browser to write, run, and debug apps and enjoy the same programming experience as that in a local IDE. App Studio also allows you to publish apps online.

Advantages

App Studio has the following core advantages:

- **Data development anytime, anywhere**
You do not need to download and install a local IDE or configure and maintain environment variables. Instead, you can use a browser to develop data in your office, at home, or anywhere that you can connect to the network.
- **Editor with complete features**
App Studio provides a browser-based editor that allows you to easily write, run, and debug projects. When you enter the code, App Studio provides code hinting, code completion, and repair suggestions. You can also find all references and the definition of a method to automatically generate code.
- **Online debugging**
App Studio comes with all breakpoint types and operations of a local IDE. It supports thread switching and filtering, variable checking and watching, remote debugging, and hot code replacement.

- Multi-feature terminal

You can directly access the runtime environment, which is currently built based on CentOS as the base image. The multi-feature terminal supports all bash commands, including vim and other interactive commands.

- Collaborative coding

You and your team members can use App Studio to share the development environment for collaborative coding. Currently, App Studio allows a maximum of eight users to edit the same file of a project online concurrently, improving work efficiency. In the future, the collaborative coding component will support chatting, bullet screen messages, code annotations, videos, and other features to make teamwork efficient and pleasant.

- Plug-in system

App Studio supports business plug-ins, tool plug-ins, and language plug-ins.

- App Studio allows you to customize any required menu or add any service portal based on your business needs.
- You can customize project management processes, project types, and templates dedicated to your business.
- You can develop common tools, such as enhanced Git features, code rule scanning, keyboard shortcuts, enhanced editing features, and code snippets, and integrate them into App Studio.
- You can use language plug-ins to enrich the languages supported by App Studio, enabling App Studio to serve users with more languages while addressing your own business needs.

- Visual building

App Studio provides a WYSIWYG designer that has rich components and deeply integrates DataService Studio and DataStudio. Among all components of DataWorks, you can call DataWorks API operations only in App Studio. In addition to calling the API operations, you can quickly build front-end apps by dragging and dropping components and configuring them in the WYSIWYG designer based on the santa file system, developing web apps without code.

- Rich templates and flexible project management

App Studio provides rich project templates, allowing you to develop your project accordingly with fewer steps and higher efficiency. You can also save your project as a template for future development and use, or share it with other users.

2.17.2. Get started with App Studio

To build a data portal, engineers need to develop data, build backend services, and develop front-end pages. This topic describes the basic features of App Studio and how to use App Studio.

Originally, DataWorks is mainly used by data engineers to implement offline or streaming data development. As DataWorks becomes increasingly easy to use, many roles such as algorithm engineers, BI analysts, operators, and product managers who are familiar with SQL can use DataWorks to develop data.

App Studio helps different types of users quickly build webpages for data viewing and apps for data query.

Go to the App Studio page

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > App Studio**. The **Projects** page appears.

Create a front-end project

App Studio provides complete front-end development capabilities that allow you to develop front-end projects in the same way as in a local integrated development environment (IDE). Without the need to master or understand any new concepts, you can create front-end projects in App Studio and develop HTML, CSS, JavaScript, and React files in a way that you are familiar with.

1. Create a project based on the sample project.
 - i. Go to the **App Studio** page and click **Projects** in the left-side navigation pane. On the **Projects** page, click **Create Project from Code**.
 - ii. On the **Create Project** page, set the **Name** and **Description** parameters, and set the runtime environment to **react-demo**.

 **Note**

- The name of the project must start with a letter and can contain digits, letters, underscores (_), and hyphens (-).
- The description of the project can be 2 to 500 characters in length.

- iii. After the configuration is completed, click **Submit**.

2. Set running parameters.

In the upper-right corner, choose **Edit Config > Edit Configurations**. In the **Run/Debug Configurations** dialog box that appears, set the required parameter. Select the instance type and specify the port number as required. You can use the default configuration unless otherwise required. Then, click **OK**.

Parameter	Description
Install Cmd	The command used to install the dependency, for example, npm install .
Start Cmd	The command used to start the app, for example, npm start .
Environment Variables	The environment variables.
Initialize Script	The path of the script used to initialize a container in the code library.
PORT	The port of the Elastic Compute Service (ECS) instance. Default value: 3000.
ECS Instance	The instance type. Valid values: 1vCPU 2GMemory , 2vCPU 3GMemory , 4vCPU 8GMemory , and 8vCPU 16GMemory .

3. Run the project.

Click the **Run** icon in the upper-right corner to run the project. Currently, you can run the `tnpm start` command to start front-end projects. You can seamlessly run projects with `webpack-dev-server` configured.

During project running, you can view the dependency installation and app startup logs. After the project running is completed, the **Preview** tab appears in the right-side navigation pane. You can edit and save the code in real time. The edited code takes effect immediately.

4. Access the project.

Click the **Preview** tab in the right-side navigation pane, and click the arrow next to the access link to open the project.

In App Studio, you can edit and develop front-end projects in the same way as in a local IDE. App Studio supports code completion, method signature, refactoring, and redirection for HTML, CSS, LESS, SCSS, JavaScript, TypeScript, JSX, and TSX files. In addition, you can develop front-end projects based on templates without the need to build any environment or download any dependency.

Create a backend project

1. Create a project based on the sample project.
 - i. Go to the **App Studio** page and click **Projects** in the left-side navigation pane. On the **Projects** page, click **Create Project from Code**.
 - ii. On the **Create Project** page, set the **Name** and **Description** parameters, and set the runtime environment to **springboot**.
 - The name of the project must start with a letter and can contain digits, letters, underscores (_), and hyphens (-).
 - The description of the project can be 2 to 500 characters in length.
 - iii. After the configuration is completed, click **Submit**.

2. Set running parameters.

In the upper-right corner, choose **Edit Config** > **Edit Configurations**. In the **Run/Debug Configurations** dialog box that appears, set the required parameter and then click **OK**.

Parameter	Description
Main class	Select the main method. If no main method is available, check whether your project has a main method.
VM options	The virtual machine (VM) options.
Program arguments	The app parameters.
Environment Variables	The environment variables.
JRE	The Java runtime environment (JRE). By default, this parameter cannot be modified.
PORT	The port of the ECS instance. Default value: <i>7001</i> .
ECS Instance	The instance type. Valid values: 1vCPU 2GMemory , 2vCPU 3GMemory , 4vCPU 8GMemory , and 8vCPU 16GMemory .
Pre-Launch Option	The commands to be run before the project is run. You can specify up to three commands.
Enable Hot Code	Specifies whether to enable hot code replacement.

You can click **Add** on the left of the **Run/Debug Configurations** dialog box to add multiple configurations for running.

3. Run the project.

Click the **Run** icon in the upper-right corner to run the project.

The first time that the project is run takes a longer time because App Studio needs to allocate the ECS instance and initialize the language service. After the running is completed, the Runtime tab appears, showing the access link.

4. Access the project.

Click **Open Link** to access the project.

Append /testapi to the link and refresh the page.

Understand App Studio

The following operations are supported for created projects:

- Top navigation bar

- Project

From the Project menu, you can configure the project or view detailed information by selecting **Character Set** or **Project Information**. Provided information about the current project includes the ID specified by **Project ID**, name specified by **Project Name**, type specified by **Project Type**, creation time specified by **Created At**, and **UUID**.

- File

From the File menu, you can create a file or open a recently created file by selecting **Create File** or **Re-Open Most Recent Files**.

- Edit

From the Edit menu, you can perform common editing operations. To search all the code in the project and open the related file, select **Find in Path**.

- **Version**

From the Version menu, you can select **Switch Branch**, **View Changes**, **Submit**, **View Log**, **Connect to Remote Repo**, and **Merge Abort**.

- **Switch Branch**

In the Check Out Branch dialog box, you can click **+ Create Branch** to create a local branch and push it to the remote repo. You can click a local branch and select **checkout** from the shortcut menu on the right to switch to the branch. You can also select **merge** to merge the selected branch to the current branch.

You can click a remote branch and select **check out as a new local branch** from the shortcut menu on the right to check out the remote branch locally. Then rename the branch. You can also select **merge** to merge the selected branch to the current branch.

- **View Changes**

Click **View Changes** to view the list of edited files on a local branch in the right-side navigation pane.

- **Submit**

Click **Submit** to commit edits on a local branch for staging. You must enter the commit information.

- **View Log**

On the Log page, you can view all commit records of branches and filter them.

- **Connect to Remote Repo**

You can associate a new project with a remote repo for version control.

- **View**

You can click **Toggle Full Screen** or press **Esc** on the keyboard to enter or exit the full screen mode of the page. You can also click **Hide Sidebar** or **Hide Status Bar** to hide the right-side navigation pane or the status bar. If they are hidden, you can click **Show Sidebar** or **Show Status Bar** to show them respectively.

- **Debug**

- If you create a front-end project, you can set running parameters and add custom images.
 - App Studio supports Java-based debugging. In addition to setting running parameters and adding custom images, you can perform many other operations for debugging backend projects. You can also perform full or incremental builds and compile the `Main.java` file.

- **Settings**

From the Settings menu, you can set the Git configuration to import the Git code to create a project. You can also configure your preference and shortcut keys.

- **Deploy**

You can choose **Deploy > Download Source Code** to download the source code.

- **Template**

You can choose **Template > Manage Templates** to go to the **My Templates** page to manage templates.

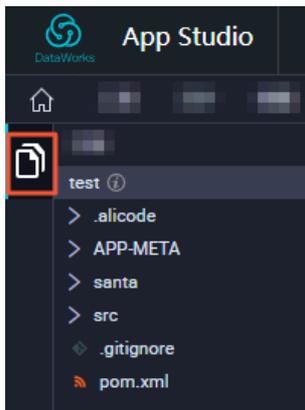

- **Left-side navigation pane**

- **Entry**

Click the icon framed in red. The project section appears.

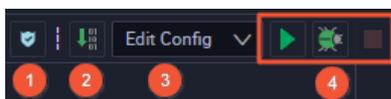

- **Edit section**

Double-click a file that you want to edit. In the Edit section that appears, right-click the code section to perform the following operations.

Action	Description
Go to Definition	Navigates to the definition page.
Peek Definition	Previews the definition.
Find All References	Searches for all references.
Workspace Symbol	Searches for a symbol in the project.
Go to Symbol...	Navigates to the symbol in the project.
Generate...	Generates the code.
Rename Symbol	Renames the symbol.
Change All Occurrences	Changes the name of all occurrences of a symbol throughout the file.
Format Document	Formats the file.
Cut	Cuts the file.
Copy	Copies the file.
Command Palette	Goes to the command palette.

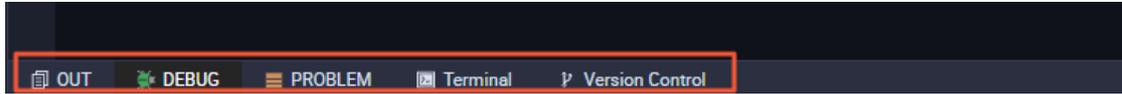

- Icons in the upper-right corner

No.	Feature
1	Alibaba Coding Guidelines
2	Build Program. You can perform this operation only when the project is running or being debugged.
3	Run/Debug Configurations. You can set parameters for running or debugging the project.

No.	Feature
4	Operations on the project, including running, debugging, or stopping the project.

- Bottom bar

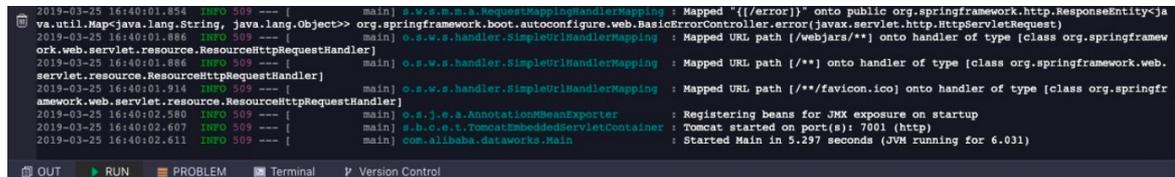

- OUT tab

You can click the OUT tab to view the output.

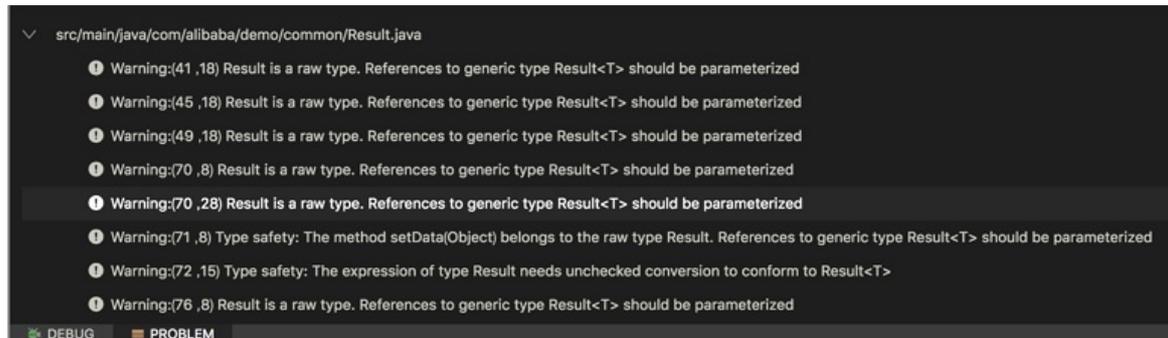

- RUN or DEBUG tab

If you click the Run or Debug icon for a project, this tab appears, showing the progress and information of the project.

- PROBLEM tab

If you click the Run or Debug icon for a project that has a problem, this tab appears.

- Terminal tab

When running or debugging a project, you can click the Terminal tab and run bash or vim commands on the ECS instance.

- Version Control tab

You can click the Version Control tab to view the logs and history of the project.

2.17.3. Navigation pane

2.17.3.1. View and manage projects

You can create and manage projects on the Projects page.

Go to the App Studio page and click **Projects** in the left-side navigation pane. On the page that appears, you can view projects that you have created. For more information about how to create template-based and code-based projects, see [Project management](#).

Click a project to go to the project editing page. You can also click **Create Template** of a project to create a template based on the project.

Create a template

1. Click **Create Template** of a project.
2. In the **Create Template** dialog box that appears, set each parameter.

Parameter	Description
Name	The name of the template.
Description	The description of the template.
Class	The class of the template.

3. After the configuration is completed, click **OK**.

2.17.3.2. View and manage templates

You can view all templates created based on projects on the Templates page.

Click a template to go to the template details page. Then, click **Code Editor** to view the project code that this template is based on.

You can also click **Create Project** of a template to create a project based on this template.

2.17.4. Project management

This topic describes how to create and manage projects.

You can create a template-based or code-based project.

Create a template-based project

1. Go to the App Studio page and click **Projects** in the left-side navigation pane. On the **Projects** page, click **Create Project from Template**.
2. On the **Create Project** page, specify **Name** and **Description**, and select a template.

Note

- You can select a custom template or a template provided by the system.
- All projects created by using templates support WYSIWYG development.

3. After the configuration is completed, click **Submit**.

Create a code-based project

You can create a project by running code. App Studio provides code templates for three types of runtime environments. Select a code template as required.

1. Go to the App Studio page and click **Projects** in the left-side navigation pane. On the **Projects** page, click **Create Project from Code**.
2. On the **Create Project** page, specify **Name** and **Description**, and select a template.
3. After the configuration is completed, click **Submit**.

View and manage projects

You can view the created projects on the **Projects** page.

You can click a project name to go to the project editing page. You can also click **Create Template** of a project to create a template based on the project.

 **Note** You can view projects shared by others but cannot create templates based on those projects.

2.17.5. Code editing

2.17.5.1. Overview

Code editing supports common IDE features, such as automatic completion, code hinting, syntax diagnosis, and global content search.

The following tables list the basic and advanced features that App Studio supports in different languages.

Basic feature	Java	Python	JavaScript and TypeScript
Completion	Supported	Supported	Supported
Hover	Supported	Supported	Supported
Diagnostics	Supported	Supported	Supported
SignatureHelp	Supported	Supported	Supported
Definition	Supported	Supported	Supported
References	Supported	Supported	Supported
Implementation	Supported (coming soon)	Not supported	Not supported
DocumentHighlight	Supported	Supported	Supported
DocumentSymbol	Supported	Supported	Supported
WorkspaceSymbol	Supported	Supported	Supported
CodeAction	Supported (Alibaba Java Guidelines coming soon)	Supported	Supported
CodeLens	References implementation	Not supported	Not supported
Formatting	Supported	Supported	Not supported

Basic feature	Java	Python	JavaScript and TypeScript
RangeFormatting	Supported	Not supported	Not supported
FindInPath	Supported	Supported	Supported

Advanced feature	Java	Python	JavaScript and TypeScript
Rename	Supported	Supported	Supported
WorkspaceEdit	Supported	Not supported	Not supported
UnitTest (quick start)	Supported	Not supported	Not supported
MainClass	Supported	Not supported	Not supported
MainClassQuickStart	Not supported	Not supported	Not supported
ListModules	Supported	Not supported	Not supported
Generate	Constructor Override Getter and Setter Implement	Not supported	Not supported

2.17.5.2. Generate code snippets

Currently, App Studio supports the Java class constructor, getter and setter methods, override methods of the parent class that a child class inherits, and API methods to be implemented.

Entry

Perform either of the following operations to generate the Java code:

- Right-click the code section and select **Generate**.
- Press Command+M on the keyboard. The Java code is automatically generated.

Constructor

On the Generate menu, click **Constructor**.

Select the fields to be included in the constructor and click **OK**.

The constructor that contains the initialization statement of the fields is generated.

Getter and setter methods

Generate the getter and setter methods in a way similar to the constructor.

 **Note** If a Java class does not have any field or the Java class is overwritten by the @data annotation of lombok, the getter or setter method is not required for the Java class. In this case, the Getter, Setter, and Getter And Setter options do not appear on the Generate menu.

Override methods

Click **Override Methods** on the **Generate** menu. All methods that can be overridden are listed in the **Generate Code** dialog box.

Select a method. The corresponding method is generated.

2.17.5.3. Run UT

App Studio currently supports unit testing (UT), including automatically generating UT code, detecting the entry for UT, running UT code, and displaying the UT result.

Automatically generate UT code

Open the target file, right-click the code editing section, select **Generate** and then click **Create Test**. The UT class file and UT code are automatically generated in the test directory.

Detect the entry for UT

 **Note**

- UT class files must be stored in the `src/test/java` directory. A Java UT class file that is not stored in this directory cannot be identified as the Java UT class.
- For a method annotated with `@Test` annotation, **Run Test** appears, indicating the entry for UT.

After the Java UT class file is created, add the `@Test` annotation of `org.junit.Test` to the corresponding sample UT method.

Run UT code

Click the **Run** icon in the upper-right corner. The sample UT starts.

2.17.5.4. Find in Path

App Studio provides the **Find in Path** feature to support global content search.

Move the pointer over **Edit** in the top navigation bar and select **Find in Path**.

You can select **Match Case**, **Words**, **Regex**, and **File Mask** as required. If you select **File Mask**, you must also select a file name extension from the right drop-down list to search in files of the specified type.

You can also search for content in the specified project, module, or directory.

After selecting a file, you can locate the searched content in the file and open the file in the editor.

2.17.6. Debugging

2.17.6.1. Configuration and startup

You can configure the entry method, start debugging, and set breakpoints to debug an app.

Configure the entry method

Parameter	Description
Main class	The entry method (which is the main method) you want to start. You can select a value from the drop-down list.

Parameter	Description
VM options	The parameters for starting a Java Virtual Machine (JVM), for example, -D, -Xms, and -Xmx.
Program arguments	The startup parameter, which is obtained by the args parameter in the main method.
Environment Variables	The environment variables.
JRE	The Java runtime environment. Default value: <i>1.8 - SDK</i> .
PORT	The port you want to expose in the app, for example, classic port 7001 or port 8080 for Spring Boot-based projects.
ECS Instance	The type of the ECS instance used for debugging.
Enable Hot Code	This configuration takes effect only in Run mode. By default, the HotCode2 plug-in that Alibaba Cloud provides is used.

Start debugging

Move the pointer over **Debug** in the top navigation bar and click **Start Debugging**.

The first startup is slower, because the system needs to prepare the runtime environment and download Maven dependencies for you. When you restart debugging, App Studio skips this process and provides user experience similar to that in a local IDE.

2.17.6.2. Online debugging

App Studio supports the online debugging of Java apps and Spring Boot-based web projects.

Before online debugging, you must configure the entry method and start debugging. For more information, see [Configuration and startup](#).

Exposed services

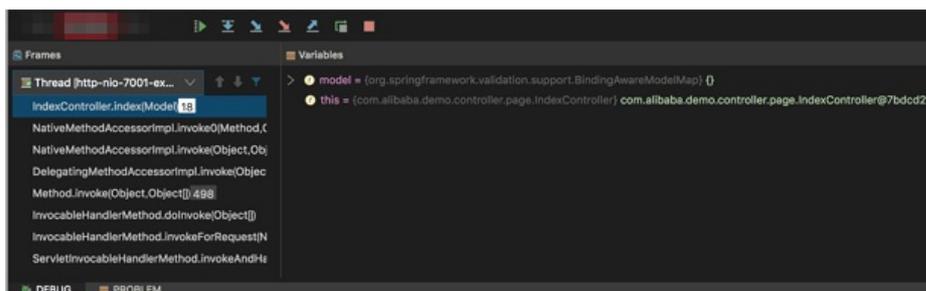

After your app is started, two basic services are provided. You can click the link next to Backend to debug the back-end Java code.

Panel introduction

- Output

The Output panel displays the standard output, excluding System.in, of all apps. It supports the ANSI color and guarantees consistent experience as a local terminal.

- Call Stack

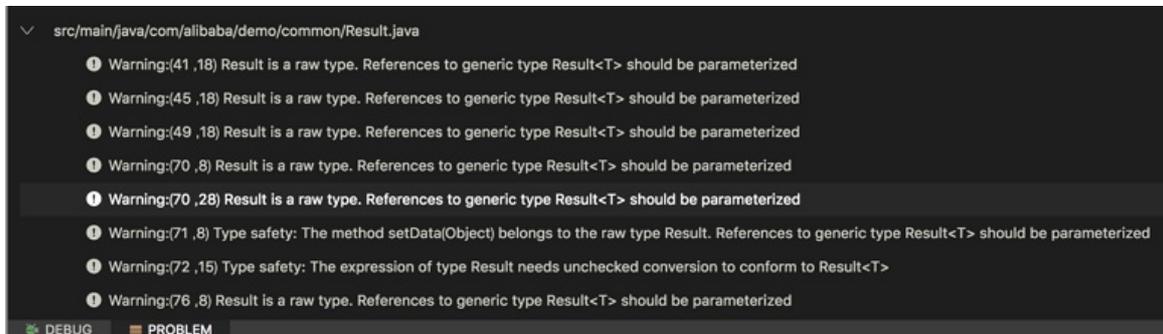

- Breakpoint

The Breakpoint panel displays the breakpoints that are currently set. For more information about the breakpoint types and usage, see Breakpoint types.

- **PROBLEM**

The **PROBLEM** panel displays compilation problems of apps. You can click a record to go to the corresponding line in the file.

2.17.6.3. Breakpoint types

App Studio supports normal line breakpoints, method breakpoints, and exception breakpoints.

Normal line breakpoint

You can click the blank section next to a line in the current file to generate a breakpoint for that line. The breakpoint also appears on the Breakpoint panel.

Method breakpoint

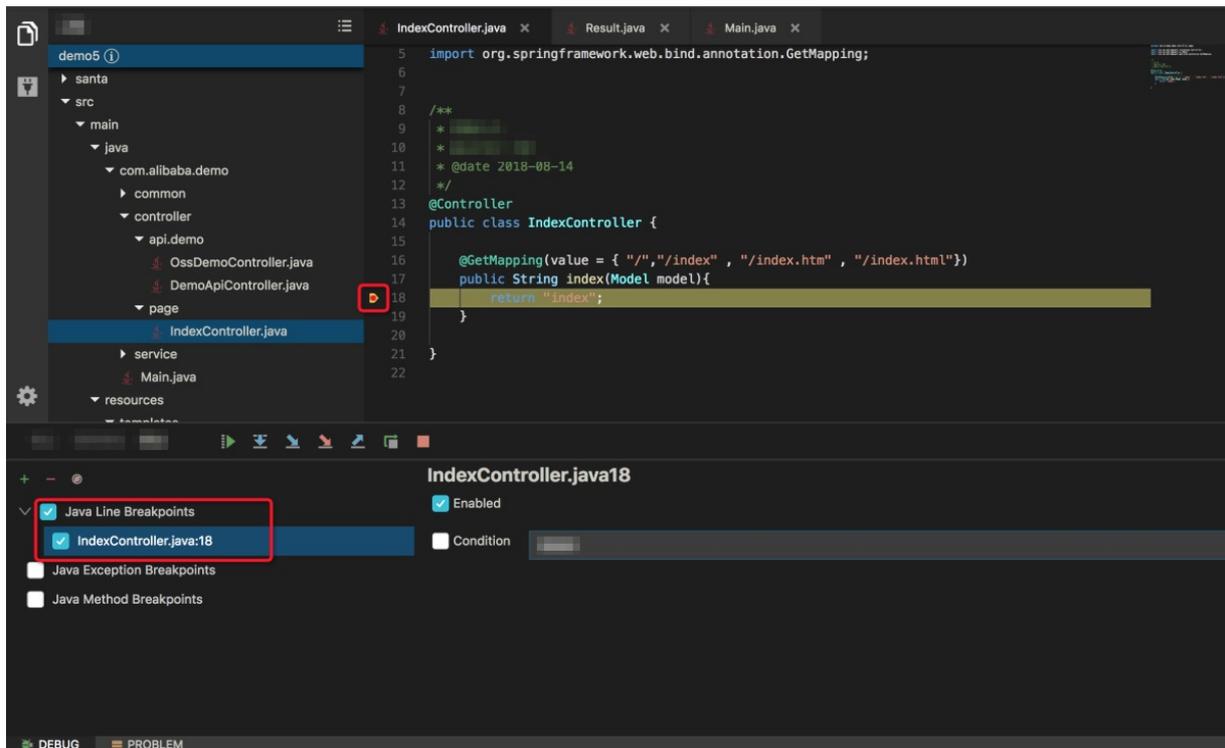

Different from a line breakpoint or an exception breakpoint, a method breakpoint triggers two events, namely, entry and exit. You can manually add a method breakpoint, or set a breakpoint at the place where the method is defined.

If the method breakpoint is triggered, the program stops when stepping into or out of the method.

Exception breakpoint

If an exception breakpoint is set, the program stops when encountering the exception.

As shown in the following figure, after index is triggered, the program stops in line 23 because **NullPointerException** appears.

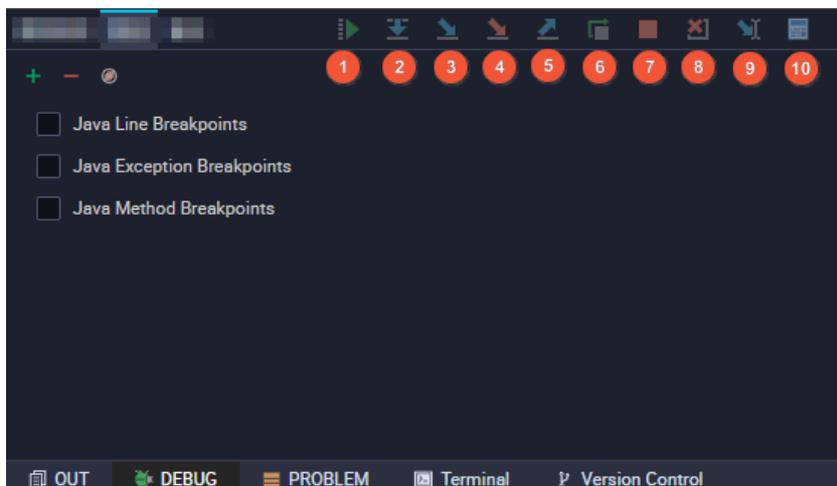

2.17.6.4. Breakpoint operations

The Breakpoint panel displays the breakpoints that are currently set. This topic describes how to operate breakpoints.

Breakpoints can be classified into normal line breakpoints, method breakpoints, and exception breakpoints. For more information, see [Breakpoint types](#).

Debugging buttons

You can perform the debugging operations by clicking the following buttons listed in the table:

No.	Feature	Description
1	Continue	Resumes the current breakpoint to continue the current thread.
2	Step Over	Runs to the next line.
3	Step Into	Steps into a method.
4	Force Step Into	Forcibly steps into a method of a class not to be stepped into. Different from Step Into , Force Step Into enables you to step into a method from a built-in Java library.
5	Step Out	Steps out of the current method.
6	Restart	Currently, the Restart button is not perfect enough and may not be able to clean up the program. This button is being optimized.
7	Stop	Stops debugging.
8	Drop Frame	Deletes the current stack and returns to the previous method.
9	Run to Cursor	Runs to the current line of code. You can set a temporary breakpoint in a line.
10	Evaluate Expression	Calculates an expression.

2.17.6.5. Terminal

You can start multiple terminals in App Studio.

The **Terminal** tab appears in the lower part of the page.

App Studio supports common shell commands such as **ls** and **cat** and interactive commands such as **vi** and **top**.

2.17.6.6. Hot code replacement

Using the hot code replacement feature, you can edit the running code of an app and make the edits effective without restarting the app.

For example, after you edit the code while debugging a Spring Boot-based app, you do not need to restart the app. The edited code takes effect once it is saved. App Studio supports this feature by default.

App Studio also supports hot code replacement while an app is running. To trigger hot code replacement, you only need to save the file without installing any plug-in or manually compiling the file.

If you are editing the code in Debug mode, App Studio automatically deletes the current running stack and returns to the method entry.

Configure hot code replacement in Run mode

Enable hot code replacement on the Run/Debug Configurations page.

After you click Run or Debug, the output information of the HotCode2 plug-in appears on the OUT tab.

Save the file after editing it.

Configure hot code replacement in Debug mode

You can use the native Java Debug Interface (JDI) to enable hot code replacement in Debug mode. However, due to Java Virtual Machine (JVM) restrictions, hot code replacement is unavailable when a method is added to or deleted from a class. You can save the file to trigger hot code replacement.

 **Note** The native JVM supports hot code replacement for operations such as adding or deleting a class. However, hot code replacement is unavailable when you change the class structure.

2.17.7. WYSIWYG designer

2.17.7.1. Get started with the WYSIWYG designer

This topic describes basic operations in the WYSIWYG designer, including creating a project and building a visual page.

Create a project

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > App Studio**. The **Projects** page appears.
3. Click **Projects** in the left-side navigation pane. On the page that appears, click **Create Project from Code**.
4. On the **Create Project** page, set the **Name** and **Description** parameters, and set **Select the runtime environment** to **appstudio**.
5. After the configuration is completed, click **Submit**.

Build a visual page

Open a project created by using the WYSIWYG designer. Go to the *santa/pages* directory in your project.

Double-click a .santa file to go to the WYSIWYG designer. For example, you can double-click the file named *home.santa*.

You can also right-click **pages** and choose **Create > Template** to develop the page based on a template.

The WYSIWYG designer consists of the component menu and operation panel.

- Component menu

The component menu lists all components that the WYSIWYG designer presets, including **layout components**, **basic components**, **form components**, **chart components**, and **advanced components**.

Select a component from the component menu and drag and drop it to the visual operation section. Click the component. The **Component Settings** panel appears on the right.

On the **Component Settings** panel, you can configure the component on the **Properties**, **Style**, and **Advance** tabs.

- Operation panel

You can click the corresponding icon on this panel to **undo an operation**, **redo an operation**, **preview the rendering result**, **enable the code mode**, **use the global style**, **configure the navigation**, **configure a global data flow**, **deploy as a template**, and **save edits**.

Click the **Configure Navigation** icon in the upper-right corner to go to the navigation configuration page. For more information, see [Navigation configuration](#).

Configure a global data flow

For more information about how to configure a global data flow, see [Global data flow](#).

On the Component Settings panel, you can configure the component on the **Properties**, **Style**, and **Advance** tabs.

- Configure component properties

On the Properties tab, you can visually configure component properties.

Based on the rules for configuring component properties, a visual form is generated on the Properties tab. After you configure component properties in this form, the WYSIWYG designer re-renders the component in the visual operation section based on the new properties. You can view the rendering results of the component with different properties in real time.

- Configure component styles

On the Style tab, you can configure the styles of a component.

A visual panel for configuring common styles is provided on the Style tab. On this panel, you can customize the basic styles of a component, including the layout, text, background, border, and effect.

After you add or modify the component styles on this tab, the WYSIWYG designer collects all the style settings and re-renders the component in the visual operation section based on the new component style. You can view the component configuration effect in real time.

- Configure association between components

On the Advanced Settings tab, you can configure association between components.

Select a component in the visual operation section and click the **Advance** tab. The properties of the selected component are listed on the left of the tab. Click the Magnifier icon on the right and select the component to be associated to your selected component.

The properties of the associated component appear on the right of the tab.

Select a property, for example, searchParams, in the left property list and connect it to a property, for example, requestParams, in the right property list.

In this way, any change of the searchParams parameter of the left component is transferred to the requestParams parameter of the right component in real time. This achieves property-based association between the two components.

Configure the code mode

By using the code mode, you can implement complex interactions in a more advanced way. For more information, see [Code mode](#).

Save, preview, run, and hot code replacement

For more information, see [Save, preview, run, and hot code replacement](#).

2.17.7.2. Code mode

By using the code mode, you can implement complex interactions in a more advanced way.

Click the **Code Mode** icon in the upper-right corner of the operation panel to enable the code mode.

The WYSIWYG designer uses domain-specific language (DSL) at the intermediate layer to switch between the visualization mode and code mode. DSL can be considered as a simplified version of React. The DSL syntax is basically the same as the React syntax.

As shown in the code section in the preceding figure, DSL uses a tag to describe a component. The tag properties are the component properties. The property value can be of a simple data type such as a string or a number. The property value can also be an expression. You can enter `state.xxx` to obtain data from the global data flow.

The code mode has the following features:

- If you drag and drop a component or configure the component properties in the visualization section, the edits are updated in the code in real time.
- If you edit the code in the code section, the edits are updated in the visualization section in real time.
- The drag-and-drop operation and component property configuration in the visualization section and code edits in the code section can be converted between each other.

2.17.7.3. DSL syntax

Domain-specific language (DSL) is a component-based language developed based on the features of React JSX and Vue templates and is more suitable for UI layout design.

JSX

The DSL syntax is similar to the JSX syntax in the `React.render` method. The following section provides a brief description of JSX:

- You can use `{}` to switch an HTML scope to a JavaScript scope. In a JavaScript scope, you can write any valid JavaScript expression. The return value appears on the page, for example, `<div>{'Hello' + ' Relim'}</div>`.

 **Note** You can write any JavaScript expressions such as computing statements or literals in `{}`.

- An HTML tag is used to switch a JavaScript scope to an HTML scope, for example, `<div>Hello Relim</div>`.
- The HTML scope and JavaScript scope can be nested, for example, `<div>{'Hello' + ' Relim'}</div>`.

Valid JavaScript expressions

```
// Computing statements
{aaa} // Variable aaa must be defined.
{aaa * 111}
{1 == 1 ? 1 : 0}
{/^123/.test(aa)}
{{1,2,3}.join("")}
{(()=>{return 1})()} // The self-executing function.
// Literals
{1}
{true}
{{11,22,33}}
{{aa:"11",bb:"22"}}
{()=>1} // Describe a function, which is valid but meaningless.
```

Note If certain complex logic must be implemented by multiple computing statements rather than only one statement, you can wrap the logic in a self-executing function, which must be a valid expression. The following statements provide an example:

```
{{function(){
  // Sum the even digits of a number array.
  var input = [1,2,3,4,5,6,7,8,9,10];
  var temp = input.filter(i => i % 2 == 0)
  return temp.reduce((buf, cur) => buf + cur, 0)
}}()
```

Invalid JavaScript expressions

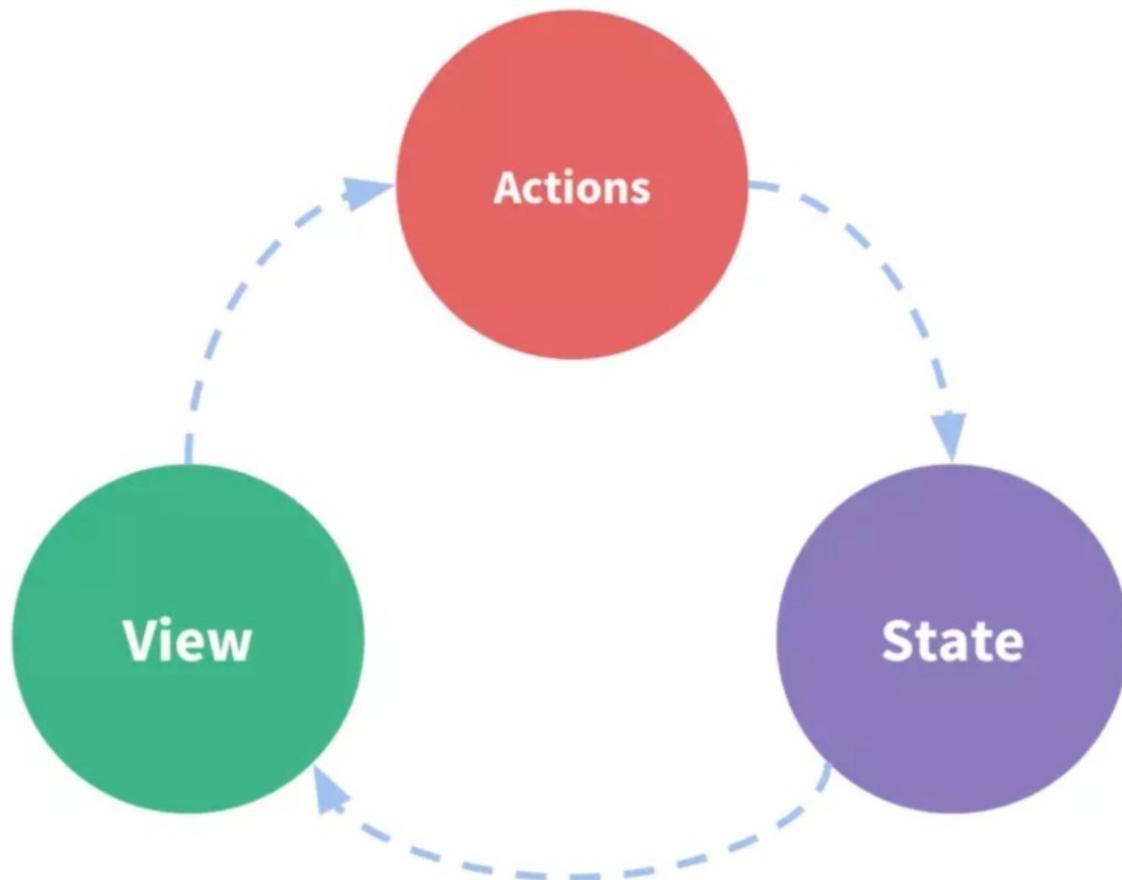

```
{ var a = 1 } // The value assignment statement.
{ aaa * 111; 2 } // Multiple statements separated with semicolons (;).
```

2.17.7.4. Global data flow

A global data flow is used for front-end data management. For multiple components that need to share a state, it is difficult to transfer the state among them. To resolve this issue, you can extract the shared state and use a global data flow to transfer it to all related components.

Principles

In a global data flow, global data is transferred in a globally unique way. Once the data declared in global data changes, the data flow shown in the following figure is executed.

1. A component triggers an action when, for example, a user clicks the component.
2. The action triggers global data changes.
3. Upon the global data changes, components that reference the global state are automatically re-rendered.

Scenarios

A global data flow is applicable to the association of two or more components on a page. You can refine public data into global data for unified management, and then use a global data flow to associate two or more components.

Configure a global data flow

1. Click the **Global Data Flow Settings** icon in the upper-right corner of the operation panel.
2. In the **Global Data Flow Settings** dialog box that appears, set **Variable Name** and **Value**.
 - The variable value can be a number, character string, or JSON string.
 - If the variable value is declared as an API endpoint, data obtained from the API is automatically used as the value of the variable name.
3. Click **Save**.

Use a global data flow

- Obtain global data

Use `state.name` in the component to obtain global data.

```
<Input value={state.name} />
```

- Modify global data

Use the `$setState()` method in the component to modify global data.

```
<Input onChange={value => $setState({ name: value })} />
```

 **Note** You must use the `$setState()` method to modify global data. If you use `state.name = 'new value'`, re-rendering cannot be triggered.

2.17.7.5. Save, preview, run, and hot code replacement

In the WYSIWYG designer, you can perform operations such as saving edits, previewing the rendering result, running an app, or making edits in hot code replacement mode.

Save edits

The WYSIWYG designer periodically saves your edits. You can also click the **Save** icon in the upper-right corner of the operation panel to save edits.

Preview the rendering results

In the WYSIWYG designer, code in the operation section is in the editable status. However, special processing is added for the editable status of some components. For these components, you can run the rendering logic only when the app is running. To preview the rendering result, click the **Preview** icon in the upper-right corner of the operation panel.

Run an app

In the WYSIWYG designer, you can open and edit only one santa file at a time. To view the effect of the entire app,

click the **Run Program** icon on the **Debug** panel of **App Studio** to run the app.

Make edits in hot code replacement mode

If you are not satisfied with any page after running the app, you can edit the code in the WYSIWYG designer and save the edits.

The edited code takes effect on the running page in hot code replacement mode.

2.17.7.6. Navigation configuration

This topic describes how to configure the site navigation in the WYSIWYG designer.

The WYSIWYG designer provides each app with a public page header, a public bottom bar, and public sidebars, where you can configure various menus and themes. You can also specify whether to display the public header, bottom bar, and sidebars as required.

Click the **Navigation Settings** icon in the upper-right corner of the operation panel to go to the page for configuring the navigation of an app.

Configure the public header

You can configure the public header based on your business requirements.

Parameter	Description
Enabled	Specifies whether to display the public header.
Theme	The theme of the public header. You can select a dark or light theme.
Logo Image	The logo image of the site. You can enter an image URL or upload a local image.
Title	The title of the site.
Fix to Page Top	Specifies whether to fix the public header to the top of the page. If you turn on this switch, the public header stays at the top of the page when the page scrolls.
Menu Items	The menu items such as the link name and link URL that are displayed in the public header.

Configure the sidebars

You can configure the sidebars based on your business requirements.

Parameter	Description
Enabled	Specifies whether to display the sidebars.
Theme	The theme of the sidebars. You can select a dark or light theme.
Enable Folding	Specifies whether the sidebar menus can be hidden.

2.18. Migration Assistant

2.18.1. Overview

The Migration Assistant service of DataWorks allows you to migrate data objects across different DataWorks versions, Alibaba Cloud accounts, regions, and workspaces.

Migration Assistant allows you to export data objects in your workspace, including auto triggered nodes, manually triggered nodes, resources, functions, data sources, table metadata, ad hoc queries, and components. You can create full export tasks, incremental export tasks, or custom export tasks to export your data objects in DataWorks based on your business requirements.

 **Notice** To create export or import tasks, you must use an Alibaba Cloud account or be the workspace administrator. If you use a Resource Access Management (RAM) user that is not assigned the administrator role, you can only view export and import tasks.

Scenarios

- Back up node code

You can use Migration Assistant to periodically back up your node code to prevent data from being deleted by mistake. In this case, we recommend that you create a full export task.

- Export a common workflow for replication

You can use Migration Assistant to export a common workflow that can be replicated in other workspaces. In this case, we recommend that you create a custom export task.

- **Build a test environment**

You can use Migration Assistant to copy all the node code and replace the production data with test data to build a test environment. In this case, we recommend that you create a full export task or a custom export task.

- **Develop data in a hybrid cloud environment**

You can use Migration Assistant to migrate node code from Alibaba Cloud public cloud to Alibaba Cloud Apsara Stack to develop data in a hybrid cloud environment. We recommend that you create a custom export task. If the difference between Alibaba Cloud public cloud and Alibaba Cloud Apsara Stack is large, a compatibility problem may occur when data objects are migrated.

- **Migrate data objects between the development environment and production environment**

If a workspace consists of the production environment and development environment that are completely isolated, you can use Migration Assistant to export nodes from the development environment and import them to the production environment for deployment.

2.18.2. Cloud tasks

2.18.2.1. Export tasks from open source engines

DataWorks allows you to migrate tasks from open source scheduling engines such as Oozie and Azkaban to DataWorks. This topic describes the requirements for the files to be exported.

Context

Before you import a task of an open source scheduling engine to DataWorks, you must export the task to your on-premises machine or Object Storage Service (OSS). For more information about the import procedure, see [Import tasks of open source engines](#).

Export a task from Oozie

Requirements and structure of the package to be exported:

- **Requirements**

The package must contain XML-formatted definition files and configuration files of a flow task. The package is exported in the ZIP format.

- **Structure**

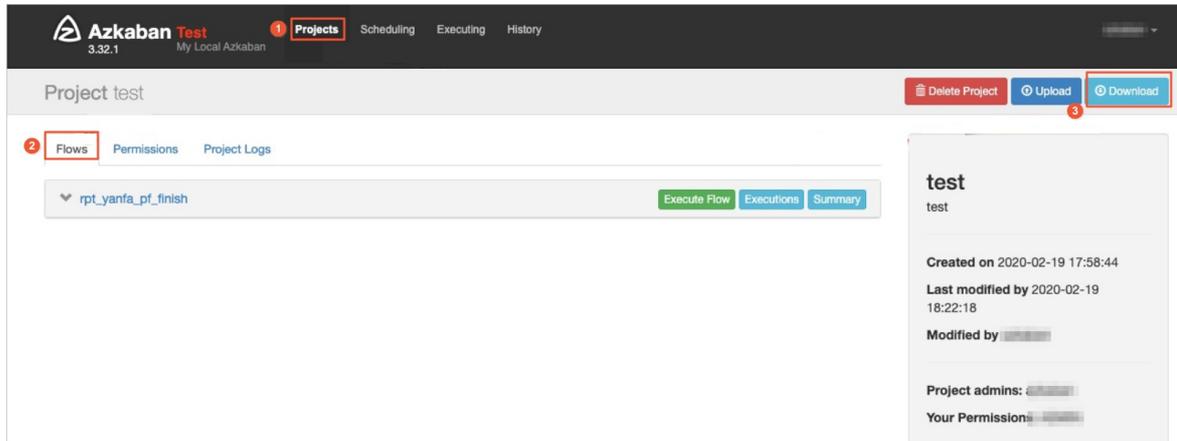

Oozie task descriptions are saved in a Hadoop Distributed File System (HDFS) directory. For example, each subdirectory under the apps directory in the Examples package at the Apache Oozie official website is a flow task of Oozie. Each subdirectory contains XML-formatted definition files and configuration files of a flow task.

```
1 $tree
2 .
3 |— aggregator
4 |   |— coordinator-with-offset.xml
5 |   |— coordinator.xml
6 |   |— job.properties
7 |   |— job-with-offset.properties
8 |   |— lib
9 |   |   |— oozie-examples-4.2.0.jar
10 |   |— workflow.xml
11 |— sqoop
12 |   |— db.hsqldb.properties
13 |   |— db.hsqldb.script
14 |   |— job.properties
15 |   |— workflow.xml
16 |— cron
17 |   |— coordinator.xml
18 |   |— job.properties
19 |   |— workflow.xml
20 |— cron-schedule
21 |   |— coordinator.xml
22 |   |— job.properties
23 |   |— workflow.xml
```

Export a task from Azkaban

You can download a specific flow task in the Azkaban console.

1. Log on to the Azkaban console and go to the **Projects** page.
2. Select a project whose package you want to download. On the page for the project, click **Flows** to show all flow tasks under the project.
3. Click **Download** in the upper-right corner of the page to download the package of the project.

Native Azkaban packages can be exported. No limit is imposed on the packages of Azkaban. The exported package in the ZIP format contains information about all tasks and relationships under a specific project of Azkaban.

Export tasks from other open source engines

DataWorks provides a standard template for you to export the tasks of open source engines except for Oozie and Azkaban. Before you run an export task, you must download the standard template and modify the content to be exported based on the file structure in the template. You can go to the **Open Source engine export** page to download the standard template and view the file structure.

1. [Log on to the DataWorks console](#).
2. On the DataStudio page, click the  icon in the upper-left corner and choose **All Products > Other > Migration Assistant**.
3. In the left-side navigation pane, choose **Cloud tasks > Open Source engine export** to go to the **Open Source engine export scheme selection** page.
4. Click the **Standard Template** tab.
5. On the **Standard Template** tab, click **standard format Template** to download the template.
6. Modify the content to be exported based on the template and generate a package to be exported.

2.18.2.2. Import tasks of open source engines

This topic describes how to import tasks that are exported from open source engines into DataWorks.

Procedure

1. Go to the **Open Source engine import** page.
 - i. [Log on to the DataWorks console](#).
 - ii. On the DataStudio page, click the  icon in the upper-left corner and choose **All Products > Other > Migration Assistant**.
 - iii. In the left-side navigation pane, choose **Cloud tasks > Open Source engine import**.
2. Create an import task.

- i. On the **Import Tasks** page, click **Create Import Task** in the upper-right corner.
- ii. In the **Create Import Task** dialog box, configure the parameters as required.

Parameter	Description
Name	The name of the import task. The name can contain only letters, digits, underscores (_), and periods (.).
Engine type	The engine type. Valid values: Azkaban , Oozie , and Standard format .
Upload From	<p>The source of the package that you want to import. Valid values: Local and OSS.</p> <ul style="list-style-type: none"> ▪ If you select Local for this parameter, perform the following steps to upload a package on your machine: <ol style="list-style-type: none"> a. Click Upload File. b. Select the package that you want to upload and click Open. c. Click Check. d. After the message The resource package has passed the check appears, verify that the file format and content are correct. <div style="background-color: #e1f5fe; padding: 5px; margin: 5px 0;"> <p> Note The size of the package that you want to upload cannot exceed 30 MB. If the size of the package exceeds 30 MB, select OSS for this parameter.</p> </div> <ul style="list-style-type: none"> ▪ If you select OSS for this parameter, enter the endpoint of an Object Storage Service (OSS) object in the OSS Endpoint field. Then, click Check and Preview in sequence to check and preview the package that you want to upload.
Remarks	The description of the import task.

iii. Click **OK**. The **Edit import task** page appears.

3. Edit the import task.

- i. On the **Edit import task** page, specify **Import objects**. **Periodic tasks** is selected for **Import objects** by default. If you want to import data objects of another type, select the required value from the **Import objects** drop-down list.
- ii. (Optional) Click **Advanced Settings**. In the **Advanced Settings** dialog box, configure the mappings between the compute engine instances and the node types and click **OK**. If multiple compute engine instances are bound to the destination workspace, you must complete the settings in the **Advanced Settings** dialog box. You can configure the mappings between compute engine instances and nodes of the **Shell**, **Hive**, and **Sqoop** types.
- iii. On the **Edit import task** page, click **start import** in the upper-right corner.

4. View the import report.

- i. In the **Import progress** dialog box, confirm the import task progress.
- ii. After the import task is completed, click **Return to import task list**.
- iii. Find the task on the **Import Tasks** page and click **View Import Report** in the **Actions** column. On the page that appears, view the task information in the **Basic Information**, **Import Settings**, **Import results**, and **Details** sections.

2.18.3. Migrate data objects in DataWorks

2.18.3.1. Create and view export tasks

Migration Assistant allows you to export data objects in your workspace, including auto triggered nodes, manually triggered nodes, resources, functions, table metadata, data sources, components, and ad hoc queries. This topic describes how to create and view export tasks.

Prerequisites

To create export or import tasks, you must use an Alibaba Cloud account or be the workspace administrator. If you use a Resource Access Management (RAM) user that is not assigned the administrator role, you can only view export and import tasks.

Context

Migration Assistant allows you to export data objects in different modes. These modes include full export, incremental export, and custom export. You can choose an export mode that best suits your business scenario.

- Full export tasks are used to export all the data objects in a workspace. For example, you can run a full export task to back up node code or clone the workspace to a test environment. When you run a full export task, data objects of the latest version are exported.

Only saved data objects can be exported. If a node is saved in both the development environment and production environment, the node saved in the development environment is exported.

- Incremental export tasks are used to export data objects that were modified after the specified date.

 **Note** You cannot configure a blacklist for incremental export tasks.

- Custom export tasks are used to export data objects that you specify. For example, you can run a custom export task to extract a common workflow and clone it to other workspaces. If a workspace runs in both a production environment and a development environment that are completely isolated from each other, you can run a custom export task to export nodes from the development environment and import them to the production environment for deployment.

Go to the Migration Assistant page

1. [Log on to the DataWorks console.](#)
2. On the DataStudio page, click the  icon in the upper-left corner and choose **All Products > Other > Migration Assistant**. The **DataWorks export** page under **DataWorks migration** appears.

Create a full export task

1. On the **Export Tasks** page, click **Create Export Task** in the upper-right corner.
2. In the **Create Export Task** dialog box, configure the parameters as required.

Parameter	Description
Name	The name of the export task. The name can contain only letters, digits, underscores (_), and periods (.).
Type	The type of the export task. Select Full export for this parameter. A full export task is used to export all the auto triggered nodes, manually triggered nodes, table metadata, and data sources that have been saved or committed in the current workspace.

Parameter	Description
Blacklist	Specifies whether to enable the blacklist feature for full export based on your business needs. If you select the Add to Blacklist check box, you can add the nodes and resources that do not need to be exported to a blacklist.
Export Version	Valid values: Standard , Private Cloud(>=V3.12) , and Private Cloud(V3.6.1-V3.1.1) . The DataWorks version determines the format in which data objects are exported. Check the DataWorks version of the destination workspace before you create an export task.
Remarks	The description of the export task.

3. (Optional)Click **Add to Blacklist** and run the export task. If you select **Add to Blacklist**, perform the following steps to configure the blacklist:
 - i. In the **Create Export Task** dialog box, click **Add to Blacklist**.
 - ii. On the **Set Blacklist** page, select the data objects that you do not want to export.
 - iii. Click **Add Selected to Blacklist**.
 - iv. Click **Export** in the upper-right corner.
 - v. In the **Export confirmation** message, click **Confirm**.
4. (Optional)If you do not select **Add to Blacklist**, click **Export** in the **Create Export Task** dialog box.
5. In the **Export Progress** dialog box, view the progress of the export task. After the task succeeds, click **Back to Export Tasks**.

Create an incremental export task

1. On the **Export Tasks** page, click **Create Export Task** in the upper-right corner.
2. In the **Create Export Task** dialog box, configure the parameters as required.

Parameter	Description
Name	The name of the export task. The name can contain only letters, digits, underscores (_), and periods (.).
Type	The type of the export task. Select Incremental for this parameter. An incremental export task is used to export data objects that were modified after the specified date. Supported data objects include auto triggered nodes, manually triggered nodes, table metadata, and data sources that have been saved or committed in the current workspace.
Start Date	The date on which data is modified. The data generated after this date is incremental data.
Export Version	Valid values: Standard , Private Cloud(>=V3.12) , and Private Cloud(V3.6.1-V3.1.1) .
Remarks	The description of the export task.

3. Click **Export**.

Create a custom export task

1. On the **Export Tasks** page, click **Create Export Task** in the upper-right corner.
2. In the **Create Export Task** dialog box, configure the parameters as required.

Parameter	Description
Name	The name of the export task. The name can contain only letters, digits, underscores (_), and periods (.).
Type	The type of the export task. Select Custom for this parameter. A custom export task is used to export data objects that you specify. Supported data objects include auto triggered nodes, manually triggered nodes, table metadata, and data sources that have been saved or committed in the current workspace.
Export Version	Valid values: Standard , Private Cloud(>=V3.12) , and Private Cloud(V3.6.1-V3.1.1) .
Remarks	The description of the export task.

3. Click **Select Export Objects**.
4. On the **Export Objects** page, select a type of data object that you want to export from the **Export Object** drop-down list. Valid values of **Export Object**: **Table**, **Periodic tasks**, **Resources**, **Manual tasks**, **Function**, **DATA_SERVICE**, **Data source**, **Components**, and **Temporary query**.
5. Select the data objects that you want to export and click **Add Selected to Export Package**. You can also configure filter conditions such as **Export Object**, **Object Type**, and **Export Environment** to search for data objects. Then, click **Add All to Export Package** to add all the data objects that have been found to the package that you want to export.
6. Click **Export** in the upper-right corner.

View and manage export tasks

On the **Export Tasks** page, you can view the name, type, creator, status, update time, and description of created export tasks. The operations that you can perform on export tasks vary based on their status.

- If an export task is in the **Successful** state, you can perform the following operations on the task:
 - Click **View Export Report** in the **Actions** column. On the page that appears, view the task information in the **Basic Information**, **Overview**, and **Details** sections.
 - Click **Download** in the upper-right corner to download the package of the export task to a local directory.
 - Clone the export task.
 - Full export task for which the blacklist feature is not enabled: Click **Clone** in the **Actions** column. In the **Clone** dialog box, specify **Name** and click **Export**.
 - Full export task for which the blacklist feature is enabled: Click **Clone** in the **Actions** column. In the **Clone** dialog box, specify **Name** and click **Add to Blacklist**.
 On the **Set Blacklist** page, select the data objects that you do not want to export, click **Add Selected to Blacklist**, and then click **Export** in the upper-right corner.
 - Custom export task: Click **Clone** in the **Actions** column. In the **Clone** dialog box, specify **Name** and click **Select Export Objects**.
 On the **Export Objects** page, select the data objects that you want to export, click **Add Selected to Export Package**, and then click **Export** in the upper-right corner.
- If an export task is in the **Export failed** state, you can click **View Export Package**, **Download Export Package**, or **Re-export** in the **Actions** column as required. To retry the export task, click **Re-export**.
- If an export task is a custom export task that is in the **Editing** state, you can perform the following operations on the task:

- Click **Edit** in the Actions column. On the **Export Objects** page, modify the data objects that you want to export.
- Click **View Export Package** in the Actions column. On the **Export Package Details** page, view the task information in the **Basic Information**, **Overview**, and **Details** sections.
- Click **Delete** in the Actions column. In the **Delete** message, click **Ok** to delete the task.
- If an export task is a full export task that is in the **Editing** state, you can click **Edit**, **Delete**, or **View Blacklist** in the Actions column as required. If you click **View Blacklist** in the Actions column, you can check the blacklist and click **Export** to run the export task or click **Close** in the dialog box that appears.

2.18.3.2. Create and view import tasks

After you run an export task to export data objects from a workspace, you can create an import task to import these data objects to a specified workspace.

Prerequisites

To create export or import tasks, you must use an Alibaba Cloud account or be the workspace administrator. If you use a Resource Access Management (RAM) user that is not assigned the administrator role, you can only view export and import tasks.

Go to the Migration Assistant page

1. [Log on to the DataWorks console.](#)
2. On the DataStudio page, click the  icon in the upper-left corner and choose **All Products > Other > Migration Assistant**. The **DataWorks export** page under **DataWorks migration** appears.

Create an import task

1. In the left-side navigation pane of Migration Assistant, choose **DataWorks migration > DataWorks import**.
2. On the **Import Tasks** page, click **Create Import Task** in the upper-right corner.
3. In the **Create Import Task** dialog box, configure the parameters as required.

Parameter	Description
Name	The name of the import task. The name can contain only letters, digits, underscores (_), and periods (.).

Parameter	Description
Upload From	<p>The source of the package that you want to import. Valid values: Local and OSS.</p> <ul style="list-style-type: none"> ◦ If you select Local for this parameter, perform the following steps to upload a package on your machine: <ul style="list-style-type: none"> a. Click Upload File. b. Select the package that you want to upload and click Open. c. Click Check. d. After the message The resource package has passed the check appears, click Preview. On the page that appears, check the package that you want to import. <div style="background-color: #e6f2ff; padding: 5px; margin: 10px 0;"> <p> Note The size of the package that you want to upload cannot exceed 30 MB.</p> </div> <ul style="list-style-type: none"> ◦ If you select OSS for this parameter, enter the endpoint of an Object Storage Service (OSS) object in the OSS Endpoint field. Then, click Check and Preview in sequence to check and preview the package that you want to upload.
Remarks	The description of the import task.

4. Click **OK**. The **Import Task Settings** page appears. Make sure that you have checked the format and content of the package before you click **OK**.
5. Configure the import task. When you configure the import task, you must complete the settings in the **Engine Instance Mapping** section. The settings in other sections are optional and can be configured as required.
 - (Optional)
 - i. In the **Engine Instance Mapping** section, select a compute engine of the destination workspace for each compute engine that is bound to the source workspace. If multiple compute engines are bound to the source workspace and only one compute engine is bound to the destination workspace, the import task fails. This is because some types of nodes cannot be created in the destination workspace due to the absence of the required compute engines.
 - ii. (Optional) In the **Resource Group Mapping** section, configure resource group mapping between the source and destination workspaces. This ensures that resource groups are available for running imported nodes.
 - iii. (Optional) In the **Dependency Mapping** section, configure workspace mapping for relevant nodes. Some nodes use the name of the source workspace in their code. In this case, you must configure workspace mapping for the nodes to run properly after they are imported. Set the **New Workspace** parameter to the name of the destination workspace. The system uses this workspace name to replace the original workspace name in the node code and the names of the ancestor and descendant nodes of the current node. After the import task is complete, the original workspace name is replaced with the new workspace name.
 - iv. (Optional) In the **Dry-run** section, find the destination node that you want to set as a dry-run node and click **Set up empty run** in the Actions column. You can also select multiple nodes and click **Batch Configure** to set these nodes as dry-run nodes.

This configuration is used to configure the scheduling mode of auto triggered nodes. The auto triggered node that is set as a dry-run node returns a success response without running and does not generate data.

- v. (Optional) In the **Commission Rules** section, configure the commission rules for **Resources**, **Tables**, and **Functions**, and specify whether to enable **Change Owner** as required.

 **Note**

- If a data object with the same name as the data object you want to import exists in the destination workspace, the imported data object cannot be committed.
- If you select No for the Change Owner parameter and no owner is specified for the node you want to import, you are automatically configured as the owner of the node after it is imported.

6. Click **Import** in the upper-right corner.
7. In the **Confirm** message, click **OK**.

View and manage import tasks

On the **Import Tasks** page, the operations that you can perform on import tasks vary based on their status.

- After an import task is complete, you can view the details of the task. To view the task details, find the task on the **Import Tasks** page and click **View Import Report** in the Actions column. On the page that appears, view the task information in the **Basic Information**, **Import Settings**, **Import results**, and **Details** sections.
- If an import task is in the **Editing** state, you can perform the following operations on the task:
 - Click **Edit** in the Actions column. On the **Import Task Settings** page, modify the task configurations.
 - Click **Preview** in the Actions column. On the page that appears, view the task information in the **Basic Information**, **Overview**, and **Details** sections.
 - Click **Delete** in the Actions column. In the message that appears, click **Ok** to delete the task.
- If an import task is in the **Import failed** state, you can click **Re-import** in the Actions column of the task. In the **Import progress** dialog box, click **Return to import task list** after the import task is complete.

2.19. Workspace management

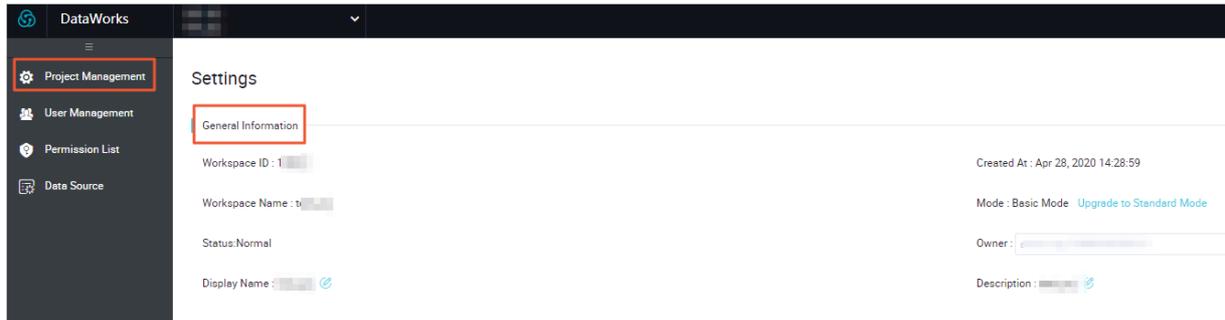

2.19.1. Configure a workspace

On the **Project Management** page of a workspace, you can manage and configure the workspace.

Go to the Project Management page

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click  in the upper-right corner.
3. On the **Project Management** page, configure the workspace as required in the **Basic properties**, **Scheduling properties**, **Security Settings**, and **Compute Engine information** sections.

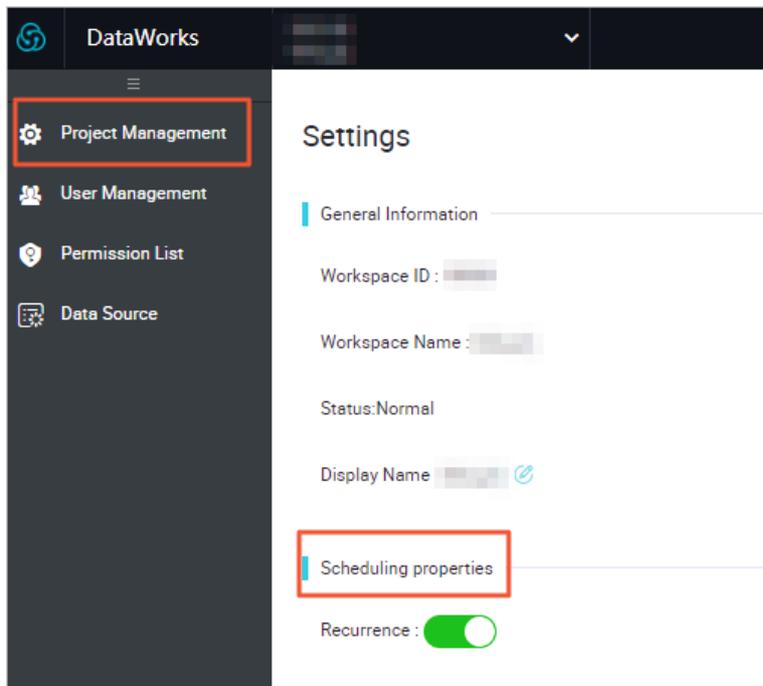

Basic properties section

Parameter	Description
Workspace ID	The ID of the workspace.
Workspace name	The name of the workspace. The name must start with a letter and can contain only letters and digits. It is not case-sensitive. It uniquely identifies the workspace and cannot be changed after the workspace is created.
Status	The status of the workspace.
Display name	The display name that is used to identify the workspace. It can contain only letters and digits. You can change the display name as required.
Creation date	The time when the workspace was created, which cannot be changed.
Mode	The mode of the workspace. Valid values: Basic Mode and Standard Mode .
The head of	The owner of the workspace. The owner of the workspace cannot be changed.
Description	The description of the workspace, which provides comments on the workspace. You can modify the description as required. The description can be up to 128 characters in length and can contain letters, special characters, and digits.

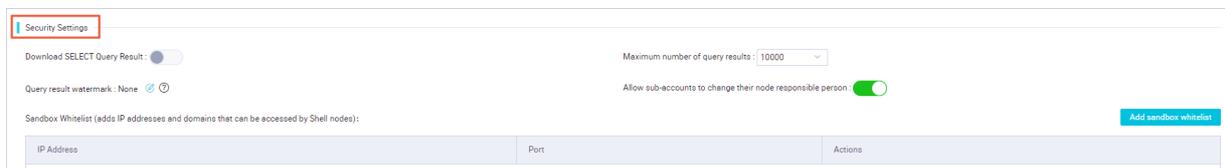

Scheduling properties section

In the **Scheduling properties** section, you can specify whether to enable the recurrence feature for the current workspace.

Recurring nodes can be run in this workspace only after you turn on the **Enable scheduling cycle** switch.

Security Settings section

Parameter	Description
Allow download of select results	Specifies whether to allow workspace members to download data query results in DataStudio. If you turn on this switch, workspace members can download data query results returned by SELECT statements in DataStudio.
Maximum number of query results	The maximum number of data records that can be returned for each query. Valid values: 10, 100, 500, 1000, 5000, and 10000 . Default value: 10000 . Assume that you set the Maximum number of query results parameter to 1000 . Go to the DataStudio page 5 minutes later. In the left-side navigation pane, click Ad-Hoc Query . On the Ad-Hoc Query tab, create an ODPS SQL node and run the node to query data in a table that has more than 1,000 data records. 1,000 records are returned.
Query result watermark	Specifies whether to display watermarks for the query results.
Allow sub-accounts to change their own node owners	Specifies whether to allow RAM users to change the owner for their nodes.

Parameter	Description
Sandbox whitelist (configure IP addresses or domain names that shell tasks can access)	The whitelist of IP addresses and domain names that a Shell node run on the default resource group can access.

To add an IP address to the whitelist, perform the following steps:

1. In the **Security Settings** section, click **Add sandbox whitelist**.
2. In the **Add sandbox whitelist** dialog box, enter the IP address and port number in the **Address** and **Port** fields respectively.
3. Click **Confirm**.

Computing Engine information section

DataWorks supports the following types of compute engines: MaxCompute, E-MapReduce, Realtime Compute, and Graph Compute.

MaxCompute

1. Click the **MaxCompute** tab in the **Computing Engine information** section. On this tab, you can view the information about all available MaxCompute instances in the current workspace.
2. Click **Add instances**.
3. In the **Add MaxCompute engine** dialog box, set the **MaxCompute project name** and **MaxCompute access identity** parameters.
4. Click **Confirm**.

E-MapReduce

1. Click the **E-MapReduce** tab in the **Computing Engine information** section. On this tab, you can view the information about all available E-MapReduce clusters in the current workspace.
2. Click **Add instances**.
3. In the **New EMR cluster** dialog box, set relevant parameters.

Parameter	Description
Instance display name	The display name of the E-MapReduce cluster to be added.
Region	The region where the current workspace resides.
Access ID	The AccessKey ID of the account that is authorized to access the E-MapReduce cluster.
Access Key	The AccessKey secret of the account that is authorized to access the E-MapReduce cluster.
Cluster ID	The ID of the E-MapReduce cluster.
EmrUserID	The ID of the user who created the E-MapReduce cluster.
Project ID	The ID of the project in the E-MapReduce cluster.
YARN resource queue	The name of the resource queue in the E-MapReduce cluster. Unless otherwise specified, set the value to <i>default</i> .

Parameter	Description
Endpoint	The endpoint of the E-MapReduce cluster. You can obtain the endpoint from the E-MapReduce console.

4. Click **Confirm**.

Realtime Compute

1. Click the **Real-time computing** tab in the **Computing Engine information** section. On this tab, you can view the information about all available Realtime Compute projects in the current workspace.
2. Click **Add engine service**.
3. In the **New Blink engine** dialog box, set the **Enter the Realtime Compute project name to add parameter**.

 **Notice** A Realtime Compute project can be bound to only one DataWorks workspace. After a Realtime Compute project is bound to a DataWorks workspace, the Realtime Compute project cannot be used in other DataWorks workspaces. After you bind a Realtime Compute project to a workspace, you cannot unbind it. Use caution when you bind a Realtime Compute project.

4. Click **Binding**.

Graph Compute

1. Click the **GraphCompute** tab in the **Computing Engine information** section.
2. Click **Bind a GraphCompute instance**.

 **Notice** A Graph Compute instance can be bound to only one DataWorks workspace. After a Graph Compute instance is bound to a DataWorks workspace, the instance cannot be used in other DataWorks workspaces.

3. In the **Bind a GraphCompute instance** dialog box, set relevant parameters.

Parameter	Description
Instance display name	The display name of the Graph Compute instance to be bound to the workspace.
GraphCompute instance name	The name of the Graph Compute instance.

4. Click **Binding**.

2.19.2. Manage workspace members

This topic describes how to add and delete members and change the roles of members on the User Management page.

Go to the User Management page

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click  in the upper-right corner.
3. In the left-side navigation pane, click **User Management**. You can view the information about each member in the following columns on the **User Management** page:

- **Members:** the display name of the Apsara Stack tenant account or RAM user that the member uses to log on to DataWorks.
- **Cloud account:** the Apsara Stack tenant account or RAM user that the member uses to log on to DataWorks.
- **Role:** the roles of the member in the current DataWorks workspace. A member can have one or more of the following roles: workspace owner, workspace administrator, developer, administration expert, deployment expert, visitor, and security expert.

 **Note** The workspace administrator can assign roles to RAM users as required. You can click **Permission List** in the left-side navigation pane to view the specific permissions of different member roles.

- **Join TIME:** the time when the member was added to the workspace.
- **Operation:** the operation that you can perform on the member. You can delete all members except the workspace owner from the workspace.

Add members

1. On the **User Management** page, click **Add Member** in the upper-right corner.
2. In the **Add Member** dialog box, select one or more accounts to add in the **Account to be added** list.
3. Click **>** to move the selected accounts to the **Added account** list.
4. Select the roles next to **Batch role setting**. You can select one or more of the following roles: **Space Administrator**, **Development**, **Operation & Maintenance (O & M)**, **Deployment**, **Visitors**, and **Security Administrator**.
5. Click **Confirm**.

Remove a member

1. On the **User Management** page, find the target member and click **Delete** in the **Operation** column.
2. In the **Member remove this workspace** message, click **OK**.

Assign a role to a member

Click the drop-down list in the **Role** column of the member and select the role to be assigned.

Revoke a role from a member

Click **x** next to the role in the **Role** column.

2.19.3. Permission list

DataWorks provides seven roles: workspace owner, workspace administrator, developer, administration expert, deployment expert, visitor, and security expert. You cannot grant the role of the workspace owner to other workspace members. This topic describes the permissions of these roles. In the following tables, Yes indicates that a role has the corresponding permission, and No indicates that a role does not have the corresponding permission.

Data management

Permission	Workspace owner	Workspace administrator	Developer	Administration expert	Deployment expert	Visitor	Security expert
Delete self-created tables	Yes	Yes	Yes	No	No	No	No
Specify categories for self-created tables	Yes	Yes	Yes	No	No	No	No
View favorite tables	Yes	Yes	Yes	No	No	No	No
Create tables	Yes	Yes	Yes	No	No	No	No
Unhide self-created tables	Yes	Yes	Yes	No	No	No	No
Modify the schemas of self-created tables	Yes	Yes	Yes	No	No	No	No
View self-created tables	Yes	Yes	Yes	No	No	No	No
View the content of self-submitted permission requests	Yes	Yes	Yes	No	No	No	No
Hide self-created tables	Yes	Yes	Yes	No	No	No	No
Specify the time-to-live (TTL) for self-created tables	Yes	Yes	Yes	No	No	No	No
Request permissions on tables created by others	Yes	Yes	Yes	No	No	No	No
Delete tables	No	Yes	Yes	No	No	No	No
Update tables	No	Yes	Yes	No	No	No	No
Preview data	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Preview table data of other organizations	Yes	Yes	No	No	No	No	No

Deployment management

Permission	Workspace owner	Workspace administrator	Developer	Administration expert	Deployment expert	Visitor	Security expert
Create deployment tasks	Yes	Yes	Yes	Yes	No	No	No
View the list of deployment tasks	Yes	Yes	Yes	Yes	Yes	Yes	No
Delete deployment tasks	Yes	Yes	Yes	Yes	No	No	No
Run deployment tasks	Yes	Yes	No	Yes	Yes	No	No

Permission	Workspace owner	Workspace administrator	Developer	Administration expert	Deployment expert	Visitor	Security expert
View the content of deployment tasks	Yes	Yes	Yes	Yes	Yes	Yes	No

Buttons

Permission	Workspace owner	Workspace administrator	Developer	Administration expert	Deployment expert	Visitor	Security expert

2.19.4. Manage connections

Connections are used to configure readers and writers during data integration. On the Data Source page of a workspace, you can view and add connections.

Procedure

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click  in the upper-right corner.
3. In the left-side navigation pane, click **Data Source**. On the **Data Source** page, you can filter connections by conditions such as **Connect To** and **Connection Name**.

Click **Add Connection** in the upper-right corner to add a connection. For more information, see [Data sources](#).

3. Realtime Compute

3.1. What is Realtime Compute?

Realtime Compute is a big data processing platform that analyzes streaming data in real time based on Apsara Stack. You can create streaming data analysis and computing jobs by using Alibaba Cloud Flink SQL. When you use Flink SQL, you do not need to develop the underlying logic for streaming data processing.

As the demands for high data timeliness and operability increase, software systems need to process more data in less time. In traditional models for big data processing, online transaction processing (OLTP) and offline data analysis are separately performed at different times.

Realtime Compute is designed to respond to the increasing demand for the timeliness of data processing. The business value of data decreases as time passes by. Therefore, data must be computed and processed as soon as possible after it is generated. Traditional models for big data processing follow the scheduled processing mode, which accumulates and processes data in a computing cycle that can last hours or even days. These models cannot satisfy the growing demand for real-time big data processing. Batch processing cannot meet the business requirements in scenarios in which an extremely low processing delay is required. These scenarios include real-time big data analysis, early warning and risk control, real-time forecasting, and financial transactions. Realtime Compute enables real-time processing over data streams. With Realtime Compute, you can shorten the data processing delay, easily implement real-time computational logic, and greatly reduce computing costs. This helps you meet business requirements for real-time processing of big data.

Streaming data

Big data can be viewed as a series of discrete events. These discrete events form event streams or data streams along a timeline. Streaming data is continuously generated from thousands of data sources and is typically sent in data records. Streaming data has a smaller scale than offline data. Each type of data is produced as a stream of events. Streaming data includes a wide variety of data, such as the log files generated by your mobile or web applications, online purchases, in-game player activities, information from social networks, financial trade centers, geospatial services, and telemetry data from connected devices in data centers.

Realtime Compute has the following advantages:

- Real-time and unbounded data streams

Realtime Compute processes data streams in real time. Streaming data is continuously generated from data sources and is subscribed and consumed in chronological order. Data streams continuously flow into the Realtime Compute system. For example, when Realtime Compute processes data streams from website visit logs, the log data streams continuously enter the Realtime Compute system as long as the website is online. In Realtime Compute, unbounded data streams are processed in real time.

- Continuous and efficient computing

Realtime Compute is an event-driven system in which unbounded event or data streams continuously trigger real-time computations. Each streaming data record triggers a computational task. Realtime Compute performs continuous and real-time computations over data streams.

- Real-time integration of streaming data

Realtime Compute writes the computing result of each streaming data record into the target data store in real time. For example, the system directly writes the data of a computed report to an ApsaraDB for RDS instance for report display. Realtime Compute continuously writes the results into the target data store in real time. Therefore, Realtime Compute can be viewed as a data source that generates data streams for the target data store.

3.2. Quick start

3.2.1. Log on to the Realtime Compute console

This topic describes how to log on to the Realtime Compute console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

Obtain the username and password that you can use to log on to the console from the operations administrator.

 **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:

- Uppercase or lowercase letters
- Digits
- Special characters, which include ! @ # \$ %

3. Click **Login**.
4. In the top navigation bar, move the pointer over Products and click **Realtime Compute**.
5. Specify **Organization** and **Region**.
6. Click **Blink**.

3.2.2. Real-time security monitoring

3.2.2.1. Overview

With the wide application of digital technologies, every industry is facing the ever-increasing demand for data security, especially for real-time monitoring and alerting. To monitor streaming data and report alerts in real time, you need to ensure that the data is accurate and is processed instantly after it has been generated. To address these challenges, Realtime Compute allows you to perform JOIN operations on source tables of streaming data and dimension tables that include blacklists. The following sections describe a use case of real-time monitoring and alerting.

3.2.2.2. Preparations

Before proceeding with the development process in the Realtime Compute console, you must create a source table and a result table in the upstream and downstream data stores, respectively. You must also upload data to the source table.

Context

To simplify operations, this example organizes incoming streaming data based on a table: datahub_lpPlace.

datahub_lpPlace

Field name	Data type	Description
name	VARCHAR	The name
Place	VARCHAR	The place

The rds_dim dimension table is described as follows.

rds_dim

Field name	Data type	Description
name	VARCHAR	The name
Place	VARCHAR	The place

A result table named rds_lpPlace is obtained after a JOIN operation is performed on the datahub_lpPlace and rds_dim tables. This result table is described as follows.

rds_lpPlace

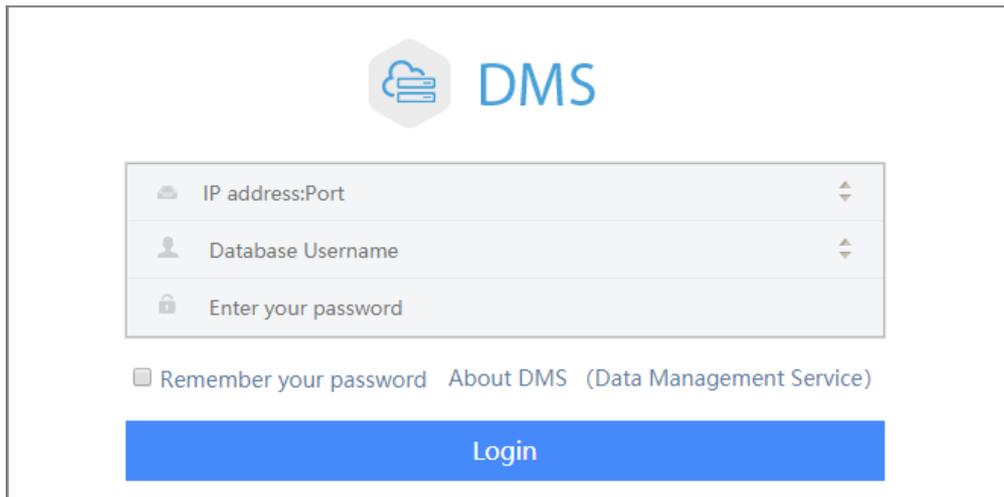

Field name	Data type	Description
name	VARCHAR	The name
Place	VARCHAR	The place

Create source and result tables

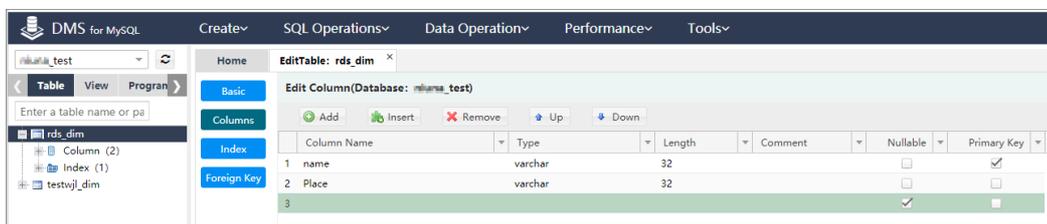

Procedure

1. Log on to the DataHub console. For more information, see the "Log on to the DataHub console" section in *DataHub User Guide*.
2. Create a project. For more information, see the "Create projects" section in *DataHub User Guide*.
3. On the page that shows the project details, create a topic. The following figure shows the schema of the source table. For more information, see the "Create a topic" section in *DataHub User Guide*.
4. Create an ApsaraDB for RDS instance. For more information, see the "Create an instance" section in *ApsaraDB for RDS User Guide*.
5. On the **Instances** page of the ApsaraDB for RDS console, click the target instance name.
6. On the **Basic Information** page, click **Log On to DB**.
7. Log on to the RDS database, and create a result table in the database.

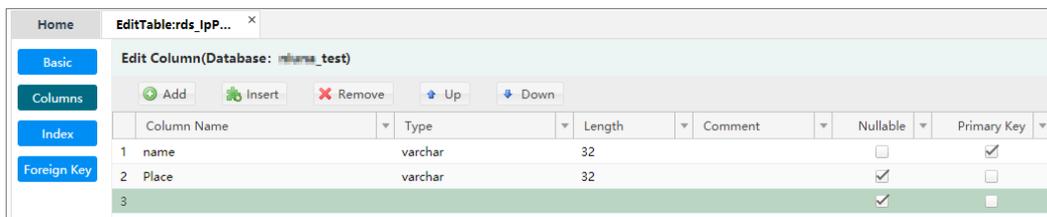

Log on to the database

Dimension table schema

Result table schema

8. Upload data to DataHub.

Log on to the **DataHub** console. In the left-side navigation pane, click **Data Acquisition**, and then click **Upload File**. On the page that appears, double-click the project, click the target DataHub topic, and then click **Select File** to upload data. For more information, see the "Upload local files" section in *DataHub User Guide*.

9. Write data into the rds_dim dimension table.

- i. Log on to the RDS database. In the top navigation bar, choose **SQL Operations > SQL Window**.
- ii. On the **SQL Window** tab, enter the following code.

```
insert into 'rds_dim'('name','Place') VALUES('test01','beijing')
```

- iii. On the **SQL Window** tab, click **execute**.

3.2.2.3. Develop a job

After you create source and result tables in external data stores, you must register the data stores in the Realtime Compute console and create references to the source and result tables. After the data stores are registered, you can proceed with the development process.

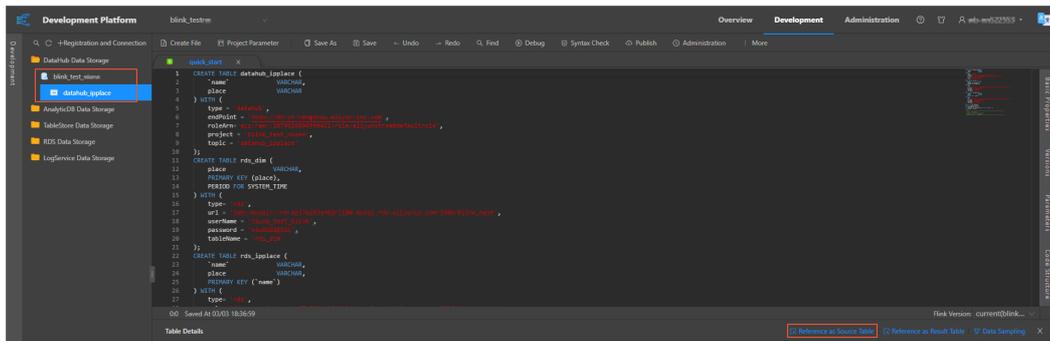

Procedure

1. [Log on to the Realtime Compute console](#) to go to the homepage of Realtime Compute.
2. In the top navigation bar, click Development.
3. On the top of the page that appears, click the **Create File** icon. Parameter description

Parameter	Description
File Name	The name of the file. The name must be 3 to 64 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a lowercase letter.
File Type	The type of the file. Valid values: FLINK_STREAM / SQL and FLINK_STREAM / DATASTREAM.
Storage Path	The folder where the job SQL file is located. You can click the folder icon on the right side of an existing folder and create a subfolder.

4. Select DataHub as the data store for a source table. You can use the DataHub parameter settings and schema information that are automatically generated on the Data Storage tab. For more information, see [Register a DataHub project](#).

Use DataHub as the data store for a source table

5. Double-click a DataHub project in the **DataHub Data Storage** folder.
6. On the top of the section that appears, click **Reference as Source Table**.
7. Create a reference to the ApsaraDB for RDS dimension table. You must specify the required parameters and the table schema. Dimension tables cannot be registered on the Storage tab. The following sample code demonstrates how to create an ApsaraDB for RDS dimension table:

```
create table rds_input (
  place varchar,
  `name` varchar,
  primary key (place),
  period for system_time
) with (
  type = 'rds',
  url = 'yourURL',
  tableName = 'yourTableName',
  password = 'yourPassword'
);
```

8. Select RDS as the data store for the result table. You can use the RDS parameter settings and schema information that are automatically generated on the Data Storage tab. For more information, see [Register an RDS instance](#).
9. To use RDS to store the result table, double-click the RDS Data Storage folder, double-click the target database, and then double-click the target table. On the top of the section that appears, click

Reference as Result Table.

10. Edit SQL statements that implement the computing logic in the code editor.

```
INSERT INTO rds_output
SELECT
  t.`name`,
  w.place
FROM datahub_input1 as t
JOIN rds_input FOR SYSTEM_TIME AS OF PROCTIME() as w
ON t.place = w.place
```

11. Click **Debug**.
12. Click **Publish**. After the computing logic is verified during the debugging, click **Publish** on the **Development** page to publish the job SQL file. Then, you can view the job on the **Administration** page of the Realtime Compute console and manage the job in the production environment, such as starting the job.

3.2.2.4. Administration

After you create and publish the job SQL file on the **Development** page, you can manage the job on the **Administration** page. For example, you can start, suspend, terminate, publish, or unpublish the job.

Procedure

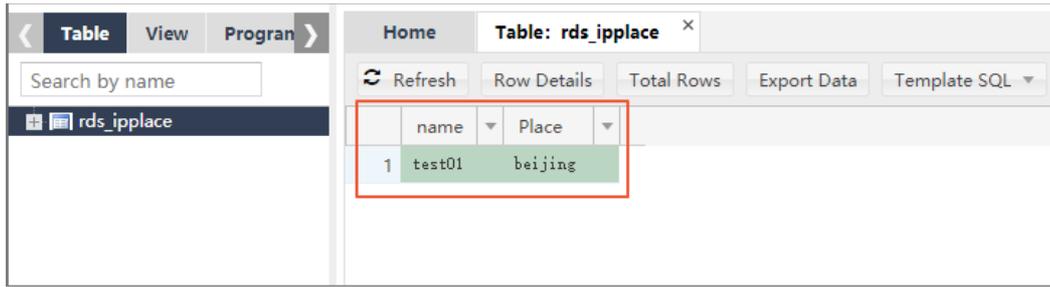

1. Go to the **Administration** page of the Realtime Compute console.
 - i. [Log on to the Realtime Compute console](#).
 - ii. In the top navigation bar, click **Administration**.
2. Click **Start** for the `bj_dim_join` job.
3. Specify the **Start Time for Reading Data** parameter. The start time for reading data is also known as the start offset. The source data store remains connected to Realtime Compute for only a short period of time. Therefore, we recommend that you specify a time that is earlier than the current time.

The **Start Time for Reading Data** parameter specifies the start time for reading data from the source data store.

Parameter	Description
Start Time for Reading Data	Specifies the start time for reading data from the source data store.
Enable Auto Upgrade	Specifies whether to enable auto upgrade.
Upgrade Time	Specifies the upgrade time range.
Offset	Specifies the range of data that is to be updated.

4. Click **OK** to start the job.
5. View the output data in the ApsaraDB for RDS data store.

View the output data in the RDS data store

3.2.3. Frequently used words

3.2.3.1. Overview

Statistical analysis of frequently used words is widely applied in diverse fields, including the analysis of frequently used words in search engines, forums, and tags. For example, you can easily view the latest and most frequently searched words in microblogging websites through real-time statistics. Statistical analysis of frequently used words is, at its core, a simple word count job. In word count jobs for streaming data, real-time processing logic is used to analyze and display frequently used words in real time.

If you are new to working with big data computing, a word count job is for you to easily get started. The word count job in big data computing is similar to a `Hello, World!` program that is often the first program that a developer learns to write. The following topics take a word count job in Realtime Compute as an example to describe how to create a word count job based on real-time processing logic. This example helps you quickly get familiar with basic Flink SQL syntax and basic operations of Realtime Compute jobs, such as creating an SQL file for a job and publishing the job.

3.2.3.2. Code development

This topic uses a word count job as an example to describe how to create a Realtime Compute job.

Prerequisites

Before creating a word count job, a source table named `stream_source` and a result table named `stream_result` are created in external data stores. The `stream_source` table includes only one column. The column is named `word` and its data type is `STRING`. The `stream_result` table includes two columns. One column is named `word` and its data type is `STRING`. The other column is named `cnt` and its data type is `BIGINT`. The two tables are registered in Realtime Compute.

1. [Log on to the Realtime Compute console.](#)
2. In the top navigation bar, click **Development**.
3. Right-click the folder where you want to store the job file.
4. Click **Create File**, and the **Create File** page appears.
5. On the page that appears, set the following parameters:
 - o File Name: Set the value to `wordcount`.
 - o File Type: Set the value to `FLINK_STREAM/SQL`.
 - o Storage Path: Keep the default setting.
6. Enter the following code in the code editor.

Note In the SQL statements for the word count job, the `STRING` data type for the referenced table must be declared as the `VARCHAR` data type.

```
create table stream_source (word varchar);
create table stream_result (word varchar, cnt bigint);
insert into
  stream_result
select
  t.word,
  count (1)
from
  stream_source t
group by
  t.word;
```

The following section explains the SQL code.

Line 1 creates a reference to the `stream_source` source table.

Note Streaming data continuously enters Realtime Compute and triggers stream processing procedures. Each streaming data record or each batch of data from the `stream_source` table triggers a stream processing procedure.

Line 2 creates a reference to the `stream_result` result table. The `stream_result` table stores the computing results of the word count job.

Note Realtime Compute does not have built-in components for data storage, and the result data is stored in external data stores, such as ApsaraDB for RDS and Tablestore. This line of code creates a reference to a result table that contains the result data.

Lines 5 through 11 implement the computing logic: Realtime Compute reads data from the `stream_source` table and counts how often words occur based on incoming data records.

Note Flink SQL supports most standard SQL statements. This allows you to easily and cost-effectively adopt Realtime Compute for stream processing.

The method of performing a word count job for stream processing is similar to that for batch processing. The word count job for stream processing continuously processes unbounded data streams until the job is terminated.

3.2.3.3. Code debugging

Realtime Compute provides a powerful debugging feature to verify SQL statements. You can debug Realtime Compute jobs by simulating data stores where streaming data, static data, and result data are stored.

- Note**
- To avoid negative impacts on online data stores, Realtime Compute is not allowed to read data from these data stores during the debugging process. Before debugging, you must prepare test data for input tables.
 - The outputs of INSERT operations are exported only to local screens. This does not affect online systems.

Debugging method

1. On the top of the **Development** page, click **Debug**.

2. On the page that appears, click **Download Template** and edit the template based on your debugging rules.

- Note** The file that is uploaded for debugging must meet the following requirements:
- The file size cannot exceed 1 MB, and the file contains maximum of 1,000 records.
 - The file must use UTF-8 encoding.
 - Commas (,) cannot be used in test data, because the file uses the comma-separated values (CSV) format.
 - Numeric values can be displayed only in the general format, and cannot be displayed in the scientific notation format.

3. Click **Upload** to upload the file.
4. Click **OK**.
5. View the debugging result in the output window.

Sample file for debugging the word count job

- Note** The file for debugging is in the CSV format. We recommend that you use the following software applications to open and modify the template:
- Excel for Windows users.
 - Vim or Sublime Text for MacOS users. We do not recommend that you use Number because it adds unnecessary fields when you modify CSV files.

Sample file for debugging the word count job

	A	B	C	D	E	F
1	word(String)					
2	aliyun					
3	aliyun					
4	aliyun					
5						
6						

Test data

You can download [test data](#) and upload the data on the **Debug File** page.

- Note** The *test data for statistical analysis of frequently used words* is unavailable for download in a PDF file. You can contact system administrators to download the test data.

View the debugging result

Real-time computing is triggered by data streams. Each data record from the `stream_source` table triggers a stream processing procedure. After each procedure is complete, a computing result is exported. The test file contains three data records. After each data record reaches Realtime Compute, a stream processing procedure is triggered. Therefore, a total of three data records are displayed on the screen. Realtime Compute uses the following computing logic:

- The first data record (aliyun) reaches Realtime Compute. This is the first time that the system has detected the word "aliyun." Therefore, the computing result is `<aliyun, 1>`, which is displayed on the screen.

- The second data record (aliyun) reaches Realtime Compute. The system detects an existing record of `<aliyun, 1>` and increases the value by one. Therefore, the computing result is `<aliyun, 2>`, which is displayed on the screen.
- The third data record (aliyun) reaches Realtime Compute. The system detects an existing record of `<aliyun, 2>` and increases the value by one. Therefore, the computing result is `<aliyun, 3>`, which is displayed on the screen.

The third computing result `<aliyun, 3>` is considered as the final output of the debugging. Another sample of **test data** is provided for you to test the debugging feature. You can use different samples of test data and view the debugging outputs.

3.2.3.4. Administration

After the SQL file has been verified, you can publish the SQL file for the job on the **Administration** page of Realtime Compute. Then, you can start the job. The job runs on a Realtime Compute cluster.

Procedure

1. On the **Development** page, click **Publish**. The **Publish New Version** dialog box appears.
2. In the **Resource Configuration** step, click **Next**.
3. In the **Check** step, click **Next**.
4. In the **Publish File** step, click **Publish**.
5. On the **Administration** page, view the published word count job.
6. Click **Start** in the **Actions** column of the word count job. The **Start** dialog box appears.
7. Specify **Start Time of Reading Data** and click **OK**. Then, the job runs on a Realtime Compute cluster.

Result

After the job is started, click the job name. The **Overview** page appears.

FAQ

Q: Why does the word count job have no input or output while it is running on the distributed compute clusters of Realtime Compute?

A: When you created the `my_source` and `my_result` tables, you did not specify the data storage type of the referenced data source. In this scenario, the source table is considered to be a random table of strings or digits, and the result table is considered to be discarded data.

3.2.4. Big screen service for the Tmall Double Eleven Global Shopping Festival

3.2.4.1. Overview

During Double 11, a big screen shows the total sales volume of Alibaba Group in real time. The big screen service is a highlight for the shopping festival.

Stream processing for the big screen service was previously based on Apache Storm that is an open source distributed real-time computation system. The Apache Storm-based development process took around one month. The application of Flink SQL reduces the period for the development of the big screen service to three days. The underlying layer of Realtime Compute removes the Apache Storm modules that are designed for execution optimization and troubleshooting. This achieves a higher processing efficiency for Realtime Compute jobs.

3.2.4.2. Scenario description

The streaming data input for the Tmall big screen service is the transaction data from the Tmall platform. The incoming transaction data is organized based on a two-dimensional table: `tmall_trade_detail`.

Field	Type	Description
tid	BIGINT	The order ID.
buyer_uid	BIGINT	The buyer ID.
seller_uid	BIGINT	The seller ID.
gmtdate	TIMESTAMP	The time when the order is completed.
payment	DOUBLE	The order amount.

Realtime Compute calculates two metrics based on the preceding table: the total number of orders and the total order amount up to the current time. The two metrics are written to an online RDS system and displayed on a big screen in real time. The online RDS system is used to store the result table: `tmall_trade_state`.

Field	Type	Description
gmtdate	VARCHAR(16)	The date when the order is completed.
trade_count	BIGINT	The total number of orders.
trade_sum	DOUBLE	The total order amount.

The following topics describe how to build an end-to-end solution for the Tmall big screen service in around 10 minutes.

3.2.4.3. Preparations

Before editing Flink SQL statements for a Realtime Compute job, you must register data stores for source tables and result tables in Realtime Compute. This topic uses DataHub as an example to describe how to register a data store in Realtime Compute.

Create a DataHub topic

1. Log on to the DataHub console. For more information, see the "Log on to the DataHub console" section in *DataHub User Guide*.
2. If one or more projects have been created, click **View** in the **Actions** column for the target project. If no projects have been created, click **Create Project** to create a project and click **View** in the **Actions** column.
3. On the page that appears, click **Create Topic**.
4. Configure the topic based on the schema of the `tmall_trade_state` RDS table in the "Scenario description" section.

After performing these steps, you can edit Flink SQL statements for the Realtime Compute job.

Upload data to DataHub

You can upload data to the DataHub topic that you have created. To do this, follow these steps. Log on to the **DataHub** console. You can upload data to the DataHub topic that you have created. To do this, follow these steps:

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Data Acquisition**.
3. Click **Upload File**.
4. On the page that appears, double-click the target project and click the target DataHub topic.
5. Click **Select File** to select a file.
6. Click **Upload**.

To simplify the test procedure, you can use the [test data about the Double 11](#). You can download the data and then upload it to the DataHub topic for data collection.

3.2.4.4. Register a data store

The data store registration feature of Realtime Compute allows you to easily register DataHub topics, create tables, and reference data stores. To register a data store, follow these steps:

Procedure

1. [Log on to the Realtime Compute console](#).
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click the **Storage** tab.
4. Click the **DataHub Data Storage** folder.
5. On the top of the page, click **+Registration and Connection**.
6. Register a DataHub project in Realtime Compute. For more information about parameter settings, see [Register a DataHub project](#).

If you use ApsaraDB for RDS for MySQL to store the result data for data visualization, you must register an RDS data store in Realtime Compute. For more information, see [Register an RDS instance](#).

3.2.4.5. Development

After the data has been collected to Realtime Compute, you can continue to edit Flink SQL statements.

1. Create a reference to the source.

To create references to the DataHub source table and RDS result table, click **Data Storage** in the left-side navigation pane of the **Development** page in the Realtime Compute console, and perform the following operations:

- Find the target DataHub topic, and click **Reference as Source Table**. Realtime Compute automatically parses the schema of the topic and adds the corresponding SQL statements to the **Development** page.
- Find the target RDS table, and click **Reference as Result Table**. Realtime Compute automatically parses the schema of the table and adds the corresponding SQL statements to the **Development** page.

2. Edit Flink SQL statements.

If you have created the DataHub topic and RDS table as described in the previous topics, the Flink SQL code for the `tmall_d11` job can be executed directly. Otherwise, change the names of the DataHub topic and RDS table based on the topic and table that you have created. The sample code is as follows:

```
replace into tmall_trade_state
select
  from_unixtime(FLOOR(tmall_trade_detail.gmtime/1000), 'yyyy-MM-dd') as gmt_date,
  count(tid) as trade_count,
  sum(payment) as trade_sum
from
  tmall_trade_detail
group by
  from_unixtime(FLOOR(tmall_trade_detail.gmtime/1000), 'yyyy-MM-dd');
```

 **Note** You can modify the information about tables and fields as required.

3. Debug the Flink SQL code.

The [data during the Double 11 Shopping Festival](#) is available for testing. To debug the code, download the test data and upload the data on the **Development** page for debugging.

4. Publish the SQL file for the tmall_d11 job.

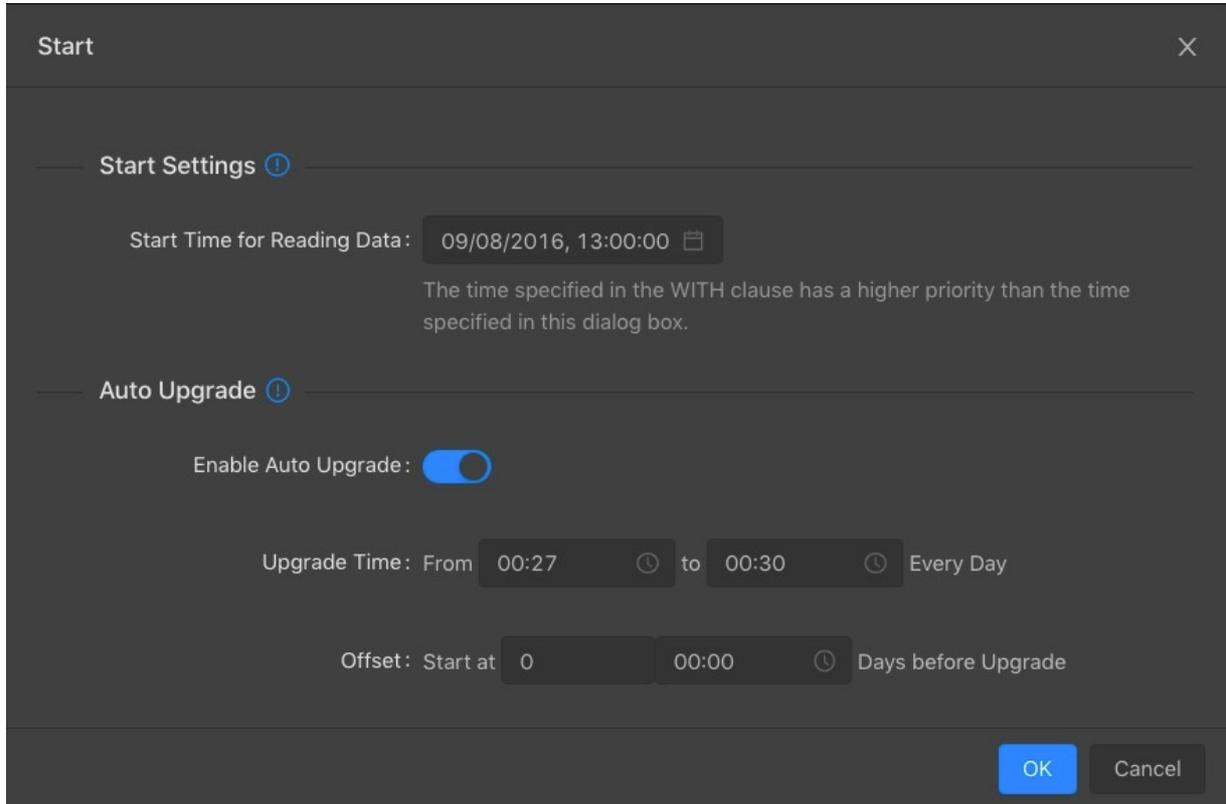

After the computational logic has been verified in the debugging phase, click **Publish** on the **Development** page to publish the SQL file for the tmall_d11 job. Then, you can view the tmall_d11 job on the **Administration** page of the Realtime Compute console, and manage the job in the production environment, such as starting the job.

3.2.4.6. Administration

On the **Administration** page, you can click **Start** in the **Actions** column and specify the parameters on the page that appears to start a stream processing job, for example, the tmall_d11 job.

 **Note** After you click **Start**, a dialog box is displayed. In the dialog box, you can specify the start time for reading data from the source data store.

The specified start time must be earlier than the file upload time. For example, the start time can be one hour earlier than the file upload time. In the Double 11 use case, the current time is 14:10, and 10 minutes have elapsed since the source data is uploaded. Therefore, the start time is set to 13:00.

The screenshot shows a 'Start' dialog box with the following settings:

- Start Settings**
 - Start Time for Reading Data: 09/08/2016, 13:00:00
 - Note: The time specified in the WITH clause has a higher priority than the time specified in this dialog box.
- Auto Upgrade**
 - Enable Auto Upgrade:
 - Upgrade Time: From 00:27 to 00:30 Every Day
 - Offset: Start at 0 00:00 Days before Upgrade

Buttons: OK, Cancel

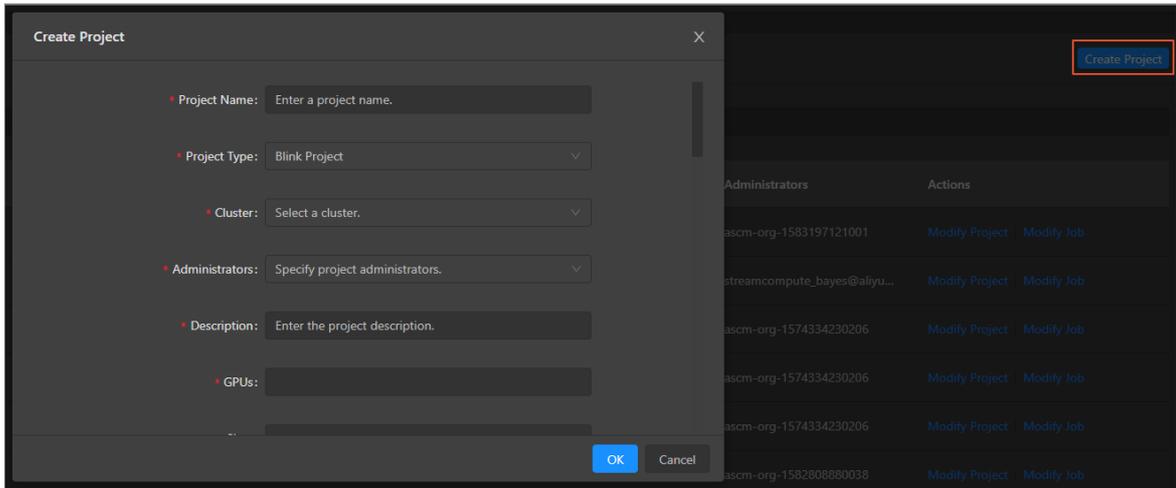

You can check the result data in the ApsaraDB for RDS data store after the job runs as expected. In the result table, five transactions and a turnover of CNY 500 are displayed. This is consistent with the source data for testing. In this way, an end-to-end verification is performed to check the SQL code.

3.3. Project management

This topic describes how to create and search for a project.

Create a project

1. [Log on to the Realtime Compute console.](#)
2. In the top navigation bar, move the pointer over your profile picture and click **Project Management**.
3. In the upper-right corner of the **Projects** page, click **Create Project**.
4. Configure the project information.

Parameter description

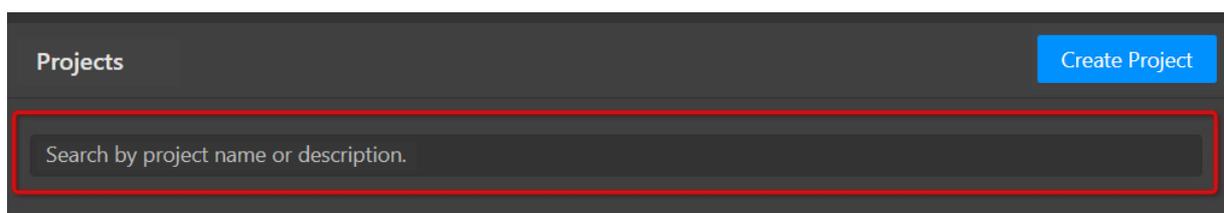

Parameter	Description
Project Name	The name of the project.
Project Type	The type of the project. Blink Project is selected by default.
Cluster	The cluster on which the jobs in the project run.
Description	The description of the project.
GPUs	The number of GPUs that are used by the project.
Slots	The number of compute units (CUs) that are used by the project. One CU is assigned with one CPU core and 4 GB memory.
Alert Methods	The methods in which alerts are sent when errors occur during job running. You can receive alerts by using text messages or TradeManager messages.
File Types	The supported file types. You can keep the default setting.
Storage Types	The supported data store types. You can keep the default setting.
Max Data Stores	The maximum number of data stores that can be registered in Realtime Compute. You can keep the default setting.
Max File Versions	The maximum number of code versions for an SQL file. You can keep the default setting.
Max Folders	The maximum number of folders that can be created in the project. You can keep the default setting.
Max Folder Levels	The maximum number of folder levels in the project. You can keep the default setting.
Max Files	The maximum number of job SQL files that can be created in the project. You can keep the default setting.
Max Resources	The maximum number of JAR files and DICT IONARY resources that can be uploaded. You can keep the default setting.

Parameter	Description
Max Referenced Resources	The maximum number of JAR files and DICTIONARY resources that can be referenced. You can keep the default setting.
Monitoring and Alerting	Specifies whether to enable the monitoring and alerting feature. You can keep the default setting.
Data Collection	Specifies whether to collect data while a job is running. You can keep the default setting.
Data Display	Specifies whether to display data. You can keep the default setting.
Metastore	Specifies whether to display metadata. You can keep the default setting.
Data Storage	Specifies whether to enable data store registration. This feature is enabled by default. You can keep the default setting.
Engine	Specifies whether to display the engine. You can keep the default setting.
Online Logs	Specifies whether to record the job running logs. This feature is enabled by default. You can keep the default setting.
Resource Management	Specifies whether resources such as JAR files can be uploaded. This feature is enabled by default. You can keep the default setting.
Switch Version	Specifies whether to enable the job version switch feature. This feature is enabled by default. You can keep the default setting.
Project Protection	Specifies whether to enable the project lock feature. You can keep the default setting.

5. Click OK.

Search for a project

On the **Projects** page, enter a keyword or full name of a project in the search box to find the project.

3.4. Data storage

3.4.1. Overview

This chapter describes data storage systems supported by Realtime Compute.

3.4.2. Overview

3.4.2.1. Overview

To facilitate data storage management, you can register data storage resources on the Realtime Compute development platform. This enables you to leverage the advantages of the one-stop Realtime Compute service. In Realtime Compute, you can manage multiple data storage systems, such as ApsaraDB for RDS, and Table Store. With this one-stop management service, you no longer have to navigate across multiple management consoles of different storage systems.

3.4.2.2. Types

Realtime Compute supports both streaming data storage and static data storage.

Streaming data storage

Streaming data storage systems provide inputs and outputs for downstream Realtime Compute jobs.

Streaming data storage

Storage system	Input	Output
DataHub	Supported	Supported
Log Service	Supported	Supported
MQ	Supported	Supported

Static data storage

Static data storage systems provide outputs for downstream Realtime Compute jobs and allow you to perform association queries.

Static data storage

Storage system	Dimension table	Output
ApsaraDB for RDS	Supported	Supported
Table Store	Supported	Supported

3.4.2.3. Registration and usage

This topic describes how to register and use external data stores in Realtime Compute.

 **Note** If a job requires the use of the data stores owned by another Apsara Stack tenant account, you can write DDL statements to reference the data stores. In the DDL statements, you must specify the AccessKey ID and AccessKey secret of the account. In this scenario, you cannot use the codeless UI to manage the data stores.

Register a data store

To register a data store, follow these steps:

1. [Log on to the Realtime Compute console](#).
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane of the page that appears, click the **Storage** tab. Select the folder for the data store that you want to register. Then, click **+Registration and Connection**.

Register a data store

4. In the dialog box that appears, configure the required parameters and click OK.

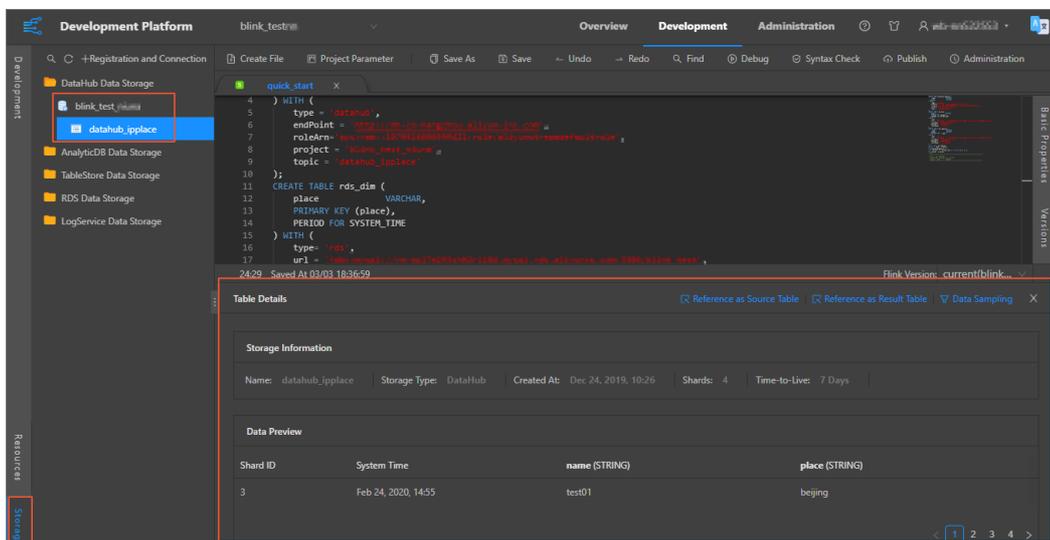

Note After you enable the data store registration feature, you can only register data stores that are owned by your organization.

Preview data from a data store

Realtime Compute provides the data preview feature for each registered data store. To preview data, click the **Storage** tab and double-click the folder of the target data store in the left-side navigation pane. The following example shows how to preview data from a DataHub data store.

1. Log on to the Realtime Compute console. In the top-navigation bar, click **Development**. On the page that appears, click the **Storage** tab and double-click the **DataHub Data Storage** folder.
2. Double-click the target project and then the target topic to view the details.

Table details

Use the auto DDL generation feature

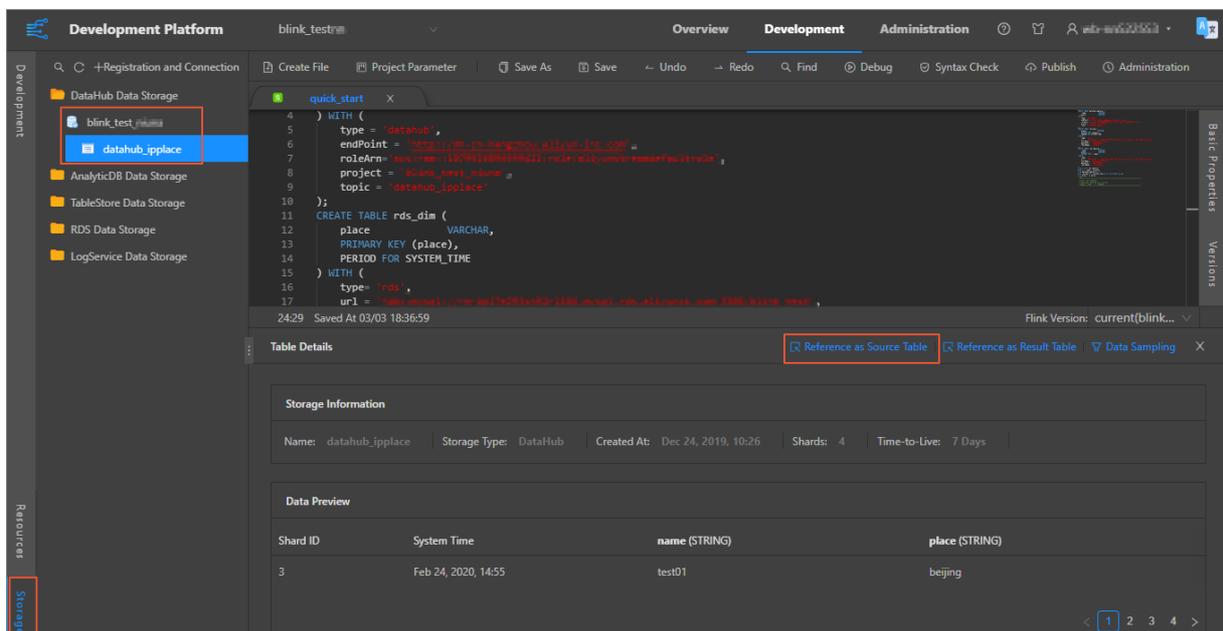

You must declare tables from external data stores before you can reference these tables. The following example shows how to reference a source table that contains streaming data:

```
CREATE TABLE in_stream( a varchar, b varchar, c timeStamp) with ( type='datahub', endPoint='http://dh-cn-hangzhou.aliyuncs.com', project='blink_test', topic='ip_count02', accessId='LTAlYtaf*****', accessKey='gUqyVwfkK2vfJl7jF90*****');
```

The field names in the table that is referenced on the Development page must be the same as those in the DataHub topic. You must declare the field data types in the code based on the field type mapping between DataHub and Realtime Compute to ensure that Realtime Compute can identify the data. Realtime Compute offers the auto DDL generation feature. The following section describes how to use this feature.

1. In the left-side navigation pane of the **Development** page, click the **Storage** tab.
2. On the **Storage** tab, navigate through cascaded folders and nodes to find the target table. Then, double-click the name of the target table.
3. In the **Table Details** pane that appears, click **Reference as Source Table**, **Reference as Result Table**, or **Reference as Dimension Table** as required. Then, you can obtain the DDL statements that are automatically generated to reference the target table.

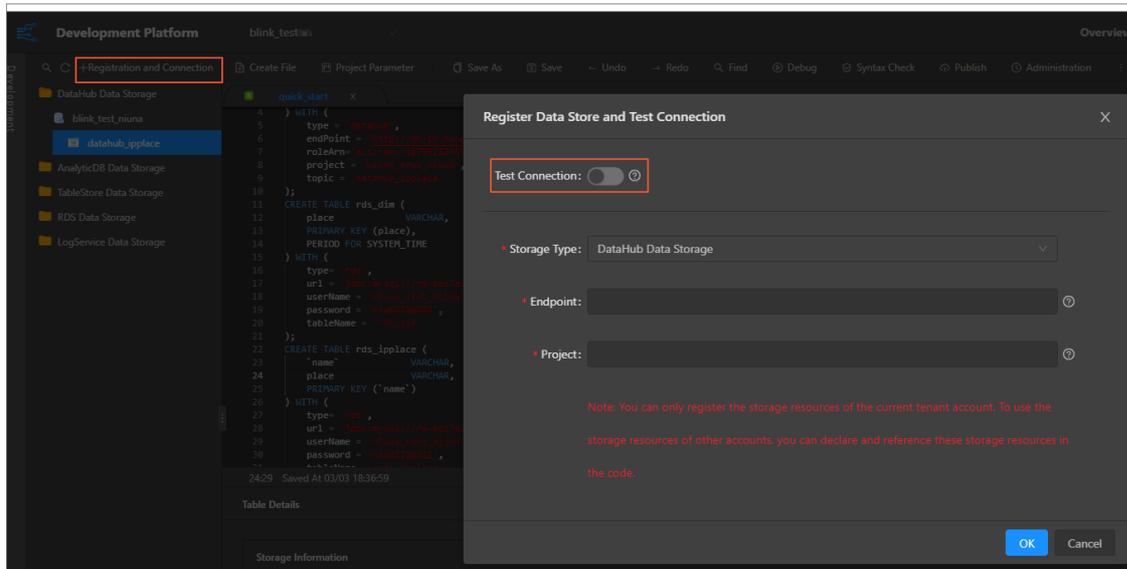

To reference a source table, log on to the Realtime Compute console and open the target SQL file on the Development page. Click the **Storage** tab, select the table for reference, and then click **Reference as Source Table**. The required DDL statements are displayed on the current page.

Test network connection

Realtime Compute offers the network connection test feature for data stores. This feature allows you to test the connection between Realtime Compute and a target data store. To enable the network connection test feature, follow these steps:

1. In the left-side navigation pane of the **Development** page, click the **Storage** tab.
2. In the upper-right corner of the **Storage** tab, click **+ Registration and Connection**.
3. In the **Register Data Store and Test Connection** dialog box, turn on **Test Connection**.

Example: Reference data stores owned by another level-1 organization

You can only register and use data stores that are owned by your level-1 organization. To use data stores that are owned by another level-1 organization, write DDL statements to create a reference to these data stores. For example, if a user from Organization A wants to use the data stores owned by Organization B, the user can enter the following DDL statements:

```
CREATE TABLE in_stream( a varchar, b varchar, c timeStamp) with ( type='datahub', endPoint='http://dh-cn-hangzhou.aliyuncs.com', project='blink_test', topic='ip_count02', accessId='AccessKey ID authorized by Organization B users', accessKey='AccessKey secret authorized by Organization B users');
```

3.4.3. Register a DataHub data store

DataHub, an Alibaba Cloud streaming data service, is a real-time data distribution platform designed to process streaming data. You can publish and subscribe to applications for streaming data in DataHub and distribute the data to other platforms. DataHub allows you to analyze streaming data and build applications based on the streaming data. Realtime Compute often uses DataHub to store source and result tables that contain streaming data.

Register a DataHub project

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click the **Storage** tab.
4. Right-click the **DataHub Data Storage** folder and select **Register Data Store** to register a DataHub project in Realtime Compute. Parameter description

Parameter	Description
Test Connection	Specifies whether to enable the network connection test feature. Network connection tests are automatically performed on data stores that can be registered in Realtime Compute. To test the connection between Realtime Compute and data stores that cannot be registered, turn on the Test Connection switch.
Storage Type	The type of the data store. DataHub Data Storage is selected by default.

Parameter	Description
Endpoint	<p>The endpoint of DataHub. The endpoint of DataHub varies with regions. For more information about endpoints, contact your administrator.</p> <p> Note To specify this parameter for Apsara Stack, contact your Apsara Stack administrator to obtain the endpoint of DataHub.</p>
Project	<p>The name of the DataHub project.</p> <p> Note You can only register DataHub projects that are owned by your level-1 organization. For example, if DataHub Project A is owned by Organization A, users from Organization B cannot register Project A in Realtime Compute.</p>
AccessKey ID	The AccessKey ID of the current account.
AccessKey Secret	The AccessKey secret of the current account. The AccessKey secret enables Realtime Compute to access the DataHub project.

Scenarios

DataHub is a streaming data storage system that can be used to store source and result tables. However, it cannot be used to store dimension tables for Realtime Compute.

FAQ

Q: Why am I unable to register a DataHub project in Realtime Compute?

A: Realtime Compute uses a storage software development kit (SDK) to access different data stores. The Storage tab in the Realtime Compute console only helps you manage data from different data stores. You can perform the following operations to troubleshoot registration errors:

- Check whether you have created a DataHub project and have the permissions to access the project. You can log on to the DataHub console and check whether you can access the project.
- Check whether you are the project owner. You can only register DataHub projects that are owned by your level-1 organization. For example, if DataHub Project A is owned by Organization A, users from Organization B cannot register Project A in Realtime Compute.
- Check whether you have specified the correct DataHub endpoint and project name.
- Check whether you have specified a classic network endpoint for the Endpoint parameter. If you specify a VPC endpoint, the DataHub project will fail to be registered.
- Check whether you have registered the DataHub project. Realtime Compute provides a registration check mechanism to prevent duplicate registration.

Q: Why does Realtime Compute only support time-based sampling?

A: DataHub stores streaming data, and you can only specify time parameters in the API. Therefore, Realtime Compute supports only time-based sampling.

3.4.4. Register a Log Service data store

Log Service (previously known as SLS) provides an end-to-end solution for log management. You can use Log Service to easily collect, subscribe to, dump, and query large amounts of log data. Realtime Compute can integrate with Log Service to process logs. This eliminates the need of data migration.

Register a Log Service project

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click the **Storage** tab.
4. Right-click the **LogService Data Storage** folder and select **Register Data Store** to register a Log Service project in Realtime Compute. Parameter description

Parameter	Description
Test Connection	Specifies whether to enable the network connection test feature. Network connection tests are automatically performed on data stores that can be registered in Realtime Compute. To test the connection between Realtime Compute and data stores that cannot be registered, turn on the Test Connection switch.
Storage Type	The type of the data store. LogService Data Storage is selected by default.
Endpoint	The endpoint of Log Service. The endpoint of Log Service varies with regions. <div style="background-color: #e6f2ff; padding: 5px;"> <p> Note For more information about the endpoint of Log Service, contact the Apsara Stack system administrator.</p> </div>
Project	The name of the Log Service project. <div style="background-color: #e6f2ff; padding: 5px;"> <p> Note You can only register Log Service projects that are owned by your level-1 organization. For example, if Log Service Project A is owned by Organization A, users from Organization B cannot register Project A in Realtime Compute.</p> </div>
AccessKey ID	The AccessKey ID of the current account.
AccessKey Secret	The AccessKey secret of the current account. The AccessKey secret enables Realtime Compute to access the Log Service project.

Scenarios

Log Service is a streaming data storage system that can be used to store source tables and result tables. However, it cannot be used to store dimension tables for Realtime Compute.

FAQ

- Q: Why am I unable to register a Log Service project in Realtime Compute?
 A: Realtime Compute uses a storage software development kit (SDK) to access different data stores. The Storage tab in the Realtime Compute console only helps you manage data from different data stores. You can perform the following operations to troubleshoot registration errors:
 - Check whether you have created a Log Service project and have the permissions to access the project. You can log on to the Log Service console and check whether you can access the project.
 - Check whether you are the project owner. You can only register Log Service projects that are owned by your level-1 organization. For example, if Log Service Project A is owned by Organization A, a user from Organization B cannot register Project A in Realtime Compute.

- Check whether you have specified the correct Log Service endpoint and project name.

Note The endpoint must start with `http` and cannot end with a forward slash (`/`). For example, `http://cn-hangzhou.log.aliyuncs.com` is correct, and `http://cn-hangzhou.log.aliyuncs.com/` is incorrect.

- Check whether you have registered the Log Service project. Realtime Compute provides a registration check mechanism that prevents duplicate registration.

- Q: Why does Realtime Compute support only time-based sampling?

A: Log Service stores streaming data, and you can only specify time parameters in the API. Therefore, Realtime Compute supports only time-based sampling.

Note To use the search feature of Log Service, log on to the Log Service console.

3.4.5. Register a Tablestore data store

Tablestore is a NoSQL database service that is based on the Apsara distributed system. Tablestore allows you to store and access large amounts of structured data in real time. Tablestore features massive data storage and low access delays, which makes it suitable to store dimension tables and result tables for Realtime Compute.

Register a Tablestore instance

1. [Log on to the Realtime Compute console](#).
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click the **Storage** tab.
4. Right-click **TableStore Data Storage** and select **Register Data Store**. In the dialog box that appears, register a Tablestore instance in Realtime Compute. Parameters

Parameter	Description
Test Connection	Specifies whether to enable the network connection test feature. Network connection tests are automatically performed on data stores that can be registered in Realtime Compute. To test the connection between Realtime Compute and data stores that cannot be registered, turn on the Test Connection switch.
Storage Type	The type of the data store. TableStore Data Storage is selected by default.
Endpoint	The endpoint of the Tablestore instance. You must enter the internal endpoint of the Tablestore instance. You can log on to the Tablestore console to view the internal endpoint of the instance.
Instance Name	The name of the Tablestore instance.
AccessKey ID	The AccessKey ID of the current account.
AccessKey Secret	The AccessKey secret of the current account. The AccessKey secret enables Realtime Compute to access the Tablestore instance.

3.4.6. Register an RDS data store

This topic describes how to register and use an ApsaraDB for RDS data store in Realtime Compute.

RDS overview

RDS offers a stable, reliable, and scalable online database service. Based on the Apsara distributed system and high performance SSD storage, RDS supports a wide range of engines, such as MySQL, PostgreSQL, and Postgres Plus Advanced Server (PPAS, highly compatible with Oracle). Realtime Compute supports the following RDS engines: MySQL and PostgreSQL.

The performance of Tablestore in high concurrency scenarios where large amounts of data need to be processed is higher than that of RDS. The performance of RDS is restricted by the limits of relational models. Therefore, RDS is often used to store result tables for Realtime Compute. In low concurrency scenarios where a small number of data needs to be processed, RDS can be used to store dimension tables.

Note Realtime Compute uses relational databases, such as ApsaraDB RDS for MySQL, to store result data. Distributed Relational Database Service (DRDS) and RDS connectors are used. If Realtime Compute frequently writes data into a DRDS or RDS table, deadlocks may occur. In scenarios that require high queries per second (QPS), high transactions per second (TPS), or highly concurrent write operations, we recommend that you do not use DRDS or RDS to store the result tables of Blink jobs. To prevent deadlocks, we recommend that you use Tablestore to store result tables.

Register an RDS instance

1. [Log on to the Realtime Compute console](#).
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click the **Storage** tab.
4. Right-click **RDS Data Storage**, and select **Register Data Store**. In the dialog box that appears, register an RDS instance in Realtime Compute. Parameters

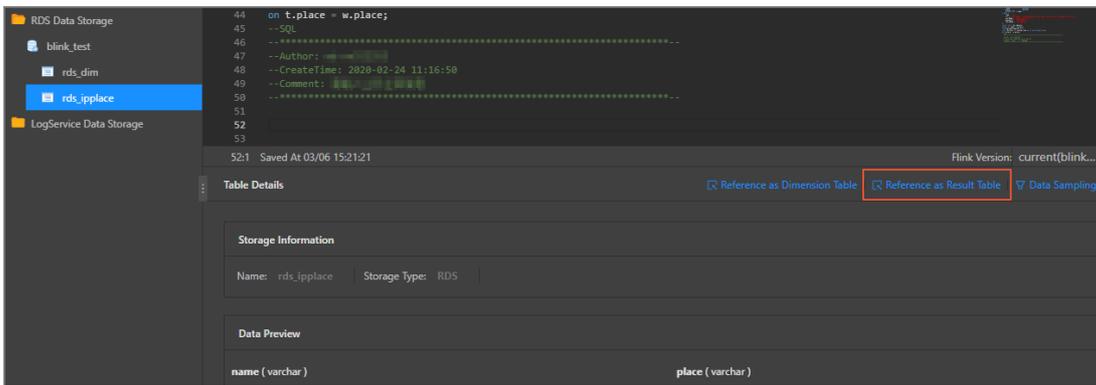

Parameter	Description
Test Connection	Specifies whether to enable the network connection test feature. Network connection tests are automatically performed on data stores that can be registered in Realtime Compute. To test the connection between Realtime Compute and data stores that cannot be registered, turn on the Test Connection switch.
Storage Type	The type of the data store. RDS Data Storage is selected by default.
URL	The connection URL of the RDS database.
DBName	<p>The name of the RDS database to be accessed by Realtime Compute.</p> <p>Note This parameter specifies the RDS database name instead of the RDS instance name.</p> <p>RDS uses whitelists for access control to ensure system security. The IP addresses of the Realtime Compute console and worker nodes must be added to RDS whitelists. Otherwise, Realtime Compute may fail to connect to RDS. For more information, see Specify whitelist settings.</p>
User Name	The username that you use to log on to the RDS database.
Password	The password that you use to log on to the RDS database.

Parameter	Description
Engine	The type of the RDS database. Valid values: <ul style="list-style-type: none"> ○ mysql ○ postgresql ○ sqlserver

Reference an RDS table as a result table

After you register an RDS data store, double-click the RDS database, double-click the RDS table that you want to reference as a result table, and then click **Reference as Result Table**.

Reference an RDS table as a result table

After you click **Reference as Result Table**, Realtime Compute automatically generates the corresponding DDL statements on the current page.

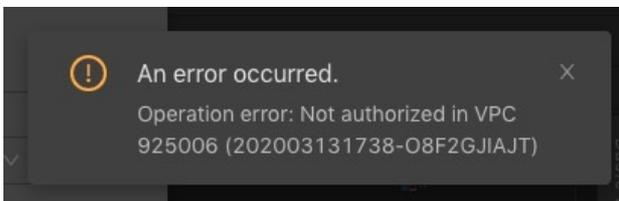

Result

```

31     place          VARCHAR,
32     PRIMARY KEY (`name`)
33 ) WITH (
34     type= 'rds',
35     url = 'dev.mysql.com:3306/blink_test?server=dev.mysql.com:3306/blink_test',
36     userName = 'blink_test_admin',
37     password = 'blink_test!!!',
38     tableName = 'rds_ipplace'
39 );
    
```

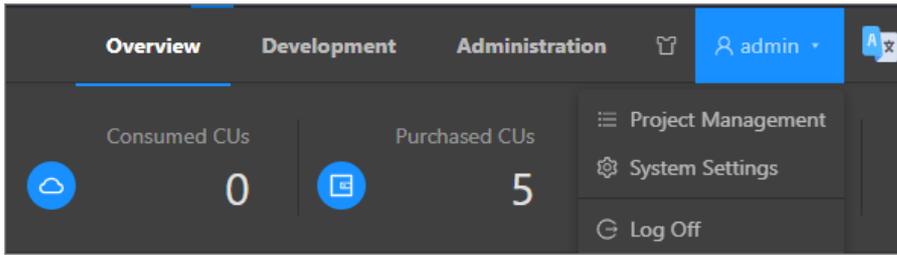

If the following error message appears, troubleshoot and rectify the fault as follows.

Error message

The error occurs because a VPC (not a classic network) was selected when you created the RDS instance. To rectify this fault, follow these steps:

1. Move the pointer over the administrator icon, as shown in the following figure.

2. Click **System Settings**.
3. In the left-side navigation pane, click **VPC Access Authorization**.
4. Click **Add Authorization**. The **Authorize StreamCompute VPC Access** page appears.

Authorization

Authorize StreamCompute VPC Access ✕

* Name:

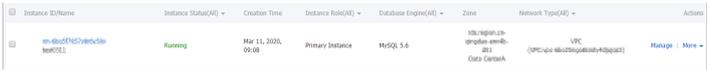

* Region: ▾

* VPC ID:

* Instance ID:

* Instance Port:

Parameters

Parameter	Description
Name	The name of the VPC.
Region	The region where RDS resides.
VPC ID	The ID of the VPC.
Instance ID	<p>The ID of the RDS instance. You can log on to the RDS console and view the instance ID.</p> <p>Instance information</p> 
Instance Port	The access port for the RDS instance. To view the internal port number, log on to the RDS console, click the target instance ID or name in the Instance ID/Name column. On the page that appears, view the internal port number in the Basic Information section.

5. Register the target RDS instance. You must specify the required parameters during the registration.

You can only register data storage resources that are owned by your level-1 organization. For example, if RDS Instance A is owned by Organization A, a user from Organization B cannot register RDS Instance A in the Realtime Compute console. To use Instance A in a stream processing job, the user from Organization B must use SQL code to create a reference to Instance A.

Note If you want to use the RDS storage resources owned by your level-1 organization, we recommend that you do not use SQL code to create a reference to these resources.

The user from Organization B must also specify the following parameters in the WITH clause based on the information of Instance A: url, userName, password, and tableName.

Configuration

```
91  
92 CREATE TABLE datahub_output (  
93   id          varchar  
94 ) WITH (  
95   type= 'rds',  
96   url = 'jdbc:mysql://  
97   userName = 'root@  
98   password = '1234567890123',  
99   tableName = 'datahub_output'  
100 );  
101
```

To use RDS storage resources by writing SQL code, the user from Organization B must specify whitelist settings.

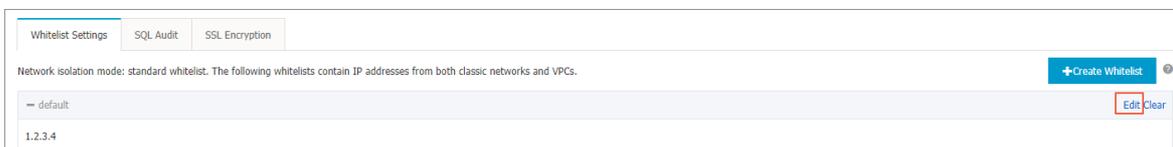

Specify whitelist settings

Some data stores use whitelists for access control to ensure high-level security. These data stores allow access only from the IP addresses that are added to the whitelists. This prevents unauthorized Apsara Stack services from accessing data in these data stores. For example, a newly created RDS database denies all access. You must add IP addresses to the RDS database whitelists to allow access to the database.

RDS can be accessed from both external and internal networks. To enable Realtime Compute to access RDS, you must add the CIDR blocks of Realtime Compute to RDS whitelists.

To do this, follow these steps:

1. Log on to the ApsaraDB for RDS console.
2. On the **Instances** page, click the ID of an instance in the **Instance ID/Name** column.
3. In the left-side navigation pane, click **Data Security**.
4. On the **Whitelist Settings** tab, click **Edit** corresponding to the **default** whitelist.

Note

- To connect an ECS instance to an RDS instance by using an internal endpoint, you must make sure that the two instances are in the same region and have the same network type. Otherwise, the connection fails.
- You can also click **Create Whitelist** to create a new whitelist.

5. In the **Edit Whitelist** dialog box that appears, specify the IP addresses or CIDR blocks that are used to access the instance, and then click **OK**.

Edit Whitelist

*Whitelist Name: default

*IP Addresses: 127.0.0.1

[Add Internal IP Addresses of ECS Instances](#)
You can add 999 more entries.

Specified IP address: If you specify the IP address 192.168.0.1, this IP address is allowed to access the RDS instance.
Specified CIDR block: If you specify the CIDR block 192.168.0.0/24, the IP addresses ranging from 192.168.0.1 to 192.168.0.255 are allowed to access the RDS instance.
When you add multiple IP addresses or CIDR blocks, separate them by a comma (no space after the comma), for example, 192.168.0.1,192.168.0.0/24.

New whitelist entries take effect in 1 minute.

OK Cancel

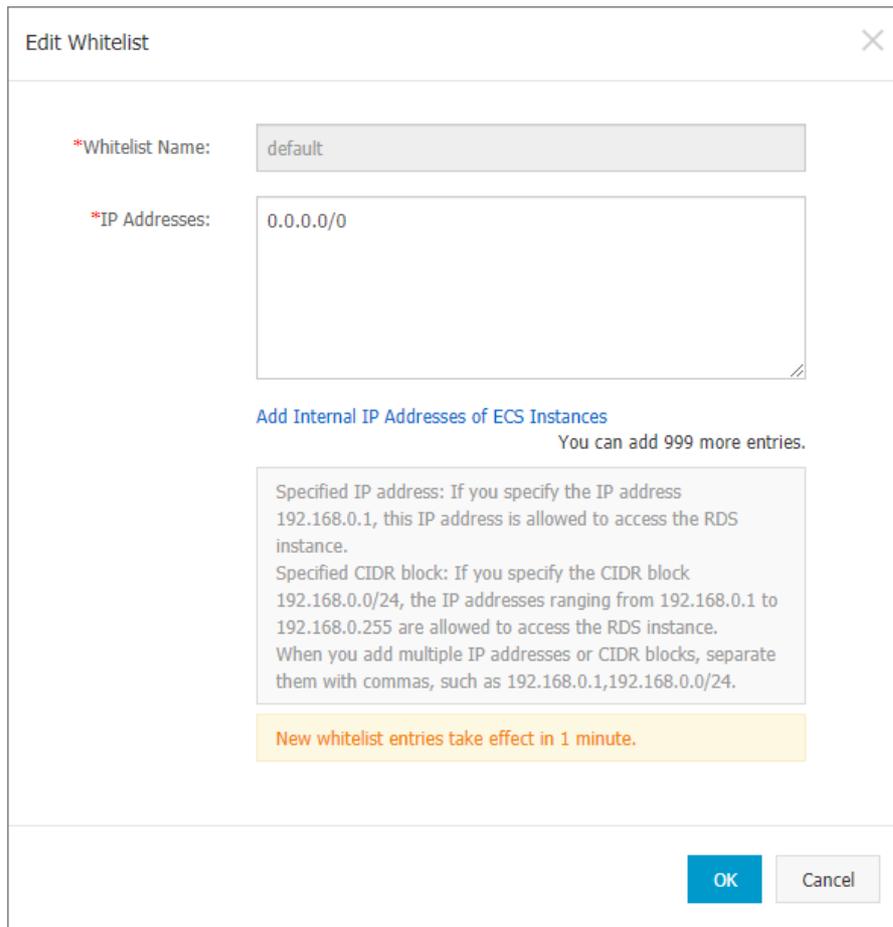

- If you specify the 10.10.10.0/24 CIDR block, IP addresses in the 10.10.10.X format are allowed to access the RDS instance.
- If you want to add multiple IP addresses or CIDR blocks, separate entries with commas (without spaces), such as 192.168.0.1,172.16.213.9.
- After you click **Add Internal IP Addresses of ECS Instances**, the IP addresses of all the ECS instances under your Apsara Stack account are displayed. You can select the required IP addresses to add to the whitelist.

Note If you add a new IP address or CIDR block to the **default** whitelist, the default address 127.0.0.1 is automatically deleted.

Troubleshooting

- Fault description

A stack exception occurs while the system is running, as shown in the following figure.

- Solution
Add the IP address of your region to an RDS whitelist. For more information, see [Specify whitelist settings](#).

3.5. Data development

3.5.1. Create a job

This topic describes how to create a Realtime Compute job.

Procedure

1. [Log on to the Realtime Compute console](#).
2. Click **Development Platform**.
3. Click **Development** in the top navigation bar.
4. Click **Create File** in the toolbar.
5. In the **Create File** dialog box, specify the required fields.

Field	Description
File Name	The name of the file. The specified name must be 3 to 64 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a lowercase letter.

Field	Description
File Type	The type of the file. Valid values: FLINK_STREAM/SQL and FLINK_STREAM/DATASTREAM.
Storage Path	The folder of the file. You can click the icon on the right side of an existing folder and create a subfolder.

6. Click **OK**.

3.5.2. Development

3.5.2.1. SQL code assistance

The development platform of Realtime Compute offers a complete set of SQL tools in the integrated development environment (IDE). These tools provide the following features to help you with Flink SQL-based development:

- **Syntax check**

On the **Development** page of Realtime Compute, the revised script is automatically saved. When the script is saved, an SQL syntax check is automatically performed. If a syntax error is detected, the **Development** page shows the row and column where the error is located, and the cause of the error.

- **Intelligent code completion**

When you enter SQL statements on the **Development** page of Realtime Compute, auto completion popups about keywords, built-in functions, tables, or fields are automatically displayed.

- **Syntax highlighting**

Flink SQL keywords are highlighted in different colors to differentiate data structures.

3.5.2.2. SQL code version management

Realtime Compute provides key features that help you complete development tasks, such as coding assistance and code version management. A new code version is generated each time you publish a job SQL file. The code version management feature allows you to track code changes and roll back to an earlier version if required.

- **Manage code versions**

On the **Development** page, you can manage Flink SQL code versions. A new code version is generated each time you publish a job SQL file. You can use the code version management feature to track versions, modify the code, and roll the code back to an earlier version.

On the **Versions** tab on the right side of the **Development** page, click **More** in the **Actions** column to manage code versions.

- **Compare**: Check the differences between the current version and an earlier version.
- **Rollback**: Roll back to an earlier version.
- **Delete**: Delete an earlier version.
- **Locked**: Lock the current version.

 **Note** You cannot submit a new version before you unlock the SQL file.

- **Delete code versions**

A snapshot of a code version is created each time you submit an SQL file for publishing a job. This allows you to track code changes. The maximum number of code versions has been specified. If you use Apsara Stack, a maximum of 20 code versions can be published. To find out the maximum number of code versions in other environments, contact the system administrator. If the number of code versions reaches the upper limit, an error message is displayed to alert you to delete one or more earlier versions.

In this scenario, you must delete one or more earlier versions before you publish new versions. To do this, click the **Versions** tab on the right side of the **Development** page, click **More** in the **Actions** column, and select **Delete** to delete expired versions that are no longer needed.

3.5.2.3. Data store management

The **Development** page of the Realtime Compute console provides an easy and effective method to manage data stores. For example, you can register external data stores to reference the data stores.

- **Data preview**

The **Development** page of Realtime Compute allows you to preview data from a wide range of data stores. Data preview allows you to analyze the characteristics of upstream and downstream data, identify key business logic, and complete development tasks with high efficiency.

- **Auto DDL generation**

Realtime Compute provides the auto DDL generation feature. The system can automatically generate DDL statements to reference data stores that can be registered in Realtime Compute. This feature provides a simple method to edit SQL statements for stream processing jobs. This improves overall efficiency and reduces errors when you manually enter SQL statements.

3.5.3. Debug job code

The Realtime Compute development platform provides a simulated running environment where you can customize uploaded data, simulate operations, and check outputs.

After you write the SQL code that implements the computing logic, follow these steps to debug the code:

1. [Log on to the Realtime Compute console.](#)
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click **Development**.
4. On the **Development** tab, double-click the target folder and file name to open the job file.
5. In the top menu bar, click **Syntax Check**.

 **Note** You can use the syntax check feature to check whether the SQL file includes syntax errors. Error messages are displayed for syntax errors.

6. In the top menu bar, click **Debug**. On the **Debug File** page, debug your SQL code.

The test data for debugging can be acquired by using either of the following two methods:

- Upload local data.
 - a. Click **Download Template**.
 - b. Prepare test data based on the template.
 - c. Click **Upload**. After the file is uploaded, you can view the uploaded data in the data preview section.
- Sample online data.
 - a. Click **Random Online Data Sampling** or **Sequential Online Data Sampling**.

- b. View the sampled data in the data preview section.
7. Click **OK**.
8. In the output window, view the debugging result.

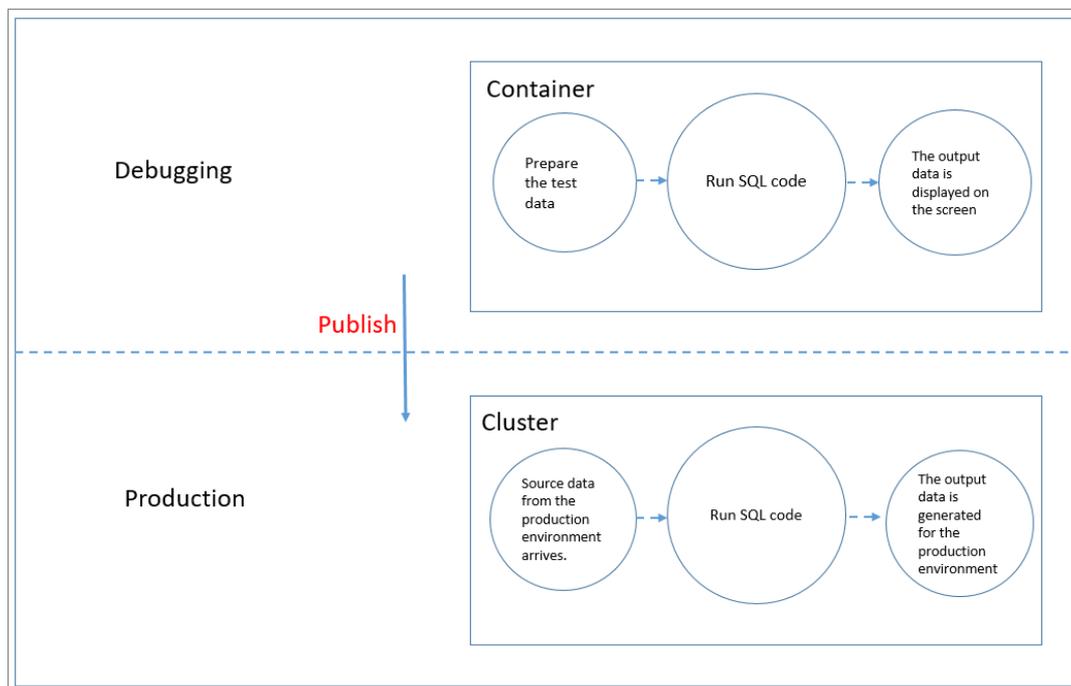

The debugging feature of Realtime Compute provides the following functions:

- Enables isolation between debugging and production environments.

In the debugging environment, the Flink SQL code runs in a separate container, and computing result data is only displayed on the screen of the **Development** page. In this way, the debugging does not affect the running jobs and data stores in the production environment.

In the debugging phase, result data is not written to external data stores. In the production environment, failures may occur due to format errors when result data is written to the target data stores. Such failures cannot be identified or prevented in the debugging phase, and can be detected only while jobs are running. For example, failures may occur in the production environment if your result data is too long. This occurs when the result data is written to a result table in ApsaraDB for RDS and the length of character strings reaches the upper limit for an RDS table. The Realtime Compute team is working on support for writing result data to external data stores in the production environment. This allows you to effectively simulate the production environment and resolve more issues in the debugging phase.

Isolation between debugging and production environments

- Supports the customization of test data.

In the debugging environment, Realtime Compute does not read data from source data stores, such as DataHub topics that store source tables and RDS instances that store dimension tables. You must create a set of test data and upload the test data on the **Development** page.

To make the debugging feature easy to use, Realtime Compute provides a template of test data for each type of job. You can download the template and enter your test data.

Note We recommend that you use the templates to prevent errors.

- Specifies a separator.

A comma (,) is used as the separator in files for debugging by default. An example of a file for debugging is described as follows:

```
id,name,age
1,alicloud,13
2,stream,1
```

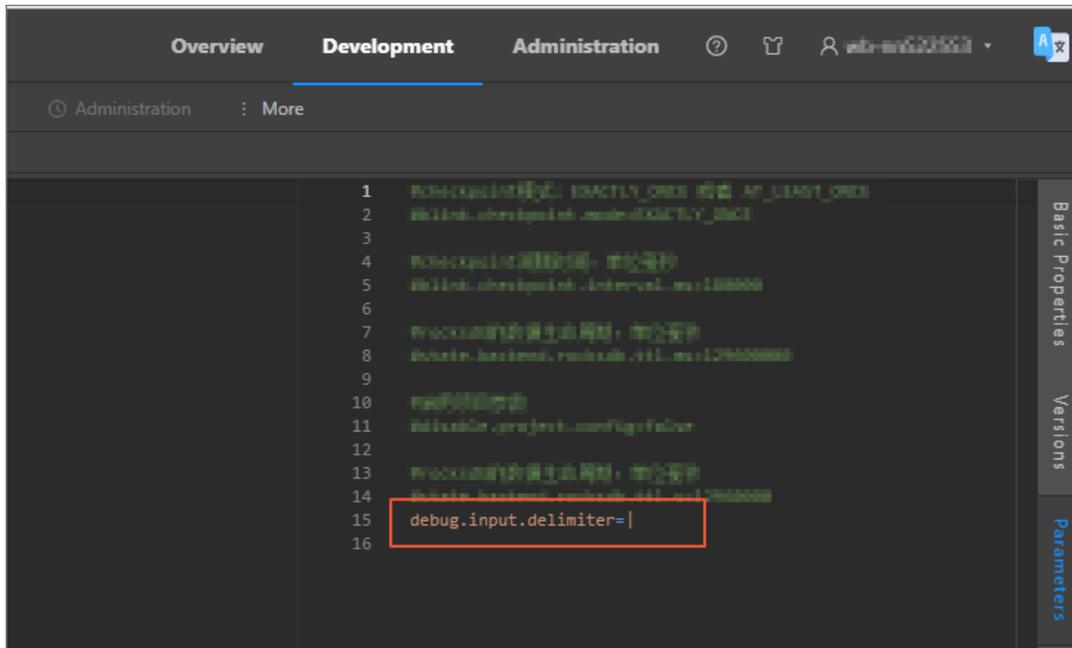

If the separator is not specified, a comma (,) is used to separate fields. If you need to use a JSON string as the field data and the string contains commas (,), you must specify another character as the separator.

Note Realtime Compute allows you to specify a character as the separator, but not a multi-character string, such as aaa.

```
id|name|age
1|alicloud|13
2|stream|1
```

In this example, specify the debug.input.delimiter parameter as follows: `debug.input.delimiter=|`.

Specify a separator

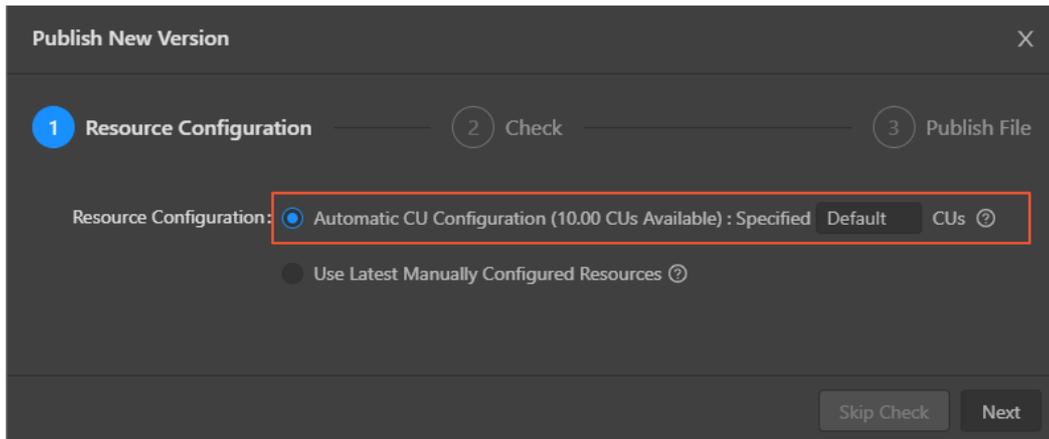

3.5.4. Publish a job SQL file

After you have created and debugged a job Flink SQL file, you can publish the SQL file and manage the job in the production environment.

Procedure

1. [Log on to the Realtime Compute console.](#)
2. In the top navigation bar, Click **Development**.
3. In the top menu bar, click **Publish**.
4. In the dialog box that appears, select **Automatic CU Configuration**. If you are performing automatic configuration for the first time, we recommend that you use the default number of CUs. Click **Next**.

Configure resources

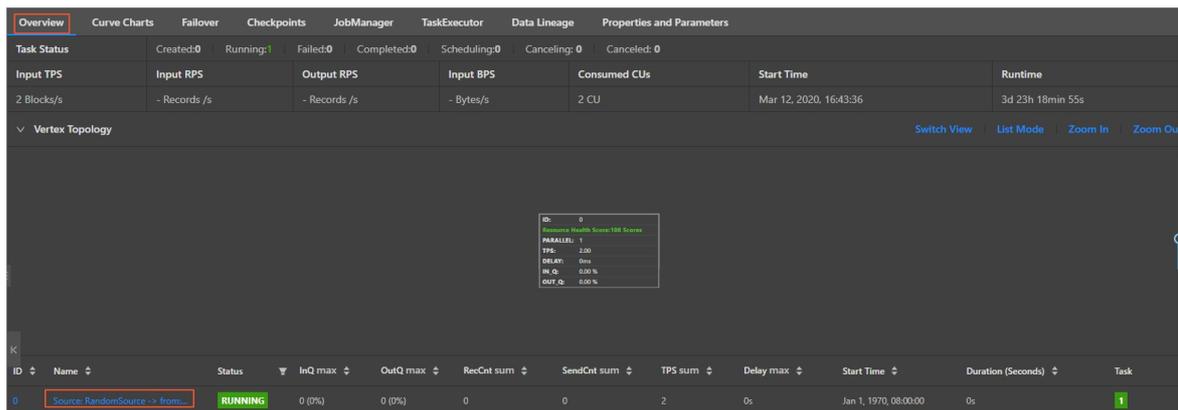

5. Check the data. After the check is completed, click **Next**.
6. Click **Publish**.
7. Go to the **Administration** page to start the job.
 - i. In the top navigation bar, click **Administration**.
 - ii. On the **Administration** page, find the target job, and click **Start** in the **Actions** column.

3.5.5. View logs

You can view job logs to check the job run information. This topic describes how to view job logs.

Procedure

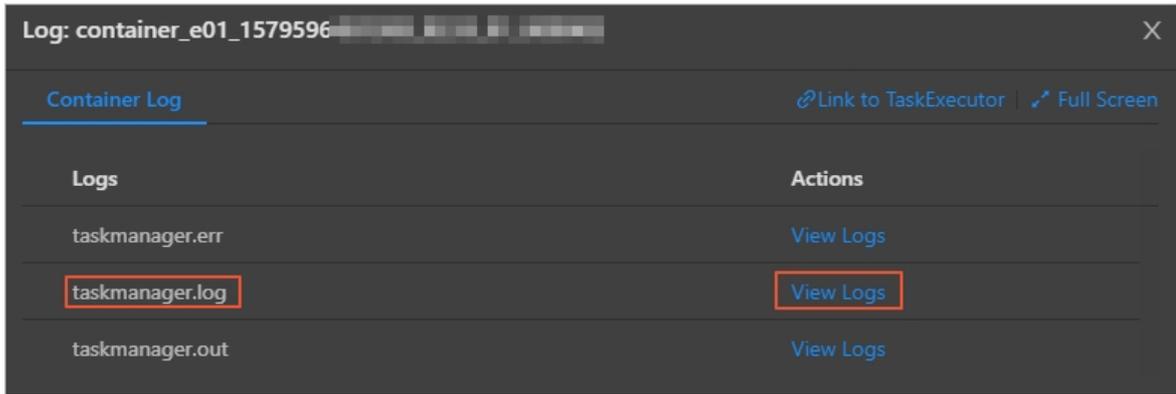

1. Go to the **Administration** page in Realtime Compute.
 - i. [Log on to the Realtime Compute console](#).
 - ii. In the top navigation bar, click **Administration**.
 - iii. On the **Jobs** page that appears, click the target job name in the **Job Name** column.
2. At the bottom of the **Overview** page, click the name of the target vertex.

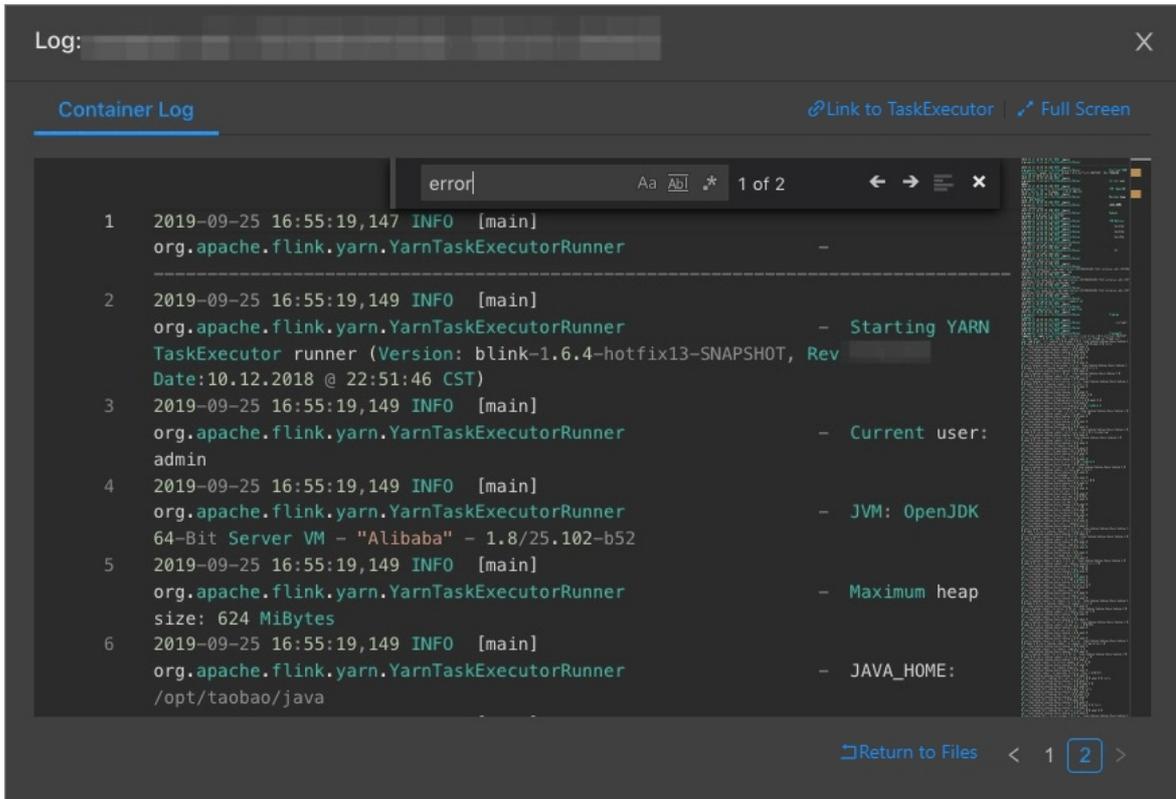

3. On the **Execution Vertex** page, click the **Subtask List** tab, and click **View Logs** in the **Actions** column.

4. In the **Log** dialog box that appears, click **View Logs** for **taskmanager.log** in the **Actions** column.

5. On the Container Log tab, view the log entries.

Note You can press Ctrl+F for Windows or Cmd+F for MacOS to search for specified log entries. We recommend that you view the logs from the last page. The first **error** log entry describes the root cause of the job error.

4. Machine Learning Platform for AI

4.1. What is machine learning?

Machine learning is a process of using statistical algorithms to learn large amounts of historical data and generate an empirical model to provide business strategies.

Apsara Stack Machine Learning Platform for AI is a set of data mining, modeling, and prediction tools. It is developed based on MaxCompute (also known as ODPS). Machine Learning Platform for AI supports the following functions:

- Provides an all-in-one algorithm service covering algorithm development, sharing, model training, deployment, and monitoring.
- Allows you to complete the entire procedure of an experiment either through the GUI or by running PAI commands. This function is typically intended for data mining personnel, analysts, algorithm developers, and data explorers.
- In Apsara Stack, Machine Learning Platform for AI runs on MaxCompute. Machine Learning Platform for AI allows you to call algorithms to decouple the applications and compute engines after you have deployed algorithm packages in MaxCompute clusters.
- Provides various algorithms and reliable technical support, providing more options to resolve service issues. In the Data Technology (DT) era, you can use Machine Learning Platform for AI to implement data-driven services.

Machine Learning Platform for AI can be applied in the following scenarios:

- Marketing: commodity recommendations, user profiling, and precise advertising.
- Finance: loan delivery prediction, financial risk control, stock trend prediction, and gold price prediction.
- Social network sites (SNSs): microblog leader analysis and social relationship chain analysis.
- Text: news classification, keyword extraction, text summarization, and text analysis.
- Unstructured data processing: image classification and image text extraction through OCR.
- Other prediction cases: rainfall forecast and football match result prediction.

Machine learning can be divided into three types:

- Supervised learning: Each sample has an expected value. You can create a model and map input feature vectors to target values. Typical examples of this learning mode include regression and classification.
- Unsupervised learning: No samples have a target value. This learning mode is used to discover potential regular patterns from data. Typical examples of this learning mode include simple clustering.
- Reinforcement learning: This learning mode is complex. A system constantly interacts with the external environment to obtain external feedback and determines its own behavior to achieve a long-term optimization of targets. Typical examples of this learning mode include AlphaGo and driverless vehicles.

4.2. Quick start

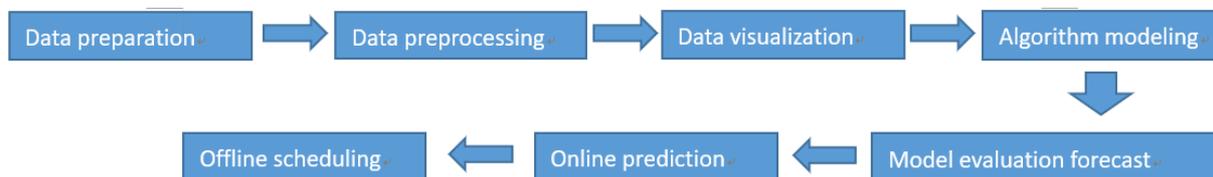

4.2.1. Overview

This topic describes how to perform data preparation, data preprocessing, data visualization, algorithm modeling, model prediction and evaluation, online prediction, and DataWorks task scheduling to set up a machine learning experiment.

Note This document covers Apsara Stack Machine Learning Platform for AI, online model service, and deep learning framework. The online model service and deep learning framework are not basic functions of Apsara Stack Machine Learning Platform for AI and must be purchased separately.

For more information, see [Machine learning experiment creation flowchart](#).

Machine learning experiment creation flowchart

1. Data preparation

Import target data into the Apsara Stack Machine Learning Platform for AI console.

2. Data preprocessing

Perform data processing, including SQL-based conversion, normalization, and standardization, to ensure that all data has the same dimensions.

3. Data visualization

Display data in charts to view the features of the data and the distribution of the values. This serves as the basis for model algorithm selection.

4. Algorithm modeling

Use machine learning algorithms to train data and ultimately build a model.

5. Model evaluation forecast

Make predictions from and evaluate the model, and use the prediction results to create business development strategies.

6. Online prediction

Use online prediction to deploy the generated model and adjust your business strategy based on the prediction results.

7. Offline scheduling

Deploy experiments in DataStudio and run them on a regular basis.

4.2.2. Log on to the Machine Learning Platform for AI console

This topic describes how to log on to the Machine Learning Platform for AI console.

Prerequisites

- The IP address or domain name of the Apsara Uni-manager Management Console is obtained from deployment engineers before you log on to the Apsara Uni-manager Management Console. The URL for logging on to the Apsara Uni-manager Management Console is in the following format: `http://IP address or domain name of the Apsara Uni-manager Management Console/manage`.
- A browser is available. We recommend that you use Google Chrome.

Procedure

1. Enter the URL of the Apsara Uni-manager Management Console in the address bar and press the Enter key.
2. Enter your username and password.

The system has a default super administrator, whose username is super. The super administrator can create system administrators. A system administrator can create system users and notify the users of the default password by SMS or email.

Note When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username as prompted. For security concerns, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two types of the following characters: letters, digits, and special characters such as exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click **Login** to go to the homepage of the Apsara Uni-manager Management Console.
4. On the top navigation bar, choose **Big Data > Machine Learning**.
5. On the page that appears, set the **Department** and **Region** parameters and click **PAI** to go to the Apsara Stack Machine Learning Platform for AI console.

Note If this is the first time that you log on to the Apsara Stack Machine Learning Platform for AI console, you must perform the following steps:

- i. Add an organization
Create an organization to store resource sets and their resources.
- ii. Create a user
Create users and assign the users different roles to meet different requirements for system access control.
- iii. Create a resource set
Create a resource set before you apply for resources.
- iv. Add a member to a resource set
Add users to the resource set.
- v. Go to the homepage of the Apsara Uni-manager Management Console. In the left-side navigation pane, choose **Big Data > MaxCompute**. Then, create a task account and a project in MaxCompute.
 - a. Create an account: Set the **Department** parameter to the department you created in Step 1.
 - b. Create a MaxCompute project: Set the **Department** parameter to the department you created in Step 1. Set the **Dt_project** parameter to the project you created in Step 2. Set the **MaxCompute Task Account** parameter to the task account that you created.
- vi. Create a Dataworks workspace. In the **Advanced Settings** section, set the **MaxCompute Project Name** parameter to the name of the project that you created in the previous step.

4.2.3. Data preparation

This topic describes how to import data into the Apsara Stack Machine Learning Platform for AI console for modelling.

Prerequisites

Make sure that you have created a MaxCompute project and imported table data into the project. You can

download the data from [Download Data](#).

Procedure

1. [Log on to the Apsara Stack Machine Learning Platform for AI console](#) and click **Experiments** in the left-side navigation pane.
2. On the **Experiments** page, right-click **My Experiments** and choose **New Experiment** from the short cut menu. In the dialog box that appears, enter the experiment name and description. Click **Create** to go to the **Components** page.
3. In the **Components** list, click **Data Source/Target**, and drag and drop the **Read MaxCompute Table** onto the canvas.
4. Click the **Read MaxCompute Table** component and configure its parameters. Enter the MaxCompute table name in **Table Name** in the right-side configuration pane.
5. In the right-side parameter setting pane, click **Column Information** to view the column name, data type, and the first 100 rows of data in the input table.

4.2.4. Data preprocessing

This topic describes how to perform data preprocessing by using methods such as normalization, SQL scripts, and data splitting.

Prerequisites

Before data preprocessing, make sure that you have completed [data preparation](#).

Procedure

1. [Log on to the Apsara Stack Machine Learning Platform for AI console](#) and click **Components** in the left-side navigation pane.
2. In the **Components** list, click **Tools**. Drag and drop the **SQL Script** component onto the canvas. Click **Data Preprocessing**. Drag and drop the **Normalization** component onto the canvas, and connect the components.
3. Click the **SQL Script** component and click the right-side **Parameters** tab. In the **SQL Script** input box, enter the following SQL scripts to convert the features from string type to numeric type.

```
select age,
(case sex when 'male' then 1 else 0 end) as sex,
(case cp when 'angina' then 0 when 'notang' then 1 else 2 end) as cp,
trestbps,
chol,
(case fbs when 'true' then 1 else 0 end) as fbs,
(case restecg when 'norm' then 0 when 'abn' then 1 else 2 end) as restecg,
thalach,
(case exang when 'true' then 1 else 0 end) as exang,
oldpeak,
(case slop when 'up' then 0 when 'flat' then 1 else 2 end) as slop,
ca,
(case thal when 'norm' then 0 when 'fix' then 1 else 2 end) as thal,
(case status when 'sick' then 1 else 0 end) as ifHealth
from ${t2};
```

4. Click the **Normalization** component and select all fields to normalize the numeric features to values ranging from 0 to 1.
5. Click **Data Preprocessing**. Drag and drop the **Split** component onto the canvas and set **Split Ratio** to **0.7**.

 **Note** This step splits data into two parts: 70% of the data is used as the model training set, and 30% of the data is used as the model prediction set.

4.2.5. Data visualization

This topic describes how to view the features and value distribution by using statistical analysis components.

Prerequisites

Before data visualization, make sure that you have completed [data preprocessing](#).

Procedure

1. [Log on to the Apsara Stack Machine Learning Platform for AI console](#) and click **Components** in the left-side navigation pane.
2. In the **Components** list, click **Statistical Analysis**. Drag and drop the **Whole Table Statistics** component onto the canvas. Connect the components, and click **Run** at the bottom of the canvas.
3. After the experiment stops running, right-click **Whole Table Statistics** and choose **View Data** from the short cut menu. The analysis report is displayed.

4.2.6. Algorithm modeling

This topic describes how to perform feature training and generate models by using the machine learning components.

Prerequisites

Before algorithm modeling, ensure that you have completed [data preprocessing](#) and learned the data characteristics and value distribution through [data visualization](#).

Procedure

1. [Log on to the Apsara Stack Machine Learning Platform for AI console](#) and click **Components** in the left-side navigation pane.
2. In the **Components** list, choose **Machine Learning > Binary Classification**. Drag and drop the **Binary Logistic Regression** component onto the canvas, and connect the corresponding components and data streams.
3. Click the component, and select 13 feature columns from **Training Feature Columns** in the right-side **Column Settings** pane. All parameters use the default settings.
4. Click **Run**.
5. Click **Models** in the left-side navigation pane to view the generated model.

4.2.7. Model prediction evaluation

This topic describes how to use a model to make predictions and evaluate its results by using the prediction and evaluation components.

Prerequisites

Before evaluating the prediction, make sure that you have completed [algorithm modeling](#) and generated a machine learning model from the experiment.

Procedure

1. Log on to the [Apsara Stack Machine Learning Platform for AI console](#) and click **Components** in the left-side navigation pane.
2. In the **Components** list, click **Machine Learning**. Drag and drop the **Prediction** component onto the canvas, and connect the corresponding components and data streams.
3. Choose **Machine Learning > Evaluation**. Drag and drop the **Binary Classification Evaluation** component onto the canvas and connect the corresponding components and data streams.
4. Click **Run** in the upper-left corner of the canvas. During the running process, select a component and click the **Developer Tool** () icon in the lower-right corner of the canvas to view the running status of the component.
5. Right-click the **Binary Classification Evaluation** component and choose **View Evaluation Report** from the shortcut menu to generate the ROC curve of the LR model trained with different parameters.

4.2.8. DataWorks task scheduling

After you have run all nodes in an experiment, you can deploy the experiment to DataWorks and schedule DataWorks to periodically run the experiment. This topic uses air quality prediction as an example scenario.

Prerequisites

Before scheduling an experiment, you must make sure that you have successfully run all nodes in the experiment and that the experiment is deployed to DataWorks.

Procedure

1. Log on to the [Apsara Stack Machine Learning Platform for AI console](#). Click **Experiments** in the left-side navigation pane.
2. Click the **My Experiments** tab and select an experiment to navigate to the canvas.

 **Notice** Make sure all components have been run in the experiment. A green check means that the component is running correctly.

3. In the upper-left corner of the canvas, choose **Deploy > Schedule DataWorks Tasks** to go to DataStudio.
4. In the DataStudio console, choose **Create > Algorithm > Machine Learning Platform for AI**, and then create a Machine Learning experiment node.
5. In the **Create Node** dialog box, enter the node name, select the target folder, and click **Submit**.

 **Notice** You must select a target folder for the algorithm type.

After the experiment node is created.

6. Select the experiment from the drop-down list.
7. Configure task scheduling parameters, including the recurrence, input, and output parameters.
8. Click **Submit**. The task will be executed the next day.
9. Click **Administration** in the upper-right corner to go to the administration page. You can view the status of the machine learning task and the system log. You can also perform other operations such as adding retroactive data and testing the experiment.

4.3. Online model service (must be activated separately)

4.3.1. Deploy an online model service

This topic describes how to deploy the generated experiment model through the online model service. You can adjust your business strategy anytime based on predicted results.

Prerequisites

Before deploying the online model service, make sure that the preceding steps are completed and the components are running properly. A green check means that the component is running correctly.

Procedure

1. Log on to the [Apsara Stack Machine Learning for AI console](#) and click **Experiments** in the left-side navigation pane.
2. Click the **My Experiments** tab and select an experiment to navigate to the canvas.

 **Notice** Make sure that the selected experiment is running properly. A green check means that the component is running correctly.

3. In the upper-left corner of the canvas, choose **Deploy > Online Model Service**.
4. Select the model to deploy and click **Next**.
5. Select a deployment mode. You can select one of the following modes:
 - o [New Service](#)
 - o [Add Existing Service Version](#)
 - o [Create Blue-green Deployment](#)

4.3.2. Create a service

This topic describes how to use the **New Service** mode to deploy online prediction services.

Procedure

1. Complete [Preparations for online model prediction](#).
2. Set **Processes** and **Quota**.

 **Note** **Processes** determines the maximum number of concurrently running programs. **Quota** determines the running speed and the parameters such as RT and QPS.

3. Click **Deploy**. It takes several minutes to create the model.
4. After the model is created, click the model name to view information about the model invocation.
5. Click the icons under **Monitor** to view statistics about QPS, response, RT, traffic, CPU utilization, memory usage, and daily invocation.

6.  **Note** Perform this step when resources are insufficient and need to be expanded.

Click **Update** to expand resources.

7. Click **Online Debugging** in the upper-right corner of the page and select the current model.

4.3.3. Add an existing service version

This topic describes how to use the **Add Existing Service Version** mode to deploy online prediction services.

Prerequisites

Before you use the **Add Existing Service Version** mode to deploy online prediction services, ensure that you have deployed one version of online prediction services through the [New Service](#) mode.

Procedure

1. Complete [Preparations for online model prediction](#).
2. Select **Add Existing Service Version**.
3. Select a deployed model. It takes several minutes to add a version.
4. After the model is deployed, select the added version from the **Current Version** drop-down list.

4.3.4. Create a blue-green deployment

This topic describes how to use the **Create Blue-green Deployment** mode to deploy online prediction services.

Prerequisites

Before you use the **Create Blue-green Deployment** mode to deploy online prediction services, ensure that you have deployed two versions of online prediction services through the [New Service](#) and [Add Existing Service Version](#) modes.

Context

In the blue-green deployment mode, you can deploy and test the target version without stopping the source version. After confirming that the target version is running normally, switch all traffic to the target version. Blue-green deployment is safe and does not interrupt services.

Procedure

1. Complete [Preparations for online model prediction](#).
2. Select the deployed model service and click **Deploy**. The deployment may take several minutes.
3. Click **Switch Traffic** and adjust the ratio of traffic forwarded to the two models. The initial ratio is 100% for both models.
4. Perform online debugging.
 - i. Click **Online Debugging** in the upper-right corner of the page and select the deployed model.
 - ii. Enter data (feature input) in **Body**. For example, the body information of the logistic regression model for heart disease prediction is as follows:

```
[{"sex":0,"cp":0,"fbs":0,"restecg":0,"exang":0,"slope":0,"thal":0,"age":0,"trestbps":0,"chol":0,"thalach":0,"oldpeak":0,"ca":0}]
```

- iii. Click **Run** and check the result.

4.4. Components

4.4.1. Overview

This topic describes how to use and configure machine learning components. When building a machine learning experiment, you can select components based on the features of existing data to generate a model and make accurate predictions for your business.

Each component has one or more input or output ports. You can move the pointer over the ports to view their descriptions and connect the components.

4.4.2. Data source and target

This topic describes components in the **Data Source/Target** category, such as the Read MaxCompute Table and Write MaxCompute Table components.

Read MaxCompute tables

You can use the Read MaxCompute Table component to read MaxCompute tables. By default, this component reads data of the current project. If you want to read data from tables in another project for which you have access, you can prefix the table name with the project name in the `project name.table name` format. For example, `tianchi_project.weibo_data`. After you specify the input table, the system reads the structural data of the table. You can click the **Column Information** tab to view the data. This component does not support views.

If the selected input table is a partitioned table, the back end automatically selects the Partition checkbox. You can select or configure partition parameters. Only one partition can be selected. If you do not select the Partition checkbox or do not specify the partition parameters, the whole table is selected. If the input table is non-partitioned, the Partition checkbox cannot be selected.

Write MaxCompute tables

You can use the Write MaxCompute Table component to write data to tables in the current project or tables in other projects. This component can write data to partitions. Partitions must be created for the table in the MaxCompute console before this component can write data to the partitions. You can set the table lifecycle measured in days.

4.4.3. Data preprocessing

4.4.3.1. Sampling and filtering

4.4.3.1.1. Random sampling

Data is sampled randomly and independently. You can specify a ratio or quantity of samples to be taken and choose whether to enable sampling with replacement.

Parameter settings

Parameters Setting
Tuning

Sample Size Specify either the sample size or...

Sampling Fraction Range: (0,2). Specify either...

Sampling with Replacement

Random Seed Positive integer.

PAI command

```

Pai -name sample
    -project algo_public
    -DinputTableName=wbpc
    -DoutputTableName=wbpc_sample
    -Dratio=0.3;
  
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of <code>partition_name=value</code> . To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.
ratio	Required. The sampling fraction.	(0, 1)	-
outputTableName	Required. The name of the output table.	-	-
outputTablePartition	Optional. The partition of the output table.	-	The output table is a non-partitioned table by default.

Parameter	Description	Valid values	Default value
lifecycle	Optional. The lifecycle of the output table.	A positive integer in the range of [1, 3650]	No lifecycle is set by default.

4.4.3.1.2. Weighted sampling

Sample data is collected based on weights. The weight column must be of double or int type. Data is sampled based on the value of its corresponding weight. For example, data with a col value of 1.2 has a higher probability to be sampled than data with a col value of 1.0.

Parameter settings

Parameters Setting

Sample Size Specify either the sample size or...

Sampling Fraction Range: (0,1). Specify either...

Sampling with Replacement

Weight Columns Double or bigint type.

Random Seed Positive integer.

Parameter settings

Parameter	Description
Sample Size	You can specify the number of samples to be taken, which is 10,000 by default. For sampling without replacement, the number of samples cannot be greater than the number of data entries.
Sampling Fraction	You can use either the Sample Size or Sampling Fraction parameter. You can choose sampling with or without replacement, the latter of which is used by default. Select the checkbox to enable sampling with replacement.
Weight Columns	You can select a weight column from the drop-down list. The weight column can be of the double or bigint type.
Random Seed	The random seed, which is a positive integer. This parameter is empty by default.

- You can choose sampling with or without replacement, the latter of which is used by default. Select the checkbox to enable sampling with replacement.
- You can specify the number of samples to be taken, which is 10,000 by default.

Note For sampling without replacement, the number of samples cannot be greater than the number of data entries.

- You can select a weight column from the drop-down list. The weight column can be of the double or bigint type.

PAI command

```
PAI -name WeightedSample
-project algo_public
-DprobCol="previous"
-DsampleSize="500"
-DoutputTableName="test2"
-DinputPartitions="pt=20150501"
-DinputTableName="bank_data_partition";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
replace	Indicates whether sampled data is replaced. If this parameter is set to true, data is replaced after it is sampled. If this parameter is set to false, data is not replaced after it is sampled.
probCol	The columns to be weighted. Each value indicates the weight of an entry. Normalization is not required.
sampleSize	The number of samples to be taken. For sampling without replacement, the number of samples cannot be greater than the number of data entries.
outputTableNames	The name of the output table. Separate multiple table names with commas (,).
inputPartitions	Optional. The partitions selected from the input table for training. If no partitions are specified, the entire table is selected.
inputTableName	The name of the input table.
replace	Optional. This parameter indicates whether sampled data is replaced. If this parameter is set to true, data is replaced after it is sampled. If this parameter is set to false, data is not replaced after it is sampled.

4.4.3.1.3. Filtering and mapping

You can filter data based on filtering expressions and rename columns.

Parameter settings

- Use the WHERE condition to filter data similar to how it would function in an SQL statement.

Filtering conditions: Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), less than or equal to (<=) signs, as well as like and rlike.

- Rename columns.

PAI command

```
PAI -name Filter
-project algo_public
-DoutTableName="test_9"
-DinputPartitions="pt=20150501"
-DinputTableName="bank_data_partition"
-Dfilter="age>=40";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
outTableName	The name of the output table.
inputPartitions	Optional. The partitions selected from the input table for training. If no partitions are specified, the entire table is selected.
inputTableName	The name of the input table.
filter	The WHERE condition to filter data. Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), less than or equal to (<=) signs, as well as like and rlike.

4.4.3.1.4. Stratified sampling

Stratified sampling is a statistical computing method. It works by dividing a population into several strata based on specified features, performing random sampling at each stratum, and creating a sample collection.

Parameter settings

Parameter	Description
Column Settings	Stratification Column: Required. Samples are stratified based on this column.
Parameter Settings	Sampling Fraction/Sample Size: Required. A value less than 1 represents the sampling fraction per stratum. A value greater than 1 represents the number of samples at each stratum.
	Other Sampling Configurations: Optional. This parameter allows you to collect different numbers of samples at different strata.
	Random Seed: Optional. Valid values: 1, 2, 3, 4, 5, 6, and 7.

PAI command

```
Pai -name sample
-project algo_public
-DinputTableName=wbpc
-DoutputTableName=wbpc_sample
-DstrataColName="label"
-DsampleSize="A:200,B:300,C:500"
-DrandomSeed=1007
-Dlifecycle=30
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
<code>inputTableName</code>	Required. The name of the input table.	-	-
<code>inputTablePartitions</code>	Optional. The partitions selected from the input table for training, in the format of <code>partition_name=value</code> . To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.
<code>strataColName</code>	Required. The stratification column.	-	-
<code>outputTableName</code>	Required. The name of the output table.	-	-
<code>sampleSize</code>	Optional. An integer value that specifies the number of samples taken from each stratum. A string value must be in the <code>strata0:n0,strata1:n1...</code> format. Each item in the string represents the number of samples to be taken from the corresponding stratum.	-	

Parameter	Description	Valid values	Default value
<code>sampleRatio</code>	Optional. A decimal value from 0 to 1 that represents the ratio of data for each stratum to be sampled. A string value must be in the <code>strata0:r0,strata1:r1...</code> format. Each item in the string represents the sampling fraction for the corresponding stratum.	-	-
<code>randomSeed</code>	Optional. The number of random seeds.	-	0
<code>lifecycle</code>	Optional. The lifecycle of the output table.	A positive integer in the range of [1, 3650]	No lifecycle is set by default.
<code>coreNum</code>	Optional. The number of cores.	-	Automatically calculated.
<code>memSizePerCore</code>	Optional. The memory size of each core.	-	Automatically calculated.

4.4.3.2. Data merge

4.4.3.2.1. Join

This component merges two tables by associating the information in the tables and outputting the specified columns. This component is similar to the JOIN statement of SQL.

Parameter settings

- Join types: left join, internal join, right join, and full join.
- Only the equation condition is supported.
- You can manually add or delete join conditions.

PAI command

No PAI command is available.

4.4.3.2.2. Merge columns

You can merge data of two tables by column. The two tables must have the same number of rows.

Parameter settings

Procedure

1. Select input columns from the left table.
2. Select input columns from the right table.

When merging columns:

- The two tables must have the same number of rows.
- The names of output columns selected from the left and right tables cannot be the same.
- When selecting an output column, you can change its name.
- If no output columns are selected from the left or right table, the whole table is selected. In this case, if **Automatically Rename Output Columns** is selected, the duplicate columns are renamed and then output.

PAI command

```
PAI -name AppendColumns
-project algo_public
-DoutputTableColNames="petal_length,petal_width,petal_length2,petal_width2"
-DautoRenameCol="false"
-DoutputTableName="pai_temp_770_6840_1"
-DinputTableNames="iris_twopartition,iris_twopartition"
-DinputPartitionsInfoList="dt=20150125/dp=20150124;dt=20150124/dp=20150123"
-DselectedColNamesList="petal_length,petal_width;sepal_length,sepal_width";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
outputTableColNames	The names of the columns in the new table. The column names must be separated with commas (.). If autoRenameCol is set to true, this parameter is ignored.
autoRenameCol	Optional. This parameter specifies whether to automatically rename the columns in the output table. If the value is true, the columns are renamed. If the value is false, the columns are not renamed. Default value: false.
outputTableName	The name of the output table.
inputTableNames	The name of the input table. Separate multiple table names with commas (.).
inputPartitionsInfoList	Optional. A list of partitions selected from the corresponding input tables. Partitions of the same table must be separated with commas (,) and partitions of different tables must be separated with semicolons (;).
selectedColNamesList	The names of selected columns. The names of columns in the same table must be separated with commas (,) and the names of columns in different tables must be separated with semicolons (;).

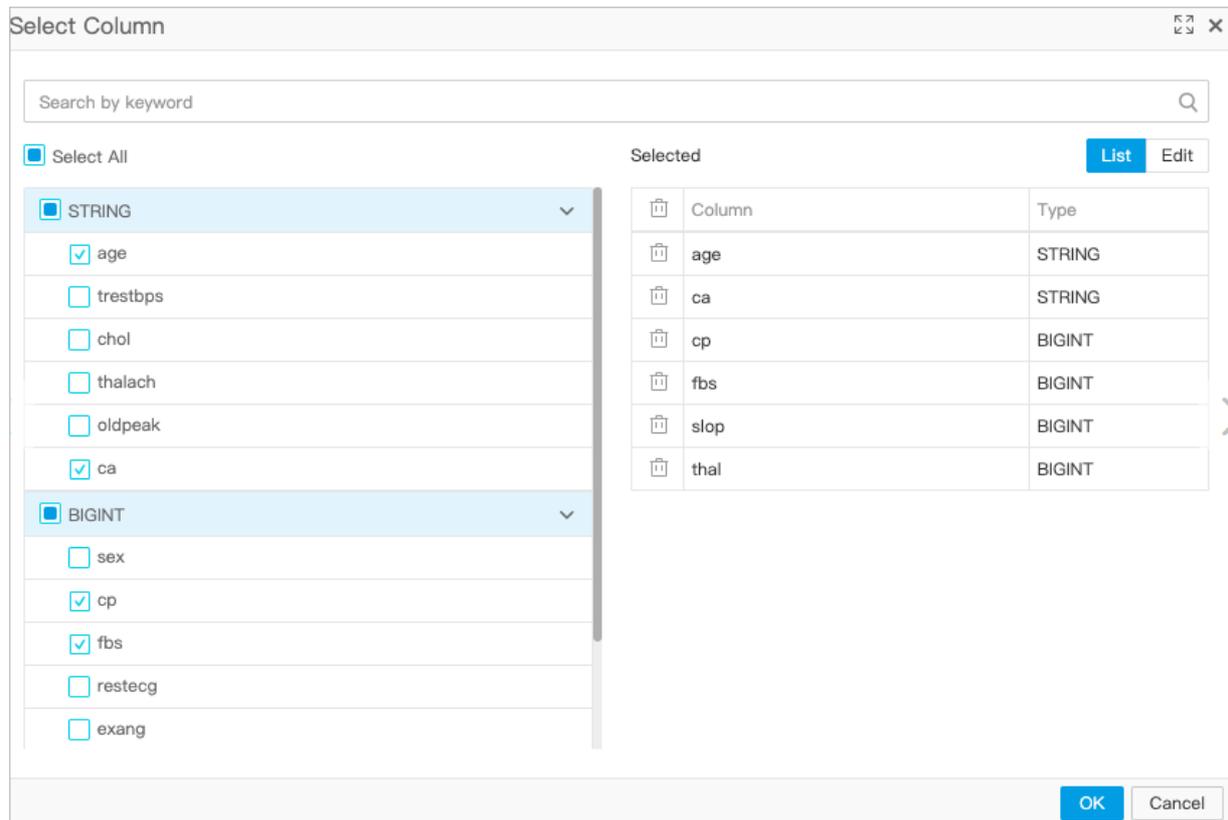

4.4.3.2.3. Merge rows (UNION)

To merge the data of two tables by row, the quantity and data type of the output columns selected from the left and right tables must be the same. The function is integrated with the UNION and UNION ALL functions.

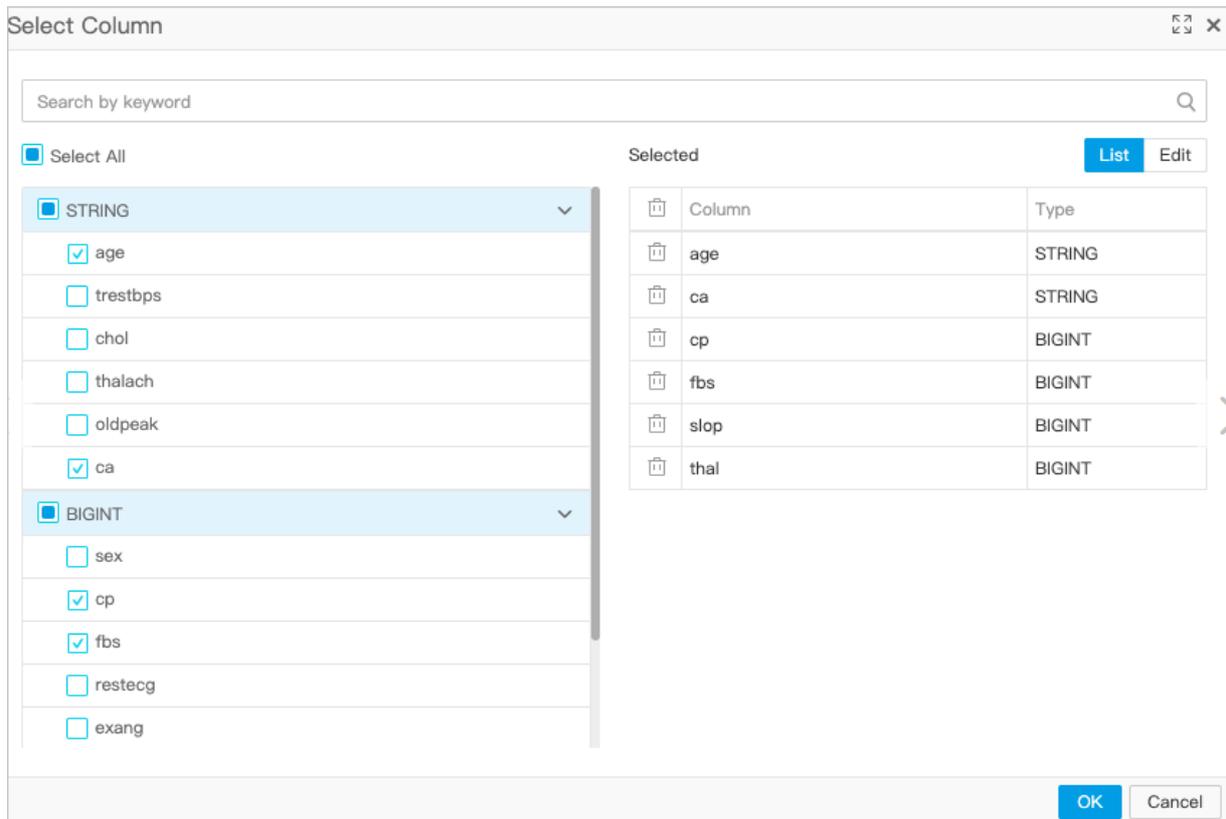

Parameter settings

- During the merge process, the numbers of columns selected from the left and right tables must be the same, and the data types of the corresponding columns must be the same.
- You can enter conditions in the text box by which to filter and select columns. The whole table is selected by default. Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), and less than or equal to (<=) signs, as well as like and rlike.
- **Remove Duplicates** is selected by default. When this option is selected, duplicate rows in the output table are removed.

The following figure shows the union columns selected from the left table.

The following figure shows the union columns selected from the right table.

PAI command

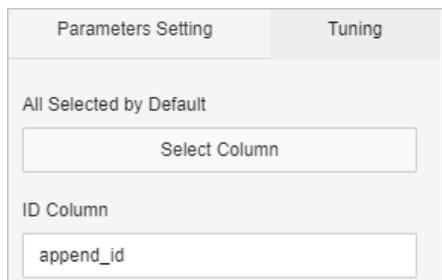

No PAI command is available.

4.4.3.3. Others

4.4.3.3.1. Add ID column

You can append an ID column to a table as the first column and save the table as a new table.

Parameter settings

PAI command

```
PAI -name AppendId
-project algo_public
-DIDColName="append_id"
-DoutputTableName="test_11"
-DinputTableName="bank_data"
-DselectedColNames="age,campaign,cons_conf_idx,cons_price_idx,emp_var_rate,euribor3m,nr_employed,pdays,poutcome,previous,y";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
IDColName	The name of the appended ID column. ID numbers start from 0 and increment by one. Example: 0, 1, 2, 3, ...
outputTableName	The name of the output table.
inputTableName	The name of the input table.
selectedColNames	The names of the columns to be retained. Separate multiple columns with commas (,).

4.4.3.3.2. Split

This component is used to split an input table or a partition based on a specified ratio, and output two tables from two output ports.

Algorithm component

Parameter settings

- The Split component has two output ports.
- In Parameter settings, if the splitting fraction is set to 0.7, the left output port outputs 70% of the data and the right output port outputs 30% of the data.

PAI command

```
pai -name split -project algo_public
-DinputTableName=wbpc
-Doutput1TableName=wbpc_split1
-Doutput2TableName=wbpc_split2
-Dfraction=0.25;
```

Parameter settings

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-

Parameter	Description	Valid values	Default value
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of <code>partition_name=value</code> . To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.
output1TableName	Required. The name of output table 1.	-	-
output1TablePartition	Optional. The partitions in output table 1.	-	Output table 1 is a non-partitioned table by default.
output2TableName	Required. The name of output table 2.	-	-
output2TablePartition	Optional. The partitions in output table 2.	-	Output table 2 is a non-partitioned table by default.
fraction	Required. The portion of data diverted to output table 1.	(0, 1)	-
lifecycle	Optional. The lifecycle of the output table.	A positive integer in the range of [1, 3650]	No lifecycle is set by default.

4.4.3.3.3. Missing value imputation

This component replaces a null value or a specified value with the maximum, minimum, average, or custom value. A list of values is defined to impute the missing values in an input table with the specified values.

- This component can replace a numeric null value with the maximum, minimum, average, or custom value.
- This component can also replace a null string, empty string, null and empty string, or specified value with a custom value.
- The missing values to be imputed can be null strings, empty strings, or custom values. If you choose empty strings, the data type of the target column must be string.

The parameters for the two input ports are as follows:

- **inputTableName**: the name of the input table for which to replace missing data.
- **inputParaTableName**: the name of the input configuration table that contains parameters generated by the missing value imputation node. Based on this parameter, configuration parameters in one table can be applied to a new table.

Parameters for the two output ports are as follows:

- **outputTableName**: the name of the imputed output table.

- **outputParaTableName:** the name of the output configuration table, which can be applied to other datasets.
- **Columns to Impute:** the names of the columns for which to replace missing values.
- **Original Value:** the values to be replaced.
- **Replaced With:** the replacement values.

PAI command

```
PAI -name FillMissingValues
  -project algo_public
  -Dconfigs="poutcome,null-empty,testing" \
  -DoutputTableName="test_3"
  -DinputPartitions="pt=20150501"
  -DinputTableName="bank_data_partition";
```

Algorithm parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
inputTablePartitions	Optional. The partitions selected from the input table for training.	Partition name	The whole table is selected by default.
outputTableName	Required. The name of the output table.	Table name	N/A
configs	Required. The configurations for missing value imputation. Example: <code>col1. null. 3.14; col2. emotv. hello: col3, empty-null, world</code> , where <i>null</i> indicates a null value and <i>empty</i> indicates an empty string. If you choose to use empty strings to fill the target columns, the data type of the target column must be string. The variables used to specify the replacement value as maximum, minimum, and average are <code>max</code> , <code>min</code> , and <code>mean</code> respectively. If you want to impute a custom value to the target column, use a user-defined variable in the <code>col4.user-defined,str,str123</code> format.	N/A	N/A

Parameter	Description	Valid value	Default value
outputParaTableName	Required. The name of the output configuration table.	Table name	N/A
inputParaTableName	Optional. The name of the input configuration table.	Table name	No input configuration table is set by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	A positive integer	Automatically calculated.

Examples

Test data

- SQL statement to generate data:

```
drop table if exists fill_missing_values_test_input;
create table fill_missing_values_test_input(
  col_string string,
  col_bigint bigint,
  col_double double,
  col_boolean boolean,
  col_datetime datetime);
insert overwrite table fill_missing_values_test_input
select
*
from
(
  select
    '01' as col_string,
    10 as col_bigint,
    10.1 as col_double,
    True as col_boolean,
    cast('2016-07-01 10:00:00' as datetime) as col_datetime
  from dual
  union all
  select
    cast(null as string) as col_string,
    11 as col_bigint,
    10.2 as col_double,
    False as col_boolean,
    cast('2016-07-02 10:00:00' as datetime) as col_datetime
  from dual
  union all
  select
    '02' as col_string,
    cast(null as bigint) as col_bigint,
    10.3 as col_double,
    True as col_boolean,
```

```

    cast('2016-07-03 10:00:00' as datetime) as col_datetime
  from dual
 union all
 select
   '03' as col_string,
   12 as col_bigint,
   cast(null as double) as col_double,
   False as col_boolean,
   cast('2016-07-04 10:00:00' as datetime) as col_datetime
  from dual
 union all
 select
   '04' as col_string,
   13 as col_bigint,
   10.4 as col_double,
   cast(null as boolean) as col_boolean,
   cast('2016-07-05 10:00:00' as datetime) as col_datetime
  from dual
 union all
 select
   '05' as col_string,
   14 as col_bigint,
   10.5 as col_double,
   True as col_boolean,
   cast(null as datetime) as col_datetime
  from dual
) tmp;

```

- Input description

```

+-----+-----+-----+-----+-----+
| col_string | col_bigint | col_double | col_boolean | col_datetime |

4.4.3.3.4. Normalization

You can normalize one or more columns in a table and save the generated data to a new table.

Linear function transformation is supported. The transformation expression is $y = \frac{x - \text{MinValue}}{\text{MaxValue} - \text{MinValue}}$.

MaxValue and *MinValue* indicate the maximum and minimum values of the sample respectively.

- Click **Columns** to select the columns to be normalized. Double and bigint types are supported.
- You can choose whether to retain the original columns. If you select the corresponding checkbox, the original columns will be retained. Processed columns will be renamed.

PAI command

```
PAI -name normalize_wf
-project algo_public
-DkeepOriginal="true"
-DoutputTableName="test_4"
-DinputPartitions="pt=20150501"
-DinputTableName="bank_data_partition"
-DselectedColNames="emp_var_rate,euribor3m";
```

Algorithm parameters

Parameters

Parameter	Description	Default value
<code>inputTableName</code>	Required. The name of the input table.	N/A
<code>selectedColNames</code>	Optional. The names of columns selected from the input table.	All columns are selected by default.
<code>inputTablePartitions</code>	Optional. The partitions selected from the input table for training.	The whole table is selected by default.
<code>outputTableName</code>	Required. The name of the output table.	N/A
<code>outputParaTableName</code>	Required. The name of the output configuration table.	N/A
<code>inputParaTableName</code>	Optional. The name of the input configuration table.	No input configuration table is set by default.
<code>outputPMMLTableName</code>	Required. The name of the output PMML table.	N/A
<code>keepOriginal</code>	Optional. This parameter specifies whether to retain the original columns. If <code>keepOriginal</code> is set to true, processed columns are renamed with the <code>normalized_</code> prefix and the original columns are retained and their data overwritten. If <code>keepOriginal</code> is set to false, all columns are retained but not renamed.	false
<code>lifecycle</code>	Optional. The lifecycle of the output table.	No lifecycle is set by default.
<code>coreNum</code>	Optional. The number of cores.	Automatically calculated.
<code>memSizePerCore</code>	Optional. The memory size of each core.	Automatically calculated.

4.4.3.3.5. Standardization

You can standardize one or more columns in a table and save the generated data to a new table.

- The formula used for standardization is $(X - \text{Mean}) / (\text{Standard deviation})$.
 - Mean: The mean of samples.
 - Standard deviation: The standard deviation of samples. This variable is used when samples are used to calculate the total deviation. To make the calculated value closer to the mean, you must moderately increase the calculated standard deviation by using the formula $\frac{1}{N-1}$.

- The formula for calculating the standard deviation of samples:

$$S = \sqrt{\frac{1}{N-1} \sum_{i=1}^N (X_i - \bar{X})^2}$$

\bar{X} represents the mean of samples X_1, X_2, \dots, X_n .

- You can choose whether to retain the original columns. If you select the corresponding checkbox, the original columns will be retained. Processed columns will be renamed.
- Click **Columns** and select columns to be standardized. Double and bigint types are supported.

PAI command

```
PAI -name Standardize
-project algo_public
-DkeepOriginal="false"
-DoutputTableName="test_5"
-DinputTablePartitions="pt=20150501"
-DinputTableName="bank_data_partition"
-DselectedColNames="euribor3m,pdays"
```

Standardization component

Parameters for the two input ports are as follows:

- `inputTableName`: the name of the input table to be standardized.
- `inputParaTableName`: the name of the input configuration table that contains the parameters generated by the standardization node. You can use an input configuration table to apply the configuration parameters of one table to a new table.

Parameters for the two output ports are as follows:

- `outputTableName`: the name of the standardized output table.
- `outputParaTableName`: the name of the output parameter table, which can be applied to other datasets.

Standardization parameters

The corresponding algorithm parameter for Reserve Original Columns is `keepOriginal`.

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
<code>inputTableName</code>	Required. The name of the input table.	-	-
<code>selectedColNames</code>	Optional. The names of columns selected from the input table.	-	All columns are selected by default.

Parameter	Description	Valid values	Default value
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of <code>partition_name=value</code> . To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.
outputTableName	Required. The name of the output table.	-	-
outputParaTableName	Required. The name of the output configuration table.	-	-
outputPartition	Optional. The partitions in the output table.	-	-
inputParaTableName	Optional. The name of the input configuration table.	-	No input configuration table is set by default.
keepOriginal	Optional. This parameter specifies whether to retain the original columns. If this parameter is set to true, the original columns are retained and the column name is suffixed with <code>_orig</code> .	true and false	false
lifecycle	Optional. The lifecycle of the output table.	-	No lifecycle is set by default.
coreNum	Optional. The number of cores.	-	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	-	Automatically calculated.

Examples

```
drop table if exists standardize_test_input;
create table standardize_test_input(
col_string string,
col_bigint bigint,
col_double double,
col_boolean boolean,
col_datetime datetime);
insert overwrite table standardize_test_input select * from (
select '01' as col_string,
10 as col_bigint,
10.1 as col_double,
True as col_boolean,
cast('2016-07-01 10:00:00' as datetime) as col_datetime from dual union all
select cast(null as string) as col_string,
11 as col_bigint,
10.2 as col_double,
False as col_boolean,
cast('2016-07-02 10:00:00' as datetime) as col_datetime from dual union all
select '02' as col_string,
cast(null as bigint) as col_bigint,
10.3 as col_double,
True as col_boolean,

4.4.3.3.6. KV to Table

This component is used to convert KV pairs to a table. The key is converted to a table column, while the value is converted to a column value in the corresponding row.

KV table format definition:

- A key is the index of a column. Key values can be of the bigint or double types.
- A KV table can be input in the sparse format to algorithm components such as logistic and linear regression.
- Keys must be of the string type. You can input a key_map table to the KV to Table component to map keys to columns. This component outputs a key_map table that contains all key-column mappings after conversion, regardless of whether you input a key_map table.

kv
1:10;2:20;3:30

key_map table format definition: a table that contains index-to-column mappings and data type information. The data types of the col_name, col_index, and col_datatype columns must be string. The default data type of the col_datatype column is double if not specified.

col_name	col_index	col_datatype
col1	1	bigint
col2	2	double

PAI command

```
PAI -name KVtoTable
-project algo_public
-DinputTableName=test
-DoutputTableName=test_out
-DoutputKeyMapTableName=test_keymap_out
-DkvColName=kv;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	The table cannot be empty.
kvColName	Required. The name of the KV column.	Only one column can be selected.	-
outputTableName	Required. The name of the output table.	Table name	-

Parameter	Description	Valid values	Default value
outputKeyMapTableName	Required. The name of the output index table.	Table name	-
inputKeyMapTableName	Optional. The name of the input index table.	Table name	No input index table is set by default.
appendColName	Optional. The name of the appended column.	Multiple columns can be selected.	No column is appended by default.
inputTablePartitions	Optional. The partitions selected from the input table.	Partition name	No partition is specified by default.
kvDelimiter	Optional. The delimiter used to separate keys and values.	Symbol	The default delimiter is a semicolon (;).
itemDelimiter	Optional. The delimiter used to separate key-value pairs.	Symbol	The default delimiter is a comma (,).
top1200	Optional. This parameter specifies whether to output the first 1,200 columns.	true and false	Default value: true. If the value is false, an error is returned when the number of columns reaches the upper limit.
lifecycle	Optional. The lifecycle of the output table.	An integer greater than or equal to -1.	Default value: -1. This value indicates that no lifecycle is set.
coreNum	Optional. The number of cores.	An integer greater than 0.	Default value: -1. This value indicates that the number of instances is determined by the amount of input data.
memSizePerCore	Optional. The memory size of each core.	(100, 65536)	Default value: -1. This value indicates that the memory size is determined by the amount of input data.

Examples

SQL statement to generate data:

```
drop table if exists test;
create table test as
select
*
from
(
select '1:1,2:2,3:-3.3' as kv from dual
union all
select '1:10,2:20,3:-33.3' as kv from dual
) tmp;
```

PAI command

```
PAI -name KVToTable
-project algo_public
-DinputTableName=test
-DoutputTableName=test_out
-DoutputKeyMapTableName=test_keymap_out
-DkvColName=kv;
```

Output

The output table is shown as follows.

```
+-----+-----+-----+
| kv_1  | kv_2  | kv_3  |
+-----+-----+-----+
| 1.0   | 2.0   | -3.3   |
| 10.0  | 20.0  | -33.3  |
+-----+-----+-----+
```

The output mapping table is shown as follows.

```
+-----+-----+-----+
| col_name | col_index | col_type |
+-----+-----+-----+
| kv_1     | 1         | double   |
| kv_2     | 2         | double   |
| kv_3     | 3         | double   |
+-----+-----+-----+
```

Input and output restrictions

Converted columns include appended columns and columns converted from KV pairs. The KV columns are output before the appended columns. MaxCompute supports a maximum of 1,200 columns. When the number of columns exceeds the maximum value, and top1200 is set to true, only the first 1,200 columns are output. If top1200 is set to false, an error is returned. The number of input data entries cannot exceed 100 million.

Restrictions and guidelines

- If a key_map table is input, columns are converted from the keys that exist in both the key_map and key-value tables.
- The converted column type can only be numeric.
- If a key_map table is input, the data type of the converted key column is the same as that of the key_map table. If no key_map table is input, the data type of the converted key column is double.

- If a `key_map` table is not input, the name of the converted key column is in the format of 'kv column name+'+key'. An error is returned if the key contains any of the following characters: %&()*+-. /;<>=?
- If an appended column is specified and the name of the appended column is the same as that of the converted key column, an error is returned indicating a column name conflict.
- If a row contains multiple keys, the values are added.
- A column name can contain up to 128 characters. If more than 128 characters are entered, only the first 128 characters are kept.

4.4.3.3.7. Table to KV

This component is used to convert data tables to KV tables. Null values in the table to be converted are not displayed in the KV table. You can specify columns to be retained in the new table. These columns will remain unchanged.

PAI command

```
PAI -name TableToKV
  -project algo_public
  -DinputTableName=maple_tabletokv_basic_input
  -DoutputTableName=maple_tabletokv_basic_output
  -DselectedColNames=col0,col1,col2
  -DappendColNames=rowid;
```

Parameters

Parameter	Description	Valid values	Default value
<code>inputTableName</code>	Required. The name of the input table.	Table name	-
<code>inputTablePartitions</code>	Optional. The partitions selected from the input table for training, in the format of <code>partition_name=value</code> . To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
<code>selectedColNames</code>	Optional. The names of selected columns from the input table.	The column type must be bigint or double.	The whole table is selected by default.
<code>appendColNames</code>	Optional. The names of columns to remain unchanged. These columns are written in the output table without any changes.	Multiple columns can be selected.	-

Parameter	Description	Valid values	Default value
outputTableName	Required. The name of the output KV table.	Table name	-
kvDelimiter	Optional. The delimiter used to separate keys and values.	Symbol	The default delimiter is a colon (:).
itemDelimiter	Optional. The delimiter used to separate key-value pairs.	Symbol	The default delimiter is a comma (,).
convertColToIndexId	Optional. This parameter specifies whether to convert columns into IDs.	0 and 1	0
inputKeyMapTableName	Optional. The name of the input index table. This parameter takes effect only in the case of <code>convertColToIndexId=1</code> . If this parameter is not specified, IDs are automatically generated.	Table name	No input index table is set by default.
outputKeyMapTableName	The name of the output index table. This parameter is required only in the case of <code>convertColToIndexId=1</code> .	Table name	The default value is determined by <code>convertColToIndexId</code> .
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with <code>memSizePerCore</code> . The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

Example 1

Data generation

rowid	kv
0	col0:1,col1:1.1,col2:2
1	col0:0,col1:1.2,col2:3
2	col0:1,col1:2.3

rowid	kv
3	col0:1,col1:0.0,col2:4

PAI command

```
PAI -name TableToKV
  -project algo_public
  -DinputTableName=maple_tabletokv_basic_input
  -DoutputTableName=maple_tabletokv_basic_output
  -DselectedColNames=col0,col1,col2
  -DappendColNames=rowid;
```

Output

The output table is shown as follows.

maple_tabletokv_basic_output

rowid: bigint	kv: string
0	1:1.1,2:2
1	1:1.2,2:3
2	1:2.3
3	1:0.0,2:4

Example 2

PAI command

```
PAI -name TableToKV
  -project projectxlib4 -DinputTableName=maple_tabletokv_basic_input
  -DoutputTableName=maple_tabletokv_basic_output
  -DselectedColNames=col0,col1,col2 -DappendColNames=rowid
  -DconvertColToIndexId=1
  -DinputKeyMapTableName=maple_test_tabletokv_basic_map_input
  -DoutputKeyMapTableName=maple_test_tabletokv_basic_map_output;
```

Output

The output table is shown as follows.

maple_test_tabletokv_basic_map_output

col_name: string	col_index: string	col_datatype: string
col1	1	bigint
col2	2	double

Restrictions and guidelines

- If a key_map table is input, columns are converted from the keys that exist in both the key_map and key-value tables.

- If a key_map table is input and its type is different from the input table, the output key_map table uses the type specified by the user.
- The type of the columns that need to be converted into KV pairs in the input table must be bigint or double.

4.4.4. Feature engineering

4.4.4.1. Feature transformation

4.4.4.1.1. PCA

You can use principal component analysis (PCA) to reduce dimensionality.

- For more information about the PCA algorithm, see [Wikipedia](#).
- This component supports the dense data format.

PAI command

```
PAI -name PrinCompAnalysis
  -project algo_public
  -DinputTableName=bank_data
  -DeigOutputTableName=pai_temp_2032_17900_2
  -DprincompOutputTableName=pai_temp_2032_17900_1
  -DselectedColNames=pdays,previous,emp_var_rate,cons_price_idx,cons_conf_idx,euribor3m,nr_employed
  -DtransType=Simple
  -DcalcuType=CORR
  -DcontriRate=0.9;
```

Algorithm parameters

Parameters

Parameter	Description	Default value
inputTableName	Required. The name of the input table for PCA.	-
eigOutputTableName	Required. The name of the output table that contains eigenvectors and eigenvalues.	-
princompOutputTableName	Required. The name of the output table after PCA dimensionality reduction.	-
selectedColNames	Required. The names of feature columns that are involved in the PCA procedure.	-
transType	Optional. The method used to transform the original table to the principal component table. Valid values: Simple, Sub-Mean, and Normalization.	Simple
calcuType	Optional. The eigendecomposition mode of the original table. Valid values: CORR, COVAR_SAMP, and COVAR_POP.	CORR
contriRate	Optional. The ratio of information to be retained after dimensionality reduction.	0.9

Parameter	Description	Default value
remainColumns	Optional. The columns retained from the original table after dimensionality reduction.	-

Sample PCA output

Table after dimensionality reduction, shows a sample table after dimensionality reduction.

Eigenvalues and eigenvectors, shows the eigenvalues and eigenvectors.

4.4.4.2. Feature importance evaluation

4.4.4.2.1. Linear model feature importance

You can evaluate the quality of a linear algorithm model based on the predicted and actual output results such as the indicators and residual histogram. Indicators include SST, SSE, SSR, R2, R, MSE, RMSE, MAE, MAD, MAPE, count, yMean, and predictMean.

PAI command

```
pai -name regression_evaluation
  -project algo_public
  -DinputTableName=input_table
  -DyColName=y_col
  -DpredictionColName=prediction_col
  -DindexOutputTableName=index_output_table
  -DresidualOutputTableName=residual_output_table
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training.	-	All partitions in the input table are selected by default.
yColName	Required. The name of the expected dependent variable column in the input table. It must be a numerical value.	-	-
predictionColName	Required. The name of the predicted dependent variable column. It must be a numerical value.	-	-
indexOutputTableName	Required. The name of the regression indicator output table.	-	-

Parameter	Description	Valid values	Default value
residualOutputTableName	Required. The name of the residual histogram output table.	-	-
intervalNum	Optional. The number of intervals to divide the histogram over.	-	100
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	-	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	-	Automatically calculated.

Output

The output table is in JSON format. [Field description](#) describes the JSON fields.

Field description

Field	Description
SST	Total sum of squares.
SSE	Sum of squared errors.
SSR	Sum of squares due to regression.
R2	Coefficient of determination.
R	Coefficient of multiple correlation.
MSE	Mean squared error.
RMSE	Root-mean-square error.
MAE	Mean absolute error.
MAD	Mean absolute difference.
MAPE	Mean absolute percentage error.
count	Number of rows.
yMean	Mean of expected dependent variables.
predictionMean	Mean of prediction results.

4.4.4.2.2. Random forest feature importance

You can calculate the importance of features in a random forest model.

Column settings

Fields Setting

Parameters Setting

Feature Columns Optional. ?

Select Column

Target Column Required.

PAI command

```

pai -name feature_importance
-p project algo_public
-DinputTableName=input
-DoutputTableName=output
-Dlabel=label
-DmodelName=model
    
```

Algorithm parameters

Parameters

Parameter	Description	Default value
inputTableName	Required. The name of the input table.	-
outputTableName	Required. The name of the output table.	-
labelColName	Required. The name of the label column.	-
modelName	Required. The name of the input model.	-
featureColNames	Optional. The names of feature columns selected from the input table.	All columns except the label column are selected by default.
inputTablePartitions	Optional. The partitions selected from the input table.	The whole table is selected by default.
lifecycle	Optional. The lifecycle of the output table.	No lifecycle is set by default.
coreNum	Optional. The number of cores.	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	Automatically calculated.

4.4.5. Statistical analysis

4.4.5.1. Data pivoting

This component allows you to view the distributions of feature values, feature columns, and label columns. Data can be analyzed more efficiently when you know its features. This component supports dense and sparse formats.

PAI command

```
PAI -name fe_meta_runner -project algo_public
-DinputTable="pai_dense_10_10"
-DoutputTable="pai_temp_2263_20384_1"
-DmapTable="pai_temp_2263_20384_2"
-DselectedCols="pdays,previous,emp_var_rate,cons_price_idx,cons_conf_idx,euribor3m,nr_employed,age,campaign,poutcome"
-DlabelCol="y"
-DcategoryCols="previous"
-Dlifecycle="28"-DmaxBins="5";
```

Algorithm parameters

Parameter	Description	Required	Default value
inputTable	The name of the input table.	Yes	N/A
inputTablePartitions	The partitions selected from the input table.	No	N/A
outputTable	The name of the output table.	Yes	N/A
mapTable	The output mapping table. The Data Pivoting component maps String and Int type data for machine learning to use for training.	Yes	N/A
selectedCols	The columns selected from the input table.	Yes	N/A
categoryCols	The columns specified to process Int or Double type columns as enumeration features.	No	null
maxBins	The maximum number of intervals for equal-distance division of continuous features.	No	100
isSparse	Indicates whether the features are in sparse format.	No	false

Parameter	Description	Required	Default value
itemSplitter	The delimiter used to separate sparse feature items.	No	","
kvSplitter	The delimiter used to separate keys and values.	No	"."
lifecycle	The lifecycle of the output table. Unit: days.	No	28

4.4.5.2. Whole table statistics

This component analyzes a table or selected columns of a table.

Parameter settings

In the Input Columns box, select the columns of the table to be analyzed. By default, all columns are selected. You can enter filtering conditions for the selected columns in the condition text box. Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), and less than or equal to (<=) signs, as well as like and rlike.

PAI command

```
PAI -name SimpleSummary
  -project algo_public
  -DsummaryColNames="euribor3m,pdays"
  -DoutputTableNames="pai_temp_667_6017_1"
  -DinputTableName="bank_data"
  -Dfilter="age>40";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
summaryColNames	The columns that require analysis. Separate the columns with commas(,).
outputTableNames	The names of the output tables generated after the system performs the whole table statistics operation.
inputTableName	The name of the input table.
filter	The filtering conditions. Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), and less than or equal to (<=) signs, as well as like and rlike.

4.4.5.3. Correlation coefficient matrix

The correlation coefficient is a measure of the correlation between columns in a matrix. The valid range of values for this parameter is [-1, 1]. The count equals the number of non-zero elements in two successive columns.

Column settings

Fields Setting
Tuning

All Selected by Default

Select Column

PAI command

```
PAI -name corrcoeff
-project algo_public
-DinputTableName=maple_test_corrcoeff_basic12x10_input
-DoutputTableName=maple_test_corrcoeff_basic12x10_output
-DcoreNum=1
-DmemSizePerCore=110
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartition	Optional. The partitions selected from the input table for training. in the format of <code>partition_name=value</code> . To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	-	All partitions are selected by default.
outputTableName	Required. A list of output table names.	Table name	-
selectedColNames	Optional. The names of columns selected from the input table.	Column name	All columns are selected by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with <code>memSizePerCore</code> . The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each node. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

Examples

Data generation describes the data generation result.

Data generation

col0:double	col1:bigint	col2:double	col3:bigint	col4:double	col5:bigint	col6:double	col7:bigint	col8:double	col9:double

4.4.5.4. Covariance

In probability theory and statistics, covariance is a measure of the joint variability of two random variables. Variance is a special case of covariance where the two measured variables are the same. If the expected values are $E(X) = \mu$ and $E(Y) = \nu$, the covariance between real-number random variables X and Y is $\text{cov}(X, Y) = E((X - \mu)(Y - \nu))$.

PAI command

```
PAI -name cov
  -project algo_public
  -DinputTableName=maple_test_cov_basic12x10_input
  -DoutputTableName=maple_test_cov_basic12x10_output
  -DcoreNum=6
  -DmemSizePerCore=110;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of <code>partition_name=value</code> . To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
outputTableName	Required. A list of output table names.	Table name	-
selectedColNames	Optional. The names of columns selected from the input table.	Column name	All columns are selected by default.

Parameter	Description	Valid values	Default value
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each node. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

4.4.5.5. Empirical probability density chart

An empirical distribution is an estimated non-parametric distribution of probability in scenarios where accurate parametric distributions cannot be made.

The algorithm uses kernel distribution to estimate the probability density of sample data. Similar to a histogram, the algorithm generates functions to describe the distribution of sample data. However, kernel distribution is different in that it overlays the contributions of all parts to generate a smooth and continuous distribution curve, while a histogram only generates discrete descriptions. When kernel distribution is used, the probability density of non-sample data points is not 0, but an overlay of weighted probability density of all sampling points in a certain kernel distribution. In this document, the kernel distribution used is Gaussian distribution.

- For more information about kernel distribution, see [Wikipedia](#).
- For more information about empirical distribution, see [Wikipedia](#).

PAI command

```
PAI -name empirical_pdf
-project algo_public
-DinputTableName="test_data"
-DoutputTableName="test_epdf_out"
-DfeatureColNames="col0,col1,col2"
-DinputTablePartitions="ds='20160101'"
-Dlifecycle=1
-DintervalNum=100
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
outputTableName	Required. The name of the output table.	Table name	-
featureColNames	Required. The names of input columns.	Multiple columns of the double or bigint type can be selected.	-

Parameter	Description	Valid values	Default value
labelColName	Optional. The name of the input label column. The feature column is stratified based on the label values in the label column.	Only one column of the bigint or string type can be selected. The number of label values cannot exceed 100.	No input label column is set by default.
inputTablePartitions	Optional. The partitions selected from the input table.	Partition name	All partitions are selected by default.
intervalNum	The number of calculation intervals. The larger the number, the higher the accuracy.	[1, 1E14)	Default value: -1. This value indicates that the number of intervals is determined based on the range of data values for each column.
lifecycle	The lifecycle of the output table.	A positive integer	Default value: -1. This value indicates that no lifecycle is set.
coreNum	Optional. The number of cores.	A positive integer	Default value: -1. This value indicates that the number of instances is determined based on the volume of input data.
memSizePerCore	Optional. The memory size of each core.	A positive integer in the range of [1024, 65536]	Default value: -1. This value indicates that the memory size is determined based on the volume of input data.

Examples

SQL statement to generate data:

```
drop table if exists epdf_test;
create table epdf_test as
select
*
from
(
select 1.0 as col1 from dual
union all
select 2.0 as col1 from dual
union all
select 3.0 as col1 from dual
union all
select 4.0 as col1 from dual
union all
select 5.0 as col1 from dual
) tmp;
```

PAI command

```
PAI -name empirical_pdf
    -project algo_public
    -DinputTableName=epdf_test
    -DoutputTableName=epdf_test_out
    -DfeatureColNames=col1;
```

Input description

You can select multiple columns to be calculated. You can select a label column and stratify the columns by label. For example, if the label column contains labels 0 and 1, the columns that need to be calculated are stratified into two groups. One group only contains columns with label 0 and the other group only contains columns with label 1. The probability density for each group is then calculated. If no label column is selected, all feature columns are calculated.

Output description

This component outputs a diagram and a result table. The columns in the result table are as follows. If no label column is selected, NULL is output in the label column.

Column name	Data type
colName	string
label	string
x	double
pdf	double

Output table:

```
+-----+-----+-----+-----+
|colname |label  |x      |pdf    |

```

Input and output restrictions

The maximum number of label columns that can be specified is 100.

4.4.5.6. Chi-square goodness of fit test

This component is used to determine the differences between the observed frequencies and the expected frequencies for each classification of a single multiclass classification nominal variable. The null hypothesis assumes that the observed frequencies and the expected frequencies are consistent.

PAI command

```

PAI -name chisq_test
  -project algo_public
  -DinputTableName=pai_chisq_test_input
  -DcolName=f0
  -DprobConfig=0:0.3,1:0.7
  -DoutputTableName=pai_chisq_test_output0
  -DoutputDetailTableName=pai_chisq_test_output0_detail

```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
colName	Required. The name of the column that requires a chi-square test.	Column name	-
outputTableName	Required. The name of the output table.	Table name that has not been used	-

Parameter	Description	Valid values	Default value
outputDetailTableName	Required. The name of the output detail table.	Table name that has not been used	-
inputTablePartitions	Optional. The partitions selected from the input table.	Partition list	All partitions are selected by default.
probConfig	Optional. The class probability configuration.	The configuration is stored in a key-value pair format: <code>class:probability</code> . The sum of all probabilities is 1.	All classes have the same probability by default.

Examples

Testing data

```
create table pai_chisq_test_input as
select * from
(
  select '1' as f0,'2' as f1 from dual
  union all
  select '1' as f0,'3' as f1 from dual
  union all
  select '1' as f0,'4' as f1 from dual
  union all
  select '0' as f0,'3' as f1 from dual
  union all
  select '0' as f0,'4' as f1 from dual
)tmp;
```

PAI command

```
PAI -name chisq_test
  -project algo_public
  -DinputTableName=pai_chisq_test_input
  -DcolName=f0
  -DprobConfig=0:0.3,1:0.7
  -DoutputTableName=pai_chisq_test_output0
  -DoutputDetailTableName=pai_chisq_test_output0_detail
```

Output description

Output table outputTableName is a JSON array containing only one row and one column.

```
{
  "Chi-Square": {
    "comment": "Pearsons chi-square test",
    "df": 1,
    "p-value": 0.75,
    "value": 0.2380952380952381
  }
}
```

Output table `outputDetailTableName` includes the following columns: data source class (`f0` or `f1`), observed frequency (`observed`), expected frequency (`expected`), and standard residuals (`residuals = (observed - expected)/sqrt(expected)`).

f0	f1	observed	expected	residuals
0	2	0.0	0.4	-0.6324555320336759
0	3	1.0	0.8	0.22360679774997894
0	4	1.0	0.8	0.22360679774997894
1	2	1.0	0.6000000000000001	0.5163977794943221
1	3	1.0	1.2000000000000002	-0.1825741858350555
1	4	1.0	1.2000000000000002	-0.1825741858350555

4.4.5.7. Chi-square test of independence

This component verifies whether two factors (each having two or more classes) are mutually independent. The null hypothesis is that two factors are independent of each other.

PAI command

```
PAI -name chisq_test
  -project algo_public
  -DinputTableName=pai_chisq_test_input
  -DxColName=f0
  -DyColName=f1
  -DoutputTableName=pai_chisq_test_output2
  -DoutputDetailTableName=pai_chisq_test_output2_detail
```

Parameters

Parameter	Description	Valid values	Default value
<code>inputTableName</code>	Required. The name of the input table.	Table name	-
<code>xColName</code>	Required. The name of the column that requires a chi-square test.	Column name	-
<code>yColName</code>	Required. The name of the column that require a chi-square test.	Column name	-
<code>outputTableName</code>	Required. The name of the output table.	Table name that has not been used	-
<code>outputDetailTableName</code>	Required. The name of the output detail table.	Table name that has not been used	-
<code>inputTablePartitions</code>	Optional. The partitions selected from the input table.	Partition list	All partitions are selected by default.

Parameter	Description	Valid values	Default value
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Examples

- Testing data

```
create table pai_chisq_test_input as
select * from
(
select '1' as f0,'2' as f1 from dual
union all
select '1' as f0,'3' as f1 from dual
union all
select '1' as f0,'4' as f1 from dual
union all
select '0' as f0,'3' as f1 from dual
union all
select '0' as f0,'4' as f1 from dual
)tmp;
```

- PAI command

```
PAI -name chisq_test
-project algo_public
-DinputTableName=pai_chisq_test_input
-DxColName=f0
-DyColName=f1
-DoutputTableName=pai_chisq_test_output2
-DoutputDetailTableName=pai_chisq_test_output2_detail
```

- Output description

Output table outputTableName is a JSON array containing only one row and one column.

```
{
  "Chi-Square": {
    "comment": "Pearsons chi-square test",
    "df": 2,
    "p-value": 0.75,
    "value": 0.8333333333333334
  }
}
```

Output table outputDetailTableName has the following columns:

Column name	Description
xColName	Class
yColName	Class
observed	Observed frequency
expected	Expected frequency

Column name	Description
residuals	Residuals = (observed - expected)/sqrt (expected)

Data:

f0	f1	observed	expected	residuals
0	2	0.0	0.4	-0.6324555320336759
0	3	1.0	0.8	0.22360679774997894
0	4	 1.0	0.8	0.22360679774997894
1	2	1.0	0.6000000000000001	0.5163977794943221
1	3	1.0	1.2000000000000002	-0.1825741858350555
1	4	1.0	1.2000000000000002	-0.1825741858350555

4.4.5.8. Scatter plot

In regression analysis, this component outputs a scatter plot that shows the distribution of data points in a Cartesian coordinate system.

Column settings

Fields Setting

Feature Columns Required. 

Select Column

Label Column Optional.

Samples Optional.

1000 

PAI command

```
PAI -name scatter_diagram
-project algo_public
-DselectedCols=emp_var_rate,cons_price_rate,cons_conf_idx,euribor3m
-DsampleSize=1000
-DlabelCol=y
-DmapTable=pai_temp_2447_22859_2
-DinputTable=scatter_diagram
-DoutputTable=pai_temp_2447_22859_1
```

Parameters

Parameter	Description	Default value
inputTable	Required. The name of the input table.	-

Parameter	Description	Default value
inputTablePartitions	Optional. The partitions selected from the input table.	-
outputTable	Required. The name of the output table that stores the samples.	-
mapTable	Required. The name of the output table that stores the maximum value, minimum value, and enumeration values of each feature.	-
selectedCols	Required. The columns selected from the input table from which to draw a scatter plot. A maximum of five features can be selected.	-
labelCol	Optional. An Int or String column to serve as the enumeration label column.	No enumeration label column is set by default.
sampleSize	Optional. The number of samples to collect from the input data.	1000
lifecycle	Optional. The lifecycle of the output table measured in days.	28

Examples

Input data

```
create table scatter_diagram as select emp_var_rate,cons_price_rate, cons_conf_idx,euribor3m,y from pai_bank_data limit 10
```

Parameters

emp_var_rate	cons_price_rate	cons_conf_idx	euribor3m	y

1.4	93.444	-36.1	4.963	0

Parameter settings

Scatter plot configuration: select `emp_var_rate`, `cons_price_rate`, `cons_conf_idx`, and `euribor3m` as the feature columns, and select `y` as the label column.

Output

You can view the distribution of classification tags between every two features in the scatter plot.

4.4.5.9. Two-sample T-test

A two-sample T-test is composed of an independent sample T-test and a paired sample T-test. Two samples independent of each other are called independent samples. An independent sample T-test checks whether two samples are significantly different from each other. The T-test is based on the premise that two samples are independent of each other and come from two normally distributed populations. A paired sample T-test checks whether the mean values from two paired populations are significantly different from each other.

PAI command

```
PAI -name t_test
-project algo_public
-DxTableName=pai_t_test_all_type
-DxColName=col1_double
-DxTablePartitions=ds=2010/dt=1
-DyTableName=pai_t_test_all_type
-DyColName=col1_double
-DyTablePartitions=ds=2010/dt=1
-DoutputTableName=pai_t_test_out
-Dalternative=less
-Dmu=47
-DconfidenceLevel=0.95
-Dpaired=False
-DvarEqual=True
```

Parameters

Parameter	Description	Valid values	Default value
xTableName	Required. The name of input table x.	Table name	-
xTablePartitions	Optional. The partitions selected from input table x for testing, in the format of Partition_name=value . To specify multiple partitions, use the following format: name1=value1/name2=value2 . Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
xColName	Required. The column selected from table x for testing.	Column name. The type must be double or bigint.	-
yTableName	Required. The name of input table y.	Table name	-
yTablePartitions	Optional. The partitions selected from input table y for testing, in the format of Partition_name=value . To specify multiple partitions, use the following format: name1=value1/name2=value2 . Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
yColName	Required. The name of the column selected from table y for testing.	Column name. The type must be double or bigint.	-
paired	Optional. A value of True indicates that it is a paired sample T-test. A value of False indicates that it is an independent sample T-test.	True and False	False
alternative	Optional. The alternative hypothesis.	two.sided, less, and greater	two.sided
mu	Optional. The hypothesized mean.	double	0
varEqual	Optional. This parameter indicates whether two population variances are equal.	True and False	False

Parameter	Description	Valid values	Default value
confidenceLevel	Optional. The confidence level.	0.8, 0.9, 0.95, 0.99, 0.995, and 0.999	0.95
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each node. Unit: MB.	A positive integer in the range of [1024, 65536].	Automatically calculated.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Custom resources

Note

- For a regular table, we recommend that you do not set coreNum and memSizePerCore, and instead allow the default values to be used automatically.
- If you do not have sufficient compute resources, use the following code to calculate the amount of compute resources needed:

```
def CalcCoreNumAndMem(row, centerCount, kOneCoreDataSize=1024):
    """Calculates the number of nodes and memory size needed for each node.
    Args:
        row: the number of rows in the input table.
        col: the number of columns in the input table.
        kOneCoreDataSize: the amount of data needed to be calculated per node. Unit: MB. The value must be a positive integer. Default value: 1024.
    Return:
        coreNum, memSizePerCore
    Example:
        coreNum, memSizePerCore = CalcCoreNumAndMem(1000,99, 100, kOneCoreDataSize=2048)
    """
    kMBytes = 1024.0 * 1024.0
    #Number of compute nodes
    coreNum = max(1, int((row * 2 * 8 / kMBytes) / kOneCoreDataSize))
    #Memory size per node = Data volume
    memSizePerCore = max(1024, int(kOneCoreDataSize*2))
    return coreNum, memSizePerCore
```

Examples

- SQL statement to generate data:

```
create table pai_test_input as
select * from
(
  select 1 as f0,2 as f1 from dual
  union all
  select 1 as f0,3 as f1 from dual
  union all
  select 1 as f0,4 as f1 from dual
  union all
  select 0 as f0,3 as f1 from dual
  union all
  select 0 as f0,4 as f1 from dual
)tmp;
```

- PAI command

```
PAI -name t_test
-project algo_public
-DxTableName=pai_test_input
-DxColName=f0
-DyTableName=pai_test_input
-DyColName=f1
-DyTablePartitions=ds=2010/dt=1
-DoutputTableName=pai_t_test_out
-Dalternative=less
-Dmu=47
-DconfidenceLevel=0.95
-Dpaired=False
-DvarEqual=True
```

- Output description

The output table is a JSON array containing only one row and one column.

```
{
  "AlternativeHypthesis": "difference in means not equals to 0",
  "ConfidenceInterval": "(-2.5465, -0.4535)",
  "ConfidenceLevel": 0.95,
  "alpha": 0.050000000000000004,
  "df": 19,
  "mean of the differences": -1.5,
  "p": 0.008000000000000007,
  "t": -3
}
```

Input and output restrictions

The input and output are not limited.

4.4.5.10. One-sample T-test

A one-sample T-test verifies whether the mean of a normally distributed population differs significantly from a target value. A T-test is performed based on the condition that the sample population is normally distributed.

PAI command

```
PAI -name t_test -project algo_public
-DxTableName=pai_t_test_all_type
-DxColName=col1_double
-DoutputTableName=pai_t_test_out
-DxTablePartitions=ds=2010/dt=1
-Dalternative=less
-Dmu=47
-DconfidenceLevel=0.95
```

Algorithm parameters

Parameter	Description	Valid values	Default value
xTableName	Required. The name of input table x.	Table name	-
xColName	Required. The column selected from table x for testing.	Column name. The type must be double or bigint.	-
outputTableName	Required. The name of the output table.	Table name that has not been used	-
xTablePartitions	Optional. The partitions selected from input table x.	Partition list	All partitions are selected by default.
alternative	Optional. The alternative hypothesis.	two.sided, less, and greater	two.sided
mu	Optional. The hypothesized mean.	double	0
confidenceLevel	Optional. The confidence level.	0.8, 0.9, 0.95, 0.99, 0.995, and 0.999	0.95

Output description

The output table is a JSON array containing only one row and one column.

```
{
  "AlternativeHypthesis": "mean not equals to 0",
  "ConfidenceInterval": "(44.72234194006504, 46.27765805993496)",
  "ConfidenceLevel": 0.95,
  "alpha": 0.05,
  "df": 99,
  "mean": 45.5,
  "p": 0,
  "stdDeviation": 3.919647479510927,
  "t": 116.081867662439
}
```

4.4.5.11. Lorenz curve

The Lorenz curve is a graph to illustrate the distribution of wealth across a population. The X axis represents the total population arranged from least wealthy to most wealthy, while the Y axis represents the total wealth. If this graph is a straight line, it indicates perfectly equal distribution of wealth. The Gini coefficient is calculated by taking the area between the equal distribution curve and the actual Lorenz curve for a population as a fraction of the total area beneath the equal distribution curve. As the distribution of wealth becomes less equal, the Gini coefficient will increase, whereas a population with equal distribution of wealth will have a Gini coefficient of 0.

To study the distribution of income among a population, American statistician Max Otto Lorenz proposed the famous Lorenz curve in 1905. In 1921, Italian economist Corrado Gini defined the Gini coefficient as a measure of inequality in a population based on the Lorenz curve.

PAI command

```
PAI -name LorenzCurve
    -project algo_public
    -DinputTableName=maple_test_lorenz_basic10_input
    -DcolName=col0
    -DoutputTableName=maple_test_lorenz_basic10_output -DcoreNum=20
    -DmemSizePerCore=110;
```

Parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
outputTableName	Required. The name of the output table.	Table name that has not been used	N/A
colName	Optional. The column name. Separate multiple columns with commas (,).	Column name	The whole table is selected by default.
N	The number of quantiles.	N/A	100
inputPartitions	Optional. The partitions selected from the input table for training, in the <code>partition_name=value</code> format. To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with <code>memSizePerCore</code> . The value must be a positive integer in the range of [1, 9999].	Automatically calculated.

Parameter	Description	Valid value	Default value
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

4.4.5.12. Normality test

This component is used to determine whether observed values are normally distributed.

This component consists of three test methods: Anderson-Darling test (see [Wikipedia](#)), Kolmogorov-Smirnov test (see [Wikipedia](#)), and Q-Q plot (see [Wikipedia](#)). You can use one or more methods as needed.

Algorithm description:

- Original hypothesis H0: The observed values are normally distributed. H1: The observed values are not normally distributed.
- The KS p-value calculation method progressively calculates CDF of KS distribution regardless of the sample size. For more information, see [Wikipedia](#).
- If the sample size is greater than 1000, the Q-Q plot method collects samples to calculate and output plots. This means that the data points in plots do not necessarily cover all samples.

PAI command

```
PAI -name normality_test
  -project algo_public
  -DinputTableName=test
  -DoutputTableName=test_out
  -DselectedColNames=col1,col2
  -Dlifecycle=1;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
outputTableName	Required. The name of the output table.	Table name that has not been used	-
selectedColNames	Optional. The names of selected columns.	Multiple double or bigint type columns can be selected.	-
inputTablePartitions	Optional. The partitions selected from the input table.	Partition name	All partitions are selected by default.
enableQQplot	Optional. This parameter specifies whether to use the Q-Q plot.	true and false	true
enableADtest	Optional. This parameter specifies whether to perform the Anderson-Darling test.	true and false	true
enableKStest	Optional. This parameter specifies whether to perform the Kolmogorov-Smirnov test.	true and false	true

Parameter	Description	Valid values	Default value
lifecycle	Optional. The lifecycle of the output table.	An integer greater than or equal to -1	Default value: -1. This value indicates that no lifecycle is set.
coreNum	Optional. The number of cores.	An integer greater than 0	Default value: -1. This value indicates that the number of instances is determined by the amount of input data.
memSizePerCore	Optional. The memory size of each core.	(100, 65536)	Default value: -1. This value indicates that the memory size is determined by the amount of input data.

Examples

- SQL statement to generate data:

```
drop table if exists normality_test_input;
create table normality_test_input as
select
*
from
(
select 1 as x from dual
union all
select 2 as x from dual
union all
select 3 as x from dual
union all
select 4 as x from dual
union all
select 5 as x from dual
union all
select 6 as x from dual
union all
select 7 as x from dual
union all
select 8 as x from dual
union all
select 9 as x from dual
union all
select 10 as x from dual
) tmp;
```

- PAI command

```
PAI -name normality_test
-project projectxlib4
-DinputTableName=normality_test_input
-DoutputTableName=normality_test_output
-DselectedColNames=x
-Dlifecycle=1;
```

- **Input description**

Input format: select the columns that need to be calculated. The columns must be of the double or bigint type.

- **Output description**

A diagram and a result table are output. The columns in the result table are as follows. The result table has two partitions:

- `p='test'` shows the result of the AD or KS test. Data is output when `enableADtest` or `enableKStest` is set to true.
- `p='plot'` shows the O-Q plot data. When `enableQQplot` is set to true, data is output and the columns that meet the `p='test'` condition are reused. In the case of `p='plot'`, the `testvalue` column records the original observed data (x axis of the Q-Q plot), and the `pvalue` column records the expected data that is normally distributed (y axis of the Q-Q plot).

Output table:

```
+-----+-----+-----+-----+-----+
| colname | testname | testvalue | pvalue | p |
+-----+-----+-----+-----+-----+
|x | NULL | 1.0 | 0.8173291742279805 | plot |
|x | NULL | 2.0 | 2.470864450785345 | plot |
|x | NULL | 3.0 | 3.5156067948020056 | plot |
|x | NULL | 4.0 | 4.3632330349313095 | plot |
|x | NULL | 5.0 | 5.128868067945126 | plot |
|x | NULL | 6.0 | 5.871131932054874 | plot |
|x | NULL | 7.0 | 6.6367669650686905 | plot |
|x | NULL | 8.0 | 7.4843932051979944 | plot |
|x | NULL | 9.0 | 8.529135549214654 | plot |
|x | NULL | 10.0 | 10.182670825772018 | plot |
|x | Anderson_Darling_Test | 0.1411092332197832 | 0.9566579606430077 | test |
|x | Kolmogorov_Smirnov_Test | 0.09551932503797644 | 0.9999888659426232 | test |
+-----+-----+-----+-----+-----+
```

Column name	Data type	Definition
colName	string	Column name
testname	string	Test name
testvalue	double	Test value on the x axis of the Q-Q plot
pvalue	double	Test p value on the y axis of the Q-Q plot
p	double	Partition name

4.4.5.13. Percentile

This component calculates the percentile of the values in a column.

Parameter settings

Select the column to be analyzed. Only the double and bigint types are supported.

PAI command

```
PAI -name Percentile
-project algo_public
-DoutputTableName="pai_temp_666_6014_1"
-DcolName="euribor3m"
-DinputTableName="bank_data";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
outputTableName	The name of the output table automatically generated after the system performs the percentile calculation.
colName	The column selected for percentile calculation. Only the numeric type is supported.
inputTableName	The name of the input table.

4.4.5.14. Pearson coefficient

This component calculates the Pearson correlation coefficient of two numeric columns in an input table or a partition, and saves the result to the output table.

Component description

- The component has only two parameters: input column 1 and input column 2. Enter the names of the two columns for which the Pearson correlation coefficient is calculated.
- After you run the component, right-click the component and choose **View Analytics Report** from the short cut menu.
- The Pearson correlation coefficient is listed in the row.

PAI command

```
pai -name pearson
-project algo_test
-DinputTableName=wpbc
-Dcol1Name=f1
-Dcol2Name=f2
-DoutputTableName=wpbc_pear;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	The partitions selected from the input table for calculation.	The parameter value must be in the <code>partition_name=value</code> format. To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	All partitions in the input table are selected by default.
col1Name	Required. The name of input column 1.	Column name	-
col2Name	Required. The name of input column 2.	Column name	-
outputTableName	Required. The name of the output table.	Table name	-

4.4.5.15. Histogram

This component analyzes data in a column and outputs a histogram.

Parameter settings

- Select the columns to be analyzed. Only the double and bigint types are supported.
- View the analysis report.
- You can adjust the step and move the slider to view the entire histogram.

4.4.6. Machine learning

4.4.6.1. Binary classification

4.4.6.1.1. GBDT binary classification

This component is used for binary classification based on GBDT regression and sorting. Values greater than the threshold value are considered positive samples, while values that are less than or equal to the threshold value are considered negative samples.

Procedure

1. Drag and drop the GBDT Binary Classification component onto the canvas for training and set the parameters, as shown in the following figure.

Fields Setting

Parameters Setting

Tuning

Feature Columns Double or bigint type. Max 8...

Select Column

Label Column Bigint type. Binary classification...

📁

Stratified Columns (optional) Double or bigint t...

📁

Parameters

Parameter	Description
Feature Columns	The double and bigint types are supported. A maximum of 800 columns can be specified.
Label Column	You can select all columns except the input column. The values must be of the binary type.
Stratification Column	Optional. The whole table is selected by default. The double and bigint types are supported.

- You can change the data type of the input columns.

The input columns of GBDT binary classification only support the continuous type and are processed in the same way as the discrete type.

- Set the parameters. Parameters

Parameter	Description
Metric Type	The normalized discounted cumulative gain (NDCG) and discounted cumulative gain (DCG).
Trees	Valid values: [1,10000]. Default value: 500.
Learning Rate	Valid values: (0, 1). Default value: 0.05.
Training Sample Fraction	Valid values: (0, 1). Default value: 0.6.
Training Feature Fraction	Valid values: (0, 1). Default value: 0.6.
Maximum Leaves	The value must be an integer in the range of [2, 1000]. Default value: 32.

Parameter	Description
Testing Data Fraction	Valid values: [0, 1]. Default value: 0.0.
Maximum Tree Depth	The value must be an integer in the range of [1, 11]. Default value: 11.
Minimum Samples per Leaf Node	The value must be an integer in the range of [100, 1000]. Default value: 500.
Random Seed	The value must be an integer in the range of [0, 10]. Default value: 0.
Maximum Splits per Feature	Valid values: [1, 1000]. Default value: 500.

4. View the output. For more information, see the description of the [Random forest](#) component.

 Note

- GBDT and GBDT_LR have different default types of loss functions. The default loss function of GBDT is regression loss: mean squared error loss. The default loss function of GBDT_LR is logistic regression loss. The system automatically writes the default loss function for GBDT_LR.
- For GBDT binary classification, the label column must be of the binary type. String type data is not supported.
- When connecting the ROC curve component, set the prediction component parameters and select a base value.

PAI command (F/L setup settings are not used)

```
PAI -name GBDT_LR
-project algo_public
-DfeatureSplitValueMaxSize="500"
-DrandSeed="0"
-Dshrinkage="0.5"
-DmaxLeafCount="32"
-DlabelColName="y"
-DinputTableName="bank_data_partition"
-DminLeafSampleCount="500"
-DgroupIDColName="nr_employed"
-DsampleRatio="0.6"
-DmaxDepth="11"
-DmodelName="xlab_m_GBDT_LR_21208"
-DmetricType="2"
-DfeatureRatio="0.6"
-DinputTablePartitions="pt=20150501"
-DtestRatio="0.0"
-DfeatureColNames="age,previous,cons_conf_idx,euribor3m"
-DtreeCount="500";
```

Parameters

Parameter	Description
name	The name of the component.

Parameter	Description
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
featureSplitValueMaxSize	Optional. The maximum number of splits per feature. Valid values: [1, 1000]. Default value: 500.
randSeed	Optional. The number of random seeds. The value must be an integer in the range of [0, 10]. Default value: 0.
shrinkage	Optional. The learning rate. Valid values: (0, 1). Default value: 0.05.
maxLeafCount	Optional. The maximum number of leaves. The value must be an integer in the range of [2, 1000]. Default value: 32.
labelColName	The name of the label column selected from the input table.
inputTableName	The name of the input table for training.
minLeafSampleCount	Optional. The minimum number of samples per leaf node. The value must be an integer in the range of [100, 1000]. Default value: 500.
groupIDColName	Optional. The name of the stratification column. The whole table is considered as a stratum by default.
sampleRatio	Optional. The fraction of samples collected for training. Valid values: (0, 1). Default value: 0.6.
maxDepth	Optional. The maximum depth of a tree. The value must be an integer in the range of [1, 11]. Default value: 11.
modelName	The name of the output model.
metricType	Optional. The type of a metric. Valid values: 0 and 1. 0 represents normalized discounted cumulative gain (NDCG) and 1 represents discounted cumulative gain (DCG).
featureRatio	Optional. The fraction of features collected for training. Valid values: (0, 1). Default value: 0.6.
inputTablePartitions	Optional. The partitions selected from the input prediction table. If no partitions are specified, the whole table is selected.
testRatio	Optional. The fraction of testing samples. Valid values: [0, 1]. Default value: 0.0.
featureColNames	The names of feature columns selected from the input table for training.
treeCount	Optional. The number of trees. Valid values: [1, 10000]. Default value: 500.

4.4.6.1.2. Linear SVM

Support-vector machines (SVMs) are developed based on the VC dimension theory and the structural risk minimization principle.

This linear SVM version is not implemented using the kernel function. For more information, see Trust Region Method for L2-SVM at <http://www.csie.ntu.edu.tw/~cjlin/papers/logistic.pdf>. This algorithm only supports binary classification.

Procedure

1. Configure column settings.
 - Feature Columns: You can select a feature column of the bigint or double type.
 - Label Column: The data type of the label column can be bigint, double, or string. This component only supports binary classification.
2. Set parameters. Parameters

Parameter	Description
Positive Sample Label	Optional. The value of the positive sample. If this parameter is not specified, the system randomly selects a value. We recommend that you specify this parameter when the positive and negative samples are significantly different.
Positive Penalty Factor	Optional. The weight of the positive sample. Valid values: (0, +∞). Default value: 1.0.
Negative Penalty Factor	Optional. The weight of the negative sample. Valid values: (0, +∞). Default value: 1.0.
Convergence Coefficient	Optional. The convergence deviation. Valid values: (0, 1). Default value: 0.001. <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> <p> Note If no base value is specified, Positive Penalty Factor and Negative Penalty Factor must be set to the same value.</p> </div>

3. View the output. For more information, see the description of the [Random Forest](#) component.

PAI command (F/L setup settings are not used)

```
PAI -name LinearSVM
-project algo_public
-DnegativeCost="1.0"
-DmodelName="xlab_m_LinearSVM_6143"
-DpositiveCost="1.0"
-Depsilon="0.001"
-DlabelColName="y"
-DfeatureColNames="pdays,emp_var_rate,cons_conf_idx"
-DinputTableName="bank_data"
-DpositiveLabel="0";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.

Parameter	Description
negativeCost	Optional. The weight of the negative sample. It is the penalty factor of the negative sample. Valid values: (0, +∞). Default value: 1.0.
modelName	The name of the output model.
positiveCost	Optional. The weight of the positive sample. It is the penalty factor of the positive sample. Valid values: (0, +∞). Default value: 1.0.
epsilon	Optional. The convergence coefficient. Valid values: (0, 1). Default value: 0.001.
labelColName	The name of the label column.
featureColNames	The names of feature columns selected from the input table for training.
inputTableName	The name of the input table for training.
positiveLabel	Optional. The value of the positive sample. If this parameter is not specified, the system randomly selects a value.

4.4.6.1.3. Logistic regression for binary classification

Binary classification is a classic logistic regression method. Logistic regression on the algorithm platform supports multiclass classification. The logistic regression component supports two data types: sparse and dense.

Parameter settings

Parameters

Parameter	Description
Regularization Type	Optional. The type of regularization. Valid values: <i>L1</i> , <i>L2</i> , and <i>None</i> . Default value: <i>L1</i> .
Maximum Iterations	Optional. The maximum number of L-BFGS iterations. Default value: 100.
Regularization Coefficient	Optional. The regularization coefficient. Default value: 1.0. If regularizedType is set to <i>None</i> , this parameter is ignored.
Minimum Convergence Deviance	Optional. The condition to terminate L-BFGS. This is the log-likelihood deviation between two iterations. Default value: <i>1.0e-06</i> .

The logistic regression component outputs a model, which is available in the model list.

Model name format: `Experiment Name + "-" + Component Name + "model"` .

PAI command (F/L setup settings are not used)

```
PAI -name LogisticRegression
-project algo_public
-DmodelName="xlab_m_logistic_regression_6096"
-DregularizedLevel="1"
-DmaxIter="100"
-DregularizedType="l1"
-Depsilon="0.000001"
-DlabelColName="y"
-DfeatureColNames="pdays,emp_var_rate"
-DgoodValue="1"
-DinputTableName="bank_data";
```

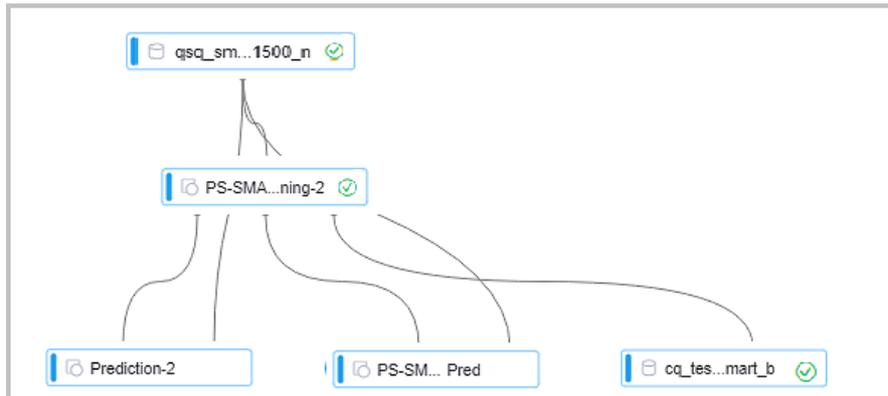

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
modelName	The name of the output model.
regularizedLevel	Optional. The regularization coefficient. Default value: 1.0. If regularizedType is set to <i>None</i> , this parameter is ignored.
maxIter	Optional. The maximum number of L-BFGS iterations. Default value: 100.
regularizedType	Optional. The type of regularization. Valid values: <i>L1</i> , <i>L2</i> , and <i>None</i> . Default value: <i>L1</i> .
epsilon	Optional. The convergence deviation. It is the condition to terminate L-BFGS. This is the log-likelihood deviation between two iterations. Default value: <i>1.0e-06</i> .
labelColName	The name of the label column selected from the input table.
featureColNames	The names of feature columns selected from the input table for training.
goodValue	Optional. The base value. For binary classification, specify the label value of the training coefficient. If this parameter is not specified, the system randomly selects a value.
inputTableName	The name of the input table for training.

4.4.6.1.4. PS-SMART binary classification

A **parameter server** (PS) is used to train a large number of models online and offline. Scalable Multiple Additive Regression Tree (SMART) is an implementation of Gradient Boosting Decision Tree (GBDT) on PS. PS-SMART can run training tasks containing up to tens of billions of samples and hundreds of thousands of features on thousands of nodes. It also supports failover for high stability. PS-SMART supports various data formats, training targets, evaluation targets, output feature importance, and histogram approximation for training acceleration.

Quick start

As shown in the figure, a PS-SMART binary classification model is learned based on training data. The model has three output ports:

- Output model: off line model, which is connected to the unified prediction component. This model does not support the output of leaf node numbers.
- Output model table: a binary table that is not readable and is used to ensure compatibility with the PS-SMART prediction component. The table supports the output of leaf node numbers, which ensures higher efficiency, less resource consumption, and higher stability.
- Output feature importance table: lists the importance of each feature. Three importance types are supported. For more information, see [Parameters](#).

PAI command

- Training

```
PAI -name ps_smart
  -project algo_public
  -DinputTableName="smart_binary_input"
  -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
  -DoutputTableName="pai_temp_24515_545859_2"
  -DoutputImportanceTableName="pai_temp_24515_545859_3"
  -DlabelColName="label"
  -DfeatureColNames="f0,f1,f2,f3,f4,f5"
  -DenableSparse="false"
  -Dobjective="binary:logistic"
  -Dmetric="error"
  -DfeatureImportanceType="gain"
  -DtreeCount="5";
  -DmaxDepth="5"
  -Dshrinkage="0.3"
  -Dl2="1.0"
  -Dl1="0"
  -Dlifecycle="3"
  -DsketchEps="0.03"
  -DsampleRatio="1.0"
  -DfeatureRatio="1.0"
  -DbaseScore="0.5"
  -DminSplitLoss="0"
```

- Prediction

```

PAI -name prediction
-project algo_public
-DinputTableName="smart_binary_input";
-DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
-DoutputTableName="pai_temp_24515_545860_1"
-DfeatureColNames="f0,f1,f2,f3,f4,f5"
-DappendColNames="label,qid,f0,f1,f2,f3,f4,f5"
-DenableSparse="false"
-Dlifecycle="28"
  
```

Parameters

- Data parameters

Command option	Parameter	Description	Valid values	Remarks
featureColNames	Feature Columns	The names of feature columns selected from the input table for training.	If the column name is in dense format, it must be of the bigint or double type. If the column name is in sparse KV format, it must be a string, and its keys and values must be numeric.	Required
labelColName	Label Column	The name of the label column selected from the input table.	The column name can be of either string or numeric type, but only numeric data can be stored in the columns. For example, in binary classification, the column value can be 0 or 1.	Required
weightCol	Weight Column	This column specifies the weight of each sample.	The column name can be of the numeric type.	Optional. Default value: null.
enableSparse	Use Sparse Format	This parameter specifies whether the data in the input table is in sparse format, in which key-value pairs are separated by spaces whereas keys and values are separated by colons (:), for example, 1:0.3 3:0.9.	[true, false]	Optional. Default value: false.

Command option	Parameter	Description	Valid values	Remarks
inputTableName	Input Table Name	N/A	N/A	Required
modelName	Output Model Name	N/A	N/A	Required
outputImportanceTableName	Output Feature Importance Table Name	N/A	N/A	Optional. Default value: null.
inputTablePartitions	Input Table Partitions	N/A	N/A	Optional. The parameter value must be in ds=1/pt=1 format.
outputTableName	Output Model Table Name	The output table is a MaxCompute table that uses the binary format and is not readable. The prediction component that comes with SMART can be used to generate leaf node numbers.	String	Optional
lifecycle	Output Table Lifecycle	N/A	Positive integer	Optional. Default value: 3.

- Algorithm parameters

Command option	Parameter	Description	Valid values	Remarks
objective	Objective Function Type	The objective function type affects learning and must be selected properly. Select binary:logistic for binary classification.	N/A	Required
metric	Evaluation Indicator Type	Evaluation indicators in the training set, which are exported to stdout of the coordinator in a logview.	logloss, error and auc	Optional. Default value: null.
treeCount	Trees	The number of trees. The training time is proportional to this number.	Positive integer	Optional. Default value: 1.

Command option	Parameter	Description	Valid values	Remarks
maxDepth	Maximum Tree Depth	The maximum depth of a tree. We recommend that you set this value to 5, which means the tree can contain up to 32 leaf nodes.	A positive integer in the range of [1, 20]	Optional. Default value: 5.
sampleRatio	Data Sampling Fraction	The data sampling rate when trees are built. The sample data is used to build a weak learner to accelerate training.	(0, 1]	Optional. The default value is 1.0, which means data sampling is disabled.
featureRatio	Feature Sampling Fraction	The feature sampling rate when trees are built. The sample features are used to build a weak learner to accelerate training.	(0, 1]	Optional. The default value is 1.0, which means feature sampling is disabled.
l1	L1 Penalty Coefficient	This parameter determines the number of leaf nodes. The greater the value, the less the leaf nodes. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 0.
l2	L2 Penalty Coefficient	This parameter determines the size of a leaf node. The greater the value, the more evenly the leaf nodes are distributed. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 1.0.
shrinkage	Learning Rate	N/A	(0, 1]	Optional. Default value: 0.3.

Command option	Parameter	Description	Valid values	Remarks
sketchEps	Sketch-based Approximate Precision	The threshold for selecting quantiles when you build a sketch. The number of buckets is $O(1.0/sketchEps)$. The smaller the parameter value, the more buckets are generated. Typically, you do not need to modify this value.	(0, 1)	Optional. Default value: 0.03.
minSplitLoss	Minimum Split Loss Change	The minimum split loss changes required for splitting a node. The greater the value, the more conservatively the node splits.	Non-negative real number	Optional. Default value: 0.
featureNum	Features	The number of features or the maximum feature ID. Specify this parameter for resource usage estimation.	Positive integer	Optional
baseScore	Global Offset	Original predicted values of all samples.	Real number	Optional. Default value: 0.5.
featureImportance Type	Feature Importance Type	The type of feature importance. weight indicates the number of times that a feature splits. gain indicates information gain brought by the feature. cover indicates the number of samples that the feature covers on the splitting nodes.	weight , gain , and cover	Optional. Default value: gain .

- Note

- Specify different values for the objective parameter in different learning models. On the binary classification Web GUI, the objective function is automatically specified and invisible to users. On the command line, set the objective parameter to `binary:logistic`.
- Mappings between metrics and objective functions are: **logloss** for **negative loglikelihood for logistic regression**, **error** for **binary classification error**, and **auc** for **Area under curve for classification**.

Execution optimization

Command option	Parameter	Description	Valid values	Remarks
coreNum	Cores	The number of cores. The greater the value, the faster the computing algorithm runs.	Positive integer	Optional. Automatically calculated.
memSizePerCore	Memory Size per Core (MB)	The memory size of each core, where 1024 represents 1 GB of memory.	Positive integer	Optional. Automatically calculated.

Example

- Data generation

The following example uses data in dense format.

```
drop table if exists lm_test_input;
create table smart_binary_input lifecycle 3 as
select
*
from
(
select 0.72 as f0, 0.42 as f1, 0.55 as f2, -0.09 as f3, 1.79 as f4, -1.2 as f5, 0 as label from dual
union all
select 1.23 as f0, -0.33 as f1, -1.55 as f2, 0.92 as f3, -0.04 as f4, -0.1 as f5, 1 as label from dual
union all
select -0.2 as f0, -0.55 as f1, -1.28 as f2, 0.48 as f3, -1.7 as f4, 1.13 as f5, 1 as label from dual
union all
select 1.24 as f0, -0.68 as f1, 1.82 as f2, 1.57 as f3, 1.18 as f4, 0.2 as f5, 0 as label from dual
union all
select -0.85 as f0, 0.19 as f1, -0.06 as f2, -0.55 as f3, 0.31 as f4, 0.08 as f5, 1 as label from dual
union all
select 0.58 as f0, -1.39 as f1, 0.05 as f2, 2.18 as f3, -0.02 as f4, 1.71 as f5, 0 as label from dual
union all
select -0.48 as f0, 0.79 as f1, 2.52 as f2, -1.19 as f3, 0.9 as f4, -1.04 as f5, 1 as label from dual
union all
select 1.02 as f0, -0.88 as f1, 0.82 as f2, 1.82 as f3, 1.55 as f4, 0.53 as f5, 0 as label from dual
union all
select 1.19 as f0, -1.18 as f1, -1.1 as f2, 2.26 as f3, 1.22 as f4, 0.92 as f5, 0 as label from dual
union all
select -2.78 as f0, 2.33 as f1, 1.18 as f2, -4.5 as f3, -1.31 as f4, -1.8 as f5, 1 as label from dual
) tmp;
```

- Training

Configure the training data and training components, as shown in [Quick start](#). Select the label column as the target column and columns f0, f1, f2, f3, f4, f5 as feature columns.

- You do not need to set the number of features because this number is calculated automatically by the algorithm. If you have a large number of features and want the algorithm to accurately estimate the amount of required resources, specify the actual number of features.
- To accelerate the training, set the number of cores on the execution optimization page. The greater the number, the faster the algorithm runs. Typically, you do not need to enter the memory size per core because the algorithm can accurately calculate the memory size. The PS algorithm starts to run only when all hosts have obtained the required resources. Therefore, you may need to wait for a longer period of time when the cluster is busy and resources are requested in large volumes.
- You can view the output values of the metrics in the stdout of the coordinator or in a logview (HTTP link starting with <http://logview.odps.aliyun-inc.com:8080/logview>). A single PS-SMART training job can contain multiple tasks, and therefore multiple logviews are created. Select the logview whose name starts with PS to view the output of the PS job.

- Prediction

- Use the unified prediction component

The model generated after training is saved in binary format and can be used for prediction. Configure the input model and test data for the prediction component, as shown in [Quick start](#).

If the dense format is used, you only need to select feature columns. (All columns are selected by default, and extra columns do not affect the prediction.) If the KV format is used, set the data format to sparse format and select the correct delimiter. In the SMART model, key-value pairs are separated by space characters. Therefore, the delimiter must be set to space or `\u0020` (escape expression of spaces).

In the "prediction_detail" column, value 1 indicates a positive sample, and value 0 indicates a negative sample. The values following 0 and 1 indicate the probabilities of the corresponding classes.

- Use the PS-SMART prediction component

The output model table obtained after training is saved in binary format and can be used by the PS-SMART prediction component for prediction. Configure the input model and test data for the prediction component, as shown in [Quick start](#). Set the required parameters, including the data format, feature columns, target column, and number of classes. The ID column can only be a string type column other than a feature column or a target column. The loss function must be set to `binary:logistic`.

The **prediction_score** column lists probabilities of predicted positive samples. A sample is predicted as a positive sample if its score is greater than 0.5. Otherwise, it is predicted as a negative sample. The **leaf_index** column lists the predicted leaf node numbers. Each sample has N numbers, where N is the number of decision trees. Each tree is mapped to a number, which indicates the leaf node number of the sample on this tree.

 Note

- The output model table is a binary table that is not readable and is used to support the PS-SMART prediction component. The table provides outputs such as leaf node numbers and evaluation indicators. However, the output table has strict requirements on data formats, which negatively affects user experience. This component is being continually improved, and may be replaced by another component in the future.
- A string type column must be selected as the label column. You can enter strings in the column but cannot be blank or NULL. A feature column can be converted to the string type by using the data type conversion component.
- The loss function must be explicitly set to `binary:logistic`. By default, the function does not work.

- View feature importance

To view feature importance, you can export the third output port to an output table, or right-click **PS-SMART training component** and choose **View Data > Output Feature Importance Table** from the shortcut menu.

order ▲	id ▲	value ▲
1	0	0.5690338015556335
2	1	0.21714292466640472
3	4	0.21382322907447815

In the table, the ID column lists the numbers of input features. In this example, the data is in dense format. The input features are **f0, f1, f2, f3, f4, f5**. Therefore, ID 0 represents f0 and ID 4 represents f4. If the KV format is used, the IDs represent keys in key-value pairs. Each value indicates a feature importance type. The default value is **gain**, indicating the sum of information gains brought by a feature in the model. The preceding figure shows only three features because only these three features are used during the tree split process. In this case, the importance of unused features is 0.

FAQ

- Q: Does PS_SMART support non-numerical features and tags?
- A: No.
- Q: What is the scale of features supported by PS-SMART? Can we use large-scale 0-1 features?
- A: Although PS-SMART supports tasks that contain hundreds of thousands of features, such tasks consume large amounts of resources and run slowly. Therefore, we recommend that you do not use such a large number of features. The GBDT algorithm is suitable for training with continuous features. The categorical features require one-hot coding to filter out infrequent features before they can be used for training. The continuous numerical features can be used for training with the GBDT algorithm directly. Discretization is not recommended for numerical features.
- Q: Why is the result different every time although the SMART algorithm has the same data and the same parameter settings?
- A: The PS-SMART algorithm applies randomness in many scenarios. For example, the `data_sample_ratio` and `fea_sample_ratio` items introduce data and feature sampling respectively. In addition, the PS-SMART algorithm uses histograms to show similarity. When multiple workers run in a cluster in distributed mode, local sketches are merged to global sketches in a random order. Although different merging orders result in different tree structures, this does not introduce too much variation to the output model. Therefore, it is normal situation to obtain different results after the algorithm runs multiple times with the same data and same parameter settings.

Note

- The target column in a PS-SMART binary classification model supports only numerical values (0 for negative samples and 1 for positive samples). Even if values in the MaxCompute table are strings, they are saved as numerical values. If the classification target is a type string similar to Good or Bad, convert it to 1 or 0.
- In the key-value format, feature IDs must be positive integers, and feature values must be real numbers. If feature IDs are strings, use the serialization component to serialize them. If the feature values are classification type strings, perform feature engineering, such as discretization.

4.4.6.2. Multiclass classification

4.4.6.2.1. KNN

The KNN algorithm is used to resolve classification issues. For a row in the prediction table, this component selects K entries nearest to the row from the training table. It then assigns the row to the class that is most common among the K entries.

PAI command

```
PAI -name knn
-DtrainTableName=pai_knn_test_input
-DtrainFeatureColNames=f0,f1
-DtrainLabelColName=class
-DpredictTableName=pai_knn_test_input
-DpredictFeatureColNames=f0,f1
-DoutputTableName=pai_knn_test_output
-Dk=2;
```

Parameters

Parameter	Description	Valid value	Default value
trainTableName	Required. The name of the training table.	Table name	N/A
trainFeatureColNames	Required. The names of feature columns selected from the training table.	Column name	N/A
trainLabelColName	Required. The name of the label column selected from the training table.	Column name	N/A
trainTablePartitions	Optional. The partitions selected from the training table.	Partition name	All partitions are selected by default.
predictTableName	Required. The name of the prediction table.	Table name	N/A
outputTableName	Required. The name of the output table.	Table name	N/A
predictFeatureColNames	Optional. The names of feature columns selected from the prediction table.	Column name	N/A
predictTablePartitions	Optional. The partitions selected from the prediction table.	Partition name	All partitions are selected by default.
appendColNames	Optional. The names of columns appended to the output table from the prediction table.	Column name	N/A
outputTablePartition	Optional. The partitions in the output table.	Partition name	The output table is non-partitioned by default.

Parameter	Description	Valid value	Default value
k	Optional. The number of the nearest neighbors.	A positive integer in the range of [1, 1000]	100
enableSparse	Optional. This parameter specifies whether the data in the input table is in sparse format.	true and false	false
itemDelimiter	Optional. The delimiter used to separate key-value pairs when the data in the input table is in sparse format.	Symbol	The default delimiter is a space.
kvDelimiter	Optional. The delimiter used to separate keys and values when the data in the input table is in sparse format.	Symbol	The default delimiter is a colon (:).
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 20000].	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Examples

- Test data

```
create table pai_knn_test_input as
select * from
(
  select 1 as f0,2 as f1, 'good' as class from dual
  union all
  select 1 as f0,3 as f1, 'good' as class from dual
  union all
  select 1 as f0,4 as f1, 'bad' as class from dual
  union all
  select 0 as f0,3 as f1, 'good' as class from dual
  union all
  select 0 as f0,4 as f1, 'bad' as class from dual
)tmp;
```

- PAI command

```
PAI -name knn
-DtrainTableName=pai_knn_test_input
-DtrainFeatureColNames=f0,f1
-DtrainLabelColName=class
-DpredictTableName=pai_knn_test_input
-DpredictFeatureColNames=f0,f1
-DoutputTableName=pai_knn_test_output
-Dk=2;
```

• Output description

f0	f1	prediction_result	prediction_score	prediction_detail
1	4	bad	1.0	{"bad": 1}
0	4	bad	1.0	{"bad": 1}
0	3	bad	0.5	{"bad": 0.5, "good": 0.5}
1	3	good	1.0	{"good": 1}
1	2	good	1.0	{"good": 1}

- o f0 and f1: the appended columns in the output table.
- o prediction_result: the classification result.
- o prediction_score: the probabilities for the classification result.
- o prediction_detail: the latest K conclusions and their probabilities.

4.4.6.2.2. Logistic regression for multiclass classification

Logistic regression of Apsara Stack Machine Learning Platform for AI supports multiclass classification. The logistic regression component supports two data formats: sparse and dense.

Parameter settings

Parameters

Parameter	Description
Regularization Type	Optional. The type of regularization. Valid values: <i>L1</i> , <i>L2</i> , and <i>None</i> . Default value: <i>L1</i> .
Max Iterations	Optional. The maximum number of L-BFGS iterations. Default value: 100.
Regularization Coefficient	Optional. The regularization coefficient. Default value: 1.0. If regularizedType is set to <i>None</i> , this parameter is ignored.
Minimum Convergence Deviance	Optional. The condition to terminate L-BFGS. This is the log-likelihood deviance between two iterations. Default value: <i>1.0e-06</i> .

The logistic regression component outputs a model, which is available in the model list.

Model naming format: Experiment Name + "-" + Component Name + "model" .

PAI command (F/L setup settings are not used)

```
PAI -name LogisticRegression
-project algo_public
-DmodelName="xlab_m_logistic_regression_6096"
-DregularizedLevel="1"
-DmaxIter="100"
-DregularizedType="l1"
-Depsilon="0.000001"
-DlabelColName="y"
-DfeatureColNames="pdays,emp_var_rate"
-DgoodValue="1"
-DinputTableName="bank_data";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
modelName	The name of the output model.
regularizedLevel	Optional. The regularization coefficient. Default value: 1.0. If regularizedType is set to <i>None</i> , this parameter is ignored.
maxIter	Optional. The maximum number of L-BFGS iterations. Default value: 100.
regularizedType	Optional. The type of regularization. Valid values: <i>L1</i> , <i>L2</i> , and <i>None</i> . Default value: <i>L1</i> .
epsilon	Optional. The convergence deviation. It is the condition to terminate L-BFGS. This is the loglikelihood deviation between two iterations. Default value: <i>1.0e-06</i> .
labelColName	The name of the label column selected from the input table.
featureColNames	The names of feature columns selected from the input table for training.
goodValue	Optional. The base value. For multiclass classification, specify the label value of the training coefficient. If this parameter is not specified, the system randomly selects a value.
inputTableName	The name of the input table for training.

4.4.6.2.3. Random forest

A random forest is a classifier that contains multiple decision trees. Its output class is decided by the mode of individual tree output classes.

Procedure

1. Drag and drop the Random Forest component onto the canvas and select columns. Parameters

Parameter	Description
-----------	-------------

Parameter	Description
Feature Columns	Optional. All columns except the label and weight columns are selected by default.
Excluded Columns	Optional. This parameter is used to exclude specified columns from training. This parameter is mutually exclusive with <code>featureColNames</code> .
Columns Forced to Convert	Optional. The default feature parsing rules are as follows: <ul style="list-style-type: none"> Parse columns of string, boolean, and datetime types to discrete columns. Parse columns of double and bigint types to contiguous columns. Set the <code>forceCategorical</code> parameter to parse bigint type columns to categorical columns.
Weight Columns	Optional. You can select all columns except the input and label columns. The double and bigint types are supported.
Label Column	You can select all columns except the input column. The bigint, double, and string types are supported.

2. Set the parameters of the Random Forest component. Parameters

Parameter	Description
Trees	The number of trees in the forest. Valid values: (0, 1000).
Single-tree Algorithm Type	Optional. The algorithm type of each tree in the forest. Valid values: <code>id3</code> , <code>c4.5</code> , and <code>cart</code> . If the forest has <code>n</code> trees and the condition is <code>algorithmTypes = a.b</code> , then <code>[0, a)</code> indicates <code>id3</code> , <code>[a, b)</code> indicates <code>cart</code> , and <code>[b, n)</code> indicates <code>c4.5</code> . If this parameter is set to <code>[2, 4]</code> for a forest with five trees, <code>[0, 1)</code> indicates the ID3 algorithm, <code>[2, 3)</code> indicates the CART algorithm, and <code>4</code> indicates the C4.5 algorithm. If the value is <code>None</code> , the algorithms are evenly allocated across the forest.
Random Features per Tree	The number of features selected randomly. Valid values: 1 to <code>N</code> . <code>N</code> indicates the number of features.
Minimum Samples per Leaf Node	Optional. The minimum number of samples per leaf node. The value must be a positive integer no less than 2.
Minimum Fraction of Samples on Leaf Node to Samples on Parent Node	The minimum fraction of samples on a leaf node to samples on a parent node. A value of <code>-1</code> indicates that no limit is set. Default value: <code>-1</code> . Valid values: <code>[0, 1]</code> .
Maximum Tree Depth	The maximum depth of a tree. <code>-1</code> indicates a completely grown tree. Valid values: <code>[1, ∞)</code> .
Random Samples Input per Tree	The number of random samples input per tree. Valid values: <code>(1000, 1000000]</code> .

 Note

- With improvement of the bagging method, the Random Forest component builds a forest without correlated trees in the big cube. Random forests are similar to the boosting method in many aspects, particularly their training processes.
- For the growth of a single tree, this method provides the id3, cart, and c4.5 options. The treeNum parameter is used to specify the number of trees in the forest, in the range of [1, 1000]. The structure of a single tree can be controlled based on the edited template. You can use other parameters to specify the minimum number of samples per leaf node, the minimum fraction of samples on a leaf node to samples on a parent node, and the maximum depth of a tree.
- Each row in the weight column corresponds to a sample and indicates the proportion of this sample in training. If the age column is selected as the weight column, the sample in the row with a higher weight value in the age column has a higher proportion during the training.
- The "input table is empty!" error may occur in the following situations: The sampling fraction is too small, which means that the value of maxRecordSize is too small, or the input table is empty.

PAI command (F/L setup settings are not used)

```
PAI -name RandomForest
-project algo_public
-DmodelName="xlab_m_random_forests_6036"
-DrandomColNum="1.0"
-DlabelColName="campaign"
-DmaxTreeDeep="10"
-DmaxRecordSize="100000"
-DfeatureColNames="age,pdays,previous,emp_var_rate,cons_price_idx,cons_conf_idx,euribor3m,nr_employed"
-DdisFeatureContinuous="1,1,1,1,1,1,1"
-DminNumPer="-1"
-DminNumObj="2"
-DinputTableName="bank_data"
-DweightColName="y"
-DtreeNum="10";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
modelName	The name of the output model.
randomColNum	Optional. The random attribute type. This parameter specifies the number of features randomly selected each time a single tree is generated. -7 indicates $\log_2 N$. Valid values: 1 to N. N indicates the number of features.
labelColName	The name of the label column selected from the input table.

Parameter	Description
maxTreeDeep	Optional. The maximum depth of a tree. <i>-1</i> indicates a completely grown tree. Valid values: $[1, \infty]$.
maxRecordSize	Optional. The maximum number of samples per tree. Valid values: (1000, 1000000). <i>-1</i> indicates 100000.
featureColNames	The names of feature columns selected from the input table for training.
isFeatureContinuous	Specifies whether the feature for subsequent columns is continuous or discrete. <i>1</i> indicates that the feature column data is continuous, while <i>0</i> indicates that the feature column data is discrete. <i>1,0,0</i> indicates that values are continuous in the first feature column and discrete in the second and third feature columns. The number of values corresponds to the feature length.
minNumPer	Optional. The minimum fraction of samples on a leaf node to samples on a parent node. A value of <i>-1</i> indicates that no limit is set. Valid values: $[0.0, 1.0]$.
minNumObj	Optional. The minimum number of samples per leaf node.
inputTableName	The name of the input table for training.
weightColName	Optional. The name of the weight column selected from the input table. If there is no weight column, set this parameter to <i>None</i> . If there is any weight column, the value of weightColName is greater than 0.
treeNum	The number of trees. Valid values: (0, 1000).

4.4.6.2.4. Naive Bayes

Naive Bayes classifier is a simple probabilistic classifier based on applying Bayes theorem with strong independence assumptions between the features. A probabilistic model that can more accurately describe this potential is called an independent feature model.

Component description

Component parameter settings (For more information, see the description of the Random Forest component.)

PAI command

```
PAI -name NaiveBayes
  -project algo_public
  -DmodelName="xlab_m_NaiveBayes_23772"
  -DinputTablePartitions="pt=20150501"
  -DlabelColName="poutcome"
  -DfeatureColNames="age,previous,cons_conf_idx,euribor3m"
  -DisFeatureContinuous="1,1,1,1"
  -DinputTableName="bank_data_partition";
```

Parameters

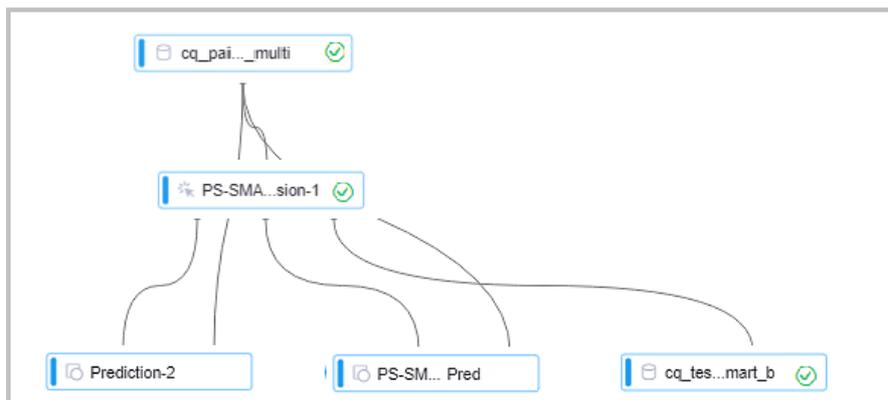

Parameter	Description
name	The name of the component.

Parameter	Description
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
modelName	The name of the model generated by training.
inputTablePartitions	Optional. The partitions selected from the input prediction table. If no partitions are specified, the entire table is selected.
labelColName	The name of the label column selected from the input table.
featureColNames	The names of feature columns selected from the input table for training.
isFeatureContinuous	Specifies whether the feature for subsequent columns is continuous or discrete. 1 indicates that the feature column data is continuous, while 0 indicates that the feature column data is discrete. 1,0,0 indicates that values are continuous in the first feature column and discrete in the second and third feature columns. The number of values corresponds to the feature length.
inputTableName	The name of the input table.

4.4.6.2.5. PS-SMART multiclass classification

A **parameter server** (PS) is used to train a large number of models online and offline. Scalable Multiple Additive Regression Tree (SMART) is an implementation of Gradient Boosting Decision Tree (GBDT) on PS. PS-SMART can run training tasks containing up to tens of billions of samples and hundreds of thousands of features on thousands of nodes. It also supports failover for high stability. PS-SMART supports various data formats, training targets, evaluation targets, output feature importance, and histogram approximation for training acceleration.

Quick start

As shown in the figure, a PS-SMART multiclass classification model is learned based on training data. The model has three output ports:

- Output model: offline model, which is connected to the unified prediction component. This model does not support the output of leaf node numbers.
- Output model table: a binary table that is not readable and is used to support the PS-SMART prediction component. The table provides outputs such as leaf node numbers and assessment metrics. However, the output table has strict requirements on data formats, which negatively affects user experience. This component is being continually improved, and may be replaced by another component in the future.

- Output feature importance table: lists the importance of each feature. Three importance types are supported. For more information, see [Parameters](#).

PAI command

- Training

```
PAI -name ps_smart
  -project algo_public
  -DinputTableName="smart_multiclass_input"
  -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
  -DoutputTableName="pai_temp_24515_545859_2"
  -DoutputImportanceTableName="pai_temp_24515_545859_3"
  -DlabelColName="label"
  -DfeatureColNames="features"
  -DenableSparse="true"
  -Dobjective="multi:softprob"
  -Dmetric="mlogloss"
  -DfeatureImportanceType="gain"
  -DtreeCount="5";
  -DmaxDepth="5"
  -Dshrinkage="0.3"
  -DL2="1.0"
  -DL1="0"
  -Dlifecycle="3"
  -DsketchEps="0.03"
  -DsampleRatio="1.0"
  -DfeatureRatio="1.0"
  -DbaseScore="0.5"
  -DminSplitLoss="0"
```

- Prediction

```
PAI -name prediction
  -project algo_public
  -DinputTableName="smart_multiclass_input";
  -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
  -DoutputTableName="pai_temp_24515_545860_1"
  -DfeatureColNames="features"
  -DappendColNames="label,features"
  -DenableSparse="true"
  -DkvDelimiter=":"
  -Dlifecycle="28"
```

Parameters

- Data parameters

Command option	Parameter	Description	Valid values	Remarks
----------------	-----------	-------------	--------------	---------

Command option	Parameter	Description	Valid values	Remarks
featureColNames	Feature Column	The names of feature columns selected from the input table for training.	If the column name is in dense format, it must be of the bigint or double type. If the column name is in sparse KV format, it must be a string, and its keys and values must be numeric.	Required
labelColName	Label Column	The name of the label column selected from the input table.	The column name can be of either string or numeric type, but only numeric data can be stored in the columns. For multiclass classification, column values can be 0, 1, 2, ..., n-1, where n is the number of classes.	Required
weightCol	Weight Column	This column specifies the weight of each sample.	The column name can be of the numeric type.	Optional. Default value: null.
enableSparse	Use Sparse Format	This parameter specifies whether the data in the input table is in sparse format, in which key-value pairs are separated by spaces whereas keys and values are separated by colons (:), for example, 1:0.3 3:0.9.	true, false	Optional. Default value: false.
inputTableName	Input Table Name	N/A	N/A	Required
modelName	Output Model Name	N/A	N/A	Required
outputImportanceTableName	Output Feature Importance Table Name	N/A	N/A	Optional. Default value: null.

Command option	Parameter	Description	Valid values	Remarks
inputTablePartitions	Input Table Partitions	N/A	N/A	Optional. The parameter value must be in ds=1/pt=1 format.
outputTableName	Output Model Table	The output table is a MaxCompute table that uses the binary format and is not readable. The prediction component that comes with SMART can be used to generate leaf node numbers.	String	Optional
lifecycle	Output Table Lifecycle	N/A	Positive integer	Optional. Default value: 3.

- Algorithm parameters

Command option	Parameter	Description	Valid values	Remarks
classNum	Classes	The number of classes in multiclass classification. If the number of classes is n, the label column name can be 0, 1, 2, ..., or n-1.	A non-negative integer, greater than or equal to 3.	Required
objective	Objective Function Type	The objective function type affects learning and must be selected properly. Set it to multi:softprob for multiclass classification.	N/A	Required
metric	Evaluation Indicator Type	Evaluation indicators in the training set, which are exported to stdout of the coordinator in a logview.	mloglossmerror	Optional. Default value: null.

Command option	Parameter	Description	Valid values	Remarks
treeCount	Trees	The number of trees. The training time is proportional to this number.	Positive integer	Optional. Default value: 1.
maxDepth	Maximum Decision Tree Depth	The maximum depth of a tree. We recommend that you set this value to 5, which means the tree can contain up to 32 leaf nodes.	A positive integer in the range of [1, 20].	Optional. Default value: 5.
sampleRatio	Data Sampling Fraction	The data sampling rate when trees are built. The sample data is used to build a weak learner to accelerate training.	(0, 1]	Optional. The default value is 1.0, which means data sampling is disabled.
featureRatio	Feature Sampling Fraction	The feature sampling rate when trees are built. The sample features are used to build a weak learner to accelerate training.	(0, 1]	Optional. The default value is 1.0, which means feature sampling is disabled.
l1	L1 Penalty Coefficient	This parameter determines the number of leaf nodes. The greater the value, the fewer the leaf nodes. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 0.
l2	L2 Penalty Coefficient	This parameter determines the size of a leaf node. The greater the value, the more evenly the leaf nodes are distributed. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 1.0.

Command option	Parameter	Description	Valid values	Remarks
shrinkage	Learning Rate	N/A	(0, 1]	Optional. Default value: 0.3.
sketchEps	Sketch-based Approximate Precision	The threshold for selecting quantiles when you build a sketch. The number of buckets is $O(1.0/sketchEps)$. The smaller the parameter value, the more buckets are generated. Typically, you do not need to modify this value.	(0, 1)	Optional. Default value: 0.03.
minSplitLoss	Minimum Split Loss	The minimum split loss changes required for splitting a node. The greater the value, the more conservatively the node splits.	Non-negative real number	Optional. Default value: 0.
featureNum	Features	The number of features or the maximum feature ID. Specify this parameter for resource usage estimation.	Positive integer	Optional
baseScore	Global Offset	Original predicted values of all samples.	Real number	Optional. Default value: 0.5.
featureImportance Type	Feature Importance Type	The type of feature importance. weight indicates the number of times that a feature splits. gain indicates information gain brought by the feature. cover indicates the number of samples that the feature covers on the splitting nodes.	weight , gain , and cover	Optional. Default value: gain .

- Note

- Specify different values for the objective parameter in different learning models. On the multiclass classification Web GUI, the objective function is automatically specified and invisible to users. On the command line, set the objective parameter to `multi:softprob`.
- Mappings between metrics and objective functions are: `mlogloss` for **multiclass negative log likelihood**, and `merror` for **multiclass classification error**.

- Execution optimization

Command option	Parameter	Description	Valid values	Remarks
coreNum	Cores	The number of cores. The greater the value, the faster the computing algorithm runs.	Positive integer	Optional. Automatically calculated.
memSizePerCore	Memory Size per Core (MB)	The memory size of each core, where 1024 represents 1 GB of memory.	Positive integer	Optional. Automatically calculated.

Example

- Data generation

The following example uses data in sparse KV format.

```
drop table if exists smart_multiclass_input;
create table smart_multiclass_input lifecycle 3 as
select
*
from
(
select 2 as label, '1:0.55 2:-0.15 3:0.82 4:-0.99 5:0.17' as features from dual
union all
select 1 as label, '1:-1.26 2:1.36 3:-0.13 4:-2.82 5:-0.41' as features from dual
union all
select 1 as label, '1:-0.77 2:0.91 3:-0.23 4:-4.46 5:0.91' as features from dual
union all
select 2 as label, '1:0.86 2:-0.22 3:-0.46 4:0.08 5:-0.60' as features from dual
union all
select 1 as label, '1:-0.76 2:0.89 3:1.02 4:-0.78 5:-0.86' as features from dual
union all
select 1 as label, '1:2.22 2:-0.46 3:0.49 4:0.31 5:-1.84' as features from dual
union all
select 0 as label, '1:-1.21 2:0.09 3:0.23 4:2.04 5:0.30' as features from dual
union all
select 1 as label, '1:2.17 2:-0.45 3:-1.22 4:-0.48 5:-1.41' as features from dual
union all
select 0 as label, '1:-0.40 2:0.63 3:0.56 4:0.74 5:-1.44' as features from dual
union all
select 1 as label, '1:0.17 2:0.49 3:-1.50 4:-2.20 5:-0.35' as features from dual
) tmp;
```

The data has five dimensions of features.

- Training

Configure the training data and training components, as shown in [Quick start](#). Select the label column as the target column and the features column as the feature column.

- You do not need to set the number of features because this number is calculated automatically by the algorithm. If you have a large number of features and want the algorithm to accurately estimate required resources, specify the actual number of features.
- To accelerate the training, set the number of cores on the execution optimization page. The greater the number, the faster the algorithm runs. Typically, you do not need to enter the memory size per core because the algorithm can accurately calculate the memory size. The PS algorithm starts to run only when all hosts have obtained the required resources. Therefore, you may need to wait for a longer time when the cluster is busy and resources are requested in large volumes.
- You can view the output values of the metrics in the stdout of the coordinator in a logview (HTTP link starting with <http://logview.odps.aliyun-inc.com:8080/logview>). A single PS-SMART training job can contain multiple tasks, which creates multiple logviews. Select the logview whose name starts with PS to view the output of the PS job.

Then, perform operations in the logview.

- Prediction

- Use the unified prediction component

The model generated after training is saved in binary format and can be used for prediction. Configure the input model and test data for the prediction component, as shown in [Quick start](#).

If the dense format is used, you only need to select feature columns. (All columns are selected by default, and extra columns do not affect the prediction.) If the KV format is used, set the data format to sparse format and select the correct delimiter. In the SMART model, key-value pairs are separated with spaces. Therefore, the delimiter must be set to space or `\u0020` (escape expression of spaces).

In the `prediction_detail` column, values 0, 1, and 2 indicate classes, and the values following them indicate probabilities of the corresponding classes. The `predict_result` column lists the selected classes with the highest probability, and the `predict_score` column lists the probability of each selected class.

- Use the PS-SMART prediction component

The output model table obtained after training is saved in binary format and can be used by the PS-SMART prediction component for prediction. Configure the input model and test data for the prediction component, as shown in [Quick start](#). Set the required parameters, including the data format, feature columns, target column, and number of classes. The ID column can only be a string type column other than a feature column or a target column. The loss function must be explicitly set to **multi:softprob**.

The **score_class_k** columns list probabilities of class k. The class with the highest probability is the predicted class. The **leaf_index** column lists the predicted leaf node numbers. Each sample has $N \times M$ numbers, where N is the number of decision trees, and M is the number of classes. In this example, each sample has 15 numbers ($5 \times 3 = 15$). Each tree is mapped to a number, which indicates the leaf node number of the sample on this tree.

Note

- The output model table is a binary table that is not readable and is used to support the PS-SMART prediction component. The table provides outputs such as leaf node numbers and evaluation indicators. However, the output table has strict requirements on data formats, which negatively affects user experience. This component is being continually improved, and may be replaced by another component in the future.
- A string type column must be selected as the label column. You can enter strings in the column but cannot be blank or NULL. A feature column can be converted to the string type by using the data type conversion component.
- The loss function must be explicitly set to **multi:softprob**. By default, the loss function does not work.

- View feature importance

To view feature importance, you can export the third output port to an output table, or right-click **PS-SMART training component** and choose **View Data > Output Feature Importance Table** from the shortcut menu. The following figure shows the output feature importance table.

order ▲	id ▲	value ▲
1	1	0.276059627532959
2	3	0.20854459702968597
3	4	0.31002077460289
4	5	0.20537501573562622

In the table, the ID column lists the numbers of input features. In this example, the data is in KV format, and the IDs represent keys in key-value pairs. If the dense format is used and input features are **f0,f1,f2,f3,f4,f5**, ID 0 represents f0 and ID 4 represents f4. Each value indicates a feature importance type. The default value is **gain**, indicating the sum of information gains brought by a feature in the model. The preceding figure shows only four features because only these four features are used during the tree split process. In this case, the importance of unused features is 0.

FAQ

- Q: Does PS_SMART support non-numerical features and tags?
- A: No.
- Q: What is the scale of features supported by PS-SMART? Can we use large-scale 0-1 features?
- A: Although PS-SMART supports tasks that contain hundreds of thousands of features, such tasks consume large amounts of resources and run slowly. Therefore, we recommend that you do not use a large number of features. The GBDT algorithm is suitable for training with continuous features. The categorical features require one-hot coding (to filter out infrequent features) before they can be used for training. The

continuous numerical features can be used for training with the GBDT algorithm directly. Discretization is not recommended for numerical features.

- Q: Why is the result different every time although the SMART algorithm has the same data and the same parameter settings?
- A: The PS-SMART algorithm applies randomness in many scenarios. For example, the `data_sample_ratio` and `fea_sample_ratio` items introduce data and feature sampling respectively. In addition, the PS-SMART algorithm uses histograms to show similarity. When multiple workers run in a cluster in distributed mode, local sketches are merged to global sketches in a random order. Although different merging orders result in different tree structures, this does not introduce too much variation to the output model. Therefore, it is normal situation to obtain different results after the algorithm runs multiple times with the same data and same parameter settings.

 Note

- The target column in a PS-SMART multiclass classification model supports only positive integer IDs (class numbers are 0, 1, 2, ..., n-1, where n is the number of classes). Even if the values in the MaxCompute table are strings, they are saved as numerical values. If the classification target is a type string similar to **Good**, **Medium**, or **Bad**, convert it into a numeric value (0, 1, 2, ..., n-1).
- In the key-value format, feature IDs must be positive integers, and feature values must be real numbers. If feature IDs are strings, use the serialization component to serialize them. If the feature values are classification type strings, perform feature engineering, such as discretization.

4.4.6.3. K-means clustering

K-means clustering is a widely used algorithm that is used to divide n objects into k clusters while maintaining high similarity within each cluster. Similarity is calculated based on the average value of objects in a cluster. This algorithm is similar to the expectation maximization algorithm for calculating mixed normality distribution, as both algorithms try to find the natural clustering center in data. K-means clustering randomly selects k objects. Each object represents the average value or center of a cluster. Based on its distance from each cluster center, each remaining object is then assigned to the nearest cluster and the average value of each cluster is re-calculated. This process is repeated until the criterion function converges. This algorithm assumes that object properties are from the spatial vector. Its objective is to minimize the sum of the mean square deviance inside each group.

Parameter settings

Parameters

Parameter	Description
Clusters	The number of clusters. Default value: 10.
Distance Measurement Method	Valid values: <i>euclidean</i> , <i>cityblock</i> (the sum of absolute deviations), and <i>cosine</i> . Default value: euclidean.
Initial Centroid Location	Valid values: <i>sample</i> (randomly selected), <i>topk</i> (first K rows), <i>uniform</i> (evenly distributed and randomly generated), <i>matrix</i> (an initial centroid table must be specified), and <i>kmpp</i> (k-means++ initialization). Default value: sample.
Maximum Iterations	The maximum number of iterations. Default value: 100.
Minimum Iteration Precision	The minimum iteration precision. Default value: 0.0.

Procedure

1. After running the K-means Clustering component, you can view the cluster center table.
 Cluster center table: The number of columns in this table is equal to the total number of columns selected from the input table. The number of rows is equal to the number of clusters, with each row representing a cluster center location.
2. Right-click the target table and choose **View Data** to view the cluster index table (idxTablename).
 - o Cluster index table: The number of rows is equal to the total number of rows in the input table. The value in each row represents the cluster index of the point in the corresponding row of the input table.
 - o The names of all columns are displayed. A classification marking column is appended to the table.
 - o 0, 1, 2, 3 are classification IDs.
 - o You can also use the table name generated by PAI command to view the cluster center table, cluster index table, and cluster count table in IDE.

 **Note** If *matrix* is selected as the initial centroid location, you must define the initial centroid table, with the same columns as the original table. The number of rows is the same as the number of clusters. When you prepare the table, configure k centers and use SQL or MapReduce for sampling, or select another method based on your requirements.

PAI command

```
PAI -name KMeans
-project algo_public
-DcenterCount="10"
-DidxTableName="bank_data_index"
-DdistanceType="euclidean"
-DappendColsIndex="0,1,2,3,4,5,6,7,8,9,10"
-DcenterTableName="pai_temp_3300_27298_3"
-Dloop="100"
-DclusterCountTableName="pai_temp_3300_27298_2"
-DinitCentersMethod="sample"
-Daccuracy="0.0"
-DinputTableName="bank_data"
-DselectedColNames="cons_conf_idx,emp_var_rate,euribor3m,pdays,previous";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
centerCount	The number of clusters. The value must be an integer. Default value: 10.
idxTableName	The name of the output cluster index table. The number of rows is equal to the total number of rows in the input table. The value in each row represents the cluster index of the point in the corresponding row of the input table.
distanceType	Optional. The method used to measure the distance. Valid values: euclidean, cityblock, and cosine. Default value: euclidean.

Parameter	Description
<code>appendColsIndex</code>	Optional. The name of the ID column appended to the output table. No ID column is appended to the output table by default.
<code>centerTableName</code>	The name of the output cluster center table. The number of columns in this table is equal to the total number of columns selected from the input table. The number of rows is equal to the number of clusters, with each row representing a cluster center location.
<code>loop</code>	Optional. The maximum number of iterations. The value must be an integer. Default value: 100.
<code>clusterCountTableName</code>	The name of the cluster point count table. The number of rows is equal to the number of clusters, which indicates the total number of cluster points in the class in each clustering centroid row.
<code>initCentersMethod</code>	Optional. The method used to determine the initial centroid location. The options include <code>sample</code> (randomly selected), <code>topk</code> (first K rows), <code>uniform</code> (evenly distributed and randomly generated), <code>matrix</code> (an initial centroid table must be specified), and <code>kmpp</code> (k-means++ initialization). Default value: <code>sample</code> .
<code>accuracy</code>	The minimum iteration precision. Default value: 0.0.
<code>inputTableName</code>	The name of the input table.
<code>selectedColNames</code>	The names of columns selected from the input table, which are separated with commas (.). Only double type is supported.
<code>initCenterTableName</code>	Optional. The name of the table that stores the initial center values. This table is not required unless <code>initCentersMethod</code> is set to <code>matrix</code> .

4.4.6.4. Regression

4.4.6.4.1. GBDT regression

Gradient boosting decision tree (GBDT) is an iterative decision tree algorithm based on multiple decision trees. The final output is the sum of conclusions of all trees. GBDT can be applied to almost all regression models (linear or nonlinear) and has a wider scope of application than logistic regression that is only applicable to linear regression.

For more information, see [A Regression Framework for Learning Ranking Functions Using Relative Relevance Judgments](#). For more information, see [GBDT binary classification](#).

PAI command

```

PAI -name gbdt
-project algo_public
-DfeatureSplitValueMaxSize="500"
-DlossType="0"
-DrandSeed="0"
-DnewtonStep="0"
-Dshrinkage="0.05"
-DmaxLeafCount="32"
-DlabelColName="campaign"
-DinputTableName="bank_data_partition"
-DminLeafSampleCount="500"
-DsampleRatio="0.6"
-DgroupIDColName="age"
-DmaxDepth="11"
-DmodelName="xlab_m_GBDT_83602"
-DmetricType="2"
-DfeatureRatio="0.6"
-DinputTablePartitions="pt=20150501"
-Dtau="0.6"
-Dp="1"
-DtestRatio="0.0"
-DfeatureColNames="previous,cons_conf_idx,euribor3m"
-DtreeCount="500"
  
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
featureColNames	Optional. The names of feature columns selected from the input table for training.	Column name	All columns are selected by default.
labelColName	Optional. The name of the label column selected from the input table.	Column name	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of <code>partition_name=value</code> . To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	-	All partitions are selected by default.
modelName	Required. The name of the output model.	-	-

Parameter	Description	Valid values	Default value
outputImportanceTableName	Optional. The name of the output feature importance table.	-	-
groupIDColName	Optional. The name of the stratification column.	Column name	The whole table is selected by default.
lossType	Optional. The loss function type. The function types include 0: <i>GBRANK</i> , 1: <i>LAMBDA MART_DCG</i> , 2: <i>LAMBDA MART_NDCG</i> , 3: <i>LEAST_SQUARE</i> , and 4: <i>LOG_LIKELIHOOD</i> .	0, 1, 2, 3, and 4	0
metricType	Optional. The type of metrics. 0 (<i>NDCG</i>) indicates the normalized discounted cumulative gain, 1 (<i>DCG</i>) indicates the discounted cumulative gain, and 2 (<i>AUC</i>) is applicable only to 0/1 label.	0, 1, and 2	2
treeCount	Optional. The number of trees.	[1, 10000]	500
shrinkage	Optional. The learning rate.	(0, 1]	0.05
maxLeafCount	Optional. The maximum number of leaves. This value must be an integer.	[2, 1000]	32
maxDepth	Optional. The maximum depth of a tree. This value must be an integer.	[1, 11]	11
minLeafSampleCount	Optional. The minimum number of samples on a leaf node. This value must be an integer.	[100, 1000]	500
sampleRatio	Optional. The fraction of training samples.	(0, 1]	0.6
featureRatio	Optional. The fraction of training features.	(0, 1]	0.6
tau	Optional. The Tau parameter in gbrank loss.	[0, 1]	0.6
p	Optional. The p parameter in gbrank loss.	[1, 10]	1

Parameter	Description	Valid values	Default value
randSeed	Optional. The random seed.	[0, 10]	0
newtonStep	Optional. This parameter specifies whether to use the Newton method.	0 and 1	1
featureSplitValueMaxSize	Optional. The maximum number of splits per feature.	[1, 1000]	500
lifecycle	Optional. The lifecycle of the output table.	-	No lifecycle is set by default.

Examples

SQL statement to generate data:

```
drop table if exists gbdt_ls_test_input;
create table gbdt_ls_test_input as select * from (
select  cast(1 as double) as f0,
        cast(0 as double) as f1,
        cast(0 as double) as f2,
        cast(0 as double) as f3,
        cast(0 as bigint) as label from dual union all
select  cast(0 as double) as f0,
        cast(1 as double) as f1,
        cast(0 as double) as f2,
        cast(0 as double) as f3,
        cast(0 as bigint) as label from dual union all
select  cast(0 as double) as f0,
        cast(0 as double) as f1,
        cast(1 as double) as f2,
        cast(0 as double) as f3,
        cast(1 as bigint) as label from dual union all
select  cast(0 as double) as f0,
        cast(0 as double) as f1,
        cast(0 as double) as f2,
        cast(1 as double) as f3,
        cast(1 as bigint) as label from dual union all
select  cast(1 as double) as f0,
        cast(0 as double) as f1,
        cast(0 as double) as f2,
        cast(0 as double) as f3,
        cast(0 as bigint) as label from dual union all
select  cast(0 as double) as f0,
        cast(1 as double) as f1,
        cast(0 as double) as f2,
        cast(0 as double) as f3,
        cast(0 as bigint) as label from dual ) a;
```

PAI command

- Training:

4.4.6.4.2. Linear regression

This component is used to resolve regression issues and analyze the linear relationship between a dependent variable and multiple independent variables. Certain columns from an input table are selected as feature columns and one column is selected as the label column for linear regression training and linear regression model generation.

PAI command

```
PAI -name linearregression
  -project algo_public
  -DinputTableName=lm_test_input
  -DfeatureColNames=x
  -DlabelColName=y
  -DmodelName=lm_test_input_model_out;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
modelName	Required. The name of the output model.	-	-
outputTableName	Optional. The name of the output model evaluation table.	This parameter must be specified when enableFitGoodness is set to <i>true</i> .	-
labelColName	Required. The name of the label column.	The name must be a double or bigint type value. Only one column can be specified.	-

Parameter	Description	Valid values	Default value
featureColNames	Required. The name of the feature column.	The name must be a double or bigint type value in dense format, or a string type value in sparse format. Multiple columns can be specified.	-
inputTablePartitions	Optional. The partitions selected from the input table for training.	-	No partitions are selected by default.
maxIter	Optional. The maximum number of iterations.	-	100
epsilon	Optional. The minimum likelihood deviance.	-	0.000001
enableSparse	Optional. This parameter specifies whether the data is in sparse format.	true and false	false
enableFitGoodness	Optional. This parameter specifies whether to perform model evaluation. Model evaluation can be performed using a variety of metrics, including R-squared, adjusted R-Squared, Akaike information criterion, degrees of freedom, residual standard deviation, and deviation.	true and false	false
enableCoefficientEstimate	Optional. This parameter specifies whether to estimate the regression coefficient. The metrics of this parameter are value t, value p, and confidence interval [2.5%, 97.5%]. This parameter takes effect only when enableFitGoodness is set to <i>true</i> . This parameter is ignored when enableFitGoodness is set to <i>false</i> .	true and false	false
itemDelimiter	Optional. The delimiter used to separate key-value pairs. This parameter takes effect only when enableSparse is set to <i>true</i> .	-	Use spaces on command lines and use commas (,) on webpages.

Parameter	Description	Valid values	Default value
kvDelimiter	Optional. The delimiter used to separate keys and values. This parameter takes effect only when enableSparse is set to <i>true</i> .	-	The default delimiter is a colon (:).
lifecycle	Optional. The lifecycle of the output table.	An integer greater than or equal to -1	Default value: -1. This value indicates that no lifecycle is set.
coreNum	Optional. The number of cores.	An integer larger than 0	Default value: -1. This value indicates that the number of instances is determined by the amount of input data.
memSizePerCore	Optional. The memory size of each core.	(100, 65536)	Default value: -1. This value indicates that the memory size is determined by the amount of input data.

Examples

- SQL statement to generate data:

```
drop table if exists lm_test_input;
create table lm_test_input as
select
*
from
(
select 10 as y, 1.84 as x1, 1 as x2, '0:1.84 1:1' as sparsecol1 from dual
union all
select 20 as y, 2.13 as x1, 0 as x2, '0:2.13' as sparsecol1 from dual
union all
select 30 as y, 3.89 as x1, 0 as x2, '0:3.89' as sparsecol1 from dual
union all
select 40 as y, 4.19 as x1, 0 as x2, '0:4.19' as sparsecol1 from dual
union all
select 50 as y, 5.76 as x1, 0 as x2, '0:5.76' as sparsecol1 from dual
union all
select 60 as y, 6.68 as x1, 2 as x2, '0:6.68 1:2' as sparsecol1 from dual
union all
select 70 as y, 7.58 as x1, 0 as x2, '0:7.58' as sparsecol1 from dual
union all
select 80 as y, 8.01 as x1, 0 as x2, '0:8.01' as sparsecol1 from dual
union all
select 90 as y, 9.02 as x1, 3 as x2, '0:9.02 1:3' as sparsecol1 from dual
union all
select 100 as y, 10.56 as x1, 0 as x2, '0:10.56' as sparsecol1 from dual
) tmp;
```

- PAI command

```
PAI -name linearregression
  -project algo_public
  -DinputTableName=lm_test_input
  -DlabelColName=y
  -DfeatureColNames=x1,x2
  -DmodelName=lm_test_input_model_out
  -DoutputTableName=lm_test_input_conf_out
  -DenableCoefficientEstimate=true
  -DenableFitGoodness=true
  -Dlifecycle=1;
pai -name prediction
  -project algo_public
  -DmodelName=lm_test_input_model_out
  -DinputTableName=lm_test_input
  -DoutputTableName=lm_test_input_predict_out
  -DappendColNames=y;
```

- Output description:
 - When enableFitGoodness is set to *true*, partitions specified by `p='goodness'` are created in the model evaluation table. The output metrics are *R-squared*, *adjusted R-Squared*, *Akaike information criterion*, *degrees of freedom*, *residual standard deviation*, and *deviation*.
 - When enableCoefficientEstimate is set to *true*, partitions specified by `p='coefficient'` are created in the model evaluation table. The table contains the intercepts and the *name*, *coefficient*, *t-score*, *p-value*, and *confidence interval [2.5%, 97.5%]* of the features.

o Output model evaluation table: `lm_test_input_conf_out`.

4.4.6.4.3. PS linear regression

Linear regression is a classic regression algorithm used to analyze the linear relationship between a dependent variable and multiple independent variables. Parameter servers (PSs) are used to run large amounts of training tasks online and offline. Parameter servers can use hundreds of billions of samples to efficiently train billions of feature models. The PS linear regression model can run training tasks with hundreds of billions of samples and billions of features, and supports L1 and L2 regular expressions.

Quick start

PAI command

- Training

```
PAI -name ps_linearregression  
-project algo_public  
-DinputTableName="lm_test_input"  
-DmodelName="linear_regression_model"  
-DlabelColName="label"  
-DfeatureColNames="features"  
-DL1Weight=1.0  
-DL2Weight=0.0  
-DmaxIter=100  
-Depsilon=1e-6  
-DenableSparse=true
```

- Prediction

```
drop table if exists logistic_regression_predict;
PAI -name prediction
-DmodelName="linear_regression_model"
-DoutputTableName="linear_regression_predict"
-DinputTableName="lm_test_input"
-DdependColNames="label,features"
-DfeatureColNames="features"
-DenableSparse=true
```

Parameters

- Data parameters

Command option	Parameter	Description	Valid values	Default value
featureColNames	Feature Columns	Required. The names of feature columns selected from the input table for training.	If a column name is in dense format, it must be of the bigint or double type. If the column name is in sparse KV format, it must be a string.	-
labelColName	Label Column	Required. The name of the label column selected from the input table.	The column name must be of the bigint or double type.	-
enableSparse	Use Sparse Format	Optional. If you choose to use the sparse KV format, do not use feature ID 0. We recommend that the feature IDs start from 1.	true and false	false
itemDelimiter	KV Pair Delimiter	Optional. The delimiter used to separate key-value pairs when data in the input table is in sparse format.	Symbol	The default delimiter is a space.
kvDelimiter	KV Delimiter	Optional. The delimiter used to separate keys and values when data in the input table is in sparse format.	Symbol	The default delimiter is a colon (:).
inputTableName	Input Table Name	Required.	Table name	-
modelName	Output Model Name	Required.	Model name	-

Command option	Parameter	Description	Valid values	Default value
inputTablePartitions	Input Table Partitions	Optional.	Partition name	The parameter value must be in the ds=1/pt=1 format.
enableModello	Output to Offline Model	Optional. When this parameter is set to false, the data is output to a MaxCompute table where you can view model weights.	true and false	true

• **Algorithm parameters**

Command option	Parameter	Description	Valid values	Default value
l1Weight	L1 Weight	Optional. The L1 regularization coefficient. The larger this value is, the fewer non-zero elements a model has. To overfit the model, set this parameter to a larger value.	A non-negative real number	1.0
l2Weight	L2 Weight	Optional. The L2 regularization coefficient. The larger this value is, the smaller the absolute values of the model parameters are. To overfit the model, set this parameter to a larger value.	A non-negative real number	0
maxIter	Maximum Iterations	Optional. The maximum number of LBFGS/OWL-QN iterations. Value 0 indicates that no limit is set.	A non-negative integer	100

Command option	Parameter	Description	Valid values	Default value
epsilon	Minimum Convergence Deviance	Optional. The mean of the relative loss change rates in ten iterations, which is used as a condition to determine whether to terminate the optimization algorithm. The smaller this value is, the stricter the condition is, and the longer the algorithm runs.	A real number between 0 and 1	1.0e-06
modelSize	Largest Feature ID	Optional. The largest feature ID among all feature IDs (feature dimension). It can be larger than the actual largest feature ID. The larger this value is, the higher the memory usage is. If you leave this parameter empty, the system starts an SQL task to calculate the largest feature ID automatically.	A non-negative integer	0

 **Note** Both the maximum iterations and minimum convergence deviance determine when the algorithm stops. If both parameters are set, the algorithm stops when one of the conditions is met.

- **Execution optimization**

Command option	Parameter	Description	Valid values	Default value
coreNum	Cores	Optional. The number of cores. The larger this value is, the faster the computing algorithm runs.	A positive integer	Automatically allocated.

Command option	Parameter	Description	Valid values	Default value
<code>memSizePerCore</code>	Memory Size per Core (MB)	Optional. The memory size of each core, where 1024 represents 1 GB of memory.	A positive integer	Automatically allocated. Typically, you do not need to set this parameter because the algorithm can accurately estimate the memory size required.

Examples

- **Data generation**

The following example uses data in sparse KV format:

```
drop table if exists lm_test_input;
create table lm_test_input as
select
*
from
(
select 2 as label, '1:0.55 2:-0.15 3:0.82 4:-0.99 5:0.17' as features from dual
union all
select 1 as label, '1:-1.26 2:1.36 3:-0.13 4:-2.82 5:-0.41' as features from dual
union all
select 1 as label, '1:-0.77 2:0.91 3:-0.23 4:-4.46 5:0.91' as features from dual
union all
select 2 as label, '1:0.86 2:-0.22 3:-0.46 4:0.08 5:-0.60' as features from dual
union all
select 1 as label, '1:-0.76 2:0.89 3:1.02 4:-0.78 5:-0.86' as features from dual
union all
select 1 as label, '1:2.22 2:-0.46 3:0.49 4:0.31 5:-1.84' as features from dual
union all
select 0 as label, '1:-1.21 2:0.09 3:0.23 4:2.04 5:0.30' as features from dual
union all
select 1 as label, '1:2.17 2:-0.45 3:-1.22 4:-0.48 5:-1.41' as features from dual
union all
select 0 as label, '1:-0.40 2:0.63 3:0.56 4:0.74 5:-1.44' as features from dual
union all
select 1 as label, '1:0.17 2:0.49 3:-1.50 4:-2.20 5:-0.35' as features from dual
) tmp;
```

The feature IDs start from 1, and the maximum feature ID is 5.

- **Training**

Configure the training data and training components based on [Quick start](#). Select the label column as the target column and features column as the feature column. Then, select the sparse data format.

- You can retain the default value 0 for the largest feature ID. The algorithm can start an SQL task to calculate the largest feature ID automatically. If you do not want to start the SQL task, enter a value greater than 5. This value indicates the number of feature columns in dense format and indicates the largest feature ID in KV format.

- To accelerate the training, you can set the number of cores on the tuning page. The larger the number is, the faster the algorithm runs. Typically, you do not need to enter the memory size per core because the algorithm can accurately calculate the memory size. The PS algorithm starts to run only when all hosts have obtained the resources. Therefore, you may need to wait a longer period of time when the cluster is busy and resources are requested in large volume.

- **Prediction**

The model generated after training is saved in binary format and can be used for prediction. Configure the input settings (model and testing data) for the prediction component and set parameters based on [Quick start](#).

Select the KV format for training and set a correct delimiter. When the KV format is used, key-value pairs are separated by spaces. Therefore, the delimiter must be set to space or `\u0020` (the escape expression of space).

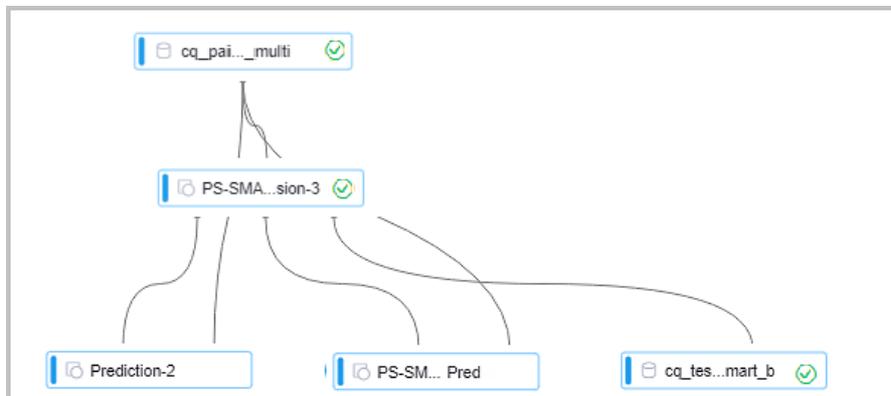

Restrictions and guidelines

In the key-value format, feature IDs must be positive integers, and feature values must be real numbers. If feature IDs are strings, use the serialization component to serialize them. If the feature values are classification type strings, perform feature engineering, such as discretization.

4.4.6.4.4. PS-SMART regression

A [parameter server](#) (PS) is used to train a large number of models online and offline. Scalable Multiple Additive Regression Tree (SMART) is an implementation of Gradient boosting decision tree (GBDT) on PS. PS-SMART can run training tasks containing up to tens of billions of samples and hundreds of thousands of features on thousands of nodes. It also supports failover for high stability. PS-SMART supports various data formats, training targets, evaluation targets, output feature importance, and histogram approximation for training acceleration.

Quick start

As shown in the figure, a PS-SMART regression model is learned based on training data. The model has three output ports:

- Output model: offline model, which is connected to the unified prediction component. This model does not support the output of leaf node numbers.
- Output model table: a binary table that is not readable and is used to ensure compatibility with the PS-SMART prediction component. The table provides outputs such as leaf node numbers and evaluation metrics. However, the output table has strict requirements on data formats, which negatively affects user experience. This component is being continually improved, and may be replaced by another component in the future.
- Output feature importance table: lists the importance of each feature. Three importance types are supported. For more information, see [Parameters](#).

PAI command

- Training

```
PAI -name ps_smart
  -project algo_public
  -DinputTableName="smart_regression_input"
  -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
  -DoutputTableName="pai_temp_24515_545859_2"
  -DoutputImportanceTableName="pai_temp_24515_545859_3"
  -DlabelColName="label"
  -DfeatureColNames="features"
  -DenableSparse="true"
  -Dobjective="reg:linear"
  -Dmetric="rmse"
  -DfeatureImportanceType="gain"
  -DtreeCount="5";
  -DmaxDepth="5"
  -Dshrinkage="0.3"
  -DI2="1.0"
  -DI1="0"
  -Dlifecycle="3"
  -DsketchEps="0.03"
  -DsampleRatio="1.0"
  -DfeatureRatio="1.0"
  -DbaseScore="0.5"
  -DminSplitLoss="0"
```

- Prediction

```
PAI -name prediction
  -project algo_public
  -DinputTableName="smart_regression_input";
  -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
  -DoutputTableName="pai_temp_24515_545860_1"
  -DfeatureColNames="features"
  -DappendColNames="label,features"
  -DenableSparse="true"
  -Dlifecycle="28"
```

Parameters

- Data parameters

Command option	Parameter	Description	Valid values	Remarks
featureColNames	Feature Column	The names of feature columns selected from the input table for training.	If the column name is in dense format, it must be of the bigint or double type. If the column name is in sparse KV format, it must be a string, and its keys and values must be numeric.	Required

Command option	Parameter	Description	Valid values	Remarks
labelColName	Label Column	The name of the label column selected from the input table.	The column name can be of either string or numeric type, but only numeric data can be stored in the columns. For example, the column value can be 0 or 1 for regression.	Required
weightCol	Weight Column	This column specifies the weight of each sample.	The column name can be of the numeric type.	Optional. Default value: null.
enableSparse	Use Sparse Format	This parameter specifies whether the data in the input table is in sparse format, in which key-value pairs are separated by spaces whereas keys and values are separated by colons (:), for example, 1:0.3 3:0.9 .	true, false	Optional. Default value: false.
inputTableName	Input Table Name	N/A	N/A	Required
modelName	Output Model Name	N/A	N/A	Required
outputImportanceTableName	Output Feature Importance Table Name	N/A	N/A	Optional. Default value: null.
inputTablePartitions	Input Table Partitions	N/A	N/A	Optional. The parameter value must be in ds=1/pt=1 format.
outputTableName	Output Model Table Name	The output table is a MaxCompute table that uses the binary format and is not readable. The prediction component that comes with SMART can be used to generate leaf node numbers.	String	Optional

Command option	Parameter	Description	Valid values	Remarks
lifecycle	Output Table Lifecycle	N/A	Positive integer	Optional. Default value: 3.

- Algorithm parameters

Command option	Parameter	Description	Valid values	Remarks
objective	Objective Function Type	The objective function type affects learning and must be selected properly. Multiple loss functions are available for regression. For more information, see the notes.		Required. The default type is Linear regression.
metric	Evaluation Indicator Type	Evaluation indicators in the training set, which must correspond to the objective function type and are exported to stdout of the coordinator in a logview. For more information, see the following notes and samples.		Optional. Default value: null.
treeCount	Trees	The number of trees. The training time is proportional to this number.	Positive integer	Optional. Default value: 1.
maxDepth	Maximum Decision Tree Depth	The maximum depth of a tree. We recommend that you set this value to 5, which means the tree can contain up to 32 leaf nodes.	A positive integer in the range of [1, 20]	Optional. Default value: 5.
sampleRatio	Data Sampling Fraction	The data sampling rate when trees are built. The sample data is used to build a weak learner to accelerate training.	(0, 1]	Optional. The default value is 1.0, which means data sampling is disabled.

Command option	Parameter	Description	Valid values	Remarks
featureRatio	Feature Sampling Fraction	The feature sampling rate when trees are built. The sample features are used to build a weak learner to accelerate training.	(0, 1]	Optional. The default value is 1.0, which means feature sampling is disabled.
l1	L1 Penalty Coefficient	This parameter determines the number of leaf nodes. The greater the value, the fewer the leaf nodes. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 0.
l2	L2 Penalty Coefficient	This parameter determines the size of a leaf node. The greater the value, the more evenly the leaf nodes are distributed. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 1.0.
shrinkage	Learning Rate	N/A	(0, 1]	Optional. Default value: 0.3.
sketchEps	Sketch-based Approximate Precision	The threshold for selecting quantiles when you build a sketch. The number of buckets is $O(1.0/sketchEps)$. The smaller the parameter value, the more buckets are generated. Typically, you do not need to change this value.	(0, 1)	Optional. Default value: 0.03.

Command option	Parameter	Description	Valid values	Remarks
minSplitLoss	Minimum Split Loss	The minimum split loss changes required for splitting a node. The greater the value, the more conservatively the node splits.	Non-negative real number	Optional. Default value: 0.
featureNum	Features	The number of features or the maximum feature ID. Specify this parameter for resource usage estimation.	Positive integer	Optional
baseScore	Global Offset	Original predicted values of all samples.	Real number	Optional. Default value: 0.5.
featureImportance Type	Feature Importance Type	The type of feature importance. weight indicates the number of times that a feature splits. gain indicates information gain brought by the feature. cover indicates the number of samples that the feature covers on the splitting nodes.	weight , gain , and cover	Optional. Default value: gain .
tweedieVarPower	Tweedie Distribution Index	Tweedie distribution index indicates the relationship between the variance and mean. For example, $\text{Var}(y) \sim E(y)^{\text{tweedie_variance_power}}$.	(1, 2)	Optional. Default value: 1.5.

- Note

- Specify different values for the objective parameter in different learning models. The regression Web GUI provides multiple objective functions.

reg:linear (Linear regression) // The range of label numbers is $(-\infty, +\infty)$.
 reg:logistic (Logistic regression) // The range of label numbers is $[0, 1]$.
 count:poisson (Poisson regression for count data, output mean of poisson distribution) // Label numbers must be greater than 0.
 reg:gamma (Gamma regression for modeling insurance claims severity, or for any outcome that might be [gamma-distributed](https://en.wikipedia.org/wiki/Gamma_distribution#Applications)) // Label numbers must be greater than 0.
 reg:tweedie (Tweedie regression for modeling total loss in insurance, or for any outcome that might be [Tweedie-distributed](https://en.wikipedia.org/wiki/Tweedie_distribution#Applications).) // Label numbers must be greater than or equal to 0.

- Metrics for these objective functions are:

rmse (rooted mean square error, corresponding to objective reg:linear)
 mae (mean absolute error, corresponding to objective reg:linear)
 poisson-nloglik (negative loglikelihood for poisson regression, corresponding to objective count:poisson)
 gamma-deviance (Residual deviance for gamma regression, corresponding to objective reg:gamma)
 gamma-nloglik (Negative log-likelihood for gamma regression, corresponding to objective reg:gamma)
 tweedie-nloglik (tweedie-nloglik@1.5, negative log-likelihood for Tweedie regression, at a specified value of the tweedie_variance_power parameter)

- Execution optimization

Command option	Parameter	Description	Valid values	Remarks
coreNum	Cores	The number of cores. The greater the value, the faster the computing algorithm runs.	Positive integer	Optional. Automatically allocated.
memSizePerCore	Memory Size per Core (MB)	The memory size of each core, where 1024 represents 1 GB of memory.	Positive integer	Optional. Automatically allocated.

Example

- Data generation

The following example uses data in sparse KV format.

```
drop table if exists smart_regression_input;
create table smart_regression_input as
select
*
from
(
select 2.0 as label, '1:0.55 2:-0.15 3:0.82 4:-0.99 5:0.17' as features from dual
union all
select 1.0 as label, '1:-1.26 2:1.36 3:-0.13 4:-2.82 5:-0.41' as features from dual
union all
select 1.0 as label, '1:-0.77 2:0.91 3:-0.23 4:-4.46 5:0.91' as features from dual
union all
select 2.0 as label, '1:0.86 2:-0.22 3:-0.46 4:0.08 5:-0.60' as features from dual
union all
select 1.0 as label, '1:-0.76 2:0.89 3:1.02 4:-0.78 5:-0.86' as features from dual
union all
select 1.0 as label, '1:2.22 2:-0.46 3:0.49 4:0.31 5:-1.84' as features from dual
union all
select 0.0 as label, '1:-1.21 2:0.09 3:0.23 4:2.04 5:0.30' as features from dual
union all
select 1.0 as label, '1:2.17 2:-0.45 3:-1.22 4:-0.48 5:-1.41' as features from dual
union all
select 0.0 as label, '1:-0.40 2:0.63 3:0.56 4:0.74 5:-1.44' as features from dual
union all
select 1.0 as label, '1:0.17 2:0.49 3:-1.50 4:-2.20 5:-0.35' as features from dual
) tmp;
```

Feature IDs are numbered starting from 1, and the maximum feature ID is 5.

- Training

Select the label column as the target column and the features column as the feature column.

- You do not need to set the number of features because this number is calculated automatically by the algorithm. If you have a large number of features and want the algorithm to accurately estimate the amount of required resources, specify the actual number of features.
- To accelerate the training, set the number of cores on the execution optimization page. The greater the number, the faster the algorithm runs. Typically, you do not need to enter the memory size per core because the algorithm can accurately calculate the memory size. The PS algorithm starts to run only when all hosts have obtained the required resources. Therefore, you may need to wait for a longer time when the cluster is busy and resources are requested in large volumes.
- You can view the output values of the metrics in the stdout of the coordinator in a logview (HTTP link starting with <http://logview.odps.aliyun-inc.com:8080/logview>). A single PS-SMART training job can contain multiple tasks, and therefore multiple logviews are created. Select the logview whose name starts with PS to view the output of the PS job.

- Prediction

- Use the unified prediction component

The model generated after training is saved in binary format and can be used for prediction. Configure the input model and test data for the prediction component, as shown in [Quick start](#).

If the dense format is used, you only need to select feature columns. (All columns are selected by default, and extra columns do not affect the prediction.) If the KV format is used, set the data format to sparse format and select the correct delimiter. In the SMART model, key-value pairs are separated with spaces. Therefore, the delimiter must be set to space or `\u0020` (escape expression of spaces).

- Use the PS-SMART prediction component

The output model table obtained after training is saved in binary format and can be used by the PS-SMART prediction component for prediction. Configure the input model and test data for the prediction component, as shown in [Quick start](#). Set the required parameters, including the data format, feature columns, target column, and number of classes. The ID column can only be a string type column other than a feature column or a target column. The loss function must be explicitly set to the objective function used for training.

The **prediction_score** column lists the predicted values. The **leaf_index** column lists the predicted leaf node numbers. Each sample has N numbers, where N is the number of decision trees. Each tree is mapped to a number, which indicates the leaf node number of the sample on this tree.

 Note

- The output model table is a binary table that is not readable and is used to support the PS-SMART prediction component. The table provides outputs such as leaf node numbers and evaluation indicators. However, the output table has strict requirements on data formats, which negatively affects user experience. This component is being continually improved, and may be replaced by another component in the future.
- A string type column must be selected as the label column. You can enter strings in the column but cannot be blank or NULL. A feature column can be converted to the string type by using the data type conversion component.
- The loss function must be explicitly set to the objective function used for training. By default, the loss function does not work.

- View feature importance

To view feature importance, you can export the third output port to an output table, or right-click **PS-SMART training component** and choose **View Data > Output Feature Importance Table** from the shortcut menu.

order ▲	id ▲	value ▲
1	1	0.14059734344482422
2	4	0.8594027161598206

In the table, the ID column lists the numbers of input features. In this example, the data is in KV format and the IDs represent keys in key-value pairs. If the dense format is used and input features are **f0,f1,f2,f3,f4,f5**, ID 0 represents f0, and ID 4 represents f4. Each value indicates a feature importance type. The default value is **gain**, indicating the sum of information gains brought by a feature in the model. The preceding figure shows only two features because only these two features are used during the tree split process. In this case, the importance of unused features is 0.

FAQ

- Q: Does PS_SMART support non-numerical features and tags?
- A: No.
- Q: What is the scale of features supported by PS-SMART? Can we use large-scale 0-1 features?
- A: Although PS-SMART supports tasks that contain hundreds of thousands of features, such tasks consume large amounts of resources and run slowly. Therefore, we recommend that you do not use a large number of features. The GBDT algorithm is suitable for training with continuous features. The categorical features require one-hot coding (to filter out infrequent features) before they can be used for training. The continuous numerical features can be used for training with the GBDT algorithm directly. Discretization is not recommended for numerical features.
- Q: Why is the result different every time although the SMART algorithm has the same data and the same

parameter settings?

- A: The PS-SMART algorithm applies randomness in many scenarios. For example, the `data_sample_ratio` and `fea_sample_ratio` items introduce data and feature sampling respectively. In addition, the PS-SMART algorithm uses histograms to show similarity. When multiple workers run in a cluster in distributed mode, local sketches are merged to global sketches in a random order. Although different merging orders result in different tree structures, this does not introduce too much variation to the output model. Therefore, it is normal situation to obtain different results after the algorithm runs multiple times with the same data and same parameter settings.

Note

- The target column in a PS-SMART regression model supports only numerical values. Even if values in the MaxCompute table are strings, they are saved as numerical values.
- In the key-value format, feature IDs must be positive integers, and feature values must be real numbers. If feature IDs are strings, use the serialization component to serialize them. If feature values are classification type strings, perform feature engineering, such as discretization.

4.4.6.5. Collaborative filtering (etrec)

etrec is an item-based collaborative filtering algorithm that takes two input columns and provides the top N items that have the highest similarity.

Set the user and item columns.

- You can configure three similarity types.
- topN indicates the first N items with the highest similarity.
- Calculation method: the method used to calculate items that appear multiple times.

PAI command

```
PAI -name pai_etrec
-project algo_public
-DsimilarityType="wbcosine"
-Dweight="1"
-DminUserBehavior="2"
-Dlifecycle="28"
-DtopN="2000"
-Dalpha="0.5"
-DoutputTableName="etrec_test_result"
-DmaxUserBehavior="500"
-DinputTableName="etrec_test_input"
-Doperator="add"
-DuserColName="user"
-DitemColName="item"
```

Parameters

Parameters

Parameter	Description	Valid value	Default value
<code>inputTableName</code>	Required. The name of the input table.	N/A	N/A

Parameter	Description	Valid value	Default value
userColName	Required. The name of the input table column selected as the user column.	N/A	N/A
itemColName	The name of the input table column selected as the item column.	N/A	N/A
payloadColName	Optional. The name of the input table column selected as the payload column.	N/A	No payload column is set by default.
inputTablePartitions	Optional. The partitions selected from the input table for training.	N/A	The whole table is selected by default.
outputTableName	Required. The name of the output table.	N/A	N/A
outputTablePartition	Optional. The partitions in the output table.	N/A	The output table is non-partitioned by default.
similarityType	Optional. The type of similarity.	wbcosine, asymcosine, and jaccard	wbcosine
topN	Optional. N items with the highest similarity.	[1, 10000]	2000
minUserBehavior	Optional. The minimum user behavior.	[2,)	2
maxUserBehavior	Optional. The maximum user behavior.	[2, 100000]	500
itemDelimiter	Optional. The delimiter used to separate items in the output table.	N/A	The default delimiter is a space.
kvDelimiter	Optional. The delimiter used to separate keys and values in the output table.	N/A	The default delimiter is a colon (:).
alpha	Optional. The value of the smoothing factor for asymcosine.	N/A	0.5
weight	Optional. The weight used for asymcosine.	N/A	1.0
operator	Optional. The action to be performed when the same items exist for one user.	add, mul, min, and max	add

Parameter	Description	Valid value	Default value
lifecycle	Optional. The lifecycle of the output table.	N/A	1

Examples

- SQL statement to generate data:

```
drop table if exists etrec_test_input;
create table etrec_test_input as select * from
(
select cast(0 as string) as user,
cast(0 as string) as item from dual
union all
select cast(0 as string) as user,
cast(1 as string) as item from dual
union all
select cast(1 as string) as user,
cast(0 as string) as item from dual
union all
select cast(1 as string) as user,
cast(1 as string) as item from dual ) a;
```

- PAI command

```
drop table if exists etrec_test_result;
PAI -name pai_etrec
-project algo_public
-DsimilarityType="wbcosine"
-Dweight="1"
-DminUserBehavior="2"
-Dlifecycle="28"
-DtopN="2000"
-Dalpha="0.5"
-DoutputTableName="etrec_test_result"
-DmaxUserBehavior="500"
-DinputTableName="etrec_test_input"
-Doperator="add"
-DuserColName="user"
-DitemColName="item"
```

- Input description etrec_test_input

User	Item
0	0
0	1
1	0
1	1

- Output description etrec_test_result

Item ID	Similarity
0	1:1
1	0:1

4.4.6.6. Evaluation

4.4.6.6.1. Regression model evaluation

You can evaluate a regression model based on the predicted and actual results. Indicators include SST, SSE, SSR, R2, R, MSE, RMSE, MAE, MAD, MAPE, count, yMean, and predictMean.

PAI command

```
Pai -name regression_evaluation
    -project algo_public
    -DinputTableName=input_table
    -DyColName=y_col
    -DpredictionColName=prediction_col
    -DoutputTableName=output_table;
```

Parameters

Parameter	Description	Default value
inputTableName	Required. The name of the input table.	-
inputTablePartitions	Optional. The partitions selected from the input table for training.	All partitions of the input table are selected by default.
yColName	Required. The name of the original dependent variable column in the input table. It must be a numerical value.	-
predictionColName	Required. The name of the predicted dependent variable column. It must be a numerical value.	-
outputTableName	Required. The name of the output table.	-
inputTablePartitions	Optional. The partitions selected from the input table.	-
lifecycle	Optional. The lifecycle of the output table.	No lifecycle is set by default.

Output

The following table describes the JSON columns.

Column description

Column	Description
SST	The sum of squares total.

Column	Description
SSE	The sum of squares error.
SSR	The sum of squares regression.
R2	The coefficient of determination.
R	The coefficient of multiple correlations.
MSE	The mean squared error.
RMSE	The root-mean-square error.
MAE	The mean absolute error.
MAD	The mean absolute difference.
MAPE	The mean absolute percentage error.
count	The number of rows.
yMean	The mean of original dependent variables.
predictionMean	The mean of prediction results.

4.4.6.6.2. Clustering model evaluation

You can evaluate clustering models, including metrics and icons, based on raw data and clustering models.

PAI command

```
PAI -name cluster_evaluation
    -project algo_public
    -DinputTableName=pai_cluster_evaluation_test_input
    -DselectedColNames=f0,f3
    -DmodelName=pai_kmeans_test_model
    -DoutputTableName=pai_ft_cluster_evaluation_out;
```

Parameters

Parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	Table name	N/A

Parameter	Description	Valid value	Default value
selectedColNames	Optional. The names of columns selected from the input table for evaluation. The column names must be separated with commas (.). The column names must be the same as the feature names saved in the model.	Column name	All columns are selected by default.
inputTablePartitions	Optional. The partitions selected from the input table for evaluation, in the <code>name1=value1/name2=value2</code> format. Separate multiple partitions with commas (.).	N/A	All partitions are selected by default.
enableSparse	Optional. This parameter specifies whether data in the input table is in sparse format.	true and false	false
itemDelimiter	Optional. The delimiter used to separate key-value pairs when data in the input table is in sparse format.	N/A	The default delimiter is a space.
kvDelimiter	Optional. The delimiter used to separate keys and values when data in the input table is in sparse format.	N/A	The default delimiter is a colon (:).
modelName	Required. The name of the input clustering model.	Model name	N/A
outputTableName	Required. The name of the output table.	Table name	N/A
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Evaluation formula

The Calinski-Harabasz metric is also known as the variance ratio criterion (VRC), which is defined as follows:

$$VRC_k = \frac{SS_B}{SS_W} \times \frac{(N-k)}{(k-1)},$$

- SS_B represents the inter-clustering variance. The definition is as follows:

$$SS_B = \sum_{i=1}^k n_i \|m_i - m\|^2,$$

- **k** represents the number of cluster centers.
- m_i represents the center of cluster i .
- **m** represents the mean of the input data.
- SS_W represents the intra-clustering variance. The definition is as follows:

$$SS_W = \sum_{i=1}^k \sum_{x \in C_i} \|x - m_i\|^2,$$

- **k** represents the number of cluster centers.
- x represents a data point.
- C_i represents the number i cluster.
- m_i represents the center of cluster i .
- **N** represents the total number of records. **k** represents the number of cluster centers.

Examples

- Test data

```
create table if not exists pai_cluster_evaluation_test_input
as select * from ( select 1 as id,
1 as f0,2 as f3 from dual union all
select 2 as id, 1 as f0,3 as f3 from dual union all
select 3 as id, 1 as f0,4 as f3 from dual union all
select 4 as id, 0 as f0,3 as f3 from dual union all
select 5 as id, 0 as f0,4 as f3 from dual )tmp;
```

- Clustering model building

```
pai -name kmeans
-project algo_public
-DinputTableName=pai_cluster_evaluation_test_input
-DselectedColNames=f0,f3
-DcenterCount=3
-Dloop=10
-Daccuracy=0.00001
-DdistanceType=euclidean
-DinitCenterMethod=random
-Dseed=1
-DmodelName=pai_kmeans_test_model
-DidxTableName=pai_kmeans_test_idx
```

- PAI command

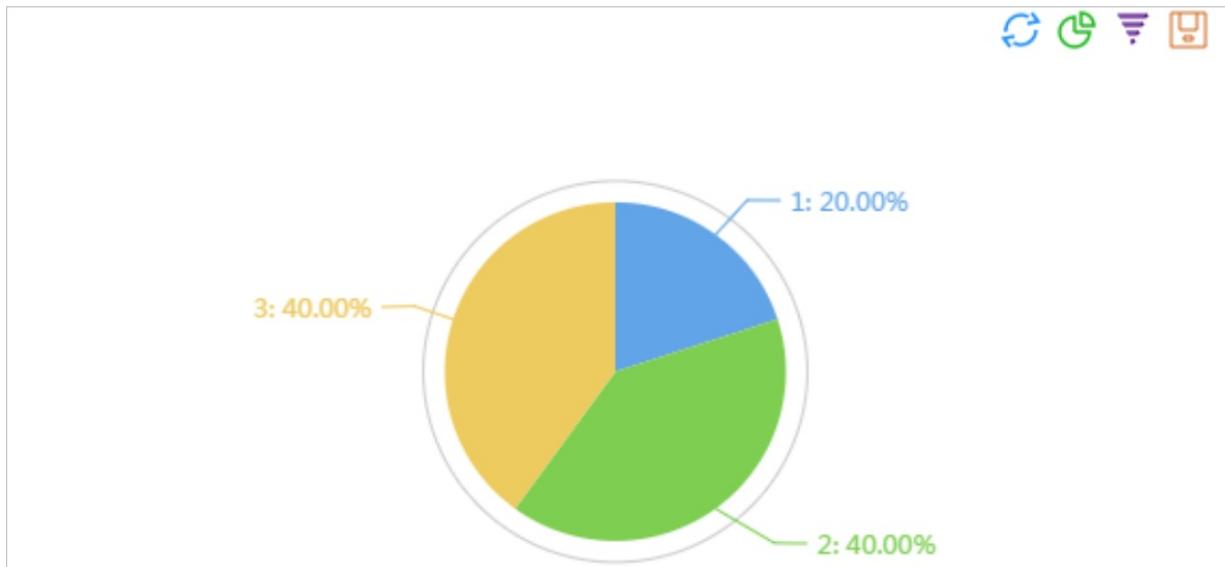

```
PAI -name cluster_evaluation
-project algo_public
-DinputTableName=pai_cluster_evaluation_test_input
-DselectedColNames=f0,f3
-DmodelName=pai_kmeans_test_model
-DoutputTableName=pai_ft_cluster_evaluation_out;
```

- Output description Output table (outputTableName)

Column	Description
count	The total number of records.
centerCount	The number of cluster centers.
calinhara	The Calinski Harabasz metric.
clusterCounts	The number of points included in each cluster.

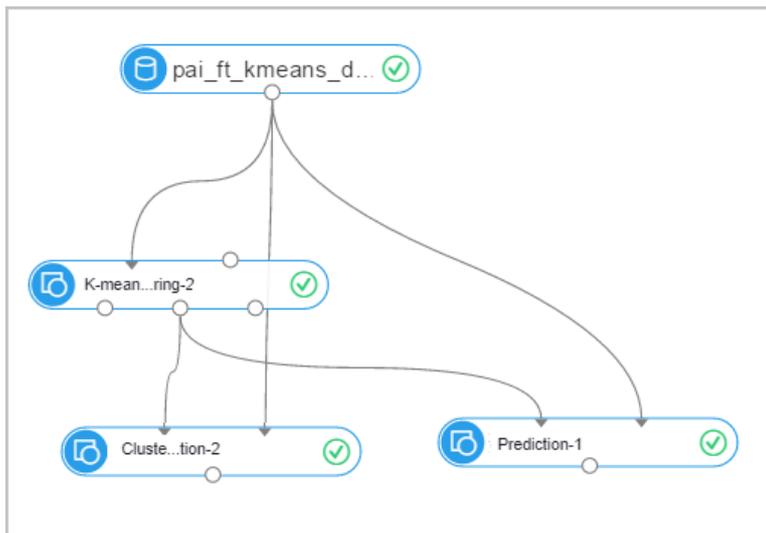

PaiWeb demonstration

Clustering model evaluation

PaiWeb-Pipeline

PaiWeb-Pipeline

4.4.6.6.3. Binary classification evaluation

You can evaluate a regression algorithm model based on its predicted and actual results. The metrics include MSE, MAE, and MAPE.

PAI command

```
pai -name evaluation
-DinputTableName=input_table
-DlabelColName=label_name
-DpredictionColName=prediction_score
-DoutputTableName=output_table;
```

Algorithm parameters

Parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	N/A	N/A
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	N/A	All partitions of the input table are selected by default.
labelColName	Required. The name of the original label column in the input table. It must be a numerical value.	N/A	N/A
predictionColName	Required. The name of the label column in the prediction result table. It must be a numerical value.	N/A	N/A
outputTableName	Required. The name of the output table.	N/A	N/A
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Output table

Output column description

Column	Description
MSE	The mean square error, which is used to measure the mean error and evaluate data changes. The smaller the MSE, the more accurately a prediction model describes the test data.
MAE	The mean absolute error, which is used to measure the mean difference between the predicted value and the actual value.
MAPE	The mean absolute percentage error, which is used to measure prediction accuracy. The value is expressed in percentage. If MAPE is set to 15, the mean absolute percentage error is 15%.

4.4.6.6.4. Confusion matrix

The Confusion Matrix component is a visualization tool typically used in supervised learning. This tool is used to calculate the classification accuracy of a confusion matrix model by comparing its results with measured values.

Procedure

1. Configure the confusion matrix parameters.

The default settings are typically used. You can also select a target column and a prediction probability column. A prediction probability column is the target column generated by the Prediction component.

2. Connect the Confusion Matrix component and the Prediction component.

 **Note** The parent node of the Confusion Matrix component must be a Prediction component. You can perform confusion matrix analysis only when a classification model is used.

3. Right-click the Confusion Matrix component and choose **View Evaluation Report**.

PAI command

```
PAI -name confusionmatrix  
-project algo_public  
-DoutputTableName="pai_temp_2954_24178_1"  
-DlabelColName="age"  
-DpredictionColName="prediction_result"  
-DinputTableName="pai_temp_2954_24176_1";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
outputTableName	The name of the output table.
labelColName	The name of the label column selected from the input table.
predictionColName	The name of the prediction result column.
inputTableName	The name of the input table for predicting results.

4.4.6.6.5. Multiclass classification evaluation

You can evaluate a multiclass classification model based on its predicted and actual results. The indicators include accuracy, kappa, and F1-Score.

Component description

The Multiclass Classification Evaluation component must be connected to a Prediction component and does not support regression models.

PAI command

```
PAI -name MultiClassEvaluation -project algo_public
-DinputTableName="test_input"
-DoutputTableName="test_output"
-DlabelColName="label"
-DpredictionColName="prediction_result"
-Dlifecycle=30;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training.	-	All partitions of the input table are selected by default.
labelColName	Required. The name of the original label column in the input table. It must be a numerical value.	-	-
predictionColName	Required. The name of the label column in the prediction result table. It must be a numerical value.	-	-
outputTableName	Required. The name of the output table.	-	-
predictionColName	Optional. The name of the probability column that lists prediction results. It must be in the {"A":0.2,"B":0.3} format.	-	-
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

4.4.6.7. Prediction

The Prediction component is used to make model-based predictions. The component has two inputs (training model and prediction data) and one output (prediction result). Conventional data mining algorithms often use this component for prediction.

Procedure

1. Connect all components.
2. Configure column settings. Parameters

Parameter	Description
Feature Columns	The feature columns used for prediction. All feature columns are selected by default.
Reserved Columns	The columns reserved and exported to the prediction result.

Parameter	Description
Output Result Column	The default value is used.
Output Score Column	The default value is used.
Output Detail Column	The default value is used.

 **Note** Feature columns must be selected if data is in sparse format such as `k1:v1,k2:v2` .

- After you configure the preceding parameters, right-click the Prediction component and choose **View Data** from the short cut menu.

The following three columns are appended to the prediction data:

- `predict_result`: the prediction result column.
- `predict_score`: the probability score in prediction results. This column is only appended onto the outputs of binary classification models.
- `predict_detail`: the prediction result of each category. This column is only appended onto the outputs of binary classification models.

PAI command

```
PAI -name Prediction
-project algo_public
-DdetailColName="prediction_detail"
-DsplitCharacteristic="2"
-DappendColNames="age,campaign,pdays,previous,poutcome,emp_var_rate,cons_price_idx,cons_conf_idx,euribor3m,nr_employed,y"
-DmodelName="xlab_m_random_forests_6036"
-DresultColName="prediction_result"
-DoutputTableName="pai_temp_675_6048_1"
-DscoreColName="prediction_score"
-DinputTableName="bank_data";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is <code>algo_public</code> . If you change the name, the system reports an error.
detailColName	Optional. The name of the detail column in the output table. The default value is <code>prediction_detail</code> .
splitCharacteristic	Optional. The type of classification. The value <code>1</code> indicates binary classification. The value <code>2</code> indicates multiclass classification.
appendColNames	Optional. The names of columns in the input prediction table to be appended to the output table.
modelName	The name of the random forest model.

Parameter	Description
<code>resultColName</code>	Optional. The name of the result column in the output table. The default value is <i>prediction_result</i> .
<code>outputTableName</code>	The name of the output prediction table.
<code>scoreColName</code>	Optional. The name of the score column in the output table. The default value is <i>prediction_score</i> .
<code>inputTableName</code>	The name of the input prediction table.

4.4.7. Deep learning (must be activated separately)

4.4.7.1. Activate deep learning

The deep learning service is not a basic function of Apsara Stack Machine Learning Platform for AI. You must purchase it separately.

If you have already deployed the deep learning service, activate it by using the following procedure:

1. Log on to the Apsara Stack Machine Learning Platform for AI console.
2. Click **Settings** in the left-side navigation pane.
3. Click **General**. Under **Deep Learning**, select **Enable GPU Compute**.

4.4.7.2. Read OSS buckets

When using the **Read OSS Bucket** component on Machine Learning Platform for AI, you must assign the default system role **AliyunODPSAIDefaultRole** to your DTplus service account. OSS buckets can be correctly read and written by algorithms of the machine learning platform only when the role is correctly assigned.

 **Note** The machine learning platform shares service accounts with MaxCompute, because it runs on the MaxCompute framework. During authorization, you must assign the default role to your MaxCompute service account.

You can use RAM authorization to grant OSS access permissions to Machine Learning Platform for AI. Click **Settings** to grant permission to read and write OSS data. For more information, see [RAM authorization](#).

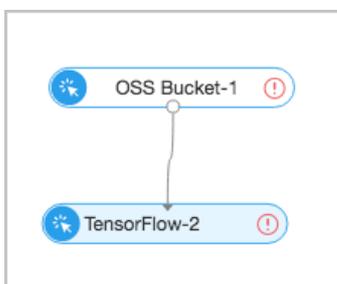

RAM authorization

1. Log on to the Machine Learning Platform For AI console, click **Settings** in the left-side navigation pane, and select **General**.
2. Under **OSS Authorization**, select **Authorize Machine Learning Platform for AI to access my OSS resources**.
3. The following page is displayed. Click **Click here to authorize access in RAM**. The RAM page is displayed.
4. Click **I Agree**.

Note To view details about the AliyunODPSPAIDefaultRole policy, log on to the [RAM console](#). The default role AliyunODPSPAIDefaultRole contains the following permission information.

Permission (Action)	Description
oss:PutObject	Upload a file or folder object.
oss:GetObject	Obtain a file or folder object.
oss:ListObjects	Query file information.
oss:DeleteObjects	Delete an object.

- Go back to the machine learning page and click **Refresh**. RAM information is automatically recorded to the components.
- Use the deep learning framework. Connect the **Read OSS Bucket** component to the corresponding deep learning component to obtain permissions to read and write OSS data.

4.4.7.3. TensorFlow 1.4

TensorFlow (TF) is an open-source machine learning framework. It is easy to use for algorithm developers. The TF framework is integrated into Apsara Stack Machine Learning Platform for AI. You can write code and adjust computing resources flexibly by using the TF compute engine. The TF computing engine is a Graphics Processing Unit (GPU) cluster.

Parameters

- Parameter settings

Parameter	Description
Python Code Files	The program execution files. Multiple files can be packaged and uploaded in the tar.gz format.
Primary Python File	Optional. The primary file in a compressed code file package.
Data Source Directory	The path of data sources. You can select Object Storage Service (OSS) data sources.
Configuration File Hyperparameters and Custom Parameters	Machine Learning Platform for AI Tensorflow allows you to use commands to pass in hyperparameter settings and try different learning rates and batch sizes during model testing.
Output Directory	The path of the output model.

- Tuning

You can specify the number of GPUs based on the complexity of jobs.

PAI command

 **Note** You do not need to set all parameters. For the definitions of these parameters, see [Parameters](#). We recommend that you do not directly copy the following command.

```
PAI -name tensorflow_ext140
-Dbuckets="oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist/"
-DgpuRequired="100"
-Darn="acs:ram::166408185518****:role/aliyunodpspaidefaultrole"
-Dscript="oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist_ext.py";
```

The following table lists the descriptions of the parameters.

Parameters

Parameter	Description	Valid values	Default value
script	Required. The TF algorithm file. This file can be a single file or compressed as a tar.gz format package.	oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist_ext.py	N/A
entryFile	Optional. The name of the primary Python file. If the script is a compressed package in the tar.gz format, this parameter is required.	train.py	Null
buckets	Required. The input OSS buckets. You can specify multiple buckets separated with commas (.). Each bucket must end with a forward slash (/).	oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist/	Null
arn	Required. The Alibaba Cloud Resource Name (ARN) of an OSS object.	N/A	Null
gpuRequired	Required. This parameter indicates the number of GPUs to be used.	200	100
checkpointDir	Optional. The TF checkpoint directory.	oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist/	Null
cluster	Optional.	A JSON format value. Quotation marks must be escaped.	Null

Parameter	Description	Valid values	Default value
hyperParameters	Optional. The path of the command line hyperparameters.	oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smlake_tensorflow/mnist/hyper_parameters.txt	Null

- script and entryFile are used to specify the TF algorithm script to be executed. If the algorithm is complex and divided into multiple files, you can package the files into a tar.gz file and use entryFile to specify the primary Python file.
- checkpointDir is used to specify the OSS path to be written by algorithms. You must specify the OSS path when you save TensorFlow models.
- buckets is used to specify the OSS path to be read by algorithms. To use OSS, you must specify an OSS bucket.
- Distributed Machine Learning Platform for AI TensorFlow supports cluster. You can use cluster to specify the number of parameter servers and workers. cluster is in JSON format, and the quotation marks must be escaped. The JSON code must contain two keys: ps and worker. Both the ps and worker parameters contain count, gpu, cpu, and memory.

Keyword	Description	Default value	Remarks
count	Required. The number of parameter servers or workers.	-	None
gpu	Optional. The number of GPUs allocated to each parameter server or worker. 100 represents a single GPU card.	For parameter servers, the default value is 0. For workers, the default value is 100.	If the number of GPUs allocated to each worker is set to 0, Machine Learning Platform for AI will reset the value to 100 to ensure the task is scheduled properly.
cpu	Optional. The number of CPUs allocated to each parameter server or worker. 100 represents a single CPU card.	600	None
memory	The memory size allocated to each parameter server or worker. 100 represents 100 MB.	30000	None

Examples

The MNIST digit classification set is a set of handwritten digits 1 through 9 that contains training and test sets for machine learning models.

1. Upload the Python execution files and training datasets to OSS. In this case, create a bucket on OSS in China (Shanghai) and name the bucket as tfmnist001. Upload the Python script and training data.
2. Drag and drop the **Read OSS Bucket** and **TensorFlow** components onto the canvas to create the following experiment. Set the region for the OSS bucket and configure RAM authorization.
3. Set the TensorFlow parameters. Set the paths for **Python Code Files**, **Primary Python File**, and **Data**

Source Directory.

4. Click **Run** and wait for the experiment to complete running.
5. Right-click the **TensorFlow** component and view the running log.

4.4.8. Time series

4.4.8.1. x13_arima

Autoregressive Integrated Moving Average Model (ARIMA) is a well-known time series prediction method defined by Box and Jenkins in the early 1970s. This model is also called the Box-Jenkins model or the Box-Jenkins method. x13-arima is an ARIMA algorithm for seasonal adjustment based on the open-source X-13ARIMA-SEATS algorithm.

PAI command

```

pai -name x13_arima
  -project algo_public
  -DinputTableName=pai_ft_x13_arima_input
  -DseqColName=id
  -DvalueColName=number
  -Dorder=3,1,1
  -Dstart=1949.1
  -Dfrequency=12
  -Dseasonal=0,1,1
  -Dperiod=12
  -DpredictStep=12
  -DoutputPredictTableName=pai_ft_x13_arima_out_predict
  -DoutputDetailTableName=pai_ft_x13_arima_out_detail
  
```

Algorithm parameters

Parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
inputTablePartitions	Optional. The partitions selected from the input table for training. in the <code>partition_name=value</code> format. To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.

Parameter	Description	Valid value	Default value
seqColName	Required. The name of the time series column.	Column name	This parameter is only used to sort the column specified by <code>valueColName</code> . The value does not affect the calculated results.
valueColName	Required. The name of the value column.	Column name	N/A
groupColNames	Optional. The name of the stratification column. Separate multiple columns with commas (,), such as <code>col0,col1</code> ; . A time series is created for each stratum.	Column name	N/A
order	Required. p , d , and q indicate the autoregressive coefficient, difference, and moving regression coefficient, respectively.	p , d , and q must be non-negative integers in the range of [0, 36].	N/A
start	Optional. The start date of a time series.	A string in the <code>year.seasonal</code> format, such as 1986.1 For more information, see the time series format section.	1.1
frequency	Optional. The frequency of a time series. Unit: months/year	A positive integer in the range of (0, 12) For more information, see the time series format section.	12
seasonal	Optional. sp , sd , and sq indicate the seasonal autoregressive coefficient, seasonal difference, and seasonal moving regression coefficient, respectively.	sp , sd , and sq must be non-negative integers in the range of [0, 36].	<code>seasonal</code> is not set by default.
period	Optional. The seasonal period.	A number in the range of (0, 100]	frequency
maxiter	Optional. The maximum number of iterations.	A positive integer	1500

Parameter	Description	Valid value	Default value
tol	Optional. The degree of tolerance.	A double type value	1e-5
predictStep	Optional. The number of prediction items.	A number in the range of (0, 365]	12
confidenceLevel	Optional. The prediction confidence level.	A number in the range of (0, 1)	0.95
outputPredictTableName	Required. The name of the output prediction table.	Table name	N/A
outputDetailTableName	Required. The name of the output detail table.	Table name	N/A
outputTablePartition	Optional. The partition in the output table.	Partition name	The output table is non-partitioned by default.
coreNum	Optional. The number of cores.	A positive integer used with memSizePerCore	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Time series format

- The start and frequency parameters specify the two time dimensions of data (valueColName): TS1 and TS2.
- The frequency parameter indicates the data frequency within a period, which equals the frequency of TS2 in each TS1.
- The start parameter must be in the `n1.n2` format. This indicates that the start date is the N2 TS2 in the N1 TS1.

Unit time	TS1	TS2	Frequency	Start date
12 months/year	Year	Month	12	1949.2 indicates the second month of year 1949.
Four quarters/year	Year	Quarter	4	1949.2 indicates the second quarter of year 1949.
Seven days/week	Day	Week	7	1949.2 indicates the second day of the 1949th week.
1	Any time unit	1	1	1949.1 indicates the 1949th (year, day, or hour).

Example: value=[1,2,3,5,6,7,8,9,10,11,12,13,14,15]

- **start=1949.3** and **frequency=12** indicate that the data frequency is monthly, and the prediction start date is 1950.06.

Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
1949			1	2	3	4	5	6	7	8	9	10
1950	11	12	13	14	15							

- **start=1949.3** and **frequency=4** indicate that the data frequency is quarterly, and the prediction start date is 1953.02.

Year	Qtr1	Qtr2	Qtr3	Qtr4
1949			1	2
1950	3	4	5	6
1951	7	8	9	10
1952	11	12	13	14
1953	14			

- **start=1949.3** and **frequency=7** indicate that the data frequency is daily, and the prediction start date is 1951.04.

Week	Sun	Mon	Tue	Wed	Thu	Fri	Sat
1949			1	2	3	4	5
1950	6	7	8	9	10	11	12
1951	13	14	15				

- **start=1949.1** and **frequency=1** indicate that the prediction start date is 1963.00 regardless of the time unit used.

Cycle	p1
1949	1
1950	2
1951	3
1951	4
1952	5
1953	6
1954	7
1955	8

Cycle	p1
1956	9
1957	10
1958	11
1959	12
1960	13
1961	14
1962	15

Examples

- Data used for testing: AirPassengers. The data set contains the number of passengers for international airlines each month from 1949 to 1960. It can be downloaded from <https://stat.ethz.ch/R-manual/R-devel/library/datasets/html/AirPassengers.html>.

```
create table pai_ft_x13_arma_input(id bigint,number bigint);
tunnel upload data/airpassengers.csv pai_ft_x13_arma_input -h true;
```

- PAI command

```
pai -name x13_arma
  -project algo_public
  -DinputTableName=pai_ft_x13_arma_input
  -DseqColName=id
  -DvalueColName=number
  -Dorder=3,1,1
  -Dseasonal=0,1,1
  -Dstart=1949.1
  -Dfrequency=12
  -Dperiod=12
  -DpredictStep=12
  -DoutputPredictTableName=pai_ft_x13_arma_out_predict
  -DoutputDetailTableName=pai_ft_x13_arma_out_detail
```

- Output description

- The columns of the output table specified by outputPredictTableName are as follows.

Column	Description
pdate	The prediction date.
forecast	The prediction result.
lower	The lower threshold of the prediction result when the confidence level is specified (default value: 0.95).
upper	The upper threshold of the prediction result when the confidence level is specified (default value: 0.95).

Output data

1	196101	444.445401291661	422.354385657496	466.536416925825

variance	127.0384

4.4.8.2. x13_auto_arima

ARIMA is described in [x13_arima](#). The x13_auto_arima algorithm includes a process of automatic model selection.

The x13_auto_arima selection process is as follows:

- **Default model estimation**

In the case of frequency = 1, the default model is (0,1,1).

In the case of frequency > 1, the default model is (0,1,1)(0,1,1).

- **Identification of differencing orders**

Skip this step if you have configured diff and SeasonalDiff.

Use `Unit root test (wiki)` to determine the difference d and the seasonal difference D .

- **Identification of ARMA model orders**

Select the optimal model based on `BIC (wiki)`. The `maxOrder` and `maxSeasonalOrder` parameters are used in this step.

- **Comparison of identified model with default model**

Use `Ljung-Box Q statistic(wiki)` to compare the models. If both models are unacceptable, use the `(3,d,1)(0,D,1)` model.

- **Final model checks**

PAI command

```
pai -name x13_auto_arima
  -project algo_public
  -DinputTableName=pai_ft_x13_arima_input
  -DseqColName=id
  -DvalueColName=number
  -Dstart=1949.1
  -Dfrequency=12
  -DpredictStep=12
  -DoutputPredictTableName=pai_ft_x13_arima_out_predict2
  -DoutputDetailTableName=pai_ft_x13_arima_out_detail2
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
<code>inputTableName</code>	Required. The name of the input table.	Table name	-
<code>inputTablePartitions</code>	Optional. The partitions selected from the input table for training, in the format of <code>partition_name=value</code> . To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
<code>seqColName</code>	Required. The name of the time series column.	Column name	This parameter is only used to sort <code>valueColNames</code> . It is not relevant to the calculated output.
<code>valueColName</code>	Required. The name of the value column.	Column name	-

Parameter	Description	Valid values	Default value
groupColNames	Optional. The name of the stratification column. Separate multiple columns with commas (,), such as <code>col0,col1</code> ; . A time series is created for each group.	Column name	-
start	Optional. The start date of a time series.	A string in the format of <code>year.seasonal</code> , such as <code>1986.1</code> For more information, see the time series format section.	1.1
frequency	Optional. The frequency of a time series.	A positive integer in the range of (0, 12) For more information, see the time series format section.	The frequency is 12 months/year by default.
maxOrder	Optional. The maximum values of p and q.	A positive integer in the range of [0, 4]	2
maxSeasonalOrder	Optional. The seasonal maximum values of p and q.	A positive integer in the range of [0, 2]	1
maxDiff	Optional. The maximum value of differential d.	A positive integer in the range of [0, 2]	2
maxSeasonalDiff	Optional. The maximum value of seasonal differential d.	A positive integer in the range of [0, 1]	1
diff	Optional. The differential d.	A positive integer in the range of [0, 2] If both <code>diff</code> and <code>maxDiff</code> are set, <code>maxDiff</code> is ignored. If <code>diff</code> is set, then <code>seasonalDiff</code> must also be set.	Default value: -1. This value indicates that <code>diff</code> is not specified by default.
seasonalDiff	Optional. The seasonal differential d.	A positive integer in the range of [0, 1] If both <code>seasonalDiff</code> and <code>maxSeasonalDiff</code> are set, <code>maxSeasonalDiff</code> is ignored.	Default value: -1. This value indicates that <code>seasonalDiff</code> is not specified by default.

Parameter	Description	Valid values	Default value
maxiter	Optional. The maximum number of iterations.	A positive integer	1500
tol	Optional. The degree of tolerance.	A double type value	1e-5
predictStep	Optional. The number of prediction items.	A number in the range of (0, 365]	12
confidenceLevel	Optional. The prediction confidence level.	A number in the range of (0, 1)	0.95
outputPredictTableName	Required. The name of the output prediction table.	Table name	-
outputDetailTableName	Required. The name of the output detail table.	Table name	-
outputTablePartition	Optional. The partitions in the output table.	Partition name	No partition is specified by default.
coreNum	Optional. The number of cores.	A positive integer used with memSizePerCore	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Time format

- The start and frequency parameters specify the two time dimensions of data (valueColName): TS1 and TS2.
- The frequency parameter indicates the data frequency within a period, which equals the frequency of TS2 in each TS1.
- The start parameter is in the format of `n1.n2`. This indicates that the start date is the N2 TS2 in the N1 TS1.

Unit time	ts1	ts2	Frequency	Start date
12	Year	Month	12	1949.2 indicates the second month of year 1949.
4	Year	Quarter	4	1949.2 indicates the second quarter of year 1949.
7	Day	Week	7	1949.2 indicates the second day of a week in year 1949.

Unit time	ts1	ts2	Frequency	Start date
1	Any time unit	1	1	1949.1 indicates the 1949th (year, day, or hour).

For example, value=[1,2,3,5,6,7,8,9,10,11,12,13,14,15].

- **start=1949.3** and **frequency=12** indicate that the data frequency is monthly, and the prediction start date is 1950.06.

Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
1949			1	2	3	4	5	6	7	8	9	10
1950	11	12	13	14	15							

- **start=1949.3** and **frequency=4** indicate that the data frequency is quarterly, and the prediction start date is 1953.02.

Year	Qtr1	Qtr2	Qtr3	Qtr4
1949			1	2
1950	3	4	5	6
1951	7	8	9	10
1952	11	12	13	14
1953	14			

- **start=1949.3** and **frequency=7** indicate that the data frequency is daily, and the prediction start date is 1951.04.

Week	Sun	Mon	Tue	Wed	Thu	Fri	Sat
1949			1	2	3	4	5
1950	6	7	8	9	10	11	12
1951	13	14	15				

- **start=1949.1** and **frequency=1** indicate that the end date is 1963.00.

Period	p1
1949	1
1950	2
1951	3
1951	4
1952	5

Period	p1
1953	6

summary	Storage details.

4.4.9. Text analysis

4.4.9.1. Word splitting

Based on Alibaba Word Segmenter (AliWS), this component performs word splitting on documents specified by columns. Segmented words are separated with spaces. If you have set the part-of-speech (POS) tagging or semantic tagging parameters, the component outputs the word splitting results, POS tagging results, and semantic tagging results. Forward slashes (/) are used as delimiters for POS tagging. Vertical bars (|) are used as delimiters for semantic tagging. Only Chinese Taobao word segmentation and Internet word segmentation are supported.

Parameter settings

Word segmentation algorithms: CRF and UNIGRAM.

Parameters

Parameter	Description
Recognition Options	Specifies whether to recognize nouns with special meanings during word splitting.
Merge Options	Considers the terms used in certain industries as a whole without splitting.
Tokenizer	Allows you to select the Taobao word segmentation or Internet word segmentation. Taobao word segmentation is recommended.
Pos Tagger	Specifies whether to mark the part of speech for each word. If this parameter is specified, the part of speech for each word is marked in the output.

Examples

The following input table consists of the id column (document IDs) and the text column (document content).

PAI command

```

pai -name split_word
-project algo_public
-DinputTableName=doc_test
-DselectedColNames=content1,content2
-DoutputTableName=doc_test_split_word
-DinputTablePartitions="region=cctv_news"
-DoutputTablePartition="region=news"
-Dtokenizer=TAOBAO_CHN
-DenableDfa=true
-DenablePersonNameTagger=false
-DenableOrganizationTagger=false
-DenablePosTagger=false
-DenableTelephoneRetrievalUnit=true
-DenableTimeRetrievalUnit=true
-DenableDateRetrievalUnit=true
-DenableNumberLetterRetrievalUnit=true
-DenableChnNumMerge=false
-DenableNumMerge=true

-DenableChnDateMerge=false
-DenableSemanticTagger=true

```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	The name of the input table.	-	-
selectedColNames	The names of the columns selected from the input table for word segmentation.	Separate multiple columns with commas (,).	-

Parameter	Description	Valid values	Default value
outputTableName	The name of the output table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of <code>partition_name=value</code> . To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (.).	-	All partitions in the input table are selected by default.
outputTablePartition	The partition in the output table.	-	The output table is non-partitioned by default.
tokenizer	The type of the classifier.	TAOBAO_CHN and INTERNET_CHN	Default value: TAOBAO_CHN. <i>TAOBAO_CHN</i> represents Taobao word segmentation. <i>INTERNET_CHN</i> represents Internet word segmentation.
enableDfa	Specifies whether to enable simple entity recognition.	true and false	true
enablePersonNameTagger	Specifies whether to enable personal name recognition.	true and false	false
enableOrgnizationTagger	Specifies whether to enable organization name recognition.	true and false	false
enablePosTagger	Specifies whether to enable part-of-speech tagging.	true and false	false
enableTelephoneRetrievalUnit	Specifies whether to enable retrieval unit configuration for telephone number recognition.	true and false	true
enableTimeRetrievalUnit	Specifies whether to enable retrieval unit configuration for time ID recognition.	true and false	true

Parameter	Description	Valid values	Default value
<code>enableDateRetrievalUnit</code>	Specifies whether to enable retrieval unit configuration for date ID recognition.	true and false	true
<code>enableNumberLetterRetrievalUnit</code>	Specifies whether to enable retrieval unit configuration for number and letter recognition.	true and false	true
<code>enableChnNumMerge</code>	Specifies whether to merge Chinese numbers into a retrieval unit.	true and false	false
<code>enableNumMerge</code>	Specifies whether to merge regular numbers into a retrieval unit.	true and false	true
<code>enableChnTimeMerge</code>	Specifies whether to merge Chinese time into a semantic unit.	true and false	false
<code>enableChnDateMerge</code>	Specifies whether to merge Chinese dates into a semantic unit.	true and false	false
<code>enableSemanticTagger</code>	Specifies whether to enable semantic tagging.	true and false	false

4.4.9.2. Deprecated word filtering

Deprecated word filtering is a preprocessing method in text analysis. This method is used to filter out the noise in word splitting results, such as of, yes, and ah.

Parameter settings

The left and right input ports are as follows:

- Input table, which is a word splitting result table for filtering. Parameter: `inputTableName`
- Deprecated word table, which is a one-column table with each row containing a deprecated word. Parameter: `noiseTableName`

PAI command

```
PAI -name FilterNoise
-project algo_public
-DinputTableName="test_input"
-DnoiseTableName="noise_input"
-DoutputTableName="test_output"
-DselectedColNames="words_seg1,words_seg2"
-Dlifecycle=30
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	All partitions in the input table are selected by default.
noiseTableName	Required. The name of the deprecated word table.	A one-column table with each row containing a deprecated word	-
noiseTablePartitions	Optional. The partitions selected from the deprecated word table.	-	All partitions in the table are selected by default.
outputTableName	Required. The name of the output table.	-	-
selectedColNames	Required. The name of the column to be filtered. Separate multiple columns with commas (,).	-	-
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of (0, 65536)	Automatically calculated.

4.4.9.3. String similarity

String similarity calculation is a basic operation in machine learning that is used in information retrieval, natural language processing, and bioinformatics. This algorithm supports five methods to calculate similarity: Levenshtein distance, longest common substring, string subsequence kernel, cosine, and simhash_hamming. It also supports two input methods: string-to-string calculation and top N calculation.

PAI command

```
PAI -name string_similarity
-project algo_public
-DinputTableName="pai_test_string_similarity"
-DoutputTableName="pai_test_string_similarity_output"
-DinputSelectedColName1="col0"
-DinputSelectedColName2="col1";
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
outputTableName	Required. The name of the output table.	-	-
inputSelectedColName 1	Optional. The name of the first column for similarity calculation.	-	By default, the first string type column in the table is selected.
inputSelectedColName 2	Optional. The name of the second column for similarity calculation.	-	The second string type column in the table is selected by default.
inputAppendColNames	Optional. The names of columns appended to the output table.	-	No column is appended by default.
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	The whole table is selected by default.
outputColName	Optional. The name of the similarity column in the output table. The column name can be up to 128 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.	-	output
method	Optional. The similarity calculation method.	levenshtein, levenshtein_sim, lcs, lcs_sim, ssk, cosine, simhash_hamming, simhash_hamming_sim, minhash_sim, and hash_jaccard_sim	levenshtein_sim
lambda	Optional. The weight of the matching string. This parameter takes effect when similarityType is set to ssk.	(0, 1)	0.5
k	Optional. The length of the substring. This parameter takes effect when similarityType is set to ssk or cosine.	(0, 100)	2
kVec	Optional. The number of MinHash instances.	A positive integer	2

Parameter	Description	Valid values	Default value
b	Optional. The number of buckets.	A positive integer	1
seed	Optional. The random seed used in a MinHash instance.	A positive integer	0
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of (0, 65536)	Automatically calculated.

Examples

- SQL statement to generate data:

```
create table pai_ft_string_similarity_input
as select * from
(select 0 as id, "Beijing" as col0,
"Beijing" as col1 from dual union all
select 1 as id,
"Beijing" as col0,
"Beijing Shanghai" as col1 from dual union all
select 2 as id,
"Beijing" as col0,
"Beijing Shanghai Hongkong" as col1 from dual )tmp;
```

- PAI command

```
PAI -name string_similarity
-project sre_mpi_algo_dev
-DinputTableName=pai_ft_string_similarity_input
-DoutputTableName=pai_ft_string_similarity_output
-DinputSelectedColName1=col0
-DinputSelectedColName2=col1
-Dmethod=simhash_hamming
-DinputAppendColNames=col0,col1;
```

- Output description
 - Output obtained by using the simhash_hamming method:

col0 ▲	col1 ▲	output ▲
beijing	beijing	0
beijing	beijing shanghai	6
beijing	beijing shanghai xianggang	13

- Output obtained by using the simhash_hamming_sim method:

col0 ▲	col1 ▲	output ▲
beijing	beijing	1
beijing	beijing shanghai	0.90625
beijing	beijing shanghai xianggang	0.796875

4.4.9.4. Convert row, column, and value to KV pair

This component converts rows, columns, and values into KV pairs. A row, column, and value set is defined as XXD or XXL, where X can represent any type, D represents Double, and L represents Bigint. The row, column, and value set is converted into KV format (row,[col_id:value]). The row and value types are consistent with the original input data. The col_id type is Bigint, and the column is mapped to col_id based on the index table.

PAI command

```
PAI -name triple_to_kv
-project algo_public
-DinputTableName=test_data
-DoutputTableName=test_kv_out
-DindexOutputTableName=test_index_out
-DidColName=id
-DkeyColName=word
-DvalueColName=count
-DinputTablePartitions=ds=test1
-DindexInputTableName=test_index_input
-DindexInputKeyColName=word
-DindexInputKeyIdColName=word_id
-DkvDelimiter=:
-DpairDelimiter=;
-Dlifecycle=3
```

Parameters

Parameters

Parameter	Description	Default value
inputTableName	Required. The name of the input table.	The input table cannot be empty.
idColName	Required. The name of the column to be retained after the table is converted into a KV table.	-
keyColName	Required. The name of the key column in the KV table.	-
valueColName	Required. The name of the value column in the KV table.	-
outputTableName	Required. The name of the output KV table.	-

Parameter	Description	Default value
<code>indexOutputTableName</code>	Required. The name of the index table for the output keys.	-
<code>indexInputTableName</code>	Optional. The name of the input index table.	No index table is set by default. The table cannot be empty and it does not need to contain indexes for all of the output keys.
<code>indexInputKeyColName</code>	Optional. The name of the key column in the input index table.	No key column is specified by default. This parameter is required if <code>indexInputTableName</code> is set.
<code>indexInputKeyIdColName</code>	Optional. The name of the index column in the input index table.	No index column is specified by default. This parameter is required if <code>indexInputTableName</code> is set.
<code>inputTablePartitions</code>	Optional. The partitions in the input table.	No partition is specified by default. Only one partition can be input.
<code>kvDelimiter</code>	Optional. The delimiter used to separate the key and value.	The default delimiter is a colon (:).
<code>pairDelimiter</code>	Optional. The delimiter used to separate KV pairs.	The default delimiter is a semicolon (;).
<code>lifecycle</code>	Optional. The lifecycle of the output table.	No lifecycle is set by default.
<code>coreNum</code>	Optional. The number of cores.	-1
<code>memSizePerCore</code>	Optional. The memory size of each core. Valid values: 100 to 65536.	-1

Examples

- SQL statement to generate data:

```
drop table if exists triple2kv_test_input;
create table triple2kv_test_input as
select * from
( select '01' as id, 'a' as word,
  10 as count from dual union all
  select '01' as id, 'b' as word,
  20 as count from dual union all
  select '01' as id, 'c' as word,
  30 as count from dual union all
  select '02' as id,
  'a' as word,
  100 as count from dual union all
  select '02' as id, 'd' as word,
  200 as count from dual union all
  select '02' as id, 'e' as word,
  300 as count from dual ) tmp;
```

- PAI command

```
PAI -name triple_to_kv  
-project algo_public  
-DinputTableName=triple2kv_test_input  
-DoutputTableName=triple2kv_test_input_out  
-DindexOutputTableName=triple2kv_test_input_index_out  
-DidColName=id  
-DkeyColName=word  
-DvalueColName=count  
-Dlifecycle=1;
```

Input description

Input table

Input description

id	word	count
01	a	10
01	b	20
01	c	30

Output description

- The output KV table is as follows, where custom KV delimiters can be used. Output description

id	key_value
01	1:10;2:20;3:30

- The output index table that contains indexes for the words is as follows. Output index table

key	key_id
a	1
b	2
c	3

4.4.9.5. String similarity - Top N

String similarity calculation is a basic operation in machine learning that is used in information retrieval, natural language processing, and bioinformatics. This algorithm supports five methods to calculate similarity: Levenshtein distance, longest common substring, string subsequence kernel, cosine, and simhash_hamming. It also supports two input methods: string-to-string calculation and top N calculation.

PAI command

```
PAI -name string_similarity_topn
-project algo_public
-DinputTableName="pai_test_string_similarity_topn"
-DoutputTableName="pai_test_string_similarity_topn_output"
-DmapTableName="pai_test_string_similarity_map_topn"
-DinputSelectedColName="col0"
-DmapSelectedColName="col1";
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
mapTableName	Required. The name of the mapping table.	-	-
outputTableName	Required. The name of the output table.	-	-
inputSelectedColName	Optional. The name of the column selected from the left table for similarity calculation.	-	The first string type column in the table is selected by default.
mapSelectedColName	Optional. The name of the column selected from the mapping table for similarity calculation. The similarities between each row in the left table and all strings in the mapping table are calculated, and the top N entries are output.	-	The first string type column in the table is selected by default.
inputAppendColNames	Optional. The names of columns appended to the output table from the input table.	-	No column is appended by default.
inputAppendRenameColNames	Optional. The aliases of columns appended to the output table from the input table. This parameter takes effect when <code>inputAppendColNames</code> is specified.	-	No alias is specified by default.
mapAppendColNames	Optional. The names of columns appended to the output table from the mapping table.	-	No column is appended by default.

Parameter	Description	Valid values	Default value
mapAppendRenameColNames	Optional. The aliases of columns appended to the output table from the mapping table.	-	No alias is specified by default.
inputTablePartitions	Optional. The partitions selected from the input table.	-	The whole table is selected by default.
mapTablePartitions	Optional. The partitions in the mapping table.	-	The whole table is selected by default.
outputColName	Optional. The name of the similarity column in the output table. The column name can be up to 128 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.	-	output
method	Optional. The similarity calculation method.	levenshtein_sim, lcs_sim, ssk, cosine, simhash_hamming_sim, minhash_sim, and hash_jaccard_sim	levenshtein_sim
lambda	Optional. The weight of the matching string. This parameter takes effect when similarityType is set to ssk.	(0, 1)	0.5
k	Optional. The length of the substring. This parameter takes effect when similarityType is set to ssk or cosine.	(0, 100)	2
kVec	Optional. The number of MinHash instances.	A positive integer	2
b	Optional. The number of buckets.	A positive integer	1
seed	Optional. The random seed used in a MinHash instance.	A positive integer	0
topN	Optional. The number of similarity maximums to be output.	(0, +∞)	10
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Parameter	Description	Valid values	Default value
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of (0, 65536)	Automatically calculated.

Examples

- SQL statement to generate data:

```
create table pai_ft_string_similarity_topn_input
as select * from
(select 0 as id,
"Beijing" as col0 from dual union all
select 1 as id,
"Beijing Shanghai" as col0 from dual union all
select 2 as id,
"Beijing Shanghai Hongkong" as col0 from dual )tmp;
```

- PAI command

```
PAI -name string_similarity_topn
-project sre_mpi_algo_dev
-DinputTableName=pai_ft_string_similarity_topn_input
-DmapTableName=pai_ft_string_similarity_topn_input
-DoutputTableName=pai_ft_string_similarity_topn_output
-DinputSelectedColName=col0
-DmapSelectedColName=col0
-DinputAppendColNames=col0
-DinputAppendRenameColNames=input_col0
-DmapAppendColNames=col0
-DmapAppendRenameColNames=map_col0
-Dmethod=simhash_hamming_sim;
```

- Output.

input_col0 ▲	map_col0 ▲	output ▲
beijing	beijing	1
beiji beijing	beijing shanghai	0.90625
beijing	beijing shanghai xianggang	0.796875
beijing shanghai	beijing shanghai	1
beijing shanghai	beijing	0.90625
beijing shanghai	beijing shanghai xianggang	0.828125
beijing shanghai xianggang	beijing shanghai xianggang	1
beijing shanghai xianggang	beijing shanghai	0.828125
beijing shanghai xianggang	beijing	0.796875

4.4.9.6. N-gram counting

N-gram counting is a step in language model training. N-grams are generated based on words. The number of the corresponding N-grams in all corpora is counted. The N-gram counting model counts the number of N-grams in all documents rather than in a single document. For more information, see [ngram-count](#).

PAI command

```
PAI -name ngram_count
  -project algo_public
  -DinputTableName=pai_ngram_input
  -DoutputTableName=pai_ngram_output
  -DinputSelectedColNames=col0
  -DweightColName=weight
  -DcoreNum=2
  -DmemSizePerCore=1000;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
outputTableName	Required. The name of the output table.	Table name	N/A
inputSelectedColNames	Optional. The names of columns selected from the input table.	Column name	The first character type column is selected by default.
weightColName	Optional. The name of the weight column.	Column name	1
inputTablePartitions	Optional. The partitions selected from the input table.	Partition name	The whole table is selected by default.
countTableName	Optional. The name of the former N-gram counting output table. This table is merged into the output result.	Table name	N/A
countWordColName	Optional. The name of the word column in the counting table.	Column name	The second column is selected by default.
countCountColName	Optional. The name of the counting column in the counting table.	Column name	The third column is selected by default.
countTablePartitions	Optional. The partitions in the counting table.	Partition name	N/A

Parameter	Description	Valid values	Default value
<code>vocabTableName</code>	Optional. The name of the bag-of-words table. The words that are not contained in the bag-of-words table are marked with \<unk\.	Table name	N/A
<code>vocabSelectedColumnName</code>	Optional. The name of the bag-of-words column.	Column name	The first character type column is selected by default.
<code>vocabTablePartitions</code>	Optional. The partitions in the bag-of-words table.	Partition name	N/A
<code>order</code>	Optional. The maximum length of N-grams.	N/A	3
<code>lifecycle</code>	Optional. The lifecycle of the output table.	A positive integer	N/A
<code>coreNum</code>	Optional. The number of cores.	A positive integer	N/A
<code>memSizePerCore</code>	Optional. The memory size of each core.	A positive integer	N/A

4.4.9.7. Text summarization

Automatic summarization uses computers to automatically extract summaries from a source document. A summary is a simple, concise, and short document that completely and accurately describes the content of a certain document. This TextRank-based algorithm generates summaries by extracting existing sentences in the document.

PAI command

```
PAI -name TextSummarization
-project algo_public
-DinputTableName="test_input"
-DoutputTableName="test_output"
-DdocIdCol="doc_id"
-DsentenceCol="sentence"
-DtopN=2
-Dlifecycle=30;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
<code>inputTableName</code>	Required. The name of the input table.	-	-

Parameter	Description	Valid values	Default value
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	All partitions in the input table are selected by default.
outputTableName	Required. The name of the output table.	-	-
docIdCol	Required. The name of the document ID column.	-	-
sentenceCol	Required. The sentence column.	Only one column can be specified.	-
topN	Optional. The top N key sentences to be output.	-	3
similarityType	Optional. The method used to calculate sentence similarity.	lcs_sim, levenshtein_sim, cosine, and ssk	lcs_sim
lambda	Optional. The weight of the matching string. This parameter takes effect when similarityType is set to ssk.	(0, 1)	0.5
k	Optional. The length of the substring. This parameter takes effect when similarityType is set to ssk or cosine.	(0, 100)	2
dampingFactor	Optional. The damping factor.	(0, 1)	0.85
maxIter	Optional. The maximum number of iterations.	[1, +]	100
epsilon	Optional. The convergence coefficient.	(0, ∞)	0.000001
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	A positive integer	Automatically calculated.

The sentence similarity options are as follows:

- **lcs_sim**: The formula is $1.0 - (\text{Length of the longest common subsequence}) / \max(\text{len}(A), \text{len}(B))$.
- **levenshtein_sim**: The formula is $1.0 - (\text{Levenshtein distance}) / \max(\text{len}(A), \text{len}(B))$.
- **cosine**: See Lodhi, Huma; Saunders, Craig; Shawe-Taylor, John; Cristianini, Nello;

Watkins. Chris (2002). "Text classification using string kernels". *Journal of Machine Learning Research*: 419-444 .

- ssk: See Leslie. C.; Eskin. E.; Noble. W.S. (2002). *The spectrum kernel: A string kernel for SVM protein classification* 7, pp. 566-575 .

 Note A and B indicate two strings, and len(A) indicates the length of string A.

Output format description

The output table contains the doc_id and abstract columns, as shown in [Output table example](#).

Output table example

doc_id	abstract
1000894	In 2008, the Shanghai Stock Exchange published disclosure guidelines for the corporate social responsibility of listed companies. Three types of companies were urged to disclose their CSR reports, and other qualified listed companies were encouraged to voluntarily disclose their CSR reports. In 2012, a total of 379 listed companies making up a 40% of all listed companies disclosed CSR reports. Of those companies, 305 were mandated to disclose CSR reports and and 75 voluntarily disclosed CSR reports. According to Hu Ruyin, Shanghai Stock Exchange will explore how to expand the scope of CSR report disclosure, revise and refine the guidelines on disclosure of the CSR reports, and encourage more organizations to promote CSR product innovation.

4.4.9.8. Keyword extraction

Keyword extraction is one of the important technologies in natural language processing. It is used to extract keywords from a document. This algorithm is based on TextRank, a variation of the PageRank algorithm used to describe the relationship between webpages. This algorithm uses the relationship between certain words to construct a network, calculate the importance of each word, and determine words with larger weights as keywords.

PAI command

```
PAI -name KeywordsExtraction
-DinputTableName=maple_test_keywords_basic_input
-DdocIdCol=docid -DdocContent=word
-DoututTableName=maple_test_keywords_basic_output
-DtopN=19;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
-----------	-------------	--------------	---------------

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of <code>partition_name=value</code> . To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	-	All partitions are selected by default.
outputTableName	Required. The name of the output table.	-	-
docIdCol	Required. The name of the document ID column.	Only one column can be specified.	-
docContent	Required. The word column.	Only one column can be specified.	-
topN	Optional. The number of top N keywords to be output. If this number is smaller than the number of keywords, all keywords are output.	-	5
windowSize	Optional. The window size of the TextRank algorithm.	-	2
dumpingFactor	Optional. The damping factor of the TextRank algorithm.	-	0.85
maxIter	Optional. The maximum number of iterations of the TextRank algorithm.	-	100
epsilon	Optional. The convergence residual threshold of the TextRank algorithm.	-	0.000001
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Parameter	Description	Valid values	Default value
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

Examples

The words in the input table are separated with spaces, and deprecated words and all punctuations are filtered out.

Examples

docid: string	word: string
---------------	--------------

docid: string	word: string
doc0	<p>The blended-wing-body aircraft is a new direction for the future development in the aviation field Many research institutions inside and outside China have carried out research on the blended-wing-body aircraft while its fully automated shape optimization algorithm has become a new hot topic Based on the existing research achievements inside and outside China common modeling and flow solver tools have been analyzed and compared The geometric modeling grid flow field solver and shape optimization modules have been designed The pros and cons between different algorithms have been compared to achieve the optimized shape of the blended-wing-body aircraft in the conceptual design stage Geometric modeling and grid generation module are achieved based on the transfinite interpolation algorithm and spline based grid generation method The flow solver module includes the finite difference solver the finite element solver and the panel method solver The finite difference solver includes mathematical modeling of the potential flow the derivation of the Cartesian grid based variable step length difference scheme Cartesian grid generation and indexing algorithm the Cartesian grid based Neumann boundary conditions expression form derivation are achieved based on finite element difference solver The aerodynamic parameters of a two-dimensional airfoil are calculated based on the finite difference solver The finite element solver includes potential flow modeling based on the variational principle of the finite element theory the derivation of the two-dimensional finite element Kutta conditional least squares based speed solving algorithm Gmsh based two-dimensional field grid generator of airfoil with wakes design The aerodynamic parameters of a two-dimensional airfoil are calculated based on the finite element solver The panel method solver includes modeling and automatic wake generation the design of the three-dimensional flow solver of the blended-wing-body drag estimation based on the Blasius solution solver implemented in the Fortran language a mixed compilation of Python and Fortran OpenMP and CUDA based acceleration algorithm The aerodynamic parameters of a three-dimensional wing body are calculated based on the panel method solver The shape optimization module includes free form deformation algorithm genetic algorithms differential evolution algorithm Aircraft surface area calculation algorithm is based on the moments integration algorithm The volume of an aircraft calculation algorithm is based on VKT data visualization format tool</p>

4.4.9.9. Sentence splitting

You can split sentences in a document by punctuation. This component is used to preprocess text summarizations. It splits text such that each row contains only a single sentence.

PAI command

```
PAI -name SplitSentences
-project algo_public
-DinputTableName="test_input"
-DoutputTableName="test_output"
-DdocIdCol="doc_id"
-DdocContent="content"
-Dlifecycle=30
```

Parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	All partitions in the input table are selected by default.
outputTableName	Required. The name of the output table.	-	-
docIdCol	Required. The name of the document ID column.	-	-
docContent	Required. The name of the document content column.	Only one column can be specified.	-
delimiter	Optional. A set of characters used to determine the end of a sentence.	-	The default delimiter set contains the period (.), question mark (!), and exclamation mark (?).
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	A positive integer	Automatically calculated.

Output format description

The output table contains the doc_id and sentence columns, as shown in [Output table example](#).

Output table example

doc_id	sentence
--------	----------

doc_id	sentence
1000894	In 2008, the Shanghai Stock Exchange published disclosure guidelines for the corporate social responsibility of listed companies. Three types of companies were urged to disclose their CSR reports, and other qualified listed companies were encouraged to voluntarily disclose their CSR reports.
1000894	In 2012, a total of 379 listed companies making up a 40% of all listed companies disclosed CSR reports. Of those companies, 305 were mandated to disclose CSR reports and and 75 voluntarily disclosed CSR reports.

4.4.9.10. Semantic vector distance

You can calculate the extension words or sentences of the specified words or sentences based on the calculated semantic vectors, such as word vectors calculated by the Word2Vec component. The extension words or sentences are a set of vectors closest to a certain vector. The following example shows how to generate a list of words that are most similar to the word that you entered based on the word vectors calculated by the Word2Vec component.

PAI command

```
PAI -name SemanticVectorDistance
-project algo_public
-DinputTableName="test_input"
-DoutputTableName="test_output"
-DidColName="word"
-DvectorColNames="f0,f1,f2,f3,f4,f5"
-Dlifecycle=30
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	All partitions in the input table are selected by default.
outputTableName	Required. The name of the output table.	-	-
idTableName	Optional. The name of the vector ID table for vector calculation. The table contains only one column and each row stores a vector ID.	-	No vector ID table is specified by default. This means that all vectors in the input table are calculated.

Parameter	Description	Valid values	Default value
idTablePartitions	Optional. The partitions selected from the ID table for calculation.	-	All partitions are selected by default.
idColName	Required. The name of the ID column.	-	3
vectorColNames	Optional. A list of vector column names, such as f1, f2,...	-	-
topN	Optional. The number of the closest vectors to output.	[1, +∞]	5
distanceType	Optional. The distance calculation method.	euclidean, cosine, and manhattan	euclidean
distanceThreshold	Optional. The distance threshold. Only the distances between two vectors that do not exceed this threshold are output.	(0, +∞)	∞
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	A positive integer	Automatically calculated.

Examples

The output table contains the original_id, near_id, distance, and rank columns.

original_id	near_id	distance	rank
hello	hi	0.2	1
hello	xxx	xx	2
Man	Woman	0.3	1
Man	xx	xx	2
..

4.4.9.11. Document similarity

This algorithm calculates the similarity between two text documents by comparing the similarities of documents or sentences separated by spaces. This algorithm's functions are similar to how the similarity of strings is calculated.

PAI command

```
PAI -name doc_similarity
-project algo_public
-DinputTableName="pai_test_doc_similarity"
-DoutputTableName="pai_test_doc_similarity_output"
-DinputSelectedColName1="col0"
-DinputSelectedColName2="col1"
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
outputTableName	Required. The name of the output table.	-	-
inputSelectedColName 1	Optional. The name of the first column for similarity calculation.	-	By default, the first string type column in the table is selected.
inputSelectedColName 2	Optional. The name of the second column for similarity calculation.	-	The name of the second string type column in the table is selected by default.
inputAppendColNames	Optional. The names of columns appended to the output table.	-	No column is appended by default.
inputTablePartitions	Optional. The partitions selected from the input table.	-	The whole table is selected by default.
outputColName	Optional. The name of the similarity column in the output table. The column name can be up to 128 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.	-	output
method	Optional. The similarity calculation method.	levenshtein, levenshtein_sim, lcs, lcs_sim, ssk, cosine, simhash_hamming, and simhash_hamming_sim	levenshtein_sim
lambda	Optional. The weight of the matching word pair. This parameter takes effect if similarityType is set to ssk.	(0, 1)	0.5

Parameter	Description	Valid values	Default value
k	Optional. The length of the substring. This parameter takes effect if similarityType is set to ssk or cosine.	(0, 100)	2
kVec	Optional. The number of MinHash instances.	A positive integer	2
b	Optional. The number of buckets.	A positive integer	1
seed	Optional. The random seed used in a MinHash instance.	A positive integer	0
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of (0, 65536)	Automatically calculated.

Examples

- SQL statement to generate data:

```
drop table if exists pai_doc_similarity_input;
create table pai_doc_similarity_input as
select * from (
select 0 as id,
"Beijing and Shanghai" as col0,
"Beijing and Shanghai" as col1 from dual union all
select 1 as id,
"Beijing and Shanghai" as col0,
"Beijing, Shanghai, and Hong Kong" as col1 from dual )tmp;
```

- PAI command

```
drop table if exists pai_doc_similarity_output;
PAI -name doc_similarity
-project algo_public
-DinputTableName=pai_doc_similarity_input
-DoutputTableName=pai_doc_similarity_output
-DinputSelectedColName1=col0
-DinputSelectedColName2=col1
-Dmethod=levenshtein_sim
-DinputAppendColNames=id,col0,col1;
```

- Input description: pai_doc_similarity_input

ID	col0	col1
1	Beijing and Shanghai	Beijing, Shanghai, and Hong Kong
0	Beijing and Shanghai	Beijing and Shanghai

- Output description: pai_doc_similarity_output

ID	col0	col1	Output
1	Beijing and Shanghai	Beijing, Shanghai, and Hong Kong	0.6666666666666667
0	Beijing and Shanghai	Beijing and Shanghai	1.0

4.4.9.12. PMI

Mutual information (MI) is a measure of information in the information theory. It can be regarded as the amount of information contained in a random variable about another variable, or the reduction in uncertainty of a random variable due to the known random variable.

This algorithm is used to count the co-occurrence of all words in several documents and calculate the point mutual information (PMI) . PMI definition: $PMI(x,y)=\ln(p(x,y)/(p(x)p(y)))=\ln(\#(x,y)D/(\#x\#y))$.

- $\#(x,y)$ indicates the number of pair(x,y).
- D indicates the total number of pairs.
- If x and y appear in the same window, the output is $\#x+=1;\#y+=1;\#(x,y)+=1$.

PAI command

```
PAI -name PointwiseMutualInformation
  -project algo_public
  -DinputTableName=maple_test_pmi_basic_input
  -DdocColName=doc
  -DoutputTableName=maple_test_pmi_basic_output
  -DminCount=0
  -DwindowSize=2
  -DcoreNum=1
  -DmemSizePerCore=110;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
outputTableName	Required. The name of the output table.	Table name	-

Parameter	Description	Valid values	Default value
docColName	Required. The name of the document column after word splitting, where words are separated with spaces.	Column name	-
windowSize	Optional. The window size. For example, the value 5 refers to the five words adjacent on the right of the current word. Words that appear in the window are considered related to the current word.	[1, sentence length]	The whole row is selected by default.
minCount	The minimum word truncation frequency. Words that appear for a number of times less than this value are filtered out.	[0, 2e63]	5
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of <code>partition_name=value</code> . To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with <code>memSizePerCore</code> . The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

Examples

- Data generation

<code>doc:string</code>
<code>w1 w2 w3 w4 w5 w6 w7 w8 w8 w9</code>

doc:string
w1 w3 w5 w6 w9
w0
w0 w0
w9 w1 w9 w1 w9

• PAI command

```
PAI -name PointwiseMutualInformation
  -project algo_public
  -DinputTableName=maple_test_pmi_basic_input
  -DdocColName=doc
  -DoutputTableName=maple_test_pmi_basic_output
  -DminCount=0
  -DwindowSize=2
  -DcoreNum=1
  -DmemSizePerCore=110;
```

• Output description

w9	w9	12	12	2	-0.8109302162163288

4.4.9.13. Word frequency statistics

Based on the word splitting results, this component outputs the words in their original order and calculates the frequency that a word occurs in the document (docContent) specified by the document ID column (docId).

Parameter settings

Input parameters: docId column and docContent column generated by the Word Splitting component.

Two output parameters:

- Output port 1: The output table contains the id, word, and count columns.
count: indicates the frequency that a word occurs in each document.
- Output port 2: The output table contains the id and word columns.

The table output by the second output port lists words in order of occurrence in the document. The table does not calculate the frequency of the occurrence. Therefore, a word may have multiple table entries in the same document. The output table format is compatible with the Word2Vec component.

Examples

In the Alibaba Cloud word splitting data, the two columns in the output table are used as the input parameters for word frequency calculation.

- Select the docId column: id.
- Select the docContent column: After the word frequency calculation is performed, the result is displayed by output port 1 on this component.

PAI command

```
pai -name doc_word_stat
    -project algo_public
    -DinputTableName=doc_test_split_word
    -DdocId=id
    -DdocContent=content
    -DoutputTableNameMulti=doc_test_stat_multi
    -DoutputTableNameTriple=doc_test_stat_triple
    -DinputTablePartitions="region=cctv_news"
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	The name of the input table.	-	-
docId	The name of the document ID column.	Only one column can be specified.	-
docContent	The name of the document content column.	Only one column can be specified.	-
outputTableNameMulti	The name of the output table that lists words in the document content after word splitting. Documents are specified by the docId column and their contents are specified by the docContent column. The words are listed in the order that they occur within the documents.	-	-

Parameter	Description	Valid values	Default value
outputTableNameTriple	The name of the output table that lists the words and the frequency of the occurrence of these words in the documents. The documents are specified by the docId column and their contents are specified by the docContent column.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of <code>partition_name=value</code> . To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.

4.4.9.14. TF-IDF

Term frequency-inverse document frequency (TF-IDF) is typically used as a weighting technology in information retrieval and text mining. TF-IDF is a statistical method to evaluate the importance of a word for a document in a collection or corpus. The importance of a word increases as the frequency that it occurs within the document increases. The importance decreases as the frequency that the word occurs in the corpus increases. TF-IDF is frequently used by search engines as a tool in scoring and ranking the correlation between documents and user queries.

- For more information, see TF-IDF in Wikipedia.
- The TF-IDF component is used to calculate the TF-IDF value of each word that appears in a collection of documents based on word frequency statistics.

Examples

The output table in the example of the word frequency statistics component is used as the input table for the TF-IDF component. The corresponding parameter settings are as follows:

- Select the document ID column: id
- Select the word column: word
- Select the word count column: count

The output table contains the following columns: docid, word, word_count (frequency that a certain word occurs in the current document), total_word_count (total number of words in the current document), doc_count (total number of documents that contain the current word), total_doc_count (total number of documents), tf, idf.

PAI command

```
pai -name tfidf
  -project algo_public
  -DinputTableName=rgdoc_split_triple_out
  -DdocIdCol=id
  -DwordCol=word
  -DcountCol=count
  -DoutputTableName=rg_tfidf_out;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
<code>inputTableName</code>	Required. The name of the input table.	Table name	-
<code>inputTablePartitions</code>	Optional. The partitions selected from the input table for word splitting.	This value must be in the <code>partition_name=value</code> format. To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	All partitions in the input table are selected by default.
<code>docIdCol</code>	Required. The name of the document ID column.	Only one column can be specified.	-
<code>wordCol</code>	Required. The name of the word column.	Only one column can be specified.	-
<code>countCol</code>	Required. The name of the count column.	Only one column can be specified.	-
<code>outputTableName</code>	Required. The name of the output table.	Table name	-
<code>outputTablePartition</code>	The partitions in the output table.	Partition name	The output table is non-partitioned by default.

4.4.9.15. PLDA

Latent Dirichlet Allocation (LDA) is a topic model that outputs the topic of a document. It outputs the topic of each document based on probability distribution. LDA is an unsupervised learning algorithm that does not require a manually tagged training set. Instead, it only requires a set of documents and the number of topics (k). It is used in text mining, including text topic recognition, text classification, and text similarity calculation.

Parameter settings

Parameters

Parameter	Description
Topics	The number of topics output by LDA.
Alpha	The AlphaPrior Dirichlet distribution parameter of $P(z/d)$.
Beta	The AlphaPrior Dirichlet distribution parameter of $P(w/z)$.
Burn-in Iterations	The number of burn-in iterations. The parameter value must be less than the total number of iterations. The default value is 100.

Parameter	Description
Total Iterations	Optional. The total number of iterations. The parameter value must be a positive integer. The default value is 150.

Note z represents topics, w represents words, and d represents documents.

Input and output settings

Input:

The data must be in the sparse matrix format. For more information about the format, see the data format description section. You can use the Convert Row, Column, and Value to KV Pair component to convert the data. Input format as shows the following picture.

```

+-----+-----+
| id      | features |
+-----+-----+
| 2       | 38:3.0,39:1.0,40:3.0,41:1.0,42:1.0,43:2.0,44:1.0,45:1.0,46:1.0,47:1.0,48:1.0,49:2.0,50:1.0,51:1.0,52:1.0,53:1.0,54:1.0,55:1.0,56:1.0,57:1.0,58:1.0,59:1.0,60:1.0,61:1.0,62:1.0,63:1.0,64:1.0,65:1.0,66:1.0,67:1.0,68:1.0,69:1.0,70:1.0,71:1.0,72:1.0,73:1.0,74:1.0,75:1.0,76:1.0,77:2.0 |
| 1       | 0:1.0,1:2.0,3:1.0,4:1.0,5:1.0,6:1.0,7:1.0,8:1.0,9:1.0,10:1.0,11:1.0,12:1.0,13:1.0,14:2.0,15:1.0,16:1.0,17:1.0,18:1.0,19:1.0,20:1.0,21:1.0,22:1.0,23:1.0,24:1.0,25:1.0,26:1.0,27:1.0,28:1.0,29:1.0,30:1.0,31:1.0,32:1.0,33:1.0,34:1.0,35:1.0,36:2.0,39:2.0,77:3.0 |
+-----+-----+
    
```

- o Column 1: the ID of a document.
- o Column 2: KV data of the word and how frequently it occurs.

Output:

The following tables are generated in sequence: topic-word frequency contribution table, P(w/z) table, P(z/w) table, P(d/z) table, P(z/d) table, and P(z) table.

The following picture shows the output format of the topic-word frequency contribution table.

```

+-----+-----+-----+
| wordid | topic_0 | topic_1 |
+-----+-----+-----+
| 0      | 1       | 0       |
| 1      | 2       | 0       |
| 2      | 0       | 0       |
| 3      | 1       | 0       |
| 4      | 1       | 0       |
| 5      | 1       | 0       |
| 6      | 1       | 0       |
| 7      | 1       | 0       |
| 8      | 0       | 1       |
| 9      | 1       | 0       |
| 10     | 1       | 0       |
| 11     | 1       | 0       |
| 12     | 1       | 0       |
+-----+-----+-----+
    
```

PAI command

```

pai -name PLDA
    -project algo_public
    -DinputTableName=lda_input
    -DtopicNum=10
    -topicWordTableName=lda_output;
    
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
-----------	-------------	--------------	---------------

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	Optional. The partitions selected from the input table for word splitting.	This value must be in the partition_name=value format. To specify multiple partitions, use the following format: name1=value1/name2=value2 . Separate multiple partitions with commas (,).	All partitions in the input table are selected by default.
selectedColNames	Optional. The names of the columns selected from the input table for LDA.	Separate multiple columns with commas (,).	All columns in the input table are selected by default.
topicNum	Required. The number of topics.	[2, 500]	-
kvDelimiter	Optional. The delimiter used to separate the key and value.	Space, comma (,), and colon (:)	The default delimiter is a colon (:).
itemDelimiter	Optional. The delimiter used to separate keys.	Space, comma (,), and colon (:)	The default delimiter is a space.
alpha	Optional. The prior Dirichlet distribution parameter of $P(z/d)$.	$(0, \infty)$	0.1
beta	Optional. The prior Dirichlet distribution parameter of $P(w/z)$.	$(0, \infty)$	0.01
topicWordTableName	Required. The name of the topic-word frequency contribution table.	Table name	-
pwzTableName	Optional. The name of the $P(w/z)$ table.	Table name	No $P(w/z)$ table is output by default.
pzwTableName	Optional. The name of the $P(z/w)$ table.	Table name	No $P(z/w)$ table is output by default.
pdzTableName	Optional. The name of the $P(d/z)$ table.	Table name	No $P(d/z)$ table is output by default.
pzdTableName	Optional. The name of the $P(z/d)$ table.	Table name	No $P(z/d)$ table is output by default.
pzTableName	Optional. The name of the $P(z)$ table.	Table name	No $P(z)$ table is output by default.

Parameter	Description	Valid values	Default value
burnIterations	Optional. The number of burn-in iterations.	A positive integer	This value must be smaller than the total number of iterations. The default value is 100.
totalIterations	Optional. The number of iterations.	A positive integer	150

4.4.9.16. Word2Vec

Word2Vec is an open-source algorithm used to convert words into vectors. By training neural networks, Word2Vec can map words to K-dimensional space vectors and map word vectors to semantics.

For information about the Google Word2Vec toolkit, visit <https://code.google.com/p/word2vec/>.

Parameter settings

- Dimension of Word Features: We recommend a value from 0 to 1000.
- Downsampling Threshold: We recommend a value from 1e-3 to 1e-5.
- Input: inputs a word column and a vocabulary.
- Output: generates a word vector table and a vocabulary.

PAI command

```
pai -name Word2Vec
    -project algo_public
    -DinputTableName=w2v_input
    -DwordColName=word
    -DoutputTableName=w2v_output;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	Optional. The partitions selected from the input table for word splitting.	The parameter value must be in the <code>partition_name=value</code> format. To specify multiple partitions, use the following format: <code>name1=value1/name2=value2</code> . Separate multiple partitions with commas (,).	All partitions in the input table are selected by default.

Parameter	Description	Valid values	Default value
wordColName	Required. The name of the word column. Each row in the word column contains a single word. </s> is used to break lines in the corpus.	Column name	-
inVocabularyTableName	Optional. The name of the input word list, which contains the wordcount output of inputTableName.	Table name	Word count is performed for the input table by default.
inVocabularyPartitions	Optional. The partitions in the input word list.	Partition name	By default, all partitions in the table specified by inVocabularyTableName are selected.
layerSize	Optional. The dimension of word features.	0 to 1000	100
cbow	Optional. The language model.	1: cbow. 0: skip-gram.	0
window	Optional. The size of the word window.	A positive integer	5
minCount	Optional. The minimum frequency of word truncation.	A positive integer	5
hs	Optional. This parameter specifies whether to use hierarchical softmax.	1: Hierarchical softmax is used. 0: Hierarchical softmax is not used.	1
negative	Optional. The negative sampling.	0: Negative sampling is unavailable. Recommended value range: 5 to 10.	0
sample	Optional. The downward sampling threshold.	0 or smaller values: downward sampling is unavailable. Recommended value range: 1e-3 to 1e-5.	0
alpha	Optional. The initial learning rate.	A value greater than 0	0.025
iterTrain	Optional. The number of training iterations.	A value greater than or equal to 1	1

Parameter	Description	Valid values	Default value
randomWindow	Optional. This parameter specifies whether to randomly set the size of the window.	1: The window size is randomly generated. The window size value will range from 1 to 5. 0: The window size is determined by the window parameter.	1
outVocabularyTableName	Optional. The name of the output word list.	Table name	No Output Word List is generated by default.
outVocabularyPartition	Optional. The partition in the output word list.	Partition name	The output word list is non-partitioned by default.
outputTableName	Required. The name of the output table.	Table name	-
outputPartition	Optional. The information about partitions in the output table.	Partition name	The output table is non-partitioned by default.

4.4.10. Network analysis

4.4.10.1. K-core

The k-core of a graph is the largest subgraph in which every vertex is connected to at least k other vertices within the subgraph. The coreness of a vertex is k if it belongs to the k-core but is not included in the (k+1)-core. Therefore, the coreness of a vertex whose degree is 1 must be 0. The graph coreness is equal to that of the vertex with the largest coreness.

Parameter settings

k: Required. The value of the coreness. Default value: 3.

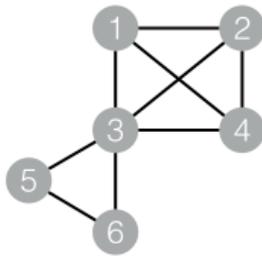

Examples - Testing data

SQL statement to generate data:

```
drop table if exists KCore_func_test_edge;
create table KCore_func_test_edge as
select * from (
select '1' as flow_out_id,
'2' as flow_in_id from dual union all
select '1' as flow_out_id,
'3' as flow_in_id from dual union all
select '1' as flow_out_id,
'4' as flow_in_id from dual union all
select '2' as flow_out_id,
'3' as flow_in_id from dual union all
select '2' as flow_out_id,
'4' as flow_in_id from dual union all
select '3' as flow_out_id,
'4' as flow_in_id from dual union all
select '3' as flow_out_id,
'5' as flow_in_id from dual union all
select '3' as flow_out_id,
'6' as flow_in_id from dual union all
select '5' as flow_out_id,
'6' as flow_in_id from dual )tmp;
```

Graph structure shows the group structure.

-Dk=2;
    
```

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the edge table.	Yes	-
toVertexCol	The end vertex column in the edge table.	Yes	-
outputTableName	The name of the output table.	Yes	-
outputTablePartitions	The partitions in the output table.	No	-
lifecycle	The lifecycle of the output table.	No	-
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096
splitSize	The data split size.	No	64
k	The number of cores.	Yes	3

4.4.10.2. Single-source shortest path

The single-source shortest path (SSSP) refers to the shortest path between a vertex and all other vertices as calculated by the Dijkstra algorithm.

Parameter settings

Start Vertex ID: Required. The ID of the start vertex used to calculate the shortest paths.

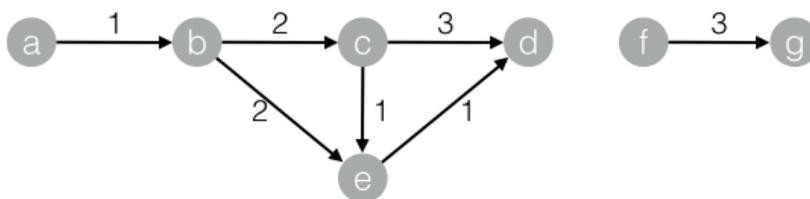

Examples - Testing data

SQL statement to generate data:

```
drop table if exists SSSP_func_test_edge;
create table SSSP_func_test_edge
as select
flow_out_id,flow_in_id,edge_weight from (
select "a" as flow_out_id,
"b" as flow_in_id,
1.0 as edge_weight from dual union all
select "b" as flow_out_id,
"c" as flow_in_id,
2.0 as edge_weight from dual union all
select "c" as flow_out_id,
"d" as flow_in_id,
1.0 as edge_weight from dual union all
select "b" as flow_out_id,
"e" as flow_in_id,
2.0 as edge_weight from dual union all
select "e" as flow_out_id,
"d" as flow_in_id,
1.0 as edge_weight from dual union all
select "c" as flow_out_id,
"e" as flow_in_id,
1.0 as edge_weight from dual union all
select "f" as flow_out_id,
"g" as flow_in_id,
3.0 as edge_weight from dual union all
select "a" as flow_out_id,
"d" as flow_in_id,
4.0 as edge_weight from dual ) tmp ;
```

Graph structure shows the graph structure.

Graph structure

Output

start_node	dest_node	distance	distance_cnt
a	b	1.0	1
a	c	3.0	1
a	d	4.0	3
a	a	0.0	0
a	e	3.0	1

PAI command

```

pai -name SSSP
-project algo_public
-DinputEdgeTableName=SSSP_func_test_edge
-DfromVertexCol=flow_out_id
-DtoVertexCol=flow_in_id
-DoutputTableName=SSSP_func_test_result
-DhasEdgeWeight=true
-DedgeWeightCol=edge_weight
-DstartVertex=a;
  
```

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	-
toVertexCol	The end vertex column in the input edge table.	Yes	-
outputTableName	The name of the output table.	Yes	-
outputTablePartitions	The partitions in the output table.	No	-
lifecycle	The lifecycle of the output table.	No	-
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096
splitSize	The data split size.	No	64
startVertex	The ID of the start vertex.	Yes	-
hasEdgeWeight	Specifies whether the edges in the input edge table have weights.	No	false
edgeWeightCol	The edge weight column in the input edge table.	No	-

4.4.10.3. PageRank

The PageRank algorithm is used to sort and calculate the rankings of web pages based on their link sources.

Features

The basic principle of the PageRank algorithm is as follows: The more web pages that direct to a web page, the more importance or higher quality the web page has. In addition to the number of links directing to a web page, the weight of the web page and the number of outgoing links are also considered during page ranking. For a social network of users, the edge weight is an important factor in addition to the influence of the users. For example, a Sina Weibo user is more likely to have influence on their family, friends, classmates, and colleagues than they will on followers with a weaker relationship. In the social network, the edge weight is equivalent to the user-to-user relationship strength index. The PageRank formula with connection weight is as follows:

$$W(A) = (1 - d) + d * \left(\sum_i W(i) * C(Ai) \right)$$

In the formula, $W(i)$ represents the weight of node i , $C(A,i)$ represents the link weight, and d represents the damping coefficient. W is the influence index of each user and represents the node weight after the algorithm iteration becomes stable.

Parameter settings

Maximum Iterations: Optional. The number of iterations performed before the algorithm automatically converges. Default value: 30.

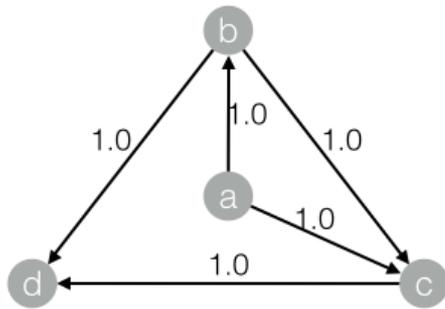

Examples - Testing data

SQL statement to generate data:

```
drop table if exists PageRankWithWeight_func_test_edge;
create table PageRankWithWeight_func_test_edge
as select * from (
select 'a' as flow_out_id,
'b' as flow_in_id,
1.0 as weight from dual union all
select 'a' as flow_out_id,
'c' as flow_in_id,
1.0 as weight from dual union all
select 'b' as flow_out_id,
'c' as flow_in_id,
1.0 as weight from dual union all
select 'b' as flow_out_id,
'd' as flow_in_id,
1.0 as weight from dual union all
select 'c' as flow_out_id,
'd' as flow_in_id,1.0 as weight from dual )tmp ;
```

[Graph structure](#) shows the graph structure.

Graph structure

```

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	-
toVertexCol	The end vertex column in the input edge table.	Yes	-
outputTableName	The name of the output table.	Yes	-

Parameter	Description	Required	Default value
<code>outputTablePartitions</code>	The partitions in the output table.	No	-
<code>lifecycle</code>	The lifecycle of the output table.	No	-
<code>workerNum</code>	The number of workers.	No	-
<code>workerMem</code>	The memory size per worker.	No	4096
<code>splitSize</code>	The data split size.	No	64
<code>hasEdgeWeight</code>	Specifies whether the edges in the input edge table have weights.	No	false
<code>edgeWeightCol</code>	The edge weight column in the input edge table.	No	-
<code>maxIter</code>	The maximum number of iterations.	No	30

4.4.10.4. Label propagation clustering

Graph clustering is used to divide a graph into subgraphs based on the topology of the graph so that the links between the nodes in a subgraph are more than the links between the subgraphs. The label propagation algorithm (LPA) is a graph-based semi-supervised machine learning algorithm. The labels of a node (community) depend on those of the neighboring nodes. The degree of dependence is determined by the similarity between nodes. Data becomes stable by iterative propagation update.

Parameters

Maximum Iterations: Optional. The maximum number of iterations. Default value: 30.

Examples - Testing data

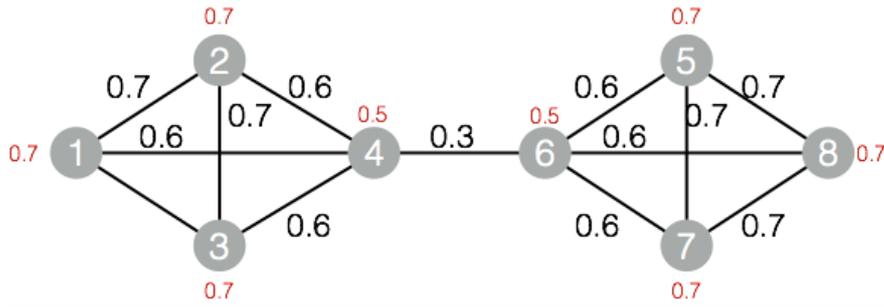

SQL statement to generate data:

```
drop table if exists LabelPropagationClustering_func_test_edge;
create table LabelPropagationClustering_func_test_edge
as select * from (
select '1' as flow_out_id,
'2' as flow_in_id,
0.7 as edge_weight from dual union all
select '1' as flow_out_id,
'3' as flow_in_id,
0.7 as edge_weight from dual union all
select '1' as flow_out_id,
'4' as flow_in_id,
0.6 as edge_weight from dual union all
select '2' as flow_out_id,
'3' as flow_in_id,
0.7 as edge_weight from dual union all
select '2' as flow_out_id,
```

```
'4' as flow_in_id,
0.6 as edge_weight from dual union all
select '3' as flow_out_id,

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.

Parameter	Description	Required	Default value
fromVertexCol	The start vertex column in the input edge table.	Yes	-
toVertexCol	The end vertex column in the input edge table.	Yes	-
inputVertexTableName	The name of the input vertex table.	Yes	-
inputVertexTablePartitions	The partitions in the input vertex table.	No	The whole table is selected by default.
vertexCol	The vertex column in the input vertex table.	Yes	-
outputTableName	The name of the output table.	Yes	-
outputTablePartitions	The partitions in the output table.	No	-
lifecycle	The lifecycle of the output table.	No	-
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096
splitSize	The data split size.	No	64
hasEdgeWeight	Specifies whether the edges in the input edge table have weights.	No	false
edgeWeightCol	The edge weight column in the input edge table.	No	-
hasVertexWeight	Specifies whether the vertices in the input vertex table have weights.	No	false
vertexWeightCol	The vertex weight column in the input vertex table.	No	-
randSelect	Specifies whether the maximum label value is to be randomly selected.	No	false
maxIter	The maximum number of iterations.	No	30

4.4.10.5. Label propagation classification

Label propagation classification is a semi-supervised classification algorithm. It uses the label information of labeled nodes to predict the label information for unlabeled nodes.

Features

During algorithm execution, the labels of each node are propagated to the neighboring nodes based on the similarity between the nodes. In each step of propagation, a node updates its labels based on the labels of the neighboring nodes so that the node is more similar to the neighboring nodes. The higher the similarity, the more labeling influences the neighboring nodes have on that node, and the easier it is for the labels to be propagated. During label propagation, the labels of the labeled data remain unchanged. These labels serve as sources for propagation to the unlabeled data.

After the iterations end, the probability distributions of similar nodes tend to be similar. These nodes can be classified into the same category. This completes the label propagation.

Parameter settings

Damping factor: The default value is 0.8. Convergence factor: The default value is 0.000001.

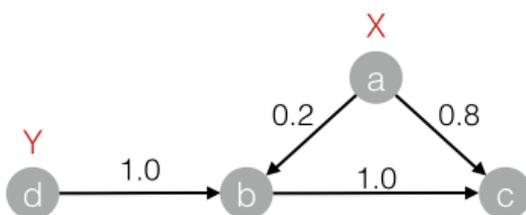

Examples - Testing data

SQL statement to generate data:

```
drop table if exists LabelPropagationClassification_func_test_edge;
create table LabelPropagationClassification_func_test_edge
as select * from (
select 'a' as flow_out_id,
'b' as flow_in_id,
0.2 as edge_weight from dual union all
select 'a' as flow_out_id,
'c' as flow_in_id,
0.8 as edge_weight from dual union all
select 'b' as flow_out_id,
'c' as flow_in_id,
1.0 as edge_weight from dual union all
select 'd' as flow_out_id,
'b' as flow_in_id,
1.0 as edge_weight from dual )tmp ;
drop table if exists LabelPropagationClassification_func_test_node;
create table LabelPropagationClassification_func_test_node
as select * from (
select 'a' as node,
'X' as label,
1.0 as label_weight from dual union all
select 'd' as node,
'Y' as label,
1.0 as label_weight from dual )tmp ;
```

Graph structure shows the graph structure.

Graph structure

Output

node	tag	weight
a	X	1.0
b	X	0.16667
b	Y	0.83333
c	X	0.53704
c	Y	0.46296
d	Y	1.0

PAI command

```

pai -name LabelPropagationClassification
  -project algo_public
  -DinputEdgeTableName=LabelPropagationClassification_func_test_edge
  -DfromVertexCol=flow_out_id
  -DtoVertexCol=flow_in_id
  -DinputVertexTableName=LabelPropagationClassification_func_test_node
  -DvertexCol=node
  -DvertexLabelCol=label
  -DoutputTableName=LabelPropagationClassification_func_test_result
  -DhasEdgeWeight=true
  -DedgeWeightCol=edge_weight
  -DhasVertexWeight=true
  -DvertexWeightCol=label_weight
  -Dalpha=0.8
  -Depsilon=0.000001;

```

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	-
toVertexCol	The end vertex column in the input edge table.	Yes	-
inputVertexTableName	The name of the input vertex table.	Yes	-
inputVertexTablePartitions	The partitions in the input vertex table.	No	The whole table is selected by default.

Parameter	Description	Required	Default value
vertexCol	The vertex column in the input vertex table.	Yes	-
vertexLabelCol	The vertex label column in the input vertex table.	Yes	-
outputTableName	The name of the output table.	Yes	-
outputTablePartitions	The partitions in the output table.	No	-
lifecycle	The lifecycle of the output table.	No	-
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096
splitSize	The data split size.	No	64
hasEdgeWeight	Specifies whether the edges in the input edge table have weights.	No	false
edgeWeightCol	The edge weight column in the input edge table.	No	-
hasVertexWeight	Specifies whether the vertices in the input vertex table have weights.	No	false
vertexWeightCol	The vertex weight column in the input vertex table.	No	-
alpha	The damping coefficient.	No	0.8
epsilon	The convergence coefficient.	No	0.000001
maxIter	The maximum number of iterations.	No	30

4.4.10.6. Modularity

Modularity is used to measure the structure of the community network. It measures the closeness of the communities divided from a network structure. A value larger than 0.3 represents an obvious community structure.

Examples - Testing data

For more information, see [Label propagation clustering](#).

Output

val
0.4230769

PAI command

```

pai -name Modularity
-project algo_public
-DinputEdgeTableName=Modularity_func_test_edge
-DfromVertexCol=flow_out_id

-DtoGroupCol=group_in_id
-DoutputTableName=Modularity_func_test_result;
  
```

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	-
fromGroupCol	The start vertex group in the input edge table.	Yes	-
toVertexCol	The end vertex column in the input edge table.	Yes	-
toGroupCol	The end vertex group in the input edge table.	Yes	-
outputTableName	The name of the output table.	Yes	-
outputTablePartitions	The partitions in the output table.	No	-
lifecycle	The lifecycle of the output table.	No	-
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096

Parameter	Description	Required	Default value
splitSize	The data split size.	No	64

4.4.10.7. Maximum connected subgraph

In an undirected graph G, vertex A is connected to vertex B if a path exists between the two vertices. Graph G contains several subgraphs. Each vertex is connected to other vertices in the same subgraph. Vertices in different subgraphs are not connected. In this case, the subgraphs of graph G are called maximum connected subgraphs.

Features

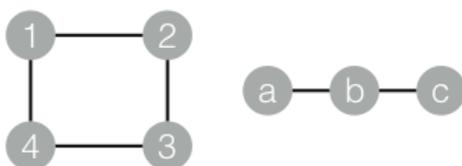

Examples - Testing data

SQL statement to generate data:

```
drop table if exists MaximalConnectedComponent_func_test_edge;
create table MaximalConnectedComponent_func_test_edge
as select * from (
select '1' as flow_out_id,
'2' as flow_in_id from dual union all
select '2' as flow_out_id,
'3' as flow_in_id from dual union all
select '3' as flow_out_id,
'4' as flow_in_id from dual union all
select '1' as flow_out_id,
'4' as flow_in_id from dual union all
select 'a' as flow_out_id,
'b' as flow_in_id from dual union all
select 'b' as flow_out_id,
'c' as flow_in_id from dual )tmp;
drop table if exists MaximalConnectedComponent_func_test_result;
create table MaximalConnectedComponent_func_test_result ( node string, grp_id string);
```

Graph structure shows the graph structure.

Graph structure

Output

node	grp_id
1	4
2	4
3	4
4	4
a	c
b	c
c	c

PAI command

splitSize	The data split size.	No	64

4.4.10.8. Vertex clustering coefficient

This coefficient is used to calculate the peripheral density of a vertex in an undirected graph G. The density of a star network is 0, and that of a fully meshed network is 1.

Parameter settings

maxEdgeCnt: Optional. If the node degree is larger than the value of this parameter, sampling is required.
Default value: 500.

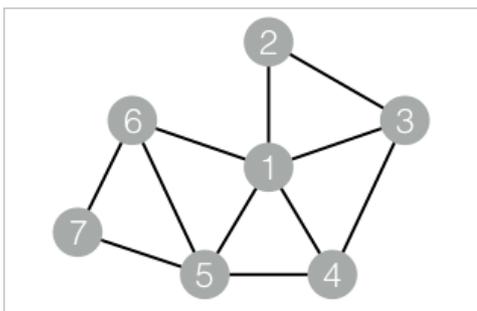

Examples - Testing data

SQL statement to generate data:

```
drop table if exists NodeDensity_func_test_edge;
create table NodeDensity_func_test_edge
as select * from (
select '1' as flow_out_id,

Parameter	Description	Required	Default value
splitSize	The data split size.	No	64

4.4.10.9. Edge clustering coefficient

This coefficient is used to calculate the peripheral density of each edge in an undirected graph G.

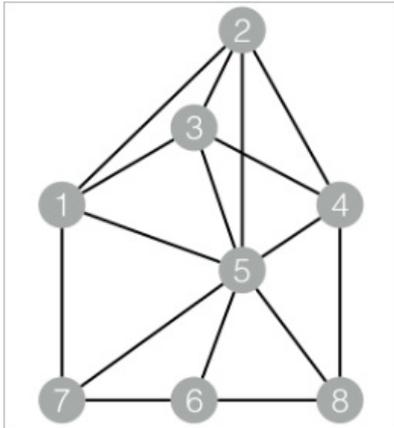

Examples - Testing data

SQL statement to generate data:

```
drop table if exists EdgeDensity_func_test_edge;
create table EdgeDensity_func_test_edge
as select * from (
select '1' as flow_out_id,
'2' as flow_in_id from dual union all
select '1' as flow_out_id,
'3' as flow_in_id from dual union all
select '1' as flow_out_id,
'5' as flow_in_id from dual union all
select '1' as flow_out_id,
'7' as flow_in_id from dual union all
select '2' as flow_out_id,
'5' as flow_in_id from dual union all
select '2' as flow_out_id,
'4' as flow_in_id from dual union all
select '2' as flow_out_id,
'3' as flow_in_id from dual union all
select '3' as flow_out_id,
'5' as flow_in_id from dual union all
select '3' as flow_out_id,
'4' as flow_in_id from dual union all
select '4' as flow_out_id,
'5' as flow_in_id from dual union all
select '4' as flow_out_id,
'8' as flow_in_id from dual union all
select '5' as flow_out_id,
'6' as flow_in_id from dual union all
select '5' as flow_out_id,
'7' as flow_in_id from dual union all
select '5' as flow_out_id,
'8' as flow_in_id from dual union all
select '7' as flow_out_id,
'6' as flow_in_id from dual union all
select '6' as flow_out_id,
'8' as flow_in_id from dual )tmp;
drop table if exists EdgeDensity_func_test_result;
create table EdgeDensity_func_test_result ( node1 string, node2 string, node1_edge_cnt bigint, node2_edge_c
nt bigint, triangle_cnt bigint, density double );
```

[Graph structure](#) shows the graph structure.

Graph structure

Output

```
1,2,4,4,2,0.5
2,3,4,4,3,0.75
2,5,4,7,3,0.75
3,1,4,4,2,0.5

-DoutputTableName=EdgeDensity_func_test_result;
```

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	-

Parameter	Description	Required	Default value
toVertexCol	The end vertex column in the input edge table.	Yes	-
outputTableName	The name of the output table.	Yes	-
outputTablePartitions	The partitions in the output table.	No	-
lifecycle	The lifecycle of the output table.	No	-
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096
splitSize	The data split size.	No	64

4.4.10.10. Counting triangle

All triangles can be output to an undirected graph G.

Parameter settings

maxEdgeCnt: Optional. If the node degree is larger than the value of this parameter, sampling is required.
 Default value: 500.

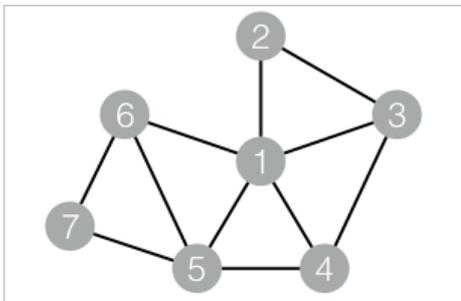

Examples - Testing data

SQL statement to generate data:

```
drop table if exists TriangleCount_func_test_edge;
create table TriangleCount_func_test_edge
as select * from (
select '1' as flow_out_id,
'2' as flow_in_id from dual union all
select '1' as flow_out_id,
'3' as flow_in_id from dual union all
select '1' as flow_out_id,
'4' as flow_in_id from dual union all
select '1' as flow_out_id,
'5' as flow_in_id from dual union all
select '1' as flow_out_id,
'6' as flow_in_id from dual union all
select '2' as flow_out_id,
'3' as flow_in_id from dual union all
select '3' as flow_out_id,
'4' as flow_in_id from dual union all
select '4' as flow_out_id,
'5' as flow_in_id from dual union all
select '5' as flow_out_id,
'6' as flow_in_id from dual union all
select '5' as flow_out_id,
'7' as flow_in_id from dual union all
select '6' as flow_out_id,
'7' as flow_in_id from dual )tmp;
drop table if exists TriangleCount_func_test_result;
create table TriangleCount_func_test_result ( node1 string, node2 string, node3 string);
```

Graph structure shows the graph structure.

Graph structure

Output

```
1,2,3
1,3,4
1,4,5
1,5,6
5,6,7
```

PAI command

```

pai -name TriangleCount
-project algo_public
-DinputEdgeTableName=TriangleCount_func_test_edge
-DfromVertexCol=flow_out_id
-DtoVertexCol=flow_in_id
-DoutputTableName=TriangleCount_func_test_result;
    
```

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	-
toVertexCol	The end vertex column in the input edge table.	Yes	-
outputTableName	The name of the output table.	Yes	-
outputTablePartitions	The partitions in the output table.	No	-
lifecycle	The lifecycle of the output table.	No	-
maxEdgeCnt	If the node degree is larger than the value of this parameter, sampling is required.	No	500
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096
splitSize	The data split size.	No	64

4.4.10.11. Tree depth

In a tree network, this component outputs the depth of each node in a tree and the tree ID.

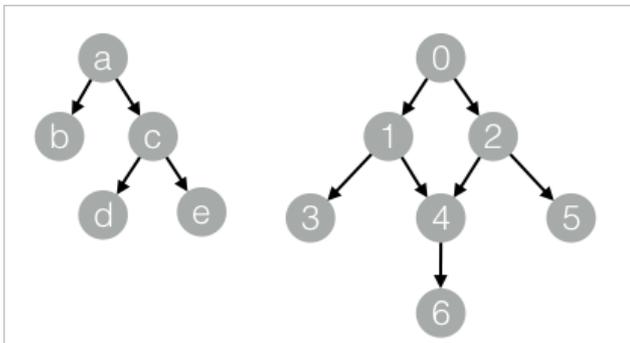

Examples - Testing data

SQL statement to generate data:

```
drop table if exists TreeDepth_func_test_edge;
create table TreeDepth_func_test_edge
as select * from (
select '0' as flow_out_id,
'1' as flow_in_id from dual union all
select '0' as flow_out_id,
'2' as flow_in_id from dual union all
select '1' as flow_out_id,
'3' as flow_in_id from dual union all
select '1' as flow_out_id,
'4' as flow_in_id from dual union all
select '2' as flow_out_id,
'4' as flow_in_id from dual union all
select '2' as flow_out_id,
'5' as flow_in_id from dual union all
select '4' as flow_out_id,
'6' as flow_in_id from dual union all
select 'a' as flow_out_id,
'b' as flow_in_id from dual union all
select 'a' as flow_out_id,
'c' as flow_in_id from dual union all
select 'c' as flow_out_id,
'd' as flow_in_id from dual union all
select 'c' as flow_out_id,
'e' as flow_in_id from dual )tmp;
drop table if exists TreeDepth_func_test_result;
create table TreeDepth_func_test_result ( node string, root string, depth bigint );
```

Graph structure shows the graph structure.

Graph structure

Output

```
0,0,0
1,0,1
2,0,1
3,0,2
4,0,2
5,0,2
6,0,3
a,a,0
b,a,1
c,a,1
d,a,2
e,a,2
```

PAI command

```
pai -name TreeDepth
-project algo_public
-DinputEdgeTableName=TreeDepth_func_test_edge
-DfromVertexCol=flow_out_id
-DtoVertexCol=flow_in_id
-DoutputTableName=TreeDepth_func_test_result;
```

Algorithm parameters

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	-
inputEdgeTablePartitions	The partitions selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	-
toVertexCol	The end vertex column in the input edge table.	Yes	-
outputTableName	The name of the output table.	Yes	-
outputTablePartitions	The partitions in the output table.	No	-
lifecycle	The lifecycle of the output table.	No	-
workerNum	The number of workers.	No	-
workerMem	The memory size per worker.	No	4096
splitSize	The data split size.	No	64

4.4.11. Tools

4.4.11.1. SQL script

You can use the SQL script editor to write SQL statements.

1. Drag and drop the **SQL Script** component onto the canvas.
2. Connect the input table to the **SQL Script** component, and then click **SQL Script**. The following configuration pane is displayed.
3. Write an SQL script in the text box.
 - An SQL script supports one to four inputs and one output.

- You can write only one SQL statement.
- The input data is automatically mapped to tables t1 through t4. You can directly call `#{t1}`, `#{t2}`, `#{t3}`, and `#{t4}` without specifying the table names.
- The sample SQL script calculates the number of rows in the input table.

4.4.12. Financials

4.4.12.1. Binning

The Binning component performs data binning based on equal-width or equal-frequency.

PAI command

```
PAI -name binning  
-project algo_public  
-DinputTableName=input  
-DoutputTableName=output
```

Parameters

Parameter	Description	Valid value	Default
inputTableName	Required. The name of the input table.	Table name	N/A
outputTableName	Required. The name of the output table.	Table name	N/A
selectedColNames	Optional. The names of columns selected from the input table for data binning.	Column name	All columns are selected, except for the label column.
labelColumn	Optional. The name of the column that stores the labels.	Column name	No label column is selected.
validTableName	Required when the binning mode (binningMethod) is set to auto. The name of the table used for calibration.	Table name	No table is specified for calibration.
validTablePartitions	Optional. The partitions selected from the calibration table.	Partition name	The whole table is selected.
inputTablePartitions	Optional. The partitions selected from the input table.	Partition name	The whole table is selected.
inputBinTableName	Optional. The name of the input binning table.	Table name	No binning table is specified.

Parameter	Description	Valid value	Default
selectedBinColNames	Optional. The names of the columns selected from the binning table.	Column name	No column is selected.
positiveLabel	Optional. The value used to represent positive samples.	N/A	1
nDivide	Optional. The number of bins.	A positive integer	10
colsNDivide	Optional. The numbers of bins customized for specified columns. Example: col0:3,col2:5. Columns specified in the colsNDivide parameter but not included in the selectedColNames parameter are also processed by the Binning component. For example, if selectedColNames is set to col0,col1 and colsNDivide is set to col0:3,col2:5, data binning is performed based on col0:3,col1:10,col2:5.	N/A	No custom binning rule is specified.
isLeftOpen	Optional. The type of the interval, which can be left-open, right-closed or left-closed, right-open.	true and false	true
stringThreshold	Optional. The discrete value threshold. Values below this threshold are put into other bins.	N/A	No discrete value threshold is set.
colsStringThreshold	Optional. The thresholds for specified columns. Specify the values in the same format of the colsNDivide parameter.	N/A	No threshold is set.
binningMethod	Optional. The binning mode.	quantile (equal-frequency), bucket (equal-width), and auto (automatic binning). If you select auto, monotonic binning is used based on equal-frequency.	quantile
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set.

Parameter	Description	Valid value	Default
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size per core.	A positive integer	Automatically calculated.

Constraints

Binning constraints must be used together with the Scorecard Training component. You can add constraints to the weight of each dummy variable when the Binning component discretizes features and transforms them into dummy variables. The definitions of the constraints are as follows:

- Ascending order: adds weights to the dummy variables of a feature based on the index values in ascending order. This means that dummy variables with higher index values have larger weights.
- Descending order: adds weights to the dummy variables of a feature based on the index values in descending order. This means that dummy variables with lower index values have lighter weights.
- Same weight: the weights of two dummy variables of a feature must be the same.
- Set weight to 0: sets the weight of a dummy variable to 0.
- Set weight to a specified value: sets the weight of a dummy variable to a floating point value.
- WOE order: adds weights to the dummy variables of a feature based on the WOE values in ascending order. This means that dummy variables with higher WOE values have larger weights.

4.4.12.2. Data conversion

Parameters

Parameter	Description
inputFeatureTableName	Required. The name of the input feature table.
inputBinTableName	Required. The name of the binning result table.
inputFeatureTablePartitions	Optional. The partitions selected from the feature table. By default, all partitions are selected.
outputTableName	Required. The name of the output table.
featureColNames	Optional. The names of the features selected from the input feature table. By default, all columns are selected.
metaColNames	Optional. The names of the columns to be reserved in the output table without data conversion. By default, no column is reserved. You can specify columns such as label and sample_id.
transformType	Optional. The type of data conversion. Valid values: normalize (normalization), dummy (discretization), and woe (WOE transformation). The default is dummy.
itemDelimiter	Optional. The delimiter used to separate features. By default, commas (,) are used. Only data discretization supports this parameter.

Parameter	Description
kvDelimiter	Optional. The delimiter used to separate keys and values. By default, colons (:) are used. Only data discretization supports this parameter.
lifecycle	Optional. The lifecycle of the output table. By default, no lifecycle is set.
coreNum	Optional. The number of cores. By default, the number of cores is automatically calculated.
memSizePerCore	Optional. The memory size per core in megabytes. By default, the memory size per core is automatically calculated.

instance

PAI command

```
PAI -name data_transform
  -project algo_public
  -DinputFeatureTableName=feature_table
  -DinputBinTableName=bin_table
  -DoutputTableName=output_table
  -DmetaColNames=label
  -DfeatureColNames=feaname1,feaname2
```

Normalization

The Normalization component transforms variable values to a scale of 0 to 1. Missing values are imputed with zeros. The algorithm is as follows:

```
if feature_raw_value == null or feature_raw_value == 0 then
  feature_norm_value = 0.0
else
  bin_index = FindBin(bin_table, feature_raw_value)
  bin_width = round(1.0 / bin_count * 1000) / 1000.0
  feature_norm_value = 1.0 - (bin_count - bin_index - 1) * bin_width
```

Output format

Normalization and WOE conversion tables output regular tables.

Dummy variable conversion in discretization outputs a table that contains KV pairs. The output variables are in the format of `[${feaname}]_bin_${bin_id}`. Taking variable `sns` as an example:

- If the variable `sns` is put into the second bin, the output variable is `[sns]_bin_2`.
- If the variable `sns` does not have a value, it is put into an empty bin. The output variable is `[sns]_bin_null`.
- If the variable `sns` has a value but it cannot be put into any of the predefined bins, it is put into the else bin. The output variable is `[sns]_bin_else`.

4.4.12.3. Scorecard training

The scorecard is a modeling tool widely used for credit score evaluation. It uses binning to discretize variables, and then uses linear models (logistic regression or linear regression) to train a model. The model training process includes feature selection and score transformation. The scorecard also allows you to add constraints to the variables during model training.

Note If you use the scorecard without binning, the entire model training process is equivalent to logistic regression or linear regression.

Feature engineering

The main difference between the scorecard and normal linear models is that the scorecard performs feature engineering before it trains linear models. The Scorecard component provides two methods for feature engineering. You must use binning to discretize the features first no matter which method you choose. One of the methods is to use one hot encoding to encode the variable binning results, and then generate N dummy variables. N represents the number of bins. The other method is to use Weight of Evidence (WOE) transformation. It replaces the original value of a variable with the WOE value of the bin where the variable is placed.

Note You can add constraints for each variable when you transform variables to dummy variables.

Score transformation

In the credit score evaluation scenario, you must use linear transformation to transform the odds of the samples in the prediction results to credit scores as follows:

$$\log(\text{odds}) = \sum(wx) = a \text{ scaled_score} + b$$

The parameters in the formula are as follows:

- scaledValue: specifies a base point to be scaled.
- odds: specifies an odd level.
- pdo: specifies the points to double the odds.

For example, if the scaledValue, odds, and pdo parameters are set to 800, 50, and 25, the two vectors that determine the score scale are as follows:

$$\begin{aligned}\log(40) &= a * 800 + b \\ \log(80) &= a * 825 + b\end{aligned}$$

Calculate the values of a and b, and then perform a linear transformation to obtain the scores.

The scaling information is specified in JSON format by using the -Dscale parameter as follows:

```
{"scaledValue":800,"odds":50,"pdo":25}
```

The three parameters must be set at the same time.

Add constraints

You can add constraints for variables during scorecard training. You can set the score of a bin to a fixed value, set a proportion between the scores of two bins, or limit the scores of bins. For example, you can sort the scores of the bins by WOE. The implementation of constraints depends on the underlying optimization algorithms with constraints. You can set a constraint in the Binning component. After you set the parameters, the component generates a constraint in JSON format, and then passes the constraint to the component connected to it. The supported constraints are as follows:

- <: sorts the weights of the variables in ascending order.
- >: sorts the weights of the variables in descending order.
- =: sets the weights of the variables to a fixed value.
- %: sets a proportion between the weights of two variables.
- UP: sets an upper limit for the weights of the variables.
- LO: sets a lower limit for the weights of the variables.

A constraint is stored in a table as a JSON string. The table contains only one row and one column.

```
{
  "name": "feature0",
  "<": [
    [0,1,2,3]
  ],
  ">": [
    [4,5,6]
  ],
  "=": [
    "3:0","4:0.25"
  ],
  "%": [
    ["6:1.0","7:1.0"]
  ]
}
```

Built-in constraints

Every original variable has a default constraint. The average score of the population in a variable must be 0. Based on this constraint, the scaled_weight in the intercept options of the scorecard model equals the average score of the entire population.

Optimization algorithms

In the advanced options of the Scorecard component, you can select optimization algorithms to be used in model training. The supported optimization algorithms are as follows:

- L-BFGS
- Newton's Method
- Barrier Method
- SQP

L-BFGS is a first-order optimization algorithm for processing large amounts of feature data. Newton's Method is a classic tier-2 optimization algorithm. It is fast in regression and accurate. However, it is not suitable for processing large amounts of feature data because it needs to calculate the second-order Hessian Matrix. The two algorithms do not have any constraints. When these algorithms are selected, the system automatically ignores the constraints.

If you do not want the system to ignore the constraints, select Barrier Method or SQP. Barrier Method and SQP are second-order optimization algorithms. When no constraint is set, they are equivalent to Newton's Method. Barrier Method and SQP have minor differences in performance and accuracy. We recommend that you choose SQP. If you are not familiar with optimization algorithms, we recommend that you choose the Auto-selected by default option. The system will automatically select an optimization algorithm based on the amount of the data and the constraints.

Feature selection

The Scorecard component supports stepwise feature selection. Stepwise is a combination of forward selection and backward selection. Each time the system selects a new variable by forward selection and adds it to the model, it must perform a backward selection. The backward selection starts with the variables in the model, and eliminates the ones with significance not meeting the requirements. Stepwise feature selection supports various types of target functions and feature transformation methods. Therefore, stepwise feature selection also supports multiple selection standards. Currently, the following standards are supported:

- Marginal contribution: It can be applied to all target functions and feature engineering methods.
- Score test: It only supports WOE transformation and logistic regression without feature engineering.
- F test: It only supports WOE transformation and linear regression without feature engineering.

Marginal contribution

The marginal contribution is the difference between the target functions of Model A without Variable X and target functions of Model B with Variable X after both models are trained. It is the marginal contribution of Variable X to all the other variables in Model B. In the scenario of transforming variables to dummy variables by feature engineering, the marginal contribution of Variable X is the difference between the target functions of all dummy variables in Model A without Variable X and target functions of all dummy variables in Model B with Variable X. Therefore, using marginal contribution to select features is supported by all feature engineering methods.

Marginal contribution makes feature selection more open-ended. It is not restricted to a certain type of models. Only variables that contribute to the target functions are passed to the model. Marginal contribution has certain disadvantages when compared with statistical significance. Typically, statistical significance chooses 0.05 as its threshold. Marginal contribution does not provide a recommended threshold for beginners. We recommend that you set the threshold to $10E-5$.

Score test

Score test is only suitable for feature selection in logistic regression. During a forward selection, a model with only intercept options is trained first. In each subsequent regression, the score chi-squares of the variables that have not been passed to the model are calculated. The variable with the largest score chi-square is passed to the model. The P-value corresponds to the largest score chi-square is also calculated based on chi-square distribution. If the P-value is greater than the given SLENTRY value, feature selection is complete.

After the forward selection is complete, a backward selection is performed for the variable passed to the model. The Wald chi-square of the variable and the corresponding P-value are calculated. If the P-value is greater than the given SLSTAY value, the variable is removed from the model. The system then starts a new regression.

F test

F test is only suitable for feature selection in linear regression. During a forward selection, a variable with only intercept options is trained first. In each subsequent regression, the F-values of the variables that have not been passed to the model are calculated. F-value calculation is similar to marginal contribution calculation. Both of them need to train two models to calculate the F-value of a variable. The F-value fits the F distribution. The corresponding P-value can be calculated based on the probability density function of the F distribution. If the P-value is greater than the given SLENTRY value, the variable is not passed to the model, and the forward selection is complete.

The backward selection process uses the F-value to calculate the significance of the variable in a way similar to a score test.

Forcibly selected variables

Before you perform feature selection, you can specify variables to be forcibly passed to the model. The specified variables are passed to the model regardless of their significance. No forward selection or backward selection is performed for these variables.

The number of regressions and significance levels (SLENTY and SLSTAY) are defined by using a JSON string in the -Dselected parameter as follows:

```
{"max_step":2, "slentry": 0.0001, "slstay": 0.0001}
```

If the -Dselected parameter is left empty or max_step is set to 0, no feature selection is performed.

Model report

The Scorecard component outputs data to a model report. The model report contains basic model evaluation statistics, such as the binning information, binning constraints, WOE values, and marginal contribution information. The following table lists the fields contained in the model report:

Field	Type	Description
feaname	string	The name of the feature.
binid	bigint	The ID of a bin.
bin	string	The description of the bin, which indicates the interval of the bin.
constraint	string	The constraints of the bin specified for model training.
weight	double	The weight of a binning variable. For a non-scorecard model without binning, this field indicates the weight of a model variable.
scaled_weight	double	For score transformation in scorecard training, this field indicates the score linearly transformed from the weight of a binning variable.
woe	double	A statistical indicator. It indicates the WOE value of a bin in the training set.
contribution	double	A statistical indicator. It indicates the marginal contribution value of a bin in the training set.
total	bigint	A statistical indicator. It indicates the total number of samples in a bin in the training set.
positive	bigint	A statistical indicator. It indicates the number of positive samples in a bin in the training set.
negative	bigint	A statistical indicator. It indicates the number of negative samples in a bin in the training set.

Field	Type	Description
percentage_pos	double	A statistical indicator. It indicates the proportion between positive samples in a bin and total positive samples in the training set.
percentage_neg	double	A statistical indicator. It indicates the proportion between negative samples in a bin and total negative samples in the training set.
test_woe	double	A statistical indicator. It indicates the WOE value of a bin in the testing set.
test_contribution	double	A statistical indicator. It indicates the marginal contribution value of a bin in the testing set.
test_total	bigint	A statistical indicator. It indicates the total number of samples in a bin in the testing set.
test_positive	bigint	A statistical indicator. It indicates the number of positive samples in a bin in the testing set.
test_negative	bigint	A statistical indicator. It indicates the number of negative samples in a bin in the testing set.
test_percentage_pos	double	A statistical indicator. It indicates the proportion between positive samples in a bin and total positive samples in the testing set.
test_percentage_neg	double	A statistical indicator. It indicates the proportion between negative samples in a bin and total negative samples in the testing set.

Algorithm parameters

Parameter	Description	Valid value	Default
inputTableName	Required. The input table that contains features.	N/A	N/A
inputTablePartitions	Optional. The partitions selected from the input table.	N/A	The whole table is selected.

Parameter	Description	Valid value	Default
inputBinTableName	Optional. The binning result table. If this parameter is set, the system automatically discretizes the original features based on the binning rules in the binning result table.	N/A	N/A
featureColNames	Optional. The names of feature columns selected from the input table.	N/A	All columns in the input table are selected by default, except for the label column.
labelColName	Required. The names of the target columns.	N/A	N/A
outputTableName	Required. The name of the output table.	N/A	N/A
inputConstraintTableName	Optional. A constraint. The constraint is a JSON string stored in a cell of a table.	N/A	
optimization	Optional. The optimization algorithm.	lbfgs, newton, barrier_method, sqp, and auto. Currently, only the sqp and barrier_method algorithms support constraints. If you set the value to auto, the system automatically selects an optimization algorithm based on the input data and corresponding parameters. We recommend that you set the value to auto if you are unfamiliar with the listed optimization algorithms.	auto
loss	Optional. The type of the loss function.	logistic_regression and least_square.	logistic_regression
iterations	Optional. The maximum number of regressions.	N/A	100
l1Weight	Optional. The weight of the L1 regularization parameter. Currently, only lbfgs supports l1weight.	N/A	0

Parameter	Description	Valid value	Default
l2Weight	Optional. The weight of the L2 regularization parameter.	N/A	0
m	Optional. The number of regressions performed by L-BFGS. Only L-BFGS supports this parameter.	N/A	10
scale	Optional. The weight scaling information of the scorecard.	N/A	Null
selected	Optional. Feature selection in scorecard training.	N/A	Null
convergenceTolerance	Optional. The convergence tolerance.	N/A	1e-6
positiveLabel	Optional. The category of positive samples.	N/A	1
lifecycle	Optional. The lifecycle of the output table.	N/A	No lifecycle is set.
coreNum	Optional. The number of vCores.	N/A	Automatically calculated.
memSizePerCore	Optional. The memory size per core.	N/A	Automatically calculated.

4.4.12.4. Scorecard prediction

The Scorecard Prediction component predicts credit scores based on the input data. It uses a model generated by a model training component. Supported model training components include the Scorecard Training, Logistic Regression for Binary Classification (in the Financials folder), and Linear Regression (in the Financials folder) components.

Input parameters

The Scorecard Prediction component has the following parameters:

- **Feature Column:** specifies the feature columns to be used for predicting credit scores. By default, all columns are selected.
- **Columns Reserved in Result Table:** specifies the columns to be appended to the prediction result table without any changes, such as the ID column and target column.
- **Output Variable Score:** specifies whether to output the score of each variable. The final score equals the score in the intercept option plus the scores of all variables.

Score table

The following is an example of the score table output by the component.

The first column churn is the column appended to the result table from the input table. The data in this column does not affect the prediction results. The remaining three columns display the prediction results. The definitions of these columns are as follows:

Column name	Type	Description
prediction_score	Double	The predicted scores column. In a linear model, the feature values and model weight values are summed up or multiplied to obtain the predicted scores. In a scorecard model, if score transformation is performed, the transformed scores are input into this column.
prediction_prob	Double	The probability values of positive samples in binary classification. The probability values are transformed from the original scores (before score transformation) by using the sigmoid function.
prediction_detail	String	The probability values of positive and negative samples described in JSON strings. Value 0 represents negative and value 1 represents positive. Example: { "0" :0.1813110520," 1" :0.8186889480}.

PAI command

```
pai -name=lm_predict
  -project=algo_public
  -DinputFeatureTableName=input_data_table
  -DinputModelTableName=input_model_table
  -DmetaColNames=sample_key,label
  -DfeatureColNames=fea1,fea2
  -DoutputTableName=output_score_table
```

Algorithm parameters

Parameter	Description	Valid value	Default
inputFeatureTableName	Required. The name of the input table that stores feature data.	N/A	N/A
inputFeatureTablePartitions	Optional. The partitions selected from the input table.	N/A	The whole table is selected.
inputModelTableName	Required. The name of the model table.	N/A	N/A

Parameter	Description	Valid value	Default
featureColNames	Optional. The names of the feature columns selected from the input table.	N/A	All columns are selected.
metaColNames	Optional. The names of the columns to be reserved in the result table.	N/A	The meta column is excluded. You can specify columns such as label and sample_id.
outputFeatureScore	Optional. It specifies whether to output variable scores to the result table.	true and false	false
outputTableName	Required. The name of the result table.	N/A	N/A
lifecycle	Optional. The lifecycle of the result table.	N/A	No lifecycle is set.
coreNum	Optional. The number of cores.	N/A	Automatically calculated.
memSizePerCore	Optional. The memory size per core.	N/A	Automatically calculated.

4.4.12.5. PSI

Population stability index (PSI) is an important metric to identify a shift in two samples of a population. For example, you can use it to measure whether the changes in the population within two months are stable. A PSI value smaller than 0.1 indicates insignificant changes. A PSI value between 0.1 and 0.25 indicates minor changes. A PSI value greater than 0.25 indicates major changes in the population.

When the changes in a population over time are unstable, you can use charts to identify the changes. You can use binning to discretize variables into multiple bins, calculate the number and proportion of the samples in each bin, and then display the statistics in a chart, as shown in the following figure.

This method can directly show whether a variable in two samples changes significantly. However, the shift in these changes cannot be measured by using this method. This means that the population stability cannot be automatically monitored. To resolve this issue, you can use the PSI component. Before you use the PSI component, you must use the Binning component to discretize the data. The formula for calculating PSI values is as follows:

Examples

The following figure shows a use case of the PSI component. The PSI component is connected to the Binning component and two sample datasets. You only need to specify the columns for PSI calculation in the PSI component.

Result

PAI command

```
PAI -name psi
-project algo_public
-DinputBaseTableName=psi_base_table
-DinputTestTableName=psi_test_table
-DoutputTableName=psi_bin_table
-DinputBinTableName=pai_index_table
-DfeatureColNames=fea1,fea2,fea3
-Dlifecycle=7
```

Algorithm parameters

Parameter	Description	Valid value	Default
inputBaseTableName	Required. The name of the base table. The shift of the population is calculated based on the samples in the base and test tables.	N/A	N/A
inputBaseTablePartitions	Optional. The partitions in the base table.	N/A	The whole table is selected.
inputTestTableName	Required. The name of the test table. The shift of the population is calculated based on the samples in the base and test tables.	N/A	N/A
inputTestTablePartitions	Optional. The partitions in the test table.	N/A	The whole table is selected.
inputBinTableName	Required. The name of the binning result table.	N/A	N/A
featureColNames	Optional. The features specified for PSI calculation.	N/A	All features are selected.
outputTableName	Required. The name of the output table (PSI statistics).	N/A	N/A
lifecycle	Optional. The lifecycle of the output table.	N/A	No lifecycle is set.
coreNum	Optional. The number of cores.	N/A	Automatically calculated.
memSizePerCore	Optional. The memory size per core.	N/A	Automatically calculated.

4.4.13. Video intelligence platform (must be separately activated)

4.4.13.1. Video preprocessing

4.4.13.1.1. Convert datasets to TFRecord files

EasyVision of Machine Learning Platform for AI allows you to convert datasets that are labeled by the data labeling module to TFRecord files. TFRecord files can be used to train models. You can use the TFRecord conversion component of EasyVision to convert labeled datasets that are stored in Object Storage Service (OSS) to TFRecord files and store the TFRecord files in OSS. If the datasets are labeled by using a method other than the data labeling module, you must first convert the labeled datasets to a format that is required by Machine Learning Platform for AI.

Machine Learning Platform for AI command example

Convert a labeled dataset for classification

```
pai -name easy_vision
  -Dbuckets='oss://pai-vision-data-hz/?role_arn=acs:ram::xxx:role/pai-vision-hz&host=oss-cn-zhangjiakou.aliyuncs.com'
  -Dcmd convert
  -Dlabel_file 'oss://pai-vision-data-hz/data/pai_test/watchdog.csv'
  -Dconvert_param_config '
--class_list_file oss://pai-vision-data-hz/data/pai_test/watchdog_class_list.txt
--max_image_size 600
--write_parallel_num 8
--num_samples_per_tfrecord 128
--test_ratio 0.1
--model_type CLASSIFICATION
'
  -Doutput_tfrecord 'oss://pai-vision-data-hz/test/convert/watchdog_tfrecord/watchdog'
  -Dcluster='{
  \ "worker" : {
  \ "count" : 3,
  \ "cpu" : 800
  }
}'
```

Convert a labeled dataset for text detection or recognition

```

pai -name easy_vision
  -Dbuckets='oss://pai-vision-data-hz/?role_arn=acs:ram::xxx:role/pai-vision-hz&host=oss-cn-zhangjiakou.aliyuncs.com'
  -Dcmd convert
  -Dlabel_file 'oss://pai-vision-data-hz/data/receipt_text/qince_data/qince_receipt_test.csv'
  -Dconvert_param_config '
    --model_type TEXT_END2END
    --default_class text
    --max_image_size 2000
    --char_replace_map_path oss://pai-vision-data-hz/data/receipt_text/qince_data/char_replace_map.csv
    --default_char_dict_path oss://pai-vision-data-hz/data/receipt_text/qince_data/char_dict
    --test_ratio 0.1
    --write_parallel_num 8
    --num_samples_per_tfrecored 64
    '
  -Doutput_tfrecored 'oss://pai-vision-data-hz/test/convert/receipt_text_end2end/'

```

Parameters

Parameter	Required	Description	Value format or sample value	Default value
cmd	Yes	Set the value to convert.	String	convert
buckets	No	The OSS bucket where the input data is stored. You can specify multiple OSS buckets by separating them with commas (,). Each bucket name must end with a forward slash (/).	"oss://bucket_name/?role_arn=xxx&host=yyy" "oss://bucket_1/?role_arn=xxx&host=yyy,oss://bucket_2/"	""
label_file	Yes	The OSS path of the labeled CSV file.	oss://your_bucket/xxx.csv	Required
convert_param_config	No	The information about the conversion task. For more information, see the following table. You can also replace the convert_param_config parameter with the convert_config parameter.	--parama valuea --paramb valueb	""
convert_config	No	The OSS path of the conversion task profile.	String	""
output_tfrecored	No	The OSS path of the TFRecord file.	oss://your_dir/prefix	""

Parameter	Required	Description	Value format or sample value	Default value
cluster	No	The information about the workers that are used to perform conversion in a distributed manner. For more information, click here .	JSON string	<pre>{"worker": {"count": 3, "cpu": 800, "gpu": 0, "memory": 20000}}</pre>

convert_param_config

Parameter	Required	Description	Value format or sample value	Default value
-----------	----------	-------------	------------------------------	---------------

Parameter	Required	Description	Value format or sample value	Default value
model_type	Yes	<p>The type of model to which the converted data applies. Valid values:</p> <ul style="list-style-type: none"> • CLASSIFICATION: single-label or multi-label image classification • DETECTION: object detection • POLYGON_SEGMENTATION: semantic segmentation based on polygon labeling • SEGMENTATION: semantic segmentation • INSTANCE_SEGMENTATION: instance segmentation • TEXT_END2END: end-to-end optical character recognition (OCR) • TEXT_RECOGNITION: single-line text recognition • TEXT_DETECTION: text detection • VIDEO_CLASSIFICATION: video classification • SELF_DEFINED: custom conversion <p>If the value of the model_type parameter is set to TEXT_END2END or TEXT_RECOGNITION, the char_replace_map_path and default_char_dict_path parameters take effect.</p> <p>If the value of the model_type parameter is set to VIDEO_CLASSIFICATION, the decode_type, sample_fps, reshape_size, decode_batch_size, and decode_keep_size parameters take effect.</p>	String	N/A

Parameter	Required	Description	Value format or sample value	Default value
class_list_file	No	<p>The OSS path of the category file. The file contains a list of category names. The category name in each line may be presented in one of the following formats:</p> <ul style="list-style-type: none"> Category name Category name:Name of the mapping category <p>If the default_class parameter is set, you must set the class_list_file or class_list parameter.</p>	oss://path/to/your/classlit	""
class_list	No	<p>The list of category names. Separate category names with commas (,). If the default_class parameter is set, you must set the class_list_file or class_list parameter.</p>	String list	""
test_ratio	No	<p>The ratio that is used to divide the set of test data into different subsets. Valid values: 0 to 1. If the value is set to 0, the total set of test data is used for training. If the value is set to 0.1, 10% of the test data is used for verification.</p>	0.1	0.1
max_image_size	No	<p>The maximum pixel value for the longer side of the images. If you have set this parameter and the size of an image exceeds the upper limit, the image is resized and saved to the TFRecord file. This reduces storage space and accelerates data reading.</p>	INT	N/A
max_test_image_size	No	<p>The maximum pixel value for the longer side of the image that is used for testing. The value of this parameter is the same as that of the max_image_size parameter. This parameter is used to configure test data.</p>	INT	\${max_image_size}

Parameter	Required	Description	Value format or sample value	Default value
default_class	No	The name of the default category. Category names that are not included in the class_list parameter will be specified as the default category.	STRING	""
error_class	No	The name of the invalid category. Objects or bounding boxes that belong to this category are not used for training.	STRING	""
ignore_class	No	The name of the category that is used only to detect models. Bounding boxes that belong to this category are not used for training.	STRING	""
converter_class	No	The name of the conversion class. Valid values: <ul style="list-style-type: none"> • PaiConverter: converts the datasets to the Machine Learning Platform for AI format • QinceConverter: converts the datasets to the traditional labeling format • A custom class name 	STRING	PaiConverter
separator	No	The separator that is used in the split() method to break the label file into substrings.	STRING	""
image_format	No	The encoding format of the images in the TFRecord file.	STRING	jpg
read_parallel_num	No	The number of concurrent reads.	INT	10
write_parallel_num	No	The number of concurrent writes to the TFRecord file.	INT	1
num_samples_per_tfrecord	No	The number of images that are saved in each TFRecord file.	INT	256
user_defined_converter_path	No	The HTTP or OSS path of the user-defined converter code. Example: http://path/to/your/converter.py.	STRING	""

Parameter	Required	Description	Value format or sample value	Default value
user_defined_generator_path	No	The HTTP or OSS path of the user-defined generator code. Example: <code>http://path/to/your/generator.py</code> .	STRING	""
generator_class	No	The name of the user-defined generator class.	STRING	""
char_replace_map_path	No	The OSS path of the CSV file for character map replacement. The CSV file contains two columns named original and replaced. The strings in the original column are replaced by the strings in the replaced column.	STRING	""
default_char_dict_path	No	The OSS path of the file that is used to map characters to IDs. In the file, each character occupies a line. The ID of a character equals the line number minus 1.	STRING	""
decode_type	No	The method that is used to decode the videos. Valid values: <ul style="list-style-type: none"> • 1: intra only • 2: keyframe only • 3: without bidir • 4: decode all 	INT	4
sample_fps	No	The number of frames that are extracted for sampling per second.	FLOAT	5
reshape_size	No	The size of the output frames, in pixels.	INT	224
decode_batch_size	No	The number of frames that are decoded at a time.	INT	0
task_id	No	The ID of the Machine Learning Platform for AI labeling job, in the format of label-xxxx. If the manifest file contains a labeling job, this parameter is not required.	STRING	""

Custom conversion

Machine Learning Platform for AI command

```

pai -name easy_vision
  -Dbuckets='oss://pai-vision-data-hz/?role_arn=acs:ram::xxx:role/pai-vision-hz&host=oss-cn-zhangjiakou.aliyuncs.com'
  -Dcmd convert
  -Dlabel_file 'oss://pai-vision-data-hz/data/image_mat/qince/imagenat.txt'
  -Dconvert_param_config '
    --model_type SELF_DEFINED
    --converter_class ImageMatConverter
    --user_defined_converter_path oss://pai-vision-data-hz/samples/code/imagenat_converter.py
    --user_defined_generator_path oss://pai-vision-data-hz/samples/code/custom_generator_example.py
    --generator_class CustomGenerator
    --max_image_size 1200
    --write_parallel_num 2
    --num_samples_per_tfreord 6
    --test_ratio 0.0
  '

```

To customize dataset conversion to TFRecord files, you must implement the following classes:

- A row class that inherits the DataRow class. The row class is used to parse data in each line of the label file and obtain image URLs and label information.
- A generator class that inherits the TFRecordGenerator class. The generator class is used to convert the data that is parsed by the row class to the tf.train.Example protocol buffers and specify the data format in TFRecord.
- A converter class that inherits the MultiProcConverter class. The converter class is used to load label files and configure train-test split policies to complete the conversion.

Example on custom_converter

```

4.4.13.1.2. General video preprocessing

This topic provides an example on how to run a Machine Learning Platform for AI command to train a model to preprocess videos. This topic also describes the command parameters.

You can run the `ev_video_process` command to train a model to preprocess videos. When you run this command, you need only to set the common parameters without the need to know the rules or logic of the EasyVision profile.

Machine Learning Platform for AI command example

```

pai -name ev_video_process
  -Dinput_oss_file='oss://pai-vision-data-hz/data/pai_test/video_decode_test.list'
  -Doutput_oss_file='oss://pai-vision-data-hz/test/tmp/ev_video_decode_result.txt'
  -Doutput_dir='oss://pai-vision-data-hz/data/ucf101_train/frames/'
  -Ddecode_type=4
  -Dsample_fps=5
  -Dreshape_size=224
  -Ddecode_batch_size=10
  -Ddecode_keep_size=0
  -Dqueue_size=256
  -Dnum_worker=4
  -DcpuRequired=400
  -DgpuRequired=100
  -Dbuckets='YOUR_OSS_BUCKET_CONFIG'

```

Parameters

Parameter	Required	Description	Value format or sample value	Default value
buckets	Yes	The endpoint of the Object Storage Service (OSS) bucket where your model is stored. This parameter is required when you use your own model to perform prediction.	"oss://bucket_name/?role_arn=xxx&host=yyy"	N/A
input_oss_file	Yes	The path of the input OSS file. Each line of the OSS object includes a video path.	oss://your_bucket/filelist.txt	N/A
output_oss_file	Yes	The path of the output OSS file where the preprocessing result is stored. The system may generate multiple result files and merge these result files into an output OSS file. The result files are prefixed with the name of the output OSS file. The number of result files is the same as the number of workers, which is specified by the num_worker parameter.	oss://your_bucket/result.txt	N/A

Parameter	Required	Description	Value format or sample value	Default value
output_dir	Yes	The directory that is used to store the frames extracted from the videos.	oss://your_bucket/your_dir	N/A
decode_type	No	The method that is used to decode the videos. Valid values: <ul style="list-style-type: none"> • 1: intra only • 2: keyframe only • 3: without bidir • 4: decode all 	INT	4
sample_fps	No	The number of frames that are extracted for sampling per second.	FLOAT	5
reshape_size	No	The size of the output frames, in pixels. If you set this parameter to -1, the frames are not resized.	INT	224
decode_batch_size	No	The number of frames that are decoded at a time.	INT	10
decode_keep_size	No	The number of overlapped frames in different batches.	INT	0
queue_size	No	The length of the preprocessing queue.	INT	256
thread_num	No	The number of threads on each worker.	INT	4
num_worker	No	The number of prediction workers.	INT	2
cpuRequired	No	The number of CPUs for a worker.	A value of 100 indicates one CPU.	800
gpuRequired	No	The number of GPUs for a worker.	A value of 100 indicates one GPU.	100

4.4.13.2. Offline training

4.4.13.2.1. Train a model for semantic image segmentation

This topic provides an example on how to run a Machine Learning Platform for AI command to train a model for semantic image segmentation in EasyVision. This topic also describes the command parameters.

A semantic segmentation model based on DeepLabv3 is implemented. For more information, see [Encoder-Decoder with Atrous Separable Convolution for Semantic Image Segmentation](#).

Machine Learning Platform for AI command example

The following code provides an example on the training of semantic image segmentation with a single GPU:

```

pai -name easy_vision
  -Dbuckets='oss://pai-vision-data-hz/?role_arn=xxx&host=oss-cn-zhangjiakou.aliyuncs.com'
  -DgpuRequired=100
  -Dcmd train
  -Dparam_config '
    --model_type DeeplabV3
    --backbone resnet_v1_50
    --backbone_feature_stride 16
    --bn_trainable true
    --num_classes 21
    --num_epochs 1
    --model_dir oss://pai-vision-data-hz/test/deeplab_stage1
    --train_data oss://pai-vision-data-hz/data/test/pascal_voc_seg_aug/voc_ev_train.tfrecord
    --test_data oss://pai-vision-data-hz/data/test/pascal_voc_seg_aug/voc_ev_train.tfrecord
    --num_test_example 2
    --train_batch_size 6
    --test_batch_size 1
    --image_crop_size 513
    --lr_type polynomial_decay
    --initial_learning_rate 0.007
    --power 0.9
  '

```

Parameters

Parameter	Required	Description	Value format or sample value	Default value
buckets	Yes	The endpoint of the Object Storage Service (OSS) bucket.	oss://pai-vision-data-hz/?role_arn=acs:ram::1217060697xxxx:role/pai-vision-hz&host=cn-hangzhou.oss.aliyun-inc.com	N/A
cluster	No	The configuration of parameters that are used for distributed training.	JSON string	""
gpuRequired	No	Specifies whether to use GPUs. By default, each worker uses one GPU. If you set this parameter to 200, each worker uses two GPUs.	100	100
cmd	Yes	The type of the EasyVision task. To train a model, you must set this parameter to train.	train	N/A

Parameter	Required	Description	Value format or sample value	Default value
param_config	Yes	The configuration of parameters that are used for model training. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. For more information, see the following table.	STRING	N/A

param_config

The param_config parameter contains the parameters that are used for model training. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. The following code provides an example on the param_config parameter:

```
-Dparam_config = '  
--backbone resnet_v1_50  
--num_classes 200  
--model_dir oss://your/bucket/exp_dir  
'
```

Note The values of all the string parameters in the param_config parameter are not enclosed in double quotation marks (") or single quotation marks (').

The following table describes all parameters that are contained in the param_config parameter.

Parameter	Required	Description	Value format or sample value	Default value
model_type	Yes	The type of the model to train. Set this parameter to DeeplabV3.	STRING	N/A
backbone	Yes	The name of the backbone network that is used by the model. Valid values: <ul style="list-style-type: none"> resnet_v1_50 resnet_v1_101 resnet_v1a_18 resnet_v1a_34 resnet_v1d_50 resnet_v1d_101 xception_41 xception_65 xception_71 	STRING	N/A
weight_decay	No	The value of L2 regularization.	FLOAT	1e-4
num_classes	Yes	The number of categories, including background categories.	21	N/A

Parameter	Required	Description	Value format or sample value	Default value
backbone_feature_stride	No	The feature downsampling step size of the backbone network.	INT	16
bn_trainable	No	Specify whether the batch normalization (BN) layer is trainable. If the value of the train_batch_size parameter is greater than 8, set the bn_trainable parameter to true.	BOOL	true
image_crop_size	No	The size of the image after cropping.	INT	513
optimizer	No	The type of the optimizer. Valid values: <ul style="list-style-type: none"> momentum: stochastic gradient descent (SGD) with momentum adam 	STRING	momentum
lr_type	No	The policy that is used to adjust the learning rate. Valid values: <ul style="list-style-type: none"> exponential_decay: the exponential decay. polynomial_decay: the polynomial decay. <p>If you set the lr_type parameter to polynomial_decay, the num_steps parameter is automatically set to the total number of training iterations. The value of the end_learning_rate parameter is automatically set to one thousandth of the value of the initial_learning_rate parameter.</p> <ul style="list-style-type: none"> manual_step: The learning rate of each epoch is manually adjusted. <p>If you set the lr_type parameter to manual_step, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate. You must also set the learning_rates parameter to specify the learning rate as needed.</p> <ul style="list-style-type: none"> cosine_decay: The learning rate of each epoch is adjusted based on the cosine curve until the learning rate decreases to 0. For more information, see SGDR: Stochastic Gradient Descent with Warm Restarts. 	STRING	exponential_decay

Parameter	Required	Description	Value format or sample value	Default value
initial_learning_rate	No	The initial learning rate.	FLOAT	0.01
decay_epochs	No	If you set the lr_type parameter to exponential_decay, the decay_epochs parameter is equivalent to the decay_steps parameter of tf.train.exponential.decay. In this case, the decay_epochs parameter specifies the epoch interval at which you want to adjust the learning rate. The system automatically converts the value of the decay_epochs parameter to the value of the decay_steps parameter based on the total number of training data entries. Typically, you can set the decay_epochs parameter to half of the total number of epochs. For example, if the total number of epochs is 20, you can set this parameter to 10. If you set the lr_type parameter to manual_step, the decay_epochs parameter specifies the epochs for which you want to adjust the learning rate. For example, a value of 16 18 indicates that you want to adjust the learning rate for the 16th and 18th epochs. Typically, if the total number of epochs is N, you can set the two values of the decay_epochs parameter to $8/10 \times N$ and $9/10 \times N$.	INTEGER list. Sample value: 20 20 40 60	20
decay_factor	No	The decay rate. This parameter is equivalent to the decay_factor parameter of tf.train.exponential.decay.	FLOAT	0.95
staircase	No	Specifies whether the learning rate changes based on the decay_epochs parameter. This parameter is equivalent to the staircase parameter of tf.train.exponential.decay.	BOOL	true
power	No	The power of the polynomial. This parameter is equivalent to the power parameter of tf.train.polynomial.decay.	FLOAT	0.9

Parameter	Required	Description	Value format or sample value	Default value
learning_rates	No	The learning rate that you want to set for the specified epochs. If you set the lr_type parameter to manual_step, this parameter is required. If you want to adjust the learning rate for two epochs, specify two learning rates in the value. For example, if the decay_epochs parameter is set to 20 40, you must specify two learning rates in the value of the learning_rates parameter, such as 0.001 0.0001. This indicates that the learning rate of the 20th epoch is adjusted to 0.001 and the learning rate of the 40th epoch is adjusted to 0.0001. We recommend that you adjust the learning rate to one tenth, one hundredth, and one thousandth of the initial learning rate in sequence.	FLOAT list	N/A
lr_warmup	No	Specifies whether to warm up the learning rate.	BOOL	false
lr_warm_up_epochs	No	The number of epochs for which you want to warm up the learning rate.	FLOAT	1
train_data	Yes	The OSS path of the data that is used to train the model.	oss://path/to/train_*.tfrecord	N/A
test_data	Yes	The OSS path of the data that is evaluated during the training.	oss://path/to/test_*.tfrecord	N/A
train_batch_size	Yes	The size of the data that is used to train the model in the current batch.	INT. Sample value: 32	N/A
test_batch_size	Yes	The size of the data that is evaluated in the current batch.	INT. Sample value: 32	N/A
train_num_readers	No	The number of concurrent threads that are used to read the training data.	INT	4
model_dir	Yes	The OSS path of the model.	oss://path/to/model	N/A
pretrained_model	No	The OSS path of the pretrained model. If this parameter is specified, the actual model is finetuned based on the pretrained model.	oss://pai-vision-data-hz/pretrained_models/inception_v4.ckpt	""
use_pretrained_model	No	Specifies whether to use a pretrained model.	BOOL	true

Parameter	Required	Description	Value format or sample value	Default value
num_epochs	Yes	The number of times the data is iterated for the training. A value of 1 indicates that all data is iterated once for the training.	INT. Sample value: 40	N/A
num_test_example	No	The number of data entries that are evaluated during the training. A value of -1 indicates that all training data is evaluated.	INT. Sample value: 2000	-1
num_visualizations	No	The number of data entries that can be visualized during the evaluation.	INT	10
save_checkpoint_epochs	No	The epoch interval at which a checkpoint is saved. A value of 1 indicates that a checkpoint is saved each time an epoch is complete.	INT	1
save_summary_epochs	No	The epoch interval at which a summary is saved. A value of 0.01 indicates that a summary is saved each time 1% of the training data is iterated.	FLOAT	0.01
num_train_images	No	The total number of data entries that are used for the training. If you use custom TFRecord files to train the model, this parameter is required.	INT	0
label_map_path	No	The category mapping file. If you use custom TFRecord files to train the model, this parameter is required.	STRING	""

4.4.13.2.2. Train an image detection model

This topic provides an example on how to run a Machine Learning Platform for AI command to train an image detection model. This topic also describes the command parameters.

EasyVision allows you to run a command to train an image detection model. You can use the `-Dparam_config` parameter to set common parameters without the need to know the rules or logic of the EasyVision profile. If you need advanced parameters to train an image detection model, you can use the `-Dconfig` parameter to pass the profile to EasyVision. The following table describes the models that are supported for image detection training.

Model	Backbone	Whether FPN is supported
-------	----------	--------------------------

Model	Backbone	Whether FPN is supported
Faster R-CNN	<ul style="list-style-type: none"> • resnet_v1_50 • resnet_v1_101 • resnet_v1a_18 • resnet_v1a_34 • resnet_v1d_50 • resnet_v1d_101 • resnet_v1d_152 	Yes
R-FCN	<ul style="list-style-type: none"> • resnet_v1_50 • resnet_v1_101 • resnet_v1a_18 • resnet_v1a_34 • resnet_v1d_50 • resnet_v1d_101 • resnet_v1d_152 	No
SSD	<ul style="list-style-type: none"> • resnet_v1_50 • resnet_v1d_50 	Yes
SSD	vgg16_reduce_fc	No
SSD	mobilenet_v1	No

Machine Learning Platform for AI command example

- The following code provides an example on how to train a single-shot detection (SSD) model by using a single GPU:

```

pai -name easy_vision
  -Dbuckets='oss://YOUR_BUCKET_NAME/?role_arn=xxx&host=oss-cn-zhangjiakou.aliyuncs.com'
  -DgpuRequired=100
  -Dcmd train
  -Dparam_config '
    --model_type SSD

Parameters

Parameter	Required	Description	Value format or sample value	Default value
buckets	Yes	The endpoint of the Object Storage Service (OSS) bucket.	oss://pai-vision-data-hz/?role_arn=acs:ram::12170606971xxx:role/pai-vision-hz&host=cn-hangzhou.oss.aliyun-inc.com	N/A
cluster	No	The configuration of parameters that are used for distributed training.	JSON string	""
gpuRequired	No	Specifies whether to use GPUs. By default, each worker uses one GPU. If you set this parameter to 200, each worker uses two GPUs.	100	100
cmd	Yes	The type of the EasyVision task. To train a model, you must set this parameter to train.	train	N/A
param_config	Yes	The configuration of parameters that are used for model training. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. For more information, see the following table.	STRING	N/A

param_config

The param_config parameter contains the parameters that are used for model training. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. The following code provides an example on the param_config parameter:

```
-Dparam_config='
--backbone resnet_v1_50
--num_classes 200
--model_dir oss://your/bucket/exp_dir
'
```

 **Note** Do not enclose the values of all the string parameters in the param_config parameter in double quotation marks (") or single quotation marks (').

Parameter	Required	Description	Value format or sample value	Default value
model_type	Yes	The type of the model to train. Valid values: <ul style="list-style-type: none"> SSD FasterRCNN RFCN 	STRING	N/A
backbone	Yes	The name of the backbone network that is used by the model. Valid values: <ul style="list-style-type: none"> mobilenet_v1 resnet_v1_50 resnet_v1_101 resnet_v1a_18 resnet_v1a_34 resnet_v1d_50 resnet_v1d_101 vgg16_reduce_fc 	STRING	N/A
weight_decay	No	The value of L2 regularization.	FLOAT	1e-4
use_fpn	No	Specifies whether to use Feature Pyramid Network (FPN).	BOOL	false
num_classes	No	The number of categories, excluding background categories.	21	N/A
anchor_scales	No	The size of the anchor box. The size of the anchor box is the same as that of the input image where the anchor box resides after the image is resized. If you use an SSD model, this parameter is not required. If you use FPN, set this parameter to the size of the anchor box in the layer that has the highest resolution. The total number of layers is five. The size of the anchor box in a layer is twice as that in the previous layer. For example, if the size of the anchor box in the first layer is 32, the sizes of the anchor boxes in the next four layers are 64, 128, 256, and 512. If you use the Faster R-CNN model or the R-FCN model without FPN support, you can specify multiple anchor sizes as needed. For example, you can set the anchor_scales parameter to 128 256 512.	FLOAT list Sample value: 32 (single scale) or 128 256 512 (multiple scales)	<ul style="list-style-type: none"> SSD: The default value is 0.1, 0.2, 0.37, 0.54, 0.71, 0.88, 0.96, or 1.0 times of the size of the input image. FPN: 32 Faster R-CNN with FPN support: 32 Faster R-CNN or R-FCN: [128 256 512]
anchor_ratios	No	The ratios of the width to the height of the anchor boxes.	FLOAT list	0.5 1 2

Parameter	Required	Description	Value format or sample value	Default value
image_sizes	No	The size of the images after they are resized. This parameter takes effect only when an SSD model is used. The value of this parameter is a list that contains two numbers, which indicate the height and width.	FLOAT list	300 300
image_min_sizes	No	The length of the shorter side of images after they are resized. This parameter is used for Faster R-CNN and R-FCN models. If you specify multiple lengths for the shorter sides of images in the value of this parameter, the last length but one is used to train the model, whereas the last one is used to evaluate the model. If you specify only one length for the shorter sides of images, this length is used for both training and evaluation.	FLOAT list	600
image_max_sizes	No	The length of the longer side of images after they are resized. This parameter is used for Faster R-CNN and R-FCN models. If you specify multiple lengths for the longer sides of images in the value of this parameter, the last length but one is used to train the model, whereas the last one is used to evaluate the model. If you specify only one length for the longer sides of images, this length is used for both training and evaluation.	FLOAT list	1024

Parameters

Parameter	Required	Description	Value format or sample value	Default value
buckets	Yes	The endpoint of the Object Storage Service (OSS) bucket.	oss://pai-vision-data-hz/?role_arn=acs:ram::12170606971xxx:role/pai-vision-hz&host=cn-hangzhou.oss.aliyun-inc.com	N/A
cluster	No	The configuration of parameters that are used for distributed training.	JSON string	""
gpuRequired	No	Specifies whether to use GPUs. By default, each worker uses one GPU. If you set this parameter to 200, each worker uses two GPUs.	100	100
cmd	Yes	The type of the EasyVision task. To train a model, you must set this parameter to train.	train	N/A
param_config	Yes	The configuration of parameters that are used for model training. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. For more information, see the following table.	STRING	N/A

param_config

The param_config parameter contains the parameters that are used for model training. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. The following code provides an example of the param_config parameter:

```
-Dparam_config='
--model_type Classification
--backbone inception_v4
--num_classes 200
--model_dir oss://your/bucket/exp_dir
'
```

 **Note** Do not enclose the values of all the string parameters in the param_config parameter in double quotation marks (") or single quotation marks (').

Parameter	Required	Description	Value format or sample value	Default value
model_type	Yes	The type of the model to train. To train a model for multi-label image classification, set this parameter to Classification.	STRING	N/A

Parameter	Required	Description	Value format or sample value	Default value
backbone	No	<p>The name of the backbone network that is used by the model. Valid values:</p> <ul style="list-style-type: none"> • vgg_16 • vgg_19 • inception_v1 • inception_v2 • inception_v3 • inception_v4 • mobilenet_v1 • mobilenet_v2 • mobilenet_v3 • resnet_v1_50 • resnet_v1_101 • resnet_v1_152 • resnet_v2_50 • resnet_v2_101 • resnet_v2_152 • resnet_v1a_18 • resnet_v1a_34 • resnet_v1a_50 • resnet_v1a_101 • resnet_v1a_152 • resnet_v1b_50 • resnet_v1b_101 • resnet_v1b_152 • resnet_v1c_50 • resnet_v1c_101 • resnet_v1c_152 • resnet_v1d_50 • resnet_v1d_101 • resnet_v1d_152 • efficientnet-b0 • efficientnet-b1 • efficientnet-b2 • efficientnet-b3 • efficientnet-b4 • efficientnet-b5 • efficientnet-b6 • efficientnet-b7 • efficientnet-b8 	STRING	inception_v4
weight_decay	No	The value of L2 regularization.	FLOAT	1e-4

Parameter	Required	Description	Value format or sample value	Default value
num_classes	Yes	The number of categories.	INT	N/A
hidden_size	No	The size of the custom Fiber Channel (FC) layer. A value of -1 indicates that the size of the original FC layer is used.	INT	-1
image_size	No	The size of the images after they are resized.	INT	224
use_crop	No	Specifies whether to crop images for data enhancement.	BOOL	true
crop_min_area	No	The minimum proportion of the original image area that is occupied by the crop box when you set the use_crop parameter to true.	FLOAT	0.7
eval_each_category	No	Specifies whether to separately evaluate each category.	BOOL	false
optimizer	No	The type of the optimizer. Valid values: <ul style="list-style-type: none"> momentum: stochastic gradient descent (SGD) with momentum adam 	STRING	momentum

Parameter	Required	Description	Value format or sample value	Default value
lr_type	No	<p>The policy that is used to adjust the learning rate. Valid values:</p> <ul style="list-style-type: none"> exponential_decay: the exponential decay. polynomial_decay: the polynomial decay. <p>If you set the lr_type parameter to polynomial_decay, the num_steps parameter is automatically set to the total number of training iterations. The value of the end_learning_rate parameter is automatically set to one thousandth of the value of the initial_learning_rate parameter.</p> <ul style="list-style-type: none"> manual_step: The learning rate of each epoch is manually adjusted. <p>If you set the lr_type parameter to manual_step, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate. You must also set the learning_rates parameter to specify the learning rate as needed.</p> <ul style="list-style-type: none"> cosine_decay: The learning rate of each epoch is adjusted based on the cosine curve. For more information, see SGDR: Stochastic Gradient Descent with Warm Restarts. 	STRING	exponential_decay
initial_learning_rate	No	The initial learning rate.	FLOAT	0.01

Parameter	Required	Description	Value format or sample value	Default value
decay_epochs	No	If you set the lr_type parameter to exponential_decay, the decay_epochs parameter is equivalent to the decay_steps parameter of tf.train.exponential.decay. In this case, the decay_epochs parameter specifies the epoch interval at which you want to adjust the learning rate. The system automatically converts the value of the decay_epochs parameter to the value of the decay_steps parameter based on the total number of training data entries. Typically, you can set the decay_epochs parameter to half of the total number of epochs. For example, if the total number of epochs is 20, you can set this parameter to 10. If you set the lr_type parameter to manual_step, the decay_epochs parameter specifies the epochs for which you want to adjust the learning rate. For example, a value of 16 18 indicates that you want to adjust the learning rate for the 16th and 18th epochs. Typically, if the total number of epochs is N, you can set the two values of the decay_epochs parameter to $8/10 \times N$ and $9/10 \times N$.	INTEGER list. Sample value: 20 20 40 60	20
decay_factor	No	The decay rate. This parameter is equivalent to the decay_factor parameter of tf.train.exponential.decay.	FLOAT	0.95
staircase	No	Specifies whether the learning rate changes based on the decay_epochs parameter. This parameter is equivalent to the staircase parameter of tf.train.exponential.decay.	BOOL	true
power	No	The power of the polynomial. This parameter is equivalent to the power parameter of tf.train.polynomial.decay.	FLOAT	0.9

Parameter	Required	Description	Value format or sample value	Default value
learning_rates	No	The learning rate that you want to set for the specified epochs. If you set the lr_type parameter to manual_step, this parameter is required. If you want to adjust the learning rate for two epochs, specify two learning rates in the value. For example, if the decay_epochs parameter is set to 20 40, you must specify two learning rates in the value of the learning_rates parameter, such as 0.001 0.0001. This indicates that the learning rate of the 20th epoch is adjusted to 0.001 and the learning rate of the 40th epoch is adjusted to 0.0001. We recommend that you adjust the learning rate to one tenth, one hundredth, and one thousandth of the initial learning rate in sequence.	FLOAT list	N/A
lr_warmup	No	Specifies whether to warm up the learning rate.	BOOL	false
lr_warm_up_epochs	No	The number of epochs for which you want to warm up the learning rate.	FLOAT	1
train_data	Yes	The OSS path of the data that is used to train the model.	oss://path/to/train_*.tfrecord	N/A
test_data	Yes	The OSS path of the data that is evaluated during the training.	oss://path/to/test_*.tfrecord	N/A
train_batch_size	Yes	The size of the data that is used to train the model in the current batch.	INT. Sample value: 32	N/A
test_batch_size	Yes	The size of the data that is evaluated in the current batch.	INT. Sample value: 32	N/A
train_num_readers	No	The number of concurrent threads that are used to read the training data.	INT	4
model_dir	Yes	The OSS path of the model.	oss://path/to/model	N/A
pretrained_model	No	The OSS path of the pretrained model. If this parameter is specified, the actual model is finetuned based on the pretrained model.	oss://pai-vision-data-sh/pretrained_models/inception_v4.ckpt	""
use_pretrained_model	No	Specifies whether to use a pretrained model.	BOOL	true

Parameter	Required	Description	Value format or sample value	Default value
num_epochs	Yes	The number of times the data is iterated for the training. A value of 1 indicates that all data is iterated once for the training.	INT. Sample value: 40	N/A
num_test_example	No	The number of data entries that are evaluated during the training. A value of -1 indicates that all training data is evaluated.	INT. Sample value: 2000	-1
num_visualizations	No	The number of data entries that can be visualized during the evaluation.	INT	10
save_checkpoint_epochs	No	The epoch interval at which a checkpoint is saved. A value of 1 indicates that a checkpoint is saved each time an epoch is complete.	INT	1
save_summary_epochs	No	The epoch interval at which a summary is saved. A value of 0.01 indicates that a summary is saved each time 1% of the training data is iterated.	FLOAT	0.01
num_train_images	No	The total number of data entries that are used for the training. If you use custom TFRecord files to train the model, this parameter is required.	INT	0
label_map_path	No	The category mapping file. If you use custom TFRecord files to train the model, this parameter is required.	STRING	""

4.4.13.2.4. Train a video classification model

This topic provides an example on how to run a Machine Learning Platform for AI command to train a video classification model. This topic also describes the command parameters.

You can run the `ev_video_classification` command to train a model to classify videos. When you run this command, you need only to set the common classification parameters without the need to know the rules or logic of the EasyVision profile.

Machine Learning Platform for AI command example

- Training on a single server

```

pai -name ev_video_classification
  -Dbackbone='resnet_3d_50'
  -Dnum_classes=101
  -Dnum_epochs=2

4.4.13.3. Offline prediction

4.4.13.3.1. General image prediction

The general image prediction component is used to make predictions. It reads data from MaxCompute tables or Object Storage Service (OSS) files for prediction, and writes the prediction results to the MaxCompute tables or OSS files. This topic provides examples on how to run a Machine Learning Platform for AI command to use the general image prediction component. This topic also describes how to define the input and output files and customize the process and prediction classes for different types of models.

Machine Learning Platform for AI command example

- Detect objects based on a region of interest

```
pai -name ev_predict
-Dmodel_path='oss://pai-vision-data-hz/pretrained_models/saved_models/faster_rcnn_with_roi_features_coco/'
-Dmodel_type='detector'
-Dinput_oss_file='oss://pai-vision-data-hz/data/pai_test/predict_oss_io_test.list'
-Doutput_oss_file='oss://pai-vision-data-hz/test/tmp/ev_predict_result.txt'
-Dimage_type='url'
-Dbuckets='oss://pai-vision-data-hz/?role_arn=xxx:role/pai-vision-hz&host=cn-hangzhou.oss.aliyun-inc.com'
```

- Customize the process and predictor classes

```
pai -name ev_predict
-Dmodel_path='oss://pai-vision-data-hz/pretrained_models/pipeline_text_models/'
-Dmodel_type='self_define'
-Dinput_oss_file='oss://pai-vision-data-hz/data/pai_test/predict_oss_io_test.list'
-Doutput_oss_file='oss://pai-vision-data-hz/test/tmp/ev_predict_result.txt'
-Dimage_type='url'
-Duser_resource='oss://pai-vision-data-hz/data/pai_test/ev_predict/test_data/self_define/user_res.tar.gz'
-Duser_predictor_cls='user_predictor.MyPredictor'
-Duser_process_config='
[
{
  \"job_name\": \"myprocess\",
  \"num_threads\": 2,
  \"batch_size\": 1,
  \"class\": \"user_process.MyProcess\"
}
]'
-Dbuckets='oss://pai-vision-data-hz/?role_arn=xxx:role/pai-vision-hz&host=oss-cn-zhangjiakou.aliyuncs.com'
```

The code file that is used to customize the process class is *user_process.py*. The class name is *MyProcess*. The code file that is used to customize the predictor class is *user_predictor.py*. The class name is

MyPredictor. The *user_process.py* and *user_predictor.py* code files are compressed in the *user_res.tar.gz* package.

- Specify the input and output OSS files

```

pai -name ev_predict
-Dmodel_path='oss://pai-vision-data-hz/pretrained_models/pipeline_text_models/'
-Dmodel_type='self_define'
-Duser_resource='oss://your_predictor_res.tar.gz'
-Duser_predictor_cls='your_predictor.DummyModalPredictor'
-Dinput_oss_file='oss://pai-vision-data-hz/data/pai_test/predict_oss_io_test.list'
-Doutput_oss_file='oss://pai-vision-data-hz/test/tmp/ev_predict_multi_modal_result.json'
-Doutput_dir='oss://pai-vision-data-hz/test/tmp/multi_modal_output'
-Dimage_type='url'
-Dbuckets='oss://pai-vision-data-hz/?role_arn=xxx/pai-vision-hz&host=oss-cn-zhangjiakou.aliyuncs.com'

```

The code file that is used to customize the predictor class is *user_predictor.py*. The class name is *DummyModalPredictor*.

- Customize the process class

You can specify the input tables to read and process, and the output table to which the processed data is written. The following content provides an example on how to extract video features. In this example, two input tables are used. One of them contains the information about video frames. The other contains the IDs of the videos from which you want to extract features. You can use the following Machine Learning Platform for AI command to read data from the input tables and write the prediction results to the output table.

- Input table 1

Field	Type	Label	Comment
video_id	bigint		
frame_id	bigint		
image	string		
shot_id	bigint		
extra_info	string		
video_id_str	string		string type video id

- Input table 2

Field	Type	Label	Comment
video_id	bigint		

- Output table

Field	Type	Label	Comment
video_id	bigint		
frame_num	bigint		
feature	string		

- Machine Learning Platform for AI command

```
pai -name ev_predict
  -Dmodel_path='oss://pai-vision-data-hz/pretrained_models/saved_models/inception_v4_central_crop_1.0/'
  -Dmodel_type='feature_extractor'
  -Dfeature_name='PreLogitsFlatten'
  -Dinput_table='odps://sre_mpi_algo_dev/tables/zwm_dummy_table_data,odps://sre_mpi_algo_dev/tables/zwm_dummy_video_id'
  -Doutput_table='odps://sre_mpi_algo_dev/tables/zwm_dummy_result_video_feature'
  -Dimage_col='image'
  -Dimage_type='url'
  -Dreserved_columns='video_id'
  -Dresult_column='frame_num,feature'
  -Dbuckets='oss://pai-vision-data-hz/?role_arn=acs:ram::xxx:role/pai-vision-hz&host=oss-cn-zhangjiakou.aliyuncs.com'
  -Dauto_create_table=false
  -DuseSparseClusterSchema=true
  -DenableDynamicCluster=false
  -DautoEnablePsTaskFailover=false
  -DgpuRequired=50
  -Dnum_worker=1
  -Dqueue_size=12
  -Dbatch_size=1
  -Dpredict_thread_num=1
  -Dpreprocess_thread_num=3
  -Duser_resource http://pai-vision-data-hz.oss-cn-zhangjiakou.aliyuncs.com/data/pai_test/ev_predict/test_data/self_define/video_feature_extract_pad.py
  -Duser_build_process_fn 'video_feature_extract_pad.build_and_run_video_decode_process'
```

Parameters

Parameter	Required	Description	Value type	Default value
model_path	Yes	The OSS path of the model. Example: "oss://your_bucket/your_model_dir".	STRING	N/A

Parameter	Required	Description	Value type	Default value
model_type	Yes	<p>The type of the model. Valid values:</p> <ul style="list-style-type: none"> feature_extractor: feature extraction classifier: image classification detector: object detection text_detector: text detection text_recognizer: text line recognition text_spotter: end-to-end text recognition segmentor: semantic image segmentation self_define: custom prediction <p>If the model_type parameter is set to self_define, the predictor class that is specified by the user_predictor_cls parameter is loaded.</p>	STRING	N/A
buckets	No	<p>The information about the OSS buckets. If you use a custom model, you must specify the OSS bucket where your model is stored. Example: "oss://bucket_name/?role_arn=xxx&host=yyy".</p>	STRING	""
feature_name	No	<p>The name of the feature to extract. This parameter is required if the model_type parameter is set to feature_extractor. Example: resnet_v1_50/logits.</p>	STRING	""
input_table	No	<p>The name of the input table. For example, you can use a non-partitioned table "odps://prj_name/tables/table_name" or a partitioned table "odps://prj_name/tables/table_name/pt=xxx".</p>	STRING	""
image_col	No	<p>The name of the column that contains the image data.</p>	STRING	"image"

Parameter	Required	Description	Value type	Default value
image_type	No	The format of the image data. Valid values: <ul style="list-style-type: none"> base64: indicates that the table stores the image data in the Base64 format. url: indicates that the table stores the URLs or OSS paths of the images. 	STRING	"base64"
reserved_columns	No	The names of reserved data columns. Separate multiple names with commas (,). Example: "col1,col2,col3".	STRING	""
result_column	No	The name of the result column.	STRING	"prediction_result"
output_table	No	The output table. The value format is the same as that of the input_table parameter. If the specified output table does not exist, an output table is automatically created and partitioned. You can also create a partitioned table as the output table before you make the prediction.	STRING	""
lifecycle	No	The lifecycle of the output table.	INT	10
num_worker	No	The number of prediction workers. More workers can accelerate offline prediction.	INT	2
cpuRequired	No	The number of CPUs for a worker. A value of 100 indicates one CPU.	INT	1600
gpuRequired	No	The number of GPUs for each worker. A value of 100 indicates one GPU. You can use up to 100 GPUs for a worker. A value of 0 indicates that a CPU cluster is used.	INT	100
memory	No	The memory size of each worker, in MB.	INT	30000
input_oss_file	No	The path of the input OSS file. Each line in the input file can be in one of the following formats: <ul style="list-style-type: none"> The OSS path or URL of an image to predict. Example: oss://your_bucket/filelist.txt. A JSON string. 	STRING	""

Parameter	Required	Description	Value type	Default value
output_oss_file	No	The path of the output OSS file that is used to store the prediction results. The system may generate multiple result files and merge these result files into an output OSS file. The result files are prefixed with the name of the output OSS file. The number of result files is the same as the number of workers, which is specified by the num_worker parameter.	STRING	""
output_dir	No	The directory of the output file. If you customize the output format, all the result images are stored in this directory.	STRING	""
user_resource	No	The path to which you want to upload your resources. You can upload tar.gz, .zip, and .py files. OSS paths and HTTP URLs are supported. Example: oss://xxx/a.tar.gz or http://a.com/c.zip.	STRING	""
user_predictor_cls	No	The module path of the custom predictor class. For example, if you implement Predictor A in <i>module.py</i> , the module path of Predictor A is module.A.	STRING	""

Parameter	Required	Description	Value type	Default value
user_process_config	No	<p>The configurations of the custom process class. You can use the following fields to configure the process class. You can also configure other custom fields.</p> <ul style="list-style-type: none"> job_name: the name of the custom process class. num_threads: the number of concurrent threads that are used by the custom process class. batch_size: the batch size of the data to be processed. user_process_cls: the module path of the custom process class. For example, if you implement Process A in <i>module.py</i>, the module path of Process A is <i>module.A</i>. <p>Example: <pre>{["job_name":"myprocess","user_process_cls": module.ClassA"num_threads":2, "batch_size":1]}</pre> </p>	JSON string	""
queue_size	No	The length of the cache queue.	INT	1024
batch_size	No	The size of data that is used for prediction in the current batch.	INT	1
preprocess_thread_num	No	The number of concurrent threads that are used for preprocessing, such as image decoding and download.	INT	4
predict_thread_num	No	The number of concurrent threads that are used for prediction.	INT	2
is_input_video	No	Specifies whether the input files are video files.	BOOL	false
use_image_predictor	No	Specifies whether the predictor supports only image input.	BOOL	true
decode_type	No	<p>The method that is used to decode the videos. Valid values:</p> <ul style="list-style-type: none"> 1: intra only 2: keyframe only 3: without bidir 4: decode all 	INT	4

Parameter	Required	Description	Value type	Default value
sample_fps	No	The number of frames that are extracted for sampling per second.	FLOAT	5
reshape_size	No	The size of the output frames, in pixels. If you set this parameter to -1, the frames are not resized.	INT	-1
decode_batch_size	No	The number of frames that are decoded at a time.	INT	10
decode_keep_size	No	The number of overlapped frames in different batches.	INT	0
float_digits	No	The number of FLOAT digits for JSON serialization. For example, if you set this parameter to 3, the generated string contains three decimal places. A value of -1 indicates that the generated string uses the original precision.	INT	-1
mediaflow_class_name	No	The path of the Mediaflow class. Example: demo.mediaflow_caller.	STRING	""
self_defined_result_formatter	No	The class that is used to format the custom results. Example: a.table_result_format.	STRING	""
user_build_process_fn	No	The custom process function. Example: a.build_process_fn.	STRING	""
enableDynamicCluster	No	Specifies whether to enable the dynamic cluster feature. If this feature is enabled, the failover of a single worker is allowed. If task exceptions frequently occur, we recommend that you enable this feature.	BOOL	false
useSparseClusterSchema	No	If the enableDynamicCluster parameter is set to true, you must also set the useSparseClusterSchema parameter to true.	BOOL	false
enable_elastic_inference	No	Specifies whether to enable the elastic inference feature.	BOOL	false

Parameter	Required	Description	Value type	Default value
restore_works_dir	No	<p>The cache directory that is used to store the data being processed by each worker. When a worker failed, the data can be used to recover the worker. You can set this parameter to an OSS path or an Apsara File Storage for HDFS directory. If the enable_elastic_inference parameter is set to true, this parameter is required. Example: egoss://path/to/dir/hdfs://path/to/dir/.</p> <p>Note The value must end with a forward slash (/).</p>	STRING	""
slice_size	No	<p>The size of a data shard that a worker processes at a time. A large value may lead to out of memory (OOM) errors, whereas a small value may lead to low reading efficiency. We recommend that you set this parameter to 1024 for image processing, and 16 for video processing.</p>	INT	1024

Input data formats

- Input table

An input table can contain one or more columns. One of the columns must contain the image URLs or Base64-encoded binary image data. The data type of the column must be STRING. The following example shows a table schema:

```

+-----+
| Field | Type | Label | Comment |
+-----+
| id    | STRING | | |
| url   | STRING | | |
+-----+

```

- Input OSS file

Each line of the input OSS file is a URL or an OSS path, for example:

```

oss://your/path/to/image.jpg
http://your.path/to/image.jpg

```

- Custom input format

By default, only image URLs or Base64-encoded image data entries are read from the input tables. Only image URLs are read from the input OSS files to download and decode images. Both of the two methods generate only the NumPy arrays of images in the {"image": np.ndarray} format. The NumPy arrays are used by the process and predictor classes to make predictions. More and more users customize the predictor and process classes. A single input data format cannot satisfy user needs. To support custom formats, the method for reading data from OSS files is improved.

The custom format can be the original OSS file format or JSON string format. Each line in the input files is a JSON string. You can enter multiple key-value pairs. All key-value pairs are saved in a dictionary and pass to the custom predictor and process classes. You can obtain the corresponding values based on custom keys.

If the values are OSS paths or URLs, the system automatically uses multiple threads to download the file content, and saves the values in a Python file-like object. You can call methods such as `read()` or `readlines()` to obtain the content of the Python file-like object. If a value points to a file with an image extension, the system automatically decodes the image. You can obtain the value from the `input_data` dictionary based on the corresponding key. The value is of the `numpy.ndarray` type.

The following code provides an example of the input data:

```
{"image":"http://your/path/to/image.jpg", "prior":"oss://your/path/to/prior.txt", "config":{"key1":1, "key2":"value2"}}
{"image":"http://your/path/to/image.jpg", "prior":"oss://your/path/to/prior.txt", "config":{"key2":1, "key2":"value2"}}
```

The preceding input data will be converted into data in the `input_data` dictionary with the following fields:

- `image`: the decoded data of an image.
- `prior`: the file-like object.
- `config`: a dictionary of JSON strings.

The `input_data` dictionary is in the following format. For all custom process and predictor classes, you can query image data based on the key.

```
input_dict = {
    "image": np.ndarray,
    "prior": file_like_object,
    "config": {"key1":1, "key2":"value2"}
}
```

 **Note** All built-in predictor classes of EasyVision use the `image` key to obtain input images. If you want to use a custom input format to call the built-in predictor classes of EasyVision, you must set the `image` key for image data.

Custom third-party library

The offline prediction framework is implemented based on PAI-TensorFlow. Therefore, the framework does not allow you to use PyTorch models to make custom predictions. In addition, if you make a custom prediction by using a third-party library that does not exist in the preset Python environment, the prediction fails. To resolve this issue, Machine Learning Platform for AI allows you to use the `requirements.txt` file to install a custom Python library.

You must add the `requirements.txt` file to the top-level code directory:

```
user_resource
├── pytorch_sr_script.py
├── requirements.txt
├── user_predictor.py
└── user_process.py
```

Then, you must package the entire code directory and upload it to OSS. The following code provides an example:

```
tar -zcf user_resource.tar.gz user_resource
osscli put user_resource.tar.gz oss://your/path/user_resource.tar.gz
```

You can specify the address of the code package in the Machine Learning Platform for AI command parameter `-Duser_resource`. When the prediction task runs, Machine Learning Platform for AI automatically installs the dependencies that are specified in the `requirements.txt` file.

Custom predictor class

The custom predictor class must inherit `easy_vision.python.inference.predictor.PredictorInterface` or `easy_vision.python.inference.predictor.PredictorInterfaceV2`. The names and default values of all functions and parameters of the custom predictor class must be the same as those in the operation definition.

The general image prediction component is compatible with V1 and V2 operation definitions of the custom predictor class.

- V1 (only serializes all prediction results to JSON strings)

The following code shows the operation definition:

```
class PredictorInterface(six.with_metaclass(abc.ABCMeta, object)):
    def __init__(self, model_path, model_config=None):
        """
        init tensorflow session and load tf model
        Args:
            model_path init model from this directory
            model_config config string for model to init, in json format
        """
        pass
    @abc.abstractmethod
    def predict(self, input_data, batch_size):
        """
        using session run predict a number of samples using batch_size
        Args:
            input_data: a list of numpy array, each array is a sample to be predicted
            batch_size: batch_size passed by the caller, you can also ignore this param and
                use a fixed number if you do not want to adjust batch_size in runtime
        Return:
            result: a list of dict, each dict is the prediction result of one sample
                eg, {"output1": value1, "output2": value2}, the value type can be
                python int str float, and numpy array
        """
        pass
```

The following code provides an example of the custom predictor class:

```
#!/usr/bin/env python
# -*- encoding:utf-8 -*-
# Filename: user_predictor.py
# Author: Qianyan (wenmeng.zwm@alibaba-inc.com)
# Date: 2019-06-10
# Description:
from easy_vision.python.inference import predictor
import tensorflow as tf
class MyPredictor(predictor.PredictorInterface):
    def __init__(self, model_path, model_config=None):
        """
        init tensorflow session and load tf model
        Args:
            model_path init model from this directory
            model_config config string for model to init, in json format
        """
        tf.logging.info('my predictor init done')
    def predict(self, input_data, batch_size):
        """
        using session run predict a number of samples using batch_size
        Args:
            input_data: a list of numpy array, each array is a sample to be predicted
            batch_size: batch_size passed by the caller, you can also ignore this param and
                use a fixed number if you do not want to adjust batch_size in runtime
        Return:
            result: a list of dict, each dict is the prediction result of one sample
                eg, {"output1": value1, "output2": value2}, the value type can be
                python int str float, and numpy array
        """
        results = [{'result1': 'my_predictor_result1', 'result2': 'my_predictor_result2'}
                    for i in range(len(input_data))]
        return results
```

- V2

The custom predictor class has the following limits:

- You can use the custom predictor class to pass only the list of images. No other information can be passed.
- The output dictionary is converted into only JSON strings and cannot save image files.

To remove the limits, Machine Learning Platform for AI provides V2 operation definition to enable you to specify the output format. V2 is developed based on V1 by adding the `get_output_type` function. This function returns a dictionary that indicates how to save the values in the key-value pairs in the dictionary returned by the prediction. The values can be saved in the following ways:

- json: All the output JSON data of keys is aggregated into a dictionary and serialized to a JSON string. Then, the JSON string is written to the output OSS file.
- image: The output data of the keys that correspond to values of the image type is saved in an OSS file *output_dir/key/filename.jpg*. The value of the filename variable is obtained from the input URL. If the output data of a key is a list of images, the images are saved as *output_dir/key/filename_idx.jpg*, where, idx is the index number of each image in the list.
- video: not supported.

To pass more information, you can also pass a list of dictionaries to the predictor class by using custom input data types.

The following code shows the operation definition:

```
class PredictorInterfaceV2(six.with_metaclass(abc.ABCMeta, object)):
    def __init__(self, model_path, model_config=None):
        """
        init tensorflow session and load tf model
        Args:
            model_path init model from this directory
            model_config config string for model to init, in json format
        """
        pass
    def get_output_type(self):
        """
        in this function user should return a type dict, which indicates
        which type of data should the output of predictor be converted to
        * type json, data will be serialized to json str
        * type image, data will be converted to encode image binary and write to oss file,
        whose name is output_dir/{key}/{input_filename}_{idx}.jpg, where input_filename
        is extracted from url, key corresponds to the key in the dict of output_type,
        if the type of data indexed by key is a list, idx is the index of element in list, otherwise {idx} will be empty
        * type video, data will be converted to encode video binary and write to oss file,
        eg: return {
            'ret_image': 'image',
            'feature': 'json'
        }
        indicating that the image data in the output dict will be save to image
        file and feature in output dict will be converted to json
        """
        return {}
    @abc.abstractmethod
    def predict(self, input_data_dict, batch_size):
        """
        using session run predict a number of samples using batch_size
        Args:
            input_data_dict: a list of dict, each dict is a sample data to be predicted
            batch_size: batch_size passed by the caller, you can also ignore this param and
            use a fixed number if you do not want to adjust batch_size in runtime
        Return:
            result: a list of dict, each dict is the prediction result of one sample
            eg, {"output1": value1, "output2": value2}, the value type can be
            python int str float, and numpy array
        """
        pass
```

The following code provides an example of the custom predictor class:

```
class DummyMultiModalPredictor(ev_predictor.PredictorInterfaceV2):
    def __init__(self, model_path, model_config=None):
        pass
    def get_output_type(self):
        return {'result1': 'json',
                'result2': 'json',
                'result_image': 'image',
                'result_image_list': 'image',
                }
    def predict(self, images, batch_size=1):
        results = [
            {'result1': 'dummy',
             'result2': 'dummy',
             'result_image': np.zeros([224,224,3],dtype=np.uint8),
             'result_image_list': [255* np.ones([224,224,3],dtype=np.uint8) for i in range(2)]
            } for i in range(len(images))]
        return results
```

Custom process class

The custom process class must inherit `easy_vision.python.pai_utils.ev_process.UserProcess`. The names and default values of all functions and parameters of the custom process class must be the same as those in the operation definition.

The following code shows the operation definition:

```
class UserProcess(Process):
    def __init__(self,
                 job_name,
                 num_threads=1,
                 input_queue=None,
                 output_queue=None,
                 process_config=None,
                 batch_size=1):
        """
        Args:
        job_name: job name for this process
        num_threads: number of threads to run your process
        input_queue: a queue containing input data, you should not read input_queue by
        yourself
        output_queue: you can push data to output_queue or just return data in process
        which will be pushed into output queue automatically
        process_config: config for your process, dict type
        batch_size: if batch_size is 1, input_data passed to in_data is a dict of one sample data
        if batch_size greater than 1, input_data passed to process is a list of dict, each dict
        contains one sample data
        """
        super(UserProcess, self).__init__(
            job_name,
            num_threads,
            input_queue=input_queue,
            output_queue=output_queue,
            batch_size=batch_size)
    def process(self, in_data):
        """
        method need to be reimplemented, one can add result to output_queue in this func
        or just return the result which will be pushed to output queue automatically.
        you should add the process result to input_data dict, and push it to the output
        queue or just return it. You can refer to easy_vision.python.pai_utils.ev_process.DataFields
        attribute to acquire what information you can get from input_dict, you can only
        write data with key like DataFields.image or DataFields.clip
        Args:
        in_data if self.batch_size is 1, input_data is a dict of one sample data
        if self.batch_size greater than 1, input_data is a list of dict, each dict
        contains one sample data
        Return
        if None, result should be added to output_queue by yourself in this func
        if not None, the returned result will be add to output_queue automatically
        """
        return input_data
    def destroy(self):
        """
        destroy resources that has been used for this process
        """
        pass
```

The following code provides an example of the custom process class:

```
#!/usr/bin/env python
# -*- encoding:utf-8 -*-
# Filename: user_process.py
# Author: Qianyan (wenmeng.zwm@alibaba-inc.com)
# Date: 2019-06-10
```

```

# Date: 2019-08-16

        logging.info('my process destroyed')

```

Result format

This section describes the result format of various models.

- feature_extractor

Sample result :

```
{"feature": [0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.4583122730255127, 0.0]}
```

The following table describes the field in the sample result.

Field	Description	Shape	Type
feature	The extracted feature.	[feature_dim]	FLOAT

- classifier

Sample result :

```
{  
  "class": 3,  
  "class_name": "coho4",  
  "class_probs": {"coho1": 4.028851974258174e-10,  
    "coho2": 0.48115724325180054,  
    "coho3": 5.116515922054532e-07,  
    "coho4": 0.5188422446937221}  
}
```

The following table describes the fields in the sample result.

Field	Description	Shape	Type
class	The ID of the category.	[]	INT 32
class_name	The name of the category.	[]	STRING
class_probs	The matching probabilities of all categories.	[num_classes]	DICT{key: STRING, value: FLOAT}

- detector

Sample result :

```
{  
  "detection_boxes": [[243.5308074951172, 197.69570922851562, 385.59625244140625, 247.7247772216797], [292.1929931640625, 114.28043365478516, 571.2748413085938, 165.09771728515625]],  
  "detection_scores": [0.9942291975021362, 0.9940272569656372],  
  "detection_classes": [1, 1],  
  "detection_class_names": ["text", "text"]  
}
```

The following table describes the fields in the sample result.

Field	Description	Shape	Type
detection_boxes	The text area with detected coordinates in the following order: [top, left, bottom, right].	[num_detections, 4]	FLOAT

Field	Description	Shape	Type
detection_scores	The detection probability of the object.	num_detections	FLOAT
detection_classes	The ID of the category to which the object belongs.	num_detections	INT
detection_class_names	The name of the category to which the object belongs.	num_detections	ISTRING
detection_masks	The segmentation masks of the object. This parameter is optional.	[num_detection, image_height, image_width]	FLOAT
detection_keypoints	The landmarks of the object. This parameter is optional.	[num_detection, num_keypoints, 2]	FLOAT
detection_roi_features	The local features of the object. This parameter is optional.	[num_detection, roi_height, roi_width, channels]	FLOAT

- segmentor

Sample result :

```
{
  "probs" : [[[0.8, 0.8], [0.6, 0.7]], [[0.8, 0.5], [0.4, 0.3]]],
  "preds" : [[[1,1], [0, 0]], [[0, 0], [1,1]]]
}
```

The following table describes the fields in the sample result.

Field	Description	Shape	Type
probs	The probability that each pixel obtained through segmentation belongs to a specific category.	[output_height, output_width, num_classes]	FLOAT
preds	The ID of the category to which the pixel obtained through segmentation belongs.	[output_height, output_widths]	INT

- text_detector

Sample result :

```

The following table describes the fields in the sample result.

Field	Description	Shape	Type
detection_boxes	The detected text area with coordinates in the following order: [top, left, bottom, right].	[num_detections, 4]	FLOAT
detection_scores	The probability that the text is detected.	num_detections	FLOAT
detection_classes	The ID of the category to which the text area belongs.	num_detections	INT
detection_class_names	The name of the category to which the text area belongs.	num_detections	STRING
detection_keypoints	The (y, x) coordinates of the four vertices of the detected text area.	[num_detections, 4, 2]	FLOAT
image_shape	The information about the input image. The value is a list that contains the following information in order: height, width, and channel.	[3]	LIST

- text_recognizer

Sample result :

```

The following table describes the fields in the sample result.

Field	Description	Shape	Type
detection_boxes	The detected text area with coordinates in the following order: [top, left, bottom, right].	[num_detections, 4]	FLOAT
detection_scores	The probability that the text is detected.	num_detections	FLOAT
detection_classes	The ID of the category to which the text area belongs.	num_detections	INT
detection_class_names	The name of the category to which the text area belongs.	num_detections	STRING
detection_keypoints	The (y, x) coordinates of the four vertices of the detected text area.	[num_detections, 4, 2]	FLOAT

Field	Description	Shape	Type
detection_texts_ids	The ID of the category to which a single line of the recognized text belongs.	[num_detections, max_text_length]	INT
detection_texts	The recognition result of the single-line text.	[num_detections]	STRING
detection_texts_scores	The probability that the single-line text is recognized.	[num_detections]	FLOAT
image_shape	The information about the input image. The value is a list that contains the following information in order: height, width, and channel.	[3]	LIST

- Custom result format

By default, `ev_predict` extracts the dictionary from the cache queue, obtains the value of `prediction_result`, serializes the value to a JSON string, and then writes the JSON string to the result column. To write results to different columns by field, you can set the `self_defined_result_formatter` parameter to the path of the custom result formatting class and the `user_resource` parameter to the path of your code.

The process class is a derived class. For more information about the operation definition of this class, see the "Custom process class" section of this topic. You need only to save the formatted results in the `input_data` dictionary with the key as `result_to_save`. Then, `TableWriter` automatically writes the prediction results to the specified table.

The following code provides an example on how to write the decoded data of a video to a table by frame. Each line is the encoded data of a frame.

```

class SelfDefineTableFormatProcess(ev_process.Process):
    def __init__(self,
                 input_queue,
                 output_queue,
                 reserved_col_names=[],
                 output_col_names=[]):
        """
        extract data from dict to prepare result dict which will be written to table or oss file
        Args:
            reserved_col_names list of str column names for reserved col
            output_col_names list of column name for output table
            input_queue the python queue for input
            output the python queue for output
            float_digits: The number of digits of precision when writing floats out
        Return:
            push a k-v pair {'result_to_save': result_dict} into data_dict and return
            a result dict or a tuple, or a list of tuple or a list of dict
            if dict is returned, each key should be the same as column name of output table
            if tuple is returned, this tuple correspond to one table record
            if list of tuple is returned, they correspond to a list of table record
            if list of dict is returned, each element in list will be automatically converted to table record in table writer
        """
        super(SelfDefineTableFormatProcess, self).__init__('SelfDefineTableFormatProcess', 1,
                                                         input_queue=input_queue,
                                                         output_queue=output_queue)
    def process(self, input_data):
        output_record = []
        frames = input_data['frames']
        frames = [base64.urlsafe_b64encode(np.array(frame)) for frame in frames]
        frame_ids = input_data['frame_id']
        url = input_data['url']
        video_records = []
        for url, fid, frame in zip(url, frame_ids, frames):
            video_records.append((url, fid, frame))
        # result should be returned with key result_to_save
        input_data['result_to_save'] = video_records
        return input_data

```

Add the preceding code to `oss://path/to/you/code.py`. Then, use the following Machine Learning Platform for AI command parameters to customize the logic for writing data to the table.

```

pai -name ev_predict
...
-Duser_resource=oss://path/to/you/code.py
-Dself_defined_result_formatter=code.SelfDefineTableFormatProcess

```

4.4.13.3.2. General video prediction

This topic provides examples on how to run a Machine Learning Platform for AI command to use the video prediction component. This topic also describes the command parameters and provides the operation definitions of and examples on custom process and predictor classes.

You can run the `ev_video_predict` command to make video predictions. When you run this command, you need only to set the common parameters without the need to know the rules or logic of the EasyVision profile.

Machine Learning Platform for AI command example

- Input OSS file

```
pai -name ev_video_predict
  -Dinput_oss_file='oss://pai-vision-data-hz/data/pai_test/video_decode_test.list'

```

The code file that is used to customize the predictor class is *user_predictor.py*. The class name is `MvPredictor`. The code file that is used to customize the process class is *user_process.py*. The class name is `MyProcess`. The *user_predictor.py* and *user_process.py* code files are compressed in the *video_res.tar.gz* package.

Parameters

Parameter	Required	Description	Value type or value format	Default value
buckets	Yes	The information about the OSS buckets.	"oss://bucket_name/?role_arn=xxx&host=yyy"	N/A
model_path	Yes	The OSS path of the model.	"oss://your_bucket/your_model_dir" The OSS path of the model that EasyVision provides is <code>oss://pai-vision-data-hz/pretrained_models/saved_models/ucf101_resnet3d_50/</code> .	N/A

Parameter	Required	Description	Value type or value format	Default value
task_type	Yes	The type of the model. Only the video classification model is supported. Set this parameter to video_classifier.	STRING	N/A
input_oss_file	Yes	The path of the input OSS file. Each line in the input file can be in one of the following formats: <ul style="list-style-type: none"> The path of a video. A JSON string. Example: {"video_binary_data": VIDEO_URL, "xxx":xxx}. 	oss://your_bucket/filelist.txt	N/A
output_oss_file	Yes	The path of the output OSS file that is used to store the prediction results. The system may generate multiple result files and merge these result files into an output OSS file. The result files are prefixed with the name of the output OSS file. The number of result files is the same as the number of workers, which is specified by the num_worker parameter.	oss://your_bucket/result.txt	N/A
output_dir	No	The directory of the output file. If you customize the output format, all the result files are stored in this directory.	oss://your_bucket/dir	""
swift_end_point	No	The URL of the online ZooKeeper server.	STRING	""
input_topic	No	The input topic. Each element in the topic is the OSS path of a video or a JSON string, for example, {"url":xxx, "user_define": xxx}.	STRING	""
output_topic	No	The output topic.	STRING	""
feature_name	No	The name of the output feature. Example: "resnet_3d_50/poo2", "resnet_3d_50/scale5/conv5", "resnet_3d_50/scale4/conv4", "resnet_3d_50/scale3/conv3", "resnet_3d_50/scale2/conv2", "resnet_3d_50/pool1", "resnet_3d_50/scale1/conv1".	STRING	""

Parameter	Required	Description	Value type or value format	Default value
decode_type	No	The method that is used to decode the videos. Valid values: <ul style="list-style-type: none"> • 1: intra only • 2: keyframe only • 3: without bidir • 4: decode all 	INT	4
sample_fps	No	The number of frames that are extracted for sampling per second.	FLOAT	-1, which indicates that 25 frames are extracted per second.
reshape_size	No	The size of the output frames, in pixels.	INT	If you set this parameter to -1, the frames are not resized.
sample_duration	No	The length of consecutive frames that are imported to the model.	INT	16
batch_size	No	The number of clips that are imported to the model.	INT	16
predict_thread_num	No	The number of threads that are used for prediction.	INT	1
queue_size	No	The length of the processing queue.	INT	256
num_worker	No	The number of prediction workers.	INT	2
cpuRequired	No	The number of CPUs for a worker. A value of 100 indicates one CPU.	INT	400
gpuRequired	No	The number of GPUs for a worker. A value of 100 indicates one GPU.	INT	100
user_resource	No	The path to which you want to upload your resources. You can upload tar.gz, .zip, and .py files. OSS paths and HTTP URLs are supported.	oss://xxx/a.tar.gz http://a.com/c.zip	""

Parameter	Required	Description	Value type or value format	Default value
user_predictor_cls	No	The module path of the custom predictor class. For example, if you implement Predictor A in module.py, the module path of Predictor A is module.A.	module.PredictorA	""
user_process_config	No	<p>The configurations of the custom process class, in the JSON string format. You can use the following fields to configure the process class. You can also configure other custom fields.</p> <ul style="list-style-type: none"> • job_name: the name of the custom process class. • num_threads: the number of concurrent threads that are used by the custom process class. • batch_size: the batch size of the data to be processed. • user_process_cls: the module path of the custom process class. For example, if you implement Process A in module.py, the module path of Predictor A is module.A. 	<pre>{["job_name": "myprocess", "user_process_cls": "module.ClassA", "num_threads": 2, "batch_size": 1]}</pre>	""

Result format

The result of each video is a JSON string, which includes the URL or OSS path and the prediction result of the video. The following code provides an example:

```

```

If you want to obtain video features, the result contains the feature field with the corresponding feature value. The following code provides an example:

```
{"feature": [0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.4583122730255127, 0.0]}
```

Parameter	Description	Shape	Value type
class	The ID of the category.	[]	INT32
class_name	The name of the category.	[]	STRING
probs	The matching probabilities of all categories.	[num_classes]	DICT {Key: STRING, Value: FLOAT}
feature	The video feature.	[]	FLOAT

Custom process class

The custom process class must inherit `easy_vision.python.pai_utils.ev_process.UserProcess`. The names and default values of all functions and parameters of the custom process class must be the same as those in the operation definition.

The following code shows the operation definition:

```
class UserProcess(Process):
    def __init__(self,
                 job_name,
                 num_threads=1,
                 input_queue=None,
                 output_queue=None,
                 process_config=None,
                 batch_size=1):
        """
        Args:
            job_name: job name for this process
            num_threads: number of threads to run your process
            input_queue: a queue containing input data, you should not read input_queue by
            yourself
            output_queue: you can push data to output_queue or just return data in process
            which will be pushed into output queue automatically
            process_config: config for your process, dict type
            batch_size: if batch_size is 1, input_data passed to in_data is a dict of one sample data
            if batch_size greater than 1, input_data passed to process is a list of dict, each dict
            contains one sample data
        """
        super(UserProcess, self).__init__(
            job_name,
            num_threads,
            input_queue=input_queue,
            output_queue=output_queue,
            batch_size=batch_size)
    def process(self, in_data):
        """
        method need to be reimplemented, one can add result to output_queue in this func
        or just return the result which will be pushed to output queue automatically.
        you should add the process result to input_data dict, and push it to the output
        queue or just return it. You can refer to easy_vision.python.pai_utils.ev_process.DataFields
        attribute to acquire what information you can get from input_dict, you can only
        write data with key like DataFields.image or DataFields.clip
        Args:
            in_data if self.batch_size is 1, input_data is a dict of one sample data
            if self.batch_size greater than 1, input_data is a list of dict, each dict
            contains one sample data
        Return
            if None, result should be added to output_queue by yourself in this func
            if not None, the returned result will be add to output_queue automatically
        """
        return in_data
    def destroy(self):
        """
        destroy resources that has been used for this process
        """
        pass
```

To use the custom process class for video prediction, you must pass a dictionary that contains the following fields:

- `url`: the URL of the video.
- `video_binary_data`: the original video stream, in the `STRING` format.
- `frames`: the frames that are decoded from the video, in the `LIST` format. In the list, each element indicates a frame in the `STRING` format.
- `time_stamp`: the timestamps, in the `LIST` format. In the list, each element indicates a timestamp in the `FLOAT` format.
- `xxx`: the custom information.

The following code provides an example of the custom process class:

```
#!/usr/bin/env python
# -*- encoding:utf-8 -*-
# Filename: user_process.py
from easy_vision.python.pai_utils import ev_process
import logging
class MyProcess(ev_process.UserProcess):
    def __init__(self,
                 job_name,
                 num_threads=1,
                 input_queue=None,
                 output_queue=None,
                 process_config=None,
                 batch_size=1):
        """
        Args:
        job_name: job name for this process
        num_threads: number of threads to run your process
        input_queue: a queue containing input data, you should not read input_queue by
        yourself
        output_queue: you can push data to output_queue or just return data in process
        which will be pushed into output queue automatically
        process_config: config for your process, dict type
        batch_size: if batch_size is 1, input_data passed to in_data is a dict of one sample data
        if batch_size greater than 1, input_data passed to process is a list of dict, each dict
        contains one sample data
        """
        super(MyProcess, self).__init__(job_name, num_threads,
                                       input_queue = input_queue,
                                       output_queue = output_queue,
                                       batch_size = batch_size)
    def process(self, in_data):
        """
        method need to be reimplemented, one can add result to output_queue in this func
        or just return the result which will be pushed to output queue automatically.
        you should add the process result to input_data dict, and push it to the output
        queue or just return it. You can refer to easy_vision.python.pai_utils.ev_process.DataFields
        attribute to acquire what information you can get from input_dict, you can only
        write data with key like DataFields.image or DataFields.clip
        Args:
        in_data if self.batch_size is 1, input_data is a dict of one sample data
        if self.batch_size greater than 1, input_data is a list of dict, each dict
        contains one sample data
        Return
        if None, result should be added to output_queue by yourself in this func
        if not None, the returned result will be add to output_queue automatically
        """
        logging.info('my process process data')
        return in_data
    def destroy(self):
        """
        destroy resources that has been used for this process
        """
        logging.info('my process destroyed')
```

Custom predictor class

The custom predictor class must inherit `easy_vision.python.inference.predictor.PredictorInterface`. The names and default values of all functions and parameters of the custom predictor class must be the same as those in the operation definition.

The general video prediction component is compatible with V1 and V2 operation definitions of the custom predictor class.

- V1

The following code shows the operation definition:

```
class PredictorInterface(six.with_metaclass(abc.ABCMeta, object)):
    def __init__(self, model_path, model_config=None):
        """
        init tensorflow session and load tf model
        Args:
            model_path init model from this directory
            model_config config string for model to init, in json format
        """
        pass
    @abc.abstractmethod
    def predict(self, input_data, batch_size):
        """
        using session run predict a number of samples using batch_size
        Args:
            input_data: a list of numpy array, each array is a sample to be predicted
            batch_size: batch_size passed by the caller, you can also ignore this param and
                use a fixed number if you do not want to adjust batch_size in runtime
        Return:
            result: a list of dict, each dict is the prediction result of one sample
                eg, {"output1": value1, "output2": value2}, the value type can be
                python int str float, and numpy array
        """
        pass
```

The following code provides an example of the custom predictor class:

```
#!/usr/bin/env python
# -*- encoding:utf-8 -*-
# Filename: user_predictor.py
# Description:
from easy_vision.python.inference import predictor
import tensorflow as tf
class MyPredictor(predictor.PredictorInterface):
    def __init__(self, model_path, model_config=None):
        """
        init tensorflow session and load tf model
        Args:
            model_path init model from this directory
            model_config config string for model to init, in json format
        """
        tf.logging.info('my predictor init done')
    def predict(self, input_data, batch_size):
        """
        using session run predict a number of samples using batch_size
        Args:
            input_data: a list of numpy array[*h*w*c], each array is a sample to be predicted
            batch_size: batch_size passed by the caller, you can also ignore this param and
                use a fixed number if you do not want to adjust batch_size in runtime
        Return:
            result: a list of dict, each dict is the prediction result of one sample
                eg, {"output1": value1, "output2": value2}, the value type can be
                python int str float, and numpy array
        """
        results = []
        for i in range(len(input_data)):
            output = {'result1':'my_predictor_result1'}
            if 'url' in input_data:
                output['url'] = input_data['url']
            if 'user_define' in input_data:
                output['user_define'] = input_data['user_define']
            results.append(output)
        return results
```

- V2

The custom predictor class has the following limits:

- You can use the custom predictor class to pass only the list of images. No other information can be passed.
- The output dictionary is converted into only JSON strings and cannot save image files.

To remove the limits, Machine Learning Platform for AI provides V2 operation definition to enable you to specify the output format. V2 is developed based on V1 by adding the `get_output_type` function. This function returns a dictionary that indicates how to save the values in the key-value pairs in the dictionary returned by the prediction. The values can be saved in the following ways:

- json: All the output JSON data of keys is aggregated into a dictionary and serialized to a JSON string. Then, the JSON string is written to the output OSS file.
- image: The output data of the keys that correspond to values of the image type is saved in an OSS file *output_dir/key/filename.jpg*. The value of the filename variable is obtained from the input URL. If the output data of a key is a list of images, each image in the list is saved as *output_dir/key/filename_idx.jpg*, where, *idx* is the index number of each image.
- video: not supported.

To pass more information, you can also pass a list of dictionaries to the predictor class by using custom input data types.

The following code shows the operation definition:

```
class PredictorInterfaceV2(six.with_metaclass(abc.ABCMeta, object)):
    def __init__(self, model_path, model_config=None):
        """
        init tensorflow session and load tf model
        Args:
            model_path init model from this directory
            model_config config string for model to init, in json format
        """
        pass
    def get_output_type(self):
        """
        in this function user should return a type dict, which indicates
        which type of data should the output of predictor be converted to
        * type json, data will be serialized to json str
        * type image, data will be converted to encode image binary and write to oss file,
        whose name is output_dir/${key}/${input_filename}_${idx}.jpg, where input_filename
        is extracted from url, key corresponds to the key in the dict of output_type,
        if the type of data indexed by key is a list, idx is the index of element in list, otherwise ${idx} will be empty
        * type video, data will be converted to encode video binary and write to oss file,
        eg: return {
            'image': 'jpg',
            'feature': 'json'
        }
        indicating that the image data in the output dict will be save to image
        file and feature in output dict will be converted to json
        """
        return {}
    @abc.abstractmethod
    def predict(self, input_data_dict, batch_size):
        """
        using session run predict a number of samples using batch_size
        Args:
            input_data_dict: a list of dict, each dict is a sample data to be predicted
            batch_size: batch_size passed by the caller, you can also ignore this param and
            use a fixed number if you do not want to adjust batch_size in runtime
        Return:
            result: a list of dict, each dict is the prediction result of one sample

            python int str float, and numpy array
        """
        pass
```

The following code provides an example of the custom predictor class:

```
class DummyMultiModalPredictor(ev_predictor.PredictorInterfaceV2):
    def __init__(self, model_path, model_config=None):
        pass
    def get_output_type(self):
        return {'result1': 'json',
                'result2': 'json',
                'result_image': 'image',
                'result_image_list': 'image',
                }
    def predict(self, images, batch_size=1):
        results = [
            {'result1': 'dummy',
             'result2': 'dummy',
             'result_image': np.zeros([224,224,3], dtype=np.uint8),
             'result_image_list': [255* np.ones([224,224,3], dtype=np.uint8) for i in range(2)]
            } for i in range(len(images))]
        return results
```

4.4.13.3.3. ASR prediction

This topic provides an example on how to run a Machine Learning Platform for AI command to use the automatic speech recognition (ASR) prediction component. This topic also describes the command parameters.

You must specify a MaxCompute table that contains the URL of the raw data as the input. Then, the ASR prediction component returns all the input data with an extra row at the end that contains the ASR result.

 **Note** You must create an empty table in advance as the output table. The schema of the output table must be the same as that of the input table. The last row of the output table contains the prediction result in the STRING format.

Machine Learning Platform for AI command example

```
PAI -name asr_predict_180 -project sre_mpi_algo_dev
-Dbuckets='oss://pai-audio-zjk/?role_arn=xxx&host=yyy'
-Dinput_tables='odps://sre_mpi_algo_dev/tables/video_asr_dev'
-Doutput_tables='odps://sre_mpi_algo_dev/tables/video_asr_dev_output'
-Durl_col_index=0
-Dmerge=1
-Dnum_workers=1
-Dnum_processes=6
-Dnum_download=7
-Dnum_memory=10000
-Doversubscription=false;
```

Set the buckets, input_tables, and output_tables parameters as needed.

Parameters

Parameter	Required	Description	Value type	Value
-----------	----------	-------------	------------	-------

Parameter	Required	Description	Value type	Value
buckets	Yes	The information about the Object Storage Service (OSS) buckets. Set this parameter to the path of a directory in an OSS bucket. The value format is the same as that of the buckets parameter of PAI-TensorFlow. Example: oss://pai-audio-zjk/?role_arn=xxx&host=yyy.	STRING	N/A
input_tables	Yes	The input tables. Example: odps://sre_mpi_algo_dev/tables/video_asr_dev.	STRING	N/A
output_tables	Yes	The output tables. Example: odps://sre_mpi_algo_dev/tables/video_asr_dev_output.	STRING	N/A
url_col_index	No	The serial number of the column that contains the data URL. The serial number starts from 0.	INT	0
merge	No	Specifies whether to return the merged recognition result. If you set this parameter to 0, the recognition result contains the speech segments and their start and stop timestamps. Example: {"detection_texts": ["你看人家想妈了吧小妈了", "小妈了", "太好了", "你呀赶紧给你妈打电话"], "time": [[["0", "2660"], ["4040", "4660"], ["5800", "6560"], ["6840", "10069"]]]}.	INT	1
num_workers	No	The number of workers that are used for prediction.	INT	1
num_processes	No	The number of threads that are used by each worker for prediction. We recommend that you set this parameter to 12 or less.	INT	6
num_download	No	The number of threads that are used by each worker to download videos. We recommend that you set this parameter to 10 or less.	INT	7
num_memory	No	The size of the memory that each worker consumes.	INT	10000

Parameter	Required	Description	Value type	Value
oversubscription	No	The value format of this parameter is the same as that of the oversubscription parameter of PAI-TensorFlow. <ul style="list-style-type: none"> true false 	BOOL	true

If an error occurs during ASR, the system returns the corresponding error code as a string in the output table. The following table describes the error codes.

Error code	Description
data_convert_error	An error occurred during data download or transcoding. Check whether the data source is normal.
data_download_error	An error occurred during data download. Check whether the URL is valid.
predict_error	An error occurred during the model prediction.

4.5. OpenAPI

4.5.1. Query PMML models

Operation name

ListPMMLModels

Description

You can call this operation to query PMML models by project ID, experiment ID, or owner.

Request parameters

Parameter	Type	Required	Example	Description
OnwerId	String	Yes	11769368777159105	The UID of a model owner.
ProjectId	Long	Yes	10009	The ID of a project.
ExperimentId	Long	No	4294	The ID of an experiment.
Action	String	Yes	ListPMMLModels	The operation that you want to perform. Set the value to ListPMMLModels.

Response parameters

Parameter	Type	Description
Experiments	List<ExperimentModelInfo>	An array of experiment properties returned.
Experiment	ExperimentModelInfo	The returned experiment information.
ExpId	Long	The ID of the experiment to which the models belong.
Models	List<ModelInfo >	An array of model properties returned.
Model	ModelInfo	The returned model information.
Name	String	The display name of the model.
Owner	String	The ID of the model owner.
Description	String	The description of the model.
ModelId	String	The ID of the model.
ModelName	String	The name of the underlying model generated by the corresponding algorithm.
CreateTime	Date	The time when the model was generated.
ExperimentId	String	The ID of the experiment from which the model is generated.
UpdateTime	Date	The time when the model was updated.
Project	String	The name of the project to which the model belongs.
ProjectId	String	The ID of the project to which the model belongs.
Action	String	The name of the API operation.
AccessKeyId	String	The AccessKey ID provided to you by Alibaba Cloud.
Signature	String	The signature string.
SignatureMethod	String	The signing method.
SignatureVersion	String	The version of the signature encryption algorithm.
SignatureNonce	String	A unique, random number used to prevent replay attacks.

Timestamp	String	The timestamp of the request.
Version	String	The version number of the API. The value must be in the YYYY-MM-DD format.
Format	String	The language of the response.

4.5.2. Query detailed information about a PMML model

Operation name

DescribePMMLMode

Description

You can call this operation to query detailed information about a model.

Request parameters

Parameter	Type	Required	Example	Description
ModelId	Integer	Yes	6200	The ID of the model.

Parameter	Type	Required	Example	Description
Action	String	Yes	DescribePMMLMode	The operation that you want to perform. Set the value to DescribePMMLMode .

Response parameters

Parameter	Type	Description
Models	List<ModelInfo >	An array of model properties returned.
Model	ModelInfo	Detailed information about the model.
Name	String	The display name of the model.
Owner	String	The ID of the model owner.
Description	String	The description of the model.
ModelId	String	The ID of the model.
ModelName	String	The name of the underlying model generated by the algorithm.
CreateTime	Date	The time when the model was generated.
ExperimentId	String	The ID of the experiment from which the model is generated.
UpdateTime	Date	The time when the model was updated.
Project	String	The name of the project to which the model belongs.
ProjectId	String	The ID of the project to which the model belongs.

Sample requests

<http://pop.pai.idst.inter.env8d.com/?Action=DescribePMMLMode&ModelId=6200&<Common request parameters>>

  }
}
```

4.5.3. Download PMML models

4.5.3.1. Generate a download URL for a model

Operation name

GeneratePMMLModelUrl

Description

You can call this operation to generate a download URL for a PMML model. The API call is executed asynchronously. After you call this operation, the system creates a download URL generation task in the background, and returns the task ID to you. You can then use the task ID to query the status of the task. If the task is successfully executed, the URL (OSS endpoint) of the model is returned.

Request parameters

Parameter	Type	Required	Example	Description
ModelId	Integer	Yes	6200	The ID of the model.
Action	String	Yes	GeneratePMMLModelUrl	The operation that you want to perform. Set the value to GeneratePMMLModelUrl.

Response parameters

Parameter	Type	Description
Data	Data	The returned data.
JobId	String	The ID of the download URL generation task.

Sample requests

```
http://pop.pai.idst.inter.env8d.com/?Action=GeneratePMMLModelUrl&ModelId=6200<Common request parameters>
```

Sample responses

```
<GeneratePMMLModelUrlResponse>
<Data>
<JobId>
asynUploadModel2Oss_395fd769-1568-4015-8aa8-a56b2e0da11c
</JobId>
</Data>
<RequestId>0a94818615695013054356697d0059</RequestId>
<ErrMsg>Successful</ErrMsg>
<ErrCode>success</ErrCode>
</GeneratePMMLModelUrlResponse>{
  "GeneratePMMLModelUrlResponse": {
    "Data": {
      "JobId": "
asynUploadModel2Oss_395fd769-1568-4015-8aa8-a56b2e0da11c
"
    },
    "RequestId": "0a94818615695013054356697d0059",
    "ErrMsg": "Successful",
    "ErrCode": "success"
  }
}
```

4.5.3.2. Query a model URL generation task

Operation name

QueryAsynJobStatus

Description

You can call this operation to query the status of a URL generation task. If the task is successfully executed, the URL (OSS endpoint) of the model is returned.

Request parameters

Parameter	Type	Required	Example	Description
JobId	String	Yes	asynUploadModel2Oss_395fd769-1568-4015-8aa8-a56b2e0da11c	The ID of the task to be queried. The task ID is returned after you call the GeneratePMMLModelUrl operation.
Action	String	Yes	QueryAsynJobStatus	The operation that you want to perform. Set the value to QueryAsynJobStatus.

Response parameters

Parameter	Type	Description
Data	Data	The returned data.
Status	String	The status of the task. Valid values: done, failed, and running.
Info	String	The URL of the model is returned if the task is successfully executed. An error message is returned if the system fails to execute the task.

Sample requests

```
http://pop.pai.idst.inter.env8d.com/?Action=QueryAsynJobStatus&JobId=asynUploadModel2Oss_395fd769-1568-4015-8aa8-a56b2e0da11c<Common request parameters>
```

Sample responses

```
<QueryAsynJobStatusResponse>
<Data>
<Status>done</Status>
<Info>

  }
}
```

4.5.4. SDKs

Alibaba Cloud SDKs

```
https://developer.aliyun.com/sdk?spm=5176.10695662.1kquk9v2l.2.1e734735x9Gptc&aly_as=m3lFQpXP<dependen
cy>
<groupId>com.aliyun</groupId>
<artifactId>aliyun-java-sdk-core</artifactId>
<version>${version}</version></dependency>
```

SDK use case

Example: call an RPC API operation.

```
import com.aliyuncs.CommonRequest;
import com.aliyuncs.CommonResponse;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.profile.DefaultProfile;
public class Sample {
    public static void main(String[] args) {
        // Create a default ACS client and initialize it.
        DefaultProfile profile = DefaultProfile.getProfile(
            "<your-region-id>", // The region ID.
            "<your-access-key-id>", // The AccessKey ID.
            "<your-access-key-secret>"); // The AccessKey secret.
        IAcsClient client = new DefaultAcsClient(profile);
        // Create an API request and configure parameters.
        CommonRequest request = new CommonRequest();
        request.setDomain("ecs.aliyuncs.com");
        request.setVersion("2014-05-26");
        request.setAction("DescribeInstanceStatus");
        request.putQueryParameter("PageNumber", "1");
        request.putQueryParameter("PageSize", "30");
        try {
            CommonResponse response = client.getCommonResponse(request);
            System.out.println(response.getData());
        } catch (ServerException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        } catch (ClientException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        }
    }
}
```

Example: call an RESTful API operation.

```
import com.aliyuncs.CommonRequest;
import com.aliyuncs.CommonResponse;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.profile.DefaultProfile;
public class Sample {
    public static void main(String[] args) {
        // Create a default ACS client and initialize it.
        DefaultProfile profile = DefaultProfile.getProfile(
            "<your-region-id>", // The region ID.
            "<your-access-key-id>", // The AccessKey ID.
            "<your-access-key-secret>");// The AccessKey secret.
        IAcsClient client = new DefaultAcsClient(profile);
        // Create an API request and configure parameters.
        CommonRequest request = new CommonRequest();
        request.setDomain("cs.aliyuncs.com");
        request.setVersion("2015-12-15");
        request.setUriPattern("/clusters");
        try {
            CommonResponse response = client.getCommonResponse(request);
            System.out.println(response.getData());
        } catch (ServerException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        } catch (ClientException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        }
    }
}
```

SDK parameters

The domain must be in the pop.\${pai_domain} format. Set the pai_domain parameter to the domain shown in the Machine Learning Platform for AI.

The version must be 2019-09-25.

The Action string specifies an API operation.

The QueryParameter string specifies API request parameters, excluding the action parameter.

Example:

```
CommonRequest request = new CommonRequest();
request.setDomain("pop.${pai_domain}");
request.setVersion("2019-09-25");
request.setAction("DescribePMMLMode");
request.putQueryParameter("ModelId", "****");
```

4.6. Data labeling

4.6.1. Register a dataset

Machine Learning Platform for AI allows you to register a dataset by creating a dataset or importing a dataset file. It also allows you to use **manifest** files to manage all registered datasets.

Register a dataset by creating a dataset

If your source data such as image, text, video, and audio files is stored in Object Storage Service (OSS), you can **create a dataset** in the console. The system scans all files of the same type in the specified directory and generates a manifest file in the specified OSS path.

1. Go to the **Register Dataset** page.
 - i. In the left-side navigation pane of the Machine Learning Platform for AI console, choose **Data Preprocessing > Dataset Manager**.
 - ii. On the **Dataset Manager** page, click **Register Dataset**.
2. On the **Register Dataset** page, set the following parameters.

Parameter	Description
Dataset Name	The name must be 1 to 24 characters in length, and can contain underscores (_) and hyphens (-). It must start with a letter or a digit.
Method	Set the Method parameter to New Dataset .
Storage Type	Only OSS is supported.
Path	Set the Path parameter to the OSS path where your source data is stored.
Data Type	Only Image is supported.
Tags	You can attach a maximum of 10 tags to each dataset. Each tag can contain underscores (_) and hyphens (-). It must start with a letter or a digit.

3. Click **Submit**. Then, a manifest file is generated. The following code provides an example on the manifest file.

```

{"data":{"picUrl":"oss://****/pics/fruit/apple-1.jpg"}}
{"data":{"picUrl":"oss://****/pics/fruit/apple-10.jpg"}}
{"data":{"picUrl":"oss://****/pics/fruit/apple-11.jpg"}}
...
    
```

After you register a dataset, you can view the dataset on the **Dataset Manager** page.

Register a dataset by importing a dataset file

If you have created an on-premises **CSV file** or **manifest file**, you can register a dataset by **importing the dataset file**. If you import a CSV file, the system automatically converts it to a **manifest** file.

1. Go to the **Register Dataset** page.
 - i. In the left-side navigation pane of the Machine Learning Platform for AI console, choose **Data Preprocessing > Dataset Manager**.
 - ii. On the **Dataset Manager** page, click **Register Dataset**.
2. On the **Register Dataset** page, set the parameters.

Parameter	Description
Dataset Name	The name must be 1 to 24 characters in length, and can contain underscores (_) and hyphens (-). It must start with a letter or a digit.

Parameter	Description
Method	Set the Method parameter to Import Dataset .
Storage Type	Only OSS is supported.
Path	Select an OSS path.
Data Type	Drag an on-premises CSV file or manifest file to the upload area on the right side of the Data Type parameter. Note If the imported file is used in a labeling job, the names of the fields in the file must comply with the data structure of the template that is used to create the labeling job. For more information, see Data labeling templates .
Tags	You can attach a maximum of 10 tags to each dataset. Each tag must be 1 to 10 characters in length, and can contain underscores (_) and hyphens (-). It must start with a letter or a digit.

3. Click **Submit**. After you register a dataset, you can view the dataset on the **Dataset Manager** page.

4.6.2. Data labeling templates

Machine Learning Platform for AI provides the following templates: object detection, semantic segmentation, comprehensive image labeling, Optical Character Recognition (OCR), single-label image classification, and multi-label image classification. When you create a labeling job, you can select a template based on your requirements.

Object detection

Object detection is used to locate a specific object in an image. The rectangle selection tool is commonly used.

- Scenarios

Object detection applies to scenarios such as vehicle detection, passenger detection, and image search.

- Data structure

- Input data

Each row in the **manifest** file contains a topic. Each topic must contain the `picUrl` field.

```
{"data":{"picUrl":"oss://****/pics/fruit/apple-1.jpg"}}  
...
```

- Output data

Each row in the **manifest** file contains a topic and the corresponding labeling result. The following code provides an example on the JSON string in each row:

```
{
  "data": {
    "picUrl": "oss://****/pics/fruit/apple-1.jpg"
  },
  "label-****(Labeling job ID)": {
    "results": [{
      "data": [{
        "id": "Znyumd-****",
        "type": "image/rectangleLabel",
        "value": {
          "rotation": 0,
          "x": 40.68320610687023,
          "width": 327.52035623409665,
          "y": 5.762467474590647,
          "height": 296.68117192104745
        }
      },
      "labelColor": "#72bf7d",
      "labels": ["apple"]
    }],
    "id": "44****",
    "type": "image"
  }
}
```

Semantic segmentation

Semantic segmentation is used to recognize an object in an image and retrieve the coordinates of the object by scanning all pixels of the object. The commonly used tools are the polygon selection tool, brush tool, and superpixel tool.

- Scenarios

Semantic segmentation applies to scenarios such as autonomous driving, facial expression recognition, and apparel classification.

- Data structure

- Input data

Each row in the **manifest** file contains a topic. Each topic must contain the `picUrl` field.

```
{"data":{"picUrl":"oss://****/pics/fruit/apple-1.jpg"}}
...
```

- Output data

Each row in the **manifest** file contains a topic and the corresponding labeling result. The following code provides an example on the JSON string in each row:

```
{
  "data": {
    "picUrl": "oss://****/pics/fruit/apple-1.jpg"
  },
  "label-****(Labeling job ID)": {
    "results": [{
      "data": [{
        "id": "Znyumd-****",
        "type": "image/polygonLabel",
        "value": {
          "points": [
            [110, 46],
            [52, 196],
            [48, 168],
            [48, 145],
            [54, 120],
            [63, 93],
            [76, 74]
          ]
        }
      },
      {
        "labelColor": "#72bf7d",
        "labels": ["apple"]
      }
    ]},
    "id": "44****",
    "type": "image"
  }
}
```

Comprehensive image labeling

Comprehensive image labeling is used to match the content of the input images against a set of labels. This template allows you to use all image labeling tools as needed.

- Scenarios

Comprehensive image labeling applies to scenarios such as autonomous driving, content moderation, and content recognition.

- Data structure

- Input data

Each row in the **manifest** file contains a topic. Each topic must contain the `picUrl` field.

```
{"data":{"picUrl":"oss://****/pics/fruit/apple-10.jpg"}}
```

- Output data

Each row in the **manifest** file contains a topic and the corresponding labeling result. The following code provides an example on the JSON string in each row:

```
{
  "data": {
    "picUrl": "oss://****/pics/fruit/apple-10.jpg"
  },
  "label-****(Labeling job ID)": {
    "results": [{
      "data": [{
        "id": "Znyumd-****",
        "type": "image/rectangleLabel",
        "value": {
          "rotation": 0,
          "x": 40.68320610687023,
          "width": 327.52035623409665,
          "y": 5.762467474590647,
          "height": 296.68117192104745
        }
      }],
      "labelColor": "#72bf7d",
      "labels": ["Red apple"]
    }],
    "id": "44****",
    "type": "image"
  }
}
```

OCR

OCR is used to extract text from input images, and then classify the images based on the text.

- Scenarios

OCR applies to scenarios such as the recognition of identity cards, tickets, license plates, and bank cards.

- Data structure

- Input data

Each row in the **manifest** file contains a topic. Each topic must contain the `picUrl` field.

```
{"data":{"picUrl":"oss://****/img/ocr_card/img0.jpeg"}}
```

- Output data

Each row in the **manifest** file contains a topic and the corresponding labeling result. The following code provides an example on the JSON string in each row:

```
{
  "data": {
    "picUrl": "oss://****/img/ocr_card/img0.jpeg"
  },
  "label-****(Labeling job ID)": {
    "results": [
      {
        "data": [
          {
            "direction_of_picture": "downward",
            "type": "ocr/meta"
          },
          {
            "id": "Y4ZFoC-****",
            "direction_of_text": "downward",
            "text": "Alibaba Cloud Intelligence",
            "type": "ocr/polygonLabel",
            "value": {
              "points": [[325.08789110183716,397.47582054138184]]
            },
            "labelColor": "#67bd3a",
            "labels": "Enterprise"
          }
        ],
        "id": "24****",
        "type": "ocr"
      }
    ]
  }
}
```

Single-label image classification

Single-label image classification is used to find a label from a set of labels to match the content of an input image, and then attach the label to the image.

- Scenarios

Single-label image classification applies to scenarios such as photo classification, image recognition, and image search.

- Data structure

- Input data

Each row in the **manifest** file contains a topic. Each topic must contain the `picUrl` field.

```
{"data":{"picUrl":"oss://****/img/ocr_card/img0.jpeg"}}
```

- Output data

Each row in the **manifest** file contains a topic and the corresponding labeling result. The following code provides an example of the JSON string in each row:

```
{
  "data": {
    "picUrl": "oss://****/img/ocr_card/img0.jpeg"
  },
  "label-****(Labeling job ID)": {
    "results": [{
      "data": [{
        "data": "red",
        "id": "33****",
        "type": "survey/value"
      }],
      "id": "33****",
      "type": "survey"
    }]
  }
}
```

Multi-label image classification

Multi-label image classification is used to find multiple labels from a set of labels to match the content of an input image, and then attach the labels to the image.

- Scenarios

Multi-label image classification applies to scenarios such as content recommendation, advertising, and image search.

- Data structure

- Input data

Each row in the **manifest** file contains a topic. Each topic must contain the picUrl field.

```
{"data":{"picUrl":"oss://****/img/ocr_card/img0.jpeg"}}
```

- Each row in the **manifest** file contains a topic and the corresponding labeling result. The following code provides an example on the JSON string in each row:

```
{
  "data": {
    "picUrl": "oss://****/img/ocr_card/img0.jpeg"
  },
  "label-****(Labeling job ID)": {
    "results": [{
      "data": [{
        "data": ["red", "more", "green"],
        "id": "33****",
        "type": "survey/multivalue"
      }],
      "id": "33****",
      "type": "survey"
    }]
  }
}
```

4.6.3. Create a labeling job

This topic describes how to create a labeling job.

Prerequisites

A dataset is registered. For more information about how to register a dataset, see [Register a dataset](#).

Procedure

1. In the left-side navigation pane of the Machine Learning Platform for AI console, choose **Data Preprocessing > Smart Labeling**.
2. On the **Smart Labeling** page, click **Create Labeling Job**.
3. In the **Basic Information** step, set the parameters and click **Next**.

Parameter	Description
Task Name	The task name must be 1 to 24 characters in length, and can contain underscores (_) and hyphens (-). It must start with a letter or digit.
Description	The description must be 1 to 64 characters in length, and can contain underscores (_) and hyphens (-). It must start with a letter or digit.
Input Dataset	You can select one or more datasets to create a labeling job. The datasets must correspond to the topic of the labeling job. If no dataset is available, click Register Dataset next to the Input Dataset parameter to register a dataset.
Output Dataset Path	Select an Object Storage Service (OSS) path to store the labeling results. When you handle a labeling job, every time you click Generate Result Dataset , a result dataset is generated in the specified OSS path. The dataset contains the results of all topics that you have completed.

4. In the **Template** step, set the parameters and click **Next**.

Parameter	Description	
Template	The template to be used in the labeling job. The system supports the following templates: <ul style="list-style-type: none"> ◦ Target detection ◦ Semantic segmentation ◦ Image comprehensive labeling ◦ OCR ◦ Single-label image classification ◦ Multi-label image classification 	
Categories	The labels that are used to classify images. This parameter takes effect only when Single-label image classification or Multi-label classification is selected for the Template parameter.	
Label Image	Label Image Orientation	Specifies whether to annotate image orientation. This parameter takes effect only when you select OCR for the Template parameter.

Parameter	Description
Flip Text	Specifies whether to annotate text orientation. If the text in an image is placed in the same direction as the image, you can turn off this switch. This parameter takes effect only when you select OCR for the Template parameter.
Text Type	The labels that are used to classify the text. This parameter takes effect only when you select OCR for the Template parameter.
Add Custom Label	The custom labels that are used to classify the text. This parameter takes effect only when you select OCR for the Template parameter.
Labels	The labels that are used to classify images. Labels are displayed in different colors. This parameter takes effect only when you select Target detection , Semantic segmentation , or Image comprehensive labeling for the Template parameter.

5. In the **Labeling Policy** step, set the parameters and click **Submit**.

Parameter	Description
Dispatch Policy	The default dispatch policy is Number of topics collected by a worker each time and cannot be changed.
Topics per Collection	<p>The number of topics that are collected by each worker each time.</p> <div style="border: 1px solid #ccc; background-color: #e6f2ff; padding: 5px;"> <p>? Note The value of the Topics per Collection parameter can be smaller than the total number of topics divided by the total number of workers. This allows workers with high efficiency to collect more topics and improves the overall efficiency of data labeling.</p> </div>
Add Worker	You can specify one or more workers. You can select both Alibaba Cloud accounts and RAM users.

4.6.4. Label images

This topic describes how to label images.

Prerequisites

A labeling job is created or assigned to you by the administrator. For more information, see [Create a labeling job](#).

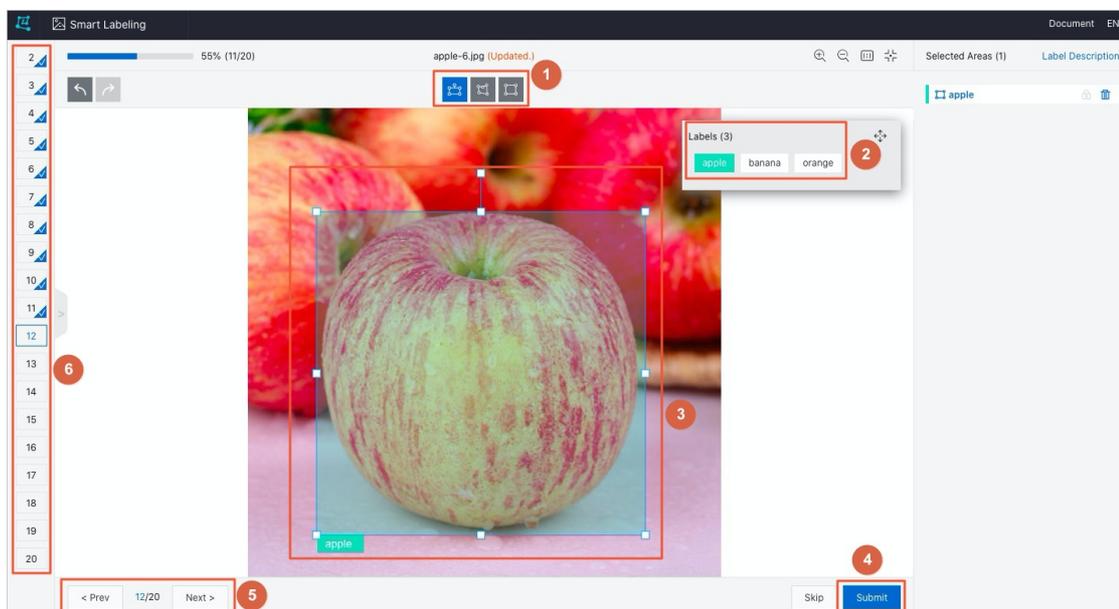

Procedure

1. Go to the Smart Labeling page.
 - i. In the left-side navigation pane of the Machine Learning Platform for AI console, choose **Data Preprocessing > Smart Labeling**.
 - ii. On the **Smart Labeling** page, click **My Labeling Jobs**.
 - iii. In the job list, find your labeling job and click **Start** in the **Actions** column.
2. Label images.
 - i. On the labeling page, click the  icon.

- ii. In the **Labels** section, select a label.

Note The system attaches the selected label to each image unless you select another label.

- iii. Use the selection tool to select an area in the image.

- iv. (Optional) If you do not need to label the image, click **Skip**.
- v. Click **Submit**.
- vi. You can use one of the following methods to browse and complete topics:
 - Click **Prev** or **Next** in the lower part of the Smart Labeling page.
 - Click the thumbnails of the topics in the left-side navigation pane.

4.7. EAS user guide

4.7.1. EAS overview

Elastic Algorithm Service (EAS) allows you to deploy machine learning models, such as PMML, PAI-OfflineModel, TensorFlow, and Caffe models, as services. You can also develop custom online services based on the API standards defined by EAS. You can simply use a JSON file to describe the service that you want to deploy, such as the path of the model, the region where the service is deployed, and the resources used by the service. After the JSON file is prepared, you can use the eascmd client or Alibaba Cloud SDK for Java to deploy it as an online service. The service can be accessed from the production environment and Internet. EAS supports various regions and different types of hardware resources (CPUs and GPUs).

4.7.2. Client

You can use the eascmd client to create, delete, view, and modify services. The eascmd client is stored in the Object Storage Service (OSS) bucket eas-utils. You can use wget or curl to download eascmd.

4.7.3. User authentication

Deployed model services use JSON Web Token (JWT) for user authentication. You can run the following command in eascmd to configure the AccessKey information.

```
./eascmd64 config -i <AccessKeyId> -k <AccessKeySecret> -e {{Domain name of EAS}}
//New users can use the admin account to pass authentication.
./eascmd64 config -i admin -k admin -e {{Domain name of EAS}}
```

4.7.4. Upload files

When you create a service, you must specify the HTTP addresses of the model and processor files. You can store the model and processor files on any HTTP servers.

4.7.5. Create a service

You can run the `create` command to create a service. When you create a service, you must specify the HTTP URLs of the model and processor files to be used by the service. You can upload the files to Object Storage Service (OSS) and specify their OSS paths.

```
eascmd create [service_desc_json]
```

The `service_desc_json` file contains service information and metadata configurations. The metadata configurations only contain cluster deployment information, such as the region where the cluster is deployed and the required resources. Example:

 **Note** When you run the `test` command to debug the service, the metadata configurations are ignored.

```
{
  "name": "mnist_saved_model_example",
  "generate_token": "true",
  "model_path": "http://eas-data.oss-cn-shanghai.aliyuncs.com/models%2Fmnist_saved_model.tar.gz",
  "processor": "tensorflow_cpu",
  "metadata": {
    "instance": 1,
    "cpu": 1,
  }
}
```

The parameters in the JSON file are described as follows:

Key	Value
name	The name of the service. Service names are unique inside each region. You can specify the region in the metadata configurations.
generate_token	Specifies whether to generate a token. If the value is set to true, you must add the token to the HTTP header of the request that you send to the service. If the value is set to false, the service is accessible to the public. No authentication is required.
token	Optional. The token used for authenticating requests sent to the service. If you do not specify a token, the <code>generate_token</code> parameter automatically generates a token.

Key	Value
model_path	The path of the model file. For more information, see the note under this table.
model_entry	Optional. The input file of the model. If no input file is specified, the file specified by the model_path parameter is used. You can specify arbitrary files in this parameter. The path of the primary file will be passed to the Load() function in the processor.
model_config	Optional. The configuration of the model. The configuration can be in any text format. The configuration is passed to the second parameter of the LoadWithConfig() function in the processor.
processor	Optional. The built-in processor used to make predictions. When this parameter is specified, the processor_path, processor_entry, processor_mainclass, and processor_type parameters are ignored.
processor_path	Optional. The path of the processor. Only custom processors support this parameter. For more information about processor packages, see the note under this table.
processor_entry	The primary file of the processor. It contains the implementations of the Load() and Process() functions. This parameter is required when you develop a custom processor using the C or C++ language.
processor_mainclass	The primary file of the processor. It defines the main class in Java. This parameter is required when you develop a custom processor using Java.
processor_type	Optional. The language used to develop the processor. Only custom processors support this parameter. Currently, only C++, Java, and Python are supported.
metadata	The metadata of the service.

Note model_path and processor_path specify the inputs of the model and processor in the format of HTTP URLs or OSS paths. When you use the test command to debug the service on your local machine, local paths are supported.

When HTTP URLs are used, the required files must be packaged in the tar.gz, tar.bz2, or ZIP format.

Metadata descriptions

Category	Parameter	Description
	workers	Optional. The number of threads used by each instance to process requests in parallel. The default is 5.

Category	Parameter	Description
Common options	instance	The number of instances launched by the service.
	CPU	The number of CPUs required by each instance.
	gpu	The number of GPUs required by each instance.
	resource	The name of the resource group. If your service uses CPU resources, ignore this parameter. Supported GPU resource groups are P4_4CORE and P4_8CORE.
Advanced parameter (use with caution)	rpc.batching	Optional. It specifies whether to enable batching at the server end for GPU optimization. The default is false.
	rpc.keepalive	Optional. The maximum amount of time that it takes to process a single request. When the time expires, the server end returns a 408 error and disconnects from the client. The default is 5000 milliseconds.
	rpc.io_threads	Optional. The number of threads used by each instance to handle network inputs and outputs. The default is 4.
	rpc.max_batch_size	Optional. The maximum size of each batch when batching is enabled. The default is 16.
	rpc.max_batch_timeout	Optional. The maximum timeout of each batch when batching is enabled. The default is 50 milliseconds.
	rpc.max_queue_size	Optional. The maximum size of the queue. The default is 64. When the queue is full, the server end returns a 450 error and closes the connection. The queue can prevent the server from being overloaded. It also can notify the client to send the request to other instances when the current instance is busy. For a queue that produces a long response time, you can set the size of the queue to a smaller value to prevent large amounts of pending requests from timing out.

Category	Parameter	Description
	rpc.worker_threads	Optional. The number of threads used by each instance to process requests in parallel. This parameter is the same as the workers parameter. The default is 5.

Example:

```
{
  ...
  "metadata": {
    "cpu": 4,
    "rpc.max_queue_size": 32,
    ...
  }
}
```

```
$ eascmd create pmml.json
[RequestId]: 1651567F-8F8D-4A2B-933D-F8D3E2DDEB2D

[OK] Waiting [Total: 1, Pending: 1, Running: 0]
[OK] Service is running
```

4.7.6. Local debugging

Before you deploy the service to the cluster, you can use the local debugging feature to start a local service for debugging. This feature requires a Docker container and Internet access. You must install Docker on the machine where eascmd runs, and then run the following command to debug the service.

```
sudo eascmd test [service_desc_json]
```

Specify the JSON file used to deploy the service in this command. The following example shows how to run this command:

```
[xingke.***@mac-3:~/code/go/src/easgo]$ bin/eascmd test tf.json
[OK] Pulling image: registry.cn-shanghai.aliyuncs.com/eas/eas-worker-amd64:0.1.4

...
[2019-02-24 00:16:30] [172.17.0.2] [INFO] Service start successfully
```

In this example, the command starts a local TensorFlow model service. The endpoint of the service is http://localhost:6942/api/predict/savedmodel_exanple.

4.7.7. Modify configurations

You can specify the `-D` parameter in the modify command to modify the metadata configurations, such as the instance, CPU, and memory configurations.

```
eascmd modify [service_name] -Dmetadata.[attr_name]=[attr_value]
```

For example, you can run the following command to set the number of instances to 10.

```
eascmd modify service_test -Dmetadata.instance=10
```

You can set multiple properties at a time. For example, you can set the number of instances to 10 and the memory size to 2,000 MB.

```
eascmd modify service_test -Dmetadata.instance=10 -Dmetadata.memory=2000
```

4.7.8. Modify a service

You can run the modify command to modify a deployed service.

```
eascmd modify [service_name] -s [service_desc_json]
```

 **Note** You cannot use this command to modify the region where the service is deployed. Note: If you only want to modify the resources used by the service, specify the metadata configurations in the service description file.

4.7.9. Delete a service

You can run the delete command to delete a service.

```
eascmd delete [service_name]
```

When you delete a service, you must specify the service name and the region where the service is deployed.

Examples:

```
$ eascmd delete savedmodel_exanple
Are you sure to delete the service [savedmodel_exanple] in [cn-shanghai]? [Y/n]
[RequestId]: 1651567F-8F8D-4A2B-933D-F8D3E2DDEB2D
[OK] Service [savedmodel_exanple] in region [cn-shanghai] is terminating
[OK] Service is terminating
[OK] Service is terminating
[OK] Service was deleted successfully
```

4.7.10. Switch service version

You can run the desc command to view the version of the current service and the latest version, and run the version command to switch the service to a version earlier than the latest version.

```
eascmd version [service_name] [version_id]
```

4.7.11. View service list

You can run the list (ls) command to view all services deployed by the current user.

```
$ eascmd ls
[RequestId]: 83945D4EED3E-4D35-A989-831E6BBA39F
+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+
|  SERVICENAME  | REGION | INSTANCE | CREATETIME | UPDATETIME | STATUS | WEIGHT | SERVICE PATH |

```

4.7.12. View service information

You can run the desc command to view detailed information about a deployed service.

```
eascmd desc [service_name]
```

Examples:

```

$ eascmd desc mnist_saved_model_example
+-----+
|   Status | Running
|   ServiceName | mnist_saved_model_example
|   Region | cn-shanghai

4.7.14. Call a prediction service

This topic describes how to call a prediction service.

To call a prediction service, you must use the HTTP URL that is generated when you create the prediction service. The HTTP URLs for on-premises testing services are generated in the same format as those for cluster-based prediction services, except that the HTTP URLs use different hosts. When you send a request to a service URL, you must add a token to the HTTP header of the request. The token is generated when you create an image. The following example shows how to call a Predictive Model Markup Language (PMML) prediction service from cURL:

```
$ curl http://{{EAS domain name in the environment}}/api/predict/pmml_example -H 'Authorization: NGE3MzM4YmRhODZjMTE2NmZjZjNINTJINDgyNmZ3YzdjMmlwOD****==' -d '{}'
```

```
["prediction_score":0.0902926730924553]
```

You can use the following methods to obtain the EAS domain name in the environment:

- Concatenate a domain name:
 - To call the API for service management, you can concatenate a domain name in the following format:

```
eas.{{global:region}}.{{global:internet-domain}}
```

- To call the API for service calls, you can concatenate a domain name in one of the following formats based on whether the prediction service is deployed across regions:
 - Secondary region: eas.pai.{{global:region}}.{{global:internet-domain}}
 - Primary region: eas.pai.{{global:internet-domain}}
- Use the EAS Meta Server to obtain the access information by performing the following steps:
 - i. Run the following command to obtain the string with Region as the key:

```
curl http://easmeta.pai.{{global:internet-domain}}/regions
```

- ii. Find the access information of the current region.

The input and output formats of a prediction service are determined by the processor of the service.

4.7.15. Use Java or C++ to develop a model service

4.7.15.1. What are processors

Processors are program packages that contain the prediction logic. User requests are processed by processors and then returned to clients. A processor contains the logic for loading models and making predictions upon user requests. Machine Learning Platform for AI supports general processors: PMML and TensorFlow. If you want to customize the prediction logic, you must follow the processor development standards to develop a processor.

You can develop a processor in C, C++, and Java languages without the need to use an SDK. You only need to define the relevant classes and functions to develop a processor. This makes it easy for you to debug the processor offline.

4.7.15.2. C/C++ processor

If you use a C or C++ processor, you must define functions `Load()` and `Process()`. Function `Load()` is used to load the model during the initialization process. Function `Process()` is used to process service calls and return the processing results to clients. The two functions are declared as follows:

```
void *initialize(const char *model_entry, const char *model_config, int *state)
```

Parameter	Type	Description
model_entry	Input parameter	Specifies a model file. This parameter corresponds to the model_entry parameter in the configuration file when you deploy a model service. You can specify a file name or directory, for example, randomforest.pmml or ./model.
model_config	Input parameter	Specifies the custom model configurations. This parameter corresponds to the model_config parameter in the configuration file when you deploy a model service.
state	Output parameter	Indicates whether the model is loaded. Value 0 indicates that the model has been loaded.
N/A	Returned value	The memory address of the user-defined model variable. The value can be any data type.

```
int process(void *model_buf, const void *input_data, int input_size, void **output_data, int *output_size)
```

Parameter	Type	Description
model_buf	Input parameter	Specifies the memory address of the model returned by function initialize().
input_data	Input parameter	Specifies the input data. String data and binary data are supported.
input_size	Output parameter	Specifies the size of the input data.
output_data	Output parameter	The data returned by the processor. You must allocate heap memory to the processor. The model will automatically release the memory.

Parameter	Type	Description
output_size	Output parameter	The size of the data returned by the processor.
N/A	Returned value	If value 0 or 200 is returned, the model service is successfully called. This parameter can return HTTP error codes to clients. If the processor cannot recognize the HTTP error code, it automatically converts it to HTTP error code 400.

Examples

In the following example, no model data is loaded. The prediction service directly returns the request to the client.

```
#include <stdio.h>
#include <string.h>
extern "C" {
    void *initialize(const char *model_entry, const char *model_config, int *state)
    {
        *state = 0;
        return NULL;
    }
    int process(void *model_buf, const void *input_data, int input_size,
               void **output_data, int *output_size)
    {
        if (inputSize == 0) {
            const char *errmsg = "input data should not be empty";
            *outputData = strdup(errmsg, strlen(errmsg));
            *outputSize = strlen(errmsg);
            return 400;
        }
        *outputData = strdup((char *)inputData, inputSize);
        *outputSize = inputSize;
        return 200;
    }
}
```

The processor does not load any model data. It directly returns the input data to the client. You can use Makefile to compile the processor into a .so file.

```
CC=g++
CCFLAGS=-I./ -D_GNU_SOURCE -Wall -g -fPIC
LDFLAGS=-shared -Wl,-rpath=. /
OBJS=processor.o
TARGET=libpredictor.so
all: $(TARGET)
$(TARGET): $(OBJS)
$(CC) -o $(TARGET) $(OBJS) $(LDFLAGS) -L./
%.o: %.cc
$(CC) $(CCFLAGS) -c $< -o $@
clean:
rm -f $(TARGET) $(OBJS)
```

If the processor is reliant on other .so files, package these files with the processor.so file, and then deploy the package.

4.7.15.3. Java processor

The Java processor also uses functions Load() and Process() besides constructors. You only need to define one class for the Java processor. The class is defined as follows:

```
package com.alibaba.eas;
import java.util.*;
public class TestProcessor {
    public TestProcessor(String modelEntry, String modelConfig) {
        /* Passes a model file name to the class and initializes the model. */
    }
    public void Load() {
        /* Loads the model information based on the specified model file name */
    }
    public String Process(String input) {
        /* Preprocesses the input data and outputs the processing results. Currently, only string type data can be input and output */
    }
    public static void main(String[] args) {
        /* The main function is optional. It can be used for debugging on your local host. */
    }
}
```

If an exception occurs, the system automatically captures the exception, and returns an error message to the client. An HTTP 400 status code is also returned to the client. You can also customize the logic for capturing exceptions and return an error message to your client as follows:

```
try{
} catch (com.alibaba.fastjson.JSONException e) {
    throw new RuntimeException("bad json format, " + e.getMessage());
}
```

4.8. AutoML (must be activated separately)

4.8.1. Automatic parameter tuning with AutoML

This topic describes the automatic parameter tuning feature of AutoML.

Parameter

1. [Log in to machine learning console](#). In the left-side navigation pane, click **Experiments**.
2. Click an experiment to go to the canvas of the experiment.

 **Note** This topic uses air quality prediction as an example.

3. In the upper-left corner of the canvas, choose **Auto ML > Auto Parameter Tuning**.
4. On the **Auto Parameter Tuning** page, select an algorithm for parameter tuning, and click **Next**.

 **Note** You can select only one algorithm to tune at a time.

5. In the **Configure Parameter Tuning** module, set the **Parameter Tuning Method** parameter and click **Next**.

Alibaba Cloud Machine Learning Platform for AI provides four **parameter tuning methods**. For more information, see [Parameter adjustment method](#).

6. In the **Configure Model Output** module, set the model output parameters and click **Next**.

Parameter	Description
Evaluation Criteria	You can select one evaluation standard from the following four dimensions: AUC , F1-score , PRECISION , and RECALL .
Saved Models	You can save up to five models. The system ranks models based on the Evaluation Criteria setting you select and save the top ranked models according to the number entered in the Saved Models field.
Pass Down Model	This switch is turned on by default. If the switch is turned off, the model generated by the default parameters of the current component are passed down to the node of the subsequent component. If the switch is turned on, the optimal model generated by automatic parameter tuning are passed down to the node of the subsequent component.

7. In the upper-left corner of the canvas, click **Run** to run the automatic parameter tuning algorithm, as shown in the following figure.

 **Note** After the preceding configuration is complete, the Auto ML switch of the related algorithm is turned on. You can turn the switch on or off as needed.

8. Right-click a model component and choose **Edit AutoML Parameters** from the shortcut menu to modify its AutoML configuration parameters.

Output model display

1. During parameter tuning, right-click the target model component and choose **Parameter Tuning Details** from the shortcut menu.
2. On the **AutoML-Parameter Tuning Details** page, click the **Metrics** tab to view the current tuning progress and the running status of each model.
3. You can sort candidate models according to indicators (**AUC**, **F1-score**, **Accuracy**, and **Recall Rate**).
4. In the **View Details** column, you can click **Log** or **Parameter** to view the logs and parameters of each candidate model.

Parameter tuning effect display

1. On the **AutoML-Parameter Tuning Details** page, you can click the **Charts** tab to view the **Model Evaluation and Comparison** and **Hyperparameter Iteration Result Comparison** charts.
2. You can view the growth trend of the evaluation indicators of updated parameters in the **Hyperparameter Iteration Result Comparison** chart.

Model storage

1. [Log in to machine learning console](#). In the left-side navigation pane, click **Models**.

2. Click **Experiment Model** to open the experiment model folder.
3. Click the corresponding experiment folder to view the model saved with Auto ML.
4. (Optional) You can apply a model to other experiments by dragging the model to the canvas of the target experiment.

4.8.2. Parameter tuning methods

AutoML supports four parameter tuning methods.

Evolutionary Optimizer

Principle:

1. Randomly selects A parameter candidate sets (where A indicates the **number of exploration samples**).
2. Takes the N parameter candidate sets with higher evaluation indicators as the parameter candidate sets of the next iteration.
3. Continues the exploration within R times (where R indicates the **convergence coefficient**) as the standard deviation range around these parameters to explore new parameter sets. The new parameter sets replace the last A-N parameter sets by the evaluation indicator in the previous round.
4. Iterates the exploration for M rounds (where M indicates the **number of explorations**) until the optimal parameter set is found, according to the preceding logic.

Based on the preceding principle, the final number of models is $A + (A - N) \times M$.

 **Note** The first value of N is $A/2 - 1$. During iteration, the default value is $A/2 - 1$ (rounded up).

Parameter	Description
Data Splitting Ratio	Splits input data sources into training and evaluation sets. 0.7 indicates that 70% of the data is used for model training and 30% for evaluation.
Exploration Samples	The number of parameter sets of each iteration. The higher the number, the greater the accuracy, the larger the calculation. This parameter must be set to a positive integer in the range of 5 to 30.
Explorations	The number of iterations. The higher the number of iterations, the greater the search accuracy, the larger the calculation. This parameter must be set to a positive integer in the range of 1 to 10.
Convergence Coefficient	Tunes the exploration ranges (R times the standard deviation range search). The smaller the range, the faster the convergence (however, optimal parameters may be missed). Valid values: 0.1 to 1 (one floating point after the decimal point).

 **Note** You must enter the tuning range for each parameter. If the current parameter range is not configured, the parameter range is set by default.

Random Search

Principle:

1. Randomly selects a value for each parameter within the parameter range.
2. Enters random values into a set of parameters for model training.
3. Performs M rounds (where M indicates the **number of iterations**) and then sorts the output models.

Parameter	Description
Data Splitting Ratio	Splits input data sources into training and evaluation sets. 0.7 indicates that 70% of the data is used for model training and 30% for evaluation.
Iterations	The number of searches in the configured range. Valid values: 2 to 50.

 **Note** You must enter the tuning range for each parameter. If the current parameter range is not configured, the parameter range is set by default.

Grid Search

Principle:

1. Splits the value range of each parameter into N segments (where N indicates the **number of split grids**).
2. Randomly takes a value from the N segments. Assuming that there are M parameters, N^M parameter sets can be combined.
3. According to the N^M parameter sets, N^M models are generated by training. The models are then sorted.

Parameter	Description
Data Splitting Ratio	Splits input data sources into training and evaluation sets. 0.7 indicates that 70% of the data is used for model training and 30% for evaluation.
Grids	The number of split grids. Valid values: 2 to 10.

 **Note** You must enter the tuning range for each parameter. If the current parameter range is not configured, the parameter range is set by default.

Custom Parameters

- You can enumerate parameter candidate sets. The system then helps score all the combinations of the candidate sets.
- You can define enumeration ranges and separate parameters with commas (,). If the ranges are not configured, the default ranges of parameters are tuned.

4.9. Terms and acronyms

4.9.1. Terms

This topic lists the basic terms used in machine learning.

experiment

A user-created data mining workflow.

project

The basic object in MaxCompute. A project is also known as a workspace. A project contains other objects, such as tables and instances.

component

The minimum operating unit that you can invoke and execute on Apsara Stack Machine Learning Platform for AI. You can use components to import and export data, process data, analyze data, train models, and make predictions.

4.9.2. Acronyms

This topic describes the acronyms used in the Machine Learning Platform for AI User Guide.

MaxCompute

MaxCompute (formerly known as ODPS) is a data processing platform developed by Alibaba Cloud for large-scale data warehousing. MaxCompute can store and compute structured data in batches to meet the requirements of most big data modeling and analysis scenarios.

MaxCompute source and target tables

Tables are data storage objects in MaxCompute. Similar to relational database tables, tables in MaxCompute have a two-dimensional logical structure. A source table is the input of an algorithm node, while a target table is the output of an algorithm node.

5.E-MapReduce (EMR)

5.1. What is E-MapReduce?

E-MapReduce (EMR) is an end-to-end big data processing and analytics service. It uses open source big data ecosystems, such as Hadoop, Spark, Kafka, and Hive, to manage clusters, jobs, and data.

EMR is built in a virtual environment, such as ECS or Docker, and developed based on open source components, such as Hadoop, Spark, Hive, and Presto. EMR allows you to use peripheral systems, such as Hive, HBase, and Presto, in the Hadoop and Spark ecosystems to analyze and process data. EMR can also read data from or write data to other storage systems and database systems, such as MySQL and Oracle.

5.2. Introduction

5.2.1. Instructions

Before you use the E-MapReduce service, familiarize yourself with information such as the software configuration of the EMR cluster and the procedure for deploying the service.

5.2.2. Introduction

5.2.2.1. Software configuration

You need to install an operating system and big data components on each ECS instance in an E-MapReduce cluster.

5.2.2.2. Software requirements

This topic describes the software requirements of EMR.

The following table describes the software requirements.

Software requirements

Software	Description
Operating system	CentOS 7 64-bit kernel-3.10.0-693.2.2.el7.x86_64

5.2.2.3. Supported components

This topic lists the components of EMR.

The following table lists the components of EMR and the supported versions.

Components

Component	Version
Hadoop	2.8.5
Hive	3.1.1
Tez	0.9.1

Component	Version
Spark	2.4.3
Oozie	5.1.0
Hue	4.4.0
Zeppelin	0.8.1
Sqoop	1.4.7
ZooKeeper	3.5.5
Kafka	1.1.1
HBase	1.4.9
Phoenix	4.14.1
Presto	0.22.1
Flink	1.7.2
Ranger	1.2.0
Flume	1.8.0

Components

Component	Version
Hadoop	2.8.5
HDFS	2.8.5-1.4.0
Hive	3.1.1-1.1.6
Spark	2.4.3-1.2.0
Knox	1.1.0-1.0.2
Zeppelin	0.8.1-1.0.1
Tez	0.9.1-1.1.0
Ganglia	3.7.2
Pig	0.14.0
Sqoop	1.4.7-1.0.0
OpenLDAP	2.4.44
Hue	4.4.0
Yarn	2.8.5-1.4.0

Component	Version
Oozie	5.1.0
HBase	1.4.9-1.0.0
ZooKeeper	3.5.5
Presto	0.221
Impala	2.12.2-1.0.0
Superset	0.28.1
Ranger	1.2.0-1.1.0
Flink	1.10-vvr-1.0.4-SNAPSHOT
Storm	1.2.2
Phoenix	4.14.1
TensorFlow	1.8.0
Oozie	5.1.0
Kafka	2.11-1.1.1-1.3.0
Kafka-Manager	1.3.3.16-1.1.0
Druid	0.14.2-1.0.0

5.2.2.4. Introduction to components

This topic introduces the big data components that can run on an EMR cluster.

Component	Description
Hadoop	<ul style="list-style-type: none"> • YARN: supports task scheduling and cluster resource management. • HDFS: a distributed file system.
Hive	A Hadoop-based offline data processing system that provides an SQL-like interface to query data. Hive uses tables to store and manage data.
Spark	An in-memory distributed computing framework that supports offline and real-time computing, SQL statements, and machine learning.
Oozie	A job scheduler that supports workflow orchestration by building a directed acyclic graph (DAG). It supports multiple types of jobs.

Component	Description
Hue	A visualized platform used to manage open source components, such as Hadoop, Hive, Oozie, and HBase.
Sqoop	A tool designed to transfer data between HDFS and relational databases.
ZooKeeper	An open source distributed application coordination service. It is an open source implementation of Chubby provided by Google and is an important component of Hadoop and HBase. ZooKeeper solves the consistency problem of distributed applications. Its services include configuration maintenance, domain name services, distributed synchronization, and group services.
Kafka	A distributed messaging system that features high throughput, scalability, reliability, and performance. It is used in real-time computing, log processing, and data aggregation.
HBase	An open source, distributed, and column-oriented database. It is a component of the Apache Hadoop project. Different from typical relational databases, HBase is designed to store unstructured data. HBase is column-oriented rather than row-oriented.
Phoenix	Provides SQL-like statements for you to analyze HBase data.
Presto	A distributed SQL query engine that retrieves large datasets from one or more data sources.

Component	Description
Hadoop	<ul style="list-style-type: none"> • YARN: supports task scheduling and cluster resource management. • HDFS: a distributed file system.
Hive	A Hadoop-based offline data processing system that provides an SQL-like interface to query data. Hive uses tables to store and manage data.
Spark	An in-memory distributed computing framework that supports offline and real-time computing, SQL statements, and machine learning.
Knox	Provides service-level access control. You can manage the permissions to access a specific service by user, user group, or IP address.
Zepplin	Supports big data analytics and visualization.
Tez	Processes data based on DAGs of complex tasks.

Component	Description
Oozie	A job scheduler that supports workflow orchestration by building a DAG. It supports multiple types of jobs.
Hue	A visualized platform used to manage open source components, such as Hadoop, Hive, Oozie, and HBase.
Sqoop	A tool designed to transfer data between HDFS and relational databases.
ZooKeeper	An open source distributed application coordination service. It is an open source implementation of Chubby provided by Google and is an important component of Hadoop and HBase. ZooKeeper solves the consistency problem of distributed applications. Its services include configuration maintenance, domain name services, distributed synchronization, and group services.
Kafka	A distributed messaging system that features high throughput, scalability, reliability, and performance. It is used in real-time computing, log processing, and data aggregation.
HBase	An open source, distributed, and column-oriented database. It is a component of the Apache Hadoop project. Different from typical relational databases, HBase is designed to store unstructured data. HBase is column-oriented rather than row-oriented.
Impala	Enables fast and real-time interactive SQL queries on petabytes of data.
Flink (VVR)	VVR provides an enterprise-edition state backend whose performance is three to five times that of open source Flink. You can use the VVR engine and the EMR data development feature to submit jobs in an EMR Hadoop cluster.
Storm	A distributed framework for real-time big data processing.
Phoenix	Provides SQL-like statements for you to analyze HBase data.
TensorFlow	When you use TensorFlow to perform high-performance computing, you can allocate CPU and GPU resources by using YARN.
Presto	A distributed SQL query engine that retrieves large datasets from one or more data sources.

5.3. Log on to the EMR console

This topic describes how to log on to the EMR console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Context

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

Obtain the username and password that you can use to log on to the console from the operations administrator.

 **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:

- Uppercase or lowercase letters
- Digits
- Special characters, which include ! @ # \$ %

3. Click **Login**.
4. In the top navigation bar, choose **Products > Big Data > E-MapReduce**.
5. Set **Organization** and **Region** and click **EMR** to go to the EMR console.

5.4. Cluster management

5.4.1. Cluster planning

5.4.1.1. Gateway clusters

When you create a gateway cluster, you must associate it with an existing EMR cluster. Gateway clusters can serve as a separate job submission node to facilitate operations on the associated cluster.

A gateway cluster is an independent cluster that consists of multiple nodes with the same configurations. Clients, such as Hadoop (HDFS and YARN), Hive, Spark, and Sqoop clients, are deployed on the cluster.

If no gateway cluster is created, jobs of a Hadoop cluster are submitted on the master node or a core node of the Hadoop cluster, which consumes the resources of this cluster. After a gateway cluster is created, you can use it to submit jobs of the cluster associated with this gateway cluster. This way, the jobs do not occupy the resources of the associated cluster, and the stability of the master and core nodes, especially the master node, in the associated cluster is improved.

Each gateway cluster can have an independent configuration environment. For example, you can create multiple gateway clusters for one cluster that is shared by multiple departments to meet their different business requirements.

5.4.2. Cluster configuration

5.4.2.1. Create a cluster

This topic describes how to create an EMR cluster.

Procedure

1. [Log on to the EMR console](#).
2. On the **Cluster Management** page, click **Cluster Wizard** in the upper-right corner.
3. Configure cluster information. To create a cluster, you must configure software, hardware, and basic parameters as guided by the wizard.

 **Notice** After a cluster is created, you cannot modify its parameters except for the cluster name. Make sure that all parameters are correctly configured when you create a cluster.

i. Configure software parameters.

Parameter	Description
EMR Version	<p>The major version of EMR. It is a complete open source software environment. It can be regularly updated based on updates made to the internal component software.</p> <p>The major version of EMR is also updated with Hadoop-related software. Clusters of an earlier version cannot be automatically updated to a later version.</p>
Cluster Type	<p>The type of the cluster you want to create. EMR supports the following types of clusters:</p> <ul style="list-style-type: none"> ▪ Hadoop: Hadoop clusters provide multiple ecosystem components, such as Hadoop, Hive, Spark, Spark Streaming, Flink, Storm, Presto, Impala, Oozie, and Pig. Hadoop, Hive, and Spark are semi-hosted services and are used to store and compute large-scale distributed data offline. Spark Streaming, Flink, and Storm provide stream computing. Presto and Impala are used for interactive queries. ▪ Kafka: Kafka clusters serve as a semi-hosted, distributed messaging system with high throughput and scalability. Kafka clusters provide a comprehensive service monitoring system that maintains cluster stability. Kafka clusters are professional, reliable, and secure. You do not need to deploy or maintain these clusters. These clusters are used in scenarios such as log collection and monitoring data aggregation. They can also be used for offline data processing, stream computing, and real-time data analysis.
Required Services	<p>The default components required for a specific cluster type. After a cluster is created, you can add, start, or stop services on the Clusters and Services page of the cluster.</p>
Optional Services	<p>The other components that you can specify as required. By default, the relevant service processes for the components you specify are started.</p> <div style="background-color: #e1f5fe; padding: 10px; border: 1px solid #cfe2f3;"> <p> Note The more components you specify, the higher instance specifications a cluster needs to handle the components. You must select the instance type that matches the number of components you specified when you configure the hardware. Otherwise, the cluster may have insufficient resources to run the components.</p> </div>
Advanced Settings	<ul style="list-style-type: none"> ▪ Kerberos Mode: specifies whether to enable Kerberos authentication for clusters. This mode is disabled by default because it is not required by clusters created for common users. ▪ Custom Software Settings: customizes software settings. You can use a JSON file to customize the parameters of basic components required for a cluster, such as Hadoop, Spark, and Hive.

ii. Configure hardware parameters.

Section	Parameter	Description
---------	-----------	-------------

Section	Parameter	Description
Network Settings	Zone	<p>The zone where a cluster is created. Zones are different geographical areas located in the same region. They are interconnected by an internal network. The instance types and disks that are available for you to create a cluster depend on the selected zone.</p> <p>Networks of zones are isolated from each other. If your business requires a low-latency network, we recommend that you deploy instances in the same zone. However, if the zone has insufficient instances, a cluster may fail to be created.</p>
	Network Type	The network type of the cluster. The VPC network type is selected by default.
	VPC	The VPC where you want to deploy the cluster. Select a VPC in the same region as the zone.
	VSwitch	The vSwitch of the cluster. Select a vSwitch in the specified zone. If no vSwitch is available in the zone, create one.
	Security Group Name	<p>The security group to which you want to add your cluster. Only the security groups that you create in EMR are available in the drop-down list.</p> <p>To create a security group, you can directly enter a name in the Security Group Name field. The name must be 2 to 64 characters in length and can contain only letters, digits, underscores (_), and hyphens (-). It must start with a letter.</p>
High Availability	High Availability	<p>Specifies whether to enable the high availability mode. By default, this mode is disabled. In this case, the cluster has only one master node.</p> <p>For a Hadoop cluster, if the high availability mode is enabled, two master nodes are created in the cluster to ensure the availability of the ResourceManager and NameNode processes.</p>

Section	Parameter	Description
Instance	Configuration	<ul style="list-style-type: none"> ■ Node type: <ul style="list-style-type: none"> ■ Master Instance: runs control processes, such as ResourceManager and NameNode. ■ Core Instance: stores all the data of a cluster. You can add core nodes as needed after a cluster is created. ■ Instance type: <p>Select an instance type for each node type as needed.</p> ■ Data disk type: <p>Data disk types include standard SSD and ultra disk. Data disk types that are available for you to create the cluster vary based on the selected zone and instance type. By default, data disks are released after the cluster is released. For a compute node with local disks, the data disk type is selected by default and cannot be changed.</p> ■ Data disk size: <p>Valid values: 40 to 32768. Unit: GB. If you use a local disk, the size of the local disk is set by the system and cannot be modified.</p> ■ Node quantity: <p>You can set the number of nodes of each type as needed. A cluster with the high availability mode disabled must contain three nodes at least. If the high availability mode is enabled, another master node must be added to the cluster.</p>

iii. Configure basic parameters.

Section	Parameter	Description
Basic Information	Cluster Name	The name of the cluster. The name must be 1 to 64 characters in length and can contain only letters, digits, hyphens (-), and underscores (_).
	Assign Public Network IP	By default, this feature is disabled.
	Password	<p>The password used to log on to the master node. The password must be 8 to 30 characters in length and contain letters, digits, and special characters.</p> <p>The following special characters are supported:</p> <p>! @ # \$ % ^ & *</p>
Advanced Settings	Bootstrap Actions	Optional. You can configure bootstrap actions to run custom scripts before a cluster starts Hadoop.

5.4.2.2. Create a gateway cluster

A gateway cluster is composed of Elastic Compute Service (ECS) instances that reside in the same internal network as the EMR cluster associated with the gateway cluster. You can use a gateway cluster to achieve load balancing and security isolation and to submit jobs to the EMR cluster.

Prerequisites

A cluster is created. For more information, see [Create a cluster](#).

Procedure

1. [Log on to the EMR console](#).
2. In the upper-right corner of the **Cluster Management** page, click **Create Gateway**.
3. On the **Create Gateway** page, configure parameters.

Parameter	Description
Cluster Name	The name of the gateway cluster. The name must be 1 to 64 characters in length and can contain only letters, digits, hyphens (-), and underscores (_).
Assign Public IP Address	Specifies whether the gateway cluster is assigned an elastic IP address.
Password	The password used to log on to the gateway cluster. The password must be 8 to 30 characters in length and must contain uppercase letters, lowercase letters, digits, and special characters. The following special characters are supported: ! @ # \$ % ^ & *
Billing Method	The billing method of the gateway cluster. The default value is Pay-As-You-Go . The system charges you for a cluster based on the time the cluster is actually used in hours.
Associated Cluster	The EMR cluster associated with the gateway cluster. The gateway cluster submits jobs to this EMR cluster. The gateway cluster is automatically configured with the same Hadoop environment as the EMR cluster.
Zone	The zone where the associated cluster resides.
Network Type	The network type of the associated cluster.
VPC	The VPC to which the associated cluster belongs.
VSwitch	The vSwitch you want the gateway cluster to use. Select the vSwitch that corresponds to the zone and VPC.
Security Group Name	The name of the security group to which the associated cluster belongs.

4. After you configure the parameters, click **Create**. The created gateway cluster appears in the cluster list. Its state changes from **Initializing** to **Idle** a few minutes later.

5.4.2.3. Cluster list and details

This topic describes the parameters in the cluster list, parameters on the cluster details page, and supported cluster operations.

Prerequisites

A cluster is created. For more information, see [Create a cluster](#).

Cluster list

The cluster list displays the basic information about all of your clusters and the operations supported by each cluster.

Parameter	Description
Cluster ID/Name	The ID and name of a cluster. Move your pointer over a cluster name and click the  icon to modify the cluster name.
Cluster Type	The type of the cluster. Hadoop and Kafka are supported.
Status	The status of the cluster. If a cluster experiences an exception, such as a creation failure, error information appears in this column. You can move the pointer over the Help icon next to the error information to view detailed error information.
Created At	The time the cluster was created.
Time Elapsed	The duration from the point of creation to the current time. After the cluster is released, the time is no longer measured.
Actions	The operations that can be performed on the cluster. The supported operations include: <ul style="list-style-type: none"> • Manage: Go to the Clusters and Services page. • Details: View detailed information about the cluster on the Cluster Overview page.

Cluster details

The Cluster Overview page displays detailed information about the cluster and consists of four sections: Cluster Info, Software Info, Network Info, and Instance Info.

- Cluster Info

Cluster Info			
Cluster Name: emrtest	I/O Optimization: Yes	Start Time: Nov 11 11:11:11	Bootstrap Actions/EMR Version: EMR-3.22.1
Cluster ID: C-5	High Availability: No	Time Elapsed: 29 Days 23 Hours 11 Minutes 18 Seconds	ECS Role: AliyunEmrEcsDefaultRole
Region: cn-q	Security Mode: Standard		
Status:  idle			

Parameter	Description
Cluster Name	The name of the cluster.
Cluster ID	The ID of the cluster.

Parameter	Description
Region	The region where the cluster resides.
Status	The current status of the cluster.
I/O Optimization	Specifies whether I/O optimization is enabled.
High Availability	Specifies whether high availability is enabled.
Security Mode	The security mode. The software of the cluster starts in Kerberos security mode.
Start Time	The time the cluster was created.
Time Elapsed	The duration from the point of creation to the current time.
Bootstrap Actions/EMR Version	Information about custom scripts and software configuration.
ECS Role	The ECS application role. You can assign an application role to a cluster. This way, EMR applies for a temporary AccessKey pair when applications running on the compute nodes of that cluster access other Alibaba Cloud services, such as OSS. You do not need to manually enter an AccessKey pair. You can grant the application role access permissions on specific Alibaba Cloud services as required.

- Software Info

Software Info

EMR Version: EMR-3.22.1

Cluster Type: Hadoop

Software Info: [HDFS 2.8.5-1.4.0](#) [Yarn 2.8.5-1.4.0](#) [Hive 3.1.1-1.1.6](#) [Ganglia 3.7.2](#) [Spark 2.4.3-1.3.0](#) [Hue 4.4.0](#) [Tez 0.9.1-1.1.0](#) [Sqoop 1.4.7-1.0.0](#) [Pig 0.14.0](#) [Knox 1.1.0-1.0.2](#)

Parameter	Description
EMR Version	The major version of EMR.
Cluster Type	The type of the cluster.
Software Info	All the applications installed in the cluster and their versions.

- Network Info

Network Info

Region ID: cn-qing

Network Type: vpc

Parameter	Description
-----------	-------------

Parameter	Description
Region ID	The ID of the zone where the cluster resides, such as cn-hangzhou-b. The value is also the zone where the ECS instance resides.
Network Type	The network type of the cluster.

• Instance Info

ECS ID	Deployment Status	Public Network IP	Internal Network IP	Created At
i-9fx017	Normal		192.	Nov 10, 2020, 16:26:36

The following table describes the parameters of Master Instance Group.

Parameter	Description
Instances	The current number of nodes and the number of nodes that you have requested.
CPU	The number of vCPUs for a single node.
Memory	The memory capacity of a single node.
Data Disk Type	The data disk type and data disk capacity of a single instance.
ECS instances	The information about ECS instances in a master node group, including: <ul style="list-style-type: none"> ECS ID: the ID of a purchased ECS instance. Deployment Status: the deployment status of the ECS instance. Valid values: Initializing, Normal, and Scaling Out. Public Network IP: the public IP address of the ECS instance. Internal Network IP: the internal IP address of the ECS instance, which can be accessed by all nodes in the cluster. Created At: the creation time of the ECS instance.

5.4.2.4. View the running status of services

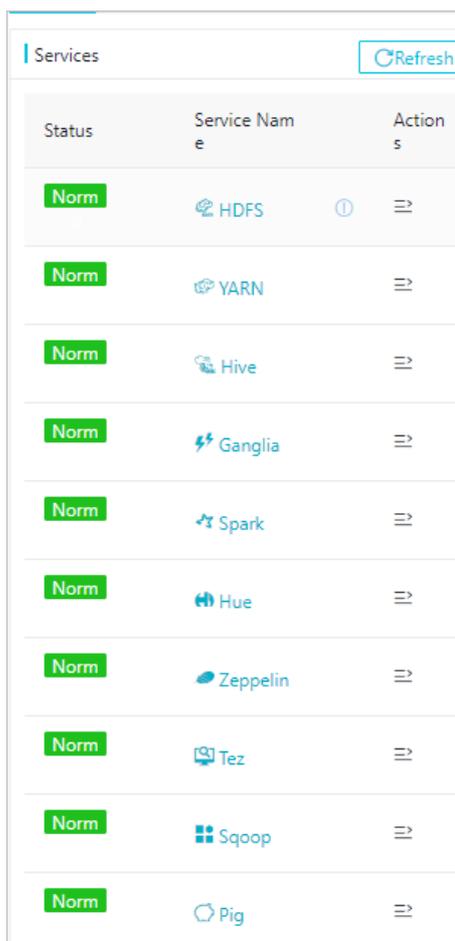

This topic describes how to view the running status of the services deployed in a cluster, such as HDFS and YARN, on the Clusters and Services page.

Prerequisites

A cluster is created. For more information, see [Create a cluster](#).

Procedure

1. [Log on to the EMR console](#).
2. On the **Cluster Management** page, find your cluster and click its **cluster ID**.
3. On the **Clusters and Services** page, you can view the service list.

Status	Service Name	Actions
Norm	HDFS	ⓘ ≡
Norm	YARN	≡
Norm	Hive	≡
Norm	Ganglia	≡
Norm	Spark	≡
Norm	Hue	≡
Norm	Zeppelin	≡
Norm	Tez	≡
Norm	Sqoop	≡
Norm	Pig	≡

If a service, such as Storm, is not selected when you create the cluster, it is not displayed in the Services section.

You can click the name of a service to view its details, including the running status, deployment topology, configurations, and historical configuration modifications. A service may be in the **Normal** or **Error** state.

5.4.2.5. Configure component parameters

EMR allows you to modify and add parameters for components such as HDFS, YARN, Spark, Kafka, and Druid.

Prerequisites

A cluster is created. For more information, see [Create a cluster](#).

Modify parameters

1. [Log on to the EMR console](#).
2. On the **Cluster Management** page, find your cluster and click its **cluster ID**.
3. In the **Services** section, click the component for which you want to modify parameters. HDFS is used as an example.
4. On the HDFS page, click the **Configure** tab.
5. Modify parameters.
 - i. In the **Configuration Filter** section, enter the keyword of the parameter you want to modify in the search box and click the  icon.

- ii. Find the parameter you want to modify and change its value.
6. Click **Save** in the upper-right corner. Perform the operations described in [Make configurations take effect](#) to make your modification take effect.

Add parameters

1. [Log on to the E-MapReduce console](#).
2. On the **Cluster Management** page, find your cluster and click its **cluster ID**.
3. In the **Services** section, click the component for which you want to add parameters. **HDFS** is used as an example.
4. On the HDFS page, click the **Configure** tab.
5. Add parameters.
 - i. In the **Service Configuration** section, click the tab to which you want to add parameters.
 - ii. Click **Custom Configuration** in the upper-right corner.

Parameter	Description
Key	The name of the parameter that you want to add.
Value	The value of the parameter.
Description	The description of the parameter.
Actions	You can click Delete in this column to remove the parameter.
Add	You can click Add to add more parameters.

- iii. After the configuration is complete, click **OK**.
6. Click **Save** in the upper-right corner. Perform the operations described in [Make configurations take effect](#) to make the added parameters take effect.

Make configurations take effect

- Client-side configurations
 - i. After you modify or add client-side configurations, click **Deploy Client Configuration** in the upper-right corner of the **Configure** tab.
 - ii. In the **Cluster Activities** dialog box, specify **Target Nodes**, **Actions on Failures**, and **Description**.
 - iii. Click **OK**.
You can click **History** in the upper-right corner to view the execution status and progress.
- Server-side configurations
 - i. After you modify or add server-side configurations, click **Actions** in the upper-right corner of the **HDFS** page and select an option to restart the related service.
 - ii. Click **Deploy Client Configuration** in the upper-right corner.
 - iii. In the **Cluster Activities** dialog box, specify **Target Nodes**, **Actions on Failures**, and **Description**.
 - iv. Click **OK**.
You can click **History** in the upper-right corner to view the execution status and progress.

5.4.3. Restart a service or component

After you modify the configuration items of a service, you must restart the service or its components to make the configurations take effect. This topic describes how to restart a service or component in the EMR console.

Prerequisites

A cluster is created. For more information, see [Create a cluster](#).

Restart a service

1. [Log on to the EMR console](#).
2. On the **Cluster Management** page, find your cluster and click its **cluster ID**.
3. In the left-side navigation pane of the Cluster Overview page, choose **Cluster Service > HDFS**. The HDFS service is used as an example in this topic.
4. In the upper-right corner of the HDFS page, choose **Actions > Restart All Components**.
5. In the **Cluster Activities** dialog box, specify **Description** and click **OK**.

Restart a component

1. [Log on to the EMR console](#).
2. On the **Cluster Management** page, find your cluster and click its **cluster ID**.
3. In the left-side navigation pane of the Cluster Overview page, choose **Cluster Service > HDFS**. **DataNode** of the HDFS service is used as an example in this topic.
4. In the upper-right corner of the HDFS page, choose **Actions > Restart DataNode**.
5. In the **Cluster Activities** dialog box, specify **Description** and click **OK**.

5.4.4. View information about instances

This topic describes how to view the information about the instances of a cluster, including configurations of disks, vCPUs, and memory.

Prerequisites

A cluster is created. For more information, see [Create a cluster](#).

Procedure

1. [Log on to the EMR console](#).
2. On the **Cluster Management** page, find your cluster and click its **cluster ID**.
3. In the left-side navigation pane, click **Instances**. On the **Instances** page, you can view the information about the instances of the cluster, including configurations of disks, vCPUs, and memory.

6.DataHub

6.1. What is DataHub?

DataHub collects, stores, and processes streaming data, allowing you to analyze streaming data and build applications based on the streaming data.

DataHub is a platform designed to process streaming data. You can publish and subscribe to streaming data in DataHub and distribute the data to other platforms. DataHub allows you to analyze streaming data and build applications based on the streaming data.

DataHub collects, stores, and processes streaming data from mobile devices, applications, website services, and sensors. You can use your own applications or Apsara Stack Realtime Compute to process streaming data in DataHub, such as real-time website access logs, application logs, and events. The processing results such as alerts and statistics presented in graphs and tables are updated in real time.

Based on the Apsara system of Alibaba Cloud, DataHub features high availability, low latency, high scalability, and high throughput. DataHub is seamlessly integrated with Realtime Compute, allowing you to use SQL to analyze streaming data.

DataHub can also distribute streaming data to Apsara Stack services such as MaxCompute and Object Storage Service (OSS).

DataHub supports the following features:

- **Data queue:** DataHub automatically generates a cursor for each record in a shard, which can be considered as a logical data queue. The cursor is a unique sequence of numbers. You can improve the performance of a topic by increasing the number of shards in the topic.
- **Offset-based data consumption:** DataHub saves consumption offsets for applications. You can resume data consumption from a saved consumption offset when your application fails.
- **Data synchronization:** Data in DataHub can be automatically synchronized to other Apsara Stack services, including MaxCompute, OSS, AnalyticDB, ApsaraDB RDS for MySQL, Tablestore, and Elasticsearch.
- **Scalable topics:** DataHub allows you to scale in or out topics by splitting or merging shards.

6.2. Usage notes

Before you use DataHub, get familiar with the limits on specific features.

The following table describes the limits of DataHub.

Limits

Item	Limit	Description
Active shards per topic	(0,256]	Each topic can contain up to 256 active shards.
Shards	(0,512]	You can create up to 512 shards in each topic.
HTTP request body size	Up to 4 MB	The size of the HTTP request body cannot exceed 4 MB.
String size	Up to 1 MB	The size of a string cannot exceed 1 MB.

Item	Limit	Description
Merge and split operations on new shards	5s	You cannot merge a shard with another shard or split the shard within the 5s after the shard is created.
Queries per second (QPS)	Up to 5,000	The write QPS limit for each shard is 5,000. Multiple queries in one batch are considered as one query.
Throughput	Up to 5 MB/s	Each shard provides a throughput of up to 5 MB/s.
Projects	Up to 100	You can create up to 100 projects with each account.
Topics per project	Up to 1,000	You can create up to 1,000 topics in each project. Contact the administrator if you need to create more topics.
Time-to-live (TTL) of records	[1,7]	The TTL of each record in a topic ranges from one to seven days.

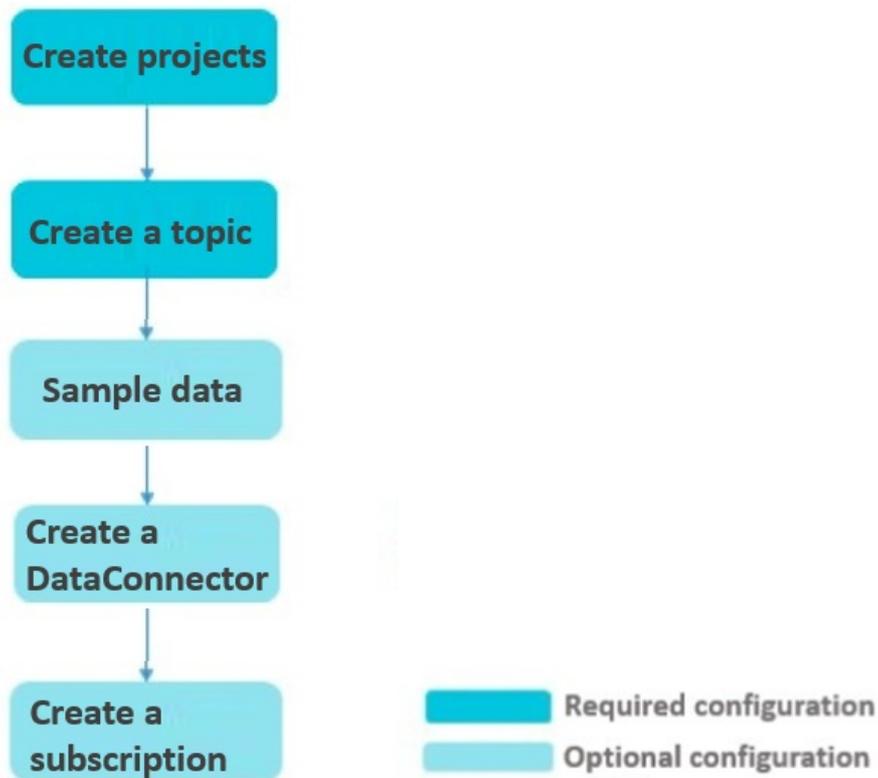

6.3. Quick Start

6.3.1. Overview

This topic describes the procedure of using DataHub.

Procedure shows the procedure of using DataHub.

Procedure

1. **Create projects.**

A project is an organizational unit in DataHub and contains one or more topics. When you use DataHub, you must create a project first.

2. **Create a topic.**

A topic is the smallest unit for data subscription and publication. You can use topics to distinguish different types of streaming data.

3. Optional. **Sample data.**

DataHub supports data sampling. You can sample data of a specific shard.

4. Optional. **Create a DataConnector.**

You can synchronize real-time data from DataHub to other data warehouses by using DataConnectors so that you can analyze and process historical data.

5. Optional. **Create a subscription.**

The subscription feature of DataHub supports saving consumption offsets on the server and allows applications to resume data consumption from saved consumption offsets. In addition, DataHub supports resetting offsets to ensure that data can be consumed at least once.

6.3.2. Log on to the DataHub console

This topic describes how to log on to the DataHub console. Google Chrome is used in this example.

Prerequisites

Before you log on to the DataHub console, make sure that the following requirements are met:

- You have obtained the URL of the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

Obtain the username and password from the operations administrator.

 **Note** If you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. To ensure the security of your account, the password must be 8 to 20 characters in length and must contain at least two types of the following characters:

- Uppercase or lowercase letters
- Digits
- Special characters: exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%)

3. Click **Login** to go to the Apsara Uni-manager Management Console.
4. In the top navigation bar, choose **Products > Big Data > DataHub** to go to the DataHub console. The **Overview** page appears.

6.3.3. Create a project

A project is an organizational unit in DataHub and contains one or more topics. When you use DataHub, you must create a project first. This topic describes how to create a project in the DataHub console.

Prerequisites

An Apsara Stack tenant account is created.

Background information

- DataHub projects are independent from MaxCompute projects. Projects you created in MaxCompute cannot be used in DataHub.
- You can create up to 100 projects with each account.

Procedure

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, click **Create Project**. On the Create Project page, set parameters in the Region and Basic Settings sections and click **Submit**.

6.3.4. Create a topic

A topic is the smallest unit for data subscription and publication. You can use topics to distinguish different types of streaming data. This topic describes how to create a topic in the DataHub console.

Prerequisites

A project is created.

Background information

You can create up to 1,000 topics in each project. Contact the administrator if you need to create more topics.

Procedure

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click **View** in the Operate column.
3. On the project details page, click **Create Topic**.
4. In the Create Topic dialog box, set relevant parameters and click **Create**.

 **Note** DataHub allows you to directly create a topic or create a topic by importing a table schema from MaxCompute.

6.3.5. Sample data

DataHub supports data sampling. You can sample data of a specific shard. This topic describes how to sample data in the DataHub console.

Prerequisites

A project and a topic are created and data is written to the topic.

Background information

Before you sample data, you must specify the start time and the maximum number of records that you want to sample.

Procedure

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click **View** in the Operate column. On the project details page, find the target topic and click **View** in the Operate column.
3. On the Shard List tab of the topic details page, find the target shard and click **Sample** in the Operate column.
4. In the dialog box that appears, specify the start time and the maximum number of records that you want to sample and click **Sample**. DataHub samples the records that are written to the shard after the specified time and displays the sampled records in the table below **Sample**.

6.3.6. Create a DataConnector

You can synchronize real-time data from DataHub to other data warehouses by using DataConnectors so that you can analyze and process historical data. This topic describes how to create a DataConnector in the DataHub console.

Prerequisites

A project and a topic are created and data is written to the topic.

Background information

You can synchronize data from DataHub to MaxCompute, AnalyticDB, ApsaraDB RDS for MySQL, Tablestore, OSS, and Elasticsearch.

Procedure

1. Log on to the DataHub console.

2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click View in the Operate column. On the project details page, find the target topic and click **View** in the Operate column.
3. On the topic details page, click **Connector**. In the Create connector dialog box, select the data warehouse to which data is synchronized.
4. In the Create connector dialog box, set relevant parameters and click **Create**.

6.3.7. Create a subscription

The subscription feature of DataHub supports saving consumption offsets on the server and allows applications to resume data consumption from saved consumption offsets. In addition, DataHub supports resetting offsets to ensure that data can be consumed at least once. This topic describes how to create a subscription in the DataHub console.

Prerequisites

A project and a topic are created and data is written to the topic.

Procedure

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click View in the Operate column. On the project details page, find the target topic and click **View** in the Operate column.
3. On the topic details page, click **Subscription**. In the Create subscription dialog box, set relevant parameters and click **Create**.

6.4. Access Control

6.4.1. Overview

DataHub allows you to improve data security by granting different permissions to Apsara Stack tenant accounts and RAM user accounts.

DataHub uses Resource Access Management (RAM) for access control. Only users that have been granted the required permissions can access the resources in your department. By default, users do not have permission to access resources in your department. This topic describes how access control for DataHub is achieved by using RAM.

 **Note** An Apsara Stack tenant account is owned by a department and requires no authorization. A RAM user account must be granted permissions by the tenant account.

6.4.2. DataHub resources in RAM

The DataHub resources in RAM are project, topic, and subscription. Subscription is the action that you specify an application to read and process the records in DataHub. DataHub supports RAM authorization of project, topic, and subscription. RAM authorization is not supported at the shard level.

In RAM, each resource type has a general description and each specific object of the resource type has a description. For example, the description of a project that resides in a certain region is *acs:dhs:\$region:\$accountid:projects/\$projectName*. *\$region*, *\$accountid*, and *\$projectName* indicate the region that the project resides, the user ID, and the project name.

Resource description

Resource type	Description
SingleProject	acs:dhs:\$region:\$accountid:projects/\$projectName
AllProject	acs:dhs:\$region:\$accountid:projects/*
SingleTopic	acs:dhs:\$region:\$accountid:projects/\$projectName/topics/\$topicName
AllTopic	acs:dhs:\$region:\$accountid:projects/\$projectName/topics/*
SingleSubscription	acs:dhs:\$region:\$accountid:projects/\$projectName/topics/\$topicName/subscriptions/\$subid
AllSubscription	acs:dhs:\$region:\$accountid:projects/\$projectName/topics/\$topicName/subscriptions/*

6.4.3. API

DataHub provides application programming interfaces (APIs) for projects, topics, shards, subscriptions, and records. Before you can call the API operations, you must grant corresponding permissions to the RAM user by using RAM authorization policies.

The RAM authorization policy and resource type for each API operation is described as follows:

API operations for projects

API operations for projects

Operation name	RAM authorization policy	Resource type
CreateProject	dhs:CreateProject	AllProject
ListProject	dhs:ListProject	AllProject
DeleteProject	dhs>DeleteProject	SingleProject
GetProject	dhs:GetProject	SingleProject
UpdateProject	dhs:UpdateProject	SingleProject

API operations for topics

API operations for topics

Operation name	RAM authorization policy	Resource type
CreateTopic	dhs:CreateTopic	AllTopic
ListTopic	dhs:ListTopic	AllTopic
DeleteTopic	dhs>DeleteTopic	SingleTopic
GetTopic	dhs:GetTopic	SingleTopic
UpdateTopic	dhs:UpdateTopic	SingleTopic

API operations for subscriptions

API operations for subscriptions

Operation name	RAM authorization policy	Resource type
CreateSubscription	dhs:CreateSubscription	AllSubscription
ListSubscription	dhs:ListSubscription	AllSubscription
DeleteSubscription	dhs>DeleteSubscription	SingleSubscription
GetSubscription	dhs:GetSubscription	SingleSubscription
UpdateSubscription	dhs:UpdateSubscription	SingleSubscription
CommitOffset	dhs:CommitOffset	SingleSubscription
GetOffset	dhs:GetOffset	SingleSubscription

API operations for shards

API operations for shards

Operation name	RAM authorization policy	Resource type
ListShard	dhs:ListShard	SingleTopic
MergeShard	dhs:MergeShard	SingleTopic
SplitShard	dhs:SplitShard	SingleTopic

API operations for shards

API operations for shards

Operation name	RAM authorization policy	Resource type
PutRecords	dhs:PutRecords	SingleTopic
GetRecords	dhs:GetRecords	SingleTopic
GetCursor	dhs:GetRecords	SingleTopic

6.4.4. Conditions

This section describes conditions that can be applied to the RAM authorization policies for DataHub.

Conditions that can be applied to the RAM authorization policies for DataHub are as follows:

RAM authorization policy conditions for DataHub

Condition keyword	Description	Valid value
acs:SourceIp	The IP address range that can access the specified object.	Any valid IP address. Wildcard masks are supported.

Condition keyword	Description	Valid value
acs:SecureTransport	Indicates whether HTTPS is used to access the specified object.	true/false
acs:MFAPresent	Indicates whether the specified object can be accessed by multiple clients.	true/false
acs:CurrentTime	The time that the specified object can be accessed.	This keyword must be described in ISO 8601 format.

6.4.5. Sample RAM authorization policy content

6.4.5.1. AliyunDataHubFullAccess

This section describes how to set the AliyunDataHubFullAccess policy content.

The authorization policy content can be set as follows:

```
{
  "Version": "1",
  "Statement": [
    {
      "Action": "dhs:*",
      "Resource": "*",
      "Effect": "Allow"
    }
  ]
}
```

6.4.5.2. AliyunDataHubReadOnlyAccess

This section describes how to set the AliyunDataHubReadOnlyAccess policy content.

The authorization policy content can be set as follows:

```
{
  "Version": "1",
  "Statement": [
    {
      "Action": ["dhs:List*", "dhs:Get*"],
      "Resource": "*",
      "Effect": "Allow"
    }
  ]
}
```

6.5. Data Acquisition

6.5.1. Overview

In addition to SDK and local file uploads, DataHub supports various data acquisition tools to help you quickly collect data to DataHub.

This section describes how to acquire data by using Fluentd, Logstash, and Oracle GoldenGate (OGG).

6.5.2. Fluentd

This topic describes how to install and use the DataHub plug-in for Fluentd.

Developed based on the open-source data collector Fluentd, the DataHub plug-in for Fluentd is easy to install and is used to write the collected data to DataHub.

Install the DataHub plug-in for Fluentd

- Install the plug-in by using RubyGems

```
gem install fluent-plugin-datahub
```

 **Notice** We recommend that you change the gem source to <https://ruby.taobao.org/>.

- Install the plug-in by using a local installation package

The agent must be installed in Linux. Before you install the agent, install Ruby. For users who have not installed Fluentd, a full installation package for installing both Fluentd and DataHub plug-in is provided. For users who have installed Fluentd, an installation package of the DataHub plug-in is provided.

- If you have not installed Fluentd, download the [full installation package](#) and run the following commands to install Fluentd with the DataHub plug-in:

 **Notice** Fluentd 0.12.23 is provided in the full installation package.

```
$ tar -xzf fluentd-with-datahub-0.12.23.tar.gz
$ cd fluentd-with-datahub
$ sudo sh install.sh
```

- If you have installed Fluentd, download the [installation package of the DataHub plug-in for Fluentd](#) and run the following command to install the plug-in.

```
$ sudo gem install --local fluent-plugin-datahub-0.0.2.gem
```

Use cases

Case 1: Collect CSV files

This example shows how to write the incremental content of a Comma-Separated Values (CSV) file to DataHub in quasi-real time by using the DataHub plug-in for Fluentd. The following CSV file is used in this example:

```
0,qe614c760fuk8judu01tn5x055rpt1,true,100.1,14321111111
1,znv1py74o8ynn87k66o32ao4x875wi,true,100.1,14321111111
2,7nm0mtpgo1q0ubuljjx9b000ybltl,true,100.1,14321111111
3,10t0n6pvonnan16279w848ukko5f6l,true,100.1,14321111111
4,0ub584kw88s6dczd0mta7itmta10jo,true,100.1,14321111111
5,1ltpf0jt7fhvf0oy4lo8m3z62c940,true,100.1,14321111111
6,zpqsfxqy9379lmcehd7q8kftntrozbt,true,100.1,14321111111
7,ce1ga9aln346xcj761c3iytshyzuxg,true,100.1,14321111111
8,k5j2id9a0ko90cykl40s6ojq6gruyi,true,100.1,14321111111
9,ns2zcx9bdip5y0aqd1tdicf7bkdmsm,true,100.1,14321111111
10,54rs9cm1xau2fk66pzyz62tf9tsse4,true,100.1,14321111111
```

Each line is a record to be written to DataHub. Columns are separated by commas (.). Save the CSV file as /temp/test.csv on the local computer. The following table shows the schema of the DataHub topic to which the CSV file is written.

DataHub topic schema

Field	Data type
id	BIGINT
name	STRING
gender	BOOLEAN
salary	DOUBLE
my_time	TIMESTAMP

After you edit the Fluentd configuration file based on the CSV file and topic schema, run the following command to start Fluentd to write the CSV file to DataHub:

```
`${FLUENTD_HOME}/fluentd-with-dataHub/bin/fluentd -c fluentd_test.conf
```

Use the following Fluentd configuration file in this example:

```
<source>
@type tail
path /xxx/yyy (Specify the path of the CSV file.)
tag test1
format csv
keys id,name,gender,salary,my_time
</source>
<match test1>
@type dataHub
access_id your_app_id
access_key your_app_key
endpoint http://ip:port
project_name test_project
topic_name fluentd_performance_test_1
column_names ["id", "name", "gender", "salary", "my_time"]
flush_interval 1s
buffer_chunk_limit 3m
buffer_queue_limit 128
dirty_data_continue true
dirty_data_file /xxx/yyy (Specify the path of the dirty record file.)
retry_times 3
put_data_batch_size 1000
</match>
```

Case 2: Collect Log4j logs

The following format of Log4j logs is used in this example:

```
11:48:43.439 [qtp1847995714-17] INFO AuditInterceptor - [c2un5sh7cu52ek6am1ui1m5h] end /web/v1/project/tefe4mfurtix9kwwyrvfqd0m/node/0m0169kapshvgc3ujskwkk8g/health GET, 4061 ms
```

Use the following Fluentd configuration file in this example:

```
<source>
@type tail
path bayes.log
tag test
format /(? <request_time>\d\d:\d\d:\d\d.\d+)\s+[(? <thread_id>[w-]+)]\s+(? <log_level>w+)\s+(? <class>w+)\s+[\s+](? <request_id>w+)\s+(? <detail>.+)/
</source>
<match test>
@type dataHub
access_id your_access_id
access_key your_access_key
endpoint http://ip:port
project_name test_project
topic_name dataHub_fluentd_out_1
column_names ["thread_id", "log_level", "class"]
</match>
```

Parameter description

Input configuration

Parameter	Description
tag test1	The tag, which is mapped to the destination information by using the specified regular expression.
format csv	The format of the file from which data is collected.
keys id,name,gender,salary,my_time	The columns to be collected from the CSV file. The column names must be the same as those in the schema of the destination DataHub topic.

Output configuration

Parameter	Description
shard_id 0	The ID of the shard to which all records are written. By default, all records are written to the shard by polling. The default ID is 0.
shard_keys ["id"]	The column used as the shard key. Hashed shard key values are used as indexes for writing data.
flush_interval 1	The interval between data flushes. The default value is 60s.
buffer_chunk_limit 3m	The maximum size of a chunk. Unit: k or m, which indicates KB or MB. We recommend you set the maximum size to 3 MB.
buffer_queue_limit 128	The maximum length of the chunk queue. Both the buffer_chunk_limit and buffer_queue_limit parameters determine the size of the buffer. The default value is 128 MB.
put_data_batch_size 1000	The number of records to be written to DataHub at a time. In this example, 1,000 records are written to DataHub each time.
retry_times 3	The number of retries for writing data to DataHub. Default value: 3.
retry_interval 3	The retry interval at which data is written. Unit: seconds. Default value: 3.
dirty_data_continue true	Specifies whether to ignore dirty records. The value true indicates that the plug-in retries the operation for a specified number of times before it writes the dirty records to the dirty record file.
dirty_data_file /xxx/yyy	The directory where the dirty record file is stored.
column_names ["id"]	The name of the columns to be written to DataHub.

6.5.3. Logstash

This topic describes how to install and use Logstash to import data to DataHub and export data from DataHub.

Logstash is a distributed log collection framework. It is often used with Elasticsearch and Kibana, known as the ELK Stack, for log data analysis. To support a wider variety of data inputs, DataHub offers Output and Input plug-ins for data transfer with Logstash. By using Logstash, you can access more than 30 types of data sources in the Logstash open source community, such as files, Syslog logs, Redis logs, Log4j logs, Apache logs, and NGINX logs. Logstash also supports filter plug-ins for customizing the fields to be transferred. This topic demonstrates how to use Logstash with DataHub.

Install Logstash and DataHub plug-ins

Java Runtime Environment (JRE) 7 or later is required to run Logstash. If the JRE version does not meet the requirement, several features of Logstash are unavailable. You can install Logstash and DataHub plug-ins with one click by downloading and decompressing the software package or install Logstash and DataHub plug-ins separately.

- Install Logstash and DataHub plug-ins with one click: Download the [software package](#).

Run the following commands to decompress the package and go to the software directory:

```
$ tar -xvf logstash-with-datahub-2.3.0.tar.gz
$ cd logstash-with-datahub-2.3.0
```

- Install Logstash and DataHub plug-ins separately
 - Install Logstash. For more information, see the [documentation on the official website of Logstash](#).
 - Install the [DataHub Output plug-in for Logstash](#). You can use this plug-in to import data to DataHub.
 - Install the [DataHub Input plug-in for Logstash](#). You can use this plug-in to export data from DataHub.

Use cases

Case 1: Collect Log4j logs

This example shows how to collect unstructured Log4j logs and derive a structure out of the logs by using Logstash. The following format of Log4j logs is used in this example:

```
20:04:30.359 [qtp1453606810-20] INFO AuditInterceptor - [13pn9kdr5tl84stzkmaa8vmg] end /web/v1/project/fhp4clxfbu0w3ym2n7ee6ynh/statistics? executionName=bayes_poc_test GET, 187 ms
```

In this example, you can derive a structure out of the logs and transfer the data to DataHub. The following table shows the schema of the DataHub topic to which the Log4j logs are written.

DataHub topic schema

Field	Data type
request_time	STRING
thread_id	STRING
log_level	STRING
class_name	STRING
request_id	STRING
detail	STRING

Use the following configuration of the Logstash task in this example:

```

input {
  file {
    path => "${APP_HOME}/log/bayes.log"
    start_position => "beginning"
  }
}
filter{
  grok {
    match => {
      "message" => "(? <request_time>\d\d:\d\d:\d\d\.\d+)\s+[[? <thread_id>[\w\.-]+]]\s+(? <log_level>\w+)\s+(? <class_name>\w+)\s+[\s+][[? <request_id>\w+]]\s+(? <detail>.+)"
    }
  }
}
output {
  datahub {
    access_id => "Your accessId"
    access_key => "Your accessKey"
    endpoint => "Endpoint"
    project_name => "project"
    topic_name => "topic"
    #shard_id => "0"
    #shard_keys => ["thread_id"]
    dirty_data_continue => true
    dirty_data_file => "/Users/ph0ly/trash/dirty.data"
    dirty_data_file_max_size => 1000
  }
}

```

Case 2: Collect CSV files

This example shows how to use Logstash to collect CSV files. The following CSV file is used in this example:

```

1111,1.23456789012E9,true,14321111111000000,string_dataxxx0,
2222,2.23456789012E9,false,14321111111000000,string_dataxxx1

```

The following table shows the schema of the DataHub topic to which the CSV file is written.

DataHub topic schema

Field	Data type
col1	BIGINT
col2	DOUBLE
col3	BOOLEAN
col4	TIMESTAMP
col5	STRING

Use the following configuration of the Logstash task in this example:

Run the following command to start Logstash:

```
$LOGSTASH_HOME/bin/logstash -f <The preceding configuration file> -b 256
```

Note -f is followed by the path of the configuration file. -b is followed by the number of records transferred to DataHub at a time. Default value: 125.

Parameters

The following table describes the parameters of the DataHub Output plug-in.

Parameters of the DataHub Output plug-in

Parameter	Description
access_id	Required. The AccessKey ID of your Apsara Stack tenant account.
access_key	Required. The AccessKey secret of your Apsara Stack tenant account.
endpoint	Required. The endpoint used to access DataHub.
project_name	Required. The name of the DataHub project.
topic_name	Required. The name of the DataHub topic.
retry_times	Optional. The maximum number of retries. The value -1 indicates unlimited retries. The value 0 indicates no retries. A value greater than 0 indicates the specified number of retries. Default value: -1.
retry_interval	Optional. The interval between retries. Unit: seconds. Default value: 5.
shard_keys	Optional. The key of the shard. The hash of the key value is used to map the ID of the shard to which the records are written. If the shard_keys and shard_id parameters are not specified, the system polls the shards to decide which shard the records are written to.
shard_id	Optional. The ID of the shard where records are written. If the shard_keys and shard_id parameters are not specified, the system polls the shards to decide which shard the records are written to.
dirty_data_continue	Optional. Specifies whether to ignore dirty records. The value true indicates that dirty records are to be ignored. Default value: false. If you set the value to true, you must specify the dirty_data_file parameter.
dirty_data_file	Optional. The name of the dirty record file. The dirty record file is divided into .part 1 and .part 2. The most recent records are stored in .part 2.
dirty_data_file_max_size	Optional. The maximum size of the dirty record file. This value is for reference only.

The following table describes the parameters of the DataHub Input plug-in.

Parameters of the DataHub Input plug-in

Parameter	Description
access_id	Required. The AccessKey ID of your Apsara Stack tenant account.

Parameter	Description
access_key	Required. The AccessKey secret of your Apsara Stack tenant account.
endpoint	Required. The endpoint used to access DataHub.
project_name	Required. The name of the DataHub project.
topic_name	Required. The name of the DataHub topic.
retry_times	Optional. The maximum number of retries. The value -1 indicates unlimited retries. The value 0 indicates no retries. A value greater than 0 indicates the specified number of retries. Default value: -1.
retry_interval	Optional. The interval between retries. Unit: seconds. Default value: 5.
shard_ids	Optional. The shards in which records are to be consumed. If this parameter is not specified, records in all the shards are consumed.
cursor	Optional. The sequence number of the record from which the consumption begins. The consumption starts from the earliest record by default.
pos_file	Required. The checkpoint file, which is used to reset the consumption offset.

6.5.4. Oracle GoldenGate

This topic describes how to install and use Oracle GoldenGate (OGG).

OGG is a tool for log-based structured data replication across heterogeneous environments. It is used for data backup between primary and secondary Oracle databases. It is also used to synchronize data from Oracle databases to other databases such as IBM Db2 and MySQL databases. OGG must be deployed in the source and destination databases. It is composed of the following components: Manager, Extract, data pump, Collector, and Replicat.

- Manager is the control process of OGG. A Manager process must be running on the source and destination databases. It is responsible for starting, stopping, and monitoring other processes.
- Extract is a process that captures data from the source database or transaction logs. You can configure the Extract process for initial data loads and incremental data synchronization. For initial data loads, Extract captures a set of data directly from their source objects. To keep source data synchronized to the destination database, Extract captures incremental DML and DDL operations after the initial data loading has taken place. This topic describes incremental data synchronization.
- A data pump is a secondary Extract group within the source OGG configuration. In a typical configuration with a data pump, the primary Extract group writes to a trail on the source database. The data pump reads the trail and sends the DML or DDL operations over the network to a remote trail on the destination database.
- Collector is a process on the destination database, which receives data from the source database and generates trail files.
- Replicat is a process that reads the trail on the destination database, reconstructs the DML or DDL operations, and then applies them to the destination database.

The DataHub agent for OGG offers the Replicat feature that applies the updated data to DataHub by analyzing the trail. The data in DataHub is processed in real time by using Realtime Compute and can be archived into MaxCompute.

The following example shows how to synchronize incremental data from an Oracle database to DataHub and process the data in DataHub.

Install OGG

Prerequisites:

- You have installed the Oracle database client.
- You have obtained the OGG installation package for the source database. We recommend that you use OGG V12.1.2.1.
- You have obtained the OGG Adapters installation package for the destination database. We recommend that you use OGG Application Adapters 12.1.2.1.
- You have installed Java 7.

Follow these steps to install OGG:

1. Install OGG for the source database.
 - i. Extract the OGG installation package for the source database and the following directories appear:

```
drwxr-xr-x install
drwxrwxr-x response
-rwxr-xr-x runInstaller
drwxr-xr-x stage
```

- ii. Install dependencies in response/oggcore.rsp. The OGG response file template is as follows:

```
oracle.install.responseFileVersion=/oracle/install/rspfmt_ogginstall_response_schema
#The installation option, which must reflect the installed Oracle version. Specify ORA11g for installing OGG for Oracle Database 11g.
INSTALL_OPTION=ORA11g
#The location in which OGG is installed.
SOFTWARE_LOCATION=/home/oracle/u01/ggate
#Indicates whether to start the Manager after installation.
START_MANAGER=false
#The port number of the Manager process.
MANAGER_PORT=7839
#The location of the Oracle database.
DATABASE_LOCATION=/home/oracle/u01/app/oracle/product/11.2.0/dbhome_1
#The location that stores the inventory files. This parameter is not required to be configured.
INVENTORY_LOCATION=
#The UNIX group of the inventory directory. In this example, OGG is installed by using the ogg_test Oracle account. You can also create a dedicated account for OGG as necessary.
UNIX_GROUP_NAME=oinstall
```

- iii. Run the following command to install OGG:

```
runInstaller -silent -responseFile {YOUR_OGG_INSTALL_FILE_PATH}/response/oggcore.rsp
```

Note

In this example, OGG is installed in `/home/oracle/u01/ggate` and the installation logs are stored in `/home/oracle/u01/ggate/cfgtoollogs/oui`. The OGG installation is complete when the following message appears in the `silentInstall{time}.log` file:

```
The installation of Oracle GoldenGate Core was successful.
```

- iv. Run the following command and enter `CREATE SUBDIRS` as required to create OGG directories:

```
/home/oracle/u01/ggate/ggsci
```

2. Perform Oracle configurations in the source database.

Navigate to *sqlplus: sqlplus / as sysdba* as the database administrator and complete the following configurations:

```
#Create a tablespace.
create tablespace ATMV datafile '/home/oracle/u01/app/oracle/oradata/uprr/ATMV.dbf' size 100m autoextend
on next 50m maxsize unlimited;
#Create a user named ogg_test. The password is also set to ogg_test.
create user ogg_test identified by ogg_test default tablespace ATMV;
#Grant required privileges to ogg_test.
grant connect,resource,dba to ogg_test;
#Check whether supplemental logging is enabled for the database.
Select SUPPLEMENTAL_LOG_DATA_MIN, SUPPLEMENTAL_LOG_DATA_PK, SUPPLEMENTAL_LOG_DATA_UI, SUP
PLEMENTAL_LOG_DATA_FK, SUPPLEMENTAL_LOG_DATA_ALL from v$database;
#If the result is NO, enable supplemental logging.
alter database add supplemental log data;
alter database add supplemental log data (primary key, unique,foreign key) columns;
#Enable rollback.
alter database drop supplemental log data (primary key, unique,foreign key) columns;
alter database drop supplemental log data;
#Enable all column logging at the database level. Note: Even when all column logging is enabled, only primary
key columns are logged for a delete operation.
ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (ALL) COLUMNS;
#Enable the forced logging mode.
alter database force logging;
#Run the marker_setup.sql script.
@marker_setup.sql
#Run the ddl_setup.sql script.
@ddl_setup.sql
#Run the role_setup.sql script.
@role_setup.sql
#Grant the GGS_GGSUSER_ROLE to ogg_test.
grant GGS_GGSUSER_ROLE to ogg_test;
#Run the ddl_enable.sql script to enable the DDL trigger.
@ddl_enable.sql
#Run the ddl_pin script to improve the performance of the DDL trigger.
@ddl_pin ogg_test
#Run the sequence.sql script.
@sequence.sql
#
alter table sys.seq$ add supplemental log data (primary key) columns;
```

3. Configure the Manager process on the source database.

Start the Oracle GoldenGate Software Command Interface (GGSCI) and perform the following steps:

- i. Run the following command to configure the Manager process:

```
edit params mgr
PORT 7839
DYNAMICPORTLIST 7840-7849
USERID ogg_test, PASSWORD ogg_test
PURGEOLDEXTRACTS ./dirdat/*, USECHECKPOINTS, MINKEEPDAYS 7
LAGREPORTHOURS 1
LAGINFOMINUTES 30
LAGCRITICALMINUTES 45
PURGEDDLHISTORY MINKEEPDAYS 3, MAXKEEPDAYS 7
PURGEMARKERHISTORY MINKEEPDAYS 3, MAXKEEPDAYS 7
```

- ii. Run the following command to start the Manager process. The logs are stored in ggate/dirrpt.

```
start mgr
```

- iii. Run the following command to check whether the Manager process is running:

```
info mgr
```

- iv. Run the following command to view the Manager parameter file:

```
view params mgr
```

4. Configure the Extract process on the source database.

Start the GGSCI and perform the following steps:

- i. Run the following command to configure the Extract process. In the following example, the group name of the process is extract.

```
edit params extractEXTRACT extract
SETENV (NLS_LANG="AMERICAN_AMERICA.AL32UTF8")
DBOPTIONS ALLOWUNUSEDCOLUMN
USERID ogg_test, PASSWORD ogg_test
REPORTCOUNT EVERY 1 MINUTES, RATE
NUMFILES 5000
DISCARDFILE ./dirrpt/ext_test.dsc, APPEND, MEGABYTES 100
DISCARDROLLOVER AT 2:00
WARNLONGTRANS 2h, CHECKINTERVAL 3m
EXTTRAIL ./dirdat/st, MEGABYTES 200
DYNAMICRESOLUTION
TRANLOGOPTIONS CONVERTUCS2CLOBS
TRANLOGOPTIONS RAWDEVICEOFFSET 0
DDL &
INCLUDE MAPPED OBJTYPE 'table' &
INCLUDE MAPPED OBJTYPE 'index' &
INCLUDE MAPPED OBJTYPE 'SEQUENCE' &
EXCLUDE OPTYPE COMMENT
DDLOPTIONS NOCROSSRENAME REPORT
TABLE OGG_TEST.*;
SEQUENCE OGG_TEST.*;
GETUPDATEBEFORES
```

- ii. Run the following command to add an Extract process. Replace extract in the following command with your actual group name.

```
add ext extract,tranlog, begin now
```

- iii. Run the following command to delete an Extract process. In the following example, the process name is DP_TEST.

```
delete ext DP_TEST
```

- iv. Run the following command to create a trail, associate the trail with the Extract group named extract, and set the maximum file size in the trail to 200 megabytes:

```
add extrail ./dirdat/st,ext extract, megabytes 200
```

- v. Run the following command to start the Extract process. The logs are stored in `ggate/dirprt`.

```
start extract extract
```

 **Note** After the Extract process configuration is complete, you can view the changes to the database in the files stored in the `ggate/dirdat` directory.

5. Create a DEFGEN parameter file.

- i. Start the GGSCI in the source database. In GGSCI, run the following command to create a DEFGEN parameter file and copy the file to the `dirdef` directory in the destination database:

```
edit params defgen  
DEFSFILE ./dirdef/ogg_test.def  
USERID ogg_test, PASSWORD ogg_test  
table OGG_TEST. *;
```

- ii. Run the following command from the shell to create a DEFGEN parameter file named `ogg_test.def`:

```
./defgen paramfile ./dirprm/defgen.prm
```

6. Install and configure OGG in the destination database.

- i. Extract the OGG installation package to the destination database.
- ii. Copy the `dirdef/ogg_test.def` file in the source database to `dirdef` of the destination database.
- iii. Start the GGSCI and run the following command to create the default directories of OGG:

```
create subdirs
```

- iv. Run the following command to configure the Manager process:

```
edit params mgr  
PORT 7839  
DYNAMICPORTLIST 7840-7849  
PURGEOLDEXTRACTS ./dirdat/*, USECHECKPOINTS, MINKEEPDAYS 7  
LAGREPORHOURS 1  
LAGINFOMINUTES 30  
LAGCRITICALMINUTES 45  
PURGEDDLHISTORY MINKEEPDAYS 3, MAXKEEPDAYS 7  
PURGEMARKERHISTORY MINKEEPDAYS 3, MAXKEEPDAYS 7
```

- v. Run the following command to start the Manager process:

```
start mgr
```

7. Configure a data pump in the source database.

Start the GGSCI and perform the following steps:

- i. Run the following command to configure a data pump:

```
edit params pump
EXTRACT pump
RMTHOST xx.xx.xx.xx, MGRPORT 7839, COMPRESS
PASSTHRU
NUMFILES 5000
RMTTRAIL ./dirdat/st
DYNAMICRESOLUTION
TABLE OGG_TEST.*;
SEQUENCE OGG_TEST.*;
```

- ii. Run the following command to create a data-pump Extract process. The process reads from the specified trail.

```
add ext pump,exttrailsources ./dirdat/st
```

- iii. Run the following command to create a trail and set the maximum file size in the trail to 200 megabytes:

```
add rmttrail ./dirdat/st,ext pump,megabytes 200
```

- iv. Run the following command to start the data pump:

```
start pump
```

 **Note** After the data pump is started, you can view the trail files in the dirdat directory of the destination database.

8. Install and configure the DataHub agent for OGG.

- i. Run the following command to configure the *JAVA_HOME* and *LD_LIBRARY_PATH* environment variables and specify the configurations in the *~/ .bash_profile*:

```
export JAVA_HOME=/xxx/xxx/jrexx
export LD_LIBRARY_PATH=${LD_LIBRARY_PATH}:$JAVA_HOME/lib/amd64:$JAVA_HOME/lib/amd64/server
```

- ii. After the environment variables are configured, restart the Manager process in the destination database.
- iii. Download the [DataHub agent for OGG](#) and extract the installation package.
- iv. Modify the *javae.properties* and *log4j.properties* files in the *conf* sub-directory of the installation directory and replace *{YOUR_HOME}* with the target path of the extracted files:

```
gg.handlerlist=ggdatahub
gg.handler.ggdatahub.type=com.aliyun.odps.ogg.handler.datahub.DatahubHandler
gg.handler.ggdatahub.configureFileName={YOUR_HOME}/datahub-ogg-plugin/conf/configure.xml
goldengate.userexit.nochkpt=false
goldengate.userexit.timestamp=utc
gg.classpath={YOUR_HOME}/datahub-ogg-plugin/lib/*
gg.log.level=debug
jvm.bootoptions=-Xmx512m -Dlog4j.configuration=file:{YOUR_HOME}/datahub-ogg-plugin/conf/log4j.properties -Djava.class.path=ggjava/ggjava.jar
```

- v. Modify the *configure.xml* file in the *conf* sub-directory of the installation directory as follows:

```
<? xml version="1.0" encoding="UTF-8"? >
<configure>
  <defaultOracleConfigure>
    <!--(Required) The Oracle database system identifier (SID) -->
```

```
<!--(Required) The Oracle database system identifier (SID).-->
<sid>100</sid>
<!--The schema of the Oracle table, which can be overwritten by oracleSchema in the column mapping
s. At least one of them must be specified.-->
<schema>ogg_test</schema>
</defaultOracleConfigure>
<defaultDatahubConfigure>
<!--(Required) The endpoint of DataHub.-->
<endPoint>YOUR_DATAHUB_ENDPOINT</endPoint>
<!--The DataHub project, which can be overwritten by datahubProject in the column mappings. At lea
st one of them must be specified.-->
<project>YOUR_DATAHUB_PROJECT</project>
<!--The AccessKey ID for accessing DataHub, which can be overwritten by datahubAccessId in the colu
mn mappings. At least one of them must be specified.-->
<accessId>YOUR_DATAHUB_ACCESS_ID</accessId>
<!--The AccessKey Secret for accessing DataHub, which can be overwritten by datahubAccessKey in th
e column mappings. At least one of them must be specified.-->
<accessKey>YOUR_DATAHUB_ACCESS_KEY</accessKey>
<!--The column in DataHub that indicates the data update type, which can be overwritten by ctypeCol
umn in the column mappings.-->
<ctypeColumn>optype</ctypeColumn>
<!-- The column in DataHub that indicates the data update time, which can be overwritten by ctimeCo
lumn in the column mappings.-->
<ctimeColumn>readtime</ctimeColumn>
<!-- The column in DataHub that indicates the sequence number of the updated data, which can be ov
erwritten by cidColumn in the column mappings. The sequence number increases as more data are updat
ed, but may not be consecutive.-->
<cidColumn>record_id</cidColumn>
</defaultDatahubConfigure>
<!--The approach to handling errors. If an error occurs, the system either ignores the error and continue
s running or retries the operation repeatedly.-->
<!--(Optional) The maximum number of records operated at one time. Default value: 1000.-->

  <!--
    src: (Required) The column names in the Oracle table.
    dest: (Required) The column names in the DataHub topic.
    destOld: (Optional) The DataHub topic column that records the data before it is updated.
    isShardColumn: (Optional) Indicates whether the shard ID is generated based on the hash key value, which can be overwritten by shardId. Default value: false.
    isDateFormat: Indicates whether the timestamp is converted into a string based on dateFormat. Default value: true. If you set the value to false, the data type in the source database must be long.
    dateFormat: The format that the timestamp is converted into. If this parameter is left blank, the default format is used.
  -->
  <column src="id" dest="id" isShardColumn="true" isDateFormat="false" dateFormat="yyyy-MM-dd HH:mm:ss"/>
  <column src="name" dest="name" isShardColumn="true"/>
  <column src="age" dest="age"/>
  <column src="address" dest="address"/>
  <column src="comments" dest="comments"/>
  <column src="sex" dest="sex"/>
  <column src="temp" dest="temp" destOld="temp1"/>
</columnMapping>
<!--(Optional) The ID of the shard prioritized to be written into.-->
<shardId>1</shardId>
</mapping>
</mappings>
</configure>

```

- vi. Run the following command in GGSCI to start the DataHub writer:

```

edit params dhwriter
extract dhwriter
getEnv (JAVA_HOME)
getEnv (LD_LIBRARY_PATH)
getEnv (PATH)
CUSEREXIT ./libggjava_ue.so CUSEREXIT PASSTHRU INCLUDEUPDATEBEFORES, PARAMS "{YOUR_HOME}/datahub-ogg-plugin/conf/javaue.properties"
sourcedefs ./dirdef/ogg_test.def
table OGG_TEST.*;

```

- vii. Run the following command to add a DataHub writer:

```
add extract dhwriter, extrailsources ./dirdef/st
```

- viii. Run the following command to start the writer:

```
start dhwriter
```

Use case

For example, you have an Oracle table that stores order information. The table has three columns. The column names are oid, pid, and num, which indicate order ID, product ID, and product quantity. You can synchronize incremental data to DataHub by using the DataHub agent for OGG. The steps are as follows:

Note Before performing incremental data synchronization, you must synchronize existing data from the source table to MaxCompute by using DataX.

1. Create a topic in DataHub. The schema of the topic is as follows:

```
string record_id, string optype, string readtime, bigint oid_before, bigint oid_after, bigint pid_before, bigint pid_after, bigint num_before, bigint num_after
```

2. Make sure that you have completed the deployment of the DataHub agent for OGG. Then configure the column mappings as follows:

```
<ctypeColumn>optype</ctypeColumn>
<ctimeColumn>readtime</ctimeColumn>
<cidColumn>record_id</cidColumn>
<columnMapping>
  <column src="oid" dest="oid_after" destOld="oid_before" isShardColumn="true"/>
  <column src="pid" dest="pid_after" destOld="pid_before"/>
  <column src="num" dest="num_after" destOld="num_before"/>
</columnMapping>
```

Note The optype parameter indicates the type of the data update. Valid values of the optype parameter are I, D, and U, which represent an insert, delete, and update operation, respectively. The readtime parameter indicates the time of the data update.

3. When the agent can run properly, data updates are synchronized from the source table to DataHub.

6.6. Data synchronization

6.6.1. Overview

You can synchronize real-time data from DataHub to other data warehouses by using DataConnectors so that you can analyze and process historical data.

The following topics describe how to synchronize data from DataHub to MaxCompute.

6.6.2. Synchronize data to MaxCompute

6.6.2.1. Create a DataConnector

This topic describes how to create a DataConnector to synchronize data from DataHub to MaxCompute.

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click View in the Operate column. On the project details page, find the target topic and click View in the Operate column.
3. On the topic details page, click **Connector**. In the Create connector dialog box, select the data warehouse to which data is synchronized.
4. In the Create connector dialog box, set relevant parameters and click **Create**.

 **Note**

The following table describes the parameters of the DataConnector for synchronizing data from DataHub to MaxCompute.

Parameter	Description
Project Name	The name of the MaxCompute project to which data in the topic is synchronized.
Table Name	The name of the MaxCompute table to which data in the topic is synchronized.
AccessID and AccessKey	The AccessKey pair used to access MaxCompute. The AccessKey pair must belong to a RAM user that has CreateInstance, Desc, and Alter permissions on the MaxCompute table.
Partition Mode	The method used to create partitions. Valid values: SYSTEM_TIME, EVENT_TIME, USER_DEFINE, and META_TIME. If you select SYSTEM_TIME, partitions are created based on the recording time. If you select EVENT_TIME, partitions are created based on the value of the event_time field. When you create the topic, you must define a field named event_time for the topic and set its data type to TIMESTAMP. The value of the event_time field must be accurate to microseconds. If you select USER_DEFINE, partitions are created based on the user-defined partition key.
Partition Config	The format of the time based on which partitions are created. This parameter takes effect only when you set the Partition Mode parameter to SYSTEM_TIME, EVENT_TIME, or META_TIME.
Time Range	The interval of creating partitions. This parameter takes effect only when you set the Partition Mode parameter to SYSTEM_TIME, EVENT_TIME, or META_TIME. The minimum value is 15 minutes.
Timezone	The time zone of the time based on which partitions are created. This parameter takes effect only when you set the Partition Mode parameter to SYSTEM_TIME, EVENT_TIME, or META_TIME.
Start Time	The time when data synchronization starts.

6.6.2.2. View data synchronization details

This section describes how to view data synchronization details after a DataConnector is created.

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click **View** in the Operate column.
3. On the project details page, find the target topic and click **View** in the Operate column.
4. On the topic details page, click the **Connector** tab. On the Connector tab, find the target DataConnector and click **View** in the Operate column.

 **Notice** You can restart or stop a DataConnector. Exercise caution when you perform the operations.

6.7. Metric statistics

This topic describes how to view the metric statistics of a topic in DataHub.

In the DataHub console, you can view the metric statistics of topics in quasi-real-time, such as QPS and throughput. The following metrics are available:

- Read and write QPS
 - Read and write records per second (RPS)
 - Read and write throughput, measured in KB per second
 - Read and write latency, measured in microseconds per request
1. Log on to the DataHub console.
 2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click **View** in the Operate column.
 3. On the project details page, find the target topic and click **View** in the Operate column.
 4. On the topic details page, click the **Metric Statistics** tab.

You can view the metric statistics for a specified time range.

6.8. Data subscription

6.8.1. Overview

Resumable consumption is required in scenarios where you consume data in DataHub topics and want to resume the consumption from the time when your application fails. If you need to resume consumption, you must save the current consumption offset and make sure that the service for saving consumption offsets supports high availability. This increases the complexity of developing applications. The subscription feature of DataHub supports saving consumption offsets to the server to solve the preceding problem. You only need to enable this feature and add a few lines of code to your application to obtain a consumption offset maintenance service with high availability.

In addition, the subscription feature allows you to reset consumption offsets. This ensures that the data can be consumed at least once. For example, if an error occurs when your application processes the data consumed in a specific time period and you need to consume the data again, you can reset the consumption offset without restarting the application. Your application automatically consumes data from the specified consumption offset.

6.8.2. Create a subscription

You can create subscriptions only in the DataHub console. Make sure that your account is authorized to subscribe to topics of the specified project.

Perform the following steps to create a subscription:

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click **View** in the Operate column. On the project details page, find the target topic and click **View** in the Operate column.
3. On the topic details page, click **Subscription**. In the Create subscription dialog box, set relevant parameters and click **Create**.
4. After the subscription is created, click the **Subscription List** tab on the topic details page to view the subscriptions of the topic.

-  **Note** You can click **Reset** or **Delete** in the Operate column of a subscription.
- **Reset**: resets the consumption offset of the subscription to the required time. Specify the time in the *mm-dd-yyyy HH:MM:SS* format.
 - **Delete**: permanently deletes the subscription, including all consumption offsets that are saved for the subscription.

6.8.3. Use case

The subscription feature allows you to save consumption offsets. You can use the read and write capabilities of DataHub with the capability of saving consumption offsets in scenarios where you must save consumption offsets after data is read.

The following sample code is used for reference only.

```
// The following sample code consumes data from a saved consumption offset and submit consumption offsets during consumption.
public void offset_consumption(int maxRetry) {
    String endpoint = "<YourEndPoint>";
    String accessId = "<YourAccessId>";
    String accessKey = "<YourAccessKey>";
    String projectName = "<YourProjectName>";
    String topicName = "<YourTopicName>";
    String subId = "<YourSubId>";
    String shardId = "0";
    List<String> shardIds = Arrays.asList(shardId);
    // Create a DataHub client.
    DatahubClient datahubClient = DatahubClientBuilder.newBuilder()
        .setDatahubConfig(
            new DatahubConfig(endpoint,
                // Specify whether to enable binary data transmission. The server of V2.12 or later supports binary data transmission.
                new AliyunAccount(accessId, accessKey), true))
        .build();
    RecordSchema schema = datahubClient.getTopic(projectName, topicName).getRecordSchema();
    OpenSubscriptionSessionResult openSubscriptionSessionResult = datahubClient.openSubscriptionSession(projectName, topicName, subId, shardIds);
    SubscriptionOffset subscriptionOffset = openSubscriptionSessionResult.getOffsets().get(shardId);
    // 1. Obtain the cursor of the record at the current consumption offset. If the record expired or the record is not consumed, obtain the cursor of the first record within the TTL of the topic.
    String cursor = "";
    // If the sequence number is smaller than 0, the record is not consumed.
    if (subscriptionOffset.getSequence() < 0) {
        // Obtain the cursor of the first record within the TTL of the topic.
        cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.OLDEST).getCursor();
    } else {
        // Obtain the cursor of the next record.
        long nextSequence = subscriptionOffset.getSequence() + 1;
        try {
            // If the SeekOutOfRangeException error is returned after you obtain the cursor based on the sequence number, the record expired.
            cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.SEQUENCE, nextSequence).getCursor();
        } catch (SeekOutOfRangeException e) {
            // Obtain the cursor of the first record within the TTL of the topic.
            cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.OLDEST).getCursor();
        }
    }
}
```

```
}
}
// 2. Read records and save consumption offsets. In this example, you read tuple records and save consumption of
// offsets each time 1,000 records are read.
long recordCount = 0L;
// Read 1,000 records each time.
int fetchNum = 1000;
int retryNum = 0;
int commitNum = 1000;
while (retryNum < maxRetry) {
    try {
        GetRecordsResult getRecordsResult = datahubClient.getRecords(projectName, topicName, shardId, schema, c
        ursor, fetchNum);
        if (getRecordsResult.getRecordCount() <= 0) {
            // If no records can be read, pause the thread for 1s and continue to read records.
            System.out.println("no data, sleep 1 second");
            Thread.sleep(1000);
            continue;
        }
        for (RecordEntry recordEntry : getRecordsResult.getRecords()) {
            // Consume data.
            TupleRecordData data = (TupleRecordData) recordEntry.getRecordData();
            System.out.println("field1:" + data.getField("field1") + "\t"
                + "field2:" + data.getField("field2"));
            // Save the consumption offset after the data is consumed.
            recordCount++;
            subscriptionOffset.setSequence(recordEntry.getSequence());
            subscriptionOffset.setTimestamp(recordEntry.getSystemTime());
            // commit offset every 1000 records
            if (recordCount % commitNum == 0) {
                // Submit the consumption offset.
                Map<String, SubscriptionOffset> offsetMap = new HashMap<>();
                offsetMap.put(shardId, subscriptionOffset);
                datahubClient.commitSubscriptionOffset(projectName, topicName, subId, offsetMap);
                System.out.println("commit offset successful");
            }
        }
        cursor = getRecordsResult.getNextCursor();
    } catch (SubscriptionOfflineException | SubscriptionSessionInvalidException e) {
        // The subscription session is exited. The Offline exception indicates that the subscription is offline. The Sessi
        onChange exception indicates that the subscription is consumed by other clients.
        e.printStackTrace();
        throw e;
    } catch (SubscriptionOffsetResetException e) {
        // The consumption offset is reset. You must obtain the version information of the consumption offset again.
        SubscriptionOffset offset = datahubClient.getSubscriptionOffset(projectName, topicName, subId, shardIds).g
        etOffsets().get(shardId);
        subscriptionOffset.setVersionId(offset.getVersionId());
        // After the consumption offset is reset, you must obtain the cursor of the record at the consumption offset ag
        ain. The method for obtaining the cursor depends on the method of resetting the consumption offset.
        // If both the sequence number and timestamp are specified to reset the consumption offset, you can obtain t
        he cursor based on the sequence number or the timestamp.
        // If only the sequence number is specified to reset the consumption offset, you can obtain the cursor only bas
        ed on the sequence number.
        // If only the timestamp is specified to reset the consumption offset, you can obtain the cursor only based on t
        he timestamp.
        // Generally, preferentially obtain the cursor based on the sequence number. If the cursor failed to be obtaine
        d based on the sequence number or the timestamp, obtain the cursor of the earliest record.
    }
}
```

```
    cursor = null;
    if (cursor == null) {
        try {
            long nextSequence = offset.getSequence() + 1;
            cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.SEQUENCE, nextSequence).getCursor();
            System.out.println("get cursor successful");
        } catch (DatahubClientException exception) {
            System.out.println("get cursor by SEQUENCE failed, try to get cursor by SYSTEM_TIME");
        }
    }
    if (cursor == null) {
        try {
            cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.SYSTEM_TIME, offset.getTimestamp()).getCursor();
            System.out.println("get cursor successful");
        } catch (DatahubClientException exception) {
            System.out.println("get cursor by SYSTEM_TIME failed, try to get cursor by OLDEST");
        }
    }
    if (cursor == null) {
        try {
            cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.OLDEST).getCursor();
            System.out.println("get cursor successful");
        } catch (DatahubClientException exception) {
            System.out.println("get cursor by OLDEST failed");
            System.out.println("get cursor failed!!");
            throw e;
        }
    }
} catch (LimitExceededException e) {
    // limit exceed, retry
    e.printStackTrace();
    retryNum++;
} catch (DatahubClientException e) {
    // other error, retry
    e.printStackTrace();
    retryNum++;
} catch (Exception e) {
    e.printStackTrace();
    System.exit(-1);
}
}
```

 **Note**

- When you start the application for the first time, your application consumes data from the earliest record. During the running of the application, you can refresh the Subscription List tab in the console.
- If you reset the consumption offset by clicking Reset in the console during the consumption, your application automatically detects the change of the consumption offset and consumes data from the specified consumption offset. When the application catches `OffsetResetedException`, the application calls the `getSubscriptionOffset` method to query the latest consumption offset from the server. Then, the application can consume data from the latest consumption offset.
- Note that a shard in a subscription cannot be consumed by multiple threads or processes at the same time. Otherwise, the consumption offset submitted by a thread is overwritten by that submitted by another thread and the server cannot determine to which thread the saved consumption offset belongs. In this case, the server throws `OffsetSessionChangedException`. We recommend that you exit the subscription session to check whether data is repeatedly consumed if this exception is caught.

6.9. Collaborative consumption

6.9.1. Note

DataHub-client-library encapsulates the Java SDK and integrates the consumer for collaborative consumption and the producer for distributing data evenly among shards.

6.9.2. Overview

Offset-based data consumption

The offset-based data consumption feature allows you to save consumption offsets to the server. A consumption offset consists of the sequence number of a record and the timestamp when the record is written to DataHub.

You can create a subscription for a topic and submit the consumption offset to the server after specific data is consumed. When your application starts the next time, the application can obtain the consumption offset from the server and consume data from the next record. The consumption offsets must be saved on the server so that your application can consume data from a submitted consumption offset after shards are reallocated. This is a prerequisite for collaborative consumption.

You do not need to manually submit consumption offsets in the consumer. You only need to specify the interval of submitting consumption offsets in the configurations of the consumer. The system considers that the previous records are consumed when it reads records. If the interval of submitting consumption offsets is exceeded, the system submits a consumption offset again. If the consumption offset fails to be submitted and your application is interrupted, the consumption offset may fail to be submitted in time. In this case, your application may repeatedly consume specific data.

Collaborative consumption

The collaborative consumption feature automatically allocates shards when multiple consumers consume a topic at the same time. This feature simplifies the data processing of clients.

 **Note** Manual shard allocation is difficult because multiple consumers may reside on different machines. If multiple consumers that subscribe to the same topic are in the same consumer group, a shard can be allocated to only one consumer in the consumer group.

Example:

Assume that A, B, and C are three consumer instances and the topic has 10 shards.

1. When the consumer instance A is started at first, 10 shards are allocated to it.
2. When the other two consumer instances are started, the shards are reallocated in the following way: four to A, three to B, and three to C.
3. When one of the shards consumed by the consumer instance A is split into two and the two shards are released after consumption, the shards are reallocated in the following way: four to A, four to B, and three to C.
4. When the consumer instance C is stopped, the shards are reallocated in the following way: six to A and five to B.

Heartbeat

You must use the heartbeat feature to notify the server of the status of consumer instances. If the server has not received heartbeats from a consumer instance after the specified interval, the server considers that the consumer instance is stopped. When the status of a consumer instance changes, the server reallocates shards. The server returns the new allocation plan in heartbeat requests. Therefore, the client takes time to detect reallocation of shards.

6.9.3. Maven dependencies and JDK

Maven dependencies

```
<dependency>
  <groupId>com.aliyun.datahub</groupId>
  <artifactId>datahub-client-library</artifactId>
  <version>1.0.6-public</version>
</dependency>
```

JDK

```
jdk: >= 1.7
```

6.9.4. Use case

The following sample code is for reference only.

Initialize the producer

```
String endpoint = "http://dh-cn-hangzhou.aliyuncs.com";
String accessId = "<YourAccessKeyId>";
String accessKey = "<YourAccessKeySecret>";
String projectName = "<YourProjectName>";
String topicName = "<YourTopicName>";
ProducerConfig config = new ProducerConfig(endpoint, accessId, accessKey);
Producer producer = new Producer(projectName, topicName, config);
```

Write data to DataHub

```
RecordSchema schema = new RecordSchema();
schema.addField(new Field("field1", FieldType.STRING));
schema.addField(new Field("field2", FieldType.BIGINT));
List<RecordEntry> recordEntries = new ArrayList<>();
for (int cnt = 0; cnt < 10; ++cnt) {
    RecordEntry entry = new RecordEntry();
    entry.addAttribute("key1", "value1");
    entry.addAttribute("key2", "value2");
    TupleRecordData data = new TupleRecordData(schema);
    data.setField("field1", "testValue");
    data.setField("field2", 1);
    entry.setRecordData(data);
    recordEntries.add(entry);
}
int maxRetry = 3;
while (true) {
    try {
        producer.send(records, maxRetry);
        break;
    } catch (MalformedRecordException e) {
        // malformed RecordEntry
    } catch (InvalidParameterException e) {
        // invalid param
    } catch (ResourceNotFoundException e) {
        // project, topic or shard not found, sometimes caused by split/merge shard
    } catch (DatahubClientException e) {
        // network or other exceptions exceeded retry limit
    }
}
// close before exit
producer.close();
```

Initialize the consumer

```
String endpoint = "http://dh-cn-hangzhou.aliyuncs.com";
String accessId = "<YourAccessKeyId>";
String accessKey = "<YourAccessKeySecret>";
String projectName = "<YourProjectName>";
String topicName = "<YourTopicName>";
String SubId = "<YourSubscriptionId>";
// 1. If you need to use the collaborative consumption feature, specify the subscription ID.
ConsumerConfig config = new ConsumerConfig(endpoint, accessId, accessKey);
Consumer consumer = new Consumer(projectName, topicName, SubId, config);
// 2. If you need to use the offset-based data consumption feature instead of the collaborative consumption feature
, specify the subscription ID and the shards to be read by the consumer.
List<String> assignment = Arrays.asList("0", "1", "2");
ConsumerConfig config = new ConsumerConfig(endpoint, accessId, accessKey);
Consumer consumer = new Consumer(projectName, topicName, SubId, assignment, config);
// 3. If you do not need to use the collaborative consumption feature nor the offset-based data consumption feature,
specify the subscription ID, the shards to be read by the consumer, and the consumption offset.
Map<String, Offset> offsetMap = new HashMap<>();
// If both the sequence number and timestamp are specified but the sequence number is invalid, obtain the cursor
based on the timestamp.
offsetMap.put("0", new Offset(100, 1548573440756L));
// If only the sequence number is specified, obtain the cursor based on the sequence number.
offsetMap.put("1", new Offset().setSequence(1));
// If only the timestamp is specified, obtain the cursor based on the timestamp.
offsetMap.put("2", new Offset().setTimestamp(1548573440756L));
ConsumerConfig config = new ConsumerConfig(endpoint, accessId, accessKey);
Consumer consumer = new Consumer(projectName, topicName, SubId, offsetMap, config);
```

Read data from DataHub

```
int maxRetry = 3;
boolean stop = false;
while (! stop) {
    try {
        while (true) {
            RecordEntry record = consumer.read(maxRetry);
            if (record != null) {
                TupleRecordData data = (TupleRecordData) record.getRecordData();
                System.out.println("field1:" + data.getField(0) + ", field2:" + data.getField("field2"));
            }
        }
    } catch (SubscriptionSessionInvalidException | SubscriptionOffsetResetException e) {
        // subscription exception, will not recover
        // print some log or just use a new consumer
        consumer.close();
        consumer = new Consumer(TEST_PROJECT, TEST_TOPIC, TEST_SUB_ID, config);
    } catch (ResourceNotFoundException | InvalidParameterException e) {
        // - project, topic, shard, subscription not found
        // - seek out of range
        // - sometimes shard operation cause ResourceNotFoundException
        // should make sure if resource exists, print some log or just exit
    } catch (DatahubClientException e) {
        // - network or other exception exceed retry limit
        // can just sleep and retry
    }
}
// close before exit
consumer.close();
```

6.9.5. Usage notes

A consumer or producer cannot access DataHub by using multiple threads. If you need to use multiple threads, specify a different consumer or producer for each thread.

7. Quick BI

7.1. What is Quick BI?

This topic describes the concept and features of Quick BI.

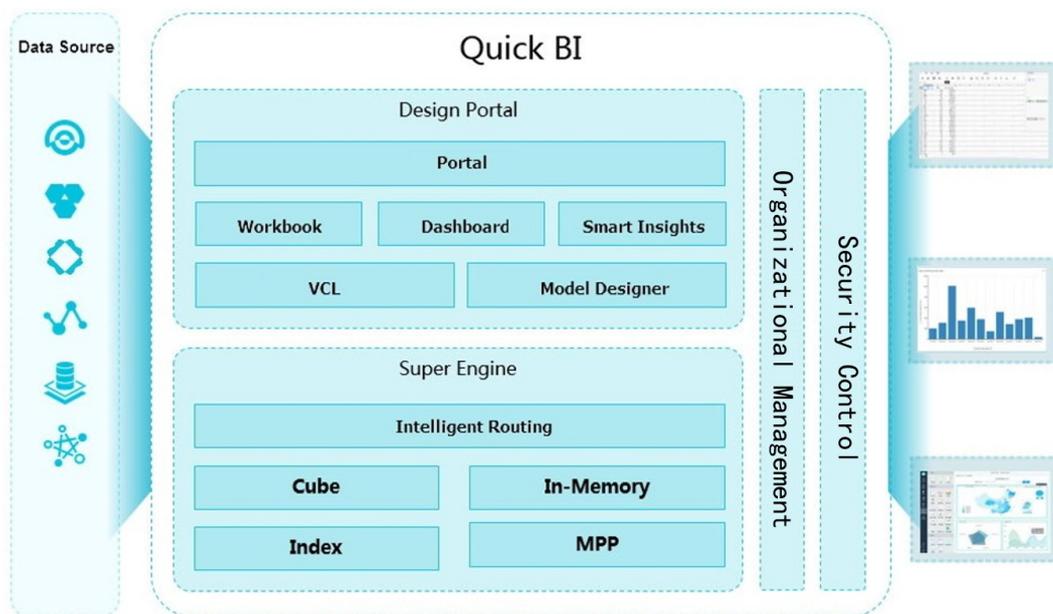

Quick BI is a flexible and lightweight self-service Business Intelligence (BI) tool based on cloud computing. It supports a wide range of data sources:

- MaxCompute (formerly known as ODPS) and ApsaraDB for RDS
- User-created MySQL and SQL Server databases that are hosted on ECS
- VPC data sources

Quick BI analyzes large amounts of data in real time and returns results within seconds. You do not need to preprocess the data. Quick BI analyzes terabytes of incremental data on a daily basis.

With an intelligent data modeling tool and a variety of visual chart tools, Quick BI significantly reduces data acquisition costs and makes it easier for you to use Quick BI features. This allows you to easily complete data analysis, self-service data acquisition, business data query, and report making.

Architecture

7.2. Log on to the Quick BI console

This topic describes how to log on to the Quick BI console.

Prerequisites

- The IP address or domain name of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console. The access address of the Apsara Uni-manager Management Console is `http://IP address or domain name of the Apsara Uni-manager Management Console/manage`.
- We recommend that you use the Google Chrome browser.

Context

If you are using a RAM account, you can use the domain name to log on to the Quick BI console. If you are using an Apsara Stack tenant account, log on to the Quick BI console by performing the following steps:

Procedure

1. In the address bar of the browser, enter the URL of the Apsara Uni-manager Management Console and press the Enter key.
2. Enter your username and password.

Obtain the username and password that are used to log on to the console from the operations administrator.

 **Note** If this is the first time you log on to the Apsara Uni-manager Management Console, you must change your password as prompted. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:

- Uppercase or lowercase letters.
- Digits.
- Special characters such as exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%).

3. Click **Login** to go to the homepage of Apsara Uni-manager Management Console.
4. In the top navigation bar, choose **Product > Big Data** and click **Quick BI**.
5. Select an organization and a region from the drop-down lists and click **Quick BI** or **Quick BI Console** to go to the Quick BI system.
 - You can click **Quick BI** to go to the product page.
 - You can click **Quick BI Console** to go to the settings page. You can manage organization members and workspaces on this page.

 **Note** If you use this method, the Apsara Stack tenant account `quickbi_admin@aliyun.com` is used to log on to the Quick BI console no matter which department you select.

7.3. Access mode

Quick BI can work in either development mode or access mode. You can view reports available to you only when Quick BI works in access mode, which provides higher data access efficiency and better user experience.

- You can view reports on the **Common**, **Favorites**, **Shared with Me**, and **Footprint** tabs, and in the **Business Navigation** section. You can click the **More** icon in the upper-right corner of a tab or section to show all reports. You can click **My Applications** to go to the destination application module and view its data.
 - You can view the reports that were accessed in the last 30 days on the **Footprint** tab.
 - You can view the top four report categories with the most visits in the **Business Navigation** section.

 **Note** In access mode, the configuration panel is unavailable.

- In development mode, only developers and analysts can edit reports in workspaces. Visitors cannot access the development mode.

7.4. Data modeling

7.4.1. Data modeling

Data modeling visualizes data and allows you to quickly identify and extract information. It also helps you make correct decisions based on data trends.

Steps of data modeling:

1. Create a data source.
2. Create a dataset.

7.4.2. Data sources

7.4.2.1. Overview

Datasets, workbooks, dashboards, and BI portals are all created based on data sources. Quick BI supports both cloud data sources and user-created data sources.

Cloud data sources include:

- MaxCompute
- MySQL
- SQL Server
- AnalyticDB for MySQL 2.0
- HybridDB for MySQL
- AnalyticDB for PostgreSQL
- PostgreSQL
- PPAS
- Data Lake Analytics
- Hive
- DRDS
- Presto
- AnalyticDB for MySQL 3.0
- PolarDB for MySQL

 **Note** VPCs only support MySQL and SQL Server data sources.

User-created data sources include:

- MySQL
- SQL Server
- PostgreSQL
- Oracle
- Hive
- Vertica
- IBM DB2 LUW
- SAP IQ (SybaseIQ)
- SAP HANA
- Presto

 **Note** You cannot check SQL Server data sources by using views.

7.4.2.2. Cloud data sources

7.4.2.2.1. Add the IP addresses of a Quick BI cluster to a database whitelist

This topic describes how to add the IP addresses of a Quick BI cluster to a database whitelist.

Prerequisites

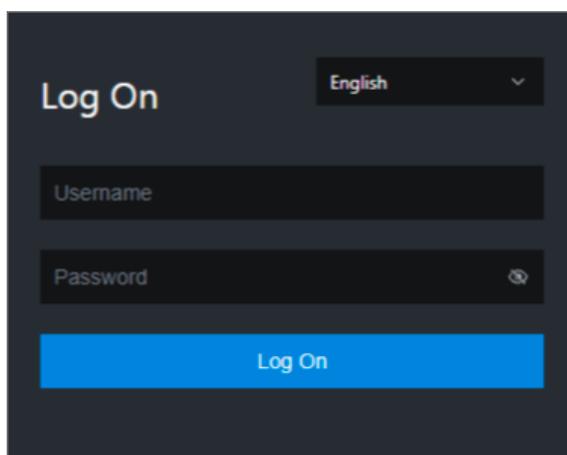

The Quick BI service is purchased.

Context

Before you add some data sources in the Quick BI console, you must first query available IP addresses of machines and add them to a whitelist of ApsaraDB RDS.

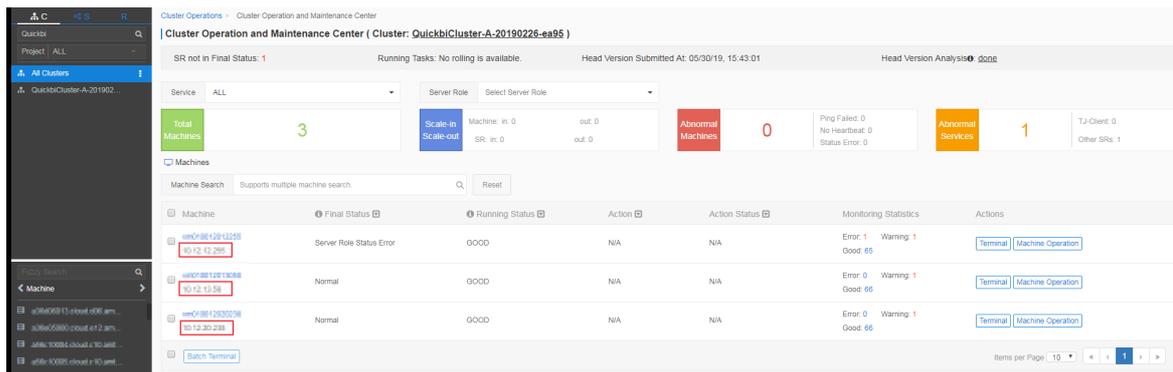

Procedure

1. Log on to the Apsara Infrastructure Management Framework console. Make sure that you have obtained the URL of the Apsara Uni-manager Operations Console, and the username and password used for logging on to the console from a deployment engineer or administrator.
 - i. Open a browser, enter the URL in the address bar, and press Enter. The URL is in the format of *ops.asconsole.intranet-domain-id.com*.

 **Note** We recommend that you use the Google Chrome browser. You can select a language from the drop-down list in the upper-right corner of the page.

- ii. Enter your username and password. If you log on to the Apsara Uni-manager Operations Console for the first time, you must change the password of your username.
 For security concerns, your password must contain the following characters:
 - Letters
 - Digits
 - Special characters, such as exclamation points (!), at signs (@), number signs (#), dollar signs (\$), and percent signs (%)
 - The password must be 10 to 20 characters in length.
 - iii. Click **Log On**.
 - iv. In the top navigation bar, click **O&M**.
 - v. In the left-side navigation pane, choose **Product Management > Products**.
 - vi. In the Apsara Stack O&M section, choose **Basic O&M > Apsara Infrastructure Management Framework**.
 - vii. In the left-side navigation pane of Infra. Operation Platform, choose **Operations > Cluster Operations**.
2. In the search box, select your project or enter the name of the Quick BI cluster. Find the cluster whose configurations you want to query. Click the cluster name or click **Operations** in the **Actions** column that corresponds to the cluster. The **Cluster Details** page appears.
 3. View the IP addresses of the Quick BI cluster on the **Machines** tab.

What's next

Add the IP addresses to an ApsaraDB RDS whitelist.

Before you add the IP addresses to an ApsaraDB RDS whitelist, change the last octet of all the addresses to 0/24. For example, if an IP address is 10.10.10.10, change it to 10.10.10.0/24. For more information about how to add an IP address to an ApsaraDB RDS whitelist, see "Configure a whitelist" in ApsaraDB RDS User Guide.

7.4.2.2.2. Add a MaxCompute data source

This topic describes how to add a MaxCompute data source.

Prerequisites

- A MaxCompute (formerly known as ODPS) project is created in the MaxCompute console.
- Parameter settings for connecting to the MaxCompute data source are obtained.

Procedure

1. [Create a data source](#).
2. Click **MaxCompute**. In the **Add MaxCompute Database** dialog box, configure the following

parameters.

3. Configure the parameters for connecting to the data source.

Parameter	Description
Name	The name of the data source.
Database Address	The default database address.
Project Name	The name of the project.
AccessKey ID	The AccessKey ID used to identify a visitor.
AccessKey Secret	The AccessKey secret is used to encrypt the signature string on the client and decrypt the signature string on the server for authentication. Keep the AccessKey secret confidential.

4. Click **Test Connection** to perform a data source connectivity test.

5. After the database passes the connectivity test, click **OK**. After the data source is added, the Data Sources page appears. Tables under the data source are listed on the right side of the page.

7.4.2.2.3. Add an ApsaraDB RDS for MySQL data source

This topic describes how to add an ApsaraDB RDS for MySQL data source.

Prerequisites

1. An ApsaraDB RDS for MySQL instance is created. For information about how to create an ApsaraDB for RDS instance, see "Create an instance" in ApsaraDB for RDS User Guide.
2. Available IP addresses of machines are obtained and added to a whitelist of the ApsaraDB for RDS instance. For information about how to query the IP addresses, see [Add the IP addresses of a Quick BI cluster to a database whitelist](#). For information about how to add the IP addresses to a whitelist of the ApsaraDB for RDS instance, see "Configure a whitelist" in ApsaraDB for RDS User Guide.
3. Parameter settings used to connect to the cloud data source ApsaraDB RDS for MySQL are obtained.

Procedure

1. [Create a data source.](#)
2. Click the **MySQL** card and configure the parameters in the dialog box that appears.

Add a cloud data source ApsaraDB RDS for MySQL

Add MySQL Database [X]

* Name: Enter a database name to be displayed.

* Database Address: Enter a hostname.

* Port Number: 3306

* Database: Enter a database name.

* Username: Enter a username.

* Password: Enter the password.

VPC Data Source:

* AccessKey ID: Enter the AccessKey ID.

* AccessKey Secret: Enter the AccessKey Secret.

* Instance ID: Enter the instance ID.

Note: To add IP addresses to the whitelist, log on to the RDS console and perform required operations. For more information about how to view the whitelisted IP addresses, see Quick BI User Guide > Create a data source > Data sources from cloud databases.

Close Test Connection OK

Note If the data source is connected over a VPC, select **VPC Data Source** and configure the parameters.

Parameter	Description
Name	The name of the data source, which is user-defined.
Database Address	The hostname or IP address of the database that is used as the data source.
Port Number	The port that you use to access the database. Default value: 3306.
Database	The name of the database that you want to access.
Username	The username that you use to access the database.
Password	The password that you use to access the database. Note If you do not know the username and password, contact the data warehouse administrator.

Parameter	Description
AccessKey ID	The AccessKey ID that you use to purchase the database instance.
AccessKey Secret	The AccessKey secret that you use to purchase the database instance.
Instance ID	The ID of the database instance.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

After a data source is added, you cannot add it again. If you attempt to add a data source for the second time, an error message appears.

7.4.2.2.4. Add an ApsaraDB RDS for SQL Server data source

This topic describes how to add an ApsaraDB RDS for SQL Server data source.

Prerequisites

1. An ApsaraDB RDS for SQL Server instance is created. For information about how to create an ApsaraDB for RDS instance, see "Create an instance" in ApsaraDB for RDS User Guide.
2. Available IP addresses of machines are obtained and added to a whitelist of the ApsaraDB for RDS instance. For information about how to query the IP addresses, see [Add the IP addresses of a Quick BI cluster to a database whitelist](#). For information about how to add the IP addresses to a whitelist of the ApsaraDB for RDS instance, see "Configure a whitelist" in ApsaraDB for RDS User Guide.
3. Parameter settings used to connect to the cloud data source ApsaraDB RDS for SQL Server are obtained.

Context

The method of using an ApsaraDB RDS for SQL Server database as a data source is similar to that of using an ApsaraDB RDS for MySQL database as a data source. The only difference is that you must set the Schema parameter when you use an ApsaraDB RDS for SQL Server database as a data source.

Procedure

1. [Create a data source](#).
2. Click the **SQL Server** card and configure the parameters in the dialog box that appears.

Add SQL Server Database ✕

* Name:

* Database Address:

* Port Number:

* Database:

Schema:

* Username:

* Password:

VPC Data Source: ⓘ

* AccessKey ID:

* AccessKey Secret:

* Instance ID:

ⓘ Note: To add IP addresses to the whitelist, log on to the RDS console and perform required operations. For more information about how to view the whitelisted IP addresses, see [Quick BI User Guide > Create a data source > Data sources from cloud databases.](#)

ⓘ **Note** If the data source is connected over a VPC, select **VPC Data Source** and configure the parameters.

Parameter	Description
Name	The name of the data source, which is user-defined.
Database Address	The hostname or IP address of the database that is used as the data source.
Port Number	The port that you use to access the database. Default value: 1433.
Database	The name of the database that you want to access.
Schema	The database schema. Default value: dbo.
Username	The username that you use to access the database.
Password	The password that you use to access the database.
AccessKey ID	The AccessKey ID that you use to purchase the database instance.
AccessKey Secret	The AccessKey secret that you use to purchase the database instance.
Instance ID	The ID of the database instance.

3. Click **Test Connection** to test connectivity with the database.

4. After the database passes the connectivity test, click **OK**.

7.4.2.2.5. Add an AnalyticDB for MySQL 2.0 data source

This topic describes how to add an AnalyticDB for MySQL 2.0 data source.

Prerequisites

An AnalyticDB database is created in the AnalyticDB console, and parameter settings used to connect to the AnalyticDB data source are obtained. For information about how to create an AnalyticDB database, see "Create a database" in AnalyticDB for MySQL User Guide.

Context

AnalyticDB for MySQL is formerly known as AnalyticDB.

Procedure

1. On the Data Sources page, click **Create Data Source** in the upper-right corner. For more information, see [Create a data source](#).
2. On the Add Data Source page, click the **Cloud Data Sources** tab. Then, click **AnalyticDB for MySQL 2.0** and set the parameters for connecting to the data source in the dialog box that appears.

The screenshot shows a dialog box titled "Add AnalyticDB for MySQL 2.0 Database". It contains the following fields and labels:

- Name:** Enter a database name to be displayed.
- Database Address:** Enter a hostname.
- Port Number:** 3306
- Database:** Enter a database name.
- AccessKey ID:** Enter the AccessKey ID.
- AccessKey Secret:** Enter the AccessKey Secret.

At the bottom of the dialog are three buttons: "Close", "Test Connection", and "Add".

Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database.
Database	The name of the database to which you want to access.
AccessKey ID	The AccessKey ID used to identify a visitor.
AccessKey Secret	The AccessKey secret is used to encrypt the signature string on the client and decrypt the signature string on the server for authentication. Keep the AccessKey secret confidential.

3. Click **Test Connection** to test connectivity with the data source.

4. After the connection is established, click **Add**.

7.4.2.2.6. Add a HybridDB for MySQL data source

This topic describes how to add a HybridDB for MySQL data source.

Prerequisites

1. A HybridDB for MySQL instance is created.
2. The available machine IP addresses are obtained and added to a whitelist of the HybridDB for MySQL instance. For more information about how to query the available IP addresses, see [Add the IP addresses of a Quick BI cluster to a database whitelist](#).
3. Parameter settings used to connect to the HybridDB for MySQL data source are obtained.

Context

The procedure for adding a HybridDB for MySQL data source is similar to that for adding an SQL Server data source. The only difference is that the default port is the port specific to HybridDB for MySQL.

Procedure

1. [Create a data source](#).
2. Click **HybridDB for MySQL** and configure the parameters for connecting to the data source in the dialog box that appears.

Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 3306.

Parameter	Description
Database	The name of the database to which you want to access.
Username	The username that you use to access the database.
Password	The password that you use to access the database.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.2.7. Add an AnalyticDB for PostgreSQL data source

This topic describes how to add an AnalyticDB for PostgreSQL data source.

Prerequisites

1. An AnalyticDB for PostgreSQL instance is created. For information about how to create an AnalyticDB for PostgreSQL instance, see "Create an instance" in AnalyticDB for PostgreSQL User Guide.
2. The available machine IP addresses are obtained and added to a whitelist of the AnalyticDB for PostgreSQL instance. For information about how to query the available IP addresses, see [Add the IP addresses of a Quick BI cluster to a database whitelist](#). For information about how to add the IP addresses to a whitelist of the AnalyticDB for PostgreSQL instance, see "Configure a whitelist" in AnalyticDB for PostgreSQL User Guide.
3. Parameter settings used to connect to the AnalyticDB for PostgreSQL data source are obtained.

Context

The procedure for adding an AnalyticDB for PostgreSQL data source is similar to that for adding an SQL Server data source. The default port is the port specific to AnalyticDB for PostgreSQL.

Procedure

1. [Create a data source](#).
2. Click the **AnalyticDB for PostgreSQL** card and configure the parameters for connecting to the data source in the dialog box that appears.

Add AnalyticDB for PostgreSQL Database ✕

* Name:

* Database Address:

* Port Number:

* Database:

Schema:

* Username:

* Password:

! Note: To add IP addresses to the whitelist, log on to the RDS console and perform required operations. For more information about how to view the whitelisted IP addresses, see [Quick BI User Guide > Create a data source > Data sources from cloud databases.](#)

Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port that you use to access the database. Default value: 5432.
Database	The name of the database to which you want to access.
Schema	The database schema. Default value: public.
Username	The username used to access the database.
Password	The password that you use to access the database.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.2.8. Add an AnalyticDB for PostgreSQL data source

This topic describes how to add an AnalyticDB for PostgreSQL data source.

Prerequisites

1. An RDS for PostgreSQL instance is created. For information about how to create an ApsaraDB for RDS instance, see "Create an instance" in ApsaraDB for RDS User Guide.
2. Available IP addresses of machines are obtained and added to a whitelist of the ApsaraDB for RDS instance. For information about how to query the IP addresses, see [Add the IP addresses of a Quick BI cluster to a database whitelist](#). For information about how to add the IP addresses to a whitelist of the ApsaraDB for RDS instance, see "Configure a whitelist" in ApsaraDB for RDS User Guide.
3. Parameter settings used to connect to a cloud data source AnalyticDB for PostgreSQL are obtained.

Procedure

1. Create a data source.
2. Click **PostgreSQL** and configure the required parameters in the dialog box that appears.

Add PostgreSQL Database

* Name: Enter a database name to be displayed.

* Database Address: Enter a hostname or an IP address.

* Port Number: 5432

* Database: Enter a database name.

Schema: public

* Username: Enter a username.

* Password: Enter the password.

SSL:

① Note: To add IP addresses to the whitelist, log on to the RDS console and perform required operations. For more information about how to view the whitelisted IP addresses, see Quick BI User Guide > Create a data source > Data sources from cloud databases.

Close Test Connection Add

Note After you select the **SSL** option, the data source supports the interactive query service MaxCompute Lightning provided by MaxCompute.

Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port that you use to access the database. Default value: 5432.
Database	The name of the database that you want to access.
Schema	Default value: public.
Username	The username that you use to access the database.
Password	The password that you use to access the database.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.2.9. Add an ApsaraDB RDS for PPAS data source

This topic describes how to add an ApsaraDB RDS for PPAS data source.

Prerequisites

1. An RDS for PPAS instance is created. For information about how to create an ApsaraDB for RDS instance, see "Create an instance" in ApsaraDB for RDS User Guide.
2. The available IP addresses are obtained and added to a whitelist of the ApsaraDB for RDS instance. For information about how to query the IP addresses, see [Add the IP addresses of a Quick BI cluster to a database whitelist](#). For information about how to add IP addresses to a whitelist of the ApsaraDB for RDS instance, see "Configure a whitelist" in ApsaraDB for RDS User Guide.
3. Parameter settings used to connect to the PPAS data source are obtained.

Procedure

1. On the Data Sources page, click Create Data Source in the upper-right corner. For more information, see [Create a data source](#).
2. Click the PPAS card and configure the parameters for connecting to the data source in the dialog box that appears.

Parameter	Description
Name	The name of the data source that is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port that you use to access the database. Default value: 5432.
Database	The name of the database that you want to access.
Schema	The database schema. Default value: public.
Username	The username that you use to access the database.
Password	The password that you use to access the database.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.2.10. Add a cloud data source Data Lake Analytics

This topic describes how to add a cloud data source Data Lake Analytics (DLA).

Prerequisites

Parameter settings used to connect to the cloud data source DLA are obtained.

Procedure

1. [Create a data source](#).
2. Click the **Data Lake Analytics** card and configure the required parameters in the dialog box that appears.

Parameter	Description
Name	The name of the data source, which is user-defined.
Database Address	The hostname or IP address of the database that is used as the data source.
Port Number	The port that you use to access the database. Default value: 10000.
Database	The name of the database that you want to access.
Username	The username that you use to access the database.
Password	The password that you use to access the database.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **Add**.

7.4.2.2.11. Add a Hive data source

This topic describes how to add a Hive data source.

Prerequisites

Parameter settings used to connect to the Hive data source are obtained.

Procedure

1. [Create a data source](#).
2. Click **Hive** and configure the parameters for connecting to the data source in the dialog box that appears.

Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 10000.
Database	The name of the database to which you want to access.
Username	The username that you use to access the database.
Password	The password that you use to access the database.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.2.12. Add a PolarDB-X data source

This topic describes how to add a PolarDB-X data source.

Prerequisites

- A PolarDB-X instance is created. For information about how to create a PolarDB-X instance, see "Create an instance" in PolarDB-X User Guide.
- Available IP addresses of machines are obtained and manually added to a whitelist of the PolarDB-X instance. For information about how to query the IP addresses, see [Add the IP addresses of a Quick BI cluster to a database whitelist](#). For information about how to add the IP addresses to a whitelist of the PolarDB-X instance, see "Configure a whitelist" in PolarDB-X User Guide.
- Parameter settings used to connect to the PolarDB-X data source are obtained.

Procedure

1. [Create a data source](#).
2. On the Add Data Source page, click the Cloud Data Sources tab. Then, click the **DRDS** card and configure the parameters for connecting to the data source in the dialog box that appears.

Add DRDS Database

* Name: Enter a database name to be displayed.

* Database Address: Enter a hostname or an IP address.

* Port Number: 3306

* Database: Enter a database name.

* Username: Enter a username.

* Password: Enter the password.

Note: To add IP addresses to the whitelist, log on to the RDS console and perform required operations. For more information about how to view the whitelisted IP addresses, see Quick BI User Guide > Create a data source > Data sources from cloud databases.

Close Test Connection Add

Parameter	Description
Name	The name of the data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port that you use to access the database. Default value: 3306.
Database	The name of the database that you want to access.
Username	The username that you use to access the database.
Password	The password that you use to access the database.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.2.13. Add a cloud Presto data source

This topic describes how to add a cloud Presto data source.

Prerequisites

Parameter settings used to connect to the Presto data source are obtained.

Procedure

1. On the Data Sources page, click **Create Data Source** in the upper-right corner. For more information, see [Create a data source](#).
2. On the Add Data Source page, click the **Cloud Data Sources** tab. Then, click **Presto** and set the parameters for connecting to the data source in the dialog box that appears.

Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 3306.
catalog	The name of the data source that you want to use Presto to query.
Schema	The current logon username is used by default.
Username	The username used to access the database.
Password	The password used to access the database.

3. Click **Test Connection** to test connectivity with the database.
4. After the connection is established, click **Add**.

7.4.2.2.14. Add an AnalyticDB for MySQL V3.0 data source

This topic describes how to add an AnalyticDB for MySQL V3.0 data source.

Prerequisites

An AnalyticDB for MySQL database is created in the AnalyticDB for MySQL console, and parameter settings for connecting to the database are obtained. For information about how to create an AnalyticDB for MySQL database, see "Create a database" in AnalyticDB for MySQL User Guide.

Context

AnalyticDB for MySQL is formerly known as AnalyticDB.

Procedure

1. **Create a data source.**
2. Click the **AnalyticDB for MySQL 3.0** card and configure the required parameters in the dialog box that appears.

The screenshot shows a dialog box titled "Add AnalyticDB for MySQL 3.0 Database". It contains the following fields and labels:

- * Name: Enter a database name to be displayed.
- * Database Address: Enter a hostname.
- * Port Number: 3306
- * Database: Enter a database name.
- * Account: Enter an account
- * Password: Enter the password.

At the bottom of the dialog are three buttons: "Close", "Test Connection", and "Add".

Parameter	Description
Name	The name of the data source that is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port that you use to access the database.
Database	The name of the database that you want to access.
Account	The username that you use to access the database.
Password	The password that you use to access the database.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.2.15. Add a PolarDB for MySQL data source

This topic describes how to add a PolarDB for MySQL data source.

Prerequisites

Parameter settings used to connect to the PolarDB for MySQL data source are obtained.

Procedure

1. **Create a data source.**
2. Click the **PolarDB for MySQL** card and configure the required parameters in the dialog box that appears.

Note If the data source is connected over a VPC, select VPC Data Source and configure the required parameters.

Add PolarDB for MySQL Database
✕

* Name:

* Database Address:

* Port Number:

* Database:

* Username:

* Password:

VPC Data Source:

* AccessKey ID:

* AccessKey Secret:

* Cluster ID:

* Region:

Note: To add IP addresses to the whitelist, log on to the RDS console and perform required operations. For more information about how to view the whitelisted IP addresses, see Quick BI User Guide > Create a data source > Data sources from cloud databases.

Close
Test Connection
Add

Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 3306.
Database	The name of the database to which you want to access.
Username	The username that you use to access the database.
Password	The password that you use to access the database.
AccessKey ID	The AccessKey ID that you use to purchase the instance where the database resides.
AccessKey Secret	The AccessKey Secret that you use to purchase the instance where the database resides.
Cluster ID	The ID of the cluster.
Region	The region where the instance resides.

Parameter	Description
-----------	-------------

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.3. User-created data sources

7.4.2.3.1. Add a user-created MySQL data source

This topic describes how to add a user-created MySQL data source.

Prerequisites

Parameter settings used to connect to the MySQL database are obtained.

Context

The procedure for configuring a user-created MySQL data source is similar to that for configuring an ApsaraDB RDS for MySQL data source. You must perform the following operations to open the specific port of the firewall to allow Quick BI to access the MySQL database:

1. Run the following command to open the configuration file of the firewall:

```
vi /etc/sysconfig/iptables
```

2. Add the following command to the configuration file:

```
-A RH-Firewall-1-INPUT -m state --state NEW -m tcp -p tcp --dport 3306 -j ACCEPT
```

3. Restart the iptable service after the configuration is complete.

```
service iptables restart
```

Procedure

1. Go to the Add Data Source page. For more information, see [Add a data source](#).
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click **MySQL** and configure the parameters for connecting to the database in the dialog box that appears.

Add PolarDB for MySQL Database ✕

* **Name:**

* **Database Address:**

* **Port Number:**

* **Database:**

* **Username:**

* **Password:**

VPC Data Source:

* **AccessKey ID:**

* **AccessKey Secret:**

* **Cluster ID:**

* **Region:** ▼

Note: To add IP addresses to the whitelist, log on to the RDS console and perform required operations. For more information about how to view the whitelisted IP addresses, see Quick BI User Guide > Create a data source > Data sources from cloud databases.

Close
Test Connection
Add

Note If you select `ssh`, you can access the database by using an SSH tunnel.

Parameter	Description
Name	The name of the data source.
Database Address	The hostname or IP address of the database that is used as the data source.
Port Number	The port that you use to access the database. Default value: 3306.
Database	The name of the database that you want to access.
Username	The username that you use to access the database.
Password	The password that you use to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username that you use to access the SSH host.
SSH Password	The password that you use to access the SSH host.
SSH Port Number	The port number that you use to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.3.2. Add a user-created SQL Server data source

This topic describes how to add a user-created SQL Server data source.

Prerequisites

Parameter settings used to connect to the SQL Server database are obtained.

Context

The procedure for configuring a user-created SQL Server data source is similar to that for configuring an ApsaraDB RDS for SQL Server data source. You must perform the following operations to open the specified port of the firewall to allow Quick BI to access the SQL Server database:

1. Run the following command to open the configuration file of the firewall:

```
vi /etc/sysconfig/iptables
```

2. Add the following command to the configuration file:

```
-A RH-Firewall-1-INPUT -m state --state NEW -m tcp -p tcp --dport 3306 -j ACCEPT
```

3. After the configuration is complete, run the following command to restart the iptable service:

```
service iptables restart
```

Procedure

1. Go to the Add Data Source page. For more information, see [Add a data source](#).
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click the **SQL Server** card and configure the parameters for connecting to the database in the dialog box that appears.

Add SQL Server Database
✕

* Name:

* Database Address:

* Port Number:

* Database:

Schema:

* Username:

* Password:

ssh:

SSH Host:

SSH Username:

SSH Password:

SSH Port Number:

Note: To add IP addresses to the whitelist, log on to the RDS console and perform required operations. For more information about how to view the whitelisted IP addresses, see Quick BI User Guide > Create a data source > Data sources from cloud databases.

Close
Test Connection
Add

Note If you select ssh, you can access the data source by using an SSH tunnel.

Parameter	Description
Name	The name of the data source.
Database Address	The hostname or IP address of the database.
Port	The port that you use to access the database. Default value: 1433.
Database	The name of the database that you want to access.
Schema	The database schema. Default value: dbo.
Username	The username that you use to access the database.
Password	The password that you use to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username that you use to access the SSH host.
SSH Password	The password that you use to access the SSH host.

Parameter	Description
SSH Port Number	The port number that you use to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **Add**.

 **Note** You cannot add a data source that has been added. If you attempt to add it again, an error message appears.

7.4.2.3.3. Add a user-created PostgreSQL data source

This topic describes how to add a user-created PostgreSQL data source.

Prerequisites

Parameter settings used to connect to the PostgreSQL database are obtained.

Context

The procedure for configuring a user-created PostgreSQL data source is similar to that for configuring an ApsaraDB RDS for PostgreSQL data source. You must perform the following operations to open the specified port of the firewall to allow Quick BI to access the PostgreSQL database:

1. Run the following command to open the configuration file of the firewall:

```
vi /etc/sysconfig/iptables
```

2. Add the following command to the configuration file:

```
-A RH-Firewall-1-INPUT -m state --state NEW -m tcp -p tcp --dport 5432 -j ACCEPT
```

3. After the configuration is complete, run the following command to restart the iptables service:

```
service iptables restart
```

Procedure

1. [Create a data source](#).
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click the **PostgreSQL** card and configure the parameters for connecting to the database in the dialog box that appears.

Add PostgreSQL Database

Add

Note If the data source is connected over a VPC, select **User-created ECS Data Source (VPC)** and configure the parameters. If you select **SSL**, MaxCompute Lightning is supported. If you select **ssh**, you can access the data source by using an SSH tunnel.

Parameter	Description
Name	The name of the data source.
Database Address	The IP address of the database.
Port Number	The port that you use to access the database. Default value: 5432.
Database	The name of the database that you want to access.
Schema	The database schema. Default value: public.
Username	The username that you use to access the database.

Parameter	Description
Password	The password that you use to access the database.
AccessKey ID	The AccessKey ID that you use to purchase the instance where the database resides.
AccessKey Secret	The AccessKey secret that you use to purchase the instance where the database resides.
Instance ID	The ID of the instance.
ECS Instance Region	The region where the data source is located.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username that you use to access the SSH host.
SSH Password	The password that you use to access the SSH host.
SSH Port Number	The port number that you use to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.3.4. Add a user-created Oracle data source

This topic describes how to add a user-created Oracle data source.

Prerequisites

Parameter settings used to connect to the Oracle database are obtained.

Procedure

1. [Add a data source](#).
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click the **Oracle** card and configure the parameters for connecting to the database in the dialog box that appears.

? **Note** If you select `ssh`, you can access the data source by using an SSH tunnel.

Parameter	Description
Name	The name to be displayed for the connected data source.
Database Address	Set the parameter to IP address.
Port Number	The port number of the database. The default port is 1521.
Database	The name of the database to which you want to access.
Schema	The schema of the database. The default value is public.
Username	The username that you use to access the database.
Password	The password that you use to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username that you use to access the SSH host.
SSH Password	The password that you use to access the SSH host.
SSH Port Number	The port number used to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.3.5. Add a self-managed Hive data source

This topic describes how to add a self-managed Hive data source.

Prerequisites

Parameter settings for connecting to the Hive data source are obtained.

Procedure

1. [Create a data source.](#)
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click **Hive** and set the parameters for connecting to the data source in the dialog box that appears.

The screenshot shows a dialog box titled "Add Hive Database" with a close button (X) in the top right corner. The dialog contains the following fields and values:

- Name:** * Name: Enter a database name to be displayed. (Required)
- Database Address:** * Database Address: IP
- Port Number:** * Port Number: 10000
- Database:** * Database: Enter a database name. (Required)
- Username:** * Username: Enter a username. (Required)
- Password:** * Password: Enter the password. (Required)
- ssh:** ssh:
- SSH Host:** SSH Host: Enter a hostname or an IP address.
- SSH Username:** SSH Username: Enter a username.
- SSH Password:** SSH Password: Enter the password.
- SSH Port Number:** SSH Port Number: 22

At the bottom of the dialog, there are three buttons: "Close", "Test Connection", and "Add".

Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	Set the parameter to IP address.
Port Number	The port number of the database. The default port is 10000.
Database	The name of the database to which you want to access.
Username	The username used to access the database.
Password	The password used to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username used to access the SSH host.

Parameter	Description
SSH Password	The password used to access the SSH host.
SSH Port Number	The port number that you use to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.3.6. Add a self-managed Vertica data source

This topic describes how to add a self-managed Vertica data source.

Prerequisites

Parameter settings for connecting to the Vertica data source are obtained.

Procedure

1. [Create Data Source](#).
2. Click the **Vertica** icon and set the parameters for connecting to the data source in the dialog box that appears.

The screenshot shows a dialog box titled "Add Vertica Database" with a close button (X) in the top right corner. The dialog contains the following fields and values:

- Name:** * Name: Enter a database name to be displayed.
- Database Address:** * Database Address: IP
- Port Number:** * Port Number: 5433
- Database:** * Database: Enter a database name.
- Schema:** Schema: public
- Username:** * Username: Enter a username.
- Password:** * Password: Enter the password.
- ssh:** ssh:
- SSH Host:** SSH Host: Enter a hostname or an IP address.
- SSH Username:** SSH Username: Enter a username.
- SSH Password:** SSH Password: Enter the password.
- SSH Port Number:** SSH Port Number: 22

At the bottom of the dialog, there are three buttons: "Close", "Test Connection", and "Add".

Parameter	Description
Name	The name to be displayed for the connected data source.
Database Address	The hostname or IP address of the database.

Parameter	Description
Port Number	The port number of the database. The default port is 5433.
Database	The name of the database to which you want to access.
Schema	The schema of the database. The default value is public.
Username	The username used to access the database.
Password	The password used to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username used to access the SSH host.
SSH Password	The password used to access the SSH host.
SSH Port Number	The port number used to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.3.7. Add a user-created IBM DB2 LUW data source

This topic describes how to add a user-created IBM DB2 LUW data source.

Prerequisites

Parameter settings for connecting to the IBM DB2 LUW data source are obtained.

Procedure

1. [Create a data source](#).
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click **IBM DB2 LUW** and set the parameters for connecting to the data source in the dialog box that appears.

Parameter	Description
Name	The name to be displayed for the connected data source.
Database Address	The IP address of the database.
Port Number	The port number of the database. The default port is 50000.
Database	The name of the database that you want to access.
Schema	The schema of the database. The default value is DB2INST1.
Username	The username that you use to access the database.
Password	The password that you use to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username that you use to access the SSH host.
SSH Password	The password that you use to access the SSH host.
SSH Port Number	The port number used to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.3.8. Add a user-created SAP IQ (Sybase IQ) data source

This topic describes how to add a user-created SAP IQ (Sybase IQ) data source.

Prerequisites

Parameter settings for connecting to the SAP IQ (Sybase IQ) data source are obtained.

Procedure

1. On the Data Sources page, click Create Data Source in the upper-right corner. For more information, see [Create a data source](#).
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click **SAP IQ (Sybase IQ)** and set the parameters for connecting to the data source in the dialog box that appears.

Parameter	Description
Name	The name to be displayed for the connected data source.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 2638.
Database	The name of the database that you want to access.
Schema	The schema of the database. The default value is sybase.
Username	The username used to access the database.
Password	The password used to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username used to access the SSH host.
SSH Password	The password used to access the SSH host.

Parameter	Description
SSH Port Number	The port number used to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the data source.
4. After the connection is established, click **Add**.

7.4.2.3.9. Add a user-created SAP HANA data source

This topic describes how to add a user-created SAP HANA data source.

Prerequisites

Parameter settings used to connect to the SAP HANA database are obtained.

Procedure

1. [Create a data source](#).
2. On the Add Data Source page, click the User-created Data Sources tab. Then, click the **SAP HANA** card and configure the parameters for connecting to the data source in the dialog box that appears.

Add SAP HANA Database

Add

Note If you select **ssh**, you can access the database by using an SSH tunnel.

Parameter	Description
Name	The name to be displayed for the connected data source.
Database Address	The hostname or IP address of the database.

Parameter	Description
Port Number	The port that you use to access the database. Default value: 30015.
Database	The name of the database that you want to access.
Schema	The database schema. Default value: public.
Username	The username that you use to access the database.
Password	The password that you use to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username used to access the SSH host.
SSH Password	The password used to access the SSH host.
SSH Port Number	The port number used to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the database.
4. After the database passes the connectivity test, click **OK**.

7.4.2.3.10. Add a user-created Presto data source

This topic describes how to add a user-created Presto data source.

Prerequisites

Parameter settings for connecting to the Presto data source are obtained.

Procedure

1. On the Data Sources page, click **Create Data Source** in the upper-right corner. For more information, see [Create a data source](#).
2. On the Add Data Source page, click the **User-created Data Sources** tab. Then, click **Presto** and set the parameters for connecting to the data source in the dialog box that appears.

Add Presto Database
✕

* Name:

* Database Address:

* Port Number:

* catalog:

Note: To add IP addresses to the whitelist, log on to the RDS console and perform required operations. For more information about how to view the whitelisted IP addresses, see Quick BI User Guide > Create a data source > Data sources from cloud databases.

Close
Test Connection
Add

Note If you select `ssh`, you can access the data source by using an SSH tunnel.

Parameter	Description
Name	The name to be displayed for the connected data source, which is user-defined.
Database Address	The hostname or IP address of the database.
Port Number	The port number of the database. The default port is 3306.
catalog	The name of the data source that you want to use Presto to query.
Schema	The current logon username is used by default.
Username	The username used to access the database.
Password	The password used to access the database.
SSH Host	The hostname or IP address of the SSH host.
SSH Username	The username used to access the SSH host.
SSH Password	The password used to access the SSH host.

Parameter	Description
SSH Port Number	The port number used to access the SSH host. Set the value to 22.

3. Click **Test Connection** to test connectivity with the data source.
4. After the connection is established, click **Add**.

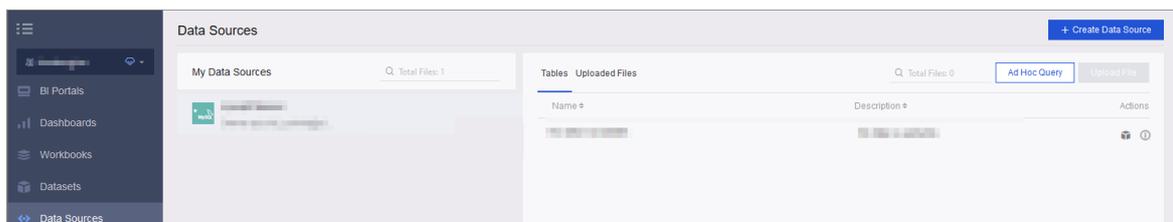

7.4.2.4. Go to the Data Sources page

This topic describes how to go to the Data Sources page.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.

On this page, you can manage data sources. For example, you can **create**, **edit**, **replace**, and **delete** a data source.

7.4.2.5. Create a data source

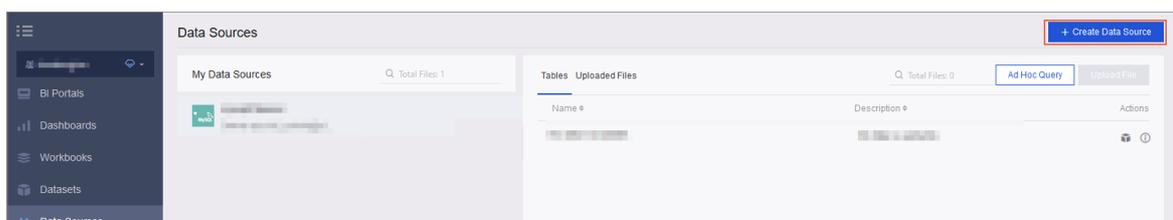

This topic describes how to create a data source.

Prerequisites

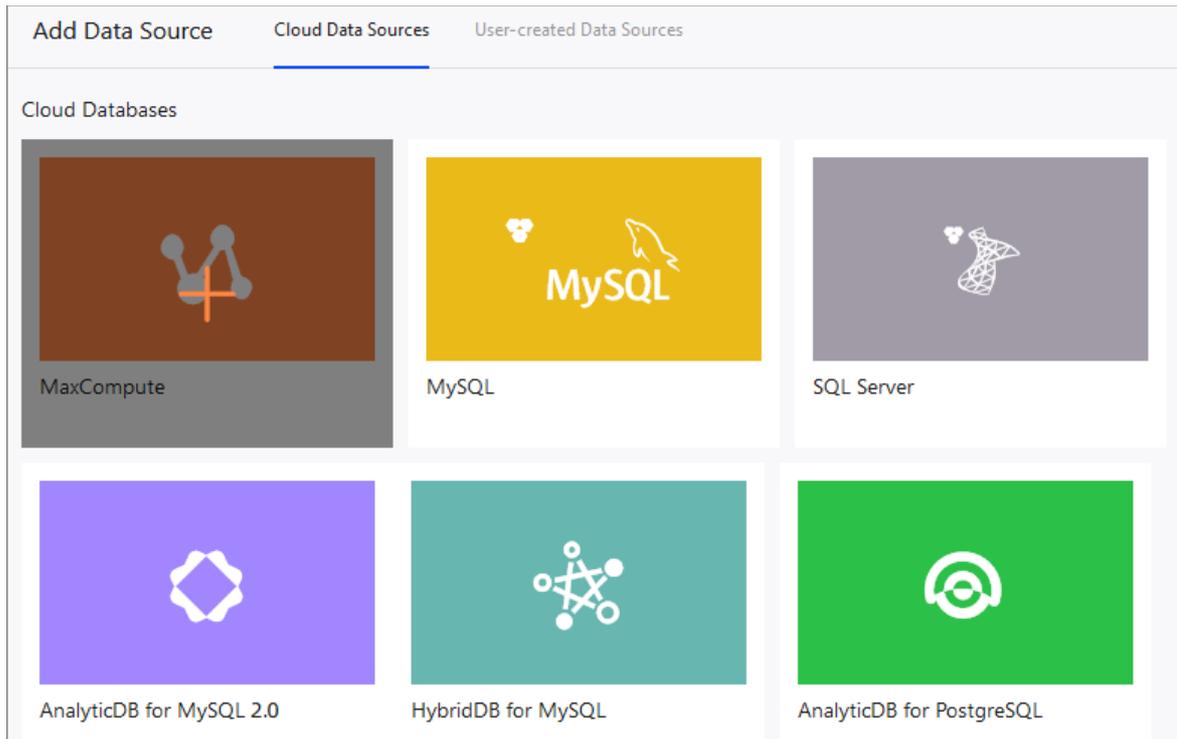

The Quick BI service is purchased.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane of the workspace page, click **Data Sources**.
4. In the upper-right corner of the Data Sources page, click **Create Data Source**.

5. In the **Add Data Source** dialog box, select a data source.

- If you want to add a cloud data source, click the **Cloud Data Sources** tab.
 - If you want to add a user-created data source, click the **User-created Data Sources** tab.
6. Select the data source type. In the dialog box that appears, enter the information required for connecting to the data source, and click **OK**.

7.4.2.6. Edit a data source

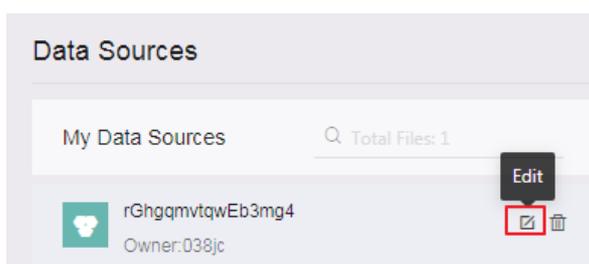

This topic describes how to edit a data source.

Prerequisites

- The Quick BI service is purchased.
- A data source is created.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.
4. Find the data source that you want to edit in the data source list.
5. Click the  icon and edit the data source.

7.4.2.7. Replace a data source

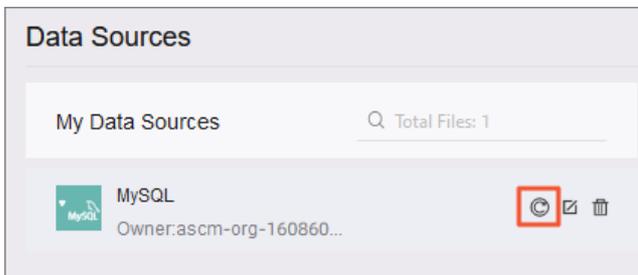

This topic describes how to replace a data source.

Prerequisites

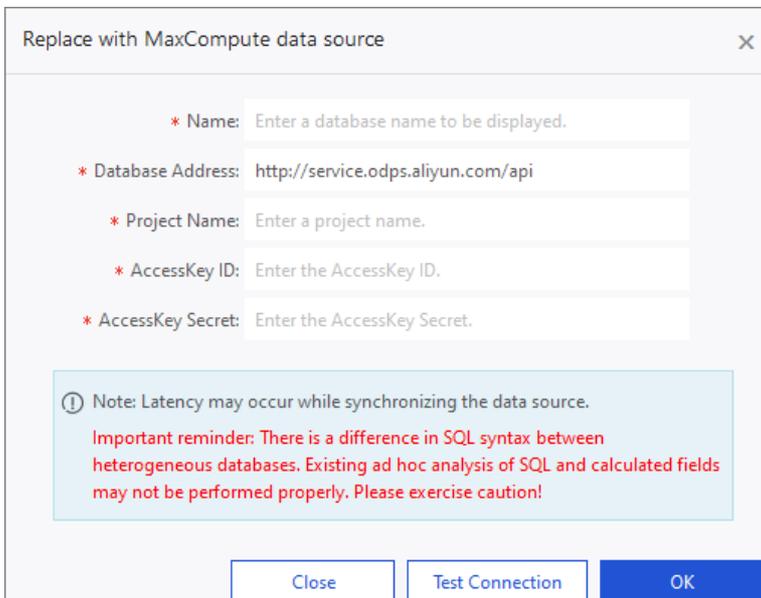

- The Quick BI service is purchased.
- A data source is created.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.
4. Find the data source that you want to replace in the data source list.
5. Click the  icon and replace the data source with another one.

6. In the **Replace Data Source** dialog box, click the target data source and configure the parameters in the dialog box that appears.

7. After the parameters are configured, click **Test Connection**.
8. After the data source passes the connectivity test, click **OK**.

7.4.2.8. Delete a data source

This topic describes how to delete a data source.

Prerequisites

- The Quick BI service is purchased.
- A data source is created.

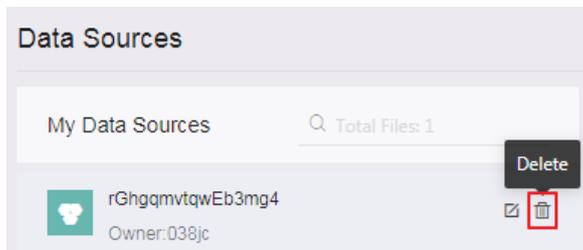

Context

If you have created datasets based on a data source, you cannot delete the data source.

✘ Cannot delete this data source; it has associated datasets.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.
4. Find the data source that you want to delete in the data source list.
5. Click the  icon to delete the data source.

7.4.2.9. Search for a data source

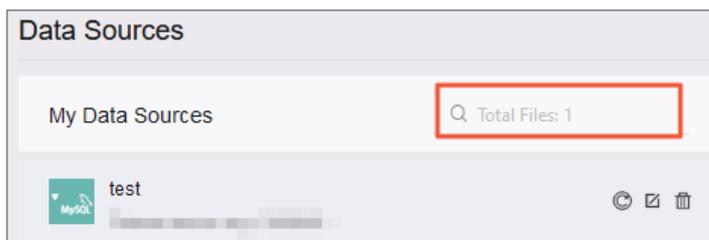

This topic describes how to search for a data source.

Prerequisites

- The Quick BI service is purchased.
- A data source is created.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.
4. On the Data Sources page, enter a keyword of the data source that you want to search for in the search box.

5. Click the  icon.

7.4.2.10. Search for a table under a data source

This topic describes how to search for a specific table under a data source.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.
4. Select the target data source. All tables under the data source are listed in the right-side part of the page.
5. Enter a keyword of the table that you want to search in the search box.

6. Click the  icon.

7.4.2.11. View the details of a table under a data source

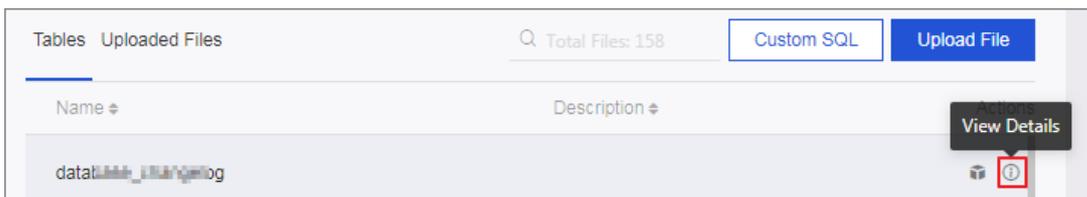

Quick BI allows you to view the tables and table details under a data source.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.
4. Select the target data source. All tables under the data source are listed in the right-side part of the page.
5. Find the table whose details you want to view and click the  icon in the Actions column.

7.4.3. Datasets

7.4.3.1. Overview of datasets

You can use tables from data sources to create datasets. The following topics describe common operations on datasets, for example, create, edit, and query a dataset.

You can use one of the following three methods to create a dataset:

- Create a dataset from a data source.
- Create a dataset by uploading a file.
- Create a dataset by using an SQL statement for ad hoc query.

7.4.3.2. Create datasets

7.4.3.2.1. Create a dataset based on a data source

This topic describes how to create a dataset based on a data source.

Prerequisites

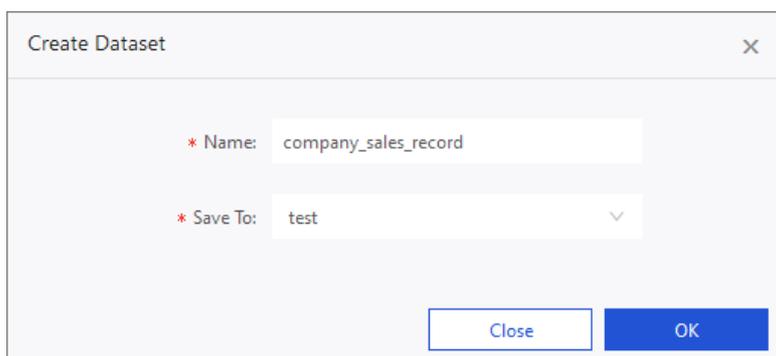

The Quick BI service is purchased.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.
4. On the Data Sources page, click the required data source. All tables under the data source are listed in the right part of the page.
5. Find the required table and click the  icon in the Actions column.

6. In the Create Dataset dialog box, enter a dataset name and location, and click **OK**.

A screenshot of the 'Create Dataset' dialog box. The dialog has a title bar with 'Create Dataset' and a close button. It contains two required fields: '* Name:' with the value 'company_sales_record' and '* Save To:' with a dropdown menu set to 'test'. At the bottom, there are two buttons: 'Close' and 'OK'.

After the dataset is created, the **Datasets** page appears. The new dataset is displayed in the dataset list and marked with NEW.

7.4.3.2.2. Create a dataset by uploading a file

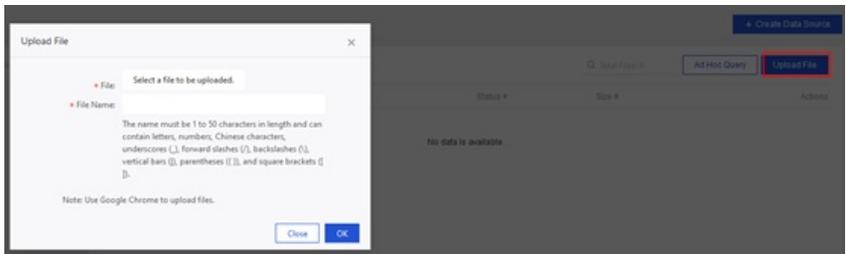

This topic describes how to create a dataset by uploading a file.

Prerequisites

- The Quick BI service is purchased.
- A data source is created.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Data Sources**.
4. On the Data Sources page, click a data source, and then click **Upload File** in the upper-right corner of the page.
5. In the **Upload File** dialog box, select the target file, enter a file name, and then click **OK**.

Note After the file is uploaded, the Uploaded Files page appears.

6. On the Uploaded Files page, find the file you uploaded and click the  icon in the Actions column to create a dataset.

7.4.3.2.3. Create a dataset by using an SQL statement for ad hoc queries

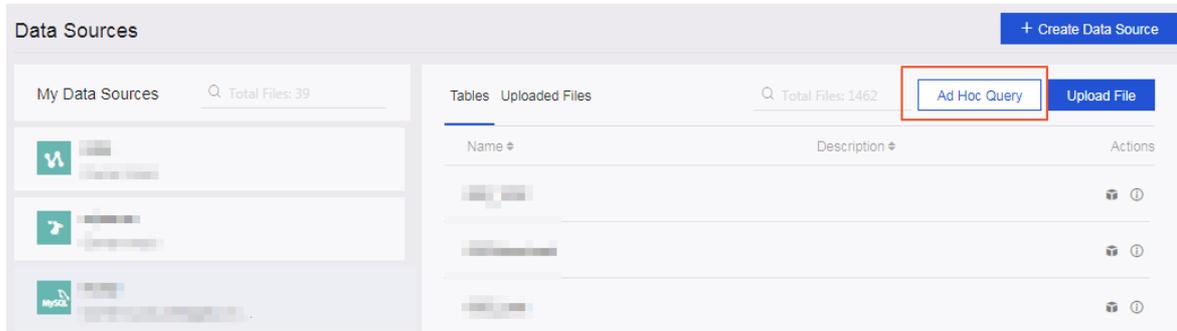

This topic describes how to create a dataset by using an SQL statement for ad hoc query to implement some complex logic for data modeling. Ad hoc queries support dynamic parameter passing to SQL statements. Modeling analysis based on dynamic parameter passing to SQL statements increases the depth of scenarios supported by Quick BI. This meets the requirements of complex data analysis scenarios.

Prerequisites

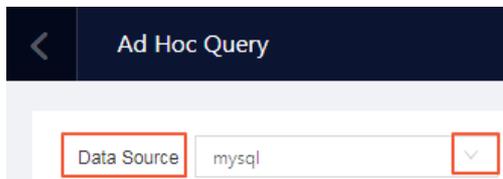

The Quick BI service is purchased.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane of the Workspace page, click **Data Sources**.
4. In the upper-right corner of the **Data Sources** page, click **Ad Hoc Query**.

5. On the **Ad Hoc Query** page, specify a data source.

6. Enter an SQL statement.

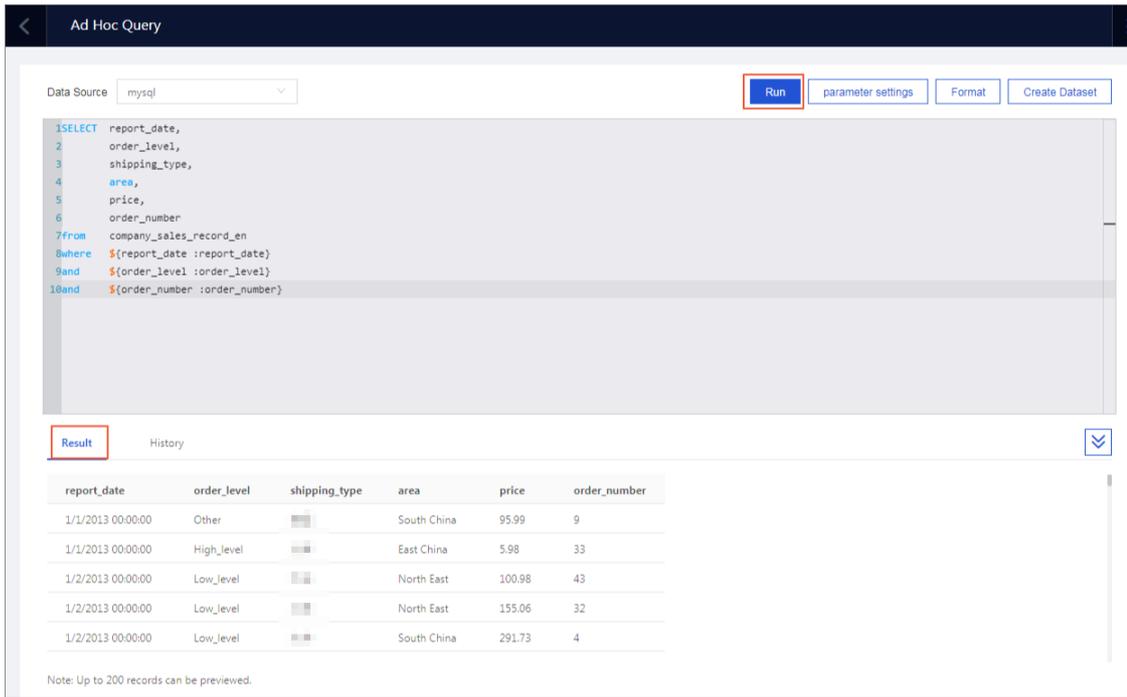

Sample SQL statement :

```
SELECT report_date,
       order_level,
       shipping_type,
       area,
       price,
       order_number
from company_sales_record
where ${report_date:report_date}
and  ${order_level:order_level}
and  ${order_number:order_number}
```

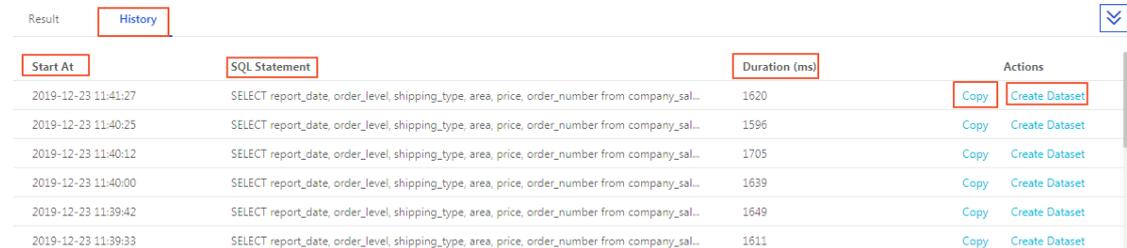

7. Click **Run** to execute the SQL statement.

You can view the execution results on the **Result** tab.

i. Click the **Result** tab.

ii. On the **History** tab, view the execution time, SQL statement, and time consumed by the ad hoc query.

- Click **Copy** in the Actions column to copy the SQL statement to the SQL statement input box.
- Click **Create Dataset**. A dataset is created by using the historical SQL statement.
- Click the  icon to hide the execution result.

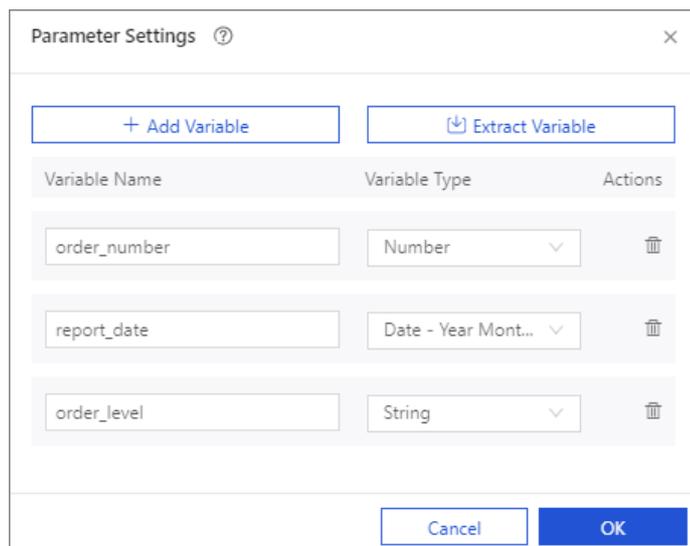

SQL statements for ad hoc queries support dynamic parameter passing and placeholders. When you create an SQL model, you can append SQL parameters to the WHERE clause in the format of \$ {Physical field name:Parameter alias}. The parameters can be referenced by the filter bar widget.

 **Note** Parameter fields are not displayed in the dataset, but are displayed in the filter bar widget.

Example of SQL statements:

```
SELECT report_date,
       order_level,
       shipping_type,
       area,
       price,
       order_number
from company_sales_record
where ${report_date:report_date}
and  ${order_level:order_level}
and  ${order_number:order_number}
```

8. Before you execute SQL statements, you can set and format parameters. After the SQL statements are executed, you can create datasets.
 - i. Click **parameter settings**. In the dialog box that appears, configure the parameters. You can add variables and modify variable types. The following variable types are supported: String, Number, Date - Year Month Day, Date - Year Month, Date - Year and Week, Date - Year, and Date - YYYYMMDD HH:MM:SS.
 - Click **New parameter variables** in the parameter settings dialog box, and specify **variable name** and **Variable type**. The variable name must be added to the WHERE clause of an SQL statement in the \${Physical field name:Variable name} format.
 - Click **Quick extraction** to obtain the variable aliases in the SQL statement. The default variable type is String, which can be changed.

After you configure the parameters, click **OK**.

- ii. Click **Format** to format SQL statements.
- iii. Click **Create Dataset** to create a dataset based on the query results of the current SQL statement.

For information about how to use the parameters in the filter bar widget, see [Use SQL statement parameters in the Filter Bar widget](#).

7.4.3.3. Specify a method to name dimensions and measures

Quick BI creates datasets based on the metadata of physical tables and converts fields in the physical tables to dimensions or measures in the datasets. The names of dimensions and measures are automatically generated. They can be the names or descriptions of the fields in the physical tables.

Prerequisites

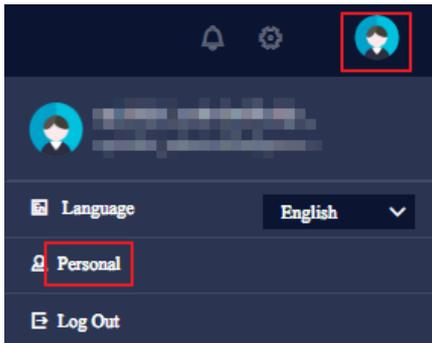

The Quick BI service is purchased.

Context

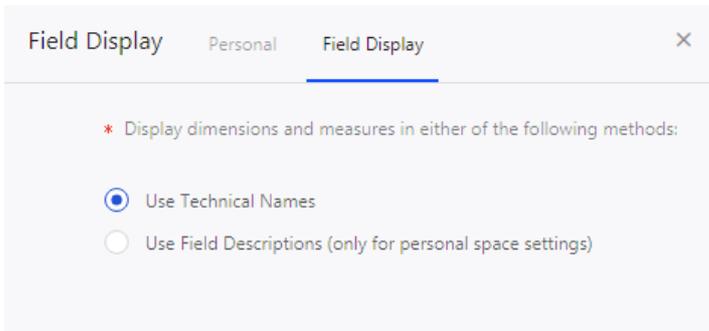

You can move the pointer over the profile picture and specify a method to name dimensions and measures in datasets. Dimensions and measures in datasets are named based on your setting.

Procedure

1. [Log on to the Quick BI console.](#)
2. Move the pointer over the profile picture in the upper-right corner and select **Personal**.

3. In the **Personal** dialog box, click the **Display** tab and select a method to name dimensions and measures in datasets.

7.4.3.4. Edit a dataset

7.4.3.4.1. Edit a dimension

If the data type of a field in a dataset table is String or Date/Time, the field is classified as a dimension by the system. You can edit the field in the Dimensions list.

Prerequisites

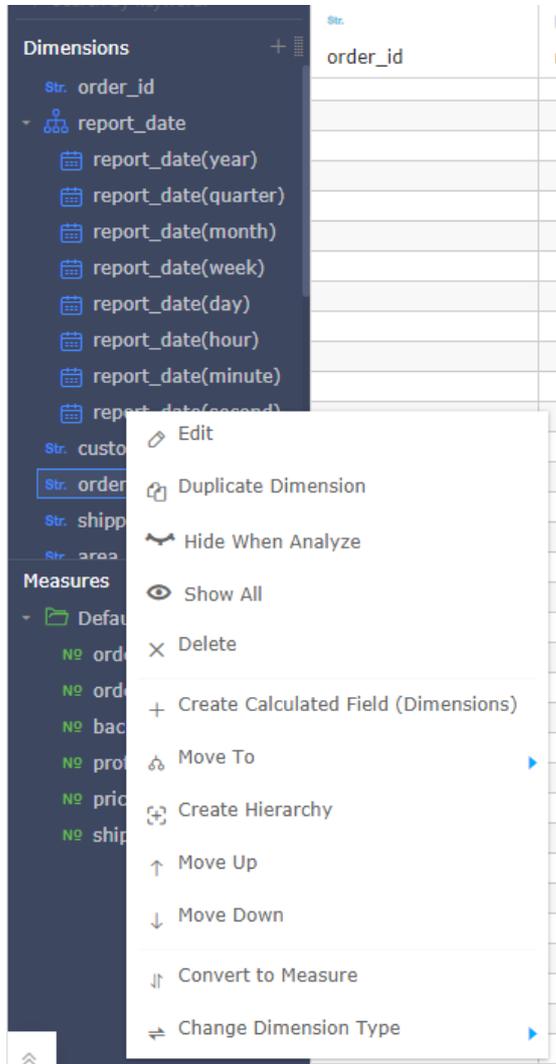

The Quick BI service is purchased.

A dataset is created.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.

4. On the Datasets page, find the required dataset and click the  icon in the Actions column to go to the dataset edit page.
5. Find the required field in the Dimensions list.
6. Right-click the field and select the operation you want to perform.

- **Edit**: Edit the name and description of the dimension.
When you edit a week dimension, you can configure the first day of a week.
- **Duplicate Dimension**: Duplicate the dimension. The name of the duplicate dimension ends with **Duplicate**.
- **Hide When Analyze**: Hide the dimension as required.
- **Show All**: Show all dimensions.
- **Delete**: Delete the dimension.
- **Create Calculated Field (Dimensions)**: Create a dimension and customize its calculation method.
- **Move To**: Move the dimension to an existing hierarchy for drilling.
- **Create Hierarchy**: Add the dimension field to a new hierarchy.
- **Move Up/Move Down**: Move the dimension. You can drag or right-click the dimension to move it.
- **Convert to Measure**: Convert the dimension to a measure.

- **Change Dimension Type:** Switch the dimension type among Date/Time (Source Format), Geo, String, and Number.

For example, you must change the data type of the province and city dimensions to Geo when you create a bubble map or colored map. Otherwise, the map cannot be created.

 **Note** You can duplicate, hide, and delete dimensions at different hierarchy levels.

7.4.3.4.2. Edit a measure

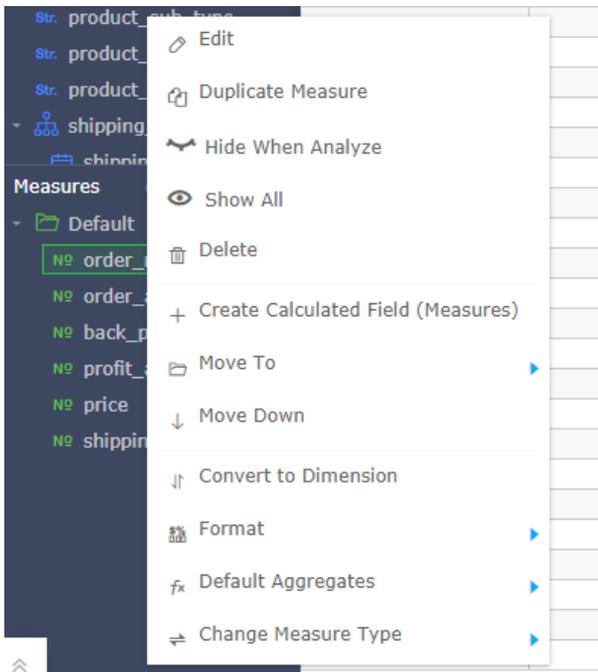

If the data type of a field in a dataset table is NUMBER, the field is classified as a measure by default. You can edit the field in the Measures list.

Prerequisites

The Quick BI service is purchased.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the Datasets page, click the required dataset to go to the dataset edit page.
5. Find the field that you want to edit in the Measures list.
6. Right-click the field and select the operation that you want to perform on the field as required.

- **Edit:** Edit the name and description of the measure.
- **Duplicate Measure:** Duplicate the measure. The name of the duplicate measure ends with **Duplicate**.
- **Hide When Analyze:** Hide the measure as required.
- **Show All:** Show all measures.
- **Delete:** Delete the measure.

- Create Calculated Field (Measures): Create a measure and customize its calculation method.
- Move To: Move the measure to an existing folder.
- Move Up/Move Down: Move the measure. You can drag or right-click the measure to move it.
- Convert to Dimension: Convert the measure to a dimension.
- Format: Specify the number format.
- Default Aggregates: Specify the aggregate function, such as SUM, MAX, or MIN.
- Change Measure Type: Switch the measure type between String and Number.

7.4.3.4.3. Toolbar and shortcut menu

On the dataset edit page, Quick BI provides a toolbar and a shortcut menu for you to edit a dataset and create reports.

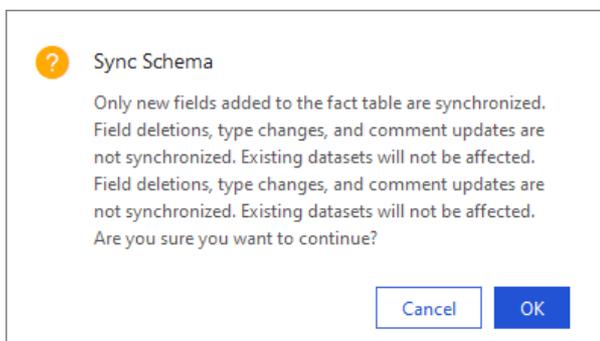

Toolbar

- Lock: provides a lock mechanism. Multiple users can edit a dataset at the same time. If you want to modify a dataset, you must first lock the dataset and refresh the page to update the dataset. Then, make and save the modifications. If you modify the dataset without refreshing the page, the changes made by other users are overwritten.
- Sync Schema: synchronizes the new fields in an online physical table to the dataset that is created based on the physical table.

However, if a field is modified or deleted from the physical table, the field in the dataset remains unchanged.

Sync Schema

- Refresh Preview: refreshes the dataset for preview. If you want to view the latest data, save the dataset and click Refresh Preview.
- Set Filter: filters out unnecessary data in the dataset to prevent full table scan.
- Save As: saves the current dataset as a new dataset. This function allows you to duplicate or backup a dataset.
- Save: saves the dataset.

After you add new fields, delete fields, or convert between dimensions and measures in a dataset, you must save the dataset. Then, you can refresh the page to view the updated dataset.

Shortcut menu

On the dataset edit page, click the  icon in the lower-left corner to expand the shortcut menu.

Short cut menu

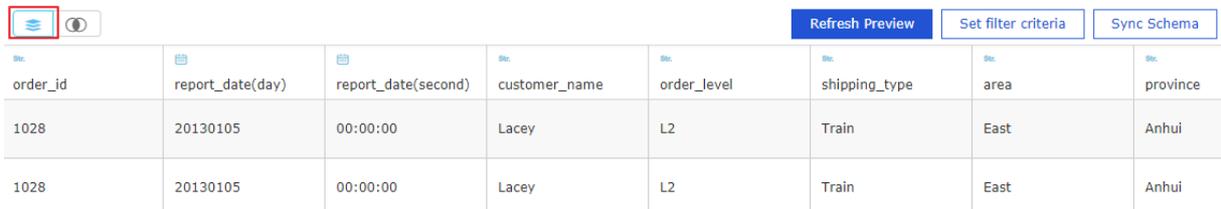

- Dashboards: You can click **Dashboards** to open the **Create Dashboard** dialog box.
- Workbooks: You can click **Workbooks** to go to the page for creating and editing a workbook.
- Datasets: You can click **Datasets** to go to the page for creating a dataset.
- BI Portals: You can click **BI Portals** to go to the page for creating and editing a BI portal.
- Retrieve Data: You can click **Retrieve Data** to go to the page for creating a data source.

7.4.3.4.4. Preview data

This topic describes how to preview data on the dataset edit page.

Click the  icon to preview data.

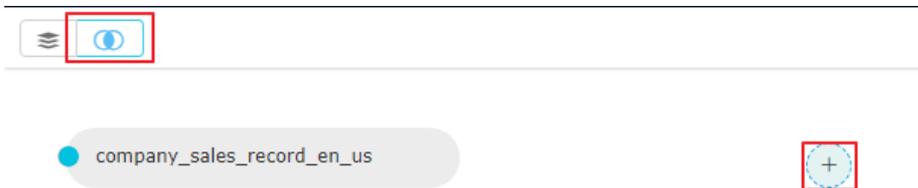

order_id	report_date(day)	report_date(second)	customer_name	order_level	shipping_type	area	province
1028	20130105	00:00:00	Lacey	L2	Train	East	Anhui
1028	20130105	00:00:00	Lacey	L2	Train	East	Anhui

7.4.3.4.5. Table join and examples

This topic describes how to join tables when you edit a dataset.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane of the Workspace page, click **Datasets**.
4. On the Datasets page, click a dataset that you want to manage and go to the dataset edit page.
5. Click the **Join** icon () to switch to the Table Join mode.

6. Click the  icon. The Build Table Join for company_sales_record Associated Mode dialog box appears. Quick BI supports five-layer horizontal join, the following figure shows details.

7. Select the fields that are used to join tables and specify a join type.

Build a table join model

Build Table Join for company_sales_record_en_us Associated Model ✕

Dataset Field	Join Type	Join Table	Join Field	Actions
order_id		company_sales_rec...	order_id	

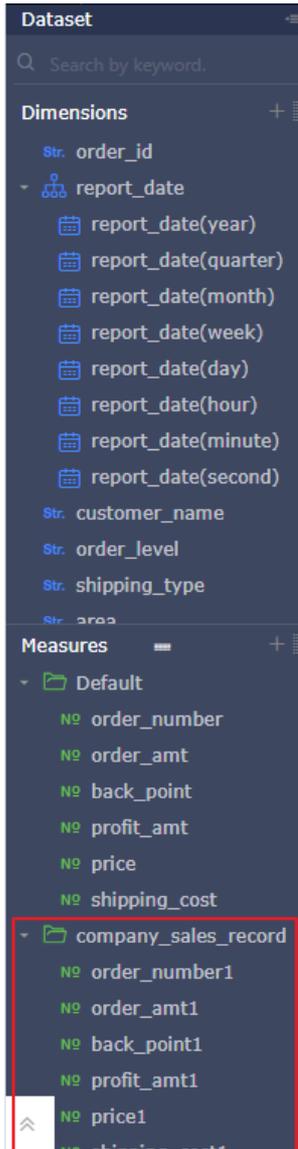

Add Join Field

Quick BI supports the following join types:

- Inner Join (): returns records with the same join fields in two tables.
- Left Outer Join (): returns all records in the left table and records in the right table that have the same join fields as the left table.
- All Join (): returns all records in two tables.

Note MySQL data sources do not support the All Join type.

8. Click **Join Field** to add multiple join fields.
9. Click **OK** to save the model.
10. Click **Save**.
11. After the model is saved, click the preview icon () to switch to the preview mode, and then click **Refresh Preview** to view the join results of the tables.

7.4.3.4.6. Calculated fields

7.4.3.4.6.1. Overview

Quick BI allows you to create fields from existing fields in data sources by using SQL functions. The new fields are referred to as calculated fields.

When you create a calculated field, take note of the following points:

- Fields that are created from the Dimensions list are classified as calculated dimensions. Fields that are created from the Measures list are classified as calculated measures.
- In the Expression field, you can select any functions or expressions supported by the current data source.
- You must enter the function name. The field name must be enclosed in a pair of brackets. You can enter the entire field name, or enter a left bracket ([) and select the required field from the displayed field list. You can also double-click the target field in the Dimensions or Measures list to add the field to the Expression field. Correct SQL expressions are highlighted.
- When you specify an SQL expression for a calculated field, do not use full-width punctuation marks. If an error occurs, check whether you have entered full-width punctuation marks in the expression field.

- After you create the calculated field, save the dataset and then refresh it to show the calculated field.
- You cannot use a calculated field in the expression of another calculated field. If a field is deleted from the physical table, a calculated field whose expression uses the deleted field becomes invalid.

7.4.3.4.6.2. Rules for using calculated fields

This topic describes the rules for using calculated fields.

- Calculated fields not using aggregate functions can be used as dimensions, or as measures after you specify the aggregate method. Calculated fields using aggregate functions can only be used as measures, and cannot be converted to dimensions.
- You can set the data type for a calculated field. Currently, you can set the data type of dimension fields to Number, Text, or Date/Time, and set the data type of measure fields to Number or Text.
- Similar to dimensions and measures generated by the original fields in a data source, dimensions and measures generated by calculated fields can be used in rows, columns, and filters, and can be selected on the Data tab for charts and maps. You can also convert a calculated field from dimension to measure or from measure to dimension.

 **Note** If you use the SUM or AVG aggregate function in an expression of a calculated field whose data type is Text and values are text data, an error occurs due to a failure in data type conversion.

7.4.3.4.6.3. Types of calculated measures

A calculated field in the measure category is a calculated measure. Calculated measures are classified into common measures and aggregate measures based on the expression type.

The following table lists differences between common measures and aggregate measures.

Common measure	Aggregate measure
Expressions exclude aggregate functions.	Expressions include aggregate functions.
You can change the aggregation method.	You cannot change the aggregation method.
You can convert common measures to dimensions.	You cannot convert aggregate measures to dimensions.
No aggregate functions are supported.	Supported aggregate functions: SUM, AVG, MIN, MAX, COUNT, and COUNT DISTINCT.

You can use the COUNT or COUNT DISTINCT function that has dimensions as its parameters to form a deduplicated aggregate measure.

For example, to calculate the average purchase price per user, you can use the following expression: `sum(purchase price)/countd(user ID)`. To calculate the proportion of order costs to order prices, you can use `sum(order cost)/sum(order price)` but not `avg(order cost/order price)`.

 **Note** Common measures cannot be used with aggregate measures. For example, `sum(order cost)/order price` is incorrect.

7.4.3.4.6.4. Expressions of calculated fields

This topic describes functions and arithmetic operations of calculated fields.

Aggregation methods

- To calculate the total order price: `sum([order_amt])`
- To calculate the average order price: `avg([order_amt])`
- To calculate the maximum order price: `max([order_amt])`
- To calculate the minimum order price: `min([order_amt])`
- To count the number of customers: `count([customer_name])`
- To count the number of unique customers: `count(distinct [customer_name])`

Basic operations

`order_cost = ([order_amt] - [profit_amt])/100`

Substring

`Substring([customer_name],1,1)`

Group values of a measure by using the CASE WHEN statement

- Group orders based on the order price
`CASE WHEN [order_amt] < 500 THEN 'small order' WHEN [order_amt] >= 500 AND [order_amt] < 2000 THEN 'medium order' WHEN [order_amt] >= 2000 AND [order_amt] < 5000 THEN 'big order' ELSE 'large order' END`
- Group dimension members by using the CASE WHEN statement. In this example, provinces are classified into a specific physical region.
`CASE WHEN [province] in ('Heilongjiang', 'Liaoning', 'Jilin') THEN 'North east' ELSE [province] END`
- Calculate a measure by using a complex expression: order price per customer
`sum([order_amt])/count(distinct [customer_name])`
- Add a UNIX timestamp
`from_unixtime([order_id] + 1234567890)`
- Locate different days in a month
`day([order date])`
Returns a number in the range of 1 to 31.
- Locate different hours in a day
`hour([report_date])`
Returns a number in the range of 0 to 23.
- Calculate the advertisement conversion rate
`CASE WHEN sum([Views]) > 0 THEN sum([Conversion times])/sum([Views]) ELSE 0 END`
The following example is an incorrect expression: `sum(CASE WHEN [Views] > 0 THEN [Conversion times]/[Views] ELSE 0 END)`. For metrics that indicate rates, you must perform the sum operation before the division operation.

7.4.3.4.6.5. Add a calculated field

This topic describes how to add a calculated field.

Prerequisites

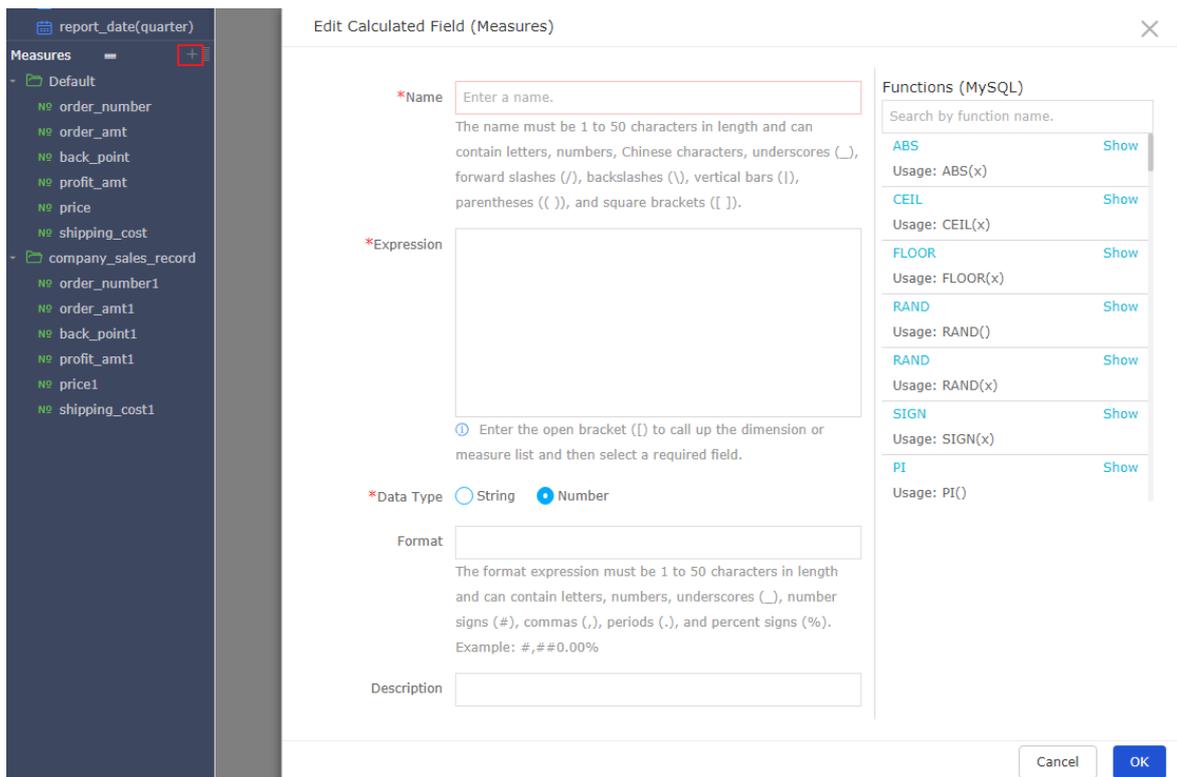

For more information about the usage and expressions of calculated fields, see [Rules for using calculated fields](#) and [Expressions of calculated fields](#).

Context

The following example uses the company_sales_record dataset to calculate the average profit of orders.

Procedure

1. Log on to the Quick BI console.
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the Datasets page, click the company_sales_record dataset.
5. In the Measures list, click the  icon. The **Edit Calculated Field (Mea.)** dialog box appears.

6. Enter the measure name and expression.

If you want to calculate the average profit of orders, enter an expression to divide the total profit of the orders by the order quantity.

Edit Calculated Field (Measures) ✕

***Name**
The name must be 1 to 50 characters in length and can contain letters, numbers, Chinese characters, underscores (`_`), forward slashes (`/`), backslashes (`\`), vertical bars (`|`), parentheses (`()`), and square brackets (`[]`).

***Expression**
Enter the open bracket (`[`) to call up the dimension or measure list and then select a required field.

***Data Type** String Number

Format
The format expression must be 1 to 50 characters in length and can contain letters, numbers, underscores (`_`), number signs (`#`), commas (`,`), periods (`.`), and percent signs (`%`).
Example: `#,##0.00%`

Description

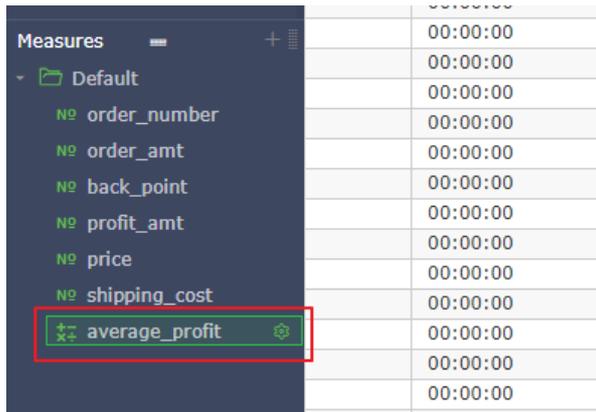

Functions (MySQL)

Search by function name.

ABS	Show
Usage: ABS(x)	
CEIL	Show
Usage: CEIL(x)	
FLOOR	Show
Usage: FLOOR(x)	
RAND	Show
Usage: RAND()	
RAND	Show
Usage: RAND(x)	
SIGN	Show
Usage: SIGN(x)	
PI	Show
Usage: PI()	

? **Note** You must use an English IME to enter the expression.

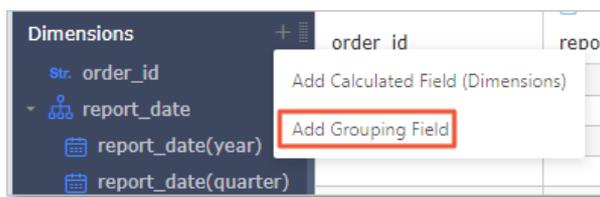

7. Select a data type. For example, if the average profit is a numeric value, you need to select **Number** for Data Type.
8. Click **OK** to add the field.
9. Click **Save** in the upper-right corner to save the dataset.
10. Click **Refresh Preview** to view the new calculated field.

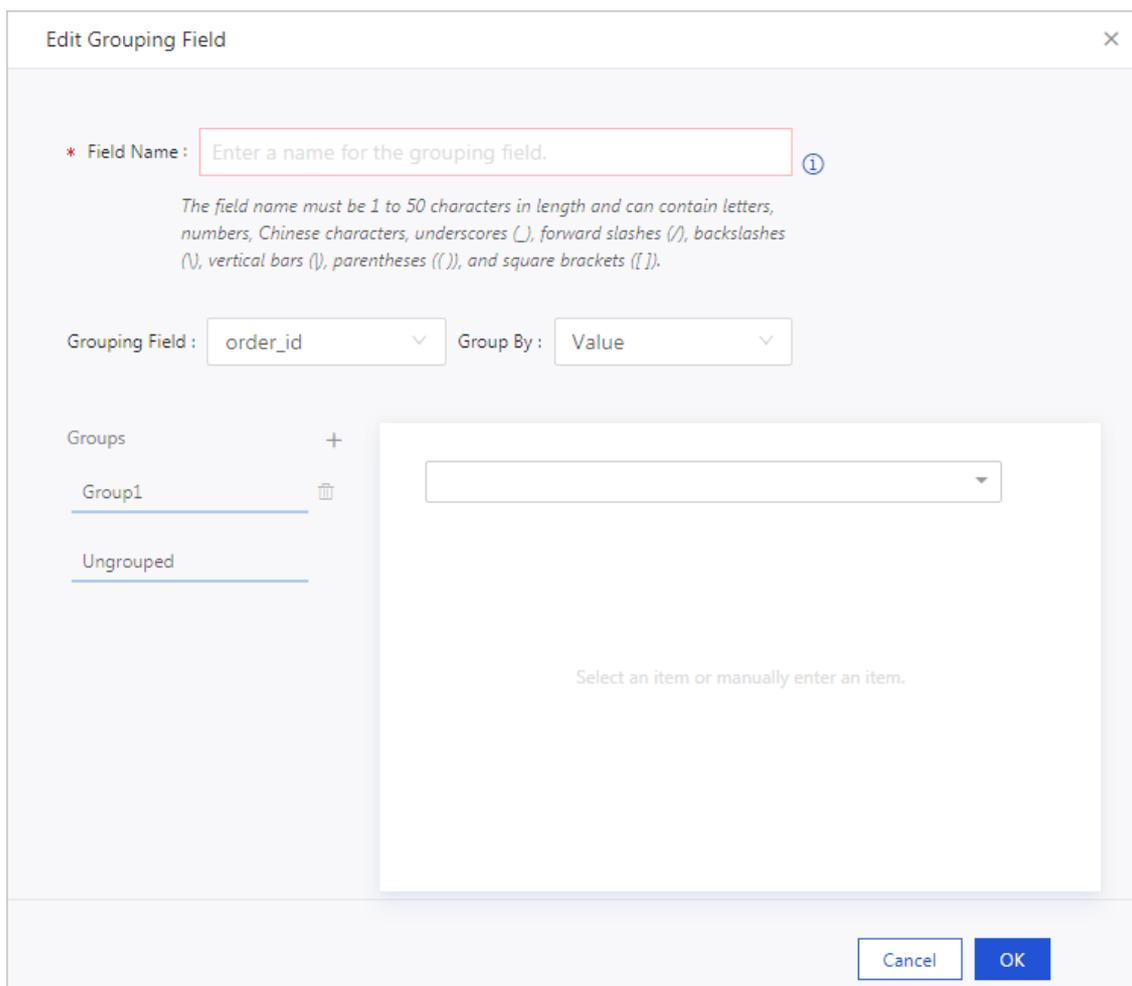

7.4.3.4.7. Add a grouping field

On the dataset edit page, you can use the **Add Grouping Field** feature to group data and store group information.

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the Datasets page, click the `company_sales_record` dataset.
5. On the dataset edit page, click the  icon next to **Dimensions** and select **Add Grouping Field**.

6. In the **Edit Grouping Field** dialog box, enter the required information and click **OK**.

7. Click **Save** and then click **Refresh Preview**. The dimension list shows the new grouping field.

7.4.3.5. Rename a dataset

This topic describes how to rename a dataset.

Prerequisites

A dataset is created.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the Datasets page, find the required dataset, click the  icon in the **Actions** column, and then select **Edit Properties**.
5. On the **Edit Properties** page, modify the dataset name and click **Save**.

7.4.3.6. Search for a dataset

This topic describes how to search for a dataset.

Prerequisites

The Quick BI service is purchased.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the **Datasets** page, find the search box.
5. Enter a keyword of the target dataset in the search box and click the **Q** icon.

7.4.3.7. Transfer a dataset

This topic describes how to transfer a dataset to another user.

Prerequisites

The Quick BI service is purchased.

Context

You can transfer a dataset to another Apsara Stack tenant account or RAM user in the same workspace.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the **Datasets** page, find the required dataset, click the **⋮** icon in the **Actions** column, and then select **Edit Properties**. You can also right-click the required dataset and select **Edit Properties**.
5. In the **Edit Properties** panel, select a new owner and click **Save**.

Edit Properties

* Name: company_sales_record_en_us

Owner: [dropdown]

description: Please add an object description

Security Level: Private (Allow Only Workspace Owner to Edit)
 Protected (Allow Other Workspace Members to Edit)

7.4.3.8. Copy a dataset from one workspace to another

This topic describes how to copy a dataset from one workspace to another.

Prerequisites

The Quick BI service is purchased.

Context

Only group workspaces support this feature. Only an administrator of two workspaces can copy a dataset from one workspace to the other.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the **Datasets** page, right-click the dataset that you want to copy and select **Copy**.
5. In the **Copy Dataset** dialog box, configure the destination workspace, storage path, and the name of the dataset in the destination workspace.

Copy Dataset

Workspaces: [blurred]

Save To: MaxComputer

Datasets: odps_sql223

A name must be 1 to 50 characters in length and can contain letters, numbers, Chinese characters, underscores (_), forward slashes (/), backslashes (\), vertical bars (|), parentheses (()), and square brackets ([]).

Cancel OK

Note If the destination workspace does not contain the data source based on which the dataset is created, the data source is also copied to the destination workspace.

6. Click OK.

7.4.3.9. Configure the dataset cache

This topic describes how to configure and clear the cache of a dataset. After you enable dataset caching, when an SQL statement is executed within the cache duration, the system queries data from the cache.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

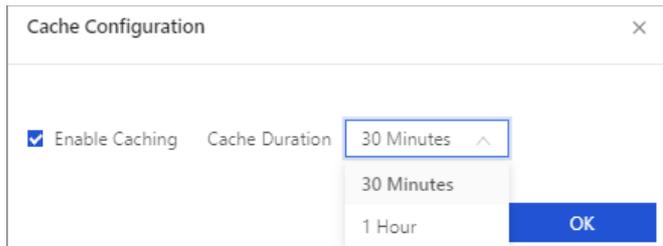

Context

After you enable caching, you can set the cache duration to 30 minutes or 1 hour.

- After the cache duration elapses, the cached data becomes invalid, and queries on the report page generate new cache. If the same SQL statement is executed again within the cache duration, the system queries data from the new cache.
- The cache is cleared based on datasets. When you trigger cache clearing for a dataset or after the cache duration elapses, the cache of all charts that are generated based on the dataset is cleared.

Configure the cache settings

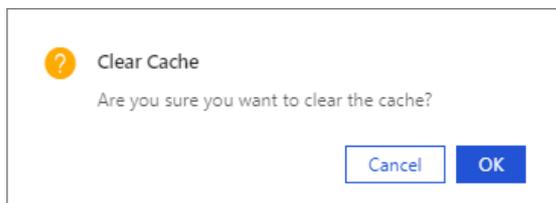

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the Datasets page, find the required dataset, click the  icon in the **Actions** column, and then select **Cache configuration**.
5. In the **Cache configuration** dialog box, select **Cache configuration** and configure the cache time.

6. Click OK.

Clear the cache of a dataset

1. On the Datasets page, find the required dataset, click the  icon in the **Actions** column, and select **clear cache**.
2. In the clear cache message, click OK.

7.4.3.10. Create a dataset folder

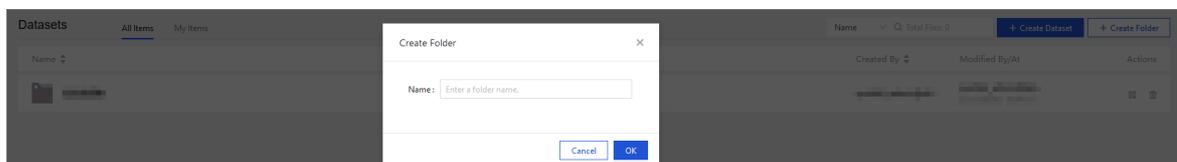

This topic describes how to create a dataset folder on the **Datasets** page.

Prerequisites

The Quick BI service is purchased.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. In the upper-right corner of the **Datasets** page, click **Create Folder**.
5. In the **Create Folder** dialog box, enter a name for the folder and click **OK**.

7.4.3.11. Rename a dataset folder

This topic describes how to rename a dataset folder.

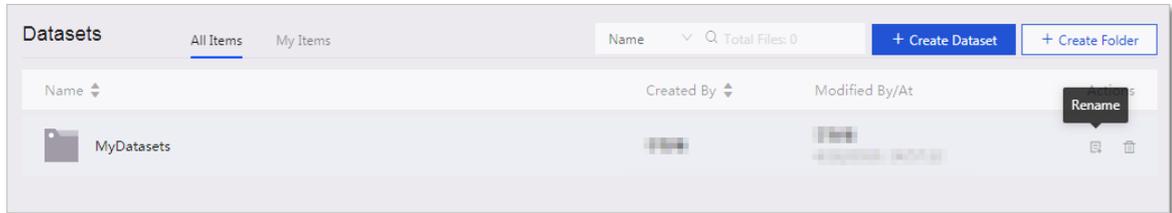

Prerequisites

The Quick BI service is purchased.

Procedure

1. [Log on to the Quick BI console.](#)

2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the **All Items** tab of the **Datasets** page, find the folder that you want to rename.
5. Right-click the folder and select **Rename**, or click the  **Rename** icon in the Actions column.

6. In the Rename dialog box, enter a new name and click **OK**.

7.4.3.12. Delete a dataset

This topic describes how to delete a dataset and the common issues that may occur when you delete a dataset.

Prerequisites

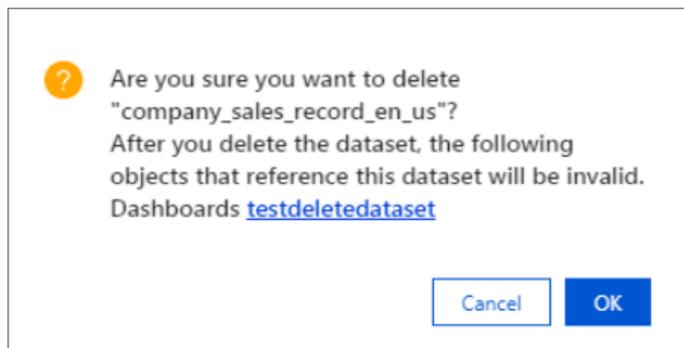

A dataset is created.

Context

If workbooks are created based on the dataset, a notification is displayed when you attempt to delete the dataset, as shown in [Notification](#).

After you delete a dataset, an error message occurs when you access the dashboard created based on that dataset, as shown in [Error message](#).

Notification

Error message

Procedure

1. [Log on to the Quick BI console](#).
2. Click the **Workspace** tab.
3. In the left-side navigation pane, click **Datasets**.
4. On the **My Items** tab of the **Datasets** page, find the dataset that you want to delete.
5. Click the  icon in the **Actions** column and select **Delete**. You can also right-click the dataset and select

Delete.

7.4.3.13. Configure row-level permissions

Row-level permissions are granted based on datasets. Quick BI supports two authorization modes: user/user group-based authorization and tag-based authorization.

User/user group-based authorization is suitable for scenarios that involve a small number of members. Tag-based authorization is suitable for scenarios that involve a large number of members. Tag-based authorization allows you to authorize all users at the same time. In scenarios that involve a large number of members, this mode reduces the costs and complexity of row-level permission configurations and facilitates permission management. For information about how to configure row-level permissions, see [Manage row-level permissions](#).

7.5. Dashboards

7.5.1. Dashboard overview

7.5.1.1. Dashboard features

This topic describes the features of a Quick BI dashboard.

- Supports the Filter Bar, Text Area, IFrame, Tab, and Image widgets. You can drag and drop widgets to create pages for various products.
- Provides a wide range of chart components. You can easily create various reports by setting chart elements. A chart can be displayed in either standard or full-screen mode.
- Uses a more flexible tile layout. A dashboard visualizes data. It allows you to filter and query data, use multiple data display modes, and highlight the key fields of data.
- Enables you to drag, drop, and click fields in a dashboard to display data. You can follow the instructions on the pages to analyze data for better user experience.

7.5.1.2. Chart types and scenarios

Different types of data need to be displayed in charts of different types. Currently, Quick BI supports various data charts, such as line charts, vertical bar charts, bubble maps, and funnel charts.

For information about how to create charts, see [Create a dashboard](#).

The following table describes the analysis types and scenarios for each chart type.

Chart types and scenarios

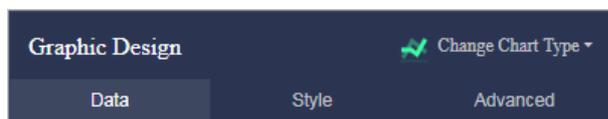

Analysis type	Description	Scenario	Applicable chart
Comparison	Compares values or compares measures by category	Compares the sales or income between different countries or regions.	Vertical bar chart, radar chart, funnel chart, cross table, polar diagram, butterfly chart, and word cloud
Percentage	Displays the proportion of a part to the total, or the proportion of a certain value to the whole.	Displays the sales of the salesperson that has the greatest percentage of total sales.	Pie chart, funnel chart, gauge, and treemap

Analysis type	Description	Scenario	Applicable chart
Relevance	Displays the relationship between values or measures.	Displays the relationship between two measures. This helps you understand the influence the first measure has on the second measure.	Scatter chart, treemap, kanban, hierarchy chart, and flow analysis chart
Trend	Displays data trends, especially trends based on time, such as year, month, or day, or the progress of a data metric or other possible patterns.	Displays trends in sales or revenue for a product over a period of time.	Line chart
Geographic map	Displays the size and distribution of data metrics of a country or region on a map. The datasets must contain geographic data.	Displays the income information about different regions of a country.	Bubble map and colored map

7.5.1.3. Data elements of a chart

This topic describes the data elements of a chart.

The Graphic Design section for each chart has three tabs: **Data**, **Style**, and **Advanced**.

- On the **Data** tab, you can specify the data you want to display in the chart.
- On the **Style** tab, you can set the chart layout and details of the chart.
- On the **Advanced** tab, you can configure the filter interaction feature to dynamically compare and display data.

Each chart has unique core data elements. For example, in a geo map, a latitude field is required. Otherwise, data cannot be displayed.

The following table lists the core data elements of each chart type.

Data elements of different types of charts

Chart type	Required data element	Data element description
Line chart	Category axis, value axis, and legend	You must specify at least one dimension for the category axis and at least one measure for the value axis. You can specify only one measure for the legend.

Chart type	Required data element	Data element description
Stacked line chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
Area chart	Category axis, value axis, and legend	You must specify at least one dimension for the category axis and at least one measure for the value axis. You can specify only one measure for the legend.
Stacked area chart	Category axis, value axis, and legend	You must specify at least one dimension for the category axis and at least one measure for the value axis. You can specify only one dimension for the legend.
100% stacked area chart	Category axis, value axis, and legend	You must specify at least one dimension for the category axis and at least one measure for the value axis. You can specify only one measure for the legend.
Vertical bar chart	Category axis, value axis, and legend	You must specify at least one dimension for the category axis and at least one measure for the value axis. You can specify only one measure for the legend.
Stacked vertical bar chart	Category axis, value axis, and legend	You must specify at least one dimension for the category axis and at least one measure for the value axis. You can specify only one measure for the legend.
100% stacked vertical bar chart	Category axis, value axis, and legend	You must specify at least one dimension for the category axis and at least one measure for the value axis. You can specify only one measure for the legend.
Circular bar	Category axis and value axis	You can specify only one dimension for the category axis and only one measure for the value axis.
Horizontal bar chart	Category axis, value axis, and legend	You must specify at least one dimension for the category axis and at least one measure for the value axis. You can specify only one measure for the legend.
Stacked horizontal bar chart	Category axis, value axis, and legend	You must specify at least one dimension for the category axis and at least one measure for the value axis. You can specify only one measure for the legend.

Chart type	Required data element	Data element description
100% stacked horizontal bar chart	Category axis, value axis, and legend	You must specify at least one dimension for the category axis and at least one measure for the value axis. You can specify only one measure for the legend.
Waterfall chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
Combination chart	Category axis and value axis	You must specify at least one dimension for the category axis and at least one measure for the value axis.
Pie chart	Labels and central angles	You can specify only one dimension for labels and only one measure for the central angles.
Cross table	Rows and columns	You can specify an unlimited number of dimensions for the rows and an unlimited number of measures for the columns.
Pivot table	Rows and values	You can specify an unlimited number of dimensions for the rows and an unlimited number of measures for the values.
Bubble map	Geo locations, bubble size, and bubble color	You can specify only one dimension for geo locations. The data type of the dimension must be Geo. You can specify one to five measures for the bubble size and only one measure for the bubble color.
Colored map	Geo locations and colorscale	You can specify only one dimension for geo locations. The dimension type must be Geo. You can specify one to five measures for the colorscale.
Gauge	Pointer angle	You can specify only one measure for the pointer angle.
Liquid fill chart	Pointer	You must specify one to five measures for the pointer.
Progress bar	Pointer	You must specify one to five measures for the pointer.
Radar chart	Labels and length	You can specify one to two dimensions for labels and at least one measure for the length.

Chart type	Required data element	Data element description
Scatter chart	Color, category, x-axis, and y-axis	You can specify only one dimension or measure for color. You can specify only one measure for the x-axis, only one measure for the y-axis, and only one dimension for the category.
Bubble chart	x-axis, y-axis, color, category, and size	You can specify only one dimension or measure for the x-axis, only one measure for the y-axis, and only one measure or dimension for color. You can specify only one dimension for the category and only one measure for the size.
Facet scatter chart	x-axis, y-axis, and legend	You can specify one to three measures for the x-axis. You can specify only one measure for the y-axis and only one dimension for the legend.
Funnel chart	Funnel layering and tier area	You can specify one to ten measures for the tier area and only one dimension for the funnel layering
Kanban	Labels and metrics	You can specify only one dimension for labels and 1 to 10 measures for metrics.
Treemap	Labels and size	You can specify only one dimension for labels and only one measure for the size.
Polar diagram	Labels and arc radius	You can specify only one dimension for the label and only one measure for the arc radius.
Word cloud	Word size and words	You can specify only one measure for the word size and only one dimension for words.
Butterfly chart	Comparison metrics and tier area	You can specify one to ten measures for the tier area. You must specify at least one dimension for the comparison metrics.
Hierarchy chart	Node labels and node metrics	You must specify at least two dimensions for node labels and at least one measure for node metrics.
Flow Analysis	Central node, node type, node name, and node indicator	You can specify only one dimension or one measure for each data element.

Chart type	Required data element	Data element description
Waterfall chart	Category axis and value axis	You must specify at least one dimension for the category axis. You can specify only one measure for the value axis.
Indicator trend graph	Date and indicator	You can specify only one dimension for the date. You must specify at least one measure for the indicator.
Sankey diagram	Node type and node height	You can specify two to five dimensions for the node type and only one measure for the node height.
Ranking board	Category and indicator	You can specify only one dimension for the category and only one measure for the indicator.
Flop	Display metrics	You can specify only one measure for the display metrics.

7.5.2. Access a dashboard

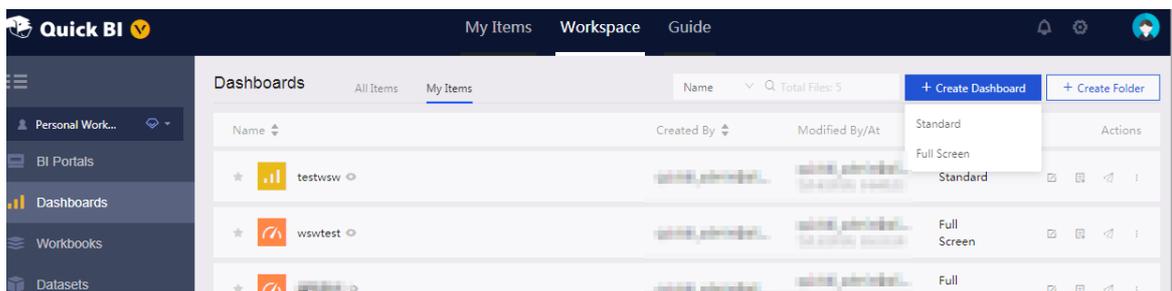

This topic describes how to access a dashboard.

Prerequisites

The Quick BI service is purchased.

Procedure

1. [Log on to the Quick BI console.](#)
2. Click the **Workspace** tab.
3. In the left-side navigation pane of the Workspace page, click **Dashboards**.
4. Choose **Create Dashboard > Standard** to go to the dashboard.

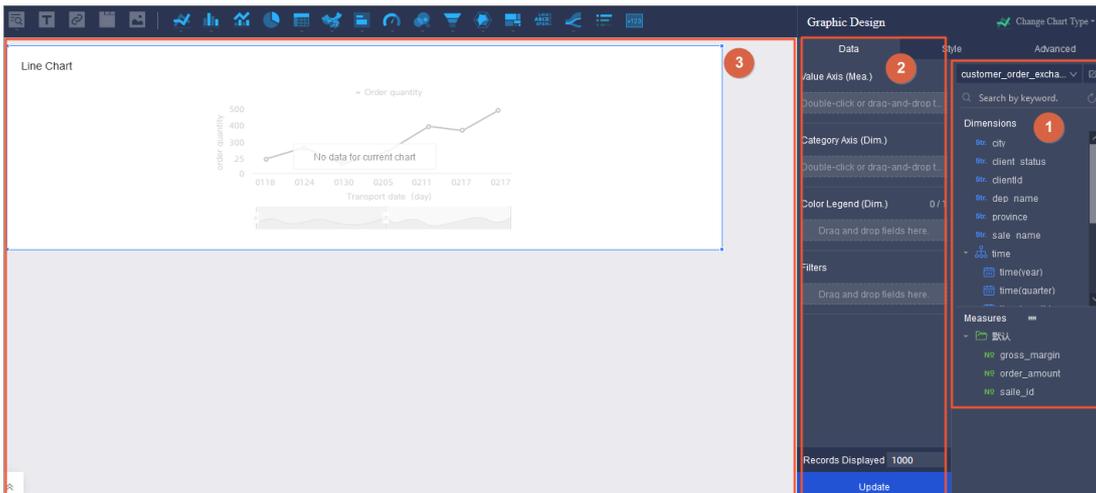

7.5.3. Areas of a dashboard

7.5.3.1. Overview

This topic describes the functional sections of the dashboard edit page.

The dashboard edit page consists of three sections, as shown in [Dashboard](#).

Dashboard

- The dataset selection section is marked as 1. In this section, you can switch the current dataset to another. The fields of a dataset are displayed in the Dimensions and Measures lists based on the data types preconfigured in the system. You can select dimensions and measures based on the chart type.
- The dashboard configuration section is marked as 2. In this section, you can select a chart type, and edit the title, layout, and legend position of a chart. On the Advanced tab, you can associate the current chart with other charts and display analysis results from multiple perspectives. You can also filter data by using filters or insert a query control to query key data in a chart.
- The dashboard display section is marked as 3. In this section, you can drag charts to adjust their positions and change chart types. For example, you can change a bar chart to a bubble map. The system displays information about missing or error elements. In the dashboard display section, you can save, preview, or create a dashboard. The dashboard provides instructions to help you learn how to create a dashboard.

7.5.3.2. Dataset selection area

7.5.3.2.1. Switch datasets

This topic describes how to switch datasets in a dashboard.

Prerequisites

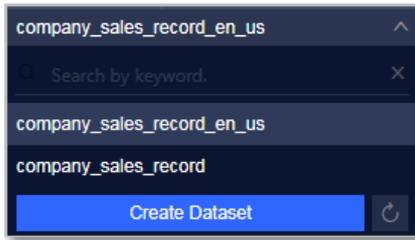

The Quick BI service is purchased.

Context

If you cannot find the required dataset in the drop-down list, go back to the dataset management page and make sure that you created the dataset. For information about how to create a dataset, see [Create a dataset](#).

Procedure

1. [Access a dashboard](#).
2. On the Data tab, click the **Switch Datasets** icon.
3. Select the required dataset from the drop-down list that appears.

7.5.3.2.2. Search for a dimension or measure

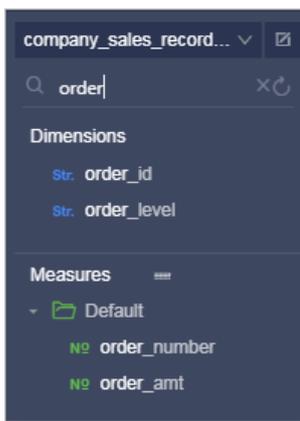

This topic describes how to search for a dimension or measure.

Prerequisites

The Quick BI service is purchased.

Procedure

1. [Access a dashboard](#).
2. On the **Data** tab in the **Graphic Design** section, find the search box and enter the keyword of the field, such as **order**.
3. Click the  icon.

For information about how to edit dimensions and measures, see [Edit a dimension](#) and [Edit a measure](#).

7.5.3.3. Dashboard graphic design area

7.5.3.3.1. Select fields

This topic describes how to select fields from a dataset.

Prerequisites

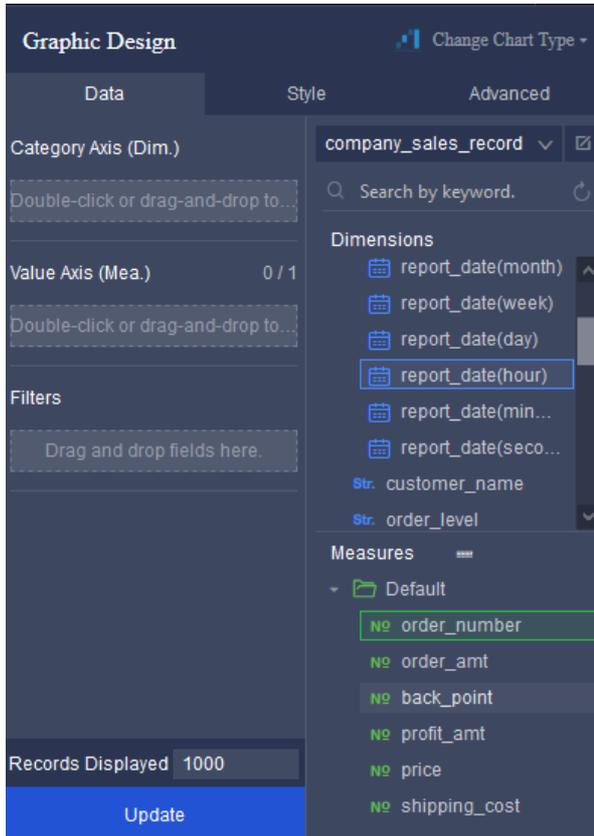

- The Quick BI service is purchased.
- A dataset is selected in the dataset selection area and is edited as needed. For information about how to edit a dataset, see [Edit a dataset](#).

Context

Procedure

1. Access a dashboard.
2. Select a chart from the toolbar on the top of the dashboard.
3. Click the chart icon. The chart appears in the display area of the dashboard. If you want to change the chart type, click **Change Chart Type** in the Graphic Design area, and select the required chart type.
4. On the **Data** tab, select the required fields, as shown in **Select fields**. Double-click a field to add it to the Dimensions or Measures list, or drag the field to the display section.

Select fields

- If you want to delete a field, click the  icon next to the field.
 - Click the  icon next to the dimension field. You can drill down to change the dimension hierarchy and the granularity of the analysis.
 - Click the  icon next to a dimension field to sort dimension fields.
 - You can click the  icon next to the field and select the method as required. The aggregation methods include SUM, COUNT, MAX, MIN, AVG, COUNT DISTINCT, median, percentile, variance, standard deviation, and compare operations.
5. Click **Update**. The chart is updated.

7.5.3.3.2. Use the color legend

This topic describes how to use the color legend.

Prerequisites

- The Quick BI service is purchased.

- A dataset is selected in the dataset selection area and is edited as needed. For information about how to edit a dataset, see [Edit a dataset](#).

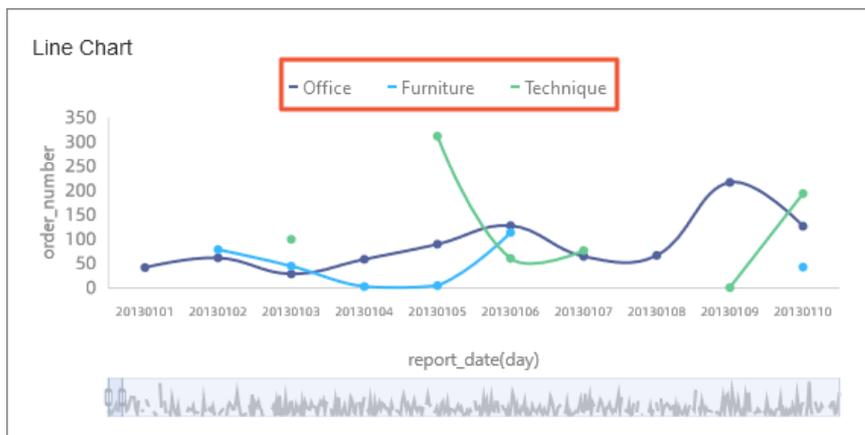

Context

The color legend feature displays the values of a selected field in different colors in a chart.

Only dimensions can be added to the Color Legend field.

Procedure

1. [Access a dashboard](#).
2. Drag a dimension, such as product_type, to the **Color Legend (Dim.)** field.
3. Click **Update**. The values of the field are displayed in different colors in the chart.

4. Change the legend color of product_type in the **Style > Series Settings** section.

7.5.3.3.3. Sort field data

This topic describes how to sort data on the **Data** tab.

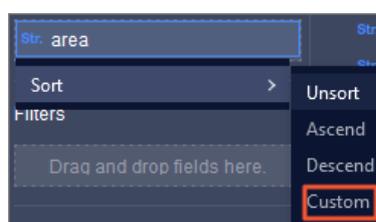

Prerequisites

- The Quick BI service is purchased.
- A dataset is selected in the dataset selection area and is edited as required. For information about how to edit a dataset, see [Edit a dataset](#).

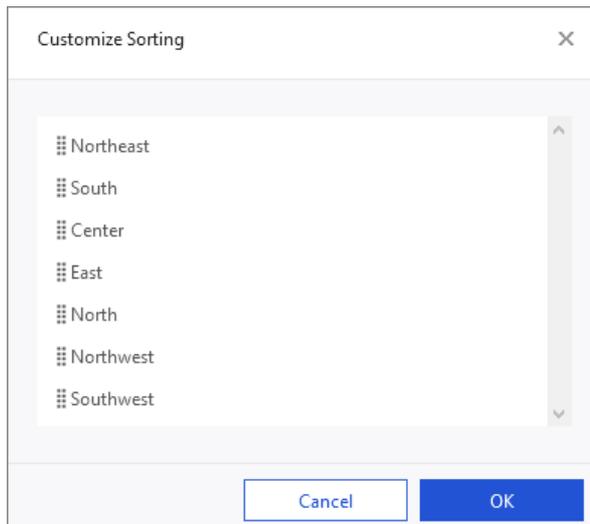

Procedure

1. [Go to the dashboard edit page](#).
2. Select a field and sort data based on the field.
 - If a dimension field is selected, perform the following steps:
 - a. Click the upward arrow next to the field, select **Sort**, and then select **Unsort**, **Ascend**, **Descend**, or **Custom**. In this example, **Custom** is selected for the region field, as shown in [Custom sorting](#).

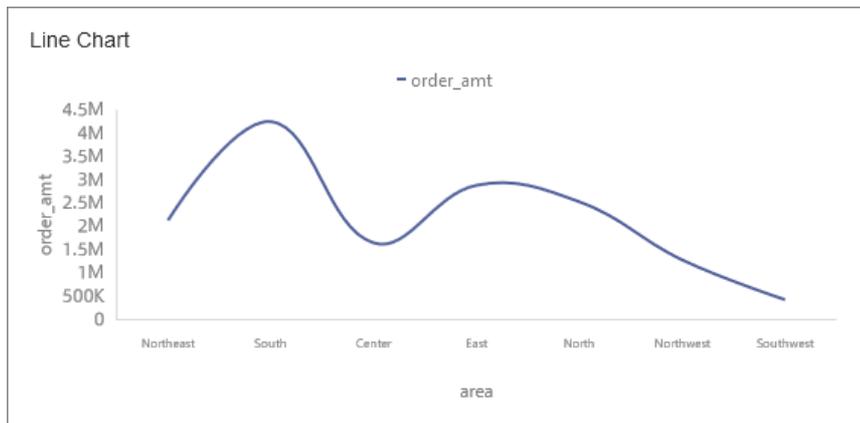

Custom sorting

- b. On the custom sorting page, move the pointer over a region, drag the region to adjust its sequence, and then click **OK**.

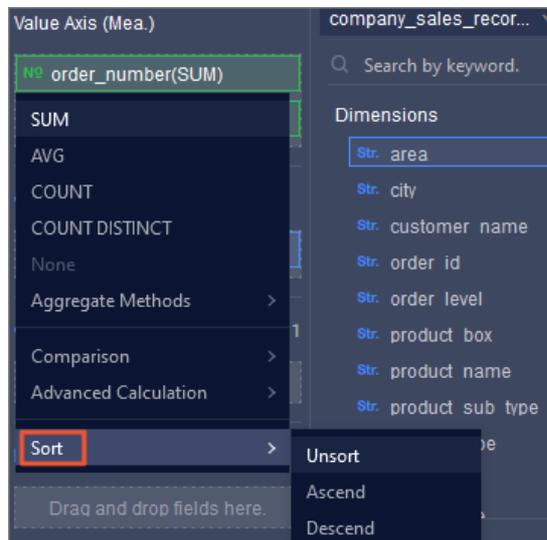

- c. After the configuration is complete, click **Update**.

- o If a measure field is selected, perform the following steps:

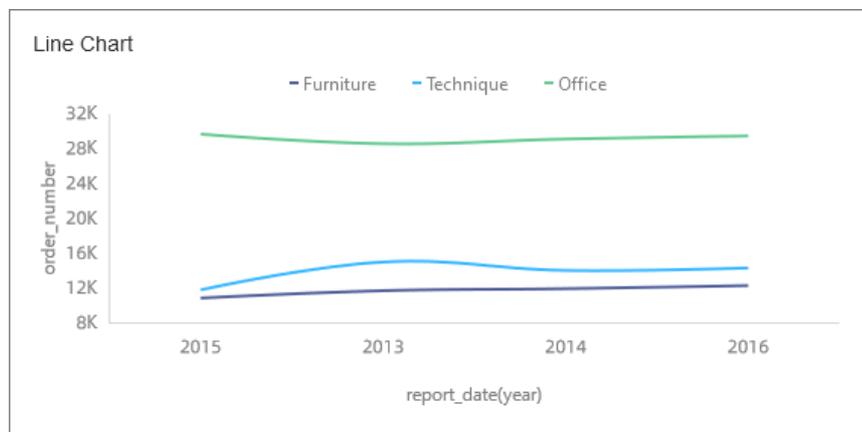

- a. Click the upward arrow next to the field, select **Sort** and then select Unsort, Ascend, Descend, or Custom. In this example, Ascend is selected for the order_number field, as shown in [Specify the sorting order](#).

Specify the sorting order

Note You can also sort data based on the comparison results and advanced calculation results.

- b. Click **Update**.

7.5.3.3.4. Configure advanced calculations

This topic describes how to perform advanced calculations on data of a specified field on the **Data** tab.

Prerequisites

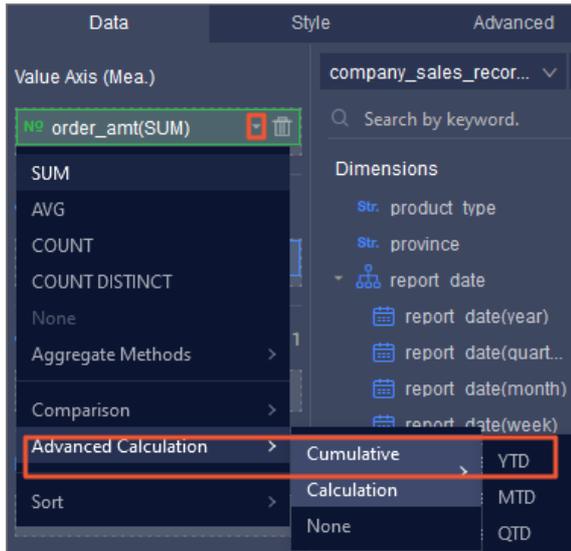

The Quick BI service is purchased.

Procedure

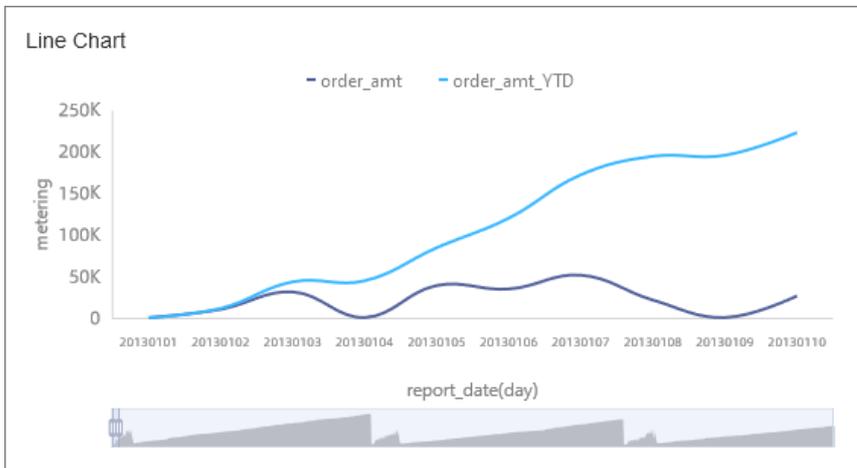

1. [Access the required dashboard](#).
2. In the dataset selection section, select a dataset and add the related fields to the measure and dimension fields. Make sure that the dataset has been edited as required. For more information, see [Edit a dataset](#).

3. Select a field, for example, order_amt.
4. Click the arrow icon next to the field, choose **Advanced Calculation > Cumulative**, and then select YTD, MTD, or QTD as required, as shown in [Configure advanced calculations](#).
 - o YTD: The value is accumulative for each year. The value is accumulated from the first day to the last day of the current year, and accumulation restarts at the beginning of the next year. In this example, the order price is accumulated from January 1, 2020 to the current time.
 - o MTD: The value is accumulative for each month.
 - o QTD: The value is accumulative for each quarter.

Configure advanced calculations

5. Click **Update**.

7.5.3.3.5. Configure the comparison feature

This topic describes how to configure the comparison feature for data of a specified field on the Data tab.

Prerequisites

- The Quick BI service is purchased.
- A dataset is selected in the dataset selection area and is edited as needed. For information about how to edit a dataset, see [Edit a dataset](#).

- A dashboard is created.
- A query control is added. For more information, see [Create a filter bar](#).

Context

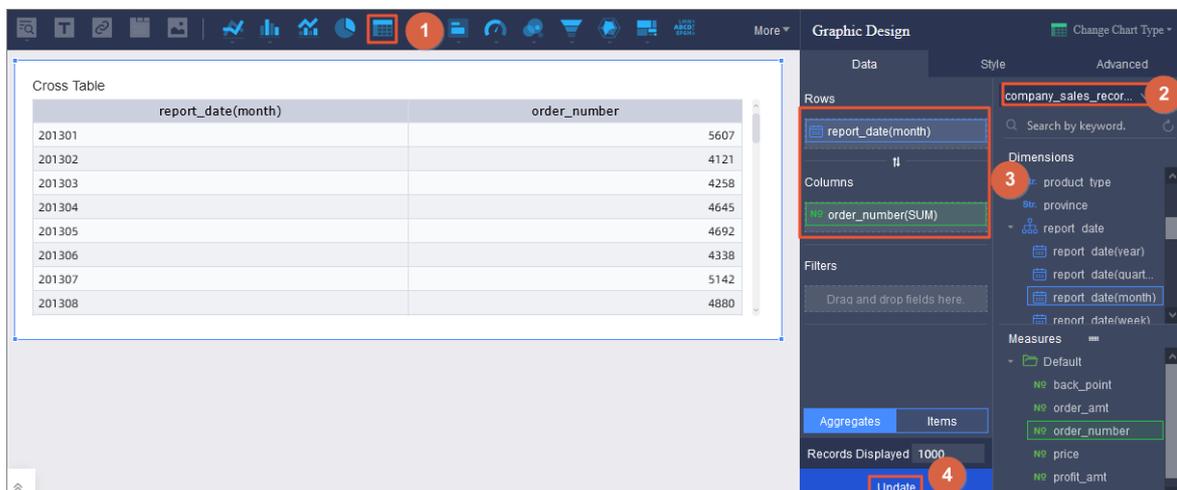

- If **Advanced Calculation** is configured for a measure, **Comparison** is unavailable.
- If **Comparison** is configured for a measure, **Advanced Calculation** is unavailable.

One DATE field in dimensions

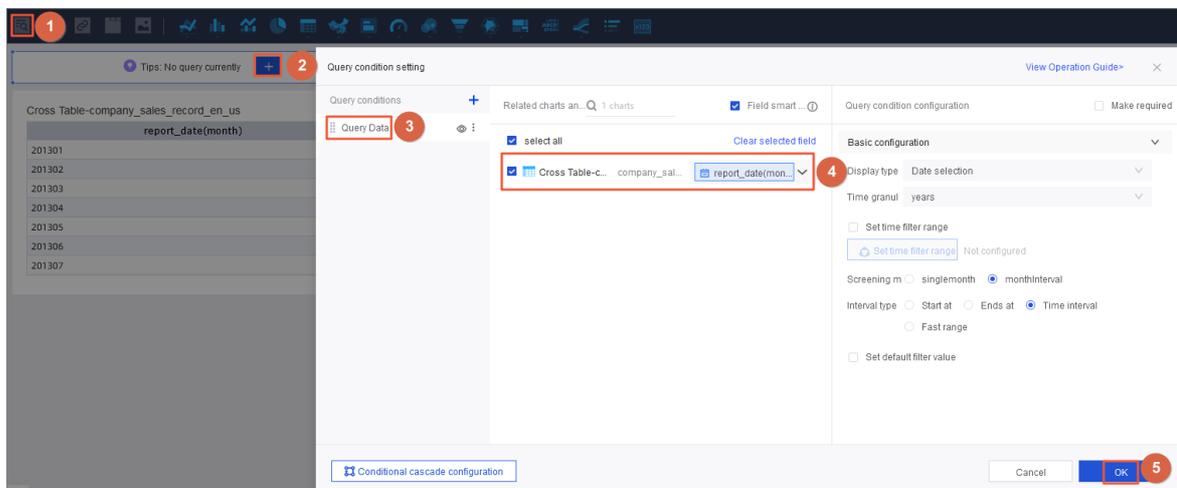

If dimensions contain only one DATE field, set the granularity for the comparison feature to the granularity of this field.

The following example demonstrates how to configure the comparison feature for a measure. A cross table is used in this example.

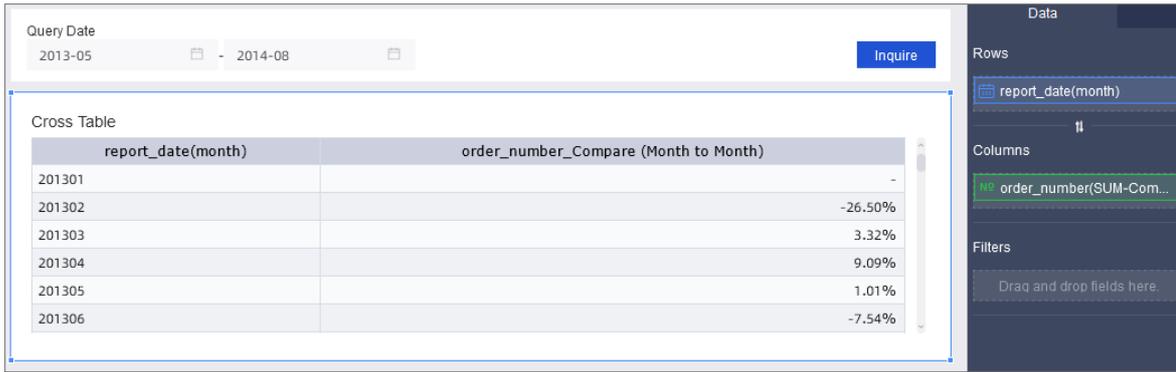

1. [Go to the dashboard edit page](#). This topic describes how to create a standard dashboard.
2. On the dashboard edit page, add a cross table and configure it, as shown in the following figure. In this example, the DATE field `order_date(month)` is added to the Rows field.

3. Move the pointer over the required measure in the Columns field and click the icon next to the measure.
4. Choose **Comparison > Compare (Month to Month)**.
5. Add a query control and configure it, as shown in the following figure.

6. In the query control, specify a time range and click **Inquire**.

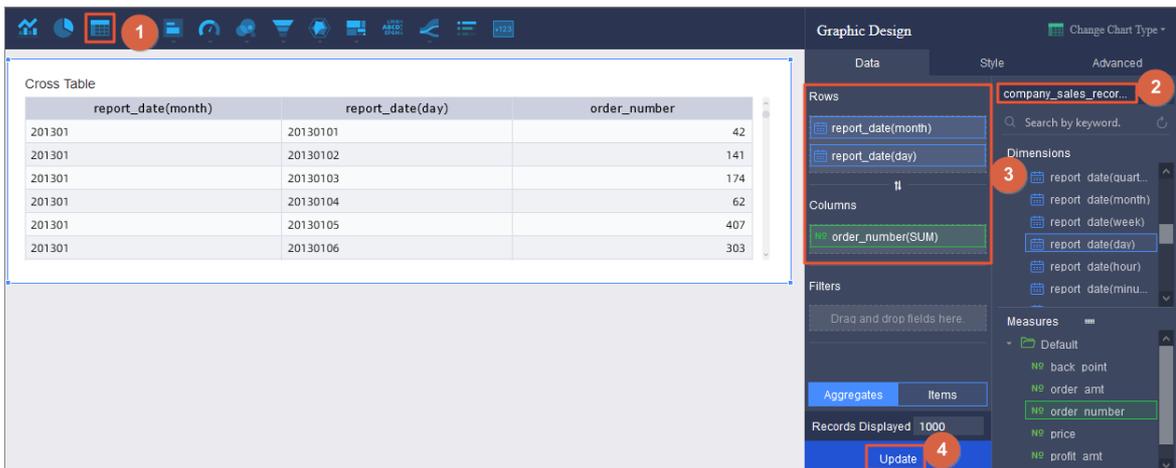

Multiple DATE fields in dimensions

If dimensions contain multiple DATE fields, the field with the smallest granularity is used to configure the comparison feature.

The following example demonstrates how to configure the comparison feature for a measure. A cross table is used in this example.

1. On the dashboard edit page, add a cross table and configure it, as shown in the following figure. In this example, DATE fields order_date(day) and order_date(month) are added to the Rows column.

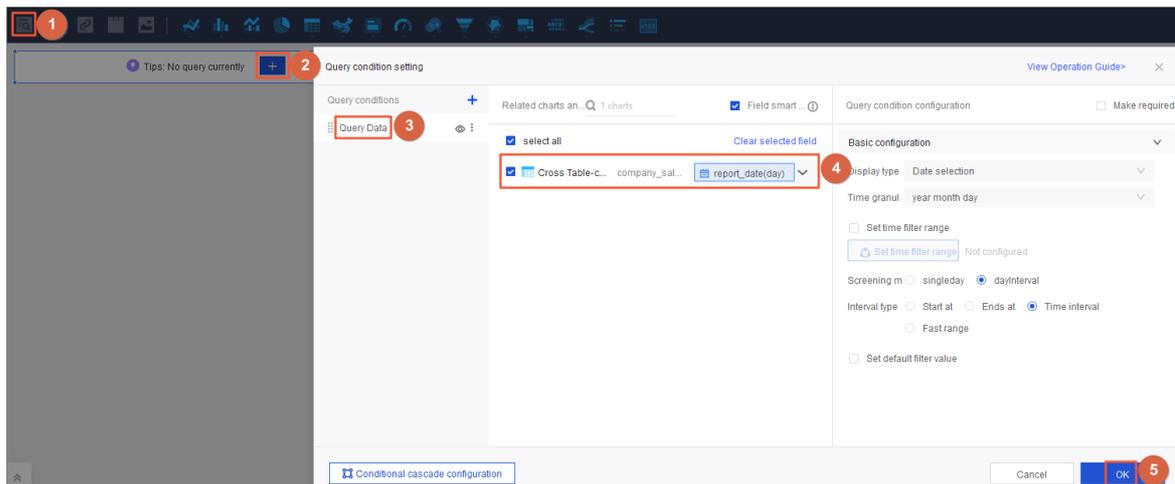

2. Move the pointer over the required measure in the Columns field and click the  icon next to the measure.
3. Choose **Comparison > Custom**.
4. In the **Comparison Settings** dialog box, configure the parameters listed in the following table.

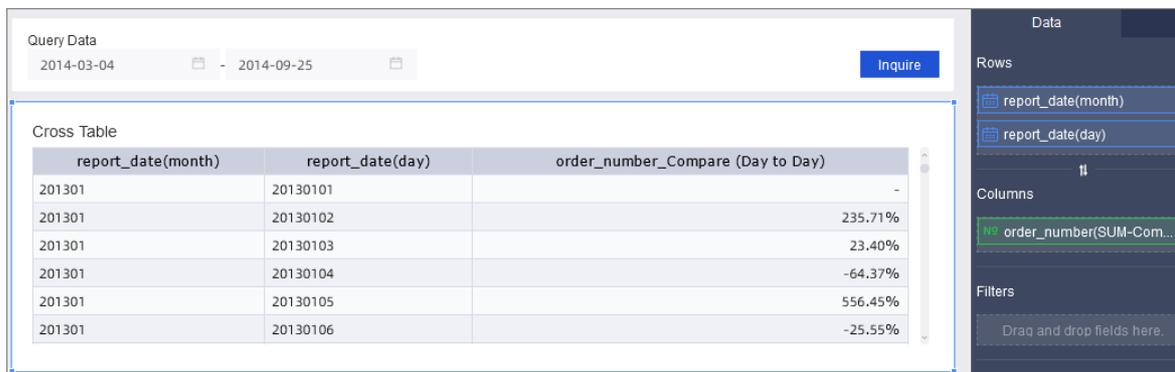

Parameter	Value	Description
Comparison Date	order_date(day)	If dimensions contain multiple DATE fields, the field with the smallest granularity is used and cannot be modified. In this example, the value is order_date(day) .
Comparison Type	<ul style="list-style-type: none"> ◦ Compare (Day to Day) ◦ Compare (of Last Week) ◦ Compare (of Last Month) ◦ Compare (of Last Year) 	The valid values of Comparison Type vary based on the setting of Comparison Date . In this example, set the value to Compare (Day to Day) .

Parameter	Value	Description
Data Settings	<ul style="list-style-type: none"> Specific Value Difference Percentage Difference 	If you set the value to Percentage Difference , you must click Advanced Settings and select a formula.
Formula	<ul style="list-style-type: none"> (Value of Current Period/Value of Previous Period - 1) × 100% (default value) 1 - (Value of Current Period/Value of Previous Period) × 100% Displayed As - 	The formula takes effect only if Data Settings is set to Percentage Difference and the value of the previous period is less than 0.

- Click **OK**.
- Add a query control and configure it, as shown in the following figure.

- In the query control, specify a time range and click **Inquire**.

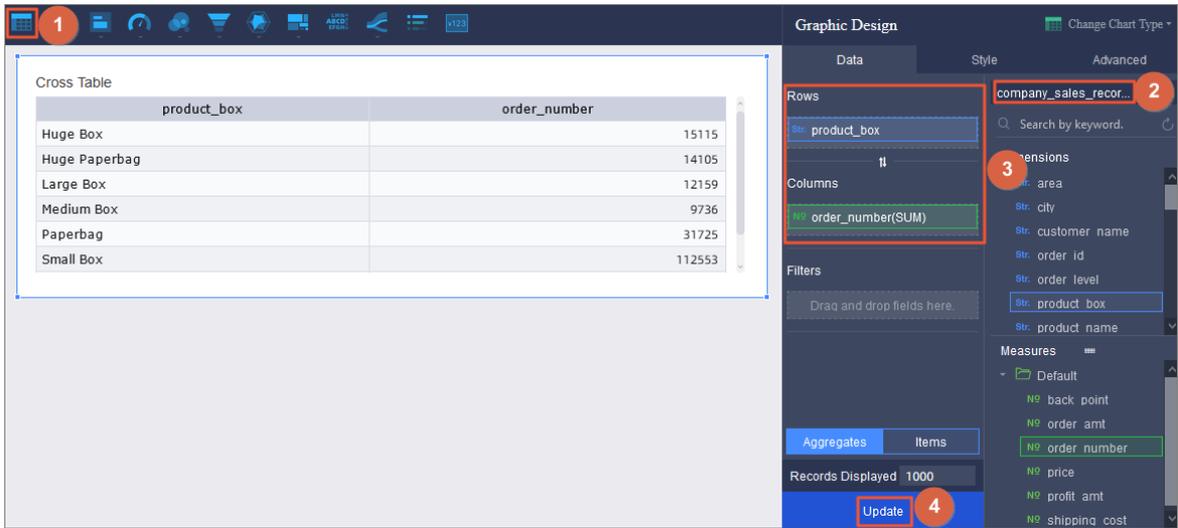

No DATE field in dimensions (year-to-year comparison)

If dimensions do not contain DATE fields and you want to configure the comparison feature for the chart, select a DATE field in a query control that is associated with the chart. Then, set Comparison Date to a field with the same granularity as this DATE field in the **Comparison Settings** dialog box.

The following example demonstrates how to configure year-to-year comparison for a measure. A cross table is used in this example.

1. On the dashboard edit page, add a cross table and configure it, as shown in the following figure.

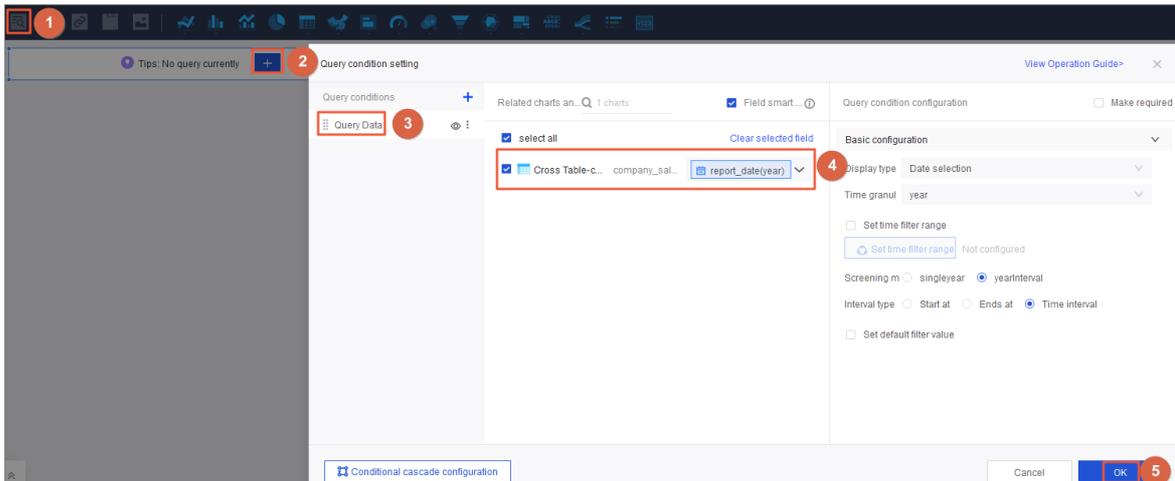

2. Move the pointer over the required measure in the Columns field and click the  icon next to the measure.
3. Choose **Comparison > Custom**.
4. In the **Comparison Settings** dialog box, configure the parameters listed in the following table.

Parameter	Value	Description
Comparison Date	order_date(year)	Configure this parameter as required. In this example, set the value to order_date(year) .
Comparison Type	<ul style="list-style-type: none"> ◦ Compare(Year to Year) ◦ Dynamic Ratio 	The valid values of Comparison Type vary based on the setting of Comparison Date . In this example, set the value to Compare (Year to Year) .
Data Settings	<ul style="list-style-type: none"> ◦ Specific Value ◦ Difference ◦ Percentage Difference 	If you set the value to Percentage Difference , you must click Advanced Settings and select a formula. In this example, set the value to Percentage Difference .
Formula	<ul style="list-style-type: none"> ◦ (Value of Current Period/Value of Previous Period - 1) × 100%: (default value) ◦ 1 - (Value of Current Period/Value of Previous Period) × 100% ◦ Displayed As - 	The formula takes effect only if Data Settings is set to Percentage Difference and the value of the previous period is less than 0.

5. Click **OK**.

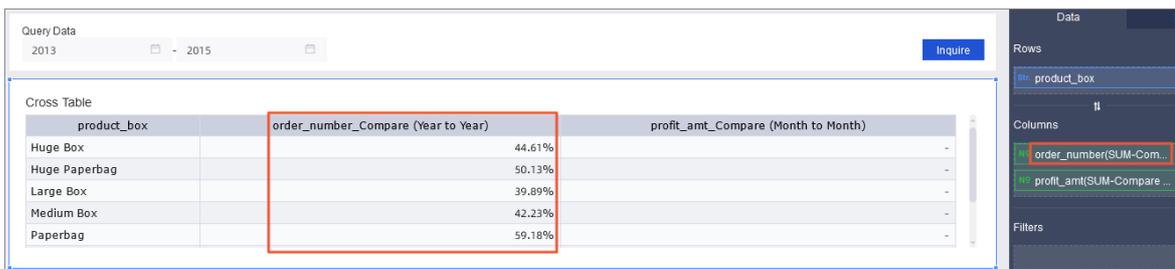

6. Add a query control and configure it, as shown in the following figure.

7. In the query control, specify a time range and click Inquire.

If the query conditions in a query control contain multiple DATE fields and the comparison feature is configured for multiple measures, the comparison feature takes effect only for the first measure.

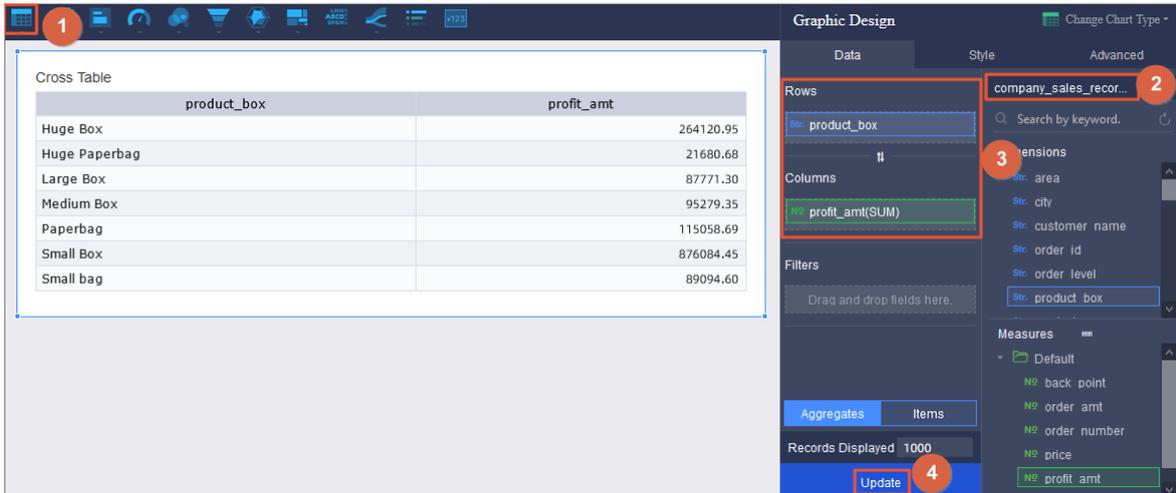

Note If the comparison result cannot be calculated, a hyphen (-) is displayed.

No DATE field in dimensions (Dynamic Ratio)

If dimensions do not contain DATE fields, you must select a DATE field in the **Comparison Settings** dialog box to configure the comparison feature.

You can also select **Dynamic Ratio**. The following example demonstrates how to configure the dynamic ratio. A cross table is used in this example.

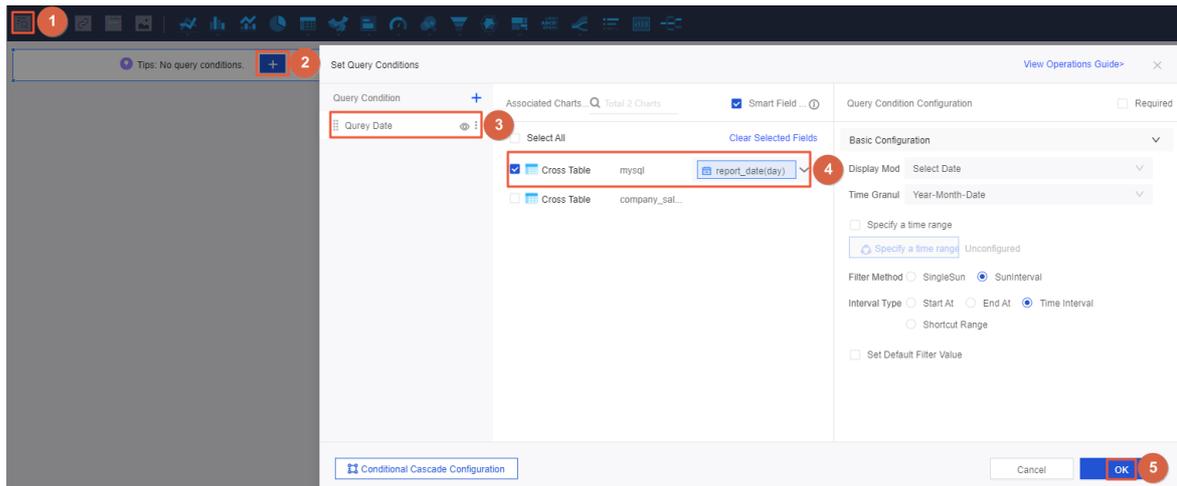

1. On the dashboard edit page, add a cross table and configure it, as shown in the following figure.

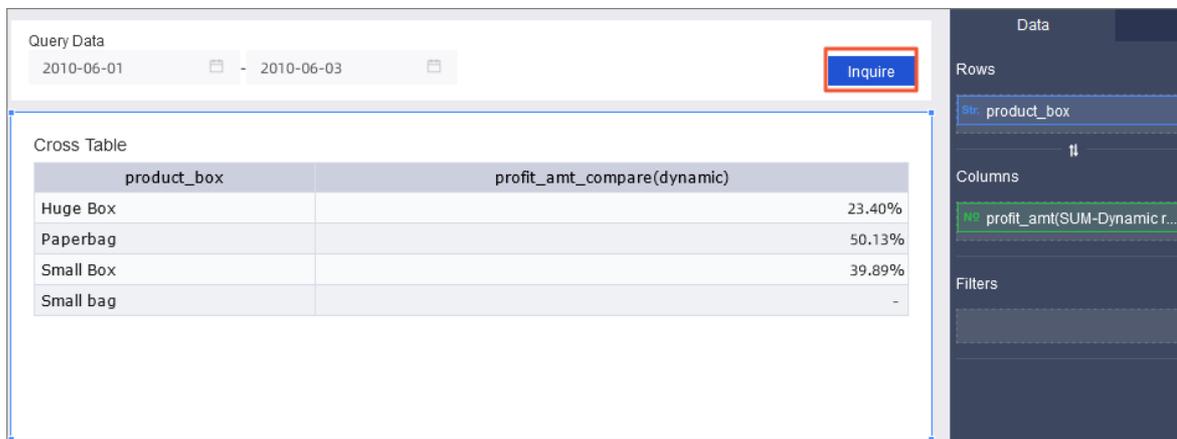

2. Move the pointer over the required measure in the Columns field and click the  icon next to the measure.
3. Choose **Comparison > Custom**.
4. In the **Comparison Settings** dialog box, configure the parameters listed in the following table.

Parameter	Value	Description
Comparison Date	order_date(day)	Configure the parameter as required. In this example, set the value to order_date(day) .
Comparison Type	<ul style="list-style-type: none"> ◦ Compare (Day to Day) ◦ Compare (of Last Week) ◦ Compare (of Last Month) ◦ Compare (of Last Year) ◦ Dynamic Ratio 	The valid values of Comparison Type vary based on the setting of Comparison Date . In this example, set the value to Dynamic Ratio .
Data Settings	<ul style="list-style-type: none"> ◦ Specific Value ◦ Difference ◦ Percentage Difference 	If you set the value to Percentage Difference , you must click Advanced Settings and select a formula. In this example, set the value to Percentage Difference .
Formula	<ul style="list-style-type: none"> ◦ (Value of Current Period/Value of Previous Period - 1) × 100% (default value) ◦ 1 - (Value of Current Period/Value of Previous Period) × 100% ◦ Displayed As - 	The formula takes effect only if Data Settings is set to Percentage Difference and the value of the previous period is less than 0.

5. Click **OK**.
6. Add a query control and configure it, as shown in the following figure.

7. In the query control, specify a time range and click **Inquire**.

8. View SQL statements. If **Comparison Type** is set to **Dynamic Ratio**, the comparison results are dynamically calculated based on the specified time range. The system calculates the difference before the specified date, and then subtracts the date that corresponds to the minus loop. For example:
- If the specified date is January 10, 2020, the date for comparison is January 9, 2020.
 - If the specified time range is January 1, 2020 to January 10, 2020, the time range for comparison is December 22, 2019 to December 31, 2019.
 - i. Click the  icon in the upper-right corner of the cross table.

ii. Select **View SQL Statements**. You can view the time ranges for comparison.

```
SQL
SELECT
  COMPANY_T_1_."product_box" AS A_PRODUCT_2_,
  SUM(COMPANY_T_1_."profit_amt") AS A_PROFIT_3_
FROM
  "public"."company_sales_record" AS COMPANY_T_1_
WHERE
  COMPANY_T_1_."report_date" >= TO_TIMESTAMP('2010-06-01 00:00:00', 'yyyy-MM-dd hh24:mi:ss')
  AND COMPANY_T_1_."report_date" <= TO_TIMESTAMP('2010-06-03 23:59:59', 'yyyy-MM-dd hh24:mi:ss')
GROUP BY
  COMPANY_T_1_."product_box"
LIMIT
  20000 OFFSET 0
SELECT
  COMPANY_T_1_."product_box" AS A_PRODUCT_2_,
  SUM(COMPANY_T_1_."profit_amt") AS A_PROFIT_3_
FROM
  "public"."company_sales_record" AS COMPANY_T_1_
WHERE
  COMPANY_T_1_."report_date" >= TO_TIMESTAMP('2010-05-29 00:00:00', 'yyyy-MM-dd hh24:mi:ss')
  AND COMPANY_T_1_."report_date" <= TO_TIMESTAMP('2010-05-31 23:59:59', 'yyyy-MM-dd hh24:mi:ss')
GROUP BY
  COMPANY_T_1_."product_box"
LIMIT
  20000 OFFSET 0
```

7.5.3.3.6. Filter field data

This topic describes how to filter field data by using the set filter feature.

Prerequisites

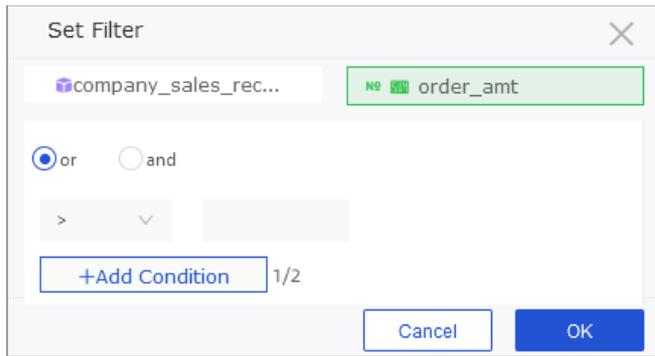

- The Quick BI service is purchased.
- A dataset is selected in the dataset selection area and is edited as need. For information about how to edit a dataset, see [Edit a dataset](#).

Context

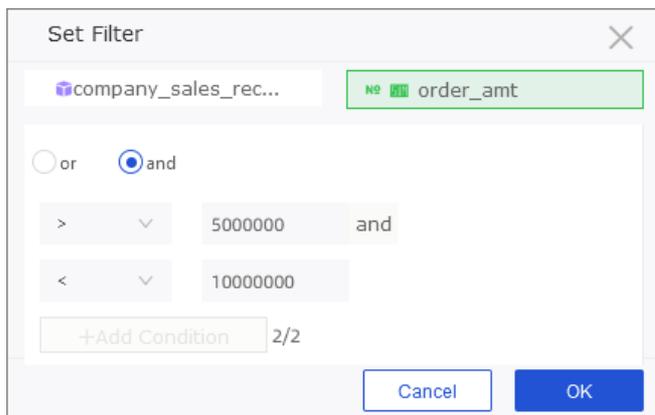

This topic describes how to filter data by using the set filter feature. The order_amt field is used in this example.

Procedure

1. [The required dashboard is displayed](#).
2. Drag order_amt to the filters field.
3. Click the  icon. The **Set Filter** dialog box appears.

4. In the Set Filter dialog box, configure a filter condition. For example, you can select Greater Than, Less Than, or Equal To and set the condition.

5. After you configure the parameters, click OK.
6. Click **Update**. The chart is updated.

7.5.3.3.7. Perform drill-down analysis

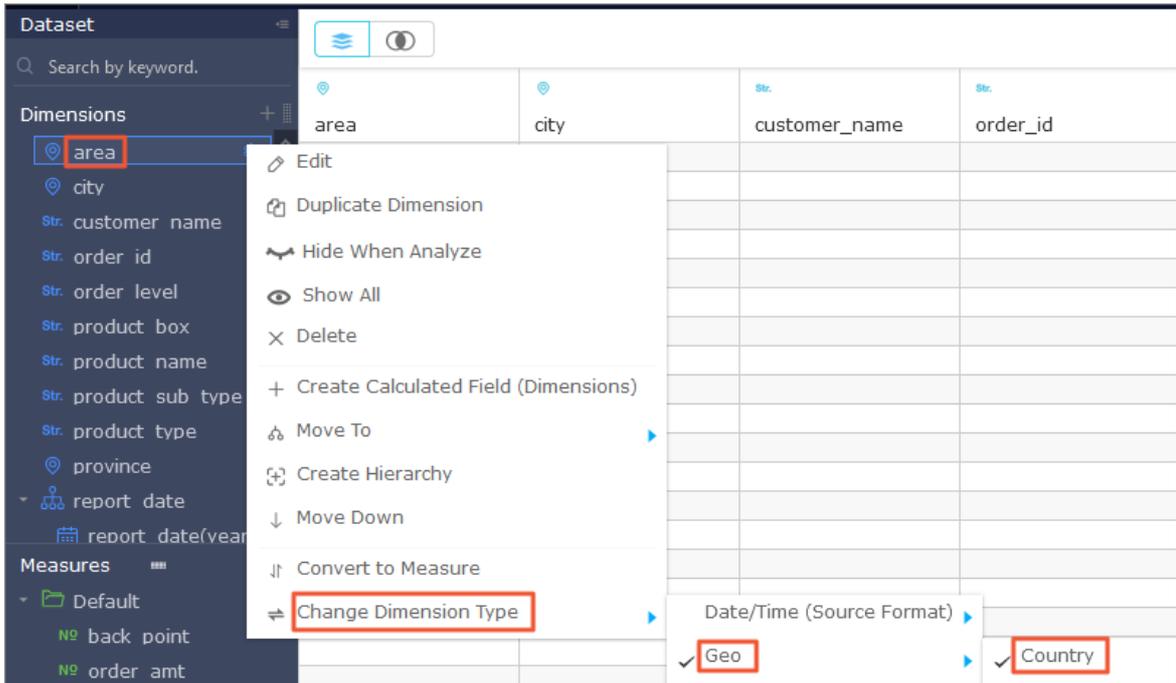

When you create a report, you need to analyze data at fine granularities to have a deep understanding of the data. Drill-down analysis can meet your requirements. Quick BI allows you to perform drill-down analysis. When you click an area in a chart, you can view the information of the provinces in this area, and when you click a province, you can view the information of the cities in this province. The following sections describe how to perform drill-down analysis. The company_sales_record dataset is used as an example.

Prerequisites

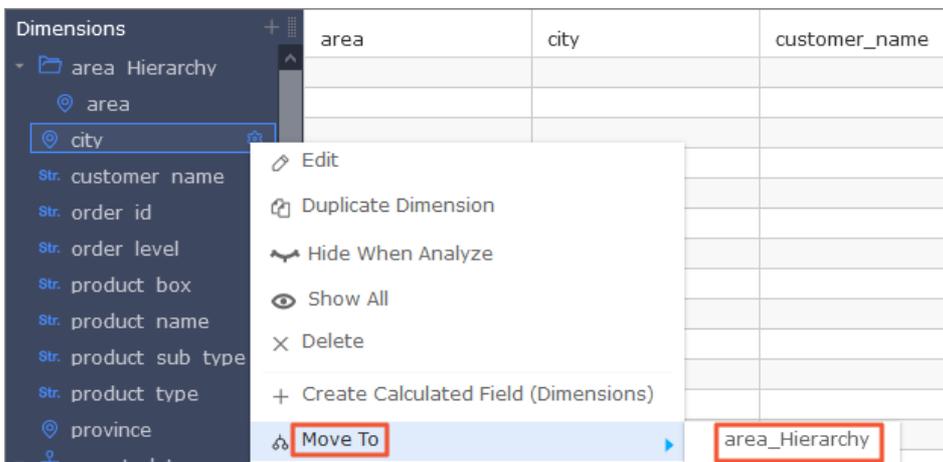

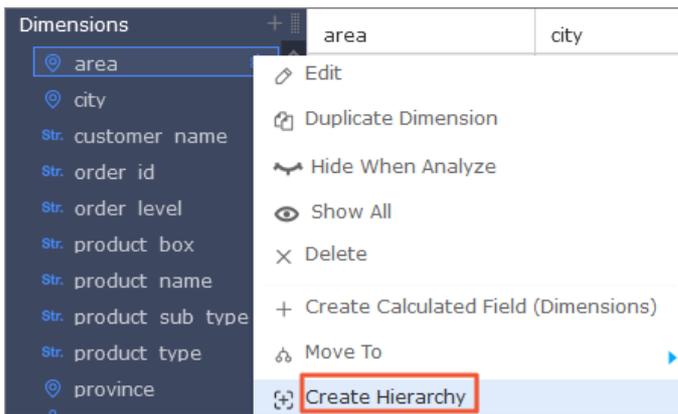

The Quick BI service is purchased.

Edit the dataset

1. [Go to the dashboard edit page.](#)
2. In the dataset selection section, find the required dataset and click the  icon.
3. Click the  icon next to the required field, choose **Change Dimension Type > Geo**, and then change area, province, and city to the required geographic fields, as shown in the following figure.

4. Create a hierarchy named **area_hierarchy** based on area and move province and city to this hierarchy, as shown in the following figure.

5. Save the dataset.

Create a dashboard to perform drill-down analysis

You can manually enable drill-down analysis on a dashboard.

1. In the dataset selection section, select the edited dataset.

For more information, see [Edit the dataset](#).

2. On the dashboard edit page, click the  icon.
3. On the Data tab, add the area and order_amt fields.
4. Click the  icon next to area.

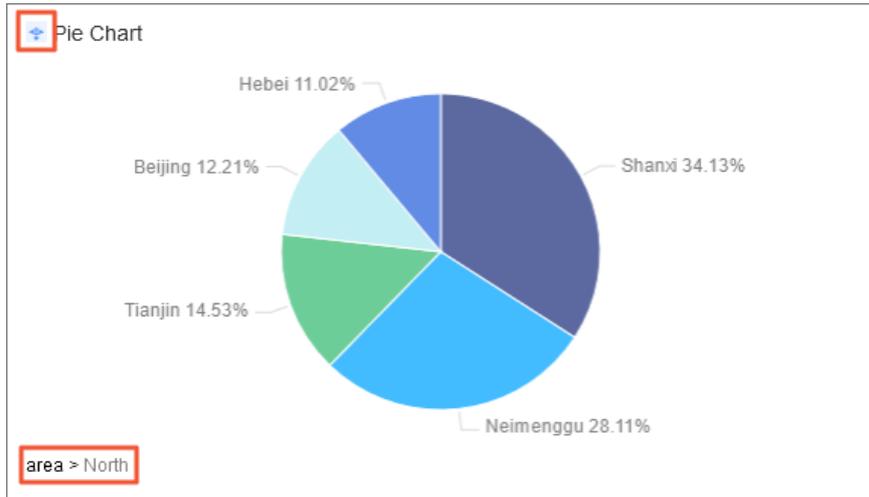

You can customize a drilling hierarchy in the **Drill/Dimension** section. If a hierarchy has been configured for the selected dimension, the hierarchy appears by default. You can also configure the hierarchy as required, as shown in the following figure.

 **Note** The maximum number of drill-down levels is six.

After you configure the drilling hierarchy, the drill-down icon appears next to the chart title. When you click the North China area, information of the provinces in this area is displayed, and the drilling levels appear in the lower-left corner of the chart.

You can click the area in the lower-left corner to display the information of the area to which the current province belongs.

7.5.3.3.8. Filter interaction

You can use the filter interaction feature when you create multiple charts on a dashboard. This topic describes the filter interaction feature.

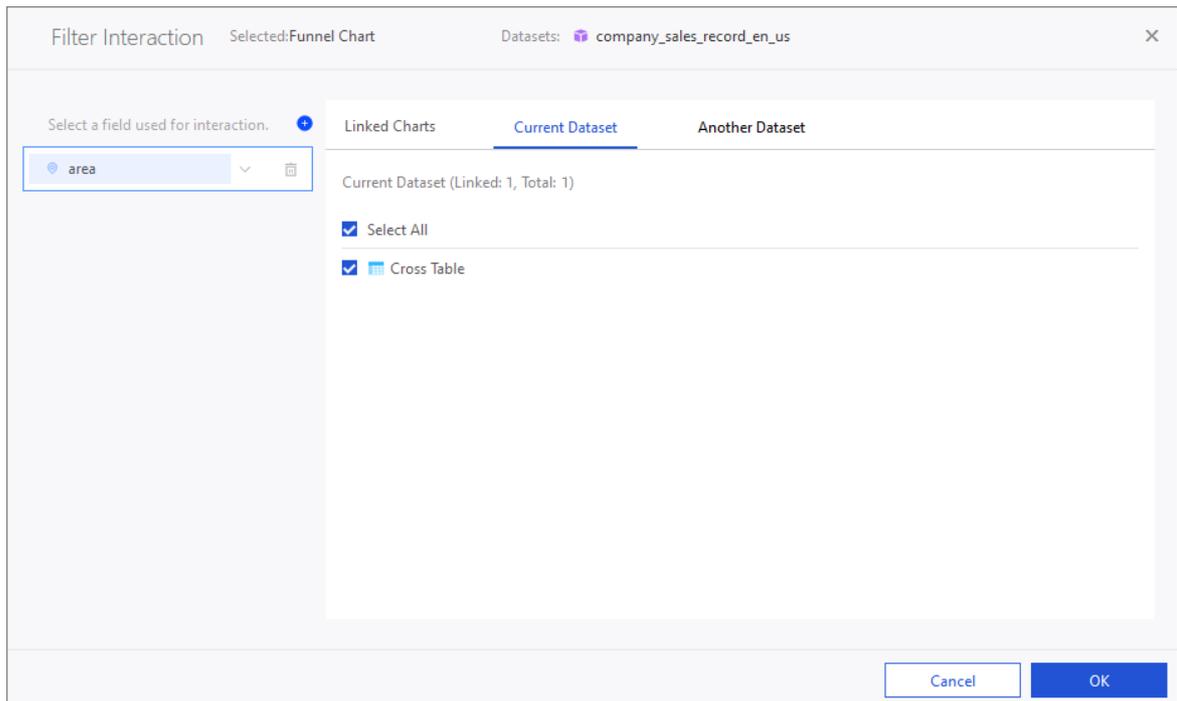

Prerequisites

- The Quick BI service is purchased.
- At least two charts are available in the display area of a dashboard.

Procedure

1. [Go to the dashboard edit page.](#)
2. Select a chart, such as a funnel chart.
3. In the Graphic Design area, click the **Advanced** tab.
4. On the **Advanced** tab, click the  icon next to Filter Interaction.

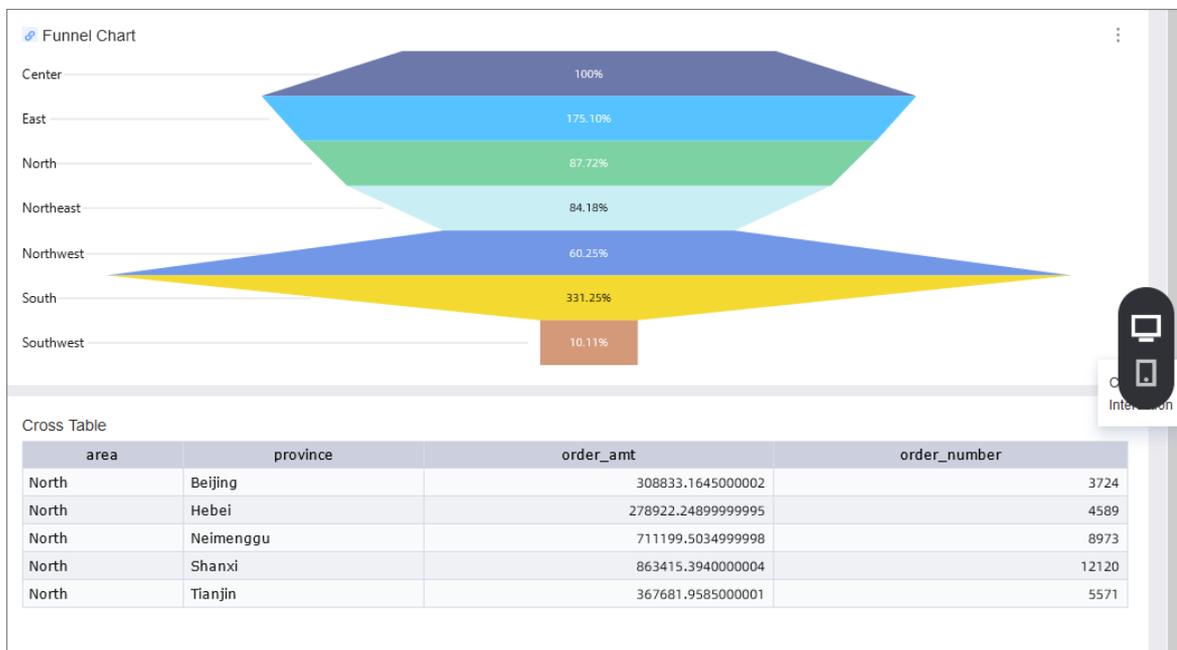

5. In the **Filter Interaction** dialog box, select a required dimension field and chart, and click **OK**.

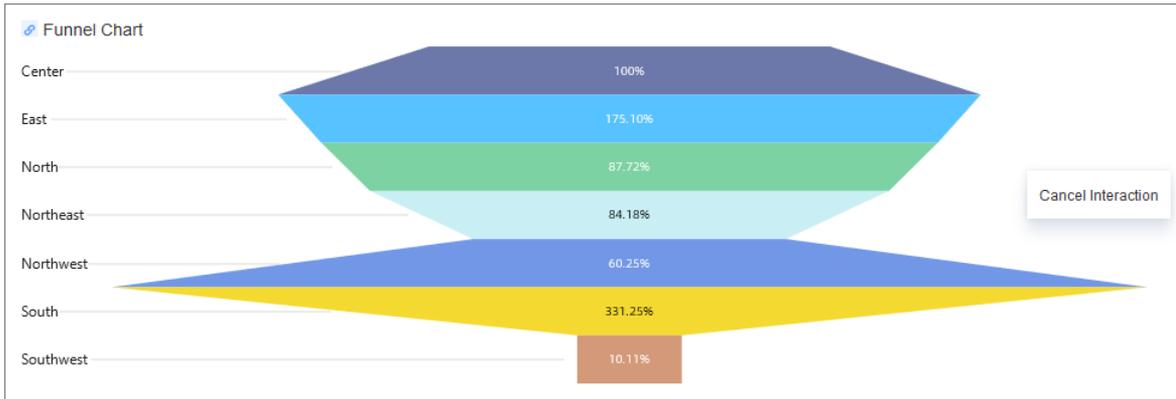

6. In the upper-right corner of the dashboard, click **Preview** to preview the current dashboard.

7. Click **China (Beijing)** in the funnel chart. The associated cross table displays data of the China (Beijing) region.

8. Move your pointer to any blank area in the funnel chart, and click **Cancel Interaction** to disable the filter interaction feature.

7.5.3.3.9. Metric analysis

This topic describes five methods of analysis: auxiliary line, trendline, prediction, anomaly detection and fluctuation analysis.

Prerequisites

- The Quick BI service is purchased.
- A dataset is selected in the dataset selection area and is edited as required.

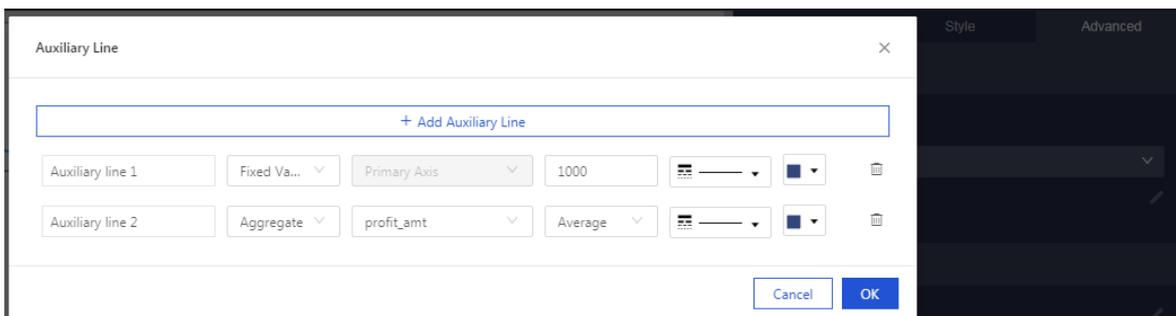

Background information

- Metric analysis allows you to analyze data from multiple perspectives. You can use this feature to obtain data trends and anomalies.
- Metric analysis supports five analysis methods: auxiliary line, trendline, prediction, anomaly detection, and fluctuation analysis.

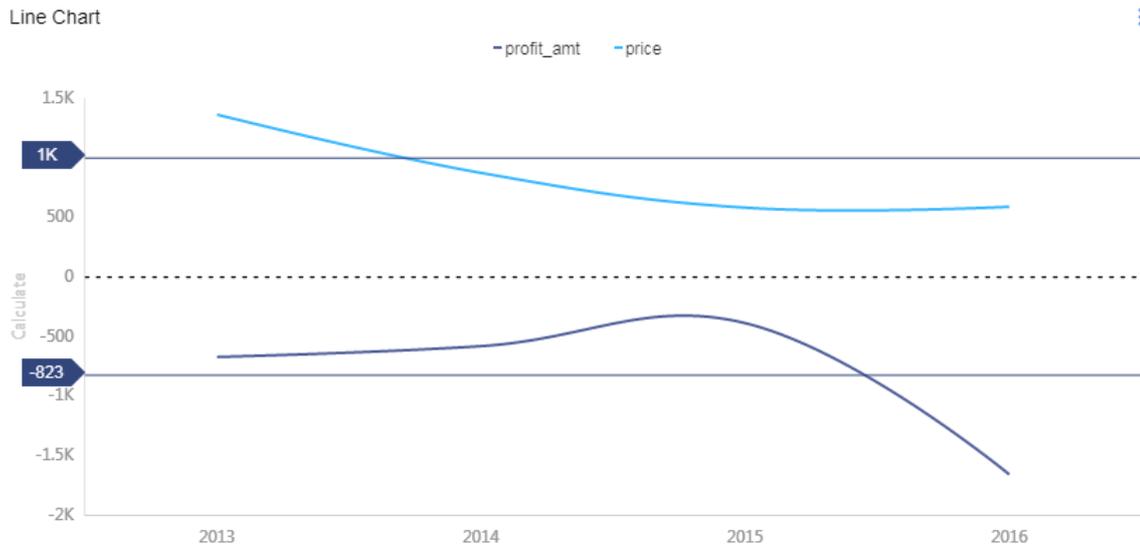

Auxiliary Line

You can add an auxiliary line to view the difference between the value of a measure and the value indicated by the auxiliary line. The value indicated by an auxiliary line can be a fixed or aggregate value. Aggregate values include average, maximum, minimum, and median values.

1. [Log on to the Quick BI console.](#)
2. On the Dashboards page of the Workspace, find the required dashboard and click the icon.
3. On the dashboard edit page, click the required chart.
4. On the **Advanced** tab of the **Graphic Design** page, click the icon next to **Gridlines** in the **Metric Analysis** section.
5. In the **Gridlines** section, click **Add Auxiliary Line** and configure the auxiliary line.

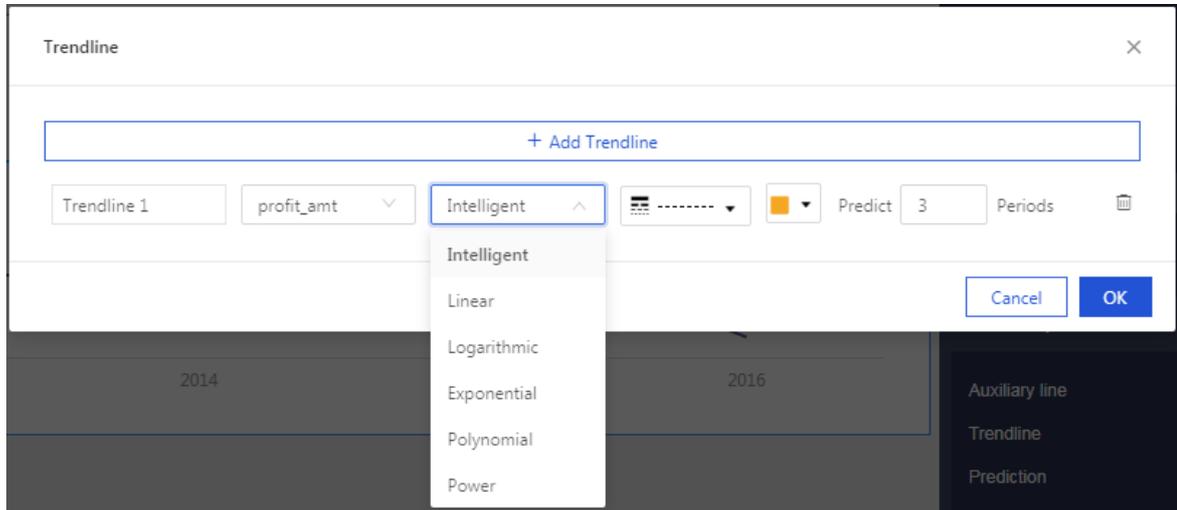

6. Click **OK**. The following figure shows a sample auxiliary line.

Trendline

A trendline displays the data trend. Types of trendlines include Intelligent, Linear, Logarithmic, Exponential, Polynomial, and Power.

1. On the **Advanced** tab of the **Graphic Design** page, click the  icon next to **Trendline** in the **Metric Analysis** section.
2. In the **Trendline** section, click **Add Trendline**. Select a measure, a trendline type, and the number of subsequent periods for which to predict trends.

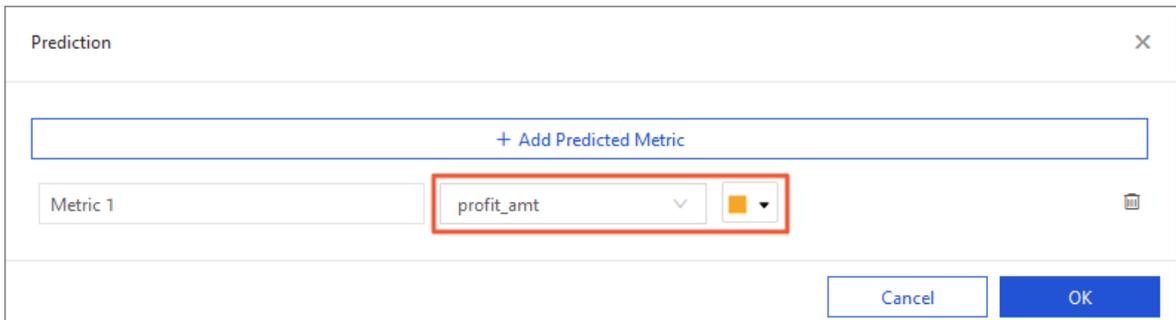

3. Click **OK**. The following figure shows a sample trendline.

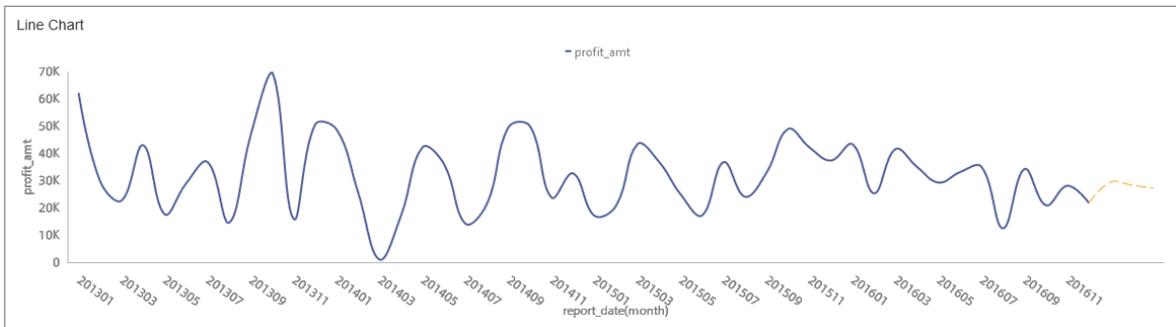

Prediction

You can add a predicted metric to view the trend of current data and predict future trends.

1. On the **Advanced** tab of the **Graphic Design** page, click the  icon next to **Prediction** in the **Metric Analysis** section.
2. In the **Prediction** section, click **Add Predicted Metric**. Select a measure and a color for the line.

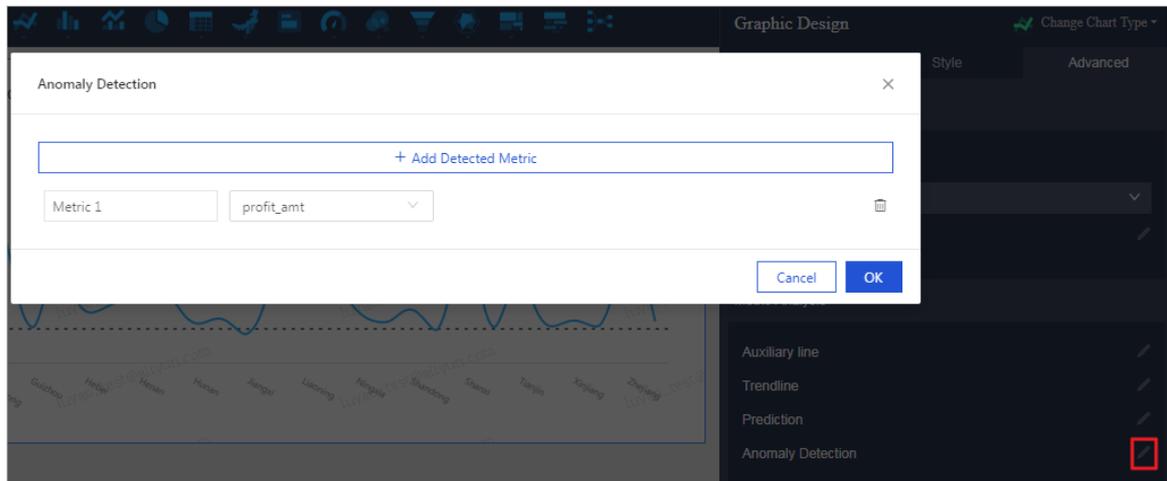

3. Click **OK**. The following figure shows sample prediction results.

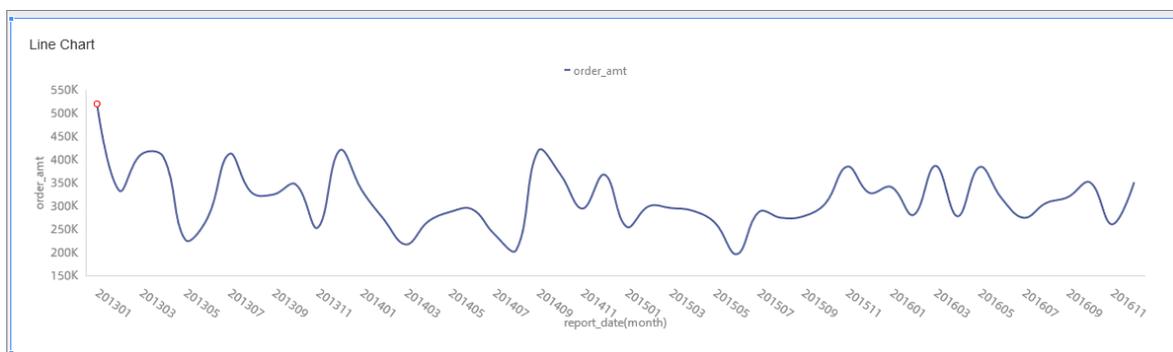

Anomaly Detection

You can use this feature to detect data anomalies.

1. On the **Advanced** tab of the **Graphic Design** page, click the  icon next to **Anomaly Detection** in the **Metric Analysis** section.
2. In the **Anomaly Detection** section, click **Add Detected Metric**. Select a measure.

3. Click **OK**. The following figure shows sample anomaly detection results.

Note An anomaly point in the line graph is marked with a red dot and an anomaly point in the column chart is marked with a full red column chart.

Fluctuation analysis

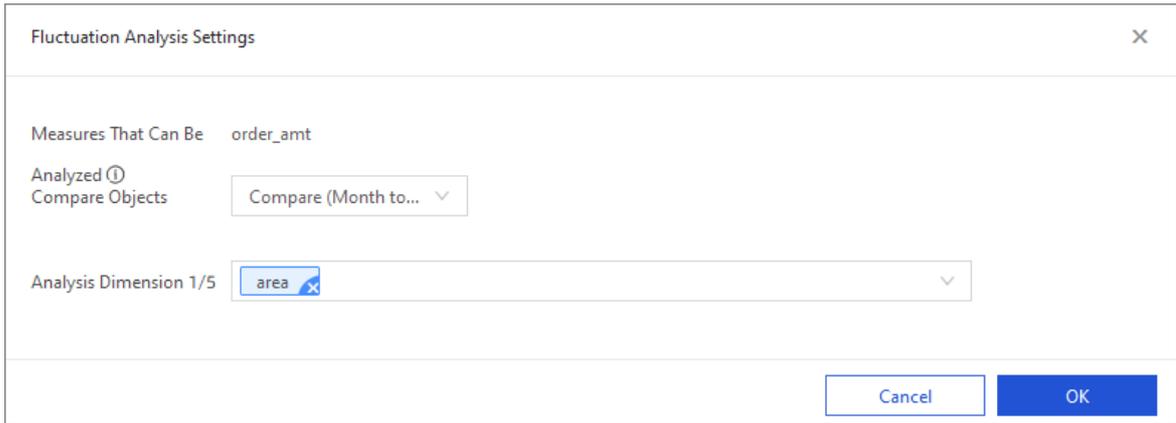

Fluctuation analysis uses machine learning algorithms to analyze the impact of dimensions on measures. You can view the contributions of dimensions to measure fluctuation and specific changes.

1. On the **Advanced** tab of the **Graphic Design** pane, click the  icon next to **Fluctuation Analysis** in the **Metric Analysis** section.

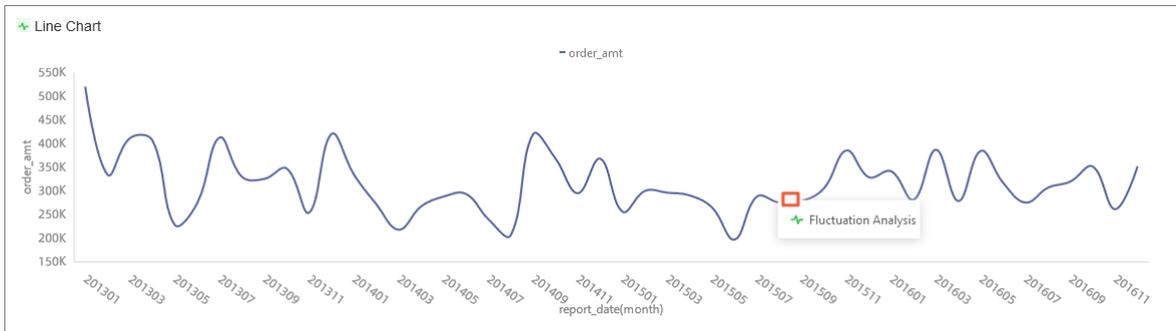

Note The charts that meet both of the following conditions support fluctuation analysis:

- A time dimension (except hour, minute, and second) is selected for Category Axis (Dim.).
- At least one measure uses the aggregate method SUM, COUNT, or COUNT DISTINCT.

2. On the **Fluctuation Analysis Settings** page, select a comparison object and an analysis dimension, and click **OK**.

3. Click a time point in the chart and then click **Fluctuation Analysis**.

4. In the **Fluctuation Analysis** section, select a measure to view the key factors that affect the measure.

Fluctuation Analysis 201508 Measures That Can Be Analyzed: order_amt

201508, order_amt: 275.21K; Compare with 201507 (order_amt: 287.91K), Change -12.69K, **-4.41%**.

Key Influencing Factors

areaisSouth Change contribution to order_amt is **490%**, order_amt: 51.79K; Change -62.15K, **-54.5%**;

areaisNorth Change contribution to order_amt is **284%**, order_amt: 37.29K; Change -36.01K, **-49.1%**;

areaisCenter Change contribution to order_amt is **34.2%**, order_amt: 19.69K; Change -4341.29, **-18.1%**;

Reverse Influencing Factors

areaisNortheast Change contribution to order_amt is **-327%**, order_amt: 64.11K; Change 41.53K, **184%**;

areaisNorthwest Change contribution to order_amt is **-206%**, order_amt: 33.06K; Change 26.20K, **382%**;

areaisSouthwest Change contribution to order_amt is **-94.9%**, order_amt: 12.86K; Change 12.05K, **1491%**;

areaisEast Change contribution to order_amt is **-79.0%**, order_amt: 56.41K; Change 10.03K, **21.6%**;

⚙️ Change contribution of a dimension = Change in the dimension / Total change

OK

7.5.3.4. Dashboard display area

7.5.3.4.1. Overview

This topic describes the features of the dashboard display area.

In the display area of a dashboard, you can perform the following operations on one or more charts:

- Adjust chart positions
- View chart data
- Change chart types
- Add to favorites
- Delete a chart

7.5.3.4.2. Toolbar

This topic describes the features of the toolbar.

The toolbar of a dashboard allows you to save, preview, and edit the dashboard, as shown in [Dashboard toolbar](#).

Dashboard toolbar

7.5.3.4.3. Adjust chart positions

Multiple charts may be displayed on the same dashboard. In this case, you can drag the charts to adjust their positions.

Prerequisites

The Quick BI service is purchased.

Procedure

1. [Go to the target dashboard](#).
2. Select a chart or widget.
3. Drag the chart or widget to the desired position.

 **Note** You can drag a chart or widget to anywhere within the display area of the dashboard.

7.5.3.4.4. View chart data

This topic describes how to view chart data.

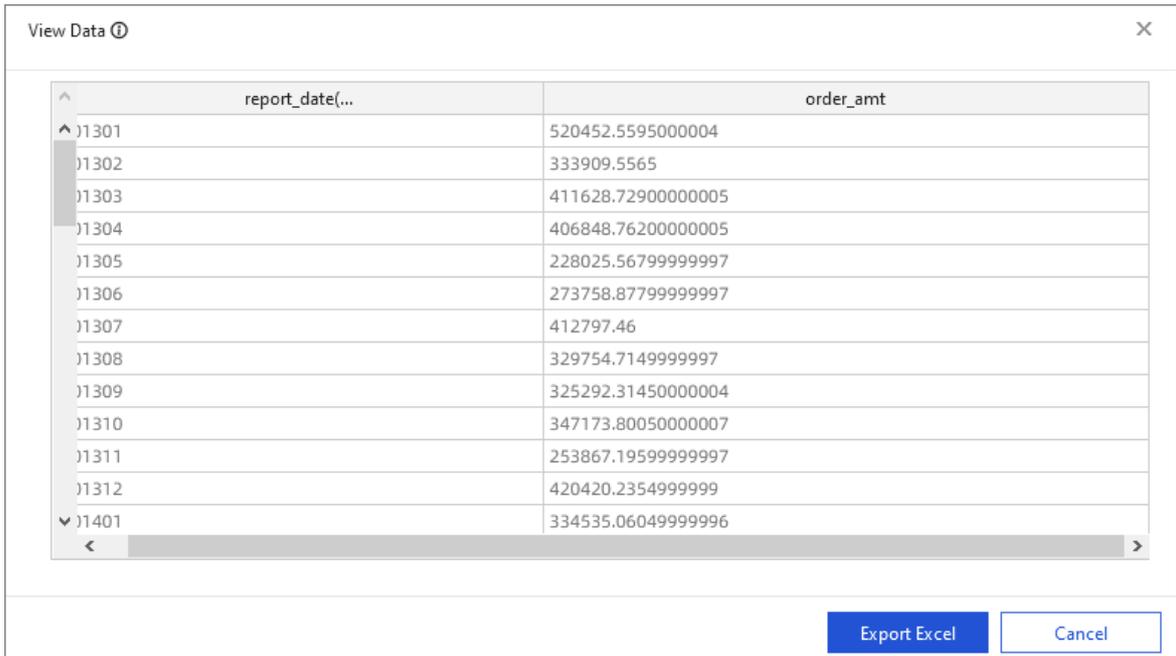

Prerequisites

The Quick BI service is purchased.

Procedure

1. [Go to the dashboard edit page](#).
2. In the dashboard display section, select a chart, such as a funnel chart.
3. Move the pointer over the upper-right corner of the chart, click the  icon, and then select **View Data**.

4. On the page that appears, click **Export Excel** to download data to your on-premises machine.

7.5.3.4.5. Change chart types

You can select different chart types from the toolbar on the top of the dashboard.

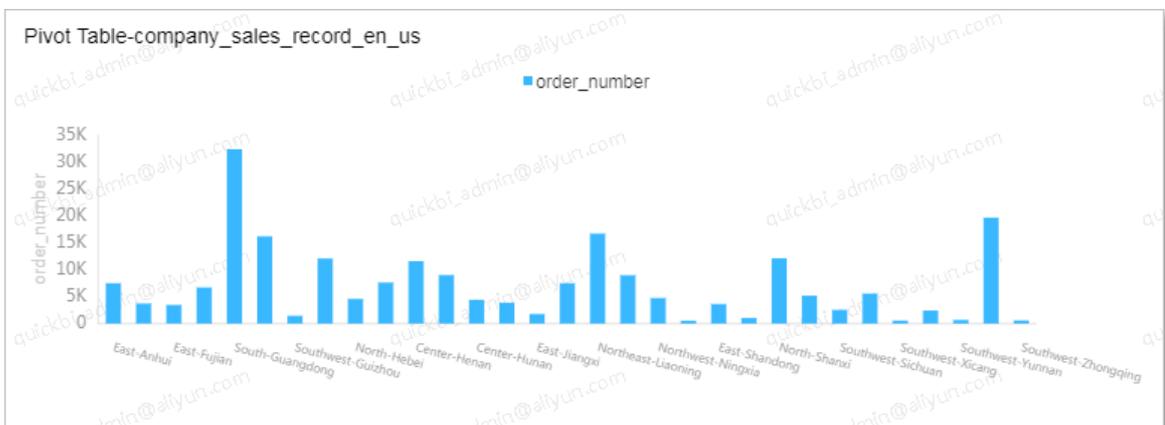

Prerequisites

The Quick BI service is purchased.

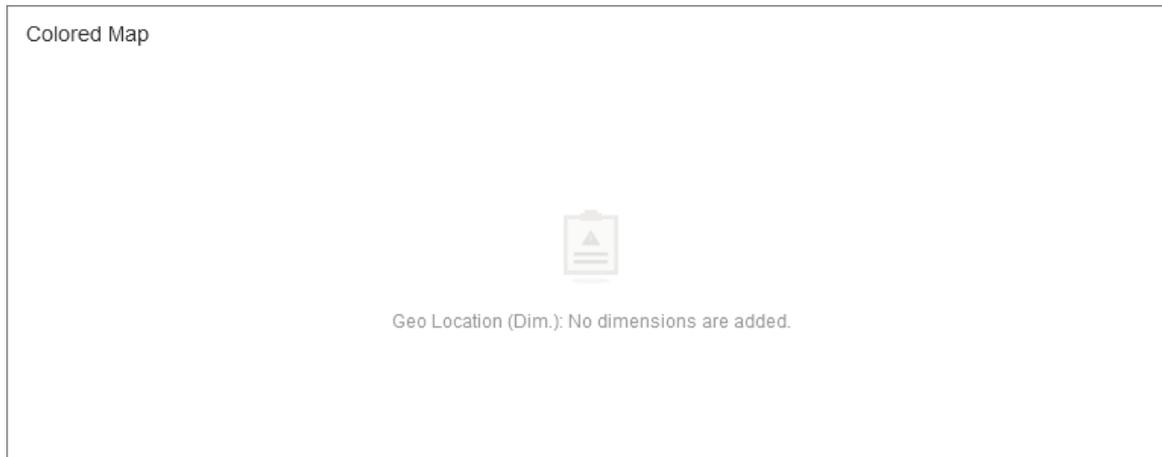

Procedure

1. Go to the dashboard edit page.
2. Select a chart, such as a cross table.
3. In the Graphic Design area, click **Change Chart Type** and select another chart type, such as a vertical bar chart.
4. Click the **Vertical Bar Chart** icon to change the chart type.

The system then converts the cross table to a vertical bar chart.

If the switch between chart types fails, the elements of the selected chart type do not match those of the current chart type. You need to modify the problematic data fields based on the requirements of the selected chart type.

To change the chart type, follow the instructions to manually adjust the dimensions and measures.

7.5.3.4.6. Add to Favorites

This topic describes how to add a dashboard to the Favorites tab.

Prerequisites

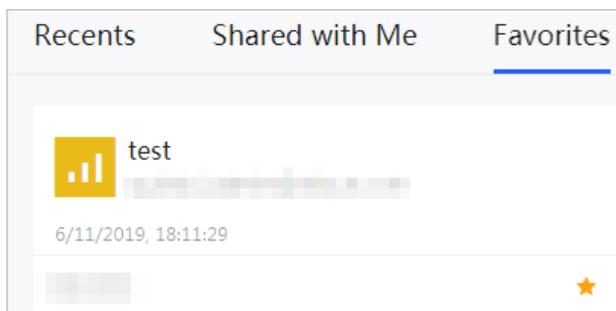

The Quick BI service is purchased.

Procedure

1. The required dashboard is displayed.
2. On the display area of the dashboard, click the  icon in the top navigation bar.

3. On the Quick BI homepage, you can click the **Favorites** tab to view the dashboards that you have added.

7.5.3.4.7. Delete a chart

This topic describes how to delete a chart.

Prerequisites

The Quick BI service is purchased.

Procedure

1. [Access a dashboard](#).
2. Select a chart, such as a radar chart.
3. Move the pointer over the upper-right corner of the chart and click the  icon. Select **Delete** to delete the chart.

7.5.3.4.8. Widgets

7.5.3.4.8.1. Overview

This topic describes the widgets of a dashboard.

The display section of a dashboard provides the following widgets:

- Query control
- Text area
- iFrame
- Tab
- Image

7.5.3.4.8.2. Filter bar

In a dashboard, you can use the Filter Bar widget to query data in one or more charts.

Create a filter bar

This topic describes how to create a filter bar.

Prerequisites

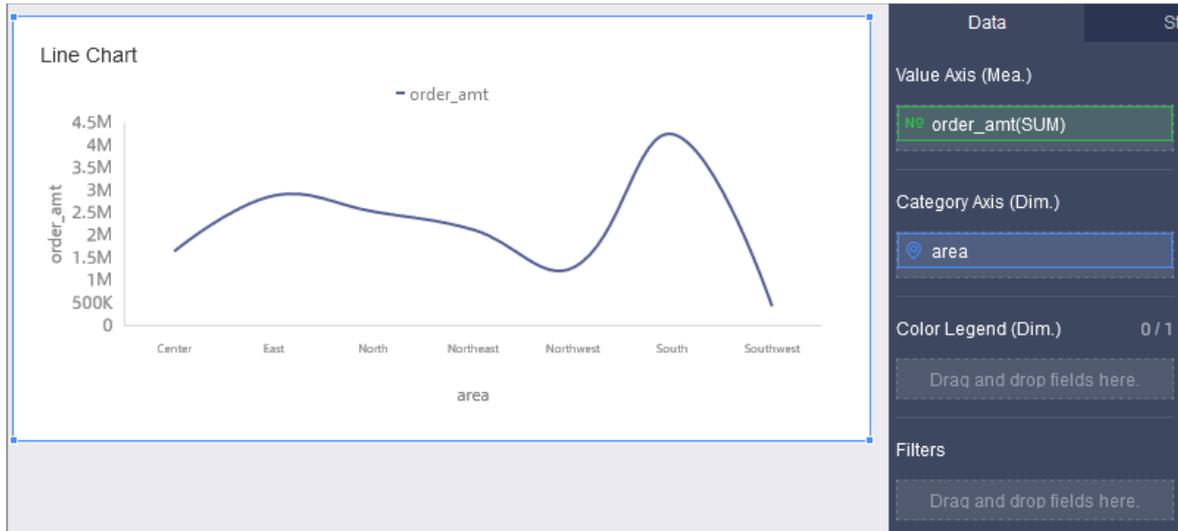

The Quick BI service is purchased.

Context

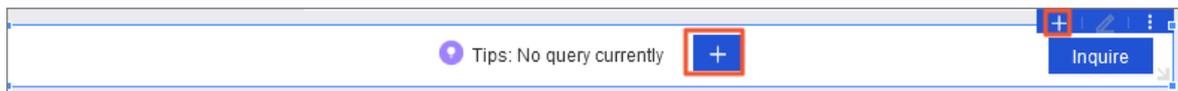

Filter bars allow you to associate charts from the same dataset or those from different datasets.

Procedure

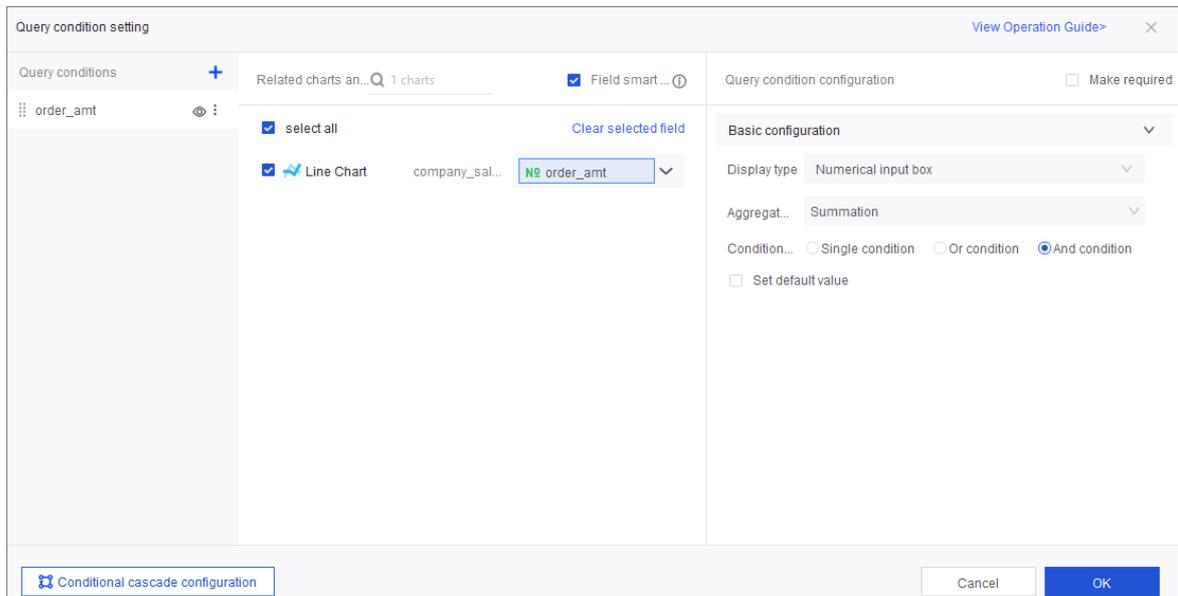

1. [Go to the dashboard edit page](#).
2. Create a line chart on the dashboard edit page. For more information, see [Create a line chart](#).

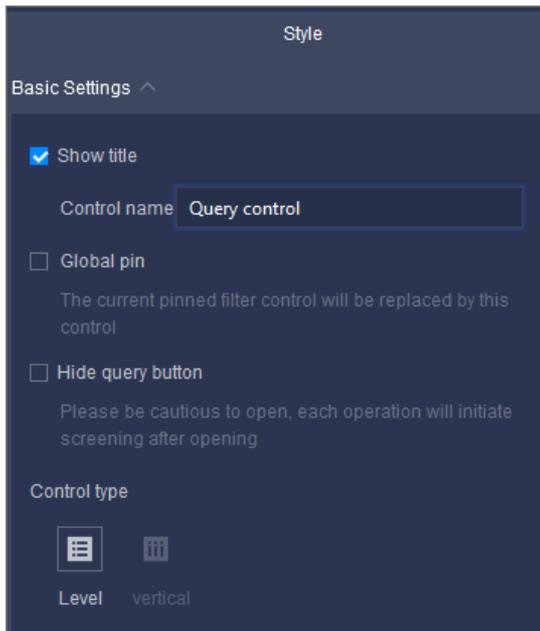

3. In the menu bar, click the  icon to add a filter bar.
4. In the dashboard display section, find the filter bar and click the  icon.

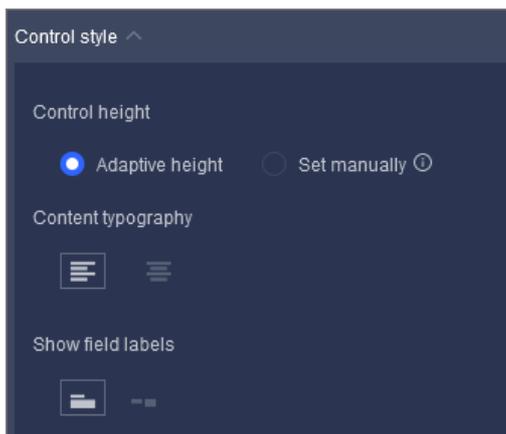

5. In the Set Query Conditions dialog box, configure the filter conditions and click OK.

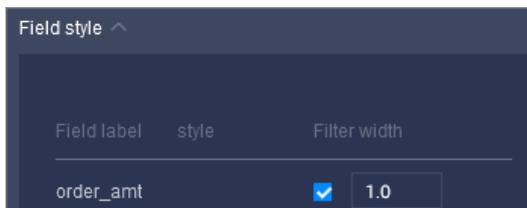

6. On the Style tab, configure the style of the filter bar.
 - o In the **Basic Settings** section, configure Show Title, Global Pin, Hide Query Button, and Control Type.

- o Control Style: In this section, you can configure Control height, Content typography, and field label positions.

- o Field Style: In this section, you can configure the styles and widths of fields.

7. In the filter bar, configure filter conditions and click **Query**. The chart that is associated with the field is automatically updated.

Perform cascade filtering

The Filter Bar widget supports cascade filtering, which makes it easier for you to specify multiple filter conditions.

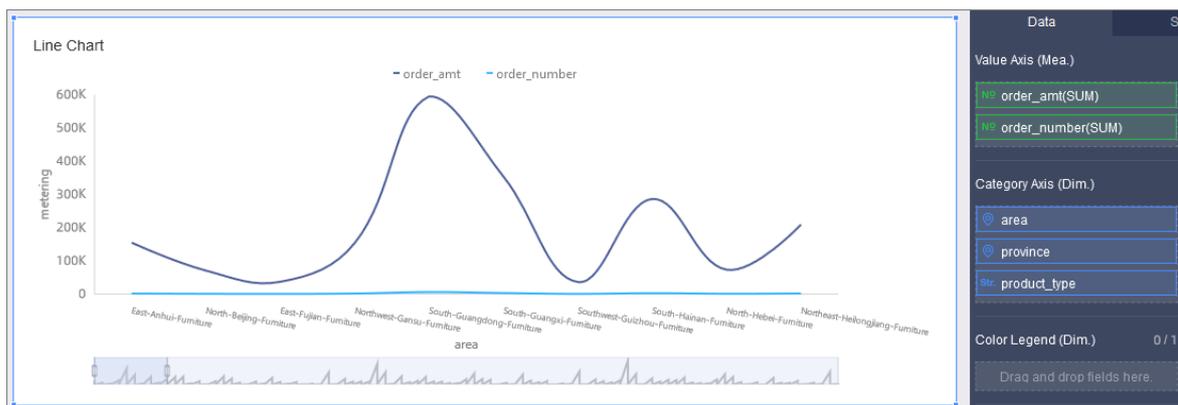

Prerequisites

- The Quick BI service is purchased.
- Two filter bars are created on the dashboard, with Display Mode set to Drop-Down List and Source set to Single Dataset. For more information, see [Create a filter bar](#).

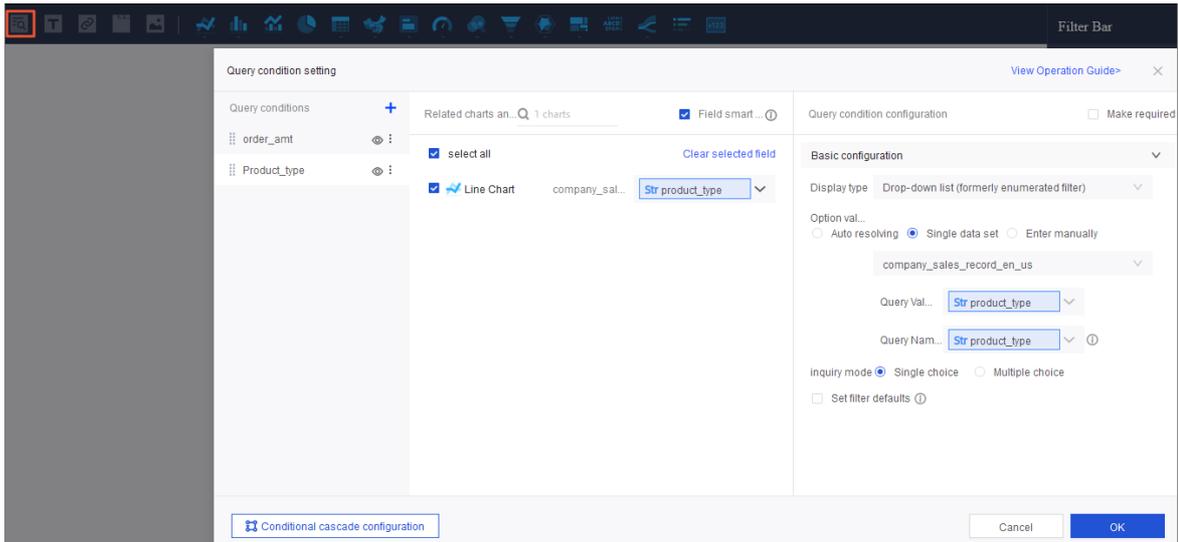

Procedure

1. [Go to the dashboard edit page](#).
2. Create a line chart on the dashboard edit page.

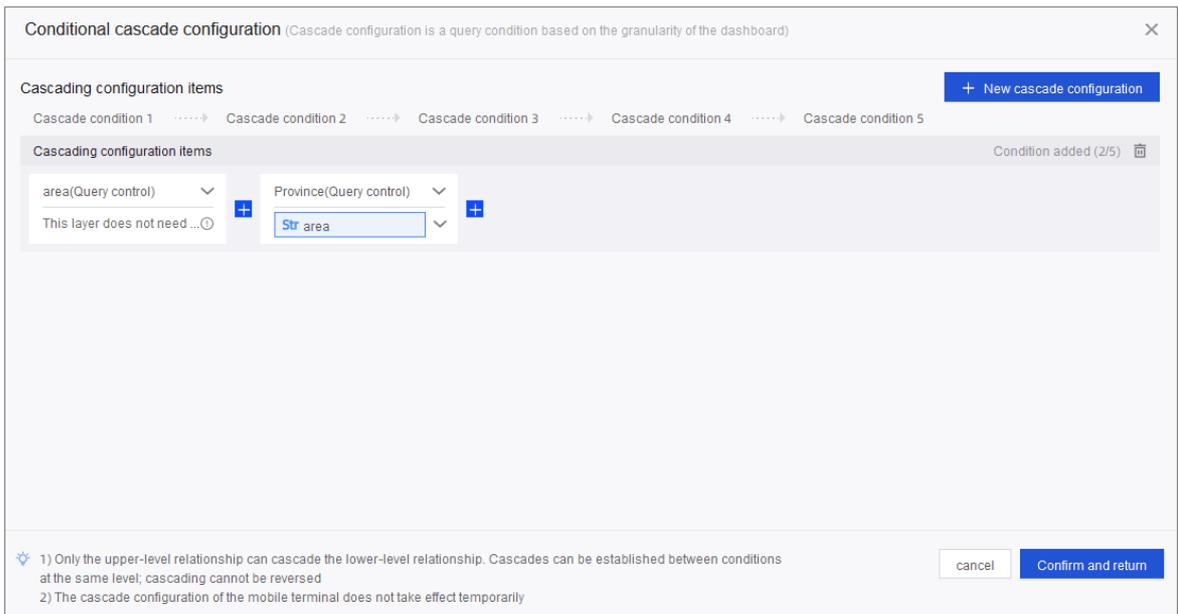

For more information, see [Create a line chart](#).

3. Add and configure the filter bar, and then click **OK** to save the configuration.

4. In the **Set Query Conditions** dialog box, click **Conditional Cascade Configuration**.
5. In the **Cascade Configuration Items** section in the **Conditional Cascade Configuration** dialog box, select **area** and click the **+** icon next to the field.
6. Select the conditional field and associated field.

- To associate multiple conditions, click **Add Cascade Configuration Item** in the upper-right corner.
7. After the configuration is completed, click **Confirm and Return**.
 8. Click **Query** in the filter bar.

Note If you want to view details of the cascade, move the pointer over the cascade icon in the upper-right corner of the line chart.

Use SQL statement parameters in the Filter Bar widget

This topic describes how to use parameters in SQL statements for ad hoc analysis as the filter fields in the Filter Bar widget.

Prerequisites

Parameters are set in SQL statements for ad hoc analysis.

Procedure

1. Click the Filter Bar icon on the dashboard edit page. On the Data tab, select a dataset. If the dataset contains parameters of SQL statements, the parameters appear at the lower part of this tab and are displayed in orange.

Note Parameters in SQL statements do not support cascade filtering.

2. Select a parameter, click the **Set Filter** icon. On the Set Filter dialog box that appears, perform filter settings.

If you select **Filter by Condition** for parameters of the date, numeric, and text types, see [Query data by date](#), [Query numeric data](#), and [Filter bars](#).

If you select **Filter by Value** for parameters of the string type, set the enumeration value range and then enter the parameter values.

Select the parameter that you want to use for data filtering and click Query.

Query data of a specific time range

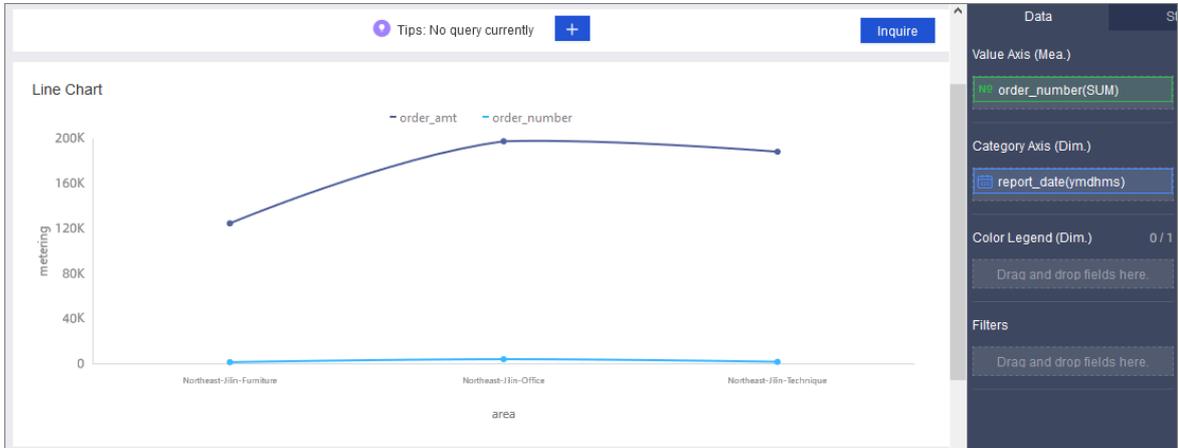

The Filter Bar widget allows you to query data of a specific time range. You can set a time range, manually set default values, and customize shortcuts to query time-related data.

Prerequisites

The Quick BI service is purchased.

Procedure

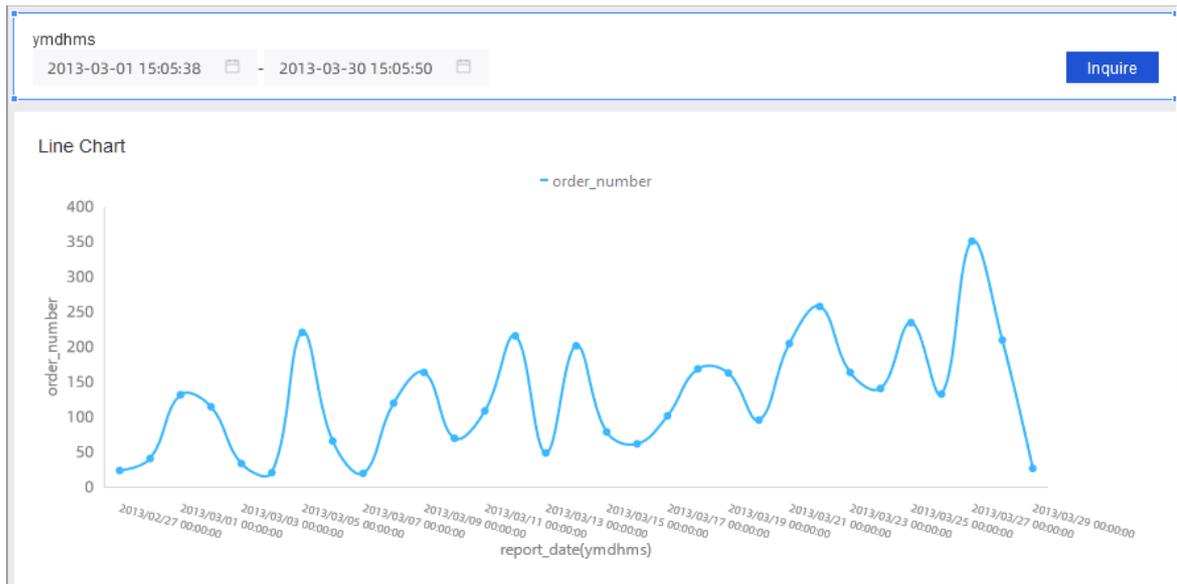

1. The required dashboard is displayed.
2. Create a line chart and a filter bar on the dashboard edit page.

3. In the Set Query Conditions dialog box, configure query conditions. In this example, configure YYYY/MM/DD HH:mm:ss.

The screenshot shows the "Query condition setting" dialog box. It has a title bar with "View Operation Guide" and a close button. The main area is divided into several sections: "Query conditions" with a "+" icon and a list of conditions including "ymdhms"; "Related charts and..." with "2 charts" and a "Field smart..." checkbox; "Query condition configuration" with a "Make required" checkbox. Under "Basic configuration", there are settings for "Display type" (Date selection), "Time granul" (Year-month-day-hour-minute-second), "Display form" (YYYY-MM-DD HH:mm:ss), "Set time filter range" (Not configured), "Screening m" (singlesecond, secondInterval), and "Interval type" (Start at, Ends at, Time interval). At the bottom, there is a "Conditional cascade configuration" button, "Cancel", and "OK" buttons.

4. After the parameters are configured, click **OK**.
5. Specify a time duration and click **Query**.

Query text data

This topic describes how to use the Query control widget to query text data.

Prerequisites

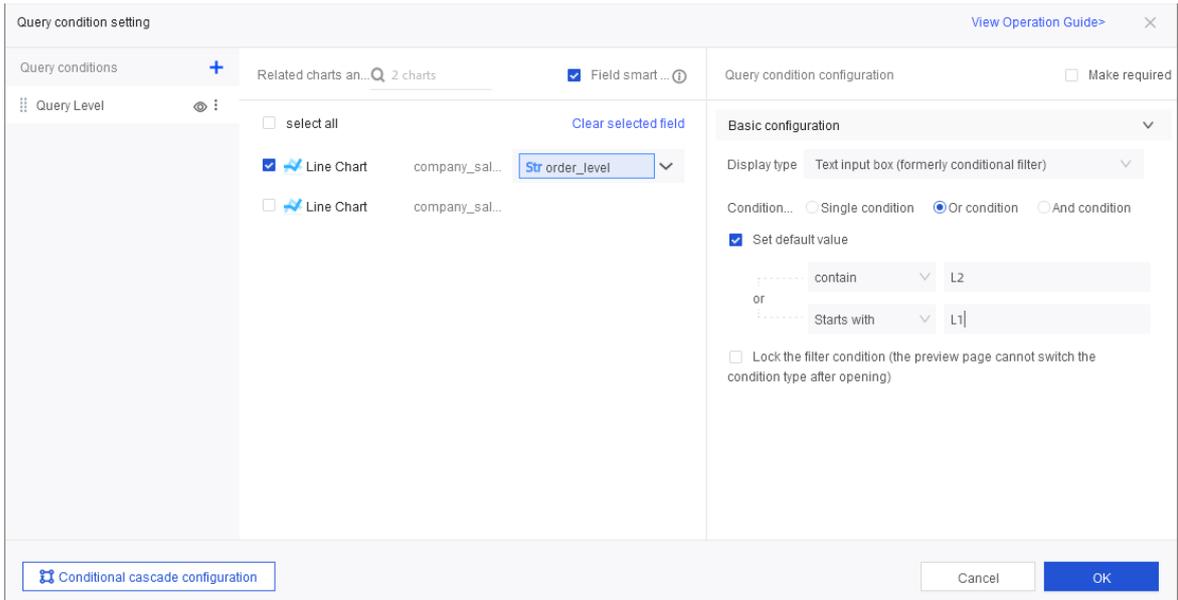

The Quick BI service is purchased.

Procedure

1. The required dashboard is displayed.
2. Create a line chart and a query control on the dashboard edit page.

3. In the Set Query Conditions dialog box, configure query conditions. In this example, order_level is selected.

- 4. After the parameters are configured, click **OK**.
- 5. In the query control, click **Query**

Query numeric data

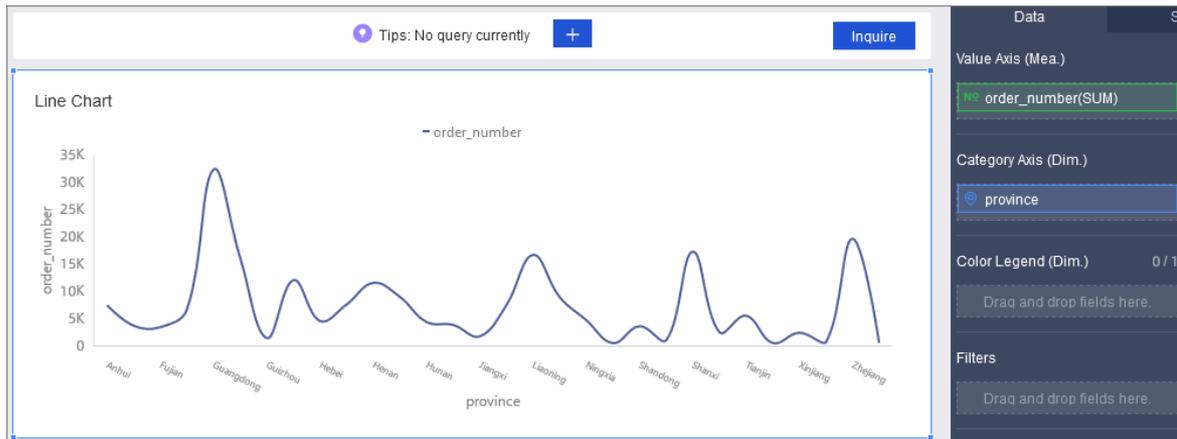

This topic describes how to use the Filter Bar widget to query numeric data.

Prerequisites

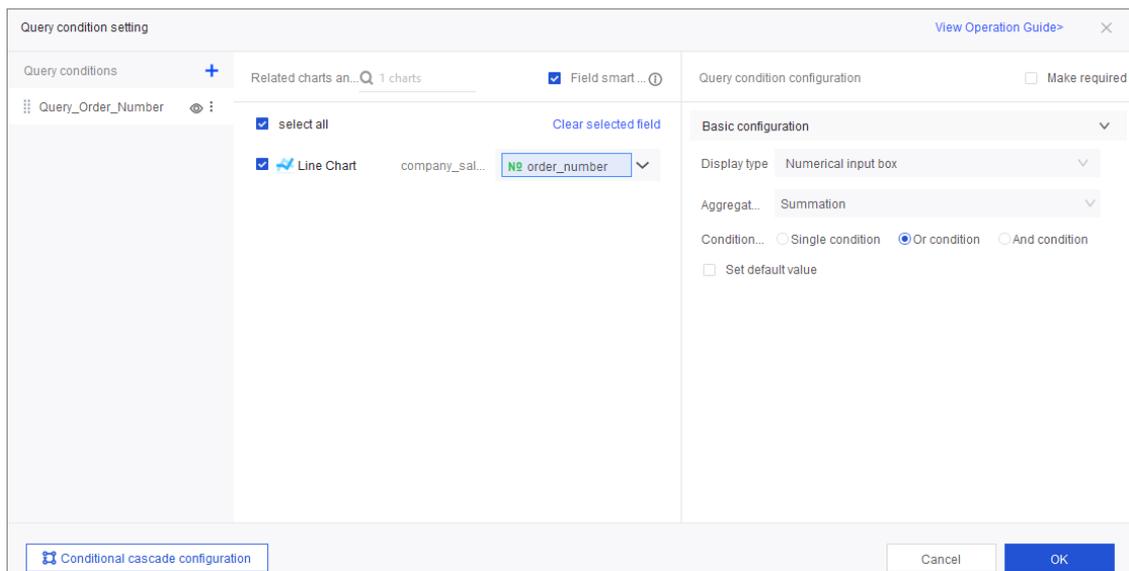

The Quick BI service is purchased.

Procedure

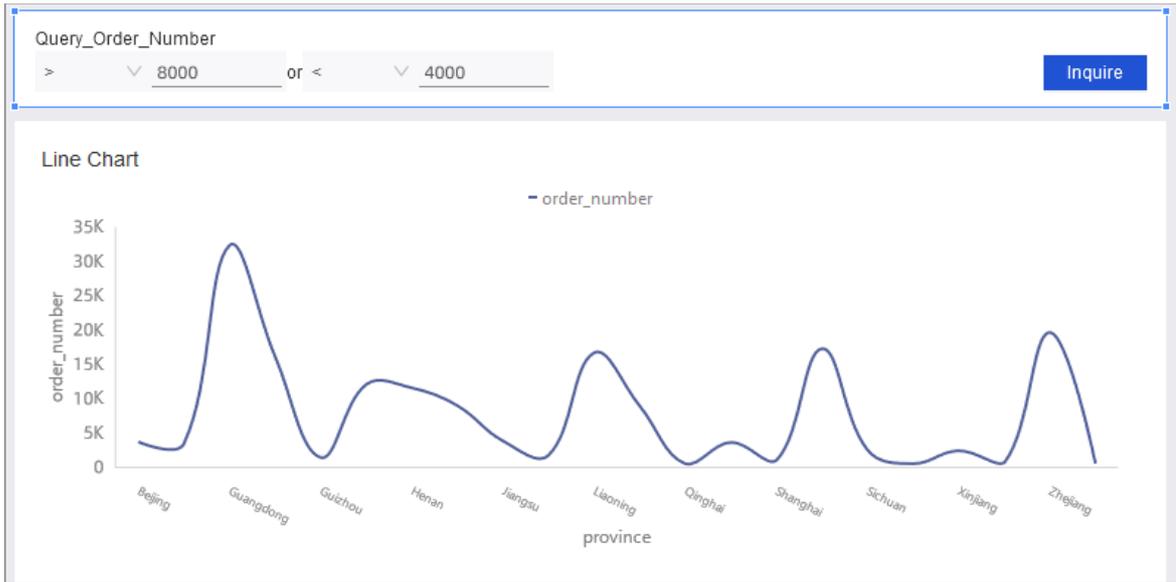

1. [Go to the dashboard edit page.](#)
2. Create a line chart and a filter bar on the dashboard edit page.

3. In the Set Query Conditions dialog box, configure query conditions.
 - i. Set the query condition name to **Order quantity query**.
 - ii. Select Line chart and the **order_number** field and associate them with the query control.
 - iii. When the field type is numeric, set Aggregation method and **Conditional form** as required. **Display type** is automatically set to **Numerical input box**. Supported aggregation methods include multiple aggregate functions, variance, and standard deviation. Supported conditional forms include **Single condition**, **Or condition** or **And condition**.

4. After the parameters are configured, click **OK**.
5. In the filter bar, configure filter conditions and click **Query**.

7.5.3.4.8.3. Compound Query Control

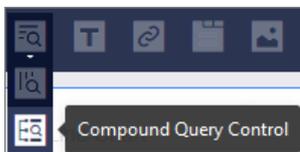

Add filter conditions

Prerequisites

- The Quick BI service is purchased.
- The target dashboard is displayed.

Procedure

1. Click the **Compound Query Control** icon.

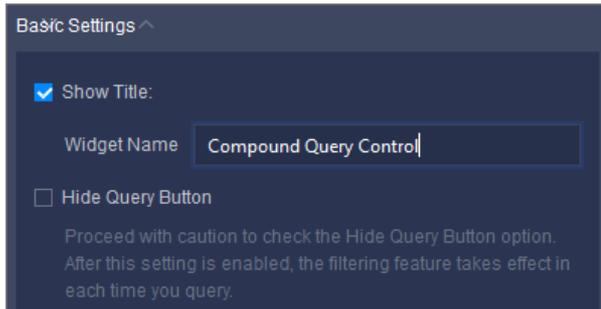

2. Click the **Data** tab and perform the following configurations:
 - Select a dataset from the Dataset drop-down list.
 - Click  to go to the dataset edit page to edit dimensions and measures as required.

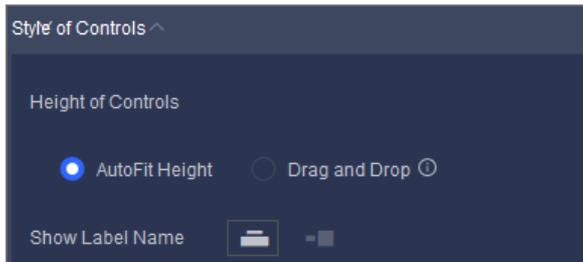

3. Click **Configure Selector** and add fields for query.

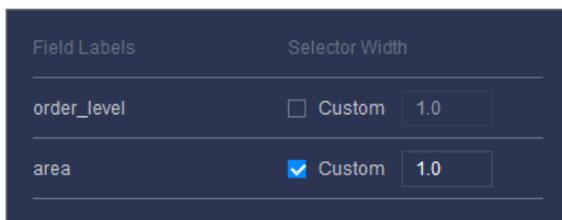

4. Click the **Style** tab and perform the following configurations:
 - In the **Basic Settings** section, configure whether to show the widget title and query button.

- o In the **Style of Controls** section, set the widget height and label name position.

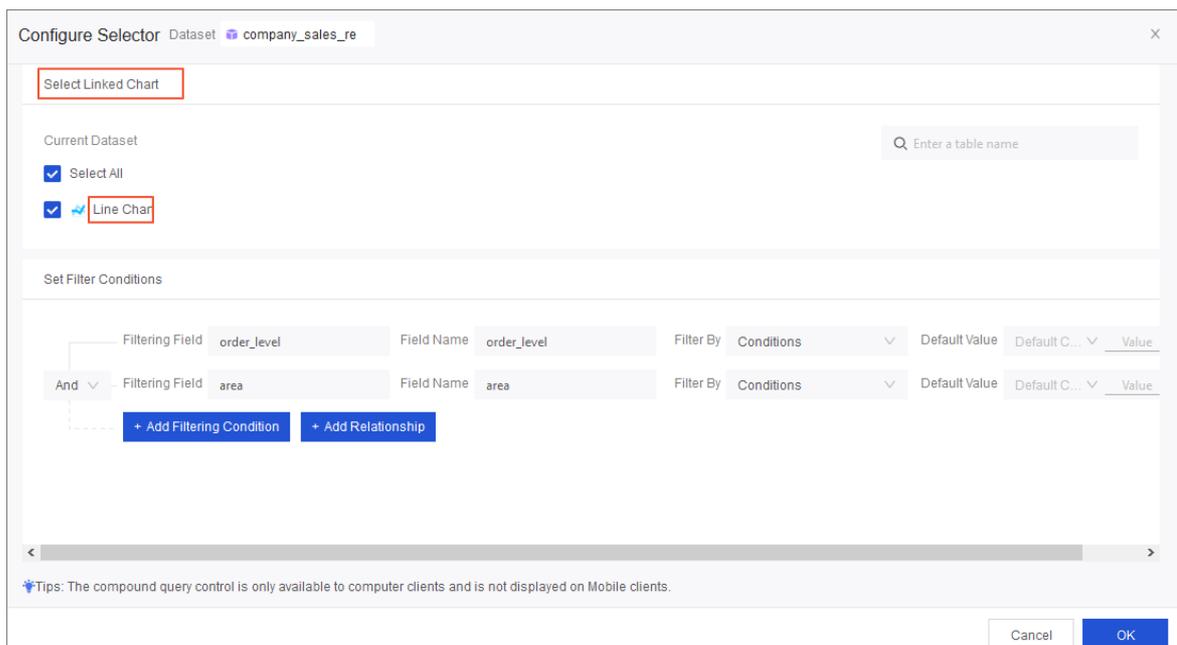

- o In the **Style of Field** section, set the field width.

5. Click **Configure Selector**. In the Configure Selector dialog box that appears, select charts for filter interaction.

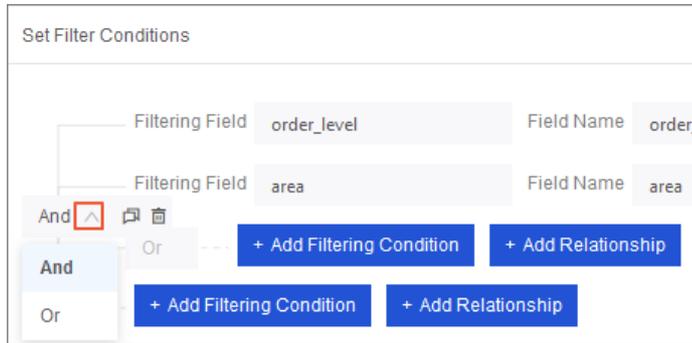

Note Compound Query Control supports only filter interaction of charts from the same dataset. The widget does not support cascade filtering.

6. In the **Set Filter Conditions** section, select filter fields and perform the following configurations:
 - i. Click **Add Filtering Condition** to add a filter condition under the current layer.
 - Search for or select a field from the Filtering Field drop-down list, change Field Name, specify Filter By, and set Default Value.
 - If you want to delete a filter condition, click the Delete icon next to the filter condition.
 - ii. Click **Add Relationship** to add a relationship node in the current layer.

- Click the outer-layer relationship node and select a relationship type as required.

- If the outer-layer relationship is **And**, the default inner-layer relationship is **Or**. If the outer-layer relationship is **Or**, the default inner-layer relationship is **And**. The relationship types of adjacent layers are opposite. They can be **And-Or**, **Or-And**, **And-Or-And**, or **Or-And-Or**.
- Click the Delete icon next to a node to delete all filter fields and relationships under the node.

Note You can add a maximum of three relationships for each node.

7. Click **OK** to complete the configuration of the Compound Query Control widget.

Query data of a specific time range

This topic describes how to use the Compound Query Control widget to query data of a specific time range. Data of a specific time range can be filtered by using Short cut or Filter By Date.

Prerequisites

- The Quick BI service is purchased.
- The target dashboard is displayed.

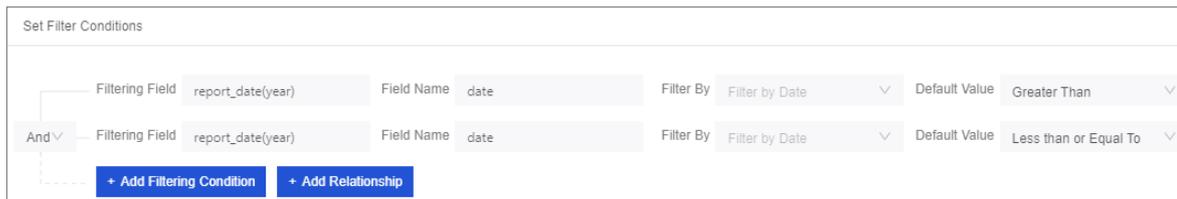

Procedure

1. Click the **Compound Query Control** icon. On the Data tab, select a dataset.
2. Click **Configure Selector**. In the Configure Selector dialog box that appears, select charts for filter interaction.

3. Click **Add Filtering Condition** to set filter conditions.

Note If you filter data of a certain period of time, you must add a date field first, and set **Default Value** to **Greater Than** or **Greater than or Equal To**. Then, add the same date field, and set **Default Value** to **Less than or Equal To** or **Less Than**.

- o Click **Add Filtering Condition**. Set Filtering Field to **report_date(year)**, Field Name to **report_date(year)**, and Default Value to **Greater Than, 2010**.
- o Click **Add Filtering Condition**. Set Filtering Field to **report_date(year)**, Field Name to **report_date(year)**, and Default Value to **Less than or Equal To, 2011**.

Note You can use the **Shortcut** feature to customize time ranges only for fields of day and month types.

4. Click **OK**.
5. Click **Query** in the display area of the Compound Query Control widget. All the charts that are filtered by the widget are updated.

Query text data

This topic describes how to use the Compound Query Control widget to query text data. Text data can be filtered in three methods: Enum - Single Choice, Enum - Multiple Choice, and Conditions.

Prerequisites

- The Quick BI service is purchased.
- **The target dashboard is displayed.**

Procedure

1. Click the **Compound Query Control** icon. On the Data tab, select a dataset.
2. Click **Configure Selector**. In the Configure Selector dialog box that appears, select charts for filter interaction.
3. In the **Set Filter Conditions** section, set filter conditions.
 - i. Click **Add Filtering Condition**. Then, set Filtering Field to **area**, Field Name to **area**, Filter By to **Enum - Single Choice**, and Default Value to **North**.
 - ii. Click **Add Filtering Condition**. Then, set Filtering Field to **order_level**, Field Name to **order_level**, Filter By to **Conditions**, and Default Value to **Matches, L1**.
4. Click **OK**.
5. Click **Query** in the display area of the Compound Query Control widget. All the charts filtered by the

widget are updated.

Query numeric data

This topic describes how to use the Compound Query Control widget to query numeric data.

Prerequisites

- The Quick BI service is purchased.
- **The target dashboard is displayed.**

Procedure

1. Click the **Compound Query Control** icon. On the Data tab, select a dataset.
2. Click **Configure Selector**. In the Configure Selector dialog box that appears, select charts for filter interaction.
3. In the **Set Filter Conditions** section, set filter conditions.
 - i. Click **Add Filtering Condition**. Then, set Filtering Field to **order_number**, Field Name to **order_number**, and Default Value to **Greater Than, 30**.
 - ii. Click **Add Filtering Condition**. Then, set Filtering Field to **order_amt**, Field Name to **order_amt**, and Default Value to **Greater Than, 10000**.
4. Click **OK**.
5. Click **Query** in the display area of the Compound Query Control widget. All the charts filtered by the widget are updated.

Note Only numeric values can be filtered. The data is displayed based on the aggregation method selected for measures in a chart. Assume that the aggregation method of the order_number field in a cross table is SUM. If you use the Compound Query Control widget to filter data records with order quantities greater than 30, the cross table displays all data records whose order quantity is greater than 30 and aggregation method is SUM.

7.5.3.4.8.4. Text Area

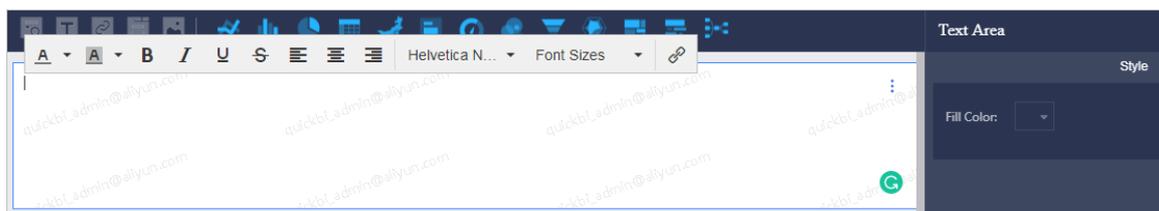

The Text Area widget allows you to enter text into a text area, for example, a title for a chart.

Prerequisites

The Quick BI service is purchased.

Procedure

1. **Go to the target dashboard.**
2. Click the **Text Area** icon.
3. Enter text in the text box.

7.5.3.4.8.5. IFrame

You can use the IFrame widget to insert web pages to query Internet data or browse web pages or websites related to the data on the current dashboard in real time.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Go to the target dashboard.
2. Click the IFrame icon.
3. In the URL input box, enter the address of the web page you want to visit.

Note The web page address must start with https.

If you want to delete the current IFrame widget, click the **More** icon in the upper-right corner of the IFrame widget and select **Delete**.

7.5.3.4.8.6. Tab

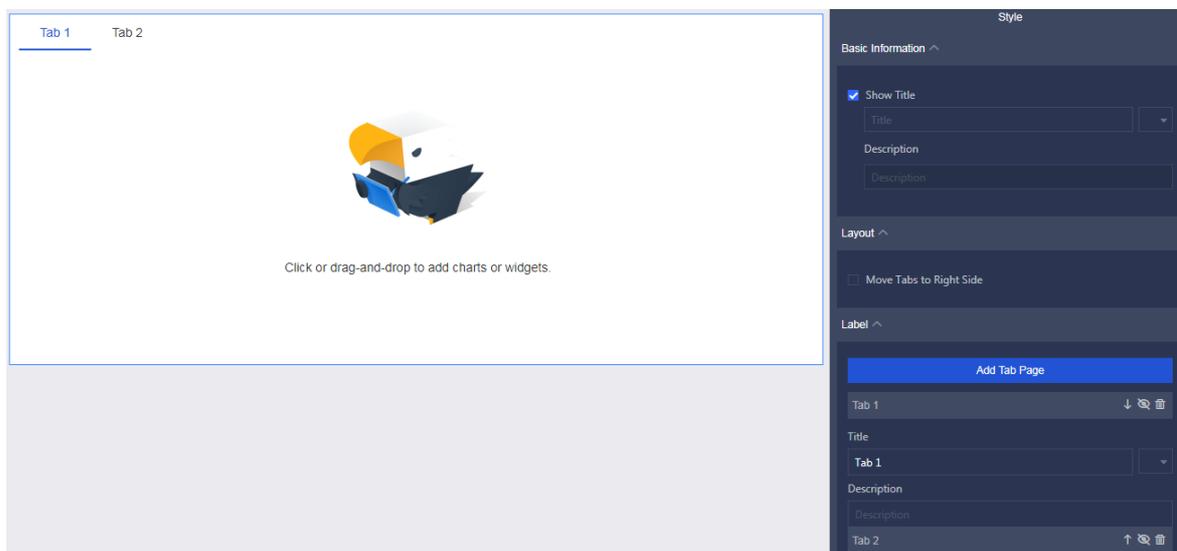

The tab widget enables you to display charts as tabs on a dashboard.

Prerequisites

The Quick BI service is purchased.

Procedure

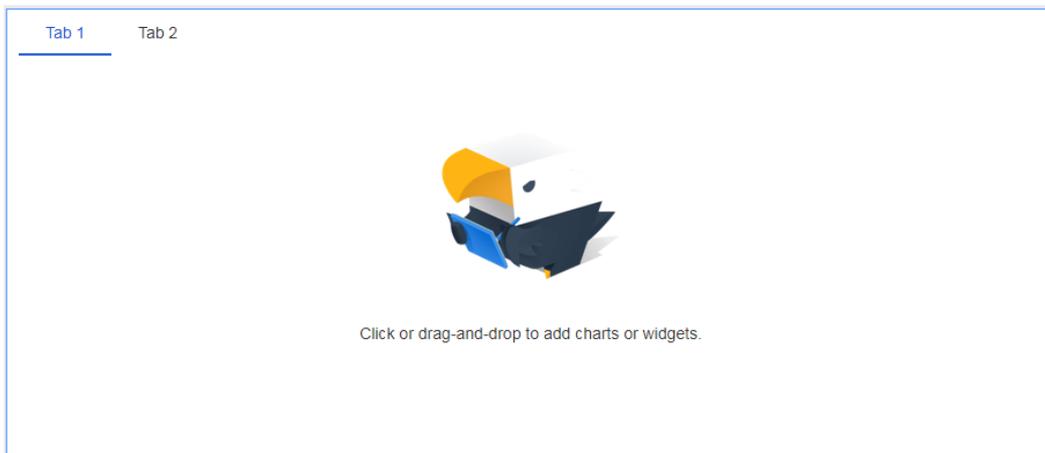

1. Go to the target dashboard.
2. Click the Tab icon.
3. Click the Style tab. Click **Add Tab Page** in the Label field.

4. Select a tab where you want to add charts, as shown in **Tabs**.

Click **Tab 1**. The tab name **Tab 1** becomes blue.

Tabs

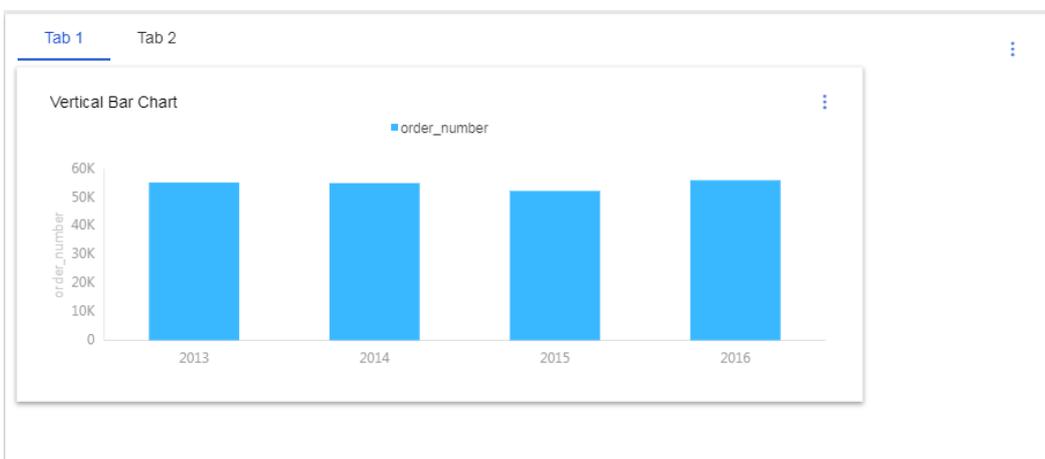

5. Click a chart icon to add a chart to Tab 1.

Add and configure a chart. **Sample tab** shows the tabs.

Sample tab

If you want to delete the current tab widget, click the **More** icon in the upper-right corner of the tab, and click **Delete**.

7.5.3.4.8.7. Image

The Image widget allows you to insert images into a dashboard. You can adjust the image position and display effects as needed.

Prerequisites

The Quick BI service is purchased.

Procedure

1. Go to the target dashboard.
2. Click the **Image** icon.
3. In the Style field, enter the URL and hyperlink of the image, and specify **Image Display**.

7.5.4. Create a chart on the dashboard

7.5.4.1. Create a line chart

A line chart shows data change trends and the interactions between multiple groups of data over a period of time. For example, you can use a line chart to analyze the sales volumes of a group of products or multiple groups of products over a period of time to forecast future sales volumes.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

When you create a line chart, you must specify **Value Axis (Mea.)**, **Category Axis (Dim.)**, and **Color Legend (Dim.)**.

- The category axis is determined by dimensions. You must specify at least one dimension, such as date, province, or product type.
- The value axis is determined by measures. You must specify at least one measure, such as order quantity.
- The color legend is determined by a dimension. You can select only one dimension, such as transportation method.

Note The color legend can be enabled when the value axis has only one measure.

The following example demonstrates the order quantity of each type of product in different provinces every year. A line chart and the `company_sales_record` dataset are used in this example.

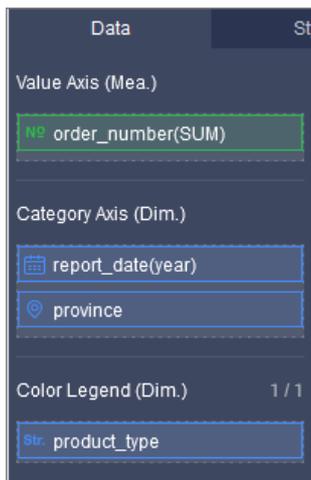

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the `company_sales_record` dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Line Chart** icon.
6. On the **Data** tab, select the required dimensions and measures.

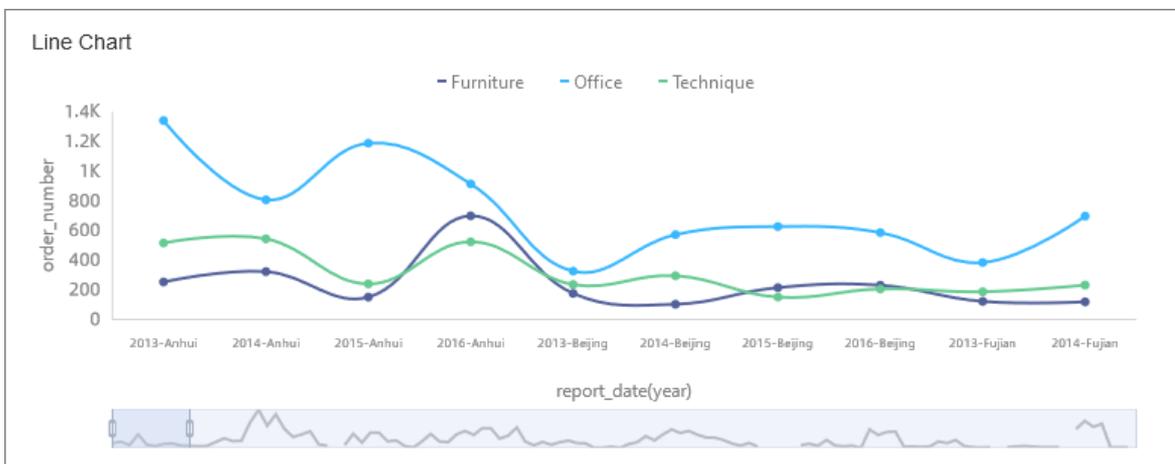

In the Dimensions list, find `order_date(year)` and `province` and add them to the Category Axis (Dim.) field. In the dimensions list, find `product_type` and add it to the Color Legend (Dim.) field. In the Measures list, find `order_number` and add it to the Value Axis (Mea.) field, as shown in [Specify fields for the line chart](#).

For information about how to convert the data type of a dimension, see [Edit a dimension](#).

Specify fields for the line chart

7. Click **Update**. The chart is updated.
8. On the **Style** tab, configure the title, chart style, and maximum and minimum values of the line chart, as well as whether to show the axis, scroll bar, and scale.

- Click **Save** in the upper-right corner. In the Save Dashboard dialog box, enter a name for the dashboard and click **OK**.

If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.2. Create an area chart

An area chart shows data change trends at equal intervals with different sizes of area. In addition, you can use an area chart to analyze the interactions between multiple groups of data over a period of time. For example, analyze the sales volumes of a group of products or multiple groups of products over a period of time to forecast future sales volumes.

Background information

When you create an area chart, you must specify **Value Axis (Mea.)**, **Category Axis (Dim.)**, and **Color Legend (Dim.)**:

- The category axis is determined by dimensions. You must specify at least one dimension, such as date, province, or product type.
- The value axis is determined by measures. You must specify at least one measure, such as order_number.
- The color legend is determined by a dimension. You can select only one dimension, such as transportation method.

 **Note** The color legend is applicable only when the value axis has one measure.

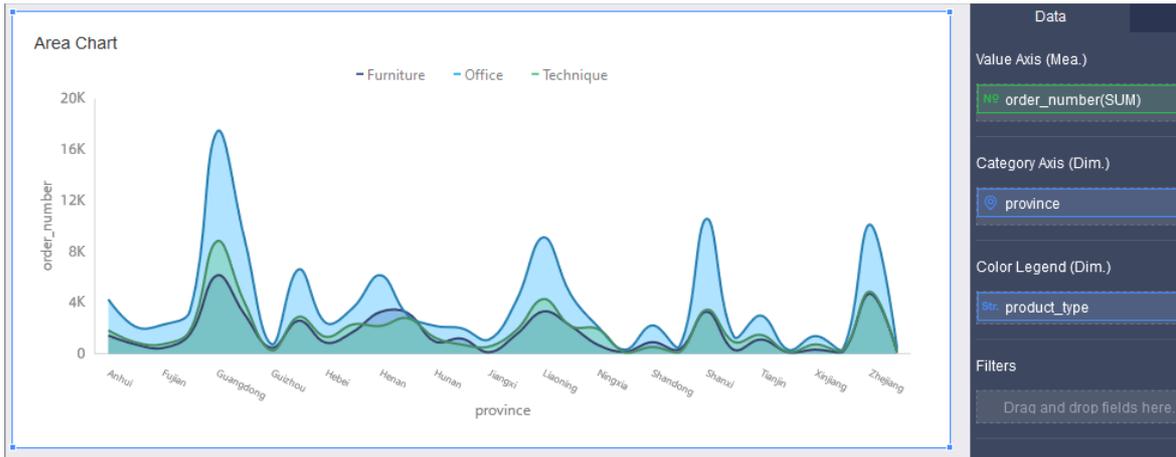

Procedure

The following example describes how to use an area chart to show the order quantity of each type of products in different provinces. The company_sales_record dataset is used in this example.

- [Log on to the Quick BI console.](#)
- In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
- On the **Datasets** page, click **MyDatasets** and find the *company_sales_record* dataset, then click the  icon in the Actions column.
- In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
- On the dashboard edit page, click **Area Chart**.
- On the **Data** tab, select required dimensions and measures.

In the Dimensions list, find **province** and drag it to the Category Axis (Dim.) field. In the Measures list, find **order_number** and drag it to the Value Axis (Mea.) field. Drag and drop **product_type** to the Color Legend (Dim.) field.

- Click **Update**.
- On the **Style** tab, you can change the title, chart type, show legend, and axis style of the chart. The following figure shows an updated area chart.

Note You can switch to another area chart type, such as stacked area chart or 100% stacked area chart as required.

9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, enter a name for the dashboard and click **OK**.

If you want to delete the chart, click **More Actions** in the upper-right corner of the chart and select **Delete**.

7.5.4.3. Create a vertical bar chart

A vertical bar chart demonstrates data changes over a period of time or comparisons between objects. For example, you can use a vertical bar chart to show the traffic flow in different periods of time at a crossing.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

Similar to a **Line chart**, a vertical bar chart consists of a category axis, a value axis, and a color legend.

This topic demonstrates how to use the filter and the dual y-axis function in a vertical bar chart.

- Scenario 1: Compare the shipping costs of different products in different provinces in East China.
- Scenario 2: Compare the order quantities and average profits of different products in different provinces.

You must specify at least one dimension, such as **province** or **product_type**, for the category axis. You must specify at least one measure, such as **order_number** or **profit_amt**, for the value axis. You can specify only one dimension for the color legend.

Note The color legend is applicable only when the value axis has one measure.

Procedure

1. [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the *company_sales_record* dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.

5. On the dashboard edit page, click the **Vertical Bar Chart** icon. Scenario 1: Compare the shipping costs of different products in different provinces in East China.

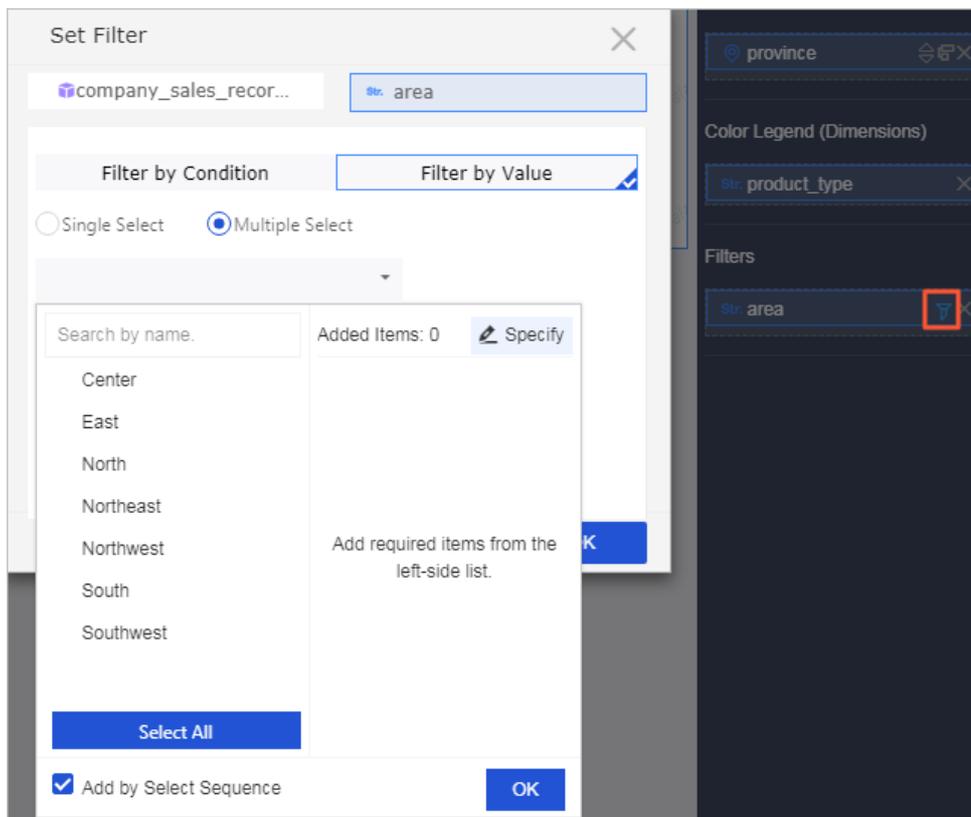

i. In the Dimensions list, find **area** and add it to the Filters field, as shown in **The filter**. Filter data of **East China** by using the Filter feature.

The filter

ii. Click the **Filter** icon.

iii. In the **Set Filter** dialog box, click **Filter by Value** and select **Multiple Select**.

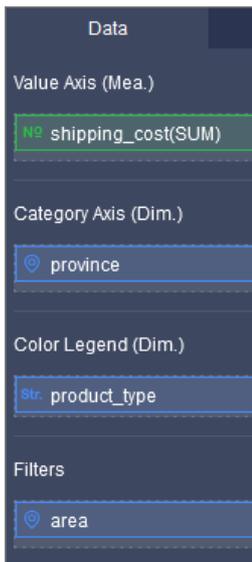

iv. Select **East** and click **OK**.

v. In the Dimensions list, find **province** and add it to the Category Axis (Dim.) field.

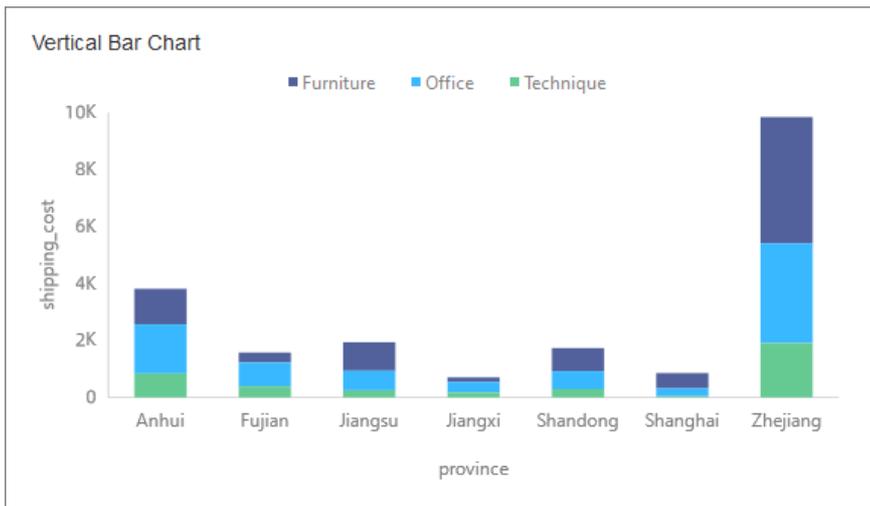

vi. In the Measures list, find **shipping_cost** and add it to the Value Axis (Mea.) field.

vii. Find **product_type** and add it to the Color Legend (Dim.) field.

viii. Click **Update**. The chart is updated.

ix. In the **Basic Information** section of the **Style** tab, select **Stacked Vertical Bar Chart** for **Chart Type**.

Scenario 2: Compare the order quantities and average profits of different products in different provinces. The `company_sales_record` dataset is used in the example.

Note

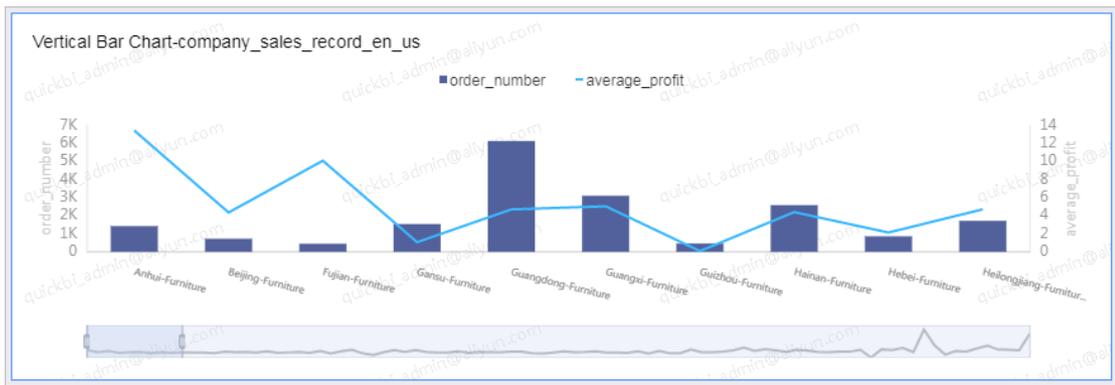

Data modeling may be required in this scenario. For information about data modeling, see [Add a calculated field](#).

i. On the **Data** tab, select required dimensions and measures.

In the Dimensions list, find **province** and **product_type** and add them to the Category Axis (Dim.) field. In the Measures list, find **order_number** and **average_profit** and add them to the Value Axis (Mea.) field.

ii. Click **Update**. The chart is updated.

iii. In the **Chart Type** section of the **Style** tab, select **Dual Y-Axis**.

iv. Click **Save** in the upper-right corner. In the **Save Dashboard** dialog box, enter a name for the dashboard and click **OK**.

7.5.4.4. Create a waterfall chart

A waterfall chart reflects data changes at different time periods or under the impact of different factors. It uses a combination of absolute and relative values and is suitable for business analysis and financial analysis.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

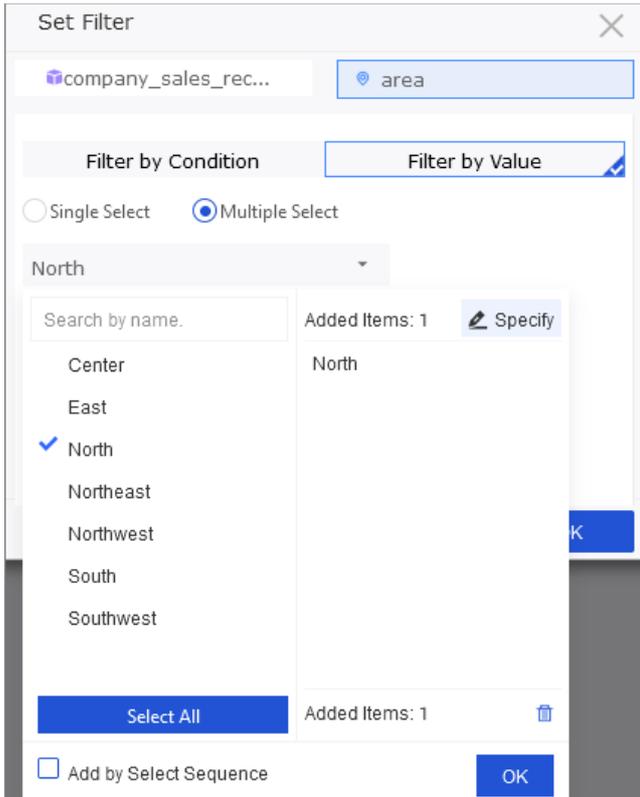

When you create a waterfall chart, you must specify **Category Axis (Dim.)** and **Value Axis (Mea.)**.

- The category axis is determined by dimensions. You must specify at least one dimension, such as province and product type.
- The value axis is determined by a measure. You can specify only one measure, such as order quantity or profit.

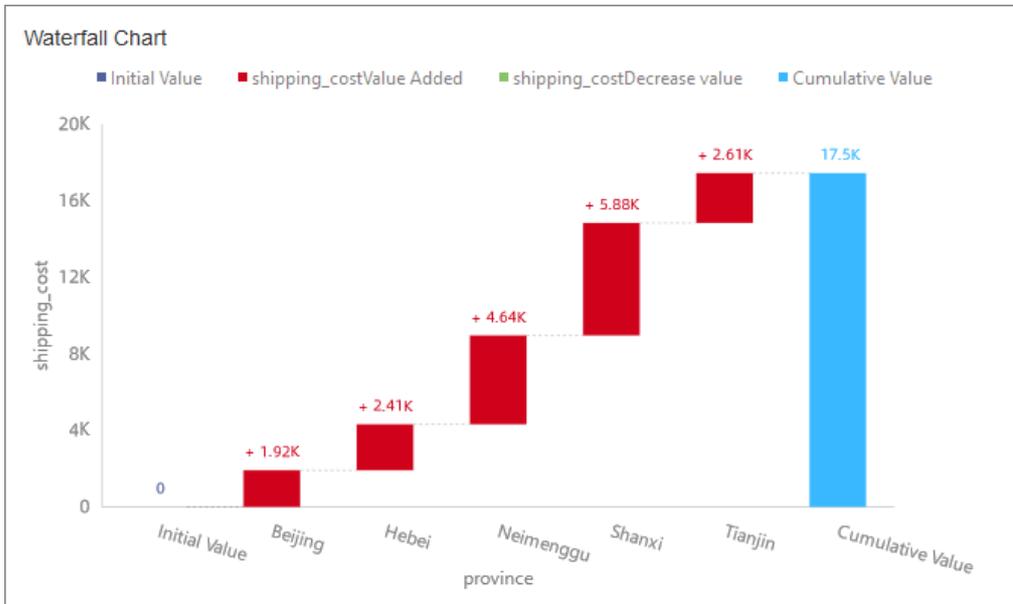

Create a waterfall chart

The following example describes how to use a waterfall chart to compare the shipping costs in the provinces of East China. The *company_sales_record* dataset is used in the example.

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, click **MyDatasets** and find the *company_sales_record* dataset, then click the  icon in the **Actions** column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Waterfall Chart** icon.
6. On the **Data** tab, select the required measures. In the **Dimensions** list, find **province** and drag it to the **Category Axis (Dim.)** field. In the **Measures** list, find **shipping_cost** and drag it to the **Value Axis (Mea.)** field. In the **Dimensions** list, drag and drop **area** to the **Filters** field.
7. Click the  icon next to **area**.

8. In the **Set Filter** dialog box, click **Filter by Value**, select **Multiple Select**, select **China (Beijing)** from the drop-down list, and then click **OK**.
9. Click **Update**. The chart is updated.
10. On the **Style** tab, configure parameters in the **Basic Information**, **Parameter Settings**, **Chart Type**, **Axes**, and **Series Settings** sections.

11. Click **Save** to save the dashboard. If you want to delete the chart, click the **More Actions** icon (⋮) in the upper-right corner of the chart and select **Delete**.

7.5.4.5. Create a horizontal bar chart

Similar to a vertical bar chart, a horizontal bar chart displays the differences between data of different categories.

Background information

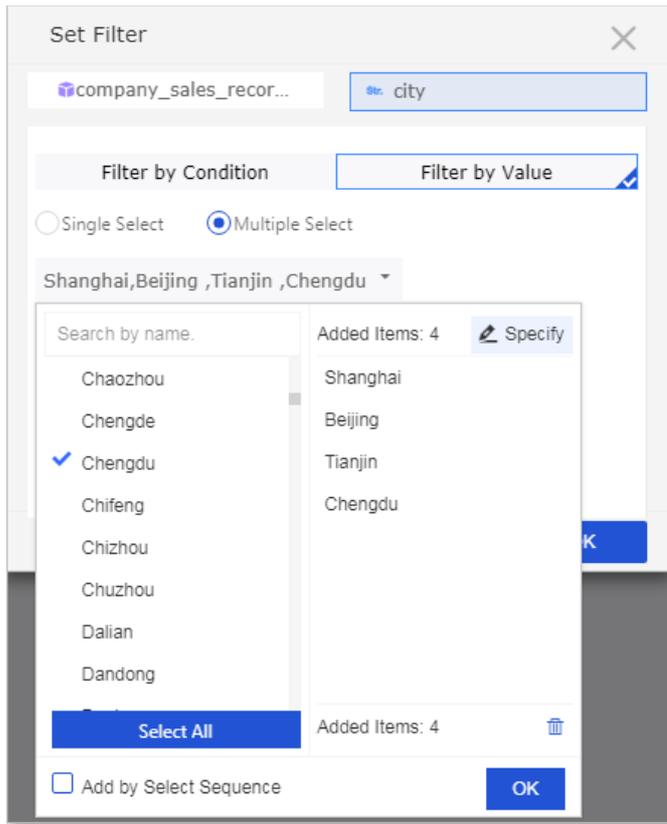

- A horizontal bar chart shows data changes in a period of time or compares differences between multiple groups of data. For example, you can use a horizontal bar chart to show the work progress of different members in a project group.
- When you create a horizontal bar chart, you must specify **Value Axis (Mea.)**, **Category Axis (Dim.)**, and **Color Legend (Dim.)**:
 - The value axis is determined by measures. You must specify at least one measure, such as order quantity or order price.
 - The category axis is determined by dimensions. You must specify at least one dimension, such as province or product type.
 - The color legend is determined by a dimension. You can select only one dimension, such as transportation method.

 **Note** The color legend is applicable only when the value axis has one measure.

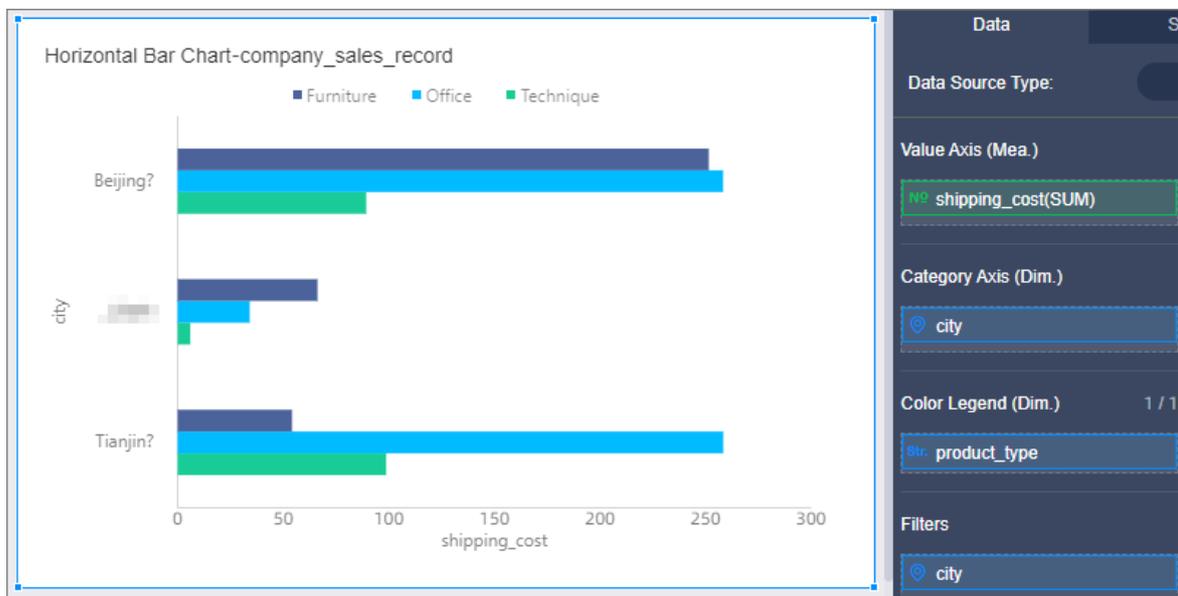

Procedure

The following example describes how to use a horizontal bar chart to compare the shipping costs of different products in different municipalities. The `company_sales_record` dataset is used in this example.

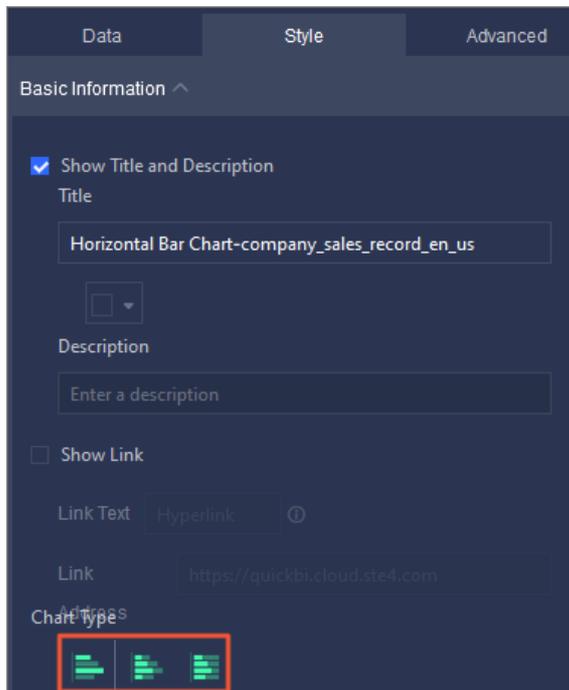

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the `company_sales_record` dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Horizontal Bar Chart** icon.
6. In the Dimensions list, find and add `city` to the Filters field and select four municipalities, as shown in the following figure.

7. In the dimensions list, find the **city** dimension and add it to the Category Axis (Dim.) field. In the measures list, find the **shipping_cost** measure and add it to the Value Axis (Mea.) field. In the dimensions list, find the **product_type** measure and add it to the Color Legend (Dim.) field.
8. Click **Update**. The chart is updated.

You can also switch the current chart to another bar chart type, such as stacked horizontal bar chart or 100% stacked horizontal bar chart.

9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, enter a name for the dashboard and click **OK**.

If you want to delete the chart, click the **More Actions** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.6. Create a progress bar

Similar to a gauge, a progress bar displays the progress of a specific metric.

Background information

A progress bar displays the progress of a task.

Progress pointers are determined by measures. You can select one to five measures, such as order quantity.

Before you use a progress bar, you must specify target values in the **Functionality** section on the **Style** tab.

Procedure

The following example describes how to use a progress bar to show order completion. The `company_sales_record` dataset is used in this example.

1. [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the `company_sales_record` dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Progress Bar** icon.
6. Click the **Data** tab and select the required measures.

In the Measures list, find `order_number` and add it to the Pointer (Mea.) field.

7. Click **Update**. The chart is updated.

8. Click the **Style** tab and configure a target value.

9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, enter a name for the dashboard and click OK.

If you want to delete the chart, click the **More Actions** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.7. Create a combination chart

A combination chart compares data across multiple categories and magnitudes.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A combination chart provides a dual y-axis to display data in multiple chart types, such as line chart, vertical bar chart, and area chart, in stacked and 100% stacked modes. For example, you can use a combination chart to display the change trends of different projects.

A combination chart consists of a category axis, a primary value axis, and a secondary value axis.

Notice You can specify at least one dimension for the category axis, such as the order_date(year). You can specify at least one measure each for the primary and secondary value axes, such as order price and profit. You can specify only one dimension for the color legend. The legend is applicable only when the primary or secondary value axis has one measure.

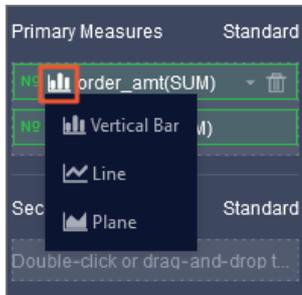

Procedure

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page, find the *company_sales_record* dataset, click  in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the  icon.

- Click the **Data** tab and select the required dimensions and measures.

In the Dimensions list, find **order_date (year)** and add it to the Category Axis (Dim.) field. In the Measures list, find **order_amt** and add it to the Primary Measures field and **profit_amt** to the Secondary Measures field.

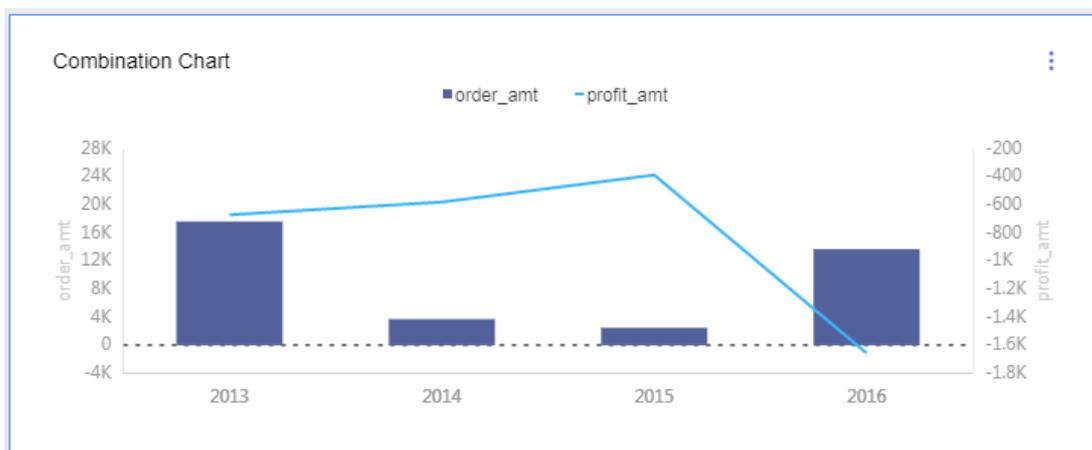

- In the Primary Measures and Secondary Measures fields, you can click the  icon to switch the chart type to vertical bar chart, line chart, or area chart.

- You can click **Standard** and select the required stack mode from the drop-down list.

- Click **Update**. The chart is updated.

- Click **Save**. The **Save Dashboard** dialog box appears. Specify Name and Save To.
- Click **OK** to save the dashboard.

If you want to delete the chart, perform the following steps:

- Click the  icon in the upper-right corner of the chart.
- Select **Delete**.

7.5.4.8. Create a pie chart

A pie chart shows data of different objects. Each object has a unique color or pattern. A pie chart shows the ratios of multiple values to the total amount. For example, you can use a pie chart to show the ratio of the income tax to the total personal income or the ratio of the sales volume of a car brand to the total sales volume.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

When you create a pie chart, you must specify **Labels (Dim.)** and **Central Angle (Mea.)**.

- Labels are determined by a dimension. You can specify only one dimension, such as area or product type.
- Central angles are determined by a measure. You can specify only one measure, such as order quantity or order price.

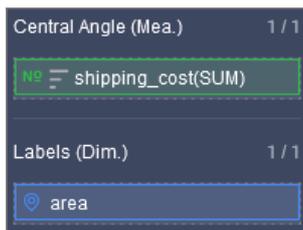

Compare the shipping costs in different regions. The `company_sales_record` dataset is used in the example.

Procedure

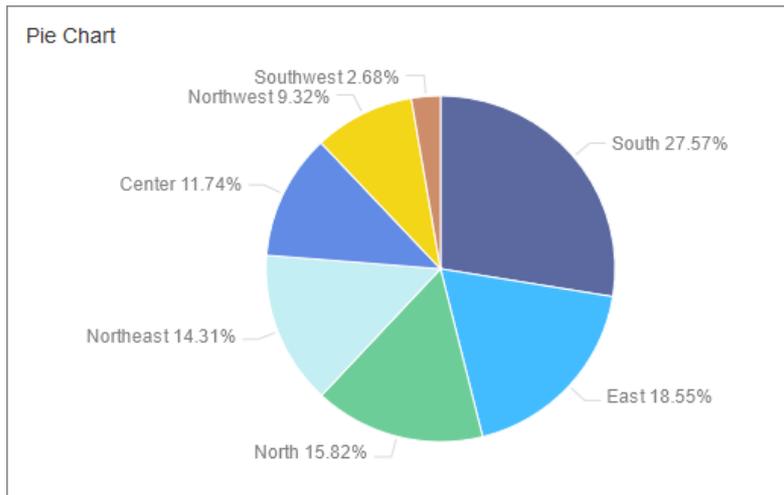

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the `company_sales_record` dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Pie Chart** icon.
6. Click the **Data** tab and select required dimensions and measures.

In the Dimensions list, find `area` and add it to the Labels (Dim.) field. In the Measures list, find `shipping_cost` and add it to the Central Angle (Mea.) field, as shown in [Specify fields for the pie chart.](#)

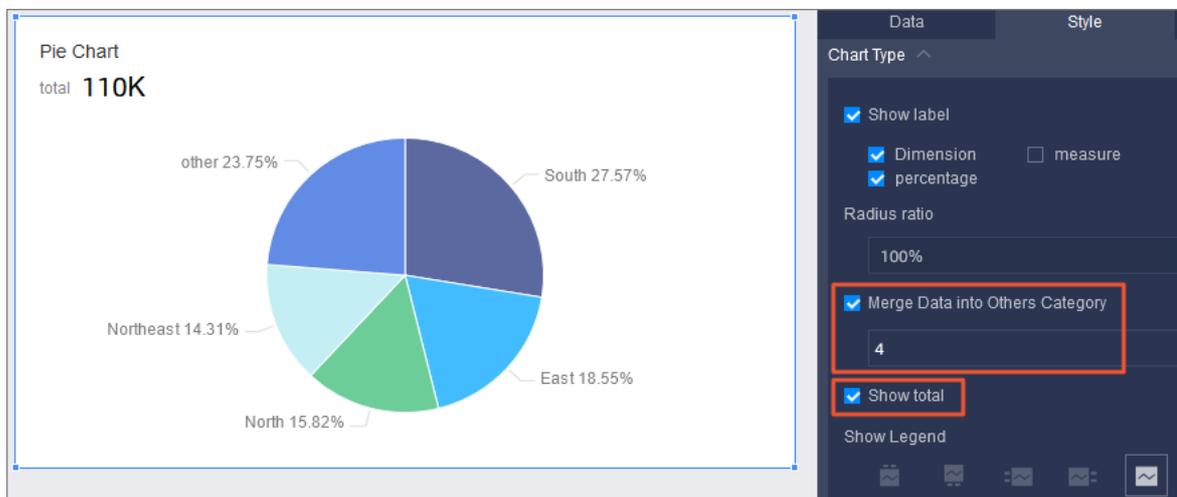

Specify fields for the pie chart

7. Click **Update**. The chart is updated.

- On the **Style** tab, you can change the title, labels, color, and value formats. In this example, select **Show total**, **Merge Data into Others Category**, and set the number to 4.

- Click **Save** in the upper-right corner. In the Save Dashboard dialog box, specify a name for the dashboard.
- Click **OK** to save the dashboard.

If you want to delete the chart, click the icon in the upper-right corner of the chart and select **Delete**.

7.5.4.9. Create a bubble map

A bubble map uses a map profile as its background and shows data distribution with bubbles of different sizes. It displays data metrics and their distribution in a country or region. For example, you can use a bubble map to display the volume of tourist arrivals at different destinations, or the average income in different regions.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A bubble map consists of geographic locations and bubbles in different sizes. Geographic locations are determined by a dimension, such as province. The bubble size is determined by one or more measures, such as shipping cost and order quantity.

When you create a bubble map, you must specify **Geo Location (Dim.)**, **Bubble Size (Mea.)**, and **Bubble color / metric**.

- The geo location is determined by the data dimension. You can select only one dimension and the dimension type must be geo, such as province.
- The Bubble color is determined by measures. You can select only one measure, such as the order_amt.
- The bubble size is determined by measures. You can specify one to five dimensions, such as shipping_cost and order_number.

Note Geo Bubble Map is unpublished. Bubble Map is provided.

The following example describes how to use a bubble map to compare the order quantities and average profits in different provinces. The company_sales_record dataset is used in this example.

Data modeling may be required for this scenario.

For information about data modeling, see [Add a calculated field](#).

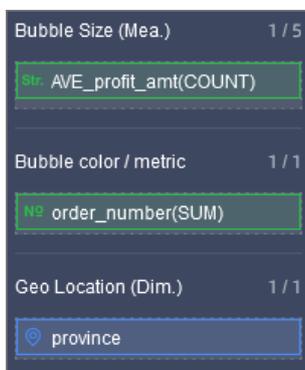

Procedure

1. [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the *company_sales_record* dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Bubble Map** icon.
6. On the **Data** tab, select required dimension and measures.

In the Dimensions list, find province and drag it to the Geo Location (Dim.) field. In the Measures list, find order_number and average_profit and drag them to the Bubble Size (Mea.) field. The following figure [Specify fields for the bubble map](#) is an example.

Note Make sure that you have converted the data type of the province and area dimensions from String to Geo. For information about how to change the data type of a dimension, see [Edit a dimension](#).

Specify fields for the bubble map

7. Click **Update**. The chart is updated.

8. On the **Style** tab, you can change the title, chart style, functionality, and data display format.

Click the **+** or **-** icon to zoom in or zoom out the map.

9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, enter a name for the dashboard.

10. Click **OK** to save the dashboard.

If you want to delete the chart, click the **More Actions** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.10. Create a colored map

Similar to a bubble map, a colored map displays data in a single color at different saturation levels. This visualization is useful to show the distribution of data across areas on a map.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

When you create a colored map, you must specify **Geo Location (Dim.)** and **Colorscale (Mea.)**.

- The geo location is determined by a dimension. You can select only one dimension and the dimension type must be geo, such as province.
- The colorscale is determined by measures. You can specify one to five dimensions, such as order price and profit.

Note Geo colored map is deprecated. The colored map is provided.

The following example describes how to use a colored map to compare the shipping costs, order prices, and profits in different regions. The `company_sales_record` dataset is used in this example.

Procedure

1. [Log on to the Quick BI console.](#)

2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, click **MyDatasets** and find the *company_sales_record* dataset, then click the  icon in the **Actions** column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Colored Map** icon.
6. On the **Data** tab, select required dimensions and measures. In the **Dimensions** list, find *area* and add it to the **Geo Location (Dim.)** field. In the **Measures** list, find *order_amt*, *profit_amt*, and *shipping_cost* and add them to the **Colorscale (Mea.)** field, as shown in [Specify fields for the colored map](#).

 **Note** Make sure that you have converted the data type of the dimension from **String** to **Geo**. For information about how to convert the data type of a dimension, see [Edit a dimension](#).

Specify fields for the colored map

7. Click **Update**. The chart is updated.
In a chart, you can adjust the map position and size. For more information, see [Create a bubble map](#).
8. Click **Save** in the upper-right corner. In the **Save Dashboard** dialog box, specify a name for the dashboard.
9. Click **OK** to save the dashboard.
If you want to delete the chart, click the **More Actions** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.11. Create a cross table

A cross table displays the summary of a field and classifies field values into different groups. Aggregate functions used in a cross table include **SUM**, **AVG**, **COUNT**, **MAX**, and **MIN**.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

When you create a cross table, you must specify **Rows** and **Columns**.

- Rows are determined by dimensions, such as province and product type.
- Columns are determined by measures, such as order quantity and order price.

 **Note** Dimensions and measures are unlimited for each cross table.

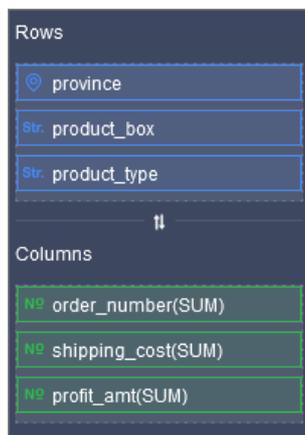

The following example describes how to use a cross table to compare the packaging, shipping costs, order quantities, and average profits of different products in different provinces. The `company_sales_record` dataset is used in this example.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the `company_sales_record` dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Cross Table** icon.
6. On the **Data** tab, select the required dimensions and measures.

In the Dimensions list, find `province`, `product_type`, and `product_box` and add them to the Rows field. In the Measures list, find `order_number`, `shipping_cost`, and `profit_amt` and add them to the Columns field, as shown in [Specify fields for the cross table](#).

Specify fields for the cross table

7. Click **Update**. The chart is updated.
8. On the **Style** tab, perform the following steps:
 - o In the **Basic Information** section, configure Title and Show Link, as shown in the following figure.

- o In the **Display Settings** section, specify whether to custom table theme, show row numbers, merge cells that belong to the same category, freeze all columns by selecting Auto (Table Head), or freeze specific columns as required. After you configure the parameters, update the table. The following figure shows an updated chart.

The screenshot shows a data table with 8 rows and 7 columns. The columns are: province, product_box, product_type, order_number, shipping_cost, and profit_amt. The rows contain data for various product types like Furniture, Office, and Technique, with different box sizes (Huge Box, Huge Paperbag, Large Box). To the right of the table is a settings panel with tabs for Data, Style, and Advanced. The Data tab is active, showing options like 'Custom Table Theme', 'Show Row Numbers', 'Merge Same Cells', 'Freeze', 'Auto Table Head', 'Columns', 'Rows', 'Wrap Text', and 'Pagination'.

	province	product_box	product_type	order_number	shipping_cost	profit_amt
1			Furniture	207	274.32	2865.04
2		Huge Box	Office	21	47.02	716.56
3			Technique	134	166.5	-2267.499999999998
4		Huge Paperbag	Furniture	245	464.67000000000001	-4920.250000000001
5			Technique	46	30.06	252.77
6			Furniture	116	151.38	3580.77
7		Large Box	Office	128	94.95999999999998	2271.33
8			Technique	73	50.97	4714.17

- o In the **Functionality Settings** section, you can specify **Conditional Formatting**, **Sort Columns**, and **Show Totals**. Conditional formatting consists of **Icon** and **Data Bar**.

Icon:

- a. In the **Conditional Formatting** section, configure **Series** and **Format**.

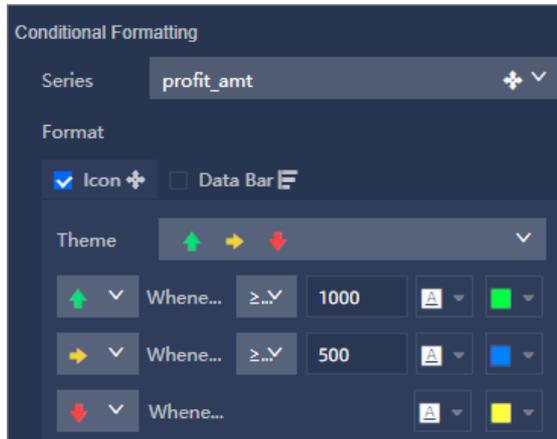

In this example, select profit_amt for **Series** and **Icon** for **Format**.

- b. Click the  icon and select an icon.

- c. Manually specify the values that you want to highlight, click the  icon, and then specify the font color and fill color for the values.

- If the data value is greater than 1000, the cell of the value is highlighted in green and a green upward arrow appears.
- If the data value is greater than or equal to 500 and less than or equal to 1000, the cell of the value is displayed in gray and an orange hyphen appears.
- If the data value is less than 500, the cell of the value is highlighted in yellow and a red downward arrow appears.

The updated chart is shown in the following figure.

	province	product_type	product_box	order_number	shipping_cost	profit_amt
1	Anhui	Furniture	Huge?Box	48	48.8	3799.59
2	Anhui	Furniture	Huge?Paperbag	45	89.3	-3033.57
3	Anhui	Furniture	Paperbag	96	8.76	956.73
4	Anhui	Office	Medium?Box	185	54.19999999999999	80.92999999999999
5	Anhui	Office	Paperbag	241	73.11999999999998	719.2300000000001
6	Anhui	Office	Small?Box	733	289.68999999999977	262.71999999999997
7	Anhui	Technique	Large?Box	27	26.47999999999999	6027.01
8	Anhui	Technique	Medium?Box	25	13.99	667.33
9	Anhui	Technique	Small?Box	244	56.410000000000004	2296.7499999999995
10	Anhui	Technique	Small?bag	11	2.96	-27.66
11	Beijing	Furniture	Huge?Box	4	30	-224.35
12	Beijing	Furniture	Huge?Paperbag	42	173.93	-1115.96

Data Bar

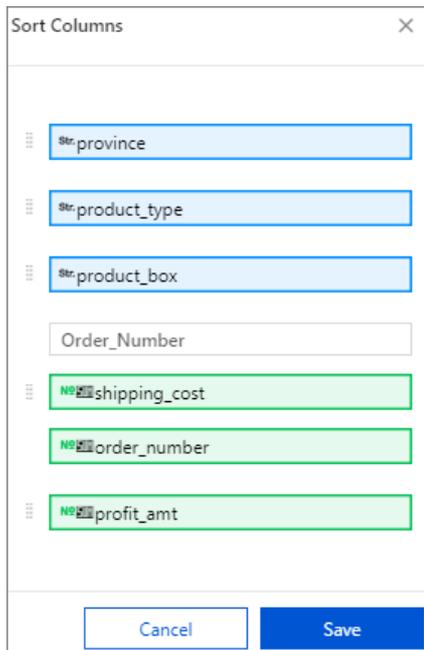

- a. Select a field and set the format to Data Bar.
- b. Configure the upper limit, lower limit, and color.

 Note Upper and lower limits can be configured automatically or manually.

Sort Columns

You can sort columns or group columns. When you group columns, specify the group names as shown in the following figure.

Show Totals

You can configure subtotals, totals, and total functions. The total functions can be aggregate functions such as SUM, AVG, and MAX. You can also customize a summation expression.

Note Before you configure subtotals, select **Merge Same Cells** in the **Display Settings** section.

- o In the **Series Settings** section, you can rename fields, specify the alignment mode and the number of records displayed on a single page.
9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, specify a name for the dashboard.
 10. Click **OK** to save the dashboard.

If you want to delete the chart, click the **More Actions** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.12. Create a pivot table

A pivot table displays aggregates of variables and allows you to analyze data in a tree structure. One variable defines the values in the header row while the other variable defines the values in the header column. Aggregation methods include SUM, AVG, COUNT, MAX, and MIN.

Background information

Similar to **Cross tables**, a pivot table consists of **Rows (Dim.)** and **Values (Mea.)**:

- The rows are determined by dimensions, such as province and product_type.
- Values are determined by measures, such as order_number and profit_amt.

Notice Dimensions and measures are unlimited for each pivot table.

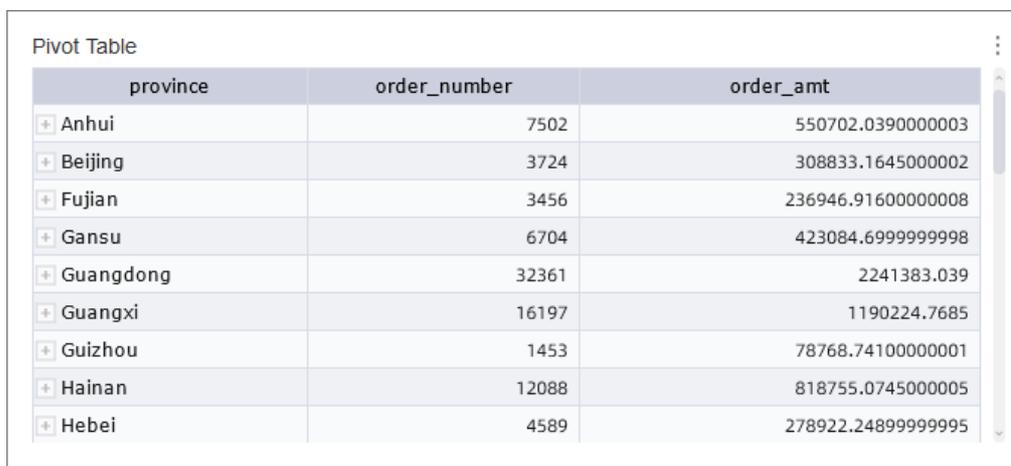

Procedure

The following example describes how to use a pivot table to show the packaging, order quantities, and order prices of different products in different provinces. The `company_sales_record` dataset is used in this example.

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the `company_sales_record` dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Pivot Table** icon.
6. Click the **Data** tab and select the required dimensions and measures.

In the Dimensions list, find **province**, **product_type** and **product_box** and add them to the Rows (Dim.) field. In the Measures list, find **order_number** and **order_amt** and add them to the Values (Mea.) field.

7. Click **Update**. The chart is updated.

province	order_number	order_amt
Anhui	7502	550702.0390000003
Beijing	3724	308833.1645000002
Fujian	3456	236946.91600000008
Gansu	6704	423084.69999999998
Guangdong	32361	2241383.039
Guangxi	16197	1190224.7685
Guizhou	1453	78768.74100000001
Hainan	12088	818755.0745000005
Hebei	4589	278922.24899999995

8. Click **Save** in the upper-right corner. In the **Save Dashboard** dialog box, enter a name for the dashboard.
If you want to delete the chart, click the **More Actions** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.13. Create a gauge

Similar to a dashboard in a car, a gauge shows the range of a specific metric. You can view the progress of a current task or determine whether a metric exceeds its value range in a gauge. For example, you can use a gauge to show the inventory status of a commodity, which helps you replenish the inventory in a timely manner.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

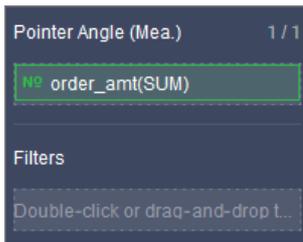

When you create a gauge, you must specify **Pointer Angle (Mea.)**. You can specify only one measure for this field, such as discount or profit.

The following example describes how to use a gauge to show order prices. The `company_sales_record` dataset is used in this example.

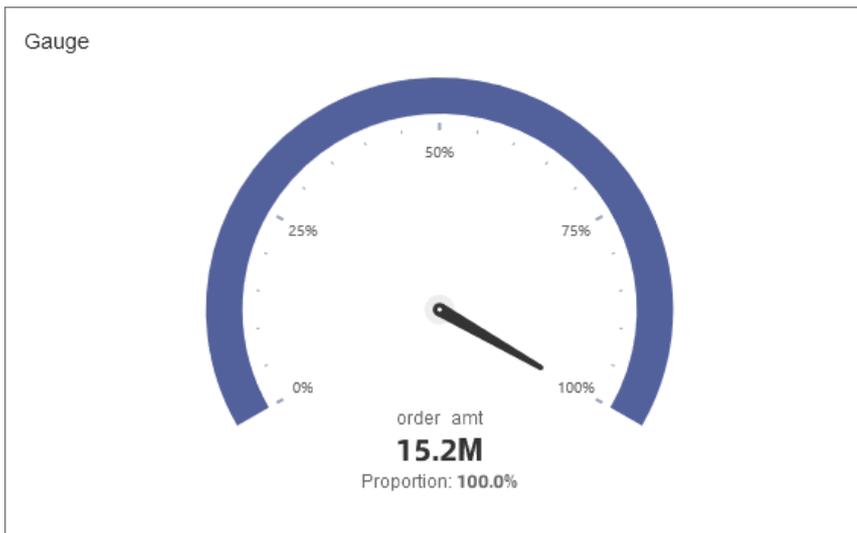

Procedure

1. On the Data Sources page, click Create Data Source in the upper-right corner. For more information, see [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the *company_sales_record* dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Gauge** icon.
6. On the **Data** tab, select the required measure.

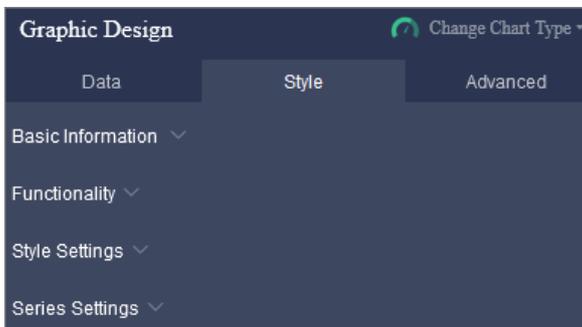

In the Measures list, find *order_amt* and add it to the Pointer Angle (Mea.) or Tooltip (Mea.) field.

7. Click **Update**. The chart is updated.

8. On the **Style** tab, configure the title, minimum and maximum values, legend position, and number format of the chart, as well as whether to display scales.

9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, specify a name for the dashboard.
10. Click **OK** to save the dashboard.

If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.14. Create a radar chart

A radar chart shows numbers or ratios obtained from analysis. It allows you to learn about the changes and trends of data metrics. For example, you can use a radar chart to show the sales volumes in different regions.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A radar chart consists of labels and label lengths. Labels are determined by dimensions, such as product type. Label lengths are determined by measures, such as shipping cost.

You can specify one or two dimensions for labels. We recommend that the dimension values be greater than or equal to three and the number of dimensions be less than or equal to 12. You can specify at least one measure for label lengths.

The following example describes how to use a radar chart to compare the order quantities and order prices in different regions. The `company_sales_record` dataset is used in this example.

Procedure

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the `company_sales_record` dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Radar Chart** icon.
6. On the **Data** tab, select required dimensions and measures.

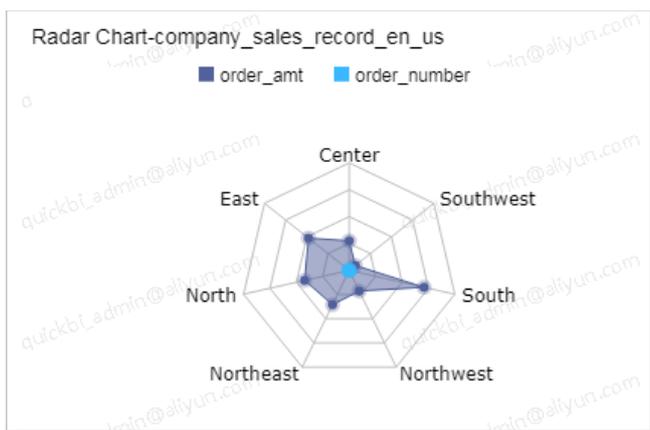

In the Dimensions list, find `area` and add it to the Labels (Dim.) field. In the Measures list, find `order_number` and `order_amt` and add them to the Length (Mea.) field, as shown in [Specify fields for the radar chart](#).

Specify fields for the radar chart

7. Click **Update**. The chart is updated.
8. On the **Style** tab, change the title, layout, and legend position of the radar chart, as shown in [Radar chart](#).

Radar chart

9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, enter a name for the dashboard.
10. Click **OK** to save the dashboard.
If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.15. Create a facet scatter chart

A facet scatter chart shows data correlation and distribution.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

When you create a facet scatter chart, you must specify **Y-Axis (Mea.)**, **X-Axis (Mea.)**, and **Color Legend (Dim.)**.

- The y-axis is determined by a measure. You can specify only one measure.
- The x-axis is determined by measures. You can specify one to three measures.
- The color legend is determined by dimensions. You can specify only one dimension. The dimension can have a maximum of 1,000 values.

For example, if you add **product_type** to the **Color Legend (Dim.)** field, a maximum of 1,000 product types are allowed.

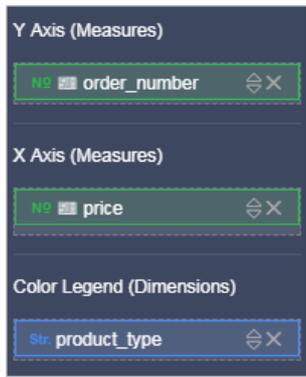

The following example describes how to use a facet scatter chart to compare the unit prices and order quantities of different products. The **company_sales_record** dataset is used in this example.

Procedure

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the *company_sales_record* dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the  icon.
6. On the **Data** tab, select the required dimension and measures.

In the Dimensions list, find `product_type` and add it to the Color Legend (Dim.) field. In the Measures list, find `order_number` and add it to the Y-Axis (Mea.) field. Find `price` and add it to the X-Axis (Mea.) field, as shown in [Specify fields for the facet scatter chart](#).

Specify fields for the facet scatter chart

7. Click **Update**. The chart is updated.
8. On the **Style** tab, configure the title, axis title, and legend position of the facet scatter chart, as shown in [Facet scatter chart](#).

Facet scatter chart

9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, enter a name for the dashboard.
10. Click **OK** to save the dashboard.

If you want to delete the chart, click the icon in the upper-right corner of the chart and select **Delete**.

7.5.4.16. Create a scatter chart

A scatter chart shows the correlation and distribution of data. It is generally used for data aggregation across categories.

Context

A scatter chart takes one variable as the x-axis and the other variable as the y-axis, which represents the general trend of the dependent variable (Y) that changes in respect to the independent variable (X). Scatter charts can also show data distribution from category and color.

A scatter chart consists of a y-axis, an x-axis, a category, and a color.

You can specify only one dimension or measure for the x-axis.

You can specify only one measure for the y-axis.

You can specify only one dimension or measure for the category.

The following example describes how to use a scatter chart to compare the prices and order quantities in different regions. The `company_sales_record` dataset is used in this example.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, click **MyDatasets** and find the `company_sales_record` dataset, then click the  icon in the **Actions** column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the  icon.
6. On the **Data** tab, select the required dimensions and measures.
 - In the **Dimensions** list, find the `area`, and drag it to the **Category (Dim.)** and **Color (Dim. or Mea.)** field.
 - In the **Measures** list, find `price`, and double-click or drag it to the **Y axis (Mea.)** field.
 - In the **Measures** list, find `order_number`, double-click or drag it to the **X axis (Dim. or Mea.)** field.

7. Click **Update**. The chart is updated.
8. On the **Style** tab, you can configure the **Title**, **Show Legend**, **Axes**, **Enable Four Quadrants** information and data display format. The **Scatter chart** is an example.

Scatter chart

9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, specify a name for the dashboard.
10. Click **OK** to save the dashboard.

If you want to delete the chart, click the  icon in the upper-right corner of the chart and select **Delete**.

7.5.4.17. Create a bubble chart

A bubble chart displays data distribution and aggregation by placing proportionally sized bubbles in corresponding locations.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Background information

A bubble chart consists of an x-axis, a y-axis, a category, bubble colors, and bubble sizes. The x-axis is determined by a dimension or measure. The y-axis is determined by a measure. The category is determined by a dimension. The color is determined by a dimension or measure. The size is determined by a measure.

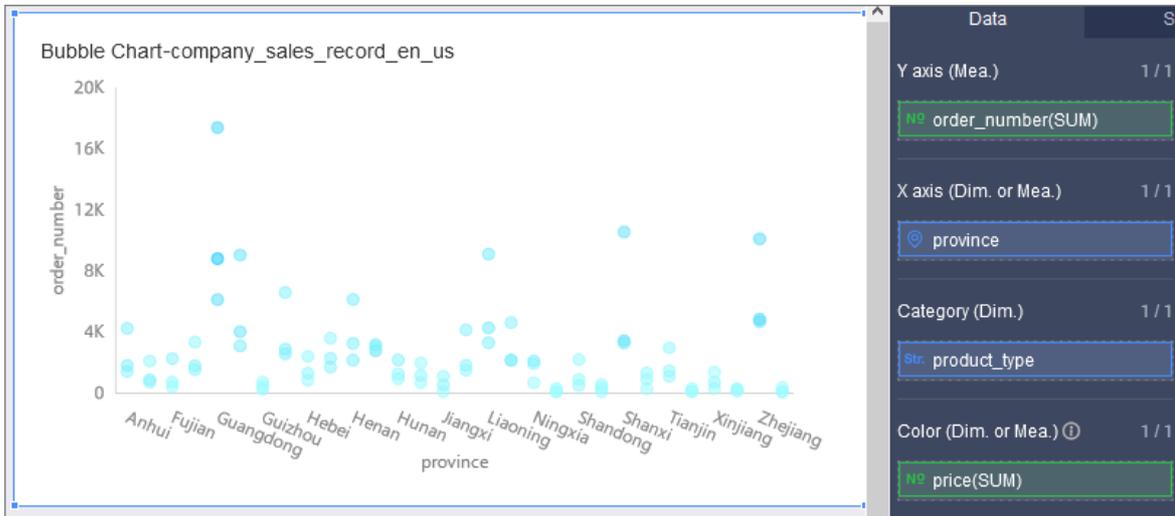

- You can specify only one dimension or measure for the x-axis.
- You can specify only one measure for the y-axis.
- You can specify only one dimension for the category.
- You can specify only one dimension or measure for the color.
- You can specify only one measure for the size.

Procedure

The following example describes how to use a bubble chart to compare the order quantities, prices and product types in different provinces. The `company_sales_record` dataset is used in this example.

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the `company_sales_record` dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
In this example, **Standard** is selected.
5. On the dashboard edit page, click the  icon.

- On the **Data** tab, select the required dimension and measure.
 - In the dimensions list, double-click or drag the province and product_type fields to the **X axis (Dim. or Mea.)** or **Category (Dim.)** section.
 - In the measures list, double-click or drag the order_number and price fields to the **Y axis (Mea.)** and **Color (Dim. or Mea.)** section.
- Click **Update**. The chart is updated.

- On the **Style** tab, you can change the title, labels, legends, axes, functionality, and value formats.
- On the **Advanced** tab, configure the following parameters.
- Click **Save** in the upper-right corner of the page. In the Save Dashboard dialog box, specify the name and save path for the dashboard, and click OK.

If you want to delete the chart, click the icon in the upper-right corner of the chart and select **Delete**.

7.5.4.18. Create a funnel chart

A funnel chart is suitable for analyzing standard, long-running, and multi-flow business processes. By comparing business data from different stages, funnel charts allow you to detect and analyze problems. You can also use a funnel chart to show the conversion rates between the stages of a business process, such as the percentage of visitors that become paying customers for a shopping website. Funnel charts are ideal for business process analysis.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

When you create a funnel chart, you must specify **Tier Area (Mea.)** and **Funnel layering / dimension**.

- The number of funnel layers is determined by a dimension. You can specify only one dimension, such as area. You can also leave this field empty.
- The tier area is determined by measures. You can specify 1 to 10 measures, such as the order price.

Notice You can configure the funnel chart in the following two methods:

- Specify one dimension for Funnel layering / dimension and one measure for Tier Area (Mea.). This type of funnel charts is suitable for analyzing the business data of a specific stage. You can easily identify exceptions.
- Specify 1 to 10 measures for Tier Area (Mea.) and leave the Funnel layering / dimension field empty. This type of funnel chart is suitable for comparing business data of multiple stages.

The following example describes how to use a funnel chart to compare the order price in different regions. The `company_sales_record` dataset is used in this example.

Procedure

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the `company_sales_record` dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Funnel Chart** icon.
6. On the **Data** tab, select the required dimensions and measures.

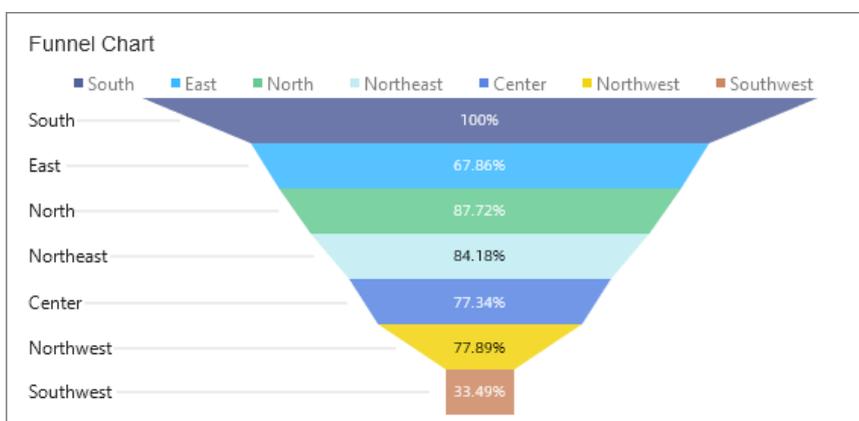

In the Dimensions list, find `area` and add it to the Funnel layering / dimension field. In the Measures list, find `order_amt` and add it to the Tier Area (Mea.) field, as shown in [Specify fields for the funnel chart.](#)

Specify fields for the funnel chart

7. Click **Update**. The chart is updated.
8. On the **Style** tab, configure the title and legend position of the funnel chart, as shown in [Funnel chart.](#)

Funnel chart

9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, enter a name for the dashboard.
10. Click **OK** to save the dashboard.

If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.19. Create a kanban

A kanban displays data such as sales or operation status, to help you formulate solutions based on the data. Kanbans help you discover and solve problems.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A kanban consists of metrics and labels. Labels are determined by a dimension, such as area. Metrics are determined by measures, such as order quantity and order price.

You can specify only one dimension for labels and one to ten measures for metrics.

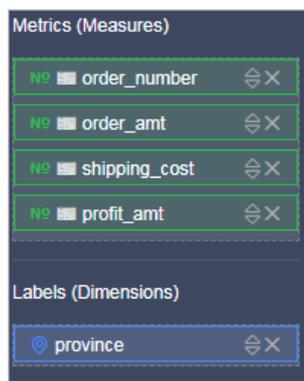

The following example describes how to use a kanban to compare the order quantities, order price, shipping costs, and profits in different provinces. The `company_sales_record` dataset is used in this example.

Procedure

1. [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the `company_sales_record` dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Kanban** icon.
6. On the **Data** tab, select required dimension and measures.

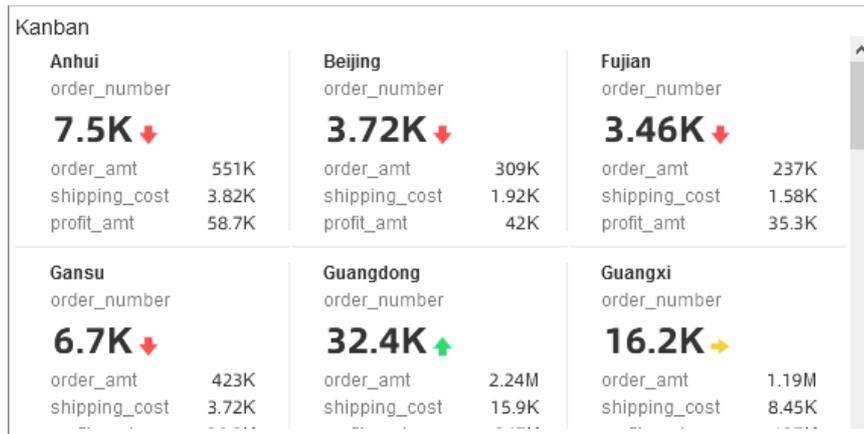

In the Dimensions list, find province and add it to the Labels (Dim.) field. In the Measures list, find order_number, order_amt, shipping_cost, and profit_amt and add them to the Metrics (Mea.) field, as shown in [Specify fields for the kanban](#).

Specify fields for the kanban

7. Click **Update**. The chart is updated.
8. On the **Style** tab, configure the title, background, font size, the number of indicators displayed in each row, conditional formatting, and data display format of the kanban, as shown in [Kanban](#).

Kanban

- Click **Save** in the upper-right corner. In the Save Dashboard dialog box, specify a name for the dashboard.
- Click **OK** to save the dashboard.

If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.20. Create an indicator trend chart

An indicator trend graph displays multiple indicators over a period of time. By default, the latest data record of each indicator is displayed.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

You can specify only one date dimension for Date (Dimensions). You must specify at least one measure for Indicator (Measures).

The following example describes how to use an indicator trend graph to compare the order quantities, order price, shipping costs, and profits in different provinces in a specified period of time. The `company_sales_record` dataset is used in this example.

Create an indicator trend chart

- [Log on to the Quick BI console.](#)
- In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
- On the **Datasets** page, click **MyDatasets**, find the `company_sales_record` dataset, and click the  icon in the Actions column.
- In the **Create Dashboard** dialog box, click **Standard** or **Full Screen**, and click **OK**.
- On the dashboard edit page, click the **Indicator trend graph** icon.
- In the Dimensions list, find `order_date(day)` and add it to the **Date (Dimensions)** field. In the Measures list, find and add `order_number`, `order_amt`, `shipping_cost`, and `profit_amt` to the **Indicator (Mea.)** field.

7. Click **Update**. The chart is updated.
8. On the **Style** tab, configure parameters in the **Basic Information**, **Chart Settings**, **Indicator Settings**, **Functionality Settings**, and **Series Settings** sections.
9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, enter a name for the dashboard.
10. Click **OK** to save the dashboard.

If you want to delete a chart, move the pointer over the chart, click the  icon in the upper-right corner, and select **Delete**.

Configure the parameters on the Style tab

1. In the **Basic Information** section, configure Title, Description, and Show Link.

 **Note**

- This example uses light color as the background color.
- If you want users to be redirected to a report or an external page, select Show Link and specify Link Text and Link Address.

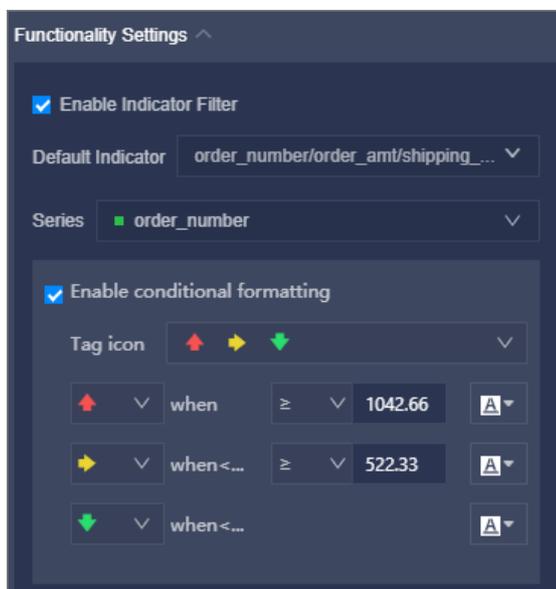

2. In the **Chart Settings** section, select Show Trend by Date, and specify a trend chart style, preview mode, and layout for multiple indicators.
 - If you select Single Choice for Select Preview Mode, the trend chart displays the trend of only one measure indicator. If you select Multiple Choice for Select Preview Mode, the trend chart displays the trend of multiple measure indicators.
 - If you select Displayed in One Line for Layout for Multiple Indicators and the indicators cannot be displayed in one line, you can slide the chart to view all indicators. If you select Displayed in Multiple Lines for Layout for Multiple Indicators, indicators are displayed in multiple lines.
3. In the **Indicator Settings** section, specify the number of indicators in each row, the font color for the primary indicator value, and the alignment mode of indicator blocks. In this example, Maximum Indicators Each Row is set to 4.
4. In the **Functionality Settings** section, configure Enable Indicator Filter and conditional formatting.

After you select Enable Indicator Filter, an indicator filter icon is displayed in the upper-right corner of the chart. You can click the icon to select the indicators that you want to display.

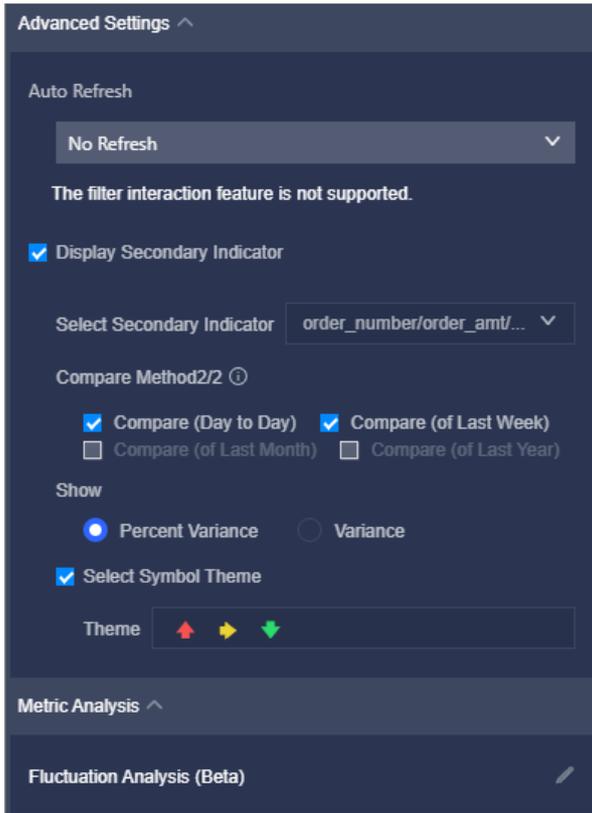

Perform the following steps to configure conditional formatting:

- i. Select the required measure from the Series drop-down list. Then, select **Enable Indicator Filter** and select icon themes from the drop-down list of the Tag icon.

- ii. Specify the rules for marking data, the icon style, and font color.
5. In the **Series Settings** section, set the measure alias, description, prefix and suffix of indicator values, and data display format.
 6. On the **Advanced** tab, select Display Secondary Indicator. Select the required measure indicator from the **Select Secondary Indicator** drop-down list, and set the comparison content, display content, and symbol theme.

The following figure shows an updated indicator trend graph.

7.5.4.21. Create a treemap

A treemap compares the proportions of metrics of an object.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A treemap displays labels in different sizes based on the measure. Labels are determined by a dimension, such as packaging. The size of each rectangle label is determined by a measure, such as shipping costs.

You can specify only one dimension for labels and one measure for sizes. The dimension must have a maximum of 12 values.

The following example uses the `company_sales_record` dataset to describe how to use a treemap to compare the order quantities of different products.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. In the Datasets page that appears, find the `company_sales_record` dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click OK.
4. On the dashboard edit page, click the **Treemap** icon.
5. Click the **Data** tab and select the required dimension and measures.

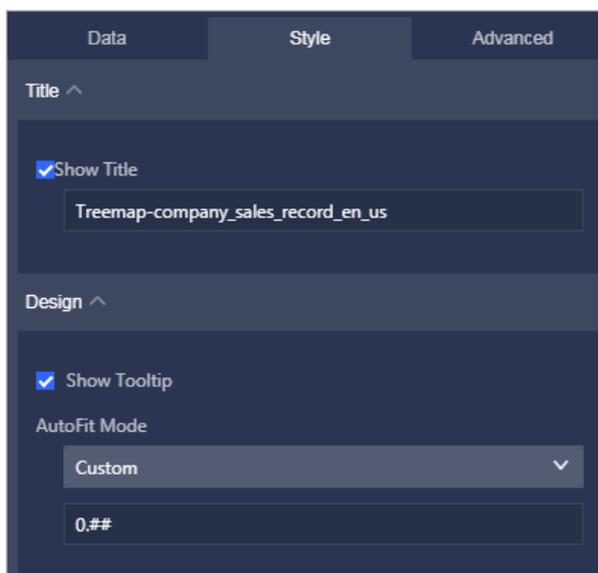

In the Dimensions list, find and add `product_type` to the Labels (Dim.) field. In the Measures list, find and add `order_number` to the Size (Mea.) field, as shown in [Specify fields for the treemap](#).

Specify fields for the treemap

6. Click **Update**. The chart is updated.
7. Click the **Style** tab and configure whether to show the title and tooltip of the treemap, as shown in [Treemap](#).

Treemap

8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.22. Create a polar diagram

A polar diagram displays data changes over a period of time or compares metric values. It is ideal for comparing data of different objects, for example, data across different regions.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

Similar to a [pie chart](#), a polar diagram consists of multiple slices. Slice labels are determined by a dimension, such as area or product type. The arc radius of each slice is determined by a measure, such as order quantity or order price.

You can specify only one dimension for slice labels and only one measure for arc radii.

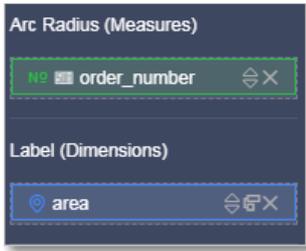

The following example uses the `company_sales_record` dataset to describe how to use a polar diagram to compare the order quantities in different regions. The number of regions must be greater than or equal to 3 and less than or equal to 12.

Procedure

1. [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the `company_sales_record` dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click **OK**.
4. On the dashboard edit page, click the **Polar Diagram** icon.
5. Click the **Data** tab and select the required dimension and measure.

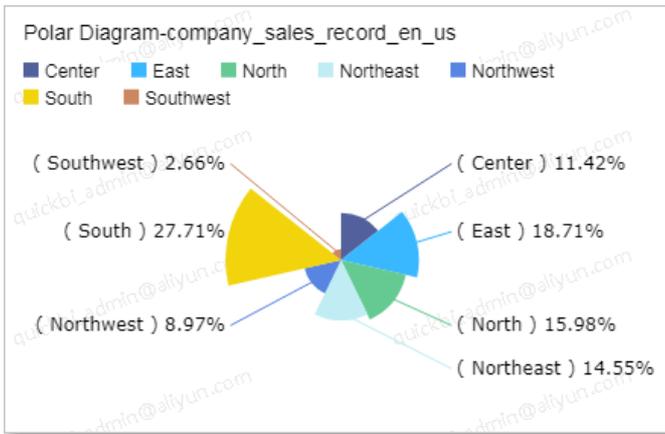

In the Dimensions list, find and add `area` to the Label (Dim.) field. In the Measures list, find and add `order_number` to the Arc Radius (Mea.) field, as shown in [Specify fields for the polar diagram](#).

Specify fields for the polar diagram

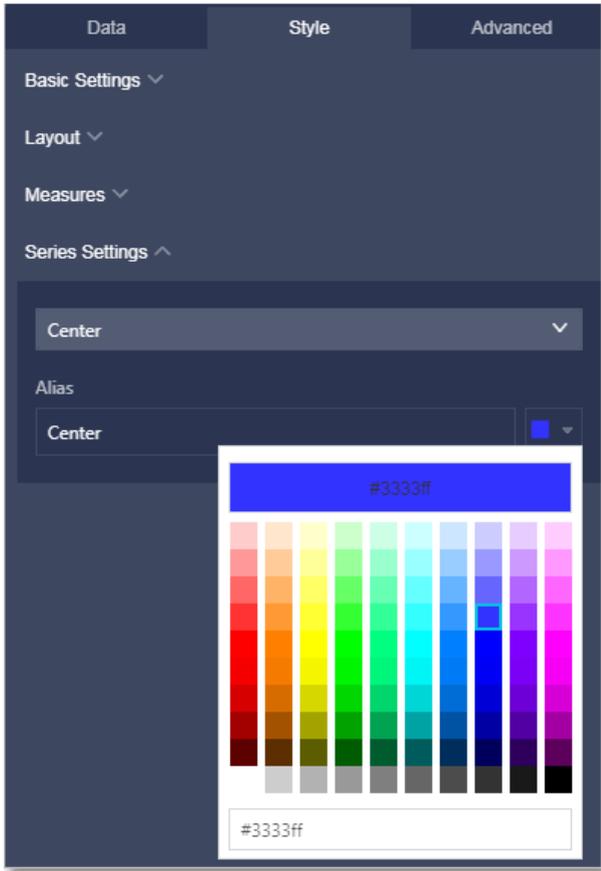

6. Click **Update**. The chart is updated.
7. Click the **Style** tab, change the title of the polar diagram, and specify the legend position, as shown in **Polar diagram**.

Polar diagram

8. Click the **Style** tab and change the legend colors in the **Series Settings** section.
Change legend colors

9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
10. Click **OK** to save the dashboard.
If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.23. Create a word cloud

A word cloud displays the frequency of words that appear in a dataset. It is ideal for creating user personas and user tags.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

When you create a word cloud, you must specify **Word Size (Mea.)** and **Word (Dim.)**:

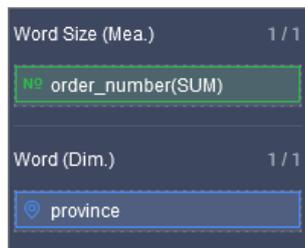

- The word size is determined by a measure. You can select only one measure, such as profit amount or unit price.
- The label is determined by a dimension. You can select only one dimension, such as customer name or product name.

The following example describes how to use a word cloud to compare the order quantities in different provinces. The company_sales_record dataset is used in this example.

Procedure

1. Log on to the Quick BI console.
2. In the left-side navigation pane of the **Workspace** tab, click the **Datasets** icon.
3. On the **Datasets** page, find the *company_sales_record* dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Word Cloud** icon.
6. On the **Data** tab, select the required dimension and measure. In the Dimensions list, find province and drag it to the Word (Dim.) field. In the Measures list, find order_number and drag it to the Word Size (Mea.) field.

Specify fields for the word cloud

7. Click **Update**. The chart is updated.
8. On the **Style** tab, change the title of the chart, word cloud shape and value display formats. The following figure **Word cloud** is an example.

Word cloud

9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, enter a name for the dashboard.
10. Click **OK** to save the dashboard.

If you want to delete the chart, click the **More Actions** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.24. Create a butterfly chart

A butterfly chart is the combination of a comparison chart and a funnel chart. A comparison chart is used to compare metrics of two different objects, such as the income and education level differences between residents in two cities. A funnel chart shows the conversion rates between the stages of business processes, such as the percentage of visitors that become paying customers for a shopping website. Funnel charts are ideal for business process analysis.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

- A comparison chart compares different metrics between two objects,
-

A butterfly chart combines the features of a comparison chart and a funnel chart.

- If no conversion relationship exists, the butterfly chart functions the same as a comparison chart.
- If a conversion relationship exists between metrics and only one comparison subject is defined, the butterfly chart functions the same as a funnel chart.
- If a conversion relationship exists between metrics and multiple comparison subject are defined, the advantages of a butterfly chart is fully exploited.

If you want to compare the percentage of the migrant populations, employment rates, and commercial housing transactions in Beijing and Shanghai, the butterfly chart shows the values of the metrics for the two cities and also the conversion rates between the metrics.

When you create a butterfly chart, you must specify **Tier Area (Mea.)** and **Comparison Metrics (Dim.)**:

- The comparison metric is determined by a dimension. You can select only one dimension, such as area or product type.
- Tier area is determined by measures. You can select one to ten measures, such as order quantity or order price.

The following example describes how to use a butterfly chart to compare the order quantities, order prices and average profits of different products. The `company_sales_record` dataset is used in this example.

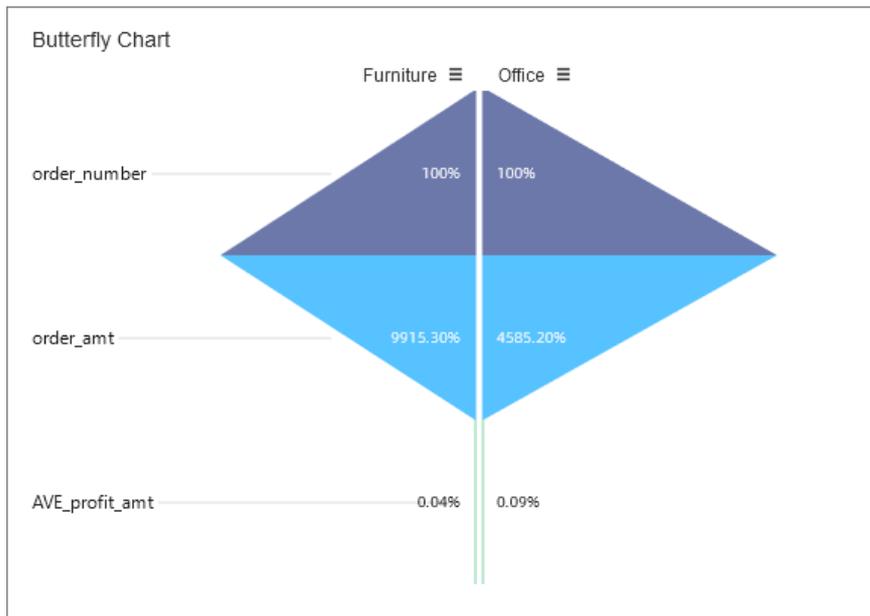

Procedure

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, click **MyDatasets** and find the `company_sales_record` dataset, then click the  icon in the **Actions** column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the  icon.
6. On the **Data** tab, select required dimensions and measures.
 - In the **Dimensions** list, find `product_type` and drag it to the **Comparison Metrics (Dim.)** field.
 - In the **Measures** list, find the `order_number`, `order_amt`, and `average profit_amt` and drag them to the **Tier Area (Mea.)** field.

Specify fields for the butterfly chart

7. Click **Update**. The chart is updated.

8. On the **Style** tab, configure parameters in the Basic Information, Chart Type, and Series Settings sections.
9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, specify a name for the dashboard.
10. Click **OK** to save the dashboard.

If you want to delete the chart, click the  icon in the upper-right corner of the chart and select **Delete**.

7.5.4.25. Create a hierarchy chart

A hierarchy chart organizes and displays hierarchical data in a tree structure. It is an implementation of the enumeration method. For example, when you view revenues of cities in a province, the relationships between the province and the cities are displayed in a hierarchical structure. Hierarchy charts are ideal for analyzing data related to organizational structures, such as the staff structure of a company or department structure of a hospital.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A hierarchy chart consists of node metrics and node labels. Node labels are determined by dimensions, such as area and product type. Node metrics are determined by measures, such as order quantity and order price.

This topic uses the following scenarios as examples to describe how to use a hierarchy chart and the filter:

- Scenario 1: Compare the order quantities of different products in the provinces of different regions.
- Scenario 2: View the average profits of different products in different municipalities.

In a hierarchy chart, you must specify at least two dimensions for node labels. Data is displayed clearly if these dimensions have a hierarchical relationship. You must specify at least one measure for node metrics.

Scenario 1: Compare the order quantities of different products in the provinces of different regions

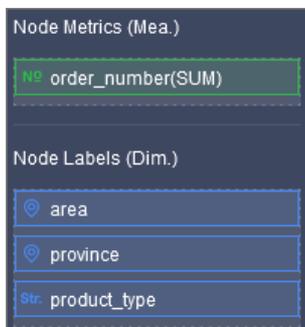

Procedure

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page that appears, find the `company_sales_record` dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click OK.
4. On the dashboard edit page, click the **Hierarchy Chart** icon.
5. Click the **Data** tab and select the required dimensions and measures.

In the Dimensions list, find and add `area`, `province`, and `product_type` to the Node Labels (Dim.) field. The sequence in which you add these dimensions determines the hierarchical relationship in the chart. In the Measurement list, find and add `order_number` to the Node Metrics (Mea.) field, as shown in the following figure.

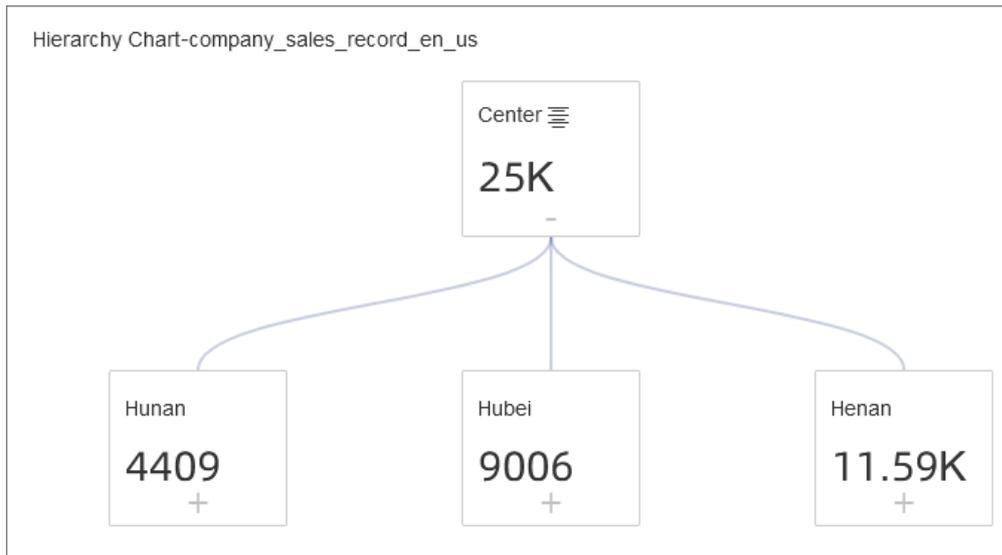

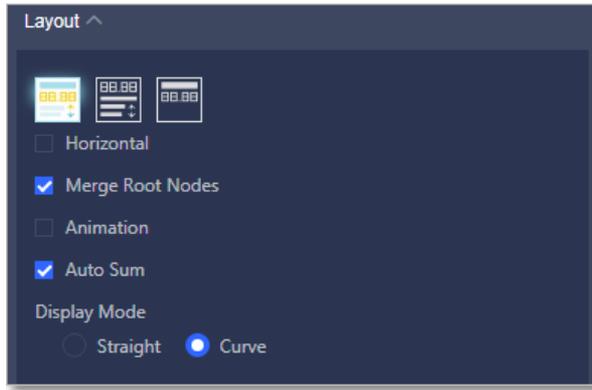

Note Ensure that you have converted the dimension type of `area` and `province` from String to Geo. For information about how to convert a dimension type, see [Edit a dimension](#).

Specify fields for the hierarchy chart

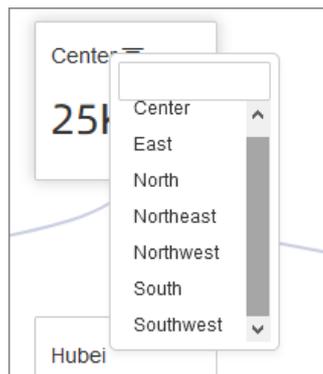

6. Click **Update**. The chart is updated.
7. Click the **Style** tab and change the title, layout, and design of the chart.
 - i. Quick BI provides three layout types for hierarchy charts. You can select a structure and display mode for the chart based on your business needs. The Merge Root Nodes check box is selected by default. In the following example, the **Straight** mode is selected.

Layout

- Move your pointer over the area field in the chart and switch to another region from the drop-down list that appears, as shown in the following figure.

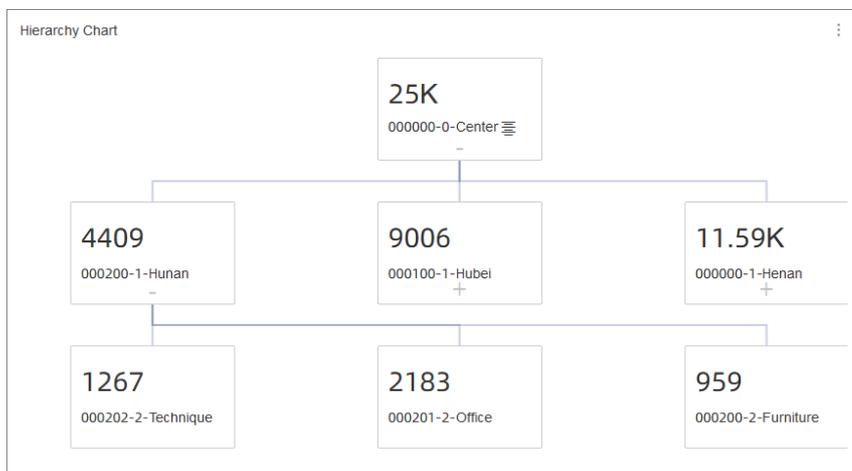

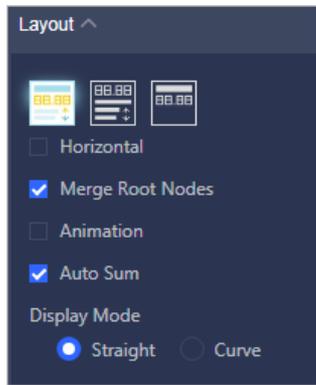

Switch to another region

- Click the minus sign (-) or plus sign (+) to fold or unfold the child nodes.

- In the Layout section, if you select **Auto Sum**, the chart displays the total amount of each node, as shown in the following figure.

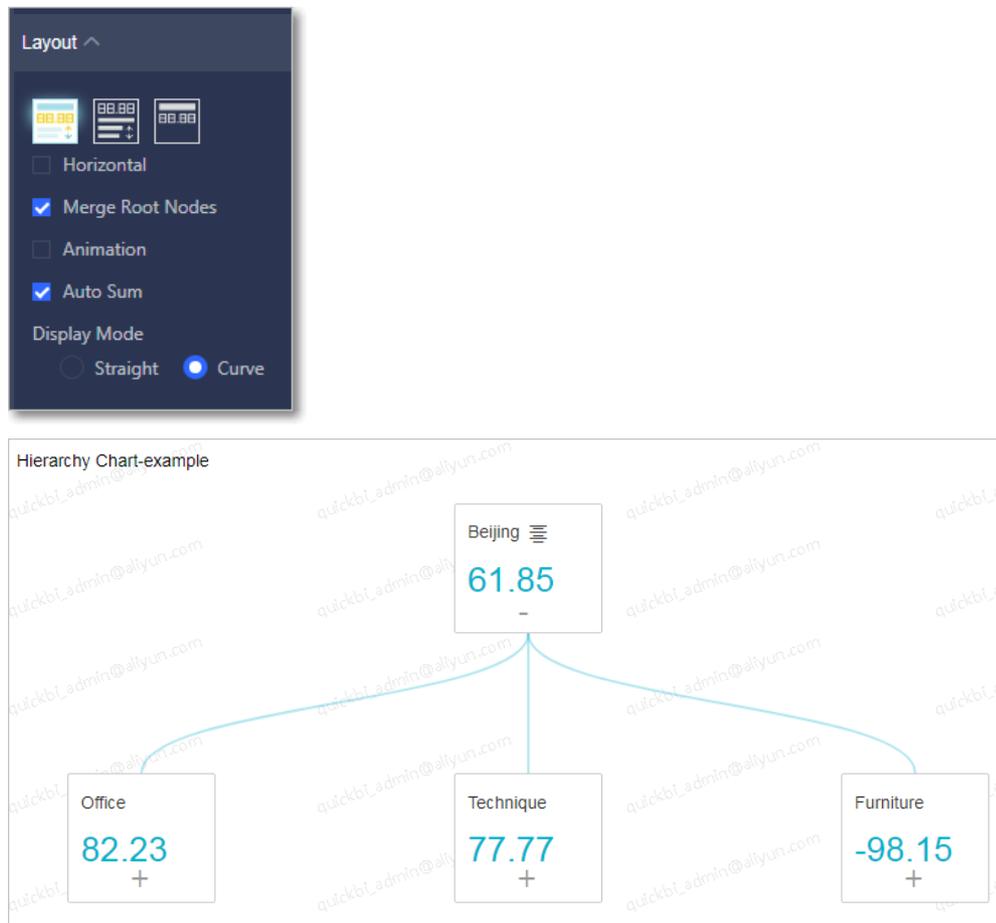

Auto Sum

- ii. In the Design section, you can configure the Levels field to specify the level of data to be displayed. You can also set a primary path, which is displayed in a different color in the chart. You can select the Show Filter Bar check box to add a toolbar to the chart. This allows you to edit the chart in preview mode or in the dashboard.

In the following example, the Primary Path parameter is set to order_number, the Sort parameter is set to Ascend, the Show Filter Bar check box is selected, and the Curve display mode is selected, as shown in the following figure.

Hierarchy chart

8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

By default, the dashboard is saved to the **My Items** tab on the Dashboards page.

Scenario 2: View the average profits of different products in different municipalities

Context

Data modeling may be required in this scenario. For information about data modeling, see [Add a calculated field](#).

Procedure

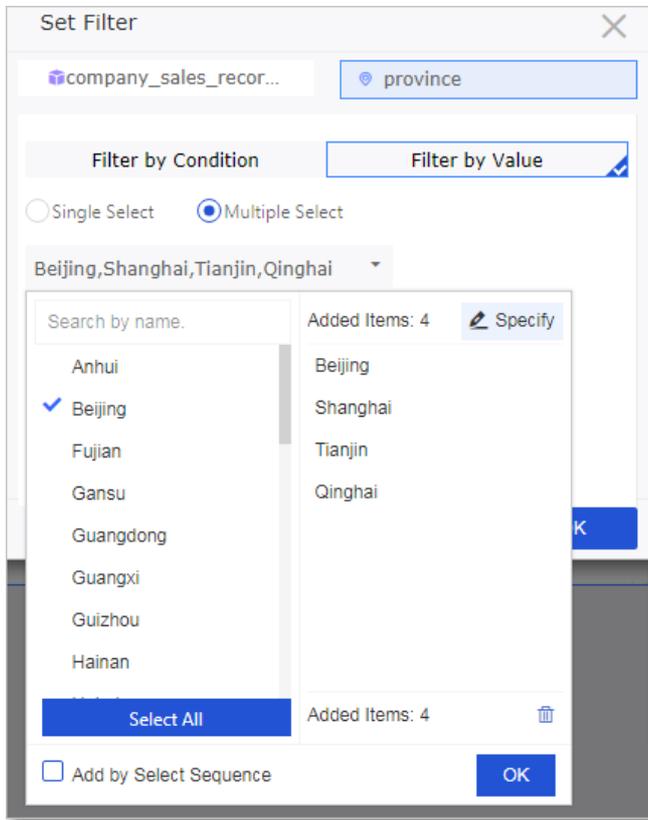

1. In the Dimensions list, find and add province to the Filters field.

This way, you can filter municipalities.

- 2. Click the **Filter** icon. In the Set Filter dialog box that appears, select **Filter by Value** and **Multiple Select**, as shown in the following figure.

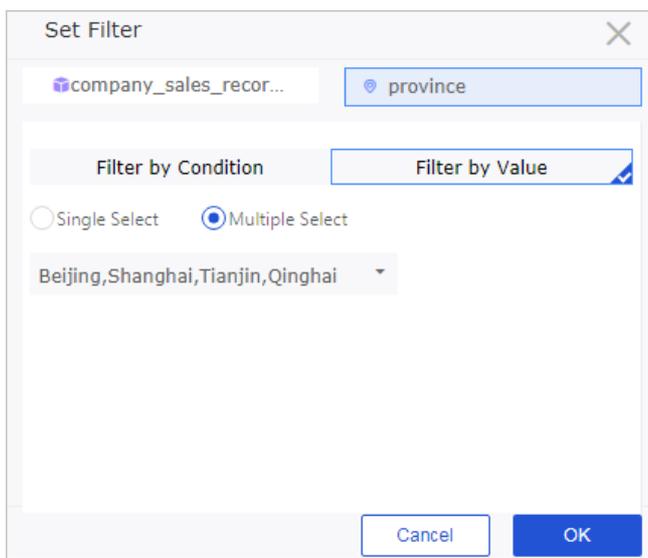

The system automatically lists all available options of the province field in the drop-down list.

Filter by Value

- 3. Select the municipalities or manually enter their names.
- 4. Click **OK** to set the filter condition, as shown in the following figure.

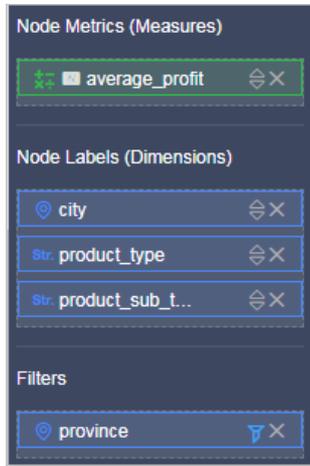

Set the filter condition

5. In the Dimensions list, find and add city, product_type, and product_sub_type to the Node Labels (Dim.) field, as shown in the following figure.

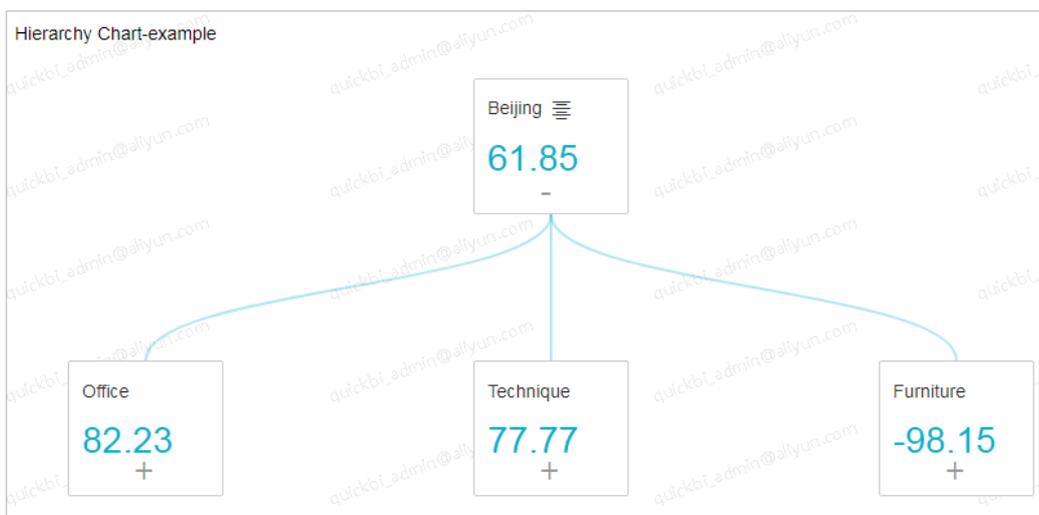

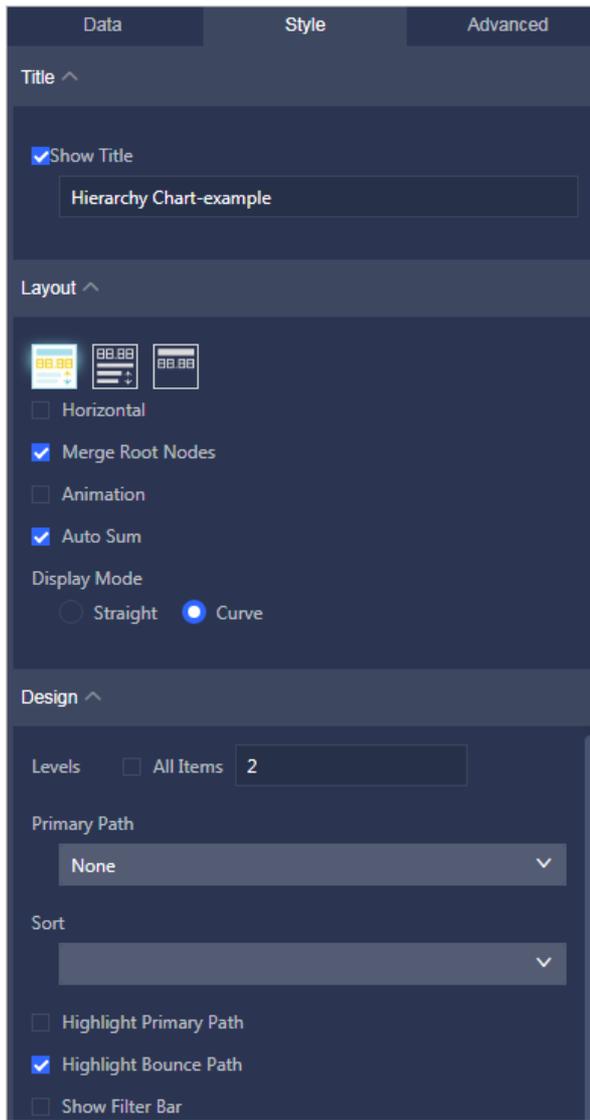

The sequence in which you add these dimensions determines the hierarchical relationship displayed in the chart. In the Measures list, find and add average_profit to the Node Metrics (Mea.) field.

Specify fields for the hierarchy chart

6. Click **Update**. The chart is updated.
7. Click the **Style** tab and change the title, layout, and design of the chart, as shown in the following figure.

Hierarchy chart

- Click **Save** in the upper-right corner. In the Save Dashboard dialog box that appears, enter a name for the dashboard.
- Click **OK** to save the dashboard.

If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

7.5.4.26. Create a flow analysis chart

A flow analysis chart shows the data flow of source, central, and destination nodes.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

A flow analysis chart displays a data flow, including data source and destination. It also displays the proportions of data that go to different destinations. For example, assume that the total number of page views (PVs) on the Taobao homepage on a specific day is 100, you can use a flow analysis chart to analyze the number and proportion of PVs on the Taobao homepage through different search engines, as well as the number and proportion of PVs that flow to other platforms.

When you create a flow analysis chart, you must specify **Central Node (Dimensions)**, **Node Type (Dimensions)**, **Node Name (Dimensions)**, and **Node Indicator (Measures)**.

- The central node is determined by a dimension. You can select only one dimension.
- The node type is determined by a dimension. You can select only one dimension.
- Node names are determined by a dimension. You can select only one dimension.
- The node indicator is determined by a measure. You can specify only one measure.

For more information, see [Flow analysis-demo](#).

Create a flow analysis chart

1. [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the *company_sales_record* dataset and click the  icon in the Actions column.
4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Flow Analysis** icon.
6. On the **Data** tab, select required dimensions and measure.

In the Dimensions list, find the required dimensions and add them to the Central Node (Dimensions), Node Type (Dimensions), and Node Name (Dimensions) fields. In the Measures list, find the required measure and add it to the Node Indicator (Measures) field.

7. Click **Update**. The chart is updated.
8. On the **Style** tab, configure the title and data display format of the chart.
9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, specify a name for the dashboard.
10. Click **OK** to save the dashboard.

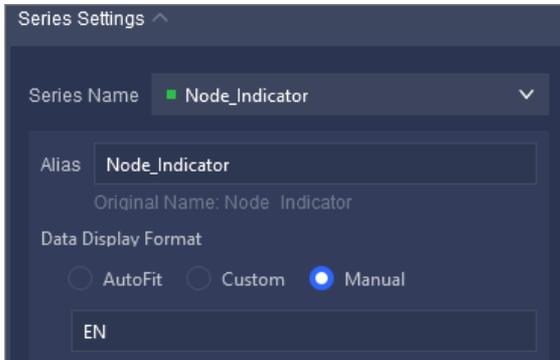

If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

Configure the parameters on the Style tab

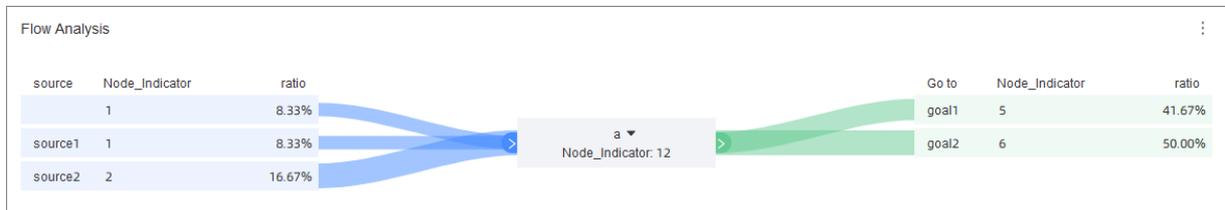

1. In the **Basic Information** section, configure Title, Description, and Show Link.

Note If you want users to be redirected to a report or an external page, select Show Link and specify Link Text and Link Address.

2. In the **Series Settings** section, configure Alias and Data Display Format for a measure.

The following figure shows an updated flow analysis chart.

7.5.4.27. Create a sankit diagram

A sankit diagram is a flow diagram in which the branch width is proportional to the flow rate. It shows the data flow between two groups of values. It is ideal for visualization analysis of energy, material composition, and finance data.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

You can specify two to five dimensions, such as province and product type, for the node type. You can specify up to one measure, such as order quantity, for the node height.

The following example describes how to use a sankit diagram to compare the order quantities and order levels of products in different regions. The company_sales_record dataset is used in this example.

Create a sankit diagram

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** tab, click **Dat assets**.
3. On the Datasets page, find the company_sales_record dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click OK.
4. On the dashboard edit page, click the **Sankey Diagram** icon.
5. On the **Data** tab, select the required dimensions and measure.

In the Dimensions list, find area and order_level and add them to the **Node Type (Dimensions)** field.

In the Measures list, find `order_number` and add it to the **Node Height (Measures)** field.

6. Click **Update**. The chart is updated.
7. On the **Style** tab, configure parameters in the Basic Information, Chart Type, and Series Settings sections.
8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, enter a name for the dashboard.
9. Click **OK** to save the dashboard.

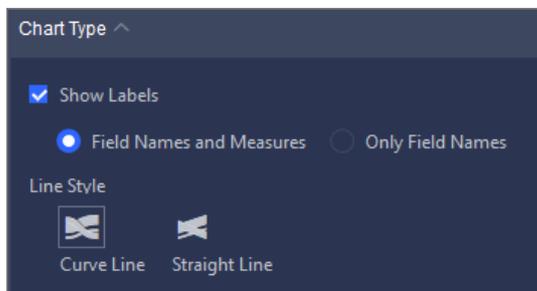

If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

Configure the parameters on the Style tab

1. In the **Basic Information** section, configure the title and whether to show the link.

 **Note** If you want to redirect to a report or an external page, select **Show Link** and specify Link Text and Link Address.

2. In the **Chart Type** section, configure Show Labels and Line Style.

3. In the **Series Settings** section, configure Display Name and Number Formatting. In this example, **AutoFit** is selected.

7.5.4.28. Create a Leaderboard

A leaderboard shows the ranking of the Top N objects from a specific measure in descending order. It objectively reflects the strengths of objects of the same category.

Prerequisites

- The Quick BI service is purchased.
- A dataset is created.

Context

You can specify only one dimension, such as area or product type, for **Category / Dimension**, and only one measure, such as order quantity or profit, for **Indicators / Measures**. A leaderboard shows 20 records by default and can show up to 50 records.

The following example describes how to use a leaderboard to compare the order quantities in different areas. The `company_sales_record` dataset is used in this example.

Procedure

1. [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the **Datasets** page, find the `company_sales_record` dataset and click the  icon in the Actions

column.

4. In the **Create Dashboard** dialog box, select **Standard** or **Full Screen**, and click **OK**.
5. On the dashboard edit page, click the **Leaderboard** icon.
6. On the **Data** tab, select the required dimension and measure.
 - o In the Dimensions list, find **area** and add it to the **Category / Dimension** field.
 - o In the Measures list, find **order_number** and add it to the **Indicators / Measures** field.
7. Click **Update**. The chart is updated.
8. On the **Style** tab, configure parameters in the Basic Information, Style Settings, Functionality Settings, and Series Settings sections.
9. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, enter a name for the dashboard.
10. Click **OK** to save the dashboard.

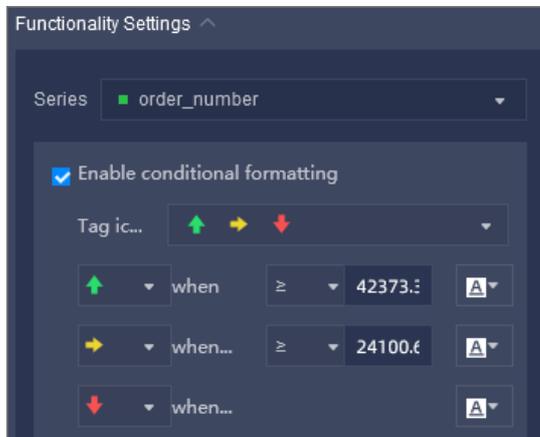

If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

Configure the parameters on the Style tab

1. In the **Basic Information** section, configure the title, color, and whether to show the link.

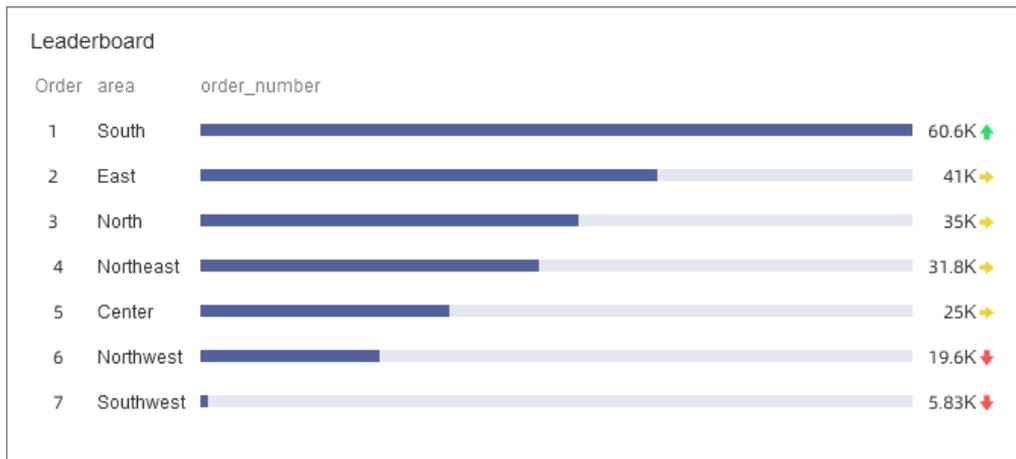

Note If you want to redirect to a report or an external page, select **Show Link** and specify Link Text and Link Address.

2. In the **Style Settings** section, configure Show Column Name, Theme for Top 3 Items, Data Display Format, Value Alignment, and Bar Color.
3. In the **Functionality Settings** section, configure conditional formatting.

- i. Select **Enable conditional formatting**, and select icon themes from the drop-down list of **Tag icon**.
 - ii. Specify the rules for marking data, the icon style, and font color.
4. In the **Series Settings** section, specify the alias for the measure or dimension, alignment mode, and data display format.

Click Update. The chart is updated, as shown in the following figure.

7.5.4.29. Create a ticker board

A ticker board displays KPI data and allows you to customize style settings such as the background color.

Prerequisites

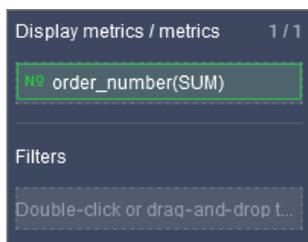

- The Quick BI service is purchased.
- A dataset is created.

Context

Ticker boards can display only metrics (measures). The following example describes how to use a ticker board to show order quantities. The `company_sales_record` dataset is used in this example.

Create a ticker board

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** tab, click **Datasets**.
3. On the Datasets page, find the `company_sales_record` dataset, click the **Create Dashboard** icon in the Actions column. In the dialog box that appears, select **Standard** and click OK.
4. On the dashboard edit page, click the **Ticker Board** icon.
5. On the **Data** tab, add the measure `order_number` to the **Indicator (Measures)** field.

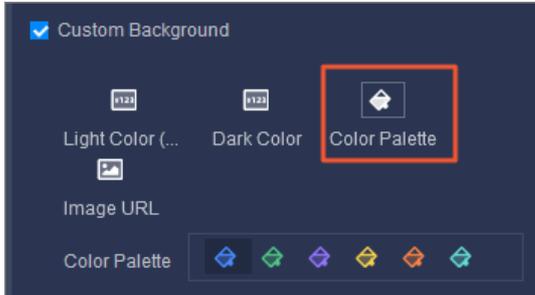

6. Click **Update**. The chart is updated.
7. On the **Style** tab, configure parameters in the Basic Information, Style Settings, Functionality Settings, and Series Settings sections.
8. Click **Save** in the upper-right corner. In the Save Dashboard dialog box, specify a name for the dashboard.
9. Click **OK** to save the dashboard.

If you want to delete the chart, click the **More** icon in the upper-right corner of the chart and select **Delete**.

Configure the parameters on the Style tab

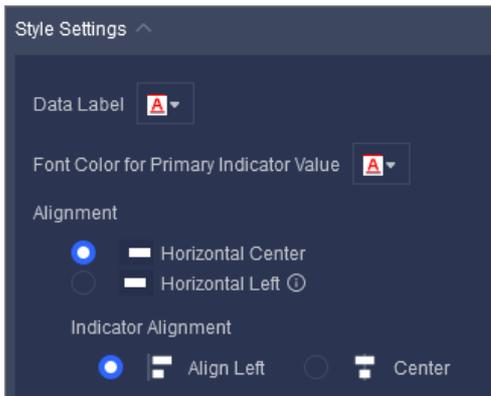

1. In the **Basic Information** section, specify Show Title and Description, Show Link, and Background.

You can select Light Color (Default), Color Palette, or Image URL for Background. Quick BI provides six color palettes.

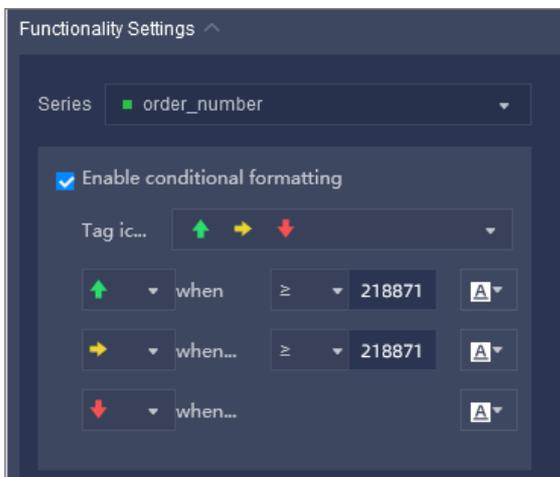

Note If you want users to be redirected to a report or an external page, select **Show Link** and specify Link Text and Link Address.

2. In the **Style Settings** section, specify the font colors for data labels and primary indicator values and the indicator position in an indicator block.

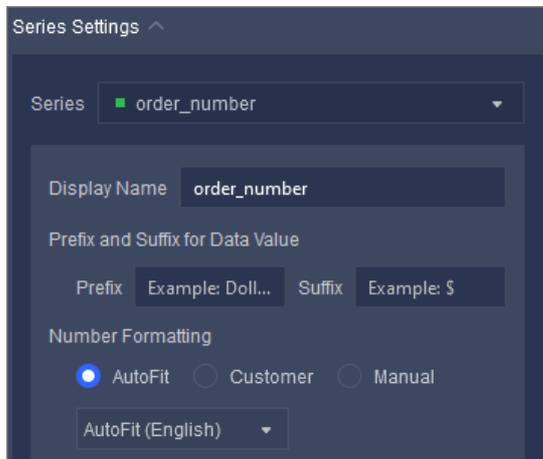

3. In the **Functionality Settings** section, configure conditional formatting.

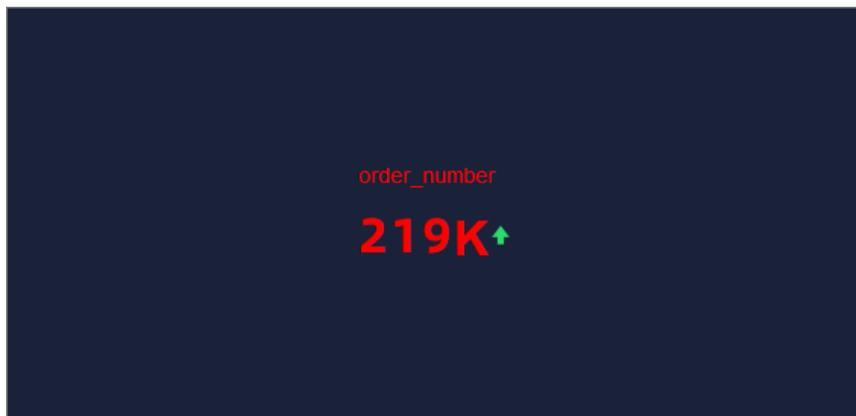

- i. Select **Enable conditional formatting**, and select icon themes from the drop-down list of **Tag icon**.

- ii. Manually enter the data value that needs to be marked, and configure the icon style and font color based on the system prompt.
4. In the **Series Settings** section, specify the measure alias, prefix, suffix, and data display format.

Click Update. The following figure shows an updated ticker board.

7.5.5. Theme design

You can use the theme design feature to change the template, skin, and theme color for a dashboard.

Prerequisites

- The Quick BI service is purchased.
- A dashboard is created. For more information, see [Go to the dashboard edit page](#).

Procedure

1. Click the  icon in the top navigation bar.
2. In the **Theme Design** section of the **Page Settings** page, configure **Official Template**, **Skin**, and **Theme Color**.

Parameter	Description
-----------	-------------

Parameter	Description
Official Template	<p>The official template is selected by default. You can change it to a custom template.</p> <p>If the templates in the drop-down list cannot meet your business requirements, click Add Custom Template to create a custom template. For more information, see Manage theme templates.</p> <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> <p>Note After you change the theme, the custom settings of the original theme cannot be restored. We recommend that you save a copy of a theme before you change it.</p> </div>
Skin	<p>Two options are provided: Light and Dark.</p> <ul style="list-style-type: none"> If you select Light, the background color of the dashboard is white. The default value is Light. If you select Dark, the background color of the dashboard is black.
Theme Color	<p>Three options are provided: Business, Classic, and Custom.</p> <p>If you select Custom for Theme Color, you can select a color system from the drop-down list.</p> <div style="border: 1px solid #333; padding: 10px; margin-top: 10px; background-color: #1a2b4d; color: white;"> <p>Theme Design</p> <p>Official Template Orange</p> <p>Skin</p> <p><input type="checkbox"/> Light <input type="checkbox"/> Dark</p> <p>Theme Color</p> <p>Business Classic Summer solstice is not</p> <p>Select Orange</p> <ul style="list-style-type: none"> Orange Data Blue female fashion Calm senior Rouge blush natural forest national tide retro </div> <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> <p>Note After you change the theme color, the custom settings of the original theme cannot be restored. We recommend that you save a copy of a theme before you change it.</p> </div>

7.5.6. Full screen mode

This topic describes the basic features of the full screen mode.

The full screen mode allows you to perform the following operations in the display area of a dashboard:

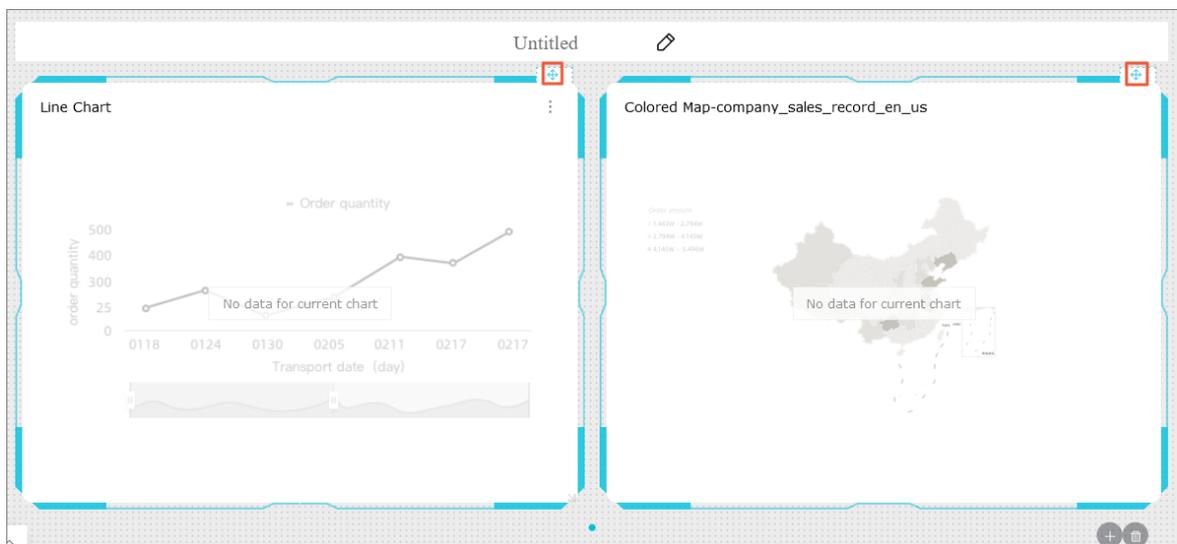

- Adjust chart positions

- Add a subscreen
- View chart data
- Delete a chart
- Change chart types
- Configure page settings

Adjust chart positions

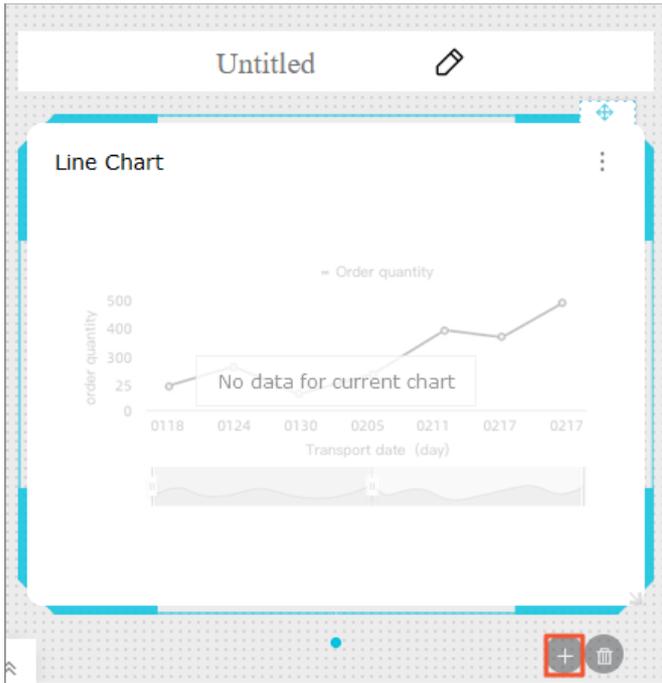

In full screen mode, a single chart can be displayed in the entire display area of a dashboard. If you have created multiple charts, you can perform the following operations to adjust their positions:

1. [Access a dashboard](#).
2. In full screen mode, you can click the cross-arrow icon in the upper-right corner of the chart to drag the chart to the specified position.

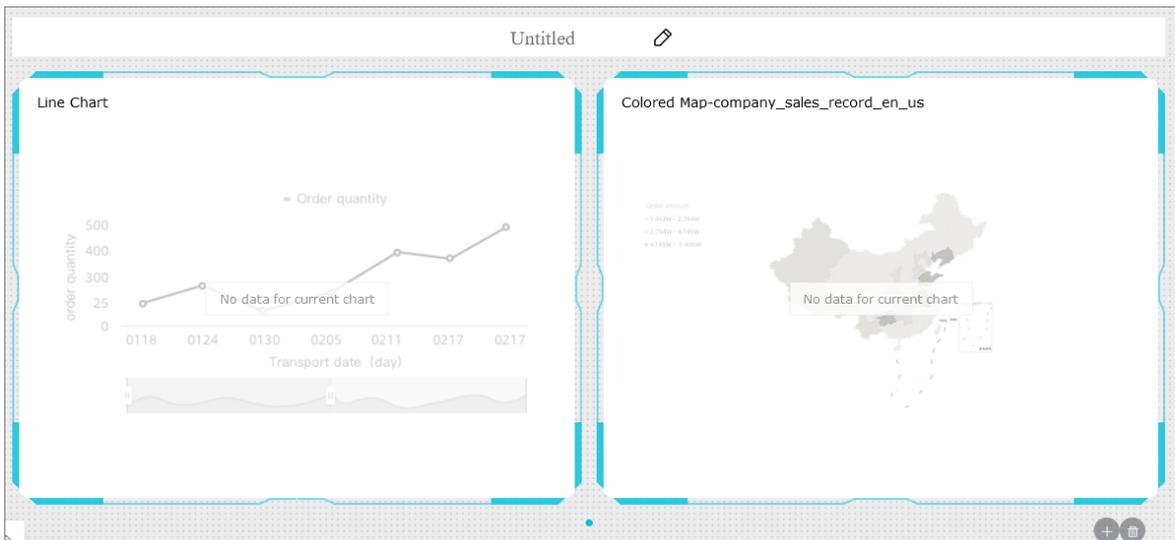

Add a subscreen

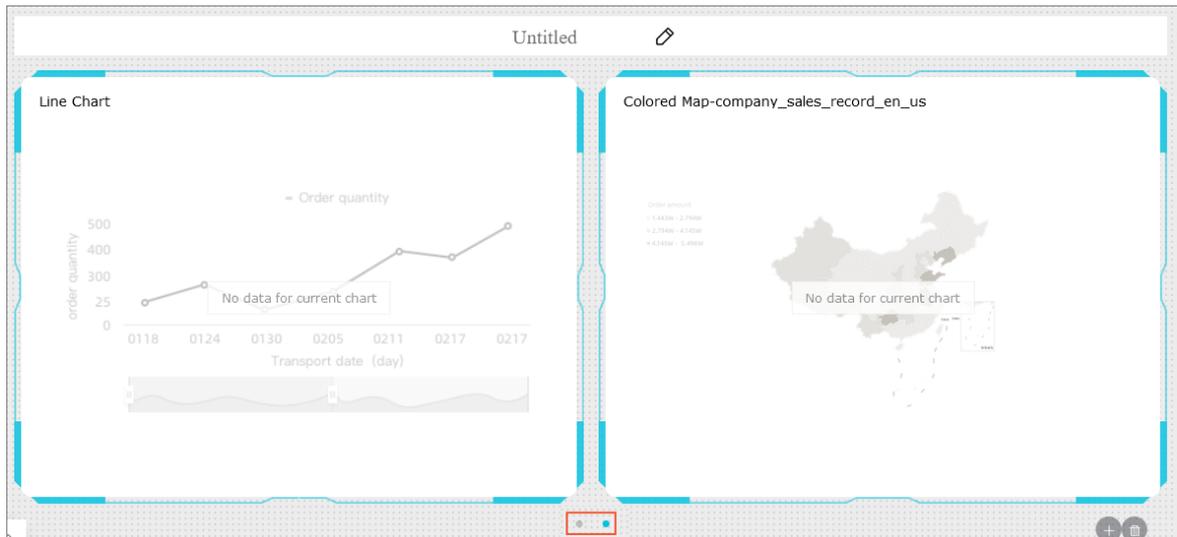

1. Click the plus sign in the lower-right corner.

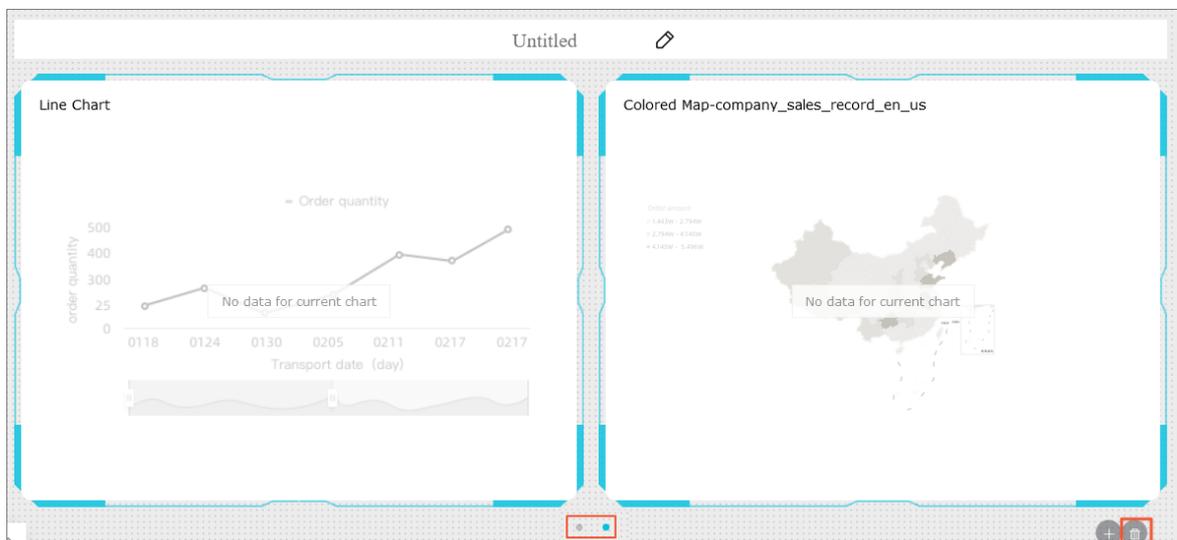

2. Add charts to the subsection.

3. Click Switch Screen to switch from the current screen to another.

4. Click the Delete icon in the lower-right corner to delete a subscreen.

Move a chart

1. Select a chart.
2. Click the  more icon in the upper-right corner of the chart.
3. Select **Move To**.

You can move the chart to a containers tab.

View chart data

1. Select a chart.
2. Click the  more icon in the upper-right corner of the chart.
3. Select **View Data**.

You can view the data of the chart.

View SQL statements

1. Select a chart.
2. Click the  more icon in the upper-right corner of the chart.
3. Select **View SQL Statements**.

You can view the SQL statements that corresponds to the chart.

View full screen

1. Select a chart.
2. Click the  more icon in the upper-right corner of the chart.
3. Select **Full Screen**.

The chart can be displayed in full screen.

Delete a chart

1. Select a chart.
2. Click the  more icon in the upper-right corner of the chart.
3. Select **Delete**.

You can delete the chart.

Change chart types

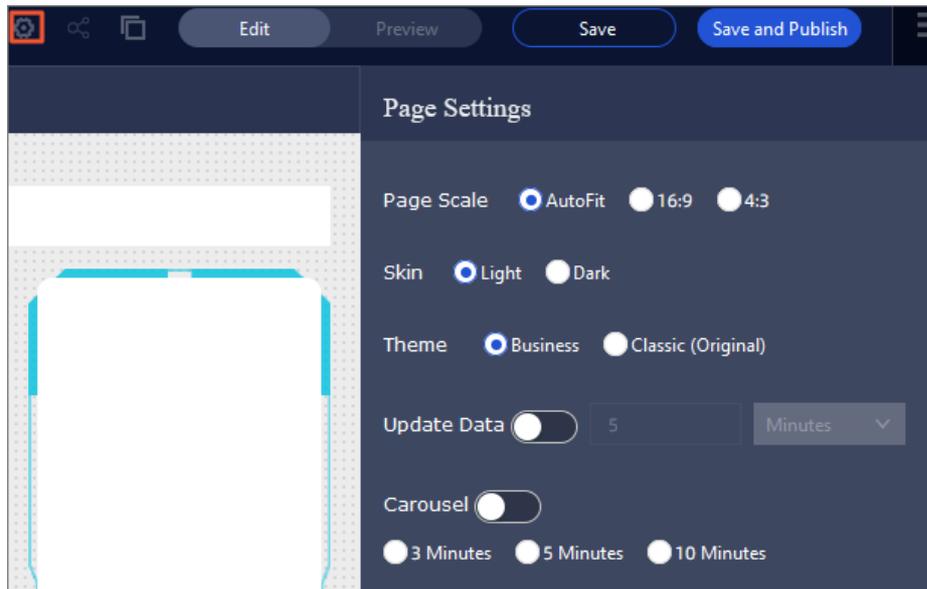

1. Select a chart.
2. In the Graphic Design area, click **Change Chart Type**.
3. Click the chart type you want.

Note

If the fields of the current chart do not match those of the target chart, the chart type cannot be changed. You must manually adjust fields before you change the chart type. The system provides instructions to help you adjust the elements based on the current and target chart types. To change the chart type, follow the instructions to adjust the dimensions and measures.

Page settings

You can click the  icon to view the page settings and specify the page scale, skin color, theme, data update interval, and time interval of data carousel.

7.5.7. Search for a dashboard

This topic describes how to search for a specific dashboard.

Prerequisites

- The Quick BI service is purchased.
- One or more dashboards are created.

Procedure

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** page, click **Dashboards**.
3. Enter a keyword in the search box to search for the required dashboard.

7.5.8. Create a dashboard folder

This topic describes how to create a dashboard folder.

Prerequisites

The Quick BI service is purchased.

Procedure

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** page, click **Dashboards**.
3. On the Dashboards page, click **Create Folder** in the upper-right corner.
4. In the **Create Folder** dialog box, specify a name for the folder and click **OK**.

7.5.9. Rename a dashboard folder

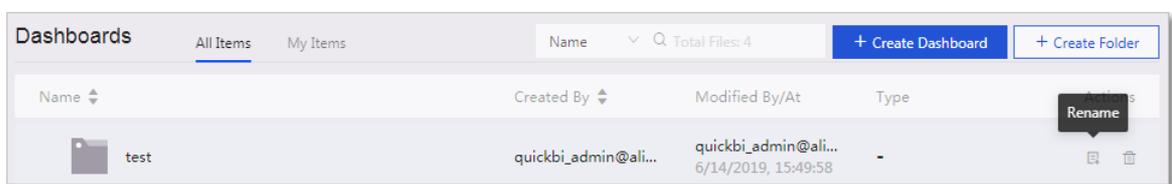

This topic describes how to rename a dashboard folder.

Prerequisites

- The Quick BI service is purchased.
- A dashboard folder is created. For information about how to create a dashboard folder, see [Create a dashboard folder](#).

Procedure

1. [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** page, click **Dashboards**.
3. On the Dashboards page, find the dashboard folder you want to rename.
4. Click the  icon.

5. In the Rename dialog box, enter a name and click **OK**.

7.5.10. View a dashboard

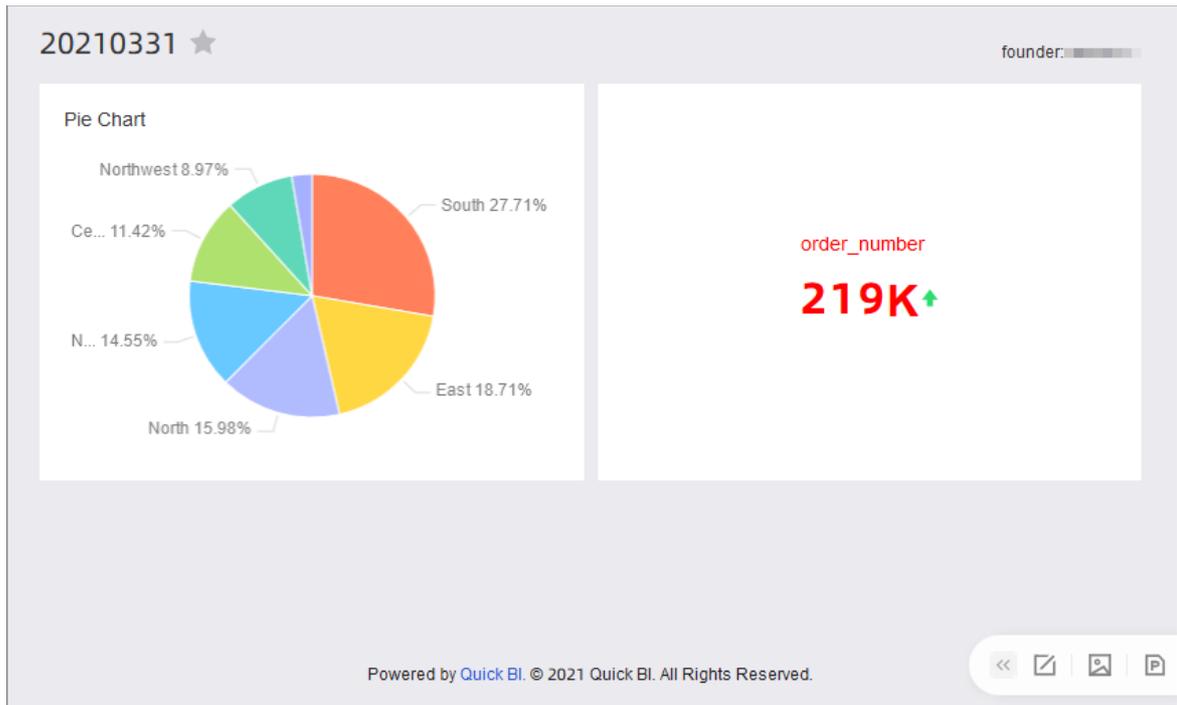

This topic describes how to view a dashboard.

Prerequisites

- The Quick BI service is purchased.
- One or more dashboards are created.

Procedure

1. [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** page, click **Dashboards**.
3. On the Dashboards page, find the required dashboard and click the  icon next to the dashboard. On the page that appears, you can view the information of the dashboard.

4. You can perform one of the following operations as required:
 - Edit: Click the  icon to go to the dashboard edit page to edit a chart.
 - Export: Click the  icon to export the chart data to a PNG file.
 - Export PDF: Click the  icon to export the chart data to a PDF file.

7.5.11. Share a dashboard

This topic describes how to share a dashboard with other users.

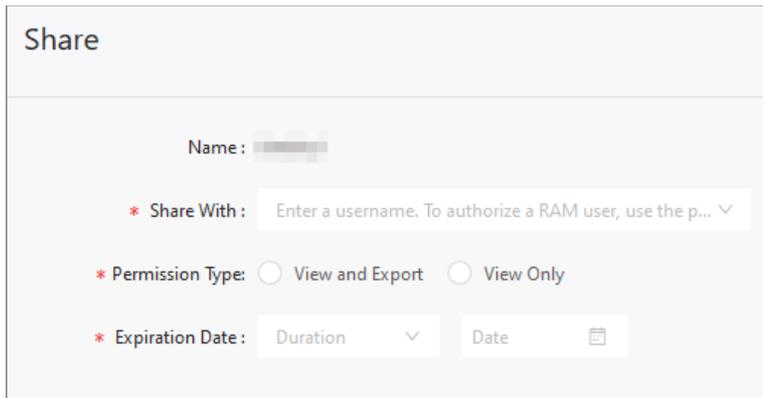

Prerequisites

- The Quick BI service is purchased.
- A dashboard is created.

Procedure

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** page, click **Dashboards**.
3. On the Dashboards page, right-click the dashboard that you want to share with others.
4. Select **Share**.
5. In the right-side panel that appears, specify Scope, Permission Type, and Expiration Date, as shown in [Share a dashboard](#).

Share a dashboard

 **Note**

- In the Basic Settings section of the right-side Page Settings panel, select **Allow Download**. If you want to download a report, you must set Permission Type to **View and Export**.
- You can set Scope to All Users, User Groups, or Users.
- Users who are authorized in one of these scopes are granted the corresponding permissions.

6. Click **Save**.

7.5.12. Make a dashboard public

After you make a dashboard public, users can access the dashboard by using a shared link.

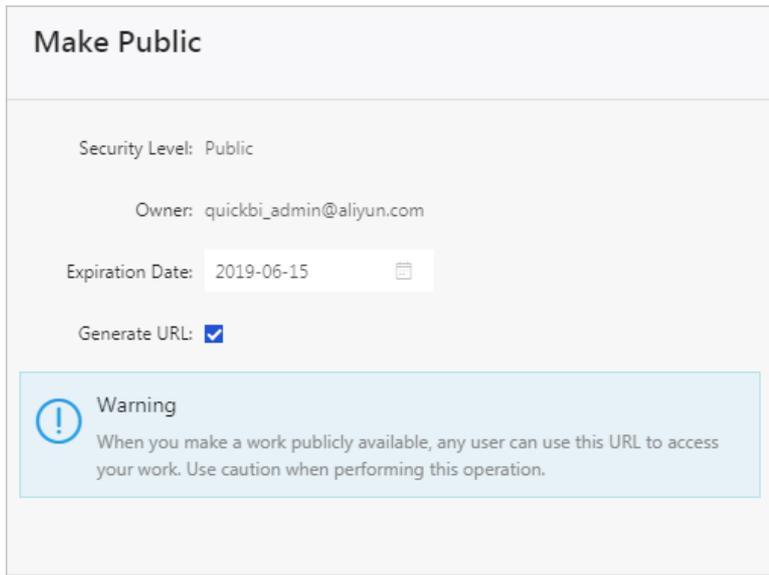

Prerequisites

- The Quick BI service is purchased.
- A dashboard folder is created. For information about how to create a dashboard folder, see [Create a dashboard folder](#).

Procedure

1. [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** page, click **Dashboards**.
3. On the Dashboards page, right-click the dashboard you want to make public.
4. Select **Make Public**.
5. Set an expiration date and click **Make Public**, as shown in [Make a dashboard public](#).

Make a dashboard public

7.5.13. Publish a dashboard

This topic describes how to save, save and publish, restore, unpublish, and republish a dashboard.

Prerequisites

- The Quick BI service is purchased.
- A dashboard is created.

Context

Dashboards are automatically published after they are saved. If developers save modifications to the dashboards, users may view the intermediate versions that are generated. To improve user experience, the save feature is separated from the publish feature, and the unpublish and republish features are added.

Go to the dashboard configuration page

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** page, click **Dashboards**.
3. On the Dashboards page, click the dashboard name to go to the dashboard editing page.

Save a dashboard

You can save only the current operation.

If you save only a dashboard, the updates to the dashboard are invisible to users:

- When you add a new dashboard, the dashboard is in the unpublished state after you save it. You can click **Save and Publish** to publish the dashboard.
- When a published dashboard is updated, you can publish the update point by clicking **Republish**.

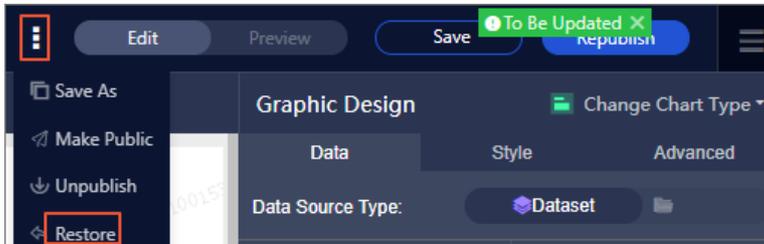

Save and publish

The save and publish feature saves the current operation and publishes the dashboard. This feature is available only for dashboards that are not published.

Restore icon

After you save your modifications to a published dashboard but have not published the modifications, you can use the **Restore** feature to restore the dashboards to the latest version.

1. Select a published dashboard.
2. Modify the dashboard and save the modifications.
The dashboard is in the **Saved But Not Published** state.
3. On the dashboard edit page, click the  icon and select **Restore**.

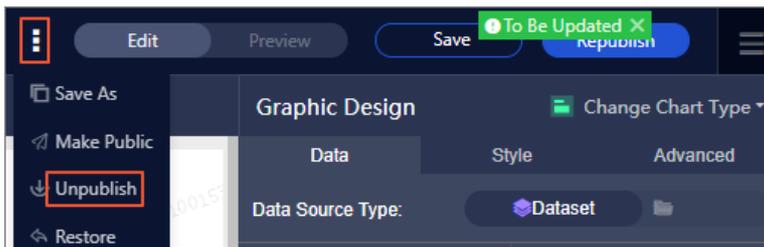

4. In the dialog box that appears, click OK.

Unpublish a dashboard

You can unpublish a dashboard. Unpublished dashboards are invisible to users.

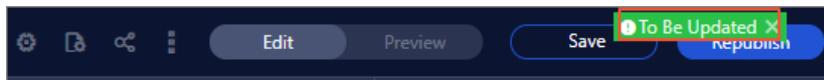

1. On the dashboard edit page, click the  icon and select **Unpublish**.

2. In the dialog box that appears, click OK.

Republish a dashboard

After you update a published dashboard, you can republish it to make the updates take effect. If "To Be Updated" is displayed for a dashboard and the dashboard is in the **Saved But Not Published** state, you can republish the dashboard.

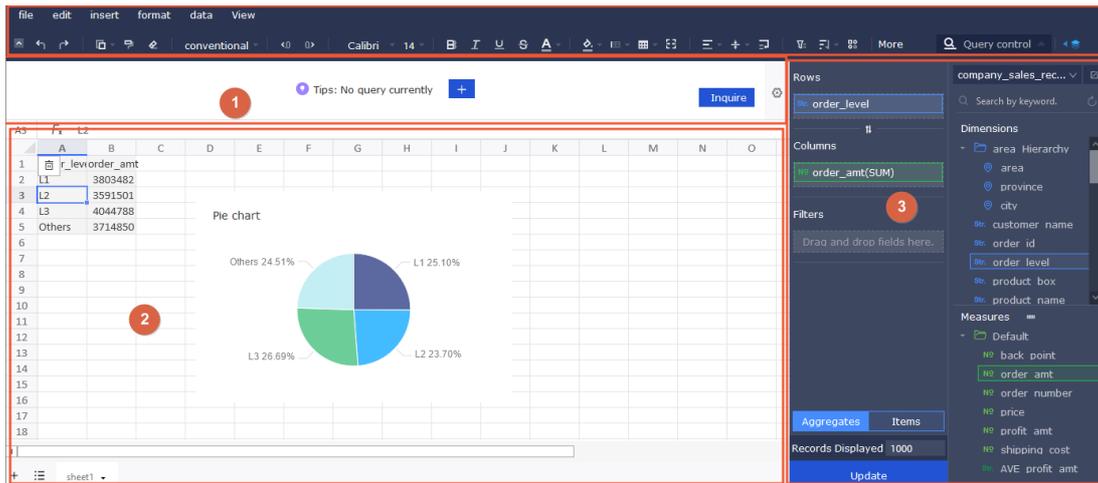

7.6. Workbooks

7.6.1. Overview

On the workbook edit page, you can filter and query data in a dataset. You can also visualize data by using different types of charts.

The workbook edit page contains three areas, as shown in [Workbook edit page](#).

Workbook edit page

- The workbook configuration section is marked as ①. In this section, you can select the chart that you want to create on the workbook, export and edit the workbook, configure the data format and style of the workbook, and add a query control.
- The workbook display section is marked as ②. In this section, you can display data in specified cells in a specified chart and reprocess data by using cell references.
- The dataset selection section is marked as ③. In this section, you can switch the current dataset to another. The fields of a dataset are displayed in the Dimensions and Measures lists based on the data types preconfigured in the system. You can select dimensions and measures based on the chart type.

7.6.2. Create a workbook

This topic describes how to create a workbook.

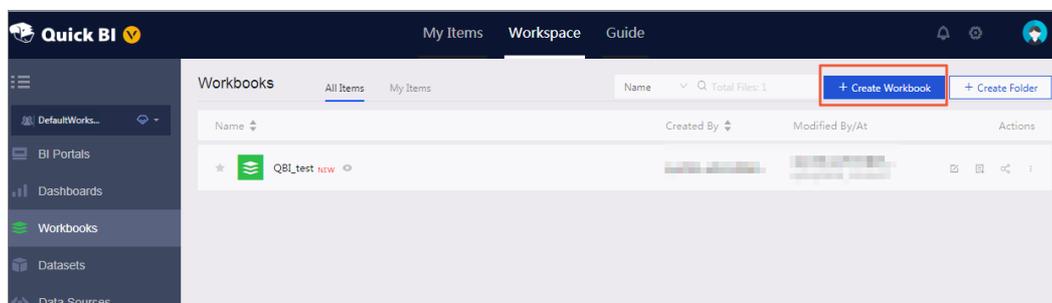

Prerequisites

The Quick BI service is purchased.

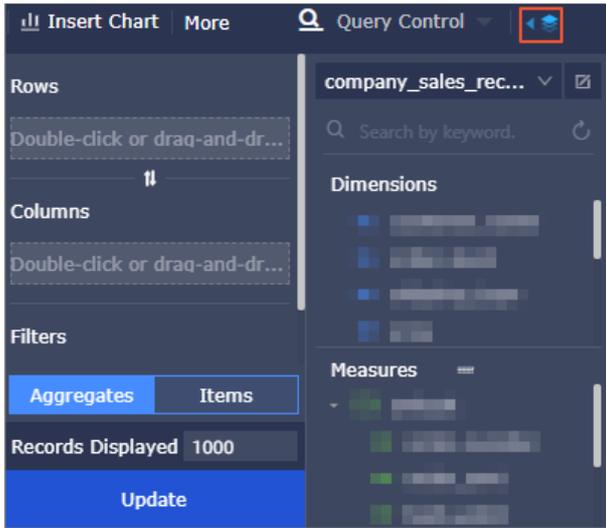

Procedure

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks**.
3. On the **Workbooks** page, click **Create Workbook**.

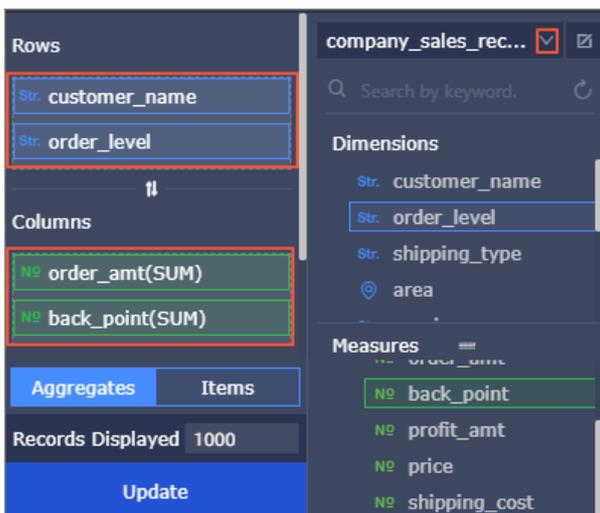

Create a workbook

4. On the workbook edit page, click the icon.

5. Click **Select a dataset** and select the required dataset from the drop-down list. Fields in the required dataset are synchronized to the **Dimensions** and **Measures** areas.
6. In the **Dimensions** and **Measures** lists, double-click or drag the corresponding fields to **Rows** and **Columns**.

7. Click **Update**.
8. Click **Save**.
9. (Optional) If it is the first time that you save the workbook, the **Save Workbook** dialog box appears. You must configure the following parameters in the dialog box. Enter a name for the workbook and specify the location where you want to store the workbook, and click **OK**.

7.6.3. Switch to another dataset

This topic describes how to select a dataset or switch from the current dataset to another dataset.

Prerequisites

The Quick BI service is purchased.

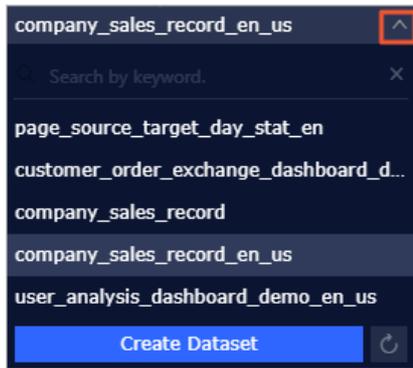

Context

If you cannot find the required dataset, go back to the dataset management page and make sure that the dataset has been created. For information about how to create a dataset, see [Create datasets](#).

Procedure

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. Click the name of the required Workbook.
4. On the workbook edit page, click the downward arrow. In the drop-down list, select or search for the dataset you want to switch to, as shown in [Switch to another dataset.](#)

Switch to another dataset

7.6.4. Search for a dimension or measure

This topic describes how to search for a specific dimension or measure.

Prerequisites

The Quick BI service is purchased.

Context

After you select a dataset, the system displays the dimensions in the Dimensions list and measures in the Measures list.

For information about how to edit dimensions and measures, see [Edit a dimension](#) and [Edit a measure](#).

Procedure

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. Click the name of the required Workbook.
4. On the workbook edit page, manually enter the keyword of the field in the search box in the dataset selection area. Click the search icon to search for the field.

Search for a field

7.6.5. Configure a workbook

You can configure a workbook in the workbook configuration section.

Prerequisites

The Quick BI service is purchased.

Go to the page of workbook configuration

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. On the Workbooks page, click the workbook that you want to set the font.

File icon

You can choose **File > Export** to export a workbook.

Edit icon

You can perform the following edit operations:

- Revoke
- Restore
- Copy
- Cut
- Paste
- Format Painter
- Clear Format
- Indent
- Unindent

Insert

You can perform the following insert operations:

- Insert rows or columns to a workbook.

- Insert row above
- Insert row below
- Insert column on the left
- Insert column on the right
- Insert a dataset to a workbook.
- Insert a chart to a workbook.

You can insert the following types of charts: line chart, bar chart, pie chart, dashboard, radar chart, scatter plot, funnel chart, and polar diagram. For more information, see [Insert a chart](#).

- Insert a picture to a workbook.

The supported image formats include PNG, JPG, and GIF.

- Insert a function to a workbook.
- Insert a hyperlink to a workbook.
- Insert a note to a workbook.
- Insert a drop-down box to a workbook.

For more information, see [Add a drop-down box](#).

Format

Operation	Description
Data Format	Set the Data format. The options include conventional, date, digital, text, percentage, and customize.
Font and Font Size	Set the font and font size.
Bold, Italic, Underline and Strikethrough	Configure the text style.
Horizontal alignment, Vertical alignment, Word wrap, Merge cells, Set line height, Set column width, Adaptive line height, and Adaptive column width	Configure the cell style.
Conditional Formatting	Add rules to filter data results. For more information, see Conditional Formatting .

Data

You can perform the following operations on the data in a workbook:

- Sort
- Filter
- Data Lookup
- Group and Ungroup

View

You can perform the following operations on the data in a workbook:

- Hide or display gridlines
- Hide selected rows or columns
- Unhide
- Freeze to the current line or column

- Unfreeze

Toolbar

You can perform the following operations on the data in a workbook.

Operation	Description
	Paste data with custom formatting.
	Copy all of the formatting from one object and apply it to another one.
	Clear the formatting.
	Decrease or increase the number of decimal places.
	Specify the font color.
	Specify the fill color for cells.
	Specify whether to show cell borders and the border color.
	Specify the theme color of the workbook.
	Search for data.
	Specify the theme style of a table.
	Create a query control

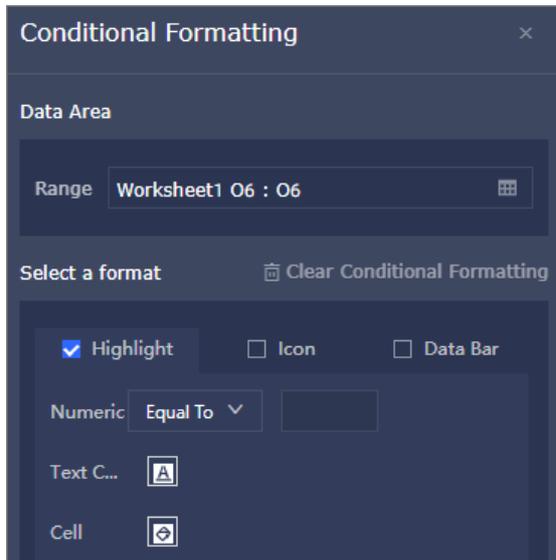

Sheet settings

You can perform the following operations on a sheet in a workbook:

- Rename the sheet.
- Delete the sheet.
- Set the border color.
- Hide the sheet.

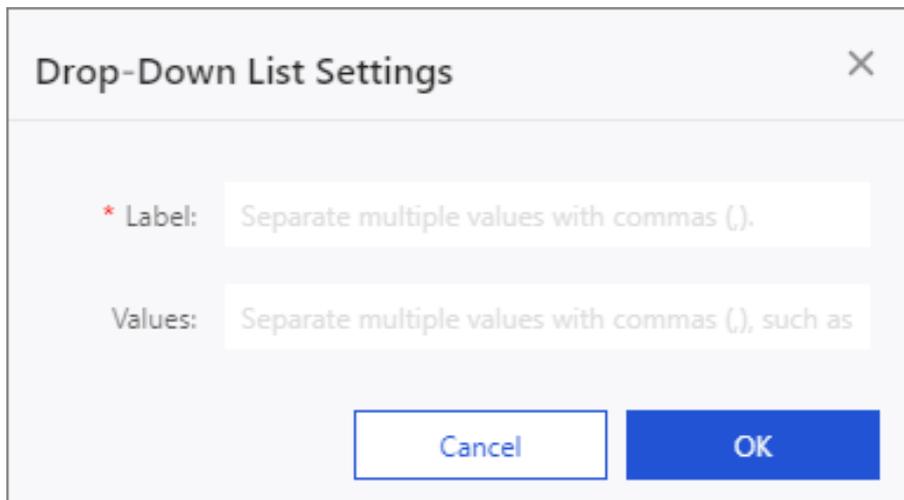

Conditional Formatting

You can click  Conditional Formatting in the toolbar and add rules to filter the data results, such as highlighting the data within a specified range, setting an icon for specified data, and adding a data bar.

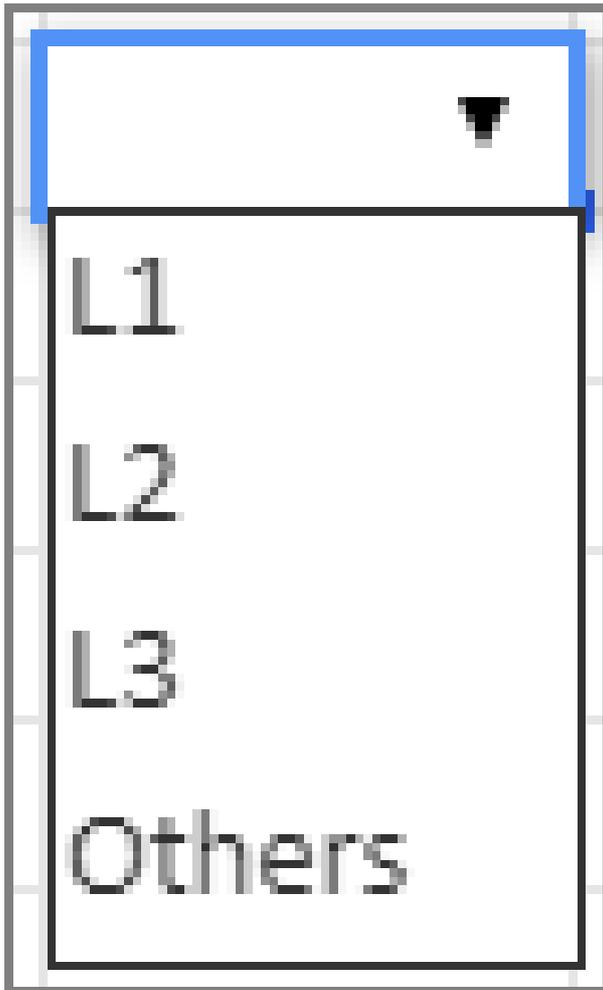

Add a drop-down box

1. In the toolbar on the workbook edit page, choose **Insert > Drop-Down Box**.
2. In the Drop-Down Box Settings dialog box, add a label for the data item.

 **Note** Separate multiple labels with commas (,).

3. Click **OK**.

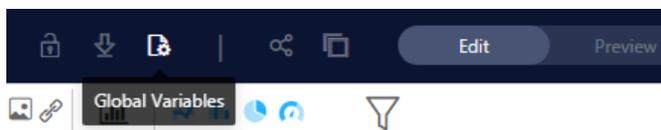

Note If the message **This operation is not allowed because it may affect the data of nearby datasets.** appears, copy the data to another area in the workbook and then repeat the operations.

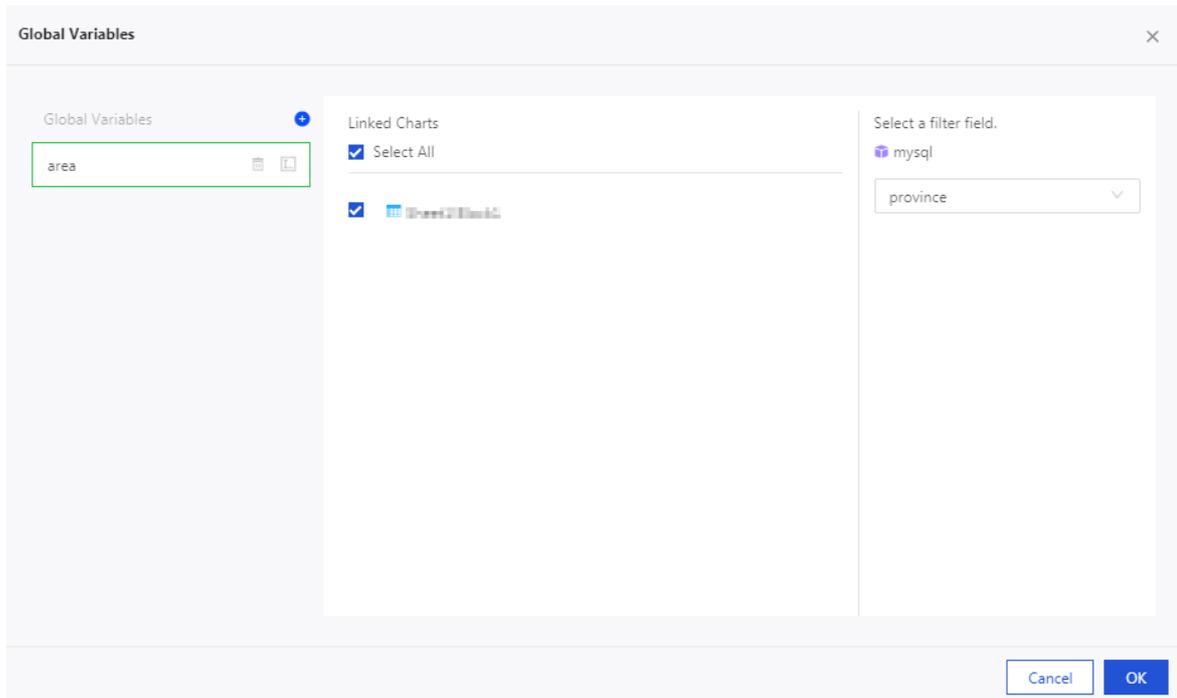

Global Variables

You can set global variables in the workbook. You can use global variables to add hyperlinks to cross tables.

1. On the workbook edit page, click the **Global Variables** icon.

2. In the **Global Variables** dialog box, enter the required variable and click **OK**, as shown in the following figure.

Insert a chart

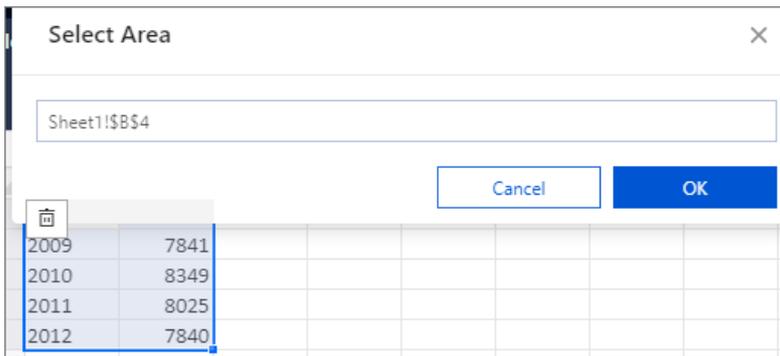

You can insert charts to a workbook based on the data in the workbook. You can insert the following types of charts: line chart, bar chart, pie chart, dashboard, radar chart, scatter chart, funnel chart, and polar diagram.

1. In the toolbar of the workbook edit page, click **Insert** and select **Chart**, and then select a chart type.

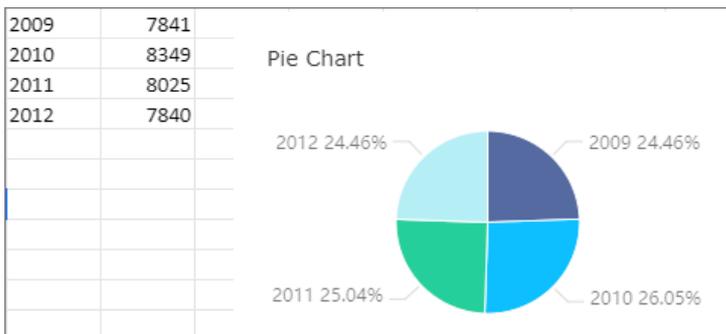

In this example, Pie Chart is selected.

- In the **Select Data Range** dialog box, specify the data range for creating the chart.

- Click **Determine** . A pie chart appears in the workbook.

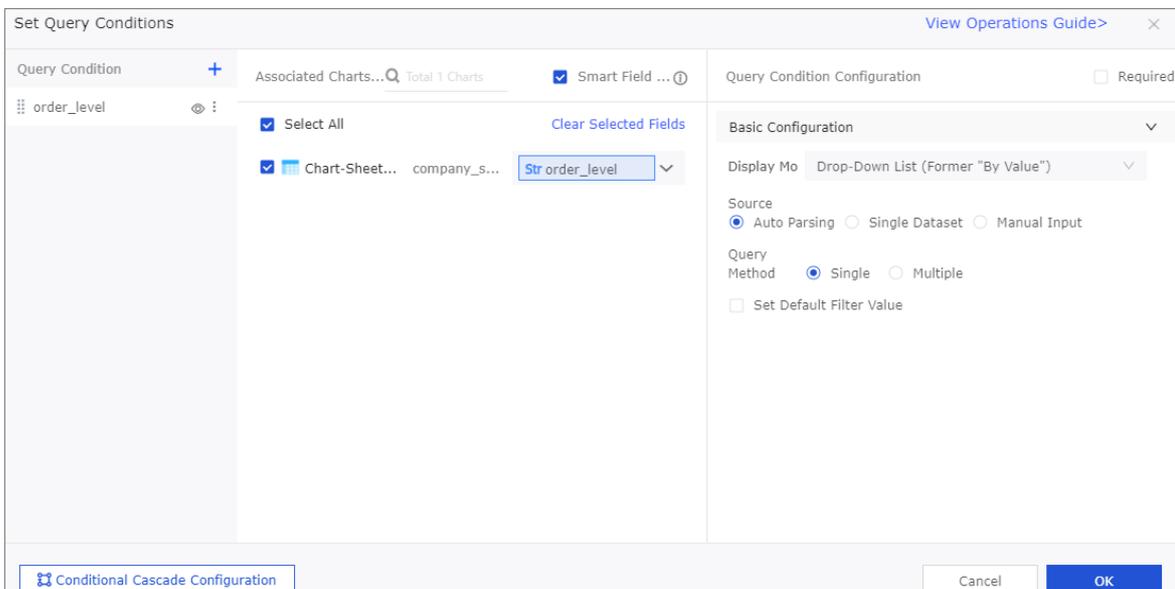

Click the chart and configure the chart style in the **Graphic Design** section on the right side.

Create a query control

- On the workbook edit page, click **Query Control** in the toolbar.

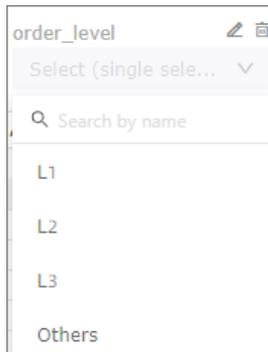

- In the workbook display section, click the **+** icon.
- In the **Query condition setting** dialog box, configure query conditions.

4. Click **OK**.

You can view the order level on the Query Control page.

7.6.6. Manage a workbook

This topic describes how to search, move, view, share, transfer, and delete a workbook. This topic also describes how to add a workbook to favorites and make a workbook public.

Prerequisites

The Quick BI service is purchased.

Search for a workbook

1. [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. On the **Workbooks** page, enter the keywords or the creator of the workbook that you want to search for in the search box, and click the **Search** icon.

Move a workbook

1. On the **Workbooks** page, find the workbook that you want to move, click the  icon in the **Actions** column, and then select **Move To**.

You can also right-click the workbook and select **Move To**.

2. On the **Move To** page, select the required directory and click **Save**.

Share a workbook

Only workbooks whose **Publish Status** is **Published** can be shared with others.

1. On the **Workbooks** page, find the workbook that you want to share with others and click the  icon in the **Actions** column.

You can also right-click the workbook and select **Share**.

2. In the right-side panel that appears, specify Scope, Permission Type, and Expiration Date.

 **Note** You can set Scope to All Users, User Groups, or Users.

3. Click **Save**.

Make a workbook public

Only workbooks whose **Publish Status** is **Published** can be made public.

1. On the **Workbooks** page, find the workbook that you want to make public, click the  icon in the **Actions** column, and then select **Make Public**.

You can also right-click the workbook and select **Make Public**.

2. In the **Make Public** panel, specify **Expiration Date** and select **Generate URL**.
3. Click **Make Public**.

Transfer a workbook, rename a workbook, and change its security level

1. On the **Workbooks** page, find the required workbook and click the  icon in the **Actions** column.

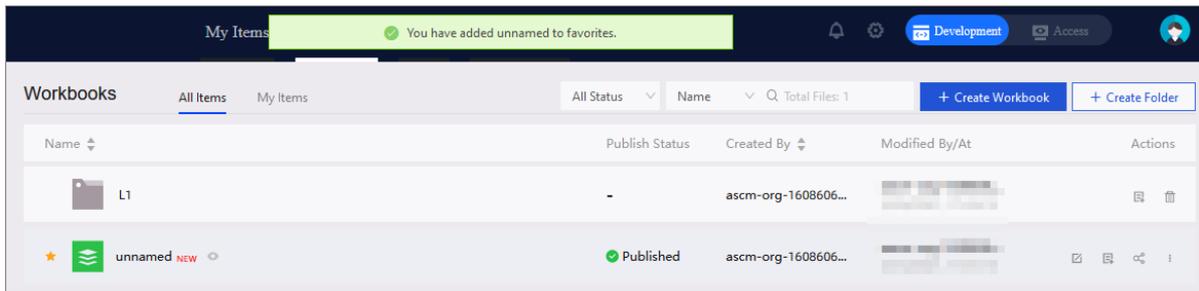

You can also right-click the workbook and select **Edit Properties**.

2. In the **Edit Properties** panel, change the name, owner, description, and security level of the workbook.
3. Click **Save**.

Add a workbook to favorites

You can use any of the following methods to add a workbook to favorites:

- On the **Workbooks** page, click the  icon next to the workbook name.

- On the workbook edit page, click the  icon next to the workbook name.

 **Note** You can click the  icon again to remove the workbook from your favorites.

Delete a workbook

1. On the **Workbooks** page, find the workbook that you want to delete, click the  icon in the **Actions** column, and then select **Delete**.

You can also right-click the workbook and select **Delete**.

2. In the message that appears, click **OK**.

Note When you delete a workbook in the **Published** state, you need to unpublish it before deleting it.

7.6.7. Publish a workbook

This topic describes how to save, save and publish, restore, unpublish, and republish a workbook.

Prerequisites

The Quick BI service is purchased.

Context

Workbooks are published automatically after they are saved. Users may view intermediate versions that are generated as developers save changes to the workbooks. To improve user experience, the save feature is separated from the publish feature, and the unpublish and republish features are added.

Go to the workbook editing page

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. On the Workbooks page, click the workbook that you want to edit.

Save a workbook

You can save only the current operation by using the save feature.

If you save only a workbook, the update points of the workbook are invisible to users:

- When you add a new workbook, the workbook is in the unpublished state after you save the workbook. You can publish the workbook by clicking **Save and Publish**.
- When a published workbook is updated, you can publish the update point by clicking **Republish**.

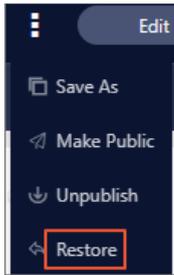

Save and publish

You can use this feature to save the current operation and publish the workbook. This feature is available only for workbooks that are not published.

Restore icon

If you save your modifications to a published workbook but have not published the modifications, you can use the **restore** feature to restore the workbook to the latest published version.

1. Select a published workbook.
2. Modify the workbook and save the modifications.
The workbook is in the **Saved But Not Published** state.
3. On the workbook edit page, click the  icon and select **Restore**.

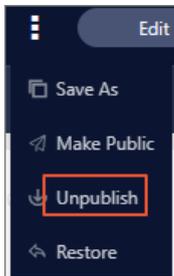

4. In the Confirm dialog box, click **OK**.

Unpublish a workbook

You can unpublish a workbook. After the workbook is unpublished, it is invisible to users.

1. Select a published workbook.
2. On the workbook edit page, click the  icon and select **Unpublish**.

3. In the dialog box that appears, click **OK**.

Republish a workbook

After you update a published workbook, you can republish it to make the updates available for users. You can republish a workbook if "To Be Updated" is displayed and the status of the workbook is **Saved But Not Published**.

7.6.8. Create a workbook folder

This topic describes how to create a workbook folder that helps you manage workbooks.

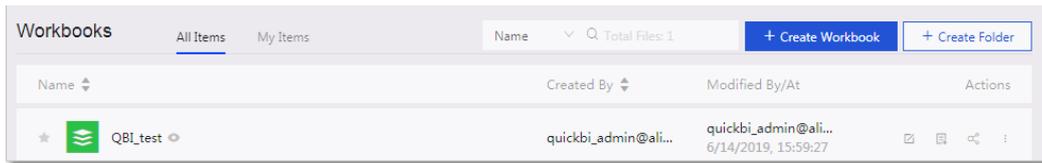

Prerequisites

The Quick BI service is purchased.

Procedure

1. [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. Click **Create Folder**, as shown in [Create Folder](#).

Create Folder

4. In the Create Folder dialog box, specify a name for the folder and click **OK**.

7.6.9. Rename a workbook folder

This topic describes how to rename a workbook folder.

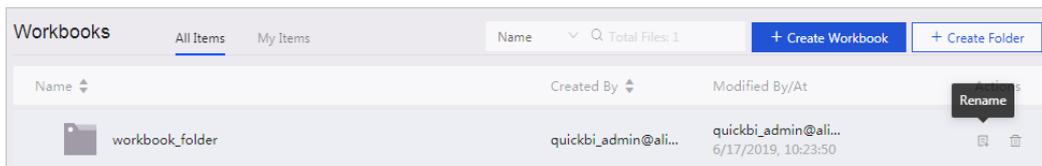

Prerequisites

The Quick BI service is purchased.

Procedure

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. Find the workbook folder you want to rename and click the  icon in the Actions column, as shown in [Rename a folder.](#)

Rename a folder

4. In the **Rename** dialog box, enter a new folder name and click **OK**.

7.6.10. Delete a workbook folder

This topic describes how to delete a workbook folder.

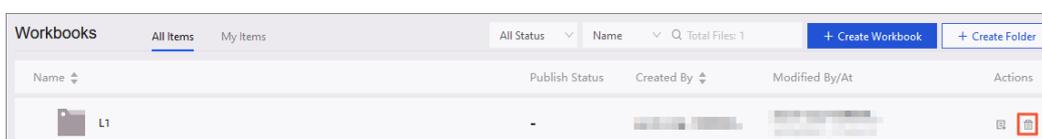

Prerequisites

The Quick BI service is purchased.

Procedure

1. [Log on to the Quick BI console.](#)
2. In the left-side navigation pane of the **Workspace** page, click **Workbooks** to go to the **Workbooks** page.
3. Find the workbook folder you want to rename and click the  icon in the Actions column, as shown in [Delete a dataset folder.](#)

Delete a dataset folder

4. In the dialog box that appears, click **OK**.

7.7. BI portals

7.7.1. Overview

A BI portal is a collection of dashboards, workbooks, and external links organized with menus. You can create a BI portal to perform complex thematic analysis with navigation panes.

7.7.2. Create a BI portal

This topic describes how to create a BI portal.

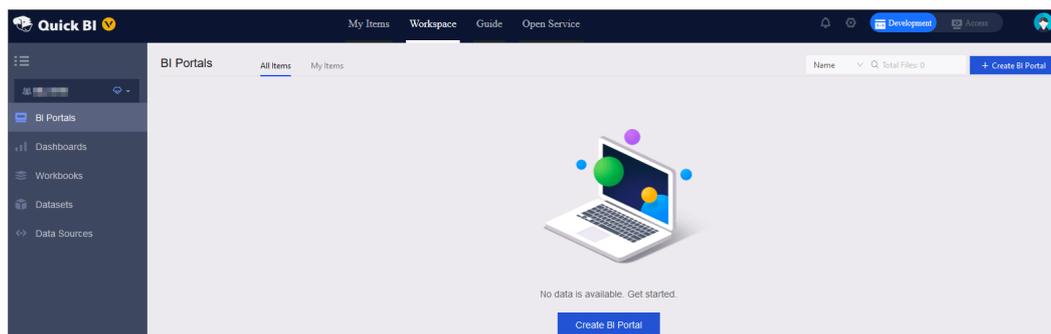

Prerequisites

The Quick BI service is purchased.

Procedure

1. [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** tab, click **BI Portals**.
3. On the BI Portals page, click **Create BI Portal** in the upper-right corner, as shown in [Create a BI portal](#).

Create a BI portal

4. On the Page Settings page, configure the parameters and click **Save** in the upper-right corner.

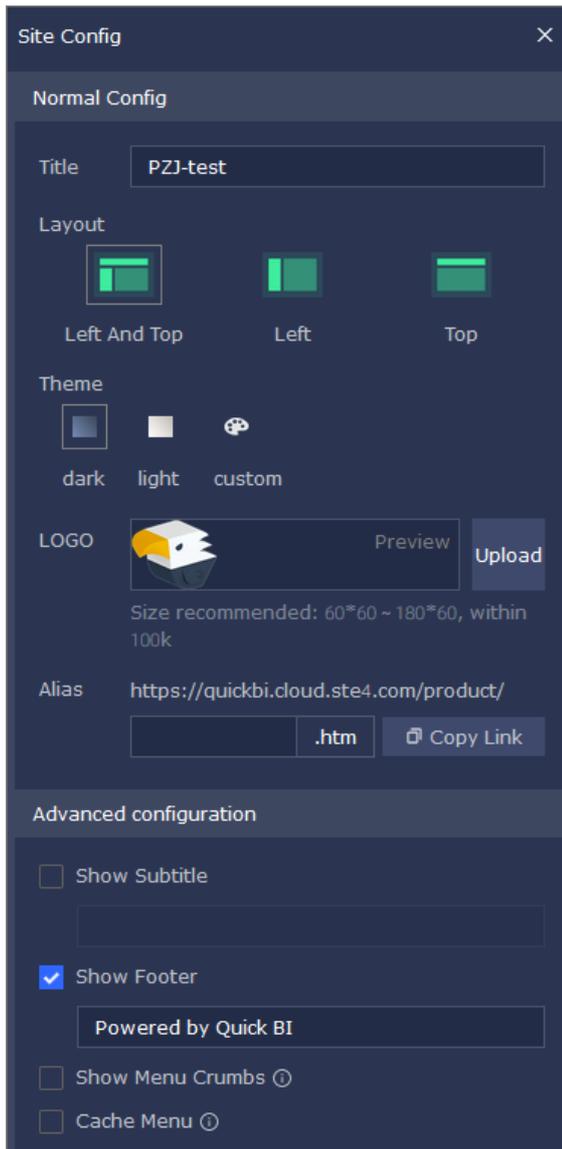

7.7.3. Configure a portal

This topic describes how to configure the title, upload the logo, and edit the footer for a BI portal on the Portal Settings page.

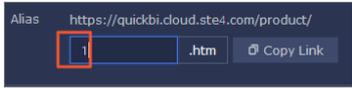

Procedure

1. [Log on to the Quick BI console](#).
2. In the left-side navigation pane of the **Workspace** tab, click **BI Portals**.
3. On the BI Portals page, click the required BI portal. For more information about how to create a BI portal, see [Create a BI portal](#).
4. Click the  icon in the top navigation bar to edit the BI portal page, as shown in [Configure a BI portal](#).

Configure a BI portal

Category	Configuration item	Description
Normal Config	Title	Customize the title of the BI portal.
	Layout	You can select Left And Top, Left, or Top.
	Theme	You can select dark, light, or custom.
	LOGO	Click Upload to upload a logo image file.

Category	Configuration item	Description
	Alias	<p>Enter a value in the text box under Alias. The value is embedded in the portal link. For example, if you enter 1, the alias is <code>http://daily.yunbi.biz.aliyun.test/product/1.htm</code>.</p> 
Advanced configuration	Show Subtitle	After you select this option, add a subtitle for the portal.
